On behalf of the 1,850 members of the Building Industry Association of Southern California, we would like to reiterate our concerns expressed to you in our September 1999 letter and our September 16, 1999 presentation before your Board on the SUSMP issue.

While our industry continues to support the goals of clean water, we remain opposed to the plan as written. The inclusion of a numerical mitigation standard whose benefits have not been proven and whose cost effectiveness has not been studied makes it impossible for us to support the December 7, 1999 staff proposal.

Let us be clear that the building industry is committed to the goal of cleaning our stormwater run off. Further, our industry is committed to participating in a process that truly seeks to achieve this goal. Such a process should include the testing and study of various best management practices with a focus on pilot programs which have proven to be effective. This process should involve all affected parties (the regulated community, the municipalities and the environmental community) and should be based on sound science.

Because the December 7, 1999 proposal does not provide for any of the process outlined above, we sincerely doubt that it will achieve its stated objective. As the industry principally impacted by this proposal, we would like to be part of a process that has a chance of actual, measured, scientifically proven success

We respectfully request that you and the Board reject the concept of a numerical mitigation standard. We look forward to making a thorough presentation outlining all of our thoughts and concerns on these issues during your January 26, 2000 public hearing.

Sincerely,

Richard J. Lambros

RE: Support for Three Quarter-Inch Standard to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

You have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. On January 26, 2000, we urge you to adopt reasonable design standards for sizing treatment control Best Management Practices at specified new and redevelopments: Ensure that these developments mitigate, through treatment or infiltration, 100% of the runoff generated by up to and including a three quarter-inch storm, with no exceptions. By adopting this standard, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

Today approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs untreated into the ocean. With the most infamous urban runoff problem in the nation, and little measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming; creeks and streams with water that is unsafe to drink; and inland and coastal waters that pose health risks to aquatic life.

The three quarter-inch standard was supported by the Los Angeles Times in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem."

The three quarter-inch standard also makes economic sense. First, reducing storm water pollution in the planning phase of construction is the most cost-effective way to solve the runoff problem. Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) - and with billions of dollars at stake, the health of our entire regional economy is impacted.

In a region that is constantly being built and rebuilt, adoption of the three quarter-inch standard will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our regional economy, and for a more livable Los Angeles, please adopt the three quarter-inch standard, with no exceptions, to mitigate the effects of urban runoff from new and redevelopment.

Sincerely,

Greg Sweel

Re: Support for Standards to Reduce Runoff from New Development and Redevelopment

Dear Mr. Dickerson:

I am writing to you as a commercial property owner, developer, environmentalist, water sport activist (surfer, swimmer, paddler, skindiver and sailor) and concerned California citizen.

On January 26, 2000 you have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. I urge you to adopt a Standard Urban Stormwater Mitigation Plan (the "Plan") for the Cities in Los Angeles County, reducing urban runoff from new development and redevelopment. By adopting the Plan, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

As a property owner and developer in Malibu, we have self-imposed runoff regulations on two proposals we currently have pending. Both of these projects will retain and treat runoff from the new development. While it would be ideal if every property developer would volunteer this, the reality of the economics is that most do not. For this reason, I urge you to not only require retention and treatment of runoff, but to make the Plan's regulations (including the definitions and standards) specific and clear so that it can be properly planned and implemented. In addition it is critical that the exemptions from the definition of runoff as contained in the December RWQCB draft of the Plan be eliminated, particularly, the exemption of rooftop runoff (which is ludicrous).

Requiring treatment makes economic sense. While it is a significant cost to the developer to provide treatment, addressing the problems in the planning phase of construction is the most cost-effective way to solve the runoff problems (versus trying to fix problems after the fact). Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business.

In a region that is constantly being built and rebuilt, adoption of new standards will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our regional economy, and for a more livable Los Angeles, please adopt standards to mitigate the effects of urban runoff from new and redevelopment.

Sincerely,

John Perenchio

Re: Proposed Standard Urban Storm Water Mitigation Plan
and Regional Board Meeting of January 26, 2000

Dear Mr. Dickerson:

We are writing this letter in response to your request for written comments in advance of your upcoming Board Meeting of January 26, 2000.

As we have previously communicated to you, we strongly oppose the numerical standards proposed in the new Standard Urban Stormwater Mitigation Plan (SUSMP) guidelines. We also object to the most recent modifications which have been made to the previously submitted SUSMP's, specifically the addition of new categories and the additional restrictions defininig "hillside development", the addition of a category for parking lots containing 25 or more spaces, and the additional category concerning projects discharging into an "environmentally sensitive" area.

The SUSMP guidelines you are proposing to adopt at the January 26, 2000, Regional Water Quality Control Board are totally unacceptable. These new SUSMP guidelines as written, will create significant cost increases for the entire development industry. This increased cost will directly affect our ability to provide affordable housing, and will have a negative impact on the profitability of commercial and industrial business as well.

We are all concerned with the environment, and we fully understand the importance of clean water, however, the development industry should not be singled out and unjustly accused of being the major cause of water pollution.

THE NEWHALL LAND AND FARMING COMPANY, 23823 VALENCIA BOULEVARD, VALENCIA, CA 91355-2194
TEL 661.255.4000 FAX 661.255.3960 WEBSITE: www.newhall.com

Forcing our industry to design expensive, possibly ineffective structures which could create a serious maintenance liability over time, in order to meet a numerical standard that will not have a beneficial effect on the water, will certainly not benefit the general public.

Our industry has made a great deal of progress towards pollution prevention in recent years. We have made great strides in implementing various design features to minimize potential pollution, and we have continued to educate the contractors who work for us about the importance of applying best management practices during the construction process. These efforts have made a significant contribution towards prevention of pollution.

We are committed to continue our pollution prevention efforts, and have already agreed to the SUSMP guidelines which were originally submitted to the Regional Water Quality Control Board. The implementation of the original SUSMP guidelines without the numerical guidelines will further minimize any impacts that our industry may have on the environment.

As you know, the County of Los Angeles recently agreed to the 0.75 numerical standard in the unincorporated areas of Los Angeles in an effort to resolve a lawsuit filed by the Natural Resource Defense Council, without the input of our industry. To date, the projects submitted to them incorporating this requirement have not been consistent in the application of their design criteria. They have each specified a different way to meet this 0.75 numerical standard, and the costs for installation, the effectiveness of each method, and the complexity and costs for maintenance are still unknown. These projects should be studied over time and evaluated.

In closing, we would like to request that any new policies which are adopted by the Board become effective only on projects which have not received Tentative Map approval from the governing agency. We hope that the Board will invest the time it will take to study some of the projects which have been submitted through the County of Los Angeles to more fully understand the .075 requirement, the various types of Best Management Practices that will be cost effective to install and maintain, and that will have the desired results before adding additional requirements which may have no benefit to the environment, at a great cost to several industries.

We hope that the Board will understand our position, and will work with us towards finding a logical, scientifically based approach to this issue.

Sincerely,

Ross Pistone

RE: Standard Urban Stormwater Mitigation Permit

Dear Mr. Dickerson:

Friends of the Los Angeles River (FoLAR) fully concur with the comments submitted by NRDC on Friday, January 14, 2000.

In addition we would like to submit comments relating to our own experiences with development standards in Los Angeles.

In November of 1998, FoLAR entered into a mitigation agreement with Legacy Partners Commercial, Inc. for the development of a business park on 49 acres at the Taylor Yards. This agreement was included in the final Mitigated Negative Declaration for the property. The Taylor Yards are a riverfront property which had never been previously developed or paved. FoLAR's concerns were related to the inherent increase in runoff that standard development practices would necessarily cause to contribute to this soft bottom section of the river. Legacy's president, Bill Shubin, being an avid surfer, shared our concerns.

FoLAR's consultants worked jointly with Legacy's engineering experts to develop a drainage design plan, which would retain and detain surface water runoff and would implement surface water quality measures. The plan was designed so as not to increase peak flows of surface water runoff in a 100-year storm event.

Facilities were designed to prevent or otherwise minimize surface water runoff from the developed parcel. Efforts resulted in a parking lot and landscaping design which direct surface water runoff to bio-swales, allowing for natural percolation of rainwater to the groundwater via an 18" perforated pipe subdrain system. The final design accomplished a system that can immediately accommodate a 1/2" rain event every 24 hours. Additionally, storm drain improvements were designed to drain surface water runoff on-site during the peak period of a 100-year storm event. This latter is accommodated through detention, which then over time allows gradual percolation through the bioswales.

11-323

The innovative design has the positive result of accommodating a capital event (and detaining the additional peak flows) while eliminating the need for certain on-site storm drain improvements. Storm drain cost savings were re-allocated to construct a system for retention and percolation.

Much of the resistance within the building industry seems to stem from a fear that approvals will be too difficult to obtain or that these new standards will send development costs skyrocketing

Our experience with Legacy shows that costs are not necessarily increased, but shifted. And while initial meetings with building and safety and other agencies were challenging, a spirit of cooperation prevailed and these innovative concepts were readily approved. Moreover, it will be easier and easier with each new project. Change is possible and in this instance, necessary.

We agree with Legacy Partners' Michael Conway, project manager who says he "can point to this project as evidencing successful cooperation between private industry and public interest." And we would encourage other developers to follow their lead.

Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) - and with billions of dollars at stake, the health of our entire regional economy is impacted.

RE: Jan. 26 hearing on storm water retention

Dear Mr. Dickerson:

I have been concerned with storm water run-off for years, since I live near the mouth of the Los Angeles River, and have seen the tremendous pollution that comes down into the Long Beach ocean waters and beaches.

I am delighted that the Federal Govt. is requiring cities to retain .75" of water on any new building development, even though I consider this too little an amount.

Please stand firm in the face of cities which do not want to comply.

Water retention on new building projects is Federal law, and costs very little to achieve, and is already being implemented in Long Beach by the River Glen Estates building 18 single family homes at 3000 San Francisco St., Long Beach 90806.

Thirty-two other cities with more rainfall have more strict water retention laws. Southern California needs water retention more than any other State!

Sincerely,

Barbara Morel

RE: Support for Three Quarter-Inch Standard to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

You have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. On January 26, 2000, we urge you to adopt reasonable design standards for sizing treatment control Best Management Practices at specified new and redevelopments: Ensure that these developments mitigate, through treatment or infiltration, 100% of the runoff generated by up to and including a three quarter-inch storm, with no exceptions. By adopting this standard, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

Today approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs untreated into the ocean. With the most infamous urban runoff problem in the nation, and little measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming; creeks and streams with water that is unsafe to drink; and inland and coastal waters that pose health risks to aquatic life.

The three quarter-inch standard was supported by the Los Angeles Times in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem."

The three quarter-inch standard also makes economic sense. First, reducing storm water pollution in the planning phase of construction is the most cost-effective way to solve the runoff problem. Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) - and with billions of dollars at stake, the health of our entire regional economy is impacted.

In a region that is constantly being built and rebuilt, adoption of the three quarter-inch standard will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who

visit Los Angeles County beaches annually, for the health of our regional economy, and for a more livable Los Angeles, please adopt the three quarter-inch standard, with no exceptions, to mitigate the effects of urban runoff from new and redevelopment.

It will probably be expensive but it will be worth it to me.

Sincerely,

Stephanie Balikos

RE: **Comments on Proposal to Reduce Runoff from New and Redevelopment under the Municipal Stormwater Permit**

Dear Mr. Dickerson:

Thank you for this opportunity to provide comments on the proposed model program for stormwater management in new and redevelopment.

Background
For your information, Playa Vista is a new residential and commercial development in West Los Angeles which has recently won the Local Government Commission western United States Awahanee Award for its unique sustainable design. Incorporated into this design is a cutting edge stormwater management program. Playa Vista, for over 10 years, has been actively incorporating evolving stormwater management concepts into its development and redevelopment plans. In fact, Playa Vista, to demonstrate its leadership on this important ocean protection issue, has chosen to set a goal for itself of no increase in pollutants of concern after development of the project. This level of performance is well above your proposed standard.

However, it is important to note that Playa Vista had a unique opportunity to accomplish this objective because of the significant off-site areas that drain through the property. Most projects will not have this kind of opportunity.

Assessment of Board Proposal
We agree with the basic concept that there is a need to develop criteria for new projects to manage stormwater in a way that reduces the increase in pollution from new developments.

You and the Los Angeles municipalities do have the opportunity to significantly reduce urban runoff pollution through the adoption of criteria for controlling urban runoff, which has been cited as the number one source of pollution to our coastal and inland waters. We encourage all parties to move forward in establishing a program to improve the runoff from development and redevelopment projects. The Playa Vista project is very concerned with the health of the Santa Monica Bay in general, and specifically the Ballona Creek estuary area and Marina del Rey. Both of these water bodies are viewed

as a ecological assets to the project and our project has been designed to integrate protections for these resources into our surface water management program. The project is very concerned about the continued degradation of these waters by general urban runoff, which includes trash and debris as well as other pollutants. The long term health of our planned restoration of the Ballona wetland and the creation of a new water feature and habitat areas adjacent to the Marina del Rey is also dependent on upstream water quality.

While we support the intent of the Board's proposal, we would like to recommend some additional technical assessments that if done before adoption of the Board's proposal would provide for a strong result. These include:

The rainfall analysis performed is very limited. First, the analysis of only a couple of raingages is problematic in that there is the potential for a wide variation in storm characteristics that might lead one to develop more specific standards. Second, the rainfall analysis was performed on a 24-hour basis. Since the average storm duration is about 11 to 14 hours (Stenstrom and Strecker,1993: Assessment of Storm Drainage Sources of Contaminants to Santa Monica Bay, Volume I), this type of analysis would tend to truncate actual rain events, potentially leading to the conclusion that more stormwater would be treated than might really occur. Third, we do not believe that the use of raingage analysis alone is appropriate for setting standards. What should occur is the use of rainfall runoff models to assess other factors that can affect the performance of BMPs.

The use of a design storm (depth of rainfall) is appropriate for BMPs where the dominant treatment mechanism is resulting either directly or indirectly from storage. It is not appropriate for BMPs which are "flow-through" such a swales, filters, and infiltration. The performance of these BMPs in terms of treatment of a certain volume of runoff is much better evaluated through the investigation of rainfall intensities rather than a rainfall depth over a long time period. This could be done through the analysis of long-term hourly or, even better, 15-minute raingage data and then rainfall/runoff modeling.

The selection of design criteria should include an evaluation of actual site designs with assessment of effectiveness through the use of rainfall/runoff modeling and analysis of costs. This serves a number of important purposes. We believe than in many cases, there is the potential to save money and achieve better water quality through good site designs. Much of the opposition that the Board is facing on this issue is the perception that imposed standards will impose economic hardships. We believe that producing a number

of site examples as a part of the criteria selection work is critical to gaining the support and approval of both the municipalities and developers, as well as the public and the environmental community.

There is a need from both a technical perspective as well as a community acceptance perspective to conduct additional technical analyses as well as cost-effectiveness evaluations. This should be done with a broad group of stakeholders to help select and implement a criteria that will be accepted and successful. Playa Vista supports the efforts to develop such a standard and would be pleased to provide more detailed input on this manner. If you should have any questions, please contact Catherine Tyrrell, Environmental Affairs Director at (310) 448-4676.

RE: Support for Three Quarter-Inch Standard to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

I am a member of the Board of Directors of TreePeople, and I wanted you to know that after five years of research, TreePeople has demonstrated the benefits and feasibility of capturing rainwater and recycling it. TreePeople brought together leading experts to develop best management practices, and then showed how easily they could be implemented.

Now, you have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. On January 26, 2000, we urge you to adopt reasonable design standards for sizing treatment control Best Management Practices at specified new and redevelopments: Ensure that these developments mitigate, through treatment or infiltration, 100% of the runoff generated by up to and including a three quarter-inch storm, with no exceptions. By adopting this standard, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

Process

We believe that a thoughtful "process driven" approach should be employed for the development of appropriate public policy regarding stormwater mitigation in Southern California. Further, we believe that the SUSMP Policy approved on January 6, 2000 by the Regional Council of the Southern California Association of Governments (SCAG) offers a quality process driven approach to SUSMPs. We support this policy, as outlined below, and would seek its inclusion in the final SUSMP resolution adopted by the LARWQCB.

The Southern California Association of Governments recommends that:

- *the Los Angeles Regional Water Quality Control Board not adopt SUSMP numeric standards until such time as the Board can validate the feasible, technical and scientific bases for numeric standards.*
- *the Board monitor pilot programs similar to those underway in Los Angeles County.*
- *the Board work closely with cities such as Calabasas, Santa Clarita and Santa Monica to assess the effectiveness of local initiatives aimed at managing runoff water flows and quality.*
- *the Board develop a Memorandum of Understanding with SCAG in which SCAG would incorporate a Best Management Practices for Preventing Storm Water Runoff Pollution in the Los Angeles Basin project in its Environmental Programs and Livable Communities work elements.*
- *the Board ask SCAG to manage a legal authorities initiative in which all of the 85 cities in the Los Angeles Basin would work to develop model language which would then be available for municipal implementation throughout the Basin.*
- *the Board invite SCAG to contribute its Section 208 authorities to a collaboration with other key organizations/stakeholders in scoping out plans for a watershed management initiative program in each watershed of the Basin.*
- *the Board evaluate the operating results of watershed (regional) mitigation programs prior to its consideration of any general retrofit mandates on existing land uses.*
- *the Board and SCAG cooperate with other stakeholders in putting best efforts into raising the new financial resources needed for planning and implementing these water quality commitments.*
- *the Board's staff be encouraged to meet with those SCAG sub-regional councils affected by the SUSMP program prior to any Board action on these matters.*

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

It is my understanding that the California Regional Water Quality Control Board - Los Angeles Region (Board) will be holding a public hearing on January 26, 2000 on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California businessperson I support the goals of clean water, however, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area," and the addition of "Parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

Once again, let me reiterate that I fully support the goal of cleaning our stormwater run off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

Blake Hinman ASLA

THE CLEAN WATER INITIATIVE

The following is an alternative approach to SUSMP implementation which is supported by a variety of public and private organizations, companies and individuals. Those supporting this initiative favor enhanced water quality and improved storm water management.

The centerpiece of this initiative is a strong commitment to clean water through actual and measurable pollutant reduction. This is achieved through an inclusive process driven approach based on sound science (water quality and waste load analysis) and proven techniques (applied and tested BMPs). This is far better than simply relying on a volumetric approach (numeric standards) which is based solely on the "quantity" of water captured rather than the "quality" of the water released.

Commitments

The public and private organizations, companies and individuals supporting this initiative make the following commitments towards clean water and stormwater mitigation in Southern California:

- We commit to clean water
- We commit to implementing quality Best Management Practices (BMPs)
- We commit to doing demonstration projects and pilot programs on specific BMPs
- We commit to developing watershed management plans for each watershed in the Basin
- We commit to work cooperatively with **all** of the other stakeholders in this issue (the regulated community, the environmental community and the municipalities) to enhance water quality and improve stormwater management

Expectations

While we as public and private organizations, companies and individuals are willing to make important commitments towards clean water and stormwater mitigation, we also expect the Los Angeles Regional Water Quality Control Board (LARWQCB) to live up to its legal responsibilities regarding this issue. It is our belief that the LARWQCB can best do this by committing to support only those policies based on sound science, quality research and proven techniques. To do this it is our expectation that the LARWQCB will do the following analysis to verify the value of their policy initiatives:

- Water Quality Analysis
- Waste Load Analysis
- Cost Effectiveness Analysis

Process

We believe that a thoughtful "process driven" approach should be employed for the development of appropriate public policy regarding stormwater mitigation in Southern California. Further, we believe that the SUSMP Policy approved on January 6, 2000 by the Regional Council of the Southern California Association of Governments (SCAG) offers a quality process driven approach to SUSMPs. We support this policy, as outlined below, and would seek its inclusion in the final SUSMP resolution adopted by the LARWQCB.

The Southern California Association of Governments recommends that:

- *the Los Angeles Regional Water Quality Control Board not adopt SUSMP numeric standards until such time as the Board can validate the feasible, technical and scientific bases for numeric standards.*
- *the Board monitor pilot programs similar to those underway in Los Angeles County.*
- *the Board work closely with cities such as Calabasas, Santa Clarita and Santa Monica to assess the effectiveness of local initiatives aimed at managing runoff water flows and quality.*
- *the Board develop a Memorandum of Understanding with SCAG in which SCAG would incorporate a Best Management Practices for Preventing Storm Water Runoff Pollution in the Los Angeles Basin project in its Environmental Programs and Livable Communities work elements.*
- *the Board ask SCAG to manage a legal authorities initiative in which all of the 85 cities in the Los Angeles Basin would work to develop model language which would then be available for municipal implementation throughout the Basin.*
- *the Board invite SCAG to contribute its Section 208 authorities to a collaboration with other key organizations/stakeholders in scoping out plans for a watershed management initiative program in each watershed of the Basin.*
- *the Board evaluate the operating results of watershed (regional) mitigation programs prior to its consideration of any general retrofit mandates on existing land uses.*
- *the Board and SCAG cooperate with other stakeholders in putting best efforts into raising the new financial resources needed for planning and implementing these water quality commitments.*
- *the Board's staff be encouraged to meet with those SCAG sub-regional councils affected by the SUSMP program prior to any Board action on these matters.*

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

It is my understanding that the California Regional Water Quality Control Board - Los Angeles Region (Board) will be holding a public hearing on January 26, 2000. The hearing is on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054).

As a Southern California Professional Civil Engineer and a Principal in a Civil Engineering Firm of Land Development Projects, I support the goals of clean water. However, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area," and the addition of "Parking lots" to the list of projects subject to the SUSMP requirements.

These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

As mentioned above, I fully support the goal of cleaning our stormwater run off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders.

This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. In addition, I ask

that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Boards efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams, wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the Board to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not Parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Very truly yours;

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

It is my understanding that the California Regional Water Quality Control Board - Los Angeles Region (Board) will be holding a public hearing on January 26, 2000 on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California businessperson I support the goals of clean water, however, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area," and the addition of "Parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

Once again, let me reiterate that I fully support the goal of cleaning our stormwater run off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Boards efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to lour local rivers, streams, wetlands, bays and ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

11-353

R0068598

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the Board to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not Parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution cased by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based job sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

RE: Support for Three Quarter-Inch Standard to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

You have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. On January 26, 2000, we urge you to adopt a Standard Urban Stormwater Mitigation Plan for the Cities in Los Angeles County that requires mitigation, by specified new and redevelopments, through treatment or infiltration, of 100% of the runoff generated by the first three quarters of an inch of rain, with no exceptions. By adopting this standard, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

I know this is a form letter but wanted you to get this. WSN

As a surfer, I can personally attest to the damage to local water safety in the aftermath of any kind of significant rainfall. I, and many of my friends, have become ill while surfing immediately after a significant storm. Trust me when I say the problem is not imaginary.

Today approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs untreated into the ocean. With the most infamous urban runoff problem in the nation, and few measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming; creeks and streams with water that is unsafe to drink; and inland and coastal waters that pose health risks to aquatic life.

The three quarter-inch standard was supported by the Los Angeles Times in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem."

The three quarter-inch standard also makes economic sense. First, reducing storm water pollution in the planning phase of construction is the most cost-effective way to solve the runoff problem. Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) - and with billions of dollars at stake, the health of our entire regional economy is impacted.

11-359

R0068604

In a region that is constantly being built and rebuilt, adoption of the three quarter-inch standard will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our regional economy, and for a more livable Los Angeles, please adopt the three quarter-inch standard, with no exceptions, to mitigate the effects of urban runoff from new and redevelopment.

Regards.

W. Scott Norton, Attorney at Law

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Board's efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams, wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

Definition of Hillsides R0068606

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the Board modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent

555 Saint Charles Drive, Suite 205, Thousand Oaks, California 91360 tel: 805-557-2100 fax: 805-557-2139

or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a

commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,
SHEA HOMES

John Franklin

re: Stormwater Runoff Standards

Dear Mr. Dickerson,

As you know, on January 26th the Los Angeles Regional Water Quality Control Board will be considering a staff proposal to require new and redevelopments to treat or infiltrate 100% of the runoff from up to and including a .75 inch storm. This three quarter-inch, 24-hour storm standard is a reasonable and necessary step toward clean coastal and inland waters. Unfortunately, the proposal is also riddled with unnecessary and crippling exemptions. As Executive Director of the Coalition for Clean Air, I am writing in order to urge you to adopt this proposal, but only after eliminating exemptions such as the rooftop, small restaurant, local practices, and impracticability exceptions.

Urban storm water runoff, as a non-point source of water pollution, is a serious environmental threat. Your proposal should be guided throughout by the goal of reducing storm water pollution loads to the maximum extent practicable, and should seek to minimize the amount of stormwater directed to impermeable areas and to maximize the percentage of permeable surface in all categories of development and redevelopment.

While adoption of a three quarter-inch, 24-hour storm standard is the right way to move forward, it will only be effective if a host of unnecessary exemptions are eliminated from the proposal. One of the worst of the exemptions included in the current proposal is the Rooftop Exclusion, which could actually have the effect of encouraging larger rooftops, and therefore less permeable surface areas per site. Furthermore, rooftop runoff is allowed to bypass mitigation measures and may pass directly into street gutters and storm drains, despite the fact that rooftops collect aerial pollutants. There is no justification of this exemption within the context of efforts to achieve water quality improvements.

Other exemptions further weaken the proposed rule. All restaurants, regardless of size, are potential sources of polluted runoff, and should be included within the rule's provisions. Furthermore, you should adopt a proposal that allows for effective, even-handed enforcement of SUSMP requirements. We are concerned that effective enforcement will be compromised by current language which gives deference to existing local practices and which allows for "so-called" impracticability waivers. Finally, we would like to see regulation of runoff from parking lots of all types, including a list of BMPs applicable to all parking lots.

11-364

R0068609

As a recent L.A. Times series made clear, toxic pollution of Santa Monica Bay, and other coastal areas is a worsening problem, and the solutions available to solve this problem are limited and often expensive. Besides endangering public health, polluted stormwater runoff endangers aquatic life, in streams and rivers, as well as offshore. Luckily, you have the opportunity to adopt a proposal that is both effective, and practical.

Clean beaches and streams are important not only for public health and aquatic wildlife, but for our economy as well. Coastal tourism and recreation supports many Southern California businesses, and as our coastline becomes polluted their business declines – and our entire regional economy is affected. Reducing stormwater pollution at the construction phase is in fact the most cost-effective way to tackle this complex problem.

Of course this solution is not cost-free, but it is critical that we anticipate the effects of new developments, and their costs to the public, so that those problems can be mitigated at the outset, and anticipated as one of the costs of new development. This is not only the most cost-effective way to address the problem, but it is consistent with the principles of a market economy, which, to function well, requires that the costs of a product be reflected in its price. Since new developments increase the problem of polluted stormwater runoff, we must ask that the costs of minimizing these effects be included in the planning process, and not shifted to the public at-large, after the fact, at much greater expense.

In sum, I ask you to please support the three-quarter inch standard, with no exceptions, to mitigate the effects of storm water runoff from new and redevelopment. It is the right thing to do, for the public health, for our economy, for aquatic wildlife.

Sincerely,

Tim Carmichael

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I understand that the Los Angeles Region Board of the California Regional Water Quality Control Board will hold a public hearing on January 26, 2000 regarding the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California homebuilder I support the goals of clean water. However, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions of the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. More specifically, I am concerned with the definitions of "Hillside" and "Environmental Sensitive Area," and the addition of "Parking Lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many communities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, forces me to oppose the proposed SUSMP as it is presently drafted.

Again, I fully support the goal of properly cleaning stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality.

The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

In review of the concerns noted above, I request that the Board delete language expanding the scope of the SUSMP, and reject the implementation of a numerical mitigation standard. In addition, I ask that the Board support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

Leonard S. Frank

RE: Support for Staff Proposal to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

You have the opportunity to significantly reduce urban runoff, the *number one source of pollution to our coastal and inland waters*. In January 2000, I urge you to adopt the reasonable proposal set forth by your own staff to curb urban runoff: Ensure that specified new and redevelopments capture, treat or infiltrate 100% of the runoff generated by up to and including a three quarter-inch storm. By adopting this proposal, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

Today approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs untreated into the ocean. With the most infamous urban runoff problem in the nation, and little measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming, creeks and streams with water that is unsafe to drink, and inland and coastal waters that pose health risks to aquatic life.

Your staff's proposal is supported by the *Los Angeles Times* in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem."

The proposed standard also makes economic sense. First, reducing storm water pollution in the planning phase of construction is the most cost-effective way to solve the runoff problem. Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) – and with billions of dollars at stake, the health of our entire regional economy is impacted.

In a region that is constantly being built and rebuilt, adoption of your staff's proposal will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our

Copy

regional economy, and for a more livable Los Angeles, please support your staff's proposal to mitigate the effects of urban runoff from new and redevelopment.

Re: Support for Staff Proposal to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

On January 6, 2000, you and the Board have the opportunity to change our course toward worsening water pollution by adopting the proposal, set forth by your own staff, to require that specified new and redevelopments capture, treat or infiltrate 100% of the runoff generated by up to a three quarter-inch storm (i.e., 85% of all storms in this region).

The Los Angeles Region already suffers from some of the worst water quality in the nation. Your staff proposal is supported by the *Los Angeles Times* in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem." The recent disastrous experience with beach closures in the city of Huntington Beach underscores the need for these measures.

In a region that is constantly being built and rebuilt, adoption of your staff proposal will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our regional economy, and for a more

livable Los Angeles, please support your staff proposal to mitigate the effects of urban runoff from new and redevelopment.

Sincerely,

Paula A. Daniels

RE: Support for Staff Proposal to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

Los Angeles stands at a critical juncture in its environmental history. Brought to this point by extensive development, with a complete disregard for the quality and quantity of runoff generated. Today, approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs, untreated, into the ocean. With the most infamous urban runoff problem in the nation, and little measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming, creeks and streams with water that is unsafe to drink, and inland and coastal waters that pose health risks to aquatic life.

On January 6, 2000, you and the Board have the opportunity to change our course toward worsening water pollution by adopting the reasonable proposal set forth by your own staff: Ensure that specified new and redevelopments capture, treat or infiltrate 100% of the runoff generated by up to a three quarter-inch storm. RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Storm Water Mitigation Plan ("SUSMP") That will be discussed by the California Water Quality Control Board – Los Angeles Region ("Board") on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System ("NPDES") for Los Angeles County Municipal Storm Water Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from storm water run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Board's efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that have made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definitions for "Hillsides," "Parking Lots" and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, I suggest that the

R0068619

15760 Ventura Boulevard, Suite 1727, Encino, California 91436 (818) 905-0406 FAX (818) 905-9849

11-374

Board modify the definition as "property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater," or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input from the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input from the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. I suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input from the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by storm Water run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a realty. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-cited problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving storm Water pollution reduction.

Malibu Creek Watershed Management Committee

January 20, 2000

Mr. Dennis Dickerson, Executive Officer
Regional Water Quality Control Board, Los Angeles Region
320 W. 4th St. Suite 200
Los Angeles CA 90013

SUBJECT: SUSMP Policy and Implementation

Dear Mr. Dickerson:

The Malibu Creek Watershed Management Committee (WMC) decided the following on its January 13, 2000 meeting:

1) The Malibu Creek WMC supports the revised SUSMP that had been worked on by several parties but was removed from discussion this week. This version provides flexibility, but also requires specific water quality actions that will result in restored beneficial uses of our waterways.

2) The Malibu Creek WMC supports the policy statement approved by Southern California Association of Governments (SCAG) as the implementation counterpart of the SUSMPs, including the idea of using a Total Maximum Daily Load (TMDL) driven numeric standard rather than a volume based numeric standard. We also encourage the Regional Board to make the SCAG policy more formal by adopting a revised resolution, commit and coordinate resources as outlined in the policy, and direct staff to use TMDLs for developing the numeric standard.

3) The Malibu Creek WMC wishes to express its concern over the letter dated December 22, 1999 from Rutan and Tucker regarding objections to the SUSMPs. The Executive Advisory Committee (EAC) did vote to have a formal presentation on three aspects of the SUSMP issue to the Regional Board members during the SUSMP agenda item, the legal aspect being one of the three. However, the EAC did not review the contents of the letter prior to Rutan and Tucker sending it to you. The Malibu Creek WMC believes it inappropriate for that firm to say it is acting on behalf of the EAC

F:\USERS\HMERENDA\TODLPROG\DEVPLAN\hmmltr.doc

when the contents and tone of the letter were not made available to the group to discuss, edit as appropriate, and vote upon.

Thank you for your time and consideration.

Sincerely,

for Tim Plasky

RE: Proposed Standard Urban Storm Water Mitigation Plan

RECOMMENDED ACTION:

Adopt the following statement of policy on storm water runoff mitigation.

The Southern California Association of Governments recommends:

- *that the Regional Board encourage pilot programs similar to those underway by Los Angeles County in which the implementation of a numeric standard for runoff volumes produced by new developments can be monitored and evaluated in a various watershed settings.*
- *that the Board work closely with cities such as Calabasas, Santa Clarita and Santa Monica to assess the effectiveness of local initiatives aimed at managing runoff water flows and quality.*
- *that the Board develop a Memorandum of Understanding with SCAG in which SCAG would incorporate a Best Management Practices for Preventing Storm Water Runoff Pollution in the Los Angeles Basin project in its Environmental Programs and Livable Communities work elements.*
- *that the Board ask SCAG to manage a legal authorities initiative in which all of the 85 cities in the Los Angeles Basin would work to develop model language which would then be available for municipal implementation throughout the Basin.*
- *that the Board invite SCAG to contribute its Section 208 authorities to a collaboration with other key organizations/stakeholders in scoping out plans for a watershed management initiative program in each watershed of the Basin.*
- *that the Board evaluate the operating results of watershed (regional) mitigation programs prior to its consideration of any general retrofit mandates on existing land uses.*
- *that the Board and SCAG cooperate with other stakeholders in putting best efforts into raising the new financial resources needed for planning and implementing these water quality commitments.*
- *that the Board's staff be encouraged to meet with those SCAG sub-regional councils affected by the SUSMP program prior to any Board action on these matters.*

SUMMARY:

At its January 26, 2000 meeting the Regional Board will consider new provisions for a storm water runoff mitigation plan with a numeric standard requiring retention and treatment of up to ¾ of an inch of runoff on a specific site. The proposed plan would be inserted into both the new Long Beach storm water permit as well as the existing Los Angeles County permit. The

plan would materially impact many new development and redevelopment sites in Los Angeles County. The EEC is scheduled to consider this same item at its meeting also on January 6.

BACKGROUND:

The current Los Angeles County Storm Water Permit that was issued in 1996 (as well as the City of Long Beach Storm Water Permit issued earlier this year) called for various programs to be developed by the permittees. Among these programs was one for addressing storm water pollution issues that may result from development planning for private projects. In August the Executive Officer of the Los Angeles Regional Board announced a new proposed rule for managing pollution carried by urban storm water runoff from certain new development sites. This rule required that these sites would need to retain and possibly treat up to the first ¾ of an inch of storm water collected on these sites from a 24 hour storm event. At a public hearing on September 16, 1999 local government and private industry responses to this proposal raised many questions and objections to the implementation of a "numeric standard" as an appropriate way to manage pollutants associated with urban storm water runoff. These responses suggested that a numeric standard was a "volume" strategy, not a water quality strategy. A numeric standard dealt with quantities of water rather than with specific pollution problems associated with a given location and general hydrology.

Following the September hearing the Water Policy Task Force scheduled two months of testimony on this issue. A wide cross section of interested parties appeared before the Task Force to give comments and suggestions on the proposed new policy. These parties included local governments in the region who have different approaches for managing this pollution, Caltrans, the storm water specialist from the Regional Board, the building industry association, the National Resources Defense Council, automobile recycling and gasoline station representatives, and a fast food restaurant representative.

In response to this testimony the Task Force instructed staff to pursue informal discussions among the various parties to search for new ideas for improving runoff water quality and preventing more runoff pollution. These discussions were convened and were helpful in highlighting the importance of looking at this runoff pollution problem as a regional or watershed problem (rather than just a problem for specific development sites) and as a problem requiring much better identification (rather than just retaining urban runoff everywhere).

These concerns were presented by Mark Pisano to Dennis Dickerson, Executive Officer of the Regional Board, at a meeting in mid-November. Following that meeting a SCAG memorandum (attached) was sent to the Executive Officer, urging him to implement a watershed management approach with BMP development and monitoring in various locations. From these efforts and with SCAG's assistance the use of a numeric standard could be used as a "backup" policy, not a "front-end" policy, when identified priority pollution problems are not mitigated. This approach would allow solutions to be tailored to actual, identified pollution occurring in specific reaches of waterbodies throughout the County. Similarly this approach would feature larger-scale solutions (not just site-by-site runoff

RE: Building Industry Comments on the Standard Urban Stormwater Mitigation Plan (SUSMP)

Dear Mr. Dickerson:

On behalf of the 1,850 members of the Building Industry Association of Southern California, we would like to reiterate our concerns expressed to you in our September 1999 letter and our September 16, 1999 presentation before your Board on the SUSMP issue.

While our industry continues to support the goals of clean water, we remain opposed to the plan as written. The inclusion of a numerical mitigation standard whose benefits have not been proven and whose cost effectiveness has not been studied makes it impossible for us to support the December 7, 1999 staff proposal.

Let us be clear that the building industry is committed to the goal of cleaning our stormwater run off. Further, our industry is committed to participating in a process that truly seeks to achieve this goal. Such a process should include the testing and study of various best management practices with a focus on pilot programs which have proven to be effective. This process should involve all affected parties (the regulated community, the municipalities and the environmental community) and should be based on sound science.

Because the December 7, 1999 proposal does not provide for any of the process outlined above, we sincerely doubt that it will achieve its stated objective. As the industry principally impacted by this proposal, we would like to be part of a process that has a chance of actual, measured, scientifically proven success.

We respectfully request that you and the Board reject the concept of a numerical mitigation standard. We look forward to making a thorough presentation outlining all of our thoughts and concerns on these issues during your January 26, 2000 public hearing.

Sincerely,

Richard J. Lambros
Executive Vice President

Los Angeles, California 90013

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

On behalf of the 1,850 members of the Building Industry Association of Southern California (BIA/SC), I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Boards efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams, wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

R0068627

11 - 339 382

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the Board to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not Parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose

benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

Richard J. Lambros
Executive Vice President

cc: Mr. Hami Nahani, Chair
California Regional Water Quality Control Board, Los Angeles Region

11- 341 384

THE CLEAN WATER INITIATIVE

The following is an alternative approach to SUSMP implementation which is supported by a variety of public and private organizations, companies and individuals. Those supporting this initiative favor enhanced water quality and improved storm water management.

The centerpiece of this initiative is a strong commitment to clean water through actual and measurable pollutant reduction. This is achieved through an inclusive process driven approach based on sound science (water quality and waste load analysis) and proven techniques (applied and tested BMPs). This is far better than simply relying on a volumetric approach (numeric standards) which is based solely on the "quantity" of water captured rather than the "quality" of the water released.

Commitments

The public and private organizations, companies and individuals supporting this initiative make the following commitments towards clean water and stormwater mitigation in Southern California:

- We commit to clean water
- We commit to implementing quality Best Management Practices (BMPs)
- We commit to doing demonstration projects and pilot programs on specific BMPs
- We commit to developing watershed management plans for each watershed in the Basin
- We commit to work cooperatively with **all** of the other stakeholders in this issue (the regulated community, the environmental community and the municipalities) to enhance water quality and improve stormwater management

Expectations

While we as public and private organizations, companies and individuals are willing to make important commitments towards clean water and stormwater mitigation, we also expect the Los Angeles Regional Water Quality Control Board (LARWQCB) to live up to its legal responsibilities regarding this issue. It is our belief that the LARWQCB can best do this by committing to support only those policies based on sound science, quality research and proven techniques. To do this it is our expectation that the LARWQCB will do the following analysis to verify the value of their policy initiatives:

- Water Quality Analysis
- Waste Load Analysis
- Cost Effectiveness Analysis

Process

We believe that a thoughtful "process driven" approach should be employed for the development of appropriate public policy regarding stormwater mitigation in Southern California. Further, we believe that the SUSMP Policy approved on January 6, 2000 by the Regional Council of the Southern California Association of Governments (SCAG) offers a quality process driven approach to SUSMPs. We support this policy, as outlined below, and would seek its inclusion in the final SUSMP resolution adopted by the LARWQCB.

The Southern California Association of Governments recommends that:

- *the Los Angeles Regional Water Quality Control Board not adopt SUSMP numeric standards until such time as the Board can validate the feasible, technical and scientific bases for numeric standards.*
- *the Board monitor pilot programs similar to those underway in Los Angeles County.*
- *the Board work closely with cities such as Calabasas, Santa Clarita and Santa Monica to assess the effectiveness of local initiatives aimed at managing runoff water flows and quality.*
- *the Board develop a Memorandum of Understanding with SCAG in which SCAG would incorporate a Best Management Practices for Preventing Storm Water Runoff Pollution in the Los Angeles Basin project in its Environmental Programs and Livable Communities work elements.*
- *the Board ask SCAG to manage a legal authorities initiative in which all of the 85 cities in the Los Angeles Basin would work to develop model language which would then be available for municipal implementation throughout the Basin.*
- *the Board invite SCAG to contribute its Section 208 authorities to a collaboration with other key organizations/stakeholders in scoping out plans for a watershed management initiative program in each watershed of the Basin.*
- *the Board evaluate the operating results of watershed (regional) mitigation programs prior to its consideration of any general retrofit mandates on existing land uses.*
- *the Board and SCAG cooperate with other stakeholders in putting best efforts into raising the new financial resources needed for planning and implementing these water quality commitments.*
- *the Board's staff be encouraged to meet with those SCAG sub-regional councils affected by the SUSMP program prior to any Board action on these matters.*

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

It is my understanding that the California Regional Water Quality Control Board - Los Angeles Region (Board) will be holding a public hearing on January 26, 2000 on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California businessperson I support the goals of clean water, however, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area," and the addition of "Parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

Once again, let me reiterate that I fully support the goal of cleaning our stormwater run off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Boards efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams, wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the Board to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county).

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not Parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Mr. Dennis Dickerson, Executive Officer
California Regional Water Quality Control Board
Los Angeles Region
320 West 4th Street, Suite 200
Los Angeles, California 90013

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

It is my understanding that the Los Angeles Regional Water Quality Control Board (Board) will be considering the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as part of the January 26, 2000 meeting agenda. As a provider of housing for very-low, low- and middle-income residents in Southern California, I am very concerned that certain requirements in the proposal will have serious impacts on housing affordability.

First, let me voice my strong support for the efforts of the Board in attempting to address the problem of water pollution caused by storm water runoff. After years of progress in cleaning our waterways by addressing point source pollution, it makes sense to continue that progress by turning our attention to non-point source pollution contained in runoff from urban areas. After reviewing your proposal, however, I have serious doubts that it will do anything to clean the water that flows to our beaches and oceans while adding to construction costs, thereby making an already unaffordable market even worse.

Currently in the Los Angeles metropolitan area, only 43 percent of households earning the median income can afford to own a home. That is 20 percentage points below the national average and one of the worst affordability rates in the nation. In my efforts to provide affordable housing I must rely on building a product that efficiently uses land to minimize the cost to the consumer. I fear that your proposal, especially the numeric design standard, will require me to use an inordinate amount of land to meet the numeric standard and unnecessarily increase costs to those who can least afford it.

R0068640

11-396

I am particularly concerned with the fact that this costly, burdensome proposal was put forward without any rational scientific basis for pollution reduction. Nowhere in the December 7th proposal is there a discussion of the goals or timetables for pollution reduction, or, more importantly, any mention of the pollutants that this proposal is trying to mitigate. It seems extremely premature to implement such a wide-ranging and potentially damaging proposal that will deny housing to very-low, low- and middle-income families without having any idea of its ability to reduce water pollution.

I have had the opportunity to review the "Clean Water Initiative", supported by the Southern California Association of Governments and a number of groups and government professionals. This initiative takes a common sense approach to clean water by first, identifying what is polluting our water and then designing a program that seeks to reduce the pollutants. I respectfully request that you and the Board adopt the "Clean Water Initiative" as an alternative to the current proposal.

Sincerely,

Bernardo M. Perez, Project Manager

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

I have received and reviewed the December 7, 1999 Standard Urban Stormwater Mitigation Plan (SUSMP) that will be discussed by the California Water Quality Control Board – Los Angeles Region (Board) on January 26, 2000. It is my understanding that the SUSMP program is called for in the National Pollutant Discharge Elimination System (NPDES) for Los Angeles County Municipal Stormwater Permit (Order #96-054).

As a Southern California resident and home building professional, I support the Board's efforts in developing and implementing policies and programs that will reduce pollution resulting from stormwater run-off and achieve clean water in the Los Angeles region. However, I am concerned with the current proposed staff recommendations to the SUSMP. As mentioned before, I support the Boards efforts for achieving clean water, but as the individual who must implement the SUSMP program as I construct new homes, I must say that this program falls short in achieving our shared goal of delivering clean water to our local rivers, streams, wetlands, bays and the ocean.

ADOPT THE SUSMP WITH AMENDMENTS

Since the release of the original SUSMP in late August, 1999 and the September 16, 1999 Board hearing, there have been many changes by staff that has made the SUSMP more complex and confusing to interpret and implement.

First, the December 7, 1999 SUSMP proposal has added several new and stricter definitions. The definition for "Hillsides," "Parking Lots," and "Environmental Sensitive Areas" have been dramatically changed since the September 16, 1999 Board hearing. These new definitions have not been discussed yet in a public hearing or with the regulated communities.

Definition of Hillsides

The December 7, 1999 SUSMP has changed the definition of "Hillside" without review by the municipalities, the regulated communities or interested parties. Therefore, we suggest that the

11-398

R0068642

23770 Valencia Blvd., Suite 200, Santa Clarita, CA 91355
(805) 260-1700 · Fax (805) 260-1778

Board to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater, or delegate the authority of this definition to the local municipalities (i.e., the cities or county). This definition has been studied extensively in many municipalities, such as Santa Clarita, and specific guidelines have been adopted.

Parking Lots

A new category subject to SUSMP, "Parking Lots" was added without a public hearing or input for the municipalities, the regulated communities or interested parties. It is unclear why and how the "Parking Lots" will be defined and implemented under the SUSMP. Furthermore, it is my understanding that the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots. I suggest that the Board wait for the results of the Long Beach study on parking lots before adding this category to the SUSMP, or that "Parking Lots" be defined to apply only to commercial "stand alone" parking lots, and not Parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

Once again, staff has added another new category of "Environmentally Sensitive Areas" to the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. This new category has many different and conflicting provisions under federal, state and local law. Furthermore, these many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, will result in the application of SUSMP criteria to an inherently vague definition leading to application of those criteria in situations where it was not intended. We suggest the Board work with the municipalities, the regulated communities and interested parties on developing one single definition.

DO NOT ADOPT A NUMERICAL DESIGN STANDARD

At the September 16, 1999 Board hearing on the SUSMP, the only significant difference between the staff's proposal and that of the municipalities, the regulated communities and interested parties was the inclusion of a numerical design standard for the sizing of Best Management Practices. The staff proposal includes a specific design standard in the SUSMP without a public hearing or input for the municipalities, the regulated communities or interested parties. Additionally, the continued inclusion of a numerical design standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

"CLEAN WATER INITIATIVE"

Once again, let me reiterate that I fully support the goal of reducing pollution caused by stormwater run-off. That is why I support the attached "Clean Water Initiative," which is also

supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, I respectfully request that you and the Board correct the above-mentioned problems to the SUSMP. In addition, I ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Very truly yours,

RE: Support for Three Quarter-Inch Standard to Reduce Runoff from New and Redevelopment

Dear Mr. Dickerson:

You have the opportunity to significantly reduce urban runoff, the number one source of pollution to our coastal and inland waters. On January 26, 2000, we urge you to adopt a Standard Urban Stormwater Mitigation Plan for the Cities in Los Angeles County that requires mitigation, by specified new and redevelopments, through treatment or infiltration, of 100% of the runoff generated by the first three quarters of an inch of rain, with no exceptions. By adopting this standard, you and the Regional Board have the opportunity to alter our current course towards worsening water pollution.

Today approximately 50% of our rainfall is converted into runoff that builds in toxicity as it crosses parking lots, building sites, industrial sites, automotive repair garages, and gas stations before it is channeled and runs untreated into the ocean. With the most infamous urban runoff problem in the nation, and few measurable requirements in the municipal storm water permits, we have countless beaches that are frequently unsafe for swimming; creeks and streams with water that is unsafe to drink; and inland and coastal waters that pose health risks to aquatic life.

The three quarter-inch standard was supported by the Los Angeles Times in its October 6th editorial as a "promising new approach . . . [that] could well keep ocean pollution from worsening and help prevent beach closings," and a "good start in dealing with a tough problem."

The three quarter-inch standard also makes economic sense. First, reducing storm water pollution in the planning phase of construction is the most cost-effective way to solve the runoff problem. Second, urban runoff is bad for our regional economy. Los Angeles County coastal tourism and recreation businesses generate over two billion dollars annually, but these businesses are largely dependent on the health of the coastal resources to attract their customers. As the health of the coastline declines, so does business (just ask any businessperson near Huntington Beach) - and with billions of dollars at stake, the health of our entire regional economy is impacted.

In a region that is constantly being built and rebuilt, adoption of the three quarter-inch standard will soon have a transformative impact on the amount of polluted runoff that invades our streams, rivers and coastal waters. For the health of local aquatic life, for the health of the 60 million people who visit Los Angeles County beaches annually, for the health of our regional economy, and for a more livable Los Angeles, please adopt the three quarter-inch standard, with no exceptions, to mitigate the effects of urban runoff from new and redevelopment.

Sincerely,

Cheri Toomey Uno

Mr. Dennis Dickerson
Executive Officer
Regional Water Quality Control
Board/Los Angeles
320 W. 4th Street
Suite 200
Los Angeles, CA 90013

Dear Mr. Dickerson:

This is submitted on behalf of the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita. Those Cities appreciate what appears on initial review of the January 18, 2000, Staff Report and Record of Decision to be continued improvements and refinements. However, please note the language "what appears on initial review...." This language was used to make the point that time has permitted only a most preliminary review. There has been insufficient time for Cities, to say nothing of those who will be affected by the SUSMP, to make any kind of detailed analysis, much less to prepare comments for the Board's consideration and your staff's evaluation.

Of course there has been no opportunity to evaluate the "Change Sheet" and the impact of "clarifications" in that document which, to my knowledge, is not yet available for public review. It is for these reasons, as a matter of procedural due process, that I am constrained to now ask you and the Board to delay this item until March, 2000, at the earliest. Recitals of the notice provided for earlier versions of the SUSMP are interesting, but they are no substitute for adequate notice of the latest changes. We must make the point that the adequacy of

notice is not determined by averaging the notice given to all prior versions of the SUSMP, it depends on how much notice was provided as to the version which is to be adopted, with all modifications, including those in the January 18, 2000, Staff Report and Record of Decision and the yet-to-be promulgated Change Sheet.

Please print this Facsimile and include it, in its entirety (and not just as a summary), in the administrative record of this matter as comments by the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita, and each of them.

In addition, the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita, and each of them, reserve the right to address the Board at the Meeting and Hearing on January 26, 2000, or any adjourned or continued meeting and hearing.

Sincerely,

STEPHEN R. ONSTOT

Reference: **STANDARD URBAN STORMWATER MITIGATION PLAN**

Via Fax #: (213) 576-6625

Dear Mr. Dickerson:

The California Regional Water Quality Control Board – Los Angeles Region (Board) is scheduled to hold a public hearing on January 26, 2000 on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California engineer and businessperson, I support the goals of clean water; however, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area", and the addition of "parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

I fully support the goal of cleaning our stormwater runoff and the attached "Clean Water Initiative" which is also supported by a number of regulated industries and business leaders. This initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. I understand that the process outlined in the initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities, and the environmental community) in a thoughtful process based on scund science and proven techniques.

11-404

R0068648

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. Also, I request that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

RE: Standard Urban Storm Water Mitigation Plan

Dear Mr. Dickerson:

The Apartment Association, California Southern Cities, represents 3,000 owners and operators of rental properties in Southern Los Angeles County and we support the goals of clean water; however, we are strongly opposed to certain provisions of the revised Standard Urban Water Mitigation Plan (SUSMP). As a partner with government for 75 years, we are concerned about any regulation or procedure that will negatively affect the development of housing in our region. Los Angeles County is approaching a near crisis situation in housing at this time without additional restraints.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, we are concerned with the attempt to define "Hillside" and "Environmental Sensitive Area," and the addition of "Parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for us to support the proposed SUSMP.

Once again, let me reiterate that we fully support the goal of cleaning our stormwater run off. That is why we support the attached "Clean Water Initiative," which is also supported by a number of regulated industries and business leaders. This Initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. The process outlined in the Initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities and the environmental community) in a thoughtful process based on sound science and proven techniques.

Therefore, the Apartment Association, California Southern Cities, respectfully requests that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. In addition, we ask that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Chairman H. David Nahai
and Members of the Board
California Regional Water Quality Control Board
Los Angeles Region
320 West 4th Street, Suite 200
Los Angeles, California 90013

Dear Chairman Nahai and Members of the Board:

On behalf of the Building Industry Association of Southern California (BIA/SC), I must express strong concern with the way the SUSMP issue has been handled by Board Staff. The lack of a set process for addressing this very important issue, coupled with last minute and seemingly arbitrary changes in the facts involved with this hearing, concern our industry greatly and leave us with a sense of "foul play." What is most disturbing is that the handling of this issue to date has most certainly limited informed public access to the decision making process.

Specific Concerns

As you will recall, at your September 16th Hearing on SUSMP several individuals noted for the Board their concerns over a lack of proper notification and other problems with how the issue had been handled. Also, our industry and others raised specific concerns over, what appeared to be, favorable treatment to the environmental community as to the rules governing their testimony and presentation to the Board.

Since the September hearing things have not gotten better and in fact have gotten even worse. Several specific actions by Board Staff continue to concern us. First of all, the meeting location for the hearing was changed late Friday afternoon, long after we (and other organizations) had already sent out numerous notices asking our members to attend and giving them the original meeting location.

Second, in a memo from Xavier Swamikannu of Board Staff dated December 17, 1999, we were told to coordinate all of the individuals speaking on behalf of our industry into one comprehensive presentation on SUSMPs. We were specifically asked to give Board staff a list of the individuals that would be speaking and the amount of time required. After complying with this request and believing that this is how the hearing would be handled, we were told just last Friday afternoon (only 3 business days before the hearing) that the hearing would be handled in a completely different fashion. We now learn that we will have only three minutes per individual and no opportunity for a comprehensive presentation from our

1-41

R0068655

industry. We are concerned, not only over the late nature of this change in plans, but also over the fact that the procedure the Board is now planning to use is in no way sufficient to cohesively convey our industry's concerns, especially considering the highly technical nature of some of our issues.

Third, we are concerned that we were given a December Draft of the SUSMP proposal to comment on. Then in the January 18th staff report we were told that a "Change Sheet" would be issued later which would make changes to the Draft SUSMP document. After regular business hours last Friday, a very hard to follow list of changes (Change Sheet) was sent out from the Board Staff. Most people did not even receive this document until Monday morning, just two days before the hearing. Even after reviewing the Change Sheet it is difficult to understand what is the exact language being proposed in the revised SUSMP that will be before the Board on Wednesday.

To give Board Staff insight into our industry's position and to gain clarification on a number of issues within the Change Sheet, we met with your Executive Officer, Dennis Dickerson yesterday. While we appreciate Mr. Dickerson's time, there were several questions that he could not answer regarding what the final language submitted to the Board would include. He referred us to Xavier Swamikannu of the Board Staff as the person writing the final language and the individual that could answer our questions. We asked to talk with Mr. Swamikannu yesterday but he was in San Diego at a meeting. This morning (Tuesday) we finally did reach Mr. Swamikannu at the Board Office and after reviewing with him the questions which Mr. Dickerson could not answer, we were still unable to confirm what would be in the specific language in the final SUSMP proposal before the Board. He further informed us that an additional Change Sheet would be issued later today or tomorrow morning before the hearing.

Our concern here is that once again the Board Staff has engaged in last minute changes that will make it difficult for our industry and all other concerned parties to provide truly informed testimony during tomorrow's hearing. The "ever-changing" nature of the staff's proposal has limited informed public access to the process and has created an environment that is not conducive to the formation of sound public policy.

Finally, after meeting with Mr. Dickerson yesterday we asked Board Staff for a copy of the full comment binder that was sent to you as Board Members. Staff was kind enough to provide us a copy, however, after we went through the binder we could not locate the January 12, 2000 request letter or the January 14, 2000 comment letter submitted to the Board by BIA/SC. Also missing from the binder was a January 14, 2000 comment letter from one of our BIA members. When we pressed Board Staff for a reason why these letter were not included we were told that Mr. Dickerson had chosen which letters went into the binder and which did not. Board Staff assured us that all letters, even those not included in the binder, were eventually sent out to the

Board Members through supplemental packages. When we asked if they had copies of the supplemental letters that had been sent or if they could just verify for us that our letters were indeed sent to the Board Members, they could not. They also could not locate the file which contains all of the original comment letters received by the Board on the SUSMP issue because Mr. Swamikannu had taken the file with him to San Diego. (This struck us as a risky policy for original documents which are part of the public record.) Since Board Staff could not confirm that our January 14, 2000 comment letter ever got to you, the voting Board Members, they did agree to send it out in yesterday's supplemental package.

This incident causes us great concern, both because we wonder what other information may not have made it to Board Members and also because of the arbitrary approach that Board Staff has used in determining what was included in your binder. For example, your binder included two old letters from our association, but not the most relevant one, our January 14th comment letter. Also, while our letter somehow didn't make the comment binder, Board Staff took the time to send all Board Members an additional binder completely dedicated to the NRDC position paper and support material. Lacking a consistent process, the staff's actions appear arbitrary and unfair.

Summary of Concerns

Taken together – and within three business days before the hearing – the Board has changed meeting locations, changed the way we will be allowed to address the Board during the hearing, and (up to the last minute) has changed the actual language of the policy being considered at the Hearing. This is hardly a professional way to do business. Further, it is hard to argue that these activities invite informed participation from the public and concerned organizations.

Please also consider that those of us wishing to address you, the Board Members, are not allowed to do so independently because of your ex parte communication policy. This means that our only opportunity to address you directly on this important issue will occur during Wednesday's hearing. This makes these proceedings extremely important to us. Yet, we are forced to try to communicate our numerous concerns on complex and technical issues in the context of a three-minute presentation to the Board. If that weren't hard enough, please consider that we have had less than three business days to prepare for this restrictive format and that we have still not even seen the final SUSMP language that will be before the Board. Add to this that we are now forced to question whether you, the Board Members, are receiving all of the valuable information that we and other interested parties are sending to you in advance on this critically important SUSMP issue.

Because of these concerns, our industry strongly objects to the way the SUSMP issue has been handled to date. We are happy to participate in a fair process, but the one that we have been subjected to is not such a process. Further, we believe that you, as Board Members,

need to know that your staff has created an environment that is not conducive to the creation of sound public policy.

Request for Time

One means by which the Board could rectify some of the concerns we have raised is by allowing for an additional half-hour presentation during tomorrow's hearing. The process you have outlined for the hearing includes two 30-minute segments of time, one segment in support of and one segment in opposition to the SUSMP proposal. The Board's memo describing this process states that, "The Board will accept, at the beginning of the meeting, a list of 10 speakers from those in favor and a list of 10 speakers from those in opposition who will use this time." While this sounds fair and impartial, the fact is that Board Staff has allowed David Beckman from NRDC to coordinate the 10 speakers (30 minutes) in support and Desi Alvarez from EAC to coordinate the 10 speakers (30 minutes) in opposition. This means that the Board will hear a 30-minute presentation from the environmental community in support of the SUSMP proposal and a 30-minute presentation from the municipalities (permitees) in opposition to the SUSMP proposal. (It should be noted that the environmental community does not completely support, nor do the municipalities completely oppose what has been presented in the SUSMP proposal.)

What is missing from this plan is a presentation from another very important group – the regulated community. Board Members should have the benefit of hearing a comprehensive presentation from those who will ultimately be asked to implement and comply with the SUSMP proposal. Failure to include the regulated community in the initial presentations is tantamount to receiving only part of the story.

With this in mind, the Building Industry Association of Southern California requests that the Board amend the procedure for public comment to include a third 30-minute presentation from the regulated community. We hope that your desire for an informative and inclusive public hearing on the SUSMP proposal will justify this request

Thank you for your attention in this important matter and for your consideration of our request.

Sincerely,

Richard J. Lambros
Executive Vice President

Los Angeles, CA 90013

RE: Standard Urban Storm Water Mitigation Plans (SUSMPs) Submitted For Approval To The Executive Officer Under The Los Angeles County Municipal Storm Water Permit (Public Notice No. 99-047)

Dear Mr. Dickerson:

The Los Angeles Area Chamber of Commerce (LAACC) has reviewed the Regional Water Quality Control Board's proposal to incorporate numeric mitigation measures (the first 0.75 inches of rainfall within a 24-hour storm event) into the SUSMPs. While the Chamber fully supports stormwater pollution reduction programs, we must express our concerns with numeric mitigation measures and offer an alternative prior to the adoption of the SUSMPs.

The Chamber supports the attached "Clean Water Initiative", which is supported by a number of regulated industries, business leaders and SCAG.

We urge the Board to reject your current proposal and, instead, adopt the "Clean Water Initiative".

Sincerely,

Ezunial Burts
President

R0068659

11-405

THE CLEAN WATER INITIATIVE

The following is an alternative approach to SUSMP implementation which is supported by a variety of public and private organizations, companies and individuals. Those supporting this initiative favor enhanced water quality and improved storm water management.

The centerpiece of this initiative is a strong commitment to clean water through actual and measurable pollutant reduction. This is achieved through an inclusive process driven approach based on sound science (water quality and waste load analysis) and proven techniques (applied and tested BMPs). This is far better than simply relying on a volumetric approach (numeric standards) which is based solely on the "quantity" of water captured rather than the "quality" of the water released.

Commitments

The public and private organizations, companies and individuals supporting this initiative make the following commitments towards clean water and stormwater mitigation in Southern California:

- We commit to clean water
- We commit to implementing quality Best Management Practices (BMPs)
- We commit to doing demonstration projects and pilot programs on specific BMPs
- We commit to developing watershed management plans for each watershed in the Basin
- We commit to work cooperatively with **all** of the other stakeholders in this issue (the regulated community, the environmental community and the municipalities) to enhance water quality and improve stormwater management

Expectations

While we as public and private organizations, companies and individuals are willing to make important commitments towards clean water and stormwater mitigation, we also expect the Los Angeles Regional Water Quality Control Board (LARWQCB) to live up to its legal responsibilities regarding this issue. It is our belief that the LARWQCB can best do this by committing to support only those policies based on sound science, quality research and proven techniques. To do this it is our expectation that the LARWQCB will do the following analysis to verify the value of their policy initiatives:

- Water Quality Analysis
- Waste Load Analysis
- Cost Effectiveness Analysis

11-416

Process

We believe that a thoughtful "process driven" approach should be employed for the development of appropriate public policy regarding stormwater mitigation in Southern California. Further, we believe that the SUSMP Policy approved on January 6, 2000 by the Regional Council of the Southern California Association of Governments (SCAG) offers a quality process driven approach to SUSMPs. We support this policy, as outlined below, and would seek its inclusion in the final SUSMP resolution adopted by the LARWQCB.

The Southern California Association of Governments recommends that:

- *the Los Angeles Regional Water Quality Control Board not adopt SUSMP numeric standards until such time as the Board can validate the feasible, technical and scientific bases for numeric standards.*
- *the Board monitor pilot programs similar to those underway in Los Angeles County.*
- *the Board work closely with cities such as Calabasas, Santa Clarita and Santa Monica to assess the effectiveness of local initiatives aimed at managing runoff water flows and quality.*
- *the Board develop a Memorandum of Understanding with SCAG in which SCAG would incorporate a Best Management Practices for Preventing Storm Water Runoff Pollution in the Los Angeles Basin project in its Environmental Programs and Livable Communities work elements.*
- *the Board ask SCAG to manage a legal authorities initiative in which all of the 85 cities in the Los Angeles Basin would work to develop model language which would then be available for municipal implementation throughout the Basin.*
- *the Board invite SCAG to contribute its Section 208 authorities to a collaboration with other key organizations/stakeholders in scoping out plans for a watershed management initiative program in each watershed of the Basin.*
- *the Board evaluate the operating results of watershed (regional) mitigation programs prior to its consideration of any general retrofit mandates on existing land uses.*
- *the Board and SCAG cooperate with other stakeholders in putting best efforts into raising the new financial resources needed for planning and implementing these water quality commitments.*
- *the Board's staff be encouraged to meet with those SCAG sub-regional councils affected by the SUSMP program prior to any Board action on these matters.*

Reference: **STANDARD URBAN STORMWATER MITIGATION PLAN**

Via Fax #: (213) 576-6625

Dear Mr. Dickerson:

The California Regional Water Quality Control Board – Los Angeles Region (Board) is scheduled to hold a public hearing on January 26, 2000 on the adoption of the proposed Standard Urban Stormwater Mitigation Plans (SUSMP) as required under the Los Angeles County Municipal Stormwater Permit (Order No. 96-054). As a Southern California engineer and businessperson, I support the goals of clean water; however, after reviewing the December 7, 1999 revision of the SUSMP, I am opposed to certain provisions within the plan.

Included in the revised SUSMP are several new and modified definitions that restrict development activity. Specifically, I am concerned with the attempt to define "Hillside" and "Environmental Sensitive Area", and the addition of "parking lots" to the list of projects subject to the SUSMP requirements. These requirements make the implementation of the SUSMP completely impractical in many municipalities in Los Angeles County.

Additionally, the continued inclusion of a numerical mitigation standard in the SUSMP, whose benefits have not been proven and whose cost effectiveness has not been studied, makes it impossible for me to support the proposed SUSMP.

I fully support the goal of cleaning our stormwater runoff and the attached "Clean Water Initiative" which is also supported by a number of regulated industries and business leaders. This initiative makes a commitment to clean water and, perhaps more importantly, it supports a process by which clean water can become a reality. I understand that the process outlined in the initiative is additionally supported by the Southern California Association of Governments and would involve all affected parties (the regulated community, municipalities, and the environmental community) in a thoughtful process based on sound science and proven techniques.

11-418

Therefore, I respectfully request that you and the Board delete the language outlined above expanding the scope of the SUSMP and reject the implementation of a numerical mitigation standard. Also, I request that you support the comprehensive "Clean Water Initiative" as a way of truly achieving stormwater pollution reduction.

Sincerely,

SIKAND ENGINEERING ASSOCIATES

Subject: SUSMP, as Amended by Staff Report and "Change Sheet" Request for Continuance

Dear Mr. Dickerson:

This is submitted on behalf of the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita. Those Cities appreciate what appears on initial review of the January 18, 2000, Staff Report and Record of Decision to be continued improvements and refinements. However, please note the language "what appears on initial review...." This language was used to make the point that time has permitted only a most preliminary review. There has been insufficient time for Cities, to say nothing of those who will be affected by the SUSMP, to make any kind of detailed analysis, much less to prepare comments for the Board's consideration and your staff's evaluation.

Of course there has been no opportunity to evaluate the "Change Sheet" and the impact of "clarifications" in that document which, to my knowledge, is not yet available for public review. It is for these reasons, as a matter of procedural due process, that I am constrained to now ask you and the Board to delay this item until March, 2000, at the earliest. Recitals of the notice provided for earlier versions of the SUSMP are interesting, but they are no substitute for adequate notice of the latest changes. We must make the point that the adequacy of notice is not determined by averaging the notice given to all prior versions of the SUSMP, it depends on how much notice was provided as to the version which is to be adopted, with all modifications, including those in the January 18, 2000, Staff Report and Record of Decision and the yet-to-be promulgated Change Sheet.

Please print this email and include it, in its entirety (and not just as a summary), in the administrative record of this matter as comments by the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita, and each of them.

In addition, the Cities of Alhambra, Compton, El Segundo, Lomita, Hawthorne, Torrance, Industry and Santa Clarita, and each of them, reserve the right to address the Board at the Meeting and Hearing on January 26, 2000, or any adjourned or continued meeting and hearing.

From: Jorge Leon
To: Xavier Swamikannu
Date: 1/25/00 2:58PM
Subject: Re: SUSMP

1. It's my belief that, since the Permit says "discretionary," we're stuck. It simply does not include nondiscretionary activities. To include them in this proposal by the EO is beyond the scope of the Permit authority. It would take an act of the Board to amend the Permit to include non-discretionary activities.

2. I would recommend reading this liberally. I.e., the enumerated categories are inclusive of all types of development, including nondiscretionary activities. The enumerated categories are included are the list because there is sound evidence showing the need to control those discharges. These are within the EO's authority to control regardless of whether they are discretionary or not.

3, 4 and 5. I don't know enough about the remaining three issues yet, but will try to be conversant by tomorrow a.m.
>>> Dennis Dickerson 01/24/00 06:19PM >>>
Need a quick check on three issues:

1) The 1996 permit talks about discretionary projects. Can SUSMPs be applied to non-discretionary projects as well as discretionary or is the board limited in this instance. See Page 4 of the NRDC letter.

2) Are the enumerated categories comprehensive of all types of development?
Or are non-discretionary projects in a specified category included?

3) We are concerned about a single family home on a hillside but not, apparently, if the runoff is to an ESA. Is this distinction appropriate.

4) Xavier: is the change sheet definition for an ESA clear or what we discussed?

5) Xavier, there are some glitches with the change sheet that must be fixed tomorrow, i.e., references to pages in the change sheet don't match the Dec 7th version.

EDITORIAL
The Hard Part in Water Cleanup

The cleanup of California waters is progressing much the way air pollution control has in the state: The easy stuff gets done first, the most difficult and costly is put off. The first big smog control efforts were aimed at developing cleaner-burning motor vehicles and controls on major industrial sites. Now, the effort is down to hard, big issues like diesel trucks and smaller sources including paint solvents, dry cleaners and even barbecue charcoal starter.

In similar fashion, we first had sewage treatment projects, then controls on waste discharges from industrial plants and other major sources of pollution. Now comes the hard part, the polluted runoff from "nonpoint" sources--streets, freeways, parking lots, construction sites and farmland, to name a few.

Approval of a California plan against nonpoint pollution was held up for four years because the **state Water Resources Control Board** and the California Coastal Commission failed to agree on the elements of an effective control program. But now the two agencies have reconciled their differences and the water board has adopted an ambitious 61-point program, to be implemented in stages over the next 15 years. The Coastal Commission is expected to ratify the plan next month. The program is of special importance to Southern California because this form of toxic runoff is a major cause of the closure of beaches to swimmers.

Significantly, the **water board's** plan extends to the entire state and not just the coastal region as currently required by the U.S. Environmental Protection Agency. Officials said it makes sense to cover all of the state because much of what reaches the ocean originates in the inland mountains and foothills. Cleanup proposals would include purifying street and freeway runoff from storm sewers before it empties into the ocean and establishing catch basins to filter sediments from hillside runoff. The cost over the next decade, to be borne mainly by taxpayers and affected businesses, has been estimated at up to $14 billion. Some money could come from a water bond issue on the March 7 primary election ballot, and approval of the project by federal authorities would trigger an increase in aid available from Washington.

State officials are concerned about the reaction of developers to the new plan, which although voluntary to begin with could lead to sanctions for defiant polluters. Existing rules require builders to control runoff from specific projects. The new plan seeks to curb discharges on a broader basis to cover entire drainage areas and watersheds.

State Resources Secretary Mary Nichols did not exaggerate when she said approval of the program is "a great success." The key now is to rally public and political support.

Regulators seek to reduce pollution from urban runoff
Thursday, December 16, 1999
Sacramento Bee

LOS ANGELES **(AP)** -- A plan aimed at cleaning up rainwater that flows from city streets into the ocean was approved by the state **Water Resources Control Board.**

The panel approved regulations Tuesday that call for strict monitoring of coastal water quality and would require state and local government to prevent pollutants such as pesticides, motor oil, restaurant grease and farm effluent from washing into the sea.

The plan will go to the California Coastal Commission next month, where it is expected to be approved, and then to two federal agencies for final review.

If a decision is stalled for long, however, more than $5 million in federal funds to jump-start the effort would be jeopardized, water board officials said.

"Polluted runoff is the major environmental pollution problem we're facing in this state," said Mary Nichols, the governor's secretary of resources. "This is definitely a step forward."

Among the changes being studied are catch basins for runoff, improved procedures for scrubbing drainage from highways and stricter rules for businesses that seep pollutants and generate large amounts of garbage.

Under the statewide plan, voluntary rules would first be developed. If the pollution problem failed to improve, concrete regulations would be set in place.

If that does not produce results, authorities could take tough enforcement steps against violators, including legal action.

A few environmentalists called the plan short on specifics and in need of strengthening before the Coastal Commission meeting next month.

"We still don't see that the state water board really wants to make it work," said Mark Gold, executive director of the environmental group Heal the Bay.

Subject: Fertilizer Article

Fertilizers turning back yards and farms into toxic dumps, study shows
Thursday, November 18, 1999
SACRAMENTO BEE
By Mary Ann Lickteig, Associated Press Writer

SAN FRANCISCO (AP) -- Fertilizers are turning California back yards and farm fields into toxic waste dumps and the state is doing too little to stop it, two advocacy groups said in a report released today.

State officials are considering adopting regulations that would allow toxic elements to remain in fertilizer at levels that are higher than federal hazardous waste standards, said Bill Walker, the California director of Environmental Working Group.

That means that a bag of fertilizer would be treated -- or disposed of -- as hazardous waste, Walker said.

"It's more toxic than toxic waste," he said.

In their report, the Environmental Working Group and California Public Interest Research Group say fertilizer manufacturers use industrial toxic waste as a cheap source of plant nutrients and fail to remove contaminants that cause cancer, as well as reproductive, developmental and other health problems.

A spokeswoman for the California Fertilizer Association defended the Department of Food and Agriculture, which proposed the regulations.

Jennifer Lombardi said the rules are based on "sound science," and that comparing levels of contaminants allowed in fertilizers with the levels allowed in hazardous waste is unfair, akin to comparing apples with oranges.

The report singles out Ironite, saying that ingestion of less than half a teaspoon of the fertilizer could be toxic to small children.

Proposed state regulations are not tough enough, the groups say. The state is considering regulating the amount of arsenic, cadmium and lead in fertilizer sold for commercial use.

Authors of the report say the proposed acceptable levels are too high.

They criticize the department for ignoring other dangerous elements, for failing to regulate fertilizer sold for home use and for failing to require manufacturers to label their bags with a list of the contaminants inside -- even though the state requires them to list the nutrients.

"State law requires them to list what's good in fertilizer, but they don't have to list what's bad," said Jonathan Kaplan, toxics program director for CALPIRG. He was also in the group organized by the Department of Food and Agriculture to study the health risks posed by fertilizer.

The report points out that most commercial and home-use fertilizers are "relatively uncontaminated, demonstrating the availability and economic viability of safer alternatives."

Calls to the Department of Food and Agriculture were not returned Wednesday.

Lombardi said the proposed regulations are based on an assessment of the health risks fertilizers pose to people.

Mark Gold

Message to Water Board: Seize the Day
The regional agency has a chance to curb polluted runoff. It must not flub a decision crucial to all of L.A.

Today, the Los Angeles Regional Water Quality Control Board is expected to make one of the most important decisions in its 50-year history, and its most significant decision ever, on the issue of polluted urban runoff. Is the board serious about creating a more livable Los Angeles by taking steps toward solving the region's urban runoff problem, now regarded as one of the nation's worst? The board is about to provide the answer.

The board, whose members are appointed by Gov. Gray Davis, will vote on an important new approach that goes to the heart of the urban runoff problem. Experts agree that polluted runoff, which in Los Angeles is often acutely toxic and loaded with pathogens that make people sick, is tied to the ever-increasing hardscape that comes with urban development. In short, more pavement equals more pollution. Because most of the region's watersheds are paved over, and because the water board until now has refused to take any meaningful action to solve the problem, the runoff problem in L.A. is especially severe.

The proposal before the board is based on one developed by the Natural Resources Defense Council and Los Angeles County to address the "pavement equals pollution" reality. By requiring large new developments, such as shopping centers, to install devices that clean up polluted runoff, the proposal targets the largest new sources of water pollution. Low-tech, inexpensive and highly effective, the devices required by the plan have a proven track record across the nation. If the board gives the go-ahead, then large new development projects in Los Angeles would have to take reasonable steps to actually clean up polluted runoff--just as their counterparts already do in cities as diverse as Denver, Austin and Portland, Ore.

Although Los Angeles County showed leadership by implementing the plan on its own last year, the proposal predictably has triggered an avalanche of opposition from many city governments that have not followed the county's lead. Yet the lack of factual and technical objections to the plan provides some optimism that, for the first time, the water board actually may be about to do something significant to help solve the polluted runoff problem. That would mean old polluting habits would have to change.

There is cause for concern, however. Perhaps recognizing that the plan has a real chance of passing, many cities and some developers succeeded recently in convincing the board's executive officer to add a multitude of eleventh-hour loopholes to the proposal. These exemptions, inserted over the objections of environmentalists and the federal Environmental Protection Agency, would rob the proposal of most of its effectiveness. By choosing to make Swiss cheese out of a proposal that might actually improve water quality, the board would revert to its old approach of appeasing virtually any objection by entrenched development interests, no matter how baseless.

By removing the exemptions and then approving the plan, however, the water board can send one of the most important messages in its history: its intention to tackle our region's most serious water pollution problem. By seizing the moment, the board can take a decisive step toward cleaner beaches and a more livable Los Angeles.

If it backs down, the future for water quality in Los Angeles looks ominous indeed.

EDITORIAL
Cleaner Beaches, Drop by Drop

Los Angeles County took a major step Wednesday toward cleaner beaches when the region's water quality board adopted tough standards to reduce urban runoff. The county now joins a handful of localities nationwide taking such aggressive steps against this pervasive pollution issue. Enforcing the new rules is the next challenge.

The culprits behind this knotty problem are oily wastes, metal residues, pet feces, pesticides and a thousand other things that wash off streets, roofs and parking lots into storm drains and out to the ocean. Runoff travels almost everywhere, and that's what makes cleaning it up so hard. In addition to fouling beaches, it contains viruses and bacteria that can infect swimmers.

Runoff pollution is particularly severe in the crowded Los Angeles Basin--so many people, so much gunk. The cleanup will be hard for the county's cities, but the responsibility for preventing runoff lies with municipalities under the federal Clean Water Act, which says they must prevent it "to the maximum extent practicable."

One set of measures approved by the **Los Angeles Regional Water Quality Control Board**, a state agency, will require new building projects across the county to limit the runoff they generate. The rules apply to new parking lots with 25 or more spaces and commercial projects of more than 100,000 square feet, as well as gas stations, auto repair garages, restaurants of more than 5,000 square feet and subdivisions with at least 10 houses.

Each project must collect or filter runoff from the first three-quarters of an inch of rainfall in a 24-hour period because that's when most pollutants are washed off. Developers can build retention ponds and trenches to collect storm water and install filters in curbside drains or leave grassed-over low spots. The water quality board puts the cost of these options for a typical five-acre, $6.5-million commercial project at between $1,500 and $28,800.

Since they will be required only on new projects, these remedies won't cut existing runoff; however, they should keep it from worsening. That would be a major accomplishment--but one that private developers and many smaller cities in the county have long resisted. Los Angeles, Santa Monica and West Hollywood were among the few cities endorsing the new standards.

Now, with the board's vote, all cities will be required to adopt ordinances within six months to implement the standards and ensure compliance by developers. From Malibu to Long Beach, these rules will lead to cleaner coastal waters.

Long Beach Press-Telegram
Wednesday, January 26, 2000
By Joshua Lowe, Staff writer

Storm runoff targeted

Did you notice an oily sheen atop the murky rain water running through gutters, storm drains and eventually San Pedro Bay on Tuesday?

That is what the **Los Angeles Regional Water Quality Control Board** would like to stop when it considers a set of new urban storm water runoff regulations at its meeting today.

It is estimated that more than 90 percent of the pollution in local waterways comes from urban runoff oil, pesticides, litter and other toxins washing from the cities into local waters.

The new regulations would require cities to step up their efforts to prevent polluted runoff from reaching waterways.

One part of the proposal is generating some controversy, though. Owners of new development, or redeveloped property, would have to trap and treat runoff from their sites under the new regulations.

Specifically, the property owners would have to catch and treat runoff during any storm that dumps less than .75 inches of rain, which is roughly 85 percent of the storms in Southern California.

"All we're saying is that when you rebuild or construct new development, apply some foresight and have some modicum of pollution control," said **Dennis Dickerson,** executive director of the water board.

Several cities, including Long Beach, have some doubts about the plan, though.

Rose Collins, the Long Beach Clean Water Program officer, said city officials are not necessarily against the standards, but are unconvinced the board did enough investigation of the problem and alternative solutions.

"There is a lot of anger among the building community," she said. "They feel like they are being singled out."

For instance, she said, instead of having parking lot builders create traps and holding ponds, why not do more to ensure cars are not leaking fluids and make it a smog-test like protocol.

Collins did not say that was a definitive solution, but said she would at least like to see it considered. She said the city also had a responsibility to ensure it spends money wisely, and when it asks others to spend money, they do so appropriately.

"We're not against the environment," she said. "This is not to drag our feet, but to study this to make sure. Is this the best way?"

Dickerson disagreed, saying the board does have enough data to support the order.

"This is not only just common sense demonstrated by what you see being washed down the street, but also from years of our storm water monitoring programs," he said. "And of all the communities, Long Beach has the most to gain from this."

The board and Los Angeles County have conducted tests of runoff and the sediments that get washed into local rivers and into San Pedro Bay, and have found pollutants that in some cases exceed clean water standards more than 100 times over.

Besides bacteria and pesticides, there are also heavy metals found in the Los Angeles River, **Dickerson** said.

During the 1997-98 rain season, water quality scientists measured 2,670 pounds of cadmium, 56,000 pounds of copper, 103,000 pounds of lead and 336,000 pounds of zinc, Dickerson said..

"This material dissolves in a very small concentration, usually in parts-per-billion, but the volume of water you are talking about means you are talking about very large loadings of these materials," he said.

Dickerson also said the effect of the standard would be minimal on cities like Long Beach that are already highly developed. The big difference, he said, would be in the long run as some buildings get torn down and then rebuilt or the last parcels of open space are developed.

ntary

PERSPECTIVE ON THE ENVIRONMENT

Message to Water Board: Seize the Day

The regional agency has a chance to curb polluted runoff. It must not flub a decision crucial to all of L.A.

By DAVID S. BECKMAN, STEVEN FLEISCHLI and MARK GOLD

Today, the Los Angeles Regional Water Quality Control Board is expected to make one of the most important decisions in its 50-year history, and its most significant decision ever, on the issue of polluted urban runoff. Is the board serious about creating a more livable Los Angeles by taking steps toward solving the region's urban runoff problem, now regarded as one of the nation's worst? The board is about to provide the answer.

The board, whose members are appointed by Gov. Gray Davis, will vote on an important new approach that goes to the heart of the urban runoff problem. Experts agree that polluted runoff, which in Los Angeles is often acutely toxic and loaded with pathogens that make people sick, is tied to the ever-increasing hardscape that comes with urban development. In short, more pavement equals more pollution. Because most of the region's watersheds are paved over, and because the water board until now has refused to take any meaningful action to solve the problem, the runoff problem in L.A. is especially severe.

The proposal before the board is based on one developed by the Natural Resources Defense Council and Los Angeles County to address the "pavement equals pollution" reality. By requiring large new developments, such as shopping centers, to install devices that clean up polluted runoff, the proposal targets the largest new sources of water pollution. Low-tech, inexpensive and highly effective, the devices required by the plan have a proven track record across the nation. If the board gives the go-ahead, then large new development projects in Los Angeles would have to take reasonable steps to actually clean up polluted runoff—just as their counterparts already do in cities as diverse as Denver, Austin and Portland, Ore.

Although Los Angeles County showed leadership by implementing the plan on its own last year, the proposal predictably has triggered an avalanche of opposition from many city governments that have not followed the county's lead. Yet the lack of factual and technical objections to the plan provides some optimism that, for the first time, the water board actually may be about to do something significant to help solve the polluted runoff problem. That would mean old polluting habits would have to change.

There is cause for concern, however. Perhaps recognizing that the plan has a real chance of passing, many cities and some developers succeeded recently in convincing the board's executive officer to add a multitude of eleventh-hour loopholes to the proposal. These exemptions, inserted over the objections of environmentalists and the federal Environmental Protection Agency, would rob the proposal of most of its effectiveness. By choosing to make Swiss cheese out of a proposal that might actually improve water quality, the board would revert to its old approach of appeasing virtually any objection by entrenched development interests, no matter how baseless.

By removing the exemptions and then approving the plan, however, the water board can send one of the most important messages in its history: its intention to tackle our region's most serious water pollution problem. By seizing the moment, the board can take a decisive step toward cleaner beaches and a more livable Los Angeles.

If it backs down, the future for water quality in Los Angeles looks ominous indeed.

David S. Beckman is a senior attorney at the Natural Resources Defense Council. Steven Fleischli is the executive director of the Santa Monica BayKeeper. Mark Gold is the executive director of Heal the Bay.

'Goldilocks' Policy for

Western communities have pioneered innovative pollution prevention programs (see On Watershed Education, this issue). These programs focus on educating homeowners and businesses on how they can reduce prevent pollutants from entering the storm drain system when its not raining.

In recent years, Western communities have been targeting their educational message to more specific target groups and populations (see On Watershed Education, this issue). For example, Los Angeles County has identified seven priority categories for intensive employee training in industrial pollution prevention -- auto scrap yards, auto repair, metal fabrication, motor freight, chemical manufacturing, car dealers, and gas stations-- on the basis of their hotspot potential and their numerical dominance (Swammikannu, 1998). In the Santa Clara Valley of California, the three key priorities for intensive commercial pollution prevention training are car repair, construction, and landscaping services. Targeting is also used to reach homeowners with specific water conservation, car washing, fertilization and pesticide messages (see On Watershed Education).

Street sweeping. Street sweeping seeks to remove the buildup of pollutants that have been deposited along the street or curb, using vacuum assisted sweeper trucks. The pollutant removal performance of new generation of street sweeper was recently reviewed in Technical Note 103. While researchers continue to debate whether street sweepers can achieve optimal performance under real world street conditions, most concede that street sweeping should be more effective in areas that have distinct wet and dry seasons, which is, of course, a defining characteristic of arid and semiarid watersheds (CDM, 1993).

Storm drain inlet clean outs. The last line of defense to prevent pollutants from entering the storm drain system is to catch them in the storm drain inlet. Mineart and Singh (1994) reported that monthly or even quarterly clean outs of sediment in storm drain inlets could reduce stormwater pollutant loads to San Francisco Bay by five to 10%. Currently, few communities clean out their storm drain inlets more than once a year, but a more aggressive efforts by public works to clean out storm drains prior to the onset of the wet season could be a viable strategy in some communities.

Better Site Design

Better site design clearly presents great opportunities to reduce impervious cover and stormwater impacts in the West, but has not been widely implemented to date. Indeed, the "California" development style, with its wide streets, massive driveways, and huge cul-de-sacs, has been copied in many Western communities and arguably produces more impervious cover per home or business than any other part of the country (Figure 1). While the popularity of the California development style reflects the importance of the car in shaping communities, it is also a strong reaction against the arid and semiarid landscape. The brown landscape is not green or pastoral, and many residents consider concrete and turf to be a more pleasing and functional land cover than the dirt and shrubs they replace.

While the techniques and benefits of better site design have been extensively profiled in the last issue of Techniques (3:2), it is worth discussing how it can be adapted for Western developments. The key adaptation is to incorporate the concept of "stormwater harvesting" into the design residential and commercial development design (COT, 1996). Water harvesting is an ancient concept, and involves capturing runoff from rooftops and other impervious surfaces and using it for drinking water or to irrigate plants (e.g. the cistern). In a more modern version, rooftop runoff is spread over landscaping areas or the yard, with the goal for complete disposal of runoff on the property for storm events up to the two-year storm (which ranges from one to 2 inches in most arid and semiarid climates. For example, the City of Tucson recommends 55 gallons of storage per 300 to 600 square feet of rooftop for residential bioretention areas (COT, 1996). In higher density settings, it may be to store water in a rain barrel or cistern, for irrigation use during dry periods.

When water harvesting is aggressively pursued, stormwater runoff is produced only from the impervious surfaces that are directly connected to the roadway system. Denver has utilized a similar strategy program to disconnect impervious areas and reduce the amount of stormwater pollution (DUDFC, 1992). A useful guidance on these techniques has also been produced for the San Francisco Bay area (BASMAA, 1997). Water harvesting may also prove to be a useful stormwater retrofitting strategy, particularly in regions where water conservation is also a high priority.

The better site design principles also need to be adapted for fire safety in Western communities adjacent to chaparral vegetation that is prone to periodic wildfires. In some case, vegetation setbacks must be increased in these habitat to protect developments from dangerous wildfires (CWP, 1998).

Developing Western Stormwater Practices

Given the many challenges and constraints that arid and semiarid watersheds impose, managers need to adapt and modify stormwater practices that were originally developed in humid watersheds. In our stormwater managers survey, four recurring principles emerged on how to design "Western" stormwater practices that are suited to the challenging climate and water resource problems of arid and semiarid watersheds. These four principles include:

1. *Carefully select and adapt stormwater practices for arid watersheds*
2. *Minimize irrigation needs for stormwater practices*
3. *Protect groundwater resources and encourage recharge*
4. *Reduce downstream channel erosion and protect from upland sediment*

1. Carefully Select and Adapt Stormwater Practices for Arid Watersheds

Some stormwater practices developed in humid watersheds are simply not applicable to arid watersheds, and most others require major modifications to be effective (Table 4). Even in semiarid watersheds, design criteria for most stormwater practices need to be revised to meet performance and

maintenance objectives. The following section highlights some of the major design and performance differences to consider for major stormwater practices.

Extended Detention Dry Ponds. The most widely utilized stormwater practices in arid and semiarid watersheds were dry ponds, according to the Center's survey (Figure 3). Most were designed exclusively for flood control but most can be easily modified to provide greater treatment of stormwater quality. While Dry ED ponds are not noted for their ability to remove soluble pollutants, they are reasonably effective in removing sediment and other pollutants associated with particulate matter (see Technical Note 95). In addition, ED ponds can play a key role in downstream channel protection, if the appropriate design storm is selected, and adequate upstream pretreatment is incorporated. Dry extended detention is the most feasible pond practice in arid watersheds, since they do not require a permanent pool of water.

Wet Ponds. Wet ponds are often impractical in arid watersheds since they cannot maintain a permanent pool without supplemental water, and they become stagnant in between storms. Wet ponds, on the other hand, are feasible in some semiarid watersheds, when carefully designed. Performance monitoring studies have demonstrated that wet ponds exhibit greater pollutant removal than other stormwater practices in Austin, Texas, at a lower cost per volume treated (COA, 1998, and Technical Note XX). In some instances, wet ponds can require supplemental water to maintain a stable pool elevation. Saunders and Gilroy (1997) reported that 2.6 acre-feet per year of supplemental water were needed to maintain a permanent pool of only 0.29 acre-foot. Generally speaking, stormwater designers working in semiarid watersheds should design for a variable pool level that can have as much as a three-foot draw down during the dry season. The use of wetland plants along the pond's shoreline margin can help conceal the drop in water level, but managers will need to reconcile themselves to chronic algal blooms, high densities of aquatic plants and the occasional episode of odor problems. The City of Austin has prepared useful wet pond design criteria to address these issues (COA, 1997).

Stormwater Wetlands. Few communities recommend the use of stormwater wetlands in either arid or semiarid watersheds. Once again, the draw down rates caused by evaporation makes it difficult too impossible to maintain standing water that can sustain emergent wetland plants, unless copious subsidies of supplemental water are supplied. One interesting exception was a gravel-based wetland that treated parking lot runoff in Phoenix, Arizona (Wass and Fox, 1995). While the wetland did require some supplemental water, evaporation was reduced by the overlying gravel bed, and it achieved relatively high removal oil and grease.

Sand Filters. Sand filters continue to be one of the most common practices used to treat the quality of stormwater in both arid and semiarid watersheds. Still, the basic sand filter design continues to evolve to counter the tough design conditions found in this region. For example, Urbonas (1997) evaluated sand filter performance in Denver, Colorado, and concluded that designs need to be modified to account for the greater sediment build-up in arid regions. Urbonas found that the test sand filter quickly became clogged with sediment after just a few storms, and recommended that

sand filters include a more frequent sediment clean out regime, an increase in the filter bed size, and upstream detention to provide greater sediment pretreatment. Some additional research on the performance and longevity of sand filters in the semiarid climate of Austin, Texas can be found in Technical Notes 111 and 112 (this issue).

Bioretention. The use of bioretention as a stormwater treatment practice is not very common in many Western communities at the present time. Clearly, this practice will require extensive modification to work in arid watersheds. This might entail xeriscape plantings, use of gravel instead of mulch as the ground cover, and better pretreatment. Sprinkler irrigation of bioretention areas should be avoided at most sites, unless intensive landscaping is already planned for the area.

Table 4. Design Modifications for Stormwater Practices in Arid and Semi-Arid Watersheds

Stormwater Practice	Arid Watersheds	Semi-Arid Watersheds
ED Dry Ponds	PREFERRED. Multiple storm ED Stable Pilot Channels "Dry"Forebay	ACCEPTABLE Dry or Wet Forebay Needed
Wet Ponds	NOT RECOMMENDED evaporation rates are too high to maintain a normal pool without extensive use of scarce water	LIMITED USE liners to prevent water loss. Require water balance analysis Design for a variable rather than permanent normal pool. Use water sources such as AC condensate for pool. Aeration unit to prevent stagnation
Stormwater Wetlands	NOT RECOMMENDED evaporation rates too great to maintain wetland plants	LIMITED USE, require supplemental water submerged gravel wetlands can help reduce water loss
Sand Filters	PREFERRED Requires Greater Pretreatment Exclude Pervious Areas	PREFERRED Refer to COA, 1997 for design criteria
Bioretention	MAJOR MODIFICATION No Irrigation	MAJOR MODIFICATION Use Runoff to Supplement

	Better Pretreatment Treat no Pervious Area Xeriscape Plants or No Plants Replace Mulch with Gravel	Irrigation Use Xeriscaping Plants Avoid Trees Replace Mulch with Gravel
Rooftop Infiltration	PREFERRED dry well design for recharge of residential rooftops	PREFERRED, recharge rooftop runoff on-site unless the land use is a hotspot.
Infiltration	MAJOR MODIFICATION No Recharge for Hotspot Land Uses Treat no Pervious Area Multiple Pretreatment Soil Limitations	MAJOR MODIFICATION No Recharge for Hotspot Land Uses Treat no Pervious Area Multiple Pretreatment
Swales	NOT RECOMMENDED for pollutant removal, but rock berms and grade control needed for open channels to prevent channel erosion	LIMITED USE, unless they are irrigated. Rock berms and grade control essential to prevent erosion in open channels

Infiltration Practices. While a number of communities allowed the use of infiltration in arid and semiarid watersheds, few really encouraged its use. Two concerns were frequently cited for their lack of enthusiasm for structural infiltration. The first concern was that infiltration practices were too susceptible to rapid clogging given the high erosion rates that are customary in arid and semiarid watersheds. The second concern was that untreated stormwater could potentially contaminate the aquifers that are used for groundwater recharge.

Swales. The use of grass swales for stormwater treatment was rarely reported for arid watersheds, but was much more common in semiarid conditions. Grass swales are widely used as a stormwater practice in residential developments in Boise, Idaho, but the dense turf can only be maintained in these arid conditions through the use of sprinkler irrigation systems. The pollutant removal performance of swales in arid and semiarid watersheds appears to be mixed (Table 5). Poor to negative pollutant removal performance was reported in a Denver swale that was not irrigated (Urbonas, 1999 -personal communication). In the semi-arid climate of Austin, Texas, Barret et al (1998) reported excellent pollutant removal in two highway swales that were vegetated but not irrigated. Similar performance was also noted in a non-irrigated swale monitored by the City of Austin (COA, 1997).

2. Minimize irrigation needs for stormwater practices

In arid climates, all sources of water, including stormwater runoff, need to be viewed as a resource. It seems senseless, therefore, to irrigate a practice with 50 inches of scarce water a year so that it can be ready to treat the stormwater runoff produced from ten inches of rain a year. Still, irrigation of stormwater practices is very common in many arid and semiarid communities. In our survey of stormwater managers, 65% of reported that irrigation was commonly used to establish and maintain vegetated cover for most stormwater practices.

Table 5. Performance of Vegetated Swales in Semiarid Climates
Source: Barrett et al, 1997, and COA, 1998.

	Highway 183 median	Walnut Creek	City of Austin Swale
Parameter	Mass Load Reduction (%)		
TSS	89	87	68
COD	68	69	33
TP	55	45	43
TKN	46	54	32
Nitrate	59	36	(-2)
Zinc	93	79	ns
Lead	52	31	ns
ns = not sampled. Fecal coliform and fecal strep removals were negative at the 183 and Walnut Creek sites.			

Irrigation should be limited by to practices that meet some other landscaping or recreational need in a community, and would be irrigated anyway, such as landscaping islands in commercial areas, road right of ways, and bioretention lawns. Irrigation may also be a useful strategy for dry ED ponds that are designed for dual use, i.e. facilities that serve as a ballfield or community park during the dry season. Even when irrigation is used, practices should be designed to "harvest" stormwater, and therefore reduce irrigation needs. Landscapers should also consider planting native drought resistant plants material to reduce water consumption.

3. Protect groundwater resources and encourage recharge

In many arid communities, protection of groundwater resources is the primary driving force behind stormwater treatment. Ironically, early efforts to use stormwater to recharge groundwater have

resulted in some groundwater quality concerns. In Arizona, for example, stormwater was traditionally injected into 10 to 40 foot deep dry wells to provide for groundwater recharge. Concerns were raised that deep injection could increase the risk of localized groundwater contamination, since untreated stormwater can be a source of pollutants, particular if the proposed land use is classified as a stormwater hotspot.

Wilson et al (1990) evaluated the risk of dry well stormwater contamination in Pima County, Arizona, and determined that dry wells had elevated pollutant concentrations in local groundwater. The build up of pollutant levels that had occurred over several decades tended to be localized, and did not exceed drinking water standards. Still, it is important to keep in mind that dry wells and other deep recharge methods should only be used to infiltrate relatively "clean" runoff, such as residential roofs. Other surface infiltration practices, such as trenches and basins, can also potentially contaminate groundwater, unless they are carefully designed for runoff pretreatment, provide a significant soil separation distance to the aquifer, and avoid "hot spot" runoff sites.

4. Design to reduce channel erosion.

Above all, the Western stormwater practice must be designed to reduce *downstream* erosion in ephemeral channels, while at the same time protecting itself from sediment deposition from *upstream* sources. This is a daunting challenge for any engineer, but the following ideas can help.

With respect to *downstream channel erosion*, designers will need to clamp down on the storm events that produce active erosion in channels. This might entail the design of ponds or basins that can provide 12 hours of extended detention for the one year return interval storm event (which is usually no more than an inch or two in most arid and semiarid watersheds) Local geomorphic assessment will probably be needed to set channel protection criteria, and these hydraulic studies are probably the most critical research priority in both arid and semiarid watersheds today. Without ED channel protection, designers must rely on clumsy and localized engineering techniques to protect ditches and channels from eroding, such as grade control, rock berms, rip-rap, or even concrete lined channels. Bioengineering options to stabilize downstream channels in arid watersheds are limited, and often require erosion control blankets to retain moisture and seeds, as well as extensive irrigation.

Upstream erosion quickly reduces the capacity of any stormwater practice in an arid or semiarid watershed, due to sparse vegetation cover and erosion from upstream gullies, ditches, or channels. Designers have several options to deal with this problem. The most effective option is to grade the practice so that it can only accept runoff from impervious areas, particularly for infiltration, sand filters and bioretention. Even then, the practice will still be subject sediments transported by the wind.

All stormwater practices in arid and semiarid watersheds require greater pretreatment *than in humid watersheds*. Seventy percent of the arid stormwater managers surveys reported that sediment

clogging or deposition problems was a major design and maintenance problem for nearly all of their stormwater practices.

Even though not all upstream erosion can be prevented, designers can compensate for sediment build-up within the stormwater practice itself. Pretreatment and over-sizing can prevent the loss of storage or clogging associated with sediment deposition. As noted in Technical Note 112, rock berms or vertical gravel filters are ideally suited as a pretreatment device

Most stormwater managers surveyed indicated that sediment clean out regimes for stormwater practices need to be more frequent in arid and semiarid watersheds, with removal after major storms, and at a minimum, at once a year. Lastly, stormwater managers consistently emphasized the need for better upland erosion control during construction. 65% of the managers reported that upstream erosion and sediment control was a major emphasis during their stormwater plan review.

Summary

It is clear that stormwater managers in arid and semiarid climates cannot simply import the stormwater programs and practices that were originally developed for humid watersheds. Instead, they will need to develop stormwater solutions that combine aggressive source control, better site design and stormwater practices in a distinctly western context. Regulators, in turn, need to recognize that western climate, terrain and water resource objectives are different, and be flexible and willing to experiment with new approaches in municipal stormwater programs. Lastly, stormwater managers from arid and semiarid watersheds work more closely together to share experiences about the stormwater solutions that work and fail. It is only through this dialogue that western communities can gradually engineer stormwater practices that are rugged enough to withstand the demanding challenges of the arid and semiarid west.

EMBARGOED UNTIL WEDNESDAY, JANUARY 19, 2000

CALIFORNIA SECRETARY FOR RESOURCES CALLS FOR OVERHAUL OF MANAGEMENT SCHEME FOR MARINE RESOURCES

FOR RELEASE ON January 19, 2000

CONTACT: Stanley Young (916) 653-5792

Brian Baird (916)657-0198

Sacramento - A groundbreaking new report issued by the Resources Agency today offers a new, simpler and more efficient approach to protecting, preserving and managing California's magnificent coastal resources. Entitled, *Improving California's System of Marine Managed Areas (MMAs)*, the new report provides the first-ever comprehensive analysis of protective classifications that were developed over the last 50 years for State ocean waters. "This report marks a major step forward in protecting our coast," said Secretary of Resources Mary Nichols. "The reforms in this report will benefit everyone who uses and values our coastal resources, from surfers and beachgoers to scientists, fishermen and State management personnel."

The report was prompted by the sheer complexity and inefficiency of the present array of classifications. Designed to address the management of the State's living marine, cultural, and recreational resources, the existing array of MMAs -- 18 separate and overlapping classifications of preserves, refuges, reserves, sanctuaries and others -- is hard to understand, implement and enforce. And with good reason. Cobbled together over half a century and through eight separate state administrations the existing system developed piecemeal as an uncoordinated complex of legislation, regulations, voter initiative processes, and guidelines.

"The current system is a regulatory crazy-quilt," noted Secretary Nichols. In place of the existing arrangement of 18 classifications, the new report presents a stripped-down and

far simpler system of only 6 different kinds of marine managed areas. "The new report," said Secretary Nichols, "wipes the slate clean by presenting a rational, effective and science-based system of classifications that is simple to understand, implement and enforce."

The report is the culmination of a year-and-a-half-long process that began when the California Resources Agency directed a task force of State management agencies to identify every law, regulation, and policy relating to these management areas off the coast. The draft report, which also included suggestions for improving the present system, was the subject of five well-attended public workshops held in coastal locations from Newport Beach to Trinidad, as well as a special session convened at the State Capitol. Support for the draft report and its conclusions has been widespread. "We believe we now have consensus to overhaul our approach to this critical aspect of ocean management and protection," said Secretary Nichols. "The spectacular marine resources off the California coast are just too important to try to make do with the status quo."

The State's marine resources are not only valued by Californians. Just last week President Clinton used the Antiquities Act to designate all rocks, islands, exposed reefs, and pinnacles under the ownership of the Bureau of Land Management as the new California Coastal National Monument. "This National Monument designation is timely, because we plan to work with BLM, other government agencies, the private sector, and the public on ways to better coordinate our management and protection of these resources. I believe that the actions in this report will go a long way to ensuring an effective and powerful partnership between all parties interested achieving this goal."

Please see the attached list of existing and proposed classifications for State MMAs.

Current Array of Marine Managed Areas (MMAs)

Eighteen Classifications

There are currently 18 classifications and sub-classifications of MMAs that can be applied to the marine or estuarine environment along the California coast. Only 16 of these classifications have actually been used; the two classifications not used to date are italicized in the list below. In some cases there are two or more state classifications that overlay one another in a particular region to achieve multiple purposes, and often there is also an overlay of a federal designation. These state classifications and sub-classifications, in alphabetical order:

1. Areas of Special Biological Significance
2. Clam Refuges (Clam Preserves)
3. *Cultural Preserves (a subunit of the State Park System)*
4. Ecological Reserves
5. Historical Units
6. Marine Resources Protection Act Ecological Reserves
7. Natural Preserves (a subunit of the State Park System)
8. Refuges
9. Reserves
10. State Coastal Sanctuary
11. State Estuaries
12. State Parks
13. State Recreation Units - State Beaches
14. State Recreation Units - State Recreation Areas
15. *State Recreation Units - Underwater Recreation Areas*
16. State Reserves
17. State Seashores
18. State Wildlife Areas

Proposed System for Marine Managed Areas

Six Classifications

The State Interagency Marine Managed Areas Workgroup has proposed a new system for state MMAs, composed of the following:

1. Marine (Estuarine) Reserve
2. Marine (Estuarine) Park
3. Marine (Estuarine) Conservation Area
4. Marine (Estuarine) Cultural Preservation Area
5. Marine (Estuarine) Recreational Management Area

L.A. plan to stop pollution at source in developments

Associated Press

LOS ANGELES — Taking action to stem the tide of urban pollutants flowing into the ocean and onto beaches every time it rains, regional water quality officials voted to require that new building projects include methods to collect or filter storm runoff.

The sweeping plan applies only to Los Angeles County, but has its roots in the federal Clean Water Act and offers a glimpse at the kind of tough decisions that may face other areas on California's rapidly developing coast.

New commercial projects over 100,000 square feet, as well as new parking lots with 25 or more spaces, gas stations and housing subdivisions would be among those subject to the new regulations.

Under the plan, developers would be required to collect or filter the first .75 inch of rain that falls in a day's time. The projects could do this by using grassy areas that absorb water, detention ponds and trenches or filters in drains.

The regulations are aimed at intercepting oily waste, pesticides, metal residue, animal feces, human viruses and bacteria that flow off paved land and buildings, which prevent the absorption of storm water.

Hotly contested by developers and most of the county's 85 cities, the plan was approved Wednesday by the Los Angeles Regional Water Quality Control Board, one of nine regional boards that are part of the California Environmental Protection Agency.

The plan, designed to protect Los Angeles County beaches from increasing pollution as population grows, would require city governments to adopt ordinances within six months to implement the standards and ensure compliance by developers.

The vote was not necessarily the final word. Board staff will produce a final version for the director to approve in about a month. At that point opponents may appeal to the State Water Resources Control Board. Failing that, they may appeal in Superior Court.

Environmentalists cheered the regional board's 6-0 vote.

"This is a big step forward in addressing the runoff problem," said Alex Helperin of the Natural Resources Defense Council. "They could have gone further but it's refreshing to see the board take the first step."

However, builders maintained the measures would drive up costs.

"This policy is a shot in the dark with no chance of improving water quality," said Ray Pearl, deputy director of the Building Industry Association of Greater Los Angeles. "It's not only bad science, but bad policy."

However, the water board estimates that the cost of the runoff controls will amount to less than 0.5 percent of each new development's total cost.

Water board adopts storm runoff plan

Associated Press

LOS ANGELES – Taking action to stem the tide of urban pollutants flowing into the ocean and onto beaches every time it rains, regional water quality officials voted to require that new building projects include methods to collect or filter storm runoff.

The sweeping plan applies only to Los Angeles County, but has its roots in the federal Clean Water Act and offers a glimpse at the kind of tough decisions that may face other areas on California's rapidly developing coast.

New commercial projects larger than 100,000 square feet as well as new parking lots with 25 or more spaces and housing subdivisions would be among those subject to the new regulations.

Under the plan, developers would be required to collect or filter the first three-quarters of an inch of rain that falls in a 24-hour period. The projects could do this by using grassy areas that absorb water, detention ponds and trenches or filters in drains.

Hotly contested by developers and most of the county's 85 cities, the plan was approved Wednesday by the Los Angeles Regional Water Quality Control Board, one of nine regional boards that are part of the California Environmental Protection Agency.

Environmentalists cheered the regional board's 6-0 vote.

"This is a big step forward in addressing the runoff problem," said Alex Helperin of the Natural Resources Defense Council.

Builders maintained the measures would drive up costs.

"This policy is a shot in the dark with no chance of improving water quality," said Ray Pearl of the Building Industry Association of Greater Los Angeles.

PERSPECTIVE ON THE ENVIRONMENT

Message to Water Board: Seize the Day

The regional agency has a chance to curb polluted runoff. It must not flub a decision crucial to all of L.A.

By DAVID S. BECKMAN, STEVEN FLEISCHLI and MARK GOLD

Today, the Los Angeles Regional Water Quality Control Board is expected to make one of the most important decisions in its 50-year history, and its most significant decision ever, on the issue of polluted urban runoff. Is the board serious about creating a more livable Los Angeles by taking steps toward solving the region's urban runoff problem, now regarded as one of the nation's worst? The board is about to provide the answer.

The board, whose members are appointed by Gov. Gray Davis, will vote on an important new approach that goes to the heart of the urban runoff problem. Experts agree that polluted runoff, which in Los Angeles is often acutely toxic and loaded with pathogens that make people sick, is tied to the ever-increasing hardscape that comes with urban development. In short, more pavement equals more pollution. Because most of the region's watersheds are paved over, and because the water board until now has refused to take any meaningful action to solve the problem, the runoff problem in L.A. is especially severe.

The proposal before the board is based on one developed by the Natural Resources Defense Council and Los Angeles County to address the "pavement equals pollution" reality. By requiring large new developments, such as shopping centers, to install devices that clean up polluted runoff, the proposal targets the largest new sources of water pollution. Low-tech, inexpensive and highly effective, the devices required by the plan have a proven track record across the nation. If the board gives the go-ahead, then large new development projects in Los Angeles would have to take reasonable steps to actually clean up polluted runoff—just as their counterparts already do in cities as diverse as Denver, Austin and Portland, Ore.

Although Los Angeles County showed leadership by implementing the plan on its own last year, the proposal predictably has triggered an avalanche of opposition from many city governments that have not followed the county's lead. Yet the lack of factual and technical objections to the plan provides some optimism that, for the first time, the water board actually may be about to do something significant to help solve the polluted runoff problem. That would mean old polluting habits would have to change.

There is cause for concern, however. Perhaps recognizing that the plan has a real chance of passing, many cities and some developers succeeded recently in convincing the board's executive officer to add a multitude of eleventh-hour loopholes to the proposal. These exemptions, inserted over the objections of environmentalists and the federal Environmental Protection Agency, would rob the proposal of most of its effectiveness. By choosing to make Swiss cheese out of a proposal that might actually improve water quality, the board would revert to its old approach of appeasing virtually any objection by entrenched development interests, no matter how baseless.

By removing the exemptions and then approving the plan, however, the water board can send one of the most important messages in its history: its intention to tackle our region's most serious water pollution problem. By seizing the moment, the board can take a decisive step toward cleaner beaches and a more livable Los Angeles.

If it backs down, the future for water quality in Los Angeles looks ominous indeed.

David S. Beckman is a senior attorney at the Natural Resources Defense Council. Steven Fleischli is the executive director of the Santa Monica BayKeeper. Mark Gold is the executive director of Heal the Bay.

'Goldilocks' Policy for

RUNOFF

Continued from B1

guidelines.

"Hopefully, we can craft a document that will respond to some of the concerns of the cities but also ensure a strong level of environmental protection," he said.

The Los Angeles region, with so many people and so much pavement, faces an almost insurmountable challenge in cleaning up its voluminous runoff. The debate over how to contain the pollution has dragged on for a decade.

Massive amounts of oily waste, pesticides, metal residue and other pollutants flow to the sea from streets and parking lots, even on dry summer days. Runoff also carries human viruses and bacteria from sewage that can give swimmers, especially children, diarrhea, respiratory infections and other illnesses.

Since 1986 the federal Clean Water Act has required municipalities to reduce storm water runoff "to the maximum extent practicable." But experts say Southern California lags behind many other urban areas because of the huge size of the task and resistance to land use restrictions.

In the Southland, attempts to wrest any control of development from municipalities have long been considered taboo, and the runoff measure has allied cities with developers in a fight against local environmentalists.

Mark Gold, executive director of the environmental group Heal the Bay, said the push for standards governing new development "has been our biggest fight for a decade" in the campaign to clean up runoff, the leading source of pollution in Santa Monica Bay.

David Beckman, a senior attorney with the Natural Resources Defense Council, accused the cities of "a bunch of denying and deflecting and delaying." The proposal is far from a cure-all but "shows that the water board is finally getting serious about storm water control," he said.

"It only covers new development and redevelopment, so it should not be construed as something that will magically solve the storm water problem. But it should prevent it from getting worse," Beckman said.

On even a dry summer day, polluted runoff from the county's 10 million people would fill the Rose Bowl. Year-round, it contaminates beaches within roughly 100 yards of river mouths and storm drains. On a rainy day, the runoff renders all beaches unsafe.

In Los Angeles County, most Ballona Creek, which empties into the ocean at Marina del Rey; Malibu Creek, which ends at Surfrider Beach; and the Los Angeles River, which flows into Long Beach Harbor. Smaller storm drains are sprinkled along the coastline.

The proposal is designed to sharply reduce runoff from new buildings in all but severe storms.

Developers and city planners would have a range of options for compliance. They could leave grassy swales and other open space so runoff could seep into the ground instead of flowing into storm drains. However, because land is at a premium in the county, most developers are likely to seek other options, such as building detention ponds, using permeable pavement or installing filters in curbside drains.

Xavier Swamikannu, who directs the regional board's storm water program, stresses that cities would have the flexibility to decide how each individual project must comply. The standards are not meant to slow development, he said, but rather to ensure that developments are more environmentally sound.

UCLA environmental engineer Mike Stenstrom, a nationally known expert in urban runoff, said the storm water limits are reasonable and can be achieved with relatively simple and inexpensive design changes at developments.

Builders, however, say there is insufficient scientific basis for setting a specific numerical limit for capturing storm water—and little data on the costs. Every project and piece of land is different, they say, so hard and fast standards are unreasonable.

New Projects Unfairly Targeted, Builders Say

Builders also complain that new projects are being unfairly targeted even though existing development pollutes the most.

"We are concerned that this approach will render some sites undevelopable, placing an unfair burden on property owners and developers," said John R. Burroughs, vice president of Commerce Construction Co.

Ray Pearl of the Building Industry Assn. of Southern California said providing housing is just as critical as protecting the environment. "We would ask you not to forget human habitat," he told the water board at a Sept. 16 hearing.

Azusa City Engineer Nasser Abbaszedeh said the proposal could prompt developers to move to runoff limits. "This would cause an inherent regional inequity throughout Southern California," he said.

The most vocal opposition has come from cities miles from the coast, in southeastern Los Angeles County and the San Gabriel Valley. But surprisingly, the debate has not pitted inland cities against coastal ones. Cities such as Long Beach, Manhattan Beach and Redondo Beach have shorelines contaminated with runoff flowing largely from inland areas, but even they do not support standards that tell cities how to govern development.

"How much can you foist on the developer and how much can you foist on local government? Do you impose a $20,000 or $30,000 cost on each development without knowing the benefits?" Miller of Manhattan Beach asked. "Nobody is opposed to cleaning up storm water. But to just throw a numerical limit out there and say, 'Figure out how to do it'—that's tough for engineers to accept. It just seems premature."

In unincorporated areas of Los Angeles County, builders already must control runoff from the first 0.75 of an inch of rain from each storm. County officials agreed to the requirement, which became effective in June, in a settlement of a lawsuit with local environmentalists.

Outside California, several counties and cities, especially along Chesapeake Bay, have already imposed similar runoff standards—some more stringent. The Los Angeles County program, however, would be the largest. Orange, Ventura and San Diego counties also face threats from runoff, but they have separate storm-water permits with regional boards that impose no runoff limits.

Since July 30, existing businesses and developments in L.A. County have been required to follow a set of "best management practices" outlined in a storm-water permit enforced by the regional water board. But it contains no numerical limits for the volume of runoff controlled. For example, auto repair shops are told to clean up oil leaks and cover waste storage areas, and cities have stenciled "No Dumping" on gutters and mounted multimillion-dollar public education campaigns.

Water officials, however, say public education and general guidelines will never go far enough. Instead, they say, communities must change the very way they are designed.

Swamikannu said runoff pollution is so severe in the Los Angeles area that setting firm limits on new development is "just a starting point" toward meeting federal standards, which require all waters to be

Swamikannu said runoff pollution is so severe in the Los Angeles area that setting firm limits on new development is "just a starting point" toward meeting federal standards, which require all waters to be

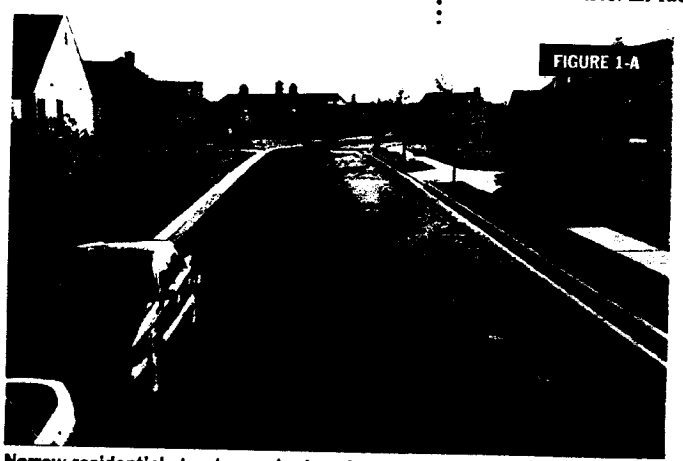
Better Site Design: Changing Development Rules to Protect the Environment

By Thomas R. Schueler and Richard A. Claytor, Jr., P.E.

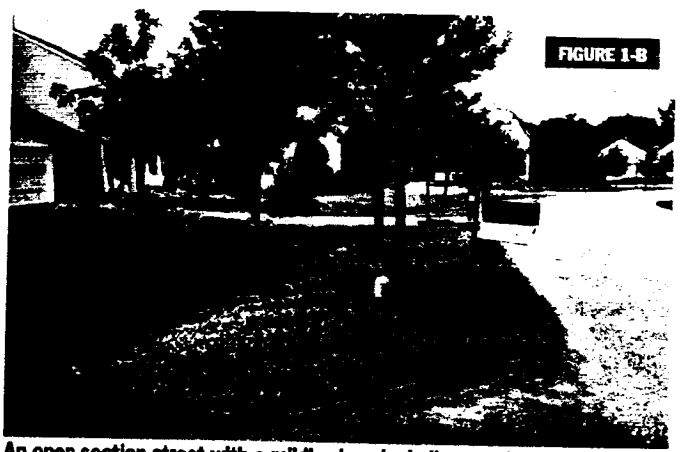
Reduced impervious surface and different drainage techniques can result in significant environmental benefits.

Few stormwater management practices simultaneously reduce pollutant loads, conserve natural areas, save money, and increase property values. Indeed, if such "wonder practices" were ever developed, they certainly would spread quickly across the nation. As it turns out, these practices have existed for years. Collectively called "better site design," the techniques employ a variety of methods to reduce total paved area, distribute and diffuse stormwater runoff, and conserve natural habitats. Despite their proven benefits, however, better site design techniques often fail to earn the endorsement of local communities. In fact, many communities simply prohibit their use.

"Better site design" describes a fundamentally different approach to the design of residential and commercial development projects. It seeks to accomplish three goals at every development site: to reduce the amount of impervious cover, to increase the amount of natural land set aside for conservation, and to use pervious areas for more effective stormwater treatment. To employ these methods, designers must scrutinize every aspect of a site plan—its streets, parking spaces, setbacks, lot sizes, driveways, and sidewalks—to see if any of these elements can be reduced in scale. At the same time, creative grading and



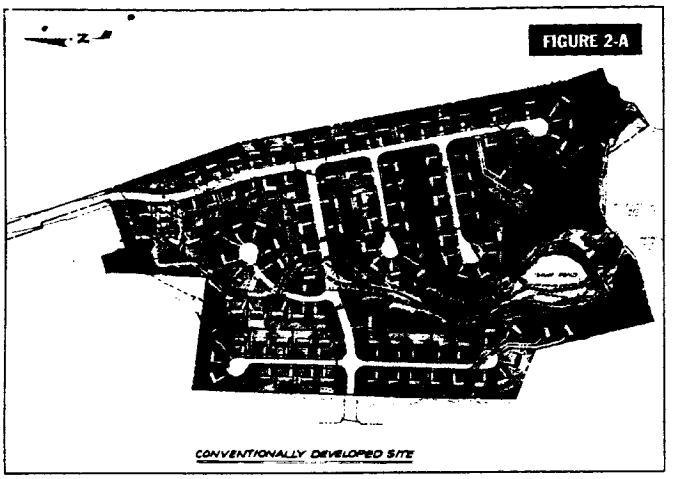
Narrow residential streets require less land and less paving materials.



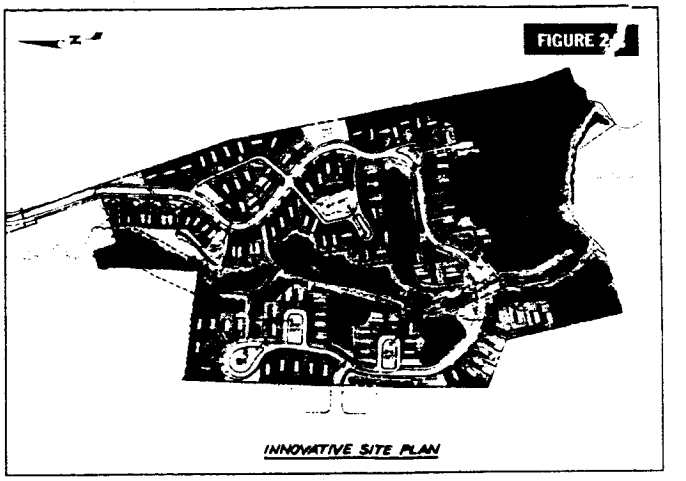
An open-section street with a mildly sloped, shallow swale eliminates the need for curbs and provides areas for stormwater runoff.

Commercial parking lots designed with low parking demand ratios and narrow drive aisles require less land.

Shared driveways for single-family residential lots use less land and less paving material.



This plan of the 108-acre Stonehill Estates in Stafford County, Virginia, demonstrates a conventionally developed site. The average lot size is 9,000 square feet; 25 percent of the site is open space; street widths are 26 and 34 feet; and the cul-de-sac radii are 45 feet.



Stonehill Estates, designed with an innovative site plan, shows that the 108 lots' average area is reduced to 6,300 square feet with 44 percent open space. The street widths are reduced to 14 feet (one-way) and 26 feet (two-way), with 14-foot-wide looping cul-de-sacs.

drainage techniques can prevent concentrations of stormwater, thereby encouraging more infiltration. Finally, undisturbed land areas conserved as forests, meadows, stream buffers, or other natural habitat areas can increase available open space, enhance property values, and reduce pollutant loads. Figures 1a through 1d illustrate some of these principles.

When all these techniques are applied simultaneously, the cumulative benefits of better site design can be impressive. For example, recent studies in Delaware, Maryland, and Virginia have demonstrated that better site design can reduce impervious cover by 25 to nearly 60 percent for a range of subdivisions. Other studies have shown that better site design reduces impervious cover by about 20 percent in shopping centers and office parks. Table 1 illustrates the potential reductions for various residential development densities. Figures 2a and 2b depict alternative designs for Stonehill Estates, a development in Virginia.

Less impervious cover translates directly into smaller pollutant loads. In fact, studies have shown that better site design produces 40 to 65 percent less phosphorous and nitrogen loads than conventional site designs—roughly the equivalent of what can be removed by a well-designed stormwater pond. The same studies have also demonstrated that better site design costs 5 to 20 percent less to build than conventional site design.

The Center for Watershed Protection recently compared the infrastructure cost of four projects that relied on standard development strategies with the same sites developed in accordance with innovative site design techniques. Table 2 illustrates these cost comparisons.

Why, then, is it so difficult to implement better site design in so many communities? The primary reason is that outdated development rules collectively govern the development process—the bewildering mix of subdivision codes, zoning regulations, parking and street standards, and other regulations that often work at cross-purposes and yield less-than-ideal results. With few developers willing to invest in something that may take years to be approved or that may never be approved at all, experiments in better site design are rare.

A new movement, however, may make better site design easier. Developers, water quality managers, and planners are taking steps to rethink land development rules in many locations across the country. For example, transportation, public works, safety, planning, and engineering organizations involved in the development industry recently participated in a national site planning roundtable and developed a nationally accepted set of model principles that foster better site development. The group embraced a total of 22 model development principles to help further better site design at the local level.

The national site planning roundtable is serving as a model for local government implementation of better site design principles. Recently, Frederick County, Maryland, initiated a local roundtable to take a critical look at its own development rules. Members of the development community in partnership with local planning and zoning and public works staff are meeting to identify and overcome impediments to better site design that are embedded in the county's codes and ordinances. The outcome of the consensus process should be development rules that encourage rather than discourage the application of better site design techniques.

Changing local development rules is not

TABLE 1. **Analysis of Residential Developments Employing Better Site Design Techniques**

Development Project	Development Density	Impervious Cover at the Site: Conventional Site	Impervious Cover at the Site: Better Site Design Site	Impervious Cover at the Site: Net Change	Percent Reduction in Stormwater Runoff
Tharpe Knoll[1]	1-acre lots	13%	7%	–46%	44%
Pleasant Hill[1]	½-acre lots	26%	11%	–58%	54%
Stonehill Estates[2]	½-acre lots	27%	21%	–22%	25%
Belle-Hall[3]	High density	35%	20%	–43%	31%

easy. Progress toward better site development will require more and more local governments to examine their current practices in the context of a broad range of concerns, such as how changes will affect development costs, local liability, property values, public safety, and a host of other factors. Advocates of better site design will have to answer some difficult questions from fire chiefs, lawyers, traffic engineers, developers, and many others in the community. Will a proposed change make it more difficult to park? Lengthen response times for emergency vehicles? Increase risks to the community's children? True change occurs only when the community addresses these and other questions to the satisfaction of all interests.

For more information, contact the Center for Watershed Protection, 8391 Main Street, Ellicott City, Maryland 21043; (410) 461–8323; fax (410) 461-8324; e-mail: mrrunoff@pipeline.com; website: www.pipeline.com/~mrrunoff/. ■

In 1997, the Center for Watershed Protection convened a national site planning roundtable. During the 18-month consensus-building process, a diverse cross-section of national planning, environmental, home builder, fire and safety, and public works organizations (as well as local planning officials) crafted 22 model development principles. Taken together, the principles can be applied to reduce impervious cover, conserve natural areas, and minimize stormwater pollution from new development—all while maintaining residents' quality of life.

The principles are presented in a consensus agreement entitled *Model Development Principles to Protect Our Streams, Lakes and Wetlands* and in a companion document *Better Site Design—A Handbook for Changing the Development Rules in Your Community.* The handbook contains a codes and ordinances worksheet to help communities assess which local development rules should be amended to promote better site design. The worksheet guides local planners, subdivision plan reviewers, and planning boards through a complete evaluation of their local development standards and ordinances. The consensus agreement is available on the center's web page at www.pipeline.com/~mrrunoff/. *Better Site Design* can be ordered from the Center for Watershed Protection by calling (410) 461-8323.

Thomas R. Schueler is executive director of the Center for Watershed Protection. He is responsible for development, research, technical support, and educational training and is the editor and major author of the center's quarterly technical journal Watershed Protection Techniques.

Richard A. Claytor, Jr., P.E., is principal engineer at the Center for Watershed Protection and has more than 15 years of experience in the field of water resource assessment and management. He is responsible for project management and research related to preparing training and guidance documents for watershed planning and restoration.

Rain Brainstorm

■ **Conservation:** Yard is landscaped in pilot project to work as a catch basin, saving runoff.

By BOB POOL
TIMES STAFF WRITER

That wasn't a rain cloud over Rozella Hall's head that sent her scurrying for an umbrella Thursday in South-Central Los Angeles.

It was the man on her roof with the fire hose—the one helping create an artificial thunderstorm over her West 50th Street home as part of a water conservation project being studied by local and federal officials.

The yard surrounding Hall's 70-year-old clapboard bungalow has been turned into a colorfully landscaped catch basin. Officials figure the yard will trap rain runoff and let it soak into the ground instead of wastefully flowing into storm drains that empty into the ocean.

A coalition of federal, state and municipal agencies chipped in $50,000 to create what experts say could become a prototype for backyard projects all over Los Angeles.

The water-recycling idea was proposed by environmentalist Andy Lipkis, founder of Los Angeles-based TreePeople. He suggests that diverting rain runoff into the ground will boost the city's underground water supply while at the same time preventing flooding along the Los Angeles River.

The collection system at Hall's house includes rain gutters and downspouts that empty into lawn areas and into a specially designed cistern system.

The grassy lawn sections are surrounded by slightly raised berms. The tiny embankments trap runoff until it can percolate through layers of mulch, compost and soil and into the underground water table.

Box-like cisterns hold 3,600 gallons of runoff. They are designed to store the water until the rainy season ends. Then it can be pumped out and used to irrigate the lawn.

Lipkis said the cost of installing similar recycling systems could be reduced to about $10,000 per home if a manufacturer can be found to mass-produce the cisterns.

But homeowners can immediately begin using the simple mulch-layering and berm-building techniques for next to no cost if they are willing to wield a pick and shovel in their yards.

To spur interest, the TreePeople group will offer tours of Hall's yard during the next eight months.

But those demonstrations won't include the artificial storm created Thursday by a tanker truck. During their simulated cloudburst, workers pumped 2,000 gallons onto Hall's roof.

To Lipkis' dismay, the spraying was done with drinking water, not recycled sewage effluent. "We couldn't get a permit to use waste water," he shrugged.

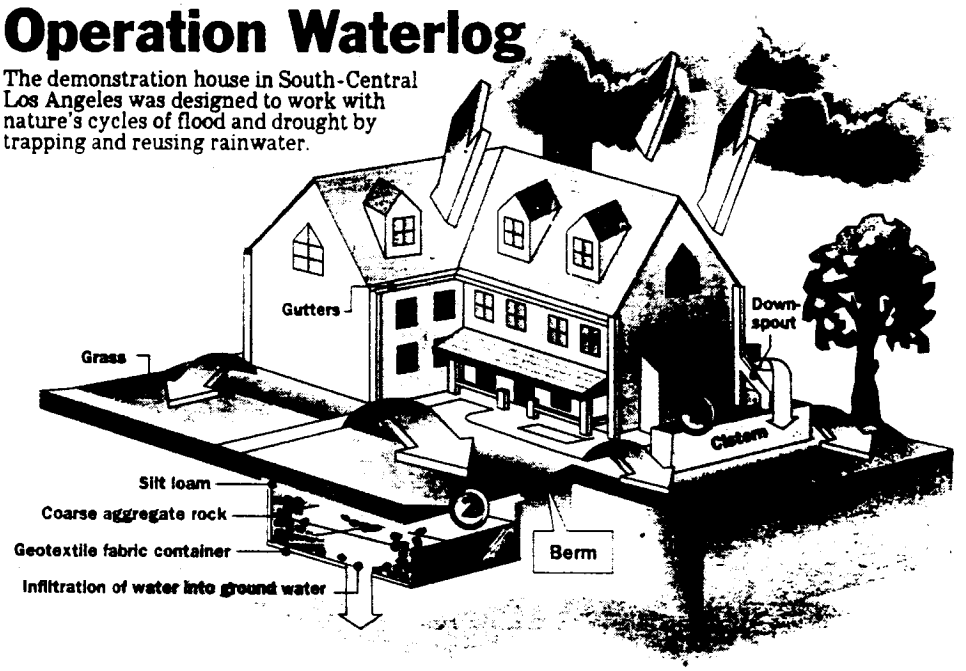
Hall, a 57-year-old former bookkeeper who has lived in the house for 25 years, said she doesn't mind what could become a parade of looky-loos tromping over her lawn and around the drought-resistant shrubs planted as part of the project.

She's a longtime supporter of TreePeople, Hall said.

But more important, she said, "I'm a people person."

Operation Waterlog

The demonstration house in South-Central Los Angeles was designed to work with nature's cycles of flood and drought by trapping and reusing rainwater.



1. Gutters and downspouts carry the rain to the lawn and into the cisterns. The water is pumped out by an electric pump on a timer system to irrigate the yard.
2. Runoff from the roof drains into depressions in the yard. The "sunken garden" holds rainwater until it can be absorbed into the ground. The grading can be placed over coarse aggregate rock for a higher infiltration rate.

IN THE GARDEN

TreePeople's L.A. Pilot Project Is Testing the Waters

By ROBERT SMAUS
TIMES GARDEN EDITOR

Wouldn't it have been great if we could have saved some of the rain that fell last winter to use in our gardens right now, when things are beginning to look a little parched?

Think of how happy the plants would be to get fresh, pure rainwater instead of municipal water, which often comes from sources high in mineral salts (such as the Colorado River).

Those salts cause the edges of the leaves on some plants to turn brown at this time of year, and they affect the health of plants in other ways too.

If we had our own backyard supplies, water companies would be happy because they'd have to find and store less water. Even flood control agencies would be tickled because any water saved on your property would not be surging down their over-taxed storm drains. Think of how much water simply rushes to the sea each winter.

That's some of the thinking behind the TreePeople's latest project garden on a typical urban lot in South-Central Los Angeles.

TreePeople has designed and built a landscape that captures and saves rainwater.

A panel of experts came up with the goals and ideas, engineers did the planning and design and two designer-contractors—Karen Bragg and Bob Cornell—made it all work.

Some of the water coming off the roof is stored on the property in huge cisterns, and some of the water is contained by berms or captured in dry wells, where it can slowly soak into the ground. In combination, these systems let very little rainfall leave the property.

In a city where so much of the land is paved or roofed over and where gutters run freely, TreePeople's ideas make good sense.

Rainwater is directed from the gutter into a filter and then into two 1,800-gallon storage tanks.

Photos by LAWRENCE K. HO / Los Angeles Times

Landscape designer Robert Cornell, left, and TreePeople President Andy Lipkis examine the rainwater storage system at demo house.

A number of interested agencies and foundations sponsored the project, including the city of Los Angeles, the Department of Water and Power, the U.S. Forest Service, the Environmental Protection Agency, the Metropolitan Water Department and the L.A. County Department of Public Works.

TreePeople estimate that retrofitting a typical Los Angeles garden to save and store water would cost in the neighborhood of $7,500 to $15,000.

Andy Lipkis of TreePeople thinks that much of this cost might be born by such public agencies as water departments and flood control districts.

Lipkis believes that retrofitting gardens might be cheaper than building new drainage systems, dams and aqueducts.

In Australia and in several island countries, individuals routinely capture and save rainwater, so it is not a new idea, though the flood control aspects of this project are a new twist, and this is the first system I've seen that saves rainwater exclusively for the garden.

The heart of the water-storing system is two cisterns that collect water from the roof like giant rain barrels. Together they hold about 3,200 gallons.

The cisterns take up very little room in the garden because most of their bulk is underground. Above ground, each is 2 feet wide, 5 feet tall and 10 feet long. This above-ground portion could do double-duty as a garden wall. The project's designers figure that they could line up along one property line to store about 20,000 gallons.

That's far short of the 60,000 to 70,000 gallons a year used to water the typical garden in city of Los Angeles, but it would make a nice dent.

Below ground, the cisterns are 10 feet long, but each becomes 4 feet wide and extends 6 feet below ground.

The tanks are made of recycled polypropylene with a fiberglass coating. When I saw them, TreePeople had not yet figured out how to put a finish coat on the fiberglass, so the containers looked a little raw.

Before the water gets to the cisterns, it runs though an elementary filter that takes out much of the particulate matter that settles on roofs, from brake lining dust to pigeon droppings.

From the interconnected tanks, the water is pumped directly into the automatic irrigation system.

The system was completed only in May but managed to "grab 300 gallons" from the last freak storm, which dropped about two inches of rain on May 12 and 13, according to Lipkis.

For the pilot project, the two tanks drain only a quarter of the roof (about 250 square feet). The water can also be pumped to the street if the cisterns are too full and a big storm is approaching.

In TreePeople's pilot project, the rest of the water from roof downspouts is directed down "swales," gentle 2% slopes that drain water away from the house but at such a slow rate that it has time to soak into the soil.

Rainwater that soaks into the ground is almost as useful as water that is saved for summer. It thoroughly waters trees and other deep-rooted plants and it eventually ends up as part of our ground-water supply. Plenty of water running down through the soil also pushes out those harmful salts that tend to accumulate from fertilizers and municipal irrigation water.

The swales are covered with either lawn grass or bark mulch, and they all slope toward the front lawn, where the water is temporarily trapped behind low berms.

In the middle of one lawn in the pilot project there is a dry well, which is simply a big hole filled with gravel where water can collect and soak into the soil. The dry well is hardly visible, only a small, round drain hole shows.

The lawns would become like little lakes during a storm, holding water behind the low, mounded berms. If the water got too deep, an overflow would let it run to the street.

Rain falling on the driveway is also sent to these lawn "lakes" and the dry well.

In nearly rainless years (which is what's being predicted for the coming winter), every drop that gets into the ground counts.

Last winter and spring, it was quite clear in most gardens how helpful deep, soaking rains can be. Some of the clever devices in this experimental garden make any rain a soaking rain, while the others stash water away for those rainless days and months.

Rain Brainstorm

■ Conservation: Yard is landscaped in pilot project to work as a catch basin, saving runoff.

By BOB POOL
TIMES STAFF WRITER

That wasn't a rain cloud over Rozella Hall's head that sent her scurrying for an umbrella Thursday in South-Central Los Angeles.

It was the man on her roof with the fire hose—the one helping create an artificial thunderstorm over her West 50th Street home as part of a water conservation project being studied by local and federal officials.

The yard surrounding Hall's 70-year-old clapboard bungalow has been turned into a colorfully landscaped catch basin. Officials figure the yard will trap rain runoff and let it soak into the ground instead of wastefully flowing into storm drains that empty into the ocean.

A coalition of federal, state and municipal agencies chipped in $50,000 to create what experts say could become a prototype for backyard projects all over Los Angeles.

The water-recycling idea was proposed by environmentalist Andy Lipkis, founder of Los Angeles-based TreePeople. He suggests that diverting rain runoff into the ground will boost the city's underground water supply while at the same time preventing flooding along the Los Angeles River.

The collection system at Hall's house includes rain gutters and downspouts that empty into lawn areas and into a specially designed cistern system.

The grassy lawn sections are surrounded by slightly raised berms. The tiny embankments trap runoff until it can percolate through layers of mulch, compost and soil and into the underground water table.

Box-like cisterns hold 3,600 gallons of runoff. They are designed to store the water until the rainy season ends. Then it can be pumped out and used to irrigate the lawn.

Lipkis said the cost of installing similar recycling systems could be reduced to about $10,000 per home if a manufacturer can be found to mass-produce the cisterns.

But homeowners can immediately begin using the simple mulch-layering and berm-building techniques for next to no cost if they are willing to wield a pick and shovel in their yards.

To spur interest, the TreePeople group will offer tours of Hall's yard during the next eight months.

But those demonstrations won't include the artificial storm created Thursday by a tanker truck. During their simulated cloudburst, workers pumped 2,000 gallons onto Hall's roof.

To Lipkis' dismay, the spraying was done with drinking water, not recycled sewage effluent. "We couldn't get a permit to use waste water," he shrugged.

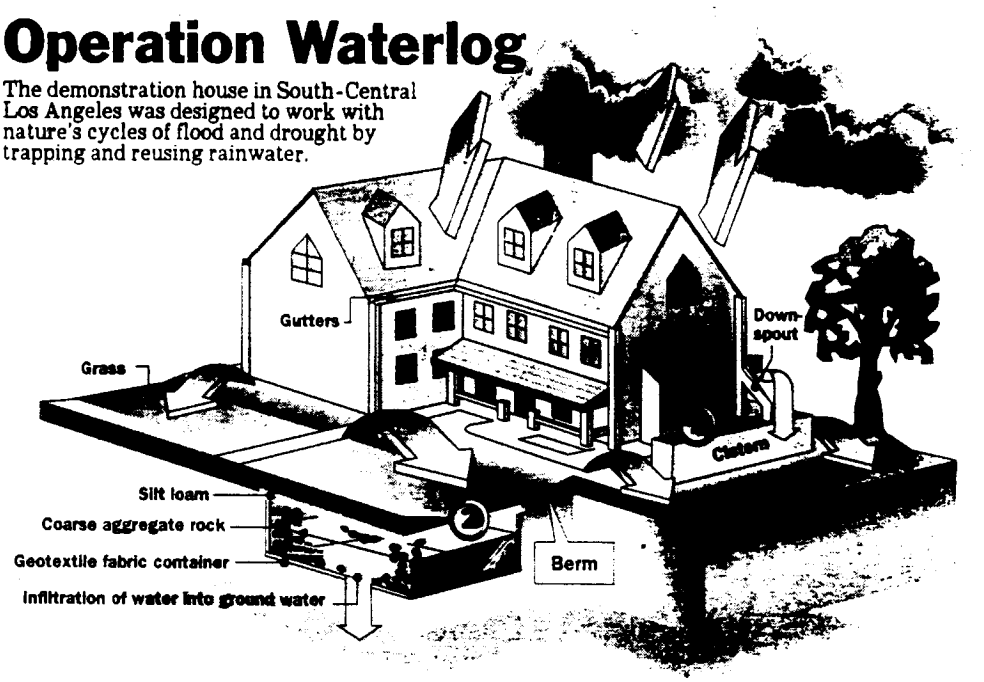
Hall, a 57-year-old former bookkeeper who has lived in the house for 25 years, said she doesn't mind what could become a parade of looky-loos tromping over her lawn and around the drought-resistant shrubs planted as part of the project.

She's a longtime supporter of TreePeople, Hall said.

But more important, she said, "I'm a people person."

Operation Waterlog

The demonstration house in South-Central Los Angeles was designed to work with nature's cycles of flood and drought by trapping and reusing rainwater.



1. Gutters and downspouts carry the rain to the lawn and into the cisterns. The water is pumped out by an electric pump on a timer system to irrigate the yard.
2. Runoff from the roof drains into depressions in the yard. The "sunken garden" holds rainwater until it can be absorbed into the ground. The grading can be placed over coarse aggregate rock for a higher infiltration rate.

TreePeople's L.A. Pilot Project Is Testing the Waters

By ROBERT SMAUS
TIMES GARDEN EDITOR

Wouldn't it have been great if we could have saved some of the rain that fell last winter to use in our gardens right now, when things are beginning to look a little parched?

Think of how happy the plants would be to get fresh, pure rainwater instead of municipal water, which often comes from sources high in mineral salts (such as the Colorado River).

Those salts cause the edges of the leaves on some plants to turn brown at this time of year, and they affect the health of plants in other ways too.

If we had our own backyard supplies, water companies would be happy because they'd have to find and store less water. Even flood control agencies would be tickled because any water saved on your property would not be surging down their over-taxed storm drains. Think of how much water simply rushes to the sea each winter.

That's some of the thinking behind the TreePeople's latest project garden on a typical urban lot in South-Central Los Angeles.

The yard surrounding Hall's 70-year-old clapboard bungalow has been turned into a colorfully landscaped catch basin. Officials figure the yard will trap rain runoff and let it soak into the ground instead of wastefully flowing into storm drains that empty into the ocean.

A coalition of federal, state and municipal agencies chipped in $50,000 to create what experts say could become a prototype for backyard projects all over Los Angeles.

The water-recycling idea was proposed by environmentalist Andy Lipkis, founder of Los Angeles-based TreePeople. He suggests that diverting rain runoff into the ground will boost the city's underground water supply while at the same time preventing flooding along the Los Angeles River.

The collection system at Hall's house includes rain gutters and downspouts that empty into lawn areas and into a specially designed cistern system.

The grassy lawn sections are surrounded by slightly raised berms. The tiny embankments trap runoff until it can percolate through layers of mulch, compost and soil and into the underground water table.

Box-like cisterns hold 3,600 gallons of runoff. They are designed to store the water until the rainy season ends. Then it can be pumped out and used to irrigate the lawn.

Lipkis said the cost of installing similar recycling systems could be reduced to about $10,000 per home if a manufacturer can be found to mass-produce the cisterns.

But homeowners can immediately begin using the simple mulch-layering and berm-building techniques for next to no cost if they are willing to wield a pick and shovel in their yards.

To spur interest, the TreePeople group will offer tours of Hall's yard during the next eight months.

But those demonstrations won't include the artificial storm created Thursday by a tanker truck. During their simulated cloudburst, workers pumped 2,000 gallons onto Hall's roof.

To Lipkis' dismay, the spraying was done with drinking water, not recycled sewage effluent. "We couldn't get a permit to use waste water," he shrugged.

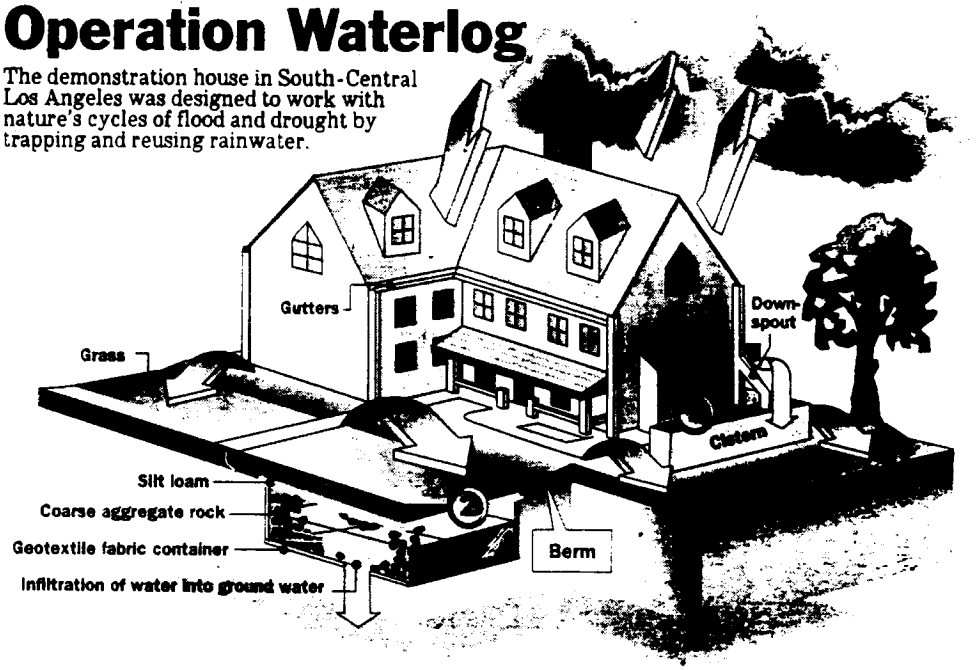
Hall, a 57-year-old former bookkeeper who has lived in the house for 25 years, said she doesn't mind what could become a parade of looky-loos tromping over her lawn and around the drought-resistant shrubs planted as part of the project.

She's a longtime supporter of TreePeople, Hall said.

But more important, she said, "I'm a people person."

Operation Waterlog

The demonstration house in South-Central Los Angeles was designed to work with nature's cycles of flood and drought by trapping and reusing rainwater.



1. Gutters and downspouts carry the rain to the lawn and into the cisterns. The water is pumped out by an electric pump on a timer system to irrigate the yard.

2. Runoff from the roof drains into depressions in the yard. The "sunken garden" holds rainwater until it can be absorbed into the ground. The grading can be placed over coarse aggregate rock for a higher infiltration rate.

IN THE GARDEN

TreePeople's L.A. Pilot Project Is Testing the Waters

By ROBERT SMAUS
TIMES GARDEN EDITOR

Wouldn't it have been great if we could have saved some of the rain that fell last winter to use in our gardens right now, when things are beginning to look a little parched?

Think of how happy the plants would be to get fresh, pure rainwater instead of municipal water, which often comes from sources high in mineral salts (such as the Colorado River).

Those salts cause the edges of the leaves on some plants to turn brown at this time of year, and they affect the health of plants in other ways too.

If we had our own backyard supplies, water companies would be happy because they'd have to find and store less water. Even flood control agencies would be tickled because any water saved on your property would not be surging down their over taxed storm drains. Think of how much water simply rushes to the sea each winter.

That's some of the thinking behind the TreePeople's latest project garden on a typical urban lot in South-Central Los Angeles.

TreePeople has designed and built a landscape that captures and saves rainwater.

A panel of experts came up with the goals and ideas, engineers did the planning and design and two designer-contractors—Karen Bragg and Bob Cornell—made it all work.

Some of the water coming off the roof is stored on the property in huge cisterns, and some of the water is contained by berms or captured in dry wells, where it can slowly soak into the ground. In combination, these systems let very little rainfall leave the property.

In a city where so much of the land is paved or roofed over and where gutters run freely, TreePeople's ideas make good sense.

Rainwater is directed from the gutter into a filter and then into two 1,800-gallon storage tanks.

Photos by LAWRENCE K. HO / Los Angeles Times

Landscape designer Robert Cornell, left, and TreePeople President Andy Lipkis examine the rainwater storage system at demo house.

A number of interested agencies and foundations sponsored the project, including the city of Los Angeles, the Department of Water and Power, the U.S. Forest Service, the Environmental Protection Agency, the Metropolitan Water Department and the L.A. County Department of Public Works.

TreePeople estimate that retrofitting a typical Los Angeles garden to save and store water would cost in the neighborhood of $7,500 to $15,000.

Andy Lipkis of TreePeople thinks that much of this cost might be born by such public agencies as water departments and flood control districts.

Lipkis believes that retrofitting gardens might be cheaper than building new drainage systems, dams and aqueducts.

In Australia and in several island countries, individuals routinely capture and save rainwater, so it is not a new idea, though the flood control aspects of this project are a new twist, and this is the first system I've seen that saves rainwater exclusively for the garden.

The heart of the water-storing system is two cisterns that collect water from the roof like giant rain barrels. Together they hold about 3,200 gallons.

The cisterns take up very little room in the garden because most of their bulk is underground. Above ground, each is 2 feet wide, 5 feet tall and 10 feet long. This above-ground portion could do double-duty as a garden wall. The project's designers figure that they could line up along one property line to store about 20,000 gallons.

That's far short of the 60,000 to 70,000 gallons a year used to water the typical garden in city of Los Angeles, but it would make a nice dent.

Below ground, the cisterns are 10 feet long, but each becomes 4 feet wide and extends 6 feet below ground.

The tanks are made of recycled polypropylene with a fiberglass coating. When I saw them, TreePeople had not yet figured out how to put a finish coat on the fiberglass, so the containers looked a little raw.

Before the water gets to the cisterns, it runs though an elementary filter that takes out much of the particulate matter that settles on roofs, from brake lining dust to pigeon droppings.

From the interconnected tanks, the water is pumped directly into the automatic irrigation system.

The system was completed only in May but managed to "grab 300 gallons" from the last freak storm, which dropped about two inches of rain on May 12 and 13, according to Lipkis.

For the pilot project, the two tanks drain only a quarter of the roof (about 250 square feet). The water can also be pumped to the street if the cisterns are too full and a big storm is approaching.

In TreePeople's pilot project, the rest of the water from roof downspouts is directed down "swales," gentle 2% slopes that drain water away from the house but at such a slow rate that it has time to soak into the soil.

Rainwater that soaks into the ground is almost as useful as water that is saved for summer. It thoroughly waters trees and other deep-rooted plants and it eventually ends up as part of our ground-water supply. Plenty of water running down through the soil also pushes out those harmful salts that tend to accumulate from fertilizers and municipal irrigation water.

The swales are covered with either lawn grass or bark mulch, and they all slope toward the front lawn, where the water is temporarily trapped behind low berms.

In the middle of one lawn in the pilot project there is a dry well, which is simply a big hole filled with gravel where water can collect and soak into the soil. The dry well is hardly visible, only a small, round drain hole shows.

The lawns would become like little lakes during a storm, holding water behind the low, mounded berms. If the water got too deep, an overflow would let it run to the street.

Rain falling on the driveway is also sent to these lawn "lakes" and the dry well.

In nearly rainless years (which is what's being predicted for the coming winter), every drop that gets into the ground counts.

Last winter and spring, it was quite clear in most gardens how helpful deep, soaking rains can be. Some of the clever devices in this experimental garden make any rain a soaking rain, while the others stash water away for those rainless days and months.

The cisterns take up very little room in the garden because most of their bulk is underground. Above ground, each is 2 feet wide, 5 feet tall and 10 feet long. This above-ground portion could do double-duty as a garden wall. The project's designers figure that they could line up along one property line to store about 20,000 gallons.

That's far short of the 60,000 to 70,000 gallons a year used to water the typical garden in city of Los Angeles, but it would make a nice dent.

Below ground, the cisterns are 10 feet long, but each becomes 4 feet wide and extends 6 feet below ground.

The tanks are made of recycled polypropylene with a fiberglass coating. When I saw them, TreePeople had not yet figured out how to put a finish coat on the fiberglass, so the containers looked a little raw.

Before the water gets to the cisterns, it runs though an elementary filter that takes out much of the particulate matter that settles on roofs, from brake lining dust to pigeon droppings.

From the interconnected tanks, the water is pumped directly into the automatic irrigation system.

The system was completed only in May but managed to "grab 300 gallons" from the last freak storm, which dropped about two inches of rain on May 12 and 13, according to Lipkis.

For the pilot project, the two tanks drain only a quarter of the roof (about 250 square feet). The water can also be pumped to the street if the cisterns are too full and a big storm is approaching.

In TreePeople's pilot project, the rest of the water from roof downspouts is directed down "swales," gentle 2% slopes that drain water away from the house but at such a slow rate that it has time to soak into the soil.

Rainwater that soaks into the ground is almost as useful as water that is saved for summer. It thoroughly waters trees and other deep-rooted plants and it eventually ends up as part of our ground-water supply. Plenty of water running down through the soil also pushes out those harmful salts that tend to accumulate from fertilizers and municipal irrigation water.

The swales are covered with either lawn grass or bark mulch, and they all slope toward the front lawn, where the water is temporarily trapped behind low berms.

In the middle of one lawn in the pilot project there is a dry well, which is simply a big hole filled with gravel where water can collect and soak into the soil. The dry well is hardly visible, only a small, round drain hole shows.

The lawns would become like little lakes during a storm, holding water behind the low, mounded berms. If the water got too deep, an overflow would let it run to the street.

Rain falling on the driveway is also sent to these lawn "lakes" and the dry well.

In nearly rainless years (which is what's being predicted for the coming winter), every drop that gets into the ground counts.

Last winter and spring, it was quite clear in most gardens how helpful deep, soaking rains can be. Some of the clever devices in this experimental garden make any rain a soaking rain, while the others stash water away for those rainless days and months.

Our wording for the 0.75 standard is as follows: "The development must be designed so as to mitigate (infiltrate and/or treat) the site runoff generated from each and every storm event of up to and including 0.75-inches of rainfall, prior to it discharging into the stormwater conveyance system."

This wording is not in any County Ordinance or Code. Also we have received several comments about this wording having the implication of having to treat more than one storm. The question has arisen, "What if there are two storms within a short time period? Does the BMP need to be designed to mitigate both storms or possibly 1.5 inches of rainfall?". It is our intend and understanding that the BMPs will need to be designed to mitigate the runoff generated from a storm event of up to and including 0.75-inches of rainfall. The design criteria to be used for each selected BMP will detail the emptying or residence time to be used for proper BMP design. Our SUSMPs can be obtained at the following URL: http://dpw.co.la.ca.us/epd/mitigation/lacdpw.htm

II. URBAN RUNOFF

A. New Development Management Measure

1. **By design or performance:**

   - **After construction has been completed and the site is permanently stabilized, reduce the average annual total suspended solid (TSS) loadings by 80 percent. For the purposes of this measure, an 80 percent TSS reduction is to be determined on an average annual basis, or**

   - **Reduce the postdevelopment loadings of TSS so that the average annual TSS loadings are no greater than predevelopment loadings, and**

2. **To the extent practicable, maintain postdevelopment peak runoff rate and average volume at levels that are similar to predevelopment levels.**

Sound watershed management requires that both structural and nonstructural measures be employed to mitigate the adverse impacts of storm water. Nonstructural Management Measures II.B and II.C can be effectively used in conjunction with Management Measure II.A to reduce both the short- and long-term costs of meeting the treatment goals of this management measure.

1. Applicability

This management measure is intended to be applied by States to control urban runoff and treat associated pollutants generated from new development, redevelopment, and new and relocated roads, highways, and bridges. Under the Coastal Zone Act Reauthorization Amendments of 1990, States are subject to a number of requirements as they develop coastal nonpoint source (NPS) programs in conformity with this management measure and will have flexibility in doing so. The application of management measures by States is described more fully in *Coastal Nonpoint Pollution Control Program: Program Development and Approval Guidance*, published jointly by the U.S. Environmental Protection Agency (EPA) and the National Oceanic and Atmospheric Administration (NOAA) of the U.S. Department of Commerce.

For design purposes, postdevelopment peak runoff rate and average volume should be based on the 2-year/24-hour storm.

2. Description

This management measure is intended to accomplish the following: (1) decrease the erosive potential of increased runoff volumes and velocities associated with development-induced changes in hydrology; (2) remove suspended solids and associated pollutants entrained in runoff that result from activities occurring during and after development; (3) retain hydrological conditions to closely resemble those of the predisturbance condition; and (4) preserve natural systems including in-stream habitat. For the purposes of this management measure, "similar" is defined as "resembling though not completely identical."

During the development process, both the existing landscape and hydrology can be significantly altered. As development occurs, the following changes to the land may occur (USEPA, 1977):

- Soil porosity decreases;
- Impermeable surfaces increase;
- Channels and conveyances are constructed;
- Slopes increase;
- Vegetative cover decreases; and
- Surface roughness decreases.

These changes result in increased runoff volume and velocities, which may lead to increased erosion of streambanks, steep slopes, and unvegetated areas (Novotny, 1991). In addition, destruction of in-stream and riparian habitat, increases in water temperature (Schueler et al., 1992), streambed scouring, and downstream siltation of streambed substrate, riparian areas, estuarine habitat, and reef systems may occur. An example of predicted effects of increased levels of urbanization on runoff volumes is presented in Table 4-4 (USDA-SCS, 1986). Methods are also available to compute peak runoff rates (USDA-SCS, 1986).

The annual TSS loadings can be calculated by adding the TSS loadings that can be expected to be generated during an average 1-year period from precipitation events less than or equal to the 2-year/24-hour storm. The 80 percent standard can be achieved by reducing, over the course of the year, 80 percent of these loadings. EPA recognizes that 80 percent cannot be achieved for each storm event and understands that TSS removal efficiency will fluctuate above and below 80 percent for individual storms.

Management Measures II.A, II.B, and II.C were selected as a system to be used to prevent and mitigate the problems discussed above. In combination, these three management measures applied on-site and throughout watersheds can be used to provide increased watershed protection and help prevent severe erosion, flooding, and increased pollutant loads generally associated with poorly planned development. Implementation of Management Measures II.B and II.C can help achieve the goals of Management Measure II.A.

Structural practices to control urban runoff rely on three basic mechanisms to treat runoff: **infiltration**, **filtration**, and **detention**. Table 4-5 *(53k)* lists specific urban runoff control practices that relate to these and includes information on advantages, disadvantages, and costs. Table 4-6 presents site-specific considerations, regional limitations, operation and maintenance burdens, and longevity for these practices.

Infiltration devices, such as infiltration trenches, infiltration basins, filtration basins, and porous and concrete block pavement, rely on absorption of runoff to treat urban runoff discharges. Water is percolated through soils, where filtration and biological action remove pollutants. Systems that rely on soil absorption require deep permeable soils at separation distances of at least 4 feet between the bottom of the structure and seasonal ground water levels. The widespread use of infiltration in a watershed can be useful to maintain or restore predevelopment

hydrology, increase dry-weather baseflow, and reduce bankfull flooding frequency. However, infiltration systems may not be appropriate where ground water requires protection. Restrictions may also apply to infiltration systems located above sole source (drinking water) aquifers. Where such designs are selected, they should be incorporated with the recognition that periodic maintenance is necessary for these areas. Long-term effectiveness in most cases will depend on proper operation and maintenance of the entire system.

NOTE: Infiltration systems, some filtration devices, and sand filters should be installed after construction has been completed and the site has been permanently stabilized. The State of Maryland has observed a high failure rate for infiltration systems. Many of these failures can be attributed to clogging due to sediment loadings generated during the construction process and/or the premature use of the device before proper stabilization of the site has occurred. In cases where construction of the infiltration system is necessary before the cessation of land-disturbing activities, diversions, covers, or other means to prevent sediment-laden runoff from entering and clogging the infiltration system should be used (State of Maryland DNR, personal communication, 1991).

Filtration practices such as filter strips, grassed swales, and sand filters treat sheet flow by using vegetation or sand to filter and settle pollutants. In some cases infiltration and treatment in the subsoil may also occur. After passing through the filtration media, the treated water can be routed into streams, drainage channels, or other waterbodies; evaporated; or percolated into ground water. Sand filters are particularly useful for ground-water protection. The influence of climatic factors must be considered in the process of selecting vegetative systems.

Detention practices temporarily impound runoff to control runoff rates, and settle and retain suspended solids and associated pollutants. Extended detention ponds and wet ponds fall within this category. Constructed urban runoff wetlands and multiple-pond systems also remove pollutants by detaining flows that lead to sedimentation (gravitational settling of suspended solids). Properly designed ponds protect downstream channels by controlling discharge velocities, thereby reducing the frequency of bankfull flooding and resultant bank-cutting erosion. If landscaped and planted with appropriate vegetation, these systems can reduce nutrient loads and also provide terrestrial and aquatic wildlife habitat. When considering the use of these devices, potential negative impacts such as downstream warming, reduced baseflow, trophic shifts, bacterial contamination due to waterfowl, hazards to nearby residents, and nuisance factors such as mosquitoes and odor should be considered. Siting development in wetlands and floodplains should be avoided. Where drainage areas are greater than 250 acres and ponds are being considered, inundation of upstream channels may be of concern.

Constructed wetlands and multiple-pond systems also treat runoff through the processes of adsorption, plant uptake, filtration, volatilization, precipitation, and microbial decomposition (Livingston and McCarron, 1992; Schueler et al., 1992). Multiple-pond systems in particular have shown potential to provide much higher levels of treatment (Schueler et al., 1992). In general, the potential concerns and drawbacks applicable to wet ponds apply to these systems. Many of these systems are currently being designed to include vegetated buffers and deep-water areas to provide habitat for wildlife and aesthetic benefits. Where such designs are selected, they should be incorporated with the recognition that periodic maintenance is necessary. Long-term effectiveness in most cases will depend on proper operation and maintenance of the entire system. Refer to Chapter 7 for additional information on constructed wetlands.

Water quality inlets, like ponds, rely on gravity settling to remove pollutants before ponds discharge water to the storm sewer or other collection system. Water quality inlets are designed to trap floatable trash and debris. When inlets are coupled with oil/grit separators, hydrocarbon loadings from areas with high traffic/parking volumes can be reduced. However, experience has shown that these devices have limited pollutant-removal effectiveness and should not be used unless coupled with frequent and effective clean-out methods (Schueler et al., 1992). Although no costs are currently available, proper maintenance of water quality inlets must include proper disposal of trapped coarse-grained sediments and hydrocarbons. The costs of clean-out and disposal may be significant when contaminated sediments require proper disposal.

Inadequate maintenance is often cited as one of the major factors influencing the poor effectiveness of structural practices. The cost of long-term maintenance should be evaluated during the selection process. In addition, responsibility for maintenance should be clearly assigned for the life of the system. Typical maintenance requirements include:

- Inspection of basins and ponds after every major storm for the first few months after construction and annually thereafter;
- Mowing of grass filter strips and swales at a frequency to prevent woody growth and promote dense vegetation;
- Removal of litter and debris from dry ponds, forebays, and water quality inlets;
- Revegetation of eroded areas;
- Periodic removal and replacement of filter media from infiltration trenches and filtration ponds;
- Deep tilling of infiltration basins to maintain infiltrative capability;
- Frequent (at least quarterly) vacuuming or jet hosing of porous pavements or concrete grid pavements;
- Quarterly clean-outs of water quality inlets;
- Periodic removal of floatables and debris from catch basins, water quality inlets, and other collection-type controls; and
- Periodic removal and proper disposal of accumulated sediment (applicable to all practices). Sediments in infiltration devices need to be removed frequently enough to prevent premature failure due to clogging.

Operation and Maintenance

Proper operation and maintenance of structural treatment facilities is critical to their effectiveness in mitigating adverse impacts of urban runoff. The proper installation and maintenance of various BMPs often determines their success or failure (Reinalt, 1992).

During a field study of 51 urban runoff treatment facilities, the Ocean County, New Jersey, planning and engineering departments determined that the major source of urban runoff

problems was a failure of the responsible party to provide adequate facility maintenance. The causes of this failure are complex and include factors such as lack of funding, manpower, and equipment; uncertain or irresponsible ownership; unassigned maintenance responsibility; and ignorance or disregard of potential consequences of maintenance neglect (Ocean County, 1989). The analysis of the field data collected during the study indicated the following trends:

- Bottoms, side slopes, trash racks, and low-flow structures were the primary sources of maintenance problems.
- Infiltration facilities seemed to be more prone to maintenance neglect and were generally in the poorest condition overall.
- Retention facilities appeared to receive the greatest amount of maintenance and generally were in the best condition overall.
- Publicly owned facilities were usually better maintained than those that were privately maintained.
- Facilities located at office development sites were better maintained than those at commercial or institutional sites; facilities in residential areas received average maintenance.
- Highly visible urban runoff facilities were generally better maintained that those in more remote, less visible locations (Ocean County, 1989).

The following program elements should be considered to ensure the proper design, implementation, and operation and maintenance of runoff treatment and control devices (adapted from The State of New Jersey Ocean County Demonstration Study's *Storm Water Management Facilities Maintenance Manual*):

- Adoption, promulgation, and implementation of planning and design standards that eliminate, reduce, and/or facilitate facility maintenance; coordination with other regulatory authorities with jurisdiction over runoff facilities;
- Establishment of a comprehensive design review program, which includes training and education to ensure adequate staff competency and expertise;
- Design standards published in a readily understandable format for all permittees and responsible parties including regulatory authorities; the provision of clear requirements to promote the adoption of planning and standards and expedite facility review and approval;
- Publication of specific obligations and responsibilities of the runoff facility owner/operator including procedures for the identification of owners/operators who will have long-term responsibility for the facility;
- Development of a procedure for addressing maintenance default by negligent owner/operators;

- Periodic review and evaluation of the runoff management program to ensure continued program effectiveness and efficiency;
- Runoff facility construction inspection program; and
- Provisions for public assumption of runoff control facilities.

3. Management Measure Selection

This management measure was selected because of the following factors.

1. Removal of 80 percent of total suspended solids (TSS) is assumed to control heavy metals, phosphorus, and other pollutants.
2. A number of coastal States, including Delaware and Florida, and the Lower Colorado River Authority (Texas) require and have implemented a TSS removal treatment standard of at least 80 percent for new development.
3. Analysis has shown that constructed wetlands, wet ponds, and infiltration basins can remove 80 percent of TSS, provided they are designed and maintained properly. Other practices or combinations of practices can be also used to achieve the goal.
4. The control of postdevelopment volume and peak runoff rates to reduce or prevent streambank erosion and stream scouring and to maintain predevelopment hydrological conditions can be accomplished using a number of water quality and flood control practices. Many States and local governments have implemented requirements that stipulate that, at a minimum, the 2-year/24-hour storm be controlled.

Management Measure II.A.(1)(b) was selected to provide a descriptive alternative to Management Measure II.A.(1)(a). Where preexisting conditions do not already present a water quality problem, preservation of predevelopment TSS loading levels is intended to promote TSS loading reductions that adequately protect surface waters and are equivalent to or greater than the levels achieved by Management Measure option II.A.(1)(a). In some cases, local conditions (e.g., mountainous areas with arid, steep slopes) may preclude the implementation of Management Measure II.A.(1)(a). Where local conditions do not allow the implementation of BMPs such as grassed swales or detention basins, and preconstruction/predevelopment (existing conditions) TSS loadings from the site are significant, it may not be cost-effective or beneficial to require 80 percent TSS postdevelopment loading reductions. Management Measure option II.A.(1)(b) was provided to allow flexibility where such conditions exist. This flexibility will be especially important in cases where loadings from surrounding undeveloped areas dwarf the TSS loadings generated from the new development. (NOTE: Predevelopment is defined, in the context of Management Measure II.A.(1)(b), as the sediment loadings and runoff volumes/velocities that exist onsite immediately before the planned land disturbance and development occur.)

4. Practices

As discussed more fully at the beginning of this chapter and in Chapter 1, the following practices are described for illustrative purposes only. State programs need not require implementation of these practices. However, as a practical matter, EPA anticipates that the management measure set

forth above generally will be implemented by applying one or more management practices appropriate to the source, location, and climate. The practices set forth below have been found by EPA to be representative of the types of practices that can be applied successfully to achieve the management measure described above.

Cost and effectiveness information for these practices is shown in Tables 4-7 *(34k)* and 4-8. Many of these practices can be used during site development, but the focus of this section is the abatement of postdevelopment impacts.

a. Develop training and education programs and materials for public officials, contractors, and others involved with the design, installation, operation, inspection, and maintenance of urban runoff facilities.

Training programs and educational materials for public officials, contractors, and the public are crucial to implementing effective urban runoff management programs. Contractor certification, inspector training, and competent design review staff are important for program implementation and continuing effectiveness. The State of New Jersey Ocean County Demonstration Study's *Storm Water Management Facilities Maintenance Manual* addresses many of these issues and provides guidance on programmatic elements necessary for the proper operation and maintenance of urban runoff facilities. Several other States and local governments, including Virginia, Maryland, Washington, Delaware, Northeastern Illinois Planning Commission, and the City of Alexandria, Virginia, have developed manuals and training materials to assist in implementation of urban runoff requirements and regulations.

The State of Delaware passed legislation requiring that "all responsible personnel involved in a construction project will have a certificate of attendance at a Departmental sponsored or approved training course for the control of sediment and storm water before initiation of land disturbing activity." The State provides personnel training and educational opportunities for contractors to meet this requirement and has delegated program elements to conservation districts, counties, and other agencies. The program has been well received and from February 1991 to July 1991, over 1,100 individuals from 300 companies and organizations participated in the program (Shaver and Piorko, 1992).

b. Ensure that all urban runoff facilities are operated and maintained properly.

Once an urban runoff facility is installed, it should receive thorough maintenance in order to function properly and not pose a health or safety threat. Maintenance should occur at regular intervals, be performed by one or more individuals trained in proper inspection and maintenance of urban runoff facilities, and be performed in accordance with the adopted standards of the State or local government (Ocean County, undated). It is more effective and efficient to perform preventative maintenance on a regular basis than to undertake major remedial or corrective action on an as needed basis (Ocean County, undated).

c. Infiltration Basins

Infiltration basins are impoundments in which incoming urban runoff is temporarily stored until it gradually infiltrates into the soil surrounding the basin. Infiltration basins should drain within 72 hours to maintain aerobic conditions,

which favor bacteria that aid in pollutant removal, and to ensure that the basin is ready to receive the next storm (Schueler, 1987). The runoff entering the basin is pretreated to remove coarse sediment that may clog the surface soil pore on the basin floor. Concentrated runoff should flow through a sediment trap, or a vegetated filter strip may be used for sheet flow.

d. Infiltration Trenches

Infiltration trenches are shallow excavated ditches that have been backfilled with stone to form an underground reservoir. Urban runoff diverted into the trench gradually infiltrates from the bottom of the trench into the subsoil and eventually into the ground water. Variations in the design of infiltration trenches include dry wells, pits designed to control small volumes of runoff (such as the runoff from a rooftop), and enhanced infiltration trenches, which are equipped with extensive pretreatment systems to remove sediment and oil. Depending on the quality of the runoff, pretreatment will generally be necessary to lower the failure rate of the trench. More costly than pond systems in terms of cost per unit of runoff treated, infiltration trenches are suited best for drainage areas of less than 5 to 10 acres or where ponds cannot be applied (Schueler et al., 1992).

e. Vegetated Filter Strips

Vegetated filter strips are areas of land with vegetative cover that are designed to accept runoff as overland sheet flow from upstream development. They may closely resemble many natural ecotones, such as grassy meadows or riparian forests. Dense vegetative cover facilitates sediment attenuation and pollutant removal. Vegetated filter strips do not effectively treat high-velocity flows and are therefore generally recommended for use in agriculture and low-density development and other situations where runoff does not tend to be concentrated. Unlike grassed swales, vegetated filter strips are effective only for overland sheet flow and provide little treatment for concentrated flows. Grading and level spreaders can be used to create a uniformly sloping area that distributes the runoff evenly across the filter strip (Dillaha et al., 1987). Vegetated filter strips are often used as pretreatment for other structural practices, such as infiltration basins and infiltration trenches. Refer to Chapter 7 of this guidance for additional information.

Filter strips are less effective on slopes of over 15 percent. Periodic inspection, repair, and regrading are required to prevent channelization (Schueler et al., 1992). Inspection is especially important following major storm events. Excessive use of pesticides, fertilizers, and other chemicals should be avoided. To minimize soil compaction, vehicular traffic and excessive pedestrian traffic should be avoided.

A berm of sediment that must be periodically removed may form at the upper edge of grassed filter strips. Mowing of grassed filter strips at a minimum of two to three times per year will maintain a thicker vegetative cover, providing better sediment retention. To avoid impacts on ground-nesting birds, mowing should be limited to spring or fall (USEPA, undated). Harvesting of mowed vegetation will allow for thicker growth and promotes the retention of nutrients that are released during decomposition (Dillaha et al., 1989).

Forested areas directly adjacent to waterbodies should be left undisturbed except for the removal of trees presenting unusual hazards and the removal of small debris near the stream that may be

chambered urban runoff inlets in which the bottom has been lowered to provide 2 to 4 feet of additional space between the outlet pipe and the structure bottom for collection of sediment. Some water quality inlets include a second chamber with a sand filter to provide additional removal of finer suspended solids by filtration. The first chamber provides effective removal of coarse particles and helps prevent premature clogging of the filter media. Other water quality inlets include an oil/grit separator. Typical oil/grit separators consist of three chambers. The first chamber removes coarse material and debris; the second chamber provides separation of oil, grease, and gasoline; and the third chamber provides safety relief should blockage occur (NVPDC, 1980). While water quality inlets have the potential to perform effectively, they are not recommended. Maintenance and disposal of trapped residuals and hydrocarbons must occur regularly for these devices to work. No acceptable clean-out and disposal techniques currently exist (Schueler et al., 1992).

j. Extended Detention Ponds

Extended detention (ED) ponds temporarily detain a portion of urban runoff for up to 24 hours after a storm, using a fixed orifice to regulate outflow at a specified rate, allowing solids and associated pollutants the required time to settle out. The ED ponds are normally "dry" between storm events and do not have any permanent standing water. These basins are typically composed of two stages: an upper stage, which remains dry except for larger storms, and a lower stage, which is designed for typical storms. Enhanced ponds are equipped with plunge pools near the inlet, a micropool at the outlet, and an adjustable reverse-sloped pipe as the ED control device (orifice) (NVPDC, 1980; Schueler et al., 1992). Temporary and most permanent ED ponds use a riser with an antivortex trash rack on top to control trash.

k. Wet Ponds

Wet ponds are basins designed to maintain a permanent pool of water and temporarily store urban runoff until it is released at a controlled rate. Enhanced designs include a forebay to trap incoming sediment where it can easily be removed. A fringe wetland can also be established around the perimeter of the pond.

l. Constructed Wetlands

Constructed wetlands are engineered systems designed to simulate the water quality improvement functions of natural wetlands to treat and contain surface water runoff pollutants and decrease loadings to surface waters. Where site-specific conditions allow, constructed wetlands or sediment retention basins should be located to have a minimal impact on the surrounding areas. (The State of Washington requires that constructed wetlands be located in uplands (Washington Department of Ecology, 1992).) In addition, constructed urban runoff wetlands differ from artificial wetlands created to comply with mitigation requirements in that they do not replicate all of the ecological functions of natural wetlands. Enhanced designs may include a forebay, complex microtopography, and pondscaping with multiple species of wetland trees, shrubs, and plants. Additional information on constructed wetlands is provided in Chapter 7.

m. Filtration Basins and Sand Filters

Filtration basins are impoundments lined with filter media, such as sand or gravel. Urban runoff

refloated by high water. Periodic harvesting of some trees not directly adjacent to waterbodies removes sequestered nutrients (Lowrance, Leonard, and Sheridan, 1985) and maintains an efficient filter through vigorous vegetation (USEPA, undated). Exposure of forested filter strip soil to direct radiation should be avoided to keep the temperature of water entering waterbodies low, and moist conditions conducive to microbial activities in filter strip soil should be maintained (Nutter and Gaskin, 1989).

f. Grassed Swales

A grassed swale is an infiltration/filtration method that is usually used to provide pretreatment before runoff is discharged to treatment systems. Grassed swales are typically shallow, vegetated, man-made ditches designed so that the bottom elevation is above the water table to allow runoff to infiltrate into ground water. The vegetation or turf prevents erosion, filters sediment, and provides some nutrient uptake (USDA-SCS, 1988). Grassed swales can also serve as conveyance systems for urban runoff and provide similar benefits.

The swale should be mowed at least twice each year to stimulate vegetative growth, control weeds, and maintain the capacity of the system. It should never be mowed shorter than 3 to 4 inches. The established width should be maintained to ensure the continued effectiveness and capacity of the system (Bassler, undated).

g. Porous Pavement and Permeable Surfaces

Porous pavement, an alternative to conventional pavement, reduces much of the need for urban runoff drainage conveyance and treatment off-site. Instead, runoff is diverted through a porous asphalt layer into an underground stone reservoir. The stored runoff gradually exfiltrates out of the stone reservoir into the subsoil. Many States no longer promote the use of porous pavement because it tends to clog with fine sediments (Washington Department of Ecology, 1991). A vacuum-type street sweeper should be used to maintain porous pavement.

Permeable paving surfaces such as modular pavers, grassed parking areas, and permeable pavements may also be employed to reduce runoff volumes and trap vehicle-generated pollutants (Pitt, 1990; Smith, 1981); however, care should be taken when selecting such alternatives. The potential for ground-water contamination, compaction, or clogging due to sedimentation should be evaluated during the selection process. (NOTE: These practices should be selected only in cases where proper operation and maintenance can be guaranteed due to high failure rates without proper upkeep.)

h. Concrete Grid Pavement

Concrete grid pavement consists of concrete blocks with regularly interdispersed void areas that are filled with pervious materials, such as gravel, sand, or grass. The blocks are typically placed on a sand or gravel base and designed to provide a load-bearing surface that is adequate to support vehicles, while allowing infiltration of surface water into the underlying soil.

i. Water Quality Inlets

Water quality inlets are underground retention systems designed to remove settleable solids. Several designs of water quality inlets exist. In their simplest form, catch basins are single-

"Quite frankly, I think we're somewhat disappointed that they're using scare tactics to alarm consumers in California," Lombardi said.

She said the state's regulations are based on human health, whereas the hazardous waste standards apply to things such as landfills, she said.

Less than one-tenth of 1 percent of fertilizer made in the United States uses recycled hazardous waste, Lombardi said. Those products have to meet federal standards.

Fertilizer sold in California is safe, she said. "Absolutely."

SPECIAL REPORT • Cities upset about proposed rules for cutting storm runoff from new developments are raising . . .

A Torrent of Opposition

By MARLA CONE
TIMES ENVIRONMENTAL WRITER

Cities throughout Los Angeles County—which suffers the worst urban runoff problem in the nation—are waging an intense battle against a proposed mandate that would help prevent toxic pollutants, bacteria and viruses from contaminating ocean waters.

The standard proposed by the region's water quality board would force Los Angeles County cities to fundamentally change how large new projects—from shopping centers to housing subdivisions—are built. If enacted, it would be the U.S.' most far-reaching restrictions on polluted storm water.

Cities would have to ensure that new developments capture either 85% of the runoff from a storm in a 24-hour period or the first three-fourths of an inch of rain. The standard would apply to new commercial projects of more than 100,000 square feet and all new gas stations, auto repair garages, restaurants and subdivisions of 10 or more houses.

Officials of about 50 cities, including Los Angeles and other beach communities, have joined with developers to fight the proposal through letters and in speeches at a packed public hearing held last month by the Los Angeles Regional Water Quality Control Board.

Because the costs of complying with the proposal are unknown, the city leaders are unconvinced that the benefits would be worth the expense, and they are asking for a thorough economic study. They also want any standards to be voluntary.

"Obviously a beach city wants to have its beaches pristine, but it's a matter of cost," said Neil Miller, Manhattan Beach's public works director.

Of the county's 85 cities, only Santa Monica—already a leader in cleaning up its polluted beach waters—has supported the runoff limits.

"The amount spent . . . is most likely a small percentage of total construction costs. The benefits, however, are regionwide," wrote Craig Perkins, the city's director of environmental and public works programs, in a letter to the water agency.

The agency's executive officer, Dennis Dickerson, does not need the support of his governing board or the cities to set the runoff limits. But he has wavered in the face of the opposition, and this month he postponed any action until at least January.

Dickerson said he wants to first try to educate city leaders and persuade them to change their minds or, if necessary, agree to a compromise. He declined to say, though, whether he is willing to turn the limits into voluntary

Ballona Creek debris illustrates runoff problem.

A Citizen's Guide to Cleaning Up

- Use a broom, not a hose, to clean sidewalks and driveways.
- Buy nontoxic products for your garden and home.
- Follow directions on pesticides, fertilizers and weed-killers to make sure you apply them sparingly. Do not use when rain is forecast.
- Do not over-water your lawn or garden. Any water flowing onto pavement becomes runoff.
- Make sure your car isn't leaking oil or antifreeze. Use a drip pan when changing car fluids and use kitty litter or sawdust to soak up spills.
- Do not pour, spill or throw anything into gutters.
- Pick up dog waste from pavement and lawns and throw it in the trash.
- Use biodegradable detergents to wash cars and use as little water as possible. Shut off hose while washing and then rinse.
- Compost leaves and yard trimmings or throw them in the trash. Do not sweep them into streets.
- Divert rain spouts onto grass or plants or install dry wells or cisterns.
- Remove pavement and plant vegetation around your house. Or use gravel, brick, cobblestones, paving stones on sand or other permeable surfaces.
- Rinse paint brushes in sink, not outdoors.
- Put tarps over loose soil or construction materials to keep out rain or water.
- Take unwanted paints, solvents, batteries, pesticides and other toxic materials to a local household hazardous waste roundup.

Standard Urban Storm Water Mitigation Plans (SUSMPs)

Presentation to
the Regional Board
January 26, 2000

Xavier Swamikannu
California Regional Water Quality Control Board,
Los Angeles Region

Numerical Storm Water Mitigation Standard

Four different and equivalent methods to determine BMP sizing criteria

- Maximized volume capture (WEF Method)
- Percent volume treatment (CA Handbook)
- All events up to 0.75 inch 24-hr precipitation
- Historical record 85th percentile rainfall event

No Flow Sensitive Standard At This Time

WEF Design Standard

The Design Storm

$$P_o = a.C.P_A$$

P_o - Maximized water quality "treatment" volume

a - "Treatment" volume coefficient

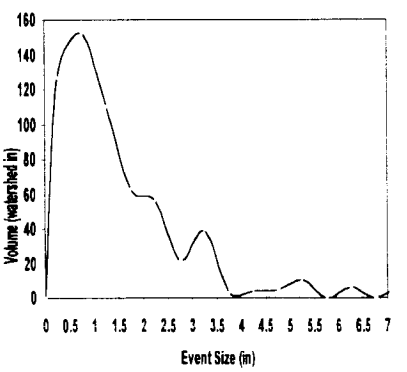
C - Area runoff coefficient

P_A - Mean storm precipitation volume

Range in coastal CA for 85% annual runoff "treatment"

» 0.12 inch - 0.86 inch

Principle



- Largest volumes of runoff are produced by smaller storms
- Criteria promotes BMP application to smaller more frequent storms

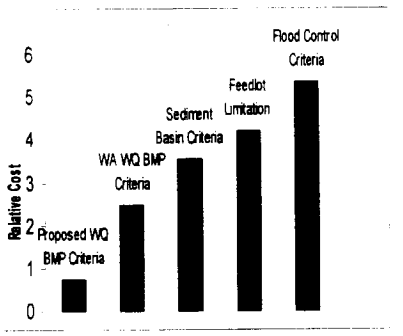
Translation

- Criterion is averaged for local communities
- Further increase in value results in fewer and fewer rainfall events being captured. ("point of diminishing returns")
- Eight-five percent of rainfall events are equal to or less than the criterion
- "First flush" pollutant concentration peaks will be treated
- Approximately eight-five percent of long term pollutant load can be reduced.

Bases

- Technically defensible
- Based on local data and nationally accepted methods
- Criteria in use by other communities range from 0.5 to 2 inches (TX, FL, WA, MD, CO)
- Similar criteria in use by Santa Monica, Calabasas, Ventura County, and unincorporated LA County

Relative Cost Comparison



- Relative cost much less than similar storm water criteria.
- Comparable criteria for wet regions, e.g., Pacific Northwest is higher.

BMP Cost

- Five Acre Commercial Development
  - » Project Cost is $6.5 million
  - » Detention Basin BMP (Example 1)
    - Excavation and Haul away = $12,870
    - Land Cost = $28,800
    - Maintenance (1 / year cleanout) = $33
    - Total Cost = About $42,000
  - » Mitigation Percent Cost = 0.6 %

BMP Cost

- » Infiltration Trench and Vegetated Swale BMPs (Example 2)
  - Trench with Gravel = $13,500
  - Land Cost = Minimal
  - Maintenance (5 yr replacement) = $1350 per yr
  - Swale = $4050
  - Land Cost / Maintenance = Within Landscaping
  - Combined Cost = About $19,000
- » Mitigation Percent Cost = 0.3 %

Generalizations

- Numerical standard provides flexibility in choice of BMPs
- Mitigation cost not likely to exceed environmental mitigation reasonable cost threshold (about 5 percent)
- BMP choice must be made on BMP effectiveness
- BMP choice may consider ease of maintenance

Presenters

STANDARD URBAN STORM WATER MITIGATION PLANS

NUMERICAL MITIGATION CRITERIA FOR DEVELOPMENT PLANNING

BMP COST ESTIMATES

Cost estimates for BMPs for a commercial development project using the numerical mitigation measure under consideration by the Regional Water Quality Control Board were performed with assistance of the City of Los Angeles staff. The cost estimates indicate that the capital and maintenance costs associated with treatment BMPs sized to meet the numerical mitigation measure are reasonable and amount to less than 0.5 percent of the project cost. The total cost of the project was estimated to be $ 6.5 million and includes the land acquisition, engineering and design, any clean-ups, construction, permits, etc.

CASE EXAMPLE 1: DETENTION BASIN

DETENTION BASIN (Unlined)

i. Excavation and haulaway - $22 / yd^3 [1]

⇨ Warehouse project: 15815 ft^3 = 585 yd^3 = $12,870

ii. Land cost - $18 / sq.ft. [2]

⇨ Warehouse project: 40'x40' = 1600 sq.ft. = $28,800

iii. Maintenance cost: 1 cleanout per year

Event Mean Concentration for Commercial Area – 91 mg/L TSS [3]

=> Total rainfall volume captured in the basin = 70% of 15 in. per year
= (10.5 in/12) x 240,000
= 210,000 ft^3 = 5,943,000L

⇨ TSS collected = 80% (91 mg/L x 5,943,000 L) = 432.6 kg / yr.

If sediment density is 1.5 tons/ yd^3, total TSS to be removed = 0.29 yd^3

Clean-out cost: 1 cu.yd / 3 years = $99 / 3 yrs. = $33/year.

➔ Total capital cost - $28,800
➔ Annual maintenance - $ 33

CASE EXAMPLE 2: INFILTRATION TRENCH & VEGETATED SWALE

a. INFILTRATION TRENCH – For roof runoff

i. Infiltration trench with gravel ≈ \$27.77 per ft^3 [4]

⇨ Warehouse project: 3' W x 6' D x 27'L = \$13,500

ii. Land cost: Negligible

iii. Maintenance cost: Replacement of gravel every 5 years.
≈ ½ of initial set up = \$6750 every 5 years

⇨ Annual maintenance cost = \$1,350

b. VEGETATED SWALE – For parking lot runoff

9 ft wide swale = \$6 per linear foot [5]

⇨ Warehouse project: 3 (9' W x 225' L) = 3 x (\$6 x 225) = \$4050

Land cost: No extra land required – Swale to be incorporated in landscaping plan.

Maintenance cost: Routine landscape upkeep will do - No additional mowing and cleaning.

➔ Total capital cost - \$17,550
➔ Annual maintenance cost - \$1,350

CASE EXAMPLE 3:

CATCHBASIN INSERTS – For the entire project

To treat the "maximized" storage volume calculated for detention basin in 24 hours, outflow = 15,815 ft^3 / 24 hours = 82 gpm

Aquashield Model 300, capacity 855 gpm = \$1335 [6]
Fossil Filter, 2' x 2' Rectangular, capacity 76 gpm = \$1,000 [6]

⇨ Warehouse project ≈ \$1200

ii. Land cost: Negligible

iii. Storm drain connection cost ≈ \$300

iv. Maintenance and disposal cost: 3 cleanings and 3 replacement

= $495 / yr. [7]

➔ Total capital cost - $1,500
➔ Annual maintenance cost - $495

Reference for Costs

1. Earthwork estimate – Bureau of Engineering, City of Los Angeles

2. Real Estate Estimator – Department of General Services, City of Los Angeles. Estimate varies from $15 to $25 in S. Central Los Angeles.

3. Watershed Model, US Environmental Protection Agency. 1983

4. Infiltration trench in Department of Transportation Parking Lot. Venice, Los Angeles
   Cost for 5'W x 3'D x 12'L trench = $5,000

5. Bird Rehab Center in San Pedro.y Trees People for City of Los Angeles
   Cost for 6 ft wide swale = $4 per linear foot.

6. BMP Demonstration projects by City of Los Angeles

7. Rick Campos – DPS Kristar Enterprise, Cotati, CA
   Schedule A: Maintenance and disposal cost for 3 cleanings and one replacement = $200 per year.
   Schedule B: 3 cleanings and 2 replacement = $275
   ≈ $45/cleaning and $75/replacement

STANDARD URBAN STORM WATER MITIGATION PLANS

NUMERICAL MITIGATION CRITERIA FOR DEVELOPMENT PLANNING

SAMPLE CALCULATIONS

Sample calculations for a commercial development project using the numerical mitigation measure under consideration by the Regional Water Quality Control Board were performed with the assistance of City of Los Angeles staff. The case examples illustrate that, (i) the three different numerical mitigation criteria for calculating Best Management Practice (BMP) sizing dimensions produce values that are within 10 percent of one another; (ii) the sizing criteria for treatment BMPs (vegetated swales and infiltration trench) based on filtration and adsorption (not storage) are reasonable and practicable using the numerical mitigation criteria being considered by the Regional Board; and (iii) commercially available catch-basin inserts are adequately manufactured to handle and treat flow equivalent to the storage volume that is needed for a detention basin BMP.

REQUIREMENT: 85th percentile rainfall runoff capture

PROJECT: Light industrial warehouse/office with parking lot in South Central L.A.

PROJECT SIZE: 240,000 ft^2 = 5.51 acres

CASE EXAMPLE 1: DETENTION BASIN: Sample calculation demonstrates the water quality treatment volume required to size a detention basin using (a) the maximized water quality treatment volume method and (b) the 85th percentile rainfall event treatment volume for Los Angeles County and (c) the 85 percent annual runoff volume capture method.

(a) WEF Manual of Practice #23 – Chapter 5

Maximized detention volume, $P_o = a\ C\ P_6$ [WEF, Pg. 175]

For 85th percentile event capture for 24 hours

Regression constant, a = 1.299 [WEF, Table 5.4, Pg. 177]
Mean storm depth, P_6 = 0.67 in. [WEF, Figure 5.3, Pg. 176]

(Note: Local precipitation record can be used to calculate more accurate P_6 for the site)

C = 0.9086 [LAMC, Code 3300]

=> P_o = 1.299 x 0.9086 x 0.67 = 0.7908 inch

Required storage volume = P_o x Area of the site
= (0.7908 in / 12) x 240,000 ft^2
= 15,815 ft^3 = 118,296 gal.

➔ Basin size ≈ 40'W x 40'L x 10' D

(b) Using treatment volume from all events up to and including 0.75" rainfall

P_o = 0.75 in.

⇨ Required storage volume = (0.75 in / 12) x 240,000 ft^2
= 15,000 ft^3 = 112,200 gal.

➔ Basin size = 40'W x 40'L x 9.5'D

(c) California Stormwater BMP Handbook

For 85 percent annual runoff volume capture for 40 hours [Industrial Handbook, Pg. D1]

⇨ Unit basin storage volume = 0.06 ac-ft/ac [Industrial Handbook, Pg. D7]

⇨ Required storage volume = Unit basin storage x Area of site
= 0.06 ac-ft/ac x 5.51 ac
= 0.3306 ac-ft
= 14,401 ft^3 = 107,719 gal.

➔Basin size = 40'W x 40'L x 9'

CASE EXAMPLE 2: VEGETATED SWALE AND INFILTRATION TRENCH: These calculations demonstrate sizing of alternative BMPs to achieve storm water treatment without storage capture as would be required with the detention basin BMP illustrated in case example 1. The method used is the maximized water quality treatment approach.

(i) VEGETATED SWALE – For Parking Lot Runoff
[Using WEF Manual of Practice #23]

Area of the parking lot, A_p = 110,000 ft^2 = 2.525 ac.

Mean storm, P_6 = 0.67 in. [WEF, Fig. 5.3, Pg. 176]

Runoff coefficient, C = 1 [WEF, Pg. 191]

Drain time = 12 hours [WEF, Pg. 191]

Regression constant, a = 1.109 [WEF, Table 5.4, Pg. 177]

=> P_o = a C P_6 = 1.109 x 1 x 0.67 = 0.74 inch

If P_o is for 2 hour storm, i = P_o / 2 [WEF, Pg. 192]

=> i = 0.74 / 2 = 0.37 in./hr.

Frequency of this storm event is 3 months [BOE, Fig. G212A]

Average slope of the flow line = 1 %

=> Velocity, V = 0.7 ft/sec for grass [Gupta, Fig. 12.7, Pg. 625]

Travel distance for runoff, L = 500 ft + 480 ft = 980 ft. [Project site plan]

Time of concentration for runoff, t_c = L / V [Gupta, Pg. 623]
=> t_c = 980 / 0.7 = 1400 sec = 23.3 minutes

For this t_c and 3-month frequent storm
=> Rainfall intensity, i = 0.95 in/hr [BOE, Fig. G212A]

Runoff discharge rate for this rainfall,
$Q = C\, i\, A_p$; Where, C = runoff coeff.= 0.9086 [LAMC, Code 3800]

⇨ $Q = 0.9086 \times 0.95 \times 2.52 = 2.18$ cfs

Discharge this runoff over three (3) identical swale with the following assumed characteristics: [WEF, Pg. 192]

Type: Trapezoidal
Center depth, D = 6" = 0.5 ft
Vegetation: Grass
Grass height = 4"
Longitudinal slope, S = 4%
Side slope ratio, Z = 6
Bottom width, B = 3 ft
Manning's n = 0.22
Runoff discharge, Q = 2.18 / 3 = 0.73 cfs

=> Flow depth in swale, Y = Grass ht. – 2" = 4" – 2" = 2" = 0.167 ft

Because B >> Y, hydraulic radius, R = Y [WEF, Pg. 194]

Using Manning's equation for flow velocity, $V = (1.486 / n) \times R^{2/3} \times S^{1/2}$

$V = (1.486 / 0.22) \times 0.167^{2/3} \times 0.04^{1/2}$
$= 0.41$ ft/sec < 0.9 sec <u>OK</u> [WEF, Pg. 192]

=> Runoff flow area = Q / V = 0.73 / 0.41 = 1.78 ft^2

Cross section area of swale $= BD + ZD^2$
$= (3 \times 0.5) + (6 \times 0.5^2)$
$= 3.0$ > Runoff flow area <u>OK</u>

For a 225 ft. long swale,

=> Hydraulic retention in swale, t_d = Length / Velocity

=> t_d = 225 / 0.41 = 550 sec
= 9.1 min > Minimum of 9 min. suggested for Pacific Northwest *(Note: local data can be used if available)*

=> Top width of swale, T = B + 2DZ = 3 + 2 (0.5 x 6) = 9 ft.

➔ Three swales (225' L x 9' W x 6" D) required.

(ii) For Rooftop Runoff – INFILTRATION TRENCH
[Using WEF Manual of Practice #23]

Size of the building roof, A_r = 130,000 ft^2 = 2.98 acres [LAMC, Code 3300]
Runoff coefficient, C = 0.9086

[WEF, Pg. 206]

Requisite site conditions:

- High groundwater must be > 4 ft. below bottom of infiltration trenches
- Bedrock must be > 4 ft. below bottom of the trenches
- No fill or recompacted soil in and around the trenches
- Soil around the trenches must be of HSG Group A or B

Assumptions:

- Sandy soil on site
- Hydraulic conductivity, k = $3.3x10^{-3}$ ft/sec [WEF, Table 5.11, Pg. 205]
- Trench is filled with mix of uniform and graded gravel [WEF, Table 5.12, Pg. 206]
- Porosity of trench fill, p = 35% [WEF, Pg. 206]
- Width of trench, W = 3 ft

"Maximized" storm volume calculated in Vegetative Swale section, [WEF, Pg. 209]
P_o = 0.74 in.

⇨ Volume to runoff to drain into infiltration trench,
$V_r = P_o A$ = (0.74 / 12) x 130,000 = 8017 ft3

=> Volume of the required trench with gravel
$V_T = V_r / p$ = 8017 / 0.35 = 22,905 ft^3

Total area of the sides of the trenches, $A_T = 2 V_T / k t$ [WEF, Eq. 5.7, Pg. 209]

If all captured runoff (V_r) is to drain out of trench in one day, [WEF, Pg. 207]
t = 24 hours = 86,400 sec

=> A_T = 2 x 22,905 / ($3.3x10^{-3}$ x 86,400) = 160.6 ft^2

➔ Required trench will be 3'W x 6'D x 27' L.

CASE EXAMPLE 3: CATCHBASIN INSERTS: This calculation demonstrates that commercially available catch-basin inserts are adequately designed for flow treatment equivalent to the storage volume required in case example 1, based on manufacturers product performance claims.

To treat the "maximized" treatment volume calculated for detention basin (case example 1) in 24 hours,

⇨ Outflow rate = 15,815 ft^3 / 24 hours = 82 gpm

Commercially available inserts:

➔ a. Aquashield Model 300, capacity 855 gpm [Aquashield]

➔ b. Fossil Filter, 2' x 2' Rectangular, capacity 76 gpm [Fossil Filter]

Each of these will require a catch basin to collect runoff and drainage pipings for outflow from the inserts.

Subject: Sacto B: Simplifying Marine Protection Efforts

Sacramento Bee
Thursday, January 20, 2000
By Nancy Vogel, Bee Staff Writer

State says the coast isn't clear: Plan would simplify marine protection

The confusing clutter of protected areas off California's coast would be streamlined under a plan issued Wednesday by the California Resources Agency.

For decades, the 18 different kinds of state restricted zones off the 1,100-mile-long coast have proved a bureaucratic and enforcement nightmare. Even the agencies in charge of managing the zones had trouble discerning what marine life could be harvested legally and what could not.

"We have ecological reserves, state reserves, things that are just called reserves, UC reserves," said Brian Baird, ocean programs manager for the Resources Agency. "Different objectives, different funding sources, different managers."

"The only way to figure it out is to open a big book and go through these things," he said.

For example, despite its name, commercial fishing is allowed within the Monterey Bay National Marine Sanctuary, although in the little Hopkins Marine Life Refuge within that sanctuary no fish may be taken -- except by scientists with permits. And in the nearby Pacific Grove Marine Gardens Fish Refuge, fish may be taken but not mollusks or crustaceans.

Only in roughly 14 of the state's 3,300 square miles of ocean water is there a total prohibition on the harvest of marine life. Environmentalists argue that a smattering of such true sanctuaries may be necessary to restore depleted marine species such as long-lived, slow-growing rockfish.

The new Resources Agency plan proposes to shrink the current 18 different designations of marine protection zones so that they fit under six classifications: marine parks, reserves, conservation areas, cultural preservations areas, recreational management areas and water quality protection areas.

"We're looking at the purpose and design," Baird said. "There's never been a clear purpose for what the system's supposed to do."

Carrying out the plan, Baird said, will require a mix of legislative and administrative action.

The report comes a week after President Clinton used the federal Antiquities Act to designate all rocks, islands, exposed reefs and pinnacles under U.S. Bureau of Land Management ownership as a new California Coastal National Monument.

Among other things, Baird said, the Resources Agency report should help the California Department of Fish and Game carry out a law passed last year, the Marine Life Protection Act by Assemblyman Kevin Shelley, D-San Francisco. That law directs Fish and Game to work with fishermen, divers, kelp harvesters and others to come up with a master plan for determining whether important habitats along the California coast are adequately protected.

"The current system of classifying California's protected waters is broken; it's a hodgepodge of incoherent jargon," said Warner Chabot, Pacific region director of the Center for Marine Conservation. "This report is

a needed first step to put it back together."

OPENING STATEMENT – Contested Items

THIS IS A PUBLIC MEETING TO CONSIDER BOARD ACTION REGARDING STANDARD URBAN STORMWATER MITIGATION PLANS (SUSMPS) WHICH HAVE BEEN SUBMITTED TO THE EXECUTIVE OFFICER PURSUANT TO REQUIREMENTS OF THE LA COUNTY MUNICIPAL STORMWATER PERMIT, ORDER NO. 96-054.

DURING THIS PUBLIC HEARING, STAFF WILL PROVIDE A REPORT TO THE BOARD DETAILING THE EXECUTIVE OFFICER'S INTENTION TO APPROVE THE SUSMPS WITH CHANGES, AND ASK THE BOARD TO ADOPT A RESOLUTION EXPRESSING THE REGIONAL BOARD'S EXPECTATIONS REGARDING SUSMP APPROVAL.

COPIES OF THE STANDARD URBAN STORMWATER MITIGATION PLAN WERE SENT TO THE U.S. EPA, STATE WATER RESOURCES CONTROL BOARD, AND OTHER INTERESTED AGENCIES, PERSONS AND ORGANIZATIONS.

THE ORDER OF PRESENTATION OF TESTIMONY AT THIS MEETING WILL BE ANNOUNCED BY THE CHAIRMAN. ANYONE SO DESIRING WILL BE HEARD; IF YOU HAVEN'T FILLED OUT ONE OF THE BLUE CARDS LOCATED ON THE TABLE AT THE BACK OF THE ROOM, PLEASE RAISE YOUR HAND AND WE'LL GET A CARD TO YOU TO FILL OUT.

IT WILL BE APPRECIATED IF ALL PERSONS APPEARING BEFORE THE BOARD TODAY WILL LEAVE WRITTEN COPIES OF THEIR TESTIMONY, IF AVAILABLE. THE BOARD WILL CONSIDER ALL TESTIMONY; HOWEVER, IN THE INTEREST OF TIME, IT IS REQUESTED THAT ALL REPETITIVE AND REDUNDANT STATEMENTS BE AVOIDED. THE SETTING OF TIME LIMITS FOR THE PRESENTATION OF EVIDENCE IS AT THE DESCRETION OF THE BOARD.

MR. CHAIRMAN, WILL YOU NOW OPEN THE MEETING AND ADMINISTER THE OATH?

Winston H. Hickox
Secretary for Environmental Protection

California Regional Water Quality Control Board

Los Angeles Region

Governor

TO: **Interested Parties**

FROM: **Dennis A. Dickerson**
Executive Officer

DATE: **January 21, 2000**

SUBJECT: **Procedure for Public Comment on January 26, 2000**

On January 26, 2000, the Los Angeles Regional Water Quality Control Board will consider the matter of Standard Urban Storm Water Mitigation Plans. This matter has been preceded by many opportunities for discussion including a formal workshop on August 10, 1999, a Board hearing on September 16, 1999, and many informal discussions with staff. An extensive written record has been received and provided to the Regional Board members.

The Standard Urban Storm Water Mitigation Plan item will be the principal item on the agenda and most of the Board meeting will be dedicated to hearing this matter. Approximately 3 hours will be dedicated to public comment. It is expected that many individuals will attend the meeting on January 26th. To accommodate as many speakers as possible in the limited time available, and to provide for as fair a distribution of the available time, the following protocol has been developed to guide the Regional Board in hearing public comment.

Speaker cards for the Standard Urban Storm Water Mitigation Plan item will be collected prior to the commencement of this item. Speakers should indicate on their card what position they are taking, i.e., in favor of the staff proposal or opposed.

All speakers will be limited to 3 minutes each.

A segment of time for speakers will be set aside immediately following the staff presentation for a statement in favor of or in opposition to the Staff's proposal before the Board. 30 minutes will be available for 10 speakers in favor and 30 minutes and 10 speakers in opposition. Questions from the Board will be held until the conclusion of each 30 minute segment. The Board will accept, at the beginning of the meeting, a list of 10 speakers from those in favor and a list 10 speakers from those in opposition who will use this time.

All other speakers will follow and will be alternated as to their position on the proposal to ensure that equal time is provided to each position.

Speakers will not be allowed to reserve their time for another speaker.

The Board Chair may, at his discretion, and if time permits, allow speakers who have already commented to add to their comments if any issues have arisen during the meeting that they wish to augment their statements to include.

NOTICE OF JANUARY 26, 2000 BOARD MEETING LOCATION CHANGE

(Govt. Code Section 11125)

NOTICE IS HEREBY GIVEN that the January 26, 2000 Regular Board Meeting location has changed (effective 1/21/00) in order to accommodate more members of the public. The original location was at the Richard H. Chambers U.S. Court of Appeals Building, 125 S. Grand Avenue, Pasadena.

The new Board Meeting location is as follows:

Holiday Inn Pasadena Hotel
303 E. Cordova
Main Ballroom
Pasadena, CA

R0068743

TENTATIVE

State of California
CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD, LOS ANGELES REGION

Resolution No. xx-xx

APPROVING THE RECORD FOR
STANDARD URBAN STORM WATER MITIGATION PLAN
FOR
MUNICIPAL STORM WATER AND URBAN RUNOFF MANAGEMENT PROGRAMS
IN LOS ANGELES COUNTY

WHEREAS, THE CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD, LOS ANGELES REGION FINDS:

1. On July 15, 1996, a municipal storm water permit was issued to the County of Los Angeles and 85 incorporated cities to control and minimize the discharge of pollutants associated with storm water and urban runoff. This permit became Regional Board Order No. 96-054, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles.

2. On June 30, 1999, a municipal storm water permit was issued to the City of Long Beach which removed the City of Long Beach from Board Order No. 96-054, giving the City of Long Beach its own distinct Municipal Storm Water and Urban Runoff NPDES permit, Regional Board Order No. 99-060, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the City of Long Beach.

3. On August 19, 1999, a statewide general storm water permit for construction activity was adopted by the State Water Resources Control Board (State Board). This permit became State Board Order No. 99-08-DWQ, and applies to construction projects that disturbs five acres or more or is part of a larger common plan of sale in the Los Angeles region.

4. Many of the rivers and streams in Los Angeles County are formally designated as impaired, pursuant to Section 303 (d) of the federal Water Pollution Control Act, for specific pollutants that are commonly found in storm water and urban runoff.

5. Storm water runoff carries with it many pollutants in varying concentrations that are suspended in, and or dissolved, in the runoff. The sources of these pollutants include nearly all properties that have been developed since the pollutants originate through the many diverse activities of habitation and land use. Pollutants generated from individual property developments vary greatly in the concentration or loading of each pollutant. Generally, the relative contribution of the pollutant from runoff from any individual property development will represent only a small portion of the entire loading of a water body given the many square miles of land upon which storm water runoff is generated. When the individual contributions from tens of thousands of discrete property units are aggregated, the pollutant loading becomes significant. The resultant pollutant loads results in the impairment of that water body and the conveyance of pollutants, including sediments, metals, complex organic compounds, oil and grease, nutrients, and pesticides to the ocean and harbors within Los Angeles County. The loading of pollutants generated in the Los Angeles area are being measured through the monitoring program being conducted by the Los Angeles County Department of Public Works in conformance with its obligations as the Principal Permittee under the Los Angeles County Municipal Storm Water and Urban Runoff NPDES permit.

6. The nature of property use is related to the types and quantities of pollutants that are transported from that property during a rainfall event.

7. As property is developed or redeveloped, the utilization of Best Management Practices provide an opportunity to reduce the loading of pollutants to water bodies. This is accomplished by various techniques and can be passive (source reduction) or active (treatment). As property is developed from undisturbed lands, the project can be designed to incorporate structural BMPs that would normally not be available or practical to use on property that has been in urban use.

8. BMPs are effective means of reducing pollutants and treatment control BMPs can be "designed-into" a project in a cost effective way and in a manner that is either transparent to or which enhances the use to which the property has been placed. Some BMPs encourage the setting aside of areas as a greenbelt to allow storm water runoff to flow over areas which are permeable, thereby allowing all or a portion of the runoff to infiltrate. Other BMPs can be designed and built into structures such as catch basins that incorporate replaceable filters to absorb oily wastes or by installing screens to prevent litter from passing through the system and into the water body.

9. Arrays of treatment control BMPs are available to developers of both new and redevelopment properties. The use of BMPs is already required by the terms of the Los Angeles County and Long Beach Municipal Storm Water and Urban Runoff NPDES permits.

10. The ability of any BMP to be effective is limited by the volume of water that the BMP is exposed to in any discrete period of time. A BMP that can only be effective for a small volume of storm water runoff is inherently less effective than one sized to accommodate a larger volume of water.

11. Storm water runoff will normally convey a disproportionate loading of pollutants in the initial period runoff is generated during a storm event. Storm events generating up to 0.75 inches of precipitation, measured over a 24-hour period, constitute 85 percent of the total amount of runoff that can be expected during an average wet season. Designing a BMP to be able to accommodate this amount of runoff will result in the application of a BMP intervention to all but 15% of the total runoff during a year, and usually all of the critical runoff that occurs in the early phase of the precipitation event, commonly referred to as the "first Flush."

12. Both the Los Angeles County (Part III.A.1.c) and the Long Beach Municipal Storm Water and Urban Runoff permits contain provisions related to the adoption of Standard Urban Storm Water Mitigation Plans (SUSMPs) requiring their development and implementation.

13. Standard Urban Storm Water Mitigation Plans are required for a specified set of discretionary "Priority Projects" and the permit specifically identifies seven distinct categories for which SUSMPs are required to be prepared. The permit specifically states that the seven categories of "Priority Projects" are the minimum categories requiring SUSMPs.

14. Standard Urban Storm Water Mitigation Plans are also required for development or redevelopment of Parking Lots 5,000 square feet or greater and Locations in Environmentally Sensitive Areas. These categories have been added to advance efforts to control storm water pollution beyond the minimum in Los Angeles County.

15. Standard Urban Storm Water Mitigation Plans are required to be approved by the Regional Board Executive Officer following which they are to be implemented by the Permittees and used by the Permittees as the minimum criteria for the approval of project specific Urban Storm Water Mitigation Plans and the issuance of grading or building permits to project applicants.

16. The statewide general storm water permit for construction activity requires that Storm Water Pollution Prevention Plans (State SWPPPs) contain post-construction BMPs that will be implemented after construction is complete.

17. Section 402 (p) of the Clean Water Act requires the Administrator of the United States Environmental Protection Agency or her designated agent, in this instance, the Regional Board, to require as part of the storm water program "controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants." [USC Section 1342 (p)(3)(B)].

18. A recent decision of the United States 9th Circuit Court of Appeals, Defenders of Wildlife v. Browner (1999) Case No. 98-71080, provides additional support and clarification of the authority of the Administrator and the Regional Board to impose additional controls on storm water pollution. The Court in Defenders of Wildlife v. Browner said that the USEPA and the States have discretion under the law to determine what pollution controls are appropriate to achieve compliance.

19. Pursuant to the requirements of Regional Board Order No. 96-054, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles, the Regional Board Executive Officer received a proposal for Standard Urban Storm Water Mitigation Plans submitted by the Principal Permittee.

20. Upon the review of the Regional Board Executive Officer, the Standard Urban Storm Water Mitigation Plan submitted for the seven applicable categories was deemed inadequate. A revised SUSMP proposal was developed subsequent to a discussion of the proposal's conceptual foundation at a public workshop held on August 10, 1999. This workshop was well attended with over 80 municipal representatives and interested parties participating.

21. On August 16, 1999, a public notice was issued indicating that the Standard Urban Storm Water Mitigation Plans proposed by the Principal Permittee would be augmented by the addition of criteria related to specifying numerical design criteria for BMP construction. The matter was noticed for the Regional Board's September meeting to allow the issue to be discussed before the Board although no formal action of the Regional Board itself is required for SUSMP approval.

22. On September 16, 1999, the Regional Board conducted a public hearing on the Standard Urban Storm Water Mitigation Plan proposal as amended by the Executive Officer. At that hearing, the Regional Board Executive Officer suggested additional time would be necessary to develop a more comprehensive proposal incorporating the comments received at the public hearing.

23. Between September 16 and December 3, 1999, the Regional Board Executive Officer met with interested parties to discuss comments and concerns from interested parties.

24. The Southern California Council of Governments (SCAG) has indicated its interest in obtaining funding to prepare a regional plan(s) to address storm water pollution and identify regional treatment solutions for implementation.

25. On December 7, 1999, the Regional Board Executive Officer released a revised Standard Urban Storm Water Mitigation Plan document to interested parties.

THEREFORE BE IT RESOLVED THAT:

1. The Regional Board endorses the Standard Urban Storm Water Mitigation Plan prepared by the Regional Board Executive Officer and noticed to the public on December 7, 1999 and the concepts therein relating to numerical storm water mitigation standards for Best Management Practices; and

2. The Regional Board ~~encourages~~ directs the Regional Board Executive Officer to approve the Standard Urban Storm Water Mitigation Plan at the earliest opportunity incorporating any specific changes recommended and formally approved by the Regional Board at the January 6, 1999 Board Hearing;

STANDARD URBAN STORM WATER MITIGATION PLAN

FOR LOS ANGELES COUNTY AND CITIES IN LOS ANGELES COUNTY

LOS ANGELES COUNTY URBAN RUNOFF AND STORM WATER NPDES PERMIT

STANDARD URBAN STORM WATER MITIGATION PLAN

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, requires the development and implementation of a program addressing storm water pollution issues in development planning for private projects. The same requirements are applicable to the City of Long Beach under its separate municipal storm water permit, which was issued on June 30, 1999.

6 mths from date of adoption + 30 days

The requirement to implement a program for development planning is based on federal and state statutes including: Section 402 (p) of the Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 ("CZARA"), and the California Water Code. The Clean Water Act amendments of 1987 established a framework for regulating storm water discharges from municipal, industrial, and construction activities under the NPDES program. The primary objectives of the municipal storm water program requirements are to:

-Effectively prohibit non-storm water discharges, and
-Reduce the discharge of pollutants from storm water conveyance systems to the Maximum Extent Practicable.

Discussion

The Standard Urban Storm Water Mitigation Plan (SUSMP) was developed as part of the municipal storm water program to address storm water pollution from new Development and Redevelopment by the private sector. This SUSMP contains a list of the minimum required Best Management Practices (BMPs) that must be used for a designated project. Additional BMPs may be required by ordinance or code adopted by the Permittee and applied generally or on a case by case basis. This SUSMP applies to projects that are Priority Projects ~~(Discretionary Projects)~~ as defined by the NPDES Permit. The Permittees are required to adopt the requirements set herein in ~~use this SUSMP to develop~~ their own ~~citywide~~ SUSMP. Developers must incorporate appropriate SUSMP requirements into their project plans. Each Permittee will approve the project plan ~~an Urban Storm Water Mitigation Plan~~ as part of the development plan approval process and prior to issuing building and grading permits for the projects covered by the SUSMP requirements.

~~Discretionary projects~~, that fall into one of seven categories are identified in the NPDES Permit as requiring SUSMPs. These categories are:

Single-Family Hillside Residences
100,000 Square Foot Commercial Developments
Automotive Repair Shops
Retail Gasoline Outlets
Restaurants
Home Subdivisions with >10 housing units*

* (Note: this category is two separate categories in the NPDES Permit)

The Regional Board Executive Officer has designated two additional categories subject to SUSMP requirements. These categories are:

Location within or directly adjacent to or discharging directly to an environmentally sensitive area, and ~~Commercial stand-alone P~~parking ~~lot~~lots 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to storm water runoff

DEFINITIONS [Note: Alpha-numeric re-ordering caused full paragraphs to be underlined and struck-out]
~~"Greater than (>) 9 unit home subdivision" means any subdivision being developed for 10 or more 10 single family or multi family dwelling units.~~

"100,000 Square Foot Commercial Development" means any commercial development that creates at least 100,000 square feet of ~~Developments based on total~~ impermeable area, including parking areas., ~~as opposed to lot size or building footprint.~~

"Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539. ~~Exceptions do apply for SIC codes 5013, 5014, and 5541. For SIC code 5013, if the business has no outside storage of any recycled oil or other hazardous substances, it is not included. For SIC code 5014, if the business does not engage in any repair work, it is not included. For SIC code 5541, if the business does not engage in any onsite repair work, it is not included.~~

"Best Management Practice (BMP)" means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

"Directly Connected Impervious Area (DCIA)" means the area covered by a building, impermeable pavement, and/ or other impervious surfaces, which drains directly into the storm drain without first flowing across permeable land area (e.g. lawns).

"Discretionary Project" means a project which requires the exercise of judgement or deliberation when the public agency or public body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether

there has been conformity with applicable statutes, ordinances, or regulations.

~~**"Environmentally Sensitive Area" means an**~~ "Environmentally Sensitive Area" means an area designated as an Area of Special Biological Significance by the State Water Resources Control Board (Water Quality Control Plan, Los Angeles Region: Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties (1994)) or an area designated as a significant natural area by the California Resources Agency or an area designated as an Area of Ecological Significance by the County of Los *Angeles (Los Angeles County Significant Areas Study, Los Angeles County Department of Regional Planning (1976)).*

"Greater than (>) 9 unit home subdivision" means any subdivision being developed for 10 or more 10 single-family of multi-family dwelling units.

"Hillside" means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is twenty-five percent or greater.

"Infiltration" means the downward entry of water into the surface of the soil.

"New Development" means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.

"Parking Lot" means land area or facility for the temporary parking or storage of motor vehicles used personally, for business or for commerce.

Redevelopment" means, on an already developed site, the creation or addition of fifty percent or more of impervious surfaces or the making of improvements to fifty percent or more of the existing structure. Redevelopment includes, but is not limited to: the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/ or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; and land disturbing activities related with structural or impervious surfaces.

"Restaurant" means a facility ~~that sells~~ prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812)

"Retail Gasoline Outlet" means a facility ~~primarily~~ engaged in selling gasoline and lubricating oils~~., which derives more than fifty percent of its annual gross receipts from the sale of gasoline, lubricating oils. These establishments frequently sell other merchandise, such as~~ tires, batteries, ~~and~~ automobile parts and other automotive services. ~~Frequently, these establishments also~~

~~perform minor automotive repair work. Gasoline stations combined with other activities, such as grocery stores, convenience stores, or car wash facilities, are classified according to the primary activity.~~

~~"Hillside" means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope and where grading contemplates cut or fill slopes.~~

~~"Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539. Exceptions do apply for SIC codes 5013, 5014, and 5541. For SIC code 5013, if the business has no outside storage of any recycled oil or other hazardous substances, it is not included. For SIC code 5014, if the business does not engage in any repair work, it is not included. For SIC code 5541, if the business does not engage in any onsite repair work, it is not included.~~

~~"Restaurant" means a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812)~~

~~"Parking Lot" means land area or facility for the parking of commercial or business or private motor vehicles.~~

~~"Environmentally Sensitive Area" means an area designated as an Area of Special Biological Significance by the State Water Resources Control Board or an area designated as a Significant Natural Area by the California Resources Agency or an area designated as an area of Ecological Significance by the County of Los Angeles.~~

~~"Best Management Practice (BMP)" means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.~~

"Source Control BMP" means any schedules of activities, prohibitions of practices, maintenance procedures,~~,~~ managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

"Storm Event" means a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather.

"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both treatment control BMPs and source control BMPs.

"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical

oxidation and UV radiation.

"Treatment Control BMP" means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

~~"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both treatment control BMPs and source control BMPs.~~

~~"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.~~

~~"Infiltration" means the downward entry of water into the surface of the soil.~~

~~"Directly Connected Impervious Area (DCIA)" means the area covered by pavement, building and other impervious surfaces which drain directly into the storm drain without first flowing across pervious areas (e.g. lawns).~~

~~"New Development" means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.~~

~~Redevelopment" means, on an already developed site, the creation or addition of impervious surfaces; the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/ or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; land disturbing activities related with structural or impervious surfaces .~~

~~"Discretionary Project" means a project which requires the exercise of judgement or deliberation when the public agency or public body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statutes, ordinances, or regulations.~~

CONFLICTS WITH LOCAL PRACTICES

Where provisions of the SUSMP requirements conflict with established local codes , (e.g., specific language of signage used on storm drain stenciling), the Permittee may continue the local practice and modify the SUSMPs contained herein to be consistent with the code, except ~~where those practices would defeat or circumvent the intent of the SUSMP requirements.~~ provided that where SUSMPs are more stringent.

SUSMP PROVISIONS APPLICABLE TO ALL CATEGORIES

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Post-development peak storm water runoff discharge rates shall not exceed the estimated pre-development ~~levels~~ rate for developments where ~~it is reasonably foreseeable that~~ ~~an~~ the increased peak storm water discharge rate ~~may result in a foreseeable~~ will result in increased potential for downstream erosion.

2. CONSERVE NATURAL AREAS

If applicable, the following items are required and must be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- ~~Every effort shall be made to c~~Concentrate or cluster ~~development~~ Development on portionss of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants. ~~Wherever practical~~, promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

3. MINIMIZE STORM WATER POLLUTANTS OF CONCERN

Storm water runoff from a site has the potential to contribute oil and grease, suspended solids, metals, gasoline, pesticides, and pathogens to the stormwater conveyance system. The development must be designed so as to minimize, to the maximum extent ~~practicable~~ practicable, the introduction of pollutants of concern that may result in significant impacts, generated from site runoff of directly connected impervious areas (DCIA), to the storm water conveyance system as approved by the building official. Pollutants of concern, ~~as defined by the Permit~~, consist of any pollutants that exhibit one or more of the following characteristics: current loadings or historic deposits of the pollutant are impacting the beneficial uses of a receiving water, elevated levels of the pollutant are found in sediments of a receiving water and/or have the potential to bioaccumulate in organisms therein, or the detectable inputs of the pollutant are at a concentrations or loads ~~level high enough to be~~ considered potentially toxic to humans and/or flora and fauna.

In meeting this specific requirement, "minimization of the pollutants of concern" will require the incorporation of a BMP or combination of BMPs best suited to maximize the reduction of pollutant loadings in that runoff to the Maximum Extent Practicable. Those BMPs best suited for that purpose are those listed in the *California Storm Water Best Management Practices*

Handbooks; *Caltrans Storm Water Quality Handbook: Planning and Design Staff Guide*; *Manual for Storm Water Management in Washington State*; *The Maryland Stormwater Design Manual*; *Florida Development Manual: A Guide to Sound Land and Water Management*; Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices* ~~[Denver]~~ and *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* , USEPA Report No. EPA-840-B-92-002, as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question. However, it is possible that a combination of BMPs not so designated, may in a particular circumstance, be better suited to maximize the reduction of the pollutants.~~.~~

Examples of BMPs that can be used for minimizing the introduction of pollutants of concern generated from site runoff are identified in Table 2. Any BMP not specifically approved by the Regional Board in Resolution No. 99-03, "Approving Best Management Practices for Municipal Storm Water and Urban Runoff Programs in Los Angeles County", for development planning may be used if they have been recommended in one of the above references.

4. PROTECT SLOPES AND CHANNELS

~~If applicable, pr~~Project plans must include BMPs consistent with local codes and ordinances to decrease the potential of slopes and/or channels from eroding and impacting storm water runoff.

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Utilize natural drainage systems to the maximum extent practicable
- Control or reduce or eliminate flow to natural drainage systems to the maximum extent practicable
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion, with the approval of all agencies with jurisdiction, e.g., the U.S. Army Corps of Engineers and the California Department of Fish and Game

5. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins within the project area must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.
- Signs and prohibitive language and/or graphical icons ~~discouraging~~ illegal dumping must be posted at public access points along channels and creeks within the project area.
- Legibility of stencils and signs must be maintained.

6. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Outdoor material storage areas refer to storage areas or storage facilities solely for the storage of materials~~.~~

Improper storage of materials outdoors may provide an opportunity for toxic compounds, oil and grease, heavy metals, nutrients, suspended solids, and other pollutants to enter the stormwater conveyance system. Where proposed project plans include outdoor areas for storage of materials that may contribute pollutants to the stormwater conveyance system, the following *structural* BMPs are required:

- ~~Areas~~ Materials with the potential to contaminate storm water ~~where materials are to be stored~~ must be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.
- The storage area must be paved and sufficiently impervious to contain leaks and spills.
- ~~Where feasible~~, the storage area ~~should~~must have a roof or awning to minimize collection of stormwater within the secondary containment area.

7. PROPERLY DESIGN TRASH STORAGE AREAS

A trash storage area refers to an area where a trash receptacle or receptacles are located for use as a repository for solid wastes.

Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas must meet the following *structural BMP* requirements(Individual single family residences are exempt from these requirements):

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).
- Trash container areas must be screened or walled to prevent off-site transport of trash.

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons why water quality controls will not function as designed or which may cause the system to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included, or is required to include~~, treatment~~, treatment control BMPs in project plans, the Permittee shall require that the applicant provide verification of maintenance provisions through such means as may be appropriate, including, but not limited to legal agreements, covenants, CEQA mitigation requirements and/or Conditional Use Permits.

For all properties, th~~is~~e verification will include the developer's signed statement, as part of ~~its~~the project application, accepting responsibility for all structural and treatment control BMP

structural / treatment

maintenance until the time the property is transferred and, where applicable, a signed agreement from the public entity assuming responsibility for structural or treatment control BMP maintenance. Thise transfer of property to a private or public owner must have conditions requiring the recipient to assume responsibility for maintenance of ~~any treatment~~any treatment control BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility. The condition of transfer ~~may~~ will include a provision that the property owner conduct maintenance inspection of all treatment control BMPs at least once a year and retain proof of inspection. For residential properties where the treatment control BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&R's). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what stormwater management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. It ~~will also encourage~~ the transfer ~~of this information~~ with subsequent sale of the property.

~~If treatment~~If treatment control BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. Treatment control BMPs proposed for transfer must meet design standards adopted by the public entity for the BMP installed and should be approved by the County or other appropriate public agency prior to its installation.

9. DESIGN STANDARDS FOR TREATMENT CONTROL BMPS

Treatment control BMPs selected for use at any project covered by this SUSMP shall meet the design standards of this Section unless specifically exempted.

a. Post-construction Treatment Control BMPs shall be designed to:

A. mitigate (infiltrate or treat) storm water runoff from either:

1. ~~each runoff event up to and including~~ the 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998)*, or

2. the volume of annual runoff based on unit basin storage water quality volume, to achieve ~~85~~80 percent or more volume treatment by the method recommended in *California Stormwater Best Management Practices Handbook – Industrial/ Commercial,* (1993), or

3. the volume of runoff produced from a 0.75 inch ~~each and every~~ storm event ~~up to and including 0.75 inch of rainfall~~, prior to its discharge to a storm water conveyance system, or

4. the volume of runoff produced from ~~each and every storm event up to and including~~ a historical-record based reference 24-hour rainfall criterion for "treatment" (0.75 inch average for the Los Angeles County area) that achieves approximately the same reduction in pollutant loads achieved by the 85th percentile

24-hour runoff event,

AND

B. control peak flow discharge to provide stream channel and over bank flood protection, based on flow design criteria selected by the local agency.

~~The~~A proportional area of roofing surfaces may be excluded from the total area for calculation of rainfall or runoff volume to be treated provided:

a. the roofing materials will not be a source of pollutants of concern in storm water, and

b. storm water from the roofing surfaces area is diverted directly to a storm water conveyance system, and

c. roof based exhaust systems, vents, filters, and air pollution control devices will not present a significant source of pollutants of concern in storm water, and

d. the storm water conveyance system does not directly ~~or indirectly~~ discharge to a natural stream or ~~unlined channel or~~ channel segment scheduled for restoration.

Exclusions

Restaurants, where the land area for development or redevelopment is less than 5,000 square feet, are excluded from the ~~requirements of this Section.~~ numerical BMP design standard requirement.

10. PROVISIONS APPLICABLE TO INDIVIDUAL PRIORITY PROJECT CATEGORIES

A. 100,000 SQUARE FOOT COMMERCIAL DEVELOPMENTS

1. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water runon or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. ~~To alleviate this problem, consider including~~ in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained~~,~~ and or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

B. RESTAURANTS

1. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

Outdoor equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, include in the project plans an area for the washing/steam cleaning of equipment and accessories. This area must meet the following:

- This area must be self-contained, equipped with a grease trap, and properly connected to a sanitary sewer.
- If this wash area is to be located outdoors, it must be covered, paved, have secondary containment, and be connected to the sanitary sewer.

C. RETAIL GASOLINE OUTLETS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant

and gasoline to the storm water conveyance system. The project plans must include the following BMPs:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The canopy's minimum dimensions must be equal to or greater than the area within the grade break. The canopy must not drain onto the fuel dispensing area, and the canopy downspouts must be routed to prevent drainage across the fueling area.
- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water to the extent practicable.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

D. AUTOMOTIVE REPAIR SHOPS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. Therefore, design plans, which include fueling areas, must contain the following:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The cover's minimum dimensions must be equal to or greater than the area within the grade break. The cover must not drain onto the fuel dispensing area and the downspouts must be routed to prevent drainage across the fueling area.
- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, ~~consider~~ including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained and/or~~,~~ covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer or to a permitted disposal facility.

4. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

E. PARKING LOTS

1. PROPERLY DESIGN PARKING AREA

Parking lots contain pollutants such as heavy metals, oil and grease, and polycyclic aromatic hydrocarbons that are deposited on ~~these~~parking lot surfaces by ~~from~~ motor vehicles~~-traffic~~. These pollutants are directly transported to surface waters. To minimize the offsite transport of pollutants, the following design criteria are required:

- Reduce impervious land coverage of parking areas
- Infiltrate runoff before it reaches storm drain system.
- Treat runoff before it reaches storm drain system

2. PROPERLY DESIGN TO LIMIT OIL AND PERFORM MAINTENANCE

Parking lots may accumulate oil, grease, and water insoluble hydrocarbons from vehicle drippings and engine system leaks.

- Treat to remove oil and petroleum hydrocarbons at parking lots that are heavily used (e.g. fast food outlets, lots with 25 or more parking spaces , sports event parking lots, shopping malls, grocery stores, discount warehouse stores)
- Ensure adequate operation and maintenance of treatment systems particularly sludge and oil removal, and system fouling and plugging prevention control

11. WAIVER

A Permittee may, through adoption of an ordinance or code ~~inc~~ incorporating the treatment requirements of the SUSMP, provide for a waiver from the requirement if ~~impracticability for~~impracticability for a specific ~~property can~~property can be established. Recognized situations of impracticability include (i) extreme limitations of space for treatment on a redevelopment project, (ii) unfavorable or unstable soil conditions at a site to attempt infiltration, and (iii) risk of ground water contamination because an existing or potential underground source of drinking water is less than 10 feet from the soil surface. Any other ~~justification for~~justification for impracticability must be separately petitioned by the Permittee and approved by the Regional Board Executive Officer before it becomes recognized and effective. A waiver granted by a Permittee to any development or redevelopment project may be revoked by the Regional Board Executive Officer for cause and with proper notice upon petition.

If a waiver is granted for impracticability, the Permittee must require the project proponent to transfer the savings in cost, as determined by the Permittee, to a storm water mitigation fund to be used to promote regional or alternative solutions for storm water pollution in the storm watershed and operated by a public agency or a non-profit entity.

12. LIMITATION ON USE OF INFILTRATION BMPS

Three factors significantly influence the potential for storm water to contaminate ground water. They are (i) pollutant mobility, (ii) pollutant abundance in storm water, (iii) ~~and~~ soluble fraction of pollutant. The risk of contamination of groundwater may be reduced by pretreatment of storm water. A discussion of limitations and guidance for infiltration practices is contained in, *Potential Groundwater Contamination from Intentional and Non-Intentional Stormwater Infiltration, Report No. EPA/600/R-94/051, USEPA (1994).*

In addition, the distance of the groundwater table from the infiltration BMP may also be a factor determining the risk of contamination. A water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic.

Infiltration BMPs are not recommended for areas of industrial activity or areas subject to high vehicular traffic (25,000 or greater average daily traffic (ADT) on main roadway or 15,000 or more ADT on any intersecting roadway) unless appropriate pretreatment is provided to ensure groundwater is protected and the infiltration BMP is not rendered ineffective by overload.

13. ALTERNATIVE CERTIFICATION FOR STORM WATER TREATMENT MITIGATION

In lieu of conducting detailed BMP review to verify treatment control BMP adequacy, ~~A~~ a

Permittee may elect to accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria established herein. The Permittee is encouraged to verify that certifying person(s) ~~must provide evidence that~~ ~~s/he~~ have been ~~received~~ trained~~ing~~ on BMP design for water quality, not more than two years prior to the signature date.~~and that the plan preparer has undergone training on designing BMPs to meet the numerical mitigation criteria, in lieu of conducting detailed BMP review to verify treatment control BMP adequacy~~. Training~~The training must have been~~ conducted by an organization with storm water BMP design expertise (e.g., a University, American Society of Civil Engineers, American Society of Landscape Architects, American Public Works Association, or the California Water Environment Association) ~~with the training and curriculum accepted by the Regional Board Executive Officer. For the certification to be valid, training must have been received not more than two years prior to the signature date on the plan.~~ ~~Will~~ may be considered qualifying.

TABLE 2: Example Best Management Practices (BMPs)

The following are examples of BMPs that can be used for minimizing the introduction of pollutants of concern that may result in significant impacts, generated from site runoff to the storm water conveyance system. (See Table 1: Suggested Resources for additional sources of information):

-Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths must still comply with regulations for the Americans with Disabilities Act and other life safety requirements.
-Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.
-Comply with all zoning and applicable ordinances to minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.
-Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).
-Use open space development that incorporates smaller lot sizes.
-Reduce building density.
-Comply with all zoning and applicable ordinances to reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.
-Comply with all zoning and applicable ordinances to reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.
-Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas, and avoid routing rooftop runoff to the roadway or the storm water conveyance system.
-Vegetated swales and strips
-Extended/dry detention basins
-Infiltration basin
-Infiltration trenches
-•——Wet ponds
-Constructed wetlands
-•—Oil/Water separators
-•—Catch basin inserts
-•—Continuous flow deflection/ separation systems

3. The Regional Board adopts the approved requirements as provisions applicable to the SUSMP requirements for the City of Long Beach.

4. The Regional Board adopts the numerical mitigation standards for storm water, endorsed herein, as the minimum design criteria for review of post-construction BMPs in the Los Angeles Region for construction projects subject to coverage under the state storm water general permit for construction activity.

5. The Regional Board encourages the Permittees and all interested parties to work together in a spirit of cooperation to effect the implementation of the Standard Urban Storm Water Mitigation Plan at the earliest possible date, and

6. The Regional Board encourages the efforts by the Southern California Council of Governments and area Council of Governments (COGs) to develop regional plans and identify regional solutions to address storm water pollution from new development and redevelopment.

I, Dennis Dickerson, Executive officer, do hereby certify that the foregoing is a full, true and correct copy of a Resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on January 6, 2000.

DENNIS A. DICKERSON
Executive Officer

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD

LOS ANGELES REGION

STAFF REPORT AND RECORD OF DECISION

STANDARD URBAN STORM WATER MITIGATION PLANS

AND

NUMERICAL DESIGN STANDARDS FOR BEST MANAGEMENT PRACTICES

1.0 EXECUTIVE SUMMARY

The Standard Urban Storm Water Mitigation Plan (SUSMP) is a model guidance document for use by builders, land developers, engineers, planners and others to select post-construction Best Management Practices (BMPs) and obtain municipal approval of the urban storm water runoff mitigation plan for projects which fall into selected categories. A proposed SUSMP (December 7, 1999 version) was developed by Regional Board staff and distributed to interested parties.

The proposed SUSMP is designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating Best Management Practices (BMPs) in the design phase of new development and redevelopment. It provides for numerical design standards (water quality design standards) to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways. Further, two additional categories are being included for storm water control requirements. These categories are, (i) parking lots 5,000 square feet (or with 25 or more parking spaces) and (ii) development of locations discharging to environmentally sensitive areas. The proposed SUSMP also attempts to respond to various concerns by providing a choice of design criteria and incorporating provisions that allow for flexibility thereby recognizing that a single numerical standard may not be appropriate in every case

The proposed SUSMP will require all new development or redevelopment that includes one of the following planning projects to select post-construction treatment BMPs for implementation:

(i) 100+ home subdivision;
(ii) 10-99 home subdivision;
(iii) 100,000+ square-foot commercial development;
(iv) automotive repair facilities;
(v) retail gasoline outlets;
(vi) restaurants;
(vii) parking lots more than 5,000 square feet or more than 25 parking spaces

(viii) hillside located single-family dwelling,
(ix) construction projects in environmentally sensitive areas

Note: The first two categories are combined in the December 7, 1999 proposed SUSMP document.

The Standard Urban Storm Water Mitigation Plan (SUSMP) proposed by the Regional Board staff takes much of the original language offered by the Co-Permittees in their submittal to the Regional Board on August 22, 1999, and consolidates it in a more concise and understandable document without duplication

2.0 STATEMENT OF THE PROBLEM

Water Quality and Storm Water

The water quality impacts of urbanization and urban storm water discharges have been summarized by several recent USEPA reports.[1] Urbanization causes changes in hydrology and increases pollutant loads which adversely impact water quality and impair the beneficial uses of receiving waters. Increases in population density and imperviousness result in changes to stream hydrology including:

(i) increased peak discharges compared to predevelopment levels;
(ii) increased volume of storm water runoff with each storm compared to pre-development levels;
(iii) decreased travel time to reach receiving water; (iv) increased frequency and severity of floods;
(iv) reduced stream flow during prolonged periods of dry weather due to reduced level of infiltration;
(v) increased runoff velocity during storms due to a combination of effects of higher discharge peaks, rapid time of concentration, and smoother hydraulic surfaces from chanellization, and
(vi) decrease infiltration and diminish groundwater recharge.

The Los Angeles County municipal storm water management (municipal separate storm sewer system [MS4]) program conducts monitoring to:

(i) quantify mass emissions for pollutants,
(ii) identify critical sources for pollutants of concern in storm water;
(iii) evaluate BMP effectiveness, and
(iv) evaluate receiving water impacts.

The monitoring indicates that instream concentrations of pathogen indicators (fecal coliform and streptococcus), heavy metals (such as Pb, Cu, Zn,) and pesticides (such as diazinon) exceed

[1] *Storm Water Phase II Report to Congress* (USEPA 1995); *Report to Congress on the Phase II Storm Water Regulations* (USEPA1999); *Coastal Zone Management Measures Guidance* (USEPA 1992)

state and federal water quality criteria.[2] The mass emissions of pollutants to the ocean are significant from the urban Watershed Management Areas (WMAs) such as the Los Angeles River WMA, Ballona Creek WMA, and Coyote Creek WMA with the Los Angeles River WMA providing more than seventy percent of the loadings. Critical sources data for facilities (such as auto-salvage yards, primary metal facilities, and automotive repair shops) showed that total and dissolved heavy metals (Pb, Cu, Zn, and Cd), and total suspended solids (TSS) exceeded state and federal water quality criteria by as much as a hundred times. The results are consistent with a limited term study conducted by the Regional Board to characterize storm water runoff in the Los Angeles region before the issuance of MS4 permits.[3] Storm water runoff data from predominant landuses showed similar patterns. Light-industrial, commercial and transportation landuses showed the highest range of exceedances. A pesticide (diazinon) showed higher ranges from residential landuse. The data for polycyclic aromatic hydrocarbons (PAHs), a known pollutant of concern in urban storm water runoff, is inconclusive but improved analytical methods may yield more definitive results next year. Receiving water impacts studies found that storm water discharges from urban watersheds exhibit toxicity that are attributable to heavy metals. Biosurveys of the sea-bottom showed bioaccumulation of toxicants. Sediment analysis showed higher concentrations of pollutants such as Pb and PAHs than rural watersheds (2 to 4 times higher). In addition, toxicity of dry weather flows was observed with the cause of toxicity undetermined.[4] Previous studies have found chemical concentration of pollutants that exceed state and federal water quality criteria in storm drains flowing to the ocean,[5] and that there are adverse health impacts from swimming near them.[6]

Treatment BMP requirements on new development and redevelopment offer the most cost effective strategy to reduce pollutant loads to surface waters. Retrofit of existing development will be expensive and may be considered on a targeted basis. Studies on the economic impacts of watershed protection indicate that storm water quality management has a positive or at least neutral economic effect while greatly improving the quality of surface waters.[7]

Municipal storm water regulations at 40 CFR 122.26 require that pollutants in storm water be reduced to the maximum extent practicable (MEP). The USEPA's definition is intentionally broad to provide maximum flexibility in MS4 permitting and to and to give municipalities the

[6] *The Health Effects of Swimming in Ocean Water Contaminated by Storm Drain Runoff*, Haile, R.W. et al. (1999), Epidemiology 10: 355-363). The study found higher risks of respiratory and gastrointestinal symptoms from swimmers.

[7] *The Economics of Watershed Protection*, T. Schuler (1999), Center for Watershed Protection, Endicott, MD. The article summarizes nationwide studies to support the statement that watershed planning and storm water management provide positive economic benefits.

opportunity to optimize pollutant reductions on a program-to-program basis.[8] The definition of MEP has generally been applied to mean implementation of economically achievable management practices. Because storm water runoff rates can vary from storm to storm, the statistical probabilities of rainfall or runoff events become economically significant and are central to the control of pollutants through cost effective BMPs. Further, it is recommended that storm water BMPs be designed to manage both flows and water quality for best performance. [9] It is equally important that treatment BMPs once implemented be routinely maintained.

Financing the MS4 program offers a considerable challenge for municipalities. A proven successful financing mechanism is the establishment of a storm water utility.[10] Utility fees, which are assessed on the property owner based on some estimate of storm water runoff generated for the site, are a predictable and dedicated source of fund. Utility fees can also provide a mechanism to provide incentives to commercial and industrial property owners to reduce impervious surface areas. Such incentives offer flexibility to property owners to choose the better economic option – paying more fees or improvements to reduce runoff from the site.

3.0 REVIEW OF STANDARDS FOR DEVELOPMENT PLANNING

The American Society of Civil Engineers (ASCE) and the Water Environment Federation (WEF) have recommended a numerical BMP design standard for storm water that is derived from a mathematical equation to maximize treatment of runoff volume for water quality based on rainfall/ runoff statistics and which is economically sound (ASCE/ WEF 1998).[11] The maximized treatment volume is cut-off at the point of diminishing returns for rainfall/ runoff frequency. On the basis of this equation the maximized runoff volume for 85 percent treatment of annual runoff volumes in California can range from 0.08 to 0.86 inch depending on the imperviousness of the watershed area and the mean rainfall.[12]

Other methods of establishing numerical BMP design standards include: (i) Percent treatment of the annual runoff; (ii) Full treatment of runoff from rainfall event equal to or less than a predetermined size; (iii) Percent reduction in runoff based on a rainfall event of standard size.[13] These numerical design standards have been applied to Development Planning in Puget Sound, WA; Alexandria, VA; Montgomery County, MD; Denver, CO, Orlando, FL and Austin, TX.

[12] Sizing and Design Criteria for Storm Water Treatment Controls, Presentation to California Storm Water Quality Task Force, November 13, 1998, Sacramento, CA. L.A. Roesner, Camp Dresser McKee .

[13] Sizing and Design Criteria for Stormwater Quality Infrastructure, Presentation at California Regional Water Quality Control Board Workshop on Standard Urban Storm Water Mitigation Plans, August 10, 1999, Alhambra, CA., R.A. Brashear, Camp Dresser McKee.

The City of Seattle requires that where new development coverage is 750 square feet or more, storm water detention be provided based on a 25 year storm return frequency and a peak discharge rate not to exceed 0.2 cubic foot per second.[14] Additionally, for projects that add more than 9,000 square feet in developmental coverage, the peak drainage water discharge rate is limited to 0.15 cubic feet per second per acre for a two-year storm. The City of Denver requires new residential, commercial, and industrial developments to capture and treat the 80th percentile runoff event. This capture and proper treatment is estimated to remove 80 to 90 percent of the annual TSS load which is a surrogate measure for heavy metal and petroleum hydrocarbon pollutants.[15]

In the Los Angeles Region, at least three different numerical mitigation measures are in use or have been proposed by a small number of municipalities.

The County of Los Angeles requires that development projects that meet the threshold criteria in the unincorporated area select treatment BMPs that mitigate "runoff generated from each and every storm event of up to and including 0.75 inch rainfall". The point of diminishing return for rainfall treatment for Los Angeles County (Civic Center rainfall record) and the coastal Los Angeles (LAX rainfall records) coincide roughly with 0.75 inch and 1.4 inches.

The City of Santa Monica requires that development projects reduce 20 percent of the projected runoff from a one-inch 24-hour storm using impervious factors based on Los Angeles County flood control benefit assessment[16]. All new parking lots are required to have the capability to treat one inch of precipitation that falls in a 24 hour period. Developers are given the option to pay in lieu fees, to be used for other water quality projects by the City, should the standard be impossible to meet because of limiting considerations.

The City of Calabasas requires that development projects demonstrate an effort to reduce projected runoff by 20 percent from the base 1985 10-year storm basis (approximately 3.5 inches).[17]

Other cities such as Arcadia, Baldwin Park, Cudahy, Culver City, El Monte, Hermosa Beach, Pasadena, Rancho Palos Verdes, Redondo Beach, San Fernando, Sierra Madre, South El Monte, South Gate, Temple City, and West Holywood, while not having formally adopted the numerical design standard of 0.75 inch, have expressed a willingness or have implemented the standard already. These communities express a preference for a simple and easy to recall numerical standard applicable countywide.[18]

---

[14] City of Seattle Municipal Code, Chapter 22.802.015 – Storm water, drainage and erosion control requirements.

[15] Urban Storm Drainage, Criteria Manual – Volume 3, Best Management Practices, Urban Drainage and Flood Control District, Denver, CO (1999). Manual provides detail design criteria for new development for the Denver Metropolitan area.

[16] City of Santa Monica Municipal Code, Chapter 7.10 – Urban Runoff Pollution (1995). The City of Santa Monica's numerical mitigation measure emphasizes flow reduction of about 0.2 inch of rainfall, which limits options for "treatment".

[17] City of Calabasas Municipal Code, Title 17, Chapter 17.56 – Urban Runoff Pollution Control (1998). The City of Calabasas numerical mitigation measure (0.7 in.) appears to be equivalent to the Los Angeles County measure for unincorporated areas (0.75 in.).

[18] See Letter dated January 18, 2000 from John Hunter & Associates, Consultants for these cities, addressed to Dennis Dickerson, Regional Board Executive Officer

Ventura County has proposed draft land development criteria that treatment BMPs be designed for using a unit basin storage volume design based on 70 percent capture of annual runoff and flow based design criteria based on 10 percent of the peak 50 year flow rate from impervious areas.[19]

A few States have already established or are in the process of finalizing numerical standards for sizing storm water post-construction BMPs for new development and significant redevelopment. The State of Maryland has established storm water numerical criteria for water quality of 0.9 to 1 inch and BMP design standards in a unified approach combining water quality, stream erosion potential reduction, groundwater recharge, and flood control objectives.[20] The State of Florida has used numerical criteria to require treatment of storm water from new development since 1982 including BMPs sized for 80 percent (95 percent for impaired waters) reduction in annual total suspended solids load derived from the 90 percent (or greater for impaired waters) annual runoff treatment volume method for water quality.[21] The State of Washington has proposed at least six different approaches of establishing storm water numerical mitigation criteria for new development which add 10,000 square feet of impervious surface or more for residential development and 5,000 square feet of impervious surface or more for other types of development[22]. The mitigation criteria options include the 90th percentile 24-hour rainfall event and the six month 24 hour rainfall event.

On a national level, the USEPA is planning to standardize minimum BMP design and performance criteria for post-construction BMPs under Title III of the Clean Water Act and will likely build from the experience of effective state and local programs to establish national criteria.[23] The USEPA, based on the National Urban Runoff Program, supports the first half-inch of rainfall as generating first flush runoff.[24] First flush runoff is associated with the highest pollutant concentrations, and not pollutant load. The USEPA considers the first flush treatment method, the rainfall volume method, and the runoff capture volume method as common approaches for sizing of water quality BMPs.

4.0 NEW DEVELOPMENT REQUIREMENTS BACKGROUND

---

[19] Letter from A. Sheyadayi, Ventura Countywide Stormwater Quality Management Program to X. Swamikannu (September 13, 1999) with attachment. 'Stormwater Treatment: A Design Approach for Volumetric and Flow Based Best Management Practices'. J. Endicott *et al.*

[20] Maryland Storm Water Design Manual - Draft (Maryland Department of the Environment 1998). The Final document is scheduled for publication in January 2000. Changes are mostly in format to improve presentation according to the authors.

[21] Florida Development Manual: A Guide to sound Land and Water Management (Florida Department of Environmental Protection 19xx). The manual describes structural and non-structural construction and post construction BMPs design criteria.

[22] Storm Water Management in Washington State Volumes 1 – 5. Public Review Draft (Washington Department of Ecology 1999). The volumes 1,3 and 5 are most relevant to new development standards and cover Hydrologic and Flow Control Designs, Minimum Technical Requirements and Treatment BMPs. The volumes will be adopted as statewide standards in early 2000 after completion of public hearings according to the agency.

[23] Storm Water Phase II Final Rule – Pre-Federal Register Version, p 53 (USEPA 1999). See USEPA's discussion on construction and post-construction BMP requirements for Phase II.

[24] A Watershed Approach to Urban Runoff: Handbook for Decisionmakers, Terene Institute and USEPA Region 5 (1996). See discussion on sizing rules for water quality purposes, p 36.

Los Angeles County and municipalities within the County (except the City of Long Beach) implement a municipal storm water program to reduce storm water and urban runoff pollution under the requirements of Board Order No. 96-054. The City of Long Beach implements a separate municipal storm water program to reduce storm water and urban runoff pollution under Board Order No. 99-060 adopted by the Regional Board on June 30, 1999. The Los Angeles County Municipal Storm Water Permit include requirements that Standard Urban Storm Water Mitigation Plans (SUSMPs) be prepared for priority planning projects and that they include appropriate Best Management Practices (BMPs) and guidelines to reduce pollutants in storm water to the maximum extent practicable (Permit Pt. 2. III.A.) The City of Long Beach municipal separate storm sewer system (MS4) permit includes requirements that make SUSMP provisions adopted by the Regional Board or approved by the Regional Board Executive Officer for Los Angeles County and Cities applicable to its program.

On April 22, 1999, the Regional Board approved a List of BMPs for MS4 Co-Permittees to select from and require implementation of the most effective BMPs in their Development Planning and Development Construction programs (Board Resolution No. 99-03). The Regional Board at that time also requested that the SUSMPs for Priority Planning Project categories, which incorporate the BMPs, be brought to it for discussion.

Los Angeles County Department of Public Works (LACDPW), on behalf of the Co-Permittees, submitted SUSMPs for Regional Board Executive Officer approval on July 22, 1999. These SUSMPs were revised and resubmitted on August 12, 1999, after a joint SUSMP workshop held on August 10, 1999, to clarify the meaning of some text. SUSMPs have been submitted for: (i) 100+ home subdivisions; (ii) 10-99 home subdivisions; (iii) 100+ square-foot commercial developments; (iv) automotive repair facilities; (v) retail gasoline outlets; (vi) restaurants; and (vii) hillside located single-family dwellings. Prior to submittal to the Regional Board, draft versions of the SUSMPs were distributed to environmental groups, contractors, developers, consultants and trade industry groups for review and comment.

The SUSMP requirements within this proposal for the Los Angeles County storm water program, will apply to the City of Long Beach MS4 permit for the following categories only: (i) 10-99 home subdivisions; (ii) 100 or more subdivisions; (iii) 100,000 or more square foot commercial developments; and (iv) projects located adjacent to or discharging to environmentally sensitive areas.

For (i) restaurents; (ii) retail gasoline outlets; and (iii) automotive repair facilities, it is expected that the City of Long Beach will require post construction BMPs to meet the numerical design standard approved by the Regional Board. The City of Long Beach MS4 permit does not require that SUSMPs be prepared for these categories, since the requirements are contained in the City of Long Beach Storm Water Management Program.

The Long Beach MS4 permit requires that the City conduct a parking lot-study (with ten or more spaces) to characterize and evaluate storm water runoff pollution and mitigation and submit a report in July 2000. It is expected that the City of Long Beach parking lot study will consider any requirements approved by the Regional Board for parking-lots, including treatment control BMPs based on a numerical design standard.

The Regional Board provided Public Notice on August 16, 1999, of proposed action on the SUSMP and proposed discussion on September 16, 1999, before the Board and invited

comments from interested parties. Comments were received from municipalities, environmental groups, businesses, environmental consultants, and the building industry.

These comments are summarized in "Comments and Response" included in the Record of Decision and was part of the package mailed out with the notice of proposed action for the January 6, 2000, Board meeting.

5.0 STANDARD URBAN STORM WATER MITIGATION PLANS (SUSMPS)

LACDPW and its Co-Permittees submitted for approval by the Executive Officer, SUSMPs for: (i) 100+ home subdivisions; (ii) 10-99 home subdivisions; (iii) 100+ square-foot commercial developments; (iv) automotive repair facilities; (v) retail gasoline outlets; (vi) restaurants; and (vii) hillside located single-family dwellings.

Post-construction BMPs to be selected include: Structural Control BMPs, Treatment Control BMPs, And Source Control BMPs. The list of treatment control BMPs includes (i) vegetated swales and strips; (ii) extended/ dry detention basins; (iii) infiltration basins; (iv) infiltration trenches; (v) wet ponds; (vi) constructed wetlands; (vii) oil/water separators; (viii) catch-basin inserts; (ix) storm drain inserts; (x) media filtration; (xi) bioretention; (xii) dry wells; (xiii) cisterns; and (xiv) foundation planting.

As submitted, the SUSMPs for the 100+ home subdivision, the 10-99 home subdivision, and 100+ square-foot commercial development categories included requirements that storm water runoff be mitigation with source control and treatment control BMPs. The SUSMPs for automotive repair facilities; retail gasoline outlets; restaurants; and hillside located single-family dwellings required only source control BMPs. No numerical design criteria were included. A 0.6-inch 24-hour rainfall criterion that was in earlier drafts of the document and circulated to Co-Permittees and interested parties for comment was deleted from the Co-Permittee's SUSMP proposal submitted to the Regional Board.

6.0 STAFF PROPOSED SUSMP IMPROVEMENTS

At the Regional Board meeting held on September 16th, the only significant difference between the staff's proposal and that of the Co-Permittee's was the inclusion of a numerical design standard for the sizing of Best Management Practices. Without including a specific design standard in the SUSMP proposal, staff hold that the SUSMPs would be left without a key provision that would ensure that BMPs would be utilized in the most effective manner as directed by the Regional Board in its April 1999 approval of the List of Best Management Practices for New Development.

With action on the SUSMP proposal delayed following the September 16, 1999 Regional Board meeting, staff were able to develop a more refined proposal that would build in additional flexibility for Co-Permittees. On December 7, 1999, staff released a revised proposal for public review and comment.

The December 7th SUSMP proposal is a substantial revision to that which was before the Board on September 16th. Much of the language of the original SUSMP proposal submitted by the Co-

Permittees remains. The following revisions to the original language (not all of the revisions made are discussed herein) represent the most significant differences between the August 1999 Co-Permittee submittal and the December 7th staff proposal:

Consolidation of Text

The August proposal contained much text that was redundant by replicating language for each individual SUSMP category. This redundant language has been consolidated in a section that applies a set of SUSMP requirements to all SUSMP categories. In addition, the two categories for residential developments have now been consolidated into one category.

Numerical Design Standard

As before the Regional Board in September, the December 7th staff proposal includes numerical design criteria for BMP. Four different numerical design criteria for BMPs have been provided while essentially retaining the technical basis of the September 7 staff proposal for numerical design standards for treatment control BMPs.

As presented in the December 7th document, the post-construction treatment BMPs shall be designed to:

A. mitigate (infiltrate or treat) storm water runoff from either:

1. each runoff event up to and including the 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998)*, or

2. the annual runoff volume, based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in *California Stormwater Best Management Practices Handbook – Industrial/ Commercial,* (1993), or

3. the volume of runoff produced from each and every storm event up to and including 0.75 inch of rainfall, prior to its discharge to a storm water conveyance system, or

4. the volume of runoff produced from each and every storm event up to and including a historical-record based reference 24-hour rainfall criterion for "treatment" (0.75 inch average for the Los Angeles County area) that achieves approximately the same reduction in pollutant loads achieved by the 85th percentile 24-hour runoff event,

AND

B. control peak flow discharge to provide stream channel and over bank flood protection, based on flow design criteria selected by the local agency.

Significantly, the December 7th staff proposal contains a provision that allows BMPs to not be sized to include runoff from roof structures under certain conditions. These conditions include ensuring that the runoff from the roof surface is directed to a storm drain system prior to allowing any commingling with other surface runoff that may be carrying contaminants. Additionally, the runoff from the roof area should not itself be contaminated. Allowance of a roof runoff exemption allows for BMPs to be designed for a smaller amount of runoff thereby resulting in a smaller structural BMP and less initial construction and maintenance costs.

In addition, staff has recognized that flow considerations may be significant in the design of certain BMPs (such as catch-basin inserts). However, limited analyses exist at this time of flow rate and rainfall intensity statistics for water quality design. Thus staff has provided a general provision, determined by the local agency, to control peak flow discharge to avoid stream channel erosion and over-bank flooding only. Flow rate criteria for flow sensitive BMPs will need to be developed in the future.

Additionally, restaurants involving land area of 5,000 square feet or less are excluded from the numerical design standard.

Definition of Hillsides

The December 7th proposal attempted to provide clarity to the definition of "Hillside" for consistent interpretation. However, the definition in the December 7th proposal was defined broadly and requires modification. A Change Sheet will be offered to modify the definition as property located in an area with known erosive soil conditions, where the development would involve regulated grading on any natural slope that is 25 percent or greater.

Redevelopment Threshold

Comments have suggested the need for a trigger threshold to the definition of 'Redevelopment' for SUSMP requirements to become applicable. A Change Sheet will provide a revision for the definition of "Redevelopment" which will provide that "on an already developed site, the creation or addition of fifty percent or more of impervious surfaces or the making of improvements to fifty percent or more of the existing structure". This change ensures that minor modifications to existing structures or properties do not unintentionally trigger SUSMP requirements.

Parking Lots

A new category subject to SUSMPs "Parking Lots" was added. Parking lots with daily vehicular traffic produce pollutants such as heavy metals, oil and grease, and petroleum hydrocarbons from vehicle drippings and engine system leaks. Studies in the Los Angeles area conducted on the quality of storm water from parking lots indicate that the concentration of the pollutants often exceed water quality criteria.[25] These results affirm studies, conducted by some business

[25] *Santa Monica Bay Area Municipal Storm Water/ Urban Runoff Pilot Project Studies: Evaluation of Potential Catchbasin Retrofits*, Santa Monica Bay Cities Consortium (1998); and *Consent Decree Report: Strip Filter*, City of Los Angeles, Stormwater

groups included in the priority-planning category, which demonstrate that pollution from commercial parking lots is similar.[26]

The Los Angeles municipal storm water permit currently includes requirements for parking lots with the threshold condition of 25 or more parking spaces (equivalent to 5,000 square feet of surface area).[27] Separately, the Long Beach municipal storm water permit includes a special study provision to characterize pollution and evaluate controls for parking lots with 10 or more spaces. It is expected that the Long Beach parking lot study will develop additional information on controls necessary, if any, for these smaller (10-25 space) parking lots.

Comments received have suggested that the staff's original intent with respect to this provision were unclear. A Change Sheet will clarify staff's intent that this requirement be applied only to commercial "stand alone" parking lots, i.e., parking lots that are not associated with small commercial developments.

Environmentally Sensitive Areas

The new category of Environmentally Sensitive Areas was added subject to SUSMPs. Urban storm water discharges that contribute pollutants to areas designated as environmentally significant or environmentally sensitive may adversely impact the ecology that has been designated for protection under state, federal and local laws.

Comments have been received that draw attention to the fact that many different provisions of law, regulation, and guidance define a variety of environmentally sensitive areas that, taken together, may result in the application of SUSMP criteria to an inherently vague definition leading to application of that criteria in situations where it was not intended. The staff proposal's definition requires careful review to ensure that it is defined to reflect Regional Board direction and regulatory clarity. A Change Sheet will address comments received. Some considerations in crafting a definition follow:

Under the federal Endangered Species Act (ESA) agency actions must not jeopardize the existence of listed species or modification of a critical habitat.[28] The Regional Board has a responsibility, as the implementing agency for a federal regulation, to ensure that its actions be consistent with the ESA. Applicability of the requirement to develop a SUSMP has been limited

---

Management Division (1999), these studies characterized parking lot storm water runoff from areas 10,000 -150,000 square feet and evaluated BMP pollutant removal effectiveness.

[26] *Results of a Retail Gasoline Outlet and Commercial Parking Lot Storm Water Runoff Study*, Western States Petroleum Association and American Petroleum Institute (1994). The study simulated runoff and found that pollutant concentrations from commercial parking lots and gas stations are similar.

[27] Board Order No. 96-054, Pt. 2. 1.E.1.a.ix. The Los Angeles permit requires that Permittees have the legal authority to require sweeping or other equally efective measures to remove debris from industrial commercial motor vehicle parking lots with more than 25 parking spaces.

[28] 62 *Fed. Reg.* 7872. The USEPA states in the preamble to the reissuance of NPDES general permits for storm water discharges from construction activities, that prohibition in the Endangered Species Act on harmful agency actions are binding on it, other federal agencies, permittees, and the public at large. EPA writes, "Federal agencies are required to consult with the Fish and Wildlife Service or the National Marine Fisheries Service to ensure that any action authorized, funded, or carried out by them are not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat."

to areas designated as environmentally sensitive or significant by the State Water Resources Control Board, the State Resources Agency, and the County of Los Angeles. The Long Beach municipal storm water permit already requires SUSMP for development in locations discharging to environmentally sensitive areas.[29]

The California Coast Act (CA) Section 30116 defines sensitive coastal resource areas as: "Those identifiable and geographically bounded land and water areas within the coastal zone of vital interest and sensitivity. "Sensitive coastal resource areas" include the following:

(a) special marine and land habitat areas, wetlands, lagoons and estuaries as mapped and designated in part 4 of the coastal plan
(b) areas possessing significant recreational value
(c) highly scenic areas
(d) archaeological sites referenced in the California coastline and recreation plan or as designated by the state historic preservation officer
(e) special communities or neighborhoods which are significant visitor destination areas.
(f) areas that provide existing coastal housing or recreation opportunities for low and moderate income persons.
(g) areas where divisions of land could substantially impair or restrict coastal access."

The Los Angeles County General Plan identifies Ecologically Significant Habitat Areas (ESHAs). Areas in Los Angeles County that are ecologically sensitive were first identified in the early 1970s by a court decision (the Judge Thomas decision) and subsequently modified based on "the England and Nelson Study" conducted by the Museum of Natural History for the Los Angeles County Department of Regional Planning ((Los Angeles County Significant Ecological Areas Study,1976). Subsequent modifications have been conducted on a case by case basis. These areas are designated Ecological Significant Areas (SEAs) and include all ESHAs.

Sensitive resources include streams and wetlands, but also some upland areas such as oak woodlands coastal sage scrub and certain desert habitat. The Coastal Act protects SEAs, streams and wetlands. The term "sensitive resource areas" include these areas. The coastal act defines an ESHA as an area in which the habitat is rare or especially valuable.

Retail Gasoline Outlets

At present, most retail gasoline outlets are operated as fueling facilities only. Automotive repair activities are no longer conducted on these sites. Consistent with this trend, the BMP requirements for retail gasoline outlet with fueling services only have been limited to guidelines in, *Best Management Practices Guide: Retail Gasoline Outlets*, California Stormwater Quality Task Force (1997). Where a retail gasoline outlet provides fueling services and operates a service bay for automotive repair, BMP requirements to reduce storm water pollution from vehicle repair/ maintenance activities would also apply.

Conflicts with Local Practices

[29] Board Order No. 99-060, Pt. 4. 1.D.5. The Long Beach municipal storm water permit states that, "the Standard Urban Storm Water Mitigation Plan [shall] be prepared for...(d) environmentally sensitive areas."

Language has been included to allow changes to provisions in the SUSMP if there is conflict with established local codes, if the modification would not otherwise defeat or circumvent the intent of the SUSMP requirements. This provision of the SUSMP enables municipalities to make changes to the SUSMP to be consistent with local codes and practices without prior approval of the Regional Board Executive Officer where the change has little bearing on SUSMP requirements to reduce storm water pollution.

Provision of Waiver

A waiver provision has been included in the SUSMP to enable municipalities to afford developers and builders the option of in lieu fees where "Impracticability" of storm water treatment can be established. Recognized situations of "Impracticability" include, (i) extreme limitations of space for treatment; (ii) unfavorable or unstable soil conditions for infiltration; and (iii) presumptive risk of groundwater contamination because an underground drinking water source or potential drinking water source is less than ten feet from soil surface.

As proposed, a waiver granted by a municipality for any project is revocable by the Regional Board Executive Officer for cause and with proper notice upon petition. Along with the waiver option is a requirement that the municipality, in turn, require that the cost savings of not implementing SUSMPs be transferred to a storm water mitigation fund, designated by the municipality, to be used to promote regional or alternative solutions for storm water pollution control. A public agency or a non-profit entity must operate the storm water pollution control project. Any other generic basis of 'Impracticability", other than the three listed above, must be submitted by the Co-Permittee to the Regional Board and approved by the Executive Officer before it can take effect. The purpose of the waiver is to provide an alternative for individual projects where storm water treatment is infeasible, while ensuring that storm water pollution control efforts are not obviated by the grant of waiver.

Groundwater Resource Protection

The SUSMP explicitly recognizes that in some circumstances, infiltration BMPs, may not be appropriate because of the risk of contamination of groundwater resources. It identifies the factors that determine potential for groundwater contamination. These are, (i) pollutant mobility; (ii) pollutant abundance in storm water, and (iii) soluble fraction of pollutant. A reference for further information on how to evaluate limitations and potential risk is provided, *Potential Groundwater Contamination from Intentional and Non-Intentional Stormwater Infiltration, Report No. EPA/600/R-94/051, USEPA (1994).*

Alternative Certification Option

The SUSMP includes a provision that authorizes municipalities, in lieu of conducting a detailed plan review, to accept a signed certification by a registered engineer or a licensed architect that the urban storm water mitigation plan submitted by the project proponent meets BMP criteria described in the SUSMP. As initially proposed in the December 7th SUSMP document, the registered engineer or licensed architect was to provide evidence that the certifying person has undergone training on designing BMPs to meet the numerical mitigation criteria and other conditions in the SUSMP not more than two years prior to the signature date on the plan. The training on SUSMP and BMP design criteria may be conducted by any institution with the

relevant expertise. Some such institutions are universities, the American Society of Civil Engineers (ASCE), the American Public Works Association (APWA), the American Society of Landscape Architects (ASLA), and the California Water Environment Association (CWEA). The purpose of the provision was to provide an option for municipalities to limit resource demands on planning departments, without reducing storm water quality protection objective of the SUSMP. While the concept remains desirable, staff will propose a modification that encourages, rather than require, Co-Permittees who elect to accept certifications from registered professional engineers and licensed architects, to verify that the certifying person has been trained, by an institution with expertise, on design of BMPs for water quality.

7.0 SAMPLE APPLICATION OF THE NUMERICAL MITIGATION MEASURE

After the Regional Board Executive Officer approves the SUSMP, municipalities will be expected to implement an urban storm water mitigation plan approval program. The municipality must require that projects that meet the criteria established in the permit and SUSMP prepare and submit an Urban Storm Water Mitigation Plan for approval. Project proponents must identify in the Plan post-construction treatment control BMPs for implementation. The treatment control BMP(s) must be sized or designed to treat the volume/ flow of storm water produced by rainfall events up to and including the design storm (numerical design criteria).

The project proponent will select source control and treatment control BMP(s) from the list approved by the Regional Board in Board Resolution No. 99-03, and included in the SUSMP. For example, for a 100+ home sub-division project, these may include swales (for the parkway); infiltration basin at the end of swale; biofilters (around parking lots); green belts (between rear yards); detention basin (as a lake); and catch-basin basket inserts (for trash). In combination, these treatment control BMPs must be sufficiently sized, i.e., designed and constructed, to treat, infiltrate, or filter the first 0.75 inch of storm water runoff from a storm or a storm event. The urban storm water mitigation plan will specify the treatment control BMPs and other source control BMPs that will be built into the project.

The municipality could then review the Urban Storm Water Mitigation Plan to make sure that it meets the requirements of the SUSMP for the project type. If the SUSMP requirements are met, the municipality may approve the project to proceed. As an alternative, the municipality, may in lieu of detailed plan checking, accept signed certification by a registered engineer or a licensed architect. The municipality may require that the certifying person provide evidence of undergoing training for BMP water quality sizing and other plan requirements. For example, training conducted by institutions with BMP water quality design expertise, within two years of the plan signature date, may be considered qualifying.

Alternatively, if the project proponent can demonstrate that construction of treatment control BMPs are impracticable the municipality may authorize the project proponent to transfer equivalent funds to alternative BMP projects to control storm water pollution managed by a public or non-profit agency. Some examples of recognized situations of impracticability are unstable soil conditions, shallow groundwater, or extreme limitations of space.

8.0 LEGAL AND REGULATORY BASIS FOR ACTION[30]

Regional Board Authority to Adopt the Proposed SUSMP.

The Regional Board has the authority to adopt the proposed SUSMP and numerical mitigation standards for new development and significant redevelopment. Regional Board Order No. 96-054 ("Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges Within the County of Los Angeles") requires that each of the Permittees develop an Urban Storm Water Mitigation Plan following the model approved by the Executive Officer.[31]The proposed action would adopt the model, or Standard Storm Water Mitigation Plan for the Co-Permittees to follow.

Although Order No. 96-054 provides that the Regional Board Executive Officer has authority to approve the model program, as proposed, the current proposal is being submitted to the Board itself for review and endorsement at an upcoming meeting. Following consideration by the Board, the Executive Officer would proceed to approve the SUSMP for Los Angeles County Co-Permittees. In addition, the proposal would make the SUSMP applicable to the City of Long Beach. This is required because the City of Long Beach has a storm water permit (Order No. 99-060 separate from the one applicable to other cities in the County.

The proposed SUSMP would require, *inter alia,* that (a) post-construction treatment control BMPs be required for nine categories of development and (b) the BMPs be designed to mitigate (treat or infiltrate) the runoff from all storms up to 0.75 inch of rainfall for 24-hour period or equivalent runoff volume. These requirements are based upon application of provisions of the Clean Water Act (CWA), section 402(p) and the 1987 Amendments to the CWA. The federal provisions require that a storm water program:

> "* * *
>
> (ii) Shall include a requirement to effectively prohibit non-storm water discharges into storm sewers; and
>
> (iii) Shall require controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants." [Section 402(p)(3)(B), USC Section 1342(p)(3)(B), emphasis added.]

The proposal is an effort to meet the CWA requirements. In a 1992 decision, the U.S. Court of Appeals for the Ninth Circuit (NRDC v. U.S. U.S. EPA, 966 F.2d 1292) interpreted the above language as providing the Administrator or the State with a substantial amount of discretion:

> "[t]he language in (iii), above, requires the Administrator or the State to design controls. Congress did not mandate a minimum standards approach or specify that U.S. EPA

[30] Section 8.0 was prepared by the Regional Board's Legal Counsel, Mr. Jorge Leon

[31] Los Angeles Municipal Permit, (Part III.A., at Page 31.)

develop minimal performance requirements...we must defer to U.S. EPA on matters such as this, where U.S. EPA has supplied a reasoned explanation of its choices."

The decision, sometimes referred to as "NRDC II," stands for the proposition that the U.S. EPA and the States are authorized to require implementation of storm water control activities that, upon "reasoned explanation," accomplish the goals of Section 402(p).

In a very recent decision, the Ninth circuit Court of Appeals reinforced the U.S. EPA's and the State's authority in this area. In Defenders of Wildlife *v.* Browner (1999) Case No. 98-71080, the Ninth Circuit Court of Appeals reviewed an action of the U.S. U.S. EPA to adopt a Storm Water Management Program in the State of Arizona. That program included best management practices such as storm water detention basins, retention basins, and infiltration ponds. The question was whether the U.S. EPA may require numeric limitations to ensure strict compliance with the state water-quality standards. The Court concluded that the CWA does not require strict compliance; however, citing the language of (iii), above, it stated: "[t]hat provision gives the U.S. EPA discretion to determine what pollution controls are appropriate. As this court stated in NRDC II, 'Congress gave the administrator discretion to determine what controls are necessary...[cites omitted] (at page 11687).

The SUSMP proposal is an effort to meet the CWA Section 402(p) requirements and the staff has provided a "reasoned explanation of its choices" in the SUSMP proposal, the staff report, and the accompanying materials. Accordingly, the proposed SUSMP requirements are well within the Regional Board's authority and discretion.

Process under Order 96-054.

The Executive Advisory Committee of the Storm Water Program for Los Angeles County has suggested that the present process, by which the Regional Board will consider endorsement of a storm water program, violates the model program adoption process as set out in Order 96-054.

The argument relies heavily on a premise that the Permit process provides significant notice, review and meet-and-confer protections that will benefit the Co-Permittees. The comment accurately sets forth the storm water program submittal, review, and approval provisions as set forth in Order No. 96-054. However, those provisions must be considered in their full context, including, significantly, the deadline set forth in the permit for implementation. That deadline (July 30, 1999) has come and gone. Because of the lapse of the deadline, the lack of countywide implementation of an effective SUSMP, and the impending expiration of Order No. 96-054 itself, the process prescribed in the permit is now obsolete.

The process now proposed by the Executive Officer would expedite implementation of an effective SUSMP while still effectively providing the protections to the Co-Permittees provided under the Order's scheme. That is, while the proposed process differs from that set forth in Order No. 96-054, it creates no actual prejudice to the Co-Permittees. None is described in the Executive Advisory Committee's (EAC) comment letter of December 22, 1999. To the contrary, in order to provide for program submittal, review, and meet-and-confer, the Executive Officer and staff have held numerous discussions with the Co-Permittees, the County and the EAC regarding the SUSMP proposal, including a workshop held August 10, 1999 and the discussion

before the Regional Board itself of September 16, 1999. During these discussions, several proposals have been exchanged between the staff and the interested parties and the record in this matter now contains a substantial number of comments and responses.

Significantly, the Executive Officer's proposal has the endorsement of the U.S. EPA.[32] Moveover, as a further consideration, the U.S. EPA's October, 1999 "NPDES Program Implementation Review" for this region was critical of the process set forth in Order 96-054 for model program approval.[33]

The unfortunate effect of adopting the EAC's argument to adhere at this time to the scheme laid out in Order 96-054 would be to further seriously delay implementation of the SUSMP without providing any real additional procedural protections to the Co-Permittees. It would also expose the Regional Board to court action for failure to timely move toward program implementation.

Given the circumstances of this matter, the fact that a change of process has not deprived the Co-Permittees of any opportunity to discuss the SUSMP provisions and propose alternatives or any other protections, and the fact that the Regional Board's primary responsibility is to protect the water quality in the Region (Water Code Section 13000), the Board may, within its legal discretion, determine that the best way to do so in the municipal storm water context, is to proceed with the SUSMP proposal under the process presented by staff, rather than delay program implementation.

Compliance with the California Environmental Quality Act.

The City of Los Angeles has requested the "Regional Board's analysis of the potential multi-media environmental impacts from the proposed requirement "(i.e. the California Environmental Quality Act documentation and supporting information developed for this specific discretionary regulatory action." The proposed action is a requirement of Order No. 96-054. The issuance of the order itself, and the requirements contained in the order, is exempt from CEQA (Water Code Section 13389). Accordingly, no specific CEQA documentation has been prepared for this proposal. Nonetheless, the staff has prepared preliminary cost-benefit analyses contained in the supporting material, and these can be provided.

Notice Sufficiency

A party commented that insufficient notice has been provided to the public regarding this matter.
An earlier version of the SUSMP proposal was issued to the public in August 1999 and a public workshop was held on August 10, 1999. Additionally, this matter was heard before the Regional Board during a discussion at its September 16, 1999 meeting. While the only applicable legal notice requirement is 10 days (Govt. Code Section 11125), the Regional Board

---

[32] See Letter of January 13, 2000 to Dennis Dickerson, Executive Officer from Alexis Strauss, Director, Water Division, U.S. EPA.

[33] See NPDES Program Implementation Review: California Regional Water Quality Control Board 4, Los Angeles Region. USEPA, Region 9, Final Report – October 1999., at page 10 of 45. The report notes at page 28 that the process was "...hindering overall progress towards achieving permit objectives".

staff has provided 30 days public notice of the revised version that is currently scheduled to be heard by the Board at its January 26, 2000 meeting. This constitutes adequate legal notice.

Implementation Date.

Order No. 96-054 contemplates that implementation of the SUSMP requirements commence no later that July 30, 1999. Since that date has passed, a new implementation date must be determined following approval of the SUSMP by the Executive Officer. There is no legal standard upon which to base a new implementation date. The Executive Officer is free to establish a revised implementation schedule. Inasmuch as the municipalities will likely be required to adopt or amend existing ordinances to require compliance with the SUSMPS, a new implementation date should take that need into account. I recommendation that the Co-Prmittees be requested to submit comments on this issue and that the Board consider alternatives proposed.

Unfunded Mandate.

The requirements of the proposed SUSMP are not within the definition of "Unfunded Mandates" that would require reimbursement of costs under the California Constitution. This is because the requirements of the SUSMP are derived from the federal Clean Water Act, not from State Law. Inasmuch as the Regional Board staff's proposal would implement a federal requirement, rather than a state requirement, the SUSMP are not unfunded mandates.

Compliance With the Administrative Procedure Act.

The EAC argues that the proposed SUSMP constitutes rulemaking, in violation of the California Administrative Procedure Act, Government Code Section 11340 et.seq. The EAC's objection to the model program adoption process comes approximately three and a half years beyond the legal statute of limitations (Water Code Section 13320 provides 30 days for an aggrieved person to petition for review of a Regional Board action). The model programs provision, contained in Order No. The Regional Board adopted Order No. 96-054, on July 15, 1996. The argument is not only grossly untimely, it is also incorrect. The APA requirements apply only to rulemaking activities. Contrary to the EAC's assertion, the proposed action is not "rulemaking" in nature. Rather, it is the identification of further requirements set forth in permit Order No. 96-054. Under the APA itself, the issuance of such permits is not subject to the rulemaking requirements of the APA (Government Code Section 11352(b).

9.0 RECOMMENDATION

Staff has reviewed the state of current technical practice and the regulatory authority vested with the Regional Board to direct implementation of actions to reduce pollutants in storm water. The municipal storm water program for Los Angeles County and cities is in its ninth year of implementation. The municipal storm water program has been widely criticized as being ineffective and there have been delays in achieving implementation of all facets of the 1996 permit requirements.[34] Some cities have adopted programs embracing many of the elements of

[34] Runoff Remedies will be Complex, Costly, Los Angeles Times, September 6, 1999. M. Cone.

the SUSMP program as proposed, including the numerical design criteria, and the County is using the 0.75 inch design standard (as a result of its own determination of the appropriateness of that value in reaching an accord regarding litigation settlement).

In view of 1) the legal authority of the Regional Board; 2) the practice already in place in a substantial portion of the County; and 3) the need to address the contribution of pollutants from storm water runoff; it is appropriate for the Regional Board to establish numerical design criteria for treatment BMPs for priority development projects. While the staff proposal cites a 0.75 inch standard, the specific design standard to be adopted and a schedule for its implementation remain matters which are within the discretion of the Regional Board.

Staff further recommends that the Regional Board adopt the numerical BMP design standard in the SUSMP as the minimum standard of review for post-construction BMPs, in the Los Angeles Region, for projects subject to coverage under the state general permit for storm water discharges associated with construction activity.

Regional Board staff recommends that the Regional Board endorse the December 7, 1999 staff proposal for SUSMPs with appropriate changes as included in the Change Sheet to be available at the Board meeting, and/or as modified and directed by the Regional Board. Comments are being received as this staff report is being developed and the Change Sheet to be submitted to the Board will likely include revisions based on comments received after the date of this Report.

STANDARD URBAN STORM WATER MITIGATION PLAN

DEVELOPMENT PLANNING

CHANGE SHEET

Summary

The Change Sheet lists proposed changes to the Final Tentative - Standard Urban Storm Water Mitigation Plan, (December 7, 1999). In general, the proposed changes respond to commenters' suggestions on improving clarity, format, and implementability of the Standard Urban Storm Water Mitigation Plan.

Noteworthy changes include, the addition of a definition for 'storm event' and the requirement of professional registration for certifying persons under the "Alternative Certification' option. Two new references have been added to augment implementation guidance. These are, (i) National Stormwater Best Management Practices (BMP) Database, Version 1.0, and (ii) Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices.*

In the Change Sheet, cross-reference to pages and paragraphs are for the 'Marked-up Version' dated January 21, 2000. New text added to a sentence is indicated by underline.

Background

1. Page 2 paragraph three, Clarify that a City has to adopt same requirements for the Citywide SUSMP

   Sentence changed to read, "The Permittees are required to adopt the requirements set herein in their own SUSMP."

2. Page 2 paragraph 3, Delete reference to Urban Storm Water Mitigation to avoid confusion

   Sentence changed to read, "Each Permittee will approve the project plan as part of the development plan approval process....

3. Page 3 paragraph 2, Clarify the environmentally sensitive area category.

   Sentence changed to read, "Location within or directly adjacent to or discharging directly to an environmentally sensitive area.

4. Page 3 paragraph 2, Make requirement applicable to stand-alone parking lots only

   Sentence changed to read, "Commercial stand-alone parking lots 5,000 square feet or more.....

Definitions

5. Order definitions alphabetically

   Definitions reordered alpha-numerically

6. Page 3, Delete exceptions in the definition of Automotive Repair Shop

   Exceptions deleted, now reads, "Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539."

7. Page 3, paragraph 3, Modify definition of 100,000 square foot commercial development for simplicity.

   Definition changed to read, "any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas".

8. Page 4 paragraph, 2, Add references for environmentally sensitive areas

   References added for Areas of Special Biological Significance and Area of Ecological Significance.

9. Page 4, paragraph 8, Change definition to include a threshold trigger for requirements to apply to redevelopment

   Definition changed to read, "Redevelopment" means, on an already developed site, the creation or addition of fifty percent or more of impervious surfaces or the making of improvements to fifty percent or more of the existing structure. Redevelopment includes.....

10. Page 5, paragraph 1, Change definition to clarify 'primarily engaged'.

    Definition changed to read, ""Retail Gasoline Outlet" means a facility engaged in selling gasoline and lubricating oils, which derives more than fifty percent of its annual gross receipts from the sale of gasoline, lubricating oils tires, batteries, automobile parts and other automotive services.

11. Page 5, Define a storm event

    Defined storm event to mean, "a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather."

SUSMP Provisions Applicable to All Categories

12. Page 7, paragraph 2, Change sentence for clarity

    Sentence changed to read, "....shall not exceed the estimated pre-development rate for developments where it is reasonably foreseeable that the increased peak storm water discharge rate will result in increased potential for downstream erosion."

13. Page 7, paragraph 3, Delete text that makes act dependent on effort

    Sentence changed to read, "Concentrate or cluster Development on portions of a site while leaving the remaining land in a natural undisturbed condition."

14. Page 7, paragraph 4, Change sentence for clarity

    Sentence changed to read, "...or the detectable inputs of the pollutant are at a concentrations or loads considered potentially toxic to humans and/or flora and fauna."

15. Page 8, paragraph 1, Add reference

    Added reference, "Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices*"

16. Page 8, paragraph 1, Add text to enable BMP combination alternative

    Added text to read, "However, it is possible that a combination of BMPs not so designated, may in a particular circumstance, be better suited to maximize the reduction of the pollutants".

17. Page 8, paragraph 3, Delete text that is tentative

    Text deleted to read, "Project plans must include BMPs consistent....."

18. Page 8, paragraph 3, Add text to promote use of natural drainage systems

    Add text to read, "Utilize natural drainage systems to the maximum extent practicable"

    17. Page 8, paragraph 3, Add text to minimize fow to natural drainage systems

    Text added to read, "Control or reduce or eliminate flow to natural drainage systems to the maximum extent practicable"

18. Page 9, paragraph 2, Change sentence for clarity

    Sentence changed to read, "Materials with the potential to contaminate storm water must be: (1) placed in an enclosure..."

19. Page 9, paragraph 4, Add text to exclude single family residences

    Sentence added to read, " Individual single family residences are exempt from these requirements"

20. Page 10, paragraph 1, Change text for clarity

    Text changed to read, "The transfer of property to a private or public owner must have conditions..."

21. Page 10, paragraph 1, Add text to require maintenance inspection and record.

    Sentence added to read, "The condition of transfer may include a provision that the property owner conduct maintenance inspection of all treatment control BMPs at least once a year and retain proof of inspection."

22. Page 10, paragraph 3, Delete text for clarity

    Text deleted, "~~each runoff event up to and including~~", Now reads, "the 85th percentile 24-hour runoff event...."

23. Page 10, paragraph 3, Correct based on revised chart treatment volume from 85 percent to 80 percent.

    Text changed to read, "to achieve 80 percent or more volume treatment....."

24. Page 10, paragraph 3, Change text for clarity

    Sentence changed to read, "....runoff produced from a 0.75 inch storm event, prior..."

25. Page 11, paragraph 1, Change text for clarity

    Sentence changed to read, "....volume of runoff produced from a historical-record based reference 24-hour rainfall criterion...."

26. Page 11, paragraph 2, Change text to offer partial credit for roofing surfaces diversion

    Sentence changed to read, "A proportional area of roofing surface may be excluded..."

27. Page 11, paragraph 2, Change text for clarity.

    Sentence changed to read, "storm water conveyance system does not directly discharge to a natural stream or channel segment scheduled for restoration".

28. Page 11, paragraph 3, Change text to clarify exemption from numerical standard only.

    Sentence changed to read, "Restaurants, where the land area for development or redevelopment is less than 5,000 square feet, are excluded from the numerical BMP design standard requirement.

Provisions Applicable to Individual Priority Projects

29. Page 12, paragraph 2, and Page 14, paragraph 1, Change text to eliminate mandatory cover.

    Sentence change to read, "...area must be self-contained and/or covered, equipped with a clarifier,..."

30. Page 14, paragraph 3, Change text for clarity.

    Text modified to read, "....hydrocarbons that are deposited on parking lot surfaces by motor vehicles"

31. Page 14, paragraph 3, Add introductory text.

    Sentence added to read, "To minimize the offsite transport of pollutants, the following design criteria are required".

Waiver

32. Page 15, paragraph 1, Add text for clarity

    Text added to read, "....because an existing or potential underground source of drinking water..."

33. Page 15, paragraph 1, Change text to clarify that Permittee is petitioner.

    Sentence modified to read, "Any other justification for impracticability must be separately petitioned by the Permittee and approved...."

Alternative Certification

34. Page 16, paragraph 1, Change sentences to require professional registration and recommend training verification.

    Sentences added to read "...accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria." And, "The Permittee is encouraged to verify that certifying person(s) have been trained on BMP design for water quality, not more than two years prior to the signature date."

    Reference added, "National Stormwater Best Management Practices (BMP) Database, Version 1.0"

STANDARD URBAN STORM WATER MITIGATION PLAN

FOR LOS ANGELES COUNTY AND CITIES IN LOS ANGELES COUNTY

Revised Final Tentative
January21, 2000.

STANDARD URBAN STORM WATER MITIGATION PLAN

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, requires the development and implementation of a program addressing storm water pollution issues in development planning for private projects. The same requirements are applicable to the City of Long Beach under its separate municipal storm water permit, which was issued on June 30, 1999.

The requirement to implement a program for development planning is based on, federal and state statutes including: Section 402 (p) of the Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 ("CZARA"), and the California Water Code. The Clean Water Act amendments of 1987 established a framework for regulating storm water discharges from municipal, industrial, and construction activities under the NPDES program. The primary objectives of the municipal storm water program requirements are to:

Effectively prohibit non-storm water discharges, and
Reduce the discharge of pollutants from storm water conveyance systems to the Maximum Extent Practicable.

The Standard Urban Storm Water Mitigation Plan (SUSMP) was developed as part of the municipal storm water program to address storm water pollution from new Development and Redevelopment by the private sector. This SUSMP contains a list of the minimum required Best Management Practices (BMPs) that must be used for a designated project. Additional BMPs may be required by ordinance or code adopted by the Permittee and applied generally or on a case by case basis. This SUSMP applies to projects that are Priority Projects (Discretionary Projects) as defined by the NPDES Permit. The Permittees are required to adopt the requirements set herein in their own SUSMP. Developers must incorporate appropriate SUSMP requirements into their project plans. Each Permittee will approve the project plan as part of the development plan approval process and prior to issuing building and grading permits for the projects covered by the SUSMP requirements.

Discretionary projects that fall into one of seven categories are identified in the NPDES Permit as requiring SUSMPs. These categories are:

Single-Family Hillside Residences
100,000 Square Foot Commercial Developments
Automotive Repair Shops

Retail Gasoline Outlets
Restaurants
Home Subdivisions with >10 housing units*

* (Note: this category is two separate categories in the NPDES Permit)

The Regional Board Executive Officer has designated two additional categories subject to SUSMP requirements. These categories are:

Location within or directly adjacent to or discharging directly to an environmentally sensitive area, and Commercial stand-alone parking lots 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to storm water runoff

DEFINITIONS

"100,000 Square Foot Commercial Development" means any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas. ,

"Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

"Best Management Practice (BMP)" means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

"Directly Connected Impervious Area (DCIA)" means the area covered by a building, impermeable pavement, and/ or other impervious surfaces, which drains directly into the storm drain without first flowing across permeable land area (e.g. lawns).

"Discretionary Project" means a project which requires the exercise of judgement or deliberation when the public agency or public body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statutes, ordinances, or regulations.

"Environmentally Sensitive Area" means an area designated as an Area of Special Biological Significance by the State Water Resources Control Board (*Water Quality Control Plan, Los Angeles Region: Basin Plan for the Coastal Watersheds of Los Angeles and Ventura Counties* (1994)) or an area designated as an Area of Ecological Significance by the County of Los *Angeles (Los Angeles County Significant Areas Study, Los Angeles County Department of Regional Planning (1976)*) or an area designated as a significant natural area by the California Resources Agency.

"Greater than (>) 9 unit home subdivision" means any subdivision being developed for 10 or more 10 single-family or multi-family dwelling units.

"Hillside" means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is twenty-five percent or greater.

"Infiltration" means the downward entry of water into the surface of the soil.

"New Development" means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.

"Parking Lot" means land area or facility for the temporary parking or storage of motor vehicles used personally, for business or for commerce.

Redevelopment" means, on an already developed site, the creation or addition of fifty percent or more of impervious surfaces or the making of improvements to fifty percent or more of the existing structure. Redevelopment includes, but is not limited to: the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/ or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; and land disturbing activities related with structural or impervious surfaces.

"Restaurant" means a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812).

"Retail Gasoline Outlet" means a facility engaged in selling gasoline and lubricating oils, which derives more than fifty percent of its annual gross receipts from the sale of gasoline, lubricating oils tires, batteries, automobile parts and other automotive services.

"Source Control BMP" means any schedules of activities, prohibitions of practices, maintenance procedures, managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

"Storm Event" means a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather.

"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both treatment control BMPs and source control BMPs.

"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

"Treatment Control BMP" means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

CONFLICTS WITH LOCAL PRACTICES

Where provisions of the SUSMP requirements conflict with established local codes, (e.g., specific language of signage used on storm drain stenciling), the Permittee may continue the local practice and modify the SUSMPs contained herein to be consistent with the code, except where those practices would defeat or circumvent the intent of the SUSMP requirements.

SUSMP PROVISIONS APPLICABLE TO ALL CATEGORIES

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Post-development peak storm water runoff discharge rates shall not exceed the estimated pre-development rate for developments where it is reasonably foreseeable that the increased peak storm water discharge rate will result in increased potential for downstream erosion.

2. CONSERVE NATURAL AREAS

If applicable, the following items are required and must be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- Concentrate or cluster Development on portions of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants. Wherever practical, promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

3. MINIMIZE STORM WATER POLLUTANTS OF CONCERN

Storm water runoff from a site has the potential to contribute oil and grease, suspended solids, metals, gasoline, pesticides, and pathogens to the stormwater conveyance system. The development must be designed so as to minimize, to the maximum extent practicable, the introduction of pollutants of concern that may result in significant impacts, generated from site

runoff of directly connected impervious areas (DCIA), to the storm water conveyance system as approved by the building official. Pollutants of concern, , consist of any pollutants that exhibit one or more of the following characteristics: current loadings or historic deposits of the pollutant are impacting the beneficial uses of a receiving water, elevated levels of the pollutant are found in sediments of a receiving water and/or have the potential to bioaccumulate in organisms therein, or the detectable inputs of the pollutant are at a concentrations or loads considered potentially toxic to humans and/or flora and fauna.

In meeting this specific requirement, "minimization of the pollutants of concern" will require the incorporation of a BMP or combination of BMPs best suited to maximize the reduction of pollutant loadings in that runoff to the Maximum Extent Practicable. Those BMPs best suited for that purpose are those listed in the *California Storm Water Best Management Practices Handbooks*; *Caltrans Storm Water Quality Handbook: Planning and Design Staff Guide*; *Manual for Storm Water Management in Washington State*; *The Maryland Stormwater Design Manual*; *Florida Development Manual: A Guide to Sound Land and Water Management*; Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices* and *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* , USEPA Report No. EPA-840-B-92-002, as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question. However, it is possible that a combination of BMPs not so designated, may in a particular circumstance, be better suited to maximize the reduction of the pollutants.

Examples of BMPs that can be used for minimizing the introduction of pollutants of concern generated from site runoff are identified in Table 2. Any BMP not specifically approved by the Regional Board in Resolution No. 99-03, "Approving Best Management Practices for Municipal Storm Water and Urban Runoff Programs in Los Angeles County", for development planning may be used if they have been recommended in one of the above references.

4. PROTECT SLOPES AND CHANNELS

Project plans must include BMPs consistent with local codes and ordinances to decrease the potential of slopes and/or channels from eroding and impacting storm water runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Utilize natural drainage systems to the maximum extent practicable
- Control or reduce or eliminate flow to natural drainage systems to the maximum extent practicable
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion, with the approval of all agencies with jurisdiction, e.g., the U.S. Army Corps of Engineers and the California Department of Fish and Game

5. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins within the project area must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.
- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted at public access points along channels and creeks within the project area.
- Legibility of stencils and signs must be maintained.

6. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Outdoor material storage areas refer to storage areas or storage facilities solely for the storage of materials. Improper storage of materials outdoors may provide an opportunity for toxic compounds, oil and grease, heavy metals, nutrients, suspended solids, and other pollutants to enter the stormwater conveyance system. Where proposed project plans include outdoor areas for storage of materials that may contribute pollutants to the stormwater conveyance system, the following *structural* BMPs are required:

- Materials with the potential to contaminate storm water must be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.
- The storage area must be paved and sufficiently impervious to contain leaks and spills.
- Where feasible, the storage area must have a roof or awning to minimize collection of stormwater within the secondary containment area.

7. PROPERLY DESIGN TRASH STORAGE AREAS

A trash storage area refers to an area where a trash receptacle or receptacles are located for use as a repository for solid wastes.

Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas must meet the following *structural BMP* requirements (individual single family residences are exempt from these requirements):

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).
- Trash container areas must be screened or walled to prevent off-site transport of trash.

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons why water quality controls will not function as designed or which may cause the system to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included, or is required to include, treatment control BMPs in project plans, the Permittee shall require that the applicant provide verification of maintenance provisions through such means as may be appropriate, including, but not limited to legal agreements, covenants, CEQA mitigation requirements and/or Conditional Use Permits.

For all properties, the verification will include the developer's signed statement, as part of the project application, accepting responsibility for all structural and treatment control BMP maintenance until the time the property is transferred and, where applicable, a signed agreement from the public entity assuming responsibility for structural or treatment control BMP maintenance. The transfer of property to a private or public owner must have conditions requiring the recipient to assume responsibility for maintenance of any treatment control BMP to be included in the sales or lease agreement for that property, and will be the owner's responsibility. The condition of transfer may include a provision that the property owner conducts maintenance inspection of all treatment control BMPs at least once a year and retain proof of inspection. For residential properties where the treatment control BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&Rs). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what stormwater management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. It will also encourage the transfer of this information with subsequent sale of the property.

If treatment control BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. Treatment control BMPs proposed for transfer must meet design standards adopted by the public entity for the BMP installed and should be approved by the County or other appropriate public agency prior to its installation.

9. DESIGN STANDARDS FOR TREATMENT CONTROL BMPS

Treatment control BMPs selected for use at any project covered by this SUSMP shall meet the design standards of this Section unless specifically exempted.

a. Post-construction Treatment Control BMPs shall be designed to:

A. mitigate (infiltrate or treat) storm water runoff from either:

1. the 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998)*, or

2. the volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in *California Stormwater Best Management Practices Handbook – Industrial/ Commercial*, (1993), or

3. the volume of runoff produced from a 0.75 inch storm event, prior to its discharge to a storm water conveyance system, or

4. the volume of runoff produced from a historical-record based reference 24-hour rainfall criterion for "treatment" (0.75 inch average for the Los Angeles County area) that achieves approximately the same reduction in pollutant loads achieved by the 85th percentile 24-hour runoff event,

AND

B. control peak flow discharge to provide stream channel and over bank flood protection, based on flow design criteria selected by the local agency.

A proportional area of roofing surface may be excluded from the total area for calculation of rainfall or runoff volume to be treated provided:

a. the roofing materials will not be a source of pollutants of concern in storm water, and

b. storm water from the roofing surface area is diverted directly to a storm water conveyance system, and

c. roof based exhaust systems, vents, filters, and air pollution control devices will not present a significant source of pollutants of concern in storm water, and

d. the storm water conveyance system does not directly discharge to a natural stream or channel segment scheduled for restoration.

Exclusions

Restaurants, where the land area for development or redevelopment is less than 5,000 square feet, are excluded from the numerical BMP design standard requirement.

10. PROVISIONS APPLICABLE TO INDIVIDUAL PRIORITY PROJECT CATEGORIES

REQUIREMENTS

A. 100,000 SQUARE FOOT COMMERCIAL DEVELOPMENTS

1. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water runon or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, consider including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained and or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

B. RESTAURANTS

1. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

Outdoor equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, include in the project plans an area for the washing/steam cleaning of equipment and accessories. This area must meet the following:

- This area must be self-contained, equipped with a grease trap, and properly connected to a sanitary sewer.
- If this wash area is to be located outdoors, it must be covered, paved, have secondary containment, and be connected to the sanitary sewer.

C. RETAIL GASOLINE OUTLETS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. The project plans must include the following BMPs:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The canopy's minimum dimensions must be equal to or greater than the area within the grade break. The canopy must not drain onto the fuel dispensing area, and the canopy downspouts must be routed to prevent drainage across the fueling area.
- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water to the extent practicable.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

D. AUTOMOTIVE REPAIR SHOPS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. Therefore, design plans, which include fueling areas, must contain the following:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The cover's minimum

dimensions must be equal to or greater than the area within the grade break. The cover must not drain onto the fuel dispensing area and the downspouts must be routed to prevent drainage across the fueling area.

- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, consider including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained and/or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer or to a permitted disposal facility.

4. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

E. PARKING LOTS

1. PROPERLY DESIGN PARKING AREA

Parking lots contain pollutants such as heavy metals, oil and grease, and polycyclic aromatic hydrocarbons that are deposited on parking lot surfaces by motor vehicles. These pollutants are directly transported to surface waters. To minimize the offsite transport of pollutants, the following design criteria are required:

- Reduce impervious land coverage of parking areas
- Infiltrate runoff before it reaches storm drain system.
- Treat runoff before it reaches storm drain system

2. PROPERLY DESIGN TO LIMIT OIL AND PERFORM MAINTENANCE

Parking lots may accumulate oil, grease, and water insoluble hydrocarbons from vehicle drippings and engine system leaks.

- Treat to remove oil and petroleum hydrocarbons at parking lots that are heavily used (e.g. fast food outlets, lots with 25 or more parking spaces , sports event parking lots, shopping malls, grocery stores, discount warehouse stores)
- Ensure adequate operation and maintenance of treatment systems particularly sludge and oil removal, and system fouling and plugging prevention control

11. WAIVER

A Permittee may, through adoption of an ordinance or code incorporating the treatment requirements of the SUSMP, provide for a waiver from the requirement if impracticability for a specific property can be established. Recognized situations of impracticability include, (i) extreme limitations of space for treatment on a redevelopment project, (ii) unfavorable or unstable soil conditions at a site to attempt infiltration, and (iii) risk of ground water contamination because an existing or potential underground source of drinking water is less than 10 feet from the soil surface. Any other justification for impracticability must be separately petitioned by the Permittee and approved by the Regional Board Executive Officer before it becomes recognized and effective. A waiver granted by a Permittee to any development or redevelopment project may be revoked by the Regional Board Executive Officer for cause and with proper notice upon petition.

If a waiver is granted for impracticability, the Permittee must require the project proponent to transfer the savings in cost, as determined by the Permittee, to a storm water mitigation fund to be used to promote regional or alternative solutions for storm water pollution in the storm watershed and operated by a public agency or a non-profit entity.

12. LIMITATION ON USE OF INFILTRATION BMPS

Three factors significantly influence the potential for storm water to contaminate ground water. They are (i) pollutant mobility, (ii) pollutant abundance in storm water, (iii) and soluble fraction

of pollutant. The risk of contamination of groundwater may be reduced by pretreatment of storm water. A discussion of limitations and guidance for infiltration practices is contained in, *Potential Groundwater Contamination from Intentional and Non-Intentional Stormwater Infiltration, Report No. EPA/600/R-94/051, USEPA (1994).*

In addition, the distance of the groundwater table from the infiltration BMP may also be a factor determining the risk of contamination. A water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic.

Infiltration BMPs are not recommended for areas of industrial activity or areas subject to high vehicular traffic (25,000 or greater average daily traffic (ADT) on main roadway or 15,000 or more ADT on any intersecting roadway) unless appropriate pretreatment is provided to ensure groundwater is protected and the infiltration BMP is not rendered ineffective by overload.

13. ALTERNATIVE CERTIFICATION FOR STORM WATER TREATMENT MITIGATION

In lieu of conducting detailed BMP review to verify treatment control BMP adequacy, a Permittee may elect to accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria established herein. The Permittee is encouraged to verify that certifying person(s) have been trained on BMP design for water quality, not more than two years prior to the signature date.,. Trainingconducted by an organization with storm water BMP design expertise (e.g., a University, American Society of Civil Engineers, American Society of Landscape Architects, American Public Works Association, or the California Water Environment Association) may be considered qualifying.

14. RESOURCES AND REFERENCE

TABLE 2

EXAMPLE BEST MANAGEMENT PRACTICES (BMPS)

The following are examples of BMPs that can be used for minimizing the introduction of pollutants of concern that may result in significant impacts, generated from site runoff to the storm water conveyance system. (See Table 1: Suggested Resources for additional sources of information):

- Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths must still comply with regulations for the Americans with Disabilities Act and other life safety requirements.
- Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.
- Comply with all zoning and applicable ordinances to minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.
- Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).
- Use open space development that incorporates smaller lot sizes.
- Reduce building density.
- Comply with all zoning and applicable ordinances to reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.
- Comply with all zoning and applicable ordinances to reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.
- Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas, and avoid routing rooftop runoff to the roadway or the storm water conveyance system.
- Vegetated swales and strips
- Extended/dry detention basins
- Infiltration basin
- Infiltration trenches
- Wet ponds
- Constructed wetlands
- Oil/Water separators
- Catch basin inserts
- Continuous flow deflection/ separation systems
- Storm drain inserts
- Media filtration
- Bioretention facility
- Dry-wells
- Cisterns
- Foundation planting
- Catch basin screens
- Normal flow storage/ separation systems
- Clarifiers
- Filtration systems
- Primary waste water treatment systems

STANDARD URBAN STORM WATER MITIGATION PLANS

SUMMARY OF COMMENTS RECEIVED AND RESPONSE

The comments received on the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Regional Board staff response is divided into two sections. The first sections, lists main issues and staff response in detail. The second section summarizes all significant comments received by the Board on SUSMP before December 6, 1999, and the staff response including any actions taken to address the comment.

A. MAIN ISSUES AND RESPONSE

1. **Comment**:The Regional Board lacks regulatory discretion to establish a numerical mitigation measure for storm water treatment.

Response: The municipal storm water permit for Los Angeles County and Cities requires that SUSMPs achieve specific objectives which include to (i) minimize adverse impacts to natural communities; (ii) maximize infiltration to the extent practicable; (iii) minimize parking lot pollution; (iv) provide for appropriate controls to reduce storm water pollutant loads.[1] Staff interprets this provision of the permit, underlying federal law, and the statutory standard of Maximum Extent Practicable (MEP) as requiring SUSMPs to incorporate numerical mitigation measures for development planning projects in order to achieve compliance with water quality standards. Without a numerical mitigation measure, developers will select no treatment BMPs because there will be no BMP sizing guideline. Board Resolution No. 99-03 which states that "The Permittees shall select and require implementation of the most effective BMPs,...." will then be without effect.[2]

The 1987 Clean Water Act amendments give USEPA and States considerable discretion on establishing provisions for implementation in storm water programs.[3] Further, interim USEPA policy guidelines on BMPs for storm water programs explains that the permitting authority can require more specific conditions or limitations to meet water quality

---

[1] Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles (Board Order No. 96-054; NPDES No. CAS614001). Part 2. III.A.2)

[2] The Regional Board adopted Resolution No. 99-03 approving BMPs for Development Planning and Development Construction on April 22, 1999.

[3] 33 U.S.C. Section 1342(p)(B)(iii). "require controls to reduce the discharge of pollutants to the maximim extent practicable, including management practices, control techniques and systems, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of pollutants."

standards where adequate information exists.[4] In addition, courts accord administrative agencies a high degree of deference in the areas of law they regulate.[5]

2. **Comment:** Anti-degradation policy prohibits new construction when water quality is already impaired.

Response: The municipal storm water permit in agreement with federal storm water regulations requires controls on new development to reduce storm water pollution. There is no prohibition on new construction.

3. **Comment**: The numerical mitigation criteria mandates the capture of storm water which will require expensive land acquisition cost.

Response: The numerical mitigation measure defines the definite volume of storm water that must be treated for water quality benefits. Treatment is the application of any physical, biological, or chemical method that can be used to remove pollutants in storm water. Providing storage volume for the runoff or capture is one form of treatment. It is not mandatory and other options may be considered such as reducing impervious cover and promoting infiltration.

4. **Comment**: The proposed numerical mitigation measure is not based on science and is an arbitrarily agreed to number in settlement of a lawsuit.

Response: The proposed numerical measures are technically defensible. The measures are based on the principle that most rainfall events are in the smaller range and higher rainfall runoff producing events are less frequent. Designing storm water treatment controls for the smaller events will reduce storm water pollutant loads significantly while optimizing BMP costs. The primary numerical method to determine BMP design criteria is the maximized water quality treatment volume method recommended by the American Society of Civil Engineers (ASCE). The 0.75-inch rainfall event method happens to be also the one that was agreed to in a lawsuit settlement agreement between the NRDC and the County of Los Angeles. The four methods proposed as choices are equivalent variants and in a technical comparison were in agreement to within 10% of one another. It is highly probable that parties that settle a litigation select a numerical criterion that is reasonable and factual.

5. **Comment**: The numerical mitigation measure will require implementation of BMPs that have not been proven to be effective in the region.

Response: The proposed numerical mitigation measure defines the quantity of storm water (volume) that has to be treated to remove pollutants. This criterion does not in anyway describe the effectiveness of BMPs to be used. The effectiveness of any particular BMP is dependent on design parameters and the range for its applications. Physical geography has little influence on the effectiveness of BMPs while proper

[4] 61 Fed. Register 43761. "The interim permitting approach uses best management practices in first-round strom water permits, and expanded or better-tailored BMPs in subsequent permits, where necessary, to provide for the attainment of water quality standards. In cases where adequate information exists to develop more specific conditions or limitations to meet water quality standards, these conditions or limitations are to be incorporated into storm water permits, as necessary and appropriate."

[5] See, e.g., Chevron U.S.A. v. Natural Res. Def. Council, (1984) 467 U.S. 837

maintenance is a big factor. Information on BMP effectiveness can be found in research reports and national BMP databases. The numerical mitigation measure in combination with the effectiveness of a BMP determines the overall annual load of pollutant that can be removed.

6. **Comment**: The post-construction treatment BMPs will require costly maintenance

Response: Treatment BMPs do require proper maintenance and maintenance costs are BMP specific. Poor or non-existent maintenance will result in an ineffective BMP. Information on BMP maintenance costs can be obtained from national databases and reports. See references in the Record of Decision. A cursory review indicates that maintenance costs are reasonable.

7. **Comment**: The Regional Board did not perform an economic analysis required by State and Federal law.

Response: The implementation of a federal regulation does not require separate economic analysis. A relative quantitative comparison performed with similar criteria for storm water management or flood control, sediment removal from construction, combined animal feedlot operations, and State of Washington water quality criteria indicated that the numerical mitigation criteria would cost about three to ten times less. In addition, staff performed BMP cost calculations for an actual site in Los Angeles in the process of development and determined that the mitigation criteria cost is less than 0.5 percent of the project cost.

8. **Comment**: The Regional Board did not provide adequate public notices to interested parties.

Response: Regional Board action was not contemplated at the September Regional Board meeting and thus no public notice was necessary. Nevertheless, Board staff provided a 30-day public notice and mailed a copy to all parties on file. Staff was unable to verify the claim by some that they did not receive copies of the public notice or provide an explanation. Staff will again provide 30 day-notice of the proposed action on the SUSMPs scheduled by the Regional Board for January 6, 2000.

B. SUMMARY OF ALL SIGNIFICANT COMMENTS AND RESPONSE

COMMENTER	COMMENT	RESPONSE	ACTION
General City of Los Angeles, Western States Petroleum Association	1. Conduct first a quantitative review of the basis of designation of selected categories as priority-planning projects.	The categories are designated in the permit and were selected based on risk sources data compiled in the first term of permit implementation.	No action necessary
Los Cerritos Channel Task Force	2. Provide level playing field for unincorporated and incorporated cities within LA County	Four methods of determining the mitigation measure are provided to ensure some flexibility. The methods are equivalent. See ROD	Four equivalent methods included as mitigation criteria in SUSMP

COMMENTER	COMMENT	RESPONSE	ACTION
Bellflower, Claremont, Commerce, Covina, Diamond Bar, Downey, Huntington Park, Industry, Irwindale, Lakewood, La Mirada, Lomita, Lynwood, Maywood, Montebello, Paramount, Norwalk, Rancho Palos Verdes, Santa Fe Springs, Whittier	3. No other MS 4 permits in California require numerical criteria for runoff mitigation	All MS4 permits are required to have controls on new development and redevelopment that will reduce pollutants to the MEP. The USEPA has identified the lack of specific criteria as a deficiency in its Report to Congress ON Phase II (1999)	No action necessary
SCAG	4. Provide the opportunity for the development of regional BMPs instead of site by site requirements	May be considered by Board in a Resolution	Will suggest interest to Regional Board
SCAG	5. Make the numerical mitigation measure voluntary pilot program for the first two years.	Federal laws and regulations require that controls on new development and redevelopment be enforceable	No action necessary
Santa Monica	6. More studies not necessary to establish mitigation criteria and evaluate BMPs	We agree that there exists sufficient information to establish numerical mitigation criteria and to design BMP for optimum performance and effectiveness.	No action necessary
Bellflower, Claremont, Commerce, Covina, Diamond Bar, Downey, Huntington Park, Industry, Irwindale, Lakewood, La Mirada, Lomita, Lynwood, Maywood, Montebello, Paramount, Norwalk, Rancho Palos Verdes, Santa Fe Springs, Whittier	7. Numerical mitigation measure is an unfunded mandate	Implementation of a federal permit program is not an unfunded mandate as described in the State constitution. See memo from legal counsel.	No action necessary
Bellflower, Claremeont, Commerce, Covina, Diamond Bar, Downey, Huntington Park, Industry, Irwindale, Lakewood, La Mirada, Lomita, Long Beach, Los Angeles, Lynwood, Maywood, Montebello, Paramount, Norwalk, Rancho Palos Verdes, Santa Clarita, Santa Fe Springs, Vernon, Whittier, BIA, EAC, New Hall Land and Farming, Long Beach Chamber of Commerce	8. Numerical mitigation measure is not based on sound science	Disagree. Our review of local data and implementation programs in states such as WA, FL, and MD indicates that the approach to establishing numerical mitigation measure is scientific and reasonable. The methods have also been endorsed by national science and engineering associations.	References to important documents provided in the SUSMP. A bibliography of references reviewed for the action is included in the ROD.
Bellflower, Cerritos, Claremont, Commerce, Covina, Diamond Bar, Downey, Huntington Park, Industry, Irwindale, Lakewood, La Mirada, Lomita, , Long Beach, Lynwood, Maywood, Montebello, Paramount, Norwalk, Rancho Palos Verdes, Santa Fe Springs, Whittier	9. Treatment controls will be required irrespective of siting factors limiting application.	Site conditions will determine what BMPs are appropriate. A provision for waiver is provided where mitigation may be infeasible. Mitigation banking may be an alternative.	Waiver provision has been included in the SUSMP where impracticability is established.
Covina, Irwindale, La Mirada, Lomita, Norwalk, Whittier	10. Provide sufficient time for Council of Governments to review and comment	Staff will mail and e-mail copies to SCAG for distribution to COGs.	Staff will mail public notice of proposed action to SCAG and COGs.
Cerritos, Diamond Bar	11. Developers will move to build in counties without numerical mitigation measures.	The mitigation measure requirement for new development is based on federal law. Other Regional Boards are likely to develop and evaluate compliance using similar criteria. The USEPA considers the absence of numerical storm water BMP design criteria for new development a deficiency. See USEPA Phase II Final Rule	No action necessary.

COMMENTER	COMMENT	RESPONSE	ACTION
Bellflower, Cerritos, Claremont, Commerce, Covina, Diamond Bar, Downey, Huntington Park, Industry, Irwindale, Lakewood, La Mirada, Lomita, , Long Beach, Lynwood, Maywood, Montebello, Paramount Glendora, , Norwalk Rancho Palos Verdes, Santa Fe Springs, Whittier, Truxaw and Associates, Long Beach Chamber of Commerce	12. BMPs will require costly maintenance	Maintenance of BMPs is essential and strategies to support maintenance activities are discussed in USEPA's Phase II Final Rule.	No action necessary.
Azusa, Claremont, EAC	13. Perform cost benefit analysis	The implementation of federal law does not require a separate cost benefit analysis. Relative cost comparisons and BMP cost calculations performed indicate that the cost of the mitigation measure is reasonable for the water quality benefits it will bring.	No action necessary
Centex Homes, Desert Partners, Bill Ehrlich, FORMA, Engineering Contractors Association, Greystone Homes, John Laing Homes, Mid-cities Escrow, JTL, New Hall Land and Farming, New Urban West, Pace Engineering, Pacific bay Homes, Pacific Soils Engineering, David Placek, Psomas, Ramseyer, Rasmussen, Shea Homes, Sikand, Southern California Contractors, Southern California Ready Mix Concrete Assoc., South Place Corp., SunCal Co., Taylsor Woodrow., Tetra Tech, Van Tilburg and Associates, Warmington Homes, Western Pacific Housing, LA County Supervisor Knabe,	14. SUSMP is stringent enough without the numerical mitigation measure	Without the numerical mitigation measure the SUSMP does not provide adequate guidance on design criteria for BMPs. Thus no treatment BMPs or BMPs inadequately sized may be selected with no benefit to water quality. The USEPA in the preamble to Phase II Final Rule makes the same observation.	No action necessary.
Technical Heal the Bay, American Oceans Campaign, Friends of the LA River, NRDC, Kudo and Daniels, Fusion Films, Santa Monica BayKeeper, Ballona Wetlands Foundation, AHHA, H & K Interiors, Kinsella & Associates, AKERS Entertainment, Ballesteros, Stenstrom-UCLA, Chatten Broan & Assoc., South Bay SurfRider (13 members), Shatz	15. Establish for all municipalities in LA County the 0.75-inch mitigation measure or similar criteria for development planning currently in effect for the unincorporated areas.	The proposed criteria provide for the treatment of 0.75 inch or equivalent volume of runoff from new development for all areas of LA County within the jurisdiction of the Regional Board.	Criteria is made applicable to all MS4 permittees in LA county
Heal the Bay, American Oceans Campaign, Friends of the LA River,	16. Require SUSMPs for development in environmentally sensitive areas	The requirement is included for the City of Long Beach but was not one of the priority categories specifically identified in the LA County MS4 permit.	This category has been added to the SUSMP.
Heal the Bay, American Oceans Campaign, Friends of the LA River,	17. Require mitigation of runoff from parking lots separately in each SUSMP	This is not one of the priority categories specifically identified in the LA County MS4 permit. Commercial categories specifically included have indicated that they are no different than parking lots. In addition, the Coastal Commission has often consulted the Board for appropriate BMPs and criteria.	This category has been added to the SUSMP.

COMMENTER	COMMENT	RESPONSE	ACTION
NRDC	18. Apply SUSMP requirement broadly rather than limit it to seven categories	A BMP checklist is already required for other priority projects. Expanding the SUSMP requirement may be appropriate once TMDLs have been allocated and other significant sources need to be controlled.	Two categories have been added: locations in environmentally sensitive areas, and parking lots.
County of Ventura and cities	19. Include an alternative method based on volumetric and flow which uses capture of annual runoff and peak flow rate control	An equivalent volumetric method is provided based on annual volume capture. Flow rate controls are left to the judgement of the local agency.	Eight five percent treatment of annual runoff volume is provided as an equivalent mitigation criteria.
Heal the Bay, American Oceans Campaign, Friends of the LA River,	20. Define hillside development and not defer definition to the local municipality	Will provide a general definition.	Defined in SUSMP.
Heal the Bay, American Oceans Campaign, Friends of the LA River,	21. Apply requirements for retail gasoline outlets to any facility with a fuelling dispenser.	This is not one of the priority categories specifically identified in the LA County MS4 permit. Expansion of the applicability may be appropriate once TMDLs have been allocated and other significant sources need to be controlled.	No action necessary
WSPA, San Gabriel Basin Water Quality Authority	22. Requirement for infiltration will promote pathways for groundwater and soil contamination	Risks for ground water contamination exist under certain situations. These are identified in a report by the USEPA (1993). Pre-treatment of storm water will reduce such risks. The soil acts as a natural filter and self regenerates.	A section is included in the SUSMP describing the limitations of infiltration BMPs.
Truxaw and Associates	23. Promote non structural BMPs	SUSMPs already require source control BMPs in addition to structural BMPs and treatment control BMPs	No action necessary.
Land Tech Engineering	24. Provide design specifications for BMPs based on criteria	Expect that BMP design specification will be developed by the municipalities based on the numerical mitigation measure. Interim BMP design information may be obtained from manuals developed by other states.	No action necessary.
Centex Homes, Engineering Contractors Assoc., John Laing Homes, Land Tech Engineering, Pace Engineering, Pacific Soils Engineering, David Placek, Ramseyer, Rasmusen, Sikand, Southern California Contractors, Southern California Ready Mix Concrete Assoc., Tetra Tech, South Place Corp., Taylor Woodrow, Western Pacific Housing, LA New Car Dealers Ass.	25. Staff proposal requires capture which is not the same as infiltration or treatment	Storm water capture is not mandatory. The proposal only requires that a certain quantity of storm water be treated with BMPs to remove pollutants in one of several ways.	No action necessary.
Vernon, Los Angeles	26. Require similar criteria for USEPA Phase I industrial facilities	The requirements are for new development in selected categories. Expansion to other categories may be considered for the next permit term. Will recommend application to construction permits in the LA Region covered by the State General Storm Water permit for construction activity.	Will propose to the Board to consider in its Resolution that the same
Brash,	27. Filter media is not an effective BMP	Disagree. Filter media are effective BMPs if properly configured. See letter to Brash from RB Executive Officer date Oct. 19, 1999.	No action necessary.

COMMENTER	COMMENT	RESPONSE	ACTION
Santa Clarita	28. Provide criteria for flow based controls in addition to volumetric based controls	Flow based controls which are essential to maintain BMP effectiveness, reduce flow velocities, minimize downstream erosion potential, and prevent over bank flooding are left to the judgement of the local agency.	A statement has been included in the SUSMP that flow design criteria be determined by the local agency.
Santa Clarita	29. Limit application of criteria to impervious surfaces	The criterion is applied to the whole area. Credit for the pervious areas is automatically considered through the runoff coefficient. Roofing areas have been excluded for commercial facilities.	No action necessary.
Santa Clarita, EAC	30. Provide greater flexibility in application of the mitigation criteria	The four methods of selecting the numerical mitigatio through criteria and waiver procedures offer sufficient flexibility in application	Provide in the SUSMP four equivalent methods of determining the numerical mitigation measure.
Los Angeles	31. The numerical mitigation measure should be a guidelines and not a requirement for land development	Federal laws and regulations require that controls on new development and redevelopment be enforceable.	No action necessary.
Legal Los Angeles	32. Setting a numerical mitigation measure is a discretionary action. Provide cost estimates of impacts and benefits and release documentation for public comment and review under CEQA.	The requirements under an NPDES permit are exempt from review under CEQA. Preliminary costing estimates indicate that they are reasonable.	No action necessary.
Los Angeles	33. Identify the regulatory authority, which authorizes the Regional Board to establish the numerical mitigation measure.	Regulatory requirement is found at 40 CFR 122.26 (d)(2)(iv)(A) (2). Statutory authority is at 33 USC 342(p)(B)(iii). See also court's opinion in Defenders of Wildlife v. Browner (No. 98-71080) (9th Cir. 1999) and in NRDC v. USEPA 966 F2d. 1292 (9th Cir. 1992)	No action necessary.
Los Angeles	34. Setting a numerical mitigation measure is a discretionary action. Provide cost estimates of impacts and benefits and release documentation for public comment and review under CEQA.	The requirements under an NPDES permit are exempt from review under CEQA. Preliminary costing estimates indicate that they are reasonable.	No action necessary.
Western States Petroleum Association (WSPA)	35. Postpone consideration because of inadequate notice.	A thirty-day notice on this action has been provided. A thirty-day notice on the September 1999 Board meeting was provided even though it was not required for a Regional Board Information item.	No action necessary.
Apartment Association, BIA	36. There is no regulatory requirement that there be a numerical measure	Disagree. See detailed explanation under main issues and response.	No action necessary.
NRDC	37. Receiving water limits and anti-degradation policies apply independently from mitigation criteria.	Agree that mitigation standards are separate from the numerical mitigation measure. The Office of Chief Counsel confirms that MS4 programs must meet water quality standards in a memo dated October 14, 1999	No action necessary.
Burke, Williams & Sorenson	38. Provide broad legal authority for the SUSMP requirement	We will include legal citations that are relevant to the jurisdiction of the Regional Board.	Relevant laws are cited in the SUSMP to provide legal justification.
Burke, Williams & Sorenson	39. Delay SUSMP requirements in light of PL 106-74 requiring USEPA to submit reports to Congress.	The USEPA has already submitted the reports to Congress and thus no delay is warranted.	No action necessary.

COMMENTER	COMMENT	RESPONSE	ACTION
Santa Monica BayKeeper	40. New development can be prohibited under the Federal Anti-degradation policy if it degrades or adds pollutants to local waters	Disagree. See detailed explanation under main issues and response.	No action necessary.
EAC, Downey, Lakewood	41. Provide authority in the Clean Water Act to regulate flow to address water quality.	The U.S. Supreme Court has held that regulation of flow to protect beneficial uses is within the authority of the Clean Water Act PUD No. 1 v. WA Dept. of Ecology, 511 U.S. 700 (1994)	No action necessary.

STANDARD URBAN STORM WATER MITIGATION PLANS

SUMMARY OF COMMENTS RECEIVED (SINCE DECEMBER 6, 1999) AND RESPONSE - SUPPLEMENT

COMMENTER	COMMENT	RESPONSE	ACTION
General Claremont, West Covina, CRA, EAC, New Hall Land	1. Postpone issuance of SUSMP until SUSMP recirculated for further study and comment.	SUSMP was public noticed to provide a 30 day review period	No action recommended
Diamond Bar West Covina, EAC, New Hall Land.	2. Should not enlarge scope of SUSMPs to include two new categories: parking lots & environmentally sensitive areas. Defer to for consideration in next permit.	Categories are already included in Long Beach permit. RB Executive Officer has discretionary authority to designate additional sources of pollutants for management.	No action recommended
City of Long Beach: Attorney	3. Revise findings in Tentative Resolution to reflect two separate permits are affected by this resolution.	Changes to the Tentative Resolution will be considered.	Will amend resolution
Diamond Bar, EAC	4. No notice to meet has been issued for the SUSMP deficiency.	RB Executive Officer has met with parties repeatedly.	No action recommended
Heal the Bay, NRDC	5. Change "Retail Gasoline Outlet" definitions to include all facilities with gas pumps.	Definition has been changed to clarify primary activity, which is the more than 50 percent sale of automotive related products.	Amended definition
West Covina, EAC, CEA, , County of LA Dept. of Public Works, Heal the Bay, State of California Santa Monica Mountains Conservancy	6. Make definitions unambiguous (Hillside, Environmentally Sensitive Areas, Redevelopment)	Will revise definitions based on comments	Amended definitions
Heal the Bay, NRDC	7. Change the "Hillside" definition- grading with occur naturally where slope is 15% or greater & plans include cut or fill slopes 30 feet high or greater.	Definition has been changed to 25 percent natural slope.	Amended definitions
Public Works Agency County of Ventura	8. Require protection of unconfined groundwater basins	Protection of unconfined may be an appropriate consideration	No action recommended at this time.
City of Rancho Palos Verdes, EAC	9. Include numerical standard trigger for hillside SUSMP to 1 acre or more.	Hillside has been defined on 25 percent slope. No basis for acreage threshold.	Amended definitions
South Gate, EAC	8. Available guidelines to "conserve natural areas" are too vague for implementation	Disagree. Guidelines are sufficiently clear without being prescriptive.	No action recommended
County of LA Dept. of Public Works,	10. Delete the statement, " "each Permittee will approve an USMP" because it is not consistent with the Model Program.	The sentence has been changed to delete the USMP reference.	Amended sentence

COMMENTER	COMMENT	RESPONSE	ACTION
State of California Santa Monica Mountains Conservancy	11. Require that funds be available to provide for BMP Maintenance.	BMP maintenance is a necessary component of SUSMP implementation. Permittees are best able to identify source of funds.	No action recommended
California Coastal Commission	12. SUSMP requirements as is will improve water quality	Requirements are intended to minimize water quality impacts of development.	No action recommended
Technical AbTech Industries, Air Liquide, AKERS Entertainment Marketing, California Coastal Commission, CALPIRG, CDS Technologies Inc., La Canada Flintridge, Pasadena: Public Works & Transportation Department, South Gate, Cruz/Kravetz: IDEAS, JBI Process Equipment, Ballona Wetlands Foundation, Center for Marine Conservation, Center for Watershed Protection, 13 Citizen Comment Letters, Community Coalition for Change, County of LA Dept. of Public Works, Defend the Bay, Earth Communications Office, Environmental Defense Center, Friends of the LA River, Heal the Bay, Malibu Bay Company, NRDC, Public Works Agency Ventura County, Santa Monica Baykeeper, Sierra Club, South Bay Surfrider Chapter, Stainless Industrial Companies, University of Alabama, University of Georgia	13. Support the "3/4-inch" criteria because it is a Design Standard **not** a "Numerical Limit". The standard is reasonable for storm water runoff and makes economic sense for the greater Los Angeles area.	The design is statistically based and reasonable.	No change recommended
Ventura County Flood Control District	14. Peak Flow Rate control condition for BMP design indicates confusion between requirements for peak flow rate control versus a standard that allows the use of low flow-based water quality treatment control BMPs.	The peak flow rate condition is intended to limit down-stream erosion and over-bank flooding. Criteria for flow-sensitive BMPs will need to be developed in the future. Suggest BMP use consistent with manufacturer specs for now.	No action recommended at this time.
Ventura County Flood Control District	15. SUSMP design options are not technically equivalent- request a review of backup calculations and modifications of the percent capture to reflect equivalent standards.	Reviewed calculations and corrected percent capture to 80 percent.	Design standard for percent capture amended.
San Gabriel Valley Council of Gov'ts, South Bay Cities Council of Gov'ts	16. Defer inclusion of numeric standards until an evaluation of effectiveness treatment control BMPs for the pollutants of concern .	The numeric design standard has no bearing on effectiveness. BMP effectiveness data is available from national databases.	No action recommended.

COMMENTER	COMMENT	RESPONSE	ACTION
San Gabriel Valley Council of Govts, South Bay Cities Council of Govts	17. Defer inclusion of numeric standards into SUSMPs until an "out clause" has been established in the event a numeric standard can't be met for reasons of economy or feasibility.	The SUSMP already includes a waiver for recognized conditions when implementation of the design standard is impracticable.	No action recommended.
ASCE-Los Angeles Section, BIA, CEA, City of Long Beach: Office of City Attorney, EAC, New Hall Land, San Gabriel Valley Council of Govts, South Bay Cities Council of Govts	18. Empirical data on the efficacy of numerical design standards as a minimum are unavailable. There is also lack of data proving the numerical standards are cost effective.	Disagree. See discussion in Staff Report.	No action recommended.
SCAG	19. The use of "numeric standards" should be used as a "backup" policy, not a "front-end" policy, when identified priority pollution problems are not mitigated.	Federal regulations require that pollutants in storm water be reduced to the maximum extent practicable. A design standard is proper.	No action recommended.
West Covina, County of LA Dept. of Public Works, EAC	20. SUSMP should not apply to storm water runoff which does not flow across a source of pollutants.	SUSMP applies to the total project. Treatment mitigation credit is allowed for directly connected roof surface area.	No action recommended.
West Covina	21. Include a parking lot credit for use of vegetation on parking lot islands.	Parking lot requirements promote infiltration. Separate credit is not required for island areas.	No action recommended.
Heal the Bay, NRDC, Malibu Bay Company, USEPA, Ventura County Flood Control District	22. Remove the roofing exclusion in order not to encourage increase in impervious areas	Roofing exclusion credit is limited to situations where water quality impact is minimal.	No action recommended.
Heal the Bay, NRDC	23. Remove small restaurant exemption- no correlation between the size of a restaurant and amount of pollution it produces.	Small restaurant exemption applies only for BMP design standard criteria. All other requirements remain the same.	No action recommended.
Legal West Covina, Heal the Bay	24. State legal basis for Permittee City to take remedial action against a private party.	Legal basis will be applicable provisions in the federal Clean Water Act, the State Water Code, the MS4 permit, and local codes and ordinances	No action recommended.
Calif. SWQTF	25. Requirements intrude into local government responsibility and have more than regional significance.	Requirements are proposed consistent with federal storm water regulations. See Staff Report, Section 8: Legal and Regulatory Basis	No action recommended.
State of California Santa Monica Mountains Conservancy	26. The SUSMP Waiver section provides loopholes for developers to use.	Waiver provision provides relief if impracticability is established.	No action recommended.
USEPA	27. The requirements of the proposed SUSMP are consistent with the requirements of the CWA, applicable NPDES regulation, and EPA guidance.	Agree that requirements are consistent with state and federal law.	No action recommended.
NRDC	28. Eliminate the Self-Certification option for SUSMP review.	The third party certification option is intended to limit resource demands on municipalities. Will discourage use of the option for significant projects.	No action recommended.

STANDARD URBAN STORM WATER MITIGATION PLAN

DEVELOPMENT PLANNING

CHANGE SHEET (Revised)

Summary

The Change Sheet lists proposed changes to the Final Tentative - Standard Urban Storm Water Mitigation Plan, (December 7, 1999). In general, the proposed changes respond to commenters' suggestions on improving clarity, format, and implementability of the Standard Urban Storm Water Mitigation Plan.

Noteworthy changes include, the addition of a definition for 'storm event' and the requirement of professional registration for certifying persons under the "Alternative Certification' option. Two new references have been added to augment implementation guidance. These are, (i) National Stormwater Best Management Practices (BMP) Database, Version 1.0, and (ii) Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices.*

In the Change Sheet, cross-reference to pages and paragraphs are for the 'Clean Version' dated December 7, 2000. New text added to a sentence is indicated by underline.

Background

1. Page 2 paragraph three, Clarify that a City has to adopt same requirements for the Citywide SUSMP

   Sentence changed to read, "The Permittees are required to adopt the requirements set herein in their own SUSMP."

2. Page 2 paragraph 3, Delete reference to Urban Storm Water Mitigation to avoid confusion

   Sentence changed to read, "Each Permittee will approve the project plan as part of the development plan approval process....

3. Page 3 paragraph 2, Clarify the environmentally sensitive area category.

   Sentence changed to read, "Location within or directly adjacent to or discharging directly to an environmentally sensitive area.

4. Page 3 paragraph 2, Make requirement applicable to stand-alone parking lots only

   Sentence changed to read, "Commercial stand-alone parking lots 5,000 square feet or more.....

Definitions

5. Order definitions alphabetically

   Definitions reordered alpha-numerically

6. Page 3, Modify definition of hillsides to add specificity.

   Definition changed to read, "property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is twenty-five percent or greater."

7. Page 3, Delete exceptions in the definition of Automotive Repair Shop

   Exceptions deleted, now reads, "Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539."

8. Page 3, Modify definition of 100,000 square foot commercial development for simplicity.

   Definition changed to read, "any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas".

9. Page 4 , Add references for definition of environmentally sensitive areas

   References added for Areas of Special Biological Significance and Area of Ecological Significance.

10. Page 4, , Change definition to include a threshold trigger for requirements to apply to Redevelopment

    Definition changed to read, "Redevelopment" means, on an already developed site, the creation or addition of fifty percent or more of impervious surfaces or the making of improvements to fifty percent or more of the existing structure. Redevelopment includes.....

11. Page 5, , Change definition for Retail gasoline outlets to clarify 'primarily engaged'.

    Definition changed to read, ""Retail Gasoline Outlet" means a facility engaged in selling gasoline and lubricating oils, which derives more than fifty percent of its annual gross receipts from the sale of gasoline, lubricating oils tires, batteries, automobile parts and other automotive services.

12. New Definition, Define a storm event

    Defined storm event to mean, "a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather."

SUSMP Provisions Applicable to All Categories

13. Page 5, paragraph 3, Change sentence for clarity

    Sentence changed to read, "....shall not exceed the estimated pre-development rate for developments where it is reasonably foreseeable that the increased peak storm water discharge rate will result in increased potential for downstream erosion."

14. Page 5, paragraph 4, Delete text that makes act dependent on effort

Sentence changed to read, "Concentrate or cluster Development on portions of a site while leaving the remaining land in a natural undisturbed condition."

15. Page 6, paragraph 1, Change sentence for clarity

    Sentence changed to read, "...or the detectable inputs of the pollutant are at a concentrations or loads considered potentially toxic to humans and/or flora and fauna."

16. Page 6, paragraph 2, Add reference

    Added reference, "Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices*"

17. Page 6, paragraph 3, Add text to enable BMP combination alternative

    Added text to read, "However, it is possible that a combination of BMPs not so designated, may in a particular circumstance, be better suited to maximize the reduction of the pollutants".

18. Page 6, paragraph 4, Delete text that is tentative

    Text deleted to read, "Project plans must include BMPs consistent....."

19. Page 6, paragraph 4, Add text to promote use of natural drainage systems

    Add text to read, "Utilize natural drainage systems to the maximum extent practicable"

19. Page 6, paragraph 4, Add text to minimize flow to natural drainage systems

    Text added to read, "Control or reduce or eliminate flow to natural drainage systems to the maximum extent practicable"

20. Page 7, paragraph 2, Change sentence for clarity

    Sentence changed to read, "Materials with the potential to contaminate storm water must be: (1) placed in an enclosure..."

21. Page 7, paragraph 3, Add text to exclude single family residences

    Sentence added to read, " Individual single family residences are exempt from these requirements"

22. Page 8, paragraph 1, Change text for clarity

    Text changed to read, "The transfer of property to a private or public owner must have conditions..."

23. Page 8, paragraph 1, Add text to require maintenance inspection and record.

    Sentence added to read, "The condition of transfer may include a provision that the property owner conduct maintenance inspection of all treatment control BMPs at least once a year and retain proof of inspection."

24. Page 8, paragraph 3, Delete text for clarity

    Text deleted, "~~each runoff event up to and including~~", Now reads, "the 85th percentile 24-hour runoff event...."

25. Page 8, paragraph 3, Correct based on revised chart treatment volume from 85 percent to 80 percent.

    Text changed to read, "to achieve 80 percent or more volume treatment....."

26. Page 8, paragraph 3, Change text for clarity

    Sentence changed to read, "....runoff produced from a 0.75 inch storm event, prior..."

27. Page 8, paragraph 3, Change text for clarity

    Sentence changed to read, "....volume of runoff produced from a historical-record based reference 24-hour rainfall criterion...."

28. Page 9, paragraph 2, Change text to offer partial credit for roofing surfaces diversion

    Sentence changed to read, "A proportional area of roofing surface may be excluded..."

29. Page 9, paragraph 2, Change text for clarity.

    Sentence changed to read, "storm water conveyance system does not directly discharge to a natural stream or channel segment scheduled for restoration".

30. Page 9, paragraph 3, Change text to clarify exemption from numerical standard only.

    Sentence changed to read, "Restaurants, where the land area for development or redevelopment is less than 5,000 square feet, are excluded from the numerical BMP design standard requirement.

Provisions Applicable to Individual Priority Projects

31. Page 10, paragraph 2, and Page 12, paragraph 1, Change text to eliminate mandatory cover.

    Sentence change to read, "...area must be self-contained and/or covered, equipped with a clarifier,..."

32. Page 12, paragraph 3, Change text for clarity.

    Text modified to read, "....hydrocarbons that are deposited on parking lot surfaces by motor vehicles"

33. Page 12, paragraph 3, Add introductory text.

    Sentence added to read, "To minimize the offsite transport of pollutants, the following design criteria are required".

Waiver

34. Page 13, paragraph 1, Add text for clarity

    Text added to read, "....because an existing or potential underground source of drinking water..."

35. Page 13, paragraph 1, Change text to clarify that Permittee is petitioner.

    Sentence modified to read, "Any other justification for impracticability must be separately petitioned by the Permittee and approved...."

Alternative Certification

36. Page 13, paragraph 1, Change sentences to require professional registration and recommend training verification.

    Sentences added to read "...accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria." And, "The Permittee is encouraged to verify that certifying person(s) have been trained on BMP design for water quality, not more than two years prior to the signature date."

Suggested Resources

37. Page 15, Add reference BMP database and on-line Texas Non-point Source Book

    Reference added, "National Stormwater Best Management Practices (BMP) Database, Version 1.0" ; and "Texas Non-Point Source Book".

STANDARD URBAN STORM WATER MITIGATION PLAN

FOR LOS ANGELES COUNTY AND CITIES IN LOS ANGELES COUNTY

LOS ANGELES COUNTY URBAN RUNOFF AND STORM WATER NPDES PERMIT

STANDARD URBAN STORM WATER MITIGATION PLAN

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, requires the development and implementation of a program addressing storm water pollution issues in development planning for private projects. The same requirements are applicable to the City of Long Beach under its separate municipal storm water permit, which was issued on June 30, 1999.

The requirement to implement a program for development planning is based on, federal and state statutes including: Section 402 (p) of the Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 ("CZARA"), and the California Water Code. The Clean Water Act amendments of 1987 established a framework for regulating storm water discharges from municipal, industrial, and construction activities under the NPDES program. The primary objectives of the municipal storm water program requirements are to:

- Effectively prohibit non-storm water discharges, and
- Reduce the discharge of pollutants from storm water conveyance systems to the Maximum Extent Practicable.

The Standard Urban Storm Water Mitigation Plan (SUSMP) was developed as part of the municipal storm water program to address storm water pollution from new Development and Redevelopment by the private sector. This SUSMP contains a list of the minimum required Best Management Practices (BMPs) that must be used for a designated project. Additional BMPs may be required by ordinance or code adopted by the Permittee and applied generally or on a case by case basis. This SUSMP applies to projects that are Priority Projects (Discretionary Projects) as defined by the NPDES Permit. The Permittees are required to use this SUSMP to develop their own citywide SUSMP. Developers must incorporate appropriate SUSMP requirements into their project plans. Each Permittee will approve an Urban Storm Water Mitigation Plan as part of the development process and prior to issuing building and grading permits for the projects covered by the SUSMP requirements.

Discretionary projects, that fall into one of seven categories are identified in the NPDES Permit

as requiring SUSMPs. These categories are:

Single-Family Hillside Residences
100,000 Square Foot Commercial Developments
Automotive Repair Shops
Retail Gasoline Outlets
Restaurants
Home Subdivisions with >10 housing units*

* (Note: this category is two separate categories in the NPDES Permit)

The Regional Board Executive Officer has designated two additional categories subject to SUSMP requirements. These categories are:

Location adjacent to or discharging to an environmentally sensitive area, and
Parking lot 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to storm water runoff

DEFINITIONS

"Greater than (>) 9 unit home subdivision" means any subdivision being developed for 10 or more 10 single-family or multi-family dwelling units.

"100,000 Square Foot Commercial Development" means Developments based on total impermeable area, including parking areas, as opposed to lot size or building footprint.

"Retail Gasoline Outlet" means a facility primarily engaged in selling gasoline and lubricating oils. These establishments frequently sell other merchandise, such as tires, batteries, and automobile parts. Frequently, these establishments also perform minor automotive repair work. Gasoline stations combined with other activities, such as grocery stores, convenience stores, or car wash facilities, are classified according to the primary activity.

"Hillside" means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope and where grading contemplates cut or fill slopes .

"Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539. Exceptions do apply for SIC codes 5013, 5014, and 5541. For SIC code 5013, if the business has no outside storage of any recycled oil or other hazardous substances, it is not included. For SIC code 5014, if the business does not engage in any repair work, it is not included. For SIC code 5541, if the business does not engage in any onsite repair work, it is not included.

"Restaurant" means a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812)

"Parking Lot" means land area or facility for the parking of commercial or business or private motor vehicles.

"Environmentally Sensitive Area" means an area designated as an Area of Special Biological Significance by the State Water Resources Control Board or an area designated as a Significant Natural Area by the California Resources Agency or an area designated as an area of Ecological Significance by the County of Los Angeles.

"Best Management Practice (BMP)" means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

"Source Control BMP" means any schedules of activities, prohibitions of practices, maintenance procedures,, managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

"Treatment Control BMP" means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both treatment control BMPs and source control BMPs.

"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

"Infiltration" means the downward entry of water into the surface of the soil.

"Directly Connected Impervious Area (DCIA)" means the area covered by pavement, building and other impervious surfaces which drain directly into the storm drain without first flowing across pervious areas (e.g. lawns).

"New Development" means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.

Redevelopment" means, on an already developed site, the creation or addition of impervious surfaces; the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/ or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; land disturbing activities related with structural or impervious surfaces .

"Discretionary Project" means a project which requires the exercise of judgement or deliberation when the public agency or public body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statutes, ordinances, or regulations.

CONFLICTS WITH LOCAL PRACTICES

Where provisions of the SUSMP requirements conflict with established local codes , (e.g., specific language of signage used on storm drain stenciling), the Permittee may continue the local practice and modify the SUSMPs contained herein to be consistent with the code, except where those practices would defeat or circumvent the intent of the SUSMP requirements.

SUSMP PROVISIONS APPLICABLE TO ALL CATEGORIES

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Post-development peak storm water runoff discharge rates shall not exceed estimated pre-development levels for developments where an increased peak storm water discharge rate may result in a foreseeable increased potential for downstream erosion.

2. CONSERVE NATURAL AREAS

If applicable, the following items are required and must be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- Every effort shall be made to concentrate or cluster development on portions of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants. Wherever practical, promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

3. MINIMIZE STORM WATER POLLUTANTS OF CONCERN

Storm water runoff from a site has the potential to contribute oil and grease, suspended solids, metals, gasoline, pesticides, and pathogens to the stormwater conveyance system. The development must be designed so as to minimize, to the maximum extent practicable , the introduction of pollutants of concern that may result in significant impacts, generated from site runoff of directly connected impervious areas (DCIA), to the storm water conveyance system as

approved by the building official. Pollutants of concern, as defined by the Permit, consist of any pollutants that exhibit one or more of the following characteristics: current loadings or historic deposits of the pollutant are impacting the beneficial uses of a receiving water, elevated levels of the pollutant are found in sediments of a receiving water and/or have the potential to bioaccumulate in organisms therein, or the detectable inputs of the pollutant are at a level high enough to be considered potentially toxic to humans and/or flora and fauna.

In meeting this specific requirement, "minimization of the pollutants of concern" will require the incorporation of a BMP or combination of BMPs best suited to maximize the reduction of pollutant loadings in that runoff to the Maximum Extent Practicable. Those BMPs best suited for that purpose are those listed in the *California Storm Water Best Management Practices Handbooks*; *Caltrans Storm Water Quality Handbook: Planning and Design Staff Guide*; *Manual for Storm Water Management in Washington State*; *The Maryland Stormwater Design Manual*; *Florida Development Manual: A Guide to Sound Land and Water Management*; and *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* , USEPA Report No. EPA-840-B-92-002, as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question..

Examples of BMPs that can be used for minimizing the introduction of pollutants of concern generated from site runoff are identified in Table 2. Any BMP not specifically approved by the Regional Board in Resolution No. 99-03, "Approving Best Management Practices for Municipal Storm Water and Urban Runoff Programs in Los Angeles County", for development planning may be used if they have been recommended in one of the above references.

4. PROTECT SLOPES AND CHANNELS

If applicable, project plans must include BMPs consistent with local codes and ordinances to decrease the potential of slopes and/or channels from eroding and impacting storm water runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion, with the approval of all agencies with jurisdiction, e.g., the U.S. Army Corps of Engineers and the California Department of Fish and Game

5. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins within the project area must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.
- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted at public access points along channels and creeks within the project area.
- Legibility of stencils and signs must be maintained.

6. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Outdoor material storage areas refer to storage areas or storage facilities solely for the storage of materials.
Improper storage of materials outdoors may provide an opportunity for toxic compounds, oil and grease, heavy metals, nutrients, suspended solids, and other pollutants to enter the stormwater conveyance system. Where proposed project plans include outdoor areas for storage of materials that may contribute pollutants to the stormwater conveyance system, the following *structural* BMPs are required:

- Areas where materials are to be stored must be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.
- The storage area must be paved and sufficiently impervious to contain leaks and spills.
- Where feasible, the storage area should have a roof or awning to minimize collection of stormwater within the secondary containment area.

7. PROPERLY DESIGN TRASH STORAGE AREAS

A trash storage area refers to an area where a trash receptacle or receptacles are located for use as a repository for solid wastes.
Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas must meet the following *structural BMP* requirements:

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).
- Trash container areas must be screened or walled to prevent off-site transport of trash.

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons why water quality controls will not function as designed or which may cause the system to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included, or is required to include, treatment control BMPs in project plans, the Permittee shall require that the applicant provide verification of maintenance provisions through such means as may be appropriate, including, but not limited to legal agreements, covenants, CEQA mitigation requirements and/or Conditional Use Permits.

For all properties, this verification will include the developer's signed statement, as part of its project application, accepting responsibility for all structural BMP maintenance until the time the property is transferred and, where applicable, a signed agreement from the public entity assuming responsibility for structural BMP maintenance. This transfer of property must have conditions requiring the recipient to assume responsibility for maintenance of any treatment control BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility. For residential properties where the treatment control BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&R's). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what stormwater management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. It will also encourage the transfer of this information with subsequent sale of the property.

If treatment control BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. Treatment control BMPs proposed for transfer must meet design standards adopted by the public entity for the BMP installed and should be approved by the County or other appropriate public agency prior to its installation.

9. DESIGN STANDARDS FOR TREATMENT CONTROL BMPS

Treatment control BMPs selected for use at any project covered by this SUSMP shall meet the design standards of this Section unless specifically exempted.

a. Post-construction Treatment Control BMPs shall be designed to:

A. mitigate (infiltrate or treat) storm water runoff from either:

1. each runoff event up to and including the 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998)*, or

2. the volume of annual runoff based on unit basin storage water quality volume, to achieve 85 percent or more volume treatment by the method recommended in *California Stormwater Best Management Practices Handbook – Industrial/ Commercial,* (1993), or

3. the volume of runoff produced from each and every storm event up to and including 0.75 inch of rainfall, prior to its discharge to a storm water conveyance system, or

4. the volume of runoff produced from each and every storm event up to and including a historical-record based reference 24-hour rainfall criterion for "treatment" (0.75 inch average for the Los Angeles County area) that achieves approximately the same reduction in pollutant loads achieved by the 85th percentile 24-hour runoff event,

AND

B. control peak flow discharge to provide stream channel and over bank flood protection, based on flow design criteria selected by the local agency.

The area of roofing surfaces may be excluded from the total area for calculation of rainfall or runoff volume to be treated provided:

a. the roofing materials will not be a source of pollutants of concern in storm water, and

b. storm water from the roofing surfaces is diverted directly to a storm water conveyance system, and

c. roof based exhaust systems, vents, filters, and air pollution control devices will not present a significant source of pollutants of concern in storm water, and

d. the storm water conveyance system does not directly or indirectly discharge to a natural stream or unlined channel or channel segment scheduled for restoration.

Exclusions

Restaurants, where the land area for development or redevelopment is less than 5,000 square feet, are excluded from the requirements of this Section.

10. PROVISIONS APPLICABLE TO INDIVIDUAL PRIORITY PROJECT CATEGORIES

A. 100,000 SQUARE FOOT COMMERCIAL DEVELOPMENTS

1. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water runon or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, consider including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained, covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

B. RESTAURANTS

1. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

Outdoor equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, include in the project plans an area for the washing/steam cleaning of equipment and accessories. This area must meet the following:

- This area must be self-contained, equipped with a grease trap, and properly connected to a sanitary sewer.
- If this wash area is to be located outdoors, it must be covered, paved, have secondary containment, and be connected to the sanitary sewer.

C. RETAIL GASOLINE OUTLETS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. The project plans must include the

following BMPs:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The canopy's minimum dimensions must be equal to or greater than the area within the grade break. The canopy must not drain onto the fuel dispensing area, and the canopy downspouts must be routed to prevent drainage across the fueling area.
- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water to the extent practicable.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

D. AUTOMOTIVE REPAIR SHOPS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. Therefore, design plans, which include fueling areas, must contain the following:

- Fuel dispensing areas should be covered with an overhanging roof structure or canopy. The cover's minimum dimensions must be equal to or greater than the area within the grade break. The cover must not drain onto the fuel dispensing area and the downspouts must be routed to prevent drainage across the fueling area.
- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water.
- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. To alleviate this problem, consider including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained, covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer or to a permitted disposal facility.

4. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

E. PARKING LOTS

1. PROPERLY DESIGN PARKING AREA

Parking lots contain pollutants such as heavy metals, oil and grease, and polycyclic aromatic hydrocarbons that deposit on these surfaces from motor vehicle traffic. These pollutants are directly transported to surface waters.

- Reduce impervious land coverage of parking areas
- Infiltrate runoff before it reaches storm drain system.
- Treat runoff before it reaches storm drain system

2. PROPERLY DESIGN TO LIMIT OIL AND PERFORM MAINTENANCE

Parking lots may accumulate oil, grease, and water insoluble hydrocarbons from vehicle drippings and engine system leaks.

- Treat to remove oil and petroleum hydrocarbons at parking lots that are heavily used (e.g. fast food outlets, lots with 25 or more parking spaces , sports event parking lots, shopping malls, grocery stores, discount warehouse stores)
- Ensure adequate operation and maintenance of treatment systems particularly sludge and oil removal, and system fouling and plugging prevention control

11. WAIVER

A Permittee may, through adoption of an ordinance or code inc incorporating the treatment requirements of the SUSMP, provide for a waiver from the requirement if impracticability for a specific property can be established. Recognized situations of impracticability include (i) extreme limitations of space for treatment on a redevelopment project, (ii) unfavorable or unstable soil conditions at a site to attempt infiltration, and (iii) risk of ground water contamination because an underground source of drinking water is less than 10 feet from the soil surface. Any other justification for impracticability must be separately approved by the Regional Board Executive Officer before it becomes recognized and effective. A waiver granted to any development or redevelopment project may be revoked by the Regional Board Executive Officer for cause and with proper notice upon petition.

If a waiver is granted for impracticability, the Permittee must require the project proponent to transfer the savings in cost, as determined by the Permittee, to a storm water mitigation fund to be used to promote regional or alternative solutions for storm water pollution in the storm watershed and operated by a public agency or a non-profit entity.

12. LIMITATION ON USE OF INFILTRATION BMPS

Three factors significantly influence the potential for storm water to contaminate ground water. They are (i) pollutant mobility, (ii) pollutant abundance in storm water, (iii) and soluble fraction of pollutant. The risk of contamination of groundwater may be reduced by pretreatment of storm water. A discussion of limitations and guidance for infiltration practices is contained in, *Potential Groundwater Contamination from Intentional and Non-Intentional Stormwater Infiltration, Report No. EPA/600/R-94/051, USEPA (1994).*

In addition, the distance of the groundwater table from the infiltration BMP may also be a factor determining the risk of contamination. A water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic.

Infiltration BMPs are not recommended for areas of industrial activity or areas subject to high vehicular traffic (25,000 or greater average daily traffic (ADT) on main roadway or 15,000 or more ADT on any intersecting roadway) unless appropriate pretreatment is provided to ensure groundwater is protected and the infiltration BMP is not rendered ineffective by overload.

13. ALTERNATIVE CERTIFICATION FOR STORM WATER TREATMENT MITIGATION

A Permittee may elect to accept a signed certification that the plan meets the criteria established herein and that the plan preparer has undergone training on designing BMPs to meet the numerical mitigation criteria, in lieu of conducting detailed BMP review to verify treatment control BMP adequacy. The training must have been conducted by an organization with storm

water BMP design expertise (e.g., a University, American Society of Civil Engineers, American Society of Landscape Architects, or the California Water Environment Association) with the training and curriculum accepted by the Regional Board Executive Officer. For the certification to be valid, training must have been received not more than two years prior to the signature date on the plan.

TABLE 2: Example Best Management Practices (BMPs)

The following are examples of BMPs that can be used for minimizing the introduction of pollutants of concern that may result in significant impacts, generated from site runoff to the storm water conveyance system. (See Table 1: Suggested Resources for additional sources of information):

- Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths must still comply with regulations for the Americans with Disabilities Act and other life safety requirements.
- Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.
- Comply with all zoning and applicable ordinances to minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.
- Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).
- Use open space development that incorporates smaller lot sizes.
- Reduce building density.
- Comply with all zoning and applicable ordinances to reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.
- Comply with all zoning and applicable ordinances to reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.
- Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas, and avoid routing rooftop runoff to the roadway or the storm water conveyance system.
- Vegetated swales and strips
- Extended/dry detention basins
- Infiltration basin
- Infiltration trenches
- • Wet ponds
- Constructed wetlands
- • Oil/Water separators
- • Catch basin inserts
- • Continuous flow deflection/ separation systems
- • Storm drain inserts
- Media filtration
- • Bioretention facility
- Dry-wells
- Cisterns
- • Foundation planting
- Catch basin screens
- Normal flow storage/ separation systems
- Clarifiers
- Filtration systems
- Primary waste water treatment systems

Los Angeles, California 90013

Re: Proposed Model Standard Urban Storm Water Mitigation Plans (SUSMPs)
Los Angeles County Municipal Stormwater Permit (NPDES No. CAS0061654)

Dear Mr. Dickerson and Members of the Board:

The Natural Resources Defense Council ("NRDC") is a national environmental organization with over 400,000 members, approximately 35,000 of whom live within the Los Angeles region. NRDC has reviewed the "Proposed Standard Urban Storm Water Mitigation Plan" (the "Proposal") issued on December 7, 1999 as a proposed "model program" of the Los Angeles County Municipal Storm Water Permit (the "Los Angeles Permit"), and as the remaining unfinished element of the Long Beach Municipal Storm Water Permit (the "Long Beach Permit"). We submit the following comments[1] on behalf of NRDC, Heal the Bay, the Santa Monica BayKeeper, and their respective members (collectively, "NRDC").

Introduction

NRDC Position

While NRDC strongly supports the Regional Board Staff's retention of the 0.75-inch numerical standard initially embraced in its August, 1999 proposal, we are extremely disappointed that Staff has included a host of exceptions, exemptions, and general limitations on the scope of the program that, collectively, render that numerical standard virtually meaningless. Taken as a whole, these limitations so severely undermine the impact of the numerical standard that it is genuinely questionable whether that standard will ever actually be effectuated. It appears that the Regional Board Staff ("Staff") has maintained the numerical standard only as a token concession to the requirements of the Clean Water Act, while essentially capitulating to the cries of those municipalities who are reflexively opposed to the idea of having to implement such a standard.

[1] In addition, NRDC joins in the comments submitted by Heal the Bay, in its letter of January 14, 2000, and those submitted by the Santa Monica Mountains Conservancy, in its letter of December 16, 1999. We also hereby incorporate our previous comments, submitted with our letter of September 9, 1999 ("September Letter"), attached hereto (without exhibits) as Exhibit A, which, in turn, incorporated the comments submitted by the Santa Monica BayKeeper on the same date, and those submitted by Heal the Bay on September 7, 1999.

www.nrdc.org

These exceptions, exemption, and general limitations are collectively so significant that they must be eliminated if the Proposal is to have any meaningful impact on local water quality. **We therefore urge the Regional Board to adopt a revised version of the current Proposal that includes no such limitations.**[2]

The approval of the Proposal without exceptions is of critical importance to the future of the region's water quality. As we noted in the September Letter, the Center for Watershed Protection (the "Center"), one of the preeminent national authorities on watershed management, has determined that "a fundamentally different approach toward development [is] needed to reliably protect streams and other aquatic resources." Site Planning for Urban Stream Protection (Center, Dec. 1995) at 1, attached hereto as Exhibit B. Indeed, **development planning is generally recognized as one of the most critical aspects of any stormwater management program, and specific performance standards are essential to the effectiveness of these programs.**

Thus, in sum:

(1) NRDC strongly agrees with Staff's proposal to include a numerical standard in the Standard Urban Stormwater Mitigation Plan ("SUSMP").

(2) NRDC also supports, as minimally-acceptable, the specific standard selected. The wealth of experiences and data from around the country, as described more fully below, lead undeniably to the conclusion that such a standard is eminently feasible, from a practical perspective; well supported, both scientifically and technically; and already broadly embraced in practice.

However, NRDC strongly opposes:

(1) the suite of exceptions, exemptions, and limitations on the scope of this program, which effectively gut the Proposal and render it as a paper exercise with very little real-world impact

Structure of this Letter

In order to protect receiving waters from ever-increasing amounts of development-related stormwater pollution, an effective development planning program must include, among other things, two elements: it must contain a specific design standard that will ensure the adequate sizing of structural best management practices ("BMPs"), and it must establish an implementation system to ensure that the standard selected is put into place. This letter is divided into two major sections, following that two-part division, with multiple subsections within each.

[2] Because of the different manner in which the Los Angeles Permit and the Long Beach Permit are being handled, the Regional Board should actually adopt the revised version of the Proposal recommended herein (for Long Beach) and instruct the Executive Officer to do the same (for Los Angeles).

The first major section of this letter addresses the implementation system. It explains in detail how the current Proposal takes away with one hand the protections that it appears to establish – via the adoption of a numerical sizing standard – with the other. We describe six separate categories of exceptions, exemptions, and general limitations that appear throughout the Proposal, all of which contribute to the weakening, and eventual complete evisceration, of the numerical standard adopted in the Proposal.

The second major section of this letter addresses the numerical standard proposed by Staff. We begin by providing compelling, indeed overwhelming evidence, supporting the practicability, effectiveness, and reasonable costs associated with the 0.75-inch standard. We also respond to some of the objections raised by many of the municipalities during the September 16, 1999 hearing. In each case, the municipalities decried an alleged lack of evidence to support the numerical standard; and in each case, we respond by referencing just a small fraction of the plethora of existing evidence from sources ranging from academia, to industry, to government, all of which support the standard as necessary, cost-effective, and reasonable overall.

The Limitations on the Scope of the Program Vitiate its Effectiveness

The current Proposal contains numerous exemptions, definitional limitations, and other provisions that could result in a program very different than the one that appears from the recital of the 0.75-inch design standard set forth in Section 9.A. Six major categories of limitations are discussed below. These sections must be modified substantially, if not eliminated completely, if the Proposal is to have the beneficial and necessary effect for which it has the potential.

Problem #1: The Proposal Needs to be Broadened in its Application

The proposed SUSMP only applies to a short list of project types. Proposal at 2-3. We are pleased to see that the Regional Board expanded the type of projects to which the SUSMP requirements apply to include parking lots and environmentally sensitive areas. Proposal at 3. However, there are many more types of projects that have the potential to add significant pollutants to municipal stormwater.

Request: We once again request that the Regional Board **adopt the full list of project and activity types used by Los Angeles County**, in its program. See Exhibit C, from the Los Angeles County Stormwater Management Manual.

Problem #2: The Requirements Should not be Limited to "Discretionary" Projects

In addition to the short list of project types currently covered, the Proposal is further limited by the fact that it would apply only to "discretionary" projects. Proposal at 2. As we noted in our September Letter, the limitation of the SUSMP requirements and the numerical design standard to "discretionary" projects is in no way mandated by any language in the statute or the relevant permits and is a significant limitation on the scope of the program.

The SUSMP should function like any other type of building code, with its requirements applying equally to ministerial development projects and to discretionary ones. It should simply become a part of the set of requirements that apply automatically to any new development.

Request: Los Angeles County removed the limitation to "discretionary" projects from its program, and we strongly encourage the Regional Board to do the same.

Problem #3: The Proposal is Rife with Exemptions, Exceptions and Overly-Restrictive Definitions

(a) Remove the Roofing Exclusion

The significance of the numerical standard is greatly diluted by the insertion of a "rooftop exclusion" that was introduced directly by the Executive Officer without any technical support or precedent. Section 9 of the current Proposal would allow developers to divert runoff from roof tops directly to the storm drains and to take credit for that volume of runoff as if it were being treated. Such an exception would be directly contrary to the purpose of the SUSMPs. Not only would it allow treatment of less runoff, but it would actively encourage developers to increase the amount of impervious surface (in the form of roof tops) built into the development process. That is because every additional inch of roof top would enable developers to build smaller BMPs and direct more runoff straight to the stormdrains. We are aware of no similar exclusion in any program anywhere in country. **The provision is nonsensical. It would function as an affirmative attack on environmental protection and must be removed.**

Staff appears to believe that roof-top runoff will not be contaminated, thus making it appropriate to send this runoff directly into the stormdrain and reduce the volume of runoff treated on-site. The Proposal does include a few provisions to ensure that some of the most obvious contaminating influences on roof tops are not present, such as roof-based exhaust systems and air pollution control devices; however, these protections are inadequate, and, more significantly, they do nothing to address the larger issue that this exemption creates incentives directly contrary to the purpose of a stormwater management system. The following paragraphs explain each of these points in more detail.

First, the only safeguard against pollution in the rooftop runoff is the limitation of the exclusion to cases in which: (1) "roofing materials will not be a source of pollutants of concern;" and (2) "roof based exhaust systems, vents, filters, and air pollution control devices will not present a significant source of pollution." Proposal at 9. The Proposal neither explains who will make these determinations, nor how they will be made. There is no explanation of what it means for roofing materials to be a source of pollutants of concern; there is no definition of "significant source of pollution" or guidance for assessing whether the structures at issue would act as such a source. Because of the vagueness of this exclusion, it provides essentially no protection against polluted roof-top runoff flowing freely into the storm system, exempt from all the otherwise-applicable treatment requirements.

Second, the Proposal makes no provision for public notice or comment on these decisions. Thus, it opens the door for decision-making that could significantly undermine the effect of the numerical standard, and that would do so without the ability for any public review or accountability. This violates Clean Water Act public participation requirements. See 40 C.F.R. §§ 25.3, 25.4, 124.5(c), 122.62, and Part 124; see also Hampson v. Superior Court, 67 Cal. App. 3d 472, 484 (1977) (granting of discretionary exemption requires regional board review).

Third, there is no protection against, or even recognition of, the potential polluting effects of aerial deposition. Studies are underway to assess the significance of this source of pollution, but the Proposal effectively prejudges the results of these studies and encourages developers to increase the area of roofing, thus increasing the amount of runoff sent directly to the stormdrains laden with any pollutants that have settled on those roofs. The aggregate amount of pollution from these roof tops may well be a significant contributor to the pollution in our receiving waters and may prevent municipal governments from meeting their responsibilities to reduce the pollution entering the receiving waters from the ends of their storm drains. It will undoubtedly make meeting those requirements more difficult. Still, the proposal completely discounts, or ignores, this source of stormwater pollution, and thus is arbitrary and capricious and without any support in the record.

Fourth, even if the water could be proved to be pristine, this provision encourages additional flow problems and a further deviation from the natural water cycle. A stormwater management program must take into account both water quality *and* water quantity concerns. A comprehensive management plan considers the entire hydrologic cycle, including infiltration and evaporation, and does not simply focus on getting rid of the water as quickly as possible. See "Storm Water: Asset or Liability," S. Dallman and T. Piechota (Dec., 1999), attached hereto as Exhibit D, see, also, "Stormwater Infiltration," B. Ferguson, 1998, presented at Urban Storm Water Management in the Southwest Conference sponsored by U.S.E.P.A., Long Beach, California, attached hereto as Exhibit E. In 1928, only five percent of the rainfall in the Los Angeles area translated into runoff in the Los Angeles River. In the 1990s, that ratio has reached fifty percent. "Storm Water: Asset or Liability" at 8. If we continue to increase the amount of rainfall that we convert to runoff, at the same time development continues to increase, we will not only exacerbate our existing water quality problem, but we will also create a flood control threat that is beyond the capacity of our current flood control system to handle.

In sum, this exclusion is riddled with problems. It will reduce, if may totally eliminate, the pollution-control benefit that the numerical standard would otherwise provide. It will encourage environmentally destructive design practices. It will subvert public accountability. And it will exacerbate our flood control problem. **This exclusion must be removed.**

(b) Modify "Retail Gasoline Outlet" definition, as specified below

The Proposal states that gas stations with associated convenience stores are to be classified based on their "primary" activity. Proposal at 3. A huge percentage of gas stations today have convenience stores associated with them. These gas stations have just as much potential to generate stormwater pollution as gas stations without associated convenience stores, and there is no reason why a gas station should be able to avoid compliance with stormwater regulations by adding in a convenience store.

Furthermore, like the roofing exclusion, this provision provides no guidance on how to determine a facility's "primary activity." Without any limitations on that phrase, this exemption could quickly become an avenue to relieve most gas stations from the requirements of the SUSMP. **Any pumping station, regardless of whether it has an associated convenience store, should have to meet the requirements of this SUSMP.**

Finally, we note that definitional limitations such as this one and the ones discussed in the following two sections are particularly troubling because they do not simply relieve the excluded facilities from the requirements of the numerical design standard; they seem to remove those facilities from *any* of the facility-specific requirements enumerated in section 10, see Proposal at 9-12. Consequently, even the most basic design requirements of that section, such as the requirement to cover fueling areas, would not apply. There is no excuse for removing such basic requirements.

(c) Change the "Hillside" definition, as specified below

The Proposal establishes three criteria, all of which must be satisfied, for an area to qualify as a "hillside." The definition is both overly restrictive and dangerously vague. Los Angeles County's stormwater management program lists three similar criteria, but meeting *any one* of these three criteria suffices to qualify as a "hillside." Furthermore, criteria such as "erosive soil conditions" are defined in the Los Angeles County program, whereas the current Proposal provides absolutely no guidance for determining whether soil conditions are erosive, nor does it specify who would make such a determination.

Request: This definition should be modified to read as follows: "'Hillside' means property located in an area that has any of the following characteristics, or where the planned development has any of the following characteristics:

"location in an area known to have erosive soil conditions as identified in the *Los Angeles County Department of Public Works Hydrology/Sedimentation Manual*;

"grading will occur on any natural slope where the natural slope is 15% or greater; or

"plans include cut or fill slopes that are 30 feet high or greater."

(d) Modify "Automotive Repair Shop" definition, as specified below

The Proposal defines automotive repair shops based on standard industrial classifications (SIC codes). Proposal at 3. In so doing, it provides exceptions for SIC codes 5013 (essentially wholesale parts suppliers), 5014 (wholesale tire suppliers), and 5541 (retail gas stations) that are unnecessarily and unacceptably broad, as well as being vague in many cases. For example, facilities providing supplies and new parts (code 5013) are exempted as long as they do not store hazardous substances or recycled oil outside; however, the definition does not define "hazardous substances," a term that has different meanings in different contexts even within the area of water quality law. The phrase should be defined to include any substance designated in 40 C.F.R. part 116, pursuant to section 311 of the Clean Water Act, which is how it is defined for the NPDES program generally. See 40 C.F.R § 122.2.

Moreover, there are many types of automotive-related supplies that may not qualify as hazardous substance, but that may nevertheless contribute pollutants of concern to the receiving waters if left outside to come in contact with runoff. Any outside storage of automotive supplies should suffice to impose the requirements related to automotive repair shops on this category of facility.

Similarly, tire and tube suppliers (SIC code 5014) are excluded from categorization as "automotive repair shops" as long as they do not engage in repair work. This should be clarified to include tire and tube installation and should include the outside storage of other automotive supplies or hazardous materials as well.

Finally, the Proposal excludes retail gasoline stations (SIC code 5541) as long as they do not perform any onsite repair work. They should only be excluded if they meet all of the prior criteria, meaning they not only do they perform no onsite repair work, but they do no installation of new parts or upgrades, and they do not store any hazardous substances (properly defined) or other automotive supplies outside.

Request: Modify the exceptions provided for facilities with SIC codes 5013, 5014, and 5541 so that they are excepted *only* if they perform none of the pollution-producing activities described above.

(e) Remove the small restaurant exemption

Section 9 of the Proposal concludes by completely excluding small restaurants (those of less than 5,000 square feet) from the BMP sizing requirements. However, there is no necessary correlation between the size of a restaurant and the amount of pollution it produces. A small restaurant can produce much greater storm water pollution than a large one, depending on the materials they use and their source control practices. All restaurants should be required to meet the same standards with respect to the runoff generated by their sites. Because smaller sites generate less runoff, the burden on them will automatically be proportionately smaller.

Problem #4: The Waiver Provision is Illegal, in Addition to Being Bad Policy

Section 11 of the Proposal provides for a waiver system based on "impracticability." Proposal at 13. It would allow municipalities to adopt a waiver system in which any developer who could show impracticability could avoid the requirements of the SUSMP. There are several problems with this provision; however, they fall into two general categories: (1) the Proposal's explicitly-recognized situations of impracticality make no sense, and (2) as written, the provision is illegal. Consequently, **the provision must be significantly modified, if not removed.**

The "recognized situations of impracticability" are inappropriate

The first problem with the waiver provision is that it establishes three "recognized situations of impracticability," two of which are based solely on site conditions that make infiltration impractical. For example, one of the three bases for an impracticability waiver is "unfavorable or unstable soil conditions at a site to attempt infiltration." This basis appears to accept the misguided arguments of so many of the municipalities and to ignore the fact that there is a long list of BMPs available to developers, with only a tiny percentage relating to infiltration. Thus, even if soil conditions at a given location were not appropriate for infiltration, the current development planning program provides developers with myriad other options to manage their runoff. There is no reason that they should be able to use the soil conditions as an excuse to avoid having to perform any other available means of mitigation (including treatment) of their polluted runoff.

The third factor in the list of the three "recognized situations of impracticability" – risk of groundwater contamination – is inappropriate for the same reason. If the groundwater is at risk, then developers can choose from a wide array of alternative BMPs that do not involve infiltration at all. Furthermore, these conditions ignore the fact that there is a separate section within the Proposal specifically addressing limitations on the use of infiltration. See Proposal § 12, at 13. Thus, there is no danger that, without the ability to obtain this waiver, developers will infiltrate where doing so would be inappropriate.

This section would illegally and unwisely provide the Executive Officer with unbridled discretion to approve any other justification for impracticability

Going beyond the "recognized situations of impracticability," however, this section also allows the Executive Officer to approve "any other justification for impracticability." Proposal at 13. It is not only unwise, from a policy perspective, to provide such unfettered discretion to the Executive Officer, but it also violates the principle of public notice and opportunity to comment, and constitutes an illegal delegation of the Regional Board's authority.

First, it is inappropriate and unwise to provide the Executive Officer with the power to wield such behind-the-scenes, discretionary decision-making authority. Particularly now, with the current controversy over Staff's independent and unreviewed actions – now on appeal to the State Board – it would be a mistake to allow the Executive Officer to grant exemptions at his sole discretion. This provisions creates significant potential for abuse.

Second, the failure to provide a means for public review and comment violates federal regulations applicable to state NPDES programs. Federal law requires that any change to an NPDES permit that does not meet one of the criteria for a "minor modification" must go through public notice and comment proceedings. 40 C.F.R. § 122.62 and 122.63. The granting of an exemption for other than purely factual reasons can constitute a permit modification. Cf. Hampson v. Superior Court, 67 Cal. App. 3d 472, 483-84 (1977).

Third, the delegation of such authority to the Executive Officer, without any provision for Regional Board review, violates the limitations on the Regional Board's ability to delegate its duties. See Cal Water Code § 13223. This statute prohibits the Regional Board from delegating its power to modify waste discharge requirements ("WDRs"). The SUSMP is a provision of an NPDES permit and of a WDR. Furthermore, in a similar situation, Hampson specifically held that, although a regional board resolution could authorize the board's executive officer to make a *preliminary* determination regarding one's eligibility for an exemption, the regional board still had the power *and duty* to review that determination if it would constitute a modification of the waste discharge requirement. Id.

In sum, this waiver provision, which could exempt an unlimited number of developments, is illogical, unwise, and, as written, illegal. **The provision must be significantly modified, if not removed.**

Request: Modify this provision to allow dischargers to seek variances for a showing of impracticability made to, and approved by, the Regional Board.

Problem #5: The SUSMP Should not Allow Self-Certification of Compliance

Section 13 allows developers to certify that they have complied with the requirements of this SUSMP, thus avoiding any municipal or Regional Board review of their development plans. Proposal at 13. Such a provision would be an abdication of the Regional Board's responsibilities under the stormwater program, and **this provision should be removed.** In no other area does the Regional Board allow the regulated community to completely remove itself from regulatory oversight. At a minimum, there must be a mandatory spot checking system so that municipalities retain some sort of oversight over these otherwise-completely unregulated developments.

This section also states that the Executive Officer will decide on the acceptable training and curriculum. This, too, exceeds the Regional Board's authority to delegate duties to the Executive Officer. Just as model programs under the Los Angeles Permit had to come back before the Regional Board for approval, any training program proposed by the Executive Officer as an element of this permit's requirements must be approved by the Regional Board before it is effective.

Problem #6: The Section on Conflicts with Local Practices Vitiates the Proposal

Finally, page 5 of the Proposal allows local practices to override the requirements of the SUSMP as long as the local practices would not "defeat or circumvent the intent of the SUSMP requirements." This vague standard is, once again, an invitation for abuse. Since the cover letter describes the purpose of the SUSMP as being "to ensure that storm water pollution is addressed . . . by incorporating [BMPs] in the design phase of new development and redevelopment," one could interpret this exemption as allowing local practices to trump the requirements of the SUSMP as long as they require the incorporation of *some* BMPs in the design phase. Since this is already required under the general development planning program adopted by the Regional Board in January of 1999, this may vitiate the entire SUSMP.

The SUSMP requirements should be implemented like any other program. There is no reason why inconsistent existing practices should trump the SUSMP. **This provision must be eliminated.**

Conclusion

In sum, Staff has proposed a host of alternatives, exemptions, and limitations that, as a whole, threaten to completely negate all of the benefits that the numerical design standard would otherwise produce. There is no justification for retreating from that design standard or providing a series of "back doors" through which developers can avoid it. The proposed standard is entirely reasonable. Indeed, as the following section demonstrates, it is far less restrictive than the standards being adopted by hundreds of other municipalities all over the country. If anything, it should be stronger.

The Proposed Numerical Standard is Necessary and Entirely Reasonable

This is the second time that Staff has recommended the inclusion of a numerical standard within the SUSMP to guide BMP-design and ensure adequate mitigation of stormwater pollution in development planning. Furthermore, Staff **both times** proposed that the numerical standard to be included should be based on the 85th percentile 24-hour runoff event and on the maximized capture storm water volume for the area, or, in the alternative, a 0.75-inch storm size standard. See Proposal § 9.A, at page 8, and Public Notice No. 99-047 (Aug. 16, 1999) at 2-3. This is the minimum acceptable standard for development planning in the Los Angeles area,[3] and it provides a good starting point for the implementation of this aspect of the Los Angeles and Long Beach Permits.

NRDC also recognizes that the current Proposal provides two additional methods for calculating the exact standard to be applied to any given development. See Section 9.A. Thus, Staff has provided maximum flexibility to developers and municipalities while still ensuring a minimally-adequate level of mitigation of stormwater pollution. **NRDC supports the use of this numerical standard and its formulation in the current Proposal.**

The first section below provides a sense of just how reasonable the proposed numerical standard is in comparison to other programs being implemented across the country. It also relays the results of a survey of similarly-structured programs that are being implemented in thirty-two different geographical areas around the country.

The other two sections address concerns that were raised by several municipalities at the September 16, 1999 hearing regarding the technical effectiveness, and the *cost*-effectiveness, of the BMPs in the program. Their complaints generally took the form of alleging – without any evidence – that there was a lack of data to support the use of these BMPs. As we demonstrate below, this claim is completely fallacious, as there is, and has been for years, an incredible wealth of data supporting both the effectiveness, and the cost-effectiveness, of these BMPs.

In responding to these municipalities' concerns, it bears repeating that the selection of BMPs is **not even at issue** in this proceeding, as the Regional Board has already adopted a list of BMPs for the development planning program under the Los Angeles Permit. See Regional Board Resolution No. 99-03, April 22, 1999, attached as Exhibit F. Thus, the Regional Board has already determined that the BMPs in this program are both cost-effective and appropriate. We nevertheless review the wealth of data regarding the effectiveness and cost-effectiveness of the structural BMPs approved by the Regional Board last April, in response to these concerns.

---

[3] As indicated in the September Letter, NRDC believes that the threshold should actually be higher. We believe that new development projects should be designed to mitigate all the runoff generated by storms of up to either 1.0-inch or the size of a one-year, 24-hour storm, whichever is greater. Many areas around the country use a 1.0-inch standard; many others use the six-month or one-year, 24-hour storm standard; and still others require BMPs in new and redevelopment to be designed with sufficient capacity to ensure that they capture 90% of the stormwater generated. See, e.g., Table 1, on page 13. Given the hydrology of the Los Angeles area, any of these standards would translate to at least a 1.0-inch storm.

Hundreds of Municipalities Across the Country Use Similar or Stronger Standards

At the September 16, 1999, hearing at which the Regional Board heard testimony on this issue, representatives of several municipalities, as well as the building industry, decried the alleged difficulties of implementing the proposed numerical standard and the alleged hardships that would befall them and (in the case of the municipalities) their constituents, if this standard were to be adopted. None of the speakers presented any evidence in support of their "parade of horrors" scare tactics. Instead, they simply – and incorrectly – implied that there was no basis for the standard that Staff had recommended.

As we showed in great detail in our September Letter, not only was there a basis, but a technically-sound, environmentally-critical basis for adopting a standard at least as stringent as the one proposed by Staff. Furthermore, there are literally hundreds of municipalities across the country already employing such standards.

Many municipalities have structured their standards in ways that make them difficult to compare. However, one of the nation's leading experts in stormwater management engineering, Dr. Richard Horner, has noted that, although there are myriad ways of articulating a standard for BMP design, in his professional judgment, "the majority of municipalities that have a numerical standard [such as the one listed in the current Proposal] have a **more stringent one than Los Angeles County's**." See Supplemental Declaration of Richard R. Horner ("Horner Suppl. Decl.") ¶ 7, attached hereto as Exhibit G (emphasis added). And in fact, **three of the Nation's leading stormwater experts have all submitted affidavits or letters supporting the use of this standard**. See Exhibit H.

Moreover, the legal standard for municipal stormwater pollution management requires that this Development Planning program be structured so as to reduce pollutants in stormwater to the "maximum extent practicable." 33 U.S.C. § 1342(p)(3)(B)(3); Los Angeles Permit, Part II, at page 12. Given this standard, the fact that other municipalities are implementing more stringent standards, **in and of itself**, should suffice to show that this is a practicable option and therefore **must** be implemented.

Presented below, in Table 1, is a partial listing of several hundred municipalities around the country that employ more stringent standards than the one currently proposed by Staff. Table 2 lists additional municipalities that employ equally stringent or more stringent standards, depending on the situation. This list is by no means comprehensive – it comes from an academic survey of 32 city, county, regional, and state programs[4] – however, it serves as an indication of how common the proposed approach is.

[4] Institutional Aspects of Urban Runoff Management: A Guide for Program Development and Implementation, Watershed Management Institute, Inc. (1997).

Table 1 – Standards Exceeding the Los Angeles County Standard of Runoff from the First 0.75 Inches of Rain:

Municipality or Municipalities	Design Standard for Treatment Control BMPs	Equivalency to Standard Proposed for Los Angeles
All municipalities in the "Puget Sound Basin," which encompasses a 12-county region, and **well over 100 individual municipalities.**	Runoff from 6-month, 24-hour rainfall.	**1.2 inches** for the Seattle area; a similar amount in most other highly urbanized areas (A few smaller urban areas have either heavier or lighter rainfall, but all have a standard exceeding Los Angeles County's.)
Clark County, Washington	Runoff from 6-month, 24-hour rainfall.	Approximately **1.2 inches**.
State of New Jersey **(all municipalities)**	Runoff from first 1.25 inch of rainfall occurring in 2 hours, or runoff from 1-year, 24-hour rainfall event, whichever is greater.	**1.25 inches or greater**
State of Delaware **(all municipalities)**	First 1 inch of runoff	**Greater than 1.0 inch**
State of Maryland (proposed new standard for **all municipalities**)	Runoff from 90% of average annual rainfall	Approximately **1 inch** of rain in most places in the state.
Northeast Illinois Planning Commission (Metropolitan Chicago)	Runoff from first 2 inches of rainfall (except runoff from 6-month [unstated duration] rainfall event for swales)	**2.0 inches**, except for swales, which could be more or less.
Austin, TX	First 0.5 inch of runoff + 0.1 inch of runoff for every 10% of impervious area above 20%	**1.3 inches or greater**.

Orlando, FL	First 0.5 inch of runoff, or runoff from first 1 inch of rainfall, whichever is greater.	**1 inch or greater**.
Winter Park, FL	First 1 inch of runoff	**Greater than 1 inch**.

Table 2

Standards Exceeding the Los Angeles County Standard (Runoff from First 0.75 Inches of Rainfall) Under All or Most Circumstances:

Municipality or Municipalities	Design Standard for Treatment Control BMPs	Equivalency to Standard Proposed for Los Angeles
Florida (Water Management Districts and municipalities that have not adopted their own standard)	First 0.5-1.5 inch of runoff, depending on BMP, receiving water, and impervious fraction.	Greater than 0.5, almost always greater than .75, and often above 2.0.
South Florida Water Management District (Miami-West Palm Beach metropolitan areas)	Runoff from first 1.0-2.5 inches of rainfall (depending on impervious fraction) multiplied by impervious fraction.	Almost always greater than 0.75
Suwanee River Water Management District, FL	First 0.5-2 inches of runoff, depending on BMP, receiving water, and impervious fraction	Usually greater than 0.75
State of Virginia	Basic treatment volume is first 0.5 inch of runoff, but wet pond is to have wet pool volume = 3 times basic treatment volume	Usually greater than 0.75, and always greater than 0.75 for wet pools.

The Relevant BMPs Have Repeatedly Been Shown to be Highly Effective

Another concern raised by several municipalities at the September 16, 1999 hearing, was over the effectiveness of the BMPs. There is no doubt that structural BMPs are a highly effective means of controlling stormwater pollution, and any uncertainty regarding the effectiveness of individual or specific BMPs has been substantially reduced by the myriad technical studies that have been performed on this subject. Indeed, contrary to the claims of several municipal representatives at the September 16, 1999 hearing, EPA has recently noted that "[t]here has been a great deal of published data documenting the efficiency of BMPs in removing pollutants from storm water." Preliminary Data Summary of Urban Storm Water Best Management Practices, EPA (Aug., 1999) ("EPA Study") at 5-50. In fact, there have been "[s]everal nationwide monitoring programs . . . to evaluate the performance of storm water BMPs," as well as data in the professional literature and "a large amount of data . . . collected by various cities and municipalities as part of the storm water permitting program." Id. at 5-46 – 5-48. Indeed, some of the data recounted below has been known for over 15 years, making the municipalities; claims perplexing. See, e.g., U.S. EPA, *Results of the Nationwide Urban Runoff Program (Volume 1-Final Report)*, December, 1983, at 6-1 – 6-64.

In addition, two separate groups have developed databases on the issue of BMP effectiveness. "The Center for Watershed Protection ... has prepared a database containing BMP performance data for 123 structural BMPs," id. at 5-47, and the American Society of Civil Engineers ("ASCE") has developed what EPA refers to as "a comprehensive database on BMP performance." www.epa.gov/OST/stormwater, visited on Dec. 10, 1999. The Center concluded that "there is enough data to select specific BMP groups on the basis of their comparative ability to remove specific pollutants." "Comparative Pollutant Removal Capability of Urban BMPs: A Reanalysis," Watershed Protection Techniques; Vol. 2, No. 4, June 1997, Technical Notes – Stormwater BMPs; Technical Note 95 at 520.

Although a complete literature review and summary is beyond the scope of this letter, the attached excerpt from Fundamentals of Urban Runoff Management: Technical and Institutional Issues, R. Horner, J. Skupien, E. Livingston, and H. Shaver (Aug., 1994), see Exhibit I, reports the results of several in-depth studies on BMP effectiveness. The information is provided as exemplary of the sort of data that has been generated regarding the effectiveness of BMPs. It is by no means the only source of information on the subject. It is but one example of the sort of detailed information that has been developed to characterize the effectiveness of structural BMPs. Some of the conclusions of the report are summarized below. Additionally, Table 5-7 from the EPA Study, attached hereto as Exhibit J, reports similar pollutant removal levels for total suspended solids, nitrogen, phosphorus, pathogens, and metals, for 10 types of BMPs.

All of the BMPs listed below are on the Regional Board's list of approved BMPs for use in the Development Planning Program under the Los Angeles Permit. See Regional Board Resolution No. 99-03, attached as Exhibit F. Thus, the following data directly reflects the effectiveness of the existing program.

A. Wet ponds

EPA's Nationwide Urban Runoff Program ("NURP") performed a comprehensive investigation of pond design and performance. Performance was found to relate best to volume ratio (the ratio of pool storage volume to mean storm volume). Total suspended solids ("TSS") reductions were found to reach 100% with sufficient volume ratio. Similarly, lead reductions could be greater than 90%, phosphorus reductions greater than 60%, and copper and zinc reductions as high as 50%. Seattle's water quality design storm is equivalent to a volume ratio of approximately 2.5, which yields reductions in TSS of 75%, lead of over 70%, phosphorus of 50%, and copper and zinc of 40%. Fundamentals of Urban Runoff Management, R. Horner et al., Exhibit I, at 120-21.

B. Extended-Detention Dry Ponds

A 1990 study by Stahre and Urbonas analyzed several studies of long-term efficiencies for various pollutants and a 40-hour detention time. The researchers concluded that dry ponds under such conditions could remove 50-70% of TSS, 75-90% of lead, 50-90% of bacteria, 50-70% of hydrocarbons, 30-60% of zinc, 20-40% of chemical oxygen demand, and 10-20% of total phosphorus and total nitrogen. Id. at 122.

C. Vegetative Practices

A 1992 performance investigation in the Puget Sound area of Washington found grass swales can be effective in capturing solids, oils, and the least soluble metals. Over a six-storm period, the swale, with an average hydraulic residence time of nine minutes, removed an average of 83% of the TSS, 75% of oil and grease/TPH, 72% of iron, over 60% of the lead, turbidity, and T-Zn/T-Al, and even removed 30% of the *dissolved* zinc. Id. at 124.

D. Constructed Wetlands

Another 1992 study, by Strecker, considered more than 140 papers and reports and assembled detailed information on 18 locations within the United States. The study found median pollutant removals of 80.5% for TSS, 44.5% for ammonia-nitrogen (NH_3-N), 58% for total phosphorus, 83% for lead, and 42% for zinc. Id. at 128-29.

E. Sand Filters

Monitoring sand filters in Austin, Texas, Shaver reported expected pollutant removal efficiencies of 75-87% for TSS, 71-88% for lead, 49-82% for zinc, 19-61% for total phosphorus, and 36-37% for fecal coliform, among other pollutant parameters. Id. at 138.

F. Leaf Compost Filters

A leaf compost filter developed and tested by W and H Pacific (1992) showed influent event mean concentrations to be reduced, on average, by 95% in TSS, 84% in turbidity, 67%

chemical oxygen demand, 41% phosphorus, 88% zinc, and 87% total petroleum hydrocarbons, among other results. Id. at 139.

G. Catch Basin Filters

Before independent testing, "MacPherson reported concentration reductions of 90 percent for total suspended solids, 87 percent for lead, 77 percent for zinc, and 86 percent for copper." Id. at 139. Dr. Michael Stenstrom has also reported removal efficiencies of 50 to 90 percent for petroleum hydrocarbons, and up to 99 percent for sediments and trash. See Santa Monica Bay Restoration Project Catch Basin Study, 1998 (Michael Stenstrom, Ph.D., primary author).

H. Continuous Deflective Systems

Robin Allison, of the University of Melbourne, in Victoria, Australia, found continuous deflective systems, or CDS, to remove 70 to 85 percent of trash, vegetation *and* TSS. R. Allison, B.E., Ph.D., "Effectiveness of Two Stormwater Trash Trapping Systems" (1998). See Exhibit K.

I. Conclusion

There is an enormous body of detailed technical information regarding the efficiency of the various structural BMPs listed above. Because the BMPs listed above are part of the existing Development Planning program, see Regional Board Resolution No. 99-03, attached as Exhibit F, this data is directly on-point and completely supportive of the Board's decision to require that these BMPs be sized to work most effectively.

The data presented herein is also highly relevant because the pollutant parameters for which these structural BMPs have been tested – and for which they have proven to be the most effective – are the same pollutants for which the vast majority of the waters of this region are listed as impaired. The Los Angeles River, for example, is presently listed as being impaired by ammonia, coliform, lead, oil, and nutrients such as nitrogen and phosphorus, among other things, see 1998 California 303(d) List and TMDL Priority Schedule, approved by EPA, May 12, 1999 ("303(d) list") at 79-81, all of which can be effectively managed by the BMPS listed above. Even a casual review of the 303(d) list reveals that most of the contaminants listed above, including copper, lead, zinc, TSS, coliform, and nutrients, are ubiquitous problems in the Los Angeles area. Indeed, with the impending development of TMDLs for these impairments, the implementation above the above BMPS may actually soon be *mandated.*

There is Ample Data Regarding the Reasonable Costs of Structural BMPs

A. The Municipalities' Demands Regarding the Consideration of Costs Show a Fundamental Misunderstanding for the Structure of the Clean Water Act.

Several of the municipal representatives who spoke at the Regional Board's September 16, 1999, hearing on this issue complained that there was insufficient data on the costs of the

various BMPs to assess whether they should be required. If effectiveness is viewed as a measure of the benefit of a BMP, they argued that, even if we knew how effective the BMPs were, and therefore what the benefits are, the absence of cost data nevertheless meant that there was not enough data to justify the BMPs on a cost-benefit basis.

As an initial matter, it should be noted that a cost-benefit analysis is not required at this stage in the implementation of the Clean Water Act's stormwater management program. Costs, to the extent they are relevant at all, have been factored into the equation in designating the beneficial uses for the receiving waters. Once uses are designated for those water bodies, the Clean Water Act requires that sufficient controls be implemented on all sources of pollution to *assure* that those standards are attained. See, e.g., 33 U.S.C. § 1313(d)(1)(C); see, also, id. at § 1312(a). Also, once again, the BMPs at issue were selected and/or approved by the Regional Board nine months ago, see Exhibit F at 16-31, so their propriety is not in issue in this action. The only question before the Board is the appropriate sizing of the pre-approved list of BMPs that the municipalities must require of new and redevelopment regardless of how the Board acts on the instant issue.

Further, although the municipalities' objections do not relate to the propriety of adopting a numerical sizing standard, it is worth noting that this element – the development of SUSMPs with meaningful standards – is *mandated* by the Los Angeles Permit. The permit *requires* that SUSMPs and guidelines for their preparation be developed. Los Angeles Permit § III.A.1.c. It also states that, in order to implement a program for planning measures consistent with the SUSMPs, permittees "shall require that the project applicant submit an [USMP] appropriate and applicable to the project." Id. at § III.A.2. Thus, the permit requires the adoption of SUSMPs and envisions that the Regional Board will develop standards, such as the numerical standard at issue, to assessing the adequacy of the specific USMPs submitted by developers.

Finally, the statute itself, as well as the permit, requires that the Development Planning program be structured to reduce pollutants in stormwater to the maximum extent practicable. 33 U.S.C. § 1342(p)(3); Los Angeles Permit, Part II, at 12. Given the number of municipalities that are implementing more stringent sizing standards than this Regional Board is considering, see section above entitled "Hundreds of Municipalities Across the Country Use Similar or Stronger Standards," there can be no doubt that the standard before the Board is not impracticable.

B. The Economic Data is Plentiful

Even if a cost-benefit assessment were required at this stage, the municipalities' claim that there is some general dearth of economic data on the cost of BMPs is simply false. EPA's Preliminary Data Summary of Urban Storm Water Best Management Practices, supra at page 15, discusses the costs (and benefits) of stormwater BMPs, in chapter 6. Table 6-1, attached hereto as Exhibit L, lists typical base capital costs, in dollars per cubic foot of treated water volume. Using that table, and even assuming 100% imperviousness, a one-half acre development would be required to spend between approximately $675 and $8,000 to construct and install a

sufficiently-sized structural stormwater BMP(s).[5] Similarly, a 10-acre complex could be required to spend as little as $13,500 or, using the most expensive BMPs, as much as $161,000.[6]

EPA goes on to note that, in part because of economies of scale, the costs of many BMPs will vary from these numbers as the sizes increase, making it useful to assess the total cost of typical applications of each BMP. Table 6-2, attached as Exhibit M, shows the costs for the same eight BMPs for 5- and 50-acre sites.[7] These amounts are likely to be only a small fraction of the overall costs to develop lots of this size. The Center for Watershed Protection concluded that "about a third of every dollar spent on stormwater pond construction was devoted to water quality control, with the remainder spend on flood control storage." "The Economics of Stormwater BMPs; An Update," Watershed Protection Techniques; Vol. 2, No. 4, June 1997; Technical Notes – Economics; Technical Note 90 at 496. Furthermore, the Regional Board Staff itself performed "BMP cost calculations for an actual site in Los Angeles in the process of development and determined that the mitigation criteria cost is **less than 0.5 percent of the project cost.**" Staff's "Summary of Comments Received and Response," Dec. 7, 1999, at 3.

In any event, the wealth of data regarding the costs of BMPs should put to rest the notion that such data is unavailable.

[5] 0.75 inches of rain on a 100% impervious surface would generate 0.75 inches (or 0.0625 feet) of runoff. One-half acre is 21,500 square feet. 0.0625 feet of water over 21,500 square feet yields 1,344 cubic feet of water, which, when multiplied by .5 to 6 (the approximate range of costs reported in Table 6-1) yields costs of between $672 and $8,064.

[6] Again assuming 100% imperviousness, since ten acres is 430,000 square feet, the site would yield 26,875 cubic feet of water. Multiplied by .5 and 6, that volume yields costs of $13,437 and $161,250.

[7] As EPA's data ranges from two to nine years old, these numbers should be adjusted for inflation, in addition to a further adjustment for regional factors.

Recommended Changes

The following is a proposed resolution for the Regional Board's adoption. Adoption of this resolution would affirm the well-supported numerical standard proposed by Staff while eliminating the exemptions and scope limitations that will undoubtedly hamper the effectiveness of this program.

The Regional Board hereby adopts the current Proposal from Staff with the following modifications:

1. Remove the roofing exclusion from section 9, on page 9.

2. Remove the final paragraph within section 9, which excludes small restaurants (those of less than 5,000 square feet) from the requirements established in that section.

3. Modify Section 11, on Waivers, to allow dischargers to seek variances only upon a showing of impracticability made to, and approved by, the Regional Board, following adequate public notice and opportunity for public comment.

4. Remove section 13, allowing self-certification of compliance.

5. Remove the section on page 5 entitled "Conflicts with Local Practices."

6. Expand the scope of the program to include all the project and activity types covered by Los Angeles County's program, including removal of the limitation to discretionary projects, by doing the following: (a) change the sentence in the last full paragraph on page 2 of the Proposal from:

"This SUSMP applies to projects that are Priority Projects (Discretionary Projects) as defined by the NPDES Permit;" to read:

"This SUSMP applies to all project and activity types described in attachment 1;" and

attach the list from the Los Angeles County Stormwater Management Manual, see Exhibit C, as attachment 1.

(b) Remove the word "discretionary" from the beginning of the last line on page 2 of the Proposal.

(c) Remove the top paragraph from page 5, defining "Discretionary Project."

7. Modify the definition of "Retail Gasoline Outlet" on page 3 of the Proposal to say that any commercial facility that includes a pumping station qualifies as a retail gasoline outlet subject to the requirements applicable to such entities. If other facilities, such as convenience stores, are associated with the pumping station, the requirements for gas stations only apply to the area around the pumping station, which will be the greater of the area 50 feet outward from the outer-most pumping stations or half way to the associated facilities.

8. Modify the definition of "Hillside" on page 3 so that it reads as follows: "'Hillside' means property located in an area that has any of the following characteristics, or where the planned development has any of the following characteristics:

"location in an area known to have erosive soil conditions as identified in the *Los Angeles County Department of Public Works Hydrology/Sedimentation Manual*;

"grading will occur on any natural slope where the natural slope is 15% or greater; or

"plans include cut or fill slopes that are 30 feet high or greater."

9. Modify the definition of "automotive repair shop" as follows:

(a) Facilities with SIC code 5013 are exempted only if they do not store hazardous substances (meaning any substance designated in 40 C.F.R. part 116, pursuant to section 311 of the Clean Water Act), recycled oil, or automotive-related supplies, outside.

(b) Facilities with SIC code 5014 are excluded only if they do not engage in repair work or tire and tube installation and do not store automotive supplies or hazardous materials (defined as any substance designated in 40 C.F.R. part 116, pursuant to section 311 of the Clean Water Act) outside.

(c) Facilities with SIC code 5144 are excluded only if they meet all of the prior criteria, meaning they not only do they perform no onsite repair work, but they do no installation of new parts or upgrades, and they do not store any hazardous substances (as any substance designated in 40 C.F.R. part 116, pursuant to section 311 of the Clean Water Act) or other automotive supplies, outside.

* * *

Thank you for the opportunity to comment on the Regional Board Staff's proposed SUSMP for the Los Angeles and Long Beach Permits. If you have any questions regarding any of the above, feel free to contact Alex Helperin at (323) 934-6900.

Re: Proposed Model Standard Urban Storm Water Mitigation Plans (SUSMPs)
Los Angeles County Municipal Stormwater Permit (NPDES No. CAS0061654)

Dear Dr. Swamikannu:

The Natural Resources Defense Council ("NRDC") has reviewed the "Standard Urban Storm Water Mitigation Plans submitted to the Executive Officer under the municipal storm water permit for Los Angeles County and Cities" (the "SUSMPs") and the Regional Board staff ("Staff") recommendation to the Executive Officer regarding approval of those SUSMPs. We hereby join in the comments submitted by Heal the Bay, in its letter of September 7, 1999, and in those submitted by the Santa Monica BayKeeper, in its letter of September 9, 1999, and also submit the following additional comments on behalf of NRDC and its members.

Introduction

The Center for Watershed Protection (the "Center") has noted that "[c]ommunities across the nation are finding that their water resources are degrading in response to growth and development." Rapid Watershed Planning Handbook (Center, Oct. 1998) at xiii, attached hereto as Exhibit A.[1] The Center's "four-year effort to examine new ways to reduce pollutant loads and protect aquatic resources" revealed that "a fundamentally different approach toward development [is] needed to reliably protect streams and other aquatic resources." Site Planning for Urban Stream Protection (Center, Dec. 1995) at 1, attached hereto as Exhibit A. **Development planning is generally recognized as one of the most critical aspects of any stormwater management program, and specific performance standards are essential to the effectiveness of these programs.**

Staff's Recommendation

Given the importance of this program, NRDC strongly agrees with Staff's recommendation to include a numerical standard in the SUSMPs to guide BMP-design and ensure adequate mitigation of stormwater pollution in development planning. NRDC also supports the specific numerical standard recommended by Staff – the 85th percentile 24-hour runoff event, based on the maximized capture storm water volume for the area, or, in the alternative, a 0.75-inch storm size standard. This is the minimum acceptable standard for development planning in the Los Angeles area,[2] and it provides a good starting point for the implementation of this aspect of the Los Angeles County Municipal Stormwater Permit (NPDES No. CAS0061654) (the "Permit").

Basis for 0.75-Inch Standard

As you know, NRDC and the Santa Monica BayKeeper successfully sued the County of Los Angeles ("County") in 1994 over its failure to comply with the then-applicable Los Angeles Municipal Stormwater Permit. In settlement of that lawsuit, the County agreed to develop a comprehensive stormwater management program. That program is now outlined in the County's Storm Water Program Implementation Manual ("County Manual"), and the SUSMPs established therein impose a 0.75-inch standard. County Manual, Volume VII, Appendix C, attached hereto as Exhibit B.

The 0.75-inch standard was not chosen at random, but was the product of extensive discussion and negotiation, and the counsel of Dr. Richard Horner, a professor at the University of Washington, and one of the foremost experts in the field of stormwater management. See Exhibit C. Dr. Horner concluded that a higher standard would be preferable, but that the 0.75-inch standard would be a minimally-acceptable standard for the Los Angeles area. Consequently, this or a more stringent standard should be adopted for all other permittees under the Permit.

Similarly, the 85th percentile 24-hour runoff event, based on the maximized capture storm water volume for the area, is also based on sound science and the recommendation of stormwater management experts. Dr. Robert Brashear, Ph.D., P.E., of Camp Dresser & McKee suggested this as one of the three legitimate methods for calculating a development planning stormwater mitigation standard when he spoke at the August 10, 1999 workshop on this subject. It is therefore an appropriate alternative to the 0.75-inch standard.

---

[2] NRDC believes that the threshold should actually be higher. We believe that new development projects should be designed to mitigate all the runoff generated by storms of up to either 1.0-inch or the size of a one-year, 24-hour storm, whichever is greater. Many areas around the country use a 1.0-inch standard, and many others use the six-month or one-year, 24-hour storm standard, such as the Puget Sound basin; Orlando and Winter Park, FL; and the States of New Jersey and Delaware. Another possible standard is to require that stormwater treatment facilities be designed with sufficient capacity to ensure that they capture 90% of the stormwater generated. Given the hydrology of the Los Angeles area, any of these standards would translate to at least a 1.0-inch storm.

These numbers are not only supported by experts in the field. They have been derived using well-recognized technical sources and uncontroversial assumptions. Exhibit D, from the California Storm Water BMP Handbooks, relates to the third method of calculating a numeric standard mentioned above in footnote 2 (based on a percentage of storm water volume captured). It demonstrates an analysis based on the STORM model, giving basin volume (not rainfall volume) in relation to a directly connected impervious area ("DCIA"). By using the 100% DCIA curve, one can approximate rainfall volume (i.e., all or almost all runs off and must be stored). The horizontal axis is in acre-ft/acre. Multiplying the numbers there by 12 gives inches. You can see that a 90% capture goal on the 100% DCIA curve requires about 0.09 acre-ft/acre, which, when multiplied by 12, results in 1.08 inches of storage.

The County's adoption of the 0.75-inch standard translates into an 80% capture rate. Looking again at the attached chart from the STORM model, an 80% capture rate translates to about .064 acre-ft/acre, which comes out to about 0.75 inches of storage. Similarly, an 85% capture rate would be about 0.95 inches. Various municipalities across the country, such as those in the Puget Sound basin; Clark County, WA; Orlando and Winter Park, FL; and the Northeast Illinois Planning Commission, employ between an 80% and a 90% (or greater) capture rate, when using capture rate as the basis for determining minimum retention capacity.

The County Adopted the 0.75-Inch Standard but has Inexplicably Removed it from the Proposed SUSMPs

Although the County adopted the 0.75-inch storm size standard in its own standard urban storm water mitigation plans, in its role as Principal Permittee under the Permit, it *removed* that numerical standard from the SUSMPs that it submitted to the Executive Officer, which are currently under consideration. As Tom Kennedy, representing the Los Angeles Countywide Permit Subcommittee, admitted at the workshop on August 10, 1999, the lowering and eventual removal of that performance standard was based on a political compromise, rather than on any scientific or environmental considerations. Thus, just as Heal the Bay expressed concern over the lack of a numerical standard, NRDC objects to the County's removal of the 0.75-inch standard and supports Staff's recommendation to re-insert it.

The 0.75-Inch Standard is Supported by Other Stormwater Management Programs

The use of a 0.75-inch (or larger) storm size as a minimum standard for the stormwater mitigation requirement in a development planning program is well supported by the experiences and policies of other municipalities around the Country. For example, Montgomery County, Maryland requires the implementation of structural BMPs sufficient to manage a 1.0-inch rainfall event according to infiltration standards/specifications; or to provide for a permanent pool equal to or greater than ½-inch of runoff from the drainage area; or to provide 24 hour detention and release of the total volume of runoff resulting from a 1 year storm or a 1 inch rainfall.

Montgomery County Regulation No. 5-90, § 4.B.3, attached hereto as Exhibit E. The city of Alexandria, Virginia has a "zero additional pollutant loading" standard. City of Alexandria Municipal Code § 13-117(A), attached hereto as Exhibit E. Right here in Los Angeles County, the city of Santa Monica's stormwater ordinance requires that parking lots be designed to be able to contain one inch of precipitation in a twenty-four hour period. Santa Monica City Municipal Code § 7.10.060(b)(3), attached hereto as Exhibit E. Accordingly, Staff's recommendation that the Executive Officer include the 0.75-inch numerical standard, or the 85th percentile 24-hour runoff event, into the SUSMPs represents a modest but appropriate initial performance standard for the implementation of a development planning stormwater pollution mitigation program in Los Angeles County.

In sum, the 0.75 inch standard is supported by sound science, the experience of other municipalities, and the precedent set by Los Angeles County itself, the principal permittee under the Permit. Given the existing precedents, the feasibility of its implementation, and the scientific bases for this standard, it is the lowest threshold that could possibly satisfy the Clean Water Act requirement to "reduce pollutants in discharges to the maximum extent practicable." 33 U.S.C. § 1342(p)(3)(B)(iii). Thus, there is every reason why the Executive Officer should adopt Staff's recommendation and insert that standard into the SUSMPs.

Scope of Application

As NRDC has repeatedly commented, the development planning program in general, and the numerical stormwater volume retention/mitigation standard, specifically, should apply much more broadly than simply to discretionary projects or the six types of development represented in the SUSMPs.[3] Once again, the County's program is both instructive and precedent-setting on the issue of scope of application. The County's program includes a list of over 20 types of projects and activities to which its stormwater review process, and its numerical mitigation standard, apply. See County Manual, Volume VII, pages 3-1 to 3-3, attached hereto as Exhibit F. Any standard adopted as part of the model SUSMPs should apply to a similar range of projects and activities.

Receiving Water Limits and Anti-Degradation Requirements

Of course, as a performance standard, Staff's recommendation is separate from the water quality-based standards that continue to apply separately and to establish – albeit indirectly – the independent requirement that whatever technology is implemented must be sufficient to ensure that stormwater and urban runoff do not introduce pollutants into the receiving waters at levels that "will cause, have the reasonable potential to cause, or contribute to an excursion above any .

[3] See, e.g., NRDC's January 8, 1999 letter re "Los Angeles County Proposed Model Development Planning Program," and NRDC's June 18, 1999 letter re "Tentative City of Long Beach Municipal Storm Water Permit."

. . water quality standard." 40 C.F.R. § 122.44(d)(1)(i). If the performance standard recommended by Staff fails to ensure the protection of beneficial uses and other aspects of receiving water quality standards, additional, or more aggressive, mitigation measures may be required.

Similarly, anti-degradation requirements prohibit the reduction of water quality from current levels. 40 C.F.R. § 131.12(a)(2). Thus, this requirement serves as an independent check to ensure that whatever performance standard is adopted protects the receiving waters from any degradation of water quality. Thus, if the current performance standard results in a lowering of water quality, it may have to be strengthened based on these regulations as well.

Requested Changes to Specific Language/Proposal

NRDC notes that Staff's recommendation is for the Executive Officer to "[i]ncorporate in, 'SUSMP Section 3. Minimize Storm Water Pollutants of Concern,' numerical mitigation measures for BMP design criteria . . ." Regional Board "Notice of Public Hearing" (August 16, 1999) ("Notice") at 2. In the interests of clarity and simplicity, we would recommend that the Executive Officer simply *replace* the non-numerical standard currently listed in the SUSMPs with the numerical standard recommended by Staff, rather than maintaining the current structure and trying to "incorporate" the numerical standard into it. Mere incorporation of the numerical standard into the existing structure would result in two separate standards and likely confusion. Included as Attachment 1 to this letter is a redlined version of "SUSMP Section 3. Minimize Storm Water Pollutants of Concern," from the 100+ Home Subdivision SUSMP, providing an explanation of how this language could be inserted.

In addition, as Staff noted in its recommendation, the SUSMPs for automotive repair facilities, retail gasoline outlets, restaurants, and hillside located single-family dwellings do not require treatment control BMPs. They also do not include a section entitled "Minimize Storm Water Pollutants of Concern," as the other three SUSMPs do. Because Staff recommended that this discrepancy be rectified, and because of the language of Staff's recommendation regarding numerical standards (to include "numerical mitigation measures for BMP design criteria"), we interpret that recommendation to apply to all seven SUSMPs. This will necessitate the addition of a section, analogous to the one reproduced in Attachment 1, into the four SUSMPs currently lacking such a section.

Thank you for the opportunity to comment on the County's proposed SUSMPs and on the Staff's recommended action with respect to them. If you have any questions regarding any of the above, feel free to contact Alex Helperin at (323) 934-6900.

Sincerely,

David S. Beckman

Introduction

A Guide to Better Site Planning

This guide represents the culmination of a four–year effort to examine new ways to reduce pollutant loads and protect aquatic resources through non–structural practices and improved construction site planning. During the project it was quickly realized that a fundamentally different approach toward development was needed to reliably protect streams and other aquatic resources. This guide describes a new approach to site planning and recommends how it can be implemented at the local level. A recurring theme is that the new site planning approach makes more environmental and economic sense than traditional subdivision codes.

This guide is aimed at all those who participate in site planning at the local level—plan reviewers, developers, engineers, landscape architects, local officials, and concerned citizens. It is hoped that each participant can find some useful ideas within the guide to improve the quality and outcomes of site plans.

Organization

The guide is organized into seven main chapters:

1. A Stream Protection Strategy
2. The Importance of Imperviousness
3. Watershed–Based Zoning
4. Stream Protection Clusters
5. The Architecture of Stream Buffers
6. Headwater Streets
7. Green Parking Lots

The first chapter, *A Stream Protection Strategy*, outlines a comprehensive framework for effective stream protection at the local level that utilizes an integrated development review process through each stage of the development cycle. The many advantages of this resource–driven approach are then described. Next, the chapter documents how three decades of traditional development standards and subdivision codes have not served their purpose. These outdated regulations result in needless impervious area, consumption of green space, and inadequate protection of resource areas and streams. A strong case is made that modest reforms of inflexible local development regulations can produce significant improvements in the future quality of streams and the community.

Chapter 2, *The Importance of Imperviousness*, is a thorough review of natural research on the impact of imperviousness on aquatic systems. The review concludes that even relatively low levels of impervious cover can produce significant and often irreversible impacts on streams and other aquatic resources. A key theme is that impervious cover can be used as a quantitative measure to test the effectiveness of site planning practices.

Chapter 3, *Watershed-Based Zoning*, examines how the measurement of impervious cover can

be a more reliable and enforceable link between individual site plans and the larger watershed in which they are built. An urban stream classification scheme based on future impervious cover is outlined and the merits of impervious cover are then discussed as the basis for watershed–based zoning. The chapter outlines the steps needed to institute watershed–based zoning at the local level and concludes with a discussion on how specific stream protection strategies can be adapted within individual subwatersheds.

Chapter 4, *Stream Protection Clusters*, examines a series of alternative development patterns that can sharply reduce the amount of impervious cover created at a site. These development patterns concentrate on cluster development in a smaller area served by a shorter road network. Many localities already allow cluster development; however, it has seldom been used for the explicit purpose of reducing impervious area. A new model for cluster development is presented that can be easily implemented by local governments to build more attractive and economic communities.

Chapter 5, *The Architecture of Stream Buffers*, documents the critical importance of buffers in the urban landscape. Twenty key benefits of buffers are reviewed. In addition, the chapter documents the experience that local governments have had in implementing effective stream buffer programs. The chapter concludes with detailed, but flexible performance standards that ensure that buffers are protected and maintained through each stage of the development cycle.

Chapter 6, *Headwater Streets*, investigates the potential of reducing imperviousness through narrower residential streets, smaller cul–de–sacs, and shorter driveways. Present local road design standards have resulted in needless impervious cover and unsafe speeds. A revised residential street classification system is presented that forms the basis for more effective performance standards for street design. The chapter also provides guidance on integrating structural practices along streets to provide the most effective control of runoff quality.

In the last chapter, *Green Parking Lots*, further reduction of impervious cover is possible in new commercial parking lot design. The "green parking" approach downsizes parking areas, thus limiting the creation of unnecessary impervious cover while still providing convenient access for motorists. A strong case is made that current local parking codes result in parking lots that are much larger than needed. From the experience of local planners, new performance criteria are proposed to curb excess parking, utilize smaller parking stalls, and design more effective best management practices (BMPs) for parking lots.

A glossary at the end of the guide provides definitions of the many planning and engineering terms involved in site planning.

The guide illustrates how innovative site planning tools can be integrated into the overall BMP system for a development site. Such tools act to reduce impervious area, protect resource protection areas, and retain

green space. Most importantly, the guide makes a strong case that when these tools are applied together, the result is generally better for the community, the stream and the developer.

Many of the issues in this manual are explored in greater depth in a series of four guidance documents that are available from MWCOG.

- Riparian Buffer Strategies for Urban Watersheds
- Cluster Development Strategies for Urban Watersheds
- Residential Street Strategies for Urban Watersheds
- Clearing and Grading Strategies for Urban Watersheds

Author's Note

The purpose of this guide is to present a new way of thinking about site planning to better protect streams. As a result, the guide is peppered with many numerical examples of new performance criteria. While these new criteria are thought to be an improvement over existing subdivision codes and standards, it is important to carefully and critically evaluate each one within the context and character of the existing community or region. After all, it has been the uncritical acceptance of design standards in the past that has often led to many present stream protection problems.

Acknowledgements

The production of this guide was primarily funded by the U.S. Environmental Protection Agency (EPA) Office of Wetlands, Oceans and Watersheds, with matching funds from the MWCOG. The Center for Watershed Protection also contributed funds to complete the effort. The guide could never have been produced without the cooperation, insights and experience of over 200 local planning agencies from 43 US states. Staff members of these agencies participated in surveys, provided literature and ordinances, and gave advice over the phone. The help of these agencies, listed below, is gratefully acknowledged.

Thanks are also extended to EPA staff whose guidance and patience were instrumental in completing this guide. They include Anne Beier (project officer), Robert Goo, Rod Frederick, and Dov Weitman, as well as each of EPA's regional nonpoint source coordinators.This guide also reflects the hard work of a number of MWCOG staffers, including Lorraine Herson–Jones, Kathy Corish, Maureen Heraty, Lynne Stabenfeldt, Peter Kumble, Mark Pfoutz and many others. Their input is gratefully acknowledged.

The author would also like to express thanks to the staff at the Center for Watershed Protection for their capable and patient work in producing the final document, with kudos to Arlene Allegretto, Jennifer McLean, Donna DeMars Claytor and Dean Geiser.

Disclaimer

This guide was produced by the Center for Watershed Protection, under a contract with the Metropolitan Washington Council of Governments through a grant from the US EPA.

Points of view expressed in this guide do not necessarily reflect the views or policies of the EPA or MWCOG.

3.1 CATEGORIZATION OF DEVELOPMENT PROJECTS

Beginning June 1999, the DPW divisions that have responsibility for review of development project plans will categorize proposed projects as "Planning Stormwater Priority Projects" or "Planning Stormwater Exempt Projects" with respect to the potential for a significant effect on stormwater quality. Planning Stormwater Priority Projects shall be required to incorporate appropriate post-construction BMPs into project plans prior to the issuance of any building or grading permit.

In order to categorize a project as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project, project type, characteristics, and activities will be assessed for potential contribution to stormwater pollution. The DPW Building and Safety/Land Development Division shall conduct a screen check for projects utilizing a standardized checklist ("Priority/Exempt Checklist") that lists project type and project characteristics and activities that are believed to be significant potential contributors to stormwater pollution. The Priority/Exempt checklist that shall be used for categorizing projects as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project is shown in Figure 3-1 and included in Appendix A.

In utilizing the Priority/Exempt Checklist, a commercial or industrial development of 100,000 or more square feet shall be based on total impermeable area as opposed to lot size or building footprint. This interpretation shall be used because of the intent to manage storm water runoff from paved areas associated with buildings. A restaurant is a facility that would use the Standard Industrial Classification (SIC) code of 5812 and an automotive repair shop is a facility that would use one of the following SIC codes: 5013, 5014, 5541, 7532-7534, or 7536-7539. Hillside development shall be defined as development having any of the following characteristics:

- location in an area known to have erosive soil conditions as identified in the *Los Angeles County Department of Public Works Hydrology/Sedimentation Manual*;
- grading on any natural slope where the natural slope is 25% or greater; or
- plans include cut or fill slopes that are 30 feet high or greater.

Since the County's Department of Regional Planning also has a fundamental role in approval of development projects, a process has been developed to incorporate the screen check for

categorizing projects as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project early in the planning stages of "discretionary"[1] projects. A flowchart depicting this process is provided as Figure 3-2.

[1] Section 15357 of the California Environmental Quality Act Guidelines defines "discretionary project" as a project which requires the exercise of judgment or deliberation when the public agency or body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statutes, ordinances, or regulations.

FIGURE 3-1. CHECKLIST FOR CATEGORIZING PROJECTS AS PLANNING STORMWATER PRIORITY OR PLANNING STORMWATER EXEMPT

Project Name: ______________________

Project Location: ______________________

The project is a Planning Stormwater Priority Project if any of the project types listed in Part A or any of the project characteristics or activities listed in Part B are applicable.

Part A. Type of Proposed Project:	Check If Applicable
A 100+ home subdivision	
A 10-99 home subdivision	
A 100,000+ square-foot commercial or industrial development	
An automotive repair shop (SIC codes 5013, 5014, 5541, 7532-7534, and 7536-7539)	
A retail gasoline outlet	
A restaurant (SIC code 5812)	
A hillside-located single-family dwelling	

Part B. Project Characteristics or Activities:	Check If Applicable
Automotive or equipment repair and/or maintenance	
Car wash	
Automotive or equipment washing or cleaning area(s)	
Gas station or fuel dispensing	
Parking lot with 25 or more parking spaces	
Outdoor material or waste handling or storage	
Chemical handling and/or storage of petroleum products, paints, solvents, concrete, or hazardous waste	
Outdoor equipment or product fabrication including welding; cutting; sawing; metal fabrication; assembly; application of paints, coatings, or finishes; pre-cast concrete fabrication; etc.	
Outdoor areas for equipment or machinery repair and/or maintenance	
Dry cleaning factory	
Food service	
Food processing plant	
Hospitals, laboratories, or other medical facilities	
Nursery (plant materials)	
Animal slaughtering	
Animal confinement, pet care facilities, stables, kennels, etc.	
Public recreation uses such as tennis courts, swimming pools, golf courses	
10 or more dwelling units	
Hillside location	
Landscaped areas > 5 acres, including cemeteries, golf courses, etc.	
Location adjoining to, bisected by, or discharging to a designated environmentally sensitive area[2], riparian corridor, or wetland	

R0068877

[2] "Environmentally sensitive areas" may be, but not limited to, wetlands, habitats of endangered, threatened, or rare species; wildlife dispersal or migration corridors; areas of locally-designated species such as heritage trees; or locally-designated natural communities such as oak forest or coastal habitat.

PREFACE

The evolution of this booklet has a long history. From the very beginnings of the Los Angeles & San Gabriel Rivers Watershed Council, alternative ways of managing storm water has been a major topic of conversation. We have acknowledged the great engineering feats that have tamed the occasional wild and raging storms that have done so much damage to lives and property in the past. And we have acknowledged that thinking and policies must change over time. The first step toward making some needed policy changes is to describe alternative ways of managing storm water in our own local context.

The Problem

We are facing a growing population in need drinking water and, with that growing population, ever increasing water quality problems in the watershed. We can address both of these problems, and storm water too by capturing more water high up in the watershed for ground water recharge to augment our drinking water supply. And by restoring wetlands and riparian habitat, we can help reduce our water quality problems. We can also positively impact our residents quality of life, soften the hard urban landscape, improve property values near the restored habitat, and encourage the redevelopment of some worn out parts of our cities. (See our Vision Statement for a more detailed explanation of the interrelationship of all of these issues.)

The Process

Two very talented academicians from UCLA donated their time and intelligence to write this paper, for which we are very grateful: Suzanne Dallman and Tom Piechota. A first draft was presented at our Stakeholders meeting March 17, 1999, when 35 copies were made available for people to take home, review, comment upon and criticize. The paper was put up on Dr. Piechota's web site at UCLA. A final draft was reproduced for all those who came and participated in our May 1 Conference. This paper was the main topic of discussion at the conference. Subsequent comments were received and incorporated into this document as well.

It has now been edited to make it a little more user friendly, and a few of the ideas have been expanded upon. More photos and diagrams have been added.

Follow up Research

Follow up research is clearly needed in several areas. We need to determine where it is appropriate to use permeable paving materials based on soil types and nearness to groundwater. We will be developing our GIS capability to be able to do this. We need a study to determine just how much water can be captured to augment our drinking water supply, especially if we can prevent runoff from all storms of less than one inch. We need to determine which facilities already built can be modified to serve multiple purposes. And we need to identify open spaces such as at freeway interchanges or under power line rights of way that could be transformed.

Research is also needed into how best to amend the Uniform Building Code so that all storm water does not have to be directed to the street and to the ocean. More cities should adopt ordinances similar to those of Santa Monica and Calabasas that require storm water be retained on site. The use of cisterns, gray water, and mulch should be expanded. The grading permitted on hillside building sites should be more closely regulated, and the amount of permeable paving increased. For starters.

Thanks. An Appreciation

Many people have given us comments, but there are a few people who have expended enormous time and energy to help make this paper as good as it is. Besides our authors, Michael Drennan, Carl Blum, Rick Sase and TreePeople's Andy Lipkis must be acknowledged. And our funders without whom this publication could not be published: US EPA Region IX, and Union Bank of California. Many thanks for all your assistance, your encouragement and your support.

Dorothy Green, Editor.

Introduction

It is ironic that modern cities tend to shunt away the rain that falls on them while they import fresh water from distant streams and reservoirs.

-- Ferguson and Debo 1990

The purpose of this paper is to educate the public about the relationship between urbanization and the natural rainfall cycle in the Los Angeles area. As we develop a greater understanding of the natural systems within which we live, and our impact on them, it will hopefully become clearer how to develop a healthier balance between us and those systems.

Land use changes can have a profound impact on natural hydrologic processes. The effects of urbanization on watershed hydrology probably represent the most extreme forms of disturbance. Urbanization alters flow pathways, water storage, pollutant levels, and rates of evaporation, infiltration and surface runoff. It can also alter the timing and extent of flooding, the sediment yield of rivers, and the suitability and viability of aquatic habitats.

It has long been the public perception that storm water runoff in an urban setting is a liability, and large flood control structures are necessary to get rid of the water as quickly and efficiently as possible. That is why public agencies have designed and constructed flood control facilities with one primary objective: the protection of life and property. While ridding our cities of storm water is the most important objective of flood control and storm water management, it is time for traditional engineering approaches to broaden their scope. Storm water runoff can also be viewed as an asset. It can be used to replenish underground aquifers and to enhance recreational opportunities and wildlife habitat. To view storm water as a multi-use resource, a comprehensive watershed management plan is required that accounts for all of the physical characteristics and constraints of the watershed and the long-term effects of urbanization.

This paper describes some of the impacts of urbanization on the natural system in the Los Angeles area, and some efforts underway to reverse some of those impacts. While this discussion is in no way exhaustive, it is intended to provide examples for others to consider when making decisions within their various professions about how best to accomplish their objectives. These examples show how it may be possible to live in a more environmentally sustainable manner through changes in the way we develop and re-develop our watersheds.

Urbanization of the Watershed

The development of a comprehensive watershed management plan requires that the underlying hydrology of the watershed, both on the surface and underground, be

understood. The driving forces in the hydrologic cycle are precipitation or rain, infiltration, and evaporation. In Southern California, the majority of precipitation occurs in the winter months, December through March. In addition, there is tremendous variability of precipitation in the Los Angeles basin. During the same storm, it may rain very heavily in some places, and almost not at all in other places within the basin. A few years ago, Carson and parts of Long Beach flooded in a major storm event but most of the basin had moderate or little rainfall.

> Definition box. Hydrology: the way water flows and works in the interconnected systems above and below the land.

The Los Angeles and San Gabriel Rivers drainage basin covers 1,460 square miles, from the San Gabriel Mountains to the Pacific Ocean (Figure 1). In the mountains, the total annual precipitation is two to three times greater than the precipitation in the coastal plain.

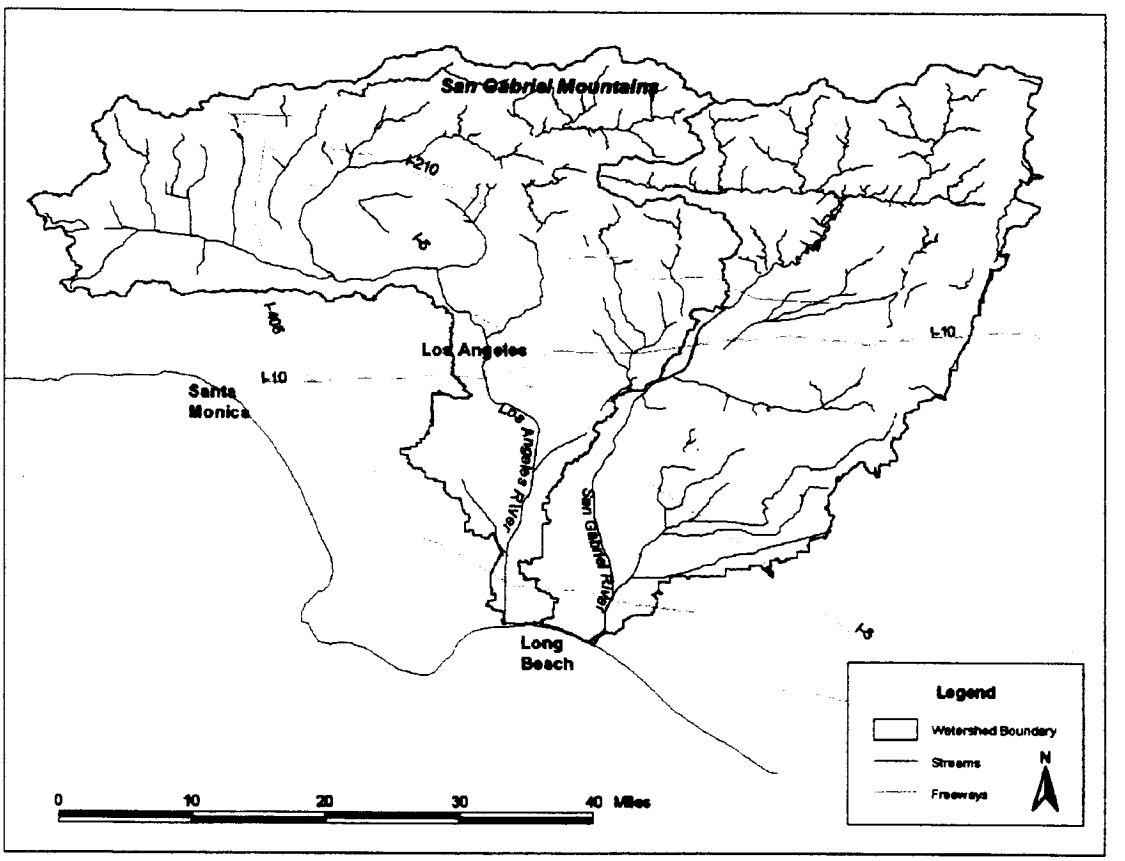

Figure 1. The Los Angeles and San Gabriel Rivers drainage basin.

A Brief History

The problem of flood control in the Los Angeles and San Gabriel Rivers watershed received little attention prior to 1914. The land in the watershed was used primarily for

agriculture and occasional flooding was just something that was accepted. In 1914, however, flooding caused significant structural damage and this captured the attention of local residents. In response, flood control reservoirs were built in the San Gabriel Mountains. By the 1930's, it was clear that more flood control facilities were needed to keep pace with the increased risk ass a result of development in flood-prone areas.

In 1934, extensive damage and loss of life occurred due to river flooding. This prompted the U.S Army Corps of Engineers to partner with the Los Angeles County Flood Control District (the County) and begin construction in 1938 of a comprehensive flood control system. This system consisted of detention/retention basins (see discussion below), channel improvements, pumping plants, and local storm drains. With minor exceptions, the river channels are concrete lined trapezoidal channels. In the upper reaches, the channels have been dug down below natural grade. In the lower reaches they are lined with levees and rip-rap. The system was designed to serve a projected population of three million. The upper watershed in the San Fernando Valley was expected to remain largely agricultural.

Photos#1and 2: trapezoidal channels, smaller entrenched channels, levees and riprap.

Increases in Runoff as the Region is Paved.

The Los Angeles and San Gabriel Rivers watershed has been the recipient of extensive development in the past 50 years. This has created a vast amount of impervious surface: areas covered with buildings, roads, driveways, parking lots and sidewalks where water cannot soak into the ground. As development has proceeded in this highly urbanized region, the natural process of rainfall runoff has been dramatically altered. Laws have also been passed requiring that the drainage from buildings be directed into the street and into the storm drain system. These factors have substantially changed the hydrology and runoff processes in the watershed. This alternation has led to a number of fundamental environmental problems including:

- decreased groundwater infiltration
- decreased evapotranspiration
- decreased stream base flows
- decreased surface runoff storage
- decreased floodplains, and wetlands
- decreased wildlife habitat and biodiversity
- increased stormwater runoff volume
- increased stormwater peak discharge rate
- increased pollutant concentrations and amounts
- increased channel erosion
- increased frequency of local flooding

Studies have shown that runoff in an area of 75-100 % impermeable cover increases by a

factor of nine or more when compared to an undeveloped area[1]. In the Los Angeles and San Gabriel Rivers basin, the storm drain system that was originally designed to convey a 100-year storm, now only provides 25 to 40 year protection in some places. The large amount of impervious surfaces in the watershed has greatly increased the volume of runoff. The peak flow is reached sooner, and is higher than before.

(Definition Box) 100-year storm: A storm that, on average, occurs once every 100 years. The probability of a 100-year storm occurring in any given year is 1%.

(Definition Box) Permeable or pervious surface is one through which water can soak down or infiltrate into the soil and into the underground aquifer. Impermeable or impervious refer to water tight surfaces such as paving or roofs from which water will run off.

(Definition) Peak flow is the maximum flow rate in a river which typically occurs a short time after the peak rainfall.

The increase in runoff due to urbanization is clearly seen in Figure 2, which presents the ratio of runoff to precipitation for the Los Angeles River watershed. From the 1930s to the mid-1960s, the percentage of rainfall that infiltrated into the ground or evaporated was more than 80%, thus 20% of the rainfall was converted into runoff. Since the mid-1960s, this ratio has steadily decreased and now approximately 50% of the rainfall is infiltrated or evaporated and the other 50% runs off to the ocean. This ratio is probably conservative. A considerable amount of runoff is diverted for recharge and retained in reservoirs, thus never reaching the river.

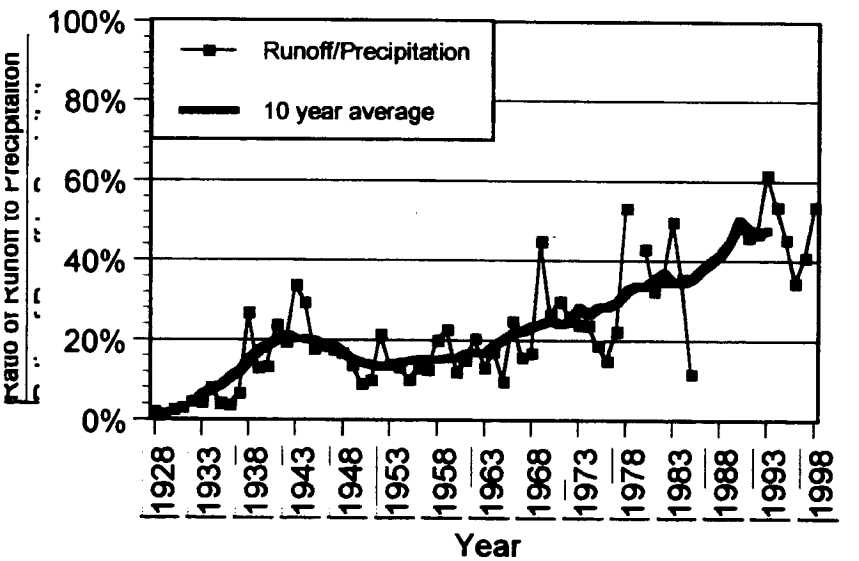

Figure 2. The ratio of annual runoff in the Los Angeles River at Firestone Blvd. to the annual precipitation at the Los Angeles Civic Center from 1928 to 1998. Data from Western Regional Climate Center.

The need for new approaches.

There is a growing realization that the traditional approaches to stormwater management have not always worked well, and in some instances the engineered solution made the situation worse. The flooding in the Mississippi River basin in 1993 forced some communities to move out of the floodplain to higher ground in order to accommodate the increase in runoff. The increase was caused development up stream, by deforestation, and by the loss of wetlands that act as giant sponges. The flood crests at St. Louis were up to 10 feet higher than a flood from an earlier storm of the same magnitude, because of the constricting effect of the upstream levees which could not contain the increased flows. Flood control channels have also created an unintended hazard to the public, in the event that someone is caught up in the swift flow of water rushing to the sea.

The following sections review traditional and non-traditional approaches to stormwater management and explore some potential opportunities for alternative stormwater management techniques in the Los Angeles and San Gabriel Rivers watershed. We are taking an approach that views stormwater as a potential asset, while at the same time maintaining the protection of life and property as the primary objective. Our focus is on ways to reduce the total volume and velocity of stormwater entering the drainage systems, primarily through techniques that capture or slow runoff at its source. This reduces the overall threat while increasing natural infiltration and local water supplies.

Traditional Approaches: Conveyance and Storage

Because natural drainage and storage processes have been altered by urbanization, stormwater management systems attempt to compensate for increased runoff and decreased infiltration, in other words, to serve as a substitute for the natural floodplain. The traditional design of stormwater systems has focused on using conveyance, usually concrete channels, and storage facilities to control runoff during a major storm event. The design of these facilities is based on historic rainfall and runoff statistics. The traditional stormwater management system consists of engineered structures such as a network of curbs, gutters, underground pipes, and open channels. Since the 1970s, there has been a trend to incorporate storage facilities (detention and retention basins) into the system to detain or retain the storm runoff. The runoff in the detention basins is released at a controlled rate into the conveyance system after the peak flow has occurred.[2]

Photo #2 of curb, gutter, catch basin.

This approach to stormwater management considers stormwater to be a liability – to be gotten rid of as efficiently as possible in channels that use the minimum required amount of space.[3] This has met the primary objective of the flood control system - the protection of property from storm runoff while, at the same time maximizing the amount of land

available for development. Most of these facilities, however, were designed for a single purpose (flood hazard mitigation) and only incorporated other uses such as recreation, or water conservation that were easily feasible.

The design criteria for these traditional stormwater systems varies depending on the magnitude of the design storm, the size of the facility, and the community's desire for a high level of flood protection. Providing the appropriate level of protection is often a political process.

(Definition Box) Design Storm: the maximum rainfall event that the system is designed to handle. Different agencies use different definitions.

- In Los Angeles County, if the drainage area is greater than 100 acres or contains a natural watercourse, then the system is designed for a 50-year storm event.
- Otherwise, in urban areas, the combination of street capacity and storm drains must afford a 25-year level of protection.
- The Federal Emergency Management Agency (FEMA) Flood Insurance program requires that all regional facilities, such as the Los Angeles River, provide 100-year flood protection. There, all finished floor elevations must equal or exceed the water surface of the predicted 100-year flood in order to qualify for federal flood insurance.

Conveyance Facilities

Conveyance facilities move water on or below the surface through a series of engineered structures. This is the oldest, most efficient, and most common approach to stormwater management. Conveyance facilities include gutters, catch basins, pipes, and open channels and have the following characteristics:

- They move water quickly through the watershed.
- They do not allow infiltration of water into the soil.
- They minimize the space needed to convey the water.
- They are economical to build and maintain.
- They are hydraulically efficient, using a minimal width of channel and the least possible surface resistance or roughness. They move the greatest amount of water with the least amount of resistance.

The impact of changing the roughness of an open channel conveyance facility is illustrated in Figure 3. It shows the roughness coefficient for a smooth concrete-lined channel, a rougher sand bottom, and an even rougher grass-lined channel. The capacity of the channel is inversely proportional to the roughness of the channel. Thus for a given channel width, if the capacity of a concrete-lined channel is 10,000 cubic feet per second (cfs), then the capacity of a grass-lined channel with the same dimensions would be reduced to 4,000 cfs. A grass-lined channel would have to be larger in size than a concrete channel to provide the same level of flood protection. A grass-lined channel that

is the same size as the concrete channel would only partially meet the flood control needs of a community. But a larger grass-lined channel or one with some habitat restored could be a multipurpose facility that could meet the flood control needs and be used for other activities during dry periods.

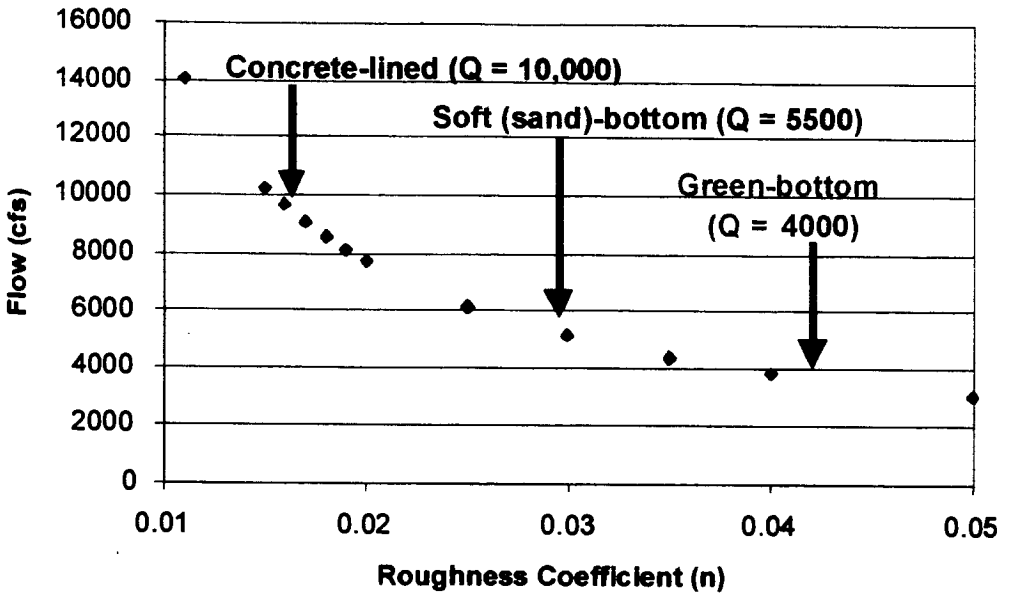

Figure 3. The effect of channel roughness on the channel capacity for a hypothetical trapezoidal channel. The x-axis is the Manning's roughness coefficient (n), Q is the design flow rate for the specified channel cross-section.

Detention Basins

Detention basins are used in a flood control system to detain a portion of the flow and slowly release the water after the peak runoff has occurred (see Figure 4). Detention basins have the following characteristics:

- They reduce peak runoff.
- The total storm water volume conveyed by the system remains unchanged.
- Multipurpose facilities, such as those used for water conservation and flood control, have a specific capacity reserved for storm water storage.
- Single purpose facilities reserve the entire basin for storm water storage.

Figure 4 demonstrates the impact of a detention basin on the magnitude of peak runoff and the change in the hydrograph (amount of runoff over time). The peak flow is substantially reduced and the shaded area in Figure 4 is the amount of runoff volume that is detained in the basin.

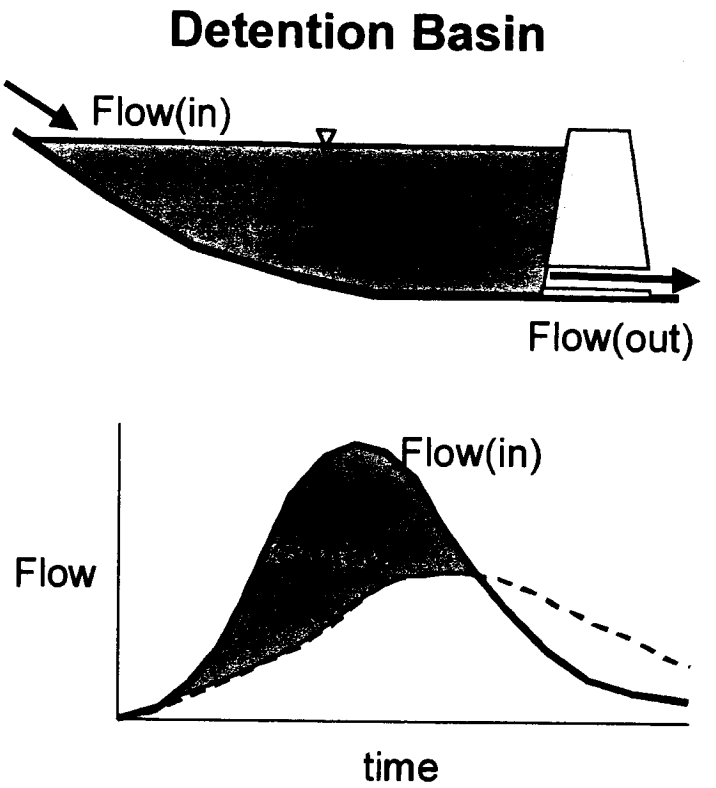

Figure 4. The impact of a detention basin on a storm hydrograph. The flow into the detention basin is the solid line and the flow out of the basin is the dashed line.

Retention or Infiltration Basins

The other type of stormwater basin used in flood control systems is a retention or infiltration basin. This type of basin reduces the total volume of storm runoff by retaining a portion of the runoff and allowing it to infiltrate and recharge the groundwater. Retention/infiltration basins have the following characteristics:[3]

- They reduce total storm water volume that is conveyed downstream.
- They reduce peak runoff.
- They help to restore the base flow in streams.

There are two types of retention or infiltration basins:

- An inline basin is located in the flow path of a channel.
- An offline basin is located outside the channel with runoff diverted into the basin.

(Definition box) base flow: the flow that is always maintained in a river due to the return flow of groundwater to the surface.[4]

Non-traditional Approaches: Reducing Volume and Velocity

Extending the Viability of Existing Stormwater Systems.

Flood control and stormwater management are evolving sciences. As new ideas develop and are adopted, the infrastructure can't easily adapt to new research findings. Traditional storm channels do not reduce the volume of water. They merely allow the flood to move elsewhere at a faster rate. Channels require continual maintenance to clear vegetation and debris that reduce the capacity and slow down the flow. The size of the system may also be inadequate, not expanding as quickly as development increases the volume of runoff. Therefore storm discharges may exceed the design capacity of the system. Since the urban floodplains are occupied, this puts more people and property at risk.[5] As our urban population increases, so do pressures on the existing storm drain system.

Therefore, reducing the volume and velocity of stormwater becomes an important and cost-effective alternative to continually expanding the existing regional stormwater system.

Benefits to be Gained by Reducing Volume and Velocity

Besides extending the viability of our existing storm drain system, other reasons for considering new approaches to stormwater management include:

- Water conservation. By increasing ground water recharge, we can become less dependent on imported water to meet our drinking water needs.
- Habitat. We have lost 95% of the wetlands in Los Angeles County and almost all of our riparian habitat due to development.
- Need for more open space and recreation. We are among the most park poor cities in the world, with only one quarter the recommended park land and open space for our population.
- Water quality. By restoring riparian habitat and wetlands, water quality can be improved in our rivers and creeks and in the ocean.
- Restoration of the natural hydrology. Restoring natural stream functions and the habitat of a stream also helps to provide erosion control and sediment management.
- Costs. It is becoming increasingly costly to build the traditional concrete box channels in already developed areas. New approaches that reduce the volume and velocity of storm water are proving to be cost effective, especially when all the multiple savings are added up.
- Greening the urban hardscape increases property values, and can encourage redevelopment nearby in the inner cities, where it is needed the most.

Muiti-Purpose Projects

As watershed management concepts gain attention, public agencies and communities are

recognizing the fact that stormwater management systems can serve more than one purpose. Single purpose conveyance systems are increasingly viewed as throwing water and money away. They typically do not address all the other watershed management concerns stated above. They also do not take into account the money that government spends, independently, on each of these other concerns. Projects in the watershed that provide multiple benefits can therefore tap into multiple sources of funds to help pay for that project, saving money and resources in the long run.

Detention basins can be used for golf courses and parks. Bicycle or equestrian trails can be added alongside stream channels. Many of the County's facilities, especially the Sepulveda Basin and Whittier Narrows already provide such multiple uses and more, and some could be modified to further enhance public use. Pan Pacific Park was designed to store storm water during major events, while providing active and passive recreation.

Photo 3: Pan Pacific Park, used as a detention basin during major storm events.

Importance of Small Storms

In addition to the traditional approach of designing systems to accommodate extreme events, newer approaches consider the idea that the more frequent small storms are significant contributors to total runoff and therefore should be evaluated when developing a stormwater management plan. Table 1 summarizes the rainfall amounts for 24-hour storms with return periods ranging from one year to 100 years.

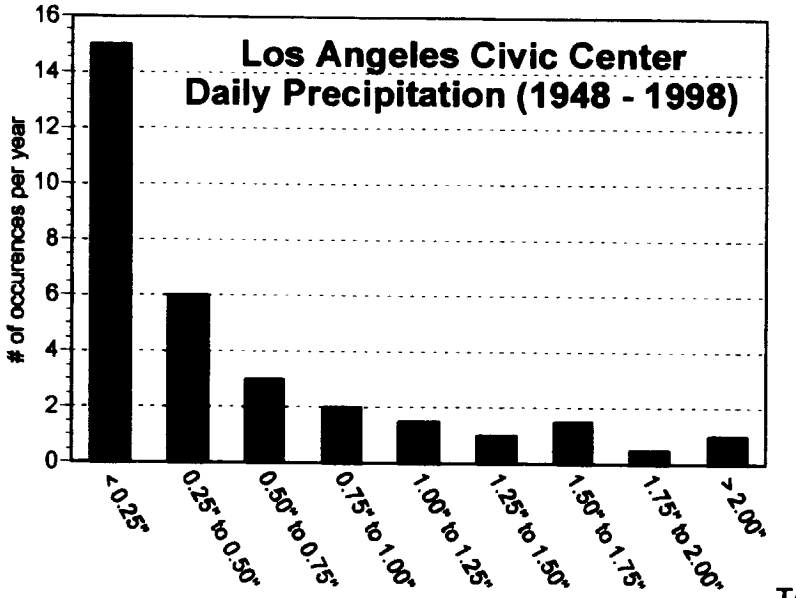
Return Period (years)	1	2	3	4	5	10	25	50	100
Rainfall Amount (inches)	1.77	2.46	2.73	2.92	3.06	3.52	4.18	4.72	5.32

Figure 5. Los Angeles Civic Center 24-Hour Precipitation for various return periods based on data from 1948-1998. Data from Western Regional Climate Center.

(Definition box) Return Period: the average recurrence of a storm of a particular size and duration, in this case for storms during a 24 hour period.

On average, a 24-hour rainfall of 2.46 inches is experienced once every two years and a 24-hour rainfall amount of 5.32 inches occurs once every 100 years. The 100-year rainfall amounts are used to design regional flood control facilities; however, the lower frequency storms should also be considered in stormwater management plans. The typical 24-hour rainfall amounts are shown in Figure 5 for the 31 days of rain that the Los Angeles Civic Center experiences on average each year. Of these 31 storms, 15 or half have rainfall amounts of less than 0.25 inches (Figure 5).

Depending on the soil type and how saturated the soil has already become, this amount of precipitation may be easily infiltrated in areas that have a permeable surface. These are the easiest places to infiltrate storm water. Therefore, one of the aims of a comprehensive stormwater management plan should be to minimize the amount of impermeable land cover. This increases opportunities for infiltration of rainfall, groundwater recharge and the reduction of overall runoff volume and velocity.



# Occurences	15	6	3	2	1.5	1	1.5	0.5	1	Total 31

Figure 6. The typical amounts of daily rainfall for an average year at the Los Angeles Civic Center based on data from 1948 to 1998. Data from Western Regional Climate Center.

SPECIFIC METHODOLOGIES

Constraints

Many of the approaches described below are primarily designed to reduce runoff volume by increasing infiltration rates. The success of these methods depends largely on the intensity of a given storm and the characteristics of the site: depth to groundwater, soil water-holding capacity, infiltration rates, and how much moisture the soil already contains. Many of these techniques also trap pollutants during infiltration. EPA studies have found that if there is sufficient clearance to the water table, many of the pollutants will be removed by the soil during percolation, causing no adverse impacts on groundwater.[6]

On-site structural methods and more efficient site designs are most commonly employed in areas of new construction or redevelopment. Reducing runoff in existing developments tends to be more expensive than when it is designed into the project, although the feasibility and cost effectiveness of retrofitting is gaining legitimacy (see TREES Project below). Providing groundwater recharge and diverting runoff for irrigation also reduces the need for imported water, another cost savings that is often overlooked.

Channel Design and Operation

Reengineering

Reengineering existing channels is expensive, and in densely urbanized areas the land may not be available. In re-developing or newly developing areas, some rethinking of traditional channel designs may be practical. As discussed earlier, the size and roughness of a channel dramatically impacts the velocity of the flow. Wider channels, which provide a greater cross-sectional flow area, will slow runoff velocity[7]. In unlined channels, reducing velocity may also increase infiltration, thus reducing the total amount of water discharged.

Temporary dams

The use of temporary dams, constructed of inflatable rubber tubing or rocks and logs provide another means of retaining flows in the channel. These small dams slow the velocity of the flow permitting water to pool behind them. When properly designed, the larger flood flows will safely spill over the dam without increasing the upstream flooding. When rubber dams are used in a channel, they can be inflated only during periods of low to moderate flows. The rubber dams can be deflated when large flows are expected in order to maximize the capacity of the channel for stormwater management purposes. Inflatable dams are in regular use by the County on the San Gabriel River to direct water into the spreading grounds now managed purposefully to capture storm water for ground water recharge.

Water Harvesting

Water harvesting is an old practice that has been continually used in many countries. County Public Works harvests as much as 90% of the San Gabriel River for ground water recharge. Water may also be harvested, or salvaged, by directing runoff toward points of use rather than diverting it into the street, into the storm drain system and into the ocean. Runoff water may be:

- detained in permanent ponds or wetlands,
- captured in tanks or cisterns,
- diverted directly into landscaped areas for infiltration,
- directed into a dry well for infiltration,
- pumped from storage into irrigation systems,

- directed into fire hydrant networks if the infrastructure permits.[8]

(Definition box) A cistern is a container set above or below ground, into which surface runoff is diverted. Cisterns can store runoff for irrigation or for emergency water supply. For household use, cisterns collect and store water from an adjacent rooftop. Newer cisterns are commonly freestanding units fabricated from plastic. There is either an open outlet or a control valve that allows it to operate in a manner similar to a detention basin. Cisterns must be covered to prevent mosquitoes from breeding and to keep out debris, and must either have a small opening or be secured to prevent access by children. To maintain capacity, the cistern must be cleaned of sediments periodically.[9]

Infiltration Facilities

Increasing infiltration restores a measure of the natural hydrologic cycle by returning water to the soil and reducing runoff volumes increased by urbanization. These facilities include drains, dry wells, and subsurface percolation basins that collect and detain water on-site, allowing it to infiltrate into the soil. These methods work well if soil conditions are appropriate to allow drainage and the site can be properly graded.

Parking lots as infiltration facilities

Parking lots can be designed so that rain water flows into planting areas instead of protecting planting areas from the water with concrete curbs. Any residual oil and grease will flow with the water into the planters, preventing it from moving out through the storm drain system to the ocean. Bacteria in the soil should neutralize the oil and grease.

Dry wells

Dry wells are constructed to capture runoff from rooftops or other surface areas for infiltration. A dry well is a hole in the ground lined on the sides with permeable material that will hold the soil in place, and filled with coarse gravel. It must be located a sufficient distance from the building to prevent saturation of the soil under the foundation, generally at least ten feet. If designed and sized appropriately, dry wells work very well over time. They are especially useful where open space and runoff volumes are limited.[10]

Photo #4 of dry well in Phoenix where it used in an industrial site to retain all rainfall on site.

Percolation basins

Percolation basins can be used to capture runoff from roof gutters, walkways, and from larger areas such as parking lots. Perforated pipe is laid in an excavated area, covered with a layer of gravel to provide stability, then paved or covered with soil. The drainage system directs water into the pipes, from where it infiltrates into the ground. If pollution levels are high and underlying soil conditions insufficient to filter out pollutants, collection systems can be installed to collect the pollutants and the water can be retained in these

basins and released slowly into storm drain systems after the peak storm flow has passed.

Diagram of perc basin

Permeable and Semi-Permeable Pavements

Permeable paving can be a porous concrete or asphalt surface or a type of structural support for a gravel or landscaped surface. It facilitates runoff capture and infiltration by increasing the void space in the surface and subsurface of the paving material. These surfaces have been in use since the early 1970s and are widely used in Europe and Japan. Many new permeable paving materials are now being developed and marketed. Depending on the type and size of the area, permeable pavements can be more expensive than standard concrete or asphalt paving and also require more manual labor to install because of the sub-base requirements. However, when the costs of the storm drainage system are added to that of conventional pavement, costs for porous surfaces become very competitive.

There are two general types of commercial porous pavement surfaces: semi-permeable and fully permeable.

Semi-permeable surfaces

Semi-permeable surfaces have a coarse, open-graded surface containing about 25% void space bonded to an impermeable underlayer. Although they do not increase infiltration, they do store rainfall and therefore reduce surface runoff. They were developed originally for airport runways to improve traction, and have been used for road surfacing as well. Caltrans has successfully used this kind of surface. The surface tends to compact, reducing its storage somewhat, but stabilizing at about 15% void space after two years use. Studies in Britain[11] found that the surface could potentially absorb up to 0.3 inches of rainfall when new, reducing to about 0.16 inches over time. This storage capacity would be adequate for many typical Southern California storms, and would slightly reduce the volume of runoff during larger storms.

Fully permeable surfaces

Fully permeable surfaces, which have a permeable underlayer, provide for a more natural runoff condition by allowing rainfall to percolate to the water table. Permeable paving may consist of a multi-layered sub-base covered with a porous asphalt or concrete surface (figure 7). The permeable surface can be achieved with the use of any number of newly produced grid or open-cell pavers. Or the surface can be as simple as cinder blocks laid end to end with gravel packed into the holes, or brick laid without mortar.

Porous asphalt

Porous asphalt utilizes a coarser grade of aggregates, consisting of fewer small particles and less asphalt, so that the resulting surface has void space through which water can pass.

Although it has less cohesive strength than regular pavement, permeable asphalt is adequate for much of the surfacing for parking lots, playgrounds and walkways. In laboratory tests, these surfaces can pass over 60 inches of simulated rainfall per hour. In practice, actual infiltration rates may vary from 5 to 25 inches of water per hour, depending on the depth and composition of the subsurface material and the infiltration capacity of the underlying soil.[12]

Open-cell pavers or grasscrete

are combinations of a concrete or plastic grid with soil fill and grass cover. The grid provides stability and structure, the grass traps runoff, and the soil allows infiltration. Concrete-based grasscretes are about 60% permeable, but the newer polyethylene-based surfaces provide up to 98% open surface area. Although structurally sound, these surfaces are best used for walkways or infrequent parking so that sufficient sunlight can reach the grass. Grasscrete is in use on the UCLA campus at the Anderson School of Management building along the south walkway, providing a transport route for emergency vehicles.

Figure 7: Permeable pavement sample installation cross-section.[13]

Photo 5: Grasscrete installation on the UCLA campus.

Combinations with porous pavement

A porous paving surface and a subsurface infiltration system can also be used, such as a permeable asphalt surface on top of a gravel or stone dry well or over perforated pipe. This surface may also have some weight and traffic limitations, although some of the newer plastic systems are extremely durable, and structurally stable enough to withstand use by heavy emergency vehicles. The infiltration rates on these combined systems are only rarely exceeded, even after a succession of storms.

Decomposed Granite

DG has been used successfully as walkways or paths in Santa Monica parks, and as sidewalks where there are many tree roots in Pasadena.

Photo 6: Decomposed Granite used as a sidewalk or walkway.

Grass Swales and Filter Strips

Swales and filter strips are shallow depressions or open drainage areas which may be planted with grass or other vegetation, into which runoff is directed. The vegetation helps reduce runoff speed and absorbs rainfall. These are used in highway medians, parks, residential areas, parking lots and many other landscaped or open space areas. Swales and strips are comparable in cost and maintenance requirements to traditional landscaping, and

have the added benefits of trapping sediments and filtering pollutants[14]. The incorporation of sand and/or peat filtration can increase infiltration capacity and offers a simple solution to water quality problems. Peat filters, when installed as part of the subsurface layer under the vegetation, and combined with a sand-gravel layer for percolation, can absorb many times its weight in oils. Peat also removes heavy metals and significant amounts of nutrients and bacteria from the water as it filters through.[15]

Photo 7: Grass swale, Phoenix.

Management or Non-structural Approaches

The so-called "non-structural" methods refer to more integrated approaches to watershed management, not to specific engineering solutions. These can take the form of planning procedures, floodplain zoning regulations, local ordinances, and design standards that encourage or require reduction of runoff through various techniques. They can apply to existing development and heavily developed floodplains, as well as to future development.

A watershed approach to reducing both volume and velocity can also aim to store and utilize stormwater and minimize discharges to receiving waters. It can detain more runoff in the upper reaches of the watershed by a whole host of techniques (see above). Additionally, floodplain management that controls activities in areas subject to flooding through special zoning, permitting, public education and enforcement of flood insurance requirements will reduce both property damages and public risk.

Sometimes simple design changes will change the runoff characteristics of an area significantly, such as using slightly graded or concave surfaces instead of convex surfaces for landscaping, and providing outlets for runoff into dry wells or vegetated areas (figure 9). Simply changing the design of parking lots, to direct the sheet flow into planted areas instead of isolating these areas with concrete curbs, captures a good deal of runoff. Increasing vegetation and the amount of permeable space in the watershed reduces runoff by enhancing infiltration of rainwater, which also provides groundwater recharge.

Photos 8 and 9: Two approaches to parking lot design: in left photo there is no outlet for runoff, right photo shows planters flush with the surface to allow access to vegetated area for drainage.

Examples of Local Government Regulations

There is an increasing trend in cities to require new developments to manage runoff to meet a specific target, such as capturing all runoff on-site during construction and ensuring that runoff is reduced, or does not increase overall, after the development is completed.

- **The City of Santa Monica's** Urban Runoff Mitigation Ordinance was developed in cooperation with builders and environmentalists, and implemented in 1993. It requires

new development projects to incorporate design measures to reduce runoff by 20%, as well as control runoff and erosion during construction. Developers are required to submit an Urban Runoff Mitigation Plan prior to project approval. An evaluation of seven of the projects completed since the ordinance took effect indicates that nearly 1.1 million gallons of runoff were diverted from Santa Monica Bay over the 1994-95 winter season, an average of 31,000 gallons per storm. Overall, runoff was reduced at these sites an estimated 24%. As additional projects are built in compliance with the ordinance, substantially more runoff diversion is anticipated. (Full text of this ordinance can be found in Appendix B.)[16]

> (Definition box) 20% of What? The target reductions often cited in municipal ordinances and development codes are relative to the amount of runoff that would occur if special measures were not taken. These amounts are based on LA County's standardized runoff calculations for various types of urban development and the percentage of impervious cover.

- **The City of Malibu** requires the adoption of a Storm Water Management Plan for new construction and for subdivision map act approval. The city also requires mitigation for any increased runoff beyond what is natural, or a system to handle a 25 year storm event. The city has adopted a formula that regulates the amount of permeable surface in the design of any new development, and encourages the use of permeable surfacing wherever feasible. The city also requires that homes in lots of up to two acres must be built in a convex shaped enclosure to retain storm water, and development on slopes is closely regulated. It also requires pollution prevention practices. (Full text of this ordinance can be found in Appendix B.)

- **The City of Calabasas.** The Urban Runoff Pollution Control section of the city's development code incorporates regulations to reduce runoff volume and slow runoff flows by increasing infiltration. The provisions apply to any new development that includes grading, building new structures, or paving. Permit issuance is conditional upon approval of a Runoff Mitigation Plan. The Plan must demonstrate total runoff reduction of 20% by incorporating a minimum area of permeable surfaces, and directing runoff either to permeable areas for infiltration or to storage areas for reuse. Recommended measures include the use of porous paving for parking lots and walkways, diverting runoff to detention basins, drains or landscaped areas such as swales and grass strips for infiltration, or capturing runoff from rooftops or in subsurface structures for reuse.

  The requirements are too new to evaluate, but Mitigation Plans received so far show a preference for the use of porous pavements because they are the easiest to install. There are limits to the weight bearing capacity of some types of pavers however, and the prevalence of expansive clay soils in the area limits the use of infiltration measures within a certain distance of building foundations. (Full text of this ordinance can be found in Appendix B.)

- **Los Angeles County**, as a National Pollutant Discharge Elimination System (NPDES) permit holder, is required to manage municipal stormwater discharges. The County's Department of Public Works has developed a program to implement the requirements of the permit, and to serve as a model for the 86 cities that are co-permittees. The program establishes guidelines for minimum standards, monitoring compliance, education and public outreach. For new or re-development, the program establishes Standard Urban Storm Water Mitigation Plans, designed to minimize runoff pollutants and reduce overall runoff volume by increasing on-site retention and infiltration. Some of the suggested techniques include porous paving and other alternatives to concrete such as vegetated swales, buffer strips, and extended detention basins.

- **The City of Los Angeles** established a stormwater pollution abatement charge in 1990, to collect funds for stormwater control, treatment and disposal.[17] The charge is levied as a property tax assessment, based on the type of land use and a runoff factor that represents the amount of runoff generated by that land use. What is interesting about this so-called "stormwater utility fee" is that the charge is based on the amount of impermeable cover on a given parcel, and may be appealed if the landowner can document a lower runoff factor. Thus it provides a potential incentive for landowners to reduce the amount of runoff generated on their property.

Non-traditional Approaches in Action

Projects in the Los Angeles Area

Cool Schools and Sustainable Schools

The Los Angeles Unified School District recently began implementing infrastructure improvements, including playground repaving for 400 schools. With the leadership of TreePeople, and the Hollywood Beautification Team, LAUSD decided to reduce paved areas by 30% thoughout the school. Although the unpaving was based primarily on the need to shade and cool classrooms to reduce air conditioning energy costs, a number of management practices are under consideration which will provide a greener, more sustainable environment, capture runoff, and reduce air and water pollutants. TreePeople developed a pilot project now under construction at the Open Charter School (formerly the Osage School) in Westchester. The Los Angeles City Stormwater Division and the Santa Monica Bay Restoration Project funded this demonstration which will include facilities to capture and treat parking lot-polluted runoff on-site for reuse as irrigation water, replace substantial paved areas with permeable surfaces and finally, provide additional landscaping, and mulching of green waste.

Under the guidance of TreePeople, North East Trees, the Los Angeles Conservation Corps and the Hollywood Beautification Team, the Los Angeles Department of Water and Power is funding Cool Schools, a program which plants up to 100 trees on 40 schools per

year throughout the district. As part of that program, two sites were targeted to be Sustainable Schools, each demonstrating a variety of stormwater capture, flood mitigation and water conservation technologies. The two schools are Multnomah School in east Los Angeles, and Broadous in Pacoima.

Green Waste and Water Conservation

Long Beach Organic, a non-profit community service organization, has been facilitating community gardening and green waste recycling on vacant lots in the greater Long Beach area since 1994.[18] They are currently securing funding for a proposed plan to divert 15,000 tons of green waste destined for landfills in Los Angeles County, to use as mulch for weed abatement, water retention, bio-filtration, and the creation of compost for soil amendment on additional acreage in Long Beach and Signal Hill.

One of the primary goals of the project is to measure the effects of mulch and compost on runoff and soil infiltration. Mulch cover provides insulation to retain soil moisture, reducing evaporation and soil erosion. Compost can hold up to eight times its weight in water, which would not only reduce runoff but also provide increased infiltration time. This project is scheduled to start as soon as funding is finalized, and will continue monitoring into 2001.

Alternatives to Engineered Flood Control

Sun Valley Watershed, a 2,681-acre sub-watershed located north of downtown Los Angeles between Tujunga Wash and the Burbank Airport and tributary to the Los Angeles River, experiences problems with flooding during heavy rains. The existing drainage system within the watershed is inadequate, but the cost of constructing a traditional storm drain to alleviate the flooding has been estimated to be $42 million. Los Angeles County is considering the possibility of alternative solutions in the watershed that would address the flooding problem while providing additional benefits to the community such as increased recreation, reduced flows and pollutant loads entering the Los Angeles River, increased water and energy conservation, and enhanced wildlife habitat.

Any alternative project must be able to provide the same level of flood protection without adversely impacting groundwater quality in the region. Retrofitting existing developments and requiring new development to capture runoff onsite are among the solutions under consideration, as are the use of permeable paving where feasible, and creating detention and/or retention basins to capture runoff, and to provide habitat and recreation during dry periods. Support for this project is high. A stakeholder group was formed late in 1998 to evaluate the feasibility of various alternatives. Economic studies of this alternative are now under way. It is hoped that this project will serve as a model for flood control design in other parts of Southern California.

Sustainable Planning – The T.R.E.E.S. Project

The Transagency Resources for Environmental and Economic Sustainability (TREES) project was founded by TreePeople in 1995 with the financial support of many

government agencies. Its goal is to demonstrate "the economic, environmental and social benefits gained by cooperative approaches to designing our urban landscapes as a series of functioning mini-watersheds." The implementation of more sustainable design and management measures would result in significant reductions in imported water use, in the volume and velocity of urban runoff generated, and in the amount of pollutants carried by runoff to the ocean. It would also reduce energy consumption, reduce tipping fees at local landfills by chipping up greenwaste and leaving it on site as mulch, and create jobs for traditionally underemployed populations.

The initial design conference brought together engineers, landscape architects and other experts to develop sustainable landscape designs for commercial, industrial, multiple and single family residential, and a public site. A design planbook called "Second Nature, Adapting LA's Landscape for Sustainable Living" was produced which includes prototype designs for retrofitting these different types of land uses . Each design includes a variety of suggestions for accomplishing a more sustainable local environment.[19]

The single family home, in the Crenshaw District of Los Angeles, was retrofitted to demonstrate the ideas generated during the design conference. It is now capable of capturing rainfall from a 2-inch storm on site. Water from the front half of the roof is directed into the lawn area that has been prepared with gravel beds placed underneath the sunken lawn, and into a dry well installed at the end of the driveway. The back half of the roof drains into cisterns made of recycled plastic, where the water is stored for use as irrigation water during dry weather. The backyard also contains a mulched swale to capture, filter and infiltrate the rain that falls in the back yard.

Photo 10: Crenshaw District home that was retrofitted.

Figure 9: Diagram of how this home was retrofitted.

TreePeople has also developed cost-benefit modeling software that allows different design scenarios to be easily evaluated prior to implementing solutions. This cost benefit model is being used by the County to evaluate the proposals for retrofitting Sun Valley.

The final component of the TREES project is an implementation plan, which will identify investment strategies for financing the wide scale retrofitting of properties throughout the entire watershed. It has begun an education program to encourage property owners and others to make their sites more sustainable. TreePeople has also been a great resource in helping to design solutions for several of the other projects discussed here.

Runoff Reduction

Venice Off-Street Parking Lot projects are currently in progress by the city of Los Angeles' Architectural Division, incorporating several methods of Storm Water Management Best Practices. One of these projects is the lot used for the Venice Farmer's Market, at the corner of Venice Boulevard and Venice Way. It was recently redesigned to

capture and filter runoff onsite. Strip filters surrounding the lot collect runoff for bio-filtration and groundwater recharge. The lot was landscaped to collect additional runoff and reduce the amount of hardscape area. The city is also installing porous paving and filtration devices on other sites.

Photo 11: Venice Farmers Market Parking Lot.

Santa Monica Urban Runoff Recycling Facility is under construction. This first in the nation of its kind project will divert the dry weather urban runoff contained in two storm drains, and treat that water to sufficiently high quality for use in landscape irrigation and to flush toilets in buildings which are especially plumbed to do this within the city. The cleaned water will be used to irrigate the Santa Monica Freeway, City parks, the Woodlawn Cemetery, and school grounds. Dual plumbed customers will include the City's Public Safety Facility and the Water Gardens complex located at Olympic and Cloverfield. The Urban Runoff Recycling Facility has also been designed to serve a public education function, providing the visitor with views of the process and explanatory texts. Pollution prevention and appreciating the facility's position in the watershed will be the messages.

Photo12: Santa Monica's Urban runoff Recycling Facility (This photo can be downloaded from the City's web site http://pen.ci.santa-monica.ca.us/epwm/smurrf.html)

(definition box) How much can we save?
Although we can not expect to capture 100% of the runoff in the watershed, what impact does capturing some portion of precipitation have on total runoff? Here is one example: over half of the LASG watershed is classified as some type of urban land use. If we could capture 80% of the rainfall that falls on the just a quarter of the urban area -- 15% of the total watershed -- we would be reducing total runoff by approximately 30%. That translates into a diversion of 43 billion gallons of water per year, or enough to supply 800,000 people for a year.
(calculations based on average annual rainfall of 15.5", average annual LA river discharge at 460,000 acre-ft, and Los Angeles DWP estimates of average per person water use of 49,275 gal/yr.)

Where Do We Go From Here?

This small sampling of projects illustrates the diversity of design strategies being implemented to manage stormwater runoff and reduce the need for more regional storm water management facilities. There are many other examples of sustainable practices in use or in the planning stages throughout the county. All of these together demonstrate the change in thinking that is taking place -- stormwater is starting to be considered more of an asset that can be put to beneficial use, while at the same time reducing the threat to the public from devastating floods.

A comprehensive watershed management plan can only be developed if appropriate tools are available to assess the different management strategies. Geographic Information Systems (GIS) are one tool that can be used to assess the cumulative impacts when different watershed management strategies are implemented in a watershed. Appendix A presents some of the data that can be used in GIS watershed management tools. The data presented in Appendix A are just a sampling of the data available for the Los Angeles - San Gabriel watershed. Future work should focus on developing new data and on using the data to assess the impacts of different watershed management strategies. One of the tasks of a project currently underway between the County and the Army Corps of Engineers is to catalog the various data sources available for the watershed that would be useful for planning.

Development of new methodologies requires interdisciplinary thinking, which may also require unconventional partnerships between different disciplines. A cooperative approach is needed to manage all of the individual but interrelated issues in the watershed. While it is highly unlikely that the existing conveyance network will be replaced by a network of smaller infiltration and retention facilities, a combination of methods will allow us to:

- promote water conservation and reuse,
- reduce our dependence on imported water,
- recharge groundwater supplies,
- provide flood protection
- provide much needed parks and open space,
- restore fish and wildlife habitat,
- increase local property values
- stimulate redevelopment in our inner cities.

A change in direction in our approach to stormwater and runoff management -- from liability to asset -- must be accomplished one step at a time. Here are a few practical steps that can be taken immediately to start this redirection:

- Understand how different types of land use impact the stormwater aspects of watershed management.
- Look for opportunities to require features that conserve, clean up, and reduce storm runoff when new development, or in more established areas, redevelopment is proposed.
- Be aware of technological advances in products and programs that can assist.
- Learn about stormwater/watershed ordinances already in place; learn from what others have already done and are doing.

If dealt with appropriately, stormwater can be an asset helping to improve the quality of life for the citizens of our cities and County for generations to come.

The time to start is now.

Appendix A:

Spatial Data for the Los Angeles-San Gabriel Watershed

A comprehensive watershed management plan must be based on different physical data of the watershed and appropriate tools for analysis. The maps presented in Figures A1-A3 present three examples of types of data that are important in forming an alternative stormwater management plan for the Los Angeles - San Gabriel Rivers watershed. Figure A1 shows the digital elevation model (DEM) for the watershed at a 30-meter spatial resolution, which may be used to derive slope. Figure A2 shows the current land uses for the watershed and Figure A3 shows the rainfall infiltration rates, based on soil type. Other useful data may include:

- habitat and wetlands
- "shrink-swell" potential of different soils
- type of vegetation cover in undeveloped areas
- location and depth of groundwater basins
- hazards such as earthquake zones
- spatial variability of precipitation amount and intensity

These data can be used to identify areas where nontraditional approaches to stormwater management may be implemented. For instance, the soil infiltration rates identify those areas where it might be appropriate to place permeable pavements and onsite infiltration facilities. Identification of these areas can also be accomplished by creating hydrologic units—combinations of soil attributes, slope, and land use—to identify areas that have common hydrologic characteristics. Finally, these data can also be used to assess the cumulative impact and cost/benefit ratio of various stormwater management practices in the watershed.

Figure A1: Digital elevation model (DEM) for the Los Angeles - San Gabriel watersheds.

Figure A2: Current land uses for the Los Angeles - San Gabriel watersheds.

Figure A3:Infiltration rates for the Los Angeles - San Gabriel watersheds based on a 0.5 inch per hour rainfall intensity.

GLOSSARY

Base Flow of Streams -- Water slowly percolates underground and then spreads laterally until it reaches the surface (not pumped up) becoming part of the natural flow in rivers and streams, its base flow. This seeping ground water is what maintains the flow in a river due to the return flow of groundwater.

Cistern -- Storage tank built either above or below ground or on a roof to store water for later use: for irrigation, fire fighting, and in some countries, for drinking and bathing.

Compost -- Decaying vegetation. Can be used as ground cover or mulch, and as fertilizer.

Dry Well -- A constructed well designed to receive water for groundwater recharge.

Design Storm -- The size of a storm, defined by duration, intensity and amount of precipitation, that storm drain systems are designed to accommodate.

Detention Basin -- Temporary storage to reduce the peak flow, but not the total volume of storm water during a storm.

Flood Plain -- The lands next to rivers and streams that flood naturally during large storm events. The flood plain's function is to store sediment and flood flows.

Groundwater -- The water that collects and is stored underground into basins defined by the underlying geology. Water pumped from underground basins provides about 1/3 of drinking water supply in the Los Angeles basin.

Groundwater Recharge -- Surface water that filters into the ground and reaches underground reservoirs, providing replenishment and/or increased storage for groundwater basins. This occurs naturally during and after rainstorms, in creek beds with

flowing water, or can be accomplished purposefully by directing storm water into specially prepared recharge areas for infiltration.

Hundred Year Storm -- There is a 1 in 100 chance of a storm of this magnitude happening in any one year. Hundred year storms are recalculated over time due to changes in the landscape.

Hydrology -- The occurrence, distribution, movement, and properties of water above and below the earth's surface. The natural hydrology of an area may be significantly altered by catastrophic events (earthquakes, landslides) and by human development (agriculture, urbanization).

Impervious or impermeable -- A surface that does not allow the passage of water and thus potentially facilitates the generation of runoff.

Infiltration -- The process by which water moves downward through the earth's surface, replenishing soil moisture and groundwater basins. The ability of the soil to infiltrate water depends on many factors, including the nature of the surface cover, and soil characteristics such as texture and depth.

Mulch -- organic material placed on the ground, sometimes many inches thick, used as a ground cover to cool the soil, discourage weeks and erosion, aid in the infiltration of water, minimize the heat island effect of the city, and reduce the costs of green waste disposal.

Percolation -- The act of water soaking into the ground. This term is used most frequently in conjunction with spreading grounds, where water is purposefully allowed to percolate through the soil to the groundwater.

Percolation Basin -- An above ground storage place - retention basin - built so as to encourage the percolation of water contained therein underground.

Pervious or Permeable Surfaces -- Surfaces that allow water or other liquids to penetrate and potentially reach the ground (depending on the thickness of the surface, how porous it is, and the amount of water.

Porosity -- A measure of the ability of water to pass through a material, which is dependent upon how much empty space occurs between the particles that make up the substance. For example, sand is much more porous than clay.

Precipitation -- Rain, hail or snow that falls from the atmosphere.

Retention Basin or Infiltration Basin -- Stores water with the purpose of reducing the volume of runoff by capturing precipitation and surface runoff for recharge to groundwater. These basins do not return captured runoff to storm water channels.

Return Period -- The average recurrence of a storm of a particular size and duration.

Riparian Habitat -- Habitat next to rivers or streams and dependent on the additional moisture in the river. Its function is to provide food and shelter for many creatures, to reduce the volume and velocity of runoff, and increase infiltration.

River Corridor -- Includes the river, the flood plain, the riparian trees and plants that grow in the high groundwater and most soils along the way.

Spreading Grounds -- A land area specifically designed to be flooded so that the water will percolate or soak into the ground, recharging the ground water.

Sustainability -- The ability to meet current needs without compromising the ability of future generations to do the same. Or the goal of securing life, liberty, and social well-being within the means of nature.

Velocity of Flow -- How quickly the storm water flows over the surface or through the storm drain system to the ocean. Velocity is determined by the design of the conveyance system: how wide, how smooth or rough, and the slope of the conveyance.

Water Conservation means different things in different contexts. Usually, it means using less (consumer or farmer or landscape) due to hardware or management strategies. In the storm water management context, it means storing water in retention basins or behind a dam for infiltration to the ground water, making the water available as an addition to the drinking water supply.

Watershed -- A region or area, all of which drains to a particular watercourse or body of water.

About the Authors

Thomas Piechota is an assistant professor in the Department of Civil and Environmental Engineering at the University of Nevada, Las Vegas. He received his B.S. in Civil Engineering in 1989 from Northern Arizona University, his M.S. in Civil and Environmental Engineering in 1993 from UCLA, and his Ph.D. in Civil and Environmental Engineering in 1997 from UCLA. His research interests are interdisciplinary in the areas of surface water hydrology, hydroclimatology, water resources planning, and stormwater quality in urban environments.

Suzanne Dallman is a Ph.D. candidate in the department of geography at UCLA. Her current research is focused on environmental policy and watershed management. Ms. Dallman received her Master's degree in geography from CSU Long Beach, and is an

instructor in the GIS certificate program offered through CSULB Extension Services. Her research interests are in the impacts of human development on natural resources and the environment, with a particular interest in watershed and water resources management, land use and environmental policy.

This paper introduces the concept and purpose of stormwater infiltration, and discuss variations in its feasibility and modes of implementation. In the United States experience has been gained in stormwater infiltration since about 1930; there are now more than 20,000 infiltration basins in the country. Examples from several regions illustrate experiences with a variety of climates, soil types, urban land uses, and construction details. Particular data and examples from the Los Angeles area are presented in order to address the particular conditions of the Southwest.

In natural watersheds infiltration is the characteristic and governing process. Vegetated soil absorbs rain water; the infiltrated water recharges ground water aquifers and restores stream base flow; overflows onto the floodplain are frequent and gentle; the soil ecosystem captures and degrades most pollutants that may be present. That natural watersheds work this way is of great benefit to people: it reduces hazards of peak flows and erosion, mitigates pollution, and protects aquatic ecosystems.

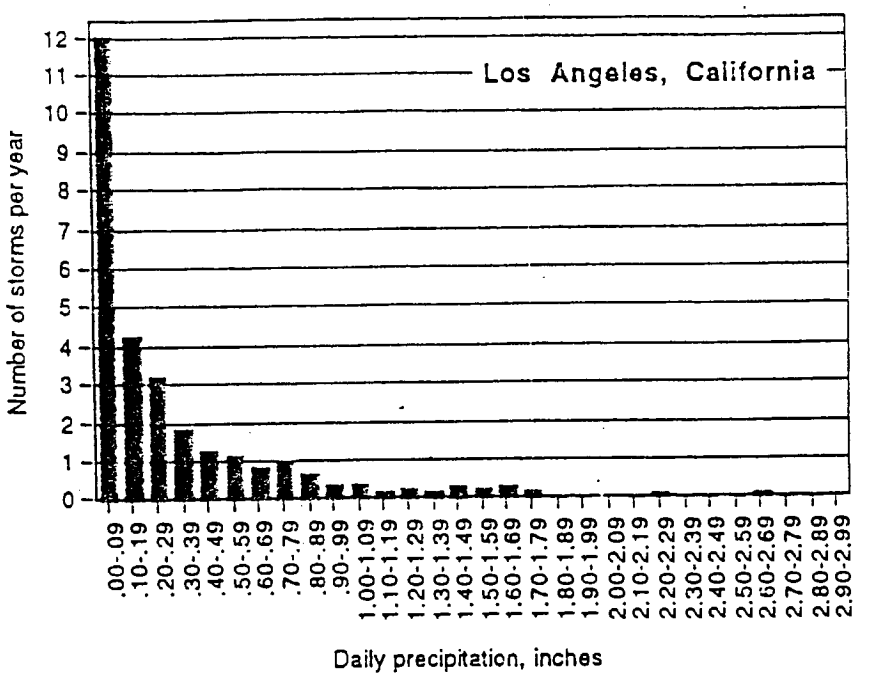
Urban development that covers the land surface with impervious surfaces tends to lose these functions. Rain water is deflected across the surface into direct runoff, which flushes pollutants directly into streams, aggravates peak flows, erodes stream banks, and destroys aquatic habitats. The loss of infiltration causes ground water to decline; streams and wetlands go dry in summer; aquatic ecosystems die; public water supplies decline.

Stormwater infiltration is the only urban stormwater management approach that restores natural watershed function. Stormwater infiltration restores hydrologic function to watersheds. In an infiltration basin, water ponds during storms. All the water from small, frequent storms, and the first water from large, infrequent storms, infiltrates the soil; the "first flush" of pollutants is consistently treated. The excess water from larger, less frequent storms, exceeding the capacity of the basin, continues to flow down the stormwater drainage system. There are some places not to do infiltration because of water quality, maintenance, and other hazards: on steep unstable slopes, on grossly permeable gravel soils, over septic tanks, over toxic soils in old industrial areas, and where upstream soil could erode and generate sediment. But outside these local spots, stormwater infiltration is the most complete possible response to broad stormwater quantity and quality issues.

In the Los Angeles area and other parts of the Southwest, water resource agencies have long practiced infiltration under the name of water spreading. Watersheds such as that of the San Gabriel River have been organized to capture mountain runoff, urban runoff and reclaimed wastewater in large basins such as Los Angeles' Rio Hondo Spreading Grounds where it recharges the coastal plain aquifer from which the city takes its water supply. Even extreme flood waters are sometimes recharged in the unlined San Gabriel River channel below Santa Fe Dam.

Infiltration basin capacity is limited on sites with slowly permeable soil and urban sites with little space. Nevertheless in small basins it is hydrologically feasible to infiltrate a large proportion of rain water over the course of a year, and to treat a large proportion of storm events, because most of the rain storms and most of the water are in small, frequent storms. For example in the Los Angeles area, daily rainfall of less than 0.1 inch occurs 12 days in an average year, and the frequency of larger storms declines logarithmically. 50 percent of Los

Angeles' annual rain falls in storms of less than 0.8 inch. Thus the bulk of the annual rain water and of the "first flush" events can be handled with infiltration basins of modest water storage capacity. Small basins cannot completely infiltrate the water from rare peak storms such as the 10-year and 100-year storms, or significantly reduce peak flow during such storms; but all other quantity and quality aspects of urban watersheds can be substantially addressed with small, feasible infiltration basins.



Open infiltration basins, constructed at the land surface, are usually vegetated. Grading and planting can conform to the needs of the urban sites where they are located. They alternately pond up and dry out with the passing of storms. Prompt drying after a storm is necessary to prevent peat formation and clogging; drying time is controlled by setting the overflow elevation in consideration of soil infiltration rate.

Subsurface infiltration basins are excavated below a proposed pavement or other surface and filled with open-graded stone or perforated pipes to produce storage capacity. Stored water infiltrates the surrounding soil. On densely developed sites with high land value such as shopping centers, the investment in construction materials can be more than compensated by the saving in land allocation.

In porous pavements, the porous pavement surface doubles as the drainage inlet system, and the pavement base course doubles as the subsurface infiltration basin; both provide preliminary treatment. Eight families of porous materials are available for selection to meet site-specific needs and constraints such as cost, appearance, and durability. Porous asphalt's surface infiltration rate has been found to decline after construction, and after 3 or 4 years to stabilize at about 1/4 to 1/10 of its initial value. Drainage should be away from the edges of a porous pavement in all directions, in order to prevent clogging sediment draining onto the pavement from adjacent eroding slopes. Curbs should be omitted in order to allow clogging debris to be washed and blown off the pavement.

State of California
CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD, LOS ANGELES REGION

Resolution No. 99-03

APPROVING BEST MANAGEMENT PRACTICES
FOR
MUNICIPAL STORM WATER AND URBAN RUNOFF MANAGEMENT PROGRAMS
IN
LOS ANGELES COUNTY

(NPDES NO. CAS614001)

WHEREAS, THE CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD, LOS ANGELES REGION FINDS:

1. Pursuant to the requirements of Order No. 96-054, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles (Permit), the Principal Permittee, in consultation with the Co-Permittees, has developed model programs for Development Construction and Development Planning. These programs must include Best Management Practices (BMPs) to control/ minimize the discharge of pollutants to receiving waters.

2. The Permit requires that the Regional Board approve these BMPs, to be part of the Development Planning and Development Construction Model Program, before implementation by Permittees.

3. The Lists of BMPs have been evaluated and are considered appropriate practices for the respective programs/ activity.

4. This Resolution adopts a master list of BMPs for Development Planning and Development Construction Projects in Los Angeles County. These BMPs when implemented at development projects, in combination, will reduce pollutants in storm water discharges to the "maximum extent practicable".

THEREFORE BE IT RESOLVED THAT:

1. The Best Management Practices contained in the following Attachments are approved:

   a. Attachment 1 - Development Planning
   b. Attachment 2 - Development Construction
   c. Attachment 3 – Supplementary List of BMPs

2. The Permittees shall select and require implementation of the most effective BMPs, approved and attached hereto (and as may hereafter be updated) for storm water/ urban runoff pollution control benefits.

3. The Regional Board Executive Officer is hereby authorized to update the master list and to incorporate additional detail to the BMPs as necessary.

I, Dennis Dickerson, Executive Officer, do hereby certify that the foregoing is a full, true and correct copy of a Resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on April 22, 1999.

DENNIS A. DICKERSON
Executive Officer

Date: April 22, 1999

Supplemental Declaration of Richard R. Horner

1. I, Richard R. Horner, do state and declare that the following facts are within my personal knowledge, and that I am competent to testify, and that if called upon to testify, I could and would give competent testimony consistent with the following facts.

2. I am a professor in the Departments of Civil and Environmental Engineering and Landscape Architecture at the University of Washington, where I have been conducting research and teaching for the past 18 years. My primary area of expertise is in urban runoff.

3. I am also the sole proprietor of my own consulting business, which I began 14 years ago.

4. I have published over 100 book chapters, articles, and technical reports on the subject of urban runoff.

5. From 1996 to 1999, I participated in discussions between the Natural Resources Defense Council and the Los Angeles County Department of Public Works (the "County") regarding the County's development of its stormwater management program, as outlined in its Stormwater Program Implementation Manual ("County's Manual"). Consequently, I am very familiar with the County's program.

6. One aspect of these discussions that received a great deal of attention was the topic of how the County would regulate future development planning and, in particular, the form and content of the standard urban stormwater mitigation plans ("SUSMPs") that were to be inserted into the volume of the County's Manual pertaining to development planning. Consequently, I am particularly familiar with the SUSMPs in the County's program.

7. In my many years of studying stormwater management programs from all over the country, and the world, I have seen that there are myriad ways of articulating a standard for the design and sizing of structural best management practices ("BMPs"). One such method is to set a numerical standard for the amount of runoff that BMPs must be designed to manage – or the amount of *rainfall* whose runoff the BMPs must be designed to manage. In my professional judgment, the majority of municipalities that have a numerical standard have a more stringent one than Los Angeles County's standard of requiring BMPs to manage the runoff from the first 0.75 inches of rain.

I declare, under penalty of perjury under the laws of the State of Washington, that the above is true and correct. Executed in Seattle, Washington, this 13 day of January, 2000.

Re: Support for the 3/4 inch standard to reduce runoff from new and redevelopment

Dear Mr. Dickerson:

I recently have had the chance to review the standard urban stormwater mitigation plan for Los Angeles County and Cities in Los Angeles County. Treatment of the stormwater quality is an essential element for protecting local watersheds, and is widely used by many municipalities around the country. I strongly support the three-quarter inch runoff treatment standard based on past scientific research on the performance of stormwater best management practices. I have also enclosed a recent article on stormwater strategies for arid and semi-arid watersheds that may be helpful in adapting effective stormwater practices for your region.

Thank you for the opportunity to comment on the proposed stormwater mitigation plan. Adoption of the three quarter inch standard will help to protect the creeks and coastlines of Los Angeles from the impacts of stormwater pollutants, and represents a fair, equitable and achievable threshold for stormwater treatment.

Sincerely,

Thomas R. Schueler

Re: Proposed Model Standard Urban Storm Water Mitigation Plan (SUSMP)

Dear Mr. Dickerson and Members of the Board:

I have reviewed the proposed *Standard Urban Stormwater Mitigation Plan for Los Angeles County and Cities in Los Angeles County* and wish to make the following general comments.

I support the Regional Water Quality Control Board's adoption of the proposed 0.75 inch standard for the design of best management practices. Many municipalities around the country have implemented standards at least as stringent as this one to minimize the stormwater pollution from new development and redevelopment, and this standard is an entirely reasonable one.

However, the current proposal includes a host of exemptions that are overly-broad and that significantly weaken the impact of the numerical standard. The 0.75-inch standard should be adopted, but it should not be subject to the waivers and other exceptions currently contained in the proposed Mitigation Plan. The rooftop exception is particularly troubling, as many researchers have found rooftops (and associated roofing materials) to be an important source of stormwater pollutants and excessive flows. By eliminating these flows from treatment and from the runoff calculations, the effectiveness of the stormwater Mitigation Plan will be significantly reduced.

Sincerely,

Robert Pitt, P.E., Ph.D., DEE

Declaration of Richard R. Horner

1. I, Richard R. Horner, do state and declare that the following facts are within my personal knowledge, and that I am competent to testify, and that if called upon to testify, I could and would give competent testimony consistent with the following facts.

2. I am a professor in the Department of Civil Engineering and Landscape Architecture at the University of Washington, where I have been conducting research and teaching for the past 18 years. My primary area of expertise is in urban runoff.

3. I am also the sole proprietor of my own consulting business, which I began 14 years ago.

4. I have published over 100 books, articles, and technical reports on the subject of urban runoff.

5. From 1996 to 1999, I participated in discussions between the Natural Resources Defense Council and the Los Angeles County Department of Public Works (the "County") regarding the County's development of its stormwater management program, as outlined in its Stormwater Program Implementation Manual ("County's Manual").

6. One aspect of these discussions that received a great deal of attention was the topic of how the County would regulate future development planning and, in particular, the form and content of the standard urban stormwater mitigation plans ("SUSMPs") that were to be inserted into the volume of the County's Manual pertaining to development planning.

7. Development planning is of central importance in any stormwater management program. The problem of stormwater pollution is directly related to the amount of directly connected impervious surfaces in an area, which increases the volume and rate of runoff. Because development generally involves an increase in the amount of impervious surfaces, designing development with stormwater management principles in mind is one of the most critical issues in the control of stormwater pollution. The Los Angeles area has one of the most severe stormwater pollution problems of any area in the United States, and it has experienced an enormous increase in development-related runoff over the last 50 years.

8. In our discussions regarding the County's development planning program and the SUSMPs to be adopted, I recommended that a specific numerical standard be inserted into the SUSMPs to ensure that future development would be designed so as to retain and mitigate a certain minimum volume of the runoff generated from the development sites. I recommended that the standard be set to require mitigation of all the runoff generated by either (1) storms of up to and including 1.0 inch; or (2) the one year, 24-hour storm.

9. My recommendation was based on my understanding of the hydrology of the Los Angeles area, my experience with other jurisdictions around the country, my twenty-plus years of research in the area of stormwater pollution, and well-established scientific and engineering principles related to stormwater and urban runoff.

10. Ultimately, the County adopted a 0.75-inch standard. I concluded that, at the present time, such a standard would be minimally acceptable.

I declare, under penalty of perjury under the laws of the State of Washington, that the above is true and correct. Executed in Seattle, Washington, this 13 day of September, 1999.

CHAPTER 8

Urban Runoff Treatment Practices

Urban runoff management in its broadest and most comprehensive form involves controlling both the quantity and quality of runoff. Control options are commonly called best management practices (BMPs).

Quantity control practices regulate the peak flow rate and sometimes the total volume from precipitation. Water quality control practices prevent the initial release of pollutants into urban runoff, or once they are released, reduce the quantities that enter surface or groundwaters. Completely recapturing released pollutants is impossible, and the expense increases for higher and higher levels of recapture. Prevention is more efficient and cost-effective. This chapter examines the principles of runoff quantity and quality control and details a number of treatment practices.

Control practices are categorized in a number of ways. One system is as follows:

- **Quantity control practices.** Methods of detaining runoff to regulate its rate of release to receiving waters or to infiltrate runoff into the ground so that it does not become surface flow.
- **Management practices.** Ways of doing business to prevent pollutant releases.
- **Source control practices.** Specific actions taken at potential sources to prevent pollutants from contacting precipitation or runoff.
- **Erosion and sediment control practices.** A variety of techniques used to control areas that have been bared from construction in progress or have not been revegetated after construction or other activities.
- **Treatment practices.** Facilities that remove pollutants already in runoff.

These practices are often divided into structural and nonstructural groups. Nonstructural practices mainly embrace preventive actions that do not require building anything, such as management and source control practices. Many erosion and sediment control practices are also preventive, although some—like filter fabric fences and sedimentation ponds—treat runoff containing eroded sediments and involve construction or hardware installation. While quantity control can be nonstructural (e.g., policies to retain natural soil and vegetation cover), it generally involves building a facility such as a detention pond or an infiltration device. Treatment practices are usually structural.

This chapter covers permanent structural quantity control and treatment practices. Chapter 14 provides specific criteria for inspecting these facilities after construction and periodically thereafter to determine maintenance needs. Chapter 12 covers management and source control practices. Erosion and sediment control practices are covered in Chapter 7 and their inspection in Chapter 14.

Structural quantity control and treatment practices can also be grouped in various ways, one of which is the following:

- **Storage practices**
  - Ponds—wet ponds, extended-detention dry ponds, and dry ponds
  - Vaults and tanks
  - Oil separators
- **Vegetative practices**
  - Swales
  - Filter strips
  - Wetlands—natural and constructed
  - Landscape management (i.e., urban forestry)

- **Infiltration practices**
  - Basins
  - Trenches
  - Perforated pipes
  - French drains
  - Porous pavements
- **Filtration practices**
  - Sand filters
  - Leaf compost filters
  - Catch basin filters (various media)

The ponds, vaults, and tanks under storage practices can benefit quantity control, quality control, or both. However, dry ponds drain too quickly to provide any substantial runoff treatment. Enclosed vaults and tanks are limited in biological activity and are usually too small to function well in water quality control. Therefore, these devices are only effective for quantity control. Wetlands and all infiltration options can also supply quantity and quality control. The remaining practices are largely treatment devices.

In a number of instances, one mode of operation (storage, vegetative treatment, or infiltration) predominates but the practice incorporates other modes. For example, wetlands involve both storage of water and vegetative action. Also, most ponds infiltrate some water unless they are lined.

The trend is to combine the capabilities of two or more options by establishing "treatment trains" arranged in series, a strategy discussed at the end of this chapter.

Practice Selection

Success in applying any management practice initially depends on selecting the appropriate option for the site's control objectives and conditions. The objectives must be clearly delineated at the outset and conditions investigated in enough detail to match the practice to the site. Objectives might include whether quantity control, quality control, or both are to be provided; what pollutants are to be treated; and what, if any, side benefits are to be produced. Conditions that determine a practice's relevance include service area, soils, hydrogeologic conditions, and circumstances of the receiving water and nearby properties.

The British Columbia Research Corporation (1992) developed charts that incorporate these considerations, adapting and extending earlier work by Schueler (1987) and the Washington Department of Ecology (1992). Figures 8.1 and 8.2 and Tables 8.1 through 8.4 present these charts as aids in practice screening.

The recently issued California Storm Water Best Management Practice Handbooks (Camp, Dresser, McKee et al. 1993) refined the process of practice selection further with several recommendations (Municipal Handbook, Section 3), one of which was the following evaluation criteria:

- Ability to meet regulatory requirements;
- Effectiveness in pollutant reduction;
- Public acceptance;
- Ability to be implemented;
- Institutional constraints; and
- Cost.

The handbook recommends assigning a rank of 1 to 5 to each practice for each criterion. Each criterion can be weighted differently by assigning a weighting multiplier.

Principles of Runoff Quantity Control

Purpose and Goals

Controlling runoff quantities is important because, as discussed in Chapter 3, hydrologic change can produce extensive ecological impacts in small-scale aquatic systems where much valuable habitat for fish and other biota is located. The possible role of hydrologic changes in degrading valued salmon resources and recent flooding have stimulated efforts to improve quantity control programs and facilities, especially in the Pacific Northwest.

This chapter does not fully discuss design for quantity control, but it does present the key principles that should be applied. These principles are currently being integrated into some of the older runoff management manuals developed in the Northwest. New versions of manuals by Washington Department of Ecology (1992) and King County Surface Water Management Division (1990) will likely integrate these principles. Several texts present the current state of the art in some detail, including Bedient and Huber (1988), Urbonas and Stahre (1993), Wanielista (1990), and Wanielista and Yousef (1993).

The goal of quantity control in runoff system design is to maintain the predevelopment hydrograph—the maximum runoff rate, dynamics, and total volume—after a change in the watershed. This means replacing the depression and belowground storage removed or bypassed in development. Maintaining the predevelopment hydrograph requires replacing all of the lost depression and soil storage. This is done only through extensive new infiltration opportunities or with large

detention volumes that hold water while the slow processes of evaporation and infiltration operate. Matching predevelopment peak rate alone means recovering one-third to two-thirds of the lost storage. Even this less restrictive criterion generally requires much larger detention volumes than customarily demanded in existing regulations.

Analysis and Control

Effective runoff quantity control depends on substantial hydrologic analysis, only now being established. The analysis depends on

- Obtaining and properly using precipitation records for the place and time to be controlled;
- Good estimates of peak runoff flow rates and volumes of critical conditions;
- Relating water movement through and beyond the quantity control device with the effect of temporary storage in the device ("routing"); and
- Using this information to set the size of the storage volume and design the outlet structure, which controls the release rate.

The first two steps pose difficult problems. Precipitation records generally lack geographic coverage, length, frequency of recording, and accuracy. Two options to estimate peak runoff are to use models based on selected precipitation events (e.g., the 25-year frequency, 12-hour duration rainfall) or a computerized continuous simulation model.

Excluding the rational method—which is completely inadequate for this purpose—the most common event-based models are the USDA SCS' curve number method and its derivatives. These models have several liabilities, such as the arbitrariness of the selected events. Because they have no way to represent depression and soil storage of runoff, they tend to overpredict the peak runoff rate before development occurs, when the storage potential is significant. Consequently, while the objective is to match the predevelopment rate, the target is set too high. To compensate for this shortcoming, base the design on a selection of events or apply a safety factor to flow rate or storage volume size and discharge rate estimates.

Another problem with event-based models is their inability to deal with unpredictable storm dynamics. If a second storm arrives before the first one drains, the facility could overflow. To compensate for this fault, select as the basis events of longer duration and some of the less frequent, larger events. In the Pacific Northwest where winter rains are frequent and prolonged, the solution is to use a seven-day event duration, which produces larger storage facilities.

Continuous simulation models—EPA's Storm Water Management Model (SWMM) or Hydrologic Simulation Program-Fortran (HSPF)—have some important advantages over event-based models. These computer models consider such complexities as soil storage and infiltration. Given sufficient input data and proper use, they can simulate a range of conditions spanning many years—critical conditions like rain-on-snow and closely spaced storms that could cause a basin to overflow. On the other hand, these models require more and better precipitation data than are often available; additional data to represent soils, topography, and vegetation; and considerable expertise.

The Pacific Northwest is also developing "runoff files" for the HSPF model. Runoff files are unit area hydrographs for limiting precipitation conditions and site characteristics. The user merely specifies those characteristics and the location. A routing routine provides pond size and release rate.

Another Northwest strategy deals with the potential impacts of greater total volumes caused by development, even if peak rates do not increase. As pointed out previously, real volume control can result only from replacing lost depression and soil storage. However, limiting peak flow to a rate lower than before development can at least partially compensate for the additional stress on stream channels from extra volume. One possibility is to limit the two-year peak release rate after development to half of the predevelopment peak release rate associated with the two-year, 24-hour event.

Treatment Practices

Pollution Removal Mechanisms

To properly specify, design, and operate treatment practices, one needs to understand the mechanisms that can operate to prevent pollutants from entering receiving waters. Table 8.5 lists all the principal mechanisms that can capture, hold, and transform various classes of contaminants in

urban runoff and the factors that promote the operation of each mechanism to improve water quality.

A factor to consider in the functioning of all mechanisms is time. The effectiveness of settling a solid particle is directly related to the time provided to complete sedimentation at the particle's characteristic settling velocity. Time is also a crucial variable to determine the degree that chemical and biological mechanisms operate. Characteristic rates of chemical reactions and biologically mediated processes must be recognized to obtain treatment benefits. For all of these reasons, water residence time is the most basic variable to apply effective treatment practice technology.

The information in Table 8.5 can also be arranged by features that promote specific pollutant control objectives. The following features fulfill the most common objectives:

- **Features that help achieve any objective**
  - Increasing hydraulic residence time
  - Low turbulence
  - Fine, dense herbaceous plants
  - Medium-fine textured soil
- **Features that help achieve specific objectives**
  - Phosphorus control
    - High soil exchangeable aluminum and/or iron content
    - Addition of precipitating agents
  - Nitrogen control
    - Alternating aerobic and anaerobic conditions
    - Low toxicants
    - Circumneutral pH
- **Metals control**
  - High soil organic content

Table 8.5—Summary of pollutant removal mechanisms.

MECHANISM	POLLUTANTS AFFECTED	PROMOTED BY
Physical sedimentation	Solids, BOD, pathogens; particulate COD, P, N, metals, synthetic organics	Low turbulence
Filtration	Same as sedimentation	Fine, dense herbaceous plants; constructed filters
Soil incorporation	All	Medium-fine texture
Chemical precipitation	Dissolved P, metals	High alkalinity
Adsorption	Dissolved P, metals, synthetic organics	High soil Al, Fe high soil organics (met.); circumneutral pH
Ion exchange	Dissolved metals	High soil cation exchange capacity
Oxidation	COD, petroleum hydrocarbons, synthetic organics	Aerobic conditions
Photolysis	Same as oxidation	High light
Volatilization	Volatile petroleum hydrocarbons and synthetic organics	High temperature and air movement
Biological microbial decomposition	BOD, COD, petroleum hydrocarbons, synthetic organics	High plant surface area and soil organics
Plant uptake and metabolism	P, N, metals	High plant activity and surface area
Natural die-off	Pathogens	Plant excretions
Nitrification	NH_3-N	Dissolved oxygen > 2 mg/L, low toxicants, temperature > 5-7°C, circumneutral pH
Denitrification	NO_3+NO_2-N	Anaerobic, low toxicants, temperature > 15°C

Source: R.R. Horner.

High soil cation exchange capacity
Circumneutral pH

- **Organics control**
  - Aerobic conditions
  - High light
  - High soil organic content
  - Low toxicants
  - Circumneutral pH

These features differ in what degree of control the treatment system designer and operator have over the operation. Fortunately, several features that promote all favorable mechanisms (possibly excluding the soil) are under a high degree of control. Features that promote more specific objectives require more intervention, such as developing some desired soil condition.

Sources of Detailed Information

The main treatment practices, the principles that govern their operation, and the primary design considerations are featured in a number of government manuals and other texts. These sources are valuable in planning, design, plan review, construction, and operational activities. The primary reference, however, should be the manual of the jurisdiction where the site is located. In addition to the material presented in this chapter and the listed sources, Chapter 14 includes inspection checklists and diagrams that provide details on design configurations and operations.

Storage Practices

Wet Ponds

Ponds reduce runoff pollutants by settling solids and allowing a variety of physical, chemical, and biological mechanisms to capture or transform dissolved pollutants. Settlement of fine solids and the soluble pollutant removal mechanisms all require time in quiescent or pool storage—from several days to as many as three weeks for maximum performance. Therefore, wet ponds, which have a permanent storage pool, offer substantially greater treatment advantages than ponds that dry out between storms. Unless they are lined, most ponds infiltrate some water to the soil and are often referred to as retention/detention ponds.

Figure 14.9 illustrates a typical wet pond, showing a number of the design recommendations discussed in the following paragraphs.

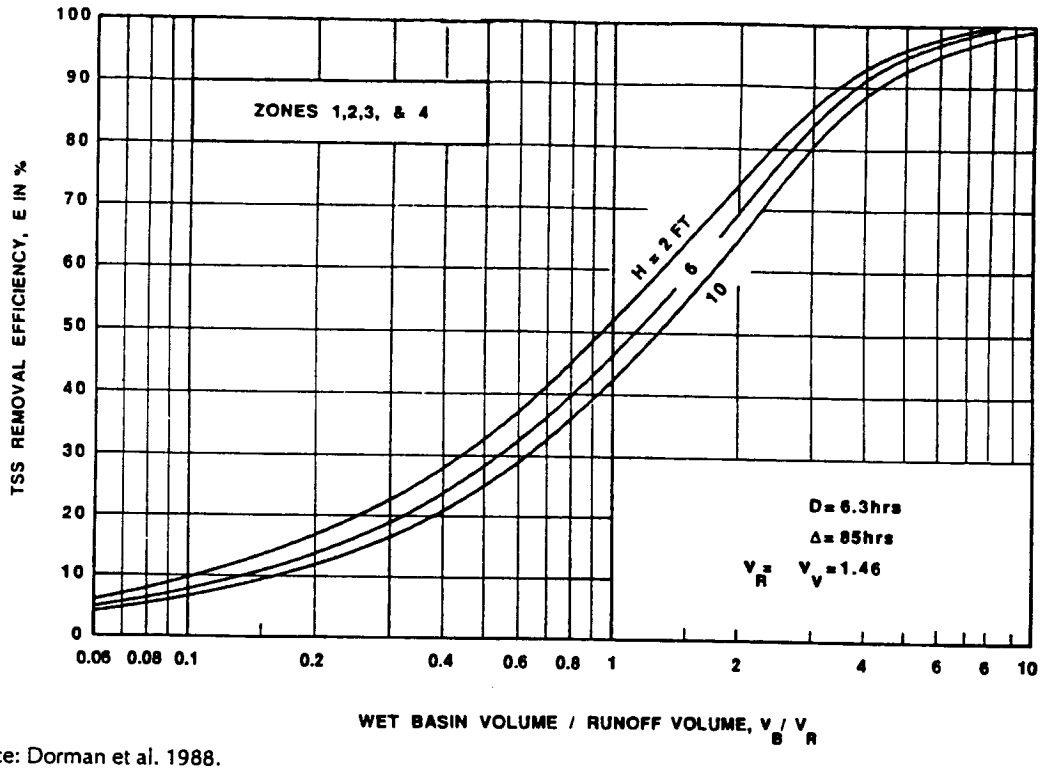
Sizing Calculations and Expected Performance. Unlike in the design of wastewater treatment plants, knowledge is insufficient as yet to design runoff ponds to obtain a specific level of treatment. However, EPA's Nationwide Urban Runoff Program (NURP) included a comprehensive investigation of pond design and associated performance at 13 locations. The investigation concluded that performance could best be related statistically to the "volume ratio." This is the ratio of pool storage volume to "mean storm volume," a statistical measure expressing the runoff volume associated with the long-term average rain storm quantity (U.S. Environ. Prot. Agency, 1986).

EPA produced total suspended solids removal curves for different climatological regions. Figure 8.3, for example, shows the curve for all of the United States east of the 96th meridian, approximately along the western Minnesota border. Reductions of other pollutants were related to total suspended solids (TSS), as illustrated in Figure 8.4. Generally, a volume ratio of about 2.5 is necessary to achieve 75 percent TSS reduction, where corresponding phosphorus removal is approximately 50 percent. Each incremental increase of the ratio above 2.5 yields decreasing benefits, reflecting the fact that the pollutants easiest to capture are removed first. The results indicate that pollutants with significant amounts in dissolved forms cannot be reduced by more than 50 to 60 percent in a wet pond.

In the phosphorus example, reduction of 60 percent is approached only as the volume ratio grows toward 5. Ponds of this size generally provide two to three weeks of pool storage hydraulic residence time and consume 3 to 7 percent of the contributing catchment, depending on impervious area, slopes, rainfall characteristics, and other factors (Walker, 1987; Hartigan, 1989; Kulzer, 1989). Further improvement in phosphorus removal can be achieved in several ways, although all have practical limitations (Walker, 1987). They include

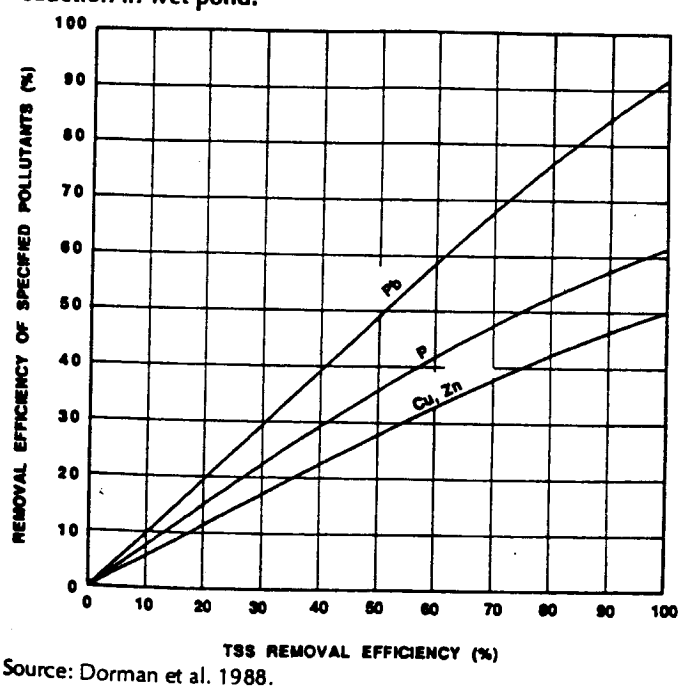
- Deepening the pond, although a practical limit of perhaps 2.5 m (about 8 ft) is imposed by the possibility that the bottom waters may become anaerobic;
- Infiltrating more water;
- Enhancing the plug-flow characteristics by design features;
- Installing certain aquatic plants, perhaps coupled with regular harvesting; or
- Chemical treatment.

Figure 8.3—Total suspended solids (TSS) reduction curves for wet ponds in the United States east of the 96th meridian.



Source: Dorman et al. 1988.

Figure 8.4—Reductions of lead (Pb), phosphorus (P), copper (Cu), and zinc (Zn) in relation to total suspended solids (TSS) reduction in wet pond.



Source: Dorman et al. 1988.

A number of agencies have adopted the NURP pond guidelines as a design basis, including the Metropolitan Washington Council of Governments (Schueler, 1987), the Federal Highway Administration (Dorman et al. 1988), and the state of California (Camp, Dresser, McKee et al. 1993). The guidelines help set performance objectives for pollutants of interest and calculate the pool storage volume from the graph and climatological statistics for the region to reach those objectives.

Other agencies have specified either a certain runoff quantity or a precipitation event as the design basis. For example, treating the first 1 in (2.5 cm) of runoff provides treatment to most storms and total runoff volume in an average year. The Washington Department of Ecology (1992) selected the six-month, 24-hour rainfall event as the "water quality design storm." The treatment system (the pool storage in a wet pond) should provide sufficient volume to hold runoff from this storm. In Seattle, this event produces about 1.2 in (3.05 cm) of rain. With a mean rain storm of 0.48 in (1.22 cm) at this location, the NURP volume ratio is thus approximately 2.5 for any runoff coefficient.

▮ ***Design Recommendations.*** Better performance can be expected by enlarging the surface area to gain volume as opposed to deepening the pond. A large surface area-to-volume ratio shortens the solids' settling distance and allows better aeration and light penetration to promote biological pollutant removal mechanisms.

Other design features are also important to performance. Features that reduce the tendency of water to short circuit, which raises actual hydraulic residence times toward the theoretical values, include the following (Schueler, 1987; Horner et al. 1989; Kulzer, 1989):

- Two or more distinct cells to promote plug flow;
- Effective length-to-width ratio of at least 5:1, preferably, and at least 3:1 at a minimum;
- Inlet and outlet remote from each other or shielded by baffling;
- Low inlet velocity;
- Uniform flow distribution across the inlet pond; and
- Discharging water with minimum turbulence from mid-depth rather than near the bed or surface.

Other safety features that should be incorporated in wet pond designs include the following:

- Side slopes of at least three horizontal to one vertical;
- An emergency overflow weir stabilized to avoid erosion and possible failure during high flow;
- A shallow "safety bench" at least 10 ft (3 m) wide at the toe of the slope surrounding the perimeter;
- A buffer planted to discourage young children from approaching the pond;
- An outlet structure placed out of reach to children; and
- Fencing to protect children from any remaining dangerous areas.

Extended-Detention Dry Ponds

With insufficient time to operate dissolved pollutant removal mechanisms, sedimentation is the main means to reduce pollutants in extended-detention basins. This method is especially good for capturing solids or other contaminants connected with particulates. In fact, Kuo et al. (1988) showed that extended detention was more cost-effective compared to dry or wet ponds or infiltration. This practice can also be the best choice where water is insufficient or too unreliable to sustain a wet pond or constructed wetland.

▮ ***Sizing Calculations and Expected Performance.*** Like wet ponds, extended-detention dry ponds are usually sized to capture a particular fraction of the runoff. In addition, this type of pond drains within a set period when filled with the design runoff volume, typically 24 to 40 hours.

Four NURP extended-detention ponds in Washington, D.C., with detention times of four to 18 hours offered at least 70 percent TSS removals with at least six hours of detention, and long-term total phosphorus reductions ranging from 13 to 56 percent (Schueler and Helfrich, 1989). Based on these somewhat conflicting results, Schueler (1987) estimated the upper limit of possible phosphorus reduction at 40 to 50 percent after 48 hours. Others, however, view the reliable efficiency to be much lower, perhaps 20 to 33 percent (Gibb et al. 1991). Schueler et al. (1992) now appear to agree with that assessment, quoting 10 to 30 percent. Stahre and Urbonas (1990) analyzed the available estimates of long-term efficiencies for various pollutants with a 40-hour detention time, as follows:

TSS	50 to 70%
chemical oxygen demand	20 to 40%
total phosphorus and total nitrogen	10 to 20%
lead	75 to 90%
zinc	30 to 60%
hydrocarbons	50 to 70%
bacteria	50 to 90%

▮ ***Design Recommendations.*** Extended-detention pond performance generally benefits from the same design features as wet ponds to prevent short circuiting. Schueler (1987) recommends incorporating the removal capabilities of plants by managing part of the basin as a shallow wetland. Schueler and Helfrich (1989) suggest an extended-detention wet pond, with a relatively small permanent pool that expands temporarily.

Oil Separators

Oil separators, devices that separate dispersed oil and water, are limited to capturing free or unemulsified oil. The two basic types are the Ameri-

can Petroleum Institute (API) separator and the coalescing plate (CP) separator. The API separator is a baffled tank that separates large volumes of free oil. The CP device separates free oil in much smaller volumes because it provides a large surface area for oil collected by the corrugated plate pack. Various spill-control devices are sometimes included in this type of treatment practice. The unit is used to catch small spills—it is not capable of separating dispersed oil. Figure 8.14 illustrates three oil separators.

API and CP separators were developed for industrial wastewater treatment. This wastewater is generally much higher in oil than most urban runoff, flow rates are more uniform, and the unit can get more operator attention. The separators are best used when discharge concentrations of oil and grease are higher than usually measured in general urban runoff. These concentrations are usually below 20 mg/L—often far below, unless an oil spill has occurred. Even the best CP separators cannot reduce concentrations below 10 mg/L, however. Therefore, these devices should be used mainly where petroleum products are handled, where vehicle traffic is heavy (e.g., trucking bases), and possibly where automobiles frequently come and go (expanding and contracting engine seals leak more oil than when engines run continuously). Otherwise, vegetated treatments can handle the usual relatively low concentrations. Spill control units should be installed anywhere slugs of oil could enter runoff, including residential areas where individual automotive maintenance is common.

▮ *Sizing Calculations and Expected Performance.* Following are procedures to size the two basic types of separators:

API SEPARATOR

1. Find oil drop rising velocity (V_p, cm/s):

$$V_p = (G/18 \cdot \mu) \cdot (d_p - d_c)D^2 \qquad [1]$$

where: μ = Dynamic viscosity of oil at coldest service temperature (use 0.015 poise at 5°C if no other information is available);

$d_p - d_c$ = Density difference between oil and water (use 0.1 g/cc if no other information is available);

D = Oil drop diameter (use 0.006 cm if no other information is available).

Convert V_p to ft/s by dividing by 30.48 cm/ft.

2. Find depth (d, ft):

$$d = (60 \cdot Q/2 \cdot V_h)^{0.5} \qquad [2]$$

where: Q = Design flow rate (cfs);

V_h = Horizontal velocity (3 ft/min or 15 times V_p, whichever is smaller; 0.5 ft/min is recommended if no other information is available).

Recommended range = 2 to 8 ft.

3. Set width in the range 2 to 3.33 times the depth.

Recommended range = 4 to 16 ft.

4. Find length (L, ft):

$$L = (d/V_p) \cdot V_h \qquad [3]$$

where: V_p = 0.033 ft/min is recommended if no other information is available.

5. Set baffle height-to-depth ratios at 0.85 for top baffles and 0.2 for bottom baffles.

CP SEPARATOR

1. Find V_p as above.
2. Find effective separation area = Q/V_p.
3. Select a unit from a manufacturer's catalog that provides at least the needed effective separation area.

A CP separator is theoretically capable of capturing free oil droplets down to 5 μm in diameter, although that performance requires a large unit. In contrast, the API type is practically limited to removing drops with diameters no smaller than 150 μm. How each reduces concentration depends on oil characteristics. CP separators can generally produce an effluent in runoff having no more than 10 mg/L oil and grease.

▮ *Design Recommendations.* A CP separator is marketed both with plates horizontal and at an angle. Angled plates are less prone to clogging by solids. The normal placement is 45 to 60 degrees from horizontal. Plates should be closely spaced to minimize oil rise distance without confining the flow so much as to raise velocity to a high level and create excessive turbulence; 3/4 in (1.90 cm) is a common spacing. Specific recommendations to improve success with API and CP units are the following:

- Exclude runoff from roofs and other areas not likely to contain oil;
- Place any pump being used downstream so as to prevent mechanical emulsification;

- Avoid detergent use upstream to prevent chemical emulsification;
- Provide a forebay sized at 20 ft^2 (1.86 m^2) of surface area per 10,000 ft^2 (929.0 m^2) of drainage area; and
- Provide an afterbay in which to place absorbents.

Vegetative Practices

Swales and Filter Strips

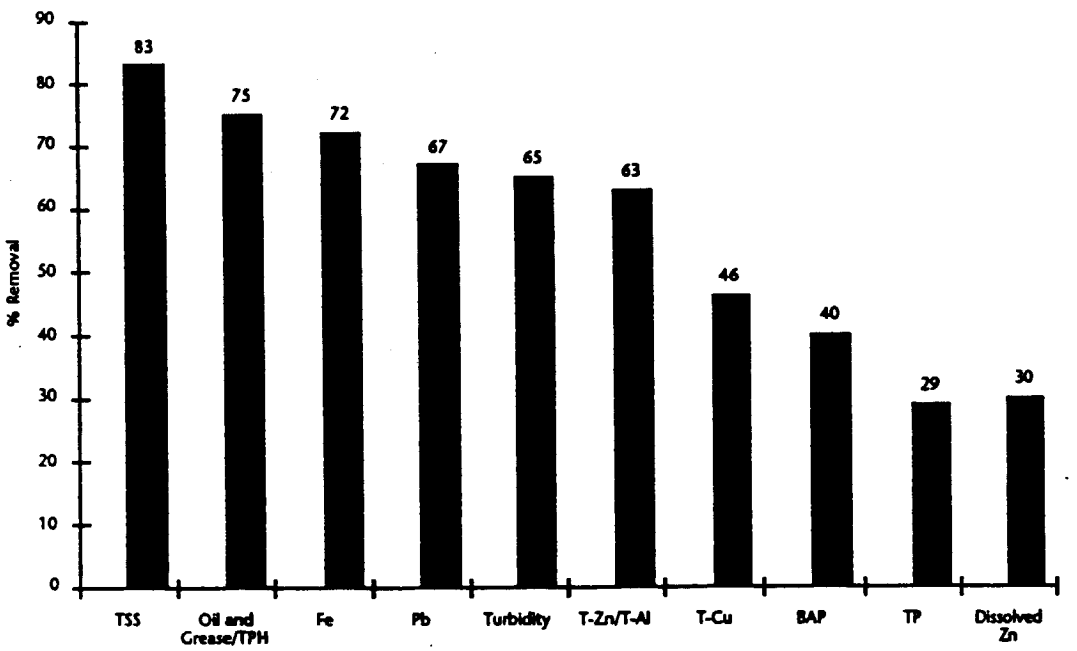
Treatment practices that use terrestrial grasses and other fine herbaceous plants are sometimes called biofiltration. These plants can be installed in a channel in which water flows at some depth—a swale—or on a broad surface area that has sheet flow—a filter strip. Biofilters can also have wetland plants in areas with the hydrology to sustain them.

A vegetated treatment strives for a plant stand that serves as a good filter. Ideal characteristics are dense, uniform growth of fine-stemmed plants tolerant of the area's water and climatological, soil, and pest conditions. Native plants generally combine the best properties. Plants serve mainly as filters; pollutant uptake is not a very important removal mechanism. Therefore, a number of species and mixes appropriate to the area will work equally well.

Sizing Calculations and Expected Performance. The results of a performance investigation of a grass swale, recently completed in the Puget Sound area of Washington (Municipality Metro. Seattle, 1992), refined a previously developed design procedure and recommended design features consistent with good performance. The report details the full design procedure, criteria, and guidelines that are excerpted here.

Figure 8.5, which summarizes the performance results, shows that the swale was relatively effective in capturing solids, oils, and the least soluble metals. The swale was less effective for more soluble metals, especially their dissolved fractions, and less yet for phosphorus. Nitrogen (not shown) exhibited little if any removal; fecal coliform's capture was inconsistent. Therefore, biofilters should generally be considered the sole

Figure 8.5—Average pollutant removal over six storms in a grass swale with an average hydraulic residence time of nine minutes.



TPH = total petroleum hydrocarbons
T = total
BAP = biologically available phosphorus

Source: Municipality of Metro. Seattle, 1992.

treatment only to reduce solids and oil. In fact, they are a better choice than oil separators to remove low concentrations of oil and grease from urban runoff. Vegetation can reduce concentrations to even lower levels, while no feasible separator can decrease them below 10 mg/L. The vegetation option is also much cheaper. One theory suggests that biofilters reduce nutrients considerably better if growth is carefully mowed and removed before it dies and releases phosphorus and nitrogen; however, that hypothesis is unproven.

The design procedure uses Manning's equation of open channel flow to obtain a swale width for a given flow and slope and selected water depth. The velocity resulting in this size channel is then compared to a criterion, and the length is calculated using a hydraulic residence time criterion. A key study result is that a residence time of nine minutes is needed to achieve the highest and most reliable performance. Performance began to deteriorate noticeably when residence time fell below five minutes, recommended as the absolute minimum. A filter strip design is handled in the same general way but with a more shallow flow depth. Steps are as follows:

1. Determine the design flow rate (Q, cfs) by appropriate hydrologic analysis. Use as a basis continuous simulation with a computer model, a design rainfall event (e.g., six-month, 24-hour storm), or a set fraction of total runoff (e.g., first inch).

2. Determine slope (s, ft/ft) and select vegetation, design vegetation height, and shape if a swale. Normally, swales are parabolic or trapezoidal to avoid erosion in sharp corners of rectangular or V shapes. The trapezoidal shape is easier to construct and will tend to assume a parabolic shape over time.

3. Set design flow depth (y, ft). A grass swale's depth should not exceed one-third of the grass height in infrequently mowed swales, or one-half of the grass height in regularly mowed swales, up to a maximum of 3 in (7.62 cm). In swales with wetlands vegetation, the depth should be at least 2 in (5.08 cm) below the height of the shortest species. A filter strip's depth should be no more than 0.5 in (1.27 cm).

4. Solve Manning's equation for the width, using the conditions established in steps 1 through 3.

$$Q = 1.49 \cdot A \cdot R^{0.67} \cdot s^{0.5}/n \qquad [4]$$

where: A = cross-sectional area (ft^2);
R = Hydraulic radius (ft) = A/wetted perimeter;
n = Manning's roughness coefficient.

The Puget Sound study used experiments to determine a value of n for flow below the full height of a local common grass mix. The recommended values are, unless other information is available, 0.20 for grass biofilters to be mowed regularly and those with herbaceous wetland plants and 0.24 for infrequently mowed swales.

Solutions of Manning's equation for two configurations follow:

TRAPEZOIDAL SWALE

$$b = Q \cdot n/(1.49 \cdot y^{1.67} \cdot s^{0.5}) - Zy \qquad [5]$$

$$T = b + 2 \cdot y \cdot Z \qquad [6]$$

FILTER STRIP

$$T = Q \cdot n/(1.49 \cdot y^{1.67} \cdot s^{0.5}) \qquad [7]$$

where: T = Top width (ft);
b = Bottom width (ft);
Z = Side slope (ft/ft; should be no steeper than 3 horizontal to 1 vertical).

The bottom width of a swale should be no less than 2 ft (0.61 m) if it will be mowed and no more than 8 ft (2.44 m), unless it will be hand finished to get a completely level bottom. If b does not fit into this range, investigate how Q can be reduced by splitting flow, or set b = 8 ft (2.44 m) and proceed with the analysis, or specify hand finishing.

5. Compute A for the configuration:

TRAPEZOIDAL SWALE

$$A = b \cdot y + Z \cdot y^2 \qquad [8]$$

FILTER STRIP

$$A = T \cdot y \qquad [9]$$

6. Find flow velocity (V, ft/s): V = Q/A. If V is greater than 0.9 ft/s, which will knock over most grass and reduce settling of finer particles, investigate how Q can be reduced, or change the width and/or depth.

7. Compute length (L, ft):

$$L = V \cdot t \cdot 60 \text{ s/min} \qquad [10]$$

where: t = Hydraulic residence time (min); t should be at least nine min, preferably, and no less than five min.

For swales, L should be at least 100 ft (30.38 m), a length below which flow short circuiting is more likely. If the length in a straight configuration cannot be fit to the site, investigate using a wide-radius curved path, reducing Q or changing the width and/or depth.

8. If flows larger than Q can enter the biofilter, the grass probably will be knocked over and provide no treatment until it becomes upright again. Therefore, flow regulation upstream or a bypass are recommended. If one of these measures is not provided, the velocity and depth with the largest flow rate must be calculated. If the velocity is above a level known to be erosive, the facility must be enlarged to accommodate it (use 3 ft/s maximum, if other information is lacking). The calculation procedure is standard and covered in open channel discussions in fluid mechanics texts, as well as in the previously cited report.

9. If the biofilter is a swale, once the maximum possible depth of flow is established, specify the swale's final depth. It should be at least 6 in (15.24 cm) deeper than the maximum possible flow depth.

▮ ***Design Recommendations.*** The following features maximize the success in establishing biofilters and in their performance:

- Locate the biofilter away from building and tree shadows to avoid poor plant growth from lack of sunlight.
- If the longitudinal slope is less than 2 percent or the water table can reach the root zone of vegetation, plant water-resistant vegetation to survive standing water or install an underdrain system to assist drainage. However, underdrains may not be practical with a large filter strip.
- If the longitudinal slope is in the 4 to 6 percent range, provide check dams approximately every 50 to 100 ft (15.24 to 30.48 m) to reduce velocity. However, check dams may not be practical on a larger filter strip.
- If the slope on which a swale is installed exceeds 6 percent, place swale to traverse the slope so that no slopes reach more than 4 percent, or 6 percent with check dams.
- Make the lateral slope entirely uniform to avoid any tendency for the flow to channelize.
- Introduce the flow so that entrance velocity is dissipated quickly, flow is distributed uniformly, and erosion is avoided (e.g., by using a riprap pad or some means of level spreading).

Natural Wetlands

Wetlands naturally regulate both water quality and quantity. In recent years, natural wetlands have been used for both purposes, sometimes with engineering changes such as modified inflow and outlet structures. This practice has been legally uncertain, since wetlands are classified as "waters of the United States" under the Clean Water Act (CWA). Using such waters to transport and treat waste is generally prohibited. However, some interpretations of the CWA allow the practice under limited circumstances. EPA's policy is not to use natural wetlands to treat urban runoff. Of course, wetlands treat water by default when they happen to receive runoff from an urbanized watershed.

Therefore, some attention has been paid to managing wetlands receiving urban runoff to learn how negative impacts can be avoided or minimized. The Puget Sound Wetlands and Stormwater Management Research Program is a long-term (1986-1996) comprehensive effort to follow ecological developments in wetlands through the urbanization process and learn what causes degradation and how it might be avoided. The program has produced preliminary management guidelines (King County Resour. Plann. Sec. 1993), with continued refinement as more information becomes available. The following summary excerpts key guideline provisions. Specifics pertain to freshwater palustrine wetlands in the Pacific Northwest, but these limits would likely be appropriate in similar communities.

▮ ***Management Guidelines.*** Hallmarks are to

- Manage on a watershed or subbasin scale and context, so that the values of all water resources are considered and all alternatives for solving water quality and quantity problems are evaluated.
- Emphasize practices, such as source controls, that prevent the development of problems. Back up those approaches with measures that reduce the effects of problems before wetlands or other water

resources are involved, such as pretreatments.

The guidelines are presented here as an example of a state strategy for managing wetlands. The guidelines, consistent with legal interpretations made by EPA Region 10 and the Washington Department of Ecology, state the conditions under which natural wetlands can be used for improving runoff quality:

- Situations must be analyzed case by case;
- Restoration or enhancement of a previously degraded wetland is warranted, and other wetland functions can be upgraded along with benefiting runoff water quality;
- Source control and treatment practices are applied in accordance with specific guideline recommendations, and any prevailing water quality standards are met; and
- The wetland is not one of certain rare or otherwise valuable types—estuarine, forested, peatland, or otherwise designated by recognized heritage and preservation programs—and does not provide habitat for rare, threatened, or endangered species.

The law is even less clear about the status of wetlands proposed for use only for runoff storage or incidentally affected by urban runoff. Of course, since all runoff contains contaminants, any distinction is artificial. Still, potential hydrologic effects are distinct from water quality impacts. In fact, the Puget Sound research has found that hydrologic change has more implications than water quality for wetland ecosystems where runoff is relatively low in pollutants. This program has devoted considerable effort to quantifying these hydrologic impacts—keying especially on plant and amphibian communities—and devising guidelines to overcome them. The following hydrologic guidelines specify limits on the wetland's hydroperiod—the depth (stage), frequency, duration, and pattern of inundation.

1. Depth limits—all wetlands, all year

Limit postdevelopment increase in annual maximum depth to 11.81 in (30 cm) (for 1.01-to-100-year return interval rainfall events).

Limit postdevelopment average monthly water level fluctuation (WLF) to

- An increase of 1.97 in (5 cm) if predevelopment WLF is greater than or equal to 5.9 in (15 cm);
- A maximum of 7.9 in (20 cm) if predevelopment WLF is less than 5.9 in (15 cm).

Note: WLF = Maximum depth – average depth in a time period.

2. Frequency and duration limits

These guidelines envision a fluctuating stage over time before development that could fluctuate more, both higher and lower; after development, these greater fluctuations are called "excursions." The guidelines set limits on the amount of the excursions and the total time, over one or more episodes, that can occur in a given period.

All wetlands—February 1 – May 31

- Limit postdevelopment stage excursions of up to 3.14 in (8 cm) above the predevelopment stage to a total duration of 24 hours in any 30-day period.

All wetlands—June 1 – September 30

- Limit postdevelopment stage excursions above or below the predevelopment stage to no more than 11.81 in (30 cm).
- Limit postdevelopment stage excursions of up to 5.9 in (15 cm) above or below the predevelopment stage to a total duration of 72 hours in any 30-day period.
- Limit postdevelopment increase or decrease in dry period—when pools dry down to the soil surface everywhere in the wetland—to two weeks.

Peat wetlands—bogs and fens (as more specifically defined by the Washington Department of Ecology)

- Limit postdevelopment stage excursions above the predevelopment stage of any amount to no more than once a year.
- Limit postdevelopment stage excursions of up to 5.9 in (15 cm) above or below the predevelopment stage to a total duration of 24 hours.

Forested wetlands and zones—wetlands or zones with at least 30 percent cover of trees at least 20 ft (6.1 m) tall

- Limit postdevelopment stage excursions of up to 7.9 in (20 cm) above the predevelopment stage to a total duration of 48 hours in any seven-day

period during March 1 to May 31 and to 96 hours over the full growing season, March 1 to August 31.

- Avoid sediment accumulation of more than 7.9 in (20 cm) in any year.

Sedge meadows—wetlands or zones with at least 20 percent cover by *Carex, Eleocharis, Scirpus,* and/or *Dilichium*

- Avoid sediment accumulation of more than 5.9 in (15 cm) in any year.

These guidelines are fairly complex to apply. Establishing predevelopment conditions requires either monitoring water levels or accurate hydrologic modeling. Postdevelopment conditions can only be established by predictive modeling. Monitoring need not be done with continuously recording instruments; simple crest-stage and staff gages are adequate. However, a continuous simulation by computer model is almost necessary for postdevelopment analysis.

The guidelines are also difficult to observe; peak runoff rate control alone is not enough, and total runoff volumes must also be controlled to prevent hydroperiod changes in a storage basin like a wetland. As pointed out in the previous discussion of quantity control, volume control is accomplished only through infiltrating excess runoff produced by urban landscapes.

Constructed Wetlands

Wetlands specifically constructed to capture pollutants from runoff draining urban and agricultural areas are gaining attention as versatile treatment options. Several major works have recently covered constructed wetland treatment, including Hammer (1989), Strecker et al. (1992), Olson (1992), and Schueler (1992). Horner (1992a) assembled a short course manual incorporating findings and recommendations from these various sources. This discussion draws on these resources and should provide a concise summary of the current state of urban runoff treatment by constructed wetlands and how to proceed in developing projects.

From a legal and regulatory standpoint, constructed wetlands are designed, built, and continuously maintained to treat waste. Thus, under the CWA they are not regarded as "waters of the United States." While no regulations control water quality within, discharge is regulated in the same way as any treatment system.

This designation contrasts with wetlands built for such purposes as mitigation of wetland losses under CWA section 404 or to develop waterfowl habitat, known as "created wetlands." These systems have the same legal protections as natural wetlands, including prohibition against conveying or treating waste. They usually have multiple functions, with water quality improvement only incidental; entering water must be managed to prevent damage to intended functions. A constructed wetland also differs in purpose and legal status from a wetland restoration, which returns a degraded system with reduced acreage or functional ability to the condition preceding its degradation. If the wetland is not completely restored but one or more functions are increased, it is termed an enhanced wetland. Restored and enhanced wetlands also have the same legal protections as natural wetlands.

The principal advantages of constructed wetlands over other treatments are

- More diversity in structure, which offers potential for relatively effective control of most pollutants;
- Wider range of potential side benefits;
- Relatively low maintenance costs; and
- Wider applicability and more reliable service than infiltration.

The disadvantages of constructed wetlands include

- Larger land requirements for equivalent service than wet ponds and other systems, especially if intended to serve quantity as well as quality control purposes;
- Relatively high construction costs;
- Delayed efficiency until plants are well established;
- Uncertainty in design, construction, and operating criteria is a drawback actually plaguing competitive methods as well; and
- Public concern about nuisances that can develop with runoff constructed wetlands if care is not taken in siting, design, construction, and operation.

Sizing Calculations and Expected Performance. Strecker et al. (1992), in a full literature review of both natural and constructed wetlands to control runoff pollution, considered more than 140 papers and reports and assembled detailed information on 18 U.S. locations. Median pollu-

tant removals in constructed wetlands were 80.5 percent for total suspended solids (TSS), 44.5 percent for ammonia-nitrogen (NH_3-N), 58.0 percent for total phosphorus (TP), 83.0 percent for lead (Pb), and 42.0 percent for zinc (Zn). Coefficients of variation (ratio of the standard deviation to the mean) for these contaminants ranged from 27.7 to 56.1 percent, showing both substantially higher and lower performance than the median levels. Pollutant reductions in constructed wetlands overall were higher than in natural ones, attributed to the specific design features and more intensive management.

Schueler (1992) recommends wetlands designs based on the overall literature. He estimates the performance of wetlands designed as he recommends as shown in Table 8.6. He considers these efficiencies to be provisional pending monitoring of the new systems.

Table 8.6—Projected long-term pollutant removal rates for wetlands constructed.

POLLUTANT	REMOVAL RATE (%)[a]
TSS	75
TP	45[b]
TN	25[c]
BOD, COD, TOC	15
Pb	75
Zn	50
FC	2 orders of magnitude

[a] Lower by an unknown amount for pocket wetlands.
[b] 65 percent in pond/marsh system.
[c] 40 percent in pond/marsh system.
Source: Schueler, 1992.

Several ways to arrange constructed wetlands, based on runoff quality and quantity control requirements, are to

- Place a runoff quantity control device on-line and a constructed wetland off-line to treat all runoff up to a certain volume;
- Construct a wetland with a permanent pool zone for treatment and a fluctuating storage zone and discharge control sized for peak runoff rate control; and
- Construct a wetland only for treatment in situations where quantity control is not required.

The first arrangement benefits from the fact that most pollutant mass loading over time is transported by runoff from the more frequent, smaller storms, and the first flush from the less frequent, larger storms. This arrangement is recommended where runoff quantity control is required because (1) the relatively shallow depths needed to maintain wetlands are somewhat inconsistent with the large storage volume needed for quantity control, and (2) large surges of water can damage the wetland.

Basic sizing decisions involve the pool storage volume (V_P), surface area, depth contouring (plus fluctuating storage volume, if runoff quantity control will be provided)—the same dimensions required in sizing a wet pond. At this point, constructed wetland technology has established no procedures to determine volume based on desired performance efficiencies and pollutant removal mechanisms. Accordingly, pool storage volume should be sized the same for wet ponds (see previous explanation).

Schueler (1992) illustrates four design concepts to configure constructed wetlands in the Mid-Atlantic area. To establish the wetland surface area (A_W), start by selecting a trial mean depth (D) from the following approximate ranges (after Schueler, 1992):

Shallow marsh	0.30-0.45 m
Pond/marsh	0.60-0.85 m
Extended-detention wetland	
permanent pool	0.25-0.30 m
extended-detention zone	1.0 m
Pocket wetland	0.15-0.40 m

Using the trial mean depth, calculate surface area by $A_W = V_P/D$.

After determining satisfactory basic dimensions, allocate depths to the different wetland zones according to the design concept. Schueler (1992) recommends the following zones to obtain diversity in structure and treatment capabilities:

Deep areas —30-180 cm deep, no emergent vegetation—forebay, micropools, deep water pools and channels
Low marsh—15-30 cm below normal pool
High marsh—0-15 cm below normal pool
Irregularly inundated zone—above normal pool

Schueler also supplies approximate depth allocations for the various zones and design concepts.

▮ ***Design Recommendations.*** Identify and adopt a natural wetland that performs water quality control well and use it as a reference model. Natural wetlands control water quality because of their structure. Therefore, the elements of this natural structure must be recreated in a wetlands. Natural wetlands tend to have a more complex structure than do most runoff treatment systems. This complexity allows a range of mechanisms to operate and diverse pollutants to be treated. The result is relatively high efficiencies, compared to competing alternatives. Structural complexity can be created with high marsh peninsulas and islands.

A structurally complex system is more expensive and difficult to construct than a simple one. In some cases, we may need to dispense with a few features of an ideal system. In addition, a complex design may not be faithfully constructed. Therefore, design personnel should be in the field to interpret the design and guide construction.

A constructed wetland must have enough time to develop before it is put in full service. Attempts to short-circuit ecological processes by over-management will probably fail.

1. Site Selection

Evaluate a prospective site carefully before making a selection. Table 8.7 summarizes the major considerations that should be analyzed. While an analysis requires gathering significant data, it is essential.

A viable constructed wetlands depends on an adequate and steady water supply. A water budget should be carefully constructed to ensure that water is available and inputs at least balance outputs throughout the year:

$$I + P + D + S > O + E + R \qquad [11]$$

where: I = Surface inflow;
P = Precipitation;
D = Groundwater discharge;
S = Wetland storage at beginning of calculation period;
O = Surface outflow;
E = Evapotranspiration; and
R = Groundwater recharge.

(All units are in terms of volume or water depth over the wetland surface.)

Table 8.7—Considerations in selecting constructed wetlands sites.

CATEGORY	CONSIDERATIONS
Land use and general	Land availability Existing site use and value Site problems (e.g., previous dumping, utility lines) Adjacent land use and value Connection to wildlife corridors and potential for adjacent areas to be biological donors Public opinion Accessibility for construction and maintenance Ability to control public access according to project objectives
Environmental and regulatory	Federal, state, and local laws and regulations Avoidance of archaelogical and cultural resources Avoidance of critical wildlife habitat areas
Hydrology and water quality	Water supply reliability Low potential for disruptive flooding Water supply of adequate quality to sustain biota Low potential for adverse effects on downstream waterbodies and adjacent properties and their water supplies Need for lining to retain water or avoid groundwater contamination
Geology	Flat or gently sloped topography Adequate soil development Sufficient depth to bedrock Soil characteristics consistent with pollution control objectives Suitability of site materials for construction

Source: R.R. Horner.

Estimate the water budget during site selection and check it after the preliminary design. In areas with pronounced seasonal drought (e.g., most of the western United States), calculate the balance for the dry period. Groundwater terms are difficult to establish, but a hydrogeologist familiar with the location should estimate them as closely as possible. Since natural wetlands often dry below the soil surface, permanent standing water is not necessarily needed to have a viable wetland. Washington State research has found that plant community richness declines substantially when drying extends longer than two months, compared to wetlands with shorter dry periods (Azous, 1991). Hence, the water balance should at least confirm that drying will not exceed two months.

2. Vegetation

Experience with wetlands creation, restoration, and construction projects shows that the plant community develops best when the soils harbor substantial vegetative roots, rhizomes, and seed banks. Development is enhanced when volunteer vegetation can enter from nearby donor sites. However, volunteers cannot be relied upon completely and should be supplemented by transplanting. While vigorous resident and volunteer stock may provide most of the vegetation, transplanting is still a wise strategy, as confirmed by most of the literature.

Hydric soils that contain vegetative plant material used to establish new wetlands are called wetland mulch. Ample use of this mulch enhances diversity and speeds plant establishment, but its content is somewhat unpredictable and donor sites are limited. Also, guidelines for extracting, handling, and storing the material are limited. In addition, exotic, opportunistic species might overtake more desirable natives—watch for this problem when obtaining material.

Potential donor sites include wetland soils removed during maintenance of highway ditches, swales, sedimentation ponds, retention/detention ponds, and clogged infiltration basins; during dredging; or from natural wetlands scheduled to be filled under permit—although these soils are best used for mitigating the loss. The upper 5.9 in (15 cm) of donor soils are best obtained at the end of the growing season and should be kept moist until installation. Establishing repositories for mulch reclaimed in maintenance operations is being explored. Despite the potential of wetland mulch and volunteer recruitment, transplanting is still the most reliable method and provides instant partial cover.

Wetland plant nurseries have sprung up recently in many places in the nation to provide material. The following list of general selection principles was compiled from Garbisch's (1986) recommendations for creating wetlands and from the comprehensive constructed wetlands literature:

- Base selections more on the prospects for success than on specific pollutant uptake capabilities. Plant uptake is an important mechanism only for nutrients, much of which are released upon the plants' death; nutrient removal is more the result of chemical and microbial processes than of plant uptake.
- Select native species; avoid natives that invade vigorously.
- Use a minimum of species adaptable to the various elevation zones; diversification will occur naturally.
- Select mostly perennial species; give priority to those that establish rapidly.
- Select species that are adaptable to the broadest ranges of depth, frequency, and duration of inundation (hydroperiod).
- Match the environmental requirements of plant selections to site conditions. Consider especially hydroperiod and light requirements.
- Give priority to species used successfully in constructed wetlands and commercially available species.
- Avoid specifying only species foraged by wildlife expected to use the site.
- Establish woody species to follow herbaceous species.
- Plant to achieve objectives other than pollution control.

Although selection based on pollution control capabilities is not recommended, considerable information on pollution control has been compiled. Kulzer's (1990) summary of plant capabilities for pollutant removal suggests that the most versatile genera, with species throughout the country, are *Carex*, *Scirpus*, *Juncus*, *Lemna*, and *Typha*.

Specific guidance for constructing wetlands is contained in Schueler (1992) and for creating wetlands in Garbisch (1986). The course manual by Horner (1992a) also incorporates this guidance on constructed wetlands.

3. Design Features

While size alone does not guarantee good performance, adequate size is necessary. If the layout permits water to traverse the wetland too fast, the theoretical hydraulic residence provided by the volume will not be achieved. The following features will help keep the flow from short circuiting the wetland.

Shape and configuration

- Create at least two distinct cells by restricting the flow to a narrow passageway between high marsh features.
- Make the wetland relatively wide at the inlet to help distribute the flow.
- Maximize the distance between the inlet and outlet.
- The effective length-to-width ratio should preferably be 5:1, and 3:1 at a minimum.
- The longitudinal slope—parallel to the flow path—should be less than 1 percent.
- The wetland should be carefully constructed to have no lateral slope—perpendicular to the flow path—to avoid concentrating the flow in preferred channels, which reduces actual residence time and risks erosion.
- Side slopes should be gradual (e.g., 5:1 to 12:1, horizontal to vertical) as in natural wetlands. In no place should the side slope be greater than 3:1.

Forebay

- Specify a relatively deep (3.93 to 5.9 ft/ 1.2 to 1.8 m) zone placed where influent water discharges. This forebay traps coarse sediments, reduces incoming velocity, and helps to distribute runoff evenly over the marsh. The forebay should be a separate cell set aside by high marsh features.
- Provide maintenance access for heavy equipment (14.76 ft/4.5 m wide and maximum 5:1 slope) directly to the forebay. The forebay bed should be hardened to prevent disturbance during clean out.

Flow channeling

- Create sheet flow to the maximum extent possible.
- Where flow must be channeled, use multiple, meandering channels rather than a single straight one.
- Open water areas should be interspersed with marsh rather than connected along the flow path.
- Minimize velocity in channels to prevent erosion.

Outlet area

- Place a micropool 3.93 to 5.9 ft (1.2 to 1.8 m) deep at the outlet.
- Install a reverse-sloped pipe 11.81 in (30 cm) below the permanent pool elevation. This outlet design avoids the clogging characteristic of constructed wetlands (Schueler, 1992).
- Install a drain capable of dewatering the wetland in 24 hours to allow for maintenance. Control the drain with a lockable, adjustable gate valve. Place an upward-facing inverted elbow on the end of the drain to extend above the bottom sediments.

Soils

- Medium-fine textures—such as loams and silt loams—work best to establish plants, capture pollutants, retain surface water, and permit groundwater discharge.
- Circumneutral pH (approximately 6 to 8) works best to support microorganisms, insects, and other aquatic animals.
- A relatively high content of highly decomposed organics (muck) is favorable for plant and microorganism growth and metal and organic pollutant adsorption. Muck soils are better than peats (less decomposed organics), which produce somewhat acidic conditions, are low in plant nutrients, and offer plants relatively poor anchoring support.
- Vegetation becomes established more quickly and effectively in constructed wetlands when soils contain seed banks or rhizomes of obligate and facultative wetland plants. Obtain soils that offer these resources.

- Soil characteristics recommended for specific pollution control objectives are
  Control of metals—high cation exchange capacity; and
  Control of phosphorus— high exchangeable aluminum and/or iron.

Liner

- An impermeable liner is required when infiltration is too rapid to sustain permanent soil saturation, when there is a substantial potential of groundwater being contaminated by percolating runoff, or both. Infiltration losses are small at most sites with USDA SCS class B, C, and D soils. Also, sediment deposition is likely to seal the bottoms of constructed wetlands. Therefore, a liner will likely be needed only in class A soils.

Emergency spillway

- An emergency spillway is required when the wetland will be used for runoff quantity control and for any other situation in which runoff might enter from a larger storm than the largest storm the facility is sized to handle.

Buffer

- A buffer should be provided around the wetland both to separate the treatment area and the human community and, if wildlife habitat is an objective, to reduce the animals' exposure to light, humans, pets, and other factors.

- The minimum buffer width should be 26.25 ft (8 m), measured from the maximum water surface elevation, plus 16.4 ft (5 m) to the nearest structure.

- If possible, preserve existing forest in the buffer area. At least 75 percent of the buffer should be forested to repel geese and provide better protection and habitat.

Avoiding Problems

- Mosquitoes, a rare but potential problem, can be prevented with diverse habitats that support predatory insects. Mosquitofish (*Gambusia*) can control mosquitoes in permanent ponds, but use caution in introducing the fish in non-native areas. Check with the state fish and wildlife agency before taking any action.

- Avoid aesthetic problems by carefully establishing construction and with vegetation. The buffer and tall emergent vegetation conceal water level fluctuation, films on the water, and other factors.

- Constructed wetlands are inherently safer than deep ponds, but deep zones may still be a hazard to children. Avoid this danger by creating gradual side slopes, a shallow marsh safety bench (16.4 ft/5 m wide) where the toe of the side slope meets any deep pool, concealing outlet piping and locking access. Fencing should only be needed on the embankment above large outfalls.

- Discourage nuisance waterfowl by maintaining the buffer largely in forest (at least 75 percent) and avoiding turf grass around the wetland. Maintain a variety of depths, especially high marsh not favored by geese and mallards, and educate citizens by placing signs to discourage feeding.

- Undesirable plant monocultures can be limited through structural diversity and a range of depths, especially in shallow areas. Plant a diverse native selection shortly after constructing the wetland.

- Metals and organics in toxicant accumulations are tightly bound in sediments and do not become mobilized over long periods. However, maintenance creates the problem of spoils disposal. Spoils that pass hazardous waste tests can be safely land-applied or placed in a landfill (Schueler, 1992). Applying spoils on-site saves disposal costs.

Landscape Management

Landscape management (Schueler [1987] uses the term urban forestry) signifies such practices as preserving trees during construction, replanting trees, and landscaping helpful to urban runoff management. One aspect of landscape management, maintaining vegetated buffers adjacent to waterbodies, advances the principle of minimizing the impervious area directly connected (by "hard" drainage facilities) to receiving waters.

Areas established using landscape management techniques can produce runoff volumes 30 to 50 percent less than conventionally developed sites (Schueler, 1987). Evidence suggests that

even low density residential development can produce runoff rivaling impervious areas when lawns replace natural vegetation and topsoil is removed close to relatively impermeable underlying layers.

The effectiveness of vegetated areas in capturing pollutants depends on the water's residence time before it enters the receiving water. Buffers and other landscape management spaces are often too small to provide the nine-minute residence time specified in the earlier discussion of biofilters, considered a minimum for water quality control. Of course, landscape management can still provide significant benefits, even without the ideal residence time.

While a riparian buffer guidance handbook by Heraty (1993) also provides recommendations for landscape management forestry programs, complete guidance is not yet available.

Infiltration Practices

Infiltration is the only structural technique that reduces both the peak runoff rates and runoff volumes from urban development. Infiltration reduces contaminants in runoff when runoff percolates in a soil column in which physical and chemical mechanisms operate. Infiltration devices that receive runoff at the surface also treat water through plant uptake and processes in surface soils. Unfortunately, these practices have the highest failure rates among all alternatives. Success requires great care in site selection, design, operation, and maintenance. Types of infiltration devices are

- Infiltration basins, also known as retention ponds;
- Infiltration trenches;
- Perforated pipes;
- French drains, also termed downspout infiltration systems; and
- Porous pavements.

An infiltration basin (see Figure 14.10) impounds water in a surface pond until it infiltrates the soil. Excess runoff discharges on the surface. An infiltration trench receives runoff in a shallow excavated trench that has been backfilled with stone to form a below-grade reservoir. Water then enters the underlying subsoil according to its infiltration rate. A perforated pipe, or underground trench, distributes runoff into the subsoil. French drains, consisting of pervious material such as gravel, disseminate inflowing water into the surrounding soil. These drains are usually used in small-scale applications, such as roof drains from homes and other small buildings. Porous pavements permit precipitation to drain through coarse-graded concrete, asphalt, or specially cast paving blocks with a pervious opening. The coarse-graded pavements can be used on roads, although they are subject to clogging; paving blocks are appropriate only for paved areas with very light or no traffic.

Recent studies and observations have documented extensive infiltration system failures. Schueler et al. (1992), in reviewing Mid-Atlantic region reports, found that 50 to 100 percent of infiltration basins had failed within five years of construction; up to 50 percent had failed almost immediately. The five-year failure rates for trenches and porous pavements were approximately 50 and 75 percent, respectively. Overwhelmingly, clogging by sediments brought in with runoff caused the failure. Microorganism growths in poorly drained soils and oils in runoff can also cause failure (Horner and Horner, 1990). This poor operating experience led Schueler et al. (1992) to advise against using infiltration basins and porous pavements and to use trenches only with careful geotechnical investigations and aggressive pretreatment protection and maintenance.

A study in Washington's Puget Sound found that successful infiltration basins were built on deep to excessively drained soils and not near seasonal high water tables or low spots in drainage catchments (Klochak, 1992; Gaus, 1993; Hilding, 1993; Jacobson, 1993). However, these basins risk groundwater contamination because metals retention was little to none in one soil type and incomplete in two others (Gaus, 1993). Most instances of poor infiltration were caused by water tables rising too near the surface. Vegetation was apparently not associated with infiltration, although plants can filter pollution, aerate soil, and improve the appearance if maintained properly.

Soil is the most critical consideration in specifying infiltration systems. Systems are generally built in the native soil; but when native soil is inappropriate, a soil system can be constructed with media like sand, peat, or a combination.

Infiltration systems normally convey most runoff directly into the soil to eventually enter the groundwater. However, an underdrain system can be installed below the infiltration system to collect water that does not percolate well through a restrictive subsoil layer. After being collected, the

water can be widely distributed to increase the percolation potential. If the grade permits, it can be discharged on the surface, after being treated while passing through the upper soils. Constructed soil systems usually require underdrains. While these systems could be considered filtration practices, this guide considers them under infiltration, reserving the filtration category for units constructed in boxes and generally having a conventional surface discharge.

The most crucial issues in using infiltration devices, in addition to soil suitability, are avoiding clogging and the potential to contaminate groundwater. Infiltration facilities should be constructed in medium textured soils. They are generally unsuitable for clay because of restricted percolation and gravel and coarse sands because of the risk of groundwater contamination, unless effective pretreatment is provided. An impermeable soil layer close to the surface may need to be penetrated. If the layer is too thick, underdrains, and possibly imported soil to provide sufficient treatment depth, may be required (Entranco Eng. 1989). As a minimum measure to prevent clogging, infiltration facilities should require a pretreatment device to settle larger solids and reject runoff from eroding construction sites.

Among the various runoff treatment options, only soil infiltration systems have been reliable in removing soluble phosphorus (Minton, 1987). This result likely applies to other relatively soluble pollutants as well. Reduction depends principally on how effectively the system prevents runoff from directly entering surface water. Reduction can be complete if surface effluent is absent and percolating water cannot get to surface water through interflow in the unsaturated zone or via rapid transit of groundwater in the saturated zone. In other circumstances, dissolved pollutant reduction is incomplete but is still higher than with any other treatment method.

Expected Performance

This manual classifies performance of soil infiltration systems as follows:

- Natural soil column infiltration basins, trenches, and perforated pipes with and without underdrains;
- Underdrained systems with selected filtration media—sand and peat-sand; and
- Porous pavements.

Natural Soil Systems. In a natural system without underdrains, the system's hydrology (directness of connection with surface water) determines how much runoff is captured and how efficient the treatment. Alternative design rules for infiltration basins and their estimated runoff reductions and pollutant removals (Schueler, 1987) are to store and infiltrate either (1) 0.5 in (1.27 cm) of runoff per impervious acre contributing, (2) the runoff resulting from a 1-inch rainfall event, or (3) the two-year frequency runoff volume. Table 8.8 estimates pollutant removals.

With the first rule, Schueler estimates that 40 to 50 percent of the runoff volume would be captured in the soil over the long term. This would rise to 65 to 75 percent with the second rule, depending on the soil and the amount of impervious area (the NURP database used to make the estimates

Table 8.8—Estimated long-term pollutant removal rates (percent) for infiltration basins.

POLLUTANT	SIZED BASED ON		
	0.5-IN RUNOFF/IMPERV. ACRE	RUNOFF FROM 1-IN RAIN	2-YEAR STORM RUNOFF VOLUME
Total suspended solids	75	90	99
Total phosphorus	50-55	60-70	65-75
Total nitrogen	45-55	55-60	60-70
Metals	75-80	85-90	95-99
Biochemical oxygen demand	70	80	90
Bacteria	75	90	98

Source: Schueler, 1987.

represents catchments with 11 to 27 percent imperviousness). The third rule would likely raise the degree of volume reduction to appropriately 90 percent. Schueler cites Maryland estimates that widespread application of the first or second rule would maintain summer baseflow levels within about 90 percent of predevelopment conditions.

In developing a management plan for phosphorus-limited Lake Sammamish, Washington, Entranco Engineers, Inc. (1989) estimated potential reduction of particulate phosphorus at 100 percent and soluble phosphorus in natural basins at 75 to 90 percent. Estimates for an underdrained system with 3 ft (0.91 m) of soil were 80 to 100 percent for total phosphorus and 50 to 85 percent for soluble phosphorus. These estimates are uncertain because backup data was lacking.

▮ ***Underdrained Systems with Artificial Media.*** A number of underdrained sand and peat-sand media configurations installed and tested differ in the layering of sand of various grain sizes, peat, and gravel. Meyer (1985) also proposes a layer of crushed limestone to precipitate phosphorus. Horner and Horner (1990) review design and performance considerations for a side-wall filter (in contrast to a basin draining through the bed) not yet built. These devices have only been extensively employed in Austin, Texas. Reported levels of pollutant reduction percentages were

Total suspended solids—60 to 80 percent;
Total phosphorus—20 to 90 percent, with most reports above 60 percent;
Nitrogen, soluble phosphorus—inconsistent in a sand-peat filter to 96 percent in a sand filter;
Metals—30 to 100 percent depending on metal and medium;
Chemical oxygen demand—40 to 90 percent;
Organics—inconsistent, but approximately 85 percent when operating well; and
Bacteria—40 to 100 percent.

In Bellevue, Washington, a large soil filter system draining to Lake Sammamish has recently been constructed to serve a housing development. The system—which includes pretreatment with catch basins, grass swales, oil/water separators, and detention—is expected to capture more than 99 percent of the total suspended solids, 50 to 95 percent of the phosphorus, and 90 to 95 percent of the copper in urban runoff from developed portions of the site (Diessner et al. 1991). The system's performance is now being monitored.

▮ ***Porous Pavements.*** Schueler (1987) distinguishes between porous pavements providing full and partial infiltration. The latter involves some type of collection system to drain surface runoff that cannot be infiltrated. Schueler estimates potential pollutant captures at 80 to 99 percent for total suspended solids, total nitrogen, chemical oxygen demand, zinc, and lead and 65 percent for phosphorus, although the actual capture would again depend on soil infiltration.

Denver's Urban Drainage and Flood Control District (1993) recommends only the modular block type of porous pavement system. The design, consisting of perforated concrete slab units underlain with gravel, is specified for use only in low traffic areas like airports, parking lanes, and driveways, and paved paths without traffic.

Site Selection, Sizing, and Design

Since all infiltration systems rely on the ability to discharge water through the soil or an equivalent artificial medium and have the same general problems, most design aspects are similar, except for media specifications for artificial systems. The following guidance is applicable to all types, with additional information on artificial media where necessary. Reference sources provide more specific detail.

▮ ***Site Selection for Natural Soil Systems.*** Needs differ, depending on whether the infiltration system is intended for quantity control alone or for quality and quantity control. While quantity control is best achieved with a rapid percolation rate, this rate could be too fast to provide sufficient contact with the soil for pollutant capture. If the runoff is quite contaminated, if the groundwater table is relatively close to the surface, or both, rapid percolation risks groundwater pollution. Therefore, the safest practices are to

- Specify a maximum and a minimum percolation rate to protect groundwater and attain pollutant capture objectives, or
- Require runoff pretreatment to meet water quality objectives before the pretreatment effluent is infiltrated for quantity control.

Infiltration authorities recommend the following criteria to reduce the substantial potential for failure, safeguard groundwater, and achieve the desired urban runoff management benefits:

- The bed of the infiltration facility should be at least 3 to 5 ft (0.91 to 1.52 m) from the

seasonal high water table, bedrock, or relatively impermeable soil layer (5 ft is conservative and warranted, unless seasonal water rise is carefully determined; 3 ft is minimum).

- With any application, the percolation rate should be at least 0.3 to 0.5 in/hr (0.76 to 1.27 cm/hr); 0.5 in/hr is conservative; 0.3 in/hr is minimum.
- With any application, the soil should not have more than 30 percent clay or more than 40 percent clay and silt combined (Wash. Dep. Ecol. 1992).
- When the infiltration facility will provide all runoff treatment (except perhaps presettling of solids) and when it will drain to groundwater (i.e., there are no underdrains), the percolation rate should not be greater than 2.4 in/hr (6.10 cm/hr) (Wash. Dep. Ecol. 1992). This, and the preceding guideline, effectively makes only loams, sandy loams, and loamy sands eligible for installing water quality infiltration systems.
- The facility should not be constructed in fill material or on a slope of greater than 15 percent.
- Baseflows should not enter infiltration facilities. The contributing catchment must be relatively small, or any permanent or intermittent flows must be diverted. Schueler et al. (1992) recommends that infiltration basins serve 2 to 15 acres (0.81 to 6.06 ha) and specified catchments be no larger than 5 acres (2.02 ha) to drain to trenches (Schueler, 1987).

Infiltration basins frequently lack good data on the soils and associated hydrogeology (Klochak, 1992; Gaus, 1993; Hilding, 1993; Jacobson, 1993). Using regional soil survey data is always very risky, and specific on-site soils investigation must be performed. Since infiltration generally occurs below the preconstruction grade level, soils and hydrogeologic observations and tests must be performed at the final grade level. Even measurement at a single location within the prospective facility location can be inadequate to characterize the soil and its new percolation rate. Hence, measurements should be repeated at several points. Finally, techniques often used to establish percolation rates (e.g., single-ring infiltrometers) have been found lacking—a double-ring device is an improvement. Standard percolation tests should also be performed in excavated holes.

Sizing Calculations. Several possible bases are used to size infiltration devices. One is to select one of Schueler's (1987) sizing rules and a maximum allowable drain time. Schueler recommends a maximum of 72 hours, except for 48 hours in marginal soils. The Washington Department of Ecology (1992) adheres to the latter time. Another way is an approach based on Darcy's law, which expresses flow through a porous medium. The resulting equations for the surface area (A_s) and infiltration system volume (V_i) are

$$A_s = V_r / f_d \cdot i \cdot t \quad [12]$$

$$V_i = \text{Inflow rate} - \text{Outflow rate} \quad [13]$$
$$= V_r - f_d \cdot i \cdot A_s \cdot t$$

where:
- V_r = Design storm runoff volume (ft^3);
- f_d = Percolation rate (ft/hour = inch/hour/12);
- i = Hydraulic gradient (ft/ft) = $(h + L)/L$;
- h = Height of water over infiltration medium when full (ft);
- L = Depth to water table or impermeable layer from infiltration medium surface (ft); and
- t = Time to drain from full condition (hour).

The design runoff volume can be established as discussed for wet ponds. With the difficulty in getting good percolation rate values, the Washington Department of Ecology (1992) recommends a conservative approach of making several on-site measurements at the infiltration medium level, adopting the minimum of those rates, and multiplying by a safety factor of 0.5. Better measuring techniques would allow dispensing with such conservatism—or at least dropping the safety factor.

Design Recommendations. The following recommendations are important to avoid past failures of infiltration systems:

- Construction runoff should never be allowed to enter an infiltration device.
- Banks and other areas must be thoroughly stabilized to prevent erosion into the device.

- At a minimum, pretreatment should be used to capture most of the runoff solids directed to an infiltration device. A recommended arbitrary removal criterion is 80 percent of total suspended solids.

- The facility should be at least 50 ft (15.24 m) from any slope greater than 15 percent and at least 100 ft (30.48 m) upslope and 20 ft (6.1 m) downslope of any building.

- The outlet orifice design must be consistent with the infiltration capacity (e.g., to avoid collecting more water than can infiltrate in 48 hours).

- After final grading, the bed should be deeply tilled to provide a well-aerated, highly porous surface texture.

- Plant a basin with grasses appropriate for conditions, and maintain the grass for both performance and appearance.

- The guidelines for wet ponds—introduction of flow at low velocity and with uniform distribution, side slopes, the emergency overflow, and safety—also apply to infiltration basins.

- Since constructed artificial soil systems are in their infancy, the following guidelines are subject to further testing (Horner and Horner, 1990):

  - A layered media structure seems to perform best. Most common are three layers, each about 1 to 2 ft (0.30 to 0.61 m) thick, separated by filter fabric. The upper layers have generally been various textures of sand or peat-sand mixtures. A crushed limestone layer has also been used for phosphorus reduction and pH adjustment.
  - Fibric peat is preferred over sapric peat because of the latter's poor hydraulic conductivity.
  - Surround the underdrain pipe with gravel or crushed rock.

Inspection and maintenance are also important for failure-prone devices like infiltration systems. Chapter 14 provides inspection checklists and maintenance standards.

Filtration Practices

Sand Filters

Sand filter chambers, similar to those used for many years in potable water and industrial treatment, have recently been introduced in urban runoff management. They differ from those described under infiltration practices by being installed in a box and having a surface effluent, instead of being a soil amendment with an underdrain system. These units are most appropriate in less than 5-acre (2.02-ha), mostly impervious catchments.

Figure 8.6 illustrates a design (Shaver, in press) being installed in Delaware, Maryland, and Virginia that consists of a sedimentation chamber followed by a filtration chamber.

▮ ***Sizing Calculations and Expected Performance.*** Design criteria are still under development. Shaver (in press) recommends sizing the sedimentation and filtration chambers each at 540 ft^3 (15.29 m^3) per contributing acre. He further recommends a surface area for each chamber of 360 ft^2 (33.45 m^3) per acre and a sand depth of at least 18 in (45.72 cm).

Based on monitoring of three similar systems in Austin, Texas, the following pollutant removal efficiencies percentages are expected (Shaver, in press):

Total suspended solids	75 to 87%
Total phosphorus	19 to 61%
Total nitrogen	31 to 44%
Ammonia-nitrogen	43 to 77%
Nitrate + nitrite-nitrogen	-79 to - 5%
Lead	71 to 88%
Zinc	49 to 82%
Copper	33 to 60%
Chemical oxygen demand	45 to 68%
Fecal coliform	36 to 37%

▮ ***Design Recommendations.*** Shaver's (in press) additional recommendations are

- Restrict the drainage area for any one filter to 5 acres (2.02 ha), which should essentially all be impervious.

- Make the outfall pipe from the sand chamber no larger than 6 in (15.24 cm) outside diameter, so that a minimum of 12 in (30.48 cm) of sand covers it. If a larger conveyance is needed, use more than one pipe.

Figure 8.6—Sand filter design.

Leaf Compost Filters

W and H Pacific (1992) has developed and tested a leaf compost filter in the Portland, Oregon, area. Monitoring 13 storms showed influent event mean concentrations to be reduced, on the average, by the following:

Total suspended solids	95%
Turbidity	84%
Chemical oxygen demand	67%
Total phosphorus	41%
Total Kjeldahl nitrogen	56%
Nitrate-nitrogen	34%
Ammonia-nitrogen	42%
Zinc	88%
Copper	67%
Total petroleum hydrocarbons	87%

Soluble phosphorus consistently increased across the filter. Work is now underway to improve the medium's anionic exchange capability (Stewart, pers. commun.). The device has not been independently tested, nor have design criteria been published.

Catch Basin Filters

Fiberglass (MacPherson, 1992) and activated carbon (Hutter, pers. commun.) filters intended for small-scale installations (e.g., catch basins) have recently been introduced on the market. Neither has been independently tested, but MacPherson reported concentration reductions of 90 percent for total suspended solids, 87 percent for lead, 77 percent for zinc, and 86 percent for copper. Specific design criteria have not been issued, but the fiberglass filter has been tested in flows up to 1 cfs, and the activated carbon filter is specified for use up to 0.13 cfs.

Series Treatment Combinations

Any treatment practices previously discussed can be combined in series arrangements, or treatment trains. This takes advantage of the capabilities of each and creates redundancy to increase the probability of capturing pollutants. The effectiveness of such systems will not be additive, however, because the first device in the series will trap the fractions easiest to remove, making subsequent reduction harder. For example, if two practices can individually capture 50 percent of a pollutant, leaving 50 percent present, the overall efficiency of a series of the two is not likely to be $0.50 + 0.50 \cdot (1 - 0.50) = 0.75$. Horner (1992b)

proposes an equation for the performance of a series of two devices:

$$E_s = 1 - X \cdot (1 - E_1) \cdot (1 - E_2) \quad [14]$$

where: E_s = Series efficiency (fraction pollutant remaining);
X = "Penalty" representing the performance reduction in the second device because of its harder removal task ($X > 1$);
E_1 = Efficiency of first device if alone; and
E_2 = Efficiency of second device if alone.

However, information was insufficient on series studies to establish X from actual data. Using this equation and an assumed $X = 1.25$, E_s for the previous example is 0.69 (69 percent) instead of 0.75.

The literature contained four performance studies of treatment trains. In one report—phosphorus removal—Meyer (1985) describes an infiltration basin design with a sand/crushed limestone underdrain filter coupled to a constructed wetland. He expected 90 percent removal of dissolved phosphorus, but no performance data have been found. Oberts and Osgood (1991) report on a detention pond that discharges into a series of six constructed wetland chambers. The system reduced total phosphorus by 79 percent and dissolved phosphorus by 57 percent in the pond, and an additional 32 and 15 percent, respectively, in the wetland. Overall system efficiencies—77 and 48 percent, respectively—were lower than the pond alone because of flows to the wetland that did not pass through the pond. The pond was believed to be so efficient because of well-distributed inflow, low-dissolved-to-total-phosphorus ratio, and phosphorus complexation by organics.

Wulliman et al. (1989) discusses a system consisting of a pond, wetland, and infiltration basin that was planned to split detention pond effluent between the wetland and infiltration basin. Modeling predicted overall 52 to 87 percent phosphorus reduction, but performance data have yet to be reported. Holler (1990) reports on a wet pond-filter (soil, limestone, and sand) system. The average wet pond reductions of both total phosphorus and orthophosphate-phosphorus were 77 percent, while the filter yielded orthophosphate and further reduced total phosphorus by only 16 percent, for an overall system total phosphorus efficiency of 85 percent.

Infiltration Systems

Infiltration systems can be considered 100 percent effective at removing pollutants in the fraction of water that is infiltrated, since the pollutants found in this volume are not discharged directly to surface waters. Quantifying the removal efficiency of infiltration systems, therefore, can perhaps best be determined by calculating the percent of the average annual runoff volume that is infiltrated, and assuming 100 percent removal of the pollutants found in that runoff volume. Since collecting samples of runoff once it has been infiltrated can be very difficult, little field data exist on the efficiency of infiltration for treatment of storm water. Since infiltrated water does not leave the BMP as a discrete flow, there is no representative way of collecting a true outflow sample. Infiltration systems can be monitored by installing a series of wells around the perimeter of the BMP for collecting samples. However, this can add significant costs to any monitoring effort. Table 5-8 summarizes the available field data on the efficiency of infiltration practices in treating storm water. Reported removal efficiencies are based on the results of three studies that evaluated the performance of infiltration trenches and two studies that evaluated the efficiency of porous pavement systems.

EFFECTIVENESS OF TWO STORMWATER TRASH TRAPPING SYSTEMS

Robin Allison, B.E., Ph.D.
Cooperative Research Centre for Catchment Hydrology
University of Melbourne, Victoria, 3052, Australia

Abstract – Litter, or trash, is regarded by the public as a major concern and indicator of poor waterway health. As well as degrading the visual amenity of receiving waters, it is a major contributor to marine debris and also contributes to drainage asset failure through blockages. Data on the movement of stormwater litter through urban catchments and the performance efficiency of trapping devices are scarce, despite increasing resources being spent on stormwater pollution control. Such data are essential to understand pollutant movements and to design appropriate pollution reduction strategies. This paper describes a field monitoring program of two promising gross pollutant (litter and debris) traps in Australia. Both Systems were installed on a 50 hectare fully urbanized catchment with one third commercial land-use. The trapping efficiencies of each system were determined and information on the gross pollutants characteristics gained.

Monitoring program

A continuous deflective separation (CDS) unit and side entry pit traps (SEPTs) were installed in a 50 hectare catchment in an inner suburb of Melbourne, Australia. The catchment is fully urbanized and has approximately one third commercial and two thirds residential land-use and also some small pockets of light-industry.

The two methods trap stormwater gross pollutants in different ways. CDS devices are large in-transit traps that separate and collect pollutants from the flow using continuous separation with a forced vortex and screen arrangement. On the other hand, SEPTs are baskets located inside roadside entry pits and capture gross pollutants as they fall into the pit with road runoff. CDS devices have relatively large construction costs and low maintenance costs, whereas the SEPTs have low installation costs but require more regular maintenance.

Following an investigation into the CDS performance, it was used as a control to assess the performance of SEPTs that were installed throughout the catchment. In total 192 SEPTs were installed in the 50 hectare catchment. Installation sites were selected to cover all publicly owned roadside entry pits to the drainage system.

CDS Performance

Two acoustic flow meters (which measure depth and velocity data) were used to monitor discharge upstream and downstream of the CDS unit. These probes provided estimates of discharge rate and volume and allowed investigation of the hydraulic losses through the system. Pressure sensors were also installed across the top of the overflow weir to collect depth data. The depth data provided estimates of the capacity of the device and the proportion of discharge that bypassed the treatment chamber via the overflow weir.

The monitoring suggested that the CDS unit is an efficient gross pollutant trap. During six months of monitoring practically all material greater than the minimum aperture size of the separation screen (4.7mm) was retained in the separation chamber (i.e. 100% retention). Analysis of material trapped found a significant proportion of the solids trapped were below the 4.7 mm minimum separation screen aperture size.

SEPT Performance

To assess the performance of SEPTs, they and the CDS unit were cleaned on the same day every two or four weeks. Collected material was taken to the University of Melbourne where it was sorted and dried. Analysis of the trapped material allowed estimates of trapping efficiency and the origin of gross pollutants that enter the stormwater system.

The results showed that SEPTs can potentially capture large amounts of litter (up to 85%) and of the total gross pollutant load (up to 75%; i.e. including vegetation), if placed on all public road entrances to stormwater systems. Regular maintenance to clean traps implies that putting traps everywhere possible (i.e. 100% coverage of road entrances) is unlikely to be feasible. It is therefore imperative to choose the entrances that contribute the most loads to the drainage system when only a proportion of the total can be selected. Figure 1 shows a plot of the load caught (%) against the proportion of the inlets covered.

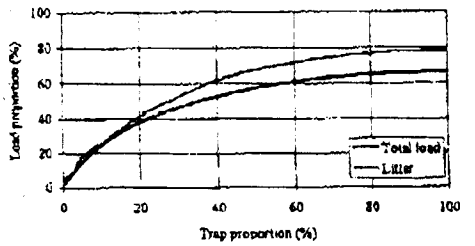

Figure 1 Distribution of trapped material ordered by total load.

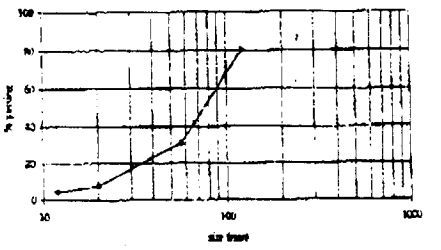

Figure 2 Size distribution of litter items caught by SEPTs.

Gross pollutant characteristics

The most litter items entered the drainage network from commercial areas, presumably due to the actions in the catchments (especially for food and drink items). Organic loads of material were relatively uniform from the different land-uses, and may be attributed to near uniform coverage of vegetation in the catchment and the influence of wind.

Various characteristics of the stormwater litter were investigated, such as composition, size, number, volume and distribution. For example, Figure 2 shows a size grading performed on some of the captured litter. Information was also collected on the quantities of gross pollutants for individual storm events. These data were compared to storm characteristics and relationships between load and rainfall established.

Conclusions

Both of the trash trapping devices reported in this paper can provide efficient gross pollutant (litter and debris) removal from stormwater systems. They are part of a growing number of gross pollutant traps being used in Australia. However, there are many claims of trapping performances without field data. It is essential that quality performance data are collected and reported to enable appropriate trapping systems to be deployed in the most suitable locations. To aid the choice of gross pollutant trapping systems a decision-support-system has been developed to simulate what-if type scenarios for different gross pollutant tapping systems. The model also simulates gross pollutant loads and estimates the installation and maintenance costs for particular systems (see reference 2).

Table 6-1. Typical Base Capital Construction Costs for BMPs

BMP Type	Typical Cost* ($/cf)	Notes	Source
Retention and Detention Basins	0.50-1.00	Cost range reflects economies of scale in designing this BMP. The lowest unit cost represents approx. 150,000 cubic feet of storage, while the highest is approx. 15,000 cubic feet. Typically, dry detention basins are the least expensive design options among retention and detention practices.	Adapted from Brown and Schueler (1997b)
Constructed Wetland	0.60-1.25	Although little data are available to assess the cost of wetlands, it is assumed that they are approx. 25% more expensive (because of plant selection and sediment forebay requirements) than retention basins..	Adapted from Brown and Schueler (1997b)
Infiltration Trench	4.00	Represents typical costs for a 100-foot long trench.	Adapted from SWRPC (1991)
Infiltration Basin	1.30	Represents typical costs for a 0.25-acre infiltration basin.	Adapted from SWRPC (1991)
Sand Filter	3.00-6.00	The range in costs for sand filter construction is largely due to the different sand filter designs. Of the three most common options available, perimeter sand filters are moderate cost whereas surface sand filters and underground sand filters are the most expensive.	Adapted from Brown and Schueler (1997b)
Bioretention	5.30	Bioretention is relatively constant in cost, because it is usually designed as a constant fraction of the total drainage area.	Adapted from Brown and Schueler (1997b)
Grass Swale	0.50	Based on cost per square foot, and assuming 6 inches of storage in the filter.	Adapted from SWRPC (1991)
Filter Strip	0.00-1.30	Based on cost per square foot, and assuming 6 inches of storage in the filter strip. The lowest cost assumes that the buffer uses existing vegetation, and the highest cost assumes that sod was used to establish the filter strip.	Adapted from SWRPC (1991)

* Base year for all cost data: 1997

In some ways there is no such value as the "average" construction cost for some BMPs, because many BMPs can be designed for widely varying drainage areas. However, there is some

value in assessing the cost of a typical application of each BMP. The data in Table 6-2 reflect base capital costs for typical applications of each category of BMP. It is important to note that, since many BMPs have economies of scale, it is not practical to extrapolate these values to larger or smaller drainage areas in many cases.

Table 6-2. Base Costs of Typical Applications of Storm Water BMPs[1]

BMP Type	Typical Cost ($/BMP)	Application	Data Source
Retention Basin	$100,000	50-Acre Residential Site (Impervious Cover = 35%)	Adapted from Brown and Schueler (1997b)
Wetland	$125,000	50-Acre Residential Site (Impervious Cover = 35%)	Adapted from Brown and Schueler (1997b)
Infiltration Trench	$45,000	5-Acre Commercial Site (Impervious Cover = 65%)	Adapted from SWRPC (1991)
Infiltration Basin	$15,000	5-Acre Commercial Site (Impervious Cover = 65%)	Adapted from SWRPC (1991)
Sand Filter	$35,000-$70,000[2,3]	5-Acre Commercial Site (Impervious Cover = 65%)	Adapted from Brown and Schueler (1997b)
Bioretention	$60,000	5-Acre Commercial Site (Impervious Cover = 65%)	Adapted from Brown and Schueler (1997b)
Grass Swale	$3,500	5-Acre Residential Site (Impervious Cover = 35%)	Adapted from SWRPC (1991)
Filter Strip	$0-$9,000[3]	5-Acre Residential Site (Impervious Cover = 35%)	Adapted from SWRPC (1991)

1. Base costs do not include land costs.
2. Total capital costs can typically be determined by increasing these costs by approximately 30%.
3. A range is given to account for design variations.
