After placement of the collector pipes, gravel, and lower geotextile layer, fill the shell with filter sand to the level of the top of the sediment pool weir. Direct clean water into the sediment chamber until both the sediment chamber and filter chamber are completely full. Allow the water to draw down until flow from the collector pipes ceases, hydraulically compacting the filter sand. After allowing the sand to dry out for a minimum of 48 hours, refill the shell with sand to a level one inch beneath the top of the weir and place the upper geotextile layer and gravel ballast.

Grates and Covers

When placed in traffic lanes, grates and covers must withstand H-20 wheelloadings. Use of standard Virginia Department of Transportation (VDOT) grates (Grate D1-1) will often be most cost-effective. Where allowed by local jurisdictions, galvanized steel bar grates are economical.

Portland Cement Concrete

Portland Cement concrete used for the trench structure shall conform to the A3 specification of the Virginia Department of Transportation ***Road and Bridge Specifications***, latest edition.

Maintenance/Inspection Guidelines

The following maintenance and inspection guidelines are not intended to be all inclusive. Specific facilities may require other measures not discussed here.

Inspection Schedule

During the first year of operation, the cover grates or precast lids on the chambers must be removed quarterly and a joint owner-jurisdiction inspection made to assure that the system is functioning. Once the jurisdiction inspectors are satisfied that the system is functioning properly, this inspection may be made on an annual basis for other than auto-related activities.

Sediment Chamber Pumpout

The sediment chamber must be pumped out when the joint owner-jurisdiction determines that . If the chamber contains an oil skim, it should be removed by a firm specializing in oil recovery and recycling. The remaining material may then be removed by vacuum pump and disposed of in an appropriate landfill. **After each cleaning, refill the first chamber with clean water to reestablish the water seals to the clearwell.**

Sand Filter

When deposition of sediments in the filtration chamber indicate that the filter media is clogging and not performing properly, sediments must be removed (a small shovel may be all that is necessary) along with the top two to three inches of sand. The coloration of the sand will provide a good indication of what depth of removal is required. Clean sand must then be placed in the filter to restore the design depth. Where a layer of geotechnical fabric overlays the filter, the fabric shall be rolled up and removed and a similar layer of clean fabric installed. Any discolored sand shall also be removed and replaced. Disposal of petroleum hydrocarbon contaminated sand or filter cloth should be coordinated with the appropriate environmental official of the local jurisdiction. On filters which employ an upper geotextile layer and ballast, the top layer of filter cloth and ballast gravel must be removed and replaced with new materials conforming to the original specifications when the filter will no longer draw down within the required 40-hour period. Any discolored or sediment contaminated sand shall also be removed and replaced with sand meeting the original specifications (ASTM C-33 Concrete Sand).

Concrete Shell Inspection

Concrete will deteriorate over time, especially if subjected to live loads. The concrete shell, risers, etc., must be examined during each annual inspection to identify areas that are in need of repair, and such repairs must be promptly effected.

Grass Clippings

Grass clippings from landscape areas on the drainage watershed flowing into the DSF must be bagged and removed from the site to prevent them washing into and contaminating the sediment chamber and filter.

Trash Collection

Trash collected on the grates protecting the inlets shall be removed no less frequently than weekly to assure preserving the inflow capacity of the BMP.

Design Procedures

The following design procedure is structured to assure that the desired water quality volume is captured and treated by the Delaware Sand Filter. The procedure assumes that a filter shell with a rectangular cross-section is to be used. **Figure 3.12B-2** shows the dimensional relationships required to compute the design.

Standard Design Logic

Employ the following design logic to design Delaware Sand Filters for use in Virginia:

1. Determine Governing Site Parameters

Determine the Impervious area on the site (I_a in acres), the water quality volume to be treated (WQV in $ft.^3 = 1816\,I_a$), and the site parameters necessary to establish 2h, the maximum ponding depth over the filter (storm sewer invert at proposed connection point, elevation to inflow invert to BMP, etc).

2. Select Filter Depth and Determine Maximum Ponding Depth

Considering the data from Step 1) above, select the Filter Depth ((d_f) and determine the maximum achievable ponding depth over the filter (2h).

3. Calculate the Required Surface Areas of the Chambers

If the maximum ponding depth above the filter (2h) is less than 2.67 feet (2'-8"), the WQV storage requirement governs and the above foumula must be used:

$$A_f = \frac{1816 I_a}{(4.1h + 0.9)} = \frac{WQV}{(4.1h + 0.9)}$$

where:

A_f = the **area of the filter** in sq.ft.

I_a = the impervious area on the watershed in acres

h = 1/2 the maximum ponding depth over the filter (ft.)

If the the maximum ponding depth above the filter (2h) is 2.67 feet or greater, use the partial sedimentation filter formula:

$$A_f = \frac{545 I_a d_f}{(h + d_f)}$$

where:

d_f = depth of the filter media in ft. (1.5-2.0)

Delaware and Virginia make the area of the filter equal the area of the sediment chamber:

$$A_f = A_s$$

4. Establish Dimensions of the Facility

Site considerations usually dictate the final dimensions of the facility. Sediment trenches and filter trenches normally be 18-30 inches wide. Use of standard VDOT D1-1 grates requires a trench width of 26". Some jurisdictions restrict the maximum allowable trench width to 36 inches.

Minimizing Filter Shell Costs

Underground vault sand filter costs have been widely varying because many developers have simply had their foundation contractors cast the vault in place. Each installation therefore became a prototype with associated costs and overhead. Precast manufacturers currently offer precasting services for D.C. and other types of sand filter vaults, which should stabilize underground vault costs. **Figure 3.12B3** is a photograph of a segmented precast shell installation in Alexandria.

Checklists

Worksheet 3.12B is for use in sizing calculations for Delaware Sand Filters. The **Construction Inspection and As-Built Survey Checklist** found in **Appendix 3D** is for use in inspecting intermittent sand filter facilities during construction and, where required by the local jurisdiction, engineering certification of the filter construction. The **Operation and Maintenance Checklist,** also found in **Appendix 3D**, is for use in conducting maintenance inspections of intermittent sand filter facilities.

MINIMUM STANDARD 3.12C

AUSTIN SURFACE SAND FILTER SYSTEMS

Definition

The City of Austin, Texas, hase been using open basin intermittent sand filtration BMPs for treating stormwater runoff since the early 1980's. The Austin program is managed by the Environmental and Conservation Services Department, which has published design criteria in their *Environmental Criteria Manual* (Austin, 1988). Austin places heavy emphasis on pretreating the stormwater runoff in a sediment trapping presettling basin to protect the filter media from excessive sediment loading. The particles selected by Austin for complete removal in the full sedimentation protection basins are those which are greater than or equal in size to silt with a particle diameter of 0.00007 foot (20 microns) and a specific gravity of 2.65.

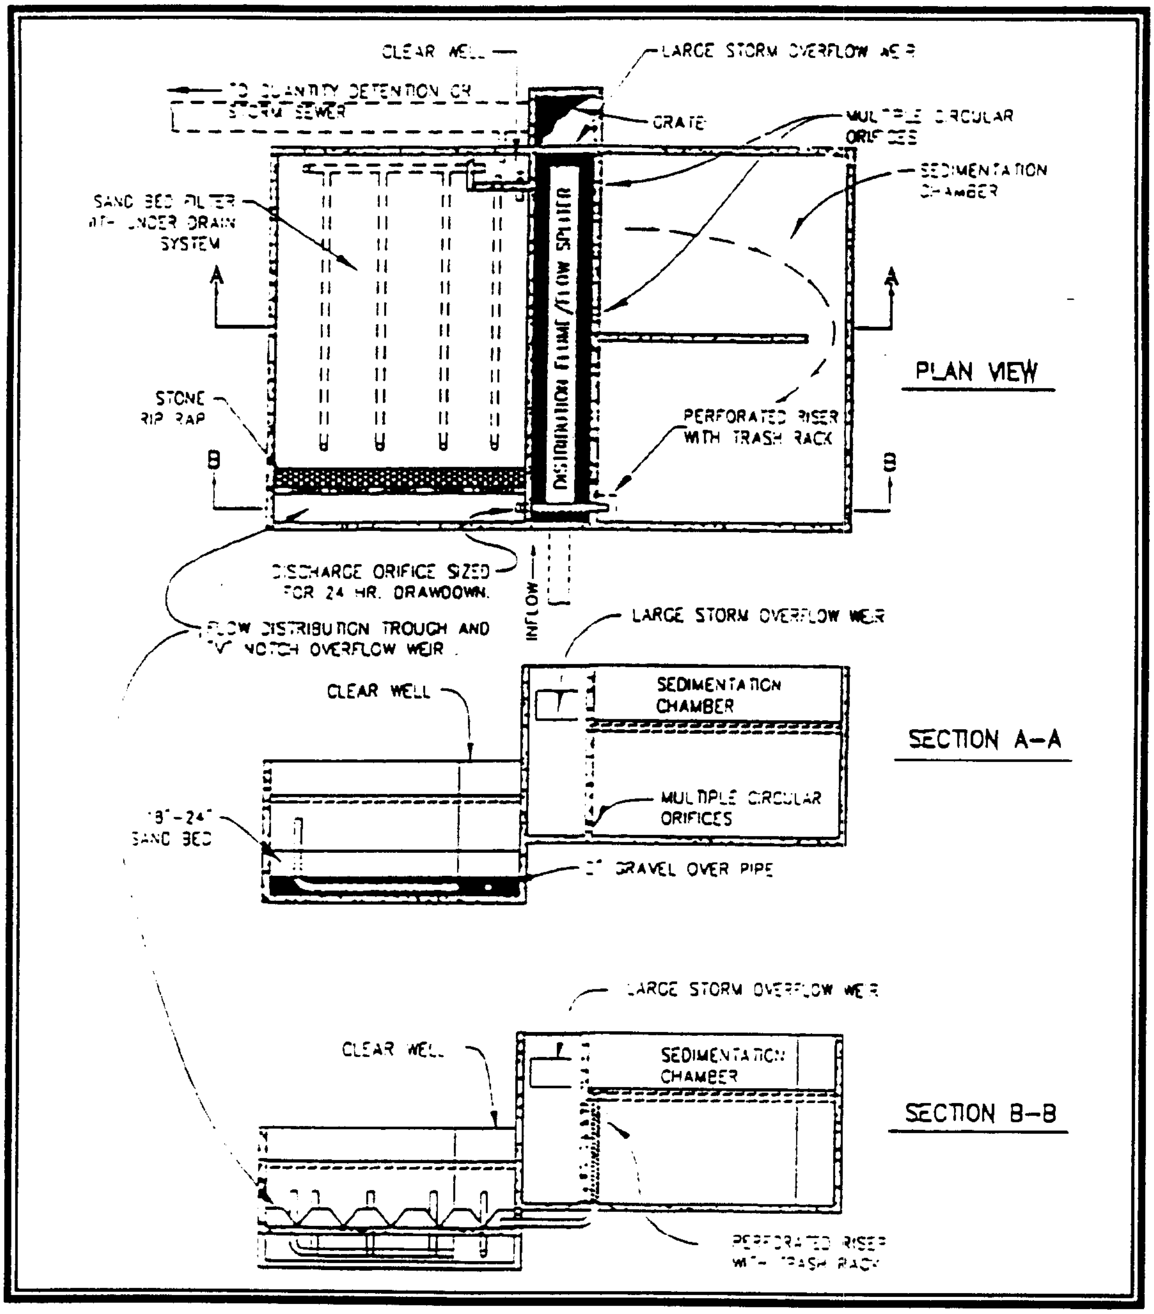
Figure 3.12C-1 illustrates an Austin Full Sedimentation Sand Filter application at a shopping center. In this system the sedimentation structure is a concrete basin designed to hold the entire WQV and then release it to the filtration basin over a 24-hour draw-down period. **Figure 3.12C-2** shows an alternative design which allows a smaller sedimentation chamber (20 percent of the WQV) while increasing the filter size to compensate for increased clogging of the filter media. Although the systems shown utilize concrete basins, a sediment pond and a geomembrane-lined filter built directly into he ground may be used where terrain and soil conditions allow.

Purpose

Austin Sand Filters are used primarily for water quality control. However, they do provide detention and slow release over time of the WQV. Whether this amount will be sufficient to provide the necessary peak flow rate reductions required for channel erosion control is dependent upon the site conditions. However, in cases where quantity detention beyond the volume of the WQV is required, an attractive alternative may well be to utilize a combined detention basin/pre-settling basin configuration, with the controlled release of the entire stored volume to the sand filter facility.

FIGURE 3.12C - 1

Austin Full Sedimentation Sand Filter System at Barton Ridge Plaza



R0009844

FIGURE 3.12C - 2

Sedimentation Basin of Jolleyville Partial Sedimentation System

(Poto Courtesy of the City of Austin, Texas)

Conditions Where Practice Applies

Austin Sand Filters Filters are ultra-urban BMPs best suited for use in situations where space is too constrained and/or real estate values are too high to allow the use of conventional retention ponds. Unlike D.C. and Delaware Sand Filters, when full sedimentation protection is provided, Austin filters may be used in situations where a higher amount of pervious surfaces are present or where higher sediment loads from deposition of wind-blown sediments are encountered. Because of their design, they may also be used on much larger drainage sheds.

Drainage Area

Austin full sedimentation and partial sedimentation basin sand filters have been used on drainage sheds up to 30 acres, and with great economy of scale. **Table 3.12-1** illustrates the relative costs of varying sized systems in Austin in mid-1990.

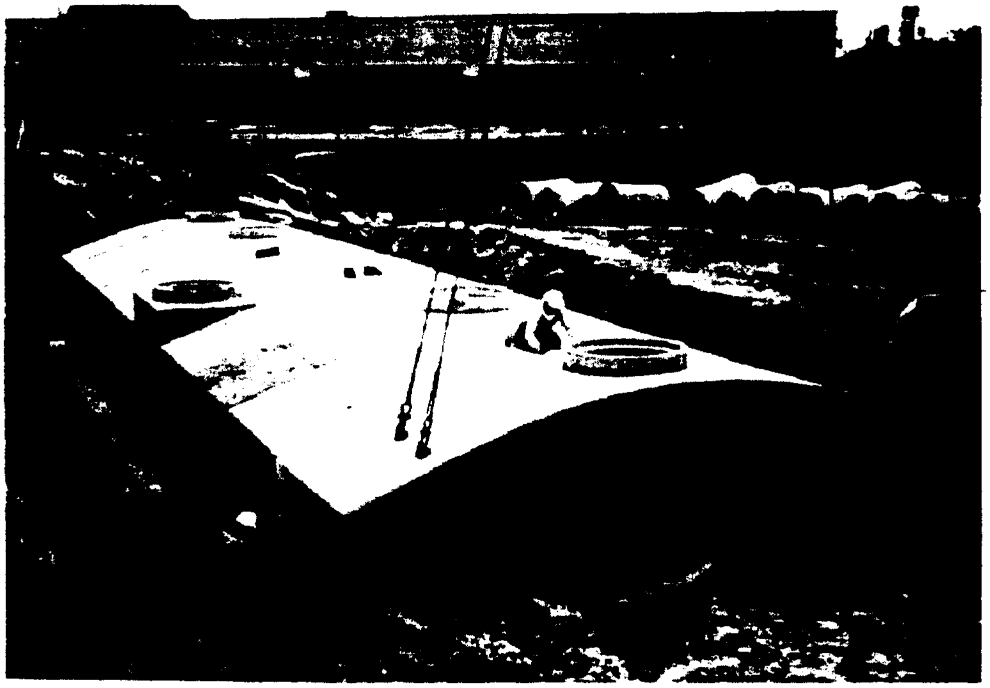
TABLE 3.12C - 1
***Cost of Austin Sand Filtration Systems** (June 1990)*

Drainage Area (Acres)	Water Quality Volume (ft^3)	Cost/Acre ($/acre)	Cost/ft^3 ($/$ft^3$)	Total Cost ($)
1.0	1815	13,613* 19,058#	7.50* 10.50#	13,613* 19,058#
2.0	3,630	8,440* 9,801#	4.65* 5.40#	16,880* 19,602#
5.0	9,075	5,136	2.83	25,682
10.0	18,150	3,812	2.10	38,115
15.0	27,225	3,086	1.70	46,283
20.0	36,300	2,723	1.50	54,450
30.0	54,450	2,360	1.30	70,785

Footnotes:
* Calculated from data provided by Murfee Engineers
# Calculated from data provided by Austin Stormwater Management staff
All other values derived from combined data

While Austin has traditionally built these systems in open basins, there appears no reason why the basic designs cannot be adapted to underground vault construction where real estate values are high enough to justify their use. Austin Partial Sedimentation Sand Filters have been built in underground vaults in Alexandria on sheds of three-four acres of impervious cover. Precast segmented underground vaults are now available in very large configurations. Besides the modified precast box culvert technology illustrated under **MS 3.12A: D.C. Sand Filters**, precast arch technology has also been adapted to the construction of underground vaults. **Figure 3.12C-3** shows such a system. It appears that approximately five acres of impervious cover is the uper limit of the area that should be treated by a single underground vault system.

FIGURE 3.12C - 3
Underground Vault Fabricated From Precast Bridge Arch Components



(Photo Courtesy of BridgeTek Bridge Technologies, LLC., Fredericksburg, Virginia)

Development Conditions

Austin Sand Filters are generally suitable BMPs for medium to high density commercial or industrial development. Because of confined space entry restrictions when constructed in underground vaults and maintenance requirements, they are not generally suitable for residential applications except for apartment complexes or large condominiums where a dedicated maintenance force will be present.

Planning Considerations

Refer to the **Planning Considerations** for **Minimum Standard 3.12: General Intermittent Sand Filter Practices**. Of special concern are the stormwater infrastructure serving the site and the requirement to isolate the sand filter from receiving flows until the drainage shed is fully stabilized.

Potential and existing elevations of stormwater infrastructure serving the site will determine one of the most critical design parameters: the maximum depth to which runoff may be pooled over the filter and preserve a gravity flow configuration (whatever the pooling depth, there must be a minimum of five feet of clearance between the top of the filter and the top slab of the filter shell to allow filter maintenance).

*Sand filter BMPS must **never** be placed in service until all site work has been completed and stabilization measures have been installed and are functioning properly.*

Design Criteria

The purpose of this section is to provide recommendations and minimum criteria for the design of Austin Sand Filter BMPs intended to comply with the Virginia Stormwater Management program's runoff quality requirements.

Refer to the **General Design Criteria** previously discussed under **General Intermittent Sand Filter Practices, Minimum Standard 3.12**

Filter Sizing Criteria

1. ***Full Sedimentation with Filtration***

In this configuration, the sedimentation basin receives the WQV and detains it for a minimum draw-down time (time required to empty the basin from a full WQV condition) of 24 hours. The effluent from the sedimentation basin is discharged into the filtration basin..

Austin conducted a literature review of sedimentation basins and slow rate filters to establish design criteria.

For filtration basins, surface area is the primary design parameter. The required surface area is a function of sand permeability, bed depth, hydraulic head and sediment loading. A filtration rate of 0.0545 gallons per minute per square foot has been selected for design criteria (10.5 feet per day or 3.4 million gallons per acre per day). This filtration rate is based on a Darcy's Law coefficient of permeability k =3.5 feet per day, an average hydraulic head (h) of three (3) feet and a sand bed depth (d_f) of 18 inches, and a filter drawdown time, t_f of 40 hours.

Substituting these values in the basic Austin Filter Formula shown in **General Intermittent Sand Filter Practices, Minimum Standard 3.12** yields:

$A_f = I_a H / 18$

where "A_f" is the minimum surface area of the filtration media in acres, "I_a" is the contributing impervious runoff area in acres and "H" is the runoff depth in feet (0.5 inch = 0.0417 feet when treating the WQV).

When treating the first 1/2-inch of runoff, this formula reduces to

$A_f = 0.0023 I_a = 100\ Ft^2$ of filter per impervious acre.

This formula is obviously based on a number of simplifying assumptions. Determining the actual average depth of ponding over the filter is an extremely complex proposition considering thet the runoff is being released from the sedimentation chamber to the filter at first a rising and then a falling head and then percolating through the sand filter at first a rising and then a falling head. However, this design procedure has worked well for austin for over a decade and may be therefore be considered to be vaild.

When treating a volume greater than the WQV (as when a combined quantity detention/presettling basin is utilized) use the following formula:

$A_f = 0.0023 I_a \times (TV / WQV)$

Where TV = the full retention volume of the detention basin/presettling basin.

2. ***Partial Sedimentation with Filtration***

In this configuration, the sedimentation basin or chamber holds a minimum of 20 percent of the WQV and is hydraulically connected to the filter basin with orifices or slots which allow the water level to equalize between the two chambers.

For Austin Sand Filters with partial sedimentation protection, utilize the following formula:

$$A_{f(m)(PS)} = \frac{545 I_a d_f}{(h + d_f)}$$

where,

I_a = impervious cover on the watershed in acres
d_f = sand bed depth (normally 1.5 to 2ft)
h = average depth of water above surface of sand media between full and empty basin conditions (ft.)

R0009849

Sedimentation Basin Sizing

1. ***Full Sedimentation with Filtration***

The sedimentation basin must hold the entire WQV (or larger treatment volume) and release it to the filter over 24 hours. The volume of the basin is thus set by the amount of area to be treated. For sedimentation basins, the removal of discrete particles by gravity settling is primarily a function of surface loading, "Q_o/A_s ", where "Q_o " is the rate of outflow from the basin and "A_s" is the basin surface area. Basin depth is of secondary importance as settling is inhibited only when basin depths are too shallow (particle resuspension and turbulence effects). For sedimentation, surface area is the primary design parameter for a fixed minimum draw-down time, t_d, of 24 hours. Removal efficiency, E, is also a function of particle size distribution. For design purposes, the particles selected for complete removal in the sedimentation basin are those which are greater than or equal in size to silt with the following characteristics: particle diameter 0.00007 foot (20 microns) and specific gravity of 2.65. These are typical values for urban runoff.

Presettling basins are usually sized using the Camp-Hazen equation (Claytor and Schueler, 1996):

$$A_S = -(Q_O / w) \times \text{Ln}(1 - E)$$

Where,

A_S = Surface area (ft^2) of the sedimentation basin
E = Trap efficiency, which is the target removal efficiency of suspended solids (use 90%)
w = Particle settling velocity; for silt, use 0.0004 ft/sec
Q_O = rate of outflow from the basin = WQV (or treatment volume) divided by the detention time (24 hours)

Substituting the values recommended above yields the simplified formula:

$$A_S = 0.066 \times WQV \quad (ft^2)$$

For 1816 ft^3, this yields an area of 120 ft^2. However, Austin recommends that the sedimentation basin be no more that 10 feet deep, which yields a surface area approximately 115% of the basin Camp-Hazen area. The Austin formula for minimum surface area is:

$$A_S = 0.0042\ I_a$$

Where I_a is the contributing impervious runoff area in acres

2. **Partial Sedimentation with Filtration**

The minimum area of the sediment chamber may be computed by the formula:

$$A_S = WQV / 2h$$

Where 2h = the maximum depth of ponding over the filter and the sediment chamber.

Additional Full Sedimentation Basin Considerations

1. ***Inlet Structure***

The inlet structure design must be adequate for isolating the water quality volume from the design storm and to convey the peak flow for the design storm past the basin. The water quality volume should be discharged uniformly and at low velocity into the sedimentation basin in order to maintain near quiescent conditions which are necessary for effective treatment. It is desirable for the heavier suspended material to drop out near the front of the basin; thus a drop inlet structure is recommended in order to facilitate sediment removal and maintenance. Energy dissipation devices may be necessary in order to reduce inlet velocities which exceed three (3) feet per second.

2. ***Outlet Structure***

The outlet structure conveys the water quality volume from the sedimentation basin to the filtration basin. The outlet structure shall be designed to provide for a minimum draw-down time of 24 hours. A perforated pipe or equivalent is the recommended outlet structure. The 24 hour draw-down time should be achieved by installing a throttle plate or other flow control device at the end of the riser pipe (the discharges through the perforations should not be used for draw-down time design purposes)

3. ***Basin Geometry***

The shape of the sedimentation basin and the flow regime within this basin will influence how effectively the basin volume is utilized in the sedimentation process. The length to width ratio of the basin should be 2:1 or greater. Inlet and outlet structures should be located at extreme ends of the basin in order to maximize particle settling opportunities.

Short-circuiting (i.e., flow reaching the outlet structure before it passes through the sedimentation basin volume) flow should be avoided. Dead storage areas (areas within the basin which are by-passed by the flow regime and are, therefore, ineffective in the settling process) should be minimized. Baffles may be used to mitigate short circuiting and/or dead storage problems. The sedimentation illustrated in **Figure 3.12C-1** (photo in **Figure 3.12-4**) illustrates the use of baffles to improve sedimentation basin performance.

4. ***Sediment Trap (Optional)***

A sediment trap is a storage area which captures sediment and removes it from the basin flow regime. In so doing the sediment trap inhibits resuspension of solids during subsequent runoff events, improving long-term removal efficiency. The trap also maintains adequate volume to hold the water quality volume which would otherwise be partially lost due to sediment storage. Sediment traps may reduce maintenance requirements by reducing the frequency of sediment removal. It is recommended that the sediment trap volume be equal to ten (10) percent of the sedimentation basin volume. Water collected in the sediment trap shall be conveyed to the filtration basin in order to prevent standing water conditions from occurring. All water collected in the sediment trap shall drain out within 60 hours. The invert of the drain pipe should be above the surface of the sand bed filtration basin. The minimum grading of the piping to the filtration basin should be 1/4 inch per foot (two (2) percent slope). Access for cleaning the sediment trap drain system is necessary.

Design Storm

The inlet design or integral large storm bypass must be adequate for isolating the WQV from the design storm for the receiving storm sewer system (usually the 10 year storm) and for conveying the peak flow of that storm past the filter system. Since D.C. Sand Filters will be used only as off-line facilities in Virginia, the interior hydraulics of the filter are not as critical as when used as an on-line facility. The system should draw down in approximately 40 hours.

Infrastructure Elevations

For cost considerations, it is preferable thatAustin Sand Filters work by gravity flow. This requires sufficient vertical clearance between the invert of the prospective inflow storm piping and the invert of the storm sewer which will receive the outflow. In cases where gravity flow is not possible, a clearwell sump and pump are required to discharge the effluent into storm sewer. Such an application would be appropriate in commercial or industrial situations where a dedicated maintenance force will be available (shopping malls, apartment houses, factories of other industrial complexes, etc.).

Special Considerations for Underground Filter Systems

When Austin Sand Filters are placed underground, a number of special considerations pertain. The restrictive orifice or gate valve for controlling the release of water from a separate sedimentation vault should be placed in a manhole located between the sedimentation vault and the filter vault. The sedimentation vault should contain a sediment sump into which accumulated sediments may be flushed with a high pressure hose for removal by vacuum trucks. Water should enter the filter vault in a separate headbox with a permanent pool for energy absorbtion and a hydrocarbon trap like that of a D.C. Sand Filter. The filter vault should also contain a separate clearwell.

Structural Requirements

The load-carrying capacity of the filter structure must be considered when it is located under parking lots, driveways, roadways, and, certain sidewalks (such as those adjacent to State highways). Traffic intensity may also be a factor. The structure must be designed by a licensed structural engineer and the structural plans require approval by the plan approving jurisdiction.

Accessibility and Headroom for Maintenance

Both the sedimentation basin and the filter must be accessible to appropriate equipment and vacuum trucks for removing accumulated sediments and trash. The sedimentation basin must be cleaned approximately once per year, and the filter will likely need raking on that frequency to remove trash and restore permeability. When filters are placed in underground vaults, all chambers must have personnel access manholes and built-in access ladders. **A minimum headspace of 60 inches above the filter is required to allow such maintenance and repair.** A 38-inch diameter maintenance manhole with eccentric nested covers (a 22-inch personnel access lid inside the 38-inch diameter lid) or a rectangular load bearing access door (minimum 4 ft. x 4 ft.) should be positioned directly over the center of the filter. A 30-inch manhole should also be placed directly over the sediment sump in an underground sedimentation vault. Similar manholes must be positioned to provide access for a high-pressure hose to reach all points in the sediment vault.

Construction Specifications

Sedimentation Basin Liners

Impermeable liners may be either clay, concrete or geomembrane. If geomembrane is used, suitable geotextile fabric shall be placed below and on the top of the membrane for puncture protection. Clay liners shall meet the specifications in **Table 3.12C-2**:

The clay liner shall have a minimum thickness of 12 inches.

If a geomembrane liner is used it shall have a minimum thickness of 30 mils and be ultraviolet resistant.

The geotextile fabric (for protection of geomembrane) shall meet the specifications in **Table 3.12C-3**.

TABLE 3.12C - 2
Clay Liner Specifications

Property	Test Method	Unit	Specification
Permeability	ASTM D-2434	Cm/Sec	1×10^{-6}
Plasticity Index of Clay	ASTM D-423 & D-424	%	Not less than 15
Liquid Limits of Clay	ASTM D-2216	%	Not less than 30
Clay Compaction	ASTM-2216	%	95% of Standard Proctor Density
Clay Particles Passing	ASTM D-422	%	Not less than 30

Mullen Burst Strength	ASTM D-751	Psi.	400 (minimum)
Tensile Strength	ASTM D-1682	Lb.	300
Equiv. Opening Size	U.S. Standard Sieve	No.	80 (minimum)

Source: City of Austin

Equivalent methods for protection of the geomembrane liner will be considered on a case by case basis. Equivalency will be judged on the basis of ability to protect the geomembrane from puncture, tearing and abrasion.

Portland Cement Concrete

Concrete liners may be used for sedimentation chambers and for sedimentation and filtration basins. Concrete shall be at least five (5) inch thick C A3 defined in the Virginia Department of Transportation *Road and Bridge Specifications*

Outlet Structure for Full Sedimentation Basin

A perforated pipe or equivalent is the recommended outlet structure. The 24-hour draw-down should be achieved by installing a throttle plate or other control device at the end of the riser pipe (the discharges through the perforations should not be used for draw-down time design purposes). The perforated riser pipe should be selected from **Table 3.12-4.**

TABLE 3.12C - 4
Perforated Riser Pipes

Riser Pipe Nominal Diameter (inches)	Vertical Spacing Between Rows (Center to Center in Inches)	Number of Perforations Per Row	Diameter of Perforations (inches)
6	2.5	9	1
8	2.5	12	1
10	2.5	16	1

Source: City of Austin

A trash rack shall be provided for the outlet. Openings in the rack should not exceed 1/3 the diameter of the vertical riser pipe. The rack should be made of durable material, resistant to rust and ultraviolet rays. The bottom rows of perforations of the riser pipe should be protected from clogging. To prevent clogging of the bottom perforations it is recommended that geotextile fabric be wrapped over the pipe's bottom rows and that a cone of one (1) to three (3) inch diameter gravel be placed around the pipe. If a geotextile fabric wrap is not used then the gravel cone must not include any gravel small enough to enter the riser pipe perforations. **Figure 3.12C-4** illustrates these considerations.

Outlet Structure for Partial Sedimentation Basin

The outlet structure should be a berm or wall with multiple outlet ports or a gabion so as to discharge the flow evenly to the filtration basin. Rock gabions should be constructed using 6-8 inch diameter rocks. The berm/wall/gabion height should not exceed six (6) feet and high flows should be allowed to overtop the structure (weir flow). Outlet ports should not be located along the vertical center axis of the berm/wall so as to induce flow-spreading. The outflow side should incorporate features to prevent gouging of the sand media (e.g., concrete splash pad or riprap)

Sand Filter Layer

For applications in Virginia, use **ASTM C33 Concrete Sand** or sand meeting the Grade A fine aggregate gradation standards of Section 202 of the VDOT ***Road and Bridge Specifications.*** The top of the sand filter must be completely level.

Geotextile Fabrics

The filter cloth layer beneath the sand shall conform to the specifications shown in **Table 3.12C-5**: The fabric rolls must be cut with sufficient dimensions to cover the entire wetted perimeter of the filtering area and lap up the filter walls at least six-inches.

FIGURE 3.12C - 4
Riser Pipe Detail for Full Sedimentation Basin

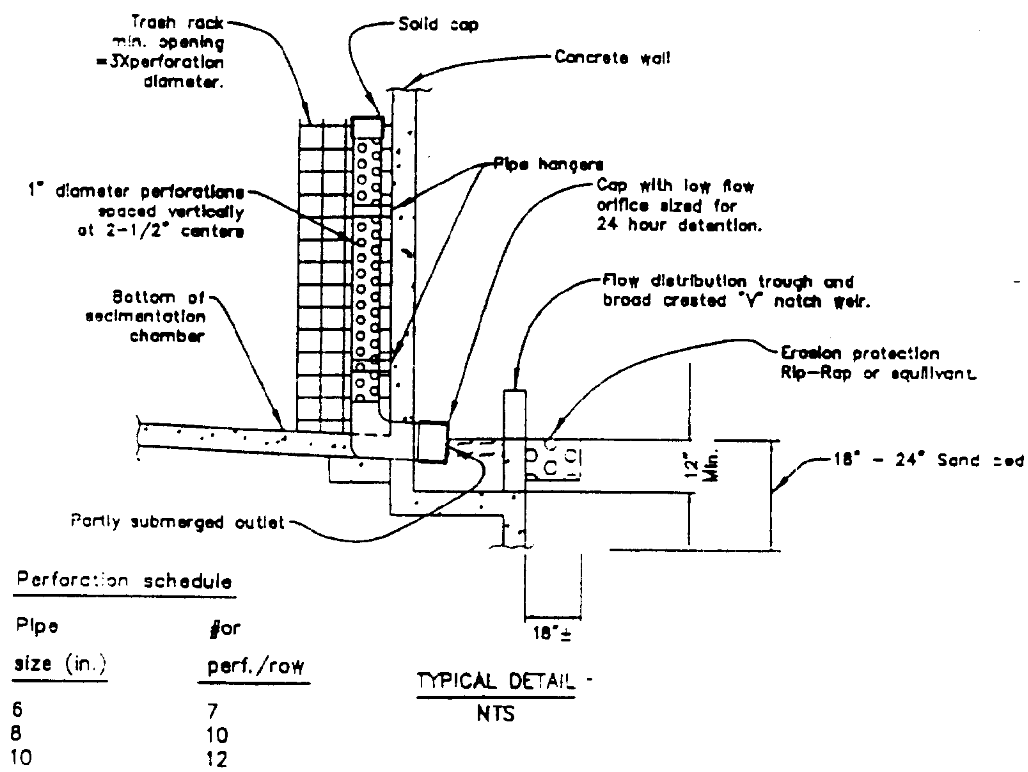

Table 3.12C - 5
Specifications for Nonwoven Geotextile Fabric Beneath Sand in Austin Sand Filter

Property	Test Method	Unit	Specification

Puncture Strength	ASTM D-751 (Modified)	Lb.	125 (min.)
Mullen Burst Strength	ASTM D-751	Psi	400 (min.)
Equiv. Opening Size	U.S. Standard Sieve	No.	80 (min.)
Tensile Strength	ASTM D-1682	Lb.	300 (min.)

Gravel Bed Around Collector Pipes

The gravel layer surrounding the collector pipes shall be ½ to two (2) inch diameter gravel and provide at least two (2) inches of cover over the tops of the drainage pipes. The gravel and the sand layer are usually separated by a layer of geotextile fabric meeting the specification listedabove. However, on small underground vault partial sedimentation systems, some jurisdictions allow the substitution for an additional six-inch layer of 1/4-inch washed pea gravel in lieu of the filter fabric. In such cases, hydraulic compaction and refilling of the filter is especially important. **FIGURE 3.12C-5** shows a cross-section of a filter with the usual configuration. **FIGURE 3.12C-6** shows an underground vault filter with a six-inch pea gravel layer.

Underdrain Piping

The underdrain piping consists of 4-inch or 6-inch schedule 40 or better polyvinyl perforated pipes reinforced to withstand the weight of the overburden. Perforations should be 3/8 inch, and each row of perforations shall contain at least four holes for four-inch pipe and six holes for six-inch pipe. Maximum spacing between rows of perforations shall be six (6) inches. Maximum spacing between pipes shall be 10 feet.

The minimum grade of piping shall be 1/8 inch per foot (one [1] percent slope). Access for cleaning all underdrain piping is needed. Clean-outs for each pipe shall extend at least six (6) inches above the top of the upper filter surface, e.g. the top layer of gravel.

Each pipe shall be thoroughly wrapped with 8 oz./sq.yd. geotextile fabric meeting the specification in **Table 3.12C-1** above.

FIGURE 3.12C - 5

Austin Sand Filter Cross-Section With Filter Fabric Layer

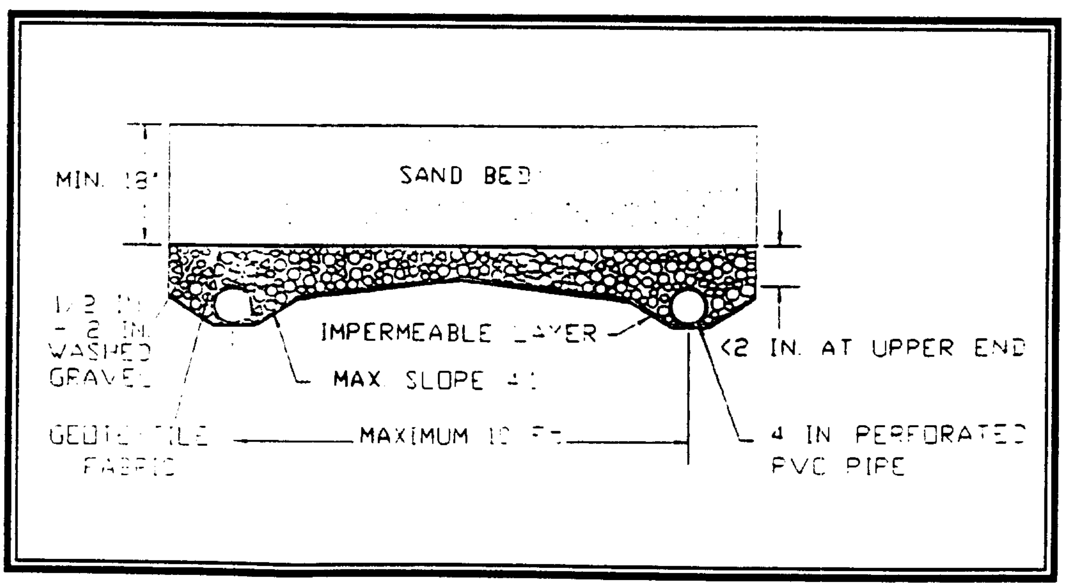

FIGURE 3.12C - 6
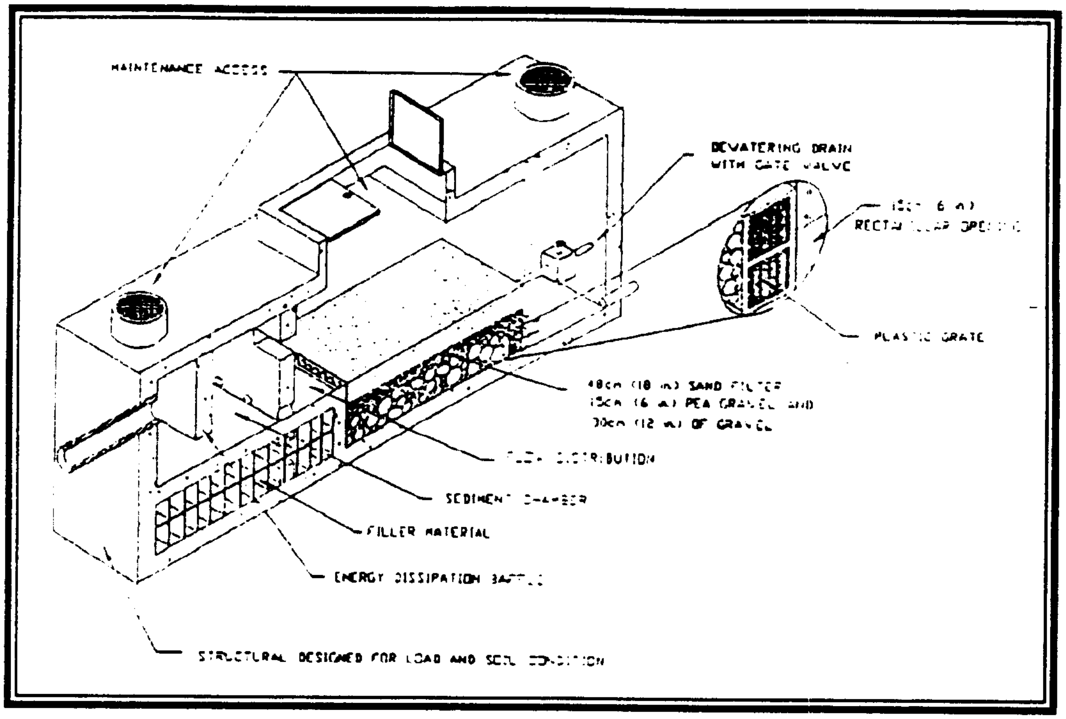
Partial Sedimentation Vault Filter With Pea Gravel Layer



Protection from Construction Sediments

The site erosion and sediment control plan must be configured to permit construction of the filter system while maintaining erosion and sediment control.

No runoff is to enter the sand filtration system prior to completion of all construction and site revegitation. Construction runoff shall be treated in separate sedimentation basins and routed to by-pass the filter system. Should construction runoff enter the filter system prior to site revegitation, all contaminated materials must be removed and replaced with new clean materials.

Watertight Integrity Test

After completion of the filter shell but before placement of the filter layers, entrances to the structure shall be plugged and the shell completely filled with water to demonstrate water tightness. Maximum allowable leakage is 5 percent of the filter shell volume in 24 hours. Should the structure fail this test, it shall be made watertight and successfully retested prior to placement of the filter layers.

R0009858

Hydraulic Compaction of Filter Components

After placement of the collector pipes, gravel, and lower geotextile layer, fill the shell with filter sand to the level of the top of the sediment pool weir. Direct clean water into the sediment chamber until both the sediment chamber and filter chamber are completely full. Allow the water to draw down until flow from the collector pipes ceases, hydraulically compacting the filter sand. After allowing the sand to dry out for a minimum of 48 hours, refill the shell with sand to a level one inch beneath the top of the weir and place the upper geotextile layer and gravel ballast.

Note: The following Construction Specifications apply to Austin Sand Filters which are to be constructed in underground vaults.

Depth of Plunge Pool in Filter Headbox

The energy absorbing "plunge pool" must be at least 36 inches deep to properly absorb energy from the incoming flow and trap any hydrocarbons which pass through the sedimentation vault.

Depth of the Underwater Opening Between Chambers

To preserve an effective hydrocarbon trap, the top of the underwater opening between the headbox and the filter chamber must be at least 18 inches below the depth of the weir which divides the filter from the pool. To retain sediment in the first chamber, the bottom of the opening should be at least six inches above the floor. The area of the opening should be at least 1.5 times the cross-sectional area of the inflow pipe(s) to assure that the water level remains equal between the first and second chambers.

Total Depth of Filter Cross-Section

The total depth of the filter cross-section must match the height of the weir dividing the sedimentation pool from the filter. Otherwise, a "waterfall" effect will develop which will gouge out the front of the filter media. If a sand filter less than 24 inches is used, the gravel layer must be increased accordingly to preserve the overall filter depth.

Dewatering Drain

When the filter is placed in an underground vault, A 6-inch dewatering drain controlled by a gate valve shall be installed between the filter chamber and the clearwell chamber with its invert at the elevation of the top of the filter. The dewatering drain penetration in the chamber dividing wall shall be sealed with a flexible strip joint sealant which swells in contact with water to form a tight pressure seal.

Access Manholes

When the filter is installed in an underground vault, access to the headbox (sediment chamber) and the clearwell shall be provided through at least 22-inch manholes. Access to the filter chamber shall be provided by a rectangular door (minimum size: 4 feet by four feet) of sufficient strength to carry prospective imposed loads or by a manhole of at least 3- inch diameter with an offset concentric 22-inch lid (Neenah R-1741-D or equivalent).

Restrictive Orifice Manhole Between Vaults

The restrictive orifice or gate valve on the outlet pipe from the sedimentation vault should be placed in a manhole between the sedimentation and filter vaults with ready personnel access. **Figure 3.12C-7** illustrates this principle.

Maintenance/Inspection Guidelines

The following maintenance and inspection guidelines are not intended to be all inclusive. Specific facilities may require other measures not discussed here.

Major Maintenance Requirements for Sedimentation Basins

1. Removal of silt when accumulation exceeds six (6) inches in sediment basins without sediment traps. In basins with sediment traps, removal of silt shall occur when the accumulation exceeds four (4) inches in the basins, and sediment traps shall be cleaned when full.

2. Removal of accumulated paper, trash and debris every six (6) months or as necessary.

3. Vegetation growing within the basin is not allowed to exceed 18 inches in height at any time.

4. Corrective maintenance is required any time a sedimentation basin does not drain the equivalent of the Water Quality Volume within 40 hours (i.e., no standing water is allowed).

5. Corrective maintenance is required any time the sediment trap (optional) does not drain down completely within 96 hours (i.e., no standing water allowed).

Major Maintenance Requirements for Filtration Components

1. Removal of silt when accumulation exceeds 1/2 inch. - Removal of accumulated paper, trash and debris every six (6) months or as necessary.

2. Vegetation growing within the basin is not allowed to exceed 18 inches in height.

3. Corrective maintenance is required any time draw-down does not occur within 36 hours after the sedimentation basin has emptied.

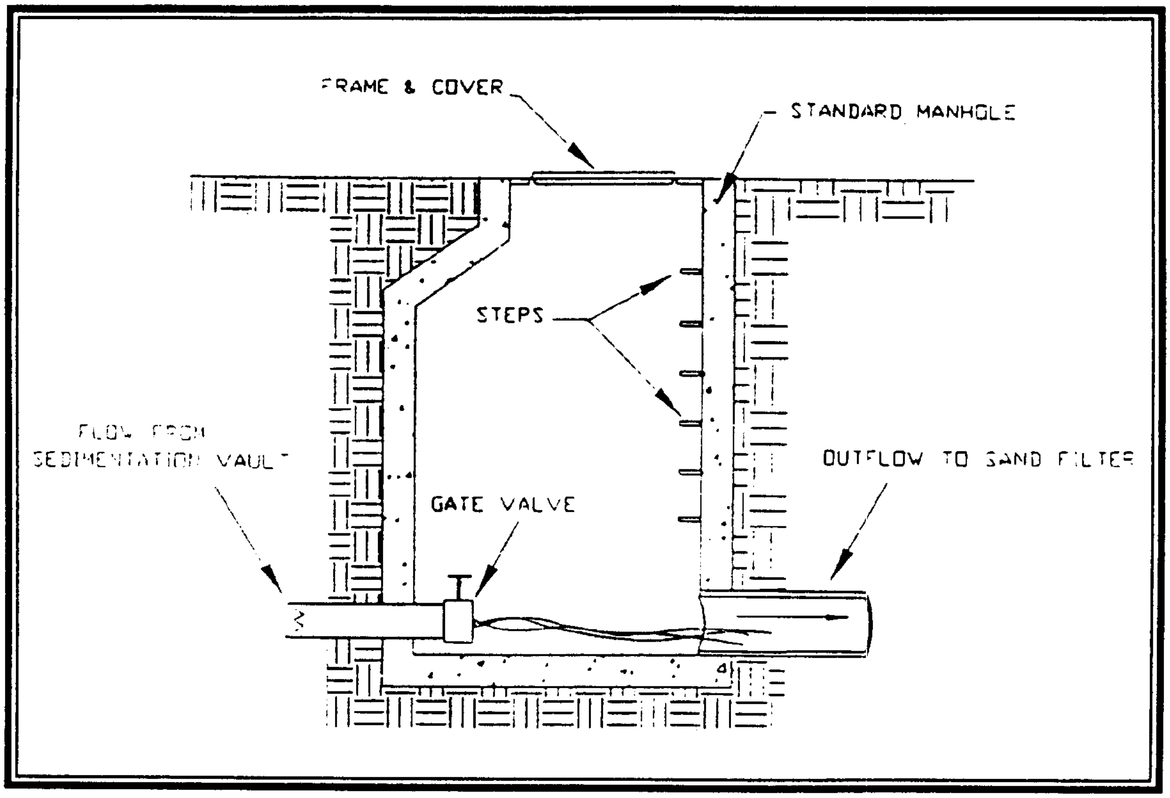
4. When an underground vault filter will no longer draw down within the required 36-hour period because of clogging with silt (approximately every 3-5 years), the upper layer of gravel and

geotechnical cloth must be replaced with new clean materials meeting the original specifications.

5. Monitoring manholes, flumes, and other facilities shall be kept clean and ready for use.

The BMP shall be inspected annually by representatives of the owner and the governing jurisdiction staff to assure continued proper functioning.

FIGURE 3.12C - 7
Restrictive Orifice Access Manhole



Sediment Chamber Pumpout

Full sedimentation chambers or basins require flushing and pumpout with a vacuum truck approximately once per year.

Concrete Shell Inspection

Concrete will deteriorate over time, especially if subjected to live loads. The concrete shell, risers, etc., must be examined during each annual inspection to identify areas that are in need of repair, and such repairs must be promptly effected.

Design Procedures

The following design procedure is structured to assure that the desired water quality volume is captured and treated by theAustin Filter. The procedure assumes that a filter shell with a rectangular cross-section is to be used.

Standard Design Logic

Employ the following design logic to design Austin Sand Filters for use in Virginia:

1. Determine Governing Site Parameters

Determine the Impervious area on the site (I_a in acres), the water quality volume to be treated (WQV in $ft.^3 = 1816\ I_a$), and the site parameters necessary to establish 2h, the maximum ponding depth over the filter (storm sewer invert at proposed connection point, elevation to inflow invert to BMP, etc).

2. Select Filter Depth and Determine Maximum Ponding Depth

Considering the data from Step 1) above, select the Filter Depth ((d_f) and determine the maximum achievable ponding depth over the filter (2h).

3. For Full Sedimantation Systems, size the sedimentation basin (vault) to hold the WQV with a minimum depth of 10 feet.

4. Compute the Minimum Area of the Sand Filter (A_{fm})

For systems with full sediment protection, provide a dediment chamber of sufficient volume to hold the WQV. Make the depth ≤ ten feet. To compute the area of the filter, use the formula:

$$A_f = 100 I_a$$

Where I_a = the impervious acreage on the drainage shed.

For systems with only partial sediment protection, utilize the formula:

$$A_{fm(PS)} = \frac{545 I_a d_f}{(h + d_f)}$$

A_{fm} = minimum surface area of sand bed (square feet)
I_a = impervious cover on the watershed in acres
d_f = sand bed depth (normally 1.5 to 2ft)
h = average depth of water above surface of sand media between full and empty basin conditions (ft.)

5. Select Filter Width and Compute Filter Length and Adjusted Filter Area

Considering site constraints, select the Filter Width (W_f). Then compute the Filter Length (L_f) and the Adjusted Filter Area (A_f)

$$L_f = A_{fm}/W_f$$

$$A_f = W_f \times L_f$$

Sizing computations are completed at this point for the full sediment protection system. The only remaining task is to assure that the filter chamber is sized to contain a minimum of 20 % of the WQV. The logic continues for the partial sedimentation system.

6. Compute the Storage Volume on Top of the Filter (V_{Tf})

$$V_{Tf} = A_f \times 2h$$

7. Compute the Storage in the Filter Voids (V_v)
(Assume 40% voids in filter media)

$$V_v = 0.4 \times A_f \times (d_f + d_g)$$

8. Compute Flow Through Filter During Filling (V_Q)
(Assume 1-hour to fill per D.C. practice)

$$V_Q = \frac{kA_f(d_f + h)}{d_f}\text{ ; use } k = 2\text{ ft./day} = 0.0833\text{/hr.}$$

9. Compute Net Volume to be Stored Awaiting Filtration (V_{st})

$$V_{st} = WQV - V_{Tf} - V_v - V_Q$$

10. Compute Length of Sediment chamber (L_{SC})

$$L_{SC} = \frac{V_{st}}{(2h \times W_f)}$$

11. Compute Minimum Length of Sediment Chamber (L_s)
(to contain 20% of WQV per Austin practice)

$$L_{sm} = \frac{0.2WQV}{(2h \times W_f)}$$

12. Set Final Length of the Sediment Chamber (L_{SCF})

If $L_{SC} \geq L_s$, make $L_{SCF} = L_{SC}$

If $L_{SC} < L_{sm}$, make $L_{SCF} = L_{sm}$

It may be economical to adjust final dimensions to correspond with standard precast structures or to round off to simplify measurements during construction.

Checklists

The **Construction Inspection and As-Built Survey Checklist** found in **Appendix 3D** is for use in inspecting intermittent sand filter facilities during construction and, where required by the local jurisdiction, engineering certification of the filter construction. The **Operation and Maintenance Checklist**, also found in **Appendix 3D**, is for use in conducting maintenance inspections of intermittent sand filter facilities.

ACKNOWLEDGEMENTS

We are most grateful for direction and guidance for this project provided by the Office of Wastewater Enforcement and Compliance, Michael B. Cook, Director; James Horne, Project Officer.

We also acknowledge the efforts of those persons who participated in the focus groups, the expert surveys, the public forums, and the "design team" session. The thoughtfulness of opinions and insights voiced is impressive.

We are encouraged by the willingness of people with very different perspectives to not only listen carefully to each other but to seek common ground. The prospects for collaborative work are strong.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

In December 1991, the Deputy Administrator of the U.S. Environmental Protection Agency (EPA) asked the Office of Water to undertake a research project with two objectives: 1) identify ways to improve and streamline the existing storm water regulatory program implemented by the agency under Section 402 (p) (2) of the Clean Water Act; and 2) define and annotate options for controlling sources of storm water runoff designed for Phase II of this same section.

In response to this request, the Office of Wastewater Enforcement and Compliance (OWEC) engaged The Rensselaerville Institute to develop a two-part project to gather and integrate diverse opinion and insight on ways to improve the efficiency and effectiveness of the existing Phase I program and the best possible response for the Phase II program designed to cover remaining storm water sources and problems.

Part I of the project was conducted during February and March, 1992 when six focus groups were held around the U.S. to gain user feedback on how the current regulations and implementation procedures could be improved and streamlined. These groups, which included representation by both public- and private-sector permittees as well as regulatory agencies, private consulting firms, industry, and environmental interests, identified numerous ways EPA and others could address permitting and compliance procedures seen as difficult or problematic.

Part II of the project began with an Expert Survey of 32 persons highly knowledgeable in storm water and its control who represented different perspectives (academic/research, state/local government,. commercial development, environmental advocacy, and consultant/engineering) and different geographic areas. Experts were asked to respond to a set of options for targeting and controlling sources and to suggest additional alternatives as well. Insights on voluntary measures that have proven effective in storm water control were solicited through a separate survey of five experts in nonpoint program approaches.

Based on the results of these surveys, three public meetings were announced in the Federal Register and held in Denver, San Francisco and Washington, DC during June, 1992. Those attending were divided into teams and asked to define their own preferred strategies for a Phase II program response, including definition of sources to be regulated, the preferred method of control (permit-based or other) and their sense of both timetable and the role EPA should play.

Finally, a small group of insightful individuals representing diverse viewpoints from both point source and nonpoint source programs was convened for a strategy design meeting for the purpose of adding greater depth and breadth to one or more Phase II approaches identified in the public meetings. From this group, a ten-point strategy was created, as well as a series of recommendations to EPA on developing the second phase of the storm water program.

This Executive Summary presents the findings from each of these activities in summary form. More complete recommendations are contained in the body of Volume I. The project data base is contained in Volume II.

Summary of Findings on Improving Phase I of the Storm Water Program

Forty individuals participated in focus groups held in Atlanta, GA; Hartford, CT; Chicago, IL; Washington, DC; Seattle, WA; and Phoenix, AZ. Together, the participants included all identified viewpoints and separable interests--including EPA regional staff, state and local government officials, engineering consultants, environmental advocates, and representatives of corporations included in Phase I permitting.

Participants responded to a set of questions which probed for opinion and insight on such matters as the unclear aspects of the Phase I regulations, additional steps that should be taken to simplify the process and help permittees to achieve compliance, and the relative merits of individual and group permits. In addition to participant responses to core questions, the afternoon of each session was used to further elaborate problems and solutions of interest to participants in an informative format.

While many issues raised were location- or source-specific, some spanned geographic and demographic boundaries. Eight issues common across all focus groups were identified as key areas to be clarified and/or modified to improve program implementation:

1. EPA has not been clear about the intended goals of the regulations. A stronger sense of the relative importance of storm water in the framework of environmental risk is needed, as is clarity about short range and long term targets. There is a difference, for example between clean water standards and stream health standards. It is clear that there are storm water permits. It is not clear how the permits reflect a coherent program.

2. The expense of program implementation is significantly higher than EPA has estimated. There is great concern over what the program's real costs have been in terms of dollars and manpower costs of preparing a permit application, and the anticipated costs of achieving compliance. A broader concern: municipalities now beleaguered by resource shortfalls cannot reasonably afford the combined costs of compliance with all environmental regulations.

3. The administrative complexity of the program is enormous at the federal, state and local levels, and has quickly outpaced the availability of resources and manpower needed to carry it out. In some cases, field staff have been

pulled in simply to process the paperwork involved.

4. Clarification is needed on the roles and expectations EPA has for itself, states and permittees. What is clear to everyone is that EPA does not have the capacity to administer and enforce the program alone. This cannot be seen as an EPA program administered in a "command and control" style totally from Washington. It must involve active participation, not simply passive compliance, from all levels involved.

5. More technical support for the program is needed. Expanded information explaining the regulations and how to implement them is especially needed. Also, there should be less "national level" support and more focus on regional conditions. Much of the content of storm water workshops held at EPA headquarters is irrelevant to any given participant.

6. States need EPA to either clarify how to interpret unclear points of the regulations, or allow them the latitude to make the interpretations themselves. One unclear area is the inconsistencies and inequalities created by use of industrial SIC codes in such areas as transportation. Another murky area is the group application process.

7. EPA should consider consolidating programs in order to address water pollution in an efficient and cost-effective manner. A watershed approach is preferable to current practices of separating problems by media.

8. General permits are "the way to go" and EPA should continue to focus on and accelerate efforts in this direction.

Many focus group members made a point of indicating their pleasure with the focus group format used and the ways in which EPA had 1) encouraged interaction and customer insight and 2) listened carefully to their advice. A complete report on focus group responses and conclusions is contained in the body of this publication.

Summary of Findings on Designing Phase II of the Storm Water Program

Expert Survey

The second part of the Rensselaerville project began with a survey of a select group of 32 point source storm water program experts from across the country. The purpose was to solicit opinions on ways to implement the second phase of the storm water program. Five perspectives were represented: academic/research; commercial development; consultant engineering/legal; environmental advocacy; and state/local government. A first mail-back survey round gained opinion and consensus on relevant issues and options for addressing Phase II sources. Data from the first set of returned surveys were analyzed and given back to participants in a second survey round, which refined positions and created more options for Phase II consideration.

To ensure inclusion of all critical perspectives, five nonpoint source program experts were asked to provide feedback, with emphasis on potential voluntary approaches for addressing Phase II sources.

While approaches recommended differed by profession and geography, these common targeting themes emerged for identifying whom to include in Phase II:

- develop a geographically-based phasing plan by watershed impairment/severity of threat;
- determine selection criteria for pollution sources and use these to identify municipalities that should participate;
- do pilot projects first, evaluate, and then develop and implement a strategy;
- encourage and fund comprehensive basin research and planning to guide targeting;
- require Phase II industries to be covered under Phase I general permits;
- develop national guidelines, and leave selection of sites and methods to state discretion;
- require smaller communities (< 100,000) to apply for permits only when their storm water contributes a significant pollution problem;
- designate problem areas, establish permit requirements for municipals regardless of population, and allow municipals to exclusively regulate industries; and
- initiate a focused dialogue with key stakeholders (applies to both targeting and controls).

Common themes expressed for control strategies included:

- build a Best Management Practices (BMPs) menu that can be used by states to implement and verify progress;

- require localities to select from a list of BMPs the ones most appropriate for their needs and apply industry-specific BMPs nationwide with allowance for state/local officials to modify;

- provide nationwide public education and community-wide public education on the need for storm water control;

- establish national or industry-specific minimum practices for controlling storm water;

- implement good housekeeping and source reduction practices;

- require routine certification and audit of storm water pollution plans and practices;

- establish industry-specific and watershed-specific BMPs; and

- establish BMPs required nationwide and strictly enforce. Require facilities to further treat storm water discharges where BMPs are not effective.

The strongest additional factor in nonpoint survey responses was the degree of emphasis placed on education at all levels, including the general public, local and state officials, and local businesses and industry. Education was seen as the key to making voluntary approaches effective. Voluntary compliance, in turn, was then advanced as highly cost effective.

Respondents feel that EPA must be the "stick" that would fall--with permit requirements, fines, etc.--if a storm water source does not voluntarily take action and achieve certain minimum goals. But limited manpower and financial resources form a rationale for not addressing Phase II with the costly conventional federal mandates of Phase I.

Public Meetings

Three meetings were conducted to gain public responses to options for targeting and controlling Phase II sources. They were held in Denver, CO; San Francisco, CA; and Washington, DC during June, 1992. At each meeting, three experts selected from the Expert Survey process presented their ideas on a regulating strategy for the moratorium sources. Participants were then divided into small task teams, and given the charge of devising their own strategies for targeting and controlling Phase II sources. A strategy template was provided to guide group consideration of three key issues: 1) who should be covered under Phase II; 2) what controls are needed; 3) over what timeframe the program should be implemented. At the end of each public meeting, the task teams presented their options to other participants for discussion.

Common strategy characteristics emerged, in many cases paralleling those apparent in the expert survey. For targeting:

- o Targeting should be done by watershed. Information gathered from Phase I should help identify sensitive watersheds. This may require intergovernmental agreements.

- o The focus should be on "bad actors", i.e., those that are known problem sources. The ones most frequently identified were: gas/auto service industries, transportation, highway systems, land use development and agricultural sources. There needs to be the ability for facilities not contributing impairment of water to gain an exemption from permits, fees, implementation of BMPs. Categories are an ineffective way to designate covered sources - should be done by the degree of risk a given facility poses, because it may not be a whole industry, but rather individual facilities.

- o Small municipalities should be included, but they should have a much simpler application process. Or, only small municipalities where a storm water problem is identified should there be required action.

- o EPA should defer on selecting targeted sources until the agency has carefully looked at the data gathered during Phase I. Numerous sources of information are available which would help determine targeting priorities, e.g., information gathered through 305b reports, information from Phase I program sources, the NURP study.

For needed and desirable controls, these themes emerged:

- ☐ If a permitting process is to be continued for point sources, NPDES general permits should be used, and focus should be on implementing Best Management Practices (BMPs). Permits should be simpler, and much less costly. EPA should make clearer to the applicant what information is required, e.g. provide the permittee with a "checklist of inclusions" for the application, develop a menu of BMPs. Permit exemptions should be granted to those targeted sources who offer no contribution to the problem.

- ☐ Education should be seen not as an "add-on", but rather as a primary tool for effective control. Locally implemented education for public and industry is especially important; the premise is that information and conviction born of education will encourage many to take the needed preventive and remedial steps.

- ☐ More emphasis should be placed on voluntary programs, e.g., 319 nonpoint source-like programs. For facilities with contact with storm water, there should be little or no government intervention, but rather emphasis on pollution prevention incentives, BMPs, and measures of pollution prevention.

Pollution prevention programs should be emphasized, particularly with new development. Some suggested prevention methods included: recycling storm water, "good housekeeping" practices, plantings to minimize runoff, street sweeping of work areas on a daily basis, storm water collection methods, coverage of storage areas, changing manufacturing processes to minimize pollutants, and improvement of air emissions.

- Closer correlation should exist between the severity of the problem and the degree of controls required. Fines and fee structures could be used as "carrot-stick" measures.

- BMPs should be required based upon the specific pollutant problem. EPA should develop a menu of BMPs to assist businesses in determining the appropriate BMP for their problem.

In terms of a timetable for phasing in Phase II, two widespread opinions emerged:

- A minimum of two years is needed to prepare for Phase II, with at least a year dedicated to looking at data gained from Phase I of the storm water program. Effectiveness of presently used BMPs needs to be studied to determine differences in effectiveness between geographic locations and pollutants.

- Whatever the period established for phase-in, it should not begin <u>until</u> promulgation of the regulations.

A final question in the strategy template: **"For whatever strategy is chosen, what could EPA do to make the decision-making process for Phase II more responsive?"** generated responses focused on some common themes:

- Coordinate information dissemination, e.g., set up regional clearinghouses offering such program information as general permit writing, effective applications of BMPs, and examples of successful efforts from programs around the country.

- Provide funding not for program implementation but for needed research, e.g., on BMP effectiveness, and for demonstration projects.

- Set broad guidelines for the program and establish minimum standards, and then allow state and local regulatory agencies determine how to achieve them.

- Develop and implement training programs for regulators, including regional and state, on the program. These people are the ones who will be the informational source for the regulated community, and need to know the details of the program.

As with the focus groups the participants in the public meetings felt positive about the format used. A mail-back survey returned by more than 30% of meeting participants showed that they strongly favored this interactive process over what they perceived as the conventional practice of a stream of public comments that encouraged adversarial positioning and boredom for those listening. Comments of attendees included:

- "The opportunity to formulate an entire strategy to deal with this issue was very useful;"

- "I obtained a better point of view of government's problems and felt that government representatives also obtained a better point of view of industry's problems;"

- "Result was a much less confrontational and much more problem-solving atmosphere;" and

- "It was a valuable way to address drafting of regulations, allowing the regulated community to feel a part of the process."

The body of this report contains a further elaboration of the process and the ways in which it might be used by the EPA in other communication and outreach efforts.

Design Team Meeting

A meeting of seven point and non-point storm water program experts, all of whom were survey respondents, and selected EPA staff was convened in Washington DC on September 17-18, 1992. The purpose was to gain the experts' varied insights on development of the Phase II storm water program and to build a strategy, or multiple strategies, for addressing Phase II sources.

Many discussions were specific to certain types of activity--not only municipal or industrial, but to specific kinds and levels of enterprise. Others focused on regional differences--for example the strong distinctions from places that are uniformly wet, uniformly dry, or highly volatile in hydrological terms. Still others found differentiation in scale--such as the difference in impact a regulation would have on a city as compared to a small town. These distinct findings are contained in the full report which follows in this volume.

A broader set of ten recommendations emerged for the major Phase II challenge which generally transcend such differences. They include:

1. **It is possible and desirable to identify priority target areas for which there is widespread consensus concerning their contribution to water pollution.** These areas begin with new development and redevelopment--both residential and commercial. They also include transportation corridors, dense existing development and automotive services.

2. **EPA needs to communicate more clearly and regularly with everyone impacted by the storm water regulations.** The priority focus should be less on the amount of communication and more on different kinds of communication.

3. **EPA could improve program effectiveness, efficiency and cost control in Phase II by "starting small".** The concept of regional and even local prototypes is a way of getting proposed new Phase II frameworks into the hands of users in prompt fashion to build and refine based on early use.

4. **Selectivity in data collection and monitoring is essential.** At present, some data collection frameworks consume tremendous time and money only to yield bad or useless data or murky or disputed conclusions. At other times, very simple actions taken with known consequences require simple verification, not extensive measuring.

5. **More customer differentiation is also needed.** At present the mind-set appears to be that one size fits all. While giving the appearance of equity, this concept actually creates strong inequalities. The same programs and regulations that befit a large corporation or municipality are simply not equitable for smaller enterprise and communities, for example.

6. **While the ultimate goal is water quality standards, this is very difficult to achieve and/or to measure in the short term.** Therefore, while retaining water quality standards as the ultimate goal, EPA should be focusing on best management practices, and in particular those that reflect preventive and non-structural solutions.

7. **The most functional unit of both analysis and intervention is the watershed.** Most people in our samples for opinion and recommendation strongly suggested the watershed approach--not only on the macro level (e.g., Chesapeake Bay) but the micro-level as well.

8. **EPA's role is to offer technical support and direction more than program funding or even full guidelines for state and local implementation.** In particular, building useful data bases and collection methodologies not only on water quality but on practices to achieve it is critical. Such practices should include education, given that prevention and voluntary compliance are much less costly than litigation.

9. **A collaborative approach to developing effective solutions is possible.** The interactive elements of this project are one reflection of the ability of those with strikingly different perspectives (ranging from strong environmental protection to a focus on economic development) to work cooperatively.

10. **Agriculture's absence from the storm water program is notable and regrettable.** In many regions, agriculture (which includes livestock as well as crops) is a primary contributor to surface water pollution. Permitting or in other ways controlling the transport of agricultural products introduces intervention too late.

The remainder of Volume I amplifies these findings and presents the rationales and key data points which underlie them. Volume II includes the complete data base, including all instruments used to collect and analyze information.

PART I: IMPROVING PHASE I OF THE STORM WATER PROGRAM

In December, 1991, the Deputy Administrator of the U.S. Environmental Protection Agency asked the Office of Water to undertake a project that would achieve two results: first, identify ways to improve and streamline the existing storm water regulatory program currently being implemented by the agency; and second, develop options for controlling sources of storm water runoff not currently required to be permitted under Section 402(p)(2) of the Clean Water Act.

In response to this request, the Office of Wastewater Enforcement and Compliance (OWEC), working with The Rensselaerville Institute, developed a two-part project. This section addresses the outcomes from Part I, which focused on identifying improvements to the existing regulatory program.

Description

As the first part of The Rensselaerville Institute's project to help EPA assess the effectiveness and efficiency of the existing Storm Water Program, focus groups were held in diverse regions of the country to gain feedback on how the regulations promulgated on November 16, 1990 could be streamlined and improved. Six such meetings comprising representatives from state, municipal, private industrial and environmental groups were conducted between February 24 - March 2, 1992.

A total of 40 individuals participated in the focus groups, which were held in Atlanta, GA; Hartford, CT; Chicago, IL; Washington, DC; Seattle, WA; and Phoenix, AZ. The format for each meeting was the same: participants provided feedback on eleven questions developed by EPA and Institute staff. The questions:

1. Which aspects of the storm water regulations are least clear?

2. What additional steps would be helpful in assisting permittees achieve compliance in the allotted timeframe? Who should take those steps?

3. Exactly what kinds of guidance and information are needed to help people implement the program? How would you prioritize these listed storm water program activities in terms of their usefulness?

4. Is there a need for EPA to do more national workshops on the storm water regulations? What about regional or local workshops? On which subjects?

5. What support should states, as opposed to EPA or other organizations, be expected to provide to their "universe" of permittees? What resources do they need in order to provide those supports?

6. If you had to name three ways to streamline the permitting process, what would they be?

7. What could EPA do to encourage those states without general permit authority to get it? What steps are needed to get general permits out? What simple, short-term grassroots efforts can associations and trade groups take to help this effort, and how could EPA support those efforts?

8. What outreach efforts to explain to permittees what they have to do to comply with the regulations have been most effective to date? Are there informational pieces that EPA could prepare that would best help these efforts?

9. What are the techniques, methods or strategies you would recommend to help permittees achieve water quality standards? In what timeframe should permittees be required to comply with WQS?

10. Given that construction activities are most often local in nature and temporary in duration, do you have suggestions about how EPA could more effectively regulate such activities?

11. What suggestions would you offer in terms of the most efficient way to enforce EPA existing regulation requirements, both application requirements and substantive permitting requirements?

Responses to question #6 were revisited in the afternoon of each session, when participants were asked to further define their recommendations, indicate who they felt should be responsible for initiating the changes, and list the initial steps they would take.

Response summaries were drafted following each meeting and sent to participants for additions and modifications. Their changes were incorporated into their respective reports. This overall report summarizes, interprets, and analyzes group discussions and conclusions.

Focus Group Findings

Despite the many issues surrounding implementation of the regulations, the consensus of all focus groups, including industrial representatives, was that storm water control is needed and appropriate. There was general agreement that storm water is a significant contributor to water pollution. Some felt that a regulatory program was appropriate to address the problem. A number of participants expressed that, overall, the storm water program is significantly more rational and easier to deal with than other EPA water programs, for example, the wetlands program.

Yet the storm water regulations still inspire much confusion and frustration. There is frustration with EPA, as well. Many felt there was a lack of consideration given to their inputs by the agency prior to promulgation of the regulations, and some thought that EPA had been unresponsive to questions and concerns voiced since the regulations went into effect. When pressed, however, most admitted that they perceived this to be an endemic or generic problem of government. For a few, this perception will not be changed. However, most were impressed that EPA was now willing to actually look at the storm water program and solicit input from those dealing with the regulations on how they could be improved or streamlined.

Reservation was voiced, however, that EPA would do nothing with the recommendations generated from these focus groups. Their concern was that the results would have as little impact on EPA's decision-making and responsiveness as had previous efforts to make their opinions known.

It is critical, therefore, that EPA identify those procedural changes made in response to the recommendations, and make them known both to focus group participants specifically and to the permitted and regulatory communities in general.

The range of concerns voiced was large, and differed between geographic regions and the representational make-up of the group. Each group raised issues that were quite specific to themselves or their region, e.g., New York City was concerned about the effects of tidal flow and backwater as they relate to water quality; Utah and other arid and semi-arid states were concerned about sampling procedures when there was scarce rainfall; Seattle felt that the regulations did not allow its storm water program to build on earlier work; general contractors do not understand why concrete mixing requires a separate permit even though it is done on the construction site, etc. The specificity of concerns for each group is reflected in the individual summary reports, which are included in Volume II.

Some issues and concerns identified, however, spanned geographic and demographic boundaries. They were raised across groups as key areas in need of clarification and/or modification. There were seven broad areas identified where members felt efforts should be made to improve and streamline the storm water regulations.

1. **Permittees and regulatory agencies feel that the EPA has not been clear about the intended goals of the regulations. A view of the "bigger picture" is wanted.**

   While group members agree that storm water is a contributory factor to water pollution, there does not seem to be an understanding of what EPA hopes to achieve with the regulations promulgated in November 1990. A frequently heard comment was that "the big picture" is missing. Participants felt that EPA has not been clear about how these regulations will accomplish the goal of achieving clean water, and in what timeframe. This has hampered efforts to comply because many do not understand what they should be setting as performance targets.

   One participant said, "What is a clean urban stream?" The point: participants were not sure what goals they need to attain to comply with the regulations and protect themselves from being sued or fined for non-attainment. Almost all participants felt that water quality standards were useful as the ultimate goal toward which to work, but were unachievable in a two- or three-year period. When asked what they felt would be a reasonable timeframe, estimates ranged from five to thirty years, with a few participants indicating that, given the large number of pollutant sources impacting on a given water body, achievement of water quality standards through the storm water program alone is a strong improbability. One participant stated that the scientific community's perspective is, "...there is no way water quality standards can be achieved with known storm water technologies"; it will take further research and development of BMPs before water quality standards could be achieved.

It was clear that members need more guidance about where the program is headed. Participants want EPA to be more explicit about what should be achieved in terms of improvement of water quality in the timeframes that have been given and with the technologies that are presently available.

Group members were aware that environmental advocacy groups will bring pressure on EPA to hold to established numerical water quality standards, and that reducing or replacing them is not likely a viable option. As one representative from an environmental advocacy organization stated regarding water quality standards, "...(they are) the heart of the Clean Water Act." Participants felt, however, that EPA needs to explicitly acknowledge that cleaning up the waters of the U.S. is a long-term effort that requires federal, state and local governments to work in partnership with permittees rather than through "command and control" relationships. Permittees fear being sued for non-compliance when in fact they are making the best efforts possible.

Permittees and regulatory agencies want EPA to provide them the time and support they need to design and implement storm water programs that make sense in terms of effectiveness and cost. They feel that EPA, by not clearly stating goals, has hampered efforts to deal with the problem; permittees are not sure which approaches to take because they don't know what they have to achieve. They want the guidance and information necessary to implement the most appropriate measures available for their discharges, and the time to evaluate those efforts. As one group member observed, "...What is needed is a longer period (than the permit period) to do BMPs - and then monitor their effectiveness. Where necessary, go back and change things. It's an evolutionary process. This is not a quick tech fix! EPA is creating more problems than answers. October 1 should not be 1992, it should be 1995."

If EPA is to achieve success with the program, it needs to address confusion over program goals and timeframes. The agency needs to be explicit about what it expects industrial and municipal permittees to accomplish in the first permit period, what they expect them to achieve in the longer term, and what they anticipate the impact of the storm water program to be on overall water quality.

2. **The cost of program implementation is significantly higher than EPA estimates. There is great concern over what the program's real costs have been in terms of dollars and manpower.**

A great concern of focus group members was the excessive cost of preparing a permit application, and the anticipated costs of achieving compliance. A number of state representatives indicated that implementation of their state program took, in terms of staff time alone, more than all other water programs combined - without the concomitant added federal dollars that those programs provided. That EPA has provided minimum federal dollars for the program is a major issue. Municipalities and industries were concerned with the significant additional costs of manpower and technology needed for both application and compliance. One focus group participant brought for discussion a study done by the School of Public and Environmental Affairs at Indiana University. The study has identified that the actual mean cost for Part 1 of the municipal application process for 59 cities exceeded by six times the EPA-estimated costs of the program [Gebhardt & Lindsey (1992), "NPDES Requirements for Municipal Separate Storm Sewer Systems: Costs and Concerns"].

That EPA has set aside some monies to assist in program development is not commonly known information. There was confusion among a number of focus group members about the availability and applicability of grant monies, e.g. 104(b) funds, that are dedicated to implementation of the program. For example, within the same focus group, one person said that they had applied for and received the funds to help prepare their application; another member replied that they were told that the monies could not be used for that purpose. Members of some groups were unaware that the funds were available at all. This indicates that communication from EPA has been inadequate in letting eligible groups know that there are some, albeit limited, dollars available to help them in setting up their programs, and that there has been inconsistent communication about the guidelines for use of those funds. Further, every person who indicated knowledge of the money also noted that the funds available were minuscule in comparison to what was needed to actually get their programs up and running.

Some states have developed the necessary revenue-gathering mechanisms to fund their storm water program. One state representative indicated that, by charging permit fees, they have been able to hire six staff people for the program. A few other state representatives indicated that storm water utilities had been successful in helping to raise the funds necessary for program operations. A significant number, however, contend that their state does not have the funds to implement the program, nor do they have a system devised to raise these funds. Therefore, wholehearted efforts are not being made to respond to the regulations. Further, some states have implied that they do not consider storm water a priority, and therefore are not willing to devote any portion of their budget to the program. This latter point creates a significant problem for the thousands of permittees in such a state that are then without a critical support system to provide them guidance and technical assistance.

The storm water field in general is perplexed that EPA could promulgate these regulations, without at least providing "seed monies" to assist the application process and help states set up their own revenue-generating systems. To some, the message EPA sent by not providing funds is that the agency itself is not invested in the program. If EPA plans to continue to regulate storm water without providing financial assistance, one way it could assist permittees is to provide guidance and examples of successful fund raising systems that some states have devised, e.g., storm water utilities.

3. **The administration of the program is enormous. Clarification is needed on the roles and expectations EPA has for itself, states and permittees.**

Much of the controversy surrounding the regulations arises from unclear delineation of the roles, responsibilities and authority of each level. What is clear to everyone is that EPA alone does not have the capacity to administer and enforce the program. Therefore, much responsibility must fall on state and municipal levels. However, the regulations do not delineate the responsibilities of each level. Group members were clear that they want EPA to be more decisive and explicit about what is expected of states and municipalities in terms of administration and enforcement, and the areas where they will be allowed authority and flexibility in decision-making.

Some state and local governments have not waited for EPA to define their roles. The regulatory deadlines were powerful motivators for them to move forward without such guidance. Thus, frequently heard was states' hesitancy to discuss with EPA what they were doing programmatically, because they were afraid they might not be doing it "right", i.e. in accord with what EPA wants done. They were concerned about asking EPA for clarity they feared the agency might take away their assumed authority since it had not been specifically assigned in the first place. A number of state representatives admitted that they interpret the regulations in their own way rather than wait for EPA to provide interpretation. As one state representative put it, "...we looked at the regs as guidance rather than rules. We do it our own way. We are not sure if it is appropriate, (so) I have concerns asking for guidance from EPA because they may take away our latitude to make our own judgments."

The vagueness in assignment of responsibility and authority has clearly hampered program implementation. It may have been the intention of EPA to be less specific so that other entities would make their own interpretations, but they clearly do not feel comfortable assuming responsibility or authority. Many have been frustrated by the agency's lack of response when trying to gain clarity of the regulations. For example, one trade association representative stated that, in order to inform his membership about the regulations, he wanted to publish in their trade newsletter an article that outlined their members' responsibilities under them. To ensure that his interpretation was in accord with EPA's, he submitted the article to

EPA for review. In his words, "I waited a month, and when EPA did not respond, I went ahead and printed it. They [EPA] didn't like that."

Some state representatives said that they were unwilling to help industrial people make decisions on whether they are covered by the regulations, because they do not want to be held accountable when EPA has not specifically given states the authority to make interpretations of the SIC codes. Participants felt that the states are more likely than EPA to know the specifics of the industries in their boundaries, and also to know which ones are high-risk pollutant sources. But states do not feel that EPA has given them the authority to use that knowledge to make their own judgments on whether an industry is covered or not.

Industries also feel unsure about their responsibilities under the regulations, and are turning to the states for guidance. The regulations are unclear, for example, about what level of program implementation is expected in a given timeframe. As one state representative put it, "...there needs to be some guidance from EPA to the states on what (industries) need to do!"

States feel they have more knowledge of the industrial risks within their boundaries, and know what is needed to bring those risks into compliance. A number of focus group members cited the uselessness of having EPA develop requirements and guidance for any given industry when it did not understand specific industries. They felt it far more effective for EPA to work with industrial representatives when developing materials to ensure clarity and correctness. This would likely create the added benefit of gaining industry's commitment to achieving certain results.

Given the magnitude of these regulations, the lack of funding available to support implementation, the fiscal constraints under which all levels of government are operating, and the limited staff at each level, working in partnership with states and permittees rather than through a "command and control" relationship could get the program in place more quickly and maximize its effectiveness. EPA needs to determine each government level's responsibilities, be explicit about what decisions and flexibility can be allowed, and be clear about what results are expected from each level of government if given the authority to interpret certain aspects of the regulations.

4. **More supporting information for the program is needed, and dissemination of that information needs to be improved.**

Information supplementary to the regulations, explaining them and providing explicit information on how to implement them, was cited as a critical need that had only partially been met. All focus group members gave feedback on those pieces of EPA-generated information they thought was useful, what they felt was not helpful, and what other information they desired or felt was needed. They also addressed the regulations themselves as a source of information.

a. Written Documents

Written information EPA has provided to supplement the regulations, such as guidance documents and supportive materials, received overall good reviews. Numerous participants stated that both the Industrial and Municipal Permit Application Guidances were helpful.

The primary problem with much of the written guidance and information is that it is coming out too late to be useful. A number of participants indicated that a model general permit would have been helpful, but that they were at the point of writing their own, so for them it was too late. Often group members' suggestions for specific informational documents were accompanied by the caveat that it was needed now, e.g., permit writers guidance; Model Permits for MS4s; a BMP manual; Construction Activity Guidance.

Not everyone wants to receive new information at this point in the program. A number of participants said, "Don't do anything...We have a track; anything that would confuse that would be a problem. Even clarification. We have an idea for what we want to do and if guidance comes out now, it might conflict with what we want to do."

One person commented that EPA should prepare guidance documents so that they can be released concurrently with promulgation of the regulations. This would avoid not having them ready in a useful timeframe. A number of participants felt that EPA should be more willing to release information in draft form if the final document is going to be late. EPA should make preparing information for Phase II of the program a priority; the timeliness of delivery is a reflection of the program's credibility and of EPA's commitment to the program. It is clear that those who have gone forth without the support of written guidance are going to be highly resistant to any input by EPA that would require them to modify what has already been done.

Dissemination of EPA documents has been inconsistent. Regions vary in their thoroughness of distribution. One group member said, "...EPA needs to be better at getting this stuff to us. I often have somebody walk into the office with something that has been out for three months that I have not seen." This frustration was echoed in a number of the focus groups. EPA needs to publish a list of available documents which people can request either in writing or through the Hotline.

b. Verbal Communications

The Storm Water Hotline received mixed reviews from group members. The primary response was that it effectively addressed very basic questions, but that the program had advanced quickly to the point where more technical information was needed. Trust in the ability of those answering the phones to address complex issues was low. However, this is not an unusual response to Hotlines; often callers complain that information given is inadequate, inconsistent, or not appropriate to the situation of the caller.

Some focus group members stated they were pleased with the response they had gotten from the Hotline. Some indicated that they were relieved just to have someone to call for program information. Others felt it was a good way to confirm their "hunches". Overall, given the size of the program and the number of phone calls that have been received, the perception of the Hotline is relatively positive.

Some alternative roles were suggested for the Hotline. Members stated that it could be used as an information clearinghouse, having available a list of sources that callers could turn to for more technical information. One person suggested that operators have lists of experts in categories to whom they could refer callers for more information.

One frustration voiced was that reaching EPA staff people was a problem. This has created for some the perception that EPA headquarters staff are unapproachable. On the practical side, however, responding to all the phone calls they receive would tie up all available staff for the duration of the program; headquarters staff would do nothing but answer phone calls. Yet it is important to recognize that this problem influences people's perception of EPA's commitment to the program. Perhaps with EPA's attention to the more substantive items listed in this report, e.g., getting documentation out in a more timely manner and with more thorough dissemination, etc., this perception will self-correct.

c. Workshops and Presentations

All groups felt that workshops of national scope were no longer needed, because the issues being dealt with were now more technically specific to certain industries or areas. The consensus was that state and local workshops, providing industry-specific guidance and information on water pollution control, were most needed. Most felt that such workshops should be sponsored and planned by trade associations and other membership associations like APWA, WEF, ASIWPCA, etc. rather than EPA. They did feel that EPA should be a speaker at the programs, and be willing to help address the federal perspectives in response to local concerns.

A main concern of group members, from coast to coast, is reaching those industries who are covered by the regulations; many businesses covered under the regulations do not know that they must apply for a permit. Trade associations were recommended as one of the best ways to get to the harder-to-reach permittees (usually referred to as "Mom-and-Pops"), but even they are limited to those businesses who are members. Group members mentioned other avenues through which they have tried to reach these businesses, such as direct mailings to municipalities and working through Chambers of Commerce. None have been completely effective. Most members said that this was not solely EPA's responsibility, but also one of states, local governments and trade associations as well. EPA could support this effort by suggesting methods for reaching these businesses, and contacts at the national level that could be helpful, e.g., Small Business Administration.

d. The Regulations as Information

The Federal Register notice of the regulations was considered by participants to be a key source of information about the program. Numerous comments were made about its inability to convey needed information clearly and concisely. Length, layout, language and accessibility were identified as deterrents for many "laypeople" to comprehend them.

One member said the length was approximately 127 pages too long; he felt it should have been three pages, with a focus on what the regulations will do to reduce water pollution. Many felt that the regulations were not user-friendly because of the language used, which they referred to as "legalese". One person remarked, "What is needed is an English version of the regs!" The citations were claimed to be confusing, and some felt substantive requirements were "buried" in the wrong section, e.g., important permitted industrial activities were in the Definitions section, and municipal requirements were scattered throughout rather than placed in a "Municipals" section. Another noted that the three-column format was difficult to read for most not used to the Federal Register format.

Many noted that the Federal Register is a publication that may be picked up by some large businesses, but would rarely find its way into the smaller ones. Given the widespread impact of the regulations, there is valid concern that EPA views the Federal Register as a primary method to "get the word out." They felt this was not a good assumption, since circulation of the Federal Register is very limited, leaving the vast majority of those industries covered by the regulations unaware that they are affected.

There is need for a more clearly stated version of the storm water regulations. Trade associations have done a great deal to try to reduce the regulations to laymen's terms for their members. But when supplemental guidance documents, which are more reader-friendly than the regulations, are not quickly forthcoming and the regulations provide the only source of information, confusion is inevitable.

5. The regulations lack clarity on a number of key aspects. State authorities need EPA to either clarify these points of the regulations, or they need EPA to allow them the latitude to make the interpretations themselves.

During each focus group, members discussed many particular points of the regulations that they had found unclear. These varied from group to group, depending on the perspectives represented. As one would guess, points that to a municipal person lacked clarity were often different than issues of concern to an industrial representative. For example, industrial representatives spoke of confusion with deadlines as a result of the Surface Transportation Act amendments, how to pick the appropriate permit to apply for, and how industries connected to municipal sewer systems should deal with the regulations. Municipal representatives, on the other hand, mentioned specific sampling and field screening methods, the definition of Maximum Extent Practicable, what to do about application sampling requirements in the face of drought conditions, and how to classify industrial parks as issues that lacked clarity. Further, participants felt there were some aspects where there was room for interpretation. Important to them was knowing where they would have latitude to make interpretations.

Presented here are the areas commonly identified as in need of clarification by EPA.

a. Who is covered under the Industrial SIC codes:

Every group questioned EPA's use of the Standard Industrial Classification codes to determine which industries should be included under the regulations. The consensus was that these codes, which are economic indicators, are inappropriate for regulations that deal with environmental issues. Their use has caused a great deal of confusion as various industries try to apply them to their "primary" activities. Businesses don't know how to use them to determine if they are included under the regulations - and regulatory agencies are very reluctant to make that call for them given the "downside" of either decision. Group members indicated that the Transportation category (#8) and the category of Exposure (#11) were the most problematic and inconsistent.

One state representative said that trying to get businesses past this first decision point had consumed most of the manpower in their office. They were receiving 80-90 phone calls a day just on that question; they had to hire a "temp" to respond to these phone calls and refer callers either to an EPA field office or a consultant. Another group member said that they did one informational mailing to businesses in their county, and were flooded with 7,000 phone calls; they did not know how to respond to callers, so they ended up hiring a consultant to handle the questions.

One comment from a member in the Phoenix group accurately represents the feeling expressed across focus groups: "It is virtually impossible to determine who needs a permit...You are not looking at the runoff quality with the SIC codes. I do not know of an existing code that looks at runoff, and that ought to be the basis of the code (used for these regulations)."

EPA needs to clarify how these codes are to be used. As one member stated, "OMB decided to use the SIC codes for other than they were intended. EPA (therefore) must define how to use it; this needs research and an environmental interpretation done." EPA also needs to be explicit about states' liability if their interpretations of coverage are different from what EPA's would have been. One group member suggested that EPA put together a brief (1-2 page) guidance summary to help industries decide whether they are covered, and also to develop descriptive categories of industries covered. EPA needs to define the minimum criteria for coverage to help regulatory agencies and industries determine their status, and then give latitude to states to use Best Professional Judgment when making decisions to include or exclude a given industry.

b. **Exposure:**

The category of "exposure" was cited by all groups as one of the two most difficult to determine. Members requested that EPA allow regulatory agencies to use Best Professional Judgment in determining which industries should be covered. Examples were mentioned, included the artist doing metal sculptures (all his activities took place indoors), and the farmer trucking potatoes to the potato chip factory (he was advised to cover his load with a tarp). As one member stated, decisions on whether an industry falls under the exposure category need to be determined on a case-by-case basis, and may require a site visit for a final decision to be made. Members did feel this category was "good" because it is the only one that is risk-based, yet "bad" primarily because exposure is "fuzzy".

EPA needs to allow states to develop their own definition and criteria for exposure, reach agreement with them, and be comfortable with the possibility that states may be different. The enormous number of covered industries under the category would otherwise exhaust EPA's resources to deal with it.

c. **The group application process**:

Focus group members feel that the group application process has created significant confusion among permittees; there is no such thing as a group permit, yet there are large numbers of industries that participated in a group application still under the impression that they will be covered by a group permit. As a number of participants stated, "(those who applied for one) think group applications mean group permits. And that is not the case."

One industrial member voiced their frustration: "Industry feels that the group application was misrepresented. (We thought,) this looks good; we can band together, demonstrate our likeness, devise sampling techniques, and regulate accordingly. Then we heard that you don't get a group permit; you get sent to the next tier down - the state. And the state then decides what you get... This has discouraged us from being proactive, forward thinking, because the rules keep changing in mid-stream."

Some members thought the group application was a useful process. One stated, "The group application process will get the best information at the least cost. It is the best research process because you can control it. For example, the textile industry: consultants will get together with them to determine how sampling and BMPs will be done. It provides a source of comparison within industry."

EPA needs to let participating industries know what the process is about, what the next steps will be for them after application review, and where there will be extended timeframes for them to submit a NOI under a general permit or an individual permit application.

6. **EPA needs to consider consolidating programs in order to address water pollution in an efficient and cost-effective manner.**

All groups suggested that EPA look at consolidating the different water programs for greater cost-efficiency and effectiveness. Rather than looking at it by different water source, e.g., storm water, wastewater, wetlands, etc., limited federal resources could be applied on a prioritized basis by watershed. Group members felt that this approach would eliminate redundant efforts across programs, allow dollars to be spent by risk priority rather than through separate program allocation, and have a more profound effect on reducing water pollution.

The perception is that present programs are more interested in "bean counting"; that is, keeping their present funding levels at the expense of the environment. One group member said, "Avoid bean counting...Transfer the funds to where it makes sense. Some water bodies have five different funding streams. (EPA) should look at one water body, and look at point and non-point factors. See if we can pull the program together to yield an environmentally efficient program that brings all this together. This would form a prototype of pollution elimination by integration of programs." Another suggested the development of a "water pollution block grant."

In no group was there a concrete discussion on how EPA would accomplish this at a federal level, although many thought that a start would be to get people from each of the programs to "sit down together in the same room" to discuss ways of working together toward the same goals. State representatives were aware of program separation at their level, and cited the different funding streams - with some programs having far more than others - available for each one. It is clear that most would like to see a strategy in place that allows monies to be allocated based upon watershed priority. This ability to be able to shift funds between programs many felt would have eased the financial burden of getting their storm water programs up and running.

7. **EPA should continue to focus on general permits in order to get the program implemented as efficiently as possible.**

One of the most-mentioned ways of reducing regulatory burden was the use of general permits to cover as many industries as possible. Many state participants voiced frustration at EPA's slowness in getting a model general permit out, and some remarked on their slowness in reviewing state applications for general permit authority. One indicated that it had taken their state nine months for approval. Yet groups were unanimous that general permits are an excellent way to streamline the program.

Participants felt that states should **want** permit authority; as one member put it, "...they should want control over their own destiny." States that have not applied for general permit authority, such as New York, are seen by permit applicants as unhelpful. One voiced frustration that his state DEC office could not provide assistance when he needed it, because the state had chosen to "ignore" the regulations; he has looked to the regional EPA office for assistance, even though he was not sure that was the "right" route for him to go. Another state representative said that her state wants authority because "they could then issue more permits, cover more people. It's revenue-producing, and the dollars would come into (our) department."

Many participants predicted that states without general permit authority will be overwhelmed by the number of individual permits. They felt that EPA, as well as state and national trade associations, should make states aware of the consequences of not having general permit authority. One suggestion often heard was to get trade associations involved in lobbying state legislatures to put pressure on their state government. Some members recommended that EPA also put pressure on states to apply for permit authority by using a carrot-stick approach: assist them to apply, but withhold program monies from non-delegated states. Others suggested that the carrot be dollars, such as the 106 monies, used as an incentive. Participants felt that getting most industries into the program under a general permit umbrella would establish a baseline for the program so that a tiered approach could be used to identify and deal with pollutant sources.

It was evident from comments that some state representatives would like to see a model general permit. They are looking for guidance in developing their own, and models--either EPA-generated or state-generated--would obviously assist states in drafting their own. Critical to this effort is that this assistance be made available as quickly as possible.

There is a common thread across these seven issues. That thread is the need for more and clearer communication, from use of terminology and language more familiar to the "layperson", to explicit guidance on fund raising approaches to support program implementation.

In many organizations, "improved communication" is cited as a sought-after end, but it is often set forth without identification of the means by which to achieve it. With this project, EPA addressed the means by asking the "experts"--those people at the regional, state and local levels who have to ensure that the regulations are implemented--where communication has faltered and what is needed to address the problem. It will be the continued involvement of these people in working on solutions that will ensure successful achievement of the end.

PART II: DESIGNING PHASE II OF THE STORM WATER PROGRAM

The second part of The Rensselaerville Institute project was conducted during April-September 1992. It consisted of three distinct efforts: a survey of point source and nonpoint source program experts to gain their insights on the development of a strategy for Phase II of the storm water program; three public meetings to gain citizen advice on key elements that should be considered for the Phase II program; and facilitation of a "design team" effort with selected experts to generate a detailed strategy to guide EPA in planning and implementing Phase II of the storm water program.

For each effort, the focus was on three elements: **targeting** (which sources shall be included and by what categories); **control** (e.g., should permits be used or another strategy developed); and **timetable** (with what schedule and over what period of time should Phase II be implemented, particularly with regard to the October 1, 1992 deadline established in the Clean Water Act amendment).

This report profiles project activities, then summarizes the findings from each of them. The reader is referred to the supporting documentation in Volume II of this report for the database compiled during this project, including analysis and comments from the Expert Survey.

Expert Survey

Part II of the project began with survey input from a select group of 32 storm water experts from throughout the country. Five perspectives were represented: academic/research; commercial development; consultant engineering/legal; environmental advocacy; and state/local government. A Delphi-type survey approach was used to obtain initial opinion and consensus on relevant issues and options for addressing Phase II sources.

Two survey rounds were conducted with point source program experts. The instruments presented respondents with a series of potential targeting and control strategies along with timing options. Survey participants were asked to identify the strengths and weaknesses as well as steps and resources needed to implement each option and were also given the chance to suggest an alternative strategy to the ones presented.

Five nonpoint program experts received one survey designed to capture more specific information on voluntary approaches for achieving program success. They were asked to provide the same level of detail for their preferred strategy as point source experts. Please see Volume II of this report for survey transcripts and analyses.

Survey Findings

Respondents were asked to identify, from a list of 18 potential sources, which sources they felt to be the top five that "must be" regulated in Phase II. In descending order with frequency of response in parentheses, the sources identified were:

1. "Some industrial activities not covered under Phase I because of anomalies in the SIC codes." (24)

2. "Suburban areas of large metro areas outside city boundaries." (20)

3. "Some commercial activities with industrial components." (18)

4. "Large retail complexes." (15)

5. "State highway systems." (13)

The themes that characterized the designation of these sources as the top five included: 1) contribution to pollution load; 2) risk posed; 3) administrative efficiency of control; and 4) cost-effectiveness of control.

Respondents were presented with specific strategies for targeting and controlling Phase II storm water sources. They were asked to assign a level of desirability and feasibility to each. The scale used ranged from "1" (least desirable, least feasible) to "7" (most desirable, most feasible).

The three targeting strategies, and ratings and comments they received, are listed below.

Responses to Strategy I were spread across the scale; 39% of respondents felt it was "very desirable" and 36% rated it "not desirable". The same response pattern was given to feasibility: 21% rated it highly feasible while 29% rated it not feasible. That strategy was:

Strategy I: "Eliminate Phase II as a separate part of the storm water program and expand the current designation authority under Section 402 (p)(2)(e)."*

> *** 402(p)(2)(e): A discharge for which the Administrator or the State, as the case may be, determines that the storm water discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.**

Some of the comments made by experts regarding this strategy included:

- "Gives the Administrator too much authority."
- "This approach provides the greatest flexibility and provides time so that we can learn from current programs."
- "Not feasible...unfortunately, the science is often not good enough to pinpoint culprits; the database...is weak; it is difficult to single out one of many candidate polluters."
- "Allows resources to be focused strictly on problem sources from the Phase II universe."
- "Arbitrary and capricious interpretation of intent of Congress."
- "Very desirable and feasible. It makes sense to target programs to areas that contribute to water quality standard violations and are significant contributors of pollutants."

Responses to Strategy I were the most mixed. While some saw it desirable because sources covered would be more selective and limited and therefore the program would require less resources and administration to implement, others did not support it because they were unsure what criteria would be used for targeting sources, and were concerned about the types of information used in decision-making as well as the experience of those making the decisions.

Most respondents felt that <u>Strategy II</u> would be costly, complex and unwieldy, and resemble Phase I in terms of its drain on resources and manpower. Some respondents felt it would expand the number of groups opposing storm water regulations.

Strategy II: "Cover all remaining point source storm water discharges under existing Phase I requirements."

This strategy received a mean rating for desirability of <u>2.25</u> and a mean rating of feasibility of <u>2.43</u>.

Some of the comments regarding this strategy included:

- "Inadequate resources would pose a major implementation problem."
- "Ill advised and will be increasingly costly. There is no need to promulgate new regulations that we know will not be enforced."
- "Would be an administrative nightmare."
- "Too broad with respect to potential benefits."

<u>Strategy III</u> was seen by a majority of respondents to be the most equitable and rational of the three choices, as well as the most scientifically based. Concern that political pressures might sway the development of targeting criteria was expressed by some respondents. That strategy is:

Strategy III: "Apply Phase II controls selectively (e.g. on the basis of such factors as population density, pollutant loadings, or geographic targeting, or others you find to be appropriate)."

This strategy received a mean rating for desirability of <u>4.64</u> and a mean rating of feasibility of <u>3.75</u>. It was rated the most desirable and feasible of the three suggested strategies.

Some expert comments on this strategy were:

- "Best of all worlds - reasonably objective."
- "Strategy III is the most desirable of the three strategies because it maximizes efficiency, effectiveness, and the flexibility to address water pollution problems based on site-specific factors, especially risk."
- "Sound on a technical basis, but probably requires too many resources, particularly information needed to do intelligent targeting."

- "Desirable - this focuses scarce resources on likely and easily identifiable problem areas. Feasible - the factors (e.g. population density) are easily identifiable."

In the second round of surveys, respondents were asked to recommend a fourth strategy if they did not support one of the three suggested by EPA. Most frequently mentioned was a strategy that was **a combination of Strategies I and III.**

Four control strategies were presented to respondents for similar ratings of desirability and feasibility. These strategies were:

1. **"Mandatory reliance on general permits."**

2. **"Direct regulation under a national Phase II guideline, which may well require a national rulemaking by EPA."**

3. **"Requiring direct regulation of Phase II municipalities under 100,000 and requiring them to develop necessary controls for priority sources discharging into the municipal storm water system."**

4. **"Control under the nonpoint source program authorized under Section 319 of the Clean Water Act."**

Desirability ratings for the first three strategies were approximately the same: respondents felt that they were "somewhat" desirable. The fourth strategy was rated as slightly less desirable. The greatest feasibility was assigned to Strategy 1. The least feasible strategy, in the respondents' opinions, was Strategy 4.

In the second survey round, respondents were asked to describe implementation of their preferred strategy. When asked what minimum control strategies they would use, the following methods were mentioned:

- a menu or roster of BMPs from which could be selected the most appropriate approaches for the industry or watershed;

- public education;

- erosion and sediment control methods;

- "good housekeeping" and source reduction/elimination methods;

- establishment of national minimum standards;

- elimination of illicit connections;

- emphasis on pollution prevention.

Few respondents saw the implementation of Phase II to be a short-term process. Most suggested a phase-in approach over a period of five to ten years. During this time, BMPs could be tested for effectiveness and cost-benefit in terms of reducing and eliminating storm water pollutant problems, and programs could establish solid components of education, training and technical assistance.

Nonpoint Source Perspectives

Nonpoint program experts also favored Strategy III: "Apply Phase II controls selectively..." for targeting Phase II sources, with a mean rating of 4.0 on Desirability. The ratings ranged, however, from "1" (not desirable) to "6" (very desirable). Some of the comments included:

- "Is inequitable. Establishes economic hardships for those required to participate. Only strength is less administrative burden."
- "Would be easy to identify sources that fall under criteria. Could be preventive since you are not waiting for a problem to happen."
- "Excellent in theory, but would require a lot of data for prioritization, and would create confusion for some period of time."

The survey instrument used for nonpoint program experts was a modified version of the point source expert survey that included a fourth EPA-suggestedtargeting strategy for consideration. It was:

Strategy IV: "Target and address problems and significant storm water sources and pollutant loadings by using Section 319 and CZARA programs."

Respondents' mean ratings of the strategy were 3.2 for desirability and 2.8 for feasibility. Comments included:

- "These programs lack real regulatory teeth. CZARA 6217 applies only to coastal regions. They just aren't aggressive enough."
- "Section 319 is broader than NPDES and has more technical experience with BMPs. CZARA 6217 results in specification by EPA of management measures, in effect setting standards and providing impetus to explore alternatives."
- "Since only limited 319 funds are available, it would be difficult to get much done."

- "This is an important piece of a multifaceted approach, but not adequate alone."

Respondents were given the same control strategies for consideration as the point source program experts. Of the four, #3: "Requiring direct regulation of Phase II municipalities under 100,000..." was most favored, with a mean rating of 5.2 for desirability and 3.8 for feasibility. This control strategy was the only one to receive ratings higher than "5" for either desirability or feasibility.

The majority of respondents were opposed to extending the October 1, 1992 deadline. The reasons given included:

- "The longer we wait to address the problem, the more costly, less technically capable and less environmentally effective the solution will be. There are more opportunities today, especially in less populated areas, than tomorrow to solve and prevent problems."

- "Storm water-related use impairment is a serious problem. Currently, there is little being done to remediate existing problems and no assurance that problems related to new development will be prevented. It is clear that the voluntary approach is not adequate."

- "Things aren't getting better. Forum and impetus are already in place - capitalize on it."

Many of the recommendations made by point source program experts for targeting and controlling storm water sources were echoed by nonpoint survey respondents. Some of the targeting similarities include:

- selection of Strategy III: "Apply Phase II controls selectively..." as the most desirable of EPA-suggested strategies. The most mentioned reasons for preference were ease of identifying targeted sources, and the more efficient use of resources;

- target by watershed impairment/threat severity;

- conduct pilot projects first, evaluate, and then develop and implement a strategy;

- develop minimum national guidelines, and leave selection of sites and methods to state discretion;

- initiate a focused dialogue with key stakeholders (for both targeting and controls).

Some of the similarities in preferred control strategies included:

- build a BMP menu that can be used to implement and verify progress; allow selection of most appropriate BMPs based on industry and watershed;

- provide public education on need for storm water control;

- provide national criteria with flexibility for local implementation of most appropriate controls;

- develop baseline control standards for all new development.

One primary difference between point and nonpoint respondents was the application of the "stick" by EPA, with the "stick" being the requirement of permits for those sources that did not achieve significant movement toward program goals via voluntary efforts within a reasonable timeframe. As one nonpoint respondent phrased it, EPA should keep permit requirements as the "gorilla in the closet" to be used as needed when voluntary efforts were not adequate for the problem.

A number of nonpoint respondents indicated that the 319 and CZARA 6217 programs do not have the "teeth" they need to ensure compliance. Most feel that a combination of programs is needed for successful achievement of water quality goals.

EPA STORM WATER PUBLIC MEETINGS

Description of the Meeting Format:

Three public meetings were conducted to gain citizen suggestions on options for targeting and controlling Phase II sources. These meetings were held in Denver, CO; San Francisco, CA; and Washington, DC. Approximately 200 people attended the three meetings.

At each meeting, three experts selected from the survey process presented their ideas on a regulating strategy for the moratorium sources. Following their presentations, attendees were divided into small task teams with an assigned facilitator, and given the charge of devising their own strategies for targeting and controlling Phase II sources. The strategy template provided to guide group consideration of key issues is presented below. During the latter half of the meeting, each task team presented their option to the other attendees for discussion.

Teams were asked to consider these issues:

1. Targeting (What light industrial, commercial, retail, residential, or other areas or other areas do you include in Phase II?)

2. Control (Do you use continued reliance on the existing NPDES permitting process or something else such as nonpoint source programs, selected permitting based on risk, geographic targeting, etc.?)

3. Timetable (How would you phase in the major components of the strategy and over what timeframe? Do you suggest full implementation on October 1, 1992 [as stated in CWA] or do you recommend a different set of deadlines and why?)

4. Key steps to implement (Please indicate up to five critical, major steps to take in implementing your strategy and the timetable for each.)

5. How will costs of your strategy be distributed over key players and how will costs be understood and controlled?

6. What measures of performance will you use and how will you verify the environmental results? (Do you rely on numerical measures and quantitative pollution indices or other factors?)

7. Strategy Strengths (Name four key strengths of your strategy which, in your judgement, make it preferable over alternative strategies.)

8. Strategy Vulnerabilities (Name four most critical points at which your strategy is most vulnerable to failure or shortfall in implementation.)

9. For whatever strategy is chosen, what could EPA do to make the decision-making process for Phase II more responsive?

Meeting Findings:

A total of sixteen task teams presented their strategies for Phase II of the storm water program. The individual task team strategy outlines offered a diversity of approaches for designing, implementing, monitoring, and funding Phase II of the storm water program. Individual strategies presented a large range of methods for targeting and controlling sources, and many different timeframes over which the program could be phased in.

Despite the different representations, experiences and expertise, there were points of congruence between many of the proposed strategies. Common strategy characteristics across task teams included the following:

1. **Targeting:**

a. Targeting should be done by watershed. Information gathered from Phase I should help identify sensitive watersheds. May require intergovernmental agreements.

b. The focus should be on "bad actors", i.e. those that are known problem sources. The ones most frequently identified were: gas/auto service industries, transportation, highway systems, land development and agricultural sources. There needs to be the ability for facilities not contributing impairment of water to gain an exemption from permits, fees, implementation of BMPs. Categories are an ineffective way to designate covered sources. Selection should be done by the degree of risk a given facility poses rather than categorical inclusion.

c. Small municipalities should have a much simpler application process, or have the opportunity to be excluded if they do not contribute to the pollution problem. In addition to impact on a watershed, proximity to larger municipalities should be considered as well.

d. EPA should defer on selecting targeted sources until the agency has carefully looked at the data gathered during Phase I. Numerous sources of information are available which would help determine targeting priorities, e.g. information gathered through 305b reports, information from Phase I program sources, NURP.

2. **Controls:**

a. If a permitting process is to be continued for point sources, NPDES general permits should be used, and focus should be on BMPs. Permits should be simpler, and much less costly. EPA should make clearer to the applicant what information is required, e.g. checklist of inclusions, menu of BMPs. Exemptions should be available for non-contributors.

b. Education should be a primary form of control. It is important at all levels and for all audiences, yet is often overlooked or underrated.

c. There should be more emphasis on voluntary programs, e.g. the "319" nonpoint source program. For facilities with contact with storm water, there should be little or no more government intervention, but rather emphasis on pollution prevention incentives, BMPs, and practical measures of pollution prevention.

Pollution prevention programs should be emphasized, particularly with new development. Some suggested prevention methods include: recycling storm water, good housekeeping practices, plantings to minimize runoff, street sweeping of work areas on a daily basis, storm water collection methods, coverage of storage areas, changing manufacturing processes to minimize pollutants, improvement of air emissions.

d. BMPs should be required based upon the specific pollutant problem and strategies known to be effective in its mitigation or elimination. The focus must be a known connection between solution and its effect on the problem. BMPs must also recognize financial constraints, providing actions that are relatively higher in terms of cost-effectiveness.

3. **Timetable:**

a. A minimum of two years is needed to prepare for Phase II, with at least a year dedicated to looking at data gained from Phase I of the storm water program. Effectiveness of presently used BMPs needs to be looked at to determine differences in effectiveness between geographic locations and pollutants.

b. Whatever the period established for phase-in, it should not begin until promulgation of the regulations.

4. **Role of EPA Headquarters.**

a. Research, information dissemination, technical assistance.
EPA should also provide focus within these areas. Also, the current efforts are too diffuse, and imply a complexity that makes applications seem difficult and formidable.

b. Funding, not for program implementation, but for research.
Two areas of research requested are water basin pollution control and determination of effectiveness of BMPs. The majority of participants recognize that EPA does not have the fiscal resources to fund programs. What they do want from EPA is guidance in establishing fund raising mechanisms, such as storm water utilities.

c. Establishing broad guidelines for the program within which local flexibility is allowed and encouraged.
Flexibility, at the same time, does not provide an excuse for inaction or postponement. Rather, it recognizes that different actions and action sequences are appropriate to different contexts and conditions.

d. Responsibility for training regulators in the storm water program.

Until those administering the program are well equipped to enable action, effective responses will be difficult.

Please see Volume II of this report for copies of the individual strategies developed at each of the public meetings.

Reflections on Meeting Format

A presumption shared by EPA and the contractor, The Rensselaerville Institute, was that the conventional format for public hearings and meetings is of limited value in engaging citizens or of making the critical transition from criticism to advice on how best to do things. Given this belief, a different format was devised that proved quite different from the typical approach of lectures by experts and/or testimonies read to the record by concerned citizens.

In the interactive approach used, participants were advised that they would be asked to form into task teams to first listen to experts offer their insights, then to develop, as a team, a preferred strategy for responding to Phase II of the storm water program. Each team comprised a cross-section of those attending--including where there are possible strong environmental, industrial, and local government perspectives.

In all three meetings, participants accepted the format and energetically engaged in the task of constructing a preferred solution. This included the session held in Washington, D.C. where participants from major interest groups were in the habit of providing critical feedback and criticism more than engaging in a positive design process.

To gauge participant responses to the different public meeting format, a mail-back questionnaire was used inviting comments by the some two hundred participants in the three public meetings. Approximately 35% of those attending completed the survey. They were first asked to comment on their assessment of the more traditional public hearing format. Most held a clear and consistent view of the traditional approach as focusing primarily on prepared statements. Where dialogue was included, it was seen as argumentative and contentious. The general conclusions:

- opinions are solicited for the record and to insure the perception of public participation but not to provide genuine input. The sense is not of active government listening.

- primary participants are those with strong convictions and often special interests; they are not a representative sampling of public opinion and tend to run the gamut of extreme perspectives on a given issue.

- sessions tend to become adversarial or at best argumentative. No mechanism for cooperation is available and differences tend to get magnified, not resolved.

- the focus is on the problem much more than on ideas for resolving it. On the one hand this attracts critics more than implementors. On the other, it provides little guidance to people who full well know the problem and are looking for ways to deal with it.

Participants were much more positive about the format used. Among the sentiments voiced:

1. Participants had a full chance to participate--not only to be heard but to be directly engaged in finding solutions.

   "It was a valuable way to address the drafting of regulations--allowing the regulated community to feel part of the process";

   "Encouraged the regulated community to get involved and feel involved";

   "Participants felt that EPA was actually listening and dialoguing."

2. The process was genuinely two-way, allowing both EPA staff and those effected to better understand each other.

   "It made you appreciate the USEPA's tough job of satisfying the concerns of many people while protecting the environment";

   "Felt it draws out better data";

   "Actually got to interact one on one with industry and government and consultant representatives. Obtained a better point of view of government's problems and felt that government representatives also obtained a better point of view of industry's problems."

3. The format created an atmosphere for cooperation and even for collaboration among people with very different viewpoints.

   "The meeting went a long way towards promoting the creative thinking, open discussion, and presentation of ideas";

   "Group discussion is a fine vehicle to provide input as well as learning tool. It forces you to think through participation, rather than just simply sitting and trying to absorb by osmosis.";

"Small diverse groups allowed ideas to be evaluated fairly and fostered "brainstorming" and allowed ideas to be developed to better fit broad based objectives."

The positive elements of the meeting extended beyond the effective communication of opinion and position to EPA to broader understandings of issues, complexities, and solutions. Indeed, the sessions seemed as influential in creating new insights as in communicating old ones.

Respondents suggested two primary ways to improve the format for future uses. The first is the need for more detailed advance preparation--in part, needed to change the mind-set and expectations which people tend to have for a traditional public hearing or meeting. The second suggestion: minimize expert presentations, even when used in the "pump-priming" mode employed in this session. Trust the process and get right to the participants.

When asked if they would advise the EPA to use this kind of interactive task-focussed approach with other meetings designed to get public input, over 90% said "Yes." Two persons indicated that it depends on the issue and only two indicated that they preferred to remain more passive.

THE "DESIGN TEAM" MEETING

Meeting Description:

A meeting of seven point and non-point storm water program experts, all of whom were survey respondents, and selected EPA staff was convened in Washington, D.C. on September 17-18, 1992. The purpose was to gain the experts' insights on development of Phase II storm water regulations, and the intended outcome was to build a strategy, or multiple strategies, for regulating Phase II sources.

Participants included:

Mr. Gail Boyd
Woodward-Clyde Consultants, Portland, Oregon

Ms. Diane Cameron
Natural Resources Defense Council, Washington, D.C.

Mr. Dennis Dreher
Northeastern Illinois Planning Commission

Mr. Tom Mumley
San Francisco Bay Regional Water Quality Control Board

Mr. Earl Shaver
State of Delaware Department of Natural Resources and Environmental Control

Ms. Coleen Sullins
State of North Carolina Division of Environmental Management

The participants selected were deemed, by their peers nationwide and EPA, insightful and highly articulate exponents of all major viewpoints on the storm water program.

Also in attendance were these key people from U.S. EPA:

Mr. Michael Cook, Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Geoffrey Grubbs, Director
Assessment and Watershed Protection Div.
U.S. EPA, Office of Wetlands, Oceans and Watersheds

Mr. James Horne, Special Assistant to the Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Ephraim King, Chief
NPDES Program Branch, Permits Div.
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Jack Lehman, Deputy Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Session Findings:

1. Development of a ten-point outline describing a potential strategy for Phase II of the storm water program.

Consistent with the overall purpose of the meeting, participants identified ten core elements that they feel constitute a potential strategy for Phase II of the storm water program. These elements are:

A. Objective: To get certain BMPs, ordinances and education programs into place over a 10-15 year period. Progress would be measured by getting these elements into place, with direction toward water quality standards and beneficial uses over a longer period of time. EPA would work with all states to help them develop Phase II programs.

B. Priorities: EPA would set these. They would include: the sources listed by the group, using a watershed approach where feasible, focusing first on those local governments with the size and capability to get going.

C. Education/outreach/technical assistance: these are all critical components of a successful program.

E. Mandatory Interim Milestones: EPA needs to determine interim milestones state programs need to meet which would show they are on track.

F. Financial Plan: states/local governments need to develop plans for financing the program.

G. Guidance: guidance is needed on BMPs and local ordinances. These would be generated at the federal level, and states could adapt/modify as needed.

H. "Default" system: local governments would take the lead with their programs, but there would be a built-in default system where the states or EPA would take over with more stringent controls if the locals fail to meet requirements.

I. Permit issuance: for high priority categories, could issue permits that allow flexibility or some alternative mechanism at state's option. Permits might be just for high priority categories; would include site design performance standards.

J. Phasing: there would be a schedule for issuing permits to key municipalities: high priority to low (e.g. coordinate by watershed); high flexibility to "getting tough" with recalcitrant localities. These would be based on inspections, on-site reviews.

K. Monitoring: this would be the difficult part of the program because of cost. Need is to be able to design something useful. The system might be "tiered" - highest to lowest priority; or "strategic" - focused only on gathering what we really need to know.

2. Sources to be targeted in Phase II.

The participants identified a number of specific unregulated pollutant sources that need to be targeted in Phase II of the storm water program. An approach recommended by some of the participants for controlling these sources is a "whole basin approach", which would focus attention and resources on activities impacting the water quality of a given watershed.

The group identified approximately 40 pollutant sources that they believe need to be included in Phase II of the storm water program. The sources identified include the following:

New Development/Redevelopment (commercial and residential)
Transportation Corridors
Dense Existing Development (commercial and residential)
Automotive Services
Federal facilities/military facilities
Feedlots (including dairy)
Failing septic systems
All incorporated places with less than 100,000
Non-urbanized watersheds yet to be determined
Parts of watersheds where land use is in a state of flux
Dry cleaning shops
Parking lots
Some forest operations
Nurseries/orchards
Recreational areas (e.g., stadiums, golf courses)
Landfills
Office parks
Grain elevators
Concrete cutting sites
Commercial pesticides
Landscaping industry
Car washes
Mobile washing units
Equipment maintenance
Boat yards
Tank farms
Shopping malls
Restaurants
Airports
Janitorial services
On-site solid waste (collection, hauling, transfer stations)
Atmospheric deposition
Cemeteries
Commercial strips
Wood stoves
Marine ports
Animal waste
Warehouses/storage facilities
Exterior building maintenance
Bridge maintenance

Members of the group suggested that rather than use the Phase I approach of including sources by category into the regulations, regulatory staff time and resources should be allocated on a water basin approach, i.e., target a watershed, identify impacting activities and their location within the watershed, and determine a set of criteria to deal with the problems impairing the watershed. This would allow limited resources to have maximum impact.

3. Source priorities.

After listing the range of sources that they felt should be included in the Phase II program, participants voted for what they considered to be the top priority sources, i.e. those sources that EPA should address immediately and diligently. The top sources selected are listed below, in order of decreasing number of votes received. All sources were selected by at least 50% of the participants. The sources identified as top priority for addressing in this order:

A. New Development/Redevelopment (commercial and residential)

B. Transportation Corridors

C. Dense Existing Development (commercial and residential)

D. Automotive Services

E. Federal facilities/military facilities

F. Feedlots (including dairy)

G. Failing septic systems

4. Lessons from a case study.

One participant presented an outline of the basic components of the Puget Sound Water Quality Management program. The program is a multifaceted approach toward the achievement of improved water quality which heavily emphasizes voluntary measures in its implementation strategy.

The program includes minimum BMP standards for all jurisdictions with additional water quality treatment BMPs, guidance and requirements for higher risk storm water dischargers. Key facets include: vigorous technical assistance, education, state financial support, education and support for storm water utility development, highway runoff regulations, a full nonpoint watershed management program, storm water operation and maintenance requirements, source controls, and local control and flexibility.

The program is being phased in over several years. It is a combination of mandatory requirements, technical guidance and voluntary compliance. There are specialized focus areas, such as shellfish protection districts and conservation districts. There is a coordination effort with individual and general permittees in the Puget Sound area.

The program views its strengths to be greater local flexibility and acceptance of requirements, a strong sense of teamwork between all levels, better water quality results, and better targeting and use of limited resources than if they were regulated by NPDES. They view the NPDES program as the "gorilla in the closet" that can be brought to bear if and when a source does not meet minimum standards and requirements.

5. Principles for Phase II.

Participants discussed the basic principles they believed should drive the Phase II program at the national level. For the program to be successful, it would require that the following pieces be put into place:

A. Require that people gather documentation of information regarding dischargers' activities and accomplishments and provide outsiders with that documentation;

B. Formally define gaps where additional information and understanding is needed. There needs to be an incentive to close these gaps;

C. Support (with encouragement and incentives) efforts that will close these gaps, and advance the state of the art and/or provide a technically sound basis for the programs' requirements;

D. Actively encourage a broad spectrum of understanding and involvement (the general public, community leaders, service groups, environmental groups) via educational programs and materials;

E. Strategically identify "good" guys and "bad" guys in the regulated community;

F. Provide clear guidance regarding programmatic and physical actions that are required/expected. Actively seek out evidence that people know <u>what</u> to do, and provide technical training to be sure that people know <u>how to do</u> what is required (technical transfer);

G. Require relevant/credible/useful monitoring only. Don't waste people's time/money/energy running data collection programs that yield bad or irrelevant data.

6. State suggestions of what EPA needs to consider in developing the Phase II program.

A sub-group of participants from state regulatory agencies met, and set forth a list of suggestions for EPA to consider in developing Phase II. The following recommendations were made:

A. EPA needs to provide states with the minimum program requirements they must achieve, and then allow states flexibility on how they will do it. The components must include:

- requirements/BMP standards for new development
- education/technical assistance
- control requirements for illicit connections/dumping
- developing state-specific priorities

B. EPA should require states to adopt regulations that specify program components that must be included;

C. To assure program funding, EPA needs to require that state and local governments set up funding mechanisms, e.g. storm water utilities, permit fees, etc.;

D. EPA needs to compile and disseminate technical information that would support programs, e.g. set up a national or regional clearinghouse of information on storm water plans being implemented, BMP-specific information and materials, etc.;

E. EPA needs to compile a national BMP manual that would assist members of the regulated community in determining and implementing appropriate BMPs to address their storm water problems. EPA needs to recognize, however, that BMP application will differ between regions, e.g. climatic differences will require different approaches;

F. EPA needs to require that states develop and implement education, technical assistance, and training programs; EPA also needs to hold the states responsible for effectiveness of these programs, and require permitting in the event that these measures do not work;

G. EPA needs to maintain the right to require permits in a reasonable amount of time (e.g. 2-3 years) if a state's program is not meeting federally determined requirements;

H. EPA needs to determine what short and long term goals they wish the storm water program to achieve.

7. Identification of problem areas and needs of the regulated community in dealing with the storm water program.

Participants were asked to identify what their "hot buttons" were, i.e. elements or considerations that EPA might include in the Phase II program which would cause major problems for them, or those which if not considered by EPA would create needs for the regulated community.

The list of "hot buttons" include the following:

A. Penalizing those who have already solved their problems by requiring permits.

B. Liability for water quality standards, sediment standards, and resource damage clean-up in the first round.

C. Failure to provide technical transfer - permittees need to know what to do and how to do it.

D. Failure to promulgate revised and simplified NPDES regulations that get around the complicated approval process.

E. Possible backlash from local governments if they are held responsible for instances of independent commercial activity that they cannot address or control when they don't know about it.

F. Lack of research on BMP effectiveness from a watershed perspective. There is inadequate federal/state money to look at BMPs because monitoring is so expensive.

G. Possibility of EPA not basing the program on permits (except in cases where the state can show that it can reach goals alternatively).

H. The inherent substantial risk of tremendous backlash that would affect people's livelihoods, i.e. failure to try to sell the program to regulators and public, including the NPDES permit process.

I. Prevention v. wetlands - determining how to prevent storm water problems while protecting wetlands.

J. Not addressing the roadblocks created by the regulations themselves. The system is so complicated, it now takes two generations for permits to get to goals.

K. Lack of federal monetary assistance. Some states may be reluctant to develop adequate programs without it.

L. Not getting rid of the acronyms in the regulatory language. No one understands what EPA is saying.

M. Concern that mainstream design is end-of-pipe treatment. This is not prevention! CZARA is on a better track.

N. Allowing states to cut monitoring activities first. They need to be encouraged to not eliminate that element disproportionately from their budget.

O. Need to figure out how to sell the program - to get through to OMB and top levels of state governments exactly what it is going to take to get the program into place.

P. Not identifying funding incentives and disincentives.

Q. Not giving praise for progress.

Additional Advice

Additional suggestions for development of the Phase II program were generated by the group during the two-day meeting. Included in those recommendations are the following:

1. **EPA needs to revisit and revise the terminology used in the regulations.**

    - the problems are often with the common words, e.g. runoff, storm water, nonpoint source, point source. EPA staff have attached certain meanings to words that are not conveyed to the regulated community, so there is inherent danger that people are not talking about the same thing. Words need to have clear and referenced meanings.

    - the enormous number of acronyms used by EPA creates significant comprehension problems for regulatees. The regulations need to be written with fewer acronyms, and all communications need to be sensitive to the level of use.

2. **EPA needs to clearly define the goals of the program.**

- all levels of feedback (focus group, survey, and meeting results) generated during The Rensselaerville Institute project have pointed out that the regulated community does not understand what EPA is trying to achieve with the storm water program. Assumption of what the goal is ranges from achievement of set water quality numerical limits to returning a water body to its original uses.

Confusion over the goals causes confusion for regulatees in terms of selecting the tools that need to be used to reach them. EPA needs to determine what the federal purpose is with regard to the storm water regulations given the reality of limitations of presently available methods and resources for preventing and treating storm water pollution.

3. **Citizen involvement can play an important role in achieving program goals. EPA, states and local governments need to promote citizen education and enforcement authority.**

Participants gave numerous examples of how citizens could play an active role in implementing and monitoring pollution reduction efforts. Given the limited resources of federal, state and local governments, voluntary citizen involvement can support successful program outcomes, including enforcement. Education of citizens at different levels, e.g. qualitative vs. quantitative monitoring, stream health vs. compliance monitoring, etc. would be needed. Guidance manuals can be developed to guide public education.

General Recommendations

The ten summary recommendations stated at the conclusion of the Executive Summary are here amplified to reflect the discussions and insights generated in this project. While not all persons involved agree with each observation and recommendation, these are advanced as having widespread support.

1. **It is possible and desirable to identify priority target areas for which there is widespread consensus concerning their contribution to water pollution.**

   These areas begin with new development and redevelopment--both residential and commercial. They also include transportation corridors, dense existing development and automotive services. Further, the priority of these target sources is relative to the watershed upon which they are impacting.

   Strategically, approaches that focus on a small number of priorities based on relative risk will show stronger results than one that initially targets a broad set of sources in Phase II. Also, it much more cost-effective to identify and pursue the "bad actors" (eg, those contributing toxicity as opposed to sediments or turbidity) as a priority, then get to those adding incremental pollution through routine activity.

2. **EPA needs to communicate more clearly and regularly with everyone impacted by the storm water regulations.**

The priority focus should be less on the amount of communication and more on different kinds of communication. Specifically, communications should be:

- more interactive--the examples of the focus groups and public meetings used in this project are often cited as productive formats for future citizen input;

- more localized to contexts--as in more regional workshops and fewer national ones. This means communications less inclined to reflect the national complexity of the program and more inclined toward addressing the specific information and guidance needs of the local person involved in a specific and delimited way. It also means less "canned" content and more consultative dialogue;

- less laden with acronyms and technical language that confuse and irritate many of the people who are the true "customers" of the program, and who are required to carry out the federal mandate. Along with this, more attention should be paid to finding and marketing simplicities rather than complexities.

3. **EPA could improve program effectiveness, efficiency and cost control in Phase II by "starting small".**

The concept of regional and even local prototypes was advanced by many people as a way of getting proposed new Phase II frameworks into the hands of users in prompt fashion to build and refine based on early use. This was generally seen as preferable to the comprehensive approach in which new programs are developed fully and then introduced comprehensively at a point when modification is difficult and expensive.

Related to prototypes is the case study--in which an analytical eye is turned to current programs that demonstrate one or more strategies or best practices for storm water implementation. An example is the Puget Sound model, with its focus on the tangible and cost-saving values of voluntary compliance by small businesses (a summary of this approach is contained in Volume 2).

The use of a small scale plays to the strength of regional differences as well as the reality that an equal stress on comprehensive large programs may so paralyze states and localities that nothing is done expeditiously.

4. **Selectivity in data collection and monitoring is essential.**

At present, some data collection frameworks consume tremendous time and money only to yield bad or useless data or murky or disputed conclusions. More attention should be paid as to what constitutes "good science" and activities that may show the appearance of effective activity but in reality be consuming scarce resources to no clear gain. This also relates to the adage, "what you measure is what you will get." While the tendency is to see monitoring and assessment as questions of methodology, they must first be viewed as questions of substance. What are we trying to measure and at what level of detail and accuracy?

Not all measuring and assessment need be arcane. In development projects, for example, the use of hay bales is known to contain overflows. No great study of cause or effect is needed. And if there is floating oil on a body of water, we can start by verifying that it is there--a useful step even if we do not "measure" its amount. At the same time, other kinds of assessment are meaningless without extensive (and expensive) levels of detail and analysis.

A related point is that documentation of discharger activity and accomplishment is as critical as scientific study of water conditions.

5. **More customer differentiation is also needed.**

At present the mind-set appears to be that one size fits all. While giving the appearance of equity, this concept actually creates strong inequalities. The same programs and regulations that befit a large corporation or municipality are simply not equitable for smaller enterprise and communities, for example. More broadly, some specific operations within a given source category contribute significant pollution; others contribute none. Some way to either make the initial process much less costly or to more quickly separate out those who do not need continuing attention must be found.

One form of general differentiation is between those who are causing a problem by clearly inappropriate activity (the "bad actors") and those contributing to storm water pollution by standard and at times inadvertent practice.

6. **While the ultimate goal is water quality standards, this is very difficult to achieve and/or to measure in the short term.**

While retaining water quality standards as the ultimate goal, EPA should be focusing on best management practices, and in particular those that reflect preventive and non-structural solutions. An example is stronger standards and technologies for storm water control in new residential and commercial construction. In many instances, the correlation is clear between the management practice and the consequences for cleaner water.

The codification and communication of best management practices applies not only to those targeted and controlled but to state and local actors implementing storm water programs. For example, a set of "carrots and sticks" known to promote voluntary compliance is just as critical to disseminate as a new approach to storm retention ponds in a sub-division.

While BMPs are set in place, interim milestones for water quality are also critical--and feasible--as a way of measuring progress. The transition from progress by practice to achievement by water quality measure must begin now.

7. **The most functional unit of both analysis and intervention is the watershed.** Most people in our samples for opinion and recommendation strongly suggested the watershed approach--not only on the macro level (e.g., Chesapeake Bay) but the micro-level as well. In particular, this means looking at stream quality issues beginning at the headwaters for early contributions and alterations. Most felt that functional differentiation of pollutant sources is not really meaningful in terms of either regulation or effective change at the watershed level.

8. **EPA's role is to offer technical support and direction more than program funding or even full guidelines for state and local implementation.** In particular, building useful data bases and collection methodologies not only on water quality but on practices to achieve it is critical. Also key are training and support programs and development of effective dissemination networks. In all EPA roles, the need is to recognize both regional differences and the need for a multi-faceted set of strategies, tools, approaches, solutions.

   Another EPA function is to focus on the connection between best management practices and long term consequences for water quality. While those who introduce them are in the best position to refine BMP's, they often do not have the tools to verify a correlation (let alone a causal connection) to water quality. This is an important EPA function.

9. **A collaborative approach to developing effective solutions is possible.** The interactive elements of this project are one reflection of the ability of those with strikingly different perspectives (ranging from strong environmental protection to a focus on economic development) to work cooperatively. If adversarial and polemical dynamics can be set aside, the gains are far greater.

   Collaboration must begin within EPA itself, where there is a tendency for those focussing on permits and "harder" tools of compliance and those focussing on education and "softer" elements of prevention to not fully connect with each other. In reality, there is a strong common theme from the need to see the storm water program as a way of enabling local communities and industries to change their behaviors to help the environment in ways that will directly benefit them as well as all other citizens.

1[illegible]. **Agriculture activities should be included more directly in the storm water program.**

In many regions, agriculture (which includes livestock as well as crops) is a primary contributor to surface water pollution. While the present NPDES program requires permitting of the <u>transport</u> of agricultural products, this brings intervention too late. The critical first steps of agricultural activities, e.g. soil preparation, growing, and harvesting, must be included.

Beyond this reality is the signal sent that for whatever set of reasons, some interests are exempt from a program in which they clearly belong.

Guidance Manual For The Preparation Of Part 2 Of The NPDES Permit Applications For Discharges From Municipal Separate Storm Sewer Systems

PB93-229821

STATE OF CALIFORNIA
CALIFORNIA REGIONAL WATER QUALITY CONTROL BOAR
LOS ANGELES REGION
320 WEST 4th ST., SUITE 200
LOS ANGELES, CALIFORNIA 90013

FOREWORD

This manual provides detailed guidance on the development of Part 2 permit applications for municipal separate storm sewer systems. It provides technical assistance and support for all municipal separate storm sewer systems subject to regulatory requirements under the National Pollutant Discharge Elimination System (NPDES) program for storm water point source discharges. This manual also emphasizes the application of pollution prevention measures and implementation of Best Management Practices (BMPs) to reduce pollutant loadings and improve water quality.

The control of pollution from urban and industrial storm water discharges is critical in maintaining and improving the quality of the Nation's waters. Pollutants in storm water discharges from many sources are largely uncontrolled. The *National Water Quality Inventory, 1990 Report to Congress*, provides a general assessment of water quality based on biennial reports submitted by the States under Section 305(b) of the Clean Water Act (CWA). The report indicates that roughly one third of the impairment in assessed waters is due to storm water runoff.

This document was issued in support of Environmental Protection Agency (EPA) regulations and policy initiatives involving the development and implementation of a national storm water program. This document is Agency guidance only. It does not establish or affect legal rights or obligations. Agency decisions in any particular case will be made applying the laws and regulations on the basis of specific facts when permits are issued or regulations promulgated.

This document will be revised and expanded periodically to reflect additional guidance. Comments from users are welcomed. Send comments to U.S. EPA, Office of Wastewater Enforcement and Compliance, 401 M Street, SW, Mail Code EN-336, Washington, D.C. 20460.

CHAPTER 1
INTRODUCTION

1.0 INTRODUCTION

1.1 OVERVIEW

Control of pollution from urban and industrial storm water discharges is an important factor in maintaining and improving the quality of the Nation's waters. To help improve the quality of storm water discharges, Congress passed the Water Quality Act (WQA) in 1987. The WQA added to the Clean Water Act (CWA) a provision [Section 402(p)] that directed the U.S. Environmental Protection Agency (EPA) to establish final regulations governing storm water discharges under the National Pollutant Discharge Elimination System (NPDES) program.

In response, EPA published regulations in the November 16, 1990, Federal Register (55 FR 47990) that established NPDES permit application requirements for storm water point source discharges. As part of these regulations, municipal separate storm sewer systems (MS4s) that serve populations greater than 250,000 ("large MS4s"), MS4s that serve populations between 100,000 and 250,000 ("medium MS4s"), and other MS4s identified by the permitting authority must be covered by NPDES permits. The regulations establish a two-part application process for these MS4s. In April 1991, EPA issued guidance on the preparation of Part 1 of the NPDES permit application for discharges from MS4s (EPA, 1991b). The present manual provides guidance on the preparation of Part 2 applications. The information in this manual should help municipalities focus their efforts on activities that meet the application requirements.

1.2 SUMMARY OF THE CLEAN WATER ACT REQUIREMENTS

Section 402 of the CWA prohibits the discharge of any pollutant to waters of the United States from a point source, unless that discharge is authorized by a NPDES permit. Efforts to improve water quality under the NPDES program have traditionally focused on reducing pollutants in discharges of industrial process wastewater and municipal sewage. As pollution control measures have been implemented for these discharges, it has become evident that diffuse sources of water pollution (those occurring over a wide area) are also major contributors to water quality degradation. Recent studies, including the Nationwide Urban Runoff Program (NURP) study (EPA, 1983), have shown that storm water runoff from urban and industrial areas typically contains the same general types of pollutants that are often found in wastewater in industrial discharges. Pollutants commonly found in storm water runoff include heavy metals, pesticides, herbicides, and synthetic organic compounds such as fuels, waste oils, solvents, lubricants, and grease. These compounds can have damaging effect on both human health and aquatic ecosystems. In addition to pollutants, the high volumes of storm water discharged from MS4s in areas of rapid urbanization have had significant impacts on aquatic ecosystems due to physical modifications such as bank erosion and widening of channels.

The statutory provisions governing discharges from MS4s are contained in CWA Section 402(p)(3)(B). In general, Congress provided that permits for discharges from MS4s:

- May be issued on either a system- or jurisdiction-wide basis;
- Shall effectively prohibit non-storm water discharges into the MS4; and
- Shall require controls to reduce the discharge of pollutants to the maximum extent practicable (MEP).

Under the storm water program, the initial round of NPDES permits will emphasize the use of Best Management Practices (BMPs) to reduce pollutant loadings from MS4s. These BMPs include pollution prevention measures, management practices, control techniques, and design and engineering practices. As with any discharger subject to the NPDES program, MS4s must meet technology-based requirements [in this case, the "maximum extent practicable" standard of Section 402(p)] as well as applicable water quality standards.

1.3 THE PERMIT APPLICATION PROCESS

The goal of the NPDES program for municipal storm water is the reduction and elimination of pollutants in storm water discharges from large and medium MS4s. The permit application process in 40 CFR 122.26(d) is designed to meet this goal by developing site-specific NPDES permits containing storm water management programs for individual MS4s. Site-specific permitting is crucial given the differing nature of discharges from MS4s in different parts of the country and the varying impacts of these discharges on receiving waters. To facilitate this process, the regulations specify a two-part permit application.

Part 1 of the permit application initiates the process through which municipalities began to identify sources of pollutants to the municipal storm sewer system. Part 1 also requires municipalities to propose strategies to characterize storm water discharges from their municipal separate storm sewer systems. *Guidance for the Preparation of Part 1 of The NPDES Permit Applications for Discharges From Municipal Separate Storm Sewer Systems* was issued in April 1991, and is available through EPA's Storm Water Hotline [(703) 821-4823].

The present manual describes how to meet the Part 2 permit application requirements for storm water discharges from large and medium MS4s. Part 2 of the permit application builds upon the foundation established in Part 1 and provides for the development of comprehensive storm water management programs. Part 2 requires particular information that MS4s must have developed to have an effective storm water control plan. However, each applicant is given flexibility on how to present and organize this information in a way which best suits the MS4's needs and is most consistent with its overall storm water management strategy. This guidance presents examples which illustrate some alternative ways to present information that will fulfill the Part 2 permit application requirements.

1.4 WHO MUST SUBMIT A PART 2 APPLICATION

Municipalities, incorporated places, and counties with unincorporated urban areas that own or operate a large or medium MS4 that discharges to waters of the United States are required to obtain a NPDES storm water permit. In addition, small MS4s (less than 100,000) that are owned or operated by a municipality other than those identified in the NPDES regulation can be designated by the permitting authority as part of the large or medium municipal separate storm sewer system due to the interrelationship between the discharges of the designated storm sewer and the discharges from municipal separate storm sewers.

Under EPA's definition of MS4, "large" MS4s serve populations greater than 250,000, and "medium" MS4s serve populations of at least 100,000, but less than 250,000. Population is determined by the most recent Decennial Census by the Bureau of the Census. A list of large and medium municipalities identified in the November 16, 1990, rule is contained in Exhibit 1-1, in which population was based on the 1980 Census. **After the publication of the November 16, 1990, rule, the Bureau of the Census released data for 1990, and, as a result, some additional municipalities may be required to submit applications, while others may fall below 100,000. These changes are not reflected in Exhibit 1-1.**

Source: 55 FR 48073, November 16, 1990.

The definition of MS4 excludes those conveyances that are designed to discharge storm water runoff combined with municipal sanitary sewers ("combined sewer systems"). Therefore, municipalities that own or operate combined sewer systems may petition to have their population, based on Bureau of the Census figures, reduced by the number of people served by the combined sewer system. If the total population served by the separate storm sewer system alone is less than 100,000, the municipality may be eligible for an exemption from NPDES storm water permit requirements. Municipalities should contact their permitting authority for additional information. **Exhibit 1-1 does not reflect any modifications in the application requirements for cities with combined sewer systems.**

1.5 SUBMITTING THE PART 2 APPLICATION

Completed Part 2 applications should be submitted to the appropriate permitting authority listed in Exhibit 1-2. For municipalities in States with authorized NPDES programs, the permitting authority is the State office listed in Exhibit 1-2. Because some of these States may have application requirements in addition to EPA's, municipalities in States with authorized NPDES programs should contact their States for guidance. For municipalities in States without approved NPDES programs, the permitting authority is the EPA Regional Office listed in Exhibit 1-2.

Municipalities with populations greater than 250,000 (large MS4s) were to submit their Part 2 applications by November 16, 1992. Municipalities with populations greater than 100,000, but less than 250,000 (medium MS4s), must submit Part 2 applications by May 17, 1993. Inquiries regarding Part 2 applications or the permitting process should be directed to the appropriate permitting authority.

1.6 USE OF INFORMATION IN PART 1 AND PART 2 APPLICATIONS

The information submitted in the Part 1 and Part 2 permit applications provides applicants with a starting point for developing comprehensive storm water management programs. For example, the field screening data submitted with the Part 1 application provides a basis for a program to control illicit discharges. Also, the application information may assist in prioritizing controls and in long-term tracking of program effectiveness.

Permitting authorities will use the information from each municipality's Part 1 and 2 applications as the basis for establishing conditions in that municipality's NPDES storm water permit. For example, if a municipality submits a satisfactory application, all or part of its proposed storm water management program is likely to become an integral part of its permit.

1.7 ORGANIZATION OF THIS MANUAL

Chapter 1, *Introduction*, provides a brief overview of the Part 2 permit application process. It discusses who must submit a Part 2 application and how the information in the applications will be used. It also contains a summary of the statutory and regulatory basis for the NPDES storm water program.

Chapter 2, *The Part 2 Application*, describes the statutory and regulatory requirements of municipal NPDES storm water permit applications in more detail. Chapter 2 outlines the specific requirements of the Part 1 and Part 2 applications, explains how Part 2 builds on the Part 1 application, and describes the interconnection among the various components of the Part 2 application.

Chapter 3, *Adequate Legal Authority*, describes how municipalities must demonstrate that they have adequate legal authority to carry out the program requirements [§122.26(d)(2)(i)].

Chapter 4, *Source Identification*, provides guidance on identifying major outfalls and inventorying dischargers to the MS4 [§122.26(d)(2)(ii)].

Chapter 5, *Discharge Characterization*, provides guidance for submitting quantitative data on the MS4 and developing a proposed monitoring program [§122.26(d)(2)(iii)].

Chapter 6, *Proposed Management Program*, describes the steps municipalities must take when they develop site-specific storm water management programs [§122.26(d)(2)(iv)]. These plans are the heart of the municipal permit application, and the permitting authority will probably incorporate all or part of the municipality's proposed management program into their NPDES storm water permit. In their proposed management programs, municipalities must describe management practices, control techniques and systems, design and engineering methods, and other provisions that are aimed at reducing the discharge of pollutants to the "maximum extent practicable."

Chapter 7, *Assessment of Controls*, explains how a municipality can assess the effectiveness of its storm water management program and target priorities through the use of direct and indirect measures [§122.26(d)(2)(v)].

Chapter 8, *Fiscal Analysis*, provides guidance on estimating necessary capital and operation and maintenance expenditures, and financing these expenditures [§122.26(d)(2)(vi)].

1.8 OTHER GUIDANCE AVAILABLE

Municipalities should use this guidance document together with the Part 1 guidance (EPA, 1991b). Exhibit 1-3 lists other sources of guidance available from EPA's Storm Water Hotline [(703) 821-4823]. In addition, applicants may wish to obtain further information from the documents identified in the bibliography at the end of this guidance (Appendix A).

CHAPTER 2
THE PART 2 APPLICATION

2.0 THE PART 2 APPLICATION

2.1 BACKGROUND

The NPDES permit application requirements for MS4s [40 CFR 122.26(d)] establish a two-part application designed to meet the goal of developing comprehensive site-specific storm water quality management programs for MS4s.

The purpose of the two-part application process is to develop information, in a reasonable time frame, that will build successful storm water management programs and allow permitting authorities to make informed decisions about permit conditions. The application process is designed to focus the efforts of municipalities in two areas: prohibiting non-storm water discharges into storm sewers, and implementing controls that reduce the discharge of pollutants from MS4s to the maximum extent practicable.

Part 1 of the application requires information on existing programs and legal authority. In addition, Part 1 requires the results from field screening of major outfalls to detect illicit connections. The **Part 2** application requirements are intended to build upon the information submitted with the Part 1 application. Each part has virtually the same major areas of concern, but the Part 2 application requires a greater level of detail. Part 2 of the permit application requires a demonstration of adequate legal authority, additional information on pollutant sources and outfalls, a limited amount of representative quantitative sampling data, a proposed monitoring program, a proposed storm water management program, an estimate of the effectiveness of storm water controls, and a fiscal analysis. The requirements for the Part 1 and Part 2 applications are summarized briefly in Exhibit 2-1, and described in more detail in Section 2.2. The storm water regulations underlying this guidance can be found in Appendix B.

Before applicants proceed with the detailed development of their permit applications, they should recognize the fundamental requirements:

- Who or what are the primary contributors of pollutants in storm water discharges from MS4s?
- Where are these sources of pollutants located in relation to receiving water resources?
- What is the magnitude of these pollutant sources and their potential impact on receiving waters?
- How does the municipality plan to reduce or eliminate the contribution of pollutants in storm water discharges or prevent the damaging influences of these discharges?
- Why did the municipality select the activities or best management practices (BMPs) it proposes?
- When will the municipality implement its proposed program?
- How will the applicant assess the effectiveness of the program? What criteria or measures will apply?
- How will the municipality fund proposed program activities?

Wherever appropriate, the applicant must also show that it has adequate legal authority to implement, enforce, or mandate compliance with applicable ordinances, statutes, contracts, or other similar vehicles as required by the storm water regulation.

Exhibit 2-1: Part 1 and Part 2 Storm Water Application Requirements.

Adequate Legal Authority

Part 1

- Identify existing ordinances that control storm water discharges to the MS4.
- Determine gaps in legal authority and develop schedule.

Part 2

- **Demonstrate that legal authority has been obtained to control industrial discharges, illicit discharges, dumping, and the contribution of pollutants from coapplicants.**
- **Show that legal authorities are enforceable.**

Source Identification

Part 1

- Describe historical use of legal controls.
- Identify major outfalls and industrial contributors to the MS4.
- Provide topographic map.

Part 2

- **Identify additional major outfalls.**
- **Identify additional industries.**
- **Organize industrial inventory by watershed.**

Charactization Data

Part 1

- Provide rain and snowfall data. List receiving water bodies, and describe water quality impacts.
- Provide results of field screening analysis, and propose representative outfalls for sampling.

Part 2

- **Provide results of sampling.**
- **Estimate annual and seasonal pollutant loadings and event mean concentrations.**
- **Propose monitoring program.**

Proposed Management Program

Part 1

- Identify existing storm water management activities.

Part 2

- **Identify commercial and residential, construction, and industrial activities to be addressed in the storm water program.**
- **Develop appropriate control measures for commercial and residential, construction, and industrial activities.**
- **Design a program to prohibit illicit discharges.**

Assessment of Controls

Part 2

- **Estimate expected reduction in pollutant loadings.**
- **Describe any known impacts of storm water controls on ground water.**

Fiscal Analysis

Part 1

- Describe budget for existing storm water programs and resources available to complete Part 2.

Part 2

- **Estimate capital and operating costs necessary for the storm water management program.**
- **List available sources of funding and legal restrictions on these sources.**

These questions (described above) that an applicant must address follow a natural progression or development. For example, before applicants can identify how they will reduce the contribution of pollutants in storm water discharges (the fourth bullet point above), they must identify pollutant sources and estimate the magnitude of pollutant loads (bullet points 1-3 above).

2.2 PART 1 APPLICATIONS

Sections 2.2.1 and 2.2.2 provide overviews of the regulatory requirements of §122.26(d). Section 2.2.3 describes the relationship among the various application provisions.

2.2.1 Overview of the Part 1 Application

Part 1 applications consist of the following six elements:

- **General information.** The applicant's name, address, telephone number of contact person, ownership status and status as a State or local government entity.

- **Legal authority.** A description of existing legal authority to control discharges to the MS4, and if this authority does not meet the required criteria, a list of additional authority needed and a schedule and commitment to seek such authority.

- **Source identification.** A description of the historic use of ordinances, guidance, or other controls that limit non-storm water discharges to any publicly owned treatment works (POTW), and a topographic map covering an area one mile beyond the service boundaries of the MS4 showing:

  - the location of known municipal sewer system outfalls;
  - a description of all land use activities;
  - the location and activities of landfills;
  - the location and permit number of any known discharge to the MS4;
  - the location of major structural controls for storm water discharges (such as retention basins, or major infiltration devices); and
  - identification of publicly owned parks, recreational areas, and other open lands.

- **Discharge characterization.** A summary of the types and characteristics of storm water discharges, including:

  - monthly mean rain and snowfall estimates and the average number of storm events per month;
  - existing quantitative data describing the volume and quality of discharges from the MS4, including a description of the outfalls and sampling methods used;
  - a list of "downstream" water bodies receiving discharge from the MS4, and a description of the impact of outfall upon them;
  - the results of field screening analysis for illicit discharges at either selected field screening points or major outfalls covered in the permit application; and
  - a proposed characterization plan for conducting sampling and obtaining the quantitative data necessary to complete Part 2 of the application.

- **Management programs.** A description of existing management programs to control pollutants from the municipal separate storm sewer system. For example, what procedures are in place to control pollution from construction activities, and how do they work? What is the program (such as investigation procedures and how they operate) for identifying illicit connections to the municipal storm sewer system?

- **Fiscal resources.** A presentation of the municipality's budget for existing storm water programs and for completing Part 2 of the permit application.

2.2.2 Overview of the Part 2 Application

The Part 2 application must include the following elements:

- **Adequate legal authority.** A demonstration that the municipality can operate according to the legal authority established by ordinance, statute, or series of contracts. The municipality also must demonstrate that its authority is enforceable. A discussion of how adequate legal authority may be demonstrated appears in Chapter 3 of this guidance.

- **Source identification.** An inventory, organized by watershed, of the facilities that may discharge storm water associated with industrial activity to the MS4. The applicant also must identify the location of any major outfall that discharges to waters of the United States that was not reported in Part 1. A discussion of the information to be submitted for each such facility in the inventory appears in Chapter 4 of this guidance.

- **Characterization data.** Sampling results for 5-10 outfalls designated by the permitting authority, estimates of cumulative annual pollutant loadings and event mean concentrations, and a proposed schedule to submit estimates of seasonal pollutant loadings and event mean concentrations for each major outfall identified in the source identification sections of Part 1 and 2. The *Characterization Data* provision of the Part 2 application also requires the development of an on-going monitoring program covering the term of the permit. Procedures for meeting the requirements of this section appear in Chapter 5.

- **Proposed management program.** A program that shows the municipality's comprehensive planning process for the reduction and control of pollutants, the staff and equipment available to implement the program, and a full description of how controls will be implemented to reduce pollutants from all sources of storm water. Municipalities must also describe how the program will be implemented and maintained. The Part 2 requirements for a proposed management program are described in Chapter 6.

- **Assessment of controls.** An estimate of the projected effectiveness of the municipal storm water management program, and an identification of the known impacts of storm water controls on ground water. The assessment of controls is discussed in Chapter 7.

- **Fiscal analysis.** A fiscal analysis of the capital and operation and maintenance expenditures needed to accomplish the activities (including implementation) required by the characterization data and proposed management program sections of the Part 2 application. This fiscal analysis must include projected expenses for each fiscal year of the permit term. A discussion of the fiscal analysis is included in Chapter 8.

2.2.3 Relationship Among Application Requirements

The required elements of the Part 2 application are related to each other. As a result, this guidance addresses how the application elements are related, and how information gathered for one requirement will assist the applicant in meeting other requirements. For example, the information gathered for the *Industrial Source Identification* provision of the Part 2 application will assist the municipality in:

- Targeting monitoring goals to potential pollutant sources, which may include selecting monitoring locations and chemical specific sampling frequencies (a requirement of the *Characterization Data* provision);
- Identifying illicit discharges (a requirement of the *Proposed Management Program's* illicit connection provision);
- Identifying facilities with the greatest potential for degrading receiving water quality (a requirement of the *Proposed Management Program's* industrial program provision); and
- Targeting sites that handle, store, or transport toxic or hazardous materials for on-site inspections (another requirement of the *Proposed Management Program's* industrial program provision).

As another example, the information that the applicant must prepare for the *Characterization Data* provision (e.g., the results of the sampling requirement and the estimated event mean concentrations and annual pollutant loads) may help the municipality:

- Evaluate the contribution of pollutants in storm water discharges from individual sources and determine which sources may require inspections or controls (a requirement of the *Proposed Management Program's* industrial program provision);
- Predict the impact of storm water discharges on receiving waters known to be impacted. (In the *Proposed Management Program*, additional controls may be warranted for construction sites or other industrial activities that discharge to these waters); and
- Determine what BMPs may be appropriate for given areas (another requirement of the *Proposed Management Program*).

Exhibit 2-2 summarizes some of these key interrelationships, although many other interrelationships exist. A more detailed discussion of specific information requirements and interrelationships among provisions is provided in subsequent chapters. As municipalities prepare their permit applications, they should coordinate all program requirements.

Exhibit 2-2
Examples of Relationship Among Part 2 Requirements

					Fiscal Analysis
				Assessment of Controls	Cost/benefit analysis identifies the most cost-effective BMPs.
			Proposed Management Program	Estimates of reductions in pollutant loadings predicts impact of storm water management activities	Fiscal analysis considers costs of controls, maintenance, and capital improvements. Management program may include feasibility analyses that consider cost.
		Characterization Data	Annual pollutant loads help prioritize areas for BMPS. On-going monitoring indicates success of BMPs and need to re-prioritize.	On-going monitoring program verifies program effectiveness. Instream monitoring verifies biological recovery.	Fiscal analysis considers cost of on-going monitoring
	Source Identification	Land use information and organization of industry by watershed defines representative sampling points.	Inventory of industrial users helps the city target facilities for inspections and control measures.	Estimates of pollutant load reductions depend on land use.	Industrial inventory identifies potential sources of storm water utility fees.
Adequate Legal Authority	Some sources or outfalls may be outside a city's jurisdiction. Interjurisdictional agreements may be necessary.	Authority to require sampling and obtain information for industries and dischargers outside of the MS4's jurisdiction at sampling points.	Legal authority needed to implement BMPS, control and inspect industry, and prohibit dumping and illicit discharge.	Need information gathering and inspection authority where it is necessary to inspect, monitor, and enter the facility or the site.	Legal authority is required for some financing plans, such as a storm water utility.

2.3 ADDITIONAL FACTORS TO BE CONSIDERED IN DEVELOPING THE PART 2 APPLICATION

As discussed in the previous section, the various provisions of the Part 2 application process are interconnected.

All municipalities covered by §122.26(d) must submit a Part 2 permit application that meets the requirements of the storm water permit application regulations. However, each MS4 is unique, and each Part 2 submission will be different. Municipal separate storm sewer systems differ in many ways, including population served, geologic and climatologic settings, density of development, and form of government. These underlying factors make each applicant unique.

The major factors that applicants should consider are:

- Population and projected growth rate;
- Zoning and existing land use patterns;
- Nature of watershed and receiving waters;
- Climatic conditions, soil types, and watershed delineations;
- Existing municipal functions and municipal lands;
- Other environmental impacts;
- Public involvement; and
- Intergovernmental coordination.

In addition, municipalities must implement their storm water management programs in a manner that is consistent with other applicable Federal, State, and local environmental laws.

<u>Population and Projected Growth Rates</u>

Some storm water BMPs are more appropriate for densely developed areas, while other methods may be more useful in developing areas. Consequently, defining current population densities and projecting future areas of population growth provides the basic information that can assist in the evaluation and prioritization of appropriate storm water control strategies.

<u>Zoning and Existing Land Use Patterns</u>

Through ordinances, permits, or contracts, municipalities may mandate storm water controls for new residential, commercial, or industrial developments in order to improve or assure maintenance of the quality of receiving waters at or near pre-development levels. The Nationwide Urban Runoff Program (NURP) study (EPA, 1983), pointed out that some of the best opportunities for implementing cost effective measures to prevent or reduce pollutants in storm water occur during new development. These measures may include structural controls, such as storm water detention basins or constructed storm water wetlands, or nonstructural alternatives such as cluster development and buffer zones. Sections 122.26(d)(1)(iii)(B)(2) and 122.26(d)(2)(ii) require the municipality to establish comprehensive management plans for new development (see Chapter 6).

<u>Nature of Watershed and Receiving Waters</u>

The types of storm water controls appropriate for a MS4 depend on the nature of the watershed and the receiving waters. This includes geologic and hydrologic features such as slope drainage patterns and stream size. For example, roadside swales may not be practical in areas with steep terrain, but can be very useful in flat areas. In addition, structural BMPs or other management measures that control the volume and timing of release are appropriate where uncontrolled storm water may cause physical impacts to receiving waters (especially small streams, rivers, and wetlands).

Information on the watershed and the receiving waters is required in the Part 1 permit application [§122.26(d)(1)(iv)(C)]. In Part 1, applicants are required to list water bodies that receive discharges from the MS4. The list of water bodies includes downstream segments, lakes, and estuaries where pollutants from the system discharges may accumulate and result in non-attainment of State water quality standards. Part 1 also requires a description of known water quality impacts. Applicants must include a discussion of water bodies that were cited in:

- State reports required by CWA Sections 305(b), 304(l), and 314(a);
- The State Nonpoint Source Report; and
- Other reports identifying sensitive watersheds.

Part 1 applicants should also include in this discussion a description of impacts caused by dissolved oxygen depression, bioaccumulation of toxics, excessive sedimentation, hydrologic modification, habitat destruction, etc.

Municipalities are expected to give priority consideration to those classes of pollutant sources that contribute significant loadings or pose a significant impact on receiving waters. Applicants must consider control methods that address storm water discharges from commercial and residential areas; illicit discharges and illegal disposal; storm water discharges from industrial areas; and storm water runoff from construction sites. Municipalities' permits will differ substantially in the emphasis placed on controlling various sources of pollutants in discharges from the MS4. Permits for older municipalities may emphasize control of cross-connections, while permits for municipalities with large areas of new development may emphasize the installation of permanent structural controls during construction.

The Part 2 storm water permit application requires descriptions of management programs to address sources of pollutants discharged to separate storm sewer systems. For management strategies to be effective, municipalities must give prior consideration to the nature (e.g., physical and biological parameters) and the designated uses of receiving waters such as streams, tributaries, and natural wetlands. For example, a storm water management program for a newly developing area with an existing shallow, slow-moving stream could include provisions to ensure that the post-development peak discharge flow rate for the stream is held to a certain percentage of its historical or pre-development peak discharge flow rate.

<u>Climatic Conditions, Soil Types, and Watershed Delineations</u>

Seasonal variations in precipitation can have a significant impact on storm water quality. For example, extended dry seasons in areas such as the southwestern United States result in pollutant loads distinctly higher than in other parts of the country during the first several storms of the wet season. Areas with more frequent rain and snowfall throughout the year may have more storm water discharges, but the discharges may have consistently lower pollutant concentrations than those in the Southwest. In addition, areas with significant snowfall may experience a peak in storm water discharge volume and pollutant concentration during the spring thaw.

Natural soil conditions affect the potential for storm water to recharge ground water. Porosity and permeability are properties of the soil that govern the size and number of the interstitial spaces through which water may flow. Compaction (e.g., compression of the soil by heavy machinery) will reduce the amount of void space in the soil and thereby reduce the amount of rainfall that infiltrates through the soil to ground water. Natural soil conditions are very important when siting structures designed for storm water infiltration. In addition, identifying such sites must take into consideration potential ground water impacts that may result whenever infiltration is part of the storm water management program.

Existing Municipal Functions and Municipal Lands

The Part 2 application affords municipalities the opportunity to discuss alternatives in the *Proposed Storm Water Management Program*. When considering the wide range of municipal functions, applicants need to establish which agencies will be responsible for implementing each portion of a storm water management program. (This could be outlined in the *Adequate Legal Authority* chapter of the Part 2 application, as discussed in Chapter 3 of this guidance.) Many of these agencies, will have primary missions other than dealing with storm water or water quality. Expansion of the established charter of an agency to include an element of storm water control may require legislative action, moderately expanding the scope of other municipal agencies' missions to include storm water concerns can be much more cost effective than the initiation of entirely new programs.

Applicants should identify existing municipal functions that impact the quality of storm water discharges. These functions may include snow removal activities such as road deicing, vehicle maintenance operations, and herbicide, pesticide, and fertilizer application to public lands. Municipalities can modify these activities to improve storm water quality through oversight of future land development, modifications to flood management structures, changes in materials used or in material handling or application practices, maintenance of roads, and installation of structures such as retention basins.

The municipal agency (or agencies) responsible for storm water runoff control should also consider the extent to which municipal lands and activities contribute pollutants to runoff. The same BMPs recommended for private lands may also be incorporated into the development and maintenance of a municipality's own lands and activities. For example, reduced use of pesticides and fertilizers on park land and open spaces usually decreases the contribution of these contaminants to storm water runoff. Implementing BMPs on municipal lands also shows the municipality's commitment to an effective storm water management program. BMPs are discussed in greater detail in Section 6.4 of this guidance.

Other Environmental Impacts

Municipalities should consider those activities that can directly or indirectly alter the natural hydrograph of a stream and potentially degrade an otherwise stable aquatic habitat. These factors are particularly important when considering impacts to wetlands, riparian areas, ground water, small rivers, and streams. In addition, the installation of detention or rapid infiltration ponds may have negative impacts on ground water. The installation of culverts or concrete drainage channels and other such structures typically increases the volume and velocity of runoff, which can lead to increased erosion, siltation, and sedimentation in receiving waters. Therefore, installation of these structures can contribute to the degradation of a neighboring habitat.

Public Involvement

Municipal applicants must ensure that they provide adequate public education and ample opportunities for public participation. Public participation should focus on spreading awareness of program objectives and components. Education and public involvement programs must be defined as part of the *Proposed Storm Water Management Program* [§122.26(d)(2)(iv)]. Generally, the public should be involved as early as possible in storm water management initiatives.

Conflict and confusion can be minimized if the program includes a schedule for initial public contact and milestones for public involvement throughout the development and implementation phases. Public education programs are expected to target specific audiences, including those regulated or affected by the storm water management program (e.g., developers, building contractors, and industrial operators) and those that can assist with program implementation (e.g., volunteers and citizens). For example, one large municipal applicant (Seattle) described an existing public participation program in its Part 1 Application submission. Elements of this program may be instructive to municipalities completing Part 2 of the application because it has generic components that are likely to be applicable to other large (and perhaps medium) municipalities. Excerpts from Seattle's public involvement program are provided in Exhibit 2-3 for reference.

Elements of this municipality's program that are particularly important to consider include of the role of an advisory and outreach group and its relationship to the entire process. Effective public participation programs clearly identify the role of the public.

The potential exists for a considerable range in the level of participation the public may actually have in the decision-making process. Generally, the municipal authority is going to make the decisions. However, the authority can choose to use the "participation" process to simply inform the public of decisions, or to allow the views of the public to be registered prior to decision milestones. In other cases, although uncommon, the public may have an actual voice or vote in making decisions.

The timing and frequency of meetings and the duration of the groups established for public participation will usually be dictated by the nature of the issues being addressed. For example, an ad hoc group established to address a single issue may discover that the issue cannot be effectively addressed without consideration of a broader range of issues that the municipality may also be considering. In this instance it may be appropriate for the group to expand its scope, hold regular meetings, and actively participate in the authority's decision making process. Therefore, applicants should outline in their Part 2 applications how such coordination will be accomplished.

<u>Intergovernmental Coordination</u>

If a number of municipal entities (e.g., multiple cities or a city and a county) are participating in the permit application process as coapplicants, various mechanisms can be used to improve intergovernmental coordination to ensure that the roles and responsibilities of each entity are well defined. Each entity must fulfill its responsibilities to implement applicable program measures. Examples of some of the appropriate coordination techniques and their benefits include:

- **Memoranda of agreement (MOA).** MOAs can define specific municipal roles, responsibilities, and points of coordination that help minimize duplication of effort and ensure accountability;

- **Cross-training of staff.** This allows for the identification of gaps in staffing (e.g., neglected areas of responsibility or insufficient staff levels) as well as providing the benefits of increased versatility and opportunities for learning from others;

- **Interagency advisory committees.** Their objective is to arm decision makers with a comprehensive understanding of the implications of proposed activities or decisions; and

- **Regularly scheduled intermunicipal staff meetings.** These can facilitate an open and thorough exchange of information and solidify new lines of communication.

Exhibit 2-3
Excerpts from a Public Involvement Program

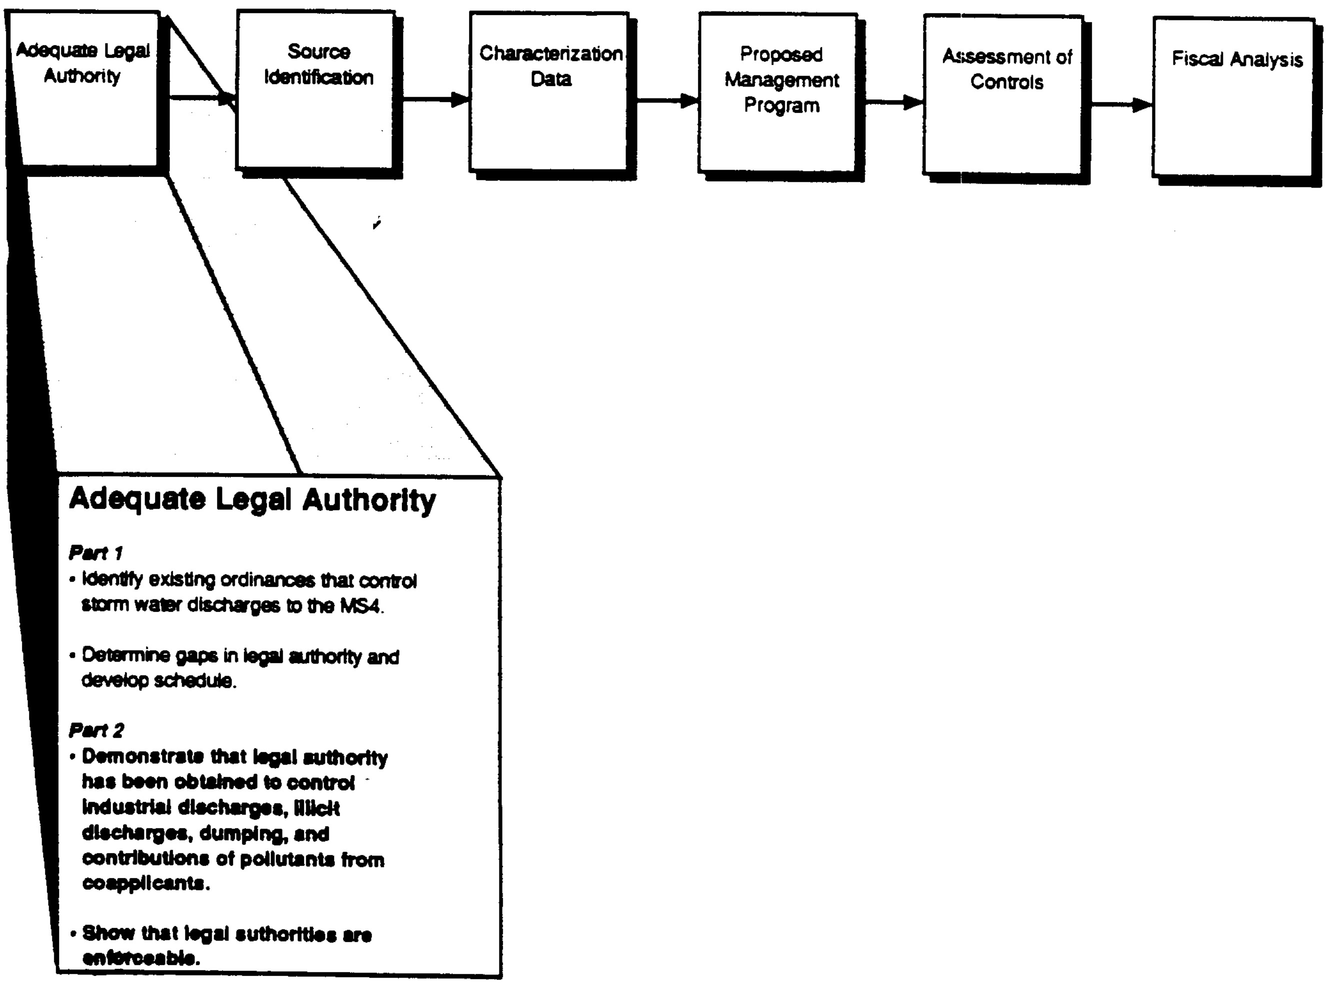
The public involvement program [of the City of Seattle] has been designed to assist in developing an acceptable city-wide plan for addressing drainage and water quality problems. Acceptable is defined as a plan that is both technically sound and sensitive to the needs and interests of the citizens. The involvement program has two major elements: a Citizen Advisory Committee (CAC) and a community outreach effort. The initial role of the CAC was to provide guidance to City staff and consultants preparing various sections of a Comprehensive Drainage Plan. Until the adoption of the Comprehensive Drainage Plan by the City Council, the CAC provided direction on drainage policy issues, assisted with the public review of the draft plan and environmental impact statement (EIS), and helped coordinate comments sent to the city from the public during the review period. Following council adoption of the plan, the CAC was reconstituted into a Drainage and Wastewater Advisory Committee which serves as an on-going sounding board to the Drainage and Wastewater Utility, the mayor, and the City Council on both sewer and drainage matters.

The community outreach effort was established for two purposes. The first was to ensure adequate public review and support of the Comprehensive Drainage Plan and EIS. Comments received during the review were used by the Drainage and Wastewater Utility, the mayor, and the City Council in making decisions about the Drainage Plan and the City's on-going drainage program. The second purpose was to begin educating residents and business people about the importance of their role in solving flooding, landslide, and water quality problems throughout the city. This community outreach/education role remains an on-going effort of the Drainage and Wastewater Utility.

Source: City of Seattle, *NPDES Storm Water Permit Application, Part 1*, City of Seattle, November 1991: 37.

Single municipalities with separate governing functions may face the same challenges as coapplicants when they prepare their Part 2 applications. Many of the same coordination steps may be necessary within a single municipal jurisdiction. The need for *intra*governmental coordination may be most crucial in large municipalities that have functions that impact storm water quality spread throughout the organizational structure of the municipality. For example, a planning department may be in charge of implementing a stream buffer policy, while a public works department may plan, site, and construct storm water BMPs. Still other agencies may be responsible for implementing erosion and sediment control requirements, and permitting and inspection functions. Storm water-related responsibilities within governmental organizations may be allocated in this manner due to the relatively recent emergence of storm water quality as an important issue. Nonetheless, effective coordination within the government of a single municipality may be as critical to the success of the storm water management program as is intergovernmental coordination for coapplicants. Therefore, applicants should outline in their Part 2 applications how such coordination will be accomplished.

CHAPTER 3
ADEQUATE LEGAL AUTHORITY



3.0 ADEQUATE LEGAL AUTHORITY

3.1 BACKGROUND

A crucial requirement of the NPDES storm water regulation is that a municipality must demonstrate that it has adequate legal authority to control the contribution of pollutants in storm water discharged to its MS4. This guidance manual and the storm water program emphasize development and implementation of storm water management programs as described in Chapter 6. In order to have an effective municipal storm water management program, a municipality must have adequate legal authority to control the contribution of pollutants discharged to the MS4.

Part 1 of the permit application requires applicants to describe their existing legal authority to control the discharge of pollutants from MS4s and evaluate the adequacy of these ordinances. Where existing ordinances were lacking, a proposed schedule to obtain the necessary authority was included with the Part 1 application. In Part 2 of the application, municipal applicants must demonstrate that they now possess adequate legal authority to:

- Control construction site and other industrial discharges to the MS4;
- Prohibit illicit discharges and control spills and dumping;
- Control potential sources of pollutants from discharges to or from coapplicants' MS4s, or MS4s that are interconnected or shared with other entities;
- Require compliance with all regulations and statutes; and
- Carry out inspection, surveillance, and monitoring procedures.

Section 3.2 reviews each of these regulatory requirements. Section 3.3 describes specific procedures a municipality may use to demonstrate adequate legal authority.

3.2 SUMMARY OF REGULATORY REQUIREMENTS

3.2.1 Control Construction Site and Other Industrial Discharges to the MS4.

> **§122.26(d)(2)(i)(A).** [The applicant must demonstrate that it can control] through ordinance, permit, contract, order or similar means, the contribution of pollutants to the municipal storm sewer by storm water discharges associated with industrial activity and the quality of storm water discharged from sites of industrial activity.

The municipality, as a permittee, is responsible for compliance with its permit and must have the authority to implement the conditions in its permit. To comply with its permit, a municipality must have the authority to hold dischargers accountable for their contributions to separate storm sewers.

"Control," in this context, means not only to require disclosure of information, but also to limit, discourage, or terminate a storm water discharge to the MS4. For example, construction sites (of 5 or more acres) and other industrial activities that discharge storm water through MS4s are required to obtain individual NPDES permits or coverage under general NPDES permits from EPA or an authorized NPDES State. These permits require compliance with applicable Federal and State regulations. However, a municipality, to satisfy its permit conditions, may need to impose additional requirements on discharges from permitted industrial facilities, as well as discharges from industrial facilities and construction sites not required to obtain permits. Therefore, a municipality should develop a mechanism to assure that all industrial facilities and constructions sites that discharge to the MS4 know their obligation to comply with the applicable terms of the municipality's storm water ordinances.

3.2.2 Prohibit Illicit Discharges and Control Spills and Dumping

> §122.26(d)(2)(i)(B). [The applicant must demonstrate that it can prohibit] through ordinance, order or similar means, illicit discharges to the municipal separate storm sewer.
>
> §122.26(d)(2)(i)(C) [The applicant must demonstrate that it can control] through ordinance, order or similar means the discharge to a municipal separate storm sewer of spills, dumping or disposal of materials other than storm water.

To demonstrate that it possesses adequate legal authority to control storm water discharges, a municipality must be able to effectively prohibit illicit discharges and illegal dumping. An illicit discharge is "any discharge that is not composed entirely of storm water except discharges pursuant to a NPDES permit . . . and discharges resulting from fire fighting activities" [40 CFR 122.26(b)(2)].

3.2.3 Control Contributions of Coapplicants

> §122.26(d)(2)(i)(D). [The applicant must demonstrate that it can control] through interagency agreements among coapplicants the contribution of pollutants from one portion of the municipal system to another portion of the municipal system.

An operator of a MS4 may participate in an application with one or more other operators, or may submit an individual application for the separate storm sewer it operates. As indicated in the box above, the operator of a discharge from a large or medium MS4 may submit, through the use of interjurisdictional agreements, a system-wide permit application. The system-wide application can accommodate existing storm water programs, on a watershed basis, as well as programs which must take into account regional differences in climate, geography, and political institutions. Such an application should cover issues of liability, financial contributions, access to records, enforcement responsibilities, and any other applicable areas of mutual concern.

When two or more municipalities submit a joint application, each coapplicant must demonstrate that it individually possesses adequate legal authority over the entire municipal system it operates or owns. A coapplicant need not fulfill every component of legal authority specified in the regulations, as long as the combined legal authority of all coapplicants satisfies the regulatory criteria for every segment of the MS4 (including authority over all sources that discharge to the MS4).

As coapplicants, for example, a county and a flood control district within that county may together possess adequate legal authority. The flood control district may have legal authority to build, operate, and maintain structures associated with major drainage channels within the county. The county itself may have legal authority to control pollutants in discharges from privately owned lands to the MS4s and legal authority to build, operate, and maintain structures associated with minor drainage channels that tie into major drainage channels. In this situation, the combined legal authority of the coapplicants may be adequate for the system, provided that the only discharge to major drainage channels comes from the county's separate storm sewer system. As another example, a department of transportation or flood control district with no land use authority could be a co-permittee with a city that does possess land use authority over the entire jurisdiction.

Coapplicants also may use interjurisdictional agreements to show adequate legal authority and to ensure planning, coordination, and the sharing of the resource burden of permit compliance. When more than one entity is submitting an application for a MS4 (either as coapplicants or as individual applicants for different parts of a system), the role of each party must be well defined. Each applicant or coapplicant must show the ability to fulfill its responsibilities, including legal authority for the separate storm sewers it owns or operates.

Applicants and coapplicants may use the procedures outlined in Section 3.3 to demonstrate adequate legal authority in their Part 2 permit applications. These procedures are guidelines, however, and are not intended to be the only possible approaches that applicants may follow.

3.2.4 Require Compliance with all Regulations and Statutes

To meet the requirements of §122.26(d)(2)(i)(E), the applicant must show that it has adequate authority to enforce its ordinances.

> **§122.26(d)(2)(i)(E).** [The applicant must demonstrate that it can require] compliance with conditions in ordinances, permits, contracts or orders.

One acceptable way to support a declaration of adequate legal authority, including the ability to enforce appropriate ordinances, is for the municipality to provide a certification from the Municipal General Counsel or equivalent. The certification should state that the applicant has the legal authority to apply and enforce the requirements of §122.26(d)(2)(i)(A)-(F) in State or local courts. The certification would, therefore, cite specific ordinances and the reasons why they are enforceable. The statement should discuss what the municipality can do to ensure full compliance with §122.26(d)(2)(i).

In a Part 2 application, through a statement from the Municipal General Counsel or through some other method, a municipality should identify the administrative and legal procedures available to mandate compliance with appropriate ordinances, and, therefore, with permit conditions. Applications should contain descriptions of how ordinances are implemented and appealed. In particular, a municipality should indicate if it can issue administrative orders and injunctions or if it must go through the court system for enforcement actions.

3.2.5 Carry Out Inspection, Surveillance, and Monitoring Procedures

In their Part 2 applications, municipalities must propose programs to control the contributions of pollutants from industrial facilities and prohibit illicit discharges. For both of these activities, municipalities must have the legal authority to carry out inspection, surveillance, and monitoring procedures necessary to determine compliance.

> **§122.26(d)(2)(i)(F).** [The applicant must demonstrate that it can carry] out all inspection, surveillance and monitoring procedures necessary to determine compliance and noncompliance with permit conditions including the prohibition on illicit discharges to the municipal separate storm sewer.

To meet this requirement, municipalities may wish to consider establishing ordinances that require industrial facilities to perform inspections and report the results to the city. In many municipalities, these facilities may perform similar inspections under a pretreatment program. In their Part 2 applications, municipalities should provide documentation of their authority to enter, sample, inspect, review, and copy records, etc., as well as demonstrate their authority to require regular reports.

3.3 PROCEDURES FOR DEMONSTRATING ADEQUATE LEGAL AUTHORITY

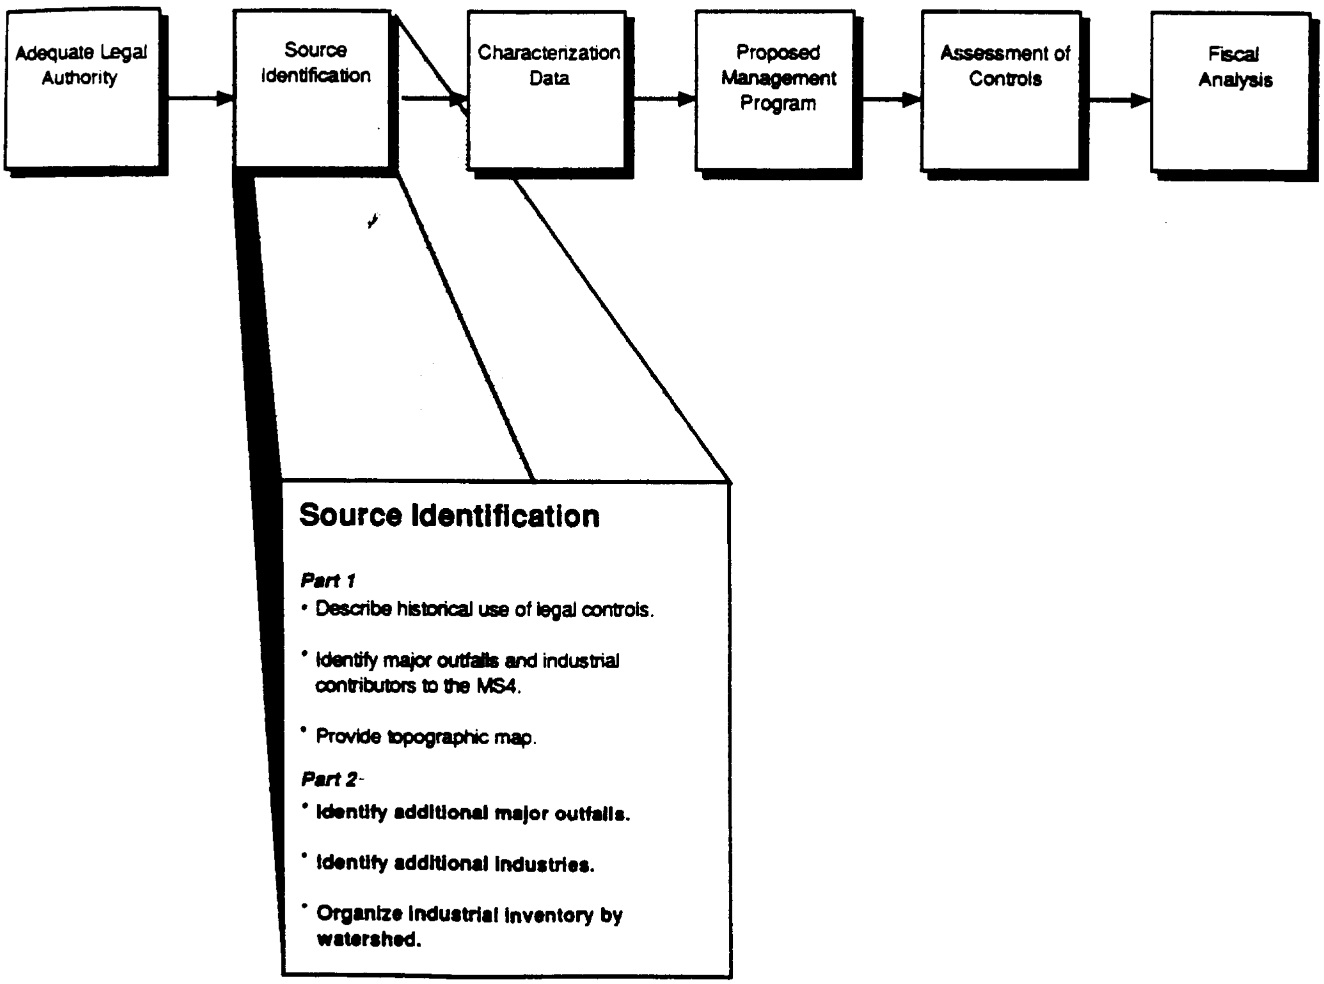
The Part 2 application requires the applicant or coapplicants to cite and describe specific ordinances currently in effect and demonstrate that the jurisdiction for these ordinances covers the entire area served by the MS4. In addition, the applicant may elect to discuss specific changes in ordinances passed since the submission of the Part 1 permit application to illustrate how legal authority has evolved to meet the regulatory requirements in §122.26(d)(2)(i). One method by which an applicant can partially demonstrate that it has adequate legal authority is to develop a matrix that compares, in a side-by-side format, the regulatory requirements in §122.26(d)(2)(i)(A)-(F) and the municipality's legal authority. Once completed, the matrix would indicate whether an adequate legal framework exists to address all key regulatory requirements identified in §122.26(d)(2)(i)(A)-(F). Furthermore, the matrix could also illustrate where the authority to mandate compliance is vested.

In order to support an assertion of adequate legal authority, applicants should include the complete text of the applicable portions of the ordinances or other such provisions in the application. The applicant should also provide a specific explanation of why and how the language of a particular ordinance or other authority meets Federal regulatory requirements. The application should indicate to whom the ordinance applies and how it will operate to control, prevent, or stop discharges that violate permit conditions. For example, the municipality may describe and provide an excerpt from a city ordinance that prohibits non-storm water discharges to the MS4.

Appendix C illustrates one way to detail the existence of ordinances that establish the legal authority required in §122.26(d)(2)(i). A narrative discussion of the historical use of these ordinances to control pollutants in storm water discharges also may be included. The example in Appendix C shows what the applicant may do to satisfy §122.26(d)(2)(i).

Substantial effort should be devoted to obtaining the necessary legal authority before the Part 2 application is submitted. However, some municipalities may find that the two-year application process does not allow enough time to secure adequate legal authority as described in this section. This may be due to the need for State statutory or legislative changes. In this instance, the Part 2 application must include a detailed description of what changes are needed and a schedule of when they will be accomplished. The schedule must include timetables for drafting proposed changes, public comment periods, and final authorizations.

CHAPTER 4
SOURCE IDENTIFICATION



4.0 SOURCE IDENTIFICATION

4.1 BACKGROUND

In Part 1 of the NPDES storm water permit application, applicants are required to identify the location of known major outfalls discharging to waters of the United States from MS4s. Applicants also are required to provide information and data on existing land use activities. The identification of outfalls and land use activities is the first step in the process of:

- Identifying the sources of pollutants in storm water runoff;
- Linking the sources of pollutants in runoff to specific water quality impacts and other impacts that may result in degradation of aquatic resources;
- Identifying those activities or physical factors that have the most significant impact on water quality;
- Defining control measures that yield improvements in storm water quality; and
- Developing methodologies by which engineers, urban planners, and managers can make long term decisions that not only provide for economic growth, but also have discernible environmental benefits through imposed storm water controls.

The source identification requirements in the Part 2 permit application reflect three basic steps. First, municipalities must **identify any major outfalls** that were not already identified in the Part 1 application. Second, applicants must **compile an inventory of industrial** activities that may discharge storm water to a MS4. Third and finally, applicants must **organize the inventory of industrial activities on a watershed basis.**

Organizing the inventory by watershed allows the municipality to focus on activities within discrete areas that may contribute pollutants in storm water discharges to waters of the United States. For example, combining outfall data with the industrial inventory organized by watershed may help the municipality to identify probable areas of illicit connections. This information will also be useful for municipalities when they develop specific strategies [e.g., best management practices (BMPs)] as part of their proposed storm water management programs. The following sections discuss regulatory requirements and procedures for completing the source identification section of the Part 2 permit application. Section 4.2 provides guidance on identifying major outfalls, Section 4.3 provides guidance on compiling an inventory of industrial dischargers, and Section 4.4 provides guidance on organizing the inventory of industrial discharges by watershed.

4.2 MAJOR OUTFALLS

The first portion of the Part 2 Source Identification provision states:

> **§122.26(d)(2)(ii).** *Source Identification.* [The applicant must provide the] location of any major outfall that discharges to waters of the United States that was not reported [in Part 1 of the application] . . . .

4.2.1 Definition of a Major Outfall

According to 40 CFR 122.26(b)(5), a major outfall is a MS4 outfall that discharges from a single pipe with an inside diameter of at least 36 inches. The term also includes discharges from a single conveyance other than a circular pipe serving a drainage area of more than 50 acres.

For those municipal separate storm sewer systems that receive storm water runoff from lands zoned for industrial activity, major outfalls also include outfalls that discharge from a single pipe with an inside diameter of 12 inches or more, or discharge from other than a circular pipe associated with a drainage area of 2 acres or more. This definition also applies to outfalls of drainage areas that have both industrial and non-industrial activity. For example, if a three acre drainage area is zoned half woodland and half industrial, the discharges from that area would still be considered a major outfall. Because the definition of major outfall includes consideration of drainage area, municipalities may need to consider conveyances such as ditches and swales when identifying major outfalls.

4.2.2 Identifying Major Outfalls

The first step in this section of the Part 2 application is the identification of major outfalls not identified in the Part 1 application [§122.26(d)(2)(ii), cited in box above]. When identifying these major outfalls, municipalities should build upon the approach used in the Part 1 application. One way to identify major outfalls is a **review of sewer system maps.** These maps can provide information on sewer system type (e.g., separate storm versus combined sewer), pipe size, and outfall location. However, depending upon the age of the sewer system maps, they may not provide complete information about newly developed areas or improvements to older areas. Often, **interviews with sewer system maintenance personnel** can provide information on the most recent changes to the sewer system. The municipality should also consider conducting field surveys (e.g., visual inspection of the banks of receiving waters) to locate major outfalls.

When submitting a Part 2 permit application, municipalities should include a brief description of how additional major outfalls were identified. This description is not intended to be a lengthy list of each sewer system employee interviewed, but rather an outline of the methods employed.

4.3 INVENTORY OF INDUSTRIAL DISCHARGERS

The second step in this portion of the Part 2 application is assembling an inventory of industrial storm water dischargers.

> **§122.26(d)(2)(ii).** *Source Identification. . . .* Provide an inventory, organized by watershed of the name and address, and a description (such as SIC codes) which best reflects the principal products or services provided by each facility which may discharge, to the municipal separate storm sewer, storm water associated with industrial activity.

This section describes how municipalities may develop the inventory of industrial facilities. Section 4.4, below, provides guidance on organizing these facilities by watershed.

4.3.1 Facilities that must be Included in the Inventory

As stated above, applicants must provide an inventory of each facility that may discharge to the MS4 storm water associated with industrial activity. Industrial storm water dischargers that must be included in this inventory fall into 11 classes of industrial activities as defined in the November 1990

R0009966

regulations. Six of these classes were defined in a narrative format and five were defined by Standard Industrial Classification (SIC) codes. Specific categories of industries are identified in §122.26(b)(14)(i)-(xi). Exhibit 4-1 provides a list of the SIC codes and industry categories cited in the regulatory definition.

4.3.2 Identifying the Industrial Facilities

As a first step in developing a comprehensive industrial storm water inventory, the applicant must review **facility notifications**. Industrial facilities were required to notify municipalities by May 15, 1991, of their intent to discharge storm water to the municipal storm sewer system [§122.26(a)(vi)(4)]. Each facility should have submitted to the municipality information including facility name, facility location, and facility type (such as SIC code or other industry categorization).

In addition, municipalities should explore other sources of information on industrial facilities to help identify gaps in inventory. One specific source of information a municipality should review is **facility information submitted under other programs**. For example, SIC codes are often required for air pollution permit applications, hazardous materials management permits, pretreatment program applications, building permits, business licenses, or local tax rolls. A municipality may take the list of SIC codes provided in Exhibit 4-1 and compare it with existing information on SIC codes or industrial categories which has been submitted by industrial facilities under other programs.

Under 40 CFR 122.28, facilities that discharge storm water associated with industrial activity must submit an individual permit application, participate in a storm water group permit application, or file a **Notice of Intent (NOI)** to be covered by a general permit. These applications and NOIs are another source of information on industrial dischargers. For existing facilities, applications or NOIs were to be submitted by October 1, 1992; for new facilities, they must be submitted prior to the commencement of industrial activity. However, in the Intermodel Surface Transportation Efficiency Act of 1991, Congress provided that permit application requirements be reserved for industrial activities owned or operated by municipalities with a population of less than 100,000, with the exception of airports, power plants, and uncontrolled sanitary landfills. If EPA is the permitting authority in a State, applications and NOIs should be submitted to EPA; if a State has NPDES authority, they should be submitted to the State. Section 308 of the CWA provides the legal authority for any individual (including a municipality) to obtain information from the NPDES permitting authority. A municipality may be able to obtain a list of the facilities in its jurisdiction that have applied for coverage under a general or individual permit or that have applied for coverage as a member of a group.

Additional sources of information on industrial facilities may include **zoning maps** showing industrial parks, manufacturing and industrial listings in **telephone books, trade association listings, pretreatment industrial waste surveys, the Chamber of Commerce Manufacturing Directory, and Dunn and Bradstreet**.

In the Part 2 application, a municipality should provide a brief description of the sources it reviewed in identifying the industrial dischargers. As part of the proposed storm water management program, which is described in Chapter 6, municipalities should describe a plan for collecting new or updated information on industrial dischargers throughout the life of the permit.

Exhibit 4-1
Industry Categories Cited in the Definition of Storm Water Associated with Industrial Activity

1. Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR Subchapter N (except facilities with toxic pollutant effluent standards which are exempted under category 11 below.

2. Facilities described by SIC 24 (except 2434), 26 (except 265 and 267), 28 (except 283), 29, 311, 32 (except 323), 33, 3441, 373.*

3. Facilities described by SIC 10 through 14 (mineral industry), including:

   - active or inactive mining operations, except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(1) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990; and

   - oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, by-products, or waste products located on the site of such operations.

4. Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of RCRA.

5. Landfills, land application sites, and open dumps that receive or have received any industrial wastes (waste that is received from any of the facilities described under this subsection) including those that are subject to regulation under Subtitle D of RCRA.

6. Facilities involved in the recycling of materials (metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards) including but not limited to SIC 5015 and 5093.

7. Steam electric power generating facilities, including coal handling sites.

8. Transportation facilities described by SIC 40, 41, 42 (except 4221-25), 43, 44, 45, and 5171, which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under 1 - 7 or 9 - 11 are associated with industrial activity.

(Continued)

Exhibit 4-1 (continued)

9. Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that is located within the confines of the facility, with a design flow of 1.0 mgd or more, or required to have an approved pretreatment program under 40 CFR Part 403. Not included are farm lands, domestic gardens, or lands used for sludge management where sludge is beneficially reused and which are not located within the facility, or areas that are in compliance with Section 405 of the CWA.

10. Construction activity including clearing, grading, and excavation activities except operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale.**

11. Facilities described by SIC 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, 4221-25, (and which are not otherwise included within categories 2 - 10).*

Source: 55 FR 48065, November 16, 1990.

*Please note the SIC 285 is covered under Category 11. Also note that for the industries identified in Category 11, the term includes only storm water discharges from all areas (except access roads and rail lines) where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to storm water.

**On June 4, 1992, the United States Court of Appeals for the Ninth Circuit found that EPA's rationale for exempting construction sites of less than five acres and certain uncontaminated storm water discharges from Category 11 light industrial facilities from Phase I of the storm water program to be invalid and has remanded these exemptions for further proceedings (see *Natural Resources Defense Council* v. *EPA* No. 91-70176).

4.4 ORGANIZING THE INDUSTRIAL INVENTORY BY WATERSHED

Once the industrial inventory is complete, the applicant must organize the inventory by watershed, or drainage area. The main objective of this requirement is to associate discrete discharges with specific watersheds, which may help the municipality identify relationships between pollutant sources and receiving water quality problems. To help organize the industrial inventory by watershed, municipalities should consider the long-term benefits of using automated database systems to help organize and update information on:

- Locations of major outfalls or system modifications;
- Land use designations and composition;
- Dischargers of storm water associated with industrial activity;
- Other NPDES permit holders;
- Location/inventory of structural controls; and
- Locations of illicit connections.

This information can help satisfy the requirement that discharges of storm water associated with industrial activity be organized by watershed. Using an automated database system or the map submitted in the Part 1 application may be helpful in satisfying this requirement. However, the regulations do not require Part 2 applicants to use a particular database or submit certain information, and municipalities may elect to use other methods.

The following procedure is provided as an example of one way to organize industrial dischargers by watershed:

1. Create a transparent overlay of tax maps covering the entire area served by the MS4.

2. Indicate on the maps the location of each industrial activity according to its address with an appropriate symbol or code.

3. Produce an overlay of existing watersheds from a topographical map, for example, United States Geological Survey (USGS) maps, covering the area that the MS4 supports. Previously performed hydrological surveys may be helpful in delineating the boundaries of existing watersheds. Municipalities may elect to sub-divide existing watersheds into smaller units if this will assist in management planning.

4. Align the tax map and watershed overlay so that industrial activity locations can be transposed to the watershed overlay.

A number of PC-based tools can be used to organize information on facilities and outfalls. For example, computer-aided design (CAD) packages, in conjunction with third-party software packages, are specifically designed to present information on separate transparent layers that can be "turned off and on" when necessary. One layer could contain information on watershed topography and another could contain the locations of industrial storm water dischargers. Additional layers might contain information on the layout of the municipal system, locations of structural source controls and outfalls, and land-use patterns (both present and future).

A CAD-based system can be useful, not only in presenting information easily and graphically, but also in its ability to transfer spatial data, such as XYZ coordinates, to commonly available PC-based database applications. This spatial data can be merged with other databases containing more generic information including facility name, address, and SIC codes. However, one potential drawback to CAD systems is that most of them cannot store "real-world" (e.g., latitude-longitude) coordinates and are not generally designed for spatial analyses.

Information stored in a CAD format may also be input into a Geographic Information System (GIS). With some conversion, the CAD system coordinates may be transformed into the "real-world" coordinates typically employed by GIS. GIS are integrated database management systems designed for the input, storage, retrieval, analysis, output, and display of geographically or spatially indexed data.

The key attribute of GIS is the relational database capabilities that make these systems powerful tools for conducting spatial analyses. Using GIS, a municipality could overlay several layers of data and derive new information from this existing information. For example, using GIS, an applicant could overlay a map showing the 100-year flood plain with a map showing locations of industrial facilities. The GIS could then calculate the amount of industrial area within the 100-year flood plain and plot this data on a new overlay. This type of spatial analysis might be a powerful tool in the design of the municipality's storm water management program.

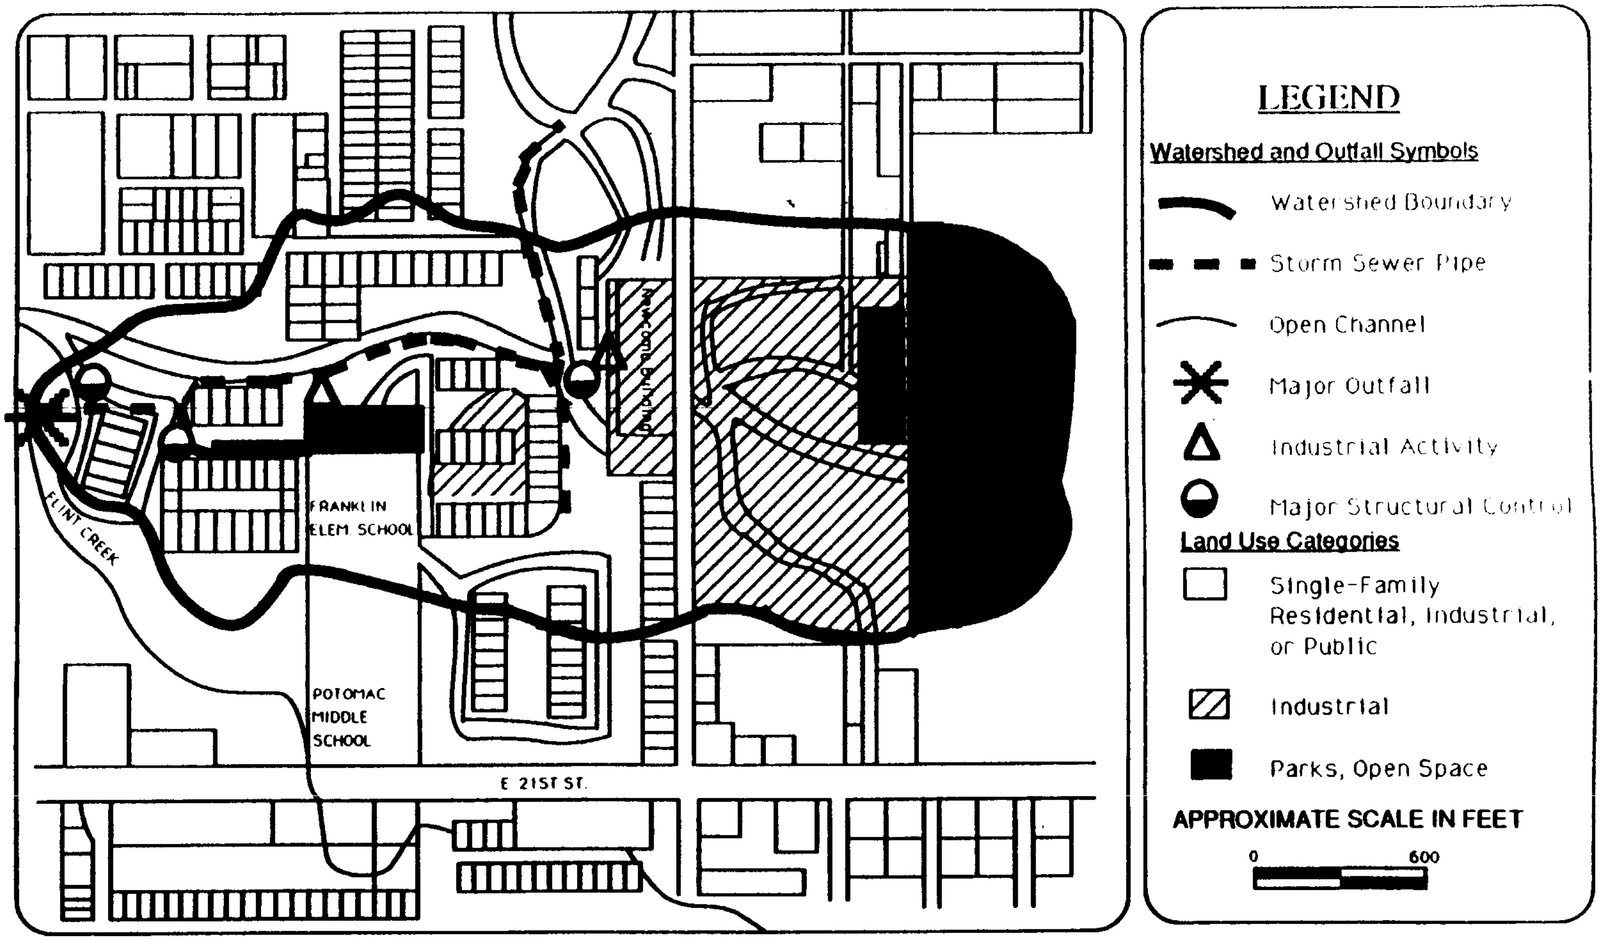
Another benefit of GIS is the ability for common data to be shared efficiently among several agencies. For example, the flood management agency, department of transportation, and storm water control agency could all contribute data to and use analyses from the same GIS. On the other hand, one potential drawback to GIS is their relatively high cost. Often, developing accurate, appropriate base maps is one of the most resource intensive parts of the system.

The techniques presented in this section to organize industrial dischargers by watershed are not the only methods that the applicant can use. For example, municipalities may elect to present the information in tabular form. Using a CAD, GIS, or other automated system is entirely up to the municipality. There is no requirement that municipalities use these systems in the development of either the Part 1 or Part 2 NPDES permit applications. Each applicant will have to examine its existing resources (including computer systems, personnel, and budget) and projected needs before deciding which method will be the most efficient and most useful in the long term.

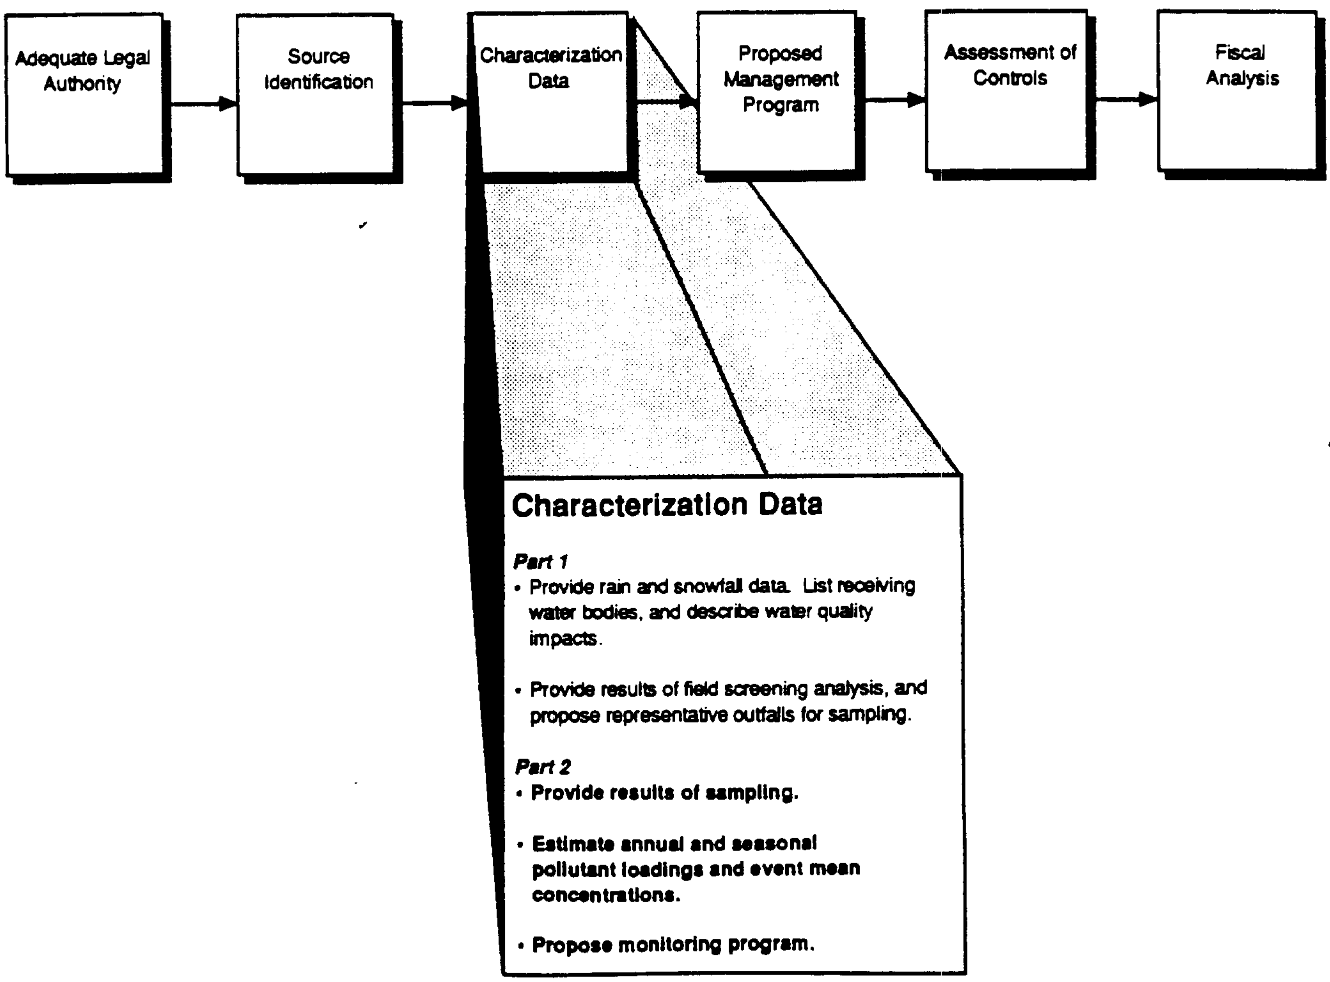
A discussion of maintaining and/or updating the industrial inventory is provided in Section 6.3.3.2 of this guidance.

Exhibit 4-2 illustrates an example of the procedure discussed in Sections 4.3 and 4.4.

Exhibit 4-2
Example of a Map Organizing Industry by Watershed



CHAPTER 5
CHARACTERIZATION DATA



5.0 CHARACTERIZATION DATA

5.1 BACKGROUND

5.1.1 Objective of this Section

This section addresses the requirements for reporting the physical and chemical characteristics of municipal storm water runoff as specified by 40 CFR 122.26(d)(2)(iii). These requirements describe the minimum quantitative and descriptive data necessary to begin characterizing storm water discharges.

The applicant is encouraged to provide additional information, if available, which may provide a basis for a more effective storm water management program. The additional information may also help the permitting authority make more informed decisions regarding the specifications of the permit to be issued.

The NPDES permit application regulations require the applicant to identify all major outfalls that are part of the MS4 [§122.26(d)(1)(iii) and 126(d)(2)(ii)]. Part 1 requires the municipality to propose a sampling plan that identifies 5-10 outfalls that would be appropriate for representative data collection under Part 2 of the application [§122.26(d)(1)(iv)(E)]. The next step is to collect and analyze samples from these outfalls (or others designated by the permitting authority) for a variety of pollutant parameters from 3 representative storm events.

5.1.2 Potential Impacts of Storm Water Runoff

The Nationwide Urban Runoff Program (NURP) study showed that discharges from MS4s contribute to the degradation of water quality in the Nation's waters (EPA, 1983). The NURP study also concluded that the effects of urban runoff on receiving water quality are very site specific. The effects depend on the types, size, and hydrology of the water body, the designated beneficial use, the pollutants which affect that use, the urban runoff quality characteristics, and the amounts of urban runoff dictated by local rainfall patterns and land use. *The National Water Quality Inventory, 1990 Report to Congress* as required by Section 305(b) of the Clean Water Act, stated that one-third of the impairment in assessed waters is due to storm water runoff (EPA, 1990d).

<u>Quantity Impacts</u>

Urbanization often increases the quantity and reduces the quality of storm water runoff. For example, vegetated or forested areas with pervious surfaces are often replaced with impervious surfaces (e.g., concrete and asphalt) that prevent or minimize the amount of rainfall available for ground water recharge. This increases the volume and velocity of storm water runoff.

Vegetated areas play a crucial role in ground water recharge and in the maintenance of stream baseflow. This is especially true during extended dry periods, when ground water is often the only source that preserves stream baseflow. In highly urbanized areas, ground water recharge may be so severely reduced that ground water flow to perennial streams during dry periods is not sufficient. Further, the natural hydrology of a watershed is often altered by urbanization, because developing areas often provide drainage appurtenances that rapidly conduct storm water runoff away from these areas. Such drainage may also affect the geometry of natural streams, especially where natural streams have been modified through the installation of man-made channels. Ultimately, reduced perviousness due to urbanization increases the magnitude and the frequency of localized flooding which can have the long term effect of substantially increasing the width of natural streams through erosion and scouring.

Increases in peak discharge velocity and runoff volume can also result in substantial erosion of natural streambanks and the washout of benthic habitats. Since streambeds often consist of unconsolidated silt and sediment, they may be stripped away substantially by excessive discharge velocities. Increased discharge velocities can also lead to undercutting and destabilization of streambanks, which may cause erosion that extends beyond the natural boundary of the streambank.

Further, silt and sediment can increase the turbidity of the receiving water, thus interfering with the growth of aquatic plants which depend on photosynthesis. Increased turbidity can also interfere with aquatic feeding, eliminate spawning areas for fish, and cause abrasion and clogging of fish gills. Also, because silt and sediment may remain in the watershed, they can blanket benthic habitats and severely reduce streamflow capacity.

In the presence of excessive volumes of storm water runoff and discharge velocities, the net impact on receiving waters can be almost indistinguishable from impacts commonly associated with the discharge of toxics (e.g., increased mortality, reduced biodiversity, and reduced reproduction).

Deposition and Resuspension of Toxicants

Research is currently on-going to examine the impact of the deposition and resuspension of toxicants as a result of wet weather events. Questions about the survivability of benthic habitats when exposed to toxicants in deposited sediments still remain. The impact of resuspended toxicants from the sediments is not well known since toxics are often bound to sediment particles that may reduce the concentrations available for biological uptake and subsequent bioaccumulation. The applicant should also be aware that different metal contaminants in sediments can exhibit different solubilities. Under varying conditions of pH and temperatures, metals deposited in sediment can become soluble again and be reintroduced into the water column.

Excessive Bacterial Levels

The NURP study final report concluded that "coliform bacteria are present at high levels in urban runoff and can be expected to exceed EPA water quality criteria during and immediately after storm events." This is of significant concern, particularly in swimming and shellfish areas.

Dissolved Oxygen Depression

The presence of oxygen-consuming pollutants in receiving waters can lead to severe dissolved oxygen depression. Factors that can cause dissolved oxygen depression include the resuspension of biodegradable organic material (which can occur in the presence of high flow velocities) or the discharge of organic pollutants in storm water discharges. The NURP study demonstrated that storm water discharges exhibit biochemical oxygen demand (BOD) levels in excess of levels commonly associated with secondary treated effluent from publicly owned treatment works (POTWs). Severe dissolved oxygen depression could contribute to fish kills, which are one of the most readily observable impacts of pollution on receiving waters.

Eutrophication

Eutrophication, or the aging of a water body, can be accelerated by excessive nutrient loadings from storm water. Advanced stages of eutrophication are often associated with substantial variations in dissolved oxygen concentration. Nutrients of concern are nitrogen and phosphorus. Phosphorus is typically the growth-limiting nutrient for plants in fresh water systems. Storm water discharges routinely contain excess concentrations of these nutrients, which can lead to excessive algal growth, commonly referred to as algal blooms. Excessive concentrations of algae can cause odor and taste problems in drinking water and can result in aesthetically unpleasant environments. In addition, the eventual decomposition of large concentrations of algae can depress dissolved oxygen in the water body to levels where fish kills occur. In nature, the process of eutrophication occurs over a substantial period of time; however, storm water discharges can rapidly accelerate this process.

Exceedance of Chronic Toxicity Criterion

Long-term exposure to toxics in excess of chronic toxicity criteria can cause sublethal effects on aquatic life. Indicators of chronic toxicity include reduced fertility, reproduction, and growth rates and a decline in the diversity of aquatic organisms. The NURP study clearly indicated that storm water discharges contain concentrations of trace metals, such as lead, cadmium, zinc, and copper in amounts that exceed the chronic toxicity criteria. Prolonged exposure to chronic concentration levels of toxics can also be lethal to aquatic organisms, primarily from the bioaccumulation of toxics within the cell tissue of the organism over a extended period of time.

Thermal Impacts

The temperature of storm water runoff may become significantly elevated via conductive and convective heat transfer with impervious, man-made surfaces. In the case of contact with impervious surfaces, the resulting temperature elevation of storm water runoff can be substantial. For example, the surface temperature of parking lots during summer months may exceed 100 degrees Fahrenheit. Consequently, storm water runoff from these parking lots will be elevated in temperature. Many aquatic organisms are extremely sensitive to changes in water temperature. Increased water temperature also reduces dissolved oxygen in streams, rivers, lakes, and wetlands. Therefore, significant discharges of storm water at elevated temperatures can, over the long term, lead to the alteration of aquatic populations.

5.1.3 Use of the Characterization Data

The NURP study analyzed storm water discharge from 28 sites representing 12 major river basins of the United States. NURP detected 77 EPA priority pollutants present in the storm water discharges sampled, including samples with concentrations that exceeded water quality criteria for certain pollutants. Those pollutants detected in at least 10 percent of the samples studied in NURP are identified in Exhibit 5-1.

The data gathered for storm water discharge characterization can be used to create a baseline measurement of pollutant concentration and loadings. The data also can be used to evaluate the effectiveness of best management practices (BMPs) as well as help identify storm water control priorities. In addition, it can be used to help identify the sources of pollutants in storm water runoff, to help establish an effective monitoring program for the life of the permit, and to help predict the impact of storm water runoff on receiving waters that are known to be impaired.

5.1.4 Storm Water Sampling and Analysis Procedures

The regulation requires that the process of collecting quantitative data for storm water characterization follow certain guidelines.

> **§122.26(d)(2)(iii)** ***Characterization data.*** When "quantitative data" for a pollutant are required under paragraph (d)(1)(iii)(A)(3) of this paragraph, the applicant must collect a sample of effluent in accordance with 40 CFR 122.21(g)(7) and analyze it for the pollutant in accordance with analytical methods approved under 40 CFR part 136. When no analytical method is approved the applicant may use any suitable method but must provide a description of the method.

Exhibit 5-1. Priority Pollutants Detected in at Least 10% of NURP Samples.

PARAMETERS	FREQUENCY OF DETECTION (%)
Metals and Inorganics:	
Antimony	13
Arsenic	52
Beryllium	12
Cadmium	48
Chromium	58
Copper	91
Cyanides	23
Lead	94
Nickel	43
Selenium	11
Zinc	94
Pesticides:	
Alpha-hexachlorocyclohexane (alpha-BHC)	20
Alpha-endosulfan	19
Chlordane	17
Lindane (gamma-BHC)	15
Halogenated aliphatics:	
Methane, dichloro-	11
Phenols and cresols:	
Phenol	14
Phenol, pentachloro-	19
Phenol, 4-nitro	10
Phthalate esters:	
Phthalate, bis(2-ethylhexyl)	22
Polycyclic aromatic hydrocarbons:	
Chrysene	10
Fluoranthene	16
Phenanthrene	12
Pyrene	15

Source: U.S. Environmental Protection Agency, *Results of the Nationwide Urban Runoff Program*, EPA Planning Division (National Technical Information Service (NTIS) Accession No. PB84-8552). December 1983.

The data collection procedures must follow the guidelines for storm water sampling outlined in §122.21(g)(7), *Effluent Characteristics*. This portion of the NPDES regulation describes the conditions under which a storm water discharge will be sampled, and which collection procedure (grab sample versus flow-weighted composite sample) is required for the water quality parameter being analyzed. These guidelines are discussed in more detail in Sections 5.3.2 and 5.3.4 of this guidance manual. In addition, EPA has available a *Storm Water Sampling Guidance Document* that describes in detail the methods used for storm water discharge sampling (EPA, 1992a).

The methods for the chemical analyses of storm water discharge samples must be conducted in accordance with 40 CFR Part 136, *Guidelines for Establishing Test Procedures for the Analysis of Pollutants*. These guidelines refer the applicant to EPA-approved methods and cite the source of the approved methods (e.g., Standard Methods for, the Examination of Water and Wastewater, ASTM methods, etc.). Note that alternative methods (i.e., those not included in Part 136) may be used under certain circumstances (see Section 5.3.4) as described in 40 CFR Part 136, and reiterated in the Characterization Data section of Part 2 of the storm water discharge NPDES permit.

The specific constituent pollutants and water quality parameters that must be analyzed in the storm water samples are presented in Section 5.3.4.

5.2 SUMMARY OF REGULATORY REQUIREMENTS

The following is a summary of the characterization data requirements for the Part 2 application:

- Quantitative data on physical and chemical characteristics of the discharge taken from at least 5 to 10 representative outfalls chosen by the permitting authority (Section 5.3);
- Estimates of both the annual pollutant load and event mean concentration of the cumulative discharges from all municipal outfalls during a storm event (Section 5.4);
- A proposed schedule to provide estimates for each major outfall of the seasonal pollutant load and the event mean concentration for constituents detected in required sampling (Section 5.5); and
- A proposed monitoring program for the life of the permit that meets specific requirements established in the regulations (Section 5.6).

5.3 QUANTITATIVE AND QUALITATIVE DATA REQUIREMENTS

5.3.1 Selection of Representative Sampling Sites

In the Part 1 application, the municipality is required to describe a plan for obtaining characterization data [§122.26(d)(1)(iv)(E)]. The plan should reflect the requirements of §122.26(d)(2)(iii).

Different types and intensities of land use activities influence, in part, the types of pollutants and the pollutant concentrations in municipal storm water runoff. Therefore, Part 1 of the permit application [§122.26(d)(1)(iii)(B)(2)] requires the applicant to describe the land use activity within the area to be covered by the permit. In Part 1, the applicant also must select a subset of all the major outfalls (see Section 4.2.1 for definition of major outfall) identified that represented surface runoff discharge of the various land use activities described. In some cases, a municipality preparing a Part 2 application may want to supplement its sampling program by collecting and analyzing samples from major outfalls that were not identified in the Part 1 application or designated by the permitting authority. This additional sampling may provide the

R0009978

municipality with data that better characterizes its MS4 discharges.

5.3.2 Criteria for Storm Water Discharge Sampling

Land use activities are not the only factors that affect the pollutant composition of storm water runoff. Storm water composition also varies according to the nature of the storm event (e.g., duration, volume), and the composition may vary throughout the duration of a single storm event (i.e., the initial discharge, or "first flush," tends to have higher pollutant loads). In order to obtain data that represents an "average" storm event, EPA requires samples from three separate storm events to characterize the surface water runoff; however, the permitting authority may allow exemptions.

> **§122.26(d)(2)(iii)(A)(*1*)** For each outfall or field screening point designated under this subparagraph, samples shall be collected of storm water discharges from three storm events occurring at least one month apart in accordance with the requirements at §122.21(g)(7) (the Director may allow exemptions to sampling three storm events when climatic conditions create good cause for such exemptions);

The criteria for sampling storm water discharge are detailed in §122.21(g)(7), *Effluent Characterization*. EPA's *Storm Water Sampling Guidance Document* addresses these criteria. For the purpose of this discussion, a brief synopsis of these criteria follows:

- For each outfall or field screening point selected, samples must be collected from three separate storm events.
- The three storm events must be at least one month apart.
- Each sampled storm event must have a rainfall of at least 0.1 inch in the drainage area.
- There must be no storm event in excess of 0.1 inch in the drainage area for at least 72 hours prior to the sampled storm event.
- The rainfall event should not vary by plus or minus 50 percent from the average or median per storm volume and duration for the region.

EPA understands that climatic conditions may make it difficult for some municipalities to sample storm events meeting these criteria. For example, storm events may be so infrequent in arid and semi-arid areas that sufficient samples cannot be obtained by the application deadline. In other areas, storms may be so frequent that it may not be possible to wait the required 72 hours between storm events. In such cases, the applicant should confer with the permitting authority in advance. In instances where representative storm events do not occur prior to the application due date, the municipality should submit its application with as much information as possible. It should include an explanation [certified by a principal executive officer or ranking elected official in accordance with §122.22(a)(3)] as to why sampling data were unavailable.

The municipality may need to perform some initial research and calculation to meet the requirements listed above. In order to determine what constitutes an average storm event for the area, the applicant should contact the National Weather Service or National Oceanographic and Atmospheric Administration's National Climate Center. Weather data is also available commercially and from airports. The applicant may also refer to the information provided in the *Storm Water Sampling Guidance Document*.

5.3.3 Narrative Description of Storm Event

> **§122.26(d)(2)(iii)(A)(2)** A narrative description shall be provided of the date and duration of the storm event(s) sampled, rainfall estimates of the storm event which generated the sampled discharge and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event;

Under §122.26(d)(2)(iii)(A)(2), the municipality must provide a narrative description of each storm that produced the discharge to be chemically and physically characterized. Such a narrative description must include:

- The date and duration of the rainfall event that produced the discharge sampled. Measurements describing the peak intensity of the storm, if available, should also be reported;

- The amount of rainfall. Rainfall conditions may vary significantly across large drainage areas, so rainfall characteristics should be spatially averaged over the drainage area, if possible. If more than one rain gauge is used, averages should be reported. Rain gauges operated near the drainage area by the National Weather Service may be used, or the discharger may collect this information;

- The time elapsed since the last rainfall event greater than 0.1 inches. Historical rainfall data from rainfall gauges can be used to provide this information. If a gauge records only daily data, municipal field personnel could be asked to provide information on times during the day a rainfall event began or ended.

5.3.4 Chemicals/Water Quality Parameters to be Measured

The storm water discharge samples must be analyzed for a number of pollutant parameters.

> **§122.26(d)(2)(iii)(A)(3)** For samples collected and described under paragraphs (d)(2)(iii)(A)(1) and (A)(2) of this section, quantitative data shall be provided for: the organic pollutants listed in Table II; the pollutants listed in Table III (toxic metals, cyanide, and total phenols) of appendix D of 40 CFR part 122, and for the following pollutants:
>
> Total suspended solids (TSS)
> Total dissolved solids (TDS)
> COD
> BOD_5
> Oil and grease
> Fecal coliform
> Fecal streptococcus
> Ph
> Total Kjeldahl nitrogen
> Nitrate plus nitrite
> Dissolved phosphorus
> Total ammonia plus organic nitrogen
> Total phosphorus
>
> *[Note that total kjeldahl nitrogen is actually a substitute for total ammonia plus organic nitrogen.]*

The complete list of chemicals is provided in Exhibits 5-2, 5-3, and 5-4. Exhibits 5-2 and 5-3 are derived from 40 CFR Part 122, Appendix D, Tables II and III, respectively. Exhibit 5-4 comes from the text of the regulation (see box above). The EPA-approved analysis procedure for the pollutants in Exhibits 5-2 and 5-3 can be found in 40 CFR Part 136. If a municipality is seeking approval to use an alternative method of analysis, then a request should be made according to procedures outlined in 40 CFR 136.4.

Section 122.21(g)(7) specifies that certain pollutant parameters will be analyzed on grab samples taken from the outfall, whereas the remainder of the pollutant parameters require that composite samples be taken from the outfall. These types of sampling procedures are differentiated as follows:

Grab samples: discrete, individual samples taken within a short period of time (usually less than 15 minutes). Analysis of grab samples characterizes the quality of a storm water discharge at a given time of the discharge. The following measurements must be made from grab samples:

- pH
- Temperature
- Cyanide
- Total phenols
- Residual chlorine
- Oil and grease
- Fecal coliform
- Fecal streptococcus

Note that measurements of temperature and pH must be taken in the field to avoid time-dependent changes that may occur between sampling time and actual analyses.

Flow-weighted composite samples: single unit volumes composed of a mixture of samples collected proportional to flow throughout the entire runoff event or at least for the first three hours of the storm water event, if it lasts more than three hours. The flow-weighted composite sample must consist of at least three discrete aliquots per hour from the storm water discharge, or a continuous sampler may be used.

All parameters (see Exhibits 5-2, 5-3, 5-4) not listed under the description of grab samples above must be analyzed from flow-weighted composite samples. Details on taking flow-weighted composite samples may be found in the EPA *Storm Water Sampling Guidance Document*.

5.3.5 Additional Quantitative Data

Section 122.26(d)(2)(iii)(A) concludes with a provision that allows the permitting authority to request additional quantitative data if necessary to determine permit conditions.

> **§122.26 (d)(2)(iii)(A)(4)** Additional limited quantitative data required by the Director for determining permit conditions (the Director may require that quantitative data shall be provided for additional parameters, and may establish sampling conditions such as the location, season of sample collection, form of precipitation (snow melt, rainfall) and other parameters necessary to insure representativeness);

To ensure the storm water discharge system is accurately represented, the permitting authority may require that quantitative data include additional parameters and may establish specific sampling conditions, such as:

- Location where the sample is taken;
- Season of sample collection;
- Form of precipitation (snowmelt, rainfall);
- Evidence of impact to aquatic ecosystems; or
- Other parameters necessary to ensure the system is accurately characterized.

The data generated from the qualitative and quantitative analyses described under §122.26 (d)(2)(iii)(A) will be used to calculate the annual pollutant loads and event mean concentrations for each pollutant as described in subsequent parts of this section. Estimates of annual pollutant loads and event mean concentrations would then be used to assist in establishing storm water management priorities and selecting BMPs.

5.4 ESTIMATION OF SYSTEM-WIDE EVENT MEAN CONCENTRATIONS AND ANNUAL POLLUTANT LOADS

The applicant must submit estimates of the event mean concentration and annual pollutant load of the cumulative discharges to waters of the United States from all identified municipal outfalls.

> **§122.26(d)(2)(iii)(B)** Estimates of the annual pollutant load of the cumulative discharges to waters of the United States from all identified municipal outfalls and the event mean concentration of the cumulative discharges to waters of the United States from all identified municipal outfalls during a storm event (as described under §122.21(g)(7)) for BOD_5, COD, TSS, dissolved solids, total nitrogen, total ammonia plus organic nitrogen, total phosphorus, dissolved phosphorus, cadmium, copper, lead, and zinc. Estimates shall be accompanied by a description of the procedures for estimating constituent loads and concentrations, including any modelling, data analysis, and calculation methods;

Estimates of annual pollutant loads will be somewhat imprecise; however, municipalities should exercise best professional judgement in deriving these estimates. A description of what assumptions were made to derive pollutant loadings must be included.

Under §122.26(d)(2)(iii)(B) (see box above) applicants must provide the following:

- Estimates for the event mean concentration for pollutants listed in Exhibit 5-5 below, which can be used to estimate the annual pollutant load associated with all municipal outfalls identified under §122.26(d)(1)(iii) and (d)(2)(ii);

R0009983

- A description of the procedures for estimating constituent loads and concentrations; and
- Details on data analysis, models used, and calculation methods.

Data sources and procedures that municipal applicants may use to estimate event mean concentrations and annual pollutant loads of the cumulative discharges are discussed below.

The primary purpose for estimating annual pollutant loads and event mean concentrations is to assign priorities for implementing BMPs. Municipalities should consider the magnitude of individual pollutant loadings when assigning priorities to resources to reduce these loadings. The areas receiving the highest priority for implementation of BMPs will be those portions of the MS4 that appear to contribute the largest load of pollutants to the system. Therefore, it is the relative value of these calculations that is of importance within this regulation, not the absolute value.

Over time the accuracy of the available methods to calculate loads and concentrations will improve and the use of these estimates may assume a larger role in determining permit conditions and estimating the success of the comprehensive municipal storm water management program. The emphasis for now, however, is on the application of the most practicable methods to reasonably estimate annual loads and event mean concentrations.

5.4.1 Data Sources

The Part 1 application requires municipalities to submit all existing storm water sampling data, along with all relevant water quality data, sediment data, fish tissue or other biosurvey data taken over the past 10 years. All historical data must accompanied by a narrative description of the watershed served by the outfall from which the data are obtained, a description of the sampling and quality control program, and the monitoring location of the receiving water.

To estimate an annual pollutant load for a given pollutant, a value must be derived for the average concentration, or event mean concentration, of that pollutant. To derive this value, applicants may use either site-specific data, or data from a national or regional study, such as NURP.

Municipalities with adequate historical data may choose to use these data to estimate annual pollutant loads in the Part 2 application. However, many applicants may not have enough site-specific data to develop valid estimates. These applicants may choose to use generic data (e.g., from regional and national studies), such as the data provided in the NURP study. The NURP study's estimated range of detected concentration for specific pollutants is summarized in Exhibit 5-6.

Exhibit 5-5: Pollutants for which Event Mean Concentrations and Annual Pollutant Loads Must be Calculated

Pollutant	Pollutant
BOD$_5$	Total phosphorus
COD	Dissolved phosphorus
TSS	Cadmium
Dissolved solids	Copper
Total nitrogen	Lead
Total ammonia plus organic nitrogen	Zinc

Source: 40 CFR 122.26(d)(2)(iii)(B) (55 FR 48070, November 16, 1990)

Exhibit 5-6. NURP Study Range of Detected Concentration for Specific Pollutants

Parameter	Concentrations µg/L
Metals and inorganics:	
Antimony	2.6 - 23
Arsenic	1 - 50.5
Beryllium	1 - 49
Cadmium	1 - 14
Chromium	1 - 90
Copper	1 - 100
Cyanides	2 - 300
Lead	4 - 23,000
Nickel	1 - 182
Selenium	0.2 - 0.8
Zinc	10 - 2400
Pesticides:	
Alpha-hexachlorocyclohexane (alpha-BHC)	0.027 - 0.10
Alpha-endosulfan	0.008 - 0.20
Chlordane	n/a
Lindane (gamma-BHC)	0.007 - 0.1
Halogenated aliphatics:	
Methane, dichloro-	5 - 14.5
Phenols and cresols:	
Phenol	1 - 13
Phenol, pentachloro-	1 - 115
Phenol, 4-nitro	1 - 37
Phthalate esters:	
Phthalate, bis(2-ethylhexyl)	4 - 62
Polycyclic aromatic hydrocarbons:	
Chrysene	0.6 - 10
Fluoranthene	0.3 - 2
Phenanthrene	0.3 - 10
Pyrene	0.3 - 16

Source: U.S. Environmental Protection Agency, *Results of the Nationwide Urban Runoff Program*, EPA Planning Division (National Technical Information Service (NTIS) Accession No. PB84-8552). December 1983.

The applicant should be aware of limitations associated with data from national and regional studies before deciding on methods to estimate pollutant loadings. In some cases, it may be more appropriate to use any available site-specific data rather than data from national or regional studies. For example, the NURP study did not collect pollutant concentration data from industrial areas. In this instance, even limited site specific concentration data from industrial areas may be more meaningful.

EPA encourages applicants to seek data from a variety of sources to better characterize the quality of their storm water discharges. Regardless of the data source, a description of the procedures for estimating constituent loads and concentrations, including any modeling, data analysis, and calculation methods, must be included.

There will be a degree of uncertainty associated with estimating pollutant loadings in the Part 2 application. The requirement to calculate pollutant loadings and concentrations is intended to be a planning and screening effort to assign program priorities, and not necessarily to determine absolute values.

5.4.2 Event Mean Concentrations

Event mean concentrations (C_i in Equation 1 on page 5-16) are determined from analyses of flow-weighted composite samples collected from each of the designated field screening points. Section 2.2.4 of the *Storm Water Sampling Guidance Document* describes procedures for collecting flow-weighted composite samples (EPA, 1992a). Concentration values must be reported in the applicant's Part 2 Permit Application for each representative storm event sampled. The applicant should report the average of these results as the event mean concentration for each parameter measured. Municipalities are encouraged to present data in a tabular format. However, the applicant has flexibility to present the data in other ways, provided the data is clearly presented.

As stated previously, applicants must sample storm events for at least three hours, or for the entire storm event if it lasts less than three hours. If a storm event lasts more than three hours, the applicant may choose among three approaches for calculating the event mean concentration of the storm. First, the applicant may report the event mean concentration for the first three hours of the event (or longer, if the applicant monitored more than three hours). Second, if the applicant has data available on the correlation between flow and concentration which allows it to be more specific about the event mean concentration, an estimation technique may be used to derive the event mean concentration. If the applicant uses such an estimation technique, the methodology must be explained. Third and finally, the applicant may monitor the entire storm event and report the actual event mean concentration.

Whichever approach the applicant uses, the same method should be used to derive event mean concentrations in the future. This will assist the applicant in identifying meaningful trends in changes in event mean concentrations over time.

5.4.3 Annual Pollutant Loadings

Municipalities may choose from a variety of acceptable procedures for estimating the annual pollutant loads of the cumulative discharge. This guidance contains an example of calculating the annual pollutant loads using the "simple method," which is adapted from Schueler (1987). The guidance also discusses some dynamic models that applicants may wish to employ.

Regardless of which method applicants choose, they must describe and document the specific technique used. The description should include (but is not limited to) the key equations used to calculate reported values, such as:

- Assumptions for selecting site-specific parameters (e.g., runoff coefficients);

- References to any source documentation (e.g., previously completed studies or reference textbooks); and

- Justification for any assumed parameter values.

The Simple Method

The following method of computing pollutant loadings is referred to as the "simple method" and is adapted from Schueler (1987). For purposes of satisfying Part 2 application requirements, the simple method provides a quick and reasonable estimate of pollutant loadings with a minimal amount of data required. Although the regulations require a system wide (cumulative) annual pollutant load calculation for each of the pollutants listed in Exhibit 5-5 (above), the single pollutant load values provide limited insights into potential problem areas and what BMPs might yield the best results. Consequently, the municipality may want to consider using the simple method to estimate "individual" pollutant loadings from drainage areas. The individual pollutant loadings can be aggregated to derive a cumulative annual pollutant loading for the entire MS4. In the procedure below, for example, Step 1 computes the annual loading for each outfall of the MS4. Then in Step 2, the resulting pollutant loadings are summed to derive annual pollutant loads on a per-watershed basis. In Step 3, the annual pollutants loads for each watershed are summed to derive a system-wide annual pollutant load.

As stated above, this procedure is only one example of how a municipality could calculate a system-wide annual pollutant load. Estimates of annual pollutant loads for individual outfalls, watersheds, or other discrete areas are not specifically required by the regulations. However, municipalities will find such estimates helpful in making relative comparisons among different areas of the MS4. Ultimately, these estimates could assist the municipality with selecting BMPs and assigning priorities to potential problem areas.

Step 1: Use the Simple Method to Calculate Annual Pollutant Loads on a Per-Outfall Basis

The first step in this example is to calculate annual pollutant loads for individual outfalls. However, the applicant may choose to begin by calculating annual pollutant loads for each watershed or other discrete area. As stated above, this example uses the simple method, which is given by the following equation:

EQUATION 1:

$$L_i = \left[\frac{(P)(CF)(Rv_i)}{12}\right](C_i)(A_i)(2.72)$$

where:
- L_i = Annual pollutant load (lb/outfall/yr)
- P = Annual precipitation (in/yr)
- CF = Correction factor that adjusts for storms where no runoff occurs (a value of 0.9 is typically used)
- Rv_i = Weighted-average runoff coefficient for the area served by the outfall (the calculation of runoff coefficients is discussed below)
- C_i = Event mean concentration of pollutant (mg/L)
- A_i = Catchment area (acres)

The numbers 12 and 2.72 are conversion factors that account for unit conversions.

Each of the parameters in Equation 1 is defined below:

- **Annual pollutant load** is the total amount of a specific pollutant discharged in pounds per time period (in this case, per year) for the particular segment of the MS4 being modeled (in this case for each outfall). Pollutant loads may also be expressed for alternative time periods, or on a system-wide or watershed basis.

- **Annual precipitation** is the total inches of rainfall occurring in a single year plus the contribution of snowmelt. Estimates of the annual rainfall can be based on the rainfall data provided in Part 1 of the application.

- **Correction factor** is an adjustment factor for the number of storm events that do not actually produce any runoff (i.e., the percentage of storm events that have a total accumulation greater than a specific threshold value). This value will vary by region. Without this adjustment factor, the municipality would be assuming that all storm events produce runoff, which may or may not be the case. A typical value for this correction factor is 0.9 (90%). However, this value can vary between climatic regions. Municipalities should review historical rainfall data to estimate the percentage of storm events that produce runoff versus the number of storm events per year.

- **Weighted-average runoff coefficient** is a relative measure of imperviousness or the percentage of rainfall that becomes surface runoff. Runoff coefficients are a function of the type of surface, intensity of the rainfall, the degree of soil saturation and storativity (storage capacity) of the soil. To deterimine runoff coefficients, the municipality may use Equations 2 or 3 (which follow). Alternatively, the municipality may use actual field measurements, relevant hydrologic studies, average values published in civil engineering reference manuals, or default values provided in Exhibit 3-12 of EPA's *NPDES Storm Water Sampling Guidance Document*.

- **Event mean concentration of pollutant** is the event mean concentration value for the specific pollutant determined from the analysis of flow-weighted composite samples. Equation 1 requires a value for each pollutant concentration. As discussed previously, the applicant may use site-specific concentration data (e.g., storm water sampling data) or generic (e.g., NURP) data to derive event mean concentrations. In other words, the applicant should use best professional judgement to decide which of the following concentration values to use:

  - a mean concentration value from the NURP study;

    OR

  - an average of all event mean concentrations from all samples over three representative storm events;

    OR

  - an event mean concentration attributable to a specific land use activity.

  The applicant will have to consider the extent of the variability of the data when selecting an appropriate concentration value. NURP or other regional studies used to estimate pollutant concentrations can be compared to existing site-specific data in order to assess the uncertainty associated with generic approaches.

- **Catchment area** is the size of the drainage area for the particular segment of the MS4 being modeled (in this case, the outfall drainage area). Areas that are served by combined sewers or that are not otherwise served by the MS4 should not be included.

Weighted-average runoff coefficient. Runoff coefficients can be based on flow measurements or estimated from land use characteristics. In order to determine an average runoff coefficient for an area with a diversity of land use activities, the following equation should be used to estimate a weighted-average runoff coefficient:

EQUATION 2

$$Rv_i = \frac{(\sum A_t R_v)}{\sum A_i}$$

where: Rv_t = Weighted-average runoff coefficient
A_t = Catchment area (acres)
R_v = Catchment runoff coefficient

As an alternative to Equation 2, Equation 3 can be used to estimate weighted-average runoff coefficients from percent imperviousness data (Shelley, 1986):

EQUATION 3

$$Rv_i = 0.05 + 0.009 * I$$

where: Rv_t = Weighted-average runoff coefficient
I = Percent imperviousness

The percent imperviousness can be estimated from land use data. Residential land can be assumed to be 24% impervious; commercial land 75% impervious; industrial land 55% impervious; and open space 15% impervious. The percent imperviousness of residential land was estimated from the following empirical equation of NURP and USGS data, which relates population density to percent imperviousness:

EQUATION 4

$$I = 9 * D^{0.5}$$

where: I = Percent imperviousness
D = Population density (persons/acre)

Similar to Equation 1, individual parameters for Equations 2, 3, and 4 can be used on a system-wide basis, or modified to reflect more realistic conditions within smaller or discrete segments (e.g., individual watersheds or outfalls).

Step 2. Use the Per-Outfall Annual Pollutant Loads to Calculate Per-Watershed Annual Pollutant Loads

If the simple method is used to compute the annual loading on a per-outfall basis, Equation 5 may be used to estimate annual pollutant loadings on a per watershed basis. The approach of computing pollutant loadings on a watershed basis is used by some counties where larger watersheds are segregated into smaller watersheds or drainage areas on the basis of similar land use designations. One county uses this method in conjunction with forecasts of future development within the county to develop preliminary estimates of future pollutant loadings. This approach minimizes the possibility of computing an annual pollutant loading that is too conservative.

EQUATION 5

$$L_w = \sum L_i$$

where: L_w = Annual pollutant load for a particular watershed
$\sum L_t$ = Summation of individual annual pollutant loadings from all major outfalls within a specific watershed

Step 3: Use the Watershed-Based Annual Pollutant Loads to Calculate System-Wide Annual Pollutant Loads

To calculate the annual loadings system-wide, use the following equation:

EQUATION 6

$$L_n = \sum L_w$$

where: L_n = Annual pollutant load for an entire MS4

$\sum L_w$ = Summation of individual annual pollutant loadings from all watersheds within a municipal separate storm sewer system

Dynamic Models

In instances where a municipality has a significant amount of historical data for the drainage areas serviced by storm sewer outfalls, including historical precipitation data and receiving water concentration and flow data, the MS4 may elect to use dynamic models to derive pollutant loads and to analyze the effects of MS4 discharges on receiving waters.

Dynamic models are designed to calculate a complete probability distribution for the output being modeled. Therefore, dynamic models take into consideration the inherent variability of data associated with MS4 discharges, such as variations in concentration, flow rate, and runoff volume.

One benefit of using a dynamic model is that the calculation of a complete probability distribution allows the modeler to consider a multitude of "what-if" scenarios. For example, when sufficient historical data is available, the modeler could consider the benefits and risks associated with alternative BMP strategies.

Dynamic models have one additional benefit over steady-state models in that dynamic models determine the entire discharge concentration frequency distribution. Consequently, this would enable the modeler to examine the effects of storm water discharges on receiving water quality in terms of the frequency by which water quality standards may be exceeded. For purposes of computing pollutant loadings, a number of models are available including EPA's Stormwater Management Model (SWMM) and Hydrologic Simulation Program (HSPF); U.S. Army Corps of Engineers' Storage, Treatment, Overflow, Runoff Model (STORM); and Illinois State Water Survey's Model QILLUDAS (or Auto-QI).

Regardless of the method employed, the applicant must document how pollutant loadings are derived. Applicants must provide estimates of annual pollutant loads and event mean concentrations for each outfall with their Part 2 applications. However, some outfalls will need to be more completely characterized, and conditions will change after the permit is approved. This is one reason why, as described in Section 5.4, data collection will continue throughout the term of the permit. Estimates of the individual contribution of pollutant loadings for each watershed or major outfall will help the applicant select priorities for specific watersheds.

5.5 PROPOSED SCHEDULE FOR SEASONAL LOADS AND REPRESENTATIVE EVENT MEAN CONCENTRATIONS OF MAJOR OUTFALLS

> **§122.26(d)(2)(iii)(C)** A proposed schedule to provide estimates for each major outfall identified in either paragraph (d)(2)(ii) or (d)(1)(iii)(B)(*1*) of this section of the seasonal pollutant load and of the event mean concentration of a representative storm for any constituent detected in any sample required under paragraph (d)(2)(iii)(A) of this section;

Seasonal pollutant loads are important because they are a more accurate representation of loadings that may occur during a short time interval. To further refine the annual pollutant load estimates, Part 2 requires the applicant to propose a schedule to estimate seasonal pollutant loadings and event mean concentrations for each major outfall.

The quality of the data available when the Part 2 application is prepared will affect the accuracy and usefulness of the initial estimates of pollutant loadings and average concentrations. These estimates can be improved as more site-specific data are collected during the term of the permit. A long-term site specific monitoring program will capture the variability in data that is essential to estimate more accurate pollutant loadings over time. Therefore, the impacts associated with these loadings can also be estimated with greater certainty. In addition, a site specific record collected over a longer time frame allows the effectiveness of the comprehensive municipal storm water management program to be evaluated.

Estimates must be submitted for any contaminant detected in any sample required under the Part 2 sampling effort [§122.26(d)(2)(iii)(B)]. Seasonal pollutant load estimates are required for any pollutants listed in Exhibits 5-2, 5-3, and 5-4 that were detected during the sampling procedure described in Section 5.3.4. Therefore, the analyses required for seasonal pollutant loads will potentially be more comprehensive than the analyses of annual pollutant loads. This results from the possibility that additional pollutants will be detected as part of the storm water characterization studies.

In some regions, precipitation patterns vary significantly from season to season, resulting in significantly different pollutant loadings throughout the year. In arid and semi-arid parts of the country, pollutants accumulate during dry spells, resulting in significantly higher pollutant concentrations in storm water discharges after extended dry weather. Because of the buildup of accumulated pollutants, pollutant concentrations in discharges from MS4s are typically highest during the "first flush," or initial discharge.

In other regions, pollutants that accumulate in snow may lead to high pollutant concentrations in runoff from the spring thaw. Therefore, using an annual average pollutant loading might disguise the impact of shock loadings (discharges that occur within a very short time period and which often exceed acute toxicity criteria) of certain pollutants. Numerous factors contribute to the total volume of snowmelt runoff including shortwave and longwave radiation, condensation or vaporization, convected heat transfer by wind, heat content of rain water, and conductive heat transfer from the ground. Therefore, for regions with significant snowfall, pollutant loading estimates need to be adjusted to account for the additional volume of runoff attributable to snowmelt.

Since snowmelt runoff can occur in either the presence or absence of a storm event, the computation of seasonal pollutant loadings becomes significantly more complex. The determination of total snowmelt runoff, however, is beyond the scope of this manual. Affected municipalities are encouraged to contact the U.S. Geological Survey or the Army Corps of Engineers for historical data on snowmelt runoff.

The effects of pollutant load can also vary by season. Nutrient pollutant loads from storm water discharges can promote algal blooms in receiving waters during the spring and summer, but they may be of little consequence during winter in surface waters with good flushing characteristics. Quantifying seasonal variations in pollutant loads may aid the development of more cost-effective storm water management programs.

Pollutant loads also may vary significantly from one outfall to another. Within a drainage area, the type of land use, the percent of surface that is impervious, and the extent of exposure of storm water to contaminants affect the pollutant load from an outfall. Procedures for estimating seasonal pollutant loadings must be proposed for major outfalls only.

Under §122.26(d)(2)(iii)(C) the regulation requires a schedule to provide estimates of:

- The seasonal pollutant load for each identified major outfall.
- The event mean concentration of a representative storm for any constituent detected in any sample required.

The following steps can be taken to develop a proposed schedule for estimating seasonal loadings at major outfalls:

1. Use historical or long-term hydrologic data to define seasons.
2. Describe the procedure to be used to estimate seasonal loads. This could be an adaption of the simple method or another mathematical model used for annual loads (e.g., instead of using a total annual rainfall accumulation, use an average rainfall accumulation associated with a specific season). If the simple method is used, the municipality could still use Equation 1. However, the amount of rainfall (P) would no longer be an annual value. Instead, it would be the amount of rainfall associated with a particular season defined by the municipality. In addition, the applicant may have to adjust the average runoff coefficient to reflect seasonal changes (e.g., frozen ground can behave like an impervious surface and substantially increase the amount of runoff). Lastly, substantial differences in the frequency and duration of seasonal storm events may increase or decrease the correction factor CF (e.g., during a dry season, the number of storms that actually produce runoff may be substantially lower than during a wet weather season).
3. Identify data elements that need to be refined. In cases where there is substantial seasonal variation, revised runoff coefficient values may be necessary. For example, during rainy seasons, ground surfaces are more saturated than during the dry season. As a result, the same amount of rainfall in the wet season will lead to a greater volume of storm water runoff than in the dry season.
4. Proposed procedures for collecting the appropriate data or otherwise improving estimates.
5. Provide an approximate time frame for data collection and submission of seasonal load estimates.

Proposed procedures for estimating seasonal pollutant loadings and event mean concentrations should explain when and how data used for the estimates will be obtained. The data can be based on site-specific information, or they can be obtained from municipal systems with similar characteristics (such as Regional NURP data).

5.6 COLLECTION OF REPRESENTATIVE DATA FOR PROPOSED MONITORING PROGRAM FOR THE TERM OF THE PERMIT

Under §122.26(d)(2)(iii)(D), applicants are given the opportunity to propose monitoring programs to be carried out during the term of the permit.

> **§122.26(d)(2)(iii)(D) A proposed monitoring program for representative data collection for the term of the permit that describes the location of outfalls or field screening points to be sampled (or the location of instream stations), why the location is representative, the frequency of sampling, parameters to be sampled, and a description of sampling equipment.**

Applicants should consider their specific needs and identify priorities for the proposed monitoring program. After receiving the Part 2 application, the permitting authority will review proposed monitoring programs and make appropriate adjustments when establishing permit conditions.

The applicant must propose a monitoring program for representative data collection for the term of the permit that describes:

- The location of outfalls or field screening points to be sampled (or the location of instream stations);
- Why the location is representative;
- The frequency of sampling;
- Parameters to be sampled; and
- A description of sampling equipment.

Municipalities must submit sampling data over the life of a permit so that changes in storm water quality can be assessed. Like initial sampling data, the data from an on-going monitoring program can be used by the municipality to allocate resources to achieve reduction in pollutants. The monitoring data will also serve as an environmental indicator of the success of the storm water management program. Many municipalities may require an extended period of time (possibly the entire permit term) and substantial data to definitively evaluate the effectiveness of a storm water management program. Therefore, a plan for data collection must be proposed by the municipality for the five-year term of the permit. During the permit term, the results of the monitoring program will be submitted in the municipality's annual report [§122.42(c)(4), discussed in Section 7.3 of this guidance].

5.6.1 Goals of a Monitoring Program

The first and most important step in developing a proposed monitoring program is to define the program's objectives as clearly as possible. Development of monitoring program goals should be closely coordinated with development of the proposed storm water management program. Applicants are required to propose monitoring programs as part of their proposed management programs to reduce pollutants from industrial site runoff. The monitoring plan is part of *Characterization Data* [§122.26(d)(2)(iii)]. The storm water management program is discussed in Section 6.

A comprehensive monitoring program should be designed to support specific goals, including:

- Characterizing discharges;
- Evaluating the source of specific pollutants;
- Evaluating the performance of specific source controls; and
- Identifying the full range of chemical, physical, and biological water quality impacts.

5.6.1.1 Characterizing Discharges

Monitoring pollutants in discharges from MS4s serves several purposes. Quantitative data on specific pollutants in storm water runoff can support estimates of annual and seasonal pollutant loadings and modelling efforts to identify the magnitude of water quality impacts. Over the long term, monitoring data may suggest that new outfalls should be selected for sampling. As municipalities gain experience in storm water sampling, they likely will target BMPs that achieve the greatest improvements in storm water quality.

5.6.1.2 Evaluating the Source(s) of Specific Pollutants

Some sources of storm water (e.g., industrial sources that must be covered by NPDES permits, highways with heavy traffic flows, and large parking lots) are expected to generate significantly higher concentrations of pollutants than typical urban runoff. Monitoring efforts to quantify sources of priority pollutants can provide support for resource allocations to address pollutant sources posing the greatest environmental risk. How proposed monitoring efforts will be structured to identify and quantify pollutant sources should be discussed in proposed storm water management programs.

The monitoring program may also include procedures to conduct dry-weather monitoring over the term of the permit to help detect illicit discharges and improper dumping. This can include recording visual observations and odors observed in dry weather flows.

5.6.1.3 Evaluating the Performance of Specific Controls

Pollutant removal efficiencies are fairly well known for certain structural BMPs. However, sampling may still be necessary to ensure that the BMP is meeting original design expectations. The expected pollutant removal efficiency for a structural control must take into account site-specific conditions. For example, an infiltration basin has a certain expected pollutant removal efficiency, but actual field efficiency is affected by subsurface soil conditions and the extent and frequency of maintenance.

The efficiency of a particular structural control will be affected by many factors, such as detention time. However, efforts to determine the efficiency of structural controls must include consideration of pollutant concentrations and flow volumes into and out of the control. The efficiency of nonstructural source controls can be characterized by comparing discharges at a given location before and after the control measures are implemented. Over time, sufficient monitoring data may be gathered to draw substantive conclusions about the effectiveness of certain BMPs. Alternatively, discharges from a sampling site with source controls can be compared with discharges from a similar site that lacks source controls. Efforts to monitor the effectiveness of controls should be closely coordinated with the assessment of control efficiencies discussed in Chapter 7.

5.6.1.4 Identifying the Full Range of Chemical, Physical, and Biological Water Quality Impacts

Characterizing the effect of storm water discharges on water quality is complicated by a number of factors. EPA recommends an integrated approach to assessing water quality impacts associated with discharges from MS4s. Monitoring procedures that help assess water quality impacts include:

- Discharge and receiving water monitoring to support water quality models and to identify hydraulic impacts of increased peak flows and to identify parameters of concern; and
- In-stream monitoring of water chemistry;
- Bioassessments and biosurveys; and
- Sediment sampling.

<u>Discharge and Receiving Water Monitoring to Support Water Quality Models</u>

As discussed above, when there is sufficient historical data available from monitoring, these data may be used as inputs to models that predict or validate the effects of pollutant loadings from MS4s on receiving water quality characteristics. In addition to monitoring data, data on receiving water quality characteristics are also necessary to calibrate a particular model.

Once the model has been calibrated to reflect site-specific conditions, future monitoring data could be used to validate long term reductions in pollutant loadings, the effectiveness of nonstructural BMPs, and/or pollutant removal efficiencies of existing structural controls.

The information gathered from this approach may also help define those BMPs that which appear to be the most effective. For example, in developing areas, monitoring data could eventually support future planning efforts that would seek to minimize the impact of future development on local receiving waters.

In-stream Monitoring

Using models to estimate pollutant concentrations in receiving waters can be inaccurate. In-stream monitoring can directly measure pollutant concentrations. General designs for in-stream monitoring are:

- **Monitoring above and below a set location.** This method is generally more useful for evaluating control effectiveness than documenting the severity of a diffuse source of pollutants.

- **Monitoring at different times.** Monitoring at different times and seasons can provide valuable information on seasonal variations in pollutant concentrations. Dry weather in-stream monitoring can be compared with in-stream monitoring during storm events.

- **Paired watersheds.** Evaluating similar water bodies can document management program improvements by controlling for meteorologic and hydrologic variability. This approach can also be used to compare receiving waters to background conditions associated with undeveloped watersheds.

Detailed guidance on applying these approaches is provided in the draft *Nonpoint Source Monitoring and Evaluation Guide*, February 26, 1988, Nonpoint Source Branch, U.S. EPA.

Bioassessments and Biosurveys

A biological assessment, or "bioassessment," is an evaluation of the biological condition of a water body using biological surveys and other direct measurements of resident biota in surface waters. A biological survey or "biosurvey," consists of collecting, processing, and analyzing representative portions of a resident aquatic community to determine the community structure and function. Biosurveys and bioassessments can be used directly to evaluate the overall biological integrity (structure and/or functional characteristics) of an aquatic community. Deviations from the biological integrity can be measured directly using biosurveys only when the impacted community is compared against a predetermined reference condition. Without the proper reference conditions, biosurveys may underestimate the extent of impairment.

Biosurveys are useful in that they can assess or detect the aggregate effect of impacts upon an aquatic community where discharges are multiple, complex, and variable, and where point, nonpoint, and storm water discharges are all affecting the biological condition of the receiving water. Because of this, biosurveys cannot measure the impacts of one particular discharge or effluent being discharged to receiving waters. Currently, biosurveys cannot be used as a predictive water quality assessment tools.

Biosurveys provide a useful monitor of both aggregate ecological impact and historical trends in the condition of an aquatic ecosystem. They can also detect impacts that other assessment methods may miss. More importantly, biosurveys can detect impacts caused by habitat degradation such as channelization, sedimentation, and historical contamination that disrupt the interactive balance of the components of the aquatic community.

Sediment Sampling

Pollutants, both organic and inorganic, associated with storm water discharges may become physically or chemically bound with sediment particles. Depending upon the size distribution of the sediment particles, a portion of the contaminated sediment particles will settle out of the water column. Consequently, the potential exists for a buildup of contaminated sediment over time. The effects of heavily contaminated sediments on both benthic habitat and water quality have been documented to the extent that EPA is developing sediment quality criteria (SQC) that will allow assessments of the toxicological effects of contaminated sediments on varying types of receiving waters.

The amount of sediment material found in storm water discharges suggests that applying sediment quality criteria could be a useful component of a monitoring program. For example, sediment quality criteria could be a valuable preventative tool to ensure that point source discharges of storm water do not cause or contribute to the contamination of sediments.

In addition, a MS4 could make comparisons of field measurements to sediment quality criteria as a means of providing an early warning of a potential problem. Consequently, an early warning could provide an opportunity to take corrective action to prevent further contamination. For long term planning, consideration could also be given to the feasibility of establishing target levels or goals that would ensure that point sources discharges of storm water do not contribute to sediment contamination.

5.6.2 Monitoring Procedures

Monitoring procedures will depend on the objectives of the monitoring effort. To a large extent, the type of receiving water will be an important factor in developing monitoring procedures and techniques. For example, grab samples may be appropriate for monitoring discharges from a retention pond, while composite samples may be appropriate for monitoring flows into the pond. The following information, at a minimum, should be included for each sampling site:

- The criteria for storm selection;
- Whether grab, composite, continuous, or other sampling techniques are to be used;
- The criteria on when to begin and end sample collection;
- The basis for selecting the time interval between sequentially collected samples;
- How seasonal factors affect the selection of monitoring frequencies;
- The method of estimating rates or volumes of flow passing the sampling point; and
- The analytical methods used for analyzing pollutant parameters and their detection limits.

Location of Monitoring Sites and Description of Drainage Basins

The selection of monitoring sites should depend on the goals of the monitoring program. Applicants should identify the location of each proposed monitoring site and the boundary of its drainage basin. They should describe the estimated size and land use characteristics of the drainage basin for each sampling location. The applicant also should explain why the sampling sites are representative or will otherwise provide information to support a monitoring program goal. Other monitoring sites can be selected to evaluate unique conditions in the drainage area that have significant or unusual potential for generating pollutants in storm water discharges.

Samples should be analyzed in accordance with the analytical methods approved under 40 CFR Part 136.

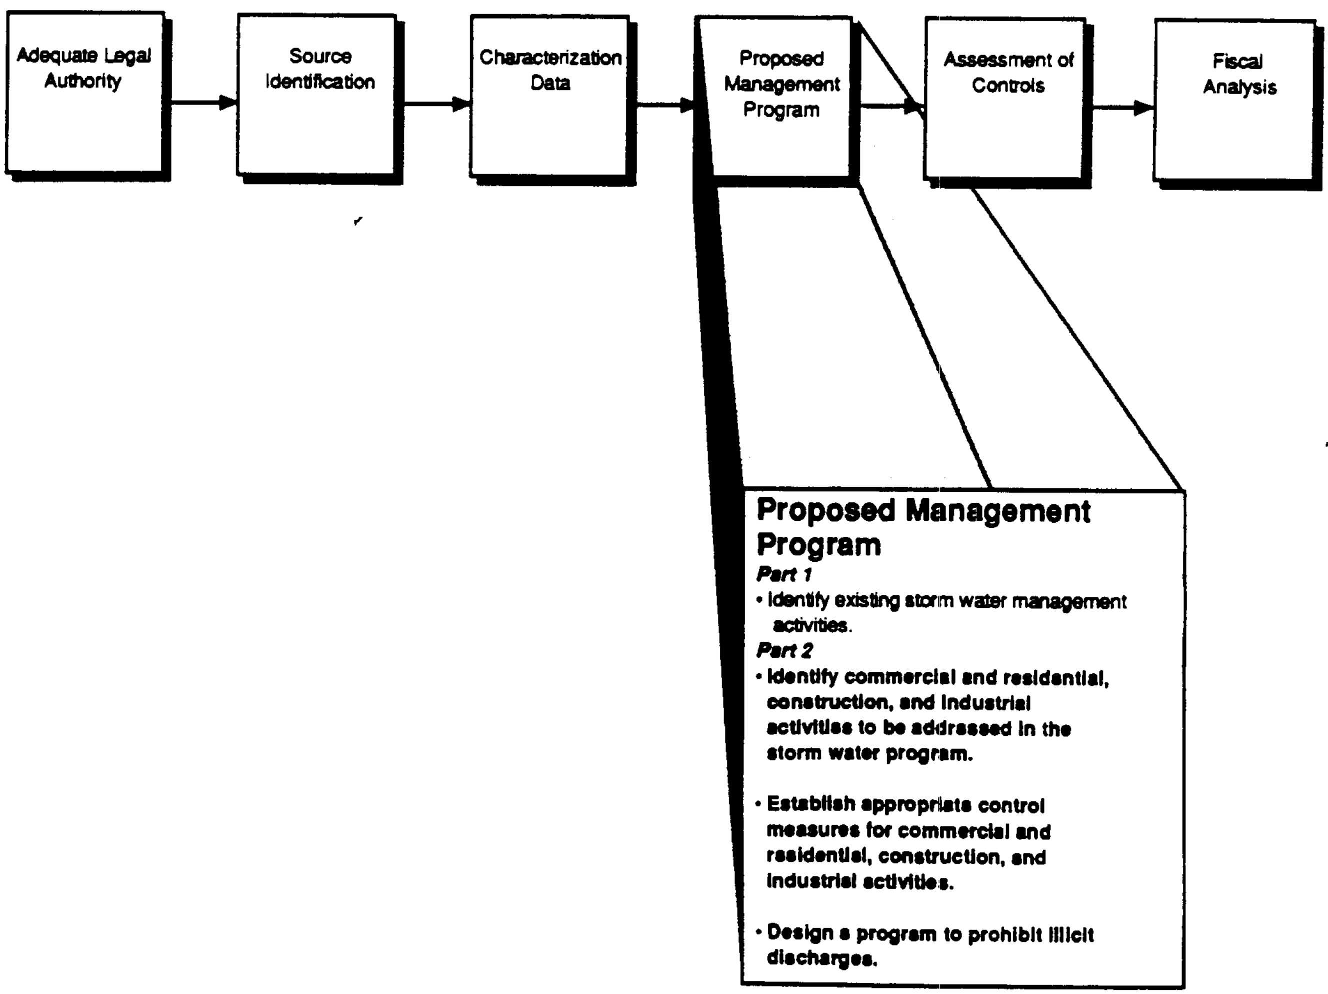
Parameters to be Analyzed

The applicant must list all parameters to be analyzed, which should depend on the objective of the sampling effort. For example, it may only be necessary to monitor several indicator parameters (such as TSS, settleable solids, nutrient, and a metal) to characterize the pollutant removal efficiency of a wet pond.

Sampling Equipment

The applicant must describe the equipment to be used in the proposed sampling program. Only the primary pieces of equipment need be identified. Descriptions can be made by reference to equipment supplied by a vendor or manufacturer if distinctive enough to be readily identified.

CHAPTER 6
PROPOSED MANAGEMENT PROGRAM



6.0 PROPOSED MANAGEMENT PROGRAM

6.1 BACKGROUND

Under the Part 2 application requirements, municipalities must propose site-specific storm water management programs. This is the most important aspect of the permit application. The Part 2 application requirements provide each MS4 with the flexibility to design a program that best suits its site-specific factors and priorities.

The regulations require the applicant to provide a description of the range of control measures considered for implementation during the term of the permit. Applicants must meet all the requirements of the Part 2 application regulation. However, flexibility in developing permit conditions is encouraged by allowing municipalities to emphasize the controls that best apply to their MS4. For example, a municipality that expects significant new development may focus more on requirements for new development and construction, while a municipality that does not expect significant new development may focus more on a program to prohibit illicit discharges or control industrial contributions. In any case, a satisfactory proposed management program will address: management practices; control techniques and systems; design and engineering methods; and other measures to ensure the reduction of pollutants to the "maximum extent practicable (MEP)."

If the municipality proposes a thorough and complete program, the permitting authority is likely to incorporate all or part of the proposed management program into the NPDES storm water permit written for that municipality. Therefore, the proposed programs provide municipalities with the opportunity to have substantial input into their NPDES permit conditions.

This section of the guidance manual describes the minimum information requirements for proposed storm water management programs. Examples of how the program elements should be addressed are provided. These examples illustrate minimum information requirements for the program elements, and occasions when municipalities may opt to go beyond minimum requirements in order to meet the MEP standard.

6.2 SUMMARY OF REGULATORY REQUIREMENTS

The municipality must develop and submit a proposed management program that covers the duration of the permit. The program must integrate the information and actions described in the Part 1 application and portions of the Part 2 application (see Chapters 3, 4, and 5 of this guidance). The regulatory requirements for the proposed management program are in 40 CFR 122.26(d)(2)(iv).

At a minimum, the proposed management program must include:

- A comprehensive planning process that involves both public participation and intergovernmental coordination;
- A description of management practices, control techniques, and system design and engineering methods to reduce the discharge of pollutants to the MEP; and
- A description of staff and equipment available to set up and assess the storm water management program.

Additional provisions under §122.26(d)(2)(iv)(A) require applicants to include:

- Programs to control storm water runoff from commercial and residential areas, construction sites, and industrial facilities (including waste handling sites), (Section 6.3);

- Identification of structural control measures to be included in these proposed programs, such as detention controls, infiltration controls, and filtration controls that the municipality plans to apply to the activities addressed in its storm water management program (Section 6.4); and

- Programs to detect and remove illicit discharges, and to control and prevent improper disposal into the MS4 of materials such as used oil or seepage from municipal sanitary sewers (Section 6.5).

6.3 PROGRAMS TO CONTROL STORM WATER RUNOFF FROM COMMERCIAL AND RESIDENTIAL AREAS, CONSTRUCTION SITES, AND INDUSTRIAL FACILITIES

A proposed management program must identify the activities or areas that require controls to reduce pollutants in storm water runoff. Specifically, a proposed management program must address storm water runoff from **commercial and residential areas** (Section 6.3.1), **construction sites** (Section 6.3.2), and **industrial facilities** (Section 6.3.3). Also, areas where illicit connections or illegal discharges may occur must be identified (Section 6.5).

In addition to the requirements of the proposed storm water management program, other provisions of the Part 1 and Part 2 applications require information that will help enable the municipality to focus on identifying activities and areas that may need control measures. Examples of these provisions include:

- Identification of sources [Part 1, §122.2(d)(1)(iii)(B)(3)-(4), and Part 2, §122.26(d)(2)(ii)];

- Identification of water bodies that may be adversely affected by storm water runoff [Part 1, §122.26(d)(1)(iv)(C)];

- Organization of sources by watershed [Part 2, §122.26(d)(2)(ii)];

- Description of land use activities [Part 1, §122.26(d)(1)(iii)(B)(2)];

- Results of field screening analysis [Part 1, §122.26(d)(1)(iv)(D)];

- Results of the sampling program [Part 2, §122.26(d)(2)(iii)(A)(3)];

- Estimates of annual pollutant loads and event mean concentrations, and schedules to submit seasonal pollutant loads and event mean concentrations [Part 2, §122.26(d)(2)(iii)(B) and (C)]; and

- Findings from an on-going monitoring program [Part 2, §122.26(d)(2)(iii)(D)].

6.3.1 Commercial and Residential Activities

Under §122.26(d)(2)(iv)(A), applicants must propose structural and source control measures to reduce pollutants from commercial and residential areas.

> **§122.26(d)(2)(iv)(A).** [The proposed management program must include a] description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas that are discharged from the municipal storm sewer system that are to be implemented during the life of the permit, accompanied with an estimate of the expected reduction of pollutant loads and a proposed schedule for implementing such controls.

To ensure that proposed control measures are effective, the applicant should study how storm water runoff from pollutant sources affects the existing municipal system, how the proposed control measures will enhance the existing system, and what impact the proposed measures will have on receiving waters. The control measures should recognize and emphasize the interaction between pollutant sources and the physical attributes of the municipal system and receiving waters.

Specific commercial and residential activities that must be addressed include maintenance activities and a maintenance schedule for structural controls to reduce pollutants in storm water runoff. This provision is discussed in Section 6.4.2. Other activities to be addressed include:

- Post-construction controls to reduce pollutants in discharges to MS4s resulting from new development and significant redevelopment (Section 6.3.1.1);
- Practices for maintaining and operating public streets, roads, and highways that will reduce the impact on receiving waters from storm water runoff discharges (Section 6.3.1.2);
- Procedures to assure that the impacts on receiving waters from flood management projects are assessed, and that existing structural control devices have been evaluated to determine if retrofit controls are feasible (Section 6.3.1.3);
- A program to monitor pollutants in runoff from operating or closed municipal landfills that identifies priorities and procedures for inspections and establishing and implementing control measures (Section 6.3.1.4); and
- A program to reduce to the maximum extent practicable, pollutants in storm water runoff associated with the application of pesticides, herbicides, and fertilizer (Section 6.3.1.5).

To reduce pollutants in storm water runoff from commercial and residential activities, a proposed management program might include the use of infiltration devices, detention and retention basins, vegetated swales, water quality inlets (which may include oil and water or oil/grit separators), screens, channel stabilization/riparian habitat enhancement efforts, wetland restoration and preservation projects, as well as various source control strategies and other nonstructural control measures.

6.3.1.1 New Development and Significant Redevelopment

Summary of Regulatory Requirement

New development or redevelopment often increases impervious land surfaces, which usually leads to increased pollutant levels in storm water runoff. Chemical and thermal changes in storm water runoff are commonly associated with new development and can adversely affect the quality of receiving waters. In addition, urbanization results in an increase in the volume of storm water discharges.

The Nationwide Urban Runoff Program (NURP) study (EPA, 1983) and more recent investigations indicate that controlling the contribution of pollutants in storm water discharges at the onset of land development is the most cost-effective approach to storm water quality management. Mitigating problems caused by pollutants after they have entered a MS4 is often more expensive and less efficient than preventing or reducing the discharge of pollutants at the source. Therefore, a satisfactory proposed management program will propose structural and nonstructural measures to reduce pollutants in storm water discharges from areas of new development and redevelopment. Examples of such measures are discussed below.

> **§122.26(d)(2)(iv)(A)(2).** [The applicant must include a] description of planning procedures including a comprehensive master plan to develop, implement and enforce controls to reduce the discharge of pollutants from municipal separate storm sewers which receive discharges from areas of new development and significant redevelopment. Such plan shall address controls to reduce pollutants in discharges from municipal separate storm sewers after construction is completed.

Provisions under §122.26(d)(2)(iv)(A)(2) focus on the reduction of pollutants in storm water runoff **after** construction in areas where new development or redevelopment is completed. Controls that are required **during** construction are discussed in Section 6.3.2 of this guidance.

Post-Construction Controls

Proposed storm water management programs should include planning procedures for both during and after construction to implement control measures to ensure that pollution is reduced to the maximum extent practicable in areas of new development and redevelopment. Design criteria and performance standards may be used to assist in meeting this objective.

Further, storm water management program goals should be reviewed during planning processes that guide development to appropriate locations and steer intensive land uses away from sensitive environmental areas. A municipality may, for example, include provisions in the planning process that ensure that all new development in targeted areas or zones provides for a certain percentage of undisturbed area to assist in preserving post-development runoff quality and velocity as similar as possible to pre-development conditions. In its Part 2 application, a municipality should describe how it plans to implement the proposed standards (e.g., through an ordinance requiring approval of storm water management programs, a review and approval process, and adequate enforcement).

The proposed storm water management program should identify and include **planning procedures and control measures** that will be used in the municipality.

Planning Procedures

Comprehensive planning procedures typically involve incorporation of land use goals and objectives into a plan document or a plan map. These plans are often called Master Plans, Comprehensive Land Use Plans, or Comprehensive Zoning Plans.

Comprehensive or master plans are often non-binding. They provide support and direction to local officials that have the authority to make land use decisions.

While applicants do not need to submit a complete comprehensive or master plan with the Part 2 application, they should detail the planning process employed by the municipality. They must thoroughly describe how the municipality's comprehensive plan is compatible with the storm water regulations. The description should clearly:

- Identify management objectives for streams, wetlands, and other receiving waters;

- Identify areas where urban development is likely to occur and areas that are sensitive to the effects of urbanization. Consideration should be given to receiving waters, topography, soil types, ground water uses and potential impacts, and other relevant factors;

- Describe standards such as design criteria and performance standards for storm water controls for new developments, such as buffer zones, open space preservation, erosion and sediment controls, etc.;

- Describe other measures to minimize the effects of new development on storm water quality (these may include local code and ordinance requirements); and
- Identify or discuss the site development review process for the evaluation and approval of storm drainage or storm water management programs. Requirements in drainage or storm water management programs can be coordinated with review of other related plans such as those for site grading or landscaping.

There will be great variation among municipalities in their sophistication of land use planning. If the municipality has recently updated its land use plan, it may detail storm water quality issues. In other instances, there may be no policy to include storm water quality considerations in land use decisions. In such cases, the applicant must describe how consideration of those activities that affect storm water quality are to be incorporated into the municipality's comprehensive or master plan and its approval process for construction projects.

<u>Control Measures</u>

Most traditional storm water control measures focus on efficient collection and conveyance of storm water runoff to an offsite location. This approach can increase downstream property damage due to increased storm water runoff quantity and flow velocity. Corrective action often involves expensive public works projects, such as enlarging and reinforcing channels or constructing swales to provide an adequate outfall from affected or damaged areas. The traditional approach has typically involved downstream channel stabilization projects. However, these projects may also result in increased storm water runoff quantity and flow velocity.

Some recent approaches to storm water management include preserving the natural features of a watershed by maintaining vegetative cover and establishing buffer zones and open space or green areas. The benefit of employing this approach is the protection afforded to riparian areas and wetlands, as well as the preservation of a stable watershed. One additional benefit from this approach includes maintaining ground water recharge through infiltration. These approaches to storm water management minimize the impact of erosion, flooding, and other damage to natural drainage features such as streams, wetlands, and lakes. Preservation of natural habitat can be achieved through effective storm water quality control measures. More recent approaches use storm water to:

- Recharge ground water sources with runoff from impervious areas;
- Preserve baseflows of surface water bodies;
- Augment water supplies used for street cleaning and other municipal functions, such as watering public lawns;
- Increase recreational opportunities including swimming, fishing, and boating; and
- Sometimes, augment drinking water supplies if it is treated and in compliance with all applicable drinking water standards.

The municipality should consider storm water controls and structural concerns in planning, zoning, and site or subdivision plan approval. An example of effective structural control is described in Exhibit 6-1. Non-structural control measures are highly recommended for new development. They can be included during the planning, site-selection, and development stages. Examples of non-structural controls include street sweeping, buffer strip preservation, and public education.

Exhibit 6-1
Storm Water Programs in Delaware and Florida

Delaware requirements for on-site measures include water quality ponds with permanent pools. Ponds must be designed to release the equivalent volume of runoff from the first 1/2 inch of runoff from the site over a 24-hour period and have a storage volume designed to accommodate at least 1/2 inch of runoff from the site. Water quality ponds without permanent pools may also be used in Delaware's program. These pools are to be designed to release the first inch of runoff from the site over a 24-hour period.

Developers are instructed to consider infiltration practices only after ponds are eliminated for engineering or hardship reasons. Infiltration structures must be designed to accept at least the first inch of runoff from all streets, roadways, and parking lots. Other practices may be acceptable if they meet the equivalent removal efficiency of 80 percent for suspended solids. More stringent requirements may be established on a case-by-case basis.

The 80 percent removal efficiency for suspended solids that Delaware requires takes into account pollutant settling. The 24-hour detention period allows for substantial settling where most of the pollutant removal occurs. In addition, the requirement that the first inch of runoff be released over a period of no less than 24 hours reduces downstream erosion.

Source: Schueler, 1987.

For significant redevelopment, municipalities can incorporate both structural and nonstructural storm water controls. However, there are generally far more constraints and limitations on the control opportunities available at redevelopment sites. One of the primary constraints is the availability of sufficient open area to accommodate structural controls such as detention ponds. In instances where redevelopment is occurring in densely urbanized areas, storm water runoff volumes may be so large that sufficient storage capacity can not be provided without further compounding problems associated with siting and retrofitting existing storm water conveyance systems. In such cases, the municipality should consider nonstructural control measures such as traffic flow control, the use of porous construction materials for roads and parking lots, revisions to street sweeping or deicing policies, or public education programs.

6.3.1.2 Public Streets, Roads, and Highways

Summary of Regulatory Requirement

Public streets, roads, and highways can be significant sources of pollutants in discharges from MS4s. Therefore, proposed management programs must include a description of practices for operation and maintenance of public streets, roads, and highways, and procedures for reducing the impact of runoff from these areas on receiving waters.

§122.26(d)(2)(iv)(A)(3). [The application must include a] description of practices for operating and maintaining public streets, roads and highways and procedures for reducing the impact on receiving waters of discharges from municipal storm sewer systems, including pollutants discharged as a result of deicing activities.

Road maintenance practices, especially **snow management** and **road repair**, and **traffic** are significant sources of pollutants in storm water discharges. Measures to reduce the pollutants in storm water runoff from these sources should be addressed in the proposed management program.

Snow Management

Deicing salts are the main source of pollutants in runoff of urban snowmelt. Municipalities can reduce these pollutants by calibrating equipment, educating equipment operators, using alternative deicing materials, and properly storing deicing materials. As alternatives to deicing salts, the Federal Highway Administration is considering many materials that may be less polluting. However, most of these deicers contain sodium or chloride ions that are harmful to roadside trees, shrubs, and soils. One deicer, calcium magnesium acetate (CMA) may be the best option for environmentally sensitive areas (Chollar, 1990). In salt storage facilities, salt piles should be completely covered, storage and handling areas should have impervious surfaces, and contaminated runoff should be contained.

Road Repair

Road maintenance and repair activities may contribute pollutants through erosion caused by the elimination of stabilizing vegetation from roadside shoulders and ditches. Maintenance crews can decrease the potential for erosion by disturbing only the area under repair. Graded areas should also be limited in size so that repairs can be completed the same day and graded areas stabilized by the end of the workday. Other measures to reduce pollutants in storm water include scheduling potential pollutant-causing repair work during dry seasons, when possible.

Municipal equipment yards and maintenance shops that support road maintenance activities can also be significant sources of pollutants. Therefore, municipalities should consider instituting procedures that address spill prevention, material management practices, and good housekeeping.

Traffic

Oil and grease and metals from traffic are the pollutants of most concern with respect to aquatic toxicity and their ability to "wash off" roadways and enter a MS4.

In almost all instances, the pollutant concentrations in initial storm water discharge from heavily travelled streets is significant. When the initial runoff reaches the velocity needed to entrain particulates, highly soluble pollutants that have accumulated between storms are transported to the storm sewer system. Therefore, shortly after a storm event begins, the pollutant loading in the initial flow to a MS4 is often the greatest.

Pollutants from traffic can be minimized by using **nonstructural controls** (e.g., traffic reduction and improved traffic management), **structural controls** (e.g., traditional and innovative BMPs), and **changing maintenance activities**. Traditional structural controls to reduce pollutants in road runoff include vegetated swales, infiltration devices and detention/retention basins. Highways often afford opportunities for using structural controls such as detention basins on entrance or exit ramps and upstream or downstream of culvert crossings (Steward, 1992). Smaller roads may also have low-cost structural control opportunities available at culvert crossings such as vegetated swales. Many structural controls can also be placed on public or private land that is outside the right-of-way, but still may be proximate enough to capture road runoff. Any time controls are placed at culvert crossings, potential wetland impacts and instream treatment issues need to be considered.

Maintenance activities that can reduce pollutants in storm water discharges include catch basin cleaning, litter control, and targeted street sweeping. For municipalities that have developed transportation plans under the Clean Air Act, applicants should describe how they will review the plan, and amend it where appropriate, to address water quality concerns. Potential locations for installing new structural controls to reduce pollutants from road and highway runoff should be identified by applicants.

6.3.1.3 Flood Management Projects

Summary of Regulatory Requirement

The traditional focus of storm water management in many communities has been water quantity (i.e., flood) control. The proposed management program must demonstrate that flood management projects take into account the effects on the water quality of receiving water bodies, and the program must discuss whether existing structural flood control devices can be retrofitted to control water quality.

> §122.26(d)(2)(iv)(A)(4). [The application must include a] description of procedures to assure that flood management projects assess the impacts on the water quality of receiving water bodies and that existing structural flood control devices have been evaluated to determine if retrofitting the device to provide additional pollutant removal from storm water is feasible.

Opportunities for pollutant reduction should be considered when determining specific controls to be proposed as the MEP standard in the storm water management program.

Control Measures

Storm water management devices and structures that focus solely on water quantity are usually not designed to remove pollutants, and may sometimes harm aquatic habitat and aesthetic values. For example, channels that are completely lined with concrete typically do not provide for aquatic habitat and tend to increase potentially erosive velocities and elevate ambient water temperatures, resulting in downstream channel enlargement and increased pollutant loadings. However, this condition can be mitigated through alternative stabilization methods.

Channel management measures that can enhance streams and their ecological values include corridor preservation, biological bank treatment, and, where necessary, geomorphic restoration (Ferguson, 1991). The municipality may also install structural devices to dampen the hydraulic energy of the flow and minimize downstream erosion. As another example, willow saplings could be planted between rip-rap, timbers, and other stabilization structures that are anchored into terraces on the side of the streambank.

Flood-control projects can be built or subsequently modified to address water quantity and water quality concerns. Sometimes existing flood control structures can be retrofitted to provide water quality benefits as well as water quantity control (EPA, 1989b). Basin retrofits are a common example. For such a retrofit, dry flood control or detention basins can be converted to wet basins by modifying outlet orifices. Additional storage can be obtained by raising the elevation of the basin embankment.

Dry retention basins, or extended dry or wet retention basins can be used to improve water quality. Dry retention basins are not as efficient or as effective in improving water quality as extended dry or wet retention basins, but dry retention basins are generally less costly to design and maintain. The decision to use dry retention or extended dry or wet retention basins should consider all these factors.

Optimally, such measures should be considered in the planning process (discussed previously). However, they can also be implemented later in the land development process (e.g., site review or public facilities requirements stage).

If a flood control authority is responsible for a portion of the MS4, the applicant should take the lead in coordinating efforts to incorporate pollutant reduction considerations in flood control projects. EPA recommends the use of Memoranda of Agreement and Memoranda of Understanding to clarify roles and responsibilities between two or more political entities.

6.3.1.4 Municipal Waste Facilities

Applicants must describe programs that identify measures to monitor and reduce pollutants in storm water discharges from facilities that handle municipal waste, including sewage sludge.

> **§122.26(d)(2)(iv)(A)(5).** [The application must include a] description of a program to monitor pollutants in runoff from operating or closed municipal landfills or other treatment, storage or disposal facilities for municipal waste, which shall identify priorities and procedures for inspections and establishing and implementing control measures for such discharges.

The first step is to identify facilities that handle municipal waste and summarize their operations. The types of facilities that should be included are:

- Active or closed municipal waste landfills;
- Publicly owned treatment works, including water and wastewater treatment plants;
- Incinerators;
- Municipal solid waste transfer facilities;
- Land application sites;
- Uncontrolled sanitary landfills;
- Maintenance and storage yards for waste transportation fleets and equipment;
- Sites for disposing or treating sludge from municipal treatment works; and
- Other treatment, storage, or disposal facilities for municipal waste.

Applicants may combine this part of the proposed management program with the program established under §122.26(d)(2)(iv)(C), which sets standards for monitoring and controlling pollutants from similar types of solid waste facilities (e.g., those with hazardous wastes, or subject to the requirements of SARA Title III—Section 313 of the Emergency Protection and Community Right-to-Know Act). Monitoring should include all the parameters listed in §122.26(d)(2)(iv)(C) and any additional parameters listed in an effluent guideline. Procedures to evaluate, inspect, monitor, and establish control measures for municipal waste sites over the term of the NPDES permit should be described. For example, after one year of monitoring each waste handling facility category listed above, the municipality may have collected enough data to decide which facilities or types of facilities should receive a higher priority for pollutant reduction. More attention could then be focused on the high-priority sites.

6.3.1.5 Pesticides, Herbicides, and Fertilizers

The proposed management program must include a description of procedures to reduce the contribution of pollutants associated with pesticides, herbicides, and fertilizers discharged to the MS4.

> §122.26(d)(2)(iv)(A)(6). [The application must include a] description of a program to reduce to the maximum extent practicable, pollutants in discharges from municipal separate storm sewers associated with the application of pesticides, herbicides and fertilizer which will include, as appropriate, controls such as educational activities, permits, certifications and other measures for commercial applicators and distributors, and controls for application in public right-of-ways and at municipal facilities.

The proposed program should include educational measures for the public and commercial applicators, and should include integrated pest management measures that rely on non-chemical solutions to pest control. The program should also describe how educational materials will be developed and distributed. Applicants are encouraged to consider providing information for the collection and proper disposal of, unused pesticides, herbicides, and fertilizers, or to establish their own program. An effective and safe program would include:

- Development of an inventory of products that may be accepted under the program, and collection of the Material Safety Data Sheets (MSDSs) for these products;
- Identification of transportation, storage, and disposal requirements;
- A shelf-life program to dispose of expired products;
- Applicator training or certification (the pretreatment program may be helpful as a source of industry-specific information or as a model approach for obtaining and tracking information on chemical applicators and distributors); and
- Safety training.

Any certification/training program for the collection and disposal of pesticides, herbicides, and fertilizers must be in compliance with Federal, State, and local laws such as the Resource Conservation and Recovery Act; the Federal Insecticide, Fungicide, and Rodenticide Act; the Department of Transportation's hazardous materials regulations; and State and local ordinances.

In addition, applicants must include a discussion of controls for the application of pesticides, herbicides, and fertilizers in public-rights-of-way and at municipal facilities. Planting low-maintenance vegetation, such as perennial ground covers, reduces pesticide and herbicide use. Native vegetation is often preferable because there is less need to apply fertilizers and herbicides, and to perform other forms of maintenance, such as mowing (Horner, 1988).

If herbicides are used, a herbicide-use plan must be proposed as part of the storm water management program. The plan might include:

- A list of selected herbicides and their specific uses;
- Information about the formulations of various products, including how to recognize the chemical constituents from the label, and directions and precautions for applicators that explain if products should be diluted, mixed, or only used alone;
- Application methods and estimated quantities to be used;
- Equipment use and maintenance;
- Training in safe use, storage, and disposal of pesticides (safety requirements for individual products are listed on the products' MSDSs);
- Inspection and monitoring procedures; and

- Recordkeeping and public notice procedures.

6.3.2 Construction Sites

As specified in §122.26(d)(2)(iv)(D), applicants must describe proposed regulatory programs to reduce pollutants in storm water runoff from construction sites to the MS4.

> **§122.26(d)(2)(iv)(D).** [The application must include a] description of a program to implement and maintain structural and nonstructural best management practices to reduce pollutants in storm water runoff from construction sites to the municipal storm sewer system.

This part of the proposed management program must address:

- Implementation of BMPs;
- Procedures for reviewing site plans to ensure that they are consistent with local sediment and erosion control plans;
- Inspection of construction sites; and
- Enforcement measures and educational activities for construction site developers and operators.

EPA encourages municipalities to (1) coordinate requirements to reduce pollutants in construction site runoff with management programs to reduce pollutants from new development, and (2) maintain, to the degree possible, pre-construction hydrologic conditions (Section 6.3.1.1). Applicants are encouraged to describe these two proposed management program components together. Implementation of this program component will rely on the establishment and maintenance of both structural and nonstructural BMPs. This requirement extends to all construction activity within the municipality.

All construction sites, regardless of size, must be addressed by the municipality. To begin to identify these sites, the applicant should obtain lists of construction site operators that are covered by general or individual storm water NPDES permits from the NPDES permitting authority. However, construction sites not covered by a storm water discharge permit also need to be addressed by the municipality. The best way to identify these construction sites and implement an effective BMP program to reduce pollutants in their runoff is through the site planning process (see Section 6.3.2.1).

The BMPs envisioned for construction site runoff are generally well established technologies and practices. They rely predominantly on erosion and sediment controls and other measures applicable to construction sites (e.g., control of solid wastes, and prohibitions on discharging concrete truck washing runoff into storm drains). The technologies proposed should be referenced, and a description of when and how the controls will be used should be included. Municipality-specific technical guidance for construction site operators, such as handbooks and inspection checklists, are examples of suitable reference sources. If an applicant chooses to develop such handbooks and checklists, they should be referenced and described in the application.

The major requirements of this program component include:

- Site planning that considers the potential impacts on water quality;
- Nonstructural and structural best management practices;
- Procedures that consider physical site characteristics when identifying priorities for inspection and enforcement; and
- Educational and training measures for construction site operators.

Each of these requirements, and the reasons that they are important elements of a proposed storm water management program, is described in more detail below.

6.3.2.1 Site Planning

Sediment runoff rates from construction sites are typically 10 to 20 times greater than those of agricultural lands, and 1,000 to 2,000 times those of forest lands. Over a short period, construction sites can contribute more sediment to streams than had been deposited over several decades. Runoff from construction sites can also include other pollutants such as phosphorus and nitrogen from fertilizer, pesticides, petroleum derivatives, construction chemicals, and solid wastes.

To address these problems, the proposed management program should describe procedures for site planning that consider potential water quality impacts.

> **§122.26(d)(2)(iv)(D)(*1*).** [The program for construction sites must include a] description of procedures for site planning which incorporate consideration of potential water quality impacts.

The objective is for the municipality and the developer to address storm water discharges from construction activity early in the project design process so that potential water quality impacts can be eliminated or minimized and consequences to the aquatic environment assessed. Nonstructural approaches to minimize the generation of runoff from the construction site will also need to be considered. These measures may include phasing development to coincide with seasonal dry periods, minimizing areas that are cleared and graded to only the portion of the site that is necessary for construction, exposing areas for the briefest period possible, and stabilizing and reseeding disturbed areas rapidly after construction activity is completed.

It is often easier and more effective to incorporate storm water quality controls during the site plan review process or earlier. The process typically culminates with the developer of the construction site submitting detailed engineering plans to the municipality for review and approval.

Upon completion of the site plan review stage, the developer and the municipality have invested considerable time and money into the project. If storm water quality issues are considered only after significant detailed engineering has gone into the project, municipal site reviewers may only address minor drainage issues. In recent years, however, many municipalities have developed separate teams of site inspectors to implement erosion and sediment control measures in the field. In these municipalities, site inspectors should be part of the site review team (if they are not already) in order to incorporate their expertise on the appropriate erosion and sediment controls for the given circumstances.

The above discussion reinforces the importance of site planning, as described in the section on site planning for new development (Section 6.3.1). In general, the sooner planners consider storm water quality issues, the better the opportunity for efficient and effective pollutant reduction. In some cases storm water issues should be considered in the conceptual stage of planning (e.g., as a planning or zoning function).

Some municipalities include a final step in the planning process that requires a developer to provide a far greater level of design detail than earlier conceptual design approvals. This step may be required as a condition of the final approval for certain zoning categories. Municipalities with such a step in the development process can consider potential storm water quality issues in detail at this stage. Municipalities that do not currently require such detailed plans should consider adopting this procedure as part of their storm water management program.

6.3.2.2 Nonstructural and Structural BMPs for Construction Activities

This component of the proposed management program should describe requirements for nonstructural and structural BMPs that operators of construction activities that discharge to MS4s must meet.

> §122.26(d)(2)(iv)(D)(2). [The program for construction sites must include a] description of requirements for nonstructural and structural best management practices.

As indicated above, applicants must propose site review and approval procedures that address sediment and erosion controls, storm water management, and other appropriate measures. Approvals should be clearly tied to commitments to implement structural and nonstructural BMPs during the construction process. Appropriate structural and nonstructural control requirements will vary by project. Project type, size, and duration, as well as soil composition, site slope, and proximity to sensitive receiving waters will determine the appropriate structural and nonstructural BMPs. Municipalities should acquire the authority to require operators to install and maintain applicable erosion and sediment control plans. Exhibit 6-2 summarizes common construction-site BMPs.

A description of the local erosion and sediment control law or ordinance is needed to satisfy this program requirement. The description should include information that links the enforcement of the law or ordinance to the legal authority of the applicant, as discussed in Section 3 of this manual.

While many municipalities have erosion and sediment control ordinances in place, their effectiveness is often limited because they are not adequately implemented and enforced. Examples include silt fencing that is not maintained, or excavated soils that are placed directly on top of the silt fencing. Therefore, construction sites covered under NPDES permit regulations must indicate whether they are in compliance with State and local sediment and erosion control plans. Site inspections are expected to be the primary enforcement mechanism by which erosion and sediment controls are maintained.

To ensure that developers are in compliance with erosion and sediment control plans, applicants may wish to consider expanding the use of performance bonds. This approach might depart from a traditional site bonding approach. For example, the size of bonds could be based on the amount of earth disturbed, the slope of the site, changes in grades, soil type, proximity to surface waters, sensitivity of surrounding area, and other relevant factors. In addition, the bond could clearly specify the storm water quality controls that must be included in the development. Appropriate maintenance and site cleanup could be tied to the bond-release process.

6.3.2.3 Site Inspections and Enforcement of Controls For Construction Sites

Storm water BMPs associated with construction activities are highly susceptible to damage due to the intensity of activities commonly associated with construction. Consequently, inspections are crucial to the effective operation of storm water BMPs. Therefore, the proposed management program should describe construction site inspection and enforcement procedures. The procedures should be flexible so that they can be tailored to specific construction activities and physical characteristics of the construction site.

> §122.26(d)(2)(iv)(D)(3). [The program for construction sites must include a] description of procedures for identifying priorities for inspecting sites and enforcing control measures which consider the nature of the construction activity, topography, and the characteristics of soils and receiving water quality.

Source: Modified from WDOE, *Public Review Draft - Stormwater Management Manual for the Puget Sound Basin*, Washington State Department of Ecology, Publication #90-73. June 1991.

Effective inspection and enforcement requires adequate staff, systematic inspection procedures, penalties to deter infractions, and intervention by the municipal authority to correct violations. Enforcement mechanisms, such as the ability to require additional storm water controls, administrative penalties (e.g., stop work orders) and injunctive relief (via citizen suits) also must be described. In addition, the applicant should describe who has the authority to require compliance.

Proposed procedures for inspecting construction sites may include minimum frequencies and an inspector's checklist. For example, the State of Delaware requires a minimum of one inspection every two weeks for sites over 50,000 square feet.

The proposed program should also specify the minimum number of inspectors that will be employed during the permit term and how they will be trained. For example, some erosion and sediment control programs require that certified private inspectors be used. In such case, procedures for inspector training and certification must also be described.

In formulating procedures to identify priorities for inspecting sites and enforcing control measures, applicants are encouraged to begin early in the process (i.e., at the site planning stage, as discussed previously) and continue throughout all ground disturbing activities. Once the nature of the construction activity has been established or perhaps modified during the site plan review process, the physical site constraints can be evaluated so that effective controls can be implemented.

For example, if the controls specified in the site plan prove to be ineffective, or if changes occur that were not anticipated during the planning process, site inspection and enforcement mechanisms can be required to mitigate the potential for pollutants to enter a downstream MS4. In this instance, a perimeter barrier, such as a temporary diversion dike, could be used to divert the concentrated runoff to a pipe slope drain terminating with a level spreader. The spreader would dissipate the erosive velocity of the runoff and release it into an undisturbed area beyond the limits of the clearing and grading at the toe of the slope.

The proximity and sensitivity of the receiving water to which the construction site discharges is an important consideration. For construction sites that discharge to receiving waters that do not support their designated use or other waters of special concern, additional construction site controls are probably warranted and should be strongly considered. These receiving waters are identified in the Part 1 municipal NPDES storm water permit application [§122.26(d)(1)(i)(C)].

6.3.2.4 Educational Measures for Construction Site Operators

Construction site operators often need training and education about the sources, control, and impacts of pollutants in runoff from construction sites (see Virginia, 1988). Therefore, applicants must describe examples of informational materials and activities to be used in education programs.

> **§122.26(d)(2)(iv)(D)(4).** [The program for construction sites must include a] description of appropriate educational and training measures for construction site operators.

Implementation and enforcement of erosion and sediment controls have historically been major problems even with many programs that may be otherwise exemplary. Therefore, technical information on how to incorporate storm water management with erosion and sediment control and other BMP training courses are recommended for municipal employees and construction site operators. Training on the available alternatives will help operators recognize and correct problems promptly. Tools for such training include videos, workshops, seminars, and demonstrations or field trips.

An acceptable program must include a training program, which should be supplemented by a certification program for all construction site operators (contractors and developers), plan reviewers, and inspectors that work on sites that discharge to a MS4. For example, one NPDES State has a certification program based on adequate training and minimum-competency level testing of all private individuals involved in the preparation and implementation of erosion and sediment control plans.

6.3.3 Program to Control Pollutants in Storm Water Discharges from Waste Handling Sites and from Industrial Facilities

> §122.26(d)(2)(iv)(C). [The application must include a] description of a program to monitor and control pollutants in storm water discharges to municipal systems from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities that are subject to Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA), and industrial facilities that the municipal permit applicant determines are contributing a substantial pollutant loading to the municipal storm sewer system.

The storm water regulations envision that NPDES permitting authorities and municipal operators will cooperate to develop programs to monitor and control pollutants in storm water discharges to municipal systems from various sites that handle waste and certain industrial facilities.

Operators responsible for storm water discharges associated with industrial activity must obtain NPDES permits from EPA or an authorized NPDES State. These industrial storm water permits will establish requirements such as controls, practices, and monitoring for storm water discharges from the industrial facilities to the MS4. The industrial storm water permits will also provide a basis for enforcement actions directly against the industrial owner or operator.

NPDES permits for MS4s will establish responsibilities for municipal system operators to control pollutants from industrial storm water discharged through their system. Proposed storm water management programs must address the reduction of pollutants in storm water discharges from municipal landfills; hazardous waste treatment, storage and disposal facilities; facilities subject to SARA Title III; and other priority industrial facilities, as determined by the applicant. Municipalities should consider the information gathered for the Part 1 application and other parts of the Part 2 application (particularly the Source Identification and Characterization Data components) when prioritizing storm water discharges from these sites. In addition, Appendix B contains a list of pollutants commonly associated with various industries.

In the Part 2 application, the Source Identification component (see Section 4 of this guidance manual) requires the applicant to provide an inventory of pollutant sources, organized by watershed. This inventory identifies and describes the products and services of each industrial facility that may discharge storm water to the MS4. The *Source Identification* component suggests applicants use standard industrial classification (SIC) codes for this description. EPA strongly recommends this information be used to identify priority waste handling sites and industrial facilities. A similar technique could be developed for sites that do not meet the regulatory definition of "storm water discharge associated with industrial activity" (i.e. not included in the *Source Identification* and *Discharge Characterization* components), but are identified as a high priority under the proposed management program. Applicants can obtain information on how SIC codes are used to describe the industrial facilities located within their jurisdictions from their NPDES permitting authority.

Characterization data should also be evaluated. Applicants should analyze quantitative data from representative outfalls to establish a monitoring and control program.

An integral part of this requirement is the adequacy of the applicant's legal authority. If a municipality believes that a discharge of storm water associated with industrial activity violates the industrial facility's NPDES permit limits, but the municipality does not have authority over the discharge, the municipality should contact the NPDES permitting authority for appropriate action. Examples of possible actions by the NPDES permitting authority are:

- For a facility that already has a NPDES individual permit, the permit may be reopened and further controls imposed;

- For a facility covered by a NPDES general permit, an individual site-specific permit application may be required; or

- For a facility not covered by a NPDES storm water permit, a permit may be required.

The municipality is ultimately responsible for discharges from their MS4. Consequently, the proposed storm water management program should describe how the municipality will help EPA and authorized NPDES States:

- Identify priority industries discharging to their systems;

- Review and evaluate storm water pollution prevention plans and other procedures that industrial facilities must develop under general or individual permits;

- Establish and implement BMPs to reduce pollutants from these industrial facilities (or require industry to implement them); and

- Inspect and monitor industrial facilities to verify that the industries discharging storm water to the municipal systems are in compliance with their NPDES storm water permit, if required.

6.3.3.1 Identifying Priorities

Proposed management programs must clearly identify priority industrial facilities.

> **§122.26(d)(2)(iv)(C)(*1*).** [The applicant must] identify priorities and procedures for inspections and establishing and implementing control measures for such discharges.

This section discusses how applicants might identify priority facilities. Section 6.3.3.2 discusses how municipalities might develop procedures for inspections and implementation of control measures.

At a minimum, priority facilities include:

- Operating and closed municipal landfills;

- Hazardous waste treatment, disposal or recovery facilities; and

- Facilities subject to SARA Title III.

Municipalities must identify these and other priority industrial facilities and describe the criteria used to identify them. For example, information from the Toxics Release Inventory is one source a municipality could use to identify industrial facilities subject to SARA Title III. Other sources may include CWA Section 205 or 208 use-attainability studies, other studies that indicate a site-specific beneficial use impairment immediately downstream of a storm water outfall, or records of industrial pretreatment programs or other permit programs that identify facilities that may be the source of a use impairment or a major contribution of pollutants. The program should also describe procedures for modifying the inventory of priority industries based on additional evaluation that occurs throughout the permit term.

Applicants may initially focus their implementation efforts on known pollution sources. The municipality may have previously identified these sources, or they may be identified through existing information compiled during the permit application process. However, the initial management program implementation strategy should be based on information gathered while completing the *Adequate Legal Authority, Source Identification*, and *Discharge Characterization* sections of the permit application (See Chapters 3, 4, and 5, respectively.)

During the term of the permit, as additional information becomes available, the municipality should target and set priorities for other program elements that emerge. For example, if the municipality has incomplete characterization data about waste handling sites identified in this program component because the inventory of dischargers to the MS4 has not been completed, the municipality could propose to direct monitoring programs to those areas. Upon acquiring sufficient characterization data, the priority of the sites discharging to these portions of the MS4 can be either determined or modified.

As noted above, when identifying priority sites, applicants must consider all the facilities listed in §122.26(d)(2)(iv)(C)(*1*). When municipalities develop criteria for identifying additional priority industrial facilities, they are advised to consider, at a minimum:

- The type of industrial activity (SIC codes can help characterize the type of industrial activity);
- The use and management of chemicals or raw products at the facility and the likelihood that storm water discharge from the site will be contaminated; and
- The size and location of the facility in relation to sensitive watersheds.

6.3.3.2 Developing Procedures

This program component should describe the specific steps that the municipality will take if it identifies a waste handling site or priority industrial facility when preparing the Part 2 application or during the permit term [§122.26(d)(2)(iv)(C)(*1*), printed in the box above]. The proposed management program must include procedures for inspecting priority industrial sites. The results of inspection may be used as a basis for requiring storm water management controls and enhanced pollution prevention measures. It should also establish an inspection schedule for each priority facility at the time it is identified.

Applicants may want to consider establishing prior notification procedures. The applicant will need to evaluate the legal authority it has over priority facilities to determine if prior notification is required. This is another example of how EPA expects the different components of the application process to be linked. In this instance, the Adequate Legal Authority section is tied directly to the prior notification procedure of the inspection and evaluation component of the proposed management plan.

Applicants also should consider developing inspection documents such as standard forms or checklists for recording observations. Forms and checklists can be used to identify high risk areas of priority facilities and to make comparisons among sites. When characterization data or baseline estimates are factored into the evaluation process, the effectiveness of pollution prevention activities at a particular site could be quantified and compared to similar sites. Other procedures that applicants should describe to effectively incorporate inspections as well as establish and implement control measures for these types of discharges can be derived from monitoring data.

Applicants also should describe a procedure for conducting follow-up inspections, where necessary, as part of this program component. For example, follow-up inspections might be needed to verify the installation of a specific control or implementation of a practice specified in a negotiated agreement between the municipality and the industrial site. A system-wide approach to establishing priorities for inspection procedures is recommended. The system-wide approach should begin with the evaluation of existing information, followed by the identification and evaluation of new information during the permit term. Therefore, applicants should link these procedures with information from the *Source Identification* and *Discharge Characterization* components.

6.3.3.3 Establishing and Implementing Controls

A municipality must consider if it should place more stringent controls on discharges associated with industrial activity than are required in an industrial facility's existing NPDES storm water permit [§122.26(d)(2)(iv)(C)(*1*), printed in box above]. Usually, the municipality will not need to impose controls beyond those required in the industrial facility's NPDES storm water permit (for more information on appropriate controls, refer to *Storm Water Management for Industrial Activities, Developing Pollution Prevention Plans and Best Management Practices*, EPA 832-R-92-006, September, 1992).

However, nothing in the Federal regulations would prohibit the municipality from requiring additional controls beyond the permit requirements for industrial activities. For this reason, EPA recommends that municipal applicants incorporate a provision in the proposed storm water management program that allows the municipality to require priority industrial facilities to implement the controls necessary for the municipality to meet its permit responsibilities.

Finally, the applicant should suggest procedures for requiring pollutant control measures in runoff from priority industrial facilities. Applicants should provide information to the industrial facilities that discharge to the MS4s and industry-specific guidance on appropriate control measures that industries discharging to their systems should follow (WDOE, 1991).

Priority industrial facilities should focus on controlling activities such as the use, storage, and handling of toxic chemicals. Standard methods for implementing control measures at different types of facilities should be described. To facilitate this, municipalities should obtain copies of the pollution prevention plans developed by industrial permittees. Control measures that the municipality may suggest include preventing exposure of pollutant sources to precipitation, on-site pretreatment, and oil/water separators. Applicants should provide a schedule for setting up this program component at priority industrial facilities. The schedule should include educational services for industrial site operators and technical BMP guidance, training courses, videos, workshops, and seminars for plan reviewers, inspectors, contractors, and developers.

6.3.3.4 Inspection and Monitoring

The proposed management program should describe the inspection procedures that will be followed. Storm water inspections can be coupled with inspections for other purposes (e.g., pretreatment programs, fire and safety). Proposed management programs should address minimum frequency for routine inspections. For example, how often, how much of the site, and how long an inspection may take are appropriate to explain in this proposed management program component. Applicants should also describe procedures for conducting inspections and provide an inspector's checklist.

In addition, these inspection procedures should identify the minimum number of inspectors that will be employed and describe the programs to train them. For example, if the number of inspectors is expected to increase over the term of the permit, it should be noted in the proposed management program. Also, if storm water inspections are combined with other program inspections, means of cross-training inspectors and coordinating schedules should be outlined.

Municipalities are urged to evaluate pollution prevention plans and discharge monitoring data collected by the industrial facility to ensure that the facility is in compliance with its NPDES storm water permit. Site inspections should include (1) an evaluation of the pollution prevention plan and any other pertinent documents, and (2) an on-site visual inspection of the facility to evaluate the potential for discharges of contaminated storm water from the site and to assess the effectiveness of the pollution prevention plan. A municipality could begin the inspection process with information from the facility's notification to the municipality, which should have been submitted by May 15, 1991. Industrial facilities must also submit an individual NPDES permit application, participate in a group storm water permit application, or file a Notice of Intent (NOI) to be covered by a general permit to the NPDES permitting authority. Section 308 of the CWA provides the legal authority for any individual (including a municipality) to obtain information from the NPDES permitting authority.

The proposed management program also must include a description of a monitoring program for storm water discharges associated with industrial facilities [§122.26(d)(2)(iv)(C)(2)].

The monitoring program should describe the framework and rationale for selecting monitoring sites. Sites that may be appropriate for monitoring include locations with several upstream industrial facilities, industrial facilities that are representative of a significant number of similar facilities, and priority industrial sites with significant potential for high levels of pollutants in their storm water discharges. The description of the proposed

> §122.26(d)(2)(iv)(C)(2). [The application must describe] a monitoring program for storm water discharges associated with the industrial facilities identified in paragraph (d)(2)(iv)(C) of this section, to be implemented during the term of the permit, including the submission of qualitative data on the following constituents: any pollutants limited in effluent guidelines subcategories, where applicable; any pollutant listed in an existing NPDES permit for a facility; oil and grease, COD, pH, BOD_5, TSS, total phosphorus, total Kjeldahl nitrogen, nitrate plus nitrite nitrogen, and any information on discharges required under 40 CFR 122.21(g)(7)(iii) and (iv).

monitoring program should address how the monitoring data will be used and what the frequency of the monitoring will be.

Identifying who will actually conduct the monitoring (e.g., industry or municipality) is appropriate to include in the program description. Linking this element of the monitoring program to the Adequate Legal Authority section of the permit application is vital. The legal authority to require monitoring should prescribe the specific monitoring protocols required elsewhere in the regulation [§122.26(d)(2)(i)(F)]. Applicants should describe proposed procedures for monitoring industrial facilities, including methods for determining parameters to be sampled throughout the term of the permit. **At a minimum, parameters that must be considered for monitoring include:**

- Any pollutant limited in effluent limitations guidelines for the subcategory of industry;
- Any pollutant that is controlled in a NPDES permit for the process discharge from an industrial site;
- Oil and grease, COD, pH, BOD_5, TSS, total phosphorus, total Kjeldahl nitrogen, nitrate plus nitrite nitrogen; and

- Certain pollutant(s) known or suspected to be in the discharge, based on §122.21(g)(7)(iii) and (iv) (Section 5.3).

If a municipality believes (based on the results of monitoring and inspections) that an industrial facility is not meeting its NPDES permit requirements, the municipality should petition the NPDES authority to either require the facility to change its pollution prevention plan or institute an enforcement action. Municipalities may also file citizen suits under CWA Section 505 to enforce the conditions of the NPDES permit.

6.4 STRUCTURAL CONTROLS

6.4.1 Description of Structural Controls

Applicants are required to identify the location of major structural controls for storm water (retention basins, detention basins, major infiltration devices, etc.) in Part 1 of the application [§122.26(d)(1)(iii)(B)(5)]. In Part 2, applicants must describe additional controls that they plan to implement [§122.26(d)(2)(iv)]. The controls must address the activities described in Section 6.3. In addition, the applicant must describe maintenance procedures [§122.26(d)(2)(iv)(A)(1), discussed in Section 6.4.2]. Later, when the municipality submits its annual report, it will have to report on its progress in implementing these controls [§122.42(c)(1), discussed in Section 7.3 of this guidance].

The matrix in Exhibit 6-3 provides information on commonly used structural and source control BMPs. Structural practices to control urban storm water runoff rely on three basic mechanisms: **detention, infiltration,** and **filtration**. More detailed technical information about source controls (particularly in the selection of structural BMPs) is available in the technical BMP manuals (MWCOG, 1991; Schueler, 1987; WDOE 1991; and EPA 1990c). The following summary of structural and source control BMPs draws extensively from those manuals.

Applicants should note that CWA Section 404 permits may be required for some structural controls, including any control projects that involve the discharge of dredged or fill material into waters of the United States, including wetlands. States may also require permits that address water quality and quantity. To the extent possible, municipalities should avoid locating structural controls in natural wetlands. Before considering siting of controls in a natural wetland, the municipality should demonstrate that it is not possible or practicable to construct them in sites that do not contain natural wetlands, and that the use of other nonstructural or source controls are not practicable or as effective. In addition, impacts to wetlands should be minimized by identifying those wetlands that are severely degraded or that depend on runoff as the primary water source. Moreover, natural wetlands should only be used in conjunction with other practices, so that the wetland serves a "final polishing" function (usually targeting reduction of primary nutrients and sediments). Finally, practices should be used that settle solids, regulate flow, and remove contaminants prior to discharging storm water into a wetland.

Another concern for siting controls is the possible adverse effect that infiltration and detention controls may have on ground water. This issue is addressed in more detail in Section 7.2.3.

Exhibit 6-3
Structural Controls Matrix

CONTROL AND MAINTENANCE REQUIREMENTS	ADVANTAGES	DISADVANTAGES
Extended Detention Dry Basin • Periodic mowing • Regular debris removal • Sediment removal annually	• Provides peak flow control • Possible to provide good particulates removal • Can serve large development • Requires less capital cost and land area when compared to wet basin • Does not usually release warmed or oxygen-depleted water downstream • Protects against downstream channel erosion • Can create valuable wetland and meadow habitat when properly landscaped	• Low removal rates for soluble pollutants • Generally not feasible for drainage areas less than 10 acres • If not adequately maintained, can become a nuisance; (becomes unsightly, breeds mosquitos, and creates undesirable odors) • Periodic mowing and maintenance can be detrimental to nesting birds or other animals inhabiting the area
Vegetative Filter Strip • Inspection • Fertilizer use if necessary to maintain stable vegetation	• Low maintenance requirements • Can be used as part of the runoff conveyance system to provide pretreatment • Can reduce particulate pollutant levels in areas where runoff velocity is low to moderate • Enhances urban wildlife habitat diversity • Economical	• May concentrate water, significantly reducing effectiveness • Soluble pollutant removal highly variable • Limited feasibility in highly urbanized areas where runoff velocities are high and flow is concentrated • Requires periodic repair, regrading, and sediment removal to prevent channelization • Maintenance can be detrimental to nesting birds or other animals inhabiting the area • Fertilizer use can lead to higher nutrient loadings in storm water runoff
Grassed Swale • Periodic mowing • Fertilizer use if necessary to maintain stable vegetation	• Requires minimal land area • Can be used as part of the runoff conveyance system to provide pretreatment • Can provide sufficient runoff control to replace curb and gutter in single-family residential subdivisions and on highway medians • Economical and aesthetically pleasing	• Low pollutant removal rates • Leaching from culverts and fertilized lawns may actually increase the presence of trace metals and nutrients • Fertilizer use can lead to higher nutrient loadings in storm water runoff

Exhibit 6-3 (continued)
Structural Controls Matrix

CONTROL AND MAINTENANCE REQUIREMENTS	ADVANTAGES	DISADVANTAGES
Porous Pavement • Routine removal of fine particles from surface • May need weight limit of traffic imposed for protection	• Provides ground water recharge • Provides water quality control without additional consumption of land • Can provide peak flow control • High removal rates for sediment, nutrients, organic matter, and trace metals • When operating properly can replicate pre-development hydrologic conditions • Eliminates the need for storm water drainage, conveyance, and treatment systems off-site	• Requires regular maintenance • Possible risks of ground water contamination • Only feasible where soil is permeable, of sufficient depth to bedrock and water table, and gentle slopes are present • Not suitable for areas with high traffic volume or heavy vehicles • Need extensive feasibility tests, inspections, and very high level of construction workmanship • High failure rate due to clogging • Not suitable to serve large offsite pervious areas • Limited use in snowy climates where sanding and salting operations occur
Concrete Grid Pavement • Periodic mowing, if planted	• Provides peak flow control • Provides ground water recharge • Provides water quality control without additional consumption of land	• Requires regular maintenance • Not suitable for area with high traffic volume • Possible risk of contaminating ground water • Only feasible where soil is permeable, of sufficient depth to bedrock and water table, and gentle slopes are present
Filtration Basin • Periodic vacuuming and power washing	• Ability to accommodate moderately large-sized development (3-80 acres) • Flexibility to provide or not provide ground water recharge • Can provide peak volume control	• Requires pretreatment of storm water through sedimentation to prevent filter media from premature clogging

Exhibit 6-3 (continued)
Structural Controls Matrix

CONTROL AND MAINTENANCE REQUIREMENTS	ADVANTAGES	DISADVANTAGES
Wet Retention Basin • Periodic dredging, preferably from forebay area, if properly designed • Mowing of impoundment to prevent successional growth	• Provides peak flow control • Can serve large developments; most effective for large, intensively developed sites • Enhances species diversity, aesthetics, and provides recreational benefits • Little ground water discharge • Permanent pool in wet ponds helps prevent scour and resuspension of sediments • Provides moderate to high removal of both particulate and soluble pollutants	• Generally not feasible for drainage area less than 10 acres • Potential for safety and liability issues if not properly built and maintained • If not adequately maintained, can become a nuisance; (becomes unsightly, breeds mosquitos, and creates undesirable odors) • Requires considerable space, which limits use in densely urbanized areas with expensive land and property values • Not suitable for hydrologic soil groups "A" and "B" (SCS classification) • Potential for thermal discharge and oxygen depletion, which may severely impact downstream aquatic life
Extended Detention Wet Basin • Periodic dredging of sediment forebay	• Provides peak flow control • Can serve large developments; most effective for large, intensively developed sites • Enhances species diversity, aesthetics, and provides recreational benefits • Permanent pool in wet ponds helps prevent scour and resuspension of sediments • Provides better nutrient removal than traditional wet basin	• Not feasible for drainage area less than 10 acres • Potential for safety and liability issues if not properly built and maintained • If not adequately maintained, can become a nuisance; (becomes unsightly, breeds mosquitoes, and creates undesirable odors) • Requires considerable space, which limits use in densely urbanized areas with expensive land and property values • Not suitable for hydrologic soil groups "A" and "B" (SCS classification) • Potential for thermal discharge and oxygen depletion, which may severely impact downstream aquatic life

Sources: Modified from MWCOG, 1991; Schueler 1987; and WDOE, 1991.

6.4.1.1 Detention Controls

Detention controls temporarily store storm water runoff to control peak runoff rates and provide a reduction in pollutant concentrations by the gravitational settling of suspended solids and associated contaminants. Except for incidental losses due to evaporation or percolation, essentially all the detained water is subsequently discharged to a surface water conveyance (e.g., a stream or MS4). The most common examples of detention practices are extended detention basins and wet (retention) basins.

Variations on these basic detention controls include constructed storm water wetlands and multiple pond systems. These types of controls also rely on detaining flows (leading to sedimentation) as the primary means of pollutant removal. Recent investigations suggest that wetlands vegetation within a detention control can also reduce nutrient loads and certain other pollutants by incorporating them into plant tissue.

If properly designed, detention controls can protect downstream channels by reducing the frequency of bankfull flood events and associated erosion. Reduction in velocity and sediment load is also important for minimizing the adverse impacts of discharges to MS4s. Detention facilities also can provide terrestrial and aquatic wildlife habitat if they are landscaped and planted appropriately.

When considering detention controls, the municipality should consider the potential negative effects of downstream warming that may be caused by the shallowness of the water in the control. The municipality should also consider negative impacts of detention controls, such as reduced baseflow; bacterial contamination due to waterfowl; and potential impacts to wildlife from concentrated contaminants, waterfowl diseases, and maintenance practices. Safety and liability issues and nuisance factors, such as mosquitoes and odor, also should be considered. Setting detention controls in sensitive floodplains or in existing wetlands should generally be avoided. The flooding effect of impounding and detaining water is a particular concern if the upstream watershed drains more than 250 acres, because the volume of runoff and required detention times can cause inundation of upstream channels to occur.

Detention controls incorporating multiple pond systems and/or constructed storm water wetlands also treat runoff through the processes of absorption, filtration, biological uptake, volatilization, precipitation, and microbial decomposition. Recent investigations by the Metropolitan Washington Council of Governments suggest that multiple pond systems, in particular, have shown potential to provide higher and more consistent levels of treatment than traditional detention controls. The redundancy afforded by the multiple pond system generally increases the reliability of the control. However, the potential concerns and drawbacks affecting retention basins also apply to these systems. Many of these systems are currently being designed to include vegetative buffers and deep water areas to enhance wildlife habitat and to improve the appearance of the facility. If a municipality selects one of these more innovative designs, it should recognize that periodic maintenance is necessary. The effectiveness of these controls, like most controls, depends on proper operation, maintenance, and monitoring of the entire system.

<u>Wet (Retention) Basins</u>

Wet (retention) basins are designed to maintain a permanent pool of water and temporarily store storm water runoff until it is released at a controlled rate. Unlike extended detention ponds, wet basins cannot detain runoff for long times, because most of their storage capacity is needed for holding the permanent pool. Enhanced designs include a forebay to trap incoming sediment where it can be easily removed. A fringe wetland also can be established around the perimeter of the basin. Similar to detention controls, locating retention basins in sensitive floodplains or existing wetlands should be avoided if possible.

Extended Detention Basins

Extended detention basins temporarily detain a portion of storm water runoff for 24 to 48 hours after a storm, gradually releasing the stored water through a fixed opening to allow urban pollutants to settle out. The basins normally return to a "dry" condition between storm events and do not have any permanent standing water. These basins are typically composed of two stages: an upper stage, which remains dry except during larger storms, and a lower stage, which is designed for typical storms. Pollutant removal from extended detention basins can be enhanced if they are equipped with plunge pools near the inlet, a micropool at the outlet, and an adjustable reverse-sloped pipe as the extended detention control device.

Water Quality Inlets

Water quality inlets (also referred to as catch basins) are small underground systems that, like retention basins, rely on settling to remove pollutants before discharging water to the MS4. Several designs of water quality inlets exist. In their simplest form, catch basins are single-chambered storm water inlets with the bottom lowered to provide 2 to 4 feet of additional space between the outlet pipe and the bottom of the structure for collection of trash and sediment. Some water quality inlets include a second chamber with a sand filter to provide additional removal by filtration. The first chamber provides effective removal of coarse particles and helps prevent premature clogging of the filter media.

Water quality inlets may include an oil/grit separator. There are 3 basic types of oil/grit separators: the spill control (SC), the coalescing plate interceptor (CPI), and a design credited to the American Petroleum Institute (API). Most of the oil/grit separators that are promoted for use in reducing hydrocarbon loads in storm water are a modification of the API design, although there are appropriate applications for all three separator designs. Oil/grit separators based on the API design consist of three chambers. The first chamber removes coarse material and debris. The second chamber provides separation of oil, grease, and gasoline from the storm water runoff; and the third chamber provides a safety relief should a blockage occur.

Recent experiences have shown that, because of their volume limitations, oil/grit separators have limited pollutant removal effectiveness. They are perhaps the best example of a structural control that is only effective with frequent maintenance. Proper disposal of the standing water, trapped sediments, and floating hydrocarbons are problems in the few locations that have been studied.

Constructed Storm Water Wetlands

Constructed storm water wetlands are a hybrid, drawing on elements of detention and retention basins. Constructed storm water wetlands are shallow pools and are often designed to simulate the pollutant removal functions of natural wetlands. Enhanced designs may include a sediment forebay, carefully contoured topography, and multiple species of wetland plants. Constructed storm water wetlands, while a promising technology for pollutant removal from storm water, may not replicate all the ecological functions of natural wetlands.

6.4.1.2 Infiltration Controls

Infiltration controls rely chiefly on absorption to treat storm water discharges. In the ideal case, storm water percolates through a porous medium and into native soils where filtration and biological action remove pollutants. Typical controls of this type include infiltration trenches, infiltration basins, filtration basins, porous pavement, and concrete or block pavers. Systems that rely on soil absorption work best in deep, highly permeable soils that are at least four feet away from the seasonal ground-water table.

The Soil Conservation Service (SCS) classifies soils into four major soil groups A-D. The soil groups are as follows:

Group A: Sand, loamy sand
Group B: Sandy loam, loam
Group C: Silt loam, sandy clay loam
Group D: Clay loam, silty clay loam, sandy clay, silty clay, and clay

Soils in Group A provide the highest infiltration rate while soils in Group D provide the lowest. Suitable soils for infiltration-type controls typically fall in soil groups A and B. Other types of soils may be suitable, provided the clay content does not exceed 30 percent (clay has very low hydraulic conductivity). The clay content of soil may be determined from the SCS soil textural triangle, which can be found in many civil engineering references texts.

If suitable soils are available, the widespread use of infiltration in a watershed can be useful in helping to maintain, restore, or replicate pre-development hydrology. Specific benefits of infiltration often include increased dry-weather baseflow in streams and a reduction in the frequency of bankfull floods. However, infiltration systems are not recommended unless soil conditions warrant. Also, infiltration should not be used where ground water requires protection. For example, the use of infiltration-type controls may not be appropriate in areas that recharge sole source aquifers.

Infiltration Basins

Infiltration basins are areas that intercept incoming storm water runoff and temporarily store it until it gradually infiltrates into the soil surrounding the basin. Infiltration basins should be designed to control drainage areas ranging from about 5 to 50 acres. They also should drain within 48 to 72 hours to maintain aerobic conditions favoring bacteria that aid in pollutant removal, and to ensure that the basin is ready to receive the next storm. The runoff entering the basin is usually pretreated to remove coarse sediment that may clog the surface soil pores on the basin floor. Concentrated runoff may flow through a sediment trap or by sheet flow (vegetative filter strip).

Infiltration Trenches

Infiltration trenches are shallow (e.g., 2 to 10 feet deep) excavated ditches or vaults that have been backfilled with a coarse stone aggregate. The aggregate forms an underground reservoir that has approximately 40 percent void space. Storm water runoff diverted into the trench gradually infiltrates from the bottom of the trench into the subsoil and eventually into the ground water. Variations in the design of infiltration trenches include dry wells and percolation pits that are designed to control small volumes of runoff, such as the runoff from a rooftop. A more complex variation is the enhanced infiltration trench, which is equipped with filter fabric or a more extensive pretreatment system to remove sediment and oil. Depending on the quality of the runoff, pretreatment may be necessary to lower the failure rate of the trench. Infiltration trenches are generally best suited for drainage areas of less than 10 acres. They are particularly applicable for use on residential lots, small commercial areas, down slope from parking lots, and under drainage swales.

Grassed Swales

A grassed swale is an infiltration method that is usually used as a form of pretreatment before discharging runoff to another storm water control device (e.g., a detention basin). However, the grassed swale itself is a control that can remove significant amounts of pollutants through sediment entrainment. A grassed swale is a shallow, vegetated, man-made ditch with the bottom elevation above the water table to allow runoff to infiltrate into the ground water. The vegetation helps to prevent erosion, filters sediment, and allows for some uptake of nutrients.

Porous Pavement

Porous pavement, which is basically traditional asphalt aggregate without the fine particles, is an alternative to conventional pavement. Proper design and application of this control can reduce or eliminate the need for curbs and gutters, storm drains and sewers, and offside controls. Instead, runoff is diverted through a porous asphalt layer into an underground stone reservoir. The stored runoff gradually exfiltrates out of the stone reservóir into the subsoil. Soil considerations are important when evaluating the appropriateness of this control. Generally, grades should be gentle, and subsoil should be at least 3 feet thick (to bedrock) and moderately permeable (capable of infiltrating about one half inch per hour). Because porous pavement tends to clog with fine sediments and because it loses its effectiveness under heavy loads, its application should generally be limited to low-traffic areas (e.g., overflow parking areas) and areas that are not exposed to large bearing loads caused by heavy vehicles.

Concrete Grid Pavement

Concrete grid pavement has concrete blocks with regularly interdispersed void areas that are filled with pervious materials, such as gravel, sand, or grass. The blocks are typically placed on a sand or gravel base. They are usually designed to provide a load-bearing surface adequate for supporting vehicles, while allowing infiltration of surface water into the underlying soil.

6.4.1.3 **Filtration Controls**

Filtration controls treat storm water flows by using vegetation or sand to filter and settle pollutants. Generally, these controls are most effective before the flows become concentrated (e.g., sheet flow). In certain instances, infiltration and treatment in the subsoil also may occur through the processes of absorption and adsorption. After passing through the filtration media, the treated water is usually directed to a stream or MS4, although it may be evaporated or percolated into the ground. Filtration controls include filter strips, grass swales, and sand filters. Sand filters are particularly useful for ground water protection. Applicants must consider the influence of climate when they select vegetative systems.

Vegetative Filter Strips

Vegetative filter strips (also called bio-filters) are vegetated sections of land designed to accept runoff as overland sheet flow from upstream development. They may adopt any natural vegetated form, from grassy meadow to small forest. The dense vegetative cover facilitates sediment reduction and pollutant removal. Filter strips cannot treat high-velocity flows. Therefore, these strips generally have been recommended for use in agriculture and low-density development and other situations where runoff does not tend to be concentrated. Unlike grassed swales, filter strips are effective only for overland sheet flow, as opposed to concentrated flow. Grading and level spreaders can be used to reduce the energy of concentrated flows and distribute the runoff evenly across the filter strip. Vegetative filter strips are often used as pretreatment for other structural practices, such as infiltration trenches. Leaving a buffer of natural vegetation along an urban stream valley is an example of a vegetative filter strip and also an example of a nonstructural control.

Filtration Basins

Filtration basins are usually small impoundments lined with filter media, such as sand or gravel. Storm water drains through the filter media and perforated pipes into the subsoil. For optimal pollutant removal, recommended detention times range from 24 to 48 hours with a maximum drainage area of about 50 acres. Grassed swales or other structural controls can be used to filter coarse sediments and thereby minimize clogging of the filter medium.

6.4.2 Maintenance Activities

After summarizing the location of major structural storm water controls, applicants must submit a description of maintenance activities and a maintenance schedule for structural controls to reduce pollutants.

> §122.26(d)(2)(iv)(A)(1). [The application must include a] description of maintenance activities and a maintenance schedule for structural controls to reduce pollutants (including floatables) in discharges from municipal separate storm sewers.

Typical maintenance requirements include:

- Inspection of basins and ponds after every major storm for the first few months after construction and annually thereafter;
- Mowing of grass filter strips and swales at the frequency necessary to prevent woody growth and promote dense vegetation;
- Regular removal of litter and debris from dry ponds, forebays, and water quality inlets;
- Periodic stabilization and revegetation of eroded areas;
- Periodic removal and replacement of filter media from infiltration trenches and filtration ponds;
- Deep tilling of infiltration basins to maintain infiltrative capability; and
- Frequent vacuuming or jet hosing of porous pavement or concrete grid pavements.

Lack of maintenance often limits the effectiveness of storm water structural controls such as detention/retention basins and infiltration devices. Maintenance programs should address measures for catch basins and drainage channels in addition to major structural controls.

The proposed program should provide for maintenance logs and identify specific maintenance activities for each class of control, such as removing sediment from retention ponds every five years, cleaning catch basins annually, and removing litter from channels twice a year. If maintenance activities are scheduled infrequently, inspections must be scheduled to ensure that the control is operating adequately. In cases where scheduled maintenance is not appropriate, maintenance should be based on inspections of the control structure or frequency of storm events. If maintenance depends on the results of inspections or if it occurs infrequently, the applicant must provide an inspection schedule. The applicant should also identify the municipal department(s) responsible for the maintenance program.

Municipalities should use caution in adopting controls that do not have sufficient history of use for their performance characteristics and maintenance requirements to be adequately evaluated. A good example is the oil/grit separator used on small commercial or retail sites. Some municipalities have required the use of these technologies, but due to poor performance, municipalities have often rescinded the requirement. In these cases, it is not clear whether the control technology was ineffective or the maintenance program was flawed.

Because maintenance is critical to successful program implementation, it must be considered throughout the term of the permit. Applicants may wish to develop a matrix that identifies maintenance tasks on a timeline indicating criteria for inspection, repair, and replacement. PERT charts, GANT charts, or other critical path analyses (available for personal computers) can help organize a maintenance program and schedule. For a summarized listing of appropriate maintenance activities and schedules refer to the matrix in Exhibit 6-3.

6.4.3 Considerations for Planning and Siting Controls

The storm water management program should describe the criteria used to identify that a particular structural control is warranted and the circumstances under which it will be required. The possibilities for new control sites should be evaluated for their storm water quality control potential. Guidelines and performance standards that identify specific structural controls for new development should be proposed in the procedures for new development. From this evaluation, priorities based on the feasibility of implementing a particular control at a given location can be determined.

6.4.3.1 Use of Municipal Lands

Applicants should discuss existing major structural controls and sites that have the potential for new structural controls which could be installed on municipal lands and other major rights-of-way (e.g., major roads and highways). Note that existing controls are identified in Part 1 applications [(§122.26(d)(1)(iii)(B)(5)]. The location of publicly owned parks, recreational areas, and other open areas are also identified [§122.26(d)(1)(iii)*(6)*].

To determine what storm water quality controls are necessary for public lands and facilities, current activities and functions that may affect the quality of storm water discharges should be identified. Such activities and functions include parks, trails, and other recreational land uses, road maintenance and snow management, and storage and repair yards/shops for municipal vehicles. An inventory of public land uses may be necessary to help make determinations of what controls are needed. An effective inventory should involve coordination among all of the local departments and agencies that have authority over the use of public lands and facilities.

Opportunities for controlling storm water quality problems that are identified through the inventory process can be evaluated on a site-specific basis and included in the proposed management program.

There are several benefits to the establishment of structural controls on municipal lands:

- Municipal lands often provide greater retrofit opportunities because they typically do not require additional property purchases;
- Municipal lands ensure opportunities to provide future maintenance and security in preservation of the retrofit control;
- Applicants may be able to adapt existing municipal functions (such as industrial pretreatment program implementation, fire-safety inspections, and flood-control activities) to address storm water quality concerns (Expanding their mission to address storm water concerns may be more cost-effective than initiating entirely new programs.);
- Applicants may be able to adapt functions of development on municipal lands (such as planning, zoning, and construction oversight functions); and
- After considering controls on municipal lands, the applicant will be in a better position to address the private land under its jurisdiction.

As a precaution, however, applicants need to consider potential conflicts arising over the multiple use of public lands. Criteria other than land ownership (e.g., locating controls downstream of developed areas) also should be considered when deciding where to locate storm water runoff controls.

6.4.3.2 Use of Private Lands

A municipality also may incorporate storm water quality controls into its land use plan to indicate controls that may be necessary for new development. Some of the best opportunities to prevent pollution and to implement effective storm water quality controls occur during development. Local governments typically play a strong role in overseeing new development and have, or can adapt, administrative infrastructure to address storm water quality concerns.

The storm water management process should begin with land use planning and zoning and continue through the development and redevelopment processes. Municipalities generally can obtain commitments from land developers more easily prior to relinquishing jurisdictional leverage over the parcel where the potential control is to be located. Leverage can be achieved through plan approval or zoning changes. The negotiation process for the dedication, condemnation, or other acquisition of land and the process for getting the land developer to construct or otherwise implement controls will vary dramatically among municipalities, particularly among those in different States.

Source and structural controls are most cost-effective when development is planned with storm water quality controls in mind. However, it is probably more appropriate for the municipality to propose a flexible plan that specifies a variety of program objectives through the development process rather than identifying a certain priority and rigid schedule. Other benefits of early and flexible planning include ecological diversity, wetlands preservation, and the creation of controls that also function as amenities. Comprehensive land use plans, zoning ordinances, and subdivision ordinances are important mechanisms to implement these controls early in the development process. Consideration of storm water quality during pre-development is one of the most effective ways to implement controls. This is because the maximum flexibility (and opportunity) to incorporate BMPs exists prior to final land use decisions and construction activities (see Section 6.3.1.1)

6.4.3.3 Siting Considerations

Imperviousness

The degree of imperviousness affects the concentration of pollutants in storm water, which in turn affects the type of structural controls that may be necessary. As the imperviousness of an area increases, the runoff volume and the pollutant loading increase. Studies show that runoff from industrial areas, which generally have a high degree of imperviousness, can have a wider variety and greater concentration of pollutants than runoff from other land uses. Recent studies also indicate that the degree of imperviousness can be inferred from the level of degradation in urban receiving streams. (For example, see Schueler 1991 and Klien 1979.) Population projections will not indicate the degree to which industrial land use will increase unless planning and zoning information is also considered.

Soil Conditions

Controls designed to infiltrate storm water will be affected by site specific soil conditions. For example, clay content of the soil and the antecedent moisture content (degree of soil saturation at the time of a given storm event) will strongly influence the effectiveness, and therefore the applicability, of infiltration controls for a given location.

6.5 PROGRAM AND SCHEDULE TO DETECT AND REMOVE ILLICIT DISCHARGES AND IMPROPER DISPOSAL

NPDES permits for discharges from MS4s require effective detection and removal from the MS4 of illicit or improper discharges and disposal.

§122.26(d)(2)(iv)(B). [The application must include a] description of a program, including a schedule, to detect and remove (or require the discharger to the municipal separate storm sewer to obtain a separate NPDES permit for) illicit discharges and improper disposal into the storm sewer.

The NURP study concluded that the quality of urban runoff can be adversely impacted by illicit connections and illegal dumping. Often, large amounts of wastes, particularly used oils, are improperly disposed of in storm sewers. Elimination of these sources of pollutants would result in a dramatic improvement in the quality of storm water discharges from MS4s. Procedures to eliminate such discharges should be an important part of the proposed management program.

The regulatory requirement cited above is intended to directly implement the mandate of Section 402(p)(3)(B)(ii) of the CWA, which requires permits for MS4s to effectively prohibit non-storm water discharges into storm sewers. In certain instances, the most appropriate action will be for the municipality to ensure that illicit discharges become covered by a NPDES permit. However, in most cases, elimination of illicit discharges or improper dumping is the appropriate focus of this program component. The quality of storm water runoff from inner-city core areas, particularly in older parts of the country, would benefit most from this component.

The applicant should propose a schedule for implementing this program component throughout the initial permit term. This schedule should reflect the priorities identified by the municipality during the application process and be based on the problems particular to the specific MS4.

6.5.1 Prohibiting Illicit Discharges

The proposed management program must include a description of inspection procedures, orders, ordinances, and other legal authorities necessary to prevent illicit discharges to the MS4.

§122.26(d)(2)(iv)(B)(*1*). [The application must include a] description of a program, including inspections, to implement and enforce an ordinance, orders or similar means to prevent illicit discharges to the municipal separate storm sewer system; this program description shall address all types of illicit discharges, however the following category of non-storm water discharges or flows shall be addressed where such discharges are identified by the municipality as sources of pollutants to waters of the United States . . . . *[these sources are listed in the guidance]*.

This proposed management program component also should describe how the prohibition on illicit discharges will be implemented and enforced. The description should include a schedule and allocation of staff and resources. A direct linkage should exist between this program component and the adequate legal authority requirements for the ordinances and orders to effectively implement the prohibition of illicit discharges.

While this program component is required to prohibit all types of illicit discharges, the following categories of non-storm water discharges need only be prohibited by the MS4 when they are identified by the MS4 as sources of pollutants to waters of the United States:

- Water line flushing
- Landscape irrigation
- Diverted stream flows
- Rising ground waters
- Uncontaminated ground water infiltration [as defined at 40 CFR 35.2005(20)] to separate storm sewers
- Uncontaminated pumped ground water
- Discharges from potable water sources
- Foundation drains
- Air conditioning condensation
- Irrigation water

- Springs
- Water from crawl space pumps
- Footing drains
- Lawn watering
- Individual residential car washing
- Flows from riparian habitats and wetlands
- Dechlorinated swimming pool discharges
- Street wash water

While EPA does not consider these flows to be innocuous, they are only regulated by the storm water program to the extent that they may be identified as significant sources of pollutants to waters of the United States under certain circumstances. If an applicant knows, for example, that landscape irrigation water from a particular site flows through and picks up pesticides or excess nutrients from fertilizer applications, there may be a reasonable potential for a storm water discharge to result in a water quality impact. In such an event, the applicant should contact the NPDES permitting authority to request that the authority order the discharger to the MS4 to obtain a separate NPDES permit (or in this case, the discharge could be controlled through the storm water management program of the MS4).

The applicant should consider the specific land use, age, and stage of development in this program component. For example, one study in an established metropolitan area found that 60 percent of automobile-related businesses had improper storm drain connections. While some of the problems discovered in this study were the result of improper plumbing or illegal connections to storm drains, the majority of the connections were approved by the municipality when they were built.

For problem identification and problem-solving, a municipality may elect to implement a follow-up study that traces identified pollution incidents to their source (e.g., up the system). A variety of pollutant-tracing techniques and field screening can be used to identify illicit discharges.

6.5.2 Field Screening

Part 1 of the application requires applicants to submit the results of field screening studies to evaluate the possible occurrence of illicit connections and improper dumping [§122.26(d)(1)(iv)(D)]. Dry weather flows that were encountered during the initial field screening were sampled and analyzed. The analysis was intended to provide information about illicit connections and improper dumping.

In Part 2, applicants are required to propose procedures for continued field screening during the term of the permit.

> §122.26(d)(2)(iv)(B)(2). [The application must include a] description of procedures to conduct on-going field screening activities during the life of the permit, including areas or locations that will be evaluated by such field screens.

Applicants can propose to use procedures similar to those used for field screening required in Part 1 of the application or they can propose alternative procedures and techniques. The Part 1 field screening requirements are found in §122.26(d)(1)(iv)(D) and are explained in the Part 1 guidance manual.

The Part 2 proposed field screening program component should describe areas of the system where the continuation of the field screening program will be conducted and the rationale for selecting these areas. For example, the rationale for continuing field screening at a given location might be that a wide variation in results was obtained during the initial screens. In addition, the applicant should propose field screening for a portion of any recently-identified major outfalls that were not known to the applicant when it prepared its Part 1 application, provided sampling of these outfalls is safe and practicable.

The potential for illicit discharges and improper disposal is generally higher for areas of older development, areas with many automobile-related industries, and areas with significant numbers of heavy industrial facilities. Therefore, in most cases applicants should include these areas in the proposed field screening program.

The description of the field screening component should provide a detailed summary of the departmental responsibility for field activities, frequency of inspections, procedures and equipment to be used, and the procedures for documenting field activities, both in the field and in the office. Generally, the Part 2 field screening program should reflect a continuously narrowing process to trace illicit and improper sources.

6.5.3 Investigation of Potential Illicit Discharges

In order to submit a comprehensive proposed management program, applicants are required to describe procedures for investigating portions of the municipal system where field screening or other information indicates a reasonable potential for illicit discharges.

> §122.26(d)(2)(iv)(B)(3). [The application must include a] description of procedures to be followed to investigate portions of the separate storm sewer system that, based on the results of the field screen, or other appropriate information, indicate a reasonable potential of containing illicit discharges or other sources of non-storm water (such procedures may include: sampling procedures for constituents such as fecal coliform, fecal streptococcus, surfactants (MBAS), residual chlorine, fluorides and potassium; testing with fluorometric dyes; or conducting in storm sewer inspections where safety and other considerations allow. Such description shall include the location of storm sewers that have been identified for such evaluation).

Applicants should propose criteria to identify portions of the system where follow-up investigations are appropriate. For example, calculating a frequency distribution of dry weather flows at each screening site could aid in establishing criteria to identify where follow-up investigations are appropriate.

Procedures to investigate priority locations for illicit connections include inspection of the storm sewer system, use of remote-control cameras, on-site inspections and dye-testing at priority or suspect facilities, and additional discharge monitoring to pinpoint pollutant sources. In some cases, these investigations may be coordinated with pretreatment program inspections. Such approaches are summarized in Exhibit 6-4. Coordinating inspections can be a very effective use of resources. For example, portions of the sanitary sewer system that need evaluation to detect illicit discharge may already be undergoing inspection by operators of the municipal treatment plant.

A checklist should be developed for inspectors to use to detect illicit connections. The checklist should be structured to ensure a comprehensive evaluation of the problem and stipulate the use of the easiest and least expensive detection methods first.

Regardless of the format in which information is compiled (e.g., table, list, text description), EPA suggests that the applicant prepare a map identifying the location of suspected problem areas. The map should be provided as part of the Part 2 application.

The proposed program component description should describe a step-by-step process to investigate, identify, and prohibit illicit discharges. If field screening leads to positive tests of fecal coliform, fecal streptococcus, surfactants, residual chlorine, fluorides, or potassium, a municipality should reconsider whether any of the non-storm water discharges described in Section 6.5.1 are the source (see previous section).

Exhibit 6-4
Sample Illicit Discharge Investigation Procedures Options

Results of Initial Field Screen	Procedures for Detailed Analysis	Comments
Plumbing unidentifiable	Cameras	Effective for identifying deterioration
Uncertain use of facility	On-site inspections	May be combined with other inspections
Several facilities or complex plumbing	Dye-testing	Simple and accurate if system not interconnected
Unusual pollutants	Monitoring	Particularly useful for fingerprinting

6.5.4 Spill Response and Prevention

The proposed management program must describe procedures that the municipality will implement during the term of the permit to prevent, contain, and respond to spills that may discharge into the MS4.

> §122.26(d)(2)(iv)(B)(4). [The application must include a] description of procedures to prevent, contain, and respond to spills that may discharge into the municipal separate storm sewer.

The municipality and the property owners (and/or operators) of sites where spills may occur need to implement procedures to prevent, contain and respond to spills. One way to implement these procedures is to modify the land use planning process and ordinance enforcement. Such modifications would require notification and emergency preparedness procedures for any land use activity that could lead to leaks and spills. Another method is to coordinate with on-going programs in other regulated areas where detection of spills is important, such as pretreatment and hazardous materials management. The goal of a spill-prevention program is to reduce the frequency and extent of spills of hazardous materials, oils, and other materials which can cause water quality impairment. Spill-containment programs may establish minimum chemical storage and handling requirements, require users to submit prevention and control plans, and ensure site inspections. The content of the descriptions that should be submitted with the Part 2 application for each of these program elements is discussed in more detail below.

Spill-response programs are intended to reduce risk to the public and the environment. Although these programs tend to focus on issues of public health and safety, such as exposure to toxic materials, fires, or explosions, spill-response teams should attempt to prevent or minimize contamination of surface water, ground water, and soil. Spill-response programs often require a coordinated response from a number of municipal departments (e.g., fire, police, health, and public works). Municipalities should describe how response procedures within these programs attempt to mitigate potential pollutant discharges to surface waters.

For example, some industrial pretreatment programs specifically require that leaks or spills be routed to the storm sewer rather than the sanitary sewer generally to protect worker health and safety and to protect biological treatment capabilities. This issue serves to reinforce the need for coordination between the various municipal programs that are related in some way to storm water.

The proposed program should identify the municipal departments responsible for implementing the program, and also should address employee training, reporting procedures, containment of spills, storage and disposal activities, documentation, and follow-up procedures. Generally, the proposed program for spill response and prevention should focus on good housekeeping and materials management practices, which are discussed in more detail below.

One of the initial elements in the development of a successful spill response and prevention program is to assess the potential of various sources at a particular property to contribute pollutants to the storm water discharges from the site. This assessment should inventory the land use, types of materials handled, and the location and types of materials management activities. Factors to consider when evaluating the pollution potential of runoff from various portions of a site include those that are likely to lead to the identification of specific structural or nonstructural controls to address problems.

Other factors to consider are the toxicity and quantity of any chemicals used, produced, stored, or discharged from the site; the history of any NPDES permit violations from a site; history of significant leaks or spills of toxic or hazardous pollutants; and the designated uses of the receiving waters.

This program element should also include a description of storm water management controls that are appropriate for the site that would control or allow for the mitigation of any leak or spill and a proposal to implement such controls. The priorities developed in the implementation proposal should reflect the nature of identified sources of pollutants at the site.

The description of spill response and prevention activities should include the steps a municipality will take to prevent, and when necessary, adequately respond to spills discharged to its MS4. The MS4 might identify special training requirements for municipal employees in order to respond to spills of hazardous chemicals from a particular facility into the storm sewer system.

Sources with the greatest potential for spills to occur (or cause the most severe damage) should be identified in the proposed storm water management program. If appropriate, specific materials handling procedures and storage requirements should be identified for these sources. Requirements for these sources could be modeled after the Spill Prevention, Control, and Countermeasure (SPCC) Plans that are required for certain facilities under Section 311 of the CWA.

Under the SPCC program, for example, personnel are trained and given responsibility for inspecting the facility for leaks and spills. These inspections include equipment and materials handling areas, which need to be investigated for evidence of, or the potential for, pollutants entering the drainage system. Procedures to ensure the availability of appropriate personnel and equipment for cleaning up spills must be identified. A system to ensure that appropriate corrective action has occurred in response to inadequacies identified during the inspection is also established under the program.

Not all of the SPCC program elements may be necessary for municipal applicants. However, EPA recommends that the proposed storm water management program describe how the records of inspections will be maintained and made available for investigations of causal factors and program effectiveness. Incidents of leaks, spills, and improper dumping, along with other information describing the quality and quantity of storm water discharges should be included in the records. Inspections and maintenance activities, such as containment berm integrity testing or the cleaning of oil/water separators should be documented and recorded in a maintenance log.

6.5.5 Public Awareness and Reporting Program

Applicants must propose a management program component that promotes, publicizes, and facilitates public reporting of illicit discharges or water quality impacts associated with discharges from MS4s.

> §122.26(d)(2)(iv)(B)(5). [The application must include a] description of a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or water quality impacts associated with discharges from municipal separate storm sewers.

Timely reporting by the public of improper disposal and illicit discharges are critical components of programs to control such sources.

To enhance public awareness, programs may include setting up a public information hotline number; educating school students; establishing community and volunteer "watchdog" groups (e.g., "Adopt-a-Stream Program"); using inserts into utility bills; and newspaper, television and radio announcements to inform the public about what to look for and how to report incidents. The public awareness efforts should clarify to the public that they are the ultimate beneficiaries of a successful storm water management program.

6.5.6 Proper Management of Used Oil and Toxics

EPA estimates that annually, 267 million gallons of used oil, including 135 million gallons of used oil from do-it-yourself automobile oil changes, are disposed of improperly. An additional 70 million gallons of used oil, most coming from service stations and repair shops, are used for road oiling (55 FR 48056, November 16, 1990). If private individuals find the proper disposal of used oil or toxic materials difficult, incidents of improper disposal increase. For example, when a large fraction of service stations do not accept do-it-yourself used oil, improper disposal into the municipal storm sewer rises. Therefore, applicants are required to propose a program component that will facilitate the proper disposal of used oil and toxics from households by establishing municipally operated collection sites, or ensuring that privately-operated collection sites are available.

> §122.26(d)(2)(iv)(B)(6). [The application must include a] description of educational activities, public information activities, and other appropriate activities to facilitate the proper management and disposal of used oil and toxic materials.

The proposed program should describe outreach plans to handlers of used oil and to the public, and operating plans for oil and household waste collection programs.

Examples of effective public outreach for these types of programs include dedicated municipal phone numbers (e.g., a used oil/toxic materials hotline), pamphlets, and requirements that oil retailers post the location of the nearest used oil collection facility. Programs can also inform the public about alternatives to toxic materials. Catch basin/storm sewer inlet stenciling programs can also be proposed as part of the program to increase public awareness of the connection between storm sewers and local water resources.

6.5.7 Infiltration of Seepage

In order to effectively complete this portion of a proposed management plan, the applicant must describe controls to limit infiltration of seepage from municipal sanitary sewers to MS4s, if necessary.

> §122.26(d)(2)(iv)(B)(7). [The application must include a] description of controls to limit infiltration of seepage from municipal sanitary sewers to municipal separate storm sewer systems where necessary.

Raw sewage can seep from sanitary sewage collection systems through leaks and cracks in aging pipes, poorly constructed manholes and joints, and main breaks. Sewage from a leaky sanitary system can flow to storm sewers or contaminate ground water supplies. Interaction between sanitary sewers and separate storm sewers may occur at manholes and where sanitary sewer laterals and storm sewer trenches cross. Separate storm sewers and sanitary sewers may share the same trench, which is generally filled with very porous material such as gravel.

One indication of seepage from a sewage collection system may be infiltration of water. Often, the rate of exfiltration (seepage) from sanitary collection systems is significantly greater than the rate of infiltration into the system. An EPA study on sewer exfiltration found significant ratios of the rate of exfiltration of sewage to the rate of infiltration of ground water or storm water into sanitary sewers. Field and laboratory results found this ratio to vary between 1.5 to 1 and 14 to 1.

In some cases, preventive maintenance surveys or on-going infiltration and inflow (I&I) programs to determine where water is entering a sanitary sewer system may be modified to locate the source and fate of exfiltration from the system.

Identifying infiltration of seepage into a MS4 is a good example of the need for various municipal functions to be effectively coordinated. Proposed storm water management programs might discuss how personnel responsible for inspections of the sanitary sewer system could inspect for sources of exfiltration during I&I inspections, and pass any findings to personnel responsible for maintaining the MS4. If seepage is believed to be a problem, a coordinated effort with the maintenance department of the municipal sanitary sewer system is recommended.

The proposed storm water management program also should include provisions to address the discovery of previously unknown problems. There should be procedures to enact a coordinated program between the operators of the storm sewer and sanitary sewer (which in many cases will be within the same municipal agency or department).

EPA recommends that the proposed storm water management program describe controls that will be used to address seepage from malfunctioning septic systems in areas not served by a sewage treatment works. Malfunctioning septic systems may lead to more significant surface runoff pollution problems than ground water problems. A malfunctioning septic system is less likely to cause ground water contamination where an impervious bacterial mat in the soil retards the downward movement of wastewater. (Poorly located septic systems that are operating properly are the greatest threat to ground water).

Surface malfunctions of septic systems are caused by clogged or impermeable soils, or when stopped up or collapsed pipes force untreated wastewater to the surface. Surface malfunctions can vary in degree from occasional damp patches on the surface to constant pooling or runoff of wastewater to a storm sewer. An improper remedy for a surface malfunction is to install a pipe or trench over soil absorption systems to route untreated overflow away from the septic system. This results in direct discharges to drainage ditches, empty lots, or surface waters.

Proper controls range from prescribing maximum intervals between tank pump-out to the installation of sand filters. Discharge from sand filters to surface waters may require a separate NPDES permit, because such discharge is not storm water.

Additional information about the most appropriate controls for use in correcting malfunctioning septic systems is probably best obtained from local or regional sources. Organizations such as extension services, soil and water conservation districts, and planning agencies may be good sources of information about methods that have been successful (and also those that have failed).

By obtaining this type of information, the applicant can determine what control techniques have been successful in correcting malfunctioning septic systems in similar types of soils. The value of this approach is that the applicant will know that a certain control technique has been used to correct a malfunctioning septic system in the same types of soils that occur in the municipality. Where only part of the MS4 drainage area is served by septic systems, proposed programs should address setting and maintenance of septic systems, including draft requirements and implementation procedures.

6.6 SIGNATORY AND CERTIFICATION REQUIREMENTS

Under the Federal NPDES regulations [§122.22(a)], all NPDES permit applications (including municipal storm water permit applications) must be signed by an authorized person, as defined in the regulations. Permit applications submitted by a municipality, State, Federal, or other public agency must be signed by either a principal executive officer or ranking elected official [§122.22(a)(3)]. To fulfill the signatory requirements, the person signing the municipal application must provide his or her name (printed or typed), title, and date signed. In addition, the applicant should provide the name, address, and telephone number of the person signing the application or another point of contact that can answer questions about the application.

In addition, §122.22(d) states that any person signing a permit application must make the following certification:

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

6.7 IMPLEMENTATION OF THE STORM WATER PROGRAM

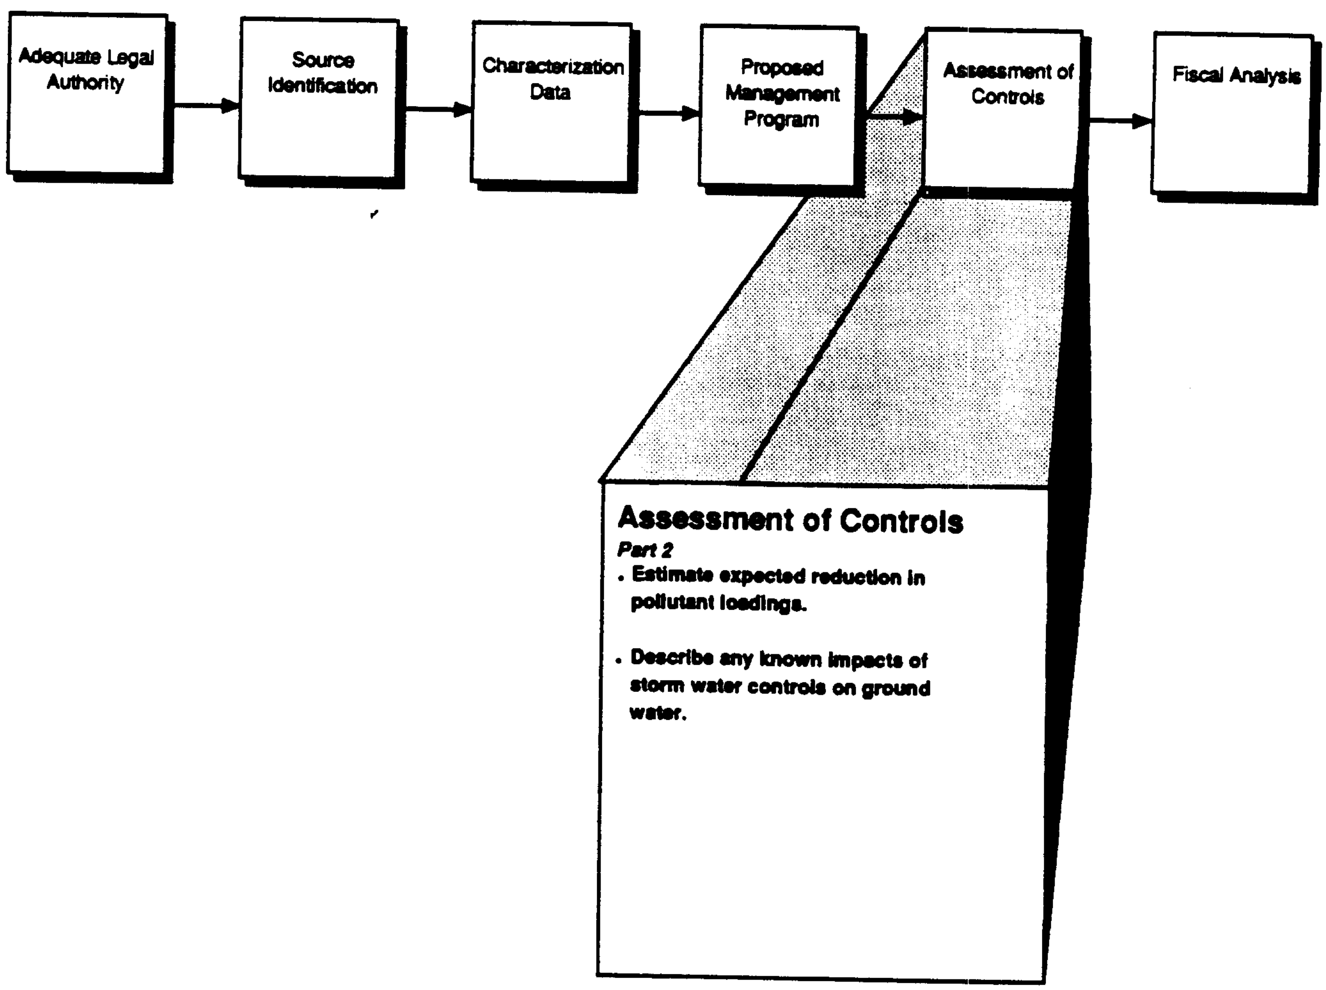
EPA anticipates that municipal storm water management programs will mature over time to reflect advances in technology, additional data collection, changing conditions, program development, stage of implementation, and improvements in water quality. Therefore, applicants may emphasize different program components to reflect implementation priorities. The proposed management program should clearly identify each of the program components and include a schedule for implementation. Each component of the Part 2 application should be classified as: full implementation, phased implementation, pilot study, or feasibility analysis. In annual reports on the progress of storm water management programs, municipalities must report on the status of implementing program provisions [§122.42(c)(1), or Section 7.3 of the guidance].

- **Full Implementation.** Fully implemented components should be proposed when the municipality is prepared to begin or continue full implementation after its permit is issued and it expects to continue the component throughout the life of the permit. Full implementation of a program component is generally the preferred way of demonstrating the required level of control.

- **Phased Implementation.** Phased implementation should be proposed when the level of effort to implement the component will vary during the term of the permit. Phased implementation may be appropriate when additional data must be collected or technical guidance, training materials, or appropriate ordinances must be developed prior to full implementation. A schedule that includes milestones should be part of the description.

- **Pilot Studies.** Although the municipality must implement and comply with *each* provision of the municipal storm water permit, the municipality may choose to carry out pilot studies that involve limited experimental implementation of a program component. In some cases, pilot studies may be authorized by the permit. Used to evaluate the effectiveness of a program component, pilot studies may be appropriate when a technology is unproven or when data must be collected to develop operating standards or procedures. A schedule including milestones should be included in the description of a pilot study. This schedule should provide options for phased implementation of the program component, showing alternatives based on various possible results of the pilot study.

CHAPTER 7
ASSESSMENT OF CONTROLS



7.0 ASSESSMENT OF CONTROLS

7.1 BACKGROUND

Part 2 applications require that municipalities estimate the effectiveness of their proposed storm water quality management programs. The regulations require an initial estimate or assessment because the performance of appropriate management controls is highly dependent on site-specific factors. Program effectiveness can be estimated through both **direct measurements** (such as reductions in annual pollutant loads) and **indirect measurements** (such as measurements that demonstrate increased public awareness of storm water quality issues). At a minimum, applicants must submit estimated reductions in pollutant loads expected to result from implemented controls and describe known impacts of storm water controls on ground water.

> **122.26(d)(2)(v).** *Assessment of controls.* The application must include] estimated reductions in loadings of pollutants for discharges of municipal storm sewer constituents from municipal storm sewer systems expected as the result of the municipal storm water quality management program. The assessment shall also identify known impacts of storm water controls on ground water.

Reductions in pollutant loads due to the implementation and maintenance of structural controls provide direct measurements of the effectiveness of the storm water management program. In addition, EPA encourages applicants to go beyond the minimum requirement and assess the effectiveness of their storm water management program through other direct measurements as well as indirect measurements. As discussed below, indirect measurements provide surrogate estimates of qualitative factors, such as increased public awareness of storm water quality issues.

Estimates of the effectiveness of the storm water management program will assist the municipality and the permit writer in:

- Determining whether the most cost-effective best management practices (BMPs) are included in the storm water management program;
- Ensuring that the storm water management program includes adequate public participation programs and intergovernmental coordination;
- Establishing on-going monitoring inspection and surveillance programs that help refine estimates of program effectiveness; and
- Developing a strategy to evaluate progress toward achieving water quality goals.

7.2 ASSESSMENT OF STORM WATER MANAGEMENT PROGRAM

For some components of a proposed storm water management program, such as structural controls (e.g., vegetative streambank stabilization, sediment pond or basin, etc.), the effect on pollution in storm water runoff is observable, and pollutant removal efficiencies can be estimated directly. For other components, pollutant reductions may be difficult to quantify. Applicants may need to use indirect estimates. For example, a program component may address source controls such as changing the behavior of citizens in the community, or improving the municipal control of industrial or commercial runoff. For components of the proposed management program where pollutant removal efficiency cannot be reasonably estimated, applicants are strongly encouraged to identify some indirect measurement that can be used to evaluate the success of the practice.

7.2.1 Direct Measurements of Program Effectiveness

As discussed above, 40 CFR 122.26(d)(2)(v) requires that applicants submit estimates of expected pollutant load reductions with their Part 2 applications. To supplement these estimates, applicants could provide estimates of other direct measurements of program effectiveness, including:

- Removal efficiencies of BMPs that control storm water quality;
- Reductions in the volume of storm water discharged;
- Reductions in event mean concentrations; or
- Reductions in seasonal pollutant loadings.

Such direct estimates do not have to be verified with quantitative data, but can be based on accepted engineering design practices. However, the applicant should describe its procedures for estimating the effectiveness of the control. Applicants should present estimates of pollutant load reductions or other measurements separately for each component of the proposed management program. Applicants should provide estimated reductions on a watershed basis and system-wide basis.

Reductions in pollutant loadings can be estimated by first estimating the pollutant loading (based on concentrations and flows) that would result without the control measure. This value should then be multiplied by the efficiency of the control expressed in terms of a fraction or percentage. Estimated control efficiencies can be obtained from published sources, such as Schueler (1987) (see bibliography in Appendix A). Note that for most control measures, the pollutant removal efficiency differs for different classes of pollutants.

After the municipality's storm water management program is implemented, the municipality can work to refine its initial assessment of the program. For example, the permit will require applicants to submit estimates of event mean concentrations and estimates of annual pollutant loadings for each outfall in the system [§122.26(d)(2)(iii)(C), discussed in Section 5.5 of this guidance]. These estimates can be compared with the applicant's initial estimates.

In addition, the estimated removal efficiencies can be refined through the monitoring program required by §122.26(d)(2)(iii)(D) (discussed in Section 5.6 of this guidance). To refine these estimates, the monitoring program should include measurements at the inflow and outflow points of the control. Throughout the permit term, the municipality must submit refinements to its assessment or additional direct measurements of program effectiveness in its annual report (Section 7.3).

The applicant should use direct measurements of program effectiveness as it begins to assess its long-term progress in improving water quality through storm water management practices. Direct measurements of program effectiveness may not provide meaningful conclusions on trends in water quality improvements for a couple of permit terms. However, applicants are encouraged to use direct measurements of program effectiveness, such as annual pollutant loads, event mean concentrations, and seasonal pollutant loadings, to begin to estimate long-term trends. Several statistical methods that rely on linear regression have been developed to model these measurements to determine if trends exist.

7.2.2 Indirect Measurements of Program Effectiveness

When pollutant reductions cannot be estimated through direct measurement, appropriate indirect measurements may be used. These may include the estimated level of increased enforcement activity, increased public awareness, or reduction in number of illegal dumping incidents. For example, a field screening program to identify illicit connections and improper dumping in Fort Worth, Texas, used reductions in observations of indicator pollutants as a measure of the success of the program (Fort Worth, 1988).

Other possible indirect measurements include:

- Gallons of used oil recycled;
- Amount of household hazardous waste collected;
- Number of educational brochures on storm water quality distributed;
- Number of public hearings on storm water and attendance at these hearings;
- Circulation of an annual report or periodic newsletters on progress in meeting storm water quality goals;
- Number of reports of illicit discharges or illegal dumping;
- Number of spill clean-ups;
- Number of sewer inlets stenciled;
- Acres of open space;
- Number of construction and erosion and sediment control plans submitted and approved.

Many of these indirect measurements will help to indicate whether the storm water management program includes adequate public participation and intergovernmental coordination.

7.2.3 Impacts of Storm Water Controls on Ground Water

Structural BMPs may have an impact on other media. Therefore, the Part 2 application requires that applicants discuss known impacts of storm water controls on ground water. Impacts should be identified separately for each component of the proposed management program. These controls may increase the quantity of ground water (such as infiltration leading to recharge), but degrade the quality of the ground water. For example, in arid parts of the Southwest, imported water is often used for irrigation. This increases the quantity of ground water, but, because of high levels of nutrients and total suspended and dissolved solids in the irrigation water, also results in impacts on ground water quality.

In addition, the applicant should evaluate whether structural controls for storm water impact other media, such as wetlands.

7.3. ANNUAL REPORTS ON THE EFFECTIVENESS OF THE STORM WATER MANAGEMENT PROGRAM

Under §122.42(c), applicants must provide annual reports on the progress of their storm water management programs. These reports, which are due on the anniversaries of permit issuance, must include:

- The status of implementing the components of the storm water management program that are required by the permit;
- Proposed changes to the storm water management programs that are established as permit conditions;

- Revisions, if necessary, to the assessment of controls and the fiscal analysis reported in the permit application;

- Summary of data, including monitoring data, that are accumulated throughout the reporting year;

- Projected annual expenditures and budget for the year following each annual report;

- A summary describing the number and nature of enforcement actions, inspections, and public education programs; and

- Identification of water quality improvements or degradation.

Applicants should refer to the specific regulatory language in §122.42(c) for a more complete discussion of annual reporting requirements.

Although the Part 2 application requirements do not specifically address annual reporting requirements, applicants should consider their strategy for preparing annual reports when they complete their Part 2 applications. A municipality may develop a strategy to assess the progress of its storm water management program throughout the term of the permit in addition to providing a baseline assessment of its program. To develop the strategy, applicants should:

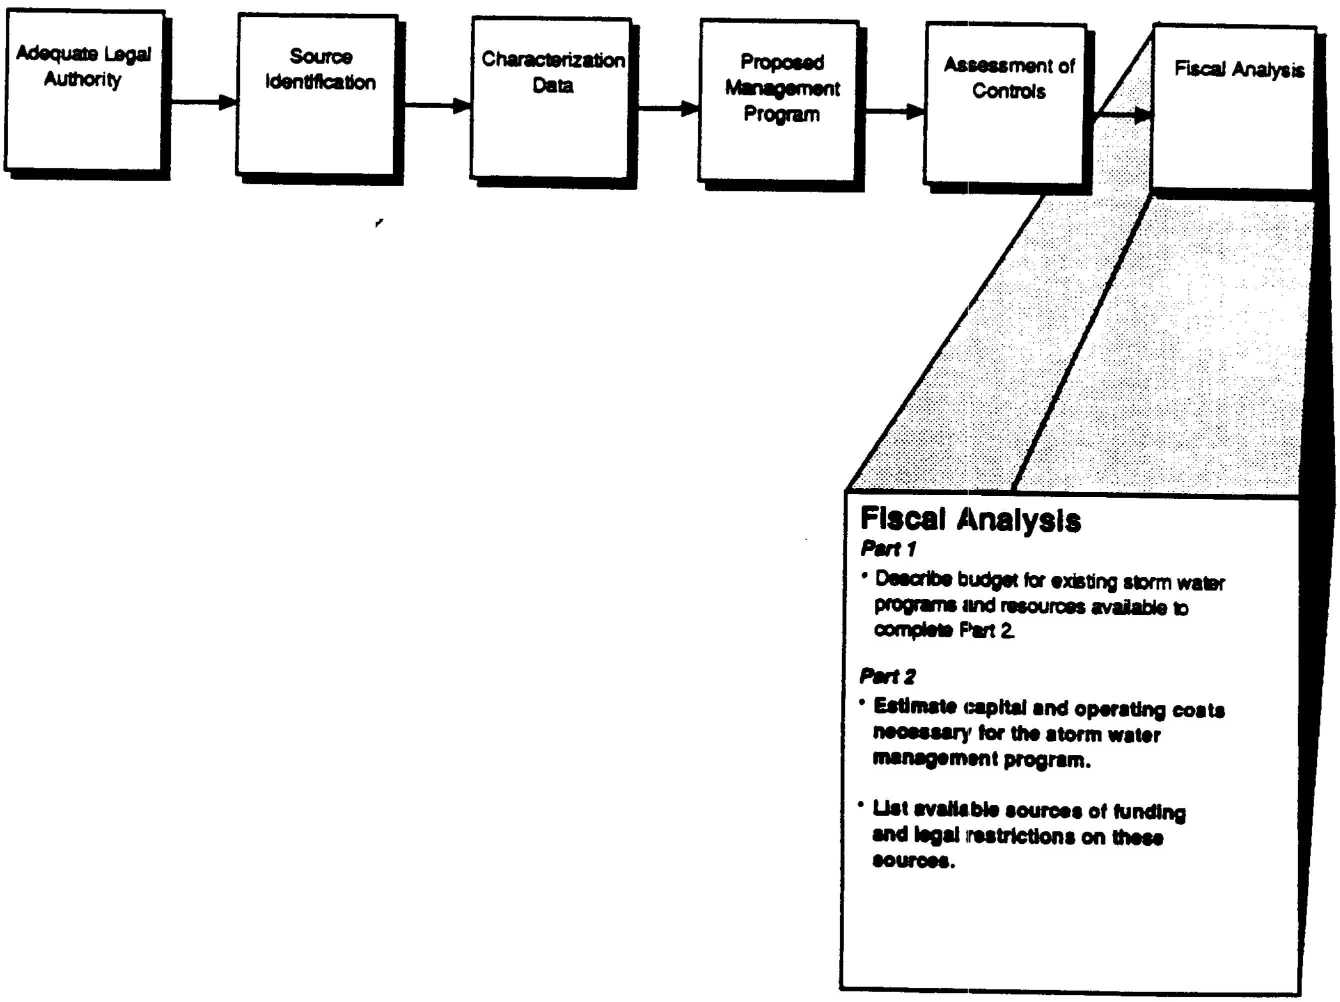
- Identify the direct or indirect measurements that will be used to track the long-term progress of the applicant's program towards achieving improvements in storm water quality (the results of this assessment would appear in the municipality's annual report);

- Discuss the role of monitoring data in substantiating or refining their assessment of the progress of their program towards established objectives and goals; and

- Discuss how future additions or revisions to the assessment measurements or strategy will be implemented by the municipality (e.g., what roles and responsibilities will participating municipal agencies and/or organizations have in this area).

It is anticipated that many municipalities will use the same criteria or measurements that were used in the baseline assessment to develop their long-term assessment strategy. This is an acceptable approach provided that the municipality delineates how their program provides for a longer term assessment of the progress of their storm water management program. The municipality is encouraged to consider in advance the information requirements for annual reporting that are identified above when developing their long-term assessment strategy.

CHAPTER 8
FISCAL ANALYSIS



8.0 FISCAL ANALYSIS

8.1 BACKGROUND

NPDES permits for discharges from MS4s will require municipal permittees to implement management programs, conduct long term storm water monitoring, and provide other information. Because these activities will result in expense to the municipality, a fiscal analysis is required in the Part 2 application.

Applicants must provide yearly cost estimates for these programs. Applicants also must provide a schedule indicating when funds will be available. Examining the levels of proposed spending and funding allows the permitting authority to gauge the ability of the applicant to implement the program and predict its effectiveness. The fiscal analysis also will help the permit writer determine whether the applicant has met the statutory requirement of reducing the discharge of pollutant to the MS4 to the maximum extent practicable. Finally, the estimates help the applicant evaluate the feasibility and cost-effectiveness of its program. A municipality must update its fiscal analysis each year for the annual report on the progress in implementing their storm water management program [40 CFR 122.42(c)(3) and (5), discussed in Section 7.3 of this guidance].

> **§122.26(d)(2)(vi).** [The application must include] for each fiscal year to be covered by the permit, a fiscal analysis of the necessary capital and operation and maintenance expenditures necessary to accomplish the activities of the programs under paragraphs (d)(2)(iii) and (iv) of this section. Such analysis shall include a description of the source of funds that are proposed to meet the necessary expenditures, including legal restrictions on the use of such funds.

8.2 PROCEDURE FOR CONDUCTING A FISCAL ANALYSIS

Under §122.26(d)(2)(vi), each applicant must demonstrate sufficient financial resources to implement the conditions of the permit.

Adequate resources may be demonstrated by performing a fiscal analysis of the estimated capital and operation and maintenance expenditures required to complete the activities required by the regulations. This fiscal analysis must be performed for each fiscal year to be covered by the permit (5 years, in most cases). The analysis must describe the source of the funds used to meet the necessary expenditures, including any legal restrictions on the appropriated funds.

The following procedure is an example of a method of conducting the necessary fiscal analysis.

Step 1. Identify the major tasks for each component covered by this application requirement, including:

- Elements of the proposed management program;
- Estimates of seasonal loads and event mean concentrations for each major outfall covered by the permit; and
- Proposed monitoring program.

Step 2. Develop a schedule outlining when each of the tasks identified in Step 1 will be undertaken. Some tasks may be performed just once, others may be on-going. For example, the schedule should include, among other things:

- The installation of any new control measures identified in the proposed management program [§122.26(d)(2)(iv), discussed in Section 6.4];

- A maintenance schedule for structural best management practices (BMPs) [§122.26(d)(2)(iv)(A)(*1*), discussed in Section 6.4.3];

- Development of seasonal pollutant loadings and event mean concentrations of a representative storm [§122.26(d)(2)(iii)(C), discussed in Section 5.5];

- Monitoring program for representative data collection for the term of the permit [§122.26(d)(2)(iii)(D), discussed in Section 5.6];

- Monitoring program for industrial facilities [§122.26(d)(2)(iv)(C)(2), discussed in Section 6.3.3];

- On-going field screening program for illicit discharges [§122.26(d)(2)(iv)(B), discussed in Section 6.5];

- Development of certification programs for construction workers or pesticide applicators, if appropriate [§122.26(d)(2)(iv), discussed in Sections 6.3.1 and 6.3.2]; and

- Implementation schedules for other components of the storm water application that have not been fully implemented at the time of application, such as additional legal authority or comprehensive development plans.

Step 3. Estimate the capital expenses necessary to accomplish the tasks identified in Step 1 and determine a schedule for purchase. Applicants may elect to define categories of capital expenditures such as "monitoring equipment," "miscellaneous monitoring supplies," "personal protective equipment," etc.

Step 4. Estimate other non-capital costs to implement the tasks identified in Step 1. Use the schedule developed in Step 2 to spread costs over the term of the permit. Costs should be presented as a total annual cost for each proposed program component. In addition, estimates of the total annual costs and annual per capita costs should be provided. Per capita costs can be compared with the per capita costs of other programs, such as sewage treatment programs.

These costs may include items such as :

- Newspaper ads announcing new programs or recycling centers;

- Holding public meetings or hearings; and

- Labor for department personnel to speak to citizens groups.

Step 5. Identify funding to be applied. Applicants must describe the sources of funding and any legal restrictions on that funding. Sources may include general revenues, storm water utilities, plan review fees, permit fees, industrial/commercial user fees, special assessment district funds, and revenue bonds. Some funding sources, such as general revenues based on property taxes, are generally unrestricted, but can be allocated by local officials annually. In a few cases, a local property tax may be dedicated to finance a storm water management program. For example, one county finances its storm water management program through a dedicated property tax of $0.135 per $100 assessed valuation. Other municipalities add special assessments to property tax bills.

A storm water utility is another source of funding dedicated to financing storm water management activities. The storm water utility offers the advantage of a stable and predictable source of funds. Other advantages of storm water utilities over general revenues are that utility charges can be more equitably based on the user's contribution to local storm water problems, and a utility provides a mechanism to incorporate incentives for on-site storm water management.

In many cases, municipalities will evaluate sources of funds that are not currently available, such as a new storm water utility. In these cases, applicants must include a schedule of when funds will be available. For example, it usually takes a municipality 18 to 24 months of planning before local elected officials authorize a storm water utility, and another 6 to 12 months to implement the utility (Lindsey, 1988). Key milestones for planning and implementing the funding mechanism must be identified in the schedule. The following components have been found to be important in establishing storm water utilities:

- Determining the most appropriate administrative structure for implementing a storm water management program;
- Adopting a storm water utility ordinance;
- Estimating revenue needs and planning for cost recovery;
- Establishing a utility rate structure and billing system;
- Establishing a system for developer contributions; and
- Implementing a public information program.

Step 6. Compare the funding sources with the funding needs. As a last step in this process, the municipality must ensure that adequate funding is available to cover the cost of implementing the storm water management program. If adequate funding is not available, the municipality must consider alternate sources of funding, such as a storm water utility.

APPENDIX B:
PART 2 APPLICATION
REQUIREMENTS

certify, pursuant to 5 U.S.C. 605(b), that these amendments do not have a significant impact on a substantial number of small entities.

List of Subjects in 40 CFR Parts 122, 123, and 124

Administrative practice and procedure, Environmental protection, Reporting and recordkeeping requirements, Water pollution control.

Authority: Clean Water Act, 33 U.S.C. 1251 *et seq.*

Dated: October 31, 1990.

William K. Reilly,

Administrator.

For the reasons stated in the preamble, parts 122, 123, and 124 of title 40 of the Code of Federal Regulations are amended as follows:

PART 122—EPA ADMINISTERED PERMIT PROGRAMS; THE NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

Subpart B—Permit Application and Special NPDES Program Requirements

1. The authority citation for part 122 continues to read as follows:

Authority: Clean Water Act, 33 U.S.C. 1251 *et seq.*

2. Section 122.1 is amended by revising paragraph (b)(2)(iv) to read as follows:

§ 122.1 Purpose and scope.

* * * * *

(b) * * *

(2) * * *

(iv) Discharges of storm water as set forth in § 122.26; and

* * * * *

3. Section 122.21 is amended by revising paragraph (c)(1), by removing the last sentence of paragraph (f)(7), by removing paragraph (f)(9), by adding two sentences at the end of paragraph (g)(3), by revising paragraph (g)(7) introductory text, by removing and reserving paragraph (g)(10) and by revising the introductory text of paragraph (k) to read as follows:

§ 122.21 Application for a permit (applicable to State programs, see § 123.25).

* * * * *

(c) *Time to apply.* (1) Any person proposing a new discharge, shall submit an application at least 180 days before the date on which the discharge is to commence, unless permission for a later date has been granted by the Director. Facilities proposing a new discharge of storm water associated with industrial activity shall submit an application 180 days before that facility commences industrial activity which may result in a discharge of storm water associated with that industrial activity. Facilities described under § 122.26(b)(14)(x) shall submit applications at least 90 days before the date on which construction is to commence. Different submittal dates may be required under the terms of applicable general permits. Persons proposing a new discharge are encouraged to submit their applications well in advance of the 90 or 180 day requirements to avoid delay. See also paragraph (k) of this section and § 122.26 (c)(1)(i)(G) and (c)(1)(ii).

* * * * *

(g) * * *

(3) * * * The average flow of point sources composed of storm water may be estimated. The basis for the rainfall event and the method of estimation must be indicated.

* * * * *

(7) *Effluent characteristics.* Information on the discharge of pollutants specified in this paragraph (except information on storm water discharges which is to be provided as specified in § 122.26). When "quantitative data" for a pollutant are required, the applicant must collect a sample of effluent and analyze it for the pollutant in accordance with analytical methods approved under 40 CFR part 136. When no analytical method is approved the applicant may use any suitable method but must provide a description of the method. When an applicant has two or more outfalls with substantially identical effluents, the Director may allow the applicant to test only one outfall and report that the quantitative data also apply to the substantially identical outfalls. The requirements in paragraphs (g)(7) (iii) and (iv) of this section that an applicant must provide quantitative data for certain pollutants known or believed to be present do not apply to pollutants present in a discharge solely as the result of their presence in intake water; however, an applicant must report such pollutants as present. Grab samples must be used for pH, temperature, cyanide, total phenols, residual chlorine, oil and grease, fecal coliform and fecal streptococcus. For all other pollutants, 24-hour composite samples must be used. However, a minimum of one grab sample may be taken for effluents from holding ponds or other impoundments with a retention period greater than 24 hours. In addition, for discharges other than storm water discharges, the Director may waive composite sampling for any outfall for which the applicant demonstrates that the use of an automatic sampler is infeasible and that the minimum of four (4) grab samples will be a representative sample of the effluent being discharged. For storm water discharges, all samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inch and at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where feasible, the variance in the duration of the event and the total rainfall of the event should not exceed 50 percent from the average or median rainfall event in that area. For all applicants, a flow-weighted composite shall be taken for either the entire discharge or for the first three hours of the discharge. The flow-weighted composite sample for a storm water discharge may be taken with a continuous sampler or as a combination of a minimum of three sample aliquots taken in each hour of discharge for the entire discharge or for the first three hours of the discharge, with each aliquot being separated by a minimum period of fifteen minutes (applicants submitting permit applications for storm water discharges under § 122.26(d) may collect flow weighted composite samples using different protocols with respect to the time duration between the collection of sample aliquots, subject to the approval of the Director). However, a minimum of one grab sample may be taken for storm water discharges from holding ponds or other impoundments with a retention period greater than 24 hours. For a flow-weighted composite sample, only one analysis of the composite of aliquots is required. For storm water discharge samples taken from discharges associated with industrial activities, quantitative data must be reported for the grab sample taken during the first thirty minutes (or as soon thereafter as practicable) of the discharge for all pollutants specified in § 122.26(c)(1). For all storm water permit applicants taking flow-weighted composites, quantitative data must be reported for all pollutants specified in § 122.26 except pH, temperature, cyanide, total phenols, residual chlorine, oil and grease, fecal coliform, and fecal streptococcus. The Director may allow or establish appropriate site-specific sampling procedures or requirements, including sampling locations, the season in which the sampling takes place, the minimum duration between the previous measurable storm event and the storm event sampled, the minimum or maximum level of precipitation required for an appropriate storm event, the form of precipitation sampled (snow melt or rain fall), protocols fo- collecting samples under 40 CFR part 136, and additional time for submitting data on a

case-by-case basis. An applicant is expected to "know or have reason to believe" that a pollutant is present in an effluent based on an evaluation of the expected use, production, or storage of the pollutant, or on any previous analyses for the pollutant. (For example, any pesticide manufactured by a facility may be expected to be present in contaminated storm water runoff from the facility.)

* * * * *

(k) *Application requirements for new sources and new discharges.* New manufacturing, commercial, mining and silvicultural dischargers applying for NPDES permits (except for new discharges of facilities subject to the requirements of paragraph (h) of this section or new discharges of storm water associated with industrial activity which are subject to the requirements of § 122.26(c)(1) and this section (except as provided by § 122.26(c)(1)(ii)) shall provide the following information to the Director, using the application forms provided by the Director:

* * * * *

4. Section 122.22(b) introductory text is revised to read as follows:

§ 122.22 Signatories to permit applications and reports (applicable to State programs, see § 123.25).

* * * * *

(b) All reports required by permits, and other information requested by the Director shall be signed by a person described in paragraph (a) of this section, or by a duly authorized representative of that person. A person is a duly authorized representative only if:

* * * * *

5. Section 122.26 is revised to read as follows:

§ 122.26 Storm water discharges (applicable to State NPDES programs, see § 123.25).

(a) *Permit requirement.* (1) Prior to October 1, 1992, discharges composed entirely of storm water shall not be required to obtain a NPDES permit except:

(i) A discharge with respect to which a permit has been issued prior to February 4, 1987;

(ii) A discharge associated with industrial activity (see § 122.26(a)(4));

(iii) A discharge from a large municipal separate storm sewer system;

(iv) A discharge from a medium municipal separate storm sewer system;

(v) A discharge which the Director, or in States with approved NPDES programs, either the Director or the EPA Regional Administrator, determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. This designation may include a discharge from any conveyance or system of conveyances used for collecting and conveying storm water runoff or a system of discharges from municipal separate storm sewers, except for those discharges from conveyances which do not require a permit under paragraph (a)(2) of this section or agricultural storm water runoff which is exempted from the definition of point source at § 122.2. The Director may designate discharges from municipal separate storm sewers on a system-wide or jurisdiction-wide basis. In making this determination the Director may consider the following factors:

(A) The location of the discharge with respect to waters of the United States as defined at 40 CFR 122.2.

(B) The size of the discharge;

(C) The quantity and nature of the pollutants discharged to waters of the United States; and

(D) Other relevant factors.

(2) The Director may not require a permit for discharges of storm water runoff from mining operations or oil and gas exploration, production, processing or treatment operations or transmission facilities, composed entirely of flows which are from conveyances or systems of conveyances (including but not limited to pipes, conduits, ditches, and channels) used for collecting and conveying precipitation runoff and which are not contaminated by contact with or that has not come into contact with, any overburden, raw material, intermediate products, finished product, byproduct or waste products located on the site of such operations.

(3) *Large and medium municipal separate storm sewer systems.* (i) Permits must be obtained for all discharges from large and medium municipal separate storm sewer systems.

(ii) The Director may either issue one system-wide permit covering all discharges from municipal separate storm sewers within a large or medium municipal storm sewer system or issue distinct permits for appropriate categories of discharges within a large or medium municipal separate storm sewer system including, but not limited to: all discharges owned or operated by the same municipality; located within the same jurisdiction; all discharges within a system that discharge to the same watershed; discharges within a system that are similar in nature; or for individual discharges from municipal separate storm sewers within the system.

(iii) The operator of a discharge from a municipal separate storm sewer which is part of a large or medium municipal separate storm sewer system must either:

(A) Participate in a permit application (to be a permittee or a co-permittee) with one or more other operators of discharges from the large or medium municipal storm sewer system which covers all, or a portion of all, discharges from the municipal separate storm sewer system;

(B) Submit a distinct permit application which only covers discharges from the municipal separate storm sewers for which the operator is responsible; or

(C) A regional authority may be responsible for submitting a permit application under the following guidelines:

(*1*) The regional authority together with co-applicants shall have authority over a storm water management program that is in existence, or shall be in existence at the time part 1 of the application is due;

(*2*) The permit applicant or co-applicants shall establish their ability to make a timely submission of part 1 and part 2 of the municipal application;

(*3*) Each of the operators of municipal separate storm sewers within the systems described in paragraphs (b)(4) (i), (ii), and (iii) or (b)(7) (i), (ii), and (iii) of this section, that are under the purview of the designated regional authority, shall comply with the application requirements of paragraph (d) of this section.

(iv) One permit application may be submitted for all or a portion of all municipal separate storm sewers within adjacent or interconnected large or medium municipal separate storm sewer systems. The Director may issue one system-wide permit covering all, or a portion of all municipal separate storm sewers in adjacent or interconnected large or medium municipal separate storm sewer systems.

(v) Permits for all or a portion of all discharges from large or medium municipal separate storm sewer systems that are issued on a system-wide, jurisdiction-wide, watershed or other basis may specify different conditions relating to different discharges covered by the permit, including different management programs for different drainage areas which contribute storm water to the system.

(vi) Co-permittees need only comply with permit conditions relating to discharges from the municipal separate storm sewers for which they are operators.

(4) *Discharges through large and medium municipal separate storm sewer systems.* In addition to meeting the requirements of paragraph (c) of this section, an operator of a storm water discharge associated with industrial activity which discharges through a large or medium municipal separate storm sewer system shall submit, to the operator of the municipal separate storm sewer system receiving the discharge no later than May 15, 1991, or 180 days prior to commencing such discharge: the name of the facility; a contact person and phone number; the location of the discharge; a description, including Standard Industrial Classification, which best reflects the principal products or services provided by each facility; and any existing NPDES permit number.

(5) *Other municipal separate storm sewers.* The Director may issue permits for municipal separate storm sewers that are designated under paragraph (a)(1)(v) of this section on a system-wide basis, jurisdiction-wide basis, watershed basis or other appropriate basis, or may issue permits for individual discharges.

(6) *Non-municipal separate storm sewers.* For storm water discharges associated with industrial activity from point sources which discharge through a non-municipal or non-publicly owned separate storm sewer system, the Director, in his discretion, may issue: a single NPDES permit, with each discharger a co-permittee to a permit issued to the operator of the portion of the system that discharges into waters of the United States; or, individual permits to each discharger of storm water associated with industrial activity through the non-municipal conveyance system.

(i) All storm water discharges associated with industrial activity that discharge through a storm water discharge system that is not a municipal separate storm sewer must be covered by an individual permit, or a permit issued to the operator of the portion of the system that discharges to waters of the United States, with each discharger to the non-municipal conveyance a co-permittee to that permit.

(ii) Where there is more than one operator of a single system of such conveyances, all operators of storm water discharges associated with industrial activity must submit applications.

(iii) Any permit covering more than one operator shall identify the effluent limitations, or other permit conditions, if any, that apply to each operator.

(7) *Combined sewer systems.* Conveyances that discharge storm water runoff combined with municipal sewage are point sources that must obtain NPDES permits in accordance with the procedures of § 122.21 and are not subject to the provisions of this section.

(8) Whether a discharge from a municipal separate storm sewer is or is not subject to regulation under this section shall have no bearing on whether the owner or operator of the discharge is eligible for funding under title II, title III or title VI of the Clean Water Act. *See* 40 CFR part 35, subpart I, appendix A(b)H.2.j.

(b) *Definitions.* (1) *Co-permittee* means a permittee to a NPDES permit that is only responsible for permit conditions relating to the discharge for which it is operator.

(2) *Illicit discharge* means any discharge to a municipal separate storm sewer that is not composed entirely of storm water except discharges pursuant to a NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and discharges resulting from fire fighting activities.

(3) *Incorporated place* means the District of Columbia, or a city, town, township, or village that is incorporated under the laws of the State in which it is located.

(4) *Large municipal separate storm sewer system* means all municipal separate storm sewers that are either:

(i) Located in an incorporated place with a population of 250,000 or more as determined by the latest Decennial Census by the Bureau of Census (appendix F); or

(ii) Located in the counties listed in appendix H, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties; or

(iii) Owned or operated by a municipality other than those described in paragraph (b)(4) (i) or (ii) of this section and that are designated by the Director as part of the large or medium municipal separate storm sewer system due to the interrelationship between the discharges of the designated storm sewer and the discharges from municipal separate storm sewers described under paragraph (b)(4) (i) or (ii) of this section. In making this determination the Director may consider the following factors:

(A) Physical interconnections between the municipal separate storm sewers;

(B) The location of discharges from the designated municipal separate storm sewer relative to discharges from municipal separate storm sewers described in paragraph (b)(4)(i) of this section;

(C) The quantity and nature of pollutants discharged to waters of the United States;

(D) The nature of the receiving waters; and

(E) Other relevant factors; or

(iv) The Director may, upon petition, designate as a large municipal separate storm sewer system, municipal separate storm sewers located within the boundaries of a region defined by a storm water management regional authority based on a jurisdictional, watershed, or other appropriate basis that includes one or more of the systems described in paragraph (b)(4) (i), (ii), (iii) of this section.

(5) *Major municipal separate storm sewer outfall* (or "major outfall") means a municipal separate storm sewer outfall that discharges from a single pipe with an inside diameter of 36 inches or more or its equivalent (discharge from a single conveyance other than circular pipe which is associated with a drainage area of more than 50 acres); or for municipal separate storm sewers that receive storm water from lands zoned for industrial activity (based on comprehensive zoning plans or the equivalent), an outfall that discharges from a single pipe with an inside diameter of 12 inches or more or from its equivalent (discharge from other than a circular pipe associated with a drainage area of 2 acres or more).

(6) *Major outfall* means a major municipal separate storm sewer outfall.

(7) *Medium municipal separate storm sewer system* means all municipal separate storm sewers that are either:

(i) Located in an incorporated place with a population of 100,000 or more but less than 250,000, as determined by the latest Decennial Census by the Bureau of Census (appendix G); or

(ii) Located in the counties listed in appendix I, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties; or

(iii) Owned or operated by a municipality other than those described in paragraph (b)(4) (i) or (ii) of this section and that are designated by the Director as part of the large or medium municipal separate storm sewer system due to the interrelationship between the discharges of the designated storm sewer and the discharges from municipal separate storm sewers described under paragraph (b)(4) (i) or (ii) of this section. In making this determination the Director may consider the following factors:

(A) Physical interconnections between the municipal separate storm sewers;

(B) The location of discharges from the designated municipal separate storm sewer relative to discharges from municipal separate storm sewers described in paragraph (b)(7)(i) of this section;

(C) The quantity and nature of pollutants discharged to waters of the United States;

(D) The nature of the receiving waters; or

(E) Other relevant factors; or

(iv) The Director may, upon petition, designate as a medium municipal separate storm sewer system, municipal separate storm sewers located within the boundaries of a region defined by a storm water management regional authority based on a jurisdictional, watershed, or other appropriate basis that includes one or more of the systems described in paragraphs (b)(7) (i), (ii), (iii) of this section.

(8) *Municipal separate storm sewer* means a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains):

(i) Owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the CWA that discharges to waters of the United States;

(ii) Designed or used for collecting or conveying storm water;

(iii) Which is not a combined sewer; and

(iv) Which is not part of a Publicly Owned Treatment Works (POTW) as defined at 40 CFR 122.2.

(9) *Outfall* means a *point source* as defined by 40 CFR 122.2 at the point where a municipal separate storm sewer discharges to waters of the United States and does not include open conveyances connecting two municipal separate storm sewers, or pipes, tunnels or other conveyances which connect segments of the same stream or other waters of the United States and are used to convey waters of the United States.

(10) *Overburden* means any material of any nature, consolidated or unconsolidated, that overlies a mineral deposit, excluding topsoil or similar naturally-occurring surface materials that are not disturbed by mining operations.

(11) *Runoff coefficient* means the fraction of total rainfall that will appear at a conveyance as runoff.

(12) *Significant materials* includes, but is not limited to: raw materials; fuels; materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; raw materials used in food processing or production; hazardous substances designated under section 101(14) of CERCLA; any chemical the facility is required to report pursuant to section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag and sludge that have the potential to be released with storm water discharges.

(13) *Storm water* means storm water runoff, snow melt runoff, and surface runoff and drainage.

(14) *Storm water discharge associated with industrial activity* means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. The term does not include discharges from facilities or activities excluded from the NPDES program under 40 CFR part 122. For the categories of industries identified in paragraphs (b)(14) (i) through (x) of this section, the term includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters (as defined at 40 CFR part 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and finished products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. For the categories of industries identified in paragraph (b)(14)(xi) of this section, the term includes only storm water discharges from all the areas (except access roads and rail lines) that are listed in the previous sentence where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to storm water. For the purposes of this paragraph, material handling activities include the storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, finished product, by-product or waste product. The term excludes areas located on plant lands separate from the plant's industrial activities, such as office buildings and accompanying parking lots as long as the drainage from the excluded areas is not mixed with storm water drained from the above described areas. Industrial facilities (including industrial facilities that are Federally, State, or municipally owned or operated that meet the description of the facilities listed in this paragraph (b)(14)(i)-(xi) of this section) include those facilities designated under the provisions of paragraph (a)(1)(v) of this section. The following categories of facilities are considered to be engaging in "industrial activity" for purposes of this subsection:

(i) Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR subchapter N (except facilities with toxic pollutant effluent standards which are exempted under category (xi) in paragraph (b)(14) of this section);

(ii) Facilities classified as Standard Industrial Classifications 24 (except 2434), 26 (except 265 and 267), 28 (except 283), 29, 311, 32 (except 323), 33, 3441, 373;

(iii) Facilities classified as Standard Industrial Classifications 10 through 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations; (inactive mining operations are mining sites that are not being actively mined, but which have an identifiable owner/operator; inactive mining sites do not include sites where mining claims are being maintained prior to disturbances associated with the extraction, beneficiation, or processing of mined materials, nor sites where minimal activities are undertaken for the sole purpose of maintaining a mining claim);

(iv) Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under subtitle C of RCRA;

(v) Landfills, land application sites, and open dumps that receive or have received any industrial wastes (waste that is received from any of the facilities described under this subsection) including those that are subject to regulation under subtitle D of RCRA;

(vi) Facilities involved in the recycling of materials, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but limited to those classified as Standard Industrial Classification 5015 and 5093;

(vii) Steam electric power generating facilities, including coal handling sites;

(viii) Transportation facilities classified as Standard Industrial Classifications 40, 41, 42 (except 4221-25), 43, 44, 45, and 5171 which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under paragraphs (b)(14) (i)-(vii) or (ix)-(xi) of this section are associated with industrial activity;

(ix) Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of 1.0 mgd or more, or required to have an approved pretreatment program under 40 CFR part 403. Not included are farm lands, domestic gardens or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with section 405 of the CWA;

(x) Construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale;

(xi) Facilities under Standard Industrial Classifications 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, 4221-25, (and which are not otherwise included within categories (ii)-(x));

(c) *Application requirements for storm water discharges associated with industrial activity*—(1) *Individual application.* Dischargers of storm water associated with industrial activity are required to apply for an individual permit, apply for a permit through a group application, or seek coverage under a promulgated storm water general permit. Facilities that are required to obtain an individual permit, or any discharge of storm water which the Director is evaluating for designation (*see* 40 CFR 124.52(c)) under paragraph (a)(1)(v) of this section and is not a municipal separate storm sewer, and which is not part of a group application described under paragraph (c)(2) of this section, shall submit an NPDES application in accordance with the requirements of § 122.21 as modified and supplemented by the provisions of the remainder of this paragraph. Applicants for discharges composed entirely of storm water shall submit Form 1 and Form 2F. Applicants for discharges composed of storm water and non-storm water shall submit Form 1, Form 2C, and Form 2F. Applicants for new sources or new discharges (as defined in § 122.2 of this part) composed of storm water and non-storm water shall submit Form 1, Form 2D, and Form 2F.

(i) Except as provided in § 122.26(c)(1)(ii)-(iv), the operator of a storm water discharge associated with industrial activity subject to this section shall provide:

(A) A site map showing topography (or indicating the outline of drainage areas served by the outfall(s) covered in the application if a topographic map is unavailable) of the facility including: each of its drainage and discharge structures; the drainage area of each storm water outfall; paved areas and buildings within the drainage area of each storm water outfall, each past or present area used for outdoor storage or disposal of significant materials, each existing structural control measure to reduce pollutants in storm water runoff, materials loading and access areas, areas where pesticides, herbicides, soil conditioners and fertilizers are applied, each of its hazardous waste treatment, storage or disposal facilities (including each area not required to have a RCRA permit which is used for accumulating hazardous waste under 40 CFR 262.34); each well where fluids from the facility are injected underground; springs, and other surface water bodies which receive storm water discharges from the facility;

(B) An estimate of the area of impervious surfaces (including paved areas and building roofs) and the total area drained by each outfall (within a mile radius of the facility) and a narrative description of the following: Significant materials that in the three years prior to the submittal of this application have been treated, stored or disposed in a manner to allow exposure to storm water; method of treatment, storage or disposal of such materials; materials management practices employed, in the three years prior to the submittal of this application, to minimize contact by these materials with storm water runoff; materials loading and access areas; the location, manner and frequency in which pesticides, herbicides, soil conditioners and fertilizers are applied; the location and a description of existing structural and non-structural control measures to reduce pollutants in storm water runoff; and a description of the treatment the storm water receives, including the ultimate disposal of any solid or fluid wastes other than by discharge;

(C) A certification that all outfalls that should contain storm water discharges associated with industrial activity have been tested or evaluated for the presence of non-storm water discharges which are not covered by a NPDES permit; tests for such non-storm water discharges may include smoke tests, fluorometric dye tests, analysis of accurate schematics, as well as other appropriate tests. The certification shall include a description of the method used, the date of any testing, and the on-site drainage points that were directly observed during a test;

(D) Existing information regarding significant leaks or spills of toxic or hazardous pollutants at the facility that have taken place within the three years prior to the submittal of this application;

(E) Quantitative data based on samples collected during storm events and collected in accordance with § 122.21 of this part from all outfalls containing a storm water discharge associated with industrial activity for the following parameters:

(*1*) Any pollutant limited in an effluent guideline to which the facility is subject;

(*2*) Any pollutant listed in the facility's NPDES permit for its process wastewater (if the facility is operating under an existing NPDES permit);

(*3*) Oil and grease, pH, BOD5, COD, TSS, total phosphorus, total Kjeldahl nitrogen, and nitrate plus nitrite nitrogen;

(*4*) Any information on the discharge required under paragraph § 122.21(g)(7)(iii) and (iv) of this part;

R0010058 B-5

(*5*) Flow measurements or estimates of the flow rate, and the total amount of discharge for the storm event(s) sampled, and the method of flow measurement or estimation; and

(*6*) The date and duration (in hours) of the storm event(s) sampled, rainfall measurements or estimates of the storm event (in inches) which generated the sampled runoff and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event (in hours);

(F) Operators of a discharge which is composed entirely of storm water are exempt from the requirements of § 122.21 (g)(2), (g)(3), (g)(4), (g)(5), (g)(7)(i), (g)(7)(ii), and (g)(7)(v); and

(G) Operators of new sources or new discharges (as defined in § 122.2 of this part) which are composed in part or entirely of storm water must include estimates for the pollutants or parameters listed in paragraph (c)(1)(i)(E) of this section instead of actual sampling data, along with the source of each estimate. Operators of new sources or new discharges composed in part or entirely of storm water must provide quantitative data for the parameters listed in paragraph (c)(1)(i)(E) of this section within two years after commencement of discharge, unless such data has already been reported under the monitoring requirements of the NPDES permit for the discharge. Operators of a new source or new discharge which is composed entirely of storm water are exempt from the requirements of § 122.21 (k)(3)(ii), (k)(3)(iii), and (k)(5).

(ii) The operator of an existing or new storm water discharge that is associated with industrial activity solely under paragraph (b)(14)(x) of this section, is exempt from the requirements of § 122.21(g) and paragraph (c)(1)(i) of this section. Such operator shall provide a narrative description of:

(A) The location (including a map) and the nature of the construction activity:

(B) The total area of the site and the area of the site that is expected to undergo excavation during the life of the permit;

(C) Proposed measures, including best management practices, to control pollutants in storm water discharges during construction, including a brief description of applicable State and local erosion and sediment control requirements;

(D) Proposed measures to control pollutants in storm water discharges that will occur after construction operations have been completed, including a brief description of applicable State or local erosion and sediment control requirements;

(E) An estimate of the runoff coefficient of the site and the increase in impervious area after the construction addressed in the permit application is completed, the nature of fill material and existing data describing the soil or the quality of the discharge; and

(F) The name of the receiving water.

(iii) The operator of an existing or new discharge composed entirely of storm water from an oil or gas exploration, production, processing, or treatment operation, or transmission facility is not required to submit a permit application in accordance with paragraph (c)(1)(i) of this section, unless the facility:

(A) Has had a discharge of storm water resulting in the discharge of a reportable quantity for which notification is or was required pursuant to 40 CFR 117.21 or 40 CFR 302.6 at anytime since November 16, 1987; or

(B) Has had a discharge of storm water resulting in the discharge of a reportable quantity for which notification is or was required pursuant to 40 CFR 110.6 at any time since November 16, 1987; or

(C) Contributes to a violation of a water quality standard.

(iv) The operator of an existing or new discharge composed entirely of storm water from a mining operation is not required to submit a permit application unless the discharge has come into contact with, any overburden, raw material, intermediate products, finished product, byproduct or waste products located on the site of such operations.

(v) Applicants shall provide such other information the Director may reasonably require under § 122.21(g)(13) of this part to determine whether to issue a permit and may require any facility subject to paragraph (c)(1)(ii) of this section to comply with paragraph (c)(1)(i) of this section.

(*2*) *Group application for discharges associated with industrial activity.* In lieu of individual applications or notice of intent to be covered by a general permit for storm water discharges associated with industrial activity, a group application may be filed by an entity representing a group of applicants (except facilities that have existing individual NPDES permits for storm water) that are part of the same subcategory (*see* 40 CFR subchapter N, part 405 to 471) or, where such grouping is inapplicable, are sufficiently similar as to be appropriate for general permit coverage under § 122.28 of this part. The part 1 application shall be submitted to the Office of Water Enforcement and Permits, U.S. EPA, 401 M Street, SW., Washington, DC 20460 (EN-336) for approval. Once a part 1 application is approved, group applicants are to submit Part 2 of the group application to the Office of Water Enforcement and Permits. A group application shall consist of:

(i) *Part 1.* Part 1 of a group application shall:

(A) Identify the participants in the group application by name and location. Facilities participating in the group application shall be listed in nine subdivisions, based on the facility location relative to the nine precipitation zones indicated in appendix E to this part.

(B) Include a narrative description summarizing the industrial activities of participants of the group application and explaining why the participants, as a whole, are sufficiently similar to be a covered by a general permit;

(C) Include a list of significant materials stored exposed to precipitation by participants in the group application and materials management practices employed to diminish contact by these materials with precipitation and storm water runoff;

(D) Identify ten percent of the dischargers participating in the group application (with a minimum of 10 dischargers, and either a minimum of two dischargers from each precipitation zone indicated in appendix E of this part in which ten or more members of the group are located, or one discharger from each precipitation zone indicated in appendix E of this part in which nine or fewer members of the group are located) from which quantitative data will be submitted in part 2. If more than 1,000 facilities are identified in a group application, no more than 100 dischargers must submit quantitative data in Part 2. Groups of between four and ten dischargers may be formed. However, in groups of between four and ten, at least half the facilities must submit quantitative data, and at least one facility in each precipitation zone in which members of the group are located must submit data. A description of why the facilities selected to perform sampling and analysis are representative of the group as a whole in terms of the information provided in paragraph (c)(1) (i)(B) and (i)(C) of this section, shall accompany this section. Different factors impacting the nature of the storm water discharges, such as processes used and material management, shall be represented, to the extent feasible, in a manner roughly equivalent to their proportion in the group.

(ii) *Part 2.* Part 2 of a group application shall contain quantitative

R0010059

data (NPDES Form 2F), as modified by paragraph (c)(1) of this section, so that when part 1 and part 2 of the group application are taken together, a complete NPDES application (Form 1, Form 2C, and Form 2F) can be evaluated for each discharger identified in paragraph (c)(2)(i)(D) of this section.

(d) *Application requirements for large and medium municipal separate storm sewer discharges.* The operator of a discharge from a large or medium municipal separate storm sewer or a municipal separate storm sewer that is designated by the Director under paragraph (a)(1)(v) of this section, may submit a jurisdiction-wide or system-wide permit application. Where more than one public entity owns or operates a municipal separate storm sewer within a geographic area (including adjacent or interconnected municipal separate storm sewer systems), such operators may be a coapplicant to the same application. Permit applications for discharges from large and medium municipal storm sewers or municipal storm sewers designated under paragraph (a)(1)(v) of this section shall include:

(1) *Part 1.* Part 1 of the application shall consist of:

(i) *General information.* The applicants' name, address, telephone number of contact person, ownership status and status as a State or local government entity.

(ii) *Legal authority.* A description of existing legal authority to control discharges to the municipal separate storm sewer system. When existing legal authority is not sufficient to meet the criteria provided in paragraph (d)(2)(i) of this section, the description shall list additional authorities as will be necessary to meet the criteria and shall include a schedule and commitment to seek such additional authority that will be needed to meet the criteria.

(iii) *Source identification.* (A) A description of the historic use of ordinances, guidance or other controls which limited the discharge of non-storm water discharges to any Publicly Owned Treatment Works serving the same area as the municipal separate storm sewer system.

(B) A USGS 7.5 minute topographic map (or equivalent topographic map with a scale between 1:10,000 and 1:24,000 if cost effective) extending one mile beyond the service boundaries of the municipal storm sewer system covered by the permit application. The following information shall be provided:

(*1*) The location of known municipal storm sewer system outfalls discharging to waters of the United States;

(*2*) A description of the land use activities (e.g. divisions indicating undeveloped, residential, commercial, agricultural and industrial uses) accompanied with estimates of population densities and projected growth for a ten year period within the drainage area served by the separate storm sewer. For each land use type, an estimate of an average runoff coefficient shall be provided;

(*3*) The location and a description of the activities of the facility of each currently operating or closed municipal landfill or other treatment, storage or disposal facility for municipal waste;

(*4*) The location and the permit number of any known discharge to the municipal storm sewer that has been issued a NPDES permit;

(*5*) The location of major structural controls for storm water discharge (retention basins, detention basins, major infiltration devices, etc.); and

(*6*) The identification of publicly owned parks, recreational areas, and other open lands.

(iv) *Discharge characterization.* (A) Monthly mean rain and snow fall estimates (or summary of weather bureau data) and the monthly average number of storm events.

(B) Existing quantitative data describing the volume and quality of discharges from the municipal storm sewer, including a description of the outfalls sampled, sampling procedures and analytical methods used.

(C) A list of water bodies that receive discharges from the municipal separate storm sewer system, including downstream segments, lakes and estuaries, where pollutants from the system discharges may accumulate and cause water degradation and a brief description of known water quality impacts. At a minimum, the description of impacts shall include a description of whether the water bodies receiving such discharges have been:

(*1*) Assessed and reported in section 305(b) reports submitted by the State, the basis for the assessment (evaluated or monitored), a summary of designated use support and attainment of Clean Water Act (CWA) goals (fishable and swimmable waters), and causes of nonsupport of designated uses;

(*2*) Listed under section 304(l)(1)(A)(i), section 304(l)(1)(A)(ii), or section 304(l)(1)(B) of the CWA that is not expected to meet water quality standards or water quality goals;

(*3*) Listed in State Nonpoint Source Assessments required by section 319(a) of the CWA that, without additional action to control nonpoint sources of pollution, cannot reasonably be expected to attain or maintain water quality standards due to storm sewers, construction, highway maintenance and runoff from municipal landfills and municipal sludge adding significant pollution (or contributing to a violation of water quality standards);

(*4*) Identified and classified according to eutrophic condition of publicly owned lakes listed in State reports required under section 314(a) of the CWA (include the following: A description of those publicly owned lakes for which uses are known to be impaired; a description of procedures, processes and methods to control the discharge of pollutants from municipal separate storm sewers into such lakes; and a description of methods and procedures to restore the quality of such lakes);

(*5*) Areas of concern of the Great Lakes identified by the International Joint Commission;

(*6*) Designated estuaries under the National Estuary Program under section 320 of the CWA;

(*7*) Recognized by the applicant as highly valued or sensitive waters;

(*8*) Defined by the State or U.S. Fish and Wildlife Services's National Wetlands Inventory as wetlands; and

(*9*) Found to have pollutants in bottom sediments, fish tissue or biosurvey data.

(D) *Field screening.* Results of a field screening analysis for illicit connections and illegal dumping for either selected field screening points or major outfalls covered in the permit application. At a minimum, a screening analysis shall include a narrative description, for either each field screening point or major outfall, of visual observations made during dry weather periods. If any flow is observed, two grab samples shall be collected during a 24 hour period with a minimum period of four hours between samples. For all such samples, a narrative description of the color, odor, turbidity, the presence of an oil sheen or surface scum as well as any other relevant observations regarding the potential presence of non-storm water discharges or illegal dumping shall be provided. In addition, a narrative description of the results of a field analysis using suitable methods to estimate pH, total chlorine, total copper, total phenol, and detergents (or surfactants) shall be provided along with a description of the flow rate. Where the field analysis does not involve analytical methods approved under 40 CFR part 136, the applicant shall provide a description of the method used including the name of the manufacturer of the test method along with the range and accuracy of the test. Field screening points shall be either major outfalls or other outfall points (or

R0010060 B-1

any other point of access such as manholes) randomly located throughout the storm sewer system by placing a grid over a drainage system map and identifying those cells of the grid which contain a segment of the storm sewer system or major outfall. The field screening points shall be established using the following guidelines and criteria:

(*1*) A grid system consisting of perpendicular north-south and east-west lines spaced ¼ mile apart shall be overlayed on a map of the municipal storm sewer system, creating a series of cells;

(*2*) All cells that contain a segment of the storm sewer system shall be identified; one field screening point shall be selected in each cell; major outfalls may be used as field screening points;

(*3*) Field screening points should be located downstream of any sources of suspected illegal or illicit activity;

(*4*) Field screening points shall be located to the degree practicable at the farthest manhole or other accessible location downstream in the system, within each cell; however, safety of personnel and accessibility of the location should be considered in making this determination;

(*5*) Hydrological conditions; total drainage area of the site; population density of the site; traffic density; age of the structures or buildings in the area; history of the area; and land use types;

(*6*) For medium municipal separate storm sewer systems, no more than 250 cells need to have identified field screening points; in large municipal separate storm sewer systems, no more than 500 cells need to have identified field screening points; cells established by the grid that contain no storm sewer segments will be eliminated from consideration; if fewer than 250 cells in medium municipal sewers are created, and fewer than 500 in large systems are created by the overlay on the municipal sewer map, then all those cells which contain a segment of the sewer system shall be subject to field screening (unless access to the separate storm sewer system is impossible); and

(*7*) Large or medium municipal separate storm sewer systems which are unable to utilize the procedures described in paragraphs [illegible](1)(iv)(D) (*1*) through (*6*) of this section, because a sufficiently detailed map of the separate storm sewer systems is unavailable, shall field screen no more than 500 or 250 major outfalls respectively (or all major outfalls in the system, if less); in such circumstances, the applicant shall establish a grid system consisting of north-south and east-west lines spaced ¼ mile apart as an overlay to the boundaries of the municipal storm sewer system, thereby creating a series of cells; the applicant will then select major outfalls in as many cells as possible until at least 500 major outfalls (large municipalities) or 250 major outfalls (medium municipalities) are selected; a field screening analysis shall be undertaken at these major outfalls.

(E) *Characterization plan.* Information and a proposed program to meet the requirements of paragraph (d)(2)(iii) of this section. Such description shall include: the location of outfalls or field screening points appropriate for representative data collection under paragraph (d)(2)(iii)(A) of this section, a description of why the outfall or field screening point is representative, the seasons during which sampling is intended, a description of the sampling equipment. The proposed location of outfalls or field screening points for such sampling should reflect water quality concerns (*see* paragraph (d)(1)(iv)(C) of this section) to the extent practicable.

(v) *Management programs.* (A) A description of the existing management programs to control pollutants from the municipal separate storm sewer system. The description shall provide information on existing structural and source controls, including operation and maintenance measures for structural controls, that are currently being implemented. Such controls may include, but are not limited to: Procedures to control pollution resulting from construction activities; floodplain management controls; wetland protection measures; best management practices for new subdivisions; and emergency spill response programs. The description may address controls established under State law as well as local requirements.

(B) A description of the existing program to identify illicit connections to the municipal storm sewer system. The description should include inspection procedures and methods for detecting and preventing illicit discharges, and describe areas where this program has been implemented.

(vi) *Fiscal resources.* (A) A description of the financial resources currently available to the municipality to complete part 2 of the permit application. A description of the municipality's budget for existing storm water programs, including an overview of the municipality's financial resources and budget, including overall indebtedness and assets, and sources of funds for storm water programs.

(2) *Part 2.* Part 2 of the application shall consist of:

(i) *Adequate legal authority.* A demonstration that the applicant can operate pursuant to legal authority established by statute, ordinance or series of contracts which authorizes or enables the applicant at a minimum to:

(A) Control through ordinance, permit, contract, order or similar means, the contribution of pollutants to the municipal storm sewer by storm water discharges associated with industrial activity and the quality of storm water discharged from sites of industrial activity;

(B) Prohibit through ordinance, order or similar means, illicit discharges to the municipal separate storm sewer;

(C) Control through ordinance, order or similar means the discharge to a municipal separate storm sewer of spills, dumping or disposal of materials other than storm water;

(D) Control through interagency agreements among coapplicants the contribution of pollutants from one portion of the municipal system to another portion of the municipal system;

(E) Require compliance with conditions in ordinances, permits, contracts or orders; and

(F) Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance and noncompliance with permit conditions including the prohibition on illicit discharges to the municipal separate storm sewer.

(ii) *Source identification.* The location of any major outfall that discharges to waters of the United States that was not reported under paragraph (d)(1)(iii)(B)(*1*) of this section. Provide an inventory, organized by watershed of the name and address, and a description (such as SIC codes) which best reflects the principal products or services provided by each facility which may discharge, to the municipal separate storm sewer, storm water associated with industrial activity;

(iii) *Characterization data.* When "quantitative data" for a pollutant are required under paragraph (d)(a)(iii)(A)(*3*) of this paragraph, the applicant must collect a sample of effluent in accordance with 40 CFR 122.21(g)(7) and analyze it for the pollutant in accordance with analytical methods approved under 40 CFR part 136. When no analytical method is approved the applicant may use any suitable method but must provide a description of the method. The applicant must provide information characterizing the quality and quantity of discharges covered in the permit application, including:

(A) Quantitative data from representative outfalls designated by the Director (based on information received

R0010061

in part 1 of the application, the Director shall designate between five and ten outfalls or field screening points as representative of the commercial, residential and industrial land use activities of the drainage area contributing to the system or, where there are less than five outfalls covered in the application, the Director shall designate all outfalls) developed as follows:

(*1*) For each outfall or field screening point designated under this subparagraph, samples shall be collected of storm water discharges from three storm events occurring at least one month apart in accordance with the requirements at § 122.21(g)(7) (the Director may allow exemptions to sampling three storm events when climatic conditions create good cause for such exemptions);

(*2*) A narrative description shall be provided of the date and duration of the storm event(s) sampled, rainfall estimates of the storm event which generated the sampled discharge and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event;

(*3*) For samples collected and described under paragraphs (d)(2)(iii)(A)(*1*) and (A)(*2*) of this section, quantitative data shall be provided for: the organic pollutants listed in Table II; the pollutants listed in Table III (toxic metals, cyanide, and total phenols) of appendix D of 40 CFR part 122, and for the following pollutants:

Total suspended solids (TSS)
Total dissolved solids (TDS)
COD
BOD_5
Oil and grease
Fecal coliform
Fecal streptococcus
pH
Total Kjeldahl nitrogen
Nitrate plus nitrite
Dissolved phosphorus
Total ammonia plus organic nitrogen
Total phosphorus

(*4*) Additional limited quantitative data required by the Director for determining permit conditions (the Director may require that quantitative data shall be provided for additional parameters, and may establish sampling conditions such as the location, season of sample collection, form of precipitation (snow melt, rainfall) and other parameters necessary to insure representativeness);

(B) Estimates of the annual pollutant load of the cumulative discharges to waters of the United States from all identified municipal outfalls and the event mean concentration of the cumulative discharges to waters of the United States from all identified municipal outfalls during a storm event (as described under § 122.21(c)(7)) for BOD_5, COD, TSS, dissolved solids, total nitrogen, total ammonia plus organic nitrogen, total phosphorus, dissolved phosphorus, cadmium, copper, lead, and zinc. Estimates shall be accompanied by a description of the procedures for estimating constituent loads and concentrations, including any modelling, data analysis, and calculation methods;

(C) A proposed schedule to provide estimates for each major outfall identified in either paragraph (d)(2)(ii) or (d)(1)(iii)(B)(*1*) of this section of the seasonal pollutant load and of the event mean concentration of a representative storm for any constituent detected in any sample required under paragraph (d)(2)(iii)(A) of this section; and

(D) A proposed monitoring program for representative data collection for the term of the permit that describes the location of outfalls or field screening points to be sampled (or the location of instream stations), why the location is representative, the frequency of sampling, parameters to be sampled, and a description of sampling equipment.

(iv) *Proposed management program.* A proposed management program covers the duration of the permit. It shall include a comprehensive planning process which involves public participation and where necessary intergovernmental coordination, to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques and system, design and engineering methods, and such other provisions which are appropriate. The program shall also include a description of staff and equipment available to implement the program. Separate proposed programs may be submitted by each coapplicant. Proposed programs may impose controls on a systemwide basis, a watershed basis, a jurisdiction basis, or on individual outfalls. Proposed programs will be considered by the Director when developing permit conditions to reduce pollutants in discharges to the maximum extent practicable. Proposed management programs shall describe priorities for implementing controls. Such programs shall be based on:

(A) A description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas that are discharged from the municipal storm sewer system that are to be implemented during the life of the permit, accompanied with an estimate of the expected reduction of pollutant loads and a proposed schedule for implementing such controls. At a minimum, the description shall include:

(*1*) A description of maintenance activities and a maintenance schedule for structural controls to reduce pollutants (including floatables) in discharges from municipal separate storm sewers;

(*2*) A description of planning procedures including a comprehensive master plan to develop, implement and enforce controls to reduce the discharge of pollutants from municipal separate storm sewers which receive discharges from areas of new development and significant redevelopment. Such plan shall address controls to reduce pollutants in discharges from municipal separate storm sewers after construction is completed. (Controls to reduce pollutants in discharges from municipal separate storm sewers containing construction site runoff are addressed in paragraph (d)(2)(iv)(D) of this section;

(*3*) A description of practices for operating and maintaining public streets, roads and highways and procedures for reducing the impact on receiving waters of discharges from municipal storm sewer systems, including pollutants discharged as a result of deicing activities;

(*4*) A description of procedures to assure that flood management projects assess the impacts on the water quality of receiving water bodies and that existing structural flood control devices have been evaluated to determine if retrofitting the device to provide additional pollutant removal from storm water is feasible;

(*5*) A description of a program to monitor pollutants in runoff from operating or closed municipal landfills or other treatment, storage or disposal facilities for municipal waste, which shall identify priorities and procedures for inspections and establishing and implementing control measures for such discharges (this program can be coordinated with the program developed under paragraph (d)(2)(iv)(C) of this section); and

(*6*) A description of a program to reduce to the maximum extent practicable, pollutants in discharges from municipal separate storm sewers associated with the application of pesticides, herbicides and fertilizer which will include, as appropriate, controls such as educational activities, permits, certifications and other measures for commercial applicators and distributors, and controls for application in public right-of-ways and at municipal facilities.

(B) A description of a program, including a schedule, to detect and remove (or require the discharger to the municipal separate storm sewer to obtain a separate NPDES permit for) illicit discharges and improper disposal into the storm sewer. The proposed program shall include:

(*1*) A description of a program, including inspections, to implement and enforce an ordinance, orders or similar means to prevent illicit discharges to the municipal separate storm sewer system; this program description shall address all types of illicit discharges, however the following category of non-storm water discharges or flows shall be addressed where such discharges are identified by the municipality as sources of pollutants to waters of the United States: water line flushing, landscape irrigation, diverted stream flows, rising ground waters, uncontaminated ground water infiltration (as defined at 40 CFR 35.2005(20)) to separate storm sewers, uncomtaminated pumped ground water, discharges from potable water sources, foundation drains, air conditioning condensation, irrigation water, springs, water from crawl space pumps, footing drains, lawn watering, individual residential car washing, flows from riparian habitats and wetlands, dechlorinated swimming pool discharges, and street wash water (program descriptions shall address discharges or flows from fire fighting only where such discharges or flows are identified as significant sources of pollutants to waters of the United States);

(*2*) A description of procedures to conduct on-going field screening activities during the life of the permit, including areas or locations that will be evaluated by such field screens;

(*3*) A description of procedures to be followed to investigate portions of the separate storm sewer system that, based on the results of the field screen, or other appropriate information, indicate a reasonable potential of containing illicit discharges or other sources of non-storm water (such procedures may include: sampling procedures for constituents such as fecal coliform, fecal streptococcus, surfactants (MBAS), residual chlorine, fluorides and potassium; testing with fluorometric dyes; or conducting in storm sewer inspections where safety and other considerations allow. Such description shall include the location of storm sewers that have been identified for such evaluation);

(*4*) A description of procedures to prevent, contain, and respond to spills that may discharge into the municipal separate storm sewer;

(*5*) A description of a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or water quality impacts associated with discharges from municipal separate storm sewers;

(*6*) A description of educational activities, public information activities, and other appropriate activities to facilitate the proper management and disposal of used oil and toxic materials; and

(*7*) A description of controls to limit infiltration of seepage from municipal sanitary sewers to municipal separate storm sewer systems where necessary;

(C) A description of a program to monitor and control pollutants in storm water discharges to municipal systems from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities that are subject to section 313 of title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA), and industrial facilities that the municipal permit applicant determines are contributing a substantial pollutant loading to the municipal storm sewer system. The program shall:

(*1*) Identify priorities and procedures for inspections and establishing and implementing control measures for such discharges;

(*2*) Describe a monitoring program for storm water discharges associated with the industrial facilities identified in paragraph (d)(2)(iv)(C) of this section, to be implemented during the term of the permit, including the submission of quantitative data on the following constituents: any pollutants limited in effluent guidelines subcategories, where applicable; any pollutant listed in an existing NPDES permit for a facility; oil and grease, COD, pH, BOD_5, TSS, total phosphorus, total Kjeldahl nitrogen, nitrate plus nitrite nitrogen, and any information on discharges required under 40 CFR 122.21(g)(7) (iii) and (iv).

(D) A description of a program to implement and maintain structural and non-structural best management practices to reduce pollutants in storm water runoff from construction sites to the municipal storm sewer system, which shall include:

(*1*) A description of procedures for site planning which incorporate consideration of potential water quality impacts;

(*2*) A description of requirements for nonstructural and structural best management practices;

(*3*) A description of procedures for identifying priorities for inspecting sites and enforcing control measures which consider the nature of the construction activity, topography, and the characteristics of soils and receiving water quality; and

(*4*) A description of appropriate educational and training measures for construction site operators.

(v) *Assessment of controls.* Estimated reductions in loadings of pollutants from discharges of municipal storm sewer constituents from municipal storm sewer systems expected as the result of the municipal storm water quality management program. The assessment shall also identify known impacts of storm water controls on ground water.

(vi) *Fiscal analysis.* For each fiscal year to be covered by the permit, a fiscal analysis of the necessary capital and operation and maintenance expenditures necessary to accomplish the activities of the programs under paragraphs (d)(2) (iii) and (iv) of this section. Such analysis shall include a description of the source of funds that are proposed to meet the necessary expenditures, including legal restrictions on the use of such funds.

(vii) Where more than one legal entity submits an application, the application shall contain a description of the roles and responsibilities of each legal entity and procedures to ensure effective coordination.

(viii) Where requirements under paragraph (d)(1)(iv)(E), (d)(2)(ii), (d)(2)(iii)(B) and (d)(2)(iv) of this section are not practicable or are not applicable, the Director may exclude any operator of a discharge from a municipal separate storm sewer which is designated under paragraph (a)(1)(v), (b)(4)(ii) or (b)(7)(ii) of this section from such requirements. The Director shall not exclude the operator of a discharge from a municipal separate storm sewer identified in appendix F, G, H or I of part 122, from any of the permit application requirements under this paragraph except where authorized under this section.

(e) *Application deadlines.* Any operator of a point source required to obtain a permit under paragraph (a)(1) of this section that does not have an effective NPDES permit covering its storm water outfalls shall submit an application in accordance with the following deadlines:

(1) For any storm water discharge associated with industrial activity identified in paragraph (b)(14) (i)–(xi) of this section, that is not part of a group application as described in paragraph (c)(2) of this section or which is not covered under a promulgated storm water general permit, a permit application made pursuant to paragraph (c) of this section shall be submitted to the Director by November 18, 1991;

Overview of the Storm Water Program

EPA

Office of Wastewater Enforcement and Compliance
Permits Division
401 M Street, SW
Washington, DC 20460

October 1993

STORM WATER PROGRAM

BACKGROUND

The 1972 amendments to the Federal Water Pollution Control Act (FWPCA, also referred to as the Clean Water Act or CWA) prohibit the discharge of any pollutant to waters of the United States from a point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit. Efforts to improve water quality under the NPDES program traditionally have focused on reducing pollutants in discharges of industrial process wastewater and from municipal sewage treatment plants. Efforts to address storm water discharges under the NPDES program have generally been limited to certain industrial categories with effluent limitations for storm water.

In response to the need for comprehensive NPDES requirements for discharges of storm water, Congress amended the CWA in 1987 to require the Environmental Protection Agency (EPA) to establish phased NPDES requirements for storm water discharges. To implement these requirements, EPA published the initial permit application requirements for certain categories of storm water discharges associated with industrial activity, and discharges from municipal separate storm sewer systems located in municipalities with a population of 100,000 or more on November 16, 1990, (55 FR 47990). Storm water discharge permits will provide a mechanism for monitoring the discharge of pollutants to waters of the United States and for establishing appropriate controls.

ENVIRONMENTAL IMPACTS

Pollutants in storm water discharges from many sources are largely uncontrolled. The "National Water Quality Inventory, 1990 Report to Congress" provides a general assessment of water quality based on biennial reports submitted by the States under Section 305(b) of the Clean Water Act. The Report indicates that roughly 30% of identified cases of water quality impairment are attributable to storm water discharges. The States identified a number of major sources of storm water runoff that cause water quality impacts including separate storm sewers, construction, waste disposal, and resource extraction.

INDUSTRIAL FACILITIES COVERED

EPA has defined the term "storm water discharge associated with industrial activity" in a comprehensive manner to address over 100,000 facilities (see Attachment VII for a complete definition). All storm water discharges associated with industrial activity that discharge through municipal separate storm sewer systems or that discharge directly to waters of the U.S., are required to obtain NPDES permit coverage, including those which discharge through systems located in municipalities with a population of less than 100,000. Discharges of storm water to a sanitary sewer system or to a Publicly Owned Treatment Works (POTW) are excluded. Facilities with storm water discharges associated with industrial activity include: manufacturing facilities; construction operations disturbing 5 or more acres; hazardous waste treatment, storage, or disposal facilities; landfills; certain sewage treatment plants; recycling facilities; powerplants; mining operations; some oil and gas operations; airports; and certain other transportation facilities. Operators of industrial facilities that are Federally, State or municipally owned or operated that meet the description of the facilities listed in 40 CFR 122.26(b)(14)(i)-(xi) must also submit applications.

TRANSPORTATION ACT OF 1991

The Transportation Act of 1991 provides an exemption from storm water permitting requirements for certain industrial activities owned or operated by municipalities with a population of less than 100,000. Such municipalities must submit storm water discharge permit applications for only airports, powerplants, and uncontrolled sanitary landfills that they own or operate, unless a permit is otherwise required by the permitting authority. The Transportation Act of 1991 also revises group application deadlines for facilities that are owned or operated by municipalities with a population of less than 250,000. See Attachment II for revised deadlines.

9th CIRCUIT COURT DECISION

The 9th Circuit United States Court of Appeals' opinion in NRDC v. EPA (June 4, 1992) and the opinion in AMC v. EPA (May 27, 1992), affirmed and upheld the basic structure and direction of the national storm water program. In "NRDC", the Court upheld the definition of "municipal separate storm sewer system," the standards for municipal storm water controls, the scope of storm water requirements for oil and gas operations, and EPA's decision not to provide public comment on Part 1 group industrial permit applications. On the question of deadlines, the Court noted that the storm water application deadlines clearly exceeded statutory requirements, but refused to "roll back" the current regulatory deadlines. The Court also emphasized, however, that any further regulatory extension would be illegal. In two other areas the Court invalidated and remanded for further proceedings two regulatory exemptions from the definition of "storm water discharges associated with industrial activity": (1) the exemption for construction sites disturbing less than 5 acres of land (category x), and (2) the exemption of certain "light" manufacturing facilities without exposure of materials and activities to storm water (category xi). In response to these two remands, the Agency intends to conduct further rulemaking proceedings on construction activities under 5 acres and light industry without exposure as ordered by the Court. EPA will not require permit applications for construction sites disturbing less than 5 acres of land and category xi facilities without exposure until this further rulemaking is completed. In "AMC," the Court upheld EPA's regulation of storm water discharges from inactive mines.

INDUSTRIAL APPLICATION OPTIONS

The November 16, 1990, storm water regulation presents three permit application options for storm water discharges associated with industrial activity. The first option is to submit an individual application consisting of Forms 1 and 2F. The second option is to participate in a group application. This option, however, is no longer available as the deadlines have passed. The third option is to file a Notice of Intent (NOI) to be covered under a general permit in accordance with the requirements of an issued general permit. The following overview briefly outlines each of these three options and the subsequent attachments provide a more detailed explanation.

A. INDIVIDUAL APPLICATIONS

Operators of facilities with storm water discharges associated with industrial activity who did not participate in a group application or did not obtain coverage under a general permit, must submit an individual application consisting of Form 1 and Form 2F. The information required in Form 2F includes a site drainage map, a narrative description of the site identifying potential pollutant sources, and quantitative testing data. There are specific requirements for construction activities and oil and gas operations and mining operations. See Attachment I for additional information.

B. GROUP APPLICATIONS

The group application procedure was an option available for facilities that have similar industrial operations, waste streams and other characteristics. Group applications reduced the burden on the regulated community by requiring the submission of quantitative data from only selected members of the group. The group application was submitted in two parts. Part 1 of the application identified all participants, provided facility specific information and proposed a representative sampling subgroup. Part 2 of the application consists of sampling data from each member of the sampling subgroup identified in Part 1 of the application. See Attachment II for additional information.

C. GENERAL PERMIT - NOI REQUIREMENTS

Industrial storm water dischargers that submit an NOI to be covered by the general permit are not required to submit an individual permit application or participate in a group application, provided the discharger is eligible for the permit and an individual permit application is not required by the Director on a case-by-case basis. Submitting an NOI represents a significantly less burden than submitting an individual application or participating in a group application. The NOI requirements for general permits usually address only general information and typically do not require the collection of monitoring data. Submittal of an NOI is only possible where applicable general permits have been issued by the permitting authority. EPA has finalized general permits for construction and industrial activity in the 12 States without NPDES authorization (57 FR 41176, September 9, 1992 and 57 FR 44412, September 25, 1992). As of September 1993, 36 of the 39 authorized NPDES States have general permit authority. See Attachments III, IV and V for additional information.

INDUSTRIAL PERMIT APPLICATION DEADLINES

Type of Application	Deadline	
▲ Individual	October 1, 1992	
▲ Group	Part 1	Part 2
All industrial activities except those owned or operated by a municipality with a population of 100,000 to 250,000.	September 30, 1991	October 1, 1992
Industrial activities owned or operated by a municipality with a population of less than 250,000.	May 18,1992	May 17, 1993
▲ General Permit NOI	October 1, 1992 (for EPA's general permits)	

MUNICIPAL APPLICATIONS

"Municipal separate storm sewer" is defined as any conveyance or system of conveyances that is owned or operated by a State or local government entity designed for collecting and conveying storm water which is not part of a POTW. The application requirements do not apply to discharges from combined sewers (systems designed as both a sanitary sewer and a storm sewer). Municipal separate storm sewer systems that are addressed by the November 16, 1990, regulations include storm sewer systems located in 173 cities with populations of 100,000 or more; located in 47 counties identified by EPA as having populations over 100,000 in unincorporated, urbanized areas; and systems that are designated by the Director based on consideration of the location of the discharge with respect to waters of the United States, the size of the discharge, the quantity and nature of the pollutants discharged to waters of the United States, the interrelationship to other regulated storm sewer systems, and other factors. The operator of a designated system will be notified by the Director. Under the November 16, 1990, storm water rule, those municipal separate storm sewer systems identified must submit a two-part application. The first part requires information regarding existing programs and the means available to the municipality to control pollutants. In addition, part one requires a field screening analysis of major outfalls to detect illicit connections. Building on this information, the second part requires a limited amount of representative quantitative data and a description of a proposed storm water management plan. See Attachment V for a detailed explanation of the two-part application process.

MUNICIPAL APPLICATIONS DEADLINES

[illegible]	Part 1	Part 2
Large Municipalities (over 250,000)	November 18, 1991	November 16, 1992
Medium Municipalities (100,000 - 250,000)	May 18, 1992	May 17, 1993

ATTACHMENT I

INDIVIDUAL APPLICATION REQUIREMENTS

These requirements address storm water discharges associated with industrial activity that are not authorized by a general permit and that are not included in a group application.

Application Forms

- Applicants for discharges composed entirely of storm water must submit **Forms 1 and 2F**
- Applicants for discharges composed of storm water and process wastewater must submit **Forms 1, 2C, and 2F**
- Applicants for new sources or new discharges composed of storm water and non-storm water must submit **Forms 1, 2D, and 2F**
- Applicants for discharges composed of storm water and nonprocess wastewater must submit **Forms 1, 2E, and 2F**
- Authorized NPDES States may establish their own forms which are at least as stringent as EPA's forms.
- Forms are available from State permitting authorities for facilities located in NPDES authorized States, or from EPA Regional Offices for facilities located in States without NPDES authorization.

Form 2F Requirements

- Site map showing topography and/or drainage areas and site characteristics.
- Estimate of impervious surface area and the total area drained by each outfall.
- Description of significant materials exposed to storm water, including current materials management practices.
- Certification that outfalls have been tested or evaluated for the presence of non-storm water discharges that are not covered by a NPDES permit.
- Information on significant leaks and spills in last 3 years.
- Quantitative testing data for the following parameters:
  - Any pollutants limited in an effluent guideline to which the facility is subject
  - Any pollutant listed in the facility's NPDES permit for process wastewater
  - Oil and grease, pH, BOD_5, COD, TSS, total phosphorus, nitrate plus nitrite nitrogen, and total Kjeldahl nitrogen
  - Certain pollutants known to be in the discharge
  - Flow measurements or estimates
  - Date and duration of storm event.

Individual Application Requirements for Construction Activities

- ▲ Provide a narrative description of:
  - Location and nature of construction activity (including a map)
  - Total area of the site and area to be excavated
  - Proposed measures to control pollutants in storm water discharges during and after construction operations
  - Estimate of runoff coefficient and increase in impervious areas after construction
  - Name of receiving water.
- ▲ No quantitative sampling.
- ▲ Application deadline
  - 90 days prior to date when construction begins.
- ▲ EPA has not developed a standard form for these discharges at this time (Form 2F is not required).

Application Requirements for Oil & Gas Operations and Mining Operations

- ▲ Operators of oil & gas facilities are not required to submit a permit application unless the facility:
  - Has had a discharge of a reportable quantity for which notice is required under CERCLA or CWA in the past 3 years, or
  - Contributes to a violation of a water quality standard.
- ▲ Operators of active and inactive mining sites are not required to submit permit applications unless the discharge has come into contact with any overburden, raw material, intermediate or finished products, byproducts, or waste products located onsite (inactive coal mining operations released from SMCRA performance bonds and non-coal mining operations released from applicable State or Federal reclamation requirements after December 17, 1990, are not required to submit permit applications).

Available Guidance

Guidance Manual For The Preparation of NPDES Permit Applications for Storm Water Discharges Associated with Industrial Activity (Order #PB92199058), available from NTIS, *(703) 487-4650*; *NPDES Storm Water Sampling Guidance Document*, available from the Storm Water Hotline, *(703) 821-4823*.

Deadline

October 1, 1992, or 180 days prior to commencement of a new discharge.

ATTACHMENT II

GROUP APPLICATION REQUIREMENTS

Facilities that discharge storm water associated with industrial activity had until September 30, 1991, to file Part I of the group application in lieu of submitting a complete individual application or an NOI to be covered by a general permit. The Transportation Act of 1991, however, extended the group application deadlines for certain industrial activities owned or operated by a municipality with a population of 100,000 to 250,000. Facilities that are part of the same effluent guideline subcategory or with similar activities and operations were eligible to submit a group application. EPA received 1,243 Part I group applications covering approximately 60,000 facilities.

The group application was submitted in two parts. Part 1 of the application was due by September 30, 1991, and Part 2 of the application was due by October 1, 1992. These deadlines applied to all industrial activities except those owned or operated by a municipality with a population of 100,000 to 250,000. For these facilities, Part 1 of the application was due by May 18, 1992, and Part 2 of the application is due by May 17, 1993. Both parts were submitted directly to U.S. EPA Headquarters, Office of Wastewater Enforcement and Compliance (EN-336), 401 M Street, SW, Washington, DC 20460, regardless of whether or not the included facilities are in a NPDES authorized State. The Transportation Act also addressed municipally owned or operated industrial activities that were denied by EPA from the group application process. Such facilities must submit an individual application or be covered by a general permit within 180 days after the denial was made, or by October 1, 1992, whichever is later.

EPA is currently taking both parts of the application and formulating model permit language. The complete applications and model permit language will then be distributed to every NPDES authorized State or EPA Region (if the State is not NPDES authorized) in which participants are located. The State then reviews the application and model permit language. The State may consider the application and model permit language when issuing permits (either individual or general). The State may ask each or any of the applicants for more information on their facility and/or discharge if the State needs additional information. EPA Regional Offices will follow these same steps for participants located in States without NPDES authorization.

<u>Part 1</u>

- ▲ A list of participants by name, location, and precipitation zone
- ▲ A summary of each participant's industrial activities
- ▲ An explanation of why the participants are sufficiently similar
- ▲ A list of significant materials stored outside by each participant and materials management practices
- ▲ A list of representative dischargers that will submit test data in Part 2.

<u>Part 2</u>

- ▲ Quantitative testing data must be submitted by those facilities identified as "samplers" in Part I of the application.

  - For groups of 4 to 20 members, 50 percent of the facilities must submit data; for groups with 21 to 99, a minimum of 10 dischargers must submit quantitative data; for groups with 100 to 1,000 members, a minimum of 10 percent of the facilities must submit data; for groups with greater than 1,000 members, no more than 100 facilities must submit data; there must be 2 dischargers from each precipitation zone in which 10 or more members of the group are located, or 1 discharger from each precipitation zone in which 9 or fewer members are located. Testing requirements are described under 40 CFR 122.26(c)(1)(i)(E) and 40 CFR 122.21(g)(7).

R0010071

Additional Information

A model group application accompanied by detailed information on how to complete both Part 1 and Part 2 group applications is available from the Storm Water Hotline, *(703) 821-4823*. Technical support with regard to sampling procedures is also available from the hotline *(NPDES Storm Water Sampling Guidance Document)*.

Deadlines

- ▲ All Industrial Activities Except Those Owned Or Operated By A Municipality With A Population of 100,000 to 250,000

  Part 1 - September 30, 1991
  Part 2 - October 1, 1992

- ▲ Industrial Activities Owned or Operated By A Municipality With A Population of 100,000 to 250,000

  Part 1 - May 18, 1992
  Part 2 - May 17, 1993

ATTACHMENT III

EPA GENERAL PERMIT REQUIREMENTS (GENERAL INFORMATION)

On September 9 and 25, 1992, EPA issued general permits for construction and industrial activities (57 FR 41176 and 44412) which are intended to initially cover the majority of storm water discharges associated with industrial activity in 12 States and 6 territories without authorized NPDES programs. As of March 1993, 35 of the 39 authorized NPDES States have authority to issue general permits. Facilities in authorized NPDES States should contact their State permitting agencies to determine the status of the general permitting program. The following tables (Attachments III, IV and V) outline conditions in EPA's general permits for industrial activities and construction activities.

Areas of Coverage

- **Region I**— MA, ME, NH; Indian lands in MA, NH, ME. **Region II**—PR and Indian lands in NY. **Region III**—DC, Federal facilities in DE. **Region IV**— FL; Indian lands in FL, MS, NC. **Region VI**—LA, NM, OK, TX. **Region VII**—SD; Indian lands in CO, MT, ND, SD, UT (except Goshute Reservation and Navajo Reservation lands), WY; Federal facilities in CO; Ute Mountain Reservation in CO, and NM. **Region IX**— American Samoa and Guam; AZ; Territories of Johnston Atoll, and Midway and Wake Island; Indian lands in CA, and NV; Goshute Reservations in UT and NV, Navajo Reservations in UT, NM, and AZ, Duck Valley Reservation in NV and ID. **Region X**—AK, and ID; Indian lands in AK, ID (except Duck Valley Reservation lands), and WA; Federal facilities in WA.

Types of Discharges Covered

- EPA's general permits cover the majority of storm water discharges associated with industrial activity. Storm water discharges associated with industrial activity that cannot be authorized by EPA's general permits include those:
  - With an existing effluent limitations guideline for storm water
  - That are mixed with non-storm water, unless the non-storm water discharges are in compliance with a different NPDES permit
  - With an existing NPDES individual or general permit for the storm water discharges
  - That are or may reasonably be expected to be contributing to a violation of a water quality standard
  - That are likely to adversely effect a listed or proposed to be listed endangered or threatened species or its critical habitat
  - From inactive mining, or inactive oil and gas operations or inactive landfills occurring on Federal lands where an operator cannot be identified (industrial permit only).

NOI Requirements

- A facility must submit a Notice of Intent (NOI) to be authorized by the general permit.
- NOI's do not require the collection of discharge sampling data.
- Facilities which discharge to a large or medium municipal separate storm sewer system must also submit signed copies of the NOI to the operator of the municipal system.
- Operators of construction activities must also submit signed copies of the NOI to State or local agencies approving sediment and erosion or storm water management plans under

R0010073

which the construction activity is operating.

Deadlines for NOI's

- On or before October 1, 1992 for existing industrial activities
- For facilities or construction activities which begin industrial activity after October 1, 1992, an NOI shall be submitted at least 2 days prior to the commencement of the industrial activity.
- NOI's must be sent to the following address:

  Storm Water Notice of Intent
  P.O. Box 1215
  Newington, VA 22122

Special Conditions

- Prohibition on most types of non-storm water discharges as a component of discharges authorized by this permit. (These discharges should already have an NPDES permit.) However, EPA's permits authorize certain types of non-storm water discharges.
- In the event there is a release(s) of a hazardous substance in excess of reportable quantities established under the CWA or CERCLA (see 40 CFR 117.3, 40 CFR 302.4) the discharger must:
  - Notify the National Response Center and the Director, and modify the storm water pollution prevention plan.

Pollution Prevention Plan Requirements

- Operators of all facilities covered by EPA's general permits must prepare and implement a storm water pollution prevention plan.

ATTACHMENT IV

EPA INDUSTRIAL GENERAL PERMIT (SPECIFIC REQUIREMENTS)

Contents of NOI for Industrial Activities

- ▲ Street address or latitude/longitude
- ▲ SIC Code or identification of industrial activity
- ▲ Operator's name, address, telephone number, and status as Federal, State, private, public, or other entity
- ▲ Permit number(s) of any existing NPDES permit(s)
- ▲ Name of receiving water(s)
- ▲ Indication of whether the owner or operator has existing quantitative data describing the concentration of pollutants in storm water discharges
- ▲ A certification that a storm water pollution prevention plan has been prepared for the facility (for industrial activities that begin operations after October 1, 1992).

Pollution Prevention Plan Requirements for Industrial Activities

The Pollution Prevention Plan is considered to be the most important requirement of the General Permit. Each industrial facility covered by the general permit must develop a Plan, tailored to the site specific conditions, and designed with the goal to control the amount of pollutants in storm water discharges from the site.

- ▲ **Pollution Prevention Team** - Each facility will select a Pollution Prevention Team from its staff, and the Team will be responsible for developing and implementing the Plan.
- ▲ **Components of the Plan** - The permit requires that the Plan contain a description of potential pollutant sources, and a description of the measures and controls to prevent or minimize pollution of storm water. The description of potential pollutant sources must include:
  - A map of the facility indicating the areas which drain to each storm water discharge point
  - An indication of the industrial activities which occur in each drainage area
  - A prediction of the pollutants which are likely to be present in the storm water
  - A description the likely source of pollutants from the site
  - An inventory of the materials which may be exposed to storm water
  - The history of spills or leaks of toxic or hazardous materials for the past 3 years.

  The measures and controls to prevent or minimize pollution of storm water must include:

  - Good housekeeping or upkeep of industrial areas exposed to storm water
  - Preventive maintenance of storm water controls and other facility equipment
  - Spill prevention and response procedures to minimize the potential for and the impact of spills
  - Test all outfalls to insure there are no cross connections (only storm water is discharged)

R0010075

- Training of employees on pollution prevention measures and controls, and record keeping.

The permit also requires that facilities:

- Identify areas with a high potential for erosion and the stabilization measures or structural controls to be used to limit erosion in these areas
- Implement traditional storm water management measures (oil/water separators, vegetative swales, detention ponds, etc) where they are appropriate for the site.

▲ **Inspection/Site Compliance Evaluation** - Facility personnel must inspect the plant equipment and industrial areas on a regular basis. At least once every year a more thorough site compliance evaluation must be performed by facility personnel

- Look for evidence of pollutants entering the drainage system
- Evaluate the performance of pollution prevention measures
- Identify areas where the Plan should be revised to reduce the discharge of pollutants
- Document both the routine inspections and the annual site compliance evaluation in a report.

▲ **Consistency** - The Plan can incorporate other plans which a facility may have already prepared for other permits including Spill Prevention Control and Countermeasure (SPCC) Plans, or Best Management Practices (BMP) Programs.

▲ **Deadlines** - The plan must be prepared on or before April 1, 1993, and the facility must be in compliance with the plan on or before October 1, 1993.

▲ **Signature** - The plan must be signed by a responsible corporate official such as the president, vice president or general partner.

▲ **Plan Review** - The plan is to be kept at the permitted facility at all times. The plan should be submitted for review only when requested by EPA.

Semi-Annual Monitoring/Annual Reporting Requirements

▲ EPCRA Section 313 facilities

▲ Primary metal industries Standard Industrial Classification (SIC) 33

▲ Land disposal units/incinerators/BIF's

▲ Wood treatment facilities

▲ Facilities with coal pile runoff

▲ Battery reclaimers

Annual Monitoring/No Reporting Requirements

▲ Airports with at least 50,000 flight operations per year

▲ Coal-fired steam electric facilities

▲ Animal handling/meat packing facilities

- Additional facilities, including:
  - SIC 30 and 28 with storage piles for solid chemicals used as raw materials that are exposed to precipitation
  - Certain automobile junkyards
  - Lime manufacturing facilities where storm water comes into contact with lime storage piles
  - Oil handling sites at oil fired steam electric power generating facilities
  - Cement manufacturing and cement kilns
  - Ready-mix concrete facilities
  - Shipbuilding and repairing facilities

Additional Monitoring Requirements

- Testing parameters for facilities are listed in the general permits.
- At a minimum, all dischargers must conduct an annual site inspection of the facility.

Alternative Certification

- A discharger is not subject to the monitoring requirements for a given outfall if there is no exposure of industrial areas or activities to storm water within the drainage area of that outfall within a given year.
- The discharger must certify, on an annual basis, that there is no exposure to storm water, and such certification must be retained in the storm water pollution prevention plan. Facilities subject to semi-annual monitoring requirements must submit this certification to EPA in lieu of monitoring data.

Numeric Effluent Limitations

- Coal pile runoff: 50 mg/l Total Suspended Solids (TSS) and 6-9 pH

Available Guidance

Storm Water Management for Industrial Activities, Developing Pollution Prevention Plans and Best Management Practices, available from NTIS (703) 487-4650, order number PB 92-235969; *Summary: Storm Water Management for Industrial Activities, Developing Pollution Prevention Plans and Best Management Practices* (October 1992), available from the Storm Water Hotline, (703) 821-4823.

ATTACHMENT V

EPA CONSTRUCTION GENERAL PERMIT REQUIREMENTS (SPECIFIC REQUIREMENTS)

Coverage

- ▲ Storm water discharges from construction sites that are authorized by this permit include those that will result in the disturbance of 5 or more acres of land.

Contents of NOI for Construction Activities

- ▲ Street address or latitude/longitude
- ▲ The name, address, telephone number of the operator(s) with day to day operational control and operator status as Federal, State, private, public, or other entity
- ▲ Permit number(s) of any existing NPDES permit(s)
- ▲ Name of receiving water(s)
- ▲ Indication of whether the owner or operator has existing quantitative data describing the concentration of pollutants in storm water discharges
- ▲ An estimate of the project start date and completion dates and estimates of the number of disturbed acres
- ▲ A certification that a storm water pollution prevention plan has been prepared for the facility

Deadlines for Notification

- ▲ An NOI shall be submitted at least 2 days prior to the commencement of construction (commencement of construction is defined as the initial disturbance of soils associated with clearing, grading, or excavating activities or other construction activities) at any site that will result in the disturbance of 5 or more acres total land area.

Pollution Prevention Plan Requirements for Construction Activities

The Pollution Prevention Plan is considered to be the most important requirement of the General Permit. Each construction activity covered by the general permit must develop a Plan, tailored to the site specific conditions, and designed with the goal to control the amount of pollutants in storm water discharges from the site.

- ▲ **Components of the Plan** - The permit requires that the Plan contain a site description, and a description of the measures and controls to prevent or minimize pollution of storm water. The site description must include:

  - A description of the nature of the construction activity
  - A sequence of major construction activities
  - An estimate of the total area of the site and of the area to be disturbed
  - An estimate of the runoff coefficient of the site after construction is complete
  - Any existing data on the quality of storm water discharge from the site
  - The name of the receiving water
  - Any information on the type of soils at the site; and
  - A site map indicating drainage patterns and slopes after grading activities are complete, areas of soil disturbance, the outline of the area to be disturbed, the location of stabilization measures and controls, and surface waters at the discharge points.

- **Measures and Controls** - Measures and controls to prevent or minimize pollution of storm water must include three different types of controls: erosion and sediment controls, storm water management controls and other controls:

  - Erosion and Sediment Controls

    - Stabilization (seeding, mulching, etc.) - Disturbed areas where construction has permanently or temporarily ceased must be stabilized within 14 days of the last disturbance or as soon as practicable in semi-arid and arid areas. (Areas which will be redisturbed within 21 days do not have to be stabilized).

    - Structural Controls - Sites with common drainage locations that serve 10 or more disturbed acres must install a sediment basin where it is attainable (where a basin is not attainable, sediment traps, silt fence or other equivalent measures must be installed. Sediment basins must provide 3,600 cubic feet of storage per acre drained. Drainage locations which serve less than 10 disturbed acres must install either a sediment basin, sediment trap or silt fence along the down slope and side slope perimeter.

- Plan shall be completed prior to submittal of an NOI and updated as appropriate.

- For construction activities that have begun after October 1, 1992, the plan shall provide for compliance with the terms and schedule of the plan beginning with the initiation of construction activities.

Available Guidance

Storm Water Management for Construction Activities, Developing Pollution Prevention Plans and Best Management Practices, available from NTIS (703) 487-4650, order number PB 92-235951; *Summary: Storm Water Management for Construction Activities, Developing Pollution Prevention Plans and Best Management Practices* (October 1992), available from the Storm Water Hotline (703) 821-4823.

ATTACHMENT VI

MUNICIPAL APPLICATION REQUIREMENTS

The CWA requires that NPDES permits for discharges from municipal separate storm sewer systems include a requirement to effectively prohibit non-storm water discharges into the storm sewers, and controls to reduce the discharge of pollutants to the maximum extent practicable (including management practices, control techniques and system design and engineering methods, and other provisions appropriate for the control of such pollutants). EPA or authorized NPDES States may issue system-wide or jurisdiction-wide permits covering all discharges from a municipal separate storm sewer system. The November 1990 storm water final rule established requirements for a two-part permit application designed to facilitate development of site specific permit conditions. The permit application requirements provide municipal applicants an opportunity to propose appropriate management programs to control pollutants in discharges from their municipal systems. This increases flexibility to develop appropriate permit conditions and ensures input from municipalities in developing appropriate controls.

<u>Part 1</u>

- ▲ General information (name, address, etc.)
- ▲ Existing legal authority and any additional authorities needed
- ▲ Source identification information
- ▲ Discharge characterization including:
  - Monthly mean rain and snow fall estimates
  - Existing quantitative data on volume and quality of storm water discharges
  - A list of receiving water bodies and existing information on the impacts of receiving waters
  - Field screening analysis for illicit connections and illegal dumping.
- ▲ Characterization plan identifying representative outfalls for further sampling in Part 2
- ▲ Description of existing management programs to control pollutants from the municipal separate storm sewer and to identify illicit connections
- ▲ Description of financial budget and resources currently available to complete Part 2.

<u>Part 2</u>

- ▲ Demonstration of adequate legal authority to control discharges, prohibit illicit discharges, require compliance, and carry out inspections, surveillance, and monitoring
- ▲ Source identification indicating the location of any major outfalls and identifying facilities that discharge storm water associated with industrial activity through the municipal separate storm sewer
- ▲ Discharge characterization data including
  - Quantitative data from 5-10 representative locations in approved sampling plans
  - For selected conventional pollutants and heavy metals, estimates of the annual pollutant load and event mean concentration of system discharges

- Proposed schedule to provide estimates of seasonal pollutant loads and the mean concentration for certain detected constituents in a representative storm event
- Proposed monitoring program for representative data collection.

▲ Proposed management program including descriptions of:

- Structural and source control measures that are to be implemented to reduce pollutants in runoff from commercial and residential areas
- Program to detect and remove illicit discharges
- Program to monitor and control pollutants from municipal landfills, hazardous waste treatment, disposal, and recovery facilities; EPCRA Section 313 facilities; and other priority industrial facilities
- Program to control pollutants in construction site runoff.

▲ Estimated reduction in loadings of pollutants as a result of the management program

▲ Fiscal analysis of necessary capital and operation and maintenance expenditures.

Available Guidance

Guidance Manual for the Preparation of Part 1 of the NPDES Permit Application for Discharges from Municipal Separate Storm Sewer Systems and *NPDES Storm Water Sampling Guidance Document*, available from NTIS *(703) 487-4650*, order number PB 92-114578; *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharges from Municipal Seperate Storm Sewers Systems*, available from the Storm Water Hotline, (703) 821-4823.

ATTACHMENT VII

STORM WATER DISCHARGE ASSOCIATED WITH INDUSTRIAL ACTIVITY

The discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. The term does not include discharges from facilities or activities excluded from the NPDES program under 40 CFR Part 122. For the categories of industries identified in subparagraphs (i) through (x) of this subsection, the term includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters (as defined at 40 CFR 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and finished products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. For the categories of industries identified in subparagraph (xi), the term includes only storm water discharges from all the areas (except access roads and rail lines) that are listed in the previous sentence where material handling equipment or activities, raw materials, intermediate products, final products, waste material, by-products, or industrial machinery are exposed to storm water. For the purposes of this paragraph, material handling activities include the: storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, finished product, by-product or waste product. The term excludes areas located on plant lands separate from the plant's industrial activities, such as office buildings and accompanying parking lots as long as the drainage from the excluded areas is not mixed with storm water drained from the above described areas. Industrial facilities (including industrial facilities that are Federally, State, or municipally owned or operated that meet the description of the facilities listed in this paragraph (i)-(xi) include those facilities designated under the provision of 122.26(a)(1)(v). The following categories of facilities are considered to be engaging in "industrial activity" for purposes of this subsection:

(i) Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR Subchapter N (except facilities with toxic pollutant effluent standards which are excepted under category (xi) of this paragraph);
(ii) Facilities classified as Standard Industrial Classifications 24 (except 2434), 26 (except 265 and 267), 28 (except 283 and 285) 29, 311, 32 (except 323), 33, 3441, 372;
(iii) Facilities classified as Standard Industrial Classifications 10 though 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990 and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations; (inactive mining operations are mining sites that are not being actively mined, but which have an identifiable owner/operator; inactive mining sites do not include sites where mining claims are being maintained prior to disturbances associated with the extraction, beneficiation, or processing of mined materials, nor sites where minimal activities are undertaken for the sole purpose of maintaining mining claim);
(iv) Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of RCRA;
(v) Landfills, land application sites, and open dumps that receive or have received any industrial wastes (waste that is received from any of the facilities described under this subsection) including those that are subject to regulation under Subtitle D of RCRA;

(vi) Facilities involved in the recycling of materials, including metal scrapyards, battery reclaimers, salvage yards, and automobiles junkyards, including but limited to those classified as Standard Industrial Classification 5015 and 5093;
(vii) Steam electric power generating facilities, including coal handling sites;
(viii) Transportation facilities classified as Standard Industrial Classifications 40, 41, 42 (except 4221-25), 43, 44, 45, and 5171 which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under paragraphs (i)-(vii) or (ix)-(xi) of this subsection are associated with industrial activity;
(ix) Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of 1.0 mgd or more, or required to have an approved pretreatment program under 40 CFR 403. Not included are farm lands, domestic gardens or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with Section 405 of the CWA;
(x) Construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale;
(xi) Facilities under Standard Industrial Classification 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, 4221-25, (and which are not otherwise included within categories (ii)-(x))

Note: The Transportation Act of 1991 provides an exemption from storm water permitting requirements for certain facilities owned or operated by municipalities with a population of less than 100,000. Such municipalities must submit storm water discharge permit applications for only airports, power plants, and uncontrolled sanitary landfills that they own or operate, unless a permit is otherwise required by the permitting authority.

State of California

Memorandum

To: Storm Water Permit Program Coordinators

Date: September 8, 1994

From: Thomas Mumley
California Regional Water Quality Control Board
San Francisco Bay Region
2101 Webster Street, Suite 500, Oakland, 94612

Subject: **MUNICIPAL STORM WATER MANAGEMENT PLAN COMPONENTS**

The attached draft Municipal Storm Water Management Plan Components is intended to provide a starting point for establishing a consistent framework for such plans for all municipal programs in the State. I have proposed the categorical program action areas based on experiences with existing programs and existing plans in the San Francisco Bay Region. As proposed, the categorical areas and sub-areas would be essential components of a Municipal Storm Water Management Plan. It would be the responsibility of a municipality to demonstrate that a specific area does not apply to their program or to propose equivalent alternatives with justification.

The categorical areas represent elements integral to the establishment of a storm water management program, as well as specific sources, specific areas of activities, or specific activities that need to managed. The actual management action, such as the type of control measures that would be implemented, or level of implementation of the control measure, would be determined mostly at the discretion of the municipal program. We should also recognize that at this time the appropriate action, in a specific area for a specific municipal program, may be to propose the steps that they will take to scope alternative control measures, prepare for implementation, implement on a reduced or pilot scale, and ultimately select and implement a control measure on a full scale. In such cases the plan would identify milestones and evaluation techniques that will be met and used in the process of progressing through the proposed steps.

Over time we would identify specific control measures that apply in each area and categorize the measure as mandatory, optional, or mandatory under specific conditions. (Mandatory would be interpreted to allow for implementation of equivalently effective alternative measures.) Over time we would also develop information of the effectiveness of specific control measures and develop performance standards for their design, operation, and maintenance. These performance standards would be developed through monitoring programs and serve as the building blocks for defining maximum extent practicable.

By establishing a consistent framework of action areas, we also provide a basis for coordination and collaboration of all municipal programs, and consistent reporting and evaluation standards.

MUNICIPAL STORM WATER MANAGEMENT PLAN COMPONENTS

The Municipal Storm Water Early Permit renewal process requires the submittal of a Storm Water Management Plan for the permitted area covering the entire five year period of the permit. A single plan is expected for each permit, with each of the permittees contributing to the plan. The plan should address all of the following components, including a discussion of how each of the components fit into a single unified program. Every element of the plan must contain compliance schedules with firm dates that will be met. The permittees should suggest schedules for submittals that are realistic for their particular fiscal year. The management plans should emphasize pollution prevention rather than relying solely on pollution control.

This document has been prepared by the staff of the State Water Resources Control Board and the Regional Water Control Boards, in an effort to assist permittees who hold municipal separate storm sewer permitsto comply with those permits. This document has not been adopted by either of the Boards. Its provisions, with the exception of the federal regulations, in italics, are not mandatory, and are provided solely as an aid to permittees.

> *122.26(d)(1)(i) General information. The applicants' name, address, telephone number of contact person, ownership status and status as a State or local government entity.*

> *122.26(d)(1)(v) Management programs. (A) A description of the existing management programs to control pollutants from the municipal separate storm sewer system. The description shall provide information on existing structural and source controls, including operation and maintenance measures for structural controls, that are currently being implemented. Such controls may include, but are not limited to: Procedures to control pollution resulting from construction activities; floodplain management controls; wetland protection measures; best management practices for new subdivisions; and emergency spill response programs. The description may address controls established under State law as well as local requirements.*

> *122.26(d)(2)(iv) Proposed management program. A proposed management program covers the duration of the permit. It shall include a comprehensive planning process which involves public participation and where necessary intergovernmental coordination, to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques and system, design and engineering methods, and such other provisions which are appropriate. The program shall also include a description of staff and equipment available to implement the program. Separate proposed programs may be submitted by each coapplicant. Proposed programs may impose controls on a systemwide basis, a watershed basis, a jurisdiction basis, or on individual outfalls. Proposed programs will be considered by the Director when developing permit conditions to reduce pollutants in discharges to the maximum extent practicable. Proposed management programs shall describe priorities for implementing controls.*

I. PROGRAM MANAGEMENT - Area wide permits are permits that are issued to a group of municipal governments. The governments are given a single permit and pay a single fee. It is anticipated that although each governmental entity will have their own program, they will function as a unified entity in their permit responses. The area wide permits require cooperation by a number of government entities including cities, counties, agencies such as flood control districts or water districts, and state agencies such as CALTRANS. Each governmental entity will have, in addition, a variety of agencies that have responsibilities either directly, or indirectly for storm water related activities. The plan must include a discussion of who is involved in the program, how they will function together, what kind of interagency funding arrangements are made. For each permittee, the plan must also outline the funding and funding mechanism to be used, and the legal authority that will be used to enforce the program.

   A. PROGRAM STRUCTURE - Each permit will require a structure for the participatory agencies to work together under a unified plan. While each permittee will have an individual program to address the particular needs of their city or agency, a framework must be developed to allow cooperation between them. In addition, cities will have common problems that will be more efficiently addressed as a whole rather than individually. For most area-wide permits, a city or county acts as the lead agency or coordinator for day to day business, setting meetings and preparing submittals. They assume no responsibility for any other city's program, and are not viewed as the responsible agency for the permit. Each area-wide permit will require a mechanism to make decisions for the permittees, develop program guidlines for each of the permit areas, assess the adequacy and consistency of each permittees submittals in each of the program areas, address the inadequate program areas with each of the permitteees, and prepare unified submittals for the Regional Boards. The mechanism can either be a single government entity such as a county, or it can be a Management Committee made up of representatives of the permittees.

      1. Management Committee - An overall decision making body that is representative of all of the permittees.
         a. Describe the purpose of the committee, and how its responsibilities fit into the overall program framework.
         b. Describe the makeup of the committee, how the committee will communicate, and how it will coordinate its activities.

c. Describe what the authority of the committee will be and its procedures for decision making.

2. Subcommittees - We expect that programs will have the need to establish focused subcommittees specific to program action areas. List the subcommittees to be formed (or that already exist), tell the focus of the group, the participants, the tasks to be accomplished, the products to come out of the group, and the time frame to be followed. These committees should develop guidelines for program implementation for each of the program areas and a methodology for determining the adequacy of each permittee's program. All of the permittees should participate on at least one of the committees.
   a. Roles/responsibilities - Develop methodology for compliance with the permit elements, and set levels of expected effort. Review the submittals of each permittee for adequacy according to the criteria established for each program element- submit the reviews as part of the annual report.

B. INSTITUTIONAL ARRANGEMENTS - Management of the storm water program will require the cooperation of all of the governmental entities named on the permit. No one agency within a city or county has the authority to assume the responsibility of all activities within the municipality. Consequently, the permit is issued to a city or county, and not to a specific agency within the municipality. (Although, certain agencies, such as flood control agencies, may be cited as a permittee.) It is expected that all of the organizations within each municipality who have programs that have an impact on storm water quality will be educated about the storm water program and actively participate in implementation of it. There must be formal arrangements whereby all municipalities can participate in the same permit program, share costs and work jointly. The agencies within a municipality must also be able to communicate with each other and work jointly.

122.26(d)(2)(i)(D) *Control through interagency agreements among coapplicants the contribution of pollutants from one portion of the municipal system to another portion of the municipal system;*

122.26(d)(2)(vii) Where more than one legal entity submits an application, the application shall contain a description of the roles and responsibilities of each legal entity and procedures to ensure effective coordination.

1. Program Participant Arrangements - Describe the relationship and formal arrangements among all permittees.

   a. City-City-County - Identify all of the governmental authorities involved, and who the lead agency will be within each of those authorities for the storm water program. Identify the lead agency for coordination of the permit. The lead agency provides no more than coordination, they do not assume responsibility for the adequacy of any city's program. Identify the responsibilities of each agency, how decisions will be made, and what communication protocols will be used. Identify what method will be used to develop a responsible management committee, or similar mechanism, and vest it with decision making powers.
   b. Format - What institutional arrangements have been used to formalize the agreement between the government entities, what arrangements have been made to allow cost sharing.
      i. Joint Powers Authority
      ii. Memorandum of Agreement/Understanding

2. Area-wide Interagency - Describe the function of each agency as it relates to the storm water program. Tell how each agency will be made aware of their responsibilities under the storm water program, and what they will do to comply with the regulations. Describe any responsibility or activity that impacts or overlaps the storm water program. Describe each activity/responsibility, how it impacts or overlaps the storm water program, how the agency will coordinate their activity with the storm water program, and how pertinent information will be exchanged. Describe the formal institutional arrangements or mechanisms that will be used to oversee or coordinate with each agency.
   a. County Hazmat - Waste regulations, Household hazardous waste program, Industrial Inspections
   b. County Health - Inspections of Restaurants and other food handling establishments.
   c. Flood Control - Operation and maintenance of the storm system
   d. Local Transportation/Congestion Management
   e. County (Regional) Parks
   f. Mosquito Abatement
   g. Fruit Fly Abatement
   h. Water Districts
   i. County Agricultural Agencies

R0010086

j. Others
3. City-specific Interagency Arrangements - This should reflect the structure in each city.
    a. Public works
        i. Engineering
        ii. Operations & Maintenance
        iii. Streets/roads - by law, these are part of the storm water conveyance system
        iv. Others
    b. Planning - New Construction and Redevelopment, coordination with CEQA and local permitting. Retrofit of existing structures.
    c. Parks and Recreation
    d. POTWs
    e. Others

C. FISCAL RESOURCES - Every permittee must have a mechanism for funding their storm water program. The plan should show what the funding is, the source of the funding, and how it will be distributed. The regulations require a budget for every year of the five year permit period. While it may not be possible for a city to commit to a set budget for future years, it is possible to make estimates about the cost of the program that is proposed. This should include an estimate of the cost of each of the elements, the personnel or contracts that will be required to implement the program, the anticipated funding source, and process and time schedule for establishing detailed annual budgets. Include a detailed budget for the first year.

122.26(d)(1)(vi) Fiscal resources. (A) A description of the financial resources currently available to the municipality to complete part 2 of the permit application. A description of the municipality's budget for existing storm water programs, including an overview of the municipality's financial resources and budget, including overall indebtedness and assets, and sources of funds for storm water programs.

122.26(d)(2)(vi) Fiscal analysis. For each fiscal year to be covered by the permit, a fiscal analysis of the necessary capital and operation and maintenance expenditures necessary to accomplish the activities of the programs under paragraphs (d)(2) (iii) and (iv) of this section. Such analysis shall include a description of the source of funds that are proposed to meet the necessary expenditures, including legal restrictions on the use of such funds.

1. Area-wide
    a. Funding source(s)
    b. Staff resources
    c. Contract services
    d. Cost share (funds associated with existing activities/related programs) - if management practices currently in place under another program are to be included as part of the storm water program, the costs associated with those practices should be included as part of the budget. The program should also have a demonstrable water quality perspective.
2. City-specific
    a. Funding source(s)
    b. Staff resources
    c. Contract services
    d. Cost share (funds associated with existing activities/related programs) - if management practices currently in place under another program are to be included as part of the storm water program, the costs associated with those practices should be included as part of the budget. The program should also have a demonstrable water quality perspective.

D. LEGAL AUTHORITY - The regulations require permittees to demonstrate adequate legal authority to carry out the storm water program, including controls on industry and construction. You must cite your legal authority, or where it does not yet exist, give a plan and timetable for developing it.

122.26(d)(1)(ii) Legal authority. A description of existing legal authority to control discharges to the municipal separate storm sewer system. When existing legal authority is not sufficient to meet the criteria provided in paragraph (d)(2)(i) of this section, the description shall list additional authorities as will be necessary to meet the criteria and shall include a schedule and commitment to seek such additional authority that will be needed to meet the criteria.

122.26(d)(2)(i) Adequate legal authority. A demonstration that the applicant can operate pursuant to legal authority

established by statute, ordinance or series of contracts which authorizes or enables the applicant at a minimum to:
(A) Control through ordinance, permit, contract, order or similar means, the contribution of pollutants to the municipal storm sewer by storm water discharges associated with industrial activity and the quality of storm water discharged from sites of industrial activity;
(B) Prohibit through ordinance, order or similar means, illicit discharges to the municipal separate storm sewer;
(C) Control through ordinance, order or similar means the discharge to a municipal separate storm sewer of spills, dumping or disposal of materials other than storm water;
(D) Control through interagency agreements among coapplicants the contribution of pollutants from one portion of the municipal system to another portion of the municipal system;
(E) Require compliance with conditions in ordinances, permits, contracts or orders; and
(F) Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance and noncompliance with permit conditions including the prohibition on illicit discharges to the municipal separate storm sewer.

1. List of essential authorities - Describe how the authority already existing in your municipality fills the requirements in the regulations. The ordinances must be adequate and they must be enforced.
2. Ordinance
   a. Exists
   b. Planned
3. Implementation procedures
4. Responsible parties

II. ILLICIT DISCHARGES - The regulations require every permittee to have a plan for fiding and preventing illegal discharges, and a mechanism for enforcing against illegal dischargers.

122.26(d)(1)(iii) Source identification. (A) A description of the historic use of ordinances, guidance or other controls which limited the discharge of non-storm water discharges to any Publicly Owned Treatment Works serving the same area as the municipal separate storm sewer system.

122.26(d)(2)(v)(B) A description of the existing program to identify illicit connections to the municipal storm sewer system. The description should include inspection procedures and methods for detecting and preventing illicit discharges, and describe areas where this program has been implemented.

122.26(d)(1)(iv)(D) Field screening. Results of a field screening analysis for illicit connections and illegal dumping for either selected field screening points or major outfalls covered in the permit application.

122.26(d)(2)(iv)(B) A description of a program, including a schedule to detect and remove (or require the discharger ... to obtain a ... NPDES permit for) illicit discharges and improper disposal into the storm sewer.

A. ILLICIT CONNECTIONS - The storm drain system should have been surveyed during the first permit period to ensure that all of the connections made to the system are both legal and appropriate. If the system has not yet been surveyed the plan should contain a proposed plan for doing it. The plan should contain a proposal for how the system will be surveyed, who will do the survey and a time table for completion. It should also specify what will be done with the illicit connections that are found. In addition, there should be a plan for ongoing system inspections.
   1. System survey
   2. Ongoing system inspections - The extent of this program would vary widely based on the needs of an individual city.
   3. Reporting

B. ILLEGAL DUMPING - It is important to stop illegal dumping. Unfortunately, it is difficult to detect, because it is usually done both irregularly and covertly. The best method for stopping illegal dumping is educating the public, both to raise the awareness of what is illegal dumping so that people are not doing it, and to encourage the public to contact the authorities if they witness illegal dumping. All city inspectors and police and fire personnel should be trained to recognize and respond to illegal dumping. There should be a clear response mechanism, such as a hotline that anyone can use to report incidence of illegal dumping. In addition there should be ongoing system surveillance. If illegal dumping or spills are reported and responded to, there should be some follow up mechanism.
   1. Outreach

2. System surveillance
3. Spill response - When a spill is identified, it must be cleaned up. The city must have the legal authority to act against the discharger, and the ability to handle the clean up or require the discharger to clean it up. The Regional Water Board and other State agencies can be brought in if a spill occurs that is beyond the ability of the city to the clean up.
4. Complaint response - When a complaint is made, it must be responded to. The city must have the legal authority to act against the discharger, and the ability to handle the clean up or require the discharger to clean it up. The Regional Water Board and other State agencies can be brought in if a spill occurs that is beyond the ability of the city to the clean up.
5. Coordination of alternative disposal - Household hazardous waste recycling programs are mandated for many of the items that are routinely illegally dumped, such as used oil. Describe these programs and any other alternative disposal programs that are available.
6. Reporting - Incidents of illegal dumping and spills should be reported to the Regional Board on a regular basis in writing. All complaint response should be tracked in writing and submitted to the Regional Board.

C. ENFORCEMENT PROCEDURES - Cite your local legal authority and describe your mechanism for enforcing against dischargers who are illegally dumping or who have illicit connections.

D. COORDINATION WITH STATE NON-STORM WATER PERMITS - All other state laws and programs that overlap with or are in conflict with the storm water program must be addressed. Non-storm water discharges are prohibited unless authorized by NPDES permit. Even if the Regional Board issues a permit for a discharge, the city can refuse to accept the discharge into their system. The regulations exclude certain non-storm water discharges from the prohibition unless a municipality identifies them as sources of pollutants. Permittees must identify the discharges they will allow, and the management measures that they will require on these discharges. However, all discharges that are prohibited by a Regional Board must also be prohibited by a municipality. A municipality cannot be less stringent than the state.

1. Identification of permissible/permitable discharges
2. Appropriate management practices
3. Reporting

III. INDUSTRIAL/COMMERCIAL SOURCES - Municipalities are responsible for all discharges from commercial facilities as well as industries and construction sites within their jurisdiction regardless of coverage under the statewide general permits. This includes facilities required to be permitted under the State Industrial Storm Water Program and industries and commercial facilities that are not required to be permitted. Pollution prevention should be emphasized. The Regional Water Board will enforce the General Permits and municipalities are expected to enforce their local ordinances.

122.26(d)(2)(ii) Source identification. The location of any major outfall that discharges to waters of the United States that was not reported under paragraph (d)(1)(iii)(B)(1) of this section. Provide an inventory, organized by watershed of the name and address, and a description (such as SIC codes) which best reflects the principal products or services provided by each facility which may discharge, to the municipal separate storm sewer, storm water associated with industrial activity;

122.26(d)(2)(iv)(A) A description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas that are discharged from the municipal storm sewer system that are to be implemented during the life of the permit, accompanied with an estimate of the expected reduction of pollutant loads and a proposed schedule for implementing such controls.

122.26(d)(2)(C) A description of a program to monitor and control pollutants in storm water discharges to municipal systems from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities that are subject to section 313 of title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA), and industrial facilities that the municipal permit applicant determines are contributing a substantial pollutant loading to the municipal storm sewer system. The program shall:

(1) Identify priorities and procedures for inspections and establishing and implementing control measures for such discharges;
(2) Describe a monitoring program for storm water discharges associated with the industrial facilities identified in paragraph (d)(2)(iv)(C) of this section, to be implemented during the term of the permit, including the submission of quantitative data on the following constituents: any pollutants limited in effluent guidelines subcategories, where applicable; any pollutant listed in an existing NPDES permit for a facility; oil and grease, COD, pH, BOD5, TSS, total phosphorus, total Kjeldahl nitrogen, nitrate plus nitrite nitrogen, and any information on discharges required under 40 CFR 122.21(g)(7) (iii) and (iv).

A. IDENTIFICATION OF SOURCES - Indicate what sources were identified during the first permit period. Tell what measures will be taken to identify other sources, what agency will do the source identification, what methods of source identification will be used, and the time table for completing this investigation. This source identification should allow cities to prioritize industrial and commercial sources and to determine the schedule for inspection. At the minimum all potential sources should be inspected at least once during the permit period. Some facilities will require more frequent inspections.
   1. Categorical list
   2. Ranking
   3. Update procedure

B. CONTROL MEASURES (identification) - For each pollutant source, either by industrial or commercial category or specific activity, determine what measures are applicable for control of the source: which, of these measures, are technically and financially feasible, and which measures will be used. Indicate who will implement the measures, how they will be implemented and the time table for implementation. The plan should include a tiered approach. Describe what measures either have been implemented already, or can be immediately implemented, other measures that can be implemented over the short term and measures that are more costly or difficult that can be used if necessary in the long term. Describe any studies or pilot projects that are contemplated to study these measures.
   1. Pollution prevention measures - Education on source minimization and pollution prevention is an important control measure.
      a. Site design options
      b. Housekeeping/maintenance practices
   2. Structural (treatment) measures
      a. Applicability
      b. Effectiveness
      c. Retrofit opportunities

C. OUTREACH - Indicate the purpose of the outreach, the target audience, the intended messages, who will be responsible for the outreach, how the outreach will be done, and the time table for implementation.
   1. General guidance - All potential industrial and commercial dischargers should be informed of their obligations under the storm water program. Dischargers should also be informed of ways of complying with the storm water program, including general outreach on pollution prevention measures.
   2. Industrial category guidance - Specific outreach should be developed for industrial or commercial categories that permittee identify as high priority industries.
   3. Industrial activity guidance - Specific outreach should be developed for high priority activities such as loading docks or vehicle washing and maintenance.

D. INSPECTIONS - Most municipalities already have programs in which they inspect businesses, these include HAZMAT, Health and Pretreatment Programs among others. Inspections for the storm water program can either be incorporated into these other inspection programs, or they can be done as a stand alone program with separate inspectors. Indicate the purpose of the inspections, the priority for inspections, how the facilities were chosen for inspection, what the inspection will consist of, how the inspection will be carried out, who will be responsible for the inspections, how the inspectors will be trained, when the inspection program will be implemented and a schedule for completion of the inspections. Indicate also how the results will be reported and to whom. If an immediate problem is found how will it be handled? To whom will it be reported? How will follow up to these inspections be handled? Will there be a mechanism for a revisit inspection?
   1. Checklist
   2. Schedule
   3. Reports
   4. Follow-up procedures

E. LOCAL PERMITS / INCENTIVE PROGRAM - While not required by the Regulations, a municipality should consider controlling industrial and commercial sources through the use of local storm water permits, or clean business incentive programs.

F. TRAINING - Implementation of an industrial storm water program will require an informed and aware staff. All public employees should be trained in the storm water regulations, both so that they abide by the regulations in the course of their work day and so that they can tell if an activity that they witness is legal. In addition inspectors who visit commercial or industrial facilities, or who go to construction sites can determine compliance with the storm water regulations and educate the facilities about the requirements of the program.

1. Public employees
2. Inspectors

G. COORDINATION WITH STATE INDUSTRIAL STORM WATER PERMIT - It is anticipated that the municipalities will have regulations through ordinance or other legal mechanisms that would be written such that compliance with a municipality's regulations would cause an industrial discharger to be in compliance with the State General Permit. It is anticipated that coordination between the Regional Boards and the municipalities will be required. As such, the municipalities should discuss the anticipated relationship or agreement they would have with the Regional Board, and the mechanism they will pursue to enact such an agreement or relationship.

1. Memorandum of Understanding - An MOU can be used to formalize the agreement between municipalities and the Regional Board on the industrial compliance program.
2. Reports
3. Other issues

IV. NEW DEVELOPMENT AND RE-DEVELOPMENT - Each permittee must have a plan for managing storm water runoff from new construction and re-development. The plan must cover both construction covered by the State Construction Storm Water General Permit and construction under five acres. The plan should emphasize pollution prevention, especially erosion prevention.

122.26(d)(2)(iv)(A)(2) A description of planning procedures including a comprehensive master plan to develop, implement and enforce controls to reduce the discharge of pollutants from municipal separate storm sewers which receive discharges from areas of new development and significant redevelopment. Such plan shall address controls to reduce pollutants in discharges from municipal separate storm sewers after construction is completed.

122.26(d)(2)(iv)(D) A description of a program to implement and maintain structural and non-structural best management practices to reduce pollutants in storm water runoff from construction sites to the municipal storm sewer system, which shall include:
(1) A description of procedures for site planning which incorporate consideration of potential water quality impacts;
(2) A description of requirements for nonstructural and structural best management practices;
(3) A description of procedures for identifying priorities for inspecting sites and enforcing control measures which consider the nature of the construction activity, topography, and the characteristics of soils and receiving water quality; and
(4) A description of appropriate educational and training measures for construction site operators.

A. PLANNING PROCESS - The planning process for new development and re-development must address a comprehensive plan to develop, implement and enforce controls to reduce the discharge of pollutants from areas of new development and significant redevelopment. Master planning and other studies regarding flood management must assess the impact on water quality.

1. Watershed protection policies
2. Coordination with CEQA
3. Site planning practices
4. General Plan changes
5. Use of master plans
6. Other policies
7. Planning - public works interface
8. Implementation procedures

B. CONSTRUCTION SITES - Construction site management must consider the requirements of the State Construction Storm Water General Permit. Erosion prevention using vegetation, soil stabilization and timing of grading should be emphasized.

1. Erosion control requirements
2. Chemical and waste management requirements
3. Inspections
   a. Checklist
   b. Schedule
   c. Reports

d. Follow-up procedures

C. LOCAL PERMITS - Optional
1. Coordination with existing permits
2. New permit issues

D. TRAINING
1. Planning personnel
2. Public Works personnel
3. Inspectors

E. CONTROL MEASURES - Permanent measures to be installed during construction to control runoff from the final development or redevelopment.
1. Pollution prevention measures
a. Site design - inlet design to allow easy and frequent cleaning.
b. Education/training
c. Other
2. Post construction (treatment) measures - grassy swales, extended detention basins, sand filters, constructed wetlands, oil/water separators.
a. Applicability
b. Effectiveness
c. Retrofit opportunities
3. Operation and maintenance - It must be clear who is responsible for the long term maintenance, and who will pay for it.
a. Requirements
b. Responsible party
4. Conflicts with other mandates - Regulations from other agencies can conflict with recommended practices in the storm water program. An example of this is the storage of materials. While the storm water program recommends covering materials, fire codes will not allow some materials to be covered. In another area, the minimization of impervious areas and design of landscaping to allow flow to the vegetated areas are recommended practices in storm water. Often local building ordinances dictate the amount of impervious areas and the configuration of the landscaping. These conflicts should be identified and an attempt made to resolve them.
a. Identification of conflicts
i. Landscaping
ii. Pavement/curbs
b. Conflict resolution

F. OUTREACH
1. Developers
2. Contractors
3. Other parties

G. ENFORCEMENT - Municipalities must enforce their ordinances, including their grading ordinances.

H. COORDINATION WITH STATE CONSTRUCTION STORM WATER PERMIT - It is anticipated that the municipalities will have regulations through ordinance or other legal mechanisms that would be written such that compliance with a municipality's regulations would cause a construction project to be in compliance with the State General Construction Permit. Coordination between the Regional Boards and the municipalities will be necessary. As such, the municipalities should discuss the anticipated relationship or agreement they would have with the Regional Board, and the mechanism they will pursue to enact such an agreement or relationship.

1. Memorandum of Understanding - An MOU can be used to formalize the agreement between municipalities and the Regional Board on the construction compliance program.
2. Reports

3. Other issues

V. PUBLIC AGENCY ACTIVITIES - All municipalities perform functions that have an impact on storm water quality. These include among other things, vehicle maintenance, landscape maintenance and weed control, water body maintenance including swimming pool maintenance, construction and maintenance of streets and roads, and construction and maintenance of the flood control system. Since municipalities must address all significant sources of pollutants, all of these activities must be examined and if appropriate, controlled.

122.26(d)(2)(iv) Management programs. (A) A description of the existing management programs to control pollutants from the municipal separate storm sewer system. The description shall provide information on existing structural and source controls, including operation and maintenance measures for structural controls, that are currently being implemented. Such controls may include, but are not limited to: Procedures to control pollution resulting from construction activities; floodplain management controls; wetland protection measures; best management practices for new subdivisions; and emergency spill response programs. The description may address controls established under State law as well as local requirements.

122.26(d)(2)(iv)(A)(1) A description of maintenance activities and a maintenance schedule for structural controls to reduce pollutants (including floatables) in discharges from municipal separate storm sewers;

122.26(d)(2)(iv)(A)(3) A description of practices for operating and maintaining public streets, roads and highways and procedures for reducing the impact on receiving waters of discharges from municipal storm sewer systems, including pollutants discharged as a result of deicing activities;

122.26(d)(2)(iv)(A)(4) A description of procedures to assure that flood management projects assess the impacts on the water quality of receiving water bodies and that existing structural flood control devices have been evaluated to determine if retrofitting the device to provide additional pollutant removal from storm water is feasible;

122.26(d)(2)(iv)(A)(5) A description of a program to monitor pollutants in runoff from operating or closed municipal landfills or other treatment, storage, or disposal facilities for municipal waste, which shall identify priorities and procedures for inspections and establishing and implementing control measures for such discharges;

122.26(d)(2)(iv)(A)(6) A description of a program to reduce to the maximum extent practicable, pollutants in discharges from municipal separate storm sewers associated with the application of pesticides, herbicides, and fertilizer which will include, as appropriate, controls such as educational activities, permits, certifications and other measures for commercial applicators and distributors, and controls for application in public right-of-ways and at municipal facilities.

A. SEWAGE SYSTEMS - Sewage spills must not be allowed to go into the storm drain. Sewage must be contained and vacuum pumped. Storm drains must be protected during a sewage spill.

B. CORPORATION YARDS - Corporation yards include any area or facility that is used for vehicle maintenance or washing, other maintenance, chemical storage or use, such as a paint facility, and waste management. Identify all corporation yards and give their locations and describe their functions.

1. Storm Water Pollution Prevention Plans - SWPPP are not required, however, municipalities are required to control any potential source of pollution, and SWPPP are a good vehicle for compliance. Identify what the potential storm water problems are, who is responsible for implementing the storm water measures, what management practices will be used, and how they will be implemented. For measures that are not already in place give a timetable for implementation. Tell how the effectiveness of the BMPs will be judged. If a municipality chooses not to use SWPPP, they must use an equivalent method to handle their corporation yard discharges.

C. PARKS AND RECREATION - Park Departments manage landscaping and swimming pools. Both of these activities involve the use of chemicals, waste management, and non-storm water discharges. Their use of chemicals must be addressed in the storm water management plan. In addition maintenance of swimming pools requires the periodic discharge of large quantities of swimming pool water.

1. Fertilizers/Pesticides
   a. Use / Application management
   b. Storage
2. Facility Management
   a. Wash waters
   b. Maintenance
   c. Swimming pool waters

D. STORM DRAIN SYSTEM OPERATION AND MANAGEMENT - The maintenance and operation of the storm drain system has an impact on storm water quality and must be addressed in the management plan. Material clogging storm drains can not be discharged into drains. It must be removed and disposed of properly.
   1. Inlet maintenance
   2. Drain maintenance
   3. Waste management
   4. New system designs
   5. Retro-fit opportunities

E. STREETS AND ROADS - Construction, operation, and maintenance of roads has an impact on storm water quality and must be addressed in the management plan..
   1. Sweeping - Street sweeping waste cannot be dumped in storm drain.
      a. Storm water quality based operation
      b. Waste management
   2. Street/pavement washing - Wash waters must be managed as non-storm water discharges.
   3. Maintenance
      a. Saw-cut slurry management
      b. Paving practices
      c. Waste management
      d. Medians/Landscaped Right of Way
         i. Irrigation
         ii. Fertilizer/pesticides

F. FLOOD CONTROL - Flood control practices have an impact on storm water quality and must be addressed in the management plan. Flood control managers must be educated about storm water quality requirements. Water quality must be a consideration in moving the water through the system.
   1. Coordination with new projects
   2. Coordination of maintenance activities
      a. Desilting/sediment removal
      b. Vegetation management
      c. Waste management
   3. Operation of facilities
      a. Detention basins - BMPs must be implemented when draining or pumping detention basins. Risers should not be directed into storm drain inlets.
      b. Other
   4. Retrofit opportunities

G. PUBLIC FACILITIES - Storm water runoff and non-storm water discharges from other public facilities must be addressed. Chemical use by these facilities should also be included. Address pressure blasting/cleaning sidewalks and concrete.
   1. Parking facilities
   2. Golf courses
   3. Schools
   4. Hospitals
   5. Parks / Landscapes
   6. Other buildings/plazas/etc.

H. PONDS, FOUNTAINS, AND OTHER PUBLIC WATER BODIES - Maintenance practices used on public water bodies, including waste management and non-storm water discharges, must be addressed in the plan.
   1. Algae control
      a. Use of chemicals
   2. Chlorine management
   3. Maintenance

VI. RESIDENTIAL (Not Elsewhere Covered) - Residential activities including private vehicle washing and maintenance; use of chemicals such as pesticides, herbicides and paints; private swimming pool maintenance; and other household and landscape maintenance can contribute to storm water pollution. Identify measures that can be taken to improve the quality of the runoff from residential area. Emphasize pollution prevention and the identification and use of safe substitutes.

VII. PUBLIC INFORMATION AND PARTICIPATION - It is necessary to involve the public in the storm water program in order to have an effective municipal program. The outreach program should be focused on the specific needs of individual cities. Tell how the public education needs were determined, who is responsible for developing and implementing the education program, what program and what materials will be developed, give a timetable for implementing the program, and the method to be used to determine its effectiveness.

122.26(d)(2)(iv) Proposed management program. A proposed management program covers the duration of the permit. It shall include a comprehensive planning process which involves public participation and where necessary intergovernmental coordination, to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques and system, design and engineering methods, and such other provisions which are appropriate.

122.26(d)(2)(iv)(B)(5) A description of a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or water quality impacts associated with discharges from municipal separate storm sewers;

122.26(d)(2)(iv)(B)(6) A description of educational activities, public information activities, and other appropriate activities to facilitate the proper management and disposal of used oil and toxic materials; and

A. GENERAL OUTREACH - Describe your outreach materials developed for the general public. Tell what the focus of the materials are, and how you arrived at that focus. Tell what materials have already been developed and how they are distributed. Tell what materials are still to be produced, what they address, who is producing them, how they will be distributed, what kind of follow up opportunities are provided, and the timetable for production and distribution.
   1. Written material
   2. Audio material
   3. Video material
   4. Distribution plan

B. FOCUSED OUTREACH - Describe your outreach materials developed for specific groups. Tell how these groups were identified and prioritized. Tell what the focus of the materials are, and how you arrived at that focus. Tell what materials have already been developed and how they are distributed. Tell what materials are still to be produced, what they address, who is producing them, how they will be distributed, what kind of follow up opportunities are provided, and the timetable for production and distribution.
   1. Pollutant specific
   2. Practice/activity specific
   3. Business specific

C. EDUCATION PROGRAMS
   1. Public employees - It is important to educate all of the public employees about the storm water program both so that they do not continue with practices that are counter productive and so that they can participate in its implementation and enforcement. Describe your public employee outreach programs. Tell what the focus of the training is, how it is implemented, who is implementing it, the schedule for training, and the opportunities for continuing education.
   2. K-12 - Describe programs developed for schools. These programs should include storm water awareness, illegal dumping awareness, source minimization and pollution prevention.
   3. Other

D. CITIZENS PARTICIPATION
   1. Volunteer monitoring
   2. Cooperative outreach
   3. Complaint procedures - Describe any mechanism available for citizen reports of illegal discharge illicit connections or potential pollution problems.

E. EFFECTIVENESS EVALUATION - Quantifying the effectiveness of education and outreach efforts may be difficult. Municipalities must develop a process by which they can evaluate the effectiveness of their program, and recommend changes to it.

VIII. PROGRAM EVALUATION - The storm water program developed under this plan must be evaluated for its effectiveness on a regular basis. The plan for this evaluation must include a schedule for evaluation, a methodology for the evaluation, a discussion of who will carry out the evaluation, and what will be evaluated. In addition, there must be a mechanism to follow up on the information generated by the evaluation. The plan should be adjusted based on the program evaluation.

122.26(d)(2)(v) Assessment of controls. Estimated reductions in loadings of pollutants from discharges of municipal storm sewer constituents from municipal storm sewer systems expected as the result of the municipal storm water quality management program. The assessment shall also identify known impacts of storm water controls on ground water.

A. PERFORMANCE STANDARDS - The permittees, possibly through management-committee sub-committees, must develop standards to judge the effectiveness of their activities and control measures. As an example, for street sweeping, permittees must devise a way of determining if the street sweeping has an impact on water quality. This could include determining what kind of pollutants are removed by the sweeping, measuring the size of the pollutants and the amount removed. Methodologies should be developed for each, which if followed, will assure that each control measure or action is implemented to the maximum extent practicable. For street sweeping, this would include the frequency of sweeping, the method of sweeping, the equipment used, how the equipment is cleaned and maintained, and the method of disposal for the material collected. Contol measure studies can be coordinated on a larger scale, such as statewide, so that each municipality is studying a different procedure.
   1. Development procedure
   2. Role of subcommittees
   3. Activity/source/action area specific

B. ANNUAL REPORTS - Reports must be submitted after the end of each fiscal year. Permittees should propose a date for submittals that works for them. The reports should be more than a simple compilation of activities. Rather, they should be used to evaluate the program and the effectiveness of the management measures. Each annual report should contain a report on the program implemented during the previous year and a plan that will be implemented during the current year. In addition, the findings of the evaluation of the previous years program should be used to suggest changes that are appropriate for implementation during the next year. Any revisions to the five year plan should be addressed here.
   1. Format/Structure - Each group of permittees under an area wide permit should develop a format that all the permittees will use for the annual report.
   2. Effectiveness measures - The co-permittees are responsible for developing methods for determining the effectiveness of the BMPs that they implement, for their particular program, and developing a level of effort that will be required in each area.
   3. Content

C. SUB-ANNUAL REPORTS - Each year, before the end of the fiscal year, the permittees should submit a report that contains a draft preliminary report addressing the implementation of that years program, a preliminary budget for the next year program addressing the funding issues for the upcoming budget process, and a preliminary plan for the next year showing what revisions to the five year plan will be required. In some regions, rather than a sub-annual report, the permittees will meet with the Regional Board to discuss these issues.
   1. Purpose
   2. Format/Structure
   3. Content

D. INTERNAL REPORTING - We suggest the development of a process for interagency - intragency exchange information among themselves and to develop the annual and semiannual reports
   1. Standard forms
   2. Procedures
   3. Record keeping - The Regional Board does not need to see all of the extraneous information, but there should be a mechanism for storage of records in case they are needed.

E. STORM WATER MANAGEMENT PLAN REVISIONS - There should be a review process which will allow you to revise the plan for the next year and for the rest of the permit period.
   1. Process
   2. Reporting

IX. MONITORING - Monitoring serves several purposes. It allows a baseline characterization of storm water/urban runoff from the permitted area, it identifies the problems and their sources and evaluates impacts on receiving waters, it allows the permittee to determine what are appropriate, and it allows a permittee to judge the effectiveness of its control measures. Monitoring is not limited to water sampling. It can include such elements as visual inspections of above and underground systems or compilation of chemical use data.

Characterization of the permitted area, the watershed, the storm drain system, the receiving waters, and the land use was required in the previous permits. The information collected from previous efforts should be used in baseline characterization. This plan should also tell what the future monitoring objectives are, what information will be collected, the purpose of the information, how it will be collected and used, and how the information will be analyzed, reported and stored.

122.26(d)(1)(B) Existing quantitative data describing the volume and quality of discharges from the municipal storm sewer, including a description of the outfalls sampled, sampling procedures and analytical methods used.

122.26(d)(2)(F) Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance and noncompliance with permit conditions including the prohibition on illicit discharges to the municipal separate storm sewer.

122.26(d)(2)(ii) Source identification. The location of any major outfall that discharges to waters of the United States that was not reported under paragraph (d)(1)(iii)(B)(1) of this section. Provide an inventory, organized by watershed of the name and address, and a description (such as SIC codes) which best reflects the principal products or services provided by each facility which may discharge, to the municipal separate storm sewer, storm water associated with industrial activity;

122.26(d)(1)(iii)(C) A list of water bodies that receive discharges from the municipal separate storm sewer system, including downstream segments, lakes and estuaries, where pollutants from the system discharges may accumulate and cause water degradation and a brief description of known water quality impacts.

122.26(d)(2)(D) A proposed monitoring program for representative data collection for the term of the permit that describes the location of outfalls or field screening points to be sampled (or the location of instream stations), why the location is representative, the frequency of sampling, parameters to be sampled, and a description of sampling equipment.

122.26(d)(2)(B) Estimates of the annual pollutant load of the cumulative discharges to waters of the United States from all identified municipal outfalls and the event mean concentration of the cumulative discharges to waters of the United States from all identified municipal outfalls during a storm event (as described under Section 122.21(c)(7)) for BOD5, COD, TSS, dissolved solids, total nitrogen, total ammonia plus organic nitrogen, total phosphorus, dissolved phosphorus, cadmium, copper, lead, and zinc. Estimates shall be accompanied by a description of the procedures for estimating constituent loads and concentrations, including any modelling, data analysis, and calculation methods;

122.26(d)(2)(C) A proposed schedule to provide estimates for each major outfall identified in either paragraph (d)(2)(ii) or (d)(1)(iii)(B)(1) of this section of the seasonal pollutant load and of the event mean concentration of a representative storm for any constituent detected in any sample required under paragraph (d)(2)(iii)(A) of this section;

A. SYSTEM CHARACTERIZATION - The previous permit required a complete characterization of the entire system. This included the storm drain system, the receiving waters and the land use activities.
   1. Watershed - Characterize each watershed including the storm drain system, the land uses and the particular problems of the receiving waters.
   2. Storm drain system - Characterize the system including all major outfalls.
      a. Inlets
      b. Outlets
   3. Receiving waters - Identify and evaluate water bodies. Use existing water quality data along with current monitoring efforts to characterize and prioritize the receiving waters. Perform additional monitoring as necessary to characterize the receiving waters.
      a. Streams
      b. Lakes
      c. Bays
      d. Wetlands

    e. Other habitat

4. Land use - Characterize the land use in the permitted area. Characterize the storm water discharges from specific land use categories and mixed land use.
    a. General categories
    b. Specific features/sources

B. SOURCE IDENTIFICATION - Do focused monitoring on pollutants of concern.
1. Specific land-use
2. Specific activities

C. CONTROL MEASURE EFFECTIVENESS - Monitor to determine the effectiveness of control measures. Identify what control measure studies will be done and how they will be prioritized. Give a schedule for doing the studies.
1. Specific Sources (e.g., corp yards)
2. Specific Activities (e.g., waste management)
3. Special Studies

D. POLLUTANT LOADING - An initial determination of the pollutant loading, both system wide and specific to land use types should be made through monitoring and modeling. Once the initial determination is made, it is important to continue a minimal long term monitoring program to track trends in the pollutant loading over time.

1. System-wide
2. Land-use specific
3. Long-term stations

E. COMPONENTS OF A MONITORING PROGRAM PLAN - These are the expected elements of a monitoring plan. The elements suggested here do not replace any directions from the regulating Regional Board.
1. Monitoring/sampling points with map
    a. rationale for sampling points
2. Dry weather sampling
    a. frequency
    b. monitored parameters
    c. method for documentation of outfall field inspections
3. Storm sampling plan
    a. number of storm events to be samples
    b. method for determining representative event
    c. worker safety plan
    d. sampling plan
    e. timing of sampling
    f. monitored parameters
        i. how were parameters chose?
    g. method to be used for flow weighted compositing of samples
        i. time duration between samples
        ii. minimum number of samples per hour
4. Manual of field techniques
    a. general field techniques
    b. manual vs automatic sampling
    c. appropriate sampling technique for each pollutant
        i. grab vs composite
    d. appropriate sample size for each pollutant
5. Flow analysis for sampled storm event
    a. method for determining flow
        i. flow rate
        ii. flow volume
6. USEPA Title 40 CFR Part 136 compliance
    a. container type

R0010098

i. preparation/cleaning of containers
b. preservation procedures
i. were composite samples preserved/stabilized during sampling?
c. maximum holding times
d. use of approved analysis method
7. Laboratory
8. Analyses to be performed
9. Monitoring report format
a. date, exact place, time of sampling
b. individual performing sampling
c. dates analysis performed
i. were analyses performed within specified holding times?
d. individual performing analysis
e. analytical techniques/methods used
i. were approved methods used?
f. results of analysis
g. quality assurance/quality control
i. sampling
ii. analytical
iii. field QC samples
(a) QC for field analyses
(b) QC for samples for laboratory
iv. laboratory QC samples
v. analysis of accuracy
(a) average accuracy
(b) standard deviation
vi. aalysis of precision
(a) average precision for each measurement parameter
(b) standard deviation
vii. detection limits
(a) do detection limits exceed target detection limits?
viii. data outside QC target limits
(a) listing
(b) explanation
h. chain of custody
i. authorized signature
j. composite/grab sample
k. method for making composite sample
i. pollutant concentration/total mass based on flow-weighted samples

F. DATA MANAGEMENT
1. Data analyses
2. Database system
3. Accessibility
4. Reports
5. Modeling - Use and applicability

Keywords: *Ergonomics, *Manual lifting, *Industrial hygiene, *Occupational safety and health, Posture, Back injuries, Musculoskeletal system disorders, Truck drivers.

Abstract: The goal of this study was to apply ergonomic controls in the soft drink beverage delivery industry, and measure the effectiveness in reducing musculoskeletal injuries through psychophysical, physiological, and biomechanical methods. Nine driver/sales workers with an average of 20 years experience participated in the study. Risk factors inherent in the job included exposure to whole body vibration from driving the trucks, pushing and pulling loads exceeding 350 pounds, repetitive lifting and moving of crates, slip and fall injuries, surface conditions, exposure to sharp glass from broken glass bottles, robberies, and moving products from bays into trucks. All nine participants reported suffering a work related musculoskeletal injury, with eight reporting back injuries, five reporting arm injuries, and four reporting leg injuries. All had taken time off as a result of the injuries, with the average time off being 2.8 months.

12a. DISTRIBUTION/AVAILABILITY STATEMENT

12b. DISTRIBUTION CODE

This document is part of a series of sets of municipal wastewater management fact sheets. These fact sheets are intended to serve a wide audience, including consulting engineers, municipal engineers, state regulators, municipal officials, and private citizens. Contents include: airplane deicing fluid recovery systems; bioretention; catch basin cleaning; coverings; dust control; employee training; flow diversion; highway ice and snow removal and minimization of associated environmental effects from these procedures; handling and disposal of collected solids/ residuals from storm water and sediment control processes; infiltration drain field infiltration trenches; internal reporting; materials inventory; non-storm water discharges; porous pavement; preventive maintenance; record keeping; sand filters; StromTreat system; spill prevention; storm water contamination assessments; storm water wetlands; vegetative covers; vegetative swales; visual inspection; vortex solids separators; water quality inlets; wet detention ponds.

MUNICIPAL WASTEWATER MANAGEMENT
FACT SHEETS:
STORM WATER BEST MANAGEMENT PRACTICES

Municipal Technology Branch (4204)
United States Environmental Protection Agency
401 M Street, SW
Washington, DC, 20460

PREFACE

This document is part of a series of municipal wastewater management fact sheets. These fact sheets are intended to serve a wide audience including: the consulting engineer who is looking for basic technical information; the municipal engineer who must understand these technologies well enough to evaluate the assets and limitations; the municipal official who must sell the technologies as part of a comprehensive pollution prevention program; the state regulator who must approve the technologies used to meet permit requirements; and ultimately the citizen who must understand the importance of preventing pollution of the Nation's waters.

The material presented is guidance for general information only. The document does not provide sufficient information to design BMPs, but does provided sufficient information to compair alternatives. In some cases, the information represents new technology or new application of existing technology and is base on very limited data. This information should not be used without first obtaining competent advice with respect to its suitability to any general or specific application. References made in this document to any specific method, product or process does not constitute or imply an endorsement, recommendation or warranty by the U.S. Environmental Protection Agency.

Municipal Wastewater Management Fact Sheets are divided into several sets: Wet Weather Flow Management Practices; Innovative and Alternative Technologies; Biosolids Technologies and Practices; Wet Weather Technologies; Water Conservation, etc. Each set is published separately starting with Storm Water Best Management Practices, September, 1993. This document incorporates and superseeds previous storm water best management practice fact sheets (EPA 832-F-93-013, September 1993 and Addendum to EPA 832-F-93-013, September 1994) . Updates to this set of fact sheets and development of additional sets is dependent upon continued resources being available.

INTRODUCTION

Storm water runoff is part of a natural hydrologic process. However, human activities, particularly urbanization, can alter drainage patterns and add pollution to the rain water and snow melt that runs off the earth's surface and enters our Nation's rivers, streams, lakes, and coastal waters. A number of recent studies have shown that storm water runoff is a major source of water pollution as indicated by a decline in fish population and diversity, beach closings or restrictions on swimming and other water sports, bans on consumption of fish and shellfish and other public health concerns. These conditions limit our ability to enjoy many of the benefits that our Nation's waters provide.

In response to this problem, the States and many municipalities have been taking the initiative to manage storm water more effectively. In acknowledgement of these storm water management concerns, the U.S. Environmental Protection Agency (EPA) has undertaken a wide variety of activities, including providing technical assistance to States and municipalities to help them improve their storm water management programs.

This document contains fact sheets on storm water best management practices (BMPs). These fact sheets represent two types of BMPs: pollution prevention and treatment. Pollution prevention BMPs include both source controls and administrative practices. Treatment BMPs include both in-line ans off-line applications. However, many are not stand alone BMPs, but are most effective when combined with other BMPs in a comprehensive storm water management plan. These BMPs are suitable for both municipal and industrial applications and can be used to supplement other EPA guidance documents such as **Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices (EPA 832-R-92-006)** and **Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices (EPA 832-R-92-005)** as well as other State or local guidance.

In order to better serve our customers and identify additional information needs, a short questionnaire is included at the end of this document. Please take a few minutes to tell us if this document was helpful in meeting your needs and what other needs you have concerning storm water management. Responses can be mailed to the Municipal Technology Branch (4204), US EPA, 401 M Street, SW, Washington, DC, 20460 or faxed to (202) 260-0116.

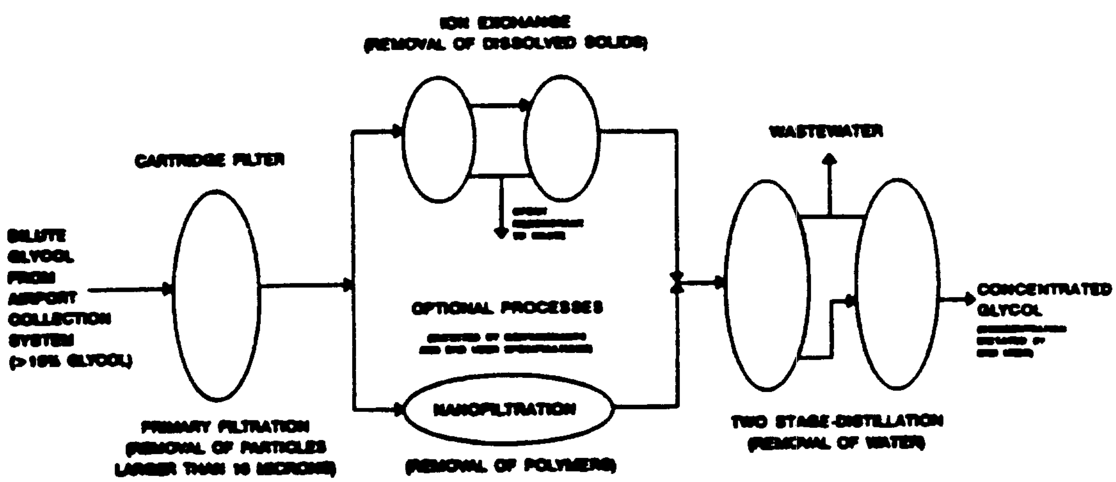
Customer Questionnaire

STORM WATER BMP: AIRPLANE DEICING FLUID RECOVERY SYSTEMS

EPA MTB
Office of Wastewater Management
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Ethylene or propylene glycol recovery is accomplished by a three-stage process typically consisting of primary filtration, contaminant removal via ion exchange or nanofiltration, and distillation as shown in Figure 1 below. The process technologies involved in glycol recovery have been proven in other industries and are now being applied to spent airplane deicing fluid (ADF).



SOURCE: Reference 3

FIGURE 1: TYPICAL AIRPLANE DEICING FLUID RECOVERY SYSTEM

The purpose of the primary filtration step is to remove entrained suspended solids from contact with the aircraft and pavement from the used ADF. The suspended solids must be removed to avoid plugging of downstream equipment and heat exchangers. Primary filtration is defined as the removal of solids greater than 10 micron in size. Primary filters employed by ADF systems may be polypropylene cartridge or bag filters. Ion exchange may be employed to remove dissolved solids such as chlorides and sulfates. Ion exchange removes ions from an aqueous solution by passing the wastewater through a solid material (called ion exchange resin) which accepts the unwanted ions, while giving back an equivalent number of desirable ions from the resin. Nanofiltration may be employed to remove polymeric additives. Nanofiltration systems are pressure-driven membrane operations that use porous membranes for the removal of colloidal material.

Colloidal material and polymeric molecules with molecular weights in excess of 500 are normally removed by nanofilters. The requirement to remove polymer additives is dictated by the specifications of the end user of the recovered ADF product.

The key process step in the overall ADF recycling system is distillation. Distillation is defined as the separation of more volatile materials (in this case, water) from less volatile materials (glycol) by a process of vaporization and condensation. Distillation is capable of recovering volatiles with little degradation, which is an important advantage in this application where the recovered product can be sold or recycled. Product purity of any desired level can theoretically be obtained by distillation, however in some cases the processing costs may be prohibitive. In most ADF applications, the separation of water from either a water-ethylene glycol or a water-propylene glycol mixture of ADF, employs a two stages of distillation process. This will typically, remove enough water to produce a recovered ADF with a minimum of a 50% glycol content. The requirement glycol concentration is dictated by the specifications of the end user of the recovered ADF product.

COMMON MODIFICATIONS

The details of the distillation process that each vendor employs are proprietary. Design variables include temperature, distillation column design (number of stages, type of packing, size) and reflux ratio. Batch distillation systems are generally employed due to the variation in the composition of the influent and the irregular supply of the feed. Secondary filtration and ion-exchange stages vary with the quality of the influent feed and the specifications of the end-user. The temperature of distillation also varies between ethylene glycol and propylene glycol recovery applications.

CURRENT STATUS

This fact sheet contains general information only, and should not be used as the basis for designing an airplane deicing fluid recovery system. While the basic technologies used to recycle ethylene and propylene glycol are well established, actual operating experience in recycling airplane deicing fluids is limited. To date, there is only one on-site application of ADF recovery operating in the United States. This is a pilot-scale operation conducted for Continental Airlines at the Denver Stapleton Airport. Another pilot-scale ADF operation is currently being conducted in Canada at the L.B. Pearson Airport in Toronto. While, recovery systems are proposed for the St. Louis, Missouri Airport and the Indianapolis, Indiana airport, these systems are not in operation. There are also three ADF recovery systems in operation at airports in Europe: Lulea, Sweden; Oslo, Norway; and Munich, Germany.

There are currently three vendors actively designing, testing or marketing ADF recovery systems for use on-site at airports in North America: DeIcing Systems (DIS), Glycol Specialists, Inc. (GSI), and Canadian Chemical Reclaiming (CCR). There are also a number of chemical waste service companies that will provide off-site processing for spent glycol for other industries. The technology and process applications of ADF are evolving rapidly. The equipment manufacturers and the airport operators should be contacted for the current state of the art information.

APPLICATIONS

Ethylene or propylene glycol recovery systems are generally applicable at any airport that collects ADF with a minimum concentration of approximately 15% glycol. Spent ADF mixtures with lower glycol content are generally impractical to recover via distillation, without expensive preconcentration steps such as reverse osmosis. Dilute streams are typically discharged to municipal wastewater treatment plants, if permitted, treated by oxidation to destroy the organics prior to direct discharge, or hauled away be a chemical waste contractor. A number of other BMPs such as water quality inlets and oil\water separators are being tested to demonstrate their ability and reliability to concentrate dilute streams.

LIMITATIONS

In order for the ADF to be recovered or regenerated, it must first be collected at the airport. The implementation of ADF collection must respond to the unique requirements of each airport. The feasibility of glycol recovery is dependent on the ability of the collection system to contain a relatively concentrated waste stream without significant contamination by other storm water components. Since distillation is an energy intensive process, it is generally not cost effective to distill and recycle waste glycol solutions at low concentrations (< 15%). However, individual airports may have to collect and recover lower concentrations of waste glycol solutions to satisfy requirements of their storm water NPDES permit. Remote or centralized deicing with the containment and collection of used glycol is one method for collecting a more concentrated used glycol. However, centralized deicing systems may be impractical for all but the largest airport operations due to their cost and physical size. For established airports, a switch to centralized deicing systems would present a number of operational and logistical problems. In lieu of a centralized facility, used glycol can be collected via vacuum trucks and fluid collections containers that siphon glycol from runway aprons. Roller sponge devices have been employed at the Toronto Airport with mixed results due to uneven surfaces.

Mixtures of ethylene and propylene glycols cannot be recovered effectively in a single batch process because the technology currently available cannot cost effectively separate the two glycols. While there is a market for either recovered ethylene glycol or propylene glycol, there is little demand for a recovered blend of both glycols by end users. In order to recover either ethylene or propylene glycol from spent ADF, an airport must use one or the other, or isolate application and runoff areas. Treated separately, each type of water-glycol mixture can then be recovered effectively via the distillation process.

DESIGN CRITERIA

There area number of important criteria that must be determined in order to properly design an ADF system. Table 1 below list some of the key criteria. Storage and handling of process chemicals, energy requirements, and disposal of spent chemicals and residuals generated in the recovery process must also be carefully considered. Other factors such as site drainage, weather patterns, water quality requirements, state and local restrictions, marketability of the recovered product, etc., will also influence the final design of the system.

Sodium hydroxide (NaOH) and hydrochloric acid (HCL) are required for regeneration of the ion exchange process unit. As a part of the recertification process, wetting agent and a corrosion inhibitor must be added to the recovered product prior to reuse as airplane deicing fluid. While recertification and reuse od recovered airplane deicing fluids is practiced in Europe, the Federal Aviation Administration (FAA) currently has no recertification guideline for reuse of recovered ADF in the United States. Care should be taken when handling these chemicals to avoid contact with skin. Eye protection should also be worn.

For the most part, energy requirements are dependent on the waste stream glycol concentration of the fluid to be recycled and the purity required by the end user. Recovery by distillation is energy-intensive, with nominal energy requirements being about 5.81×10^5 to 2.79×10^6 J/kg of feed (250 to 1200 BTU/lb of feed). As the technology is refined and as operating experience grows, these costs should decrease.Flush and spent

wastewater are generated by recovery processes which employ ion-exchange systems. These fluids may be disposed of, after neutralization by addition of acids or bases, to the sanitary sewer. Spent filter cartridges may be generated in some systems and may be disposed of to landfills. Distillation condensate, with less than 1.5% glycol, is also generated and may be reused or disposed. Currently discharges to the sanitary sewer system may require permitting under local pretreatment programs.

PERFORMANCE

Three ADF recovery systems were evaluated using data provided by three vendors. In each ADF recovery system investigated, the quality of the fluid recovered was dictated by the specification objective. The data provided for the ethylene glycol recovery system at the Toronto Airport shows that the process reliably produced an effluent with a glycol content over 80%. The data from the ADF recovery system in Denver showed that high purity (98.5% glycol) can be reliably produced. The process at the Munich Airport reliably produced an effluent with a glycol content over 50%, which meets the lower end-user requirements in Europe.

COSTS

Since there are no full-scale ADF systems currently operation in the U.S., it is difficult to determine the actual construction costs. However, based on pilot study at the Denver Stapleton Airport, the total capital cost for the complete project, including deicing and anti-icing application equipment, collection piping, storage facilities, and glycol recovery system has been estimated to be between $6 and $7 million dollars. The construction costs for the ADF collection system, storage and handling facilities, piping, and recovery system has been estimated at approximately $600,000 (GSI, 1993).

The total capital cost for the new Denver International Airport, including deicing and anti-icing application pads and equipment, drainage and collection piping, storage and handling facilities, and complete glycol recovery system is currently estimated at between $20 and $25 million dollars. These costs are based on a complete package including planning, engineering design, equipment, construction and installation, start-up services and other contingencies. The construction costs for the ADF collection system, storage and handling facilities, piping, controls and instrumentation, and complete recovery system is currently estimated at approximately $5 million dollars.

The major operating expense for all ADF systems is cost of energy used in the distillation process. Other maintenance costs include flushing of filters and ion-exchange units, disposal of spent filter cartridges, process and neutralization chemical, lubrication of pumping equipment, and inspection and repairs to the distillation equipment and heat exchanger. The collection system and storage facilities will also require periodic cleaning and maintenance. Based on vary limited operating data from the pilot study at the Stapleton Airport, the cost for processing ADF with a 28 percent glycol concentration, is approximately 35 cents per gallon treated. However, this cost will vary depending on the volume treated and concentration of glycol in the waste stream. As the technology is refined and as operating experience grows, these costs should decrease.

ENVIRONMENTAL IMPACT

While the potential for volatile-organic emissions to the air is considered small, the discharges of air emissions from the distillation process through losses from condenser vents, accumulator tank vents, and storage tank vents must be considered. Ion-exchange flush and spent wastewater are generated by recovery processes may generally be discharged to the sanitary sewer. These spent byproducts may require neutralization by addition of acids or bases before discharge. Currently discharges to the sanitary sewer system may require permitting under local pretreatment programs. Spent filter cartridges may be generated in some systems. In most cases these can be disposed of in the local landfill.

Distillation condensate, with less than 1.5% glycol, is also generated and may be reused or disposed. However, release of more than 1 pound of ethylene glycol to the environment must be reported under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) requirements. The EPA currently has under review a proposal to raise the disposal limit to 5000 pounds. This proposal is expected to be promulgated as a rule in calendar year 1995. A spill prevention control and countermeasure (SPCC) plan should be developed for all ADF systems to address the handling, storage and accidental release of chemicals, regenerated products and waste byproducts.

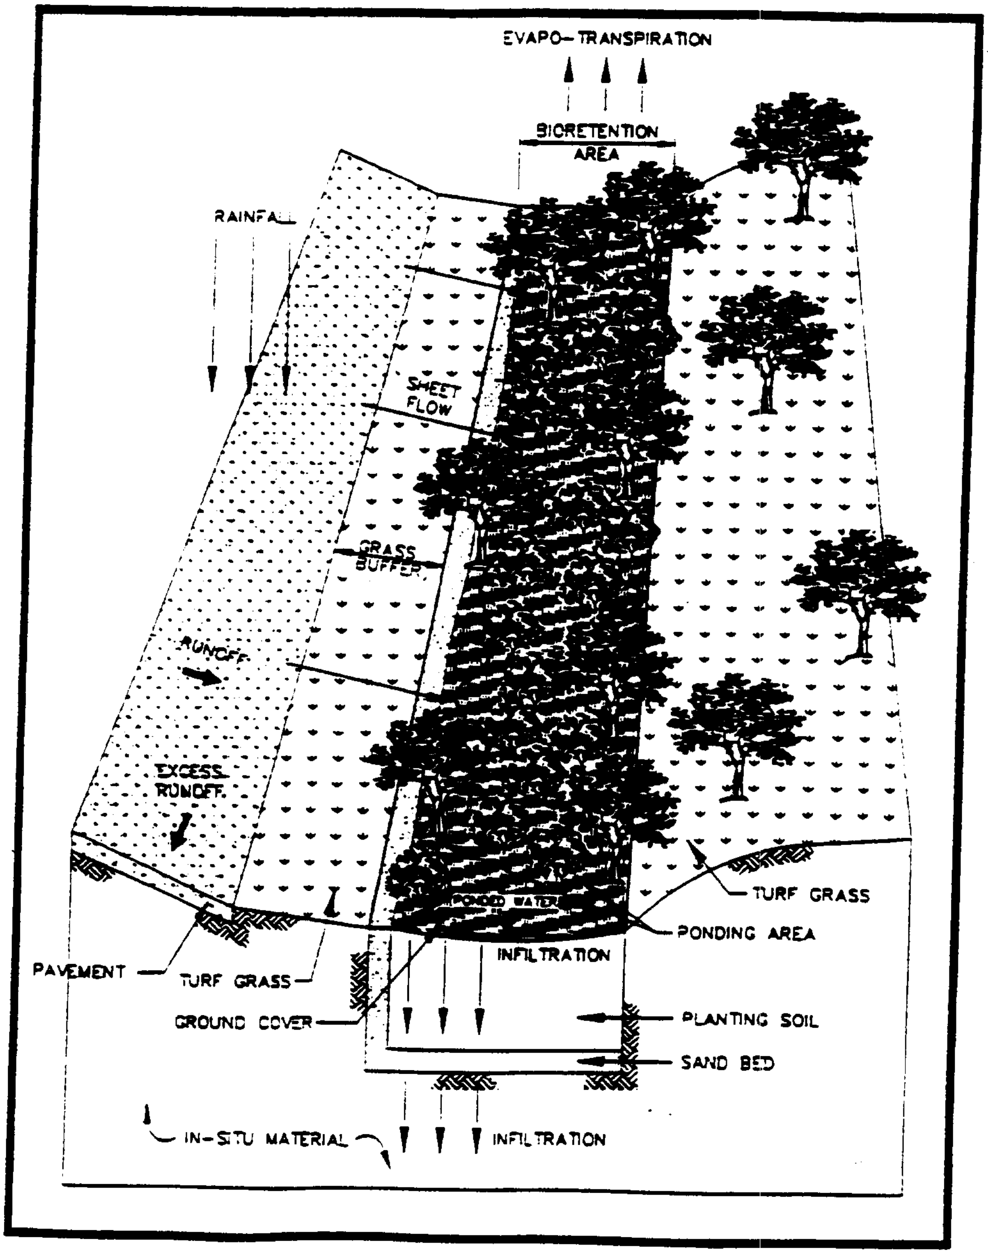
STORMWATER BMP: BIORETENTION

DESCRIPTION

Bioretention is a recently developed best management practice (BMP) developed by the Prince George's County, Maryland Department of Environmental Resources (PGDER). The BMP utilizes soils and plants to remove pollutants from stormwater runoff. As shown in Figure 1, runoff is conveyed as

FIGURE 1 BIORETENTION AREA



Source: PGDER, 1993.

sheet flow to the BMP, which consists of a grass buffer strip, sand bed, ponding area, organic layer or mulch layer, planting soil, and plants. Runoff first passes over a sand bed, which slows the velocity and evenly distributes the runoff over the ponding area. Runoff also infiltrates the sand bed, which adds to the infiltration capacity of the bioretention area. After runoff passes over or infiltrates the sand bed it enters the ponding area. The ponding area is formed by depressing the surface organic layer and/or ground cover and the underlying planting soil. Water is ponded to a depth of 6 inches and gradually infiltrates the bioretention area or is evapotranspired. The grading of the bioretention area is done so that excess runoff is diverted away from the BMP. Stored water in the bioretention area planting soil exfiltrates over a period of days into the underlying soils of the BMP.

COMMON MODIFICATIONS

The City of Alexandria, Virginia has modified the design to include an underdrain within the sand bed to collect the infiltrated water and discharge it to a downstream sewer system. Underdrains were required due to impervious subsoils and marine clays. This modified design makes the bioretention area act more as a filter that discharges treated water than an infiltration device. The BMP can also be modified to include or not include a sand bed. The benefit of using a sand bed is the reduction in velocity and infiltration achieved with the bed. Design modifications are also being reviewed to potentially utilize both aerobic and anaerobic zones in the BMP. The anaerobic zone will promote denitrification.

CURRENT STATUS

Bioretention has been used successfully at urban and suburban areas in Prince George's County, Maryland (MD), Montgomery County, MD, Baltimore County, MD, and Prince William County, Virginia. The first system was installed nearly four years ago (1992). The BMP is planned for installation in Alexandria, Virginia and locations in North Carolina.

APPLICATIONS

Bioretention typically provides stormwater treatment for impervious surfaces at commercial, residential, and industrial areas. Three prime locations where the BMP could be used are at median strips, parking lot islands, and in swales. They are usually best used at locations that are upland from inlets that receive sheet flow from graded areas and at areas that will be excavated. Sheet flow should be conveyed to the BMP to minimize erosive conditions and to maximize treatment effectiveness. Low environmental impacts to a site are desired. Therefore, construction of bioretention areas best suited to sites where grading or excavation will occur so that the bioretention area can be readily incorporated in the site plan. Bioretention areas should be used in stabilized drainage areas to minimize the sediment loading to the BMP.

LIMITATIONS

Bioretention is not an appropriate BMP at locations where the water table is within 6 feet of the ground surface and when the surrounding soil stratum is unstable. In cold climates there is the potential for the soil to freeze and prevent runoff from infiltrating into the planting soil. The BMP is also not recommended for areas with slopes greater than 20 percent or where mature tree removal will be required. Clogging may be a potential problem, particularly if the BMP receives runoff with high sediment loads.

PERFORMANCE

Stormwater pollutant removal in bioretention is attributed to physical and biological processes that occur in the plants and soils of the BMP. These processes include adsorption, filtration, plant uptake, microbial activity, decomposition, sedimentation and volatilization.

Adsorption is the process where pollutants attach to soil (e.g., clay) or vegetation surfaces. Adequate contact time between the surface and pollutant must be provided for in the design of the system for this removal process to occur. Therefore, the infiltration rate of the soils must not exceed those specified or pollutant removal may decrease. Pollutants removed by adsorption include metals, phosphorus, and some hydrocarbons.

Filtration occurs as runoff passes through the bioretention area media, such as the sand bed, ground cover and planting soil. The media trap particulate matter and allows water to pass through. The filtering effectiveness of the bioretention area may potentially decrease over time. Common particulates removed from stormwater include particulate organic matter and suspended solids.

Biological processes that occur in wetlands result in pollutant uptake by plants and microorganisms in the soil. Plant growth is sustained by the uptake of nutrients from the soils. Microbial activity within the soil also contributes to the removal of nitrogen and organic matter. Nitrogen is removed by nitrifying and denitrifying bacteria and aerobic bacteria are responsible for the decomposition of the organic matter (e.g., petroleum). Microbial processes require oxygen and can result in depleted oxygen levels if the bioretention area is not adequately aerated.

Sedimentation occurs in the swale or ponding area as the velocity slows and suspended solids fall out of suspension. Volatilization also plays a role in pollutant removal. Pollutants such as oils, hydrocarbons, and mercury can be removed from the wetland via evaporation or by aerosol formation under windy conditions.

Data is not available on the removal effectiveness of bioretention; however, results from performance studies for infiltration BMPs can be used due to the similarities in the BMPs. The microbial activity and plant uptake occurring in the bioretention area will likely result in higher removal rates than those determined for infiltration BMPs, as shown in Table 1. As shown, the BMP could potentially have greater than 90 percent removal rates for total suspended solids, organics, metals, and bacteria. Excessive pollutant loadings (e.g., suspended solids) may exceed the removal capabilities of the bioretention area.

TABLE 1 ESTIMATED PERFORMANCE OF BIORETENTION (1)

Pollutant	Removal Rate
Total Suspended Solids	90 %
Total Phosphorus	60 %
Total Nitrogen	60 %
Organics	90 %
Metals	90 %
Bacteria	90 %

DESIGN CRITERIA

Design details have been specified by the Prince George's County DER in a document entitled *Design Manual for Use of Bioretention in Stormwater Management* (PGDER, 1993). The specifications were developed after extensive research on soil adsorption capacities and rates, water balance, plant pollutant removal potential, plant adsorption capacities and rates, and maintenance requirements. A case study was performed using the specifications at three commercial sites and one residential site in Prince George's County, Maryland.

Each of the components of the bioretention area is designed to perform a specific function. The function of the grass buffer strip is to reduce incoming runoff velocity and filter particulates from the runoff. The sand bed also reduces the velocity and provides some particulate filtration, as well as evenly spreading the flow over the bioretention area. Aeration and drainage of the planting soil is provided by the 1 foot deep sand bed. The ponding area provides a temporary storage location for runoff prior to its evaporation or infiltration. Particulates that had not been previously filtered out by the grass filter strip or the sand bed settle within the ponding area. The organic or mulch layer also filters pollutants and provides an environment conducive to the growth of microorganisms which degrade petroleum based products and other organic material. This layer acts as the leaf litter in a forest and prevents the erosion and drying of underlying soils. Planted ground cover and mulch reduce the potential for erosion, with mulch being slightly less effective than planted ground cover. The maximum sheet flow velocity prior to erosive conditions is 1 ft/sec and 3 ft/sec for planted ground cover and mulch, respectively. The clay in the planting soil provides adsorption sites for hydrocarbons, heavy metals, nutrients and other pollutants. Storage of stormwater is also provided by the voids in the planting soil. The stored water and nutrients in the water and soil are then available to the plants for uptake.

The layout of the bioretention area is determined after site constraints such as location of utilities, underlying soils, existing vegetation, and drainage are considered. The existence of utilities (e.g., electric or gas) which would be costly to relocate may limit the feasibility of a site. Sites with loamy sand soils are especially appropriate for bioretention because the excavated soil can be backfilled and used as the planting soil, thus eliminating the cost of importing planting soil. An unstable surrounding soil stratum (e.g., Marlboro Clay) and soils with a clay content of greater than 25 percent may preclude the use of bioretention, as would a site with slopes greater than 20 percent or a site with mature trees that would be removed during construction of the BMP. Bioretention can be designed to be off-line or on-line of the existing drainage system. The "first flush" of runoff is diverted to the off-line system. On-line systems capture the first flush but that volume of water will likely be washed out by subsequent runoff.

The size of the drainage area for one bioretention area should be between 0.25 and 1 acre. Multiple bioretention areas may be required for larger drainage areas. The maximum drainage area for one area is determined by the amount of sheet flow generated from the 10-year storm. Flows greater than 5 cfs may potentially erode stabilized areas. In Maryland, a flow of 5 cfs generally occurs with a 10-year storm at one-acre commercial or residential sites. The designer should determine the potential for erosive conditions at the site.

The size of the bioretention area is a function of the drainage area and the runoff generated from the area. The size should be 5 to 7 percent of the drainage area multiplied by the rational method runoff coefficient, "c", determined for the site. The 5 percent specification applies to a bioretention area that includes a sand bed and 7 percent applies to an area designed without the sand bed. An example of sizing a facility is shown in Figure 2. Sizing specifications are based on 0.5 inches to 0.7 inches of precipitation over a 6-hour period, which is the mean storm event for the Baltimore-Washington area, infiltrating into the bioretention area. Other areas with a different mean storm event will need to account for that in the design of the BMP.

Recommended minimum dimensions of the bioretention area are 15 feet wide by 40 feet in length. The minimum width allows enough space for a dense randomly distributed area of trees and shrubs to become established that replicates a natural forest and creates a microclimate. This enables the bioretention area to tolerate the effects of heat stress, acid rain, runoff pollutants, and insect and disease infestations which landscaped areas in urban settings typically are unable to tolerate. The preferred width is 25 feet, with a length of twice the width. Any facilities with widths greater than 20 feet should have a length of twice the width. This length requirement promotes the distribution of flow and decreases the chances of concentrated flow.

FIGURE 2 BIORETENTION AREA SIZING

   = .07 x 23,900 + 1,673 OR SAY 1,700 SQ. FT.

*SEE CHAPTER IV, PRINCE GEORGES COUNTY STORMWATER MANAGEMENT MANUAL

Source: PGDER, 1993

The maximum ponding depth of the bioretention area has been determined to be 6 inches. This depth provides for adequate storage and prevents excessive periods of time for standing water. Water left to stand for longer than four days restricts the type of plants that can be used due the water tolerance of most plants. Mosquitoes and other insects may also start to breed if water is standing for longer than four days.

The appropriate planting soil should be backfilled into the excavation bioretention area. Planting soils should be sandy loam, loamy sand, or loam texture and have a clay content ranging from 10 to 25 percent. The soil should have infiltration rates greater than 0.5 inches per hour (in/hr), which is typical of sandy loams, loamy sands, or loams. Silt loams and clay loams generally have rates of less than 0.27 in/hr. The pH of the soil should be between 5.5 and 6.5. Pollutants (e.g., organic nitrogen and phosphorus) can be adsorbed by the soil and microbial activity can flourish within this pH range. Other requirements for the planting soil are a 1.5 to 3 percent organic content and a maximum 500 ppm concentration of soluble salts. In addition, criteria for magnesium, phosphorus, and potassium are 35 lbs/acre, 100 lbs/acre, and 85 lbs/acre, respectively. Soil tests should be performed for every 500 cubic yards of planting soil with the exception of tests run for pH and organic content, which is only required once per bioretention area.

A minimum planting soil depth of 4 feet should be used in a bioretention facility. This depth will provide adequate soil for the plants root system to become established in and prevent plant damage due to severe wind. Four feet of soil also provides adequate moisture capacity. To obtain the 4 foot depth, most sites will require excavation. Depths of greater than 4 feet may require additional construction practices (e.g., shoring measures). Planting soil should be placed in 18 inches or greater lifts and lightly compacted until the desired depth is reached.

The bioretention area should be vegetated to resemble a terrestrial forest community ecosystem, that is dominated by trees and has discrete soil zones. A terrestrial forest community also has a mature canopy and a distinct sub-canopy of understory trees, a shrub layer and herbaceous ground covers. Three species of both trees and shrubs are recommended at a rate of 1,000 trees and shrubs per acre. For example, a 15' by 40' bioretention area (600 ft^2 or 1.4 percent of an acre) would require 14 trees and shrubs. The tree to shrub planting ratio should be 2:1 to 3:1. On average, the trees should be spaced 12 feet apart and the shrubs should be spaced 8 feet apart. In the metropolitan Washington, D.C. area trees and shrubs should be planted from mid-March through the end of June or from mid-September through mid-November. Planting periods in other areas of the US will vary. Vegetation should be watered at the end of each day for fourteen days following its planting.

Native species that are tolerant to pollutant loads and varying wet and dry conditions should be used in the bioretention area. These species can be determined from several published sources, including *Native Trees, Shrubs, and Vines for Urban and Rural America* (Hightshoe, 1988). The designer should assess aesthetics, site layout, and maintenance requirements when selecting plant species. Adjacent non-native invasive species should be identified and the designer should take measures (e.g., provide a soil breach) to eliminate the threat of these species invading the bioretention area. Regional landscaping manuals should be consulted to ensure that the planting of the bioretention area meets the landscaping requirements established by the local authorities.

The optimal placement of vegetation within the bioretention area should be evaluated by the designer. Plants should be placed randomly to replicate a natural forest. Shade and shelter from the wind will be provided to the bioretention area if the designer places the trees on the perimeter of the area. Damaging flows to trees and shrubs can be minimized if they are placed away from the path of the incoming runoff. Certain species that are more tolerant to cold winds (e.g., evergreens) should be placed in areas of the site where these winds typically enter the site.

After placing the trees and shrubs, the ground cover and/or mulch should be established. Ground cover such as grasses or legumes can be planted during the spring of the year. There are no restraints to the timing of mulch placement, except that it should immediately follow tree and shrub planting. Two to three inches of commercially available fine shredded hardwood mulch or shredded hardwood chips should be applied to the bioretention area to provide protection from erosion. Depths greater than 3 inches should not be applied because it would negatively impact the cycling of carbon dioxide and oxygen between the soil and the atmosphere. The mulch should be aged for at least six months, (one year is optimal), and applied uniformly over the site.

MAINTENANCE

Recommended maintenance for a bioretention area includes inspection and repair or replacement of the BMP components. Trees and shrubs should be inspected twice per year to determine their health and remove and replace any dead or severely diseased vegetation. Diseased vegetation that can be treated should be done on an as needed basis. Pruning and weeding may also be necessary to maintain the appearance of the BMP.

Mulch replacement is recommended when erosive conditions are evident or when the aesthetics of the bioretention area are declining. Spot mulching may be adequate when there are random void areas; however, once every two to three years the entire area may require mulch replacement. This activity should be performed during the spring. The previous layer of mulch should be removed prior to application of the replacement mulch.

The application of an alkaline product, such as limestone, is recommended one to two times per year due to increasing acidity of the soil that results from slightly acidic precipitation and runoff. Prior to applying the limestone, the soils and organic layer should be tested to determine the pH and determine the quantity of limestone required. Testing should also be performed to determine concentrations of heavy metals and other toxic substances in the soil. Forest buffers and grass swales, which accept similar sources of runoff as the bioretention area, tend to accumulate toxins and heavy metals within five years of installation. This suggests the possibility of a similar accumulation at a bioretention area. Soil replacement may be required when toxic levels of heavy metals or other pollutants are reached which impairs plant growth and the effectiveness of the BMP (PGDER, 1993).

COSTS

Construction cost estimates for a bioretention area are slightly greater than the required landscaping for a new development. Recently constructed 400 ft^2 bioretention areas in Prince George's County cost approximately $500. These units are rather small and are on the low side for cost estimation purposes particularly if a larger unit is required. The cost estimate includes the cost for excavating 2 to 3 feet and vegetating the site with 1 to 2 trees and 3 to 5 shrubs. The estimate does not include the cost for the planting soil. Purchasing soils will increase the cost for a bioretention area. Retrofitting a site typically has higher costs with an average cost of $6,500 per bioretention area. The higher costs are attributed to the demolition of existing concrete, asphalt, and/or existing structures and the replacement of fill material with planting soil. Plans for retrofitting a commercial site in Maryland (Kettering Development) was estimated at $111,600, which included 15 bioretention areas. The final costs for the retrofit were much lower due to only six bioretention areas being constructed.

The use of bioretention can decrease the cost for stormwater conveyance systems at a site. A medical office building in Maryland was able to reduce the required amount of storm drain pipe from 800 to 230 feet with the use of bioretention. The drainage pipe costs were reduced by $24,000 or 50 percent of the total drainage cost for the site (PGDER, 1993). Landscaping costs that would be required at a development regardless of the installation of the bioretention area should also be considered when determining the net cost of the BMP.

The operation and maintenance costs for a bioretention facility will be comparable to typical landscaping required for a site. Costs beyond the normal landscaping fees will include the cost for testing the soils.

ENVIRONMENTAL IMPACTS

Bioretention provides stormwater treatment that enhances the quality of downstream water bodies. Runoff is temporarily stored in the BMP and released over a period of four days to the receiving water. The BMP is also able to provide shade and wind breaks, absorb noise, and improve an area's landscape.

STORM WATER BMP: CATCH BASIN CLEANING

DESCRIPTION

Catch basins are chambers or sumps, usually built at the curb line, which allow surface water runoff to enter the storm water conveyance system. Many catch basins have a low area below the invert of the outlet pipe intended to retain sediment. By trapping coarse sediment, the catch basin prevents solids from clogging the storm sewer and being washed into receiving waters. Catch basins must be cleaned out periodically to maintain their sediment trapping ability. The removal of sediment, decaying debris, and highly polluted water from catch basins has aesthetic and water quality benefits, including reducing foul odors, reducing suspended solids, and reducing the load of oxygen-demanding substances that reach surface water.

CURRENT STATUS

Catch basin cleaning is an easily implemented but often overlooked Best Management Practice. Frequently, the cleaning procedures deal with removal of debris from grate openings but do not extend down into the catch basin itself.

APPLICATIONS

Catch basin cleaning is applicable to any facility that has an on-site storm sewer system which includes catch basins and manholes.

LIMITATIONS

Limitations associated with cleaning catch basins include:

- Catch basin debris usually contains appreciable amounts of water and offensive organic material which must be properly disposed of.
- Catch basins may be difficult to clean in areas with poor accessibility and in areas with traffic congestion and parking problems.
- Cleaning is difficult during the winter when snow and ice are present.

PERFORMANCE

It is not possible, based on current data, to quantify the water quality benefits to receiving waters of catch basin cleaning. The rate at which catch basins fill with debris, as well as the total amount of material which can be removed by different frequencies of cleaning, are highly variable and cannot be readily predicted. Past studies have estimated that typical catch basins retain up to 57 percent of coarse solids and 17 percent of equivalent biological oxygen demand (BOD).

MAINTENANCE

A catch basin should be cleaned if the depth of deposits are equal to or greater than one-third the depth from the basin bottom to the invert of the lowest pipe or opening into or out of the basin. Catch basins should be, at a minimum, inspected annually. If a catch basin is found during the annual inspection to significantly exceed the one-third depth standard, it should be inspected and cleaned on a more frequent basis. If woody debris or trash is likely to accumulate in a catch basin, it should, at a minimum, be inspected and cleaned, if necessary, on a monthly basis.

In addition, data collected as part of a Nationwide Urban Runoff Program (NURP) project in Castro Valley Creek, California indicated that a typical catch basin, which were cleaned once per year or once every other year contained approximately 60 pounds of material each.

Catch basins can be cleaned either manually or by specially designed equipment. These include bucket loaders and vacuum pumps. Material removed from catch basins is usually disposed of in landfills.

COSTS

Catch basin cleaning costs will vary depending upon the method used, required cleaning frequency, amount of debris removed, and debris disposal costs. Cleaning costs for catch basins were estimated in three NURP program studies (Midwest Research Institute, 1982). These estimates are summarized in Table 1 below.

TABLE 1. CLEANING COST PER CATCH BASIN

LOCATION	METHOD	COST
Castro Valley, CA	Vacuum attached to street sweeper	$7.70
Salt Lake County, UT,	Vacuum attached to street sweeper	$10.30
Winston-Salem, NC	Vacuum attached to street sweeper	$6.30

SOURCE: Reference 1.

In communities equipped with vacuum street sweepers, a cleaning cost of $8 per basin cleaned is recommended for budgetary purposes (Southeastern Wisconsin Regional Planning Commission, 1991). Cleaning catch basins manually costs approximately twice as much as cleaning the basins with a vacuum attached to a sweeper. Therefore, a cost estimate of $16 per catch basin cleaned may be used for manual cleaning. It should be noted that costs vary depending on local market conditions.

ENVIRONMENTAL IMPACTS

Sediment and debris removed from catch basins must be disposed of in a proper manner to avoid negative environmental impacts.

STORM WATER BMP: COVERINGS

Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

A simple yet effective Best Management Practice (BMP) is covering. Covering is the partial or total enclosure of raw materials, byproducts, finished products, containers, equipment, process operations, and material storage areas which, when exposed to rain and/or runoff, could contaminate stormwater. Tarpaulins, plastic sheeting, roofs, buildings, and other enclosures are examples of temporary or permanent covering that are effective in preventing stormwater contamination. The most prominent advantage of covering is that it is inexpensive in comparison to other BMPs.

CURRENT STATUS

A review of numerous NPDES group applications indicates that covering is a commonly implemented BMP. As more facilities identify potential sources of stormwater contamination, the use of coverings will increase significantly due to its effectiveness from a performance and cost perspective.

APPLICATIONS

Covering is appropriate for loading/unloading areas, raw material, byproduct and final product outdoor storage areas, fueling and vehicle maintenance areas, and other high risk areas.

LIMITATIONS

Limitations associated with covering as a BMP include:

- Temporary methods such as plastic sheeting can become torn or ripped, exposing the contaminant to precipitation and/or stormwater runoff.
- Costs may prohibit the building of complete enclosures.
- May pose health or safety problems for enclosures built over certain materials or activities.
- Requires frequent inspection.
- A structure with only a roof may not keep out all precipitation.

PERFORMANCE

It is difficult, based on data currently available, to quantify the mitigation of runoff contamination when covering is used. However, significant runoff water quality benefits are expected by simply reducing the contact between potential contaminants and precipitation or stormwater runoff. One source has estimated that 80 percent of the environmental damage from de-icing chemicals is caused by inadequate storage facilities.

DESIGN CRITERIA

Evaluate the integrity and durability of the covering, as well as its compatibility with the material or activity being enclosed. When designing an enclosure, one should consider materials access, handling and transfer. Materials that pose environmental and/or safety dangers because they are radioactive, pathogenic, flammable, explosive, or reactive require special ventilation and temperature considerations.

Covering alone may not protect exposed materials from stormwater contact. Placing material on an elevated impermeable surface or building curbing around the outside of the materials may be required to prevent contact with stormwater runoff from adjacent areas.

Practicing proper materials management within an enclosure or underneath a covered area is essential. For example, floor drainage within an enclosure should be properly designed and connected to a sanitary sewer. The local publicly owned treatment works should be consulted to determine if there are any pretreatment requirements, restrictions, or compatibility problems prior to discharge.

MAINTENANCE

Maintenance involves frequent inspection of the covering for rips, holes, and general wear. Inspecting coverings should be part of an overall preventive maintenance program.

COSTS

Covering costs vary in proportion to the degree of protection desired, and the required lifespan. The most inexpensive covering is plastic sheeting, but it is not suitable where a high degree of protection is desired for a long period. An enclosed building is the most expensive type of covering when materials for the structure, lighting, and ventilation are considered, but it offers the highest degree of protection for the longest period.

ENVIRONMENTAL IMPACTS

The impact from a covered area depends on the degree of complexity in the covering design. A simple plastic sheeting can possibly have a stormwater diversion, and allow for disposal of uncontaminated water to a storm sewer. A structure with a permanent roof may be less effective, if the material inside is not sufficiently protected from contact with runoff. An enclosed structure may need to have internal drainage. If this is the case, it must not be connected to the storm sewer, and may not be suitable connection to a sanitary sewer, if the stored material is considered hazardous. The internal drains would then need to be connected to some suitable containment area for later disposal.

STORM WATER BMP: DUST CONTROL

DESCRIPTION

Dust controls are methods that prevent pollutants from entering stormwater discharges by reducing the surface and air transport of dust caused by industrial or construction activities. Control measures can prevent dust from spreading into areas of a facility where runoff may eventually transport the material to a storm sewer collection system or directly to a receiving waterbody.

Dust control for industrial activities normally involves mechanical systems designed to reduce dust emissions from in-plant, processing activities, and/or materials handling. These may include hoods, cyclone collectors, bag-type collectors, filters, negative pressure systems, or mechanical sweepers.

Dust control measures for construction activities include windbreaks, minimization of soil, spray-on adhesives, tillage, chemical treatment, and water spraying.

COMMON MODIFICATIONS

There are a number of temporary alternatives for dust control. However, another consideration is to eliminate the need for temporary dust control completely by permanent modification of the site. This could include such measures as covering exposed areas with vegetation, stone, or concrete.

APPLICATIONS

Dust control measures may be applied to any site where dust generation can cause damage to the site or adjacent properties. However, application of dust controls is especially critical in arid areas where reduced rainfall levels expose soil particles for transport by air and runoff into water bodies. Dust control measures should also be applied to any industrial activity where dust poses a threat of contamination to water bodies.

LIMITATIONS

Primary limitations of dust control include :

- Some temporary dust controls must be reapplied or replenished on a regular basis.
- Some controls are expensive (e.g., chemical treatment) and may be ineffective under certain conditions.
- Some controls may cause an increase in the amount of mud being tracked off-site.
- Typical windbreaks are not as effective as chemical treatment or mulching and seeding, and may require land space that might not be available at all locations.
- Industrial dust control is typically labor and equipment intensive and may not be effective for all sources of pollution (e.g. street sweepers).
- More elaborate industrial dust control systems require trained personnel to operate them, an require the implementation of a preventive maintenance and repair program to ensure operational readiness.

PERFORMANCE

The decision on which dust control measures to implement must take into consideration the performance objectives required for a particular site. Some examples of performance objectives include:

- Prevent wind and water-based erosion of disturbed areas
- A reduction of employee respiratory problems.
- Rapid implementation at low cost and effort.
- Little or no impact on the environment.
- Permanent control of the dust problem.

Based on the objectives simply sweeping the impervious areas for larger particles on a routine basis may provide an efficient and reliable method of dust control that can be quickly implemented. Other controls might include vegetative windbreaks which would provide a much more permanent and environmentally safe alternative to chemical use.

DESIGN CRITERIA

The main goals of the dust control project design is to limit dust generation and reduce the amount of soil or dust particulate exposed. However this must also take into consideration the performance objectives established for the particular project. Additionally, some project sites may require solutions to both industrial and dust control problems. Realistically it may not be practical or possible to develop a design that meets all of the project goals and objectives at one time. Therefore it may be more appropriate to develop a phased design approach that utilizes a combination of temporary, permanent, or mechanical measures for dust control.

TEMPORARY MEASURERS

- Vegetative Coverings: Temporary seeding and mulching may be applied to cover bare soil and prevent wind erosion.
- Adhesives: Use spray-on adhesives according to Table 1 below. It is recommended using these adhesives only if other methods cannot be used as many of them are difficult to work with and form fairly impenetrable surfaces.
- Wetting: This is generally done as an emergency treatment. The site is sprinkled with water until the surface is wet and repeated as necessary. If this method is to be employed, it is recommended that a temporary gravel rock entrance be created to prevent carry-out of mud onto local streets.
- Tillage: This practice roughens the soil and brings clods to the surface. It is an emergency measure that should be used before wind erosion starts. Plowing should begin on the windward side of the site using chisel-type plows spaced about 12 inches apart, spring-tooth harrows, or similar plows.
- Barriers: Solid board fences, snow fences, burlap fences, crate walls, bales of hay, and similar material can be used to control air currents and soil blowing. Barriers placed at right angles to prevailing currents at intervals of about 15 times the barrier height are effective in controlling wind erosion.

Calcium Chloride: This material is applied at a rate that will keep the surface moist. Pretreatment may be necessary due to varying site and climatic conditions.

TABLE 1: DESIGN OF ADHESIVE MEASURERS

Type of Emulsion	Water Dilution	Nozzle Type	Application Rate (gallons per acre)
Anionic Asphalt	7 to 1	Coarse	1,200
Latex	12.5 to 1	Fine	235
Resin and Water	4 to 1	Fine	300

SOURCE: Reference L

PERMANENT MEASURERS

- Permanent Vegetation: Seeding and sodding should be done to permanently stabilize exposed areas against wind erosion. It is recommended that existing trees and large shrubs remain in place to the greatest extent possible during site grading processes.

- Stone: The purpose of this method is to place coarse gravel or crushed stone over highly erodible soils.

- Topsoiling: This method is recommended when permanent vegetation cannot be established on a site. Topsoiling is a process in which less erosive soil material is placed on top of highly erodible soils.

- Cyclone Collectors. Cyclone collectors separate dry dust and particulate pollutants in the air by centrifugal force.

- Bag Collectors/Fabric Filters. Bag collectors or fabric filters remove dust by filtration. Storage of collected dust should be carefully considered so that it does not become a source of fugitive dust.

- Negative Pressure Systems. These systems minimize the release of dust from an operation by maintaining a small negative pressure or suction to confine the dust to a particular operation.

- Water Spraying. This temporary mechanical method confines and settles the dust from the air by dust and water particle adhesion. Water is sprayed through nozzles over the problem area.

- Street Sweepers. Two kinds of street sweepers are common in mechanical dust collection systems. The brush system has proven to be an efficient method at an industrial facility generating dust on a daily basis. It has proven to be extremely dependable and picks up the majority of the dust. Vacuum sweepers are presumed to be more efficient because the pollutants typically associated with contaminating stormwater are the smaller particles which may be left behind by a brush street sweeper. However, no performance data are as yet available to verify that vacuum sweepers are more efficient than brush sweepers.

MAINTENANCE

Typically, all dust control measures require periodic and diligent maintenance. For example, mechanical equipment should be operated according to the manufacturers recommendations and inspected regularly as part of an industrial site's preventive maintenance program. Temporary dust control measures, such as chemical spraying, watering, etc. require periodic renewal. Permanent solutions such as vegetation, wind barriers, impervious services also require upkeep and maintenance in order to remain effective.

COSTS

The costs associated with dust control measures are generally lower for vegetative and barrier methods, and increases significantly for chemical and mechanical treatments. For example, an industrial facility purchased a mechanical brush sweeper for approximately $35,000.

ENVIRONMENTAL IMPACTS

There are several negative environment impacts which are related to the dust control BMPs. These include :

- If over-application of a chemical treatment to control dust occurs, excess chemicals could be exposed to both wind and rain erosion with potential for both surface and groundwater contamination.

- Oil should never be used to control dust because of the high potential for polluting stormwater discharges.

- When using mechanical measures such as street sweepers, disposal is a major problem and could involve parameter testing of dust particulate. RCRA regulations may be applicable to this situation.

STORM WATER BMP: EMPLOYEE TRAINING

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

In-house training programs are designed and implemented to teach employees about stormwater management, potential sources of contaminants, and Best Management Practices (BMPs). Employee training programs should instill all personnel with a thorough understanding of their Stormwater Pollution Prevention Plan (SWPPP). This includes identification of BMP's, processes and materials they are working with, safety hazards, practices for preventing discharges, and procedures for responding quickly and properly to toxic and hazardous material incidents.

CURRENT STATUS

Typically, most industrial facilities have an employee training program. Usually these address such areas as health and safety training, or fire protection. The effort required to modify these programs to include discussion of stormwater management and BMP implementations should be reasonable.

APPLICATIONS

Employee training program implementation can be achieved through posters and bulletin boards designed to raise awareness of stormwater management, potential contaminant sources, and prevention of surface water runoff contamination. Field training programs where employees are shown areas of potential stormwater contamination and associated pollutants, followed by a discussion of site-specific BMPs by trained personnel, would also be beneficial for implementing the program.

LIMITATIONS

Limitations of an employee training program include:

- Lack of employee motivation
- Lack of incentive to become involved in BMP implementation
- Lack of commitment from senior management

PERFORMANCE

Quantitative performance will vary between facilities because performance is dependent on employee participation and commitment from senior management to reduce point and nonpoint sources of pollution. Employee training programs that teach identification of potential sources of contaminants, are highly recommended for implementation at all facilities. Support of these programs should given the highest priority, by senior management.

DESIGN CRITERIA

Specific design criteria for implementing an employee training program include:

- Meetings should be held at intervals frequent enough to ensure adequate understanding of SWPPP goals and objectives.
- A strong commitment by, and periodic input from, senior management.
- Transmission of knowledge from past spill causes and solutions to prevent future spills.
- Making employees aware of internal reporting procedures relative to BMP monitoring and spill reporting procedures.
- Operating manuals and standard procedures.
- Implementation of spill drills to minimize potential contamination of stormwater runoff from toxic pollutants.

MAINTENANCE

An employee training program should be an on-going yearly process. There should be, at a minimum, annual meetings to discuss SWPPPs. These meetings could be held in conjunction with other training programs. Figure 1 below illustrates a sample employee training tracking worksheet.

EMPLOYEE TRAINING

Worksheet
Completed by: ____________
Title: ____________
Date: ____________

Instructions: Describe the employee training program for your facility below. The program should, at a minimum, address spill prevention and response, good housekeeping, and material management practices. Provide a schedule for the training program and list the employees who attend training sessions.

Spill Prevention and Response			
Good Housekeeping			
Material Management Practices			
Other Topics			

SOURCE: Reference 2.

FIGURE 1: SAMPLE WORKSHEET FOR TRACKING EMPLOYEE TRAINING

COSTS

Costs for implementing an employee training program are highly variable. It is anticipated that most stormwater training program costs will be directly related to labor and associated overhead costs. however, the example shown in Table 1 below can be used to estimate what the annual costs might be for an in-house training program at your facility. Figure 2 can be used as a worksheet to calculate the estimated cost for an employee training program.

TABLE 1: EXAMPLE OF ANNUAL EMPLOYEE TRAINING COSTS

Title	Quantity		Avg. Hourly Rate ($)		Overhead* Multiplier		Estimated Yearly Hours on SW Training		Est. Annual Cost ($)
Stormwater Engineer	1	x	15	x	2.0	x	20	=	600
Plant Management	5	x	20	x	2.0	x	10	=	2,000
Plant Employees	100	x	10	x	2.0	x	5	=	10,000
					TOTAL ESTIMATED ANNUAL COST				$12,600

Note: Defined as a multiplier (typically ranging between 1 and 3) that takes into account those costs associated with payroll expenses, building expenses, etc.

SOURCE: EPA

STORM WATER BMP: FLOW DIVERSION

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Structures which collect and divert runoff (such as gutters, drains, sewers, dikes, berms, swales, and graded pavement), are used in two ways to prevent the contamination of storm water and receiving water bodies. First, flow diversion structures may be used to channel storm water away from industrial areas so that storm water does not mix with on site pollutants. Second, they may also be used to carry contaminated runoff directly to a treatment facility.

Storm water conveyance systems can be constructed from many different materials, including concrete, clay tiles, asphalt, plastics, metals, rip-rap, and compacted soils covered with vegetation. The type of material used depends upon the design criteria used for conveyance of storm water runoff. These conveyances can be temporary or permanent.

Some advantages of storm water conveyance systems used for flow diversion purposes are:

- Direct storm water flows around industrial sites.
- Prevent temporary flooding of industrial site.
- Require low maintenance.
- Provide erosion-resistant conveyance of storm water runoff.
- Can typically be installed at any time.
- Provide long-term control of storm water flows.

COMMON MODIFICATIONS

Flow diversion structures can be modified by incorporating them with other pollution control best management practices. For example, diverted flow can be fed into an infiltration drain field system, diverted to an infiltration basin, diverted to a constructed wetland treatment facility, or diverted to an onsite treatment facility for discharge under the NPDES program. Another common modification is to construct a temporary flow diversion to determine its effectiveness. If the diversion structure is proven effective, it could then be converted to a permanent structure.

APPLICATIONS

Storm water diversions work well at most industrial sites. Storm water can be directed away from industrial areas by collecting it in a channel or drain system. Diversions can be used to collect storm water from the site and direct it down slope where it can be kept separate from runoff that has not been in contact with those areas. When potentially contaminated storm water is collected in a conveyance system, it can be directed to a treatment facility.

A good example of the utilization of a diversion structure is The Isle La Plume Wastewater Treatment Plant in La Crosse, WI The area immediately surrounding the facility has been regraded so that storm water runoff can be directed into the process tanks where it is treated right along with other wastewater. Figure 1 below illustrates this storm water runoff control method.

PERFORMANCE

Properly designed storm water diversion systems are very effective in preventing storm water from being contaminated or in routing contaminated flows to a proper treatment facility. For example, at the Denver Stapleton International Airport, flow diversion techniques intercept 99 percent of the glycol used and prevent its introduction to Sand Creek, the local receiving waterbody. At the La Crosse, WI Wastewater Treatment Plant, it is estimated that approximately one-third of the storm water runoff from the facility is diverted into their treatment process.

DESIGN CRITERIA

Planning for flow diversion structures should consider the typical volume and rate of storm water runoff present. Also, the patterns of storm water drainage should be considered so that the channels may be located to efficiently collect and divert the flow. When deciding on the type of material for the conveyance structure, consider the resistance of the material to erosion, its durability and compatibility with any pollutants it may carry.

Diversion systems are most easily installed during facility construction. Existing grades should be used to limit costs. Positive grades should be provided to allow for continued movement of runoff through the conveyance system. (Note: care must be exercised to limit velocities which could potentially increase erosion.) A typical diversion swale is shown in Figure 2 Below.

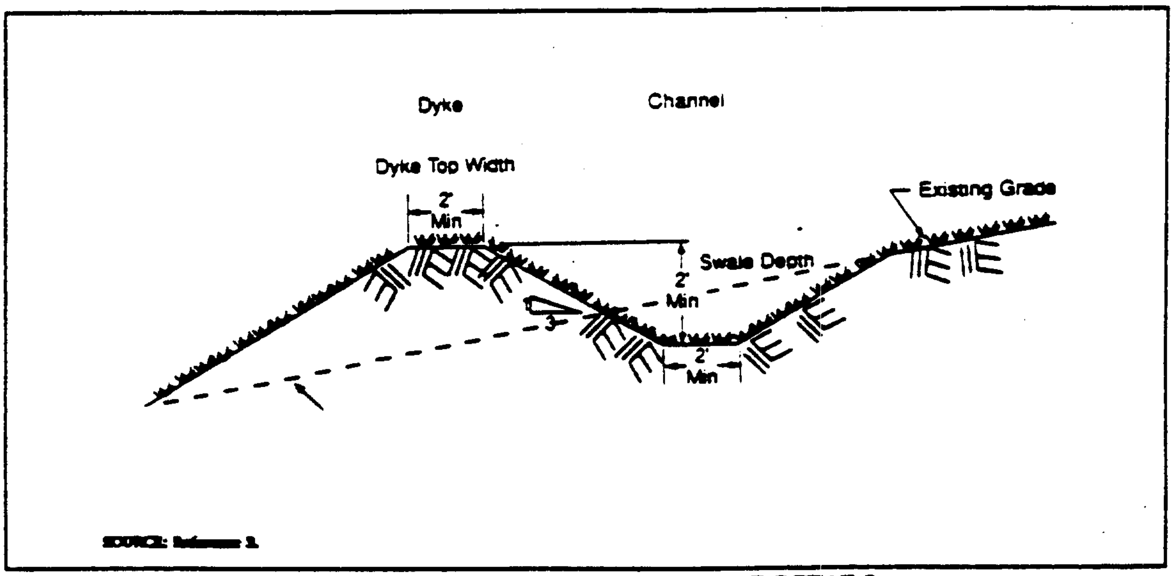

FIGURE 2: TYPICAL DIVERSION SWALE DETAILS

MAINTENANCE

A maintenance program should be established to ensure proper functioning of the system. Storm water diversion systems should be inspected to remove debris within 24 hours after a significant rainfall event since heavy storms may clog or damage them. Flow diversion structures should also be inspected on an annual basis to ensure that they meet their hydraulic design requirements for proper performance.

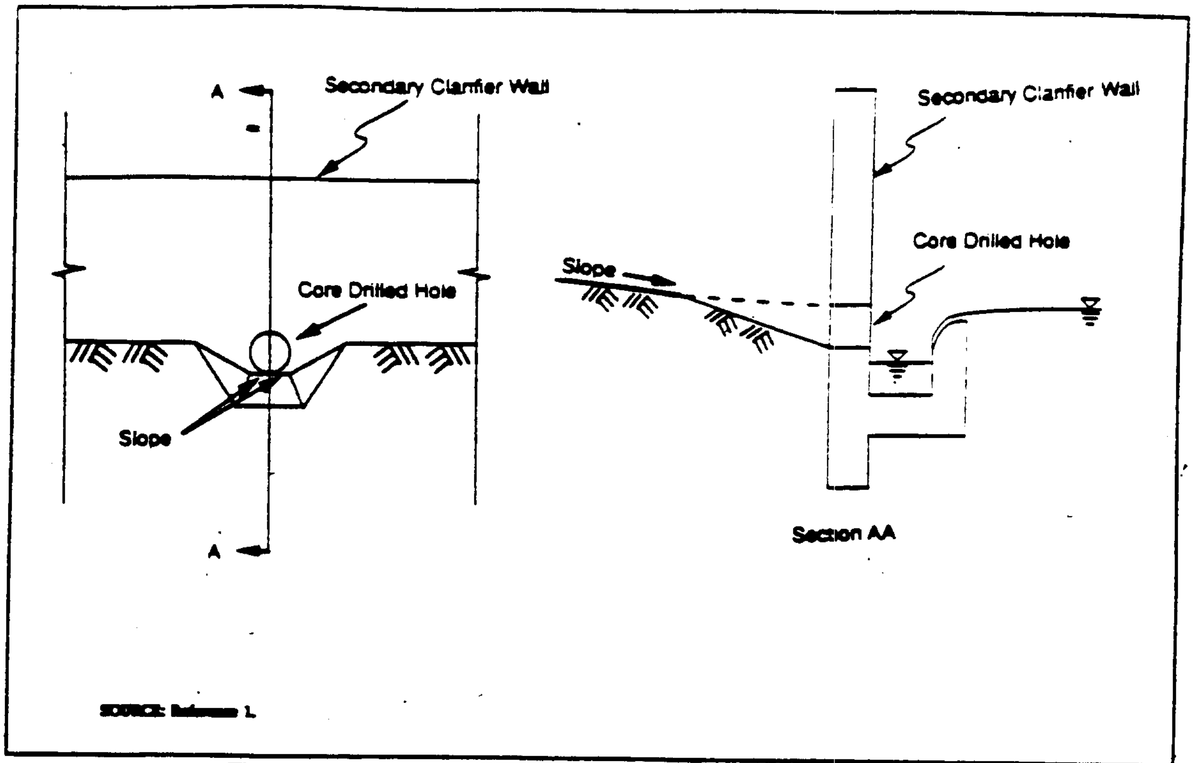

FIGURE 1: STORM WATER RUNOFF CONTROL MEASURERS

At the Denver Stapleton International Airport, the terminal area, aprons, and support facility areas (0.5 square miles), where activities resulting in storm water contamination are concentrated, are served by four individual large diameter storm sewers which collect storm water, snow melt, fuel spills, de-icing agents, and wash down flows. These storm sewers have hydraulic diversion structures in place which convey storm water flows to a 9 mgd detention basin. The basin contents are pumped to a sanitary sewer interceptor where it is then transferred to a local treatment facility.

Another concept being adapted into the new regional airport in Denver is based on centralized de-icing areas for use by all airlines. All de-icing area flows will be diverted to an on-site glycol recovery system or diverted to detention basins for discharge to the local treatment facility.

LIMITATIONS

Storm water flow diversion structure limitations include:

- Once flows are concentrated, they must be routed through stabilized structures, or treatment facilities in order to minimize erosion prior to discharging to receiving waters.
- May increase flow rates.
- May be impractical if there are space limitations.
- May not be economical especially for small facilities or after a site has been constructed.
- May require maintenance after heavy rains.

COSTS

Costs vary depending on the type of flow diversion structure used. For example, if vegetated swales are to be used for flow diversions, the Southeastern Wisconsin Regional Planning Commission (SEWRPC) reported that, in 1991, costs may vary between $8.50 to $50 per lineal foot, depending upon swale depth in feet and bottom width. Capital costs for the Stapleton International Airport flow diversion system, including basins, diversion structures in each of the four main storm sewers, and additional flow diversion modifications made by airport staff were $6 million in 1988. Clearly the cost will be determined by the scope of the project and design requirements..

ENVIRONMENTAL IMPACTS

Environmental impacts include:

- Erosion problems due to concentrated flows.
- Potential groundwater contamination if conveyance channels have high infiltration capacities.
- Undersized water treatment facilities may result in discharges that have not been adequately treated.

STORMWATER BMP: HIGHWAY ICE AND SNOW REMOVAL AND MINIMIZATION OF ASSOCIATED ENVIRONMENTAL EFFECTS FROM THESE PROCEDURES

OWM MTB
Excellence in compliance through optimal technical solutions
MUNICIPAL TECHNOLOGY BRANCH

INTRODUCTION

The United States is critically dependent on the nation's road system to support the rapid, reliable movement of people, goods, and services. The widespread expectation holds that even in the face of winter storms, roads and highways will be maintained to provide safe travel conditions. In many states, this requires substantial planning, training, manpower, equipment, and material resources to clear roads and streets throughout the winter.

The dependency on deicing chemicals has increased since the 1940s and 1950s to provide "bare pavement" for safe and efficient winter transportation. Sodium chloride (salt) is one of the most commonly used deicing chemicals. Concern about the effects of sodium chloride on the nation's environment and water quality has increased with this chemical usage. Automobile and highway bridge deck corrosion has also become a concern. However, in most cases sodium chloride is the most cost effective deicing chemical. Such concerns have led to major research efforts by the Strategic Highway Research Program (SHRP), the highway community, industry, government, and academia. This ongoing research is exploring many different areas in an effort to maintain the safest roads possible in the most economical way while protecting the environment.

This fact sheet summarizes research addressing water pollution and associated effects from deicing chemicals, and describes the methods used to control snow and ice on roadways while minimizing impacts on the environment. Due to the broad nature of this topic, sources for research and alternative methods are listed and can be referenced for more detail. This fact sheet emphasizes methods and practices for snow removal which are feasible and cost effective for local governments to implement consistent with sound environmental quality goals.

BACKGROUND

Salt was first used on roads in the United States for snow and ice control in the 1930s (Salt Institute, 1994). Beginning in the late 1940s and 1950s, the "bare pavement" policy was gradually adopted by highway agencies as the standard for pavement condition during inclement weather providing safer travel conditions on roadways. The "bare pavement" policy became a useful concept for roadway maintenance because it was a simple and self-evident guideline for highway crews. However, this policy should be implemented with the application of the minimum amount of salt needed rather than the maximum (Lord, 1988). A common perception that "more is better" led to practices of high application rates of salt. Dispersion of city populations into suburbs, higher travel speeds, and growing dependence upon automobiles for commuting and commerce increased the need for snow and ice removal for safer roadways (Lord, 1988). In the 1960s, the use of salt as a deicing chemical became widespread in the United States because it is readily available, it is effective on ice and snow, and it is the lowest cost alternative (Salt Institute, 1994).

In the late 1950's, damage to roadside sugar maples (a salt intolerant species) in New England gave rise to concern about the widespread use of salt. Shortly thereafter, contamination to drinking water from wells located near unprotected salt storage areas heightened this concern (Lord, 1988). Runoff of road salts also became recognized as causing additional environmental damage in many areas. Other adverse effects of the increased use of salt included the pitting and "rust out" of automobiles and corrosion of highway structures, especially bridge decks (Lord, 1988).

These environmental concerns have spawned a number of research programs. The goal of this research has been to minimize the environmental effects of deicing while still providing a cost effective means of clearing roadways for safe travel conditions. Early in the 1960s, research began on alternative deicing chemicals, reduced chemical use, improved operational practices, pavement heating, pavement modification, and mechanical approaches (Lord, 1988). More recently, a "Snow and Ice Control" study was conducted by the Strategic Highway Research Program (SHRP). SHRP is a unit of the National Research Council that was authorized by Section 128 of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (SHRP-H-381, 1994). The snow and ice control research included five major initiatives: snowplows, snow fences, road weather information systems, pretreatment, and deicing chemicals (SHRP, 1991).

INITIATIVES TO CONTROL SNOW AND ICE ON ROADWAYS WHILE MINIMIZING ASSOCIATED ENVIRONMENTAL EFFECTS

Improved Operational Practices

Clearing roadways after winter storms accounts for a large portion of the highway maintenance budget for many northern states. According to the Salt Institute's 1991 *Snowfighters Handbook*, snow removal in 33 snow belt states accounted for 16.2 percent of total maintenance costs and 3.6 percent of all highway expenditures (Salt Institute, 1991). To ensure public safety, minimize environmental effects, and minimize costs, a well planned and operated snow and ice removal program is essential.

To aid highway management personnel in improving operational practices, the Salt Institute initiated a "sensible salting" program in 1967 (Lord, 1988). These guidelines have evolved with technology to include the following: planning; personnel training; equipment maintenance; spreader calibration; proper storage; proper maintenance around chemical storage areas; and environmental awareness (Salt Institute, 1994). Further information on the "sensible salting" program can be obtained from the Salt Institute located in Alexandria, Virginia. While all of these guidelines reflect key concerns, proper storage is considered one of the most effective in source control of deicing chemicals (EPA, 1974).

In a 1988 paper by Lord, the estimated annual loss of uncovered stockpiled salt in the United States due to rainfall was 400,000 tons, which is approximately 5 percent of the 8 million tons of salt used annually in the United States. An estimate of $30 per ton of salt equates to a monetary loss of $12 million dollars each winter (Lord, 1988). Rock salt may be purchased in bulk for approximately $15 to $20 per ton. Including transportation, these costs increase to $35 to $70 per ton (Lord, 1988). Monetary loss calculations by Lord used a unit cost estimate for salt of $30 per ton which is between estimates including and excluding transportation. Guidelines for siting and design of deicing chemical storage facilities are provided in the *Manual for Deicing Chemicals: Storage and Handling* (EPA-670/2-74-033, 1974).

Another source, the Regional Groundwater Center (1995), estimated that 10 million tons of salt are used each winter in the United States to melt snow and ice on roads and surface streets (Regional Groundwater Center, 1995, Salt Institute, 1994). The cost for salt is currently estimated at $17 to $20 per ton excluding transportation costs (Jesperson, 1995). To minimize environmental impacts associated with briny runoff due to rain and an uncovered stockpile of salt, proper storage facilities must be implemented.

One of the most effective measures for reducing chemical application has been the use of a calibrated spreader using the optimal application rate. Salt application rates range from 300 to 800 pounds per two-lane mile, depending on road, storm, and temperature conditions (Salt Institute, 1994). Automatic controls on spreaders are recommended to ensure a consistent and correct application rate. The spreader should be calibrated prior to and periodically during the snow season, regardless of whether automatic or manual controls are used. Uncalibrated controls and poor maintenance are often responsible for excessive salt use (Salt Institute, 1994). Guidelines for the calibration of spreaders and determination of application rates are given in the Salt Institute's *Snowfighters Handbook* (1991) and in the EPA document entitled *Manual for Deicing Chemicals: Application Practices* (EPA-670/2-74-045, 1974).

Road Weather Information Systems

The United States and Canada spend over $2 billion dollars each year on snow and ice control (SHRP, 1993). In an effort to reduce these costs and maximize efforts, the SHRP sponsored research using road weather information systems (RWIS) for highway snow and ice control. Components of the RWIS include meteorological sensors, pavement sensors, site-specific forecasts, temperature profiles of roadway, other available weather information (including a weather advisor), communications, and planning (SHRP, 1993).

The RWIS can be used to maximize icing and plowing efforts by pinpointing and prioritizing roadways which need attention. It is also designed to eliminate unnecessary call-outs and provide better scheduling of crews based on knowledge of the probable extent and severity of the winter storms. Research indicated that the use of the RWIS technologies can improve efficiency and effectiveness as well as reduce the costs of highway winter maintenance practices (SHRP, 1993). It was concluded in this report that road weather information system technology has the potential for improving service. This conclusion led to the recommendation that every agency that regularly engages in snow and ice control should consider acquiring some form of road weather information systems; at a minimum, forecast services should be used. The SHRP also pointed out that additional research beyond the scope of the original RWIS project would be helpful (SHRP, 1993). Additional information about RWIS and intelligent and localized weather prediction are provided in the following SHRP manuals: *Road Weather Information Systems, Volumes 1 and 2* (SHRP-H-350 and SHRP-H-351); and *Intelligent and Localized Weather Prediction* (SHRP-H-333).

Alternative Deicing Chemicals

The most commonly used salts for deicing are sodium chloride (NaCl) and calcium chloride (CaCl) (Salt Institute, 1994). Approximately 10 million tons of salt are used each year at a cost of approximately $17 to $20 a ton (Jesperson, 1995). The eastern and north-central sectors of the country use more than 90 percent of this salt each year (Lord, 1988). Salt has proven to be a very effective and feasible deicing chemical. However, the importance of snow and ice removal programs, public safety, economic concerns, and environmental factors have led to research utilizing alternative deicing chemicals.

An acceptable alternative to salt as a deicer must have an effective melting range similar to salt, lack detrimental effects, and be cost-comparable. Some alternative deicers evaluated include formamide, urea, urea-formamide mixture, tetrapotassism phosphate (TKPP), ethylene glycol, ammonium acetate, and calcium magnesium acetate (Lord, 1988). The only alternative that warranted further consideration was calcium magnesium acetate (CMA). CMA is made from delometric limestone treated with acetic acid. While CMA does not overcome all the undesirable characteristics of salt, it is an effective deicing chemical (although more material does need to be applied to result in the same deicing achieved with salt). Since CMA has less potential to effect the environment and is not as corrosive as salt, it is a frequently used deicing chemical. However, the cost of CMA was estimated to exceed salt by a factor of 10 to 20 (Lord, 1988). Efforts have been made to find a more effective production technology to lower the cost of CMA, but these efforts have had limited success (Lord, 1988). Alternative deicers can cost anywhere from $200 to $700 a ton (Jesperson, 1995). Therefore, salt is still the most cost effective deicing agent. Another study performed by the Michigan Department of Transportation also found salt to be the most cost effective deicing agent of those evaluated. Those evaluated included sodium chloride (road salt), CMA, CMS-B (also known as Motech), CG-90 Surface Saver (a patented corrosion-inhibiting salt), Verglimit (patented concrete surface containing calcium chloride pellets), and calcium chloride (MDOT, 1993).

In 1992, the SHRP published a handbook to standardize testing procedures for evaluating deicing chemicals (SHRP, 1992). Parameters evaluated include fundamental properties (e.g., ice melting potential, fundamental thermodynamic factors), physicochemical characteristics, deicing performance (e.g., ice melting, ice penetration, ice undercutting), materials compatibility, and additional engineering parameters. This handbook is a valuable tool for the on-going research and technology of evaluating deicing chemicals. Additional information on these testing procedures is provided in the *Handbook of Test Methods for Evaluating Chemical Deicers* (SHRP-H-332, 1992).

Pretreatment

Limited experience (mainly in Scandinavian and other European countries) has shown that applying a chemical freezing-point depressant on a highway pavement prior to, or very shortly after, the start of accumulation of frozen precipitation minimizes the formation of an ice-pavement bond (SHRP, 1994). Liquid salt solution has been practiced in Scandinavia and has proven successful for pretreatment (SHRP, 1994). The anti-icing or pretreatment practice reduces the task of clearing the highway and requires smaller chemical amounts than are generally required under conventional deicing practices (e.g., applying after snow or ice have begun to accumulate). When properly implemented, pretreatment practices may reduce costs and be more effective than conventional practices. However, most state highway agencies generally have not adopted pretreatment due to uncertainty regarding how to implement this practice and which conditions most favor it. Other concerns with pretreatment practices include the imprecision with which icing events can be predicted, the uncertainty about the condition of the pavement surface, and the public's perception of wasted chemicals. Some early attempts to utilize pretreatment practices in the United States have failed because of these uncertainties (SHRP, 1994).

The technological improvements in weather forecasting and in assessment of pavement surface conditions, as previously mentioned, offer the potential for successful implementation of pretreatment. Research during the winters of 1991-92 and 1992-93 by the SHRP indicated that a 40 percent and 62 percent reduction, respectively, in chemical usage was possible using pretreatment (SHRP, 1994). The success of pretreatment depends on accurate RWIS, a technology which is still evolving. Development of spreaders specifically designed or retrofitted to distribute prewetted solid material or liquid chemicals, calibration and evaluation of spreaders, training of maintenance personnel, and effective communication are also items that need further attention to ensure the success of a pretreatment program (SHRP, 1994). Additional information on pretreament is available in the SHRP manual entitled, *Development of Anti-Icing Technology* (SHRP-H-385, 1994).

Mechanical and Design Approaches

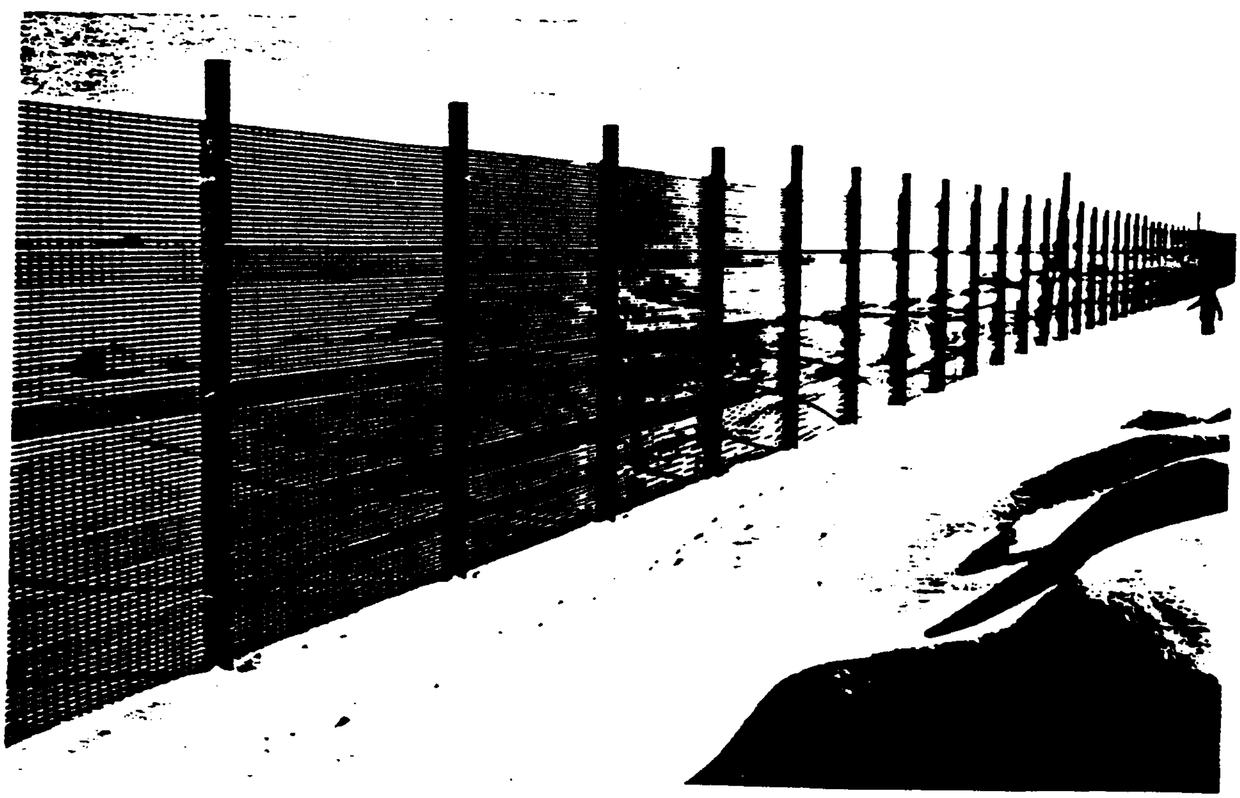
Many mechanical and design approaches have been and are being evaluated in an effort to improve snow and ice control practices. Some of these attempts have been very successful, while others have had limited success or need additional research. Pavement heating, pavement coatings, mobile thermal deicing equipment, snow fences, and snowplows are examined in this section. This is not an inclusive list of mechanical and design approaches to improve snow and ice control procedures.

Pavement heating and pavement coatings are two approaches to snow and ice removal that have had limited success due to cost or feasibility. Pavement heating systems are costly to install, and operational costs exceed salt on the order of 15 to 30 times (Lord, 1988). Mobile thermal deicing equipment has also been evaluated and determined to be impractical. Pavement coatings involve using hydrophobic or icephobic coatings to reduce the adhesion of ice and snow to the roadway. Pavement coatings are required to weaken or prevent bonding, while not decreasing traction in no snow conditions. They are also required to persist in extremely harsh conditions. Pavement coatings were generally unsuccessful because they were unable to meet these goals (Lord, 1988 and EPA, 1976). A 1976 EPA Manual, *Development of a Hydrophobic Substance to Mitigate Pavement Ice Adhesion* (EPA-600/2-76-242) describes this research.

Snow fences minimize costs associated with snow clearing, reduce the formation of compacted snow, and reduce the need for chemicals. Mechanical snow removal costs approximately 100 times more than trapping snow with fences (SHRP, 1991). However, the snow fence must be properly positioned and designed. A 4 foot picket fence in contact with the ground and improperly positioned was common 20 years ago (SHRP, 1991). Properly designed and positioned, taller fences are more effective than the traditional low picket fence. Lightweight plastics allow the construction of portable fences up to 8 feet tall (SHRP, 1991). A 15 foot tall snow fence used at Prudhoe Bay, Alaska is shown in Figure 1. To minimize improper positioning and design of snow fences, the SHRP provided publications such as *Design Guidelines for the Control of Blowing and Drifting Snow* (SHRP-H-381, 1994), *Snow Fence Guide* (SHRP-W/FR-91-106, 1991), and a 21 minute video entitled *"Effective Snow Fences"*.

Snowplow designs in the United States have evolved empirically, with scant regard to physical properties of the material being handled and with little consideration to aerodynamic and hydrodynamic principles involved in the flow of fluidizing snow. Consequently, the energy expended in displacing snow is disproportionate to the work performed, and the low cast distance requires unnecessary rehandling of the snow (Lord, 1988). The SHRP funded research at two universities to improve development of plow blade design and cutting edges for the plow blades (SHRP, 1991).

FIGURE 1. SNOW FENCE (15 FT TALL) LOCATED AT PRUDHOE BAY, ALASKA



Source: Design Guidelines for the Control of Blowing and Drifting Snow, SHRP-H-381, 1994

The first research project, conducted by the University of Wyoming Department of Mechanical Engineering, focused on developing an improved snowplow blade. The objective of this design was to produce a plow that minimizes energy needed to throw snow clear of the roadway. The plow design, based on analytical methods and laboratory scale experiments, showed a 20 percent improvement in efficiency over conventional plows. The plow underwent testing in West Yellowstone, Montana during the winter of 1990-1991 (SHRP, 1991). Research for additional technological advances in plow design is ongoing.

Another research project, conducted by the University of Iowa Institute of Hydraulic Research, evolved to improve snowplow efficiency by improving cutting edges of plow blades based on mechanics of ice cutting (SHRP, 1993). Laboratory tests were performed with a hydraulic ice cutting ram to determine the effects of the geometry on the cutting edge of a snow plow blade on the force required to remove ice from a highway pavement surface. Results of this research indicate that changes in the cutting edge geometry result in substantially improved ice cutting, although the cutting edge performance may benefit from further studies (SHRP, 1993). An Iowa Department of Transportation "plowing truck" is shown in Figure 2. Figure 3 shows a plowing truck which is cutting ice. Additional information can be obtained in the SHRP manual entitled, *Improved Cutting Edges for Ice Removal* (SHRP-H-346, 1993).

SUMMARY OF FINDINGS

The importance of snow and ice control in terms of public safety, environmental effects, and costs have prompted significant breakthroughs in technology. Technological breakthroughs and on-going research have increased and will continue to increase the effectiveness of snow and ice removal programs across the United States. However, these advances should be supplemented by additional research and testing in the future.

To date, one of the most important advances to these programs has been improving operational practices. These operational practices include guidelines on the following: planning, personnel training, equipment maintenance, spreader calibration, proper storage of deicing chemicals, proper maintenance around chemical storage areas, and an increased environmental awareness. Using proper storage facilities for deicing chemicals and proper application rates has significantly reduced improper and overuse of these chemicals. Best management practices for snow and ice removal should implement improved operational procedures supplemented by technological advances if they are feasible and cost effective.

STORMWATER BMP: HANDLING AND DISPOSAL OF COLLECTED STORMWATER AND SEDIMENT CONTROL SOLIDS/RESIDUALS

INTRODUCTION

The total watershed has become increasingly important in defining modern urban stormwater management. Not long ago, stormwater management programs often provided little more than local storm drainage, with scant regard for downstream effects. Today, a broad range of "best management practices" (BMPs) have evolved because of increasing concern about comprehensive watershed protection. These practices are intended to protect aquatic and terrestrial habitat, wetlands and cultural resources by preventing or controlling erosion, sedimentation, and pollution runoff.

As technology has evolved to afford better environmental protection, operations and maintenance requirements have increased. Many modern stormwater BMPs are designed to capture and retain solids. The continued effectiveness of such BMPs depends on periodic inspection and removal of these "residuals".

This fact sheet summarizes the nature of the residuals problem, discusses the regulatory framework and presents the management options available, along with typical unit costs and practical considerations. In addition to the available literature, the following draws on the experience of a number of practitioners at both the state and local levels.

POLLUTION FROM URBAN RUNOFF

Urban runoff carries a wide variety of pollutants from many sources and activities. Oil and salt on roads, automobiles, atmospheric deposition, chemicals used in homes and offices, erosion from construction sites, industrial plants, pet wastes, wastes from processing and salvage facilities, and chemical spills are all typical sources of pollutant runoff. The quality of runoff water tends to worsen as urbanization increases. This is caused by an increase in the density of sources and a decrease in natural systems for capturing pollutants. Urbanization reduces the coverage of trees and other vegetation which once intercepted rainfall. Natural paths, such as stream banks, become channels. The erosive conditions increase the amount of sediment carried by runoff. Natural dips or depressions that had formed temporary ponds for rainwater storage may be lost by grading and filling for development. As asphalt and concrete replace vegetation, the quantity of runoff increases and it reaches surface water faster. When the land loses its ability to absorb and store rainwater, the groundwater table drops and stream flows decrease during dry weather.

Urban runoff can affect water quality in various ways depending on the type of pollutant in the runoff, the quantity and concentration of the pollutant, and the nature of the receiving waters. Some of the major pollutants include sediment (organic and inorganic), nutrients, bacteria, oil and grease, and heavy metals. Other activities, parameters, and pollutants which may affect water quality include the disturbance of stream habitats due to construction and erosion, impervious surfaces, temperature, toxic substances, chlorides, and trash/debris. Urban runoff can also cause loss of property and vegetation through erosion.

URBAN BEST MANAGEMENT PRACTICES

BMPs are an integral part of an urban stormwater management program. For new development, BMPs intended for an erosion and sediment control plan during the site development stage can be designed with long-term runoff management as part of the objective. Some BMPs are designed for long-term control; others are retrofit projects intended to correct problems resulting from the lack of stormwater management. Goals of a BMP are to reduce the erosive effects of runoff and minimize the pollutants in urban runoff, including toxic pollutants which may effect downstream waters. Selection of the proper BMPs or combination of BMPs is critical to achieve this goal. BMP selection criteria include: the site's physical condition and development; runoff control benefits provided by each BMP option; the pollutant removal capability of each BMP option under several design scenarios; the environmental and human health advantages of each BMP option; the ultimate use of the receiving water body; and the long-term maintenance cost of the BMP.

Urban BMPs can generally be grouped in the following categories: detention basins, retention/infiltration devices, vegetative controls, and pollution prevention. Detention basins are widely used and are very effective in reducing suspended solid particles by temporarily holding the stormwater runoff and allowing the sediments to settle. Dry ponds, wet ponds, and extended detention dry ponds are examples of detention basins. Detention basins can reduce suspended solids concentrations by 50 to 95 percent. In addition, since detention basins delay the amount of runoff released into receiving waters, downstream flooding and streambank erosion from high flows are reduced and stress on the physical habitat is lessened.

Infiltration devices allow runoff to percolate into the ground, thereby reducing the amount of pollutants released into the receiving water. Infiltration basins, infiltration trenches and dry wells, and porous pavement are some examples of infiltration devices. The filtration and adsorption mechanism traps many pollutants (e.g., suspended solids, bacteria, heavy metals, and phosphorus) in the upper soil layers and prevents them from reaching groundwater. Infiltration devices can remove up to 99 percent of some runoff pollutants, depending on the percolation rate and area, soil type, pollutants present, and available storage volume. Retention devices are also used as pretreatment devices to treat runoff before it enters the stormwater collection system or infiltrates into the ground. Sand filters and oil/grit separators are examples of these devices. There has been limited success with some of these devices. Negative aspects of oil/grit separators are their limited ability to remove pollutants caused by low average detention times, and the resuspension and release of settled material during later storms.

Vegetative BMPs are used to decrease the velocity of stormwater runoff. This promotes infiltration and settling of suspended solids and also prevents erosion. Basin landscaping, filter strips, grassed swales, and riparian reforestation are examples of vegetative BMPs. Vegetative BMPs also remove organic material, nutrients, and trace metals. For maximum effectiveness, vegetative controls should be used as a first line of defense in removing pollutants in combination with other BMPs.

Pollution prevention is a source reduction program usually classified as a non-structural BMP. Local governments and industries establish pollution prevention programs to reduce the generation and exposure of pollutants that accumulate on streets, parking lots, and other surfaces, and eventually wash into streams and lakes. Examples of pollution prevention controls include land use planning, zoning strategies, street sweeping, good housekeeping practices, public education/awareness, and community involvement. A combination of a pollution prevention program and a structural urban BMP within the framework of a watershed management plan is usually required.

OPERATION AND MAINTENANCE OF URBAN BMPS

Proper operation and maintenance (O&M) procedures for all structural BMPs are essential to ensure their continued effectiveness. These O&M procedures may include the following: periodic inspections; pipe, pump, and structure maintenance; erosion control; nuisance control; general housekeeping; and debris and sediment removal. Periodic inspections are important to ensure that the structure operates in the manner originally intended. Inspections of municipal BMPs are usually performed by the local jurisdiction under state inspection criteria. Ideally, these inspections occur annually during wet weather to assess the BMP's effectiveness.

Erosion control may be necessary for some types of BMPs. Corrective measures such as regrading and revegetation may be necessary. Nuisance control is probably the most frequent maintenance item demanded by the local residents. Control of insects, weeds, odors, and algae may be needed with some BMPs. Some general housekeeping maintenance practices include grass cutting, vegetation control, and litter/debris removal.

For the BMP to achieve maximum pollutant removal it is necessary to periodically remove the stormwater residuals and sediment solids from the system. The removal of collected stormwater and sediment control solids/residuals is very site specific. However, it is possible to provide a general discussion for each structural BMP category (i.e., detention basins, retention/infiltration devices, and vegetative controls). O&M procedures for removing and handling stormwater solids/residuals from BMPs should be planned in the design stages of the BMP.

Detention Basins

Wet ponds will eventually accumulate enough sediment to significantly reduce storage capacity of the permanent pool. This loss of capacity can reduce both the appearance and the pollutant removal efficiency of the pond. The best available estimate is that approximately one percent of the storage volume capacity associated with the two year design storm can be lost annually (MWCOG, 1987). Even more storage capacity can be lost if the pond receives large sediment input during the construction phase. A sediment clean-out cycle of 10 to 20 years is frequently recommended in the Washington, D.C. metropolitan area (APWA, 1981; MWCOG, 1983b). According to the Center for Watershed Protection, stormwater ponds should require sediment clean-out on a 15 to 25 year cycle (Schueler and Yousef, 1994). Most ponds are now designed with a forebay to capture the majority of sediments decreasing the solids load to the wet pond. A common forebay sizing criterion is that it should constitute at least 10 percent of the total pool volume (Schueler and Yousef, 1994). This forebay could lose 25 percent of its capacity within 5 to 7 years based on a 0.5 inch/year muck deposition rate and the assumption that a forebay traps 50 percent of all muck deposited in the pond (Schueler and Yousef, 1994). However, using a forebay, the sediment removal frequency for the main pond may be extended to 50 years (Schueler and Yousef, 1994).

To clean out a larger wet pond, dragline or hydraulic dredge methods may be necessary. Dipper, clamshell, or bucket dredges are mechanical dredge methods, which are sometimes used on ponds which are not large enough to warrant a hydraulic dredge method. With smaller wet ponds, the pond level may be drawn down to a point where the residuals can begin to dry in place. After the material is dried, a front end loader can be used to remove it from the pond bottom.

Dry ponds and extended detention dry ponds also accumulate significant quantities of sediments over time. This sediment gradually reduces available stormwater management storage capacity within the pond and also reduces pollutant removal efficiency. Sediment accumulation can make dry ponds unsightly. In addition, sediment may tend to accumulate around the control device of the dry extended detention ponds. This sediment deposition increases the risk that either the orifice or the filter medium will become clogged, and also gradually reduces storage capacity reserved for pollutant removal in the lower stage. Therefore, in an extended detention dry pond it is recommended that sediment be removed from the lower stage every 5 to 10 years (MWCOG, 1987). Sediment removal from these systems is relatively simple if access is available for the equipment. Therefore, it is essential that access be included in the pond design. Front-end loaders or backhoes can be used to remove the accumulated sediment.

Retention/Infiltration Devices

Infiltration basins are usually located in smaller residential watersheds that do not generate large sediment loads or are equipped with some kind of sediment trap. Even when the sediment loads are low, they still have a negative impact on the basin's performance. The sediment deposits reduce the storage capacity reserved for exfiltration and may also clog the surface soils. Methods to remove sediment are different from those utilized for detention basins. Removal should not begin until the basin has thoroughly dried out, preferably to the point where the top layer begins to crack. The top layer should then be removed using lightweight equipment, being careful not to unduly compact the basin surface. The remaining soil can then be deeply tilled with a rotary tiller or disc harrow to restore infiltration capacity. Vegetated areas disturbed during sediment removal should be revegetated immediately to prevent erosion.

Infiltration trenches require that the pretreatment inlets of underground trenches be checked periodically and cleaned out when sediment depletes more than 10 percent of the available trench capacity. This can be done using a vacuum pump or manually. Inlet and outlet pipes should also be checked for clogging and vandalism. Dry wells should also be checked periodically for clogging. Performance of sand filter systems may be sustained through frequent inspections and replacement of the filter media every 3 to 5 years depending on the pollutant load. Accumulated trash and debris should be removed from the sand filters every 6 months or as necessary. Sand filter systems are usually cleaned manually (Parsons ES, 1995). Sediment is removed from porous pavement using vacuum sweeping. It has been recommended that the porous pavement be vacuum swept four times per year, followed by high-pressure jet hosing, to keep the pores open in the asphalt (MWCOG, 1987).

Ideally, oil/grit separators should be cleaned out after every storm event to prevent re-entry of any residuals or pollutants into the storm sewer system during the next storm event. However, due to the O&M costs and manpower requirements associated with this cleaning schedule, less frequent cleaning usually occurs at a point when an oil/grit separator is no longer operating effectively. The Metropolitan Washington Council of Governments recommends that oil/grit separators be cleaned out at least twice a year (MWCOG, 1987). As with all BMPs, the cleaning frequency depends upon the pollutant load which is site specific. Oil/grit separators can be cleaned out using several methods. One method to clean an oil/grit separator is to pump out the contents of each chamber. The turbulence of the vacuum pump in the chamber produces a slurry of water and sediment that can then be transferred to a tanker truck. The other method involves carefully siphoning or pumping out the liquid from each chamber (without creating a slurry). If needed, chemicals can then be added to help solidify the residuals. The solidified solids/residuals can then be removed manually from the separator.

Vegetative Controls

Vegetative controls (basin landscaping, filter strips, grassed swales, and riparian reforestation) rely on various forms of vegetation to enhance pollutant removal, habitat value, or appearance of a development site. These controls should be used in combination with other BMPs. Some natural systems require periodic sediment removal. For example, accumulated sediments deposited near the top of a filter strip will periodically need to be removed manually to keep the original grade.

PROPERTIES OF STORMWATER SOLIDS/RESIDUALS

Stormwater solids/residuals have properties that are very site specific. It is difficult to precisely estimate "typical" stormwater or sediment residual properties by the BMP employed or even by site classification such as residential, commercial, or industrial. A recent study by Schueler and Yousef reviewed bottom sediment chemistry data from 37 wet ponds, 11 detention basins, and two wetland systems, as reported from 14 different researchers. This research covered a broad range of geography, although nearly 50 percent of the sites were located in Florida or the Mid-Atlantic states. These stormwater ponds had been in use from 3 to 25 years. Sampling and analysis was restricted to mean dry weight concentrations of the surface sediments that comprise the muck layer, which is usually the top 5 centimeters (Schueler and Yousef, 1994). Properties of stormwater solids/residuals presented in this 1994 study and in three other technical papers, discussed in the next paragraph, are presented in the following sections. A summary of this data is presented in Table 1.

A 1982 study performed at Marquette University, Milwaukee, Wisconsin, obtained urban runoff residuals from a field-assembled sedimentation basin in Racine, Wisconsin, swirl and helical bend solids separators in Boston, Massachusetts, and an in-line upsized storm conduit in Lansing, Michigan. The residual samples from Racine and Boston were obtained from individual storm events, while the Lansing samples represent a six month accumulation of residuals. All of the sample locations were primarily residential (EPA - Marquette University, 1982). Results from the sampling are shown in Table 1. Also shown in Table 1 are the findings documented in two other technical papers (EPA - Rexnord, Inc., 1982, and Field and O'Shea, 1992).

In a 1994 paper on Pond Muck (pond sediment), Schueler and Yousef indicate that the properties of the solids/residuals from all BMPs are similar except for oil/grit separators. Analyzed properties mentioned in the paper include the following: nutrients, trace metals (cadmium, copper, lead, zinc, nickel, chromium), hydrocarbons, and priority pollutants. A noted exception, was that grassed swale soils tend to have about twice as much phosphorus and lead as detention ponds. Only one sand filter had been sampled, but these characteristics appeared similar to other BMPs (Schueler and Yousef, 1994). Characteristics of solids/residuals from BMPs are discussed in the following sections, with the exception of oil/grit separators which warrant a separate subsection.

Solids

Solids from stormwater and sediment BMPs can consist of organic and inorganic material. According to Schueler and Yousef (1994), the muck layer of a pond has a high organic matter content. An average of nearly 6 percent volatile suspended solids was reported. Pond muck solids have a very soupy texture with an average total solids content of 43 percent, although this parameter was reported from only 15 out of the 50 site locations. It was also described as having a distinctive grey to black color. These residuals have a low density averaging approximately 1.3 g/cm3. These solids/residuals also consist of poorly-sorted sands and silts dominating the muck layer (Schueler and Yousef, 1994).

According to a 1982 EPA study at Marquette University, total solids concentration of residuals samples from a sedimentation basin in Racine, Wisconsin ranged from 233 to 793 mg/l, with 104 to 155 mg/l being volatile. Urban runoff residual samples from swirl and helical bend solids separators in Boston, Massachusetts ranged from a total solids concentration of 344 to 1,140 mg/l, with 107 to 310 mg/l being volatile. The six month accumulated samples from the in-line upsized storm conduit in Lansing, Michigan had a total solids concentration of 161,000 mg/l with 25,800 mg/l being volatile (EPA - Marquette University, 1982). A 1992 paper by Field and O'Shea reported estimated annual residual/sludge volumes for urban storm runoff in the United States ranging from 27 to 547 million cubic meters (35 to 715 million cubic yards) at an average total solids content ranging from 0.5 to 12 percent (Field and O'Shea, 1992).

TABLE 1
PROPERTIES OF URBAN STORMWATER SOLIDS/RESIDUALS

Properties of Residuals	Wet Ponds[1]	Sedimentation Basin[2]	Swirl and Helical Bend Solids Separators[3]	In-Line Upsized Storm Conduit[4]	Urban Stormwater Runoff Residuals[5]
<u>Solids</u>					
VSS	6%	104-155 mg/l	107-310 mg/l	25,800 mg/l	90 mg/l
TSS	43%	233-793 mg/l	344-1,140 mg/l	161,000 mg/l	415 mg/l
<u>Nutrients</u>					
Phosphorus	583 mg/kg	< 5 mg/l	< 5 mg/l	0.3-2,250 mg/l	502 - 1,270 mg/kg
TKN	2,931 mg/kg	< 5 mg/l	< 5 mg/l	0.3-2,250 mg/l	1,140 - 3,370 mg/kg
<u>Heavy Metals</u>					
Zinc	6 - 3,171 mg/kg	-	-	-	302 - 352 mg/kg
Lead	11 - 748 mg/kg	-	-	-	251 - 294 mg/kg
Chromium	4.8 - 120 mg/kg	-	-	-	168 - 458 mg/kg
Nickel	3 - 52 mg/kg	-	-	-	69 - 143 mg/kg
Copper	2 - 173 mg/kg	-	-	-	251 - 294 mg/kg
Cadmium	ND - 15 mg/kg	-	-	-	-
Iron	-	6.1 - 2,970 mg/l	6.1 - 2,970 mg/l	6.1 - 2,970 mg/l	-
Hydrocarbons	2,087 - 12,892 mg/kg	-	-	-	-
PCBs	-	0.19 - 24.6 µg/l	-	0.19 - 24.6 µg/l	-

Nutrients

The muck layer is enriched with nutrients. In the 1994 paper by Schueler and Yousef, phosphorus concentrations were reported for 23 studies. The phosphorus concentrations ranged from 110 to 1,936 mg/kg, with an average concentration of 583 mg/kg. Nearly all of the nitrogen found in pond muck is organic in nature. Total kjeldahl nitrogen (TKN) concentrations were reported for 20 studies and ranged from 219 to 11,200 mg/kg, with an average concentration of 2,931 mg/kg. Nitrate was found to be present in very small quantities. This either indicates that some denitrification is occurring in the sediments or perhaps that less nitrate is initially trapped in the muck layer. The nitrogen to phosphorus ratio in this pond study averages 5 to 1. In comparison, the nitrogen to phosphorus ratio for incoming stormwater usually averages about 7 to 1. Ponds appear to be more effective in trapping phosphorus than nitrogen. Another explanation for the lower ratio is that the decay rate for nitrogen in the muck layer is thought to be more rapid than for phosphorus (Schueler and Yousef, 1994).

A 1982 EPA report and a 1992 paper by Field and O'Shea reported urban sludge nutrient concentrations ranging from 502 to 1,270 mg/kg total phosphorus as P and 1,140 to 3,370 mg/kg TKN. These nutrient concentrations were reported as being lower than nutrients found in combined sewer overflows (CSOs) and raw primary sludges (EPA - Rexnord, Inc., 1982 and Field and O'Shea, 1992). Another 1982 EPA report presented the concentration of individual nutrients [total phosphorus, TKN, ammonia-nitrogen (NH_3), nitrite-nitrogen (NO_2), and nitrate-nitrogen (NO_3)] in stormwater sediment samples from Boston, Massachusetts and Racine, Wisconsin as never exceeding 5 mg/l. Urban stormwater sediment samples taken from Lansing, Michigan were between 0.3 and 2.250 mg/l for individual nutrients (total phosphorus, TKN, NH_3, NO_2, and NO_3) (EPA - Marquette University, 1982).

Heavy Metals

According to the Northern Virginia Planning District Commission (NVPDC), sediment toxicity has been measured and analyzed in the Northern Virginia area (Guliea, 1995). One of these studies by Dewberry and Davis, 1990, is entitiled "Investigation of Potential Sediment Toxicity From BMP Ponds". This report analyzed sediments from 21 ponds in Northern Virginia under various land use conditions. Many of these ponds are owned and maintained by a property owner or a homeowners' association. Testing was performed for the presence of metals and to determine if the metals concentration is classified as toxic. The Extraction Procedure (EP) toxicity test was used by Dewberry and Davis in the analysis. Conclusions of this report indicate that the stormwater sediments tested were not hazardous and could be safely disposed of on-site or in a landfill. Sediments should be tested further for there use as backfill material or topsoil maintenance (Dewberry and Davis, 1990).

NVPDC had noted that while the 1990 study by Dewberry and Davis determined the material to be non-hazardous, characteristics of stormwater sediments are very site specific. In every jurisdiction in Northern Virginia, it is the responsibility of the owner/operator of the BMP to maintain and operate the system. However, this may vary from state to state. In addition, it is also recommended to plan and design a BMP for on-site disposal of the material (Guilea, 1995).

Trace metal levels are typically 5 to 30 times higher in the muck layer of a pond than in the parent soil below the muck layer (Schueler and Yousef, 1994). Trace metal levels were also reported to follow a relatively consistent pattern and distribution. The zinc concentration in the muck layer was the highest followed by lead. Zinc and lead concentrations were much greater than chromium, nickel, and copper concentrations which were approximately equal. Cadmium had the lowest concentration in the muck layer. In the 1994 Schueler and Yousef study, 50 ponds and wetlands were examined and found to have zinc concentrations ranging from 6 to 3,171 mg/kg (dry weight). Lead and chromium concentrations ranged from 11 to 748 mg/kg, and from 4.8 to 120 mg/kg, respectively. Nickel and copper concentrations ranged from 3 to 52 mg/kg, and from 2 to 173 mg/kg, respectively. Cadmium concentrations ranged from being non-detectable to 15 mg/kg (Schueler and Yousef, 1994).

Field and O'Shea indicate that median concentrations of zinc, lead, copper, nickel, and chromium in urban runoff sludges and residuals were reported as 316, 268, 263, 131, and 189 mg/kg, respectively (Field and O'Shea, 1992). In the 1982 study at Marquette University, iron was found as the highest concentration of metals in all of the samples ranging in concentration from 6.1 to 2,970 mg/l. Lead and zinc concentrations ranked second and third, respectively (EPA - Marquette University, 1982).

As with all pond parameters, trace metal concentrations are site specific. Ponds that primarily service roadways and highways are enriched with trace metals which are presumably associated with automotive loading sources (e.g., cadmium, copper, lead, nickel, and chromium). On the other hand, stormwater ponds that service primarily residential areas have the lowest trace metal concentrations (Schueler and Yousef, 1994). In general, the muck layer is highly enriched with metals; however, in most cases it should not be considered an especially toxic or hazardous material. For example, none of over 400 muck layer samples from any of the 50 pond sites examined in the referenced 1994 study exceeded EPA's current land application criteria for metals (Schueler and Yousef, 1994).

Hydrocarbons

There is limited data on hydrocarbon and poly-aromatic hydrocarbon (PAH) concentration in the muck layer of ponds. It was reported that the concentration of total PAH and aliphatic hydrocarbons in the muck layer of a 120 year old London basin were 3 to 10 times greater, respectively, than the base "parent" sediments. Minor degradation of the hydrocarbons trapped in the muck layer appeared to have occurred in the basin in recent years. On the other hand, hydrocarbons were rarely detected in the muck of Florida ponds. Hydrocarbon concentrations were reported for 2 out of the 50 sites in the 1994 report by Schueler and Yousef. These concentrations were reported for a industrial and residential site as 12,892 and 2,087 mg/kg, respectively (Schueler and Yousef, 1994).

Bacteria

Urban stormwater solids may contain high levels of bacteria and viral strains, including fecal streptococcus and fecal coliform from animal and human wastes. These bacteria have the potential to be spread from land application of stormwater residuals or landfill sites unless the proper precautions are taken. Measures which reduce their concentration in the sludge and minimize any sludge-vector contact include the following: stabilization of the solids; immediate covering of landfill trenches after disposal of these solids; the treatment of these bacteria in the solids by pasteurization, heat treatment, irradiation, etc; and public and animal access control away from the site (Field and O'Shea, 1992).

Other Pollutants

Other pollutants which may be toxic include pesticides and polychlorinated biphenyls (PCBs). Toxic wastes may also be present in fertilizers, herbicides, and household substances such as paints and cleaning materials. All of these pollutants may find their way into stormwater solids/residuals. In the 1982 report from Marquette University, PCBs were observed in measurable concentrations in the Racine, Wisconsin and the Lansing, Michigan samples. These concentrations ranged from 0.19 to 24.6 μg/l. Of eight pesticides surveyed only three (DDT, DDD, and Dieldrin) were observed in measurable concentrations (EPA - Marquette University, 1982).

Oil/Grit Separators

As previously mentioned, the stormwater and sediment solids collected by an oil/grit separator contain unique characteristics compared to other stormwater BMPs. The metal content of trapped sediments in an oil/grit separator may be 5 to 20 times higher than in other BMPs, especially if this separator services a gas station. Priority pollutant and hydrocarbon levels are also much higher. These higher levels reflect the fact that most oil/grit separators service areas that may discharge higher pollutant levels such as at gas stations or industrial sites, and are designed to trap lighter fractions of oil which may not be trapped by other BMPs. Other BMPs, such as detention basins, usually drain larger watersheds that dilute the influence of higher hydrocarbon or metal concentrations like those seen from gas stations or industries. Therefore, it is doubtful if solids from other BMPs would approach metal and hydrocarbon concentrations as high as those recorded with oil/grit separators (Schueler and Yousef, 1994).

STORMWATER SOLIDS/SLUDGE HANDLING ALTERNATIVES
Centralized Treatment (Bleed/Pump Back To The Dry Weather Treatment Plant)

Centralized treatment involves temporary storage of stormwater solids followed by its regulated release into a sanitary sewer during dry weather flow conditions. Advantages of this residuals handling alternative include the possible achievement of flow equalization through the timed addition of urban storm runoff to the dry weather influent, and the use of a central, pre-existing treatment facility and transportation system. Disadvantages of this system include: the deposition of large amounts of grit in the sewer system; the potential for exceeding the capacity of the dry weather treatment facility; any impacts to the treatment plant operation and efficiency which may arise due to differences in the characteristics of sanitary wastewater and urban storm runoff residuals; and additional cost for treatment (Field and O'Shea, 1992). The problems associated with bleed/pump back solids stormwater/sediment solids are similar to those evaluated with regard to CSO sludges.

Huibregste determined that "Centralized Treatment" was generally not practical (Huibregtse et al, 1977). In addition to the disadvantages already listed, some problems which may be associated with this type of system include: difficulties in effectively equalizing flow to the dry weather treatment plant due to the high solids/low volume characteristic of sludges; and difficulties maintaining sludge quality. Significant increases in heavy solids and toxic substance loadings will have an impact on treatment plant operation and effluent quality. The addition of large amounts of gritty solids can grossly overload solids handling facilities at treatment plants, and have a negative impact on overall sludge quality. Moreover, the addition of these stormwater and sediment residuals to the treatment system will increase the quantity of sludge which must be handled (Field and O'Shea, 1992). In a 1982 EPA report, research indicated that the number of days required for bleed/pump back of the residuals without overloading the dry weather treatment facility ranged from 2.8 to 3.9. This was considered an unacceptable bleed/pump back period, considering the likelihood of overlapping rainfall events (Huibregste et al, 1977).

Stormwater Solids Handling at Satellite Treatment Facilities

Another handling alternative for urban stormwater and sediment solids is treatment at a satellite facility. Average characteristics of urban storm runoff differ substantially from those of sanitary wastewater. For the treatment of stormwater runoff, biological processes are generally not employed due to its low organic and nutrient content as well as the intermittent and varying quantity and quality of the storm flow. The major differences affecting treatment process design include urban runoff's high grit content, low organic content, intermittent nature, and short flow duration (Field and O'Shea, 1992).

Evaluation of several CSO sludge handling processes by Huibregste found the most effective unit processes to be: conditioning through chemical treatment; gravity thickening; stabilization through lime addition; dewatering through vacuum or pressure filtration; and disposal through land application or landfill (Huibregste et al, 1977). In a 1982 report by Huibregste a cost analysis was performed specifically for the handling and disposal of urban storm runoff residuals. This cost analysis compared the following six alternative sludge handling scenarios for either swirl or sedimentation concentrated solids: (1) gravity thickening, vacuum filtration and landfill; (2) gravity thickening, vacuum filtration and landspreading; (3) gravity thickening, pressure filtration and landfill; (4) gravity thickening, pressure filtration and landspreading; (5) gravity thickening and landspreading; or, (6) landspreading. These cost estimates by Huibregste et al, 1982, are presented in terms of dollars per acre for residuals handling in an urban storm runoff area of 15,000 acres. These estimates were updated to July 1995 dollars and are presented in Table 2. As shown on Table 2, the most cost effective solids handling scenario based on annual costs is lime stabilization, gravity thickening, pressure filtration, and landfilling.

A 1982 EPA report from Marquette University concluded that of those options evaluated the most cost-effective means for handling and disposal of urban stormwater runoff residuals is gravity thickening followed by lime stabilization and landspreading or landfilling (EPA - Marquette University, 1982). This conclusion was based on urban stormwater studies from Boston, Massachusetts, Racine, Wisconsin, and Lansing, Michigan involving solids sampling, characterization, analysis, and treatability. The characterization study included analyses for nine metals, eight pesticides and PCBs, solids, nutrients, and organics. The treatability study included bench scale sedimentation tests, centrifugation tests, lime stabilization tests and capillary suction time tests (EPA - Marquette University, 1982). Other bench scale studies were performed by Carr in 1982 that evaluated the effectiveness of three dewatering alternatives for stormwater runoff residuals from sedimentation basins and swirl concentrators. These dewatering alternatives were gravity thickening, centrifugation, and capillary suction. Data from these studies indicated that the most effective method for concentrating urban stormwater runoff residuals was gravity thickening (Carr et al, 1982).

These bench scale studies identified some effective treatment methods for urban stormwater runoff residuals. However, characteristics of urban stormwater residuals are very site specific. Testing and analysis may be necessary to determine what level of treatment is necessary to dispose of these residuals.

On-Site Handling of Stormwater Solids/Sludge

The third alternative for handling/disposal of stormwater runoff residuals is on-site handling. This option may be used after the residuals have been analyzed and determined to be a non-hazardous material. During the design stage of a BMP, a dedicated area on the site should be set aside for land application or land disposal of the residuals. The area for this material should be carefully selected to prevent residuals from flowing back into the BMP during rainfall. On-site handling of this material is usually very cost effective as it avoids transportation costs and landfill tipping fees.

The stormwater runoff residuals must first be removed from the BMP. Alternatives for removing solids from various BMPs were discussed previously. After the solids are removed from the BMP, they will usually require dewatering. Dewatering is accomplished by spreading the material out on the ground and occasionally turning it. A front-end loader can be used for this. This material is then either land applied or land disposed. Land application involves spreading the material to the land at approved application rates. This material cannot be applied to a direct food chain crop and would probably be applied to a meadow or vegetated area. There is very little nutrient value associated with stormwater residuals. Land disposal consists of piling the material on an approved location at the site.

In some cases it may not be feasible to land apply or land dispose of the material on-site. This may be due to limited space on-site initially or limited space due to the accumulation of material. In any case, after the material is removed from the BMP it should be dewatered on-site if this is feasible. This will cut down on the volume of material to be transported. The material can then be loaded using a front-end loader and transported to either a landfill or another site for land application or land disposal.

TABLE 2

COST ESTIMATE ($/acre) FOR RESIDUALS HANDLING IN AN URBAN STORMWATER RUNOFF AREA OF 15,000 ACRES (1)

Sludge Handling Method	Sedimentation			Swirl Concentration		
	Capital	O&M	Annual	Capital	O&M	Annual
Lime Stabilization Gravity Thickening Vacuum Filtration Landfill	475	71	134	507	64	130
Lime Stabilization Gravity Thickening Vacuum Filtration Landspreading	507	76	171	531	67	155
Lime Stabilization Gravity Thickening Pressure Filtration Landfill	492	60	124	550	49	117
Lime Stabilization Gravity Thickening Pressure Filtration Landspreading	522	64	156	569	50	139
Lime Stabilization Gravity Thickening Landspreading	—	—	—	394	87	166
Lime Stabilization Landspreading	308	104	186	1025	856	1194

Note: (1) Huibregste et al. 1982. Costs have been updated to July 1995 dollars using the ENR.

REGULATIONS (CURRENT AND PENDING) AND LIABILITIES

Traditional point sources of water pollution are regulated by the EPA and individual states under the National Pollutant Discharge Elimination System (NPDES) permit program. This program was established by section 402 of the Clean Water Act, and establishes permit requirements for certain municipal and industrial stormwater discharges. However, the regulations governing the handling and disposal of stormwater runoff residuals is not as well defined.

Most states have regulations for runoff quality control. To adhere to these regulations, many local governments have implemented drainage and flood control regulations. Some local governments have also adopted localized stormwater quality and erosion/sediment control regulations which require BMPs. To help local governments implement and properly operate these BMPs, states issue guidance documents for local jurisdictions which are responsible for inspecting, maintaining, and ensuring proper operation of stormwater BMPs. Some states will also periodically inspect a local jurisdiction's stormwater management program.

In reality, many local jurisdictions do not have the manpower to inspect all BMPs regularly. BMPs which are not maintained do not perform efficiently. If not maintained, pollutants removed by the BMPs can be released back into the stormwater. An oil/grit separator is a good example of this. Some BMPs, such as detention basins, were installed by local jurisdictions in the 1980s and are now requiring or have not yet required cleaning/dredging for the first time. This is a learning experience for many jurisdictions that have not yet had to (or are doing it for the first time) dredge this material or handle/dispose of it.

Stormwater and sediment solids/residuals should initially be tested prior to disposal. If they are not hazardous, they will usually require dewatering prior to disposal. Some disposal methods for this material can be landfilling, land application, land disposal, and even incineration (e.g, non-hazardous solids from oil/grit separators). Historically, and in most cases, the disposal of sediments removed from BMPs has posed no special regulatory or legal difficulty. Many municipalities and industries have disposed of such sediments in the same way that they would have any uncontaminated soil (Jones et al, 1994). In fact, after drying, stormwater sediment has been mixed with other soil and reused as backfill on construction projects (Jones et al, 1994) as well as cover for landfills (Cox, 1995).

If the residuals/solids from a BMP are determined to be hazardous, they must be managed according to the Resource Conservation and Recovery Act of 1976 (RCRA) requirements. Wastes can be defined by RCRA as hazardous because they either have certain characteristics or contain constituents specifically listed in the RCRA regulations. Certain characteristics include ignitability, corrosivity, explositivity, or toxicity. In nearly all cases involving stormwater BMP solids, sediments could be classified as a hazardous waste because they contained listed chemicals rather than because the sediments are hazardous by characteristic (Jones et al, 1994). Simply because a chemical regulated by RCRA is detected in BMP sediments, does not render the sediment a hazardous waste. If no sample containing greater than ten percent of the listed chemical (by volume), or if contact with precipitation/runoff is unlikely, the sediment would not be classified as hazardous (Jones et al, 1994). Hazardous waste material must be disposed or handled according to RCRA regulations which would either require treatment to lessen the concentration of the hazardous constituent or disposal in a hazardous waste landfill.

EXAMPLES/CASE STUDIES

The following BMP residual management programs have been implemented by several municipalities, states, and a company which cleans oil/grit separators for various clients. This section is not inclusive, but is presented to illustrate how some states, municipalities, and industries manage the solids/sediments from BMPs.

Waste Reduction, Disposal, and Recycling Services

A Baltimore, Maryland firm cleans oil/grit separators for many commercial areas and industries. They use a three man crew and two trucks to clean these BMPs. A liquid tanker truck is used to pump the oil and water out of the separator. This mixture is transported to their facility in Baltimore for treatment (Schorr, 1995).

The solids in the oil/grit separator are further solidified using chemical addition. Once the material is solidified, it is shoveled out of the separator into 55 gallon drums. A composite sample is taken from each drum. This material is analyzed for toxicity, ignitibility (flash test), and PCBs. If the material is determined to be non-hazardous, the drums are taken back to their Baltimore facility. The material is then loaded into roll-off dumpsters and transported to an incinerator where they receive a certificate of destruction for the material (Schorr, 1995).

As each cleaning and maintenance job is site specific, this firm charges by the hour. The cost for cleaning is $202/hr for the three employees and two trucks. In addition, disposal of the liquid waste is $0.35/gallon, charge for the chemical that aids in solidification is $9.95/bag, drum purchase cost is $25/drum, drum disposal cost is $100, analytical charge is $145, and transportation charge is $250. It was emphasized that these oil/grit separators should be cleaned periodically. Cleaning schedules of oil/grit separators are site specific. For example, a typical commercial building may be cleaned one time per year, whereas, an industry may have its oil/grit separators cleaned approximately every three months (Schorr, 1995).

If the material is determined to be hazardous, it is dealt with in an appropriate method depending on the hazardous constituent of the waste. A copy of the analytical results are faxed to the generator. Additional testing is usually required to determine what constituent(s) is present in the sediment to classify it as a hazardous material (Schorr, 1995).

A hazardous material is handled on a case-by-case basis. Additional analytical testing and handling of the hazardous material will increase costs. In most cases, treatment to lower the hazardous chemical concentration to a non-hazardous level is preferred over landfilling in a hazardous waste landfill. For example, a sediment that contained a high hydrocarbon content, which may occur at a service station, would be spread out on an approved site for a period of time sufficient to allow the concentration to decrease in the sediment (Schorr, 1995).

Prince George's County, Maryland

In Prince George's County, Maryland, BMPs such as wet ponds have been in service long enough that they are just beginning to require dredging. In some cases, on-site disposal of the sediment was planned for in the design of the BMP. However, if on-site disposal is not an alternative then locating a site for disposal of the material is a major operation. Residual sand and gravel material from the BMP is transported to construction-sites for use or is disposed of on-site (Coffman, 1995).

Oil/grit separators are being phased out in Prince George's County for the following reasons all of which pertain to residuals management: sometimes the landfill will not accept the material; they require frequent maintenance and cleaning; the material is difficult to dewater; and the material is expensive to dewater, haul, and landfill (when the landfill accepts the material). In addition, the county does not have the personnel to routinely inspect and enforce the cleaning of oil/grit separators. As an alternative to this BMP, the county is focusing on pollution prevention and is also evaluating bioretention (Coffman, 1995).

Fairfax County, Virginia

Fairfax County has very few wet ponds. The wet ponds in the county are large lakes which can properly function up to 100 years without dredging (Henry, 1995). The county has not dredged a wet pond since 1991. A small mini-dredge is used for dredging wet ponds. For the smaller ponds, the lake level is lowered and attempts are made to dry the sediment material. After this, a clamshell or bucket dredge is used to remove the material. Material is either disposed of on-site or in a landfill. Sediments from dry ponds are dried on-site and removed using a front-end loader. This material is either landfilled or disposed of on-site (Henry, 1995).

Montgomery County, Maryland

Montgomery County has wet ponds and dry ponds, the majority of which have not required dredging. The State of Maryland has determined that the sediment from these ponds are a non-hazardous material. Thus, the material can be disposed of either on-site or in a landfill. The state law requires that BMPs be inspected annually. In practice, this typically does not occur because of resource limitations. The county has recently hired two more people to help with these inspections, but there are many BMPs in the county and the county does not anticipate achieving the annual inspection goal (Brush, 1995).

Typical oil/grit separators require much maintenance attention, and Montgomery County is trying to phase them out. The county has many sand filters proposed to replace the oil/grit separators, but information on their maintenance is not available due to the limited experience with cleaning and maintaining these filters (Brush, 1995).

State of Florida

The State of Florida does not have a specific regulation stating that each jurisdiction must dredge or remove material from BMPs periodically. They have issued a "Guidance Manual" as a supplement to the regulations which are considered inadequate for handling stormwater sediments for BMPs. Most BMPs were implemented in 1982, and are just to the point where they require dredging (Cox, 1995).

The guidance manual recommends testing of all BMP sediments, using the Toxicity Characteristics Leaching Procedure (TCLP), before disposal. The state has performed numerous analytical studies on this material, and in no cases was BMP sediment from any location determined to be hazardous. However, oil/grit separators were not tested as part of this study. Materials considered to be non-hazardous must have the appropriate laboratory TCLP paperwork before most landfills in Florida will accept it. Some cities and counties avoid this testing by sending BMP residuals to construction/debris landfills which are not as stringent. This practice is not supported by the state (Cox, 1995).

Even if a material is considered not hazardous using the TCLP test, the State of Florida also has a clean soil criterion. This is to protect community exposure from a material with elevated concentrations of a material which might not be classified hazardous. If a material does not pass the clean soil criterion, (e.g., if metal concentrations are high, but not hazardous) then it can only be used in an area where public access is controlled. Material such as this can be used as a landfill cover because public access is limited to most landfills. If the material does pass the TCLP and clean soil criterion then it can be used or disposed of in any manner. A beneficial use of the material is to blend it with soil as a conditioner (Cox, 1995).

Sediments from dry ponds in Florida are removed using a front-end loader and a dump truck. It is then recommended that a TCLP test be conducted on this material before either disposing on-site, landfilling, or disposing of in another manner. Wet ponds are dredged, however, these ponds are sometimes directly connected to a waterway so caution is taken to ensure solids are not resuspended in this operation. This material is usually spread out on the site to allow drying and disposed of on-site. If on-site disposal is not an alternative, then the sediments are usually transported to a landfill (Cox, 1995).

State of Delaware

The State of Delaware has followed Florida's lead as far as handling and disposal of stormwater BMP residuals. The State of Delaware has not conducted testing of stormwater BMP sediments, but considers the material as non-hazardous based on Florida's research and other research/reports. The state also has a stormwater management program in which local jurisdictions are required to inspect BMPs on an annual basis (Shaver, 1995).

The state's stormwater management plan includes BMP construction guidelines for ease of maintenance for the BMP and on-site disposal of the stormwater residuals. Oil/grit separators are not a BMP alternative in the State of Delaware. In addition to detention basins, sand filters are commonly used. The cleaning schedule for a sand filter is site specific, but three to four times a year is a general estimate. Three people are used to clean a "typical" Delaware Filter manually and shovel out the material which takes approximately 4 hours. Labor cost to clean the filter is approximately $120. The material is then transported to the landfill for disposal as this sediment was tested and not considered a hazardous material (Shaver, 1995).

State of Maryland

The State of Maryland conducted a four year study on oil/grit separators with the Metropolitan Washington Council of Governments. This study evaluated material from oil/grit separators in Maryland to determine if it was hazardous. The study also evaluated maintenance of oil/grit separators, as well as disposal of the residuals/solids from an oil/grit separator. Results from the study indicated that the solids from oil/grit separators were not hazardous, therefore, this material could be disposed of at a landfill after dewatering. However, as this material is site specific it was recommended that it be tested prior to sending to a landfill (Pencil, 1995).

Inspections of BMPs are required of all local jurisdictions. Every three years, the state reviews stormwater programs and procedures utilized by the local jurisdiction. The state has noted that many BMPs are not being properly maintained. This is due to cost and manpower requirements associated with regularly inspecting all BMPs by the local jurisdiction. Many homeowners' associations have BMPs on their property. Maintenance of these BMPs is another area of concern for the state because many homeowner's associations do not implement proper O&M procedures to maintain the BMP on their property (Pencil, 1995).

Sediments from wet ponds and dry ponds, as long as they are not hazardous, are usually dewatered and then disposed of on-site or landfilled. It is a common practice to spread this material out on a site for use as a soil amendment (Pencil, 1995).

SUMMARY OF FINDINGS

Data is available for solids content, nutrients, heavy metals, and other pollutants such as PCBs for many urban stormwater BMP solids/residuals. However, the data on stormwater residual's PAH and hydrocarbon concentrations is limited. Additional sampling and analysis would be beneficial to further examine these parameters.

Inspection and maintenance programs are the key to success for all BMPs. Guidelines for inspection and frequency of inspection are provided by most states for local jurisdictions. However, manpower requirements associated with enforcing the guidelines on the state level and inspection of these BMPs on the local level do not seem to be adequate. BMPs located on private property are not usually properly maintained or inspected. A possible solution to this lack of maintenance is to put a maintenance requirement in the deed for the land. This would require all owners of that property to properly maintain the BMP.

Difficulties in maintaining oil/grit separators and disposing of the residuals have resulted in some jurisdictions phasing their use out. Oil/grit separators require frequent maintenance and cleaning, the material is difficult to dewater, and the material is expensive to dewater, haul, and dispose of in a landfill (when the landfill accepts the material). Also, if oil/grit separators are not properly maintained then pollutants removed by the BMP can be released back into the stormwater.

Since many wet ponds and dry ponds were implemented in the 1980's, they have not required dredging or handling of the dredge material. Some local jurisdictions planned for on-site disposal of the material in the BMP design which is very cost effective because it avoids transportation charges. Local jurisdictions which did not plan for on-site disposal in the design of these BMPs are searching for disposal options for this material. Testing of stormwater sediment in many studies have indicated that this material is non-hazardous. Therefore, in most situations it can be disposed of on-site (land application or land disposal), in a landfill, or in an incinerator.

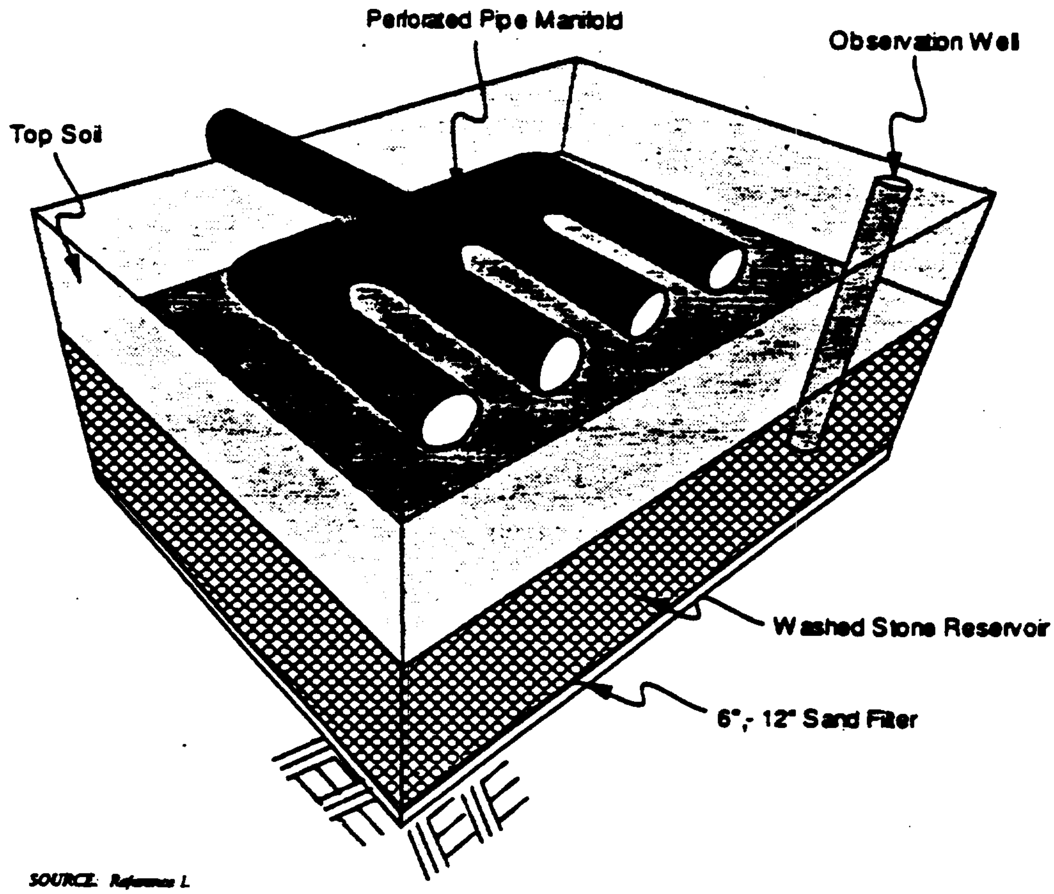
STORM WATER BMP: INFILTRATION DRAINFIELDS

DESCRIPTION

Infiltration drainfield structures are constructed to aid in stormwater runoff collection and are designed to allow stormwater to infiltrate into the subsoils. Runoff is diverted into a storm sewer system which passes through a pretreatment structure such as an oil and grit separator. The oil and grit chamber effectively removes coarse sediment, oils, and grease. Stormwater runoff continues through a manifold system into the infiltration drainfield. The manifold system consists of perforated pipe which distributes the runoff evenly throughout the infiltration drainfield. The runoff then percolates through the aggregate sand filter, the filter fabric and into the subsoils. A schematic of a typical system is illustrated in Figure 1 below.



SOURCE: Reference L

FIGURE 1: TYPICAL INFILTRATION DRAINFIELD SCHEMATIC

COMMON MODIFICATIONS

Common design modifications include the installation of porous pavement surrounded by a grass filter strip over the infiltration drainfield or insertion of an emergency overflow pipe in the oil and grit pretreatment chamber. The overflow pipe allows runoff volumes exceeding design capacities to discharge directly to a trunk storm sewer system. Infiltration drainfields are very similar to infiltration trenches and basins.

CURRENT STATUS

Currently there is little information on infiltration drainfields. However. in general the same principals that apply to infiltration basins and infiltration trenches will apply to design of infiltration drainfields. The Environmental Protection Agency is currently evaluating the following issues related to the design and operation of infiltration drainfields:

- Is the oil and grit separator the most effective pretreatment system to protect infiltration capacity?
- What is the pollutant removal capacity of infiltration drainfields with various pretreatment systems?
- Is the performance of infiltration drainfields better than infiltration basins and trenches during subfreezing weather and snow melt runoff conditions?
- What level of maintenance is required to ensure proper performance?

APPLICATIONS

Infiltration drainfields are most applicable on sites with a relatively small drainage area (less than 15 acres). They can be used to control runoff from parking lots, rooftops, impervious storage areas, or other land uses. Infiltration drainfields should not be used in locations that receive a large sediment load that could clog a pretreatment system, which in turn, would plug the infiltration drainfield and reduce its effectiveness.

Soils should have field-verified permeability rates of greater than 0.5 inches per hour and there should be a 4-foot minimum clearance between the bottom of the system and bedrock or the water table.

LIMITATIONS

The use of infiltration drainfields may be restricted in regions with colder climates, arid regions, regions with high wind erosion rates (increased windblown sediment loads), and areas where sole source potable aquifers could be contaminated. Some specific limitations of infiltration drainfields include:

- High maintenance when sediment loads to the drainfield are heavy.
- High costs of excavation, fill material, engineering design, and pretreatment systems.
- Short life span if not well maintained.
- Not suitable for use in regions with clay or silty soils.
- Not suitable for use in regions where groundwater is used locally for human consumption.

- Systems require sufficient time between storm events to allow the soil to dry out, or anaerobic conditions may develop in underlying soils which could clog the soil and reduce the capacity and performance of the system.

PERFORMANCE

The effectiveness of infiltration drainfields depends upon their design. When runoff enters the drainfield, many of the pollutants are prevented from entering surface water. However, any water that bypasses the pretreatment system and drainfield will not be treated. Pollutant removal mechanisms include absorption, straining, microbial decomposition in the soil below the drainfield, and trapping of sediment, grit, and oil in the pretreatment chamber.

Currently there is little monitoring data on the performance of infiltration drainfields. However, some monitoring data is available on porous pavements which incorporate many similar design criteria as infiltration drainfields. An estimate of porous pavement pollutant removal efficiencies range between 82 and 95 percent for sediment, 65 percent for total phosphorus, and 80 to 85 percent for total nitrogen.

Some key factors that increase performance and pollutant removal efficiencies include:

- Good housekeeping practices in the tributary drainage area.
- Sufficient drying time (24 hours) between storm events.
- Highly permeable soils and subsoils.
- Pretreatment system incorporated.
- Sufficient organic matter in subsoils.
- Proper maintenance.
- Use of a sand layer on top of a filter fabric at the bottom of the drainfield.

DESIGN CRITERIA

Infiltration drainfields, along with most other infiltration BMPs (infiltration basins, trenches, etc.) have demonstrated relatively short life spans in the past. Failures have generally been attributed to poor design, poor construction techniques, subsoils with low permeability and lack of adequate preventive maintenance. Some design factors which can significantly increase the performance and reduce the risk of failure of infiltration drainfields and other infiltration processes are shown in Table 1 below.

MAINTENANCE

Routine maintenance of infiltration drainfields is extremely important. The pretreatment grit chamber should be checked at least four times per year and after major storm events. Sediment should be cleaned out when the sediment depletes more than 10 percent of the available capacity. This can be done manually or by vacuum pump. Inlet and outlet pipes should also be inspected at this time.

The infiltration drainfield should contain an observation well. The purpose of the monitoring well is to provide information on how well this system is operating. It is recommended that the observation well be monitored daily after runoff-producing storm events. If the infiltration drainfield does not drain after three days, it usually means that the drainfield is clogged. Once the performance characteristics of the structure have been verified, the monitoring schedule can be reduced to a monthly or quarterly basis.

TABLE 1: INFILTRATION DRAINFIELD DESIGN CRITERIA

Design Criteria	Guidelines
Site Evaluation	• Take soil borings to a depth of at least 4 feet below bottom of stone reservoir to check for soil permeability, porosity, depth to seasonally high water table, and depth to bedrock. • Not recommended on slopes greater than 5 percent and best when slopes are as flat as possible. • Minimum infiltration rate 3 feet below bottom of stone reservoir: 0.5 inches per hour. • Minimum depth to bedrock and seasonally high water table: 4 feet. • Minimum setback from water supply wells: 100 feet. • Minimum setback from building foundations: 10 feet downgradient, 100 feet upgradient. • Drainage area should be less than 15 acres.
Design Storm Storage Volume	• Literature values suggest this parameter is highly variable and dependent upon regulatory requirements. One typically recommended storage volume is the stormwater runoff volume produced in the tributary watershed by the 6-month, 24-hour duration storm event.
Drainage Time for Design Storm	• Minimum: 12 hours. • Maximum: 72 hours. • Recommended: 24 hours.
Construction	• Excavate and grade with light equipment with tracks or oversized tires to prevent soil compaction. • As needed, divert stormwater runoff away from site before and during construction. • A typical infiltration cross-section consists of the following: 1) a stone reservoir consisting of coarse 1.5 to 3-inch diameter stone (washed); 2) 6 to 12-inch sand filter at the bottom of the drainfield; and 3) filter fabric.
Pretreatment	• Pretreatment is recommended to treat runoff from all contributing areas.
Dispersion Manifold	• A dispersion manifold should be placed in the upper portions of the infiltration drainfield. The purpose of this manifold is to evenly distribute stormwater runoff over the largest possible area. Two to four manifold extension pipes are recommended for most typical infiltration drainfield applications.

SOURCE: Reference 2.

COSTS

There is little information on the cost of infiltration drainfields. However, the construction costs for installing an infiltration drainfield that is 100 feet long, 50 feet wide, 8 feet deep and with 4 feet of cover can be estimated using the general information in Table 2 below.

TABLE 2: ESTIMATED COST FOR INSTALLING AN INFILTRATION DRAINFIELDS

Excavation Costs:	(2,220 cy) ($5.00/cy)	$11,100
Stone Fill	(1,296 cy) ($20.00/cy)	25,920
Sand Fill	(185 cy) ($10.00/cy)	1,850
Filter Fabric	Top and Bottom = 10,000 sf Sides = 1,600 + 800 = 2,400 sf Total = 12,400 sf + 10% = 13,640 sf (13,640 sf) (1 sy/9 sf) ($3.00/sy)	4,550
Perforated Manifold and Inlet Pipe	75' + 4(40') = 235' 40' (275) ($10.00/ft)	2,750
Observation Well	1 at $500 ea	500
Pretreatment Chamber	1 at $10,000	10,000
Miscellaneous (Backfilling, overflow pipe, sodding, etc.)		1,000
	SUBTOTAL	$57,670
Contingencies (Engineering, administration, permits, etc.) = 25%		14,420
	TOTAL	$72,090

Note: Unit prices will vary greatly depending upon local market conditions.

SOURCE: Reference 1.

ENVIRONMENTAL IMPACTS

One potential negative impact of infiltration drainfields is the risk of groundwater contamination. Studies to date do not indicate that this is a major risk. However, migration of nitrates and chlorides has been documented.

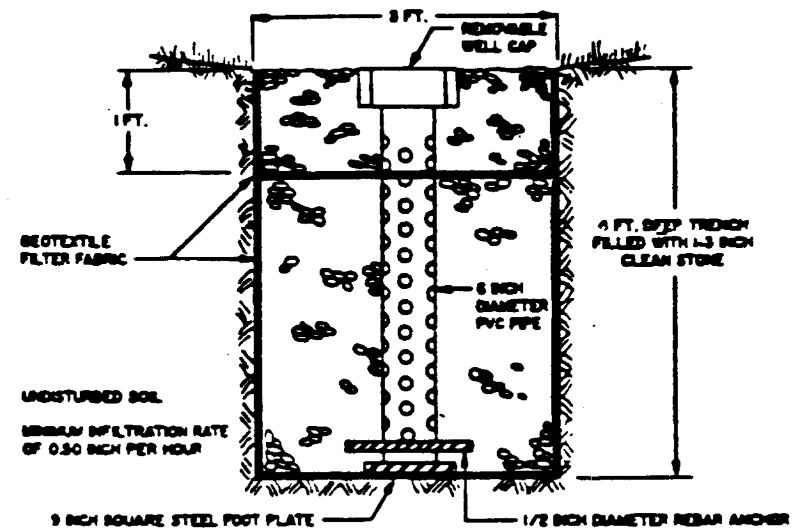
STORM WATER BMP: INFILTRATION TRENCH

DESCRIPTION

Infiltration trenches are used to remove suspended solids, particulate pollutants, coliform bacteria, organics and some soluble forms of metals and nutrients from storm water runoff. An infiltration trench, as shown in Figure 1 below, is an excavated trench, 3 to 12 feet deep, backfilled with stone aggregate. A small portion of the runoff, usually the first flush, is diverted to the infiltration trench, which is located either underground or at grade. The captured runoff exits the trench by infiltrating into the surrounding soils. Filtration through the soil is the primary pollutant removal mechanism. Infiltration trenches also provide groundwater recharge and preserve base-flow in nearby streams.



SOURCE: Reference 6

FIGURE 1: TYPICAL INFILTRATION TRENCH

Infiltration trenches capture and treat small amounts of runoff, but do not control peak hydraulic flows. Infiltration trenches may be used in conjunction with another best management practice (BMP), such as a detention pond, to provide both water quality control and peak flow control (Schueler, 1992, Harrington, 1989). Runoff that contains high levels of sediments or hydrocarbons (oil and grease) that may clog the trench are often pretreated with other BMPs. Examples of pretreatment BMPs include grit chambers, water quality inlets, sediment traps, swales and vegetated filter strips (SEWRPC, 1991, Harrington, 1989).

COMMON MODIFICATIONS

The infiltration trench can be modified by substituting pea gravel for stone aggregate in the top 1 foot of the trench. The pea gravel improves sediment filtering and maximizes the pollutant removal in the top of the trench. When the modified trenches become clogged, they can generally be restored to full performance by removing and replacing only of the pea gravel layer with out replacing the lower stone aggregate layers. Infiltration trenches can also be modified by adding a layer of organic material (peat) or loam to the trench subsoil. This modification appears to enhance the removal of metals and nutrient through adsorption.

CURRENT STATUS

Infiltration trenches are often used in place of other BMPs where limited land is available. Infiltration trenches are most widely used in warmer, less arid regions of the U.S. However, recent studies conducted in Maryland and New Jersey on trench performance and operation and maintenance, have demonstrated the applicability of infiltration trenches in colder climates (Lindsey, et al, 1991).

LIMITATIONS

The use of infiltration trenches may be limited by a number of factors, including type of soils, climate, and location of groundwater tables. Site characteristics, such as the slope of the drainage area, soil type, and location of the water table and bedrock, may preclude the use of infiltration trenches. The surrounding area slope should be such that the runoff is evenly distributed in sheet flow as it enters the trench. Generally, infiltration trenches are not suitable for areas with relatively impermeable soils such as clayey and silty soils or in areas with fill. The trench should be located above the water table so that the runoff can filter through the trench and into the surrounding soils and eventually into the groundwater. In addition, the drainage area should not convey heavy levels of sediments or hydrocarbons to the trench. For this reason, trenches serving parking lots should be preceded by appropriate pretreatment. Generally, trenches that are constructed under parking lots are also difficult to access for maintenance.

As with any infiltration BMP, the potential of groundwater contamination must be carefully considered, especially if the groundwater is used for human consumption or agricultural purposes. . In some cases the infiltration trench may not be suitable for sites that use or store chemicals or hazardous materials. In these areas other BMPs that do not interact with the groundwater should be considered. If infiltration trenches are selected, hazardous and toxic materials must be prevented from entering the trench. The potential for spills can be minimized by aggressive pollution prevention measures. Many municipalities and industries have developed comprehensive spill prevention control and countermeasure (SPCC) plans. These plans should be modified to include the infiltration trench and the contributing drainage area. For example, diversion structures can be used to prevent spills from entering the infiltration trench.

An additional limitation is the climate. In cold climates, trench surface may freeze, thereby preventing the runoff from entering the trench and allowing the untreated runoff to enter surface water. The surrounding soils may also freeze reducing infiltration into the soils and groundwater. However, recent studies indicate if properly designed and maintained infiltration trenches can operate effectively in colder climates. By keeping the trench surface free of compacted snow and ice and by ensuring the part of the trench is constructed below the frost line, will greatly improve the performance of the infiltration trench during cold weather.

PERFORMANCE

Infiltration trenches function similarly to rapid infiltration systems that are used in wastewater treatment. Estimated pollutant removal efficiencies from wastewater treatment performance and modeling studies are shown in Table 1 below. Based on this data, infiltration trenches can be expected to remove up to 90 percent of sediments, metals, coliform bacteria and organic matter, and up to 60 percent of phosphorus and nitrogen in the runoff (Schueler, 1987, 1992). Biochemical oxygen demand (BOD) removal is estimated to be between 70 to 80 percent. Lower removal rates for nitrate, chlorides and soluble metals should be expected especially in sandy soils (Schueler, 1992).

TABLE 1: TYPICAL POLLUTANT REMOVAL EFFICIENCY

Pollutant	Typical Percent Removal Rates
Sediment	90%
Total Phosphorus	60%
Total Nitrogen	60%
Metals	90%
Bacteria	90%
Organics	90%
Biochemical Oxygen Demand	70 - 80%

SOURCE: References 4 and 5

Pollutant removal efficiencies may be improved by using washed aggregate and adding organic matter and loam to the subsoil. The stone aggregate should be washed to remove dirt and fines before placement in the trench. The addition of organic material and loam to the trench subsoil will enhance metals and nutrient removal through adsorption.

LONGEVITY

There have been a number of concerns raised about the long term effectiveness of infiltration trench systems. In the past, infiltration trenches have demonstrated a relatively short life span with over 50 percent of the systems checked, having partially or completely failed after 5 years. A recent study of infiltration trenches in Maryland (Lindsey et al., 1991) found that 53 percent were not operating as designed, 36 percent were partially or totally clogged, and another 22 percent exhibited slow filtration. Longevity can be increased by careful geotechnical evaluation prior to construction. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration trench. Pretreatment structures, such as a vegetated buffer strip or water quality inlet, can increase longevity by removing sediments, hydrocarbons and other materials that may clog the trench. Regular maintenance including the replacement of clogged aggregate, will also increase the effectiveness and life of the trench.

DESIGN CRITERIA

Prior to trench construction, a review of the design plans may be required by state and local governments. The design plans should include a geotechnical evaluation that determines the feasibility of using an infiltration trench at the site. Soils should have a low silt and clay content and have infiltration rates greater than 0.5 inches per hour. Acceptable soil texture classes include sand, loamy sand, sandy loam and loam. These soils are within the A or B hydrologic group. Soils in the C or D hydrologic groups should be avoided. Soil survey reports published by the Soil Conservation Service can be used to identify soil types and infiltration rates. However, sufficient soil borings should always be taken to verify site conditions. Feasible sites should have a minimum of 4 feet to bedrock in order reduce excavation costs. There should also be a least 4 feet below the trench to the water table to prevent potential ground water problems. Trenches should also be located at least 100 feet up gradient from water supply wells and 100 feet from building foundations. Land availability, the depth to bedrock and the depth to the water table will determine whether the infiltration trench is located underground or at grade. Underground trenches receive runoff though pipes or channels, whereas surface trenches collect sheet flow from the drainage area.

In general infiltration trenches are suitable for drainage areas up to 10 acres (SEWRPC, 1991, Harrington, 1989). However, when the drainage area exceed 5 acres, other BMPs should be carefully considered (Schueler, 1989 and 1992). The drainage area must be fully developed and stabilized with vegetation before constructing an infiltration trench. High sediment loads from unstabilized areas will quickly clog the infiltration trench. Runoff from unstabilized areas should be diverted away from the trench until vegetation is established.

The drainage area slope determines the velocity of the runoff and also influences the amount of pollutants entrained in the runoff. Infiltration trenches work best when the up gradient drainage area slope is less than 5 percent (SEWRPC, 1991). The down gradient slope should be no greater than 20 percent to minimize slope failure and seepage.

The trench surface may consist of stone or vegetation with inlets to evenly distribute the runoff entering the trench (SEWRPC, 1991, Harrington, 1989). Runoff can be captured by depressing the trench surface or by placing a berm at the down gradient side of the trench. Underground trenches are covered with an impermeable geotextile membrane overlain with topsoil and grass.

A vegetated buffer strip (20 to 25 foot wide) should be established adjacent to the infiltration trench to capture large sediment particles in the runoff. The buffer strip should be installed immediately after trench construction using sod instead of hydroseeding (Schueler, 1987). The buffer strip should be graded with a slope between 0.5 and 15 percent so that runoff enters the trench as sheet flow. If runoff is piped or channeled to the trench, a level spreader can be installed to create sheet flow (Harrington, 1989).

During excavation and trench construction, only light equipment such as backhoes or wheel and ladder type trenchers should be used to minimize compaction of the surrounding soils. Filter fabric should be placed around the walls and bottom of the trench and 1 foot below the trench surface. The filter fabric should overlap each side of the trench in order to cover the top of the stone aggregate layer (see Figure 1). The filter fabric prevents sediment in the runoff and soil particles from the sides of the trench from clogging the aggregate. Filter fabric that is placed 1 foot below the trench surface will maximize pollutant removal within the top layer of the trench and decrease the pollutant loading to the trench bottom.

The required trench volume can be determined by several methods. One method calculates the volume based on capture of the first flush, which is defined as the first 0.5 inches of runoff from the contributing drainage area (SEWRPC, 1991). The State of Maryland (MD., 1986) also recommends sizing the trench based on the first flush, but defines first flush as the first 0.5 inches from the contributing impervious area. The Metropolitan Washington Council of Governments (MWCOG) suggests that the trench volume be based on the first 0.5 inches per impervious acre or the runoff produced from a 1 inch storm. In Washington D.C., the capture of 0.5 inches per impervious acre accounts for 40 to 50 percent of the annual storm runoff volume. The runoff not captured by the infiltration trench should be bypassed to another BMP (Harrington, 1989) if treatment of the entire runoff from the site is desired.

Trench depths are usually between 3 and 12 feet (SEWRPC, 1991, Harrington, 1989). However, a depth of 8 feet is most commonly used (Schueler, 1987). A site specific trench depth can be calculated based on the soil infiltration rate, aggregate void space, and the trench storage time (Harrington, 1989). The stone aggregate used in the trench is normally 1 to 3 inches in diameter, which provides a void space of 40 percent (SEWRPC, 1991, Harrington, 1989, Schueler, 1987).

A minimum drainage time of 6 hours should be provided, to ensure satisfactory pollutant removal in the infiltration trench (Schueler, 1987, SEWRPC, 1991). Although trenches may be designed to provide temporary storage of storm water, the trench should drain prior to the next storm event. The drainage time will vary by precipitation zone. In the Washington, D.C. area, infiltration trenches are designed to drain within 72 hours.

An observation well is recommended to monitor water levels in the trench. The well can be a 4 to 6 inch diameter PVC pipe, which is anchored vertically to a foot plate at the bottom of the trench as shown in Figure 1 above. Inadequate drainage may indicate the need for maintenance.

MAINTENANCE

Maintenance should be performed as needed. The principal maintenance objective is to prevent clogging, which may lead to trench failure. Infiltration trenches and any pretreatment BMPs should be inspected after large storm events and any accumulated debris or material removed. A more through inspection of the trench should be conducted at least annually. Annual inspection should include monitoring of the observation well to confirm that the trench is draining within the specified time. Trenches with filter fabric should be inspected for sediment deposits by removing a small section of the top layer. If inspection indicates that the trench is partially or completely clogged, it should be restored to its design condition.

When vegetated buffer strips are used, they should be inspected for erosion or other damage after each major storm event. The vegetated buffer strip should have healthy grass that is routinely mowed. Trash, grass clippings and other debris should be removed from the trench perimeter. Trees and other large vegetation adjacent to the trench should also be removed to prevent damage to the trench.

COSTS

Construction costs include clearing, excavation, placement of the filter fabric and stone, installation of the monitoring well, and establishment of a vegetated buffer strip. Additional costs include planning, geotechnical evaluation, engineering and permitting. The Southeastern Wisconsin Regional Planning Commission (SEWRPC, 1991) has developed cost curves and tables for infiltration trenches based on 1989 dollars. The 1993 construction cost for a relatively large infiltration trench (i.e., 6 feet deep and 4 feet wide with a 2,400 cubic foot volume) ranges from $8,000 to $19,000. A smaller infiltration trench (i.e., 3 feet deep and 4 feet wide with a 1,200 cubic foot volume) is estimated to cost from $3,000 to $8,500 (1993).

Maintenance costs include buffer strip maintenance and trench inspection and rehabilitation. SEWRPC (1991) has also developed maintenance costs for infiltration trenches. Based on the above examples, annual operation and maintenance costs would average $700 for the large trench and $325 for the small trench. Typically, annual maintenance costs are approximately 5 to 10 percent of the capital cost (Schueler, 1987). Trench rehabilitation, may be required every 5 to 15 years. Cost for rehabilitation will vary depending on site conditions and the degree of clogging. Estimated rehabilitation cost run from 15 to 20 percent of the original capital cost (SEWRPC, 1991).

ENVIRONMENTAL IMPACTS

Infiltration trenches provide efficient removal of suspended solids, particulate pollutants, coliform bacteria, organics and some soluble forms of metals and nutrients from storm water runoff. Infiltration trenches also reduce the volume of runoff by providing a storage reservoir. The captured runoff infiltrates the surrounding soils and increases groundwater recharge and base-flow in nearby streams.

Negative impacts include the potential for groundwater contamination. Fortunately, most pollutants have a low potential to contaminate groundwater (Schueler, 1987). However, an EPA study (USEPA, 1991) found that chloride and nitrate, which are very soluble pollutants, can migrate from infiltration trenches into groundwater. In the future, federal or state agencies may require a groundwater injection permit for infiltration trench sites (Schueler, 1992).

STORM WATER BMP: INTERNAL REPORTING

DESCRIPTION

Internal reporting provides a framework for "chain-of-command" reporting of stormwater management issues. Typically, a facility develops a Stormwater Pollution Prevention Team (SWPPT) concept for implementing, maintaining, and revising the facility's Stormwater Pollution Prevention Plan (SWPPP). The purpose of identifying a SWPPT is to clarify the chain of responsibility for stormwater pollution prevention issues and provide a point of contact for personnel outside the facility who need to discuss the SWPPP.

CURRENT STATUS

The U.S. EPA first identified internal reporting as a Best Management Practice (BMP) in the late 1970s. Currently, internal reporting has evolved into development of an SWPPT for facilities implementing an SWPPP as part of their NPDES stormwater discharge permit. This SWPPT concept is a new and innovative part of the SWPPP.

IMPLEMENTATION

The key to implementing internal reporting as a BMP is to establish a qualified SWPPT. Where setting up an SWPPP is appropriate, it is important to identify key people on-site who are most familiar with the facility and its operations, and to provide adequate structure and direction to the facility's entire stormwater management program. Limitations involved in developing an internal reporting system are the potential lack of corporate commitment in designating appropriate funds, inadequate staff hours available for proper implementation, and a potential lack of motivation from SWPPT members that could inhibit the transfer of key stormwater pollution information.

PERFORMANCE

The performance and effectiveness of an internal reporting system is highly variable and dependent upon several factors. Key factors include:

- Commitment of senior management.
- Sufficient time and financial resources.
- Quality of implementation.
- Background and experience of the SWPPT members.

DESIGN CRITERIA

When establishing an internal reporting structure, it is important to select appropriate personnel to serve on the team. Both team and individual responsibilities should be designated with clear goals defined for proper stormwater management. Internal reporting should be tied to other baseline BMPs such as employee training, individual inspections, and record keeping to ensure proper implementation. Figure 1 below illustrates an example SWPPT organization chart.

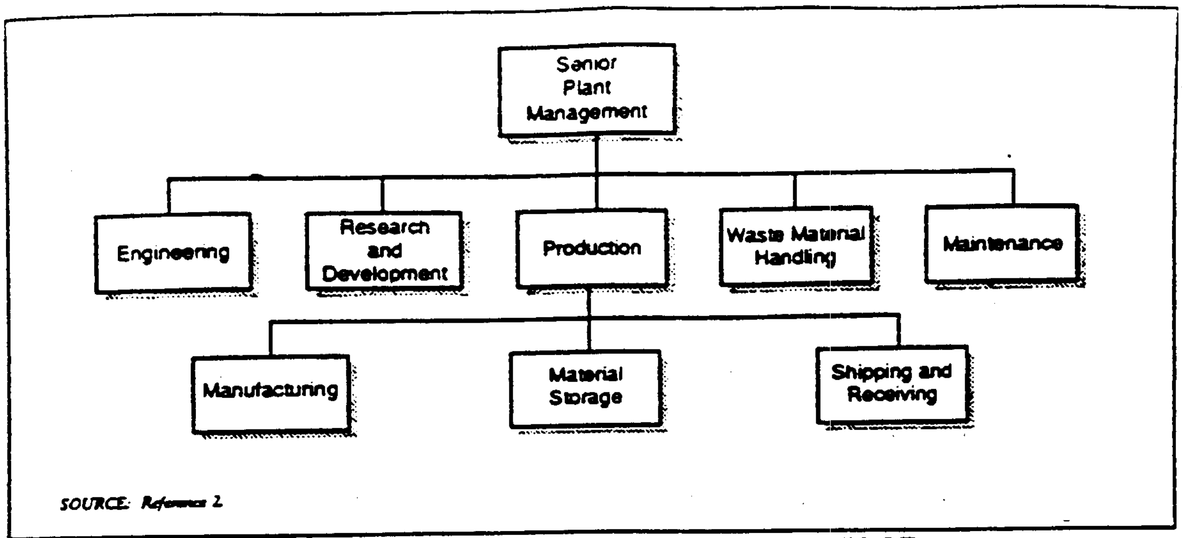

FIGURE 1: EXAMPLE SWPPT ORGANIZATION CHART

MAINTENANCE

To ensure that an internal reporting system remains effective, the person or team responsible for maintaining the SWPPP must be aware of any changes in plant operations or key team members to determine if modifications must be made in the overall execution of the SWPPP.

COSTS

Costs associated with implementing an internal reporting system are those associated with additional staff hours and related overhead costs. Annual costs can be estimated using the example shown in Table 1 below. Figure 2 can be used as a worksheet to calculate the estimated costs for an internal record keeping program.

TABLE 1: EXAMPLE OF ANNUAL INTERNAL REPORTING COSTS

Title	Quantity		Avg. Hourly Rate ($)		Overhead* Multiplier		Estimated Yearly Hours on SW Training		Est. Annual Cost ($)
Stormwater Engineer	1	x	15	x	2.0	x	20	=	600
Plant Management	5	x	20	x	2.0	x	10	=	2,000
Plant Employees	100	x	10	x	2.0	x	5	=	10,000
SOURCE: EPA			TOTAL ESTIMATED ANNUAL COST						$12,600

Note: Defined as a multiplier (typically ranging between 1 and 3) that takes into account those costs associated with payroll expenses, building expenses, etc.

STORM WATER BMP: MATERIALS INVENTORY

DESCRIPTION

A materials inventory system involves the identification of all sources and quantities of materials that may be exposed to direct precipitation or storm water runoff at a particular site. Significant materials are substances related to industrial activities such as process chemicals, raw materials, fuels, pesticides, and fertilizers. When these substances are exposed to direct precipitation or storm water runoff, they may be carried to a receiving waterbody. Therefore, identification of these substances and other materials helps to determine sources of potential contamination and is the first step in pollution control.

CURRENT STATUS

Most facilities already have in place a materials inventory system. However, the inventory of significant materials is not generally performed from a storm water contamination viewpoint. Modification of the existing materials inventory program to include storm water considerations should be minimal. The inventory should be incorporated into the Storm Water Pollution Prevention Plan (SWPPP).

APPLICATIONS

A materials inventory system is applicable to most industrial facilities. Inventory of exposed materials should be part of a baseline administrative program and is directly related to both record keeping and visual inspection Best Management Practices (BMP).

LIMITATIONS

Limitation of materials inventory system BMP include:

- It is an on-going process that continually needs updating.
- Qualified personnel are required to perform the materials inventory from a storm water perspective.
- Materials inventory records should be readily accessible.

PERFORMANCE

It is not possible to quantify water quality benefits to receiving waters of a materials inventory program since the program is intended to prevent pollution before it occurs. However, it is anticipated that an effective materials inventory program will result in improved storm water discharge quality.

DESIGN CRITERIA

Keeping an up-to-date inventory of all materials (hazardous and non-hazardous) on the site will help to limit material costs caused by overstocking, track how materials are stored and handled on site, and identify which materials and activities pose the greatest risk to the environment. The following basic steps should be used in completing a materials inventory:

- Identify all chemical substances present in the work place. Walk through the facility and review the purchase orders for the previous year. List all chemical substances used in the work place and then obtain the material safety data sheets (MSDS) for each.

- Label all containers to show the name and type of substance, stock number, expiration date, health hazards, suggestions for handling, and first aid information. This information can usually be found on the MSDS. Unlabeled chemicals and chemicals with deteriorated labels are often disposed of improperly or unnecessarily.

- Clearly mark on the inventory hazardous materials that require specific handling, storage, use, and disposal considerations.

Improved material tracking and inventory practices, such as instituting a shelf life program, can reduce the wastes resulting from overstocking and the disposal of outdated materials. Careful tracking of all materials ordered may also result in more efficient materials use. Figure 1 below illustrates a simple material inventory tracking system.

Based on your materials inventory, describe the significant materials that were exposed to storm water during the past three years and/or are currently exposed. Other BMPs should then be evaluated and implemented or constructed to eliminate exposure of theses materials to storm water or that provide appropriate treatment before discharge to receiving waters. Figure 2 below illustrates a sample worksheet for evaluating exposed materials.

FIGURE 2: EXPOSED MATERIAL WORKSHEET

MAINTENANCE

The key to a proper materials inventory system is continual updating of records. Maintaining an up-to-date materials inventory is an efficient way to identify what materials are handled on-site that may contribute to storm water contamination problems.

COSTS

The major cost of implementing a materials inventory system is the time required to implement a program that places emphasis on storm water quality. Typically, this is a small incremental increase if a materials inventory program already exists at the facility. Keeping an up-to-date inventory of all materials present on your site will help to keep material costs down by identifying waste and overstocking.

STORM WATER BMP: NON-STORM WATER DISCHARGES

DESCRIPTION

Identifying and eliminating non-storm water discharges is an important and very cost-effective Best Management Practice (BMP). Examples of non-storm water discharges include process water, leaks from portable water tanks or pipes, excess landscape watering, vehicle wash water, and sanitary wastes. Non-storm water discharges are typically the result of unauthorized connections of sanitary or process wastewater drains that discharge to the storm sewer rather than to the sanitary sewer. Connections of non-storm water discharges to a storm water collection system are common, yet often go undetected. Another form of non-storm water discharge is wash water discharge to a storm drain. Typically these discharges are significant sources of pollutants, and unless regulated by an NPDES permit, are illegal.

CURRENT STATUS

Identifying and eliminating non-storm water discharges as a BMP have rarely been used at industrial facilities. Part of the problem is educational. Many facility operators are unaware of what constitutes a non-storm water discharge, and the potential impact. The new NPDES permit requirements for the presence of non-storm water discharges will greatly improve the implementation of this BMP.

APPLICATIONS

Identification of potential non-storm water discharges is applicable to almost every industrial facility that has not been tested or evaluated for the presence of such non-storm water discharges. Generally, a non-storm discharge evaluation includes:

- Identification of potential non-storm water discharges locations.
- Results of a physical site evaluation for the presence of non-storm water discharges.
- The evaluation criteria or test method used.
- The date of testing and/or evaluation.
- The on-site drainage points that were directly observed during the test and/or evaluation.

LIMITATIONS

Possible problems in identifying non-storm water discharges include:

- The possibility that a non-storm water discharge may not occur on the date of the test or evaluation.
- The method used to test or evaluate the discharge may not be applicable to the situation.
- Identifying an illicit connection may prove difficult due to the lack of available data on the location of storm drains and sanitary sewers, especially in older industrial facilities.

PERFORMANCE

The question of whether or not the elimination of non-storm water discharges is an effective BMP is answered by evaluating the environmental impact of these discharges. If a significant loading of pollutants is common from these discharges, then their elimination will be an effective BMP.

Several studies exist on the contents of non-storm water discharges. Pitt and Shawley (1982) reported that non-storm water discharges were found to contribute substantial quantities of many pollutants, even though the concentrations were not high. The long duration of the base flows offset the lower concentration leading to a substantial loading of pollutants. Gartner, Lee and Associates, Ltd. (1983) conducted an extensive survey of non-storm water discharges in the Humber River watershed (Toronto). Out of 625 outfalls, about 10 percent were considered significant pollutant sources. Further investigations identified many industrial and sanitary non-storm water discharges into the storm drainage system. For example, problems found in industrial areas included liquid dripping from animal hides stored in tannery yards and washdowns of storage yards at meat packing facilities. Therefore, it is anticipated that elimination of non-storm water discharges will be a highly effective BMP.

DESIGN CRITERIA

Key program criteria includes the identification and location of non-storm water entries into storm drainage systems. It is important to note that for any effective investigation of pollution within a storm water system, all pollutant sources must be included. For many pollutants, storm water may contribute the smaller portion of the total pollutant mass discharged from a storm drainage system. Significant pollutant sources may include dry-weather entries occurring during both warm and cold months and snowmelt runoff, in addition to conventional storm water associated with rainfall. consequently, much less pollution reduction benefit will occur if only storm water is considered in a control plan for controlling storm drainage discharges. The investigations may also identify illicit point source outfalls that do not carry storm water. Obviously, these outfalls also need to be controlled and permitted. Figure 1 below can be used as a sample worksheet to report non-storm water discharges.

SOURCE: Reference 4

FIGURE 1: SAMPLE WORKSHEET FOR RECORDING NON-STORM WATER DISCHARGES

There are four primary methods for investigating non-storm water discharges. These methods include:

- Sanitary and Storm Sewer Map Review. A review of a plant schematic is a simple way to determine if there are any unauthorized connections to the storm water collection system. A sanitary or storm sewer map, or plant schematic is a map of pipes and drainage systems used to carry process wastewater, non-contact cooling water, and sanitary wastes. These maps (especially as-built plans or record drawings of the facility) should be reviewed to verify that there are no unauthorized connections. A common problem is that sites often do not have accurate or current schematics or plans.

- Visual Inspection. The most simple method for detecting non-storm water connections in the storm water collection system is to observe all discharge points during periods of dry weather. Key parameters to look for are the presence of stains, smudges, odors, and other abnormal conditions.

- Sampling and Chemical Analysis. Sewer mapping and visual inspection are also helpful in identifying locations for sampling. Chemical tests are needed to supplement the visual or physical inspections. Chemical tests can help quantify the approximate components of the mixture at the outfall or discharge point. Samples should be collected, stored, and analyzed in accordance with standard quality control and quality assurance (QA\QC) procedures. Statistical analysis of the chemical test results can be used to estimate the relative magnitude of the various flow sources. In most cases, non-storm water discharges are made up of may separate sources of flow (such as leaking domestic water systems, sanitary discharges, ground water infiltration, automobile washwater, etc.). Key parameters that can be helpful in identifying the source of the no -storm water flows include, biochemical oxygen demand (BOD), chemical oxygen demand (COD), total organic carbon (TOC), specific conductivity, temperature, fluoride, hardness, ammonia ammonium, potassium, surfactant fluorescence, pH, total available chlorine, and toxicity screening. It may be possible to identify the source of the non-storm water discharge by examining the flow for specific chemicals.

  Just as high levels of pathogenic bacteria are usually associated with a discharge from a sanitary, waste water sources, the presence of certain chemicals are generally associated with specific industries. Table 1 below includes a listing of various chemicals that may be associated with a variety of different activities.

- Dye Testing. Another method for detecting improper connections to the storm water collection system is dye testing. A dye test can be performed by simply releasing a dye (either pellet or powder) into either the sanitary or process wastewater system. Discharge points from the storm water collection system are them examined for color change.

MAINTENANCE

A maintenance program consists of annual inspections for non-storm water discharges, even if previous tests have been negative. New processes, building additions, and other plant changes, if they are not carefully reviewed during design, may result in future unauthorized connections to the storm water conveyance system.

TABLE 1: CHEMICALS COMMONELY FOUND INDUSTRIAL DISCHARGES

Chemical:	Industry:
Acetic acid	Acetate rayon, pickle and beetroot manufacture
Alkalies	Cotton and straw kiering, cotton manufacture, mercerizing, wool scouring, laundries
Ammonia	Gas and coke manufacture, chemical manufacture
Arsenic	Sheep-dipping, felt mongering
Chlorine	Laundries, paper mills, textile bleaching
Chromium	Plating, chrome tanning, aluminum anodizing
Cadmium	Plating
Citric acid	Soft drinks and citrus fruit processing
Copper	Plating, pickling, rayon manufacture
Cyanides	Plating, metal cleaning, case-hardening, gas manufacture
Fats, oils	Wool scouring, laundries, textiles, oil refineries
Fluorides	Gas and coke manufacture, chemical manufacture, fertilizer plants, transistor manufacture, metal refining, ceramic plants, glass etching
Formalin	Manufacture of synthetic resins and penicillin
Hydrocarbons	Petrochemical and rubber factories
Hydrogen peroxide	Textile bleaching, rocket motor testing
Lead	Battery manufacture, lead mining, paint manufacture, gasoline manufacture
Mercaptans	Oil refining, pulp mills
Mineral acids	Chemical manufacture, mines, Fe and Cu pickling, brewing, textiles, photoengraving, battery manufacture
Nickel	Plating
Nitro compounds	Explosives, and chemical works
Organic acids	Distilleries and fermentation plants
Phenols	Gas and coke manufacture, synthetic resin manufacture, textiles, tanneries, tar, chemical, and dye manufacture, sheep-dipping
Silver	Plating, photography
Starch	Food, textile, wallpaper manufacture
Sugars	Dairies, foods, sugar refining, preserves, wood process
Sulfides	Textiles, tanneries, gas manufacture, rayon manufacture
Sulfites	Wood process, viscose manufacture, bleaching
Tannic acid	Tanning, sawmills
Tartaric acid	Dyeing, wine, leather, and chemical manufacture
Zinc	Galvanizing, plating, viscose manufacture, rubber process

SOURCE: Reference 7.

COSTS

The above methods are mostly time-intensive and their cost are dependent on the amount of effort and level of expertise employed. Visual inspections are the least expensive of the three. Dye testing may be more cost effective for buildings that do not have current schematics of their sanitary and storm sewer systems. The cost of disconnecting illicit discharges from the storm water system will vary depending on the type and location of the connection and the type of corrective action needed.

The Full use of all of the applicable procedures is most likely necessary to successfully identify pollutant sources. Attempting to reduce costs, for example, by only examining a certain class of outfalls, or using inappropriate testing procedures, will significantly reduce the utility of the testing program and result in inaccurate conditions.

ENVIRONMENTAL IMPACTS

Eliminating non-storm water discharges can have significant impacts on improving water quality in the receiving waters.

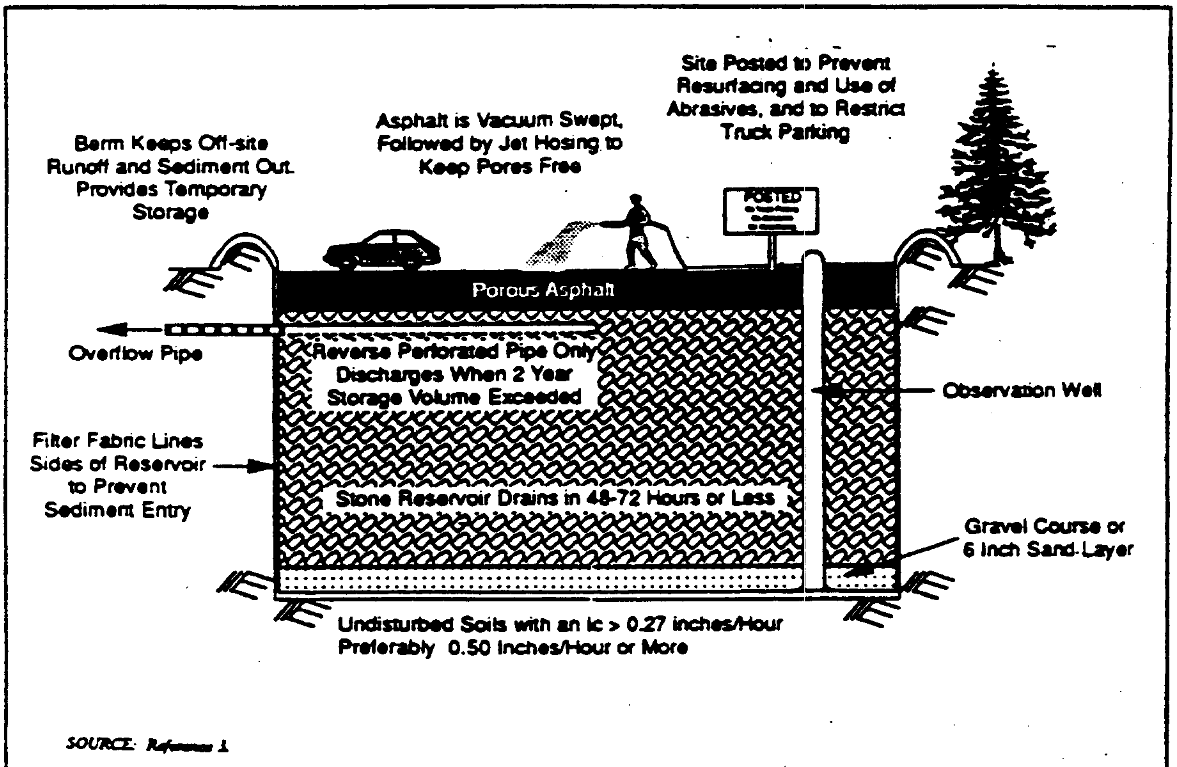
STORM WATER BMP: POROUS PAVEMENT

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Porous pavement is a specially designed and constructed pavement which allows stormwater to pass through it. The purpose of porous pavement is to reduce the speed and amount of runoff from a site, and to filter potential pollutants from the stormwater. There are two principal types of porous pavement: porous asphalt pavement, and pervious concrete pavement. Porous asphalt pavement consists of an open graded coarse aggregate bound together by asphalt with sufficient interconnected voids to provide a high rate of water percolation. Pervious concrete consists of specially formulated mixtures of Portland cement, uniform open graded coarse aggregate, and water. When properly handled and installed, pervious concrete has a high percentage of void space which allows rapid percolation of liquids through the pavement.

The porous pavement surface is typically placed over a highly permeable layer of open graded gravel and crushed stone. The void spaces in the aggregate layers provide a storage reservoir for runoff. A filter fabric is placed beneath the gravel and stone layers to prevent the movement of fine soil particles into these layers. Figure 1 below illustrates a common porous asphalt pavement installation.



SOURCE: Reference 1

FIGURE 1: TYPICAL POROUS PAVEMENT INSTALLATION

Porous pavement offers a number of advantages including:

Provides water quality improvement by removing pollutants.

- Reduces the need for curbing and storm sewer installation.
- Improves road safety by increasing skid resistance. (Tests have shown that there is up to 15 percent less hydro-planing and skidding on porous pavement surfaces.)
- Provides recharge to local aquifers.

COMMON MODIFICATIONS

A common modification for porous pavement design systems consists of varying the amount of storage to be provided in the stone reservoir located directly beneath the pavement, and adding perforated pipes near the top of the reservoir to discharge stormwater runoff after the reservoir has been filled to design capacity. Stone reservoirs may be designed to accept the first flush of stormwater runoff or provide enough storage to accommodate runoff from a chosen design storm for infiltration through the underlying subsoil. Pretreatment of off-site runoff is highly recommended. Another variation of pervious concrete is the use of a concrete block or brick system with individual blocks separated by a pervious material.

CURRENT STATUS

Currently there is little information on porous pavement. However, in general information about infiltration trenches and basins also applies to porous pavement. The following concerns are currently being evaluated by the EPA.

- Can pavement porosity be maintained over the long term, particularly with resurfacing needs and snow removal?
- What is the pollutant removal capability of porous pavement during subfreezing weather and snow removal conditions?
- What are the optimal relationships between porous pavement, groundwater, sandy soils, and high water table conditions?
- What are the costs of maintenance and rehabilitation options for restoration of porosity?

APPLICATIONS

Porous pavement is applicable as a substitute for conventional pavement on parking areas and low traffic volume roads provided that the grades, subsoils, drainage characteristics, and groundwater table conditions are suitable. Slopes should be very gentle to flat. Soils should have field-verified permeability rates of greater than 0.5 inches per hour, and there should be a 4-foot minimum clearance from the bottom of the system to bedrock or the water table. Additional areas for use of porous pavement include fringe overflow parking areas and taxiway and runway shoulders at airports.

LIMITATIONS

The use of porous pavement may be restricted in regions with extremely cold climates, arid regions or regions with high wind erosion rates (increased windblown sediment loads) and areas where sole source potable aquifers could be contaminated. The use of porous pavement is highly constrained, requiring deep permeable soils, restricted traffic, and adjacent land uses. Some specific disadvantages of porous pavement include:

- The lack of experience with this technology with most pavement engineers and contractors.

- Porous pavement has a tendency to become clogged if improperly installed or maintained.

- The high failure rate of porous pavement sharply limits the ability to meet watershed stormwater quality and quantity goals.

- Slight to moderate risk of groundwater contamination depending on soil conditions and aquifer susceptibility.

- Possible transport of hydrocarbons from vehicles and leaching of toxic chemicals from asphalt and/or binder surface.

- Some building codes may not allow for the installation of porous pavement.

- The possibility exists that anaerobic conditions may develop in underlying soils if the soils, are unable to dry out between storm events.

PERFORMANCE

Traditionally, porous pavement sites have had a high failure rate (75 percent). Failure has been attributed to poor design, inadequate construction techniques, low permeability soils, heavy vehicular traffic, and resurfacing with nonporous pavement materials.

Porous pavement pollutant removal mechanisms include absorption, straining, and microbiological decomposition in the soil underlying the aggregate chamber and trapping of particulate matter within the chamber. An estimate of porous pavement pollutant removal efficiency is provided by two long-term monitoring studies. These studies indicate long-term removal efficiencies of between 82 and 95 percent for sediment, 65 percent for total phosphorus, and 80-85 percent of total nitrogen. They also indicated high removal rates for zinc, lead, and chemical oxygen demand. Some key factors to increase pollutant removal and prevent failure include:

- Routine vacuum sweeping and high pressure washing.

- Maximum recommended drainage time of 24 hours.

- Highly permeable soils.

- Pretreatment of off-site runoff.

- Inspection and enforcement of specifications during construction.

- Organic matter in subsoils.

- Clean-washed aggregate.

- Use only in low-intensity parking areas.

- Restrictions on use by heavy vehicles.

- Limiting use of de-icing chemicals and sand.

DESIGN CRITERIA

Porous pavement, along with other infiltration BMPs (infiltration basins, trenches, etc.) have demonstrated relatively short life spans in the past. Failures have general been attributed to poor design, poor construction techniques, subsoils with low permeability, and lack of adequate preventive maintenance. Key design factors that can significantly increase the performance and reduce the risk of failure of porous pavements and other infiltration BMPs is shown in Table 1 below.

TABLE 1: DESIGN CRITERIA FOR POROUS PAVEMENT

Design Criteria	Guidelines
Site Evaluation	• Take soil borings to depth of at least 4 feet below bottom of stone reservoir to check for soil permeability, porosity, depth to seasonally high water table, and depth to bedrock.
	• Not recommended on slopes greater than 5 percent and best with slopes as flat as possible.
	• Minimum infiltration rate 3 feet below bottom of stone reservoir: 0.5 inches per hour.
	• Minimum depth to bedrock and seasonally high water table: 4 feet.
	• Minimum setback from water supply wells: 100 feet.
	• Minimum setback from building foundations: 10 feet downgradient, 100 feet upgradient.
	• Not recommended in areas where wind erosion supplies significant amounts of windblown sediment.
	• Drainage area should be less than 15 acres.
Traffic Conditions	• Use for low volume automobile parking areas and lightly used access roads.
	• Avoid moderate to high traffic areas and significant truck traffic.

SOURCE: Reference 2

TABLE 1: DESIGN CRITERIA FOR POROUS PAVEMENTS.

(CONTINUED)

Design Criteria	Guidelines
	• While the standard porous pavement design is believed to withstand freeze/thaw conditions normally encountered in most regions of the country, the porous pavement system is sensitive to clogging during snow removal operations. Therefore, the area should be posted with signs to restrict the use of sand, salt, and other deicing chemicals typically associated with snow cleaning activities.
Design Storm Storage Volume	• Literature values suggest this parameter is highly variable and dependent upon regulatory requirements. One typically recommended storage volume is the stormwater runoff volume produced in the tributary watershed by the produced in the tributary watershed by the 6-month, 24-hour duration storm event.
Drainage Time for Design Storm	• Minimum: 12 hours. • Maximum: 72 hours. • Recommended: 24 hours.
Construction	• Excavate and grade with light equipment with tracks or oversized tires to prevent soil compaction. • As needed, divert stormwater runoff away from planned pavement area to keep runoff and sediment away from site before and during construction. • A typical porous pavement cross-section consists of the following layers: 1) porous asphalt course, 2-4 inches thick; 2) filter aggregate course; 3) reservoir coarse of 1.5-3-inch diameter stone; and 4) filter fabric.
Porous Pavement Placement	• Pavement temperature: 240-260° F. • Minimum air temperature: 50° F. • Compact with one or two passes of a 10-ton roller. • Prevent any vehicular traffic on pavement for at least two days. Pretreatment•Pretreatment is recommended to treat runoff from all off-site areas. An example would be a 25-foot wide vegetative filter strip placed around the perimeter of the porous pavement where drainage flows onto the pavement surface.

SOURCE: Reference 2.

MAINTENANCE

Routine maintenance of porous pavements is extremely important. Maintenance should include vacuum sweeping at least four times per year, followed by high-pressure hosing to limit sediment clogging in the pores of the top layer. Potholes and cracks can be filled with typical patching mixes unless more than 10 percent of the surface area needs repair. Spot-clogging may be fixed by drilling half-inch holes through the porous pavement layer every few feet.

The pavement should be inspected several times during the first few months following installation and then annually thereafter. Inspections after large storms are necessary to check for pools of water. These pools may indicate clogging. The condition of adjacent pretreatment facilities should also be inspected.

COSTS

The costs of developing a porous pavement system 100 feet by 50 feet and with a 4 foot deep storage area can be estimated using the example in table 2 below.

Estimated costs for an average annual maintenance program of a porous pavement parking lot are approximately $200 per acre per year. This cost assumes four inspections, vacuum sweeping and jet hosing treatments per year.

TABLE 2: ESTIMATED COSTS FOR A POROUS PAVEMENT SYSTEM

1.	Excavation Costs:	740 cy x $5.00/cy	$ 3,700
2.	Filter Aggregate/Stone Fill	740 cy x $20.00/cy	14,800
3.	Filter Fabric	760 sy x $3.00/sy	2,280
4.	Porous Pavement	556 sy x $13.00/sy	7,228
5.	Overflow Pipes	200 ft x $12.00/ft	2,400
6.	Observation Well	1 at $200 ea	200
7.	Grass Buffer	833 sy x $1.50/sy	1,250
8.	Erosion Control	$1,000/lump sum	1,000
		SUBTOTAL	$32,858
9.	Contingencies (Engineering, Administration, etc.) = 25%		8,215
	SOURCE: Reference 4	TOTAL*	$41,073

* Costs for traditional pavement, including any storm sewers, curb and gutter should be subtracted from this amount to reflect the difference in total cost for implementing a porous pavement system. Unit costs will vary according to local market conditions.

ENVIRONMENTAL IMPACTS

One potential negative impact of porous pavement is the risk of groundwater contamination. Pollutants (such as nitrates and chlorides) not easily trapped, absorbed, or reduced may continue to move through the soil profile and into groundwater. This is not a desirable condition, as it could lead to contamination of drinking water supplies. Therefore, until more scientific data is available, it is advisable not to site porous pavement near groundwater drinking supplies.

STORM WATER BMP: PREVENTIVE MAINTENANCE

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Preventive maintenance involves the regular inspection and testing of plant equipment and operational systems. These inspections should uncover conditions such as cracks or slow leaks which could cause breakdowns or failures that result in discharges of chemicals to surface waters either by direct overland flow or through storm drainage systems. The purpose of the preventive maintenance program should be to prevent breakdowns and failures by adjustment, repair, or replacement of equipment before a major breakdown or failure can occur.

Preventive maintenance has been practiced predominantly in those industries where excessive down time is extremely costly. As a storm water best management practice BMP, preventive maintenance should be used selectively to eliminate or minimize the spill of contaminants to receiving waters. For many facilities this would simply be an extension of the current plant preventive maintenance program to include items to prevent storm water runoff contamination.

For sites that have storm drainage facilities, proper maintenance is necessary to ensure that they serve their intended function. Without adequate maintenance, sediment and other debris can quickly clog facilities and render them useless. Typically, a preventive maintenance program should include inspections of catch basins, storm water detention areas, and water quality treatment systems.

CURRENT STATUS

Most plants already have preventive maintenance programs that provide some degree of environmental protection. This program could be expanded to include stormwater considerations, especially the upkeep and maintenance of storage tanks, valves, pumps, pipes, and storm water management devices.

APPLICATIONS

Preventive maintenance procedures and activities are applicable to almost every industrial facility. Preventive maintenance should be part of a general good housekeeping program designed to maintain a clean and orderly work environment. Often the most effective first step towards preventing storm water pollution from industrial sites simply involves good common sense to improve the facility preventive maintenance and general good housekeeping methods.

LIMITATIONS

Primary limitations of implementing a preventive maintenance program include:

- Additional costs.
- Availability of trained preventive maintenance staff technicians.
- Management direction and staff motivation in expanding the preventive maintenance program to include storm water considerations.

PERFORMANCE

Quantitative data is not available on the effectiveness of preventive maintenance as a best management practice. However, it is clear that an effective preventive maintenance program can result in improved storm water discharge quality.

DESIGN CRITERIA

Elements of a good preventive maintenance program should include:

- Identification of equipment or systems which may malfunction and cause spills, leaks, or other situations that could lead to contamination of storm water runoff. Typical equipment to inspect include pipes, pumps, storage tanks and bins, pressure vessels, pressure release valves, process and material handling equipment, and storm water management devices.
- Once equipment and areas to be inspected have been identified at the facility, establish schedules and procedures for routine inspections.
- Periodic testing of plant equipment for structural soundness is a key element in a preventive maintenance program.
- Promptly repair or replace defective equipment found during inspection and testing.
- Keep spare parts for equipment that need frequent repair.
- It is important to include a record keeping system for scheduling tests and documenting inspections in the preventive maintenance program.
- Record test results and follow up with corrective action taken. Make sure records are complete and detailed. These records should be kept with other visual inspection records.

MAINTENANCE RECORDS

The key to properly tracking a preventive maintenance program is through the continual updating of maintenance records. Records should be updated immediately after preventive maintenance, or when any repair has been performed on any item in the plant. An annual review of these records should be conducted to evaluate the overall effectiveness of the preventive maintenance program. Refinements to the preventive maintenance procedures and tasking should be implemented as necessary.

COSTS

The major cost of implementing a preventive maintenance program that places emphasis on storm water quality is the staff time required to implement the program. Typically, this is a small incremental increase if a preventive for training and maintenance program already exists at the facility.

STORM WATER BMP: RECORD KEEPING

DESCRIPTION

A record keeping system should be implemented for documenting spills, leaks, and other discharges such as hazardous substances. Keeping records and reporting events that occur on-site are effective ways of tracking the progress of pollution prevention efforts and waste minimization. Analyzing records of past spills can provide useful information for developing improved Best Management Practices (BMPs) to prevent future spills. Record keeping represents a good operating practice because it can increase the efficiency of a facility by reducing down time and increase the effectiveness of other prevention and treatment BMPs. Typical record keeping items include reported incidents and follow-up on results of inspections, and reported spills, leaks, or other discharges.

IMPLEMENTATION

Record keeping as a BMP should be an integral part of a BMP implementation program and should be incorporated into Stormwater Pollution Prevention Plans (SWPPP).If a separate record keeping system for tracking BMPs, monitoring results, etc., is not currently in place at a facility, existing record keeping structures could be easily adapted to incorporate this data. An ideal tool for implementation is the record keeping procedures laid out in an SWPPP. In many cases the record keeping system can be maintained on a personal or desk top computer using standard spreadsheet or data base management software.

LIMITATIONS

Limitations associated with a record keeping system are:

- It is an on-going process that continually needs updating.
- Qualified personnel required to complete the record keeping forms.
- Accessible of records.
- Security of confidential information.

PERFORMANCE

Record keeping performance as a BMP is highly variable. It depends on the time and commitment dedicated to implementing an effective system. The benefit of an effective record keeping system being incorporated into an overall SWPPP is improved stormwater discharge leaving facility grounds. The effectiveness of the record keeping system is often dependent on the following:

- The commitment of senior management to implementing and maintaining an effective record keeping system.
- The quality of the record keeping program.
- The background and experience of the assigned record keeping team.

DESIGN CRITERIA

Record keeping and reporting procedures for spills, leaks, inspections, maintenance, and monitoring activities should include the following. a sample worksheet for keeping records of spills and leaks is shown in Figures 1 below.

- The date, location, and time of material inventories, site inspections, sampling observations, etc.
- The individual(s) who performed site inspections, sampling observations, etc.
- The date(s) analyses were performed and the time(s) analyses were initiated, the individual or individual(s) who performed the analyses, analytical techniques or methods used, and results of such analysis.
- Quality assurance/quality control results.
- The date, time, exact location,and complete characterization of significant spills or leaks.
- Visual observation and sample collection exception records.
- All calibration and maintenance records of instruments used in stormwater monitoring.
- All original strip chart recordings for continuous monitoring equipment.

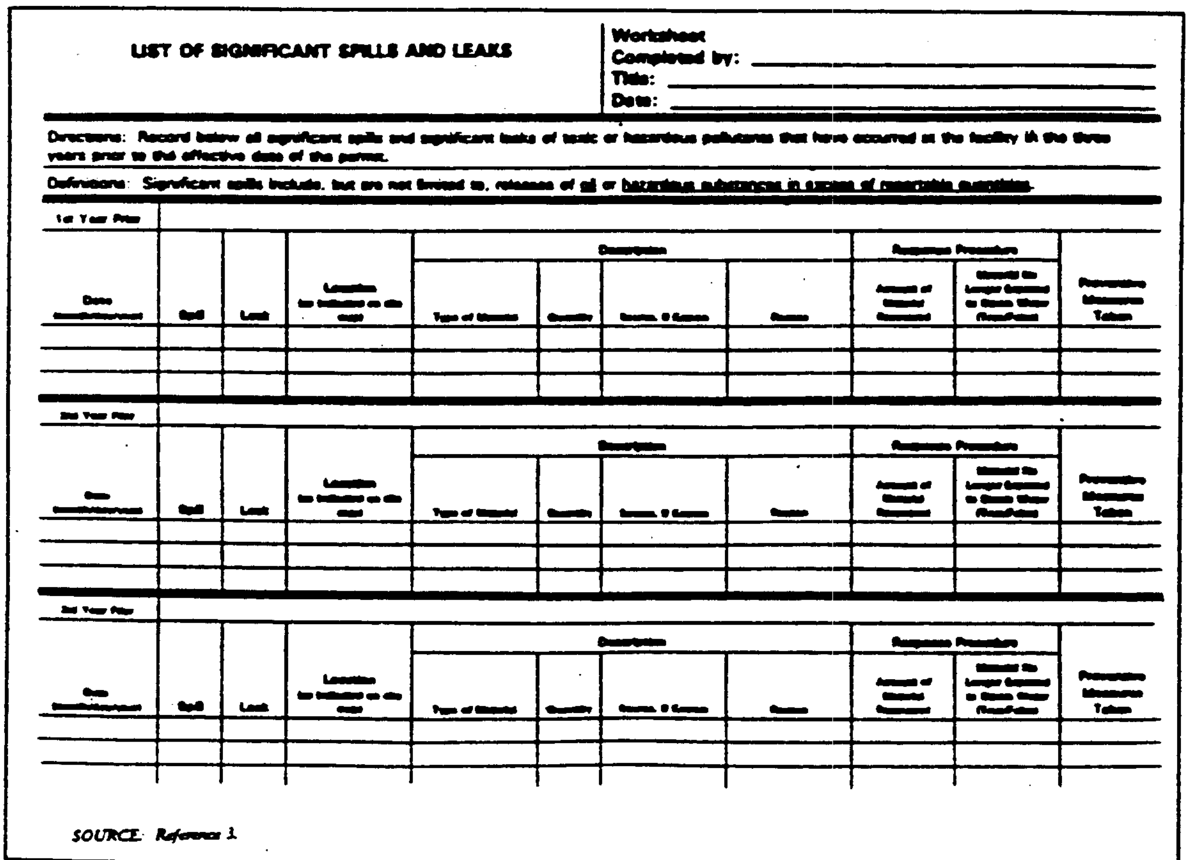

FIGURE 1: SAMPLE WORKSHEET FOR TRACKING SPILLS AND LEAKS

MAINTENANCE

The key to a proper maintenance program for record keeping is continual updating. Records should be updated with the correct name and address of the facility, name and location of receiving waters, number and location of discharge points, principal product and significant changes in raw material storage outside, and reports of monitoring results and spills at the site. It is recommended that all reports be maintained for a period of at least five years from the date of sample observation, measurement, or spill report. Some simple techniques used to accurately document and report results include:

- Field notebooks
- Timed and dated photographs
- Videotapes
- Drawings and maps
- Computer spreadsheet and database programs

COSTS

Costs associated with implementing a record keeping system are those associated with additional staff hours to initially develop the system and to keep records up to date, along with related overhead costs. Annual costs can be estimated using the example shown in Table 1 below. Figure 4 can be used as a worksheet to calculate the estimated annual cost for a record keeping system.

TABLE 1: EXAMPLE OF ANNUAL RECORD KEEPING COSTS

Title	Quantity		Avg. Hourly Rate ($)		Overhead* Multiplier		Estimated Yearly Hours on SW Training		Est. Annual Cost ($)
Stormwater Engineer	1	x	15	x	2.0	x	20	=	600
Plant Management	5	x	20	x	2.0	x	10	=	2,000
Plant Employees	100	x	10	x	2.0	x	5	=	10,000
			TOTAL ESTIMATED ANNUAL COST						$12,600

Note: Defined as a multiplier (typically ranging between 1 and 3) that takes into account those costs associated with payroll expenses, building expenses, etc.

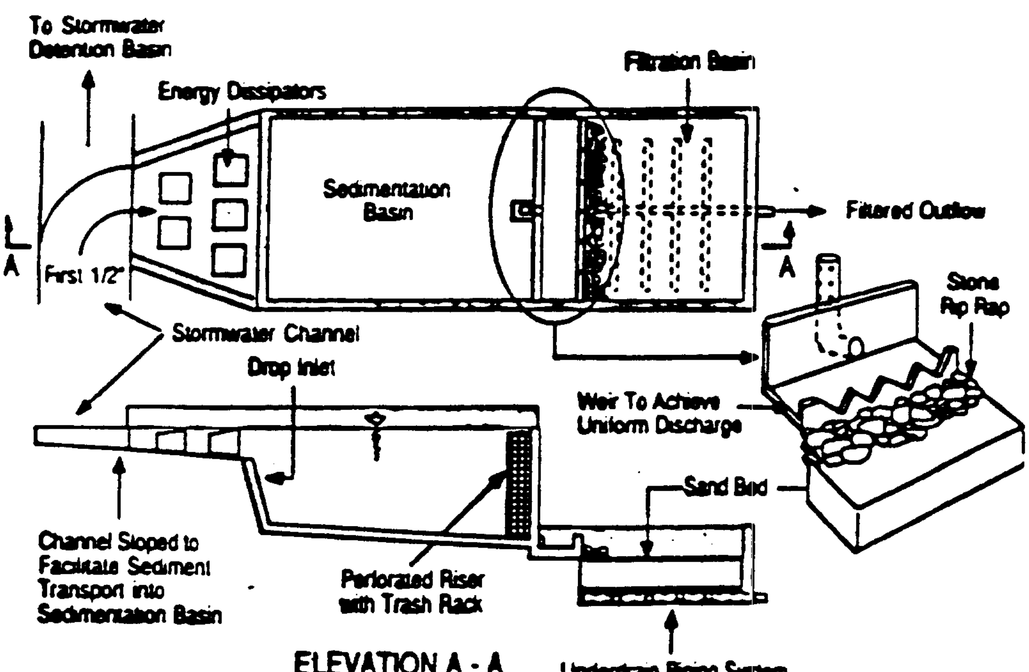
STORM WATER BMP: SAND FILTERS

MTB
Office of Wastewater Management
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Sand filters are most often designed for storm water quality control and generally provide limited storm water quantity management. A typical sand filter system consists of at least two chambers or basins with one designed for sedimentation and one for filtration. The first chamber, the sedimentation chamber, removes floatables and heavy sediments. The second chamber, the filtration chamber, removes additional pollutants by filtering the runoff through a sand bed. The treated filtrate normally is discharged through an underdrain system to a storm drainage system or directly to surface waters. Sand filters can achieve high removal efficiencies for sediment, biochemical oxygen demand (BOD) and fecal coliform bacteria. However, total metals removal is moderate and nutrient removal is often low.

There are three main sand filter designs currently in common use: the Austin sand filtration system (Figure 1a), the Washington, D.C. sand filter (Figure 1b) and the Delaware sand filter (Figure 1c). The primary differences in these designs are location (i.e., underground or surface and on-line or off-line), drainage area served, filter surface areas, land requirements, and quantity of runoff treated.

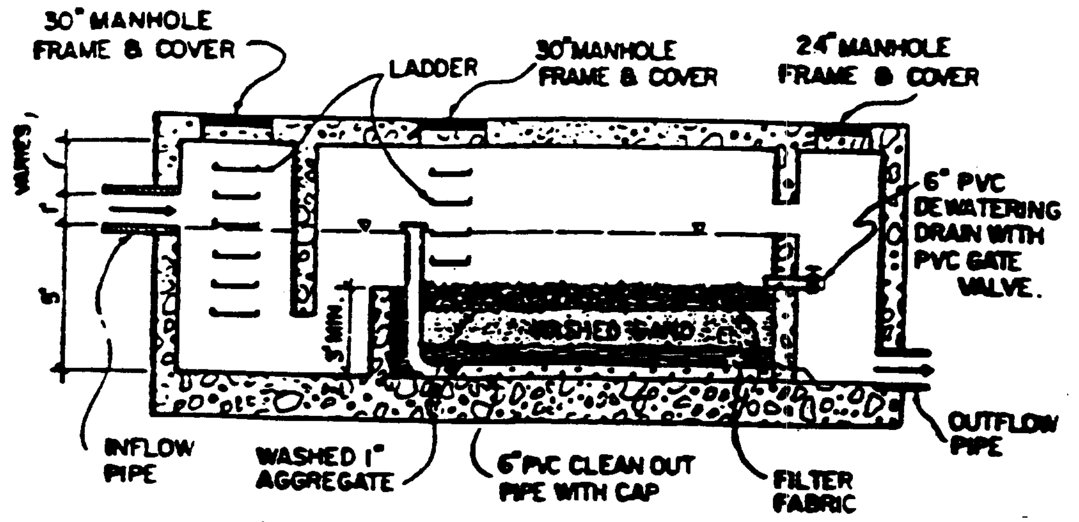


SOURCE: Reference 2

FIGURE 1a: TYPICAL AUSTIN SAND FILTER DESIGN

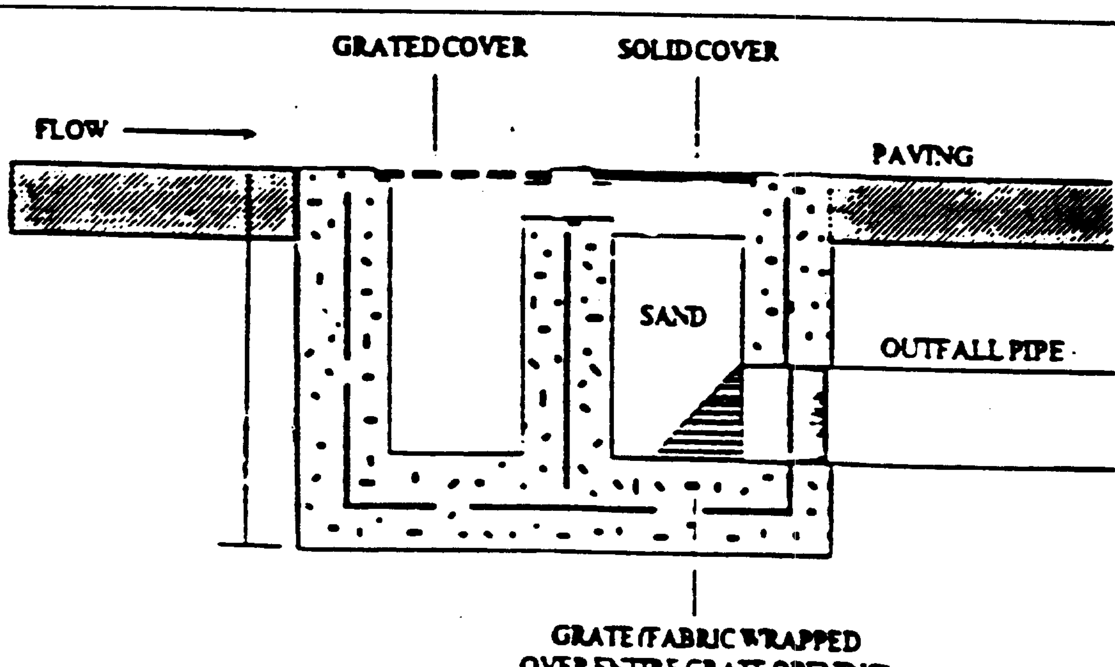
COMMON MODIFICATIONS

Modifications that may improve sand filter design and performance are being tested. One modification is the addition of a peat layer in the filtration chamber. The properties and characteristics of the peat may increase the microbial growth within the sand filter and improve pollutant (e.g., metals and nutrients) removal rates. Another design variation, which is included in the Washington, D.C. sand filter design, includes an underdrain that is extended above the sand filter layer. This allows for backwashing of the filter when it becomes clogged.



SOURCE: Reference 3

FIGURE 1b: TYPICAL WASHINGTON, DC SAND FILTER DESIGN



SOURCE: Reference 1

FIGURE 1c: TYPICAL DELAWARE SAND FILTER DESIGN

CURRENT STATUS

Sand filters are currently in use in the State of Delaware; and the Cities of Austin, Texas; Alexandria, Virginia; and Washington, D.C. Studies on the pollutant removal efficiencies are currently being performed for the Washington, D.C. and the Austin sand filters. However, additional evaluations need to be conducted in other locations and on alternative designs and media.

APPLICATIONS

In general, sand filters are preferred over infiltration practices, such as infiltration trenches, when groundwater contamination is of concern due to high ground water tables or in areas where underlying soils are unsuitable. In most cases, sand filters can be constructed with impermeable basin or chamber bottoms to collect, treat, and discharge runoff to a storm drainage system or directly to surface water without the contaminated runoff coming into contact with the groundwater.

The selection of the type of sand filter depends largely on the drainage area characteristics. For example, the Washington, D.C. and Delaware sand filter systems are well suited for highly impervious areas where land availability for structural controls is limited. Both the Washington, D.C. and Delaware sand filter designs are intended for underground installation. These sand filters are often used to treat runoff from parking lots, driveways, loading docks, service stations, garages, airport runways/taxiways, and storage yards. The Austin sand filtration system is more suited for larger drainage areas with both impervious and pervious surfaces. This system is located at grade and is often used at transportation facilities, large parking areas and commercial developments.

All three types of sand filters can generally be used as alternatives for water quality inlets, which are more frequently used to treat oil and grease contaminated runoff from drainage areas with heavy vehicle usage. In climatic zones where evaporation exceeds rainfall, the Austin sand filtration systems can also be used as an alternative to wet ponds for treatment of contaminated storm water runoff. In high evaporation zones, wet ponds will not likely be able to maintain the required permanent pool unless there is adequate baseflow from the groundwater.

LIMITATIONS

The size and characteristics of the drainage area as well as the pollutant loading will greatly influence the effectiveness of the sand filter system. In some cases other best management practices (BMPs), such as wet ponds, may be less costly for sites with large drainage areas and should also be considered if removal of nutrients and metals is required. Drainage areas with heavy sediment loads may result in frequent clogging of the filter. The lack of maintenance to the clogged filters will limit the performance. Certain climatic conditions may also limit the performance of the filters. For example, it is not known how well sand filters will operate in colder climates where sustained freezing conditions are encountered.

PERFORMANCE

Particulates are removed by both sedimentation in the sedimentation chamber and by filtration in the filtration chamber. The City of Austin has estimated pollutant removal efficiencies (Austin, 1988) based on preliminary findings of the City's storm water monitoring program. The estimates shown in Table 1 below, are average values for various sand filters serving several different size drainage areas.

As shown in Table 1, no removal of nitrate was observed in the preliminary findings. The removal of other dissolved pollutants was not monitored. Additional monitoring is currently being performed by the City of Austin to supplement the preliminary estimates.

LONGEVITY

There have been a number of concerns raised about the long term effectiveness of sand filter systems. Proper design and maintenance are critical factors in maintaining the useful life of any filter system. The life of the filter media may be increased by a number of methods including: stabilizing the drainage area so that sediments loadings in the runoff are minimized; placing a sedimentation chamber that removes sediments prior to the filtration chamber; providing adequate detention times for sedimentation and filtration to occur; and frequently inspecting and maintaining the sand filter to ensure proper operation. In some cases, replacement of the filter media may be required every 3 to 5 years. The useful life of the media will depend on the pollutant loading to the filter and the design and maintenance of the system.

TABLE 1: TYPICAL POLLUTANT REMOVAL EFFICIENCY

Pollutant	Typical Percent Removal
Fecal Coliform	76
Biochemical Oxygen Demand (BOD)	70
Total Suspended Solids (TSS)	70
Total Organic Carbon (TOC)	48
Total Nitrogen (TN)	21
Total Kjeldahl Nitrogen (TKN)	46
Nitrate as Nitrogen (NO_3-N)	0
Total Phosphorus (TP)	33
Iron (Fe)	45
Lead (Pb)	45
Zinc (Zn)	45

SOURCE: Reference 4

DESIGN CRITERIA

Typically the Austin sand filter system is designed to handle runoff from drainage areas up to 50 acres. The collected runoff is first diverted to the sedimentation basin, where heavy sediments and floatables are removed. There are two designs for the sedimentation basin: the full sedimentation system, as shown in Figure 1a, and a partial sedimentation system, where only the initial flow is diverted. Both systems are located off-line and are designed to collect and treat the first 0.5 inch of runoff. The partial system has the capacity to hold only a portion (at least 20%) of the first flush volume in the sedimentation basin, whereas the full system captures and holds the entire flow volume. Equations that are used to determine the sedimentation basin surface areas (A_s) in acres are shown in Table 2 below.

TABLE 2: SURFACE AREA EQUATION FOR THE AUSTIN SAND FILTER SYSTEM

Partial Sedimentation	Full Sedimentation
$A_s = (A_D)(H)/(1/D_s - 1/10)$	$A_s = (A_D)(H)/10$
$A_f = (A_D)(H)/10$	$A_f = (A_D)(H)/18$

Note:
D_s (feet) = depth of the sedimentation basin;
H (feet) = depth of rainfall, 0.042 ft (0.5 inches); and
A_D (acres) = impervious and pervious areas that provide contributing drainage.

SOURCE: Reference 4

Flow is conveyed from the sedimentation basin either through a perforated riser, gabion wall, or berm to the filtration basin. The filtration basin consists of an 18-inch layer of sand 0.02 to 0.04 inch in diameter that may be underlain with a gravel layer. Equations that are used to determine the filtration basin surface areas (A_f) in acres are also shown in Table 2. The filtrate is discharged from the filtration basin through underdrain piping 4 to 6 inches in diameter with 3/8-inch perforations. Filter fabric is placed around the underdrain piping to prevent sand and other particulates from being discharged.

Typically the Washington, D.C. sand filter system is designed to handle runoff from completely impervious drainage areas of 1 acre or less. The system, as shown in Figure 1b, consists of three chambers: a sedimentation chamber, a filtration chamber, and a discharge chamber. The reinforced concrete chambers are located underground. The sand filter system is designed to accept the first 0.5 inch of runoff. Coarse sediments and floatables are removed from the runoff within the sedimentation chamber. Runoff is discharged from the sedimentation chamber through a submerged weir, where it then enters the filtration chamber. The filtration chamber consists of a combination of sand and grave layers totaling 3 feet in depth with an underdrain system wrapped in filter fabric. The underdrain system collects the filtered water and discharges it to the third chamber, where the water is collected and discharged to a storm water channel or sewer system. An overflow weir is located between the second and third chambers to bypass excess flow. The Washington, D.C. sand filter is often constructed on-line, but can be constructed off-line. When the system is off-line the overflow between the second and third chambers is not included.

The Delaware sand filter, as shown in Figure 1c, is similar to the Washington, D.C. sand filter; both utilizing underground concrete vaults. However, the Delaware sand filter has two chambers: a sedimentation chamber and a filtration chamber. A 1-inch design storm was selected for the sizing of the sedimentation basin because it is representative of most frequent storm events. In Delaware, 92% of all storms are less than 1 inch in depth. Runoff enters the sedimentation chamber through a grated cover and then overflows into the filtration chamber, which contains a sand layer 18 inches in depth. Gravel is not normally used in the filtration chamber, although the filter can be modified to include gravel. Typical systems are designed to handle runoff from drainage areas of 5 acres or less. A major advantage of the Delaware sand filter is its shallow structure depth of only 30 inches, thereby reducing excavation requirements.

MAINTENANCE

All filter system designs must provide adequate access to the filter to perform the required inspection and maintenance. The sand filters should be inspected after all storm events to verify that they are working as designed. Since the D.C. and Austin sand filter systems can be relatively deep, they may be designated as confined spaces, therefore, require compliance with confined space entry safety procedures.

Typically, sand filters begin to experience clogging problems within 3 to 5 years (NVPDC, 1992). Accumulated trash, paper and debris should be removed from the sand filters every 6 months or as necessary to keep the filter clean. A record should be kept of the dewatering times for all sand filters to determine if maintenance is necessary. Corrective maintenance of the filtration chamber includes removal and replacement of the top layers of sand, gravel and/or filter fabric that have become clogged. The removed media may usually be disposed of in a landfill. The City of Austin has tests their waste media before disposal. Results thus far indicate that the waste media is not toxic and can be safely landfilled (Schueler, 1992). Sand filter systems may also require the periodic removal of vegetative growth.

COSTS

The construction cost for an Austin sand filtration system is approximately $17,750 (1993 dollars) for a 1-acre drainage area. The cost per acre decreases with increasing drainage area. For example the cost for a 15-acre site is approximately $3,300 (1993 dollars) per acre for a total of $49,500 (Austin, 1990b). The cost for precast Washington, D.C. sand filters with drainage areas of less than 1 acre ranges between $6,300 and $10,500. This is considerably less than the cost for the same size cast-in-place system of approximately $26,400 (D.C., 1992). Costs for the Delaware sand filter are similar to that of the D.C. system, except the excavation costs are generally lower, because of the filters shallower depth.

Annual costs for maintaining sand filter systems averages about 5 percent of the initial construction cost (Schueler, 1992). Media replacement is performed as needed. Currently the sand is being replaced in the D.C. filter systems about every 2 years. The cost to replace the gravel layer, filter fabric and top portion of the sand for D.C. sand filters is approximately $1,600 (D.C. 1992). The City hopes that improved maintenance procedures will extend the life of the filter media and reduce the overall maintenance costs.

ENVIRONMENTAL IMPACTS

The three types of sand filters achieve high removal efficiencies for sediment, BOD and fecal coliform bacteria and generally require less land than other BMPs, such as ponds or wetlands. Sand filters constructed with impermeable basin liners limit the potential for groundwater contamination. Sand filters generally do not provide storm water quantity control and, therefore, do not prevent downstream stream bank and channel erosion. Sand filters may also be of limited value in some applications because of their traditionally low nutrient removal and metals removal capabilities. Waste media from the filters does not appear to be toxic and is environmentally safe for landfill disposal.

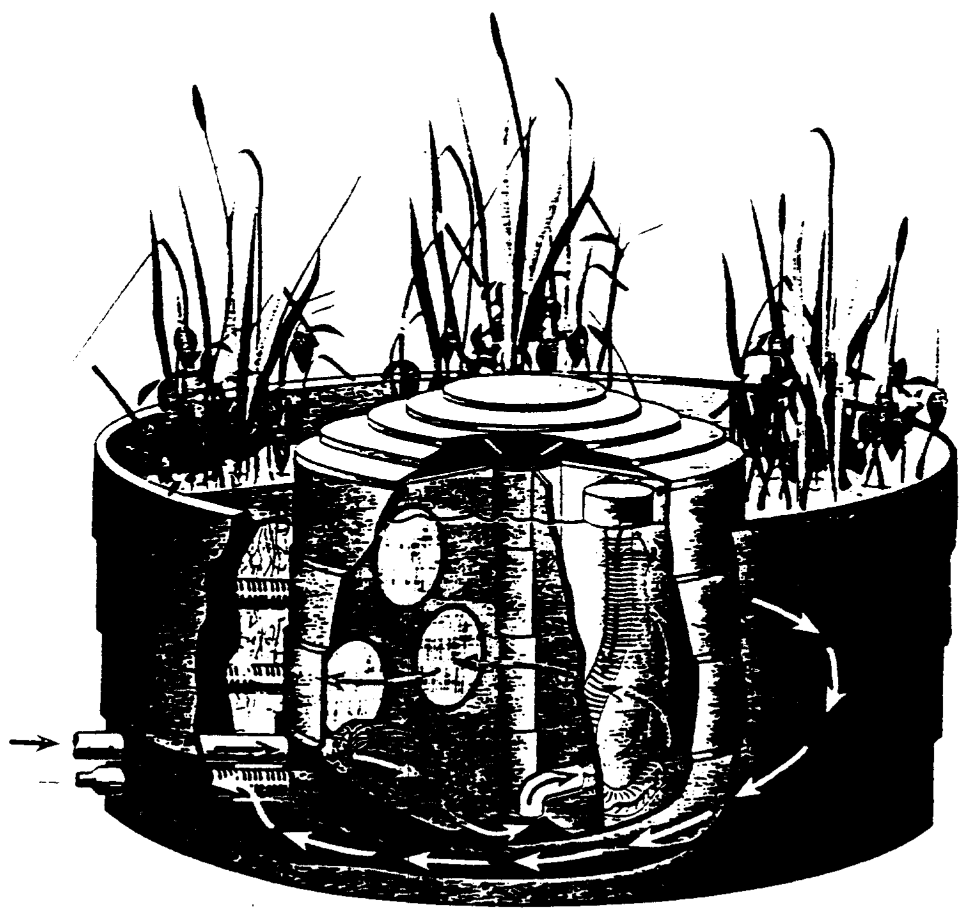
STORMWATER BMP:
STORMTREAT™ SYSTEM

DESCRIPTION

The STORMTREAT™ System (STS), developed in 1994, is a stormwater treatment technology consisting of a series of sedimentation chambers and constructed wetlands which are contained within a modular, 9.5-foot diameter recycled-polyethylene tank. The STS is shown in Figure 1. Influent is piped into the sedimentation chambers where pollutant removal processes such as sedimentation and filtration occur. Stormwater is conveyed from the sedimentation chambers to a fringing constructed wetland where it is retained for five to ten days prior to discharge. Unlike most constructed wetlands for stormwater treatment, the stormwater is conveyed into the subsurface of the wetland and through the root zone. It is within the root zone that greater pollutant attenuation occurs through processes such as filtration, adsorption, and biochemical reactions.

FIGURE 1 STORMTREAT™ SYSTEM



Source: StormTreat Systems, Inc.

COMMON MODIFICATIONS

The STS design allows for modifications when the system is installed in areas with high groundwater levels or in areas tidally affected. In areas with high groundwater, modifications to the discharge pipe work can be made so that runoff is discharged to a remote downgradient area with a lower water table level. In tidally influenced areas, a check valve can be installed to prevent flow from reentering the unit from its discharge point after the flow has discharged and allow discharge only during mid to low tide conditions. The valve would be adjusted for higher than normal flow velocities (those velocities used with a non-tidally influenced unit) so that the system maintains an average holding time of five to ten days.

The manufacturers of the system indicate that the STS could be used throughout the US, with only minor modifications to the system to make it effective in different geographical areas. In cold climates, where the 4 foot height unit would be installed above the frost line, modifications may be necessary to prevent the water within the tank from freezing. Adding a greenhouse to cover the system or insulating the subgrade tank may prove to be effective.

Modifications may also be necessary in an arid region due to insufficient water to support the wetland vegetation. In these areas the unit could be modified to discharge the flow at a slower rate which would increase the water retained in the bottom of the unit. Soils that retain water more efficiently could also be used. Alternately, the unit could have an alternate water supply for the extended dry periods.

CURRENT STATUS

An STS has been installed in Kingston, Massachusetts (MA) and has been operational since November 1994. The need for a stormwater treatment system in this area became evident as increased bacteria levels caused the closing of shellfish beds in the Jones River. Additional systems are planned for installation in Gloucester, MA, Harwich, MA, and Waltham, MA. Two systems will be installed in Gloucester to help mitigate impacts to the downstream shellfish beds which have also been identified as having high counts of fecal coliform bacteria. The system planned for installation in Harwich will treat polluted runoff from the town landing prior to discharge to Wychmere Harbor, a scenic boating harbor on Cape Cod. A system will be installed at GTE in Waltham during the Fall of 1995. The industrial complex is located in a sensitive watershed. The system will collect rooftop runoff and runoff from a parking lot. If these installed systems prove to be cost effective, there are additional needs in Massachusetts where 40 percent of the shellfish beds have been closed due to high levels of metals and bacteria.

APPLICATIONS

The STS has applications in a wide range of settings. The system's size and modular configuration make it adaptable to a wide range of site constraints and watershed sizes. Designers of the system indicate that the system can be used to treat runoff from highways, parking lots, airports, marinas, and commercial, industrial and residential areas. The STS is an appropriate stormwater treatment technology for both coastal and inland areas.

LIMITATIONS

As discussed previously, the STS is relatively new and untested in different geographical locations. There may be possible limitations in these areas. Soil types surrounding the modular unit will not limit the system's effectiveness nor will high water tables.

PERFORMANCE

Preliminary monitoring results from four sets of samples collected in November 1994, December 1994, and February 1995 indicate removal rates of 94% for total coliform bacteria, 83% for fecal coliform bacteria, 95% for total suspended solids, and 90% for total petroleum hydrocarbons, as shown in Table 1. Preliminary nutrient removal rates have been determined to be 44% for total dissolved nitrogen, 89% for total phosphorus (TP), and 32% for ortho-phosphorus. Total nitrogen (TN) performance data are not available at this time; however, the manufacturer of the system indicates that they should be high based on the results of other wetland systems where particulates, and therefore TN, are removed. Removal rates are anticipated to increase as the wetland vegetation becomes more established and during warmer months. The pollutant removal rates achieved by the system for other pollutants are as follows: 65% for lead, 98% for chromium, and 90% for zinc.

TABLE 1 STORMTREAT™ MONITORING RESULTS

Pollutant	Percentage Removed
Total Coliform Bacteria	94
Fecal Coliform Bacteria	83
Total Suspended Solids	95
Chemical Oxygen Demand	75
Total Dissolved Nitrogen	44
Total Phosphorus	89
Ortho-phosphorus	32
Total Petroleum Hydrocarbons	90
Lead	65
Chromium	98
Zinc	90

DESIGN CRITERIA

The STS is a modular, 9.5-foot diameter recycled-polyethylene tank containing a series of sedimentation chambers and constructed wetlands. The sedimentation chambers are in the inner ring of the tank, which has a diameter of nearly 5.5 feet. The 9.5 feet diameter outer ring, which surrounds the sedimentation chambers, contains the wetland. The tank walls and bulkheads, which separate the sedimentation chambers, have a height of 4 feet.

The STS tanks are designed to withstand the hydrostatic pressures that result from the saturated soils surrounding the tanks. The STS unit connects to existing catch basins with PVC piping. Influent is conveyed through the PVC piping to the first of six internal sedimentation chambers. The 4 inch diameter inlet pipe is covered with a burlap sack that traps larger particles and debris. Synthetic screens and woven geotextiles placed within the bulkheads filter the flow as it passes into the succeeding chamber. Flow is conveyed through larger mesh sizes in the first series of sedimentation chambers, followed by smaller mesh sizes in the remaining sedimentation chambers. In addition to the filter screens, skimmers have been installed in the tanks. Skimmers replace the previously used screens and combination of screens and skimmers. The screens and skimmers perform the same pollutant removal mechanism; however, the screens require more maintenance than the skimmers. The skimmers float on the water surface within each chamber and have an opening 6 inches below the surface through which flow is conveyed to the following tank. Sediments which collect in the bottom of the chamber remain in that chamber until the unit is maintained. The skimmers prevent sediment from being conveyed to the subsequent chamber. The bulkhead separating the last two sedimentation chambers is fitted with an inverted elbow which traps oil and grease within the fifth chamber. The elbow is located approximately 10 inches from the chamber bottom.

Flow is conveyed from the sedimentation chamber through four, 4 inch diameter, PVC, slotted outlet pipes into the wetland portion of the STS. Stormwater flows subsurface through the length of the wetland, which has a length of 23 feet, width of 2.4 feet, and contains 3 feet of gravel and sand. The gravel used at the Kingston facility is 1/4 inch rice stone and 3/8 inch bluestone. The weight of the gravel provides the force that counteracts the buoyancy forces that would be present at a high water table site. The wetland has an approximate storage capacity of 760 gallons. The entire system has a capacity of 1,390 gallons.

Vegetation within the wetland will vary depending on the local, naturally occurring wetland vegetation and the maximum expected root depth of the plant. Bulrush and burreeds have been used in Massachusetts and have maximum root depths of 2.6 and 2 feet, respectively (USEPA, 1993). Mature vegetation should have roots that extend into the permanent 6 inches of water in the bottom of the tank. Insufficient root depth may result in a lack of water supply to the plants during the periods between storm events.

Effluent from the wetland is discharged through a 2 inch diameter pipe that is controlled by a valve. Flow rates and holding times can be varied by manipulating the outlet control valve. At the Kingston facility, the control valve is adjusted to provide for a recommended discharge rate of 0.2 gal/min. and a 5-day holding time in the wetland. The valve has an added benefit that in the event of an upstream toxic spill the valve can be closed and the pollutants will be trapped in the STS.

Tanks are available in one size but multiple tanks can be installed at a site to capture the volume of runoff from the site. The size of the tank was selected so that the prefabricated tanks could be transported without requiring conformance to oversized load regulations. The determination of the number of tanks needed for a site is based on three factors:

- Area of impervious drainage surfaces;
- Design storm to be treated; and
- Detention storage prior to the STS tanks.

To capture and treat the first 0.25 inches of runoff from a one acre, completely impervious drainage area, the designers of the system estimate that two tanks would be required when preliminary detention is provided and five tanks when it is not. For a design storm of 0.5 inches, four tanks are required with preliminary detention and ten tanks without preliminary detention. Preliminary detention may be provided in the drainage pipes and catch basins which convey flow to the STS. In some instances, settling tanks may be located upstream that detain the runoff. A typical site would require 100 ft^2 per tank, which includes sufficient space for the tank and access to the tank for maintenance.

MAINTENANCE

Anticipated maintenance of the STS is minimal. The system should be observed at least once a year to be sure that it is operating effectively. At that time the burlap sack that covers the influent line should be removed and replaced. If the system installed uses filters, these should be removed, cleaned, and reinstalled. Sediment should be removed from the system once every 2 to 3 years, unless the system has higher than normal sediment loads. After six months of operation the unit installed in Kingston, MA was found to have 2 inches of accumulated sediment. The sediment can be pumped from the tank by septic haulers or by maintenance personnel responsible for sediment removal from catchbasins. It is not anticipated that the sediment will be toxic and may be safely landfilled. However, sediment toxicity will depend on the activities in the contributing drainage area and testing of the sediment may be required to determine if it should be considered hazardous.

COSTS

The STS is a prefabricated unit that is easily installed in most locations. Installation time for a normal site (i.e., bedrock not encountered) is approximately four man-days. This time includes both site preparation and installation. The estimated cost for one installed tank is $3,600 to $4,000, which includes the site work, tank, skimmers, gravel, wetland plants, external PVC piping, and installation by the manufacturer. Costs of systems that have been installed or are planned for installation have been lower that the estimated costs due to the municipalities providing the site preparation at no charge. The higher end of the cost range may be encountered if complications with site preparation occur. Capital and installation costs decrease as the number of units on a site increases. The cost for a system installed by the manufacturer and consisting of four tanks is approximately $15,000. The four tank system would effectively treat a one acre, completely impervious drainage area with preliminary detention designed to capture the first 0.5 inches of runoff.

The estimated maintenance cost for removal of sediment from one tank ranges from $100 to $150. This cost is incurred every two to three years when sediment removal is necessary. Costs have not been determined for an annual site inspection and removing any debris and leaves from the wetland area. However, these costs should be minimal (i.e., one day of labor for one person).

ENVIRONMENTAL IMPACTS

Systems have been installed in Massachusetts due to the increased bacteria levels resulting in the closing of shellfish beds. Regulators and environmental groups in Massachusetts are concerned over the closing of 40 percent of the shellfish beds in the state and are utilizing stormwater management practices, including the STS, to improve the water quality in the downstream beds. The STS also protects the groundwater by removing pollutants prior to infiltration. The STS has shown high TPH, TP, metals, and suspended solids removal rates, which improves water quality. An additional benefit of the STS is the system's spill containment feature which results in capture of an upstream release, and therefore, lessens the impact from the spill on the environment.

STORM WATER BMP: SPILL PREVENTION PLANING

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

A Spill Prevention Plan identifies areas where spills can occur on site, specifies materials handling procedures, storage requirements, and identifies spill clean-up procedures. The purpose of this plan is to establish standard operating procedures, and the necessary employee training to minimize the likelihood of accidental releases of pollutants that can contaminate stormwater runoff. Spill Prevention is prudent from both an economic as well as environmental standpoint because spills increase operating costs and lower productive

Storm water contamination assessment, flow division, record keeping, internal reporting, employee training, and preventive maintenance are associated BMPs that should be incorporate into a comprehensive Spill Prevention Plan.

CURRENT STATUS

Typically, most businesses and public agencies that generate hazardous waste and/or produce, transport, or store petroleum products are required by state and federal law to prepare spill control and cleanup plans. Therefore, a Spill Prevention and Response Plan may have already been developed in response to other environmental regulatory requirements. Existing plans should be re-evaluated and revised if necessary to address stormwater management issues.

APPLICATIONS

A Spill Prevention Plan is applicable to facilities that transport, transfer, and store hazardous materials, petroleum products, and fertilizers that can contaminate stormwater runoff. An important factor of an effective spill prevention plan is quick notification of the appropriate emergency response teams. In some plants each area or process may have a separate team leader and team of experts. Figure 1 below illustrates a sample spill prevention team roster for quick identification of team leaders and their responsibilities.

LIMITATIONS

Spill Prevention Planing can be limited by the following:

- Lack of employee motivation to implement plan.
- Lack of commitment from senior management.
- Key individuals identified in the Spill Prevention Plan may not be properly trained in the areas of spill prevention, response, and cleanup.

PERFORMANCE

Past experience has shown that the single most important obstacle to an effective Spill Prevention Plan is its implementation. Qualitatively, implementation of a well prepared Spill Prevention Plan should significantly decrease contamination of stormwater runoff.

FIGURE 1: SAMPLE SPILL PREVENTION TEAM ROSTER

DESIGN CRITERIA

General guidelines for the preparation of a Spill Prevention Plan include:

- The first part of the plan should contain a description of the facility including the owner's name and address, the nature of the facility activity, and the general types of chemicals used in the facility.

- The plan should contain a site plan showing the location of storage areas for chemicals, location of the storm drains, tributary drainage areas with drainage arrows, and the location and description of any devices to stop spills from leaving the site such as collection basins.

- The plan should describe notification procedures to be used in the event of a spill such as phone numbers of key personnel, and appropriate regulatory agencies such as local Pollution Control Agencies and the local Sewer Authority.

- The plan should provide specific instructions regarding cleanup procedures.

- The owner, through an internal reporting procedure, should have a designated person with overall responsibility for spill response. Through an employee training program, key personnel should be trained in the use of this plan. All employees should have basic knowledge of spill control procedures.

- A summary of the plan should be written and posted at appropriate points in the building (i.e., lunch rooms, cafeteria, and areas with a high spill potential), identifying the spill cleanup coordinators, location of cleanup kits, and phone numbers of regulatory agencies to be contacted in the event of a spill.

- Cleanup of spills should begin immediately. No emulsifier or dispersant should be used.

- In fueling areas, absorbent should be packaged in small bags for easy use and small drums should be available for storage of absorbent and/or used absorbent. Absorbent materials shall not be washed down the floor drain or into the storm sewer.

- Emergency spill containment and cleanup kits should be located at the facility site. The contents of the kit should be appropriate to the type and quantities of chemical or goods stored at the facility.

Some structural methods to consider when developing a Spill Prevention Plan include:

- Containment diking-- Containment dikes are temporary or permanent earth or concrete berms or retaining walls that are designed to hold spills. Diking can be used at any industrial facility, but is most common for controlling large spills or releases from liquid storage and transfer areas. Diking can provide one of the best protective measures against the contamination of stormwater because it surrounds the area of concern and holds the spill, keeping spill materials separated from the stormwater outside of the diked area.

- Curbing-- Like containment diking, curbing is a barrier that surrounds an area of concern. Because curbing is usually small-scale, it cannot contain large spills like diking can. However, curbing is common at many facilities and small areas where liquids are handled and transferred.

- Collection basins. Collection basins are permanent structures where large spills or contaminated stormwater are contained and stored before cleanup or treatment. Collection basins are designed to receive spills, leaks, etc., that may occur and prevent these materials from being released to the environment. Unlike containment dikes, collection basins can receive and contain materials from many locations across a facility.

Once a hazardous material spill occurs and is contained, the material has to be cleaned up and disposed of to protect plant personnel from potential health and fire hazards, and to prevent the release of the substance to surface waters. Methods of cleanup, recovery, treatment, or disposal include:

- Physical. Physical methods for cleanup of dry chemicals include the use of brooms, shovels, sweepers, or plows.

- Mechanical. Mechanical methods for cleanup include the use of vacuum cleaning systems and pumps.

- Chemical. Chemical cleanup of material can be accomplished with the use of sorbents, gels, and foams. Sorbents are compounds that immobilize materials by surface absorption or adsorption in the sorbent bulk. Gelling agents interact with the spilled chemical(s) by concentrating and congealing to form a rigid or viscous material more conducive to mechanical cleanup. Foams are mixtures of air and aqueous solutions of proteins and surfactant-based foaming agents. The primary purpose of foams is to reduce the vapor concentration above the spill surface thereby controlling the rate of evaporation.

- Create a map of the facility site to locate pollutant sources and determine stormwater management opportunities. This site map should include all surface waterbodies on or next to the site, and should also identify, if any that are in place. Tributary drainage areas with identification of flow direction should also bed identified during this mapping phase. Table 1 contains a list of features that should be indicated on the site map.

- Conduct a material inventory throughout the facility.

- Evaluate past spills and leaks.

- Identify non-stormwater discharges and non-approved connections to stormwater facilities.

- Collect and evaluate stormwater quality data.

- Summarize the findings of this assessment.

TABLE 1: CRITERIA FOR DEVELOPING A SITE MAP

DEVELOPING A SITE MAP	Worksheet Completed by: ____________ Title: ____________ Date: ____________

Instructions: Draw a map of your site including a footprint of all buildings, structures, paved areas, and parking lots. The information below describes additional elements

- All outfalls and storm water discharges
- Drainage areas of each storm water outfall
- Structural storm water pollution control measures, such as:
  - Flow diversion structures
  - Retention/detention ponds
  - Vegetative swales
  - Sediment traps
- Name of receiving waters (or if through a Municipal Separate Storm Sewer System)
- Locations of exposed significant materials
- Locations of past spills and leaks
- Locations of high-risk, waste-generating areas and activities common on industrial sites such as:
  - Fueling stations
  - Vehicle/equipment washing and maintenance areas
  - Area for unloading/loading materials
  - Above-ground tanks for liquid storage
  - Industrial waste management areas (landfills, waste piles, treatment plants, disposal areas)
  - Outside storage areas for raw materials, by-products, and finished products
  - Outside manufacturing areas
  - Other areas of concern (specify:________________)

SOURCE: Reference 1.

MAINTENANCE

A facility Spill Prevention Plan should be reviewed at least annually and following any spills to evaluat the Spill Prevention Plan's level of success and how it can be improved. Other times for significant review of the plan should be when a new material is introduced to the plant as a result of a processing modification, or when a change has occurred in a materials handling procedure.

COSTS

If a facility already has a Spill Control and Cleanup Plan in-place, modifications, to address stormwater contamination concerns, will require minimal cost. If a facility will be developing a Spill Prevention Plan for the first time, initial cost will depend on the type of materials at the facility, facility size, and other related parameters. Costs for structural containment devices will also need to be identified for each facility.

ENVIRONMENTAL IMPACTS

Preventing or containing spills, especially toxic or hazardous materials, is important in reducing storm water contamination and in maintaining the water quality of the receiving water.

STORM WATER BMP: CONTAMINATION ASSESSMENT

DESCRIPTION

A Stormwater Contamination Assessment (SWCA) provides a review of a facility and site to determine what materials or practices may be a source of contaminants to the stormwater. The purpose of the assessment is to help target the most important pollutant sources for corrective and/or preventive action.

A SWCA program is closely related to other BMP's, such as materials inventory, non-stormwater discharges, record keeping, and visual inspections. To be effective these, and other BMP's should be incorporated into a comprehensive pollution prevention program.

APPLICATIONS

A SWCA program is applicable to any industrial facility which contains areas, activities, or materials which may contribute pollutants to stormwater runoff from the total site. An assessment for stormwater purposes may also be applicable in situations where a formal site assessment for hazardous waste purposes is being performed.

LIMITATIONS

Limitations associated with a contamination assessment program include:

- Assessments need to be performed by qualified personnel.
- A corporate commitment must exist to reduce the contamination sources once discovered.
- Assessments need to be periodically updated.

PERFORMANCE

It is not possible, based on currently available data, to quantify the water quality benefits to receiving waters of a stormwater contamination assessment program. Results are entirely based on the severity of the contamination uncovered, and the corrective actions taken. Qualitatively, implementation of a program that identifies areas of high pollutant concentrations and eliminate or reduces their potential pollutant capabilities will result in positive water quality benefits.

DESIGN CRITERIA

A SWCA program should include the following key activities:

- Assess potential pollutant sources and associated high risk activities such as loading and unloading operations, outdoor storage activities, outdoor manufacturing or processing activities, significant dust or particulate-generating activities, and on-site waste disposal practices.

Once you have completed the above steps in your pollutant source assessment, you have enough information to determine which areas, activities, or materials are a risk towards contributing pollutants to stormwater runoff from your site. An important benefit is that by using this information, you car effectively select other cost-effective BMPs to prevent or control pollutants.

IMPLEMENTATION

In addition to identifying problems within the storm sewer system, it is even more important to prevent problems from developing at all, and to provide an environment in which future problems can be avoided. Thus, an effective stormwater assessment program should include implementation activities to insure success and follow-up activities to measure results. Keys to a successful implementation program should include:

- Public education, on organized systematic program of disconnecting commercial and industrial stormwater entries into the storm drainage system.
- Tackling the problem of widespread septic system failure.
- Disconnecting direct sanitary sewerage connections.
- Rehabilitating storm or sanitary sewers to abate contaminated water infiltration.
- Developing zoning and other ordinances.

In extreme cases, it may be that while it was thought that a community had a separate sanitary sewer system and a separate storm sewer system, in reality the storm sewer system is acting as a combined sewer system. In these cases, consideration should be given to the economic and practical advantages of designating the storm sewer system a combined sewer and applying end-of-pipe treatment to the entire system.

A SWCA program needs to be periodically updated. Updating is especially important upon the introduction of new raw materials or changes in processes at the site.

It is also important to establish parameters for measuring the success of the correction program. If results do not meet expectation, then reassessment and appropriate changes to the correction program should be made.

COSTS

Costs for the initial assessment may be high. However, by pinpointing high potential areas or activities a SWCA program may reduce overall costs associated with a complete BMP implementation program. The costs associated with an assessment program for stormwater are small when compared to or a part of a larger overall hazardous waste site assessment.

ENVIRONMENTAL IMPACT

A comprehensive SWCA program can eliminate pollution sources that can significantly impair receiving water quality.

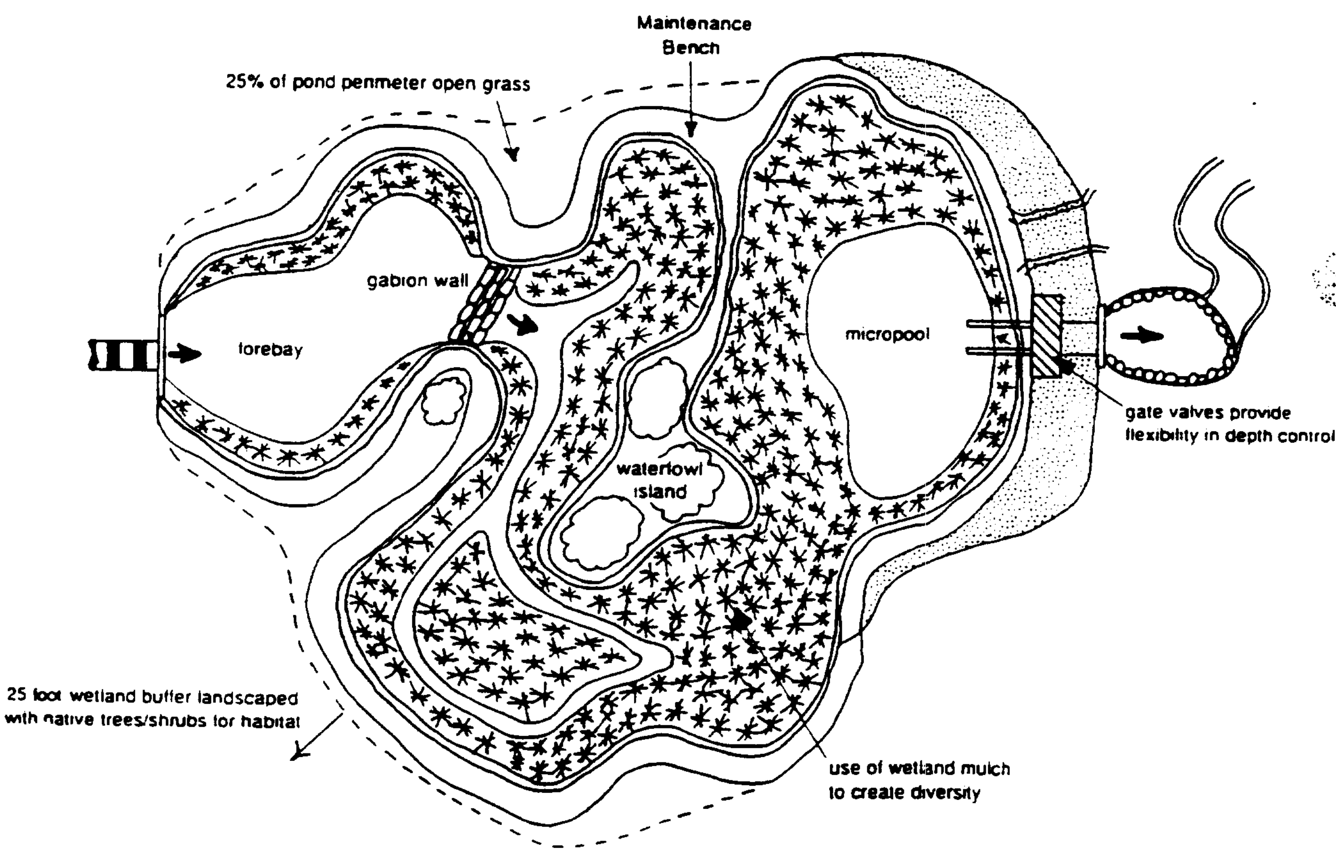
STORMWATER BMP:
STORMWATER WETLANDS

DESCRIPTION

Wetlands are those areas that are typically inundated with surface or ground water and support plants adapted to saturated soil conditions. A typical shallow marsh wetland is shown in Figure 1. Wetlands have been described as "nature's kidneys" due to the physical, chemical, and biological processes that occur in wetlands which result in transformation of some elements (e.g., nitrogen, sulfate) and filtration of others (Hammer, 1989). The natural pollutant removal capabilities of wetlands have brought increased attention to their usage as a stormwater best management practice (BMP).

FIGURE 1 SHALLOW MARSH WETLAND



Source: MWCOG, 1992.

Wetlands used for stormwater treatment can be constructed, incidental or natural. Incidental wetlands are those that were created as a result of previous development or human activities. The use of natural wetlands for stormwater treatment is discouraged by many and may not be an option. Some states, however, allow their usage but only in very restricted circumstances. For example, the State of Florida allows the use of natural wetlands that have been severely degraded or wetlands that are intermittently connected (flows when groundwater rises above ground level) to other waters (Livingston, 1994). Conversion of natural wetlands to stormwater wetlands are done on a case-by-case basis and require the appropriate state and federal permits (e.g., 401 water quality certification and 404 wetland permit).

Two types of constructed wetlands have been used successfully for wastewater treatment: the subsurface flow (SF) and the free water surface (FWS) constructed wetland. In the FWS wetland runoff flows through the soil lined basin at shallow depths. The wetland consists of a shallow pool planted with emergent vegetation (vegetation which is rooted in the sediment but the leaves are at or above the water surface). The SF wetland also has a basin, however, the basin contains a suitable depth of rock or gravel, through which the runoff is conveyed. The water level in a SF wetland remains below the top of the rock or gravel bed. Studies have indicated that the SF wetland is well suited for the diurnal flow pattern of wastewater, however, the peak flows from stormwater or combined sewer overflows (CSO) may be several orders of magnitude higher than the average flow. The cost for a gravel bed to contain the peak storm event would be very high, and therefore, preclude the use of SF wetlands for stormwater or CSO treatment. The remainder of this factsheet addresses the FWS constructed wetland or natural and incidental wetlands.

COMMON MODIFICATIONS

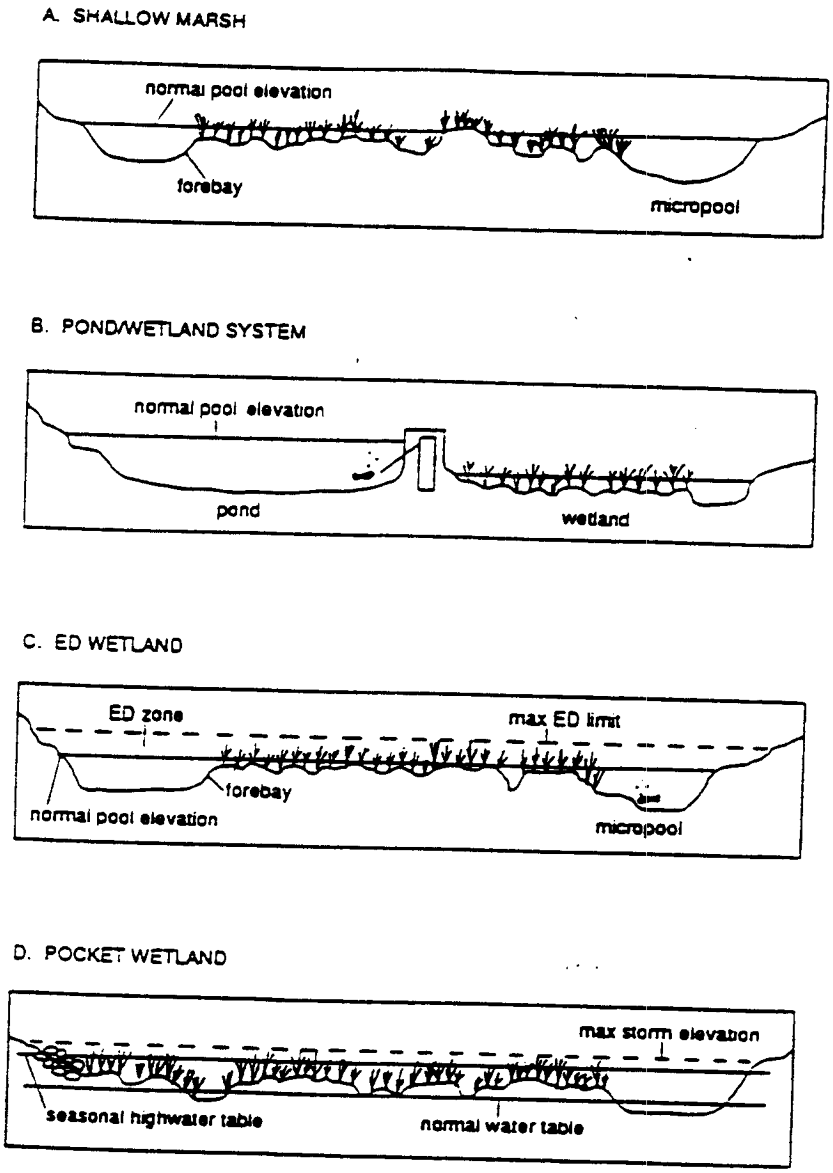
There are four basic designs of constructed wetlands: shallow marsh, pond/wetland system, extended detention (ED) wetland, and pocket wetland. The wetland designs, as shown in Figure 2, store runoff in a shallow basin vegetated with wetland plants. The selection of one design over the other will depend on various factors, including the land availability, level and reliability of pollutant removal, and size of contributing drainage area. The shallow marsh design requires the largest amount of land and a sufficient baseflow to maintain water within the wetlands. The marsh can be modified to include extra vertical runoff storage. This modified marsh system, known as the ED wetland, attenuates flows and relieves downstream flooding.

Another variation, the pond/wetland system, has two separate cells: one being a wet pond and the other a shallow marsh. The wet pond traps sediments and reduces velocities prior to runoff entry into the wetland. Land requirements for a pond/wetland system are less than for the shallow marsh system. Areas with insufficient land area for construction of a larger wetland system, may be appropriate sites for the fourth wetland design, a pocket wetland. Pocket wetlands have contributing drainage areas of 1 to 10 acres and usually will require excavation down to the water table in order to provide a reliable water source to the wetland. Unreliable water sources and fluctuating water levels result in low plant diversity and poor wildlife habitat value (MWCOG, 1992).

CURRENT STATUS

In the past the use of natural treatment processes occurring within wetlands has generally focused on the the treatment of wastewater. Wetlands for stormwater treatment have gained attention in recent years and many systems are now operational. Studies are ongoing to determine the effectiveness of wetlands, design modifications that improve their performance, and required maintenance to sustain their performance.

FIGURE 2 COMPARATIVE PROFILES OF FOUR STORMWATER WETLAND DESIGNS



Cross-sectional profiles of the four stormwater wetlands are not drawn to scale. In Panel A, the majority of the shallow marsh is devoted to shallow depths that support emergent wetland plants. The pond/wetland system (Panel B) is composed of deep and a shallow pool. In ED wetlands (Panel C), the runoff storage of the wetland is augmented by temporary, vertical ED storage. Pocket wetlands (Panel D) are excavated to the groundwater table to provide a more or less constant water elevation.

Source: MWCOG, 1992.

APPLICATIONS

Wetlands provide the benefit of stormwater quality control, with the option of achieving quantity control (e.g., extended detention wetland). Wetlands are one of the more reliable BMPs capable of removing pollutants and are adaptable to most locations in the US. Locations with existing wetlands used for stormwater treatment include, but are not limited to, Washington, California, Minnesota, Michigan, Illinois, Florida, Maine, Maryland, and Virginia. They have been used to treat runoff from agricultural, commercial, industrial, and residential areas.

LIMITATIONS

Urban settings and established communities may preclude the use of wetlands due to the large land requirement for the systems. The presence of trout, sculpins and other temperature sensitive fish species or aquatic insects located in downstream waters may also preclude the use of wetlands due to the stream warming that could occur within a wetland, especially during the warmer months. Communities may be opposed to a wetland due to their preconceived notion that wetlands will result in an infestation of mosquitoes and other nuisances. Communities may also be opposed due to the appearance of the wetlands. Wetlands, however, can be designed to be attractive and features (e.g., morphology, fish, and vegetation) can be added to decrease, if not eliminate, a problem with mosquitoes and other nuisances.

Limitations in pollutant removal may be experienced during the non-growing season and in localities with lower temperatures. Decreases in pollutant removal efficiency have been observed when wetlands are covered with ice or receive snowmelt runoff.

PERFORMANCE

Stormwater pollutant removal in wetlands is attributed to the physical, chemical, and biological processes that occur within the wetland. Chemical and physical assimilation mechanisms include sedimentation, adsorption, filtration, and volatilization. Sedimentation is the primary removal mechanism for pollutants such as suspended solids, particulate nitrogen, and heavy metals. The settling of the particulates is influenced by the velocity of the runoff through the wetland, the particle size, and turbulence. Sedimentation can be maximized by creating sheet flow conditions, slowing the velocities through the wetland, and providing morphology and vegetation conducive to settling. The vegetation and its root system will also decrease the resuspension of settled particles.

Adsorption is the process where pollutants attach to surfaces of suspended or settled sediments and vegetation. Adequate contact time between the surface and pollutant must be provided for in the design of the system for this removal process to occur. Pollutants removed by adsorption include metals, phosphorus, and some hydrocarbons.

Wetland plants act as filters for pollutants such as trash, debris, and other floatables. Filtration can be enhanced by slow velocities, sheet flow, and sufficient quantities of vegetation. The plants also increase the pollutant removal achieved through sedimentation, adsorption, and microbial activity by providing for an increased detention and contact time and a surface for microbial growth.

Volatilization plays a minor role in pollutant removal from wetlands. Pollutants such as oils, hydrocarbons, and mercury can be removed from the wetland via evaporation or by aerosol formation under windy conditions.

Biological processes that occur in wetlands result in pollutant uptake by wetland plants and algae. Emergent wetland plants uptake settled nutrients and metals through their roots. The process creates new sites in the sediment for pollutant adsorption. During the fall the above ground parts typically die back and the plants may potentially release the nutrients and metals back into the water column (MWCOG, 1992). Recent studies, however, indicate that most pollutants are stored in the roots of aquatic plants, rather than the stems and leaves (CWP, 1995). Additional studies are required to determine the extent of pollutant release during the fall die back.

Microbial activity contributes to the removal of nitrogen and organic matter. Nitrogen is removed by nitrifying and denitrifying bacteria and aerobic bacteria are responsible for the decomposition of the organic matter. Microbial processes require oxygen and can result in depleted oxygen levels in the top layer of wetland sediments. The low oxygen levels and the decomposed organic matter contribute to the immobilization of metals.

Soluble pollutants such as phosphorus and ammonia are partially removed by planktonic or benthic algae. The algae consume the nutrients and convert it into biomass. The biomass settles to the bottom of the wetland.

Evaluation of the removal effectiveness of wetlands is ongoing and limited data are currently available; however, some conclusions can be drawn from available preliminary data. The projected long term pollutant removal rates for constructed wetlands in the Mid-Atlantic Region as reported by MWCOG (1992) and Strecker (1995) are presented in Table 1. As shown, total suspended solids (TSS) and lead removal rates are anticipated to approach 75 percent. Lower removal rates are expected for nutrients and organic carbon. The removal rates will vary with the loadings to the wetland. Excessive pollutant loadings (e.g., suspended solids) may exceed the wetlands removal capabilities.

TABLE 1 PERFORMANCE OF STORMWATER WETLANDS (1)

Pollutant	Removal Rate
Total Suspended Solids	75 %
Total Phosphorus	45 %
Total Nitrogen	25 %
Organic Carbon	15 %
Cadmium (2)	70%
Copper (2)	40%
Lead	75%
Zinc	50%
Bacteria	2 log reduction

(1) Source: MWCOG, 1992
(2) Source: Strecker, 1995

Conclusions have been determined from studies performed on wetlands with regard to their effectiveness compared to other BMPs and construction practices that affect performance. Data indicate that the pollutant removal achieved with wetlands is similar to that achieved with conventional pond systems. Studies also indicate that constructed stormwater wetlands achieve higher pollutant removal rates than natural wetlands. This is likely due to the intricate design of the constructed systems and the continued monitoring and maintenance of the systems (MWCOG, 1992). The effectiveness of the wetland seems to improve after the first few years of use as the vegetation becomes established and organic matter accumulates in the wetland. During construction and excavation, many constructed wetlands lose organic matter in the soils. The organic matter provides exchange sites for pollutants, and therefore, plays an important role in pollutant removal. Replacing or adding organic matter after construction improves performance.

LONGEVITY

Well designed wetlands can function as designed for 20 years or longer. Accumulated sediments will gradually cause a decrease in storage and performance, and therefore, should be removed as necessary or the water level in the wetland should be raised (e.g., adjust outlet to increase discharge elevation). Sediment forebays will decrease the accumulation of sediments within the wetland and increase the wetlands longevity.

DESIGN CRITERIA

Required local, state and federal permits should be established prior to wetland design with the appropriate regulatory authorities. Required permits and certifications may include 401 water quality certifications, 402 stormwater NPDES permit, 404 wetland permits, dam safety permits, sediment and erosion control plans, waterway disturbance permits, forest clearing permits, local grading permits, and land use approvals.

Prior to construction, a site should be selected that is appropriate for a wetland. The site must have an adequate water balance and appropriate underlying soils. This requires that the baseflow from the drainage area or groundwater is sufficient to maintain a shallow pool in the wetland and support the vegetation. Certain species are more susceptible to damage during dry periods. Underlying soils that are type B, C, or D will have relatively insignificant infiltration losses. High infiltration rates may be experienced at sites with type A soils or at sites underlain by karst, limestone, or fractured bedrock. These sites may require geotextile liners or a 6 inch layer of clay. After any necessary excavation and grading of the wetland at least 4 inches of soil should be applied to the site. This material may be the soil previously excavated or sand and other suitable material. The soils are needed to provide a substrate that the vegetation can become established in and anchor to. The substrate should be soft for ease of insertion of the plants.

The Metropolitan Washington Council of Governments (MWCOG) has made recommendations for the design of wetlands that require the designer to meet several basic sizing criteria. The volume of the wetland is determined as the quantity of runoff generated by 90 percent of the runoff producing storms. This volume will vary throughout the US due to the different rainstorms experienced. In the Mid-Atlantic Region, for example, the 1.25 inch storm is used as the sizing criterion. The imperviousness of a watershed will impact the runoff volume generated. The following equations are used to determine the treatment volume (Vt):

(1) $Rv = 0.05 + 0.009 (I)$

where:

Rv = storm runoff coefficient

I = percent site imperviousness

(2) $Vt = [(1.25)(Rv)(A)/12](43{,}560)$

where:

Vt = treatment volume (ft^3)

A = contributing area (acres)

Sizing criteria for wetlands vary with some states having their own methods. For example, shallow wetland basins constructed in Maryland are designed to maximize the surface area. The surface area should be a minimum of 3 percent of the area of the watershed draining to it. The preferred design would include extended detention, the volume of which is determined by detaining the 1-year storm for 24 hours. The Washington State Department of Ecology sizes wetlands using the runoff generated from the 6-month, 24-hour rainfall event.

Criteria are also established by MWCOG for the water balance, maximum flow path, allocation of treatment volume, minimum surface area, allocation of the surface area, and extended detention. The water balance, as discussed previously, must be adequate during dry weather to provide a baseflow and maintain the vegetation. The flow path should be maximized to increase contact time between the plants and sediments and the runoff. The recommended length to width ratio is 2:1. A ratio of greater than 1:1 should prevent short circuiting where runoff escapes treatment. Suggested allocation of treatment volumes, as shown in Table 2, are provided to improve removal efficiency. The minimum surface area requirement for shallow marshes established by MWCOG is that the wetland to watershed area ratio be greater than 2 percent. The remaining three wetland designs can have wetland to watershed ratios greater than 1 percent.

TABLE 2 GUIDELINES FOR ALLOCATING WETLAND SURFACE AREA AND TREATMENT VOLUME

Target Allocations	Shallow Marsh	Pond/Wetland	ED Wetland	Pocket Wetland
Percent of Surface Area (%)				
Forebay	5	0	5	0
Micropool	5	5	5	0
Deepwater	5	40	0	5
Low Marsh	40	25	40	50
High Marsh	40	25	40	40
Semi-Wet	5	5	10	5
Percent of Treatment (%) Volume				
Forebay	10	0	10	0
Micropool	10	10	10	0
Deepwater	10	60	0	20
Low Marsh	45	20	20	55
High Marsh	25	10	10	25
Semi-Wet	0	0	50	0

Source: MWCOG, 1992
Deepwater - 1.5 to 6 feet below normal pool
Low Marsh - 6 to 18 inches below normal pool
High Marsh - 0 to 6 inches below normal pool
Semi-Wet - 0 to 2 feet above normal pool (includes ED)

The wetland surface area is allocated to four different depth zones: deepwater (1.5 to 6 feet), low marsh (18 to 6 inches below normal pool), high marsh (up to 6 inches below normal pool), and semi-wet areas (above normal pool). The allocation to the various depth zones will create a complex internal topography. This is important because various wetland plants have different depth requirements, therefore the internal complexity should maximize plant diversity and increase pollutant removal. Allocation guidelines established by MWCOG are shown in Table 2. The State of Maryland requires that 75 percent of the shallow marsh should have depths less than 12 inches and the remaining 25 percent should have depths ranging from 2 to 3 feet. The 75 percent portion is additionally broken down so that 25 percent ranges from 6 to 12 inches and the remaining 50 percent is 6 inches or less.

Extending detention within the wetland increases the time for sedimentation and other pollutant removal processes to occur and also provides for attenuation of flows. Up to 50 percent of the wetland treatment volume can be added into the wetland system for extended detention. The ED elevation should not, however, exceed 3 feet above the normal pool elevation. This will prevent large fluctuations in the water level that could potentially harm the vegetation. The ED volume should be detained between 12 and 24 hours.

Sediment forebays are recommended to decrease the velocity and sediment loading to the wetland. The forebays provide additional benefits of creating sheet flow, extending the flow path, and preventing short circuiting. The volume of the forebay should be at least 10 percent of the wetland treatment volume and have a depth of 4 to 6 feet. The State of Maryland recommends a depth of at least 3 feet. The forebay is typically separated from the wetland by gabions or an earthen berm (MWCOG, 1992).

Flow from the wetland should be conveyed though an outlet structure that is located within the deeper areas of the wetland. Discharging from the deeper areas using a reverse slope pipe prevents the outlet from becoming clogged. A micropool can be constructed where the outlet structure is to be located that will also prevent outlet clogging. The micropool should contain approximately 10 percent of the treatment volume and be 4 to 6 feet deep. An adjustable gate controlled drain capable of dewatering the wetland within 24 hours should be located within the micropool. A typical drain may be constructed with an upward facing inverted elbow with its opening above the accumulated sediment. The dewatering feature eases planting and follow-up maintenance (MWCOG, 1992).

Vegetation can be established by one of five methods: mulching, allowing volunteer vegetation to become established, planting nursery vegetation, planting underground dormant parts of a plant, and seeding. Donor soils from existing wetlands can be used to establish vegetation within a wetland. This technique, known as mulching, has the advantage of quickly establishing a diverse wetland community. However, the types of species that grow within the wetland is unpredictable with mulching. Another unpredictable technique is allowing the species to voluntarily become established. Wind and waterfowl provide volunteer species to wetlands. Volunteer species are usually well established within 3 to 5 years. Wetlands established with volunteers are usually characterized by low plant diversity with monotypic stands of exotic or invasive species. A higher diversity wetland can be established when nursery plants or dormant rhizomes are planted. Planting of the vegetation from a nursery should take place during the growing season and not during late summer and fall. Planting during the growing season gives the vegetation time to store up food reserves in the underground parts for the dormant period. Underground parts of vegetation are planted during the plants dormant period, usually October through April, but the months will vary in the US due to local climate. Another planting technique, the spreading of seeds, has not been very successful, and therefore, is not widely practiced as a principal planting technique.

Selection of plant types will vary for different locations and climates. The designer of the wetland should select five to seven plants that grow native to the area and design the depth zones in the wetland to be appropriate for the type of plant and its associated maximum water depth. Approximately half of the wetland should be planted. Of the five to seven species selected, three should be aggressive plants or those that become established quickly. Examples of aggressive species used in the Mid-Atlantic Region include softstem bulrush (*Scirpus validus*) and common three-square (*Scirpus americanus*). Aggressive plants as well as other native wetland plants are available from numerous nurseries. Most vendors require an advance order of 3 to 6 months.

After wetland excavation and grading the wetland should be inundated and allowed to stand until planting. Six to nine months later, the wetland is typically surveyed, drained, and staked. The wetland is surveyed two weeks prior to planting to ensure that depth zones are appropriate for plant growth. Revisions may be necessary to account for any depths different from that originally excavated. Staking the site ensures that the planting crew spaces the plants within the correct planting zone. Planting zones are used to avoid mixing species and creating competition within the planted areas. The State of Maryland recommends planting two aggressive or primary species in 4 monospecific areas and planting an additional 40 clumps (one or more individuals of a single species) per acre of each primary species over the rest of the wetland. Three secondary species are planted close to the edge of the wetland at an application rate of 10 clumps of 5 individual plants per acre of wetland, for a total of 50 individuals of each secondary species per acre of wetland. At least 48 hours prior to planting, the wetland should be drained. At the completion of planting and within 24 hours the wetland should be re-flooded.

The wetland design should include a buffer to separate the surrounding land uses from the wetland. Buffers may alleviate some of the potential nuisances associated with the wetland, such as accumulated floatables or odors. MWCOG recommends a buffer of 25 feet from the maximum water surface elevation, plus an additional 25 feet when wildlife habitat is of concern. An enhanced wildlife habitat can be obtained if during construction the removal of existing forested areas is minimized. If removal is necessary, the buffer area should be reforested. The reforestation also decreases the potential for a goose pond due to their preference for open areas.

MAINTENANCE

The use of wetlands for stormwater treatment is relatively new, and therefore, specific guidelines on their maintenance have not been established. The wetlands will require monitoring, reinforcement planting, sediment removal, and possibly plant harvesting. Access should be incorporated in the design to facilitate these maintenance activities. Monitoring the wetland during the first three years is crucial to the performance of the wetland. Inspections should be conducted twice per year for the first three years, and on an annual basis thereafter. Reinforcement planting may be required during this time period if the original plants do not flourish in the wetland. The inspector should determine sediment accumulation within the wetland and also take note of the species distribution/survival, water elevations, and outlet condition. Water elevations can be raised or lowered by adjusting the outlet's gate valve if it is determined that plants are not receiving an appropriate water supply. The forebay will likely require sediment clean-out every three to five years. The design of the forebay should allow for it to be drained so that a skid loader or backhoe can be used to remove the accumulated deposits (MWCOG, 1992). Mowing of the embankment and maintenance bench should occur twice per year. Other areas surrounding the wetland will not require mowing.

Numerous studies have been performed to determine the toxicity of pond sediments and whether landfilling or land application can be accomplished without having to meet hazardous waste requirements. Studies to date have not found sediments to be hazardous. Therefore, on-site land application of the sediments away from the shoreline will most likely be the most cost effective disposal method. On-site disposal is preferred over off-site disposal due to the cost savings associated with transportation and off-site disposal fees. Wetlands that receive flow from a drainage area containing industry and activities associated with hazardous waste may contain toxic levels in the sediments and testing may be required for these sediments prior to land application.

COSTS

Costs incurred for stormwater wetlands include those for permitting, design, construction and maintenance. The permitting costs vary depending on state and local regulations, but it has been estimated that permitting and design costs are between 15 and 25 percent of the construction cost. Construction costs for an emergent wetland range from $12,000 to $20,000 per acre of wetland and for a forested wetland range from $20,000 to $40,000 per acre of wetland. These costs include the costs for clearing and grubbing, erosion and sediment control, excavating, grading, staking, and planting. The cost for constructing the wetland is largely dependant upon the amount of excavation required at a site. Maintenance costs are estimated at 10 to 15 percent per year of the construction costs (Bowers, 1995).

ENVIRONMENTAL IMPACTS

Benefits associated with stormwater wetlands include increased downstream water quality, wetland creation, enhancement of wildlife habitat, and flood attenuation. Water quality is improved due to the partial removal of suspended solids, metals, nutrients, and bacteria. The creation of wetlands is typically looked upon as positive, particularly when the nation has lost considerable acres of wetlands within the past century. The wetlands provide an environment attractive to wildlife, such as sandpipers and herons. ED wetlands also attenuate runoff and alleviate downstream flooding.

Potential adverse impacts attributed with stormwater wetlands can occur upstream, in the wetland, and downstream of the wetland. There is potential for stormwater wetlands located in a large watershed (>100 acres) to experience degradation of upstream headwaters since they receive no effective hydrologic control (MWCOG, 1992). The wetland designer can incorporate upstream modifications to relieve this negative impact.

Concerns within the wetland are the potential for a fish barrier, habitation by undesirable species, and groundwater contamination. A fish barrier may be created by the wetland, which prohibits fish access to the full length of the stream. This may result in a lowering of fish diversity in the stream. Geese and mallards may become year round residents of the wetland if structural complexity is not included in the wetland design. Geese and mallards favor deep and open water areas. Forested buffer areas and a reduction of grassy areas will also deter the geese and mallards. The geese and mallards will increase the nutrient and coliform loadings to the wetland and will also likely be a nuisance to local residents. The issue of groundwater contamination resulting from migration of polluted sediments to the groundwater has been considered a potential negative environmental impact. However, studies to date indicate that there is little risk of groundwater contamination (MWCOG, 1992).

Stormwater wetlands can act as a heat sink, especially during the summer, and discharge warmer waters to downstream water bodies. The increased temperatures can negatively impact sensitive fish species and aquatic insects located downstream. Avoidance of the use of wetlands with temperature sensitive downstream species is recommended. Regardless of the sensitivity of downstream species, the designer should still take precautions in the design of wetlands to reduce the magnitude of warming in the wetland. The adverse impact can be minimized through careful design. Several possible remedies to each of the negative impacts (e.g., upstream degradation, stream warming, etc.) described are suggested in the publication *Design of Stormwater Wetland Systems* (MWCOG, 1992).

STORM WATER BMP: VEGETATIVE COVERS

MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

This Best Management Practice (BMP) involves preserving existing vegetation or revegetating disturbed soil as soon as possible after land disturbance activities in order to control erosion and dust. Vegetative covers include sod, temporary and permanent seeding and other vegetative covers, as well as preservation of existing vegetation. Sod is a strip of permanent grass cover placed over disturbed areas to provide an immediate and permanent turf that both stabilizes the soil surface and eliminates sediment due to erosion, mud, and dust. Temporary vegetative cover involves planting grass seed immediately after rough grading to provide protection until establishment of final cover. Permanent vegetative cover is the establishment of perennial vegetation in disturbed areas. Preservation of natural vegetation (existing trees, vines, bushes, and grasses) provides a natural buffer zone during land disturbance activities.

Vegetative covers provide dust control and a reduction in erosion potential by increasing infiltration, trapping sediment, stabilizing the soil, and dissipating the energy of hard rain. Application of mulch may be required for seeded areas. Mulch is the application of plant residues or other suitable materials to the soil surface to protect the soil surface from rain impact and the velocity of stormwater runoff.

APPLICATIONS

Vegetative covers are applicable to all land uses. Soils, topography, and climate will be determinants in the selection of appropriate tree, shrub, and ground cover species. Local climatic conditions determine the appropriate time of year for planting. Temporary seeding should be performed on areas disturbed by construction left exposed for several weeks or more. Permanent seeding and planting is appropriate for any graded or cleared area where long-lived plant cover is desired. Some areas where permanent seeding is especially important are filter strips, buffer areas, vegetated swales, steep slopes, and stream banks. Design criteria for vegetative covers is included in Table 1 below.

LIMITATIONS

Limitations of vegetative covers as a BMP include:

- The establishment of vegetative covering must be coordinated with climatic conditions for proper establishment. For example, cold climate areas have limited growing seasons and arid regions require careful selection of species.

- The key to proper performance is implementation of a maintenance program to ensure healthy vegetative covering.

PERFORMANCE

Qualitatively, vegetative covers are clearly effective in controlling dust and erosion when properly implemented. The amount of runoff generated from vegetated areas is considerably reduced and is of better quality than from unvegetated areas. However, it is not possible, based on data currently available, to quantify the water quality benefits of the vegetative coverings as a BMP.

TABLE 1; DESIGN CRITERIA FOR VEGETATIVE COVERS

Measure	Extent and Material	Dimensions	Hydraulic	Avoid	Miscellaneous
Temporary Seeding	Place topsoil as needed to enhance plant growth. A loamy soil with an organic content of 1.5 percent or greater is preferred. Use rapid-growing annual grasses, small grains, or legumes. Apply seeds using a cyclone seeder, drill, cultipacker seeder, or hydroseeder.	Place topsoil, where needed, to a minimum compacted depth of 2 inches on 3:1 slopes or steeper, and of 4 inches on flatter slopes.	Divert channelized flow away from temporarily seeded areas to prevent erosion and scouring.	Heavy clay or organic soils as topsoil. Hand-broadcasting of seeds (not uniform), except in very small areas. Mowing temporary vegetation. High-traffic areas.	Use where vegetative cover is needed for less than 1 year. Use chisel plow or tiller to loosen compacted soils. As needed, apply water, fertilizer, lime, and mulch. Incorporate lime and fertilizer into top 4-6 inches of soil. Plant small grains 1 inch deep. Plant grasses and legumes 1/2-inch deep.
Permanent Seeding	Place topsoil as needed to enhance plant growth. A loamy soil with an organic content of 1.5 percent or greater is preferred. Where possible, use low maintenance local plant species. Apply seeds using a cyclone seeder, drill, cultipacker seeder, or hydroseeder.	Apply mulch to slopes 4:1 or steeper, if soil is sandy or clayey or if weather is excessively hot or dry. Place topsoil where needed.	Divert channelized flow away from seeded areas to prevent erosion and scouring.	Heavy clay or organic soils as topsoil. Hand-broadcasting of seeds (not uniform), except in very small areas. High traffic areas.	Use chisel plow or tiller to loosen compacted soils. As needed, apply water, fertilizer, lie, and mulch. Incorporate lime and fertilizer into top 4-6 inches of soil. Plant small grains 1 inch deep. Plant grasses and legumes 1/2-inch deep.

TABLE 1: DESIGN CRITERIA FOR VEGETATIVE COVERS (Continued)

Measure	Extent and Material	Dimensions	Hydraulic	Avoid	Miscellaneous
Mulching	Prefer Organic mulches such as straw (from wheat or oats), wood chips, and shredded bark. Commercial mats and fabrics may also be very effective. Chemical soil stabilizers or binders are less effective, but may be used to tack wood fiber mulches.	Application rates (per acre): straw, one to two tons; wood chips, five to six tons; wood fiber, 0.5 to one ton; bark, 35 cubic yards; asphalt (spray), 0.10 gallon per square yard. After spreading much, less than 25 percent of the ground surface should be visible.	–	–	Mulch may be applied by machine or by hand. Chemical mulches and wood fiber mulches, when used alone, often do not provide adequate soil protection. Use nets or mats in areas subject to water flow. Anchor mulch by punching into soil, or by applying chemical agents, nets, or mats. ?Secure nets and mats with 6 inches or longer. No. 8 gauge or heavier, wire staples placed at 3-foot intervals

SOURCE: Reference 1.

TABLE 1: DESIGN CRITERIA FOR VEGETATIVE COVERS
(Continued)

Measure	Extent and Material	Dimensions	Hydraulic	Avoid	Miscellaneous
Sodding	Sod should be machine-cut at a uniform thickness of 1/2 to 2 inches.		In waterways, select plant types able to withstand design flow velocity.	Gravel or nonsoil surfaces. Unusually wet or dry weather. Frozen soils. Mowing for at least two to three weeks.	Prior to laying sod, clear soil surface of debris, roots, branches, and stones bigger than 2 inches in diameter. Sod should be harvested, delivered, and installed within 36 hours. Lay sod with staggered joints along the contour. Lightly irrigate soils before sod placement during dry or hot periods. After placement, roll sod and wet soil to a depth of 4 inches. On slopes steeper than 3:1, secure sod with stakes. In waterways, lay sod perpendicular to water flow. Secure sod with stakes, wire, or netting.
Preservation of Natural Vegetation	Careful planning is required prior to start of construction.	Wherever possible, maintain existing contours.	Maintain existing hydraulic characteristics.	Activities within the drop line of trees. Concentrating flows at new locations.	Preservation of vegetation should be planned before any site disturbance begins. Proper maintenance is vitally important. Clearly mark areas to be preserved.

SOURCE: Reference 1.

MAINTENANCE

Areas should be checked following each rain to ensure that seed, sod, and mulch have not been displaced. Staking the sod or netting for seeded areas may be required.

Newly sodded areas need to be inspected frequently for the first new months to ensure the sod is maturing. Failures may be due to improper conditioning of the subsoil, lack of irrigation, improper staking, or improper placement of sod pieces.

Newly seeded areas need to be inspected frequently for the first few months to ensure the grass is growing at a proper rate and density. If the seeded area is damaged, determine the cause of the damage before repeating seed bed preparation and seeding procedures.

Once a vegetative cover has been established, it is important to water the sod frequently and uniformly. If the grass is to be mowed, keep grass to a height appropriate for the species selected and the intended use. Occasional soil tests should be collected and analyzed to determine if the soil is appropriately fertilized. Weed control should only be done if absolutely required. Spot seeding should be done to small and damaged areas.

COSTS

Cost estimates for sodding, seeding, and mulching are provided in Table 2 below. These costs were developed by the Southeastern Wisconsin Regional Planning Commission (1991). Please note that costs very depending on local conditions.

TABLE 2: INSTALLATION COSTS

Description	Unit	Material	Labor	Equipment	Indirect Cost	Total Cost	Year of Cost	Comments
Sodding								
Level								
>400 square yards	Square yard	$0.98	$0.85	$0.17	$0.56	$2.56	January 1989	--
100 square yards	Square yard	1.36	1.07	0.22	0.70	3.35		
50 square yards	Square yard	1.95	1.14	0.23	0.80	4.12		
Slopes

Seeding								
Mechanical Seeding	Acre	$410.00	$435.00	$165.00	$290.00	$1,300.00	January 1989	--
	Square yard	0.08	0.09	0.03	0.06	0.26		
Fine Grade/Seed	Square yard	0.15	0.85	0.17	0.48	1.65		Includes fertilizer and lime
Push Spreader								
Grass Seed	1,000 square feet	$8.60	$0.67	$0.26	$1.22	$10.75	January 1989	--
Limestone	1,000 square feet	2.05	0.67	0.26	0.58	3.56		
Fertilizer	1,000 square feet	5.40	0.67	0.26	0.92	7.25		
Level Areas	Acre	578.21	149.30	80.63	251.00	1,059.14	Mid-1988	--
Sloped Areas	Acre	578.21	238.88	129.00	328.75	1,274.84		
Mulching								
Hay	Acre	$255.76	$74.65	$40.31	$118.50	$489.22	Mid-1988	--
	Square yard	--	--	--	--	0.58 0.25-1.00	1983	Average Typical range

NOTE: Total cost includes operation and maintenance, taxes, insurance and other contingencies.

SOURCE: Modified from Reference 4.

ENVIRONMENTAL IMPACTS

None for proper installation of vegetative covers. However, care must be taken to avoid contamination of run off and ground water from over use of fertilizers, weed control herbicides and other hazardous chemicals.

STORM WATER BMP: VEGETATED SWALES

DESCRIPTION

Vegetated swales are natural or man made, broad, shallow channels with a dense stand of vegetation covering the side slopes and main channel. Vegetated swales trap particulate pollutants (total suspended solids and trace metals), promote infiltration, and reduce the flow velocities of stormwater runoff. Figure 1 below illustrates an example of a vegetated swale.

Vegetated swales can serve as an integral part of an area's minor stormwater drainage system by replacing curbs and gutters and storm sewer systems in low-density residential, industrial, and commercial areas. The swale's advantages over a storm sewer system generally include reduced peak flows, increased pollutant removal, and lower capital costs. However, vegetated swales typically have a limited capacity to accept runoff from large storm, since high velocity flows can cause erosion of the swale or damage the vegetated cover.

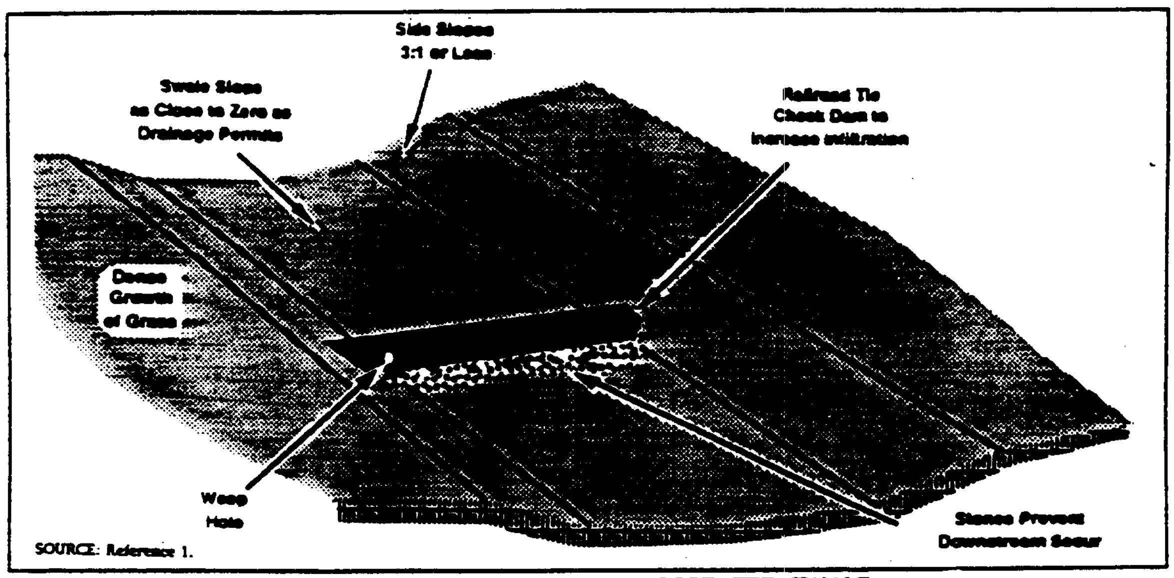

FIGURE 1: EXAMPLE OF A VEGETATED SWALE

COMMON MODIFICATIONS

The effectiveness of vegetated swales can be enhanced by adding check dams approximately every 50 feet to increase storage, decrease flow velocities, and promote particulate settling. Structures to skim off floating debris may also be added. Incorporating vegetated filter strips parallel to the top of the channel banks can also help to treat sheet flows entering the swale.

CURRENT STATUS

Vegetated swales are relatively easy to design and incorporate into a site drainage plan. While swales are not generally used as a stand alone Stormwater Best Management Practice (BMP), they are very effective when used in conjunction with other BMP's such as wet ponds, infiltration strips, wetlands, etc.

APPLICATIONS

Vegetated swales can be used in all regions of the country where climate and soils permit the establishment and maintenance of a dense vegetative cover. The suitability of a vegetated swale at a particular site depends on the area, slope, and imperviousness of the contributing water shed, as well as the dimensions, slope, and vegetative covering employed in the swale system.

GENERAL LIMITATIONS

The limitations of vegetated swales include:

- Vegetated swales are generally impractical in areas with very flat grades, steep topography, or wet or poorly drained soils.
- Swales provide minimal water quantity and quality benefits when flow volumes and/or velocities are high.
- Swales may pose a potential drowning hazards, create mosquito breeding areas, and cause odor problems.
- The use of vegetated swales may be limited by the availability of land.
- Many local municipalities prohibit the use of vegetated swales if peak discharges exceed five cubic feet per second (cfs) or flow velocities are greater than three feet per second (fps).
- Vegetative swales are generally impractical in areas with erosive soils or where a dense vegetative cover is difficult to maintain.
- Certain quantitative aspects of vegetated swales are not known at this time. These include whether pollutant removal rates of swales decline with age, the effect of slope on the filtration capacity of vegetation, the benefit of check dams, and the degree to which design factors can enhance the effectiveness of pollutant removal.

PERFORMANCE

Conventional vegetated swale designs have achieved mixed results in removing particulate pollutants, such as suspended solids and trace metals. For example, three grass swales in the Washington, DC, area were monitored by the Nationwide Urban Runoff Program (NURP). NURP found no significant improvement in urban runoff quality for the pollutants analyzed. However, the weak performance of these swales was attributed to the high flow velocities in the swales, soil compaction, steep slopes, and short grass height. A Durham, NC, project monitored the performance of a carefully designed artificial swale that received runoff from a commercial parking lot. The project monitored 11 storm and concluded that particulate concentrations of heavy metals (Cu,Pb,Zn, and Cd) were reduced by approximately 50 percent. However, the swale proved largely ineffective for removing soluble nutrients. A conservative estimate is that properly designed vegetated swales may achieve a 25 to 50 percent reduction in particulate pollutants, including sediment and sediment-attached phosphorus, metals, and bacteria. Lower removal rates (less than 10 percent) can be expected for dissolved pollutants, such as soluble phosphorus, nitrate, and chloride.

The literature suggest that vegetated swales represent a practical and potentially effective technique for control of urban runoff quality. While limited quantitative performance data exists for vegetated swales, some known positive factors for pollutant removal are check dams, flatter slopes, permeable soils, dense grass cover, longer contact time, and smaller storm events. Negative factors include compacted soils, short runoff contact time, larger storm events, frozen ground, short grass heights, steep slopes, and high runoff velocities and discharge rates.

The useful life of a vegetated swale system is directly proportional to the effectiveness and frequency of maintenance. If properly designed and regularly maintained, vegetated swales can last an indefinite period of time.

DESIGN CRITERIA

Although specific quantitative performance data for vegetated swales is limited, design criteria have been established for implementation of the vegetated swales and is presented below.

- Location. Vegetated swales are typically located along property boundaries, although they can be used effectively wherever the site provides adequate space. Swales can be used in place of curbs and gutters along parking lots.

- Soil Requirements. Gravelly and coarse sandy soils that cannot easily support dense vegetation should be avoided. If available, alkaline soils and subsoils should be used to promote the removal and retention of metals. Soil infiltration rates should be greater than one-half inch per hour, therefore, care must be taken to avoid compacting the soil during construction.

- Vegetation. Fine, close-growing, water-resistant grass should be selected for use in vegetated swales. Dense vegetation maximizes water contact, improving the effectiveness of the swale system. The vegetation should be selected on the basis of pollution control objectives and the ability to thrive in the conditions present in the conditions present at the site. Some examples of vegetation appropriate for swales include reed canary grass, grass-legume mixtures, and red fescue.

- General Channel Configuration. It is recommended that a parabolic or trapezoidal cross-section with side slopes no steeper than 3:1 be used, maximizing the wetted, channel perimeter. Recommendations for longitudinal channel slopes vary within the existing literature. For example, Shuler (1987) recommends a vegetated swale slope as close to zero as drainage permits. The Minnesota Pollution Control Agency (1989) recommends that the channel slope be less than 2 percent. The Stormwater Management Manual for the Puget Sound Basis (1992) specifies channel slopes between 2 and 4 percent; slopes of less than 2 percent can be used if drain tile is incorporated into the design, and slopes greater than 4 percent can be used if check dams are placed in the channel to reduce flow velocity.

- Drainage Area. The maximum flow rate (Q) to the swale can be calculated using the Rational Formula, depending on the size of the drainage area (A), the percentage of the drainage area that is impervious (C) and the rainfall intensity (I) for the design storm.

$$Q = CiA$$

A typical design storm used for sizing swales is a six-month frequency, 24- hour storm event. The exact intensity must be calculated for your location and is generally available from the US Geological Survey (USGS). Swales are generally not used where the maximum flow rate exceeds 5 cfs.

- Sizing Procedures. The width of the swale can be calculated using various forms of the Manning equation. However, this methodology can be simplified to the following rule of thumb: the total surface area of the swale should be 500 square feet for each acre that drains to the swale.

Unless a bypass is provided, the swale must be sized as both a treatment device and to pass the peak hydraulic flows. But to be most effective as a treatment device, the depth of the stormwater should not exceed the height of the grass in the swale.

Design Parameters. Based on limited research, swales can generally be designed using the following parameters:

1. Minimum grass height of 6 inches (Figure 2).

2. Maximum depth of stormwater during the design storm of 4 inches (Figure 2).

3. Maximum flow in the swale of 5 cfs.

4. Maximum velocity in the swale of 3 fps.

5. Channel slope between 2 and 5 percent.

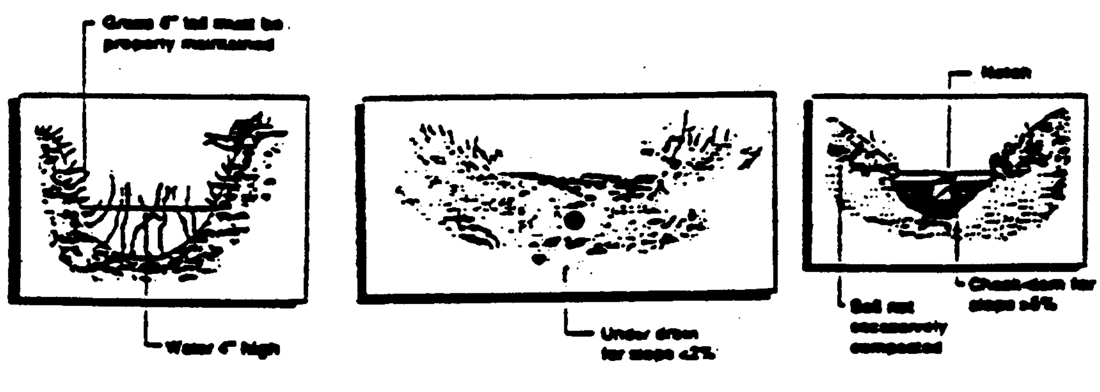
   - Slopes of less than 2 % can be used if the swale is drained to prevent ponding (Figure 2).

   - Slopes of more than 5 % can be used if check dams are placed in the swale to maintain channel velocity below 3 fps (Figure 2).

6. To provide maximum long term treatment effectiveness, the swale width should be calculated using a design flow of 0.2 cfs per acre of area draining into the swale. However, the minimum width is 18 inches.

7. If a by-pass is not provided, the channel width and/or height should be increased, if needed, to pass peak hydraulic flows.

8. In order to provide adequate treatment, the swale should have a minimum length of 200 feet. If a shorter length must be used, the width should be increased proportionally to maintain a treatment surface area of at least 500 square feet, as discussed above. However, the minimum length is 25 feet.



SOURCE: Reference 3.

FIGURE 2: DESIGN PARAMETERS

- Construction. The subsurface of the swale should be carefully constructed to avoid compaction of the soil. Compacted soil reduces the infiltration and inhibits growth of the grass. Damaged areas should be restored immediately to ensure that the desired level of treatment is maintained and to prevent further damage due to erosion of exposed soil.

- Check Dams. Check dams can be installed in swales to promote additional infiltration, increase storage, and reduce velocities. The check dam may be a railroad tie embedded into the swale with riprap placed on the downstream side of the tie to prevent a scour hole from forming. Earthen check dams are not recommended because of their potential to erode. Check dams should be installed every 50 feet if longitudinal slope exceeds 4 percent.

MAINTENANCE

The primary swale maintenance objectives are to maintain the hydraulic efficiency of the channel and maintain a dense, healthy grass cover. Maintenance activities should include periodic mowing (with grass never cut shorter than the design flow depth), Weed control, watering during drought conditions, reseeding bare areas, and clearing of debris and blockages. Cuttings should be removed from the channel and disposed in a local composting facility. Accumulated sediment should be removed periodically. Application of fertilizers and pesticides should be minimal, if required.

Research has not yet identified proper mowing strategies. However, mowings during the spring and summer should keep the grass at the 6" design height. In some commercial applications where 6" may cause an aesthetic problem the grass can be cut to 4" but the last mowing of the season should not be below 6". Mowing encourages growth thereby improving the removal of soluble pollutants. The final mowing should occur near the end of the growth season. Failure to remove the growth before the dormant season will cause a loss of pollutants back to the stormwater.

Any damage to the channel such as rutting must be repaired with suitable soil, properly tamped and seeded. The grass cover should be thick; if it is not reseeding as necessary.

Any standing water removed during the maintenance operation must be disposed to a sanitary sewer at an approved discharge location. Residuals (ie, silt, grass cuttings, etc.) must be disposed of in accordance with local or state requirements.

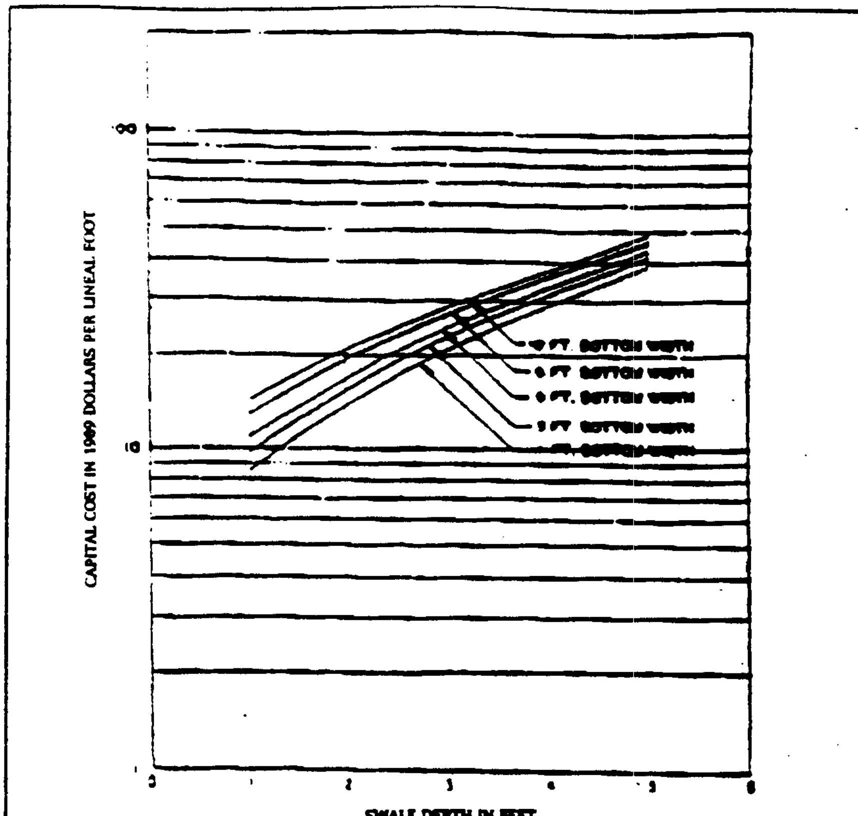
COSTS

Vegetated swales typically cost less to construct than curbs and gutters or underground storm sewers. Shuler (1987) reported that costs may vary from $4.90 to $9.00 per lineal foot for a 15-foot wide channel (top width).

The Southeastern Wisconsin Regional Planning Commission (SEWRPC) reported that costs may vary from $8.50 to $50.00 per lineal foot depending upon swale depth and bottom width (1991). The SEWRPC cost estimates are higher than other published estimates because they include the cost of activities such as clearing, grubbing, leveling, filling, and sodding, which may not be included in many of the reported costs. Construction costs depend on specific site considerations and local costs for labor and materials. The Table 1 below shows estimates capital cost of a vegetated swale.

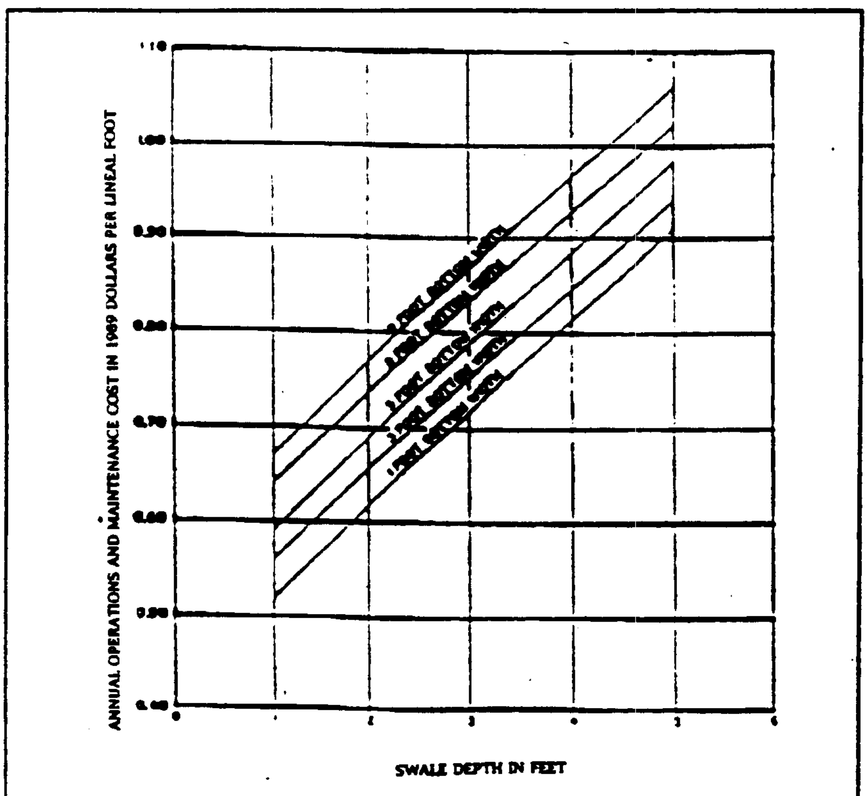
Annual costs associated with maintaining vegetated swales are approximately $0.58 per lineal foot for a 1.5-foot deep channel, according to SEWRPC (1991). Estimated average annual operating and maintenance costs of vegetated swales can be estimated using Table 2 below.

TABLE 1: ESTIMATED CAPITAL COSTS



SOURCE: Reference 4.

TABLE 2: ESTIMATED O & M COSTS



SOURCE: Reference 4.

ENVIRONMENTAL IMPACTS

Negative environmental impacts of vegetated swales may include:

- Leaching from culverts and fertilized lawns may increase the presence of trace metals and nutrients in the runoff.
- Infiltration through the swale may affect local groundwater quality.
- Standing water in vegetated swales can result in potential safety, odor, and mosquito problems.

STORM WATER BMP: VISUAL INSPECTIONS

EPA MTB
Office of Wastewater Enforcement & Compliance
MUNICIPAL TECHNOLOGY BRANCH

DESCRIPTION

Visual inspection is the process by which members of a Stormwater Pollution Prevention Team (SWPPT) visually inspects stormwater discharge from material storage and outdoor processing areas to identify contaminated stormwater and its possible sources.

An example of a visual inspection is examination within the first hour of a storm event that produces significant stormwater runoff for the presence of floating and suspended materials, oil and grease, discolorations, turbidity, odor, or foam. Another example would be to examine a raw materials storage area where materials are stored in 55-gallon drums and look for leaks, discolorations, or other abnormalities that may cause a pollutant to contaminate stormwater runoff.

CURRENT STATUS

The U.S. EPA has recognized visual inspections as a baseline Best Management Practice (BMP) for over 10 years. Its implementation across the country, however, has been sporadic. Stormwater Pollution Prevention Plan (SWPPP) development will increase implementation of visual inspections in the future as facility management recognizes it to be an effective BMP from a water quality and cost savings perspective.

LIMITATIONS

Limitations associated with visual inspections include:

- Inspections are limited to those areas clearly visible to the human eye
- Visual inspections need to be performed by qualified personnel
- Lack of a corporate commitment to actively implement inspections on a routine basis
- Inspectors need to be properly motivated to perform a thorough visual inspection.

PERFORMANCE

The performance of visual inspections as an effective tool in reducing stormwater runoff contamination is highly variable and dependent upon site-specific parameters such as industrial activity occurring at the facility, maintenance procedures, and employees. Currently there is no quantitative data regarding the effectiveness of visual inspections as a BMP.

DESIGN CRITERIA

Visual inspections should be performed routinely for the presence of non-stormwater discharges. Flows during a dry period should be observed to determine the presence of any dry weather flows, stains, sludges, odors, and other abnormal conditions.

Visual inspections should be made of all stormwater discharge outlet locations during the first hour of a storm event that produces a significant amount of stormwater runoff. In geographic locations with a high frequency of storm events, inspections should be performed at least once per month. Inspection for the presence of floating and suspended materials, oil and grease, discolorations, turbidity, foam, and odor should be performed.

The inspection frequency interval is a key design criterion in a visual inspection program. To determine the inspection frequency, experienced personnel should evaluate the causes of previous incidents and assess the probable risks for occurrence in the future. Conditions in the stormwater discharge permit may also dictate inspection frequency.

Another key design criterion is proper record keeping of an inspection. Record keeping should include the date of the inspection, the names of the personnel who performed the inspection, and the observations made during the inspection. Records should be forwarded to appropriate personnel through an internal reporting system. Remedial modifications to a facility can then be implemented based on documented inspections.

Visual inspections of a facility should focus on the following key areas:

- Storage facilities
- Transfer pipelines
- Loading and unloading areas
- Pipes, pumps, valves, and fittings
- Internal and external inspection for tank corrosion
- Wind blowing of dry chemicals
- Tank support or foundation deterioration
- Deterioration of primary or secondary containment facilities
- Damage to shipping containers
- Wind blowing of dry chemicals and dust particles
- Integrity of stormwater collection system
- Leaks, seepage, and overflows from sludge and waste disposal sites

IMPLEMENTATION

A visual inspection BMP program should be incorporated within the facility's record keeping and internal reporting BMP structure. Estimates of outfall flow rates, and noting the presence of oil sheens, floatables, coarse solids, color, odors, etc. will probably be the most useful indicators of potential problems. Specific parameters to look for in completing a visual inspection include:

- Odor--The odor of a discharge can vary widely and sometimes directly reflects the source of contamination. Industrial discharges will often cause the flow to smell like a particular spoiled product, oil, gasoline, specific chemical, or solvent. As an example, for many industries, the decomposition of organic wastes in the discharge will release sulfide compounds into the air above the flow in the sewer, creating an intense smell of rotten eggs. In particular, industries involved in the production of meats, dairy products, and the preservation of vegetables or fruits, are commonly found to discharge organic materials into storm drains. As these organic materials spoil and decay, the sulfide production creates this highly apparent and unpleasant smell. Significant sanitary wastewater contributions will also cause pronounced and distinctive odors.

- Color--Color is another important indicator of inappropriate discharges, especially from industrial sources. Industrial discharges may be of any color. Dark colors, such as brown, gray, or black, are most common. For instance, the color contributed by meat processing industries is usually a deep reddish-brown. Paper mill wastes are also brown. In contrast, textile wastes are varied. Other intense colors, such as plating-mill wastes, are often yellow. Washing of work areas in cement and stone working plants can s\cause cloudy discharges. Potential sources causing various colored contaminated waters from industrial areas can include process waters (slug or continuous discharges), equipment and work area cleaning water discharged to floor drains, spills during loading operations (and subsequent washing of the material into the storm drains).

- Turbidity--Turbidity of water is often affected by the degree of gross contamination. Industrial flows with moderate turbidity can be cloudy, while highly turbid flows can be opaque. High turbidity is often a characteristic of undiluted industrial discharges, such as those coming from some continual flow sources, or some intermittent spills. Sanitary wastewater is also often cloudy in nature.

- Floatable matter--A contaminated flow may also contain floatables (floating solids or liquids). Evaluation of floatables often leads to the identity of the source of industrial or sanitary wastewater pollution, since these substances are usually direct products or byproducts of the manufacturing process, or distinctive of sanitary wastewater. Floatables of industrial origin may include substances such as animal fats, spoiled food products, oils, plant parts, solvents, sawdust, foams, packing materials, or fuel, as examples.

- Deposits and Stains--Deposits and stains (residue) refer to any type of coating which remains after a non-stormwater discharge has ceased. They will cover the area surrounding the stormwater discharge and are usually of a dark color. Deposits and stains often will contain fragments of floatable substances and, at times, take the form of a crystalline or amorphous powder. These situations are illustrated by the grayish-black deposits that contain fragments of animal flesh and hair which often are produced by leather tanneries, or the white crystalline powder which commonly coats sewer outfalls due to nitrogenous fertilizer wastes.

- Vegetation--Vegetation surrounding a stormwater discharge may show the effects of the wastewater. Industrial pollutants will often cause a substantial alteration in the chemical composition and Ph of the discharge water. This alteration will affect plant growth, even when the source of contamination is intermittent. For example, decaying organic materials coming from various food product wastes would cause an increase in plant life. In contract, the discharge of chemical dyes and inorganic pigments from textile mills could noticeably decrease vegetation, as these discharges often have a very acidic Ph. In either case, even when the cause of industrial pollution is gone, the vegetation surrounding the discharge will continue to show the effects of the contamination.

  In order to accurately judge if the vegetation surrounding a discharge is normal, the observer must take into account the current weather conditions, as well as the time of year in the area. Thus, flourishing or inhibited plant growth, as well as dead and decaying plant like, are all signs of pollution or scouring flows when the condition of the vegetation just beyond the discharge disagrees with the plant conditions near the discharge. It is important not to confuse the adverse effects of high stormwater flows on vegetation with highly toxic flows. Poor plant growth could be associated with scouring flows occurring during storms.

Structural Damage--Structural damage is another readily visible indication of industrial discharge contamination. Cracking, deterioration, and spalling of concrete or peeling of surface paint, occurring at an outfall are usually caused by severely contaminated discharges, usually of industrial origin. These contaminants are usually very acidic or basic in nature. For instance, primary metal industries have a strong potential for causing structural damage because their batch dumps are highly acidic. Poor construction, hydraulic scour, and old age may also adversely affect the condition of structures.

Implementation of visual inspections should be assigned to qualified staff such as maintenance personnel or environmental engineers. Figure 1 provides a sample visual evaluation worksheet which can be used to record the results of the inspections.

FIGURE 1: VISUAL INSPECTION WORKSHEET

MAINTENANCE

Maintenance involved with visual inspections as a BMP include developing a schedule for performing visual inspections and follow-up to make sure the inspections are performed on schedule. Continual record updates need to be performed with each inspection, and properly routed through the internal reporting structure of a SWPPT.

COSTS

Costs are those associated with direct labor and overhead costs for staff hours. Annual costs can be estimated using the example in Table 1 below. Figure 2 can be used as a worksheet to calculate the estimated annual cost for implementing a visual inspection program.

TABLE 1: EXAMPLE OF ANNUAL VISUAL INSPECTION PROGRAM COSTS

Title	Quantity		Avg. Hourly Rate ($)		Overhead* Multiplier		Estimated Yearly Hours on SW Training		Est. Annual Cost ($)
Stormwater Engineer	1	x	15	x	2.0	x	20	=	600
Plant Management	5	x	20	x	2.0	x	10	=	2,000
Plant Employees	100	x	10	x	2.0	x	5	=	10,000
					TOTAL ESTIMATED ANNUAL COST				$12,600

ENVIRONMENTAL IMPACTS

Visual inspections is an effective way to identify a variety of problems. Correcting these problems can have a significant impact on improving water quality in the receiving water.

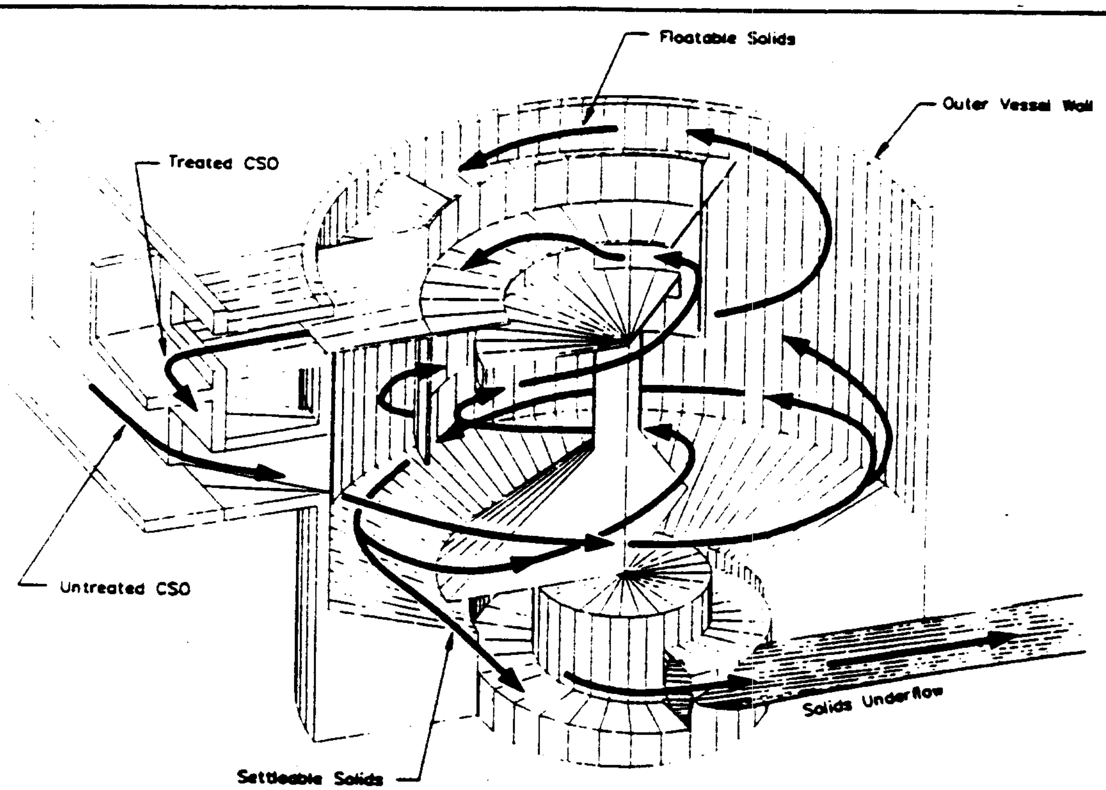
STORM WATER BMP: VORTEX SOLIDS SEPARATOR

DESCRIPTION

A vortex solids separator is a wastewater treatment technology with no moving parts which uses velocities imparted from vortex swirling to assist the settling and removal of concentrated solids. During a storm event, flow enters the cylindrical unit tangentially and induces a swirling vortex which concentrates solids in the underflow and reduces their concentration in the clarified liquid. A general view of the vortex solid separator and liquid flow paths is shown in Figure 1 below.



SOURCE: Reference 19

FIGURE 1: GENERAL VIEW OF THE VORTEX SOLID SEPARATOR

Vortex units are most often applied to combined sewer overflow (CSOs), but can also be used to treat storm water runoff. In CSO treatment applications, the concentrated solids are removed from the bottom of the unit and conveyed via the sanitary sewer to a wastewater treatment plant (WWTP). In separate storm water applications, the concentrated underflow would likely go to a holding tank or pond. Effluent exits the top of the unit and is discharged to the receiving water. Vortex units may be used on-line or off-line, and in combination with other Best Management Practices (BMPs) such as storage tanks or detention ponds.

CURRENT STATUS

This fact sheet contains general information only, and should not be used as the basis for designing a vortex solids separators for storm water applications . While the basic vortex separator technologies used for CSO applications are well established, actual operating experience for storm water applications is limited. The three types of vortex solids separators currently being actively marketed in the United States are listed below. While all three types use the same basic principal, this fact sheet will discuss some of the differences in design and performance of the different units. The technology for storm water applications is evolving rapidly. The equipment manufacturers and the municipal operators should be contacted for the current state of the art information.

- The EPA Swirl Concentrator.
- The Fluidsep.
- The Storm King.

The design specifications for the EPA Swirl Concentrator were developed by the U.S. Environmental Protection Agency (EPA) in the early 1970s. Currently, there are 20 full-scale EPA Swirl Concentrator units in the U.S. and four in Japan (EPA, 1977). All of these units were designed for CSO treatment. However, the EPA Swirl Concentrator design was extensively tested during a study for separated storm water treatment in West Roxbury, Massachusetts in the early 1980s (EPA, 1982, 1984).

Fluidsep is a patented design that is licensed by a German firm, but is available in the U.S. There are 13 full-scale Fluidsep units operating in the U.S. and Europe, with additional units planned for construction. Fluidsep has been consistently used for CSO applications and has not been tested on separated storm-sewer systems.

Storm King, a patented unit, is available in the U.S. from H.I.L. Technology, Inc. There are no full-scale Storm King units in operation in the U.S. at this time. However, there are more than 100 Storm King treatment units in operation in Europe and Canada, almost exclusively on CSOs. Full-scale Storm King units have been selected by the City of Columbus to treat CSOs. Storm water treatment by the Storm King has been limited to a pilot study in Bradenton, Florida and a full-scale unit in Surrey Heath, England.

APPLICABILITY

Vortex separators are most effective where the separation of gritty materials, heavy particulates or floatables from wet-weather runoff is required. The technology is particularly well suited to locations where there is limited land availability which may preclude the use of other BMPs such as settling basins or detention ponds. Vortex separators can also be applied as satellite units to treat smaller subareas of the collection system, minimizing the high cost of conveyance systems needed for centralized treatment facilities. Units can be designed to remove solids and capture floatables. However, solids with poor settleability are not effectively removed in vortex solids separators.

LIMITATIONS

The use of vortex solids separators as a wet-weather treatment option may be limited by the poor net solids removal (10-34 percent). In some cases this level of solids removal may not meet the treatment objectives for a potential location. There is even less information on the ability of vortex solids separators to remove pollutants other than solids. Pollutants such as nutrients and metals that adhere to fine particulates or are dissolved will not be significantly removed by the vortex separator.

Site constraints, including the availability of suitable land, appropriate soil depth and stability to structurally support the unit, may also limit the applicability of the vortex separator. The slope of the site or collection system may dictate the use of an underground unit, which can result in extensive excavation. For above-ground units, pumping may be required. Maintaining and operating these pumping facilities will increase the capital costs as well as the energy, operations and maintenance cost of the vortex solids separator.

DESIGN

Regardless of the type of vortex separator selected, the type and quantity of pollutants to be removed must first be determined. The settleability characteristics and the quantity of flow to be treated will then established for proper design to achieve the desired treatment level. The settling characteristics of particulates anticipated in the influent are the basis of the design of all unit types.

The performance of each unit is based on the vortex separation mechanism. Each unit type has its own design criteria to achieve solids/liquids separation. The design of the EPA Swirl Concentrator is based on settleability studies developed in the 1970s. This information is available in the public domain from EPA design manuals (USEPA, 1977). Design of the Storm King units is based on pilot-scale treatability studies. Pilot-scale testing is conducted at each installation to select the appropriate full-scale unit design that best suits the intended application. The Fluidsep design is based on modeling of particulate settleability determined during site-specific studies, including flow gauging and rainfall measurements.

PERFORMANCE

Vortex separators designed primarily for removing grittier material, may have difficulty removing the less settleable solids often found in storm water runoff. For CSO applications, average total mass solids removals varied between 38%, at the EPA Swirl Concentrator facility in Washington, D.C., to 61%, at the Storm King pilot-study facility in Columbus, Georgia. For storm water runoff applications, average total mass solids removal was observed to be approximately 26%, at the pilot-scale Swirl Concentrator demonstration test in West Roxbury, Massachusetts. Average performance characteristics for the three different types of separators in shown in Table 1 below. This data is for CSO applications only.

Solids are removed in the underflow by flow splitting even if there is no concentration of particulates in the underflow from the vortex unit. The removal of solids in the underflow may account for a large portion of the total mass solids removed in the unit. To discount the solids removed by the underflow without concentration by the unit, net solids removals were determined. Net solids removals exclude from the total solids removal, the solids removed by the underflow by flow-splitting. Net solids removals for CSO applications, as shown in Table 1, were observed to a low of 7% for Tengen, Germany and a high of 34%, for Columbus, Georgia. The average net mass solids removal for separate storm water applications was observed to be a high of 17% for the EPA Swirl Concentrator tested at West Roxbury, Massachusetts and a low of 12% for the Storm King unit tested at Bradenton, Florida. However, the data for storm water runoff applications is not considered sufficient to allow for the evaluation of performance between unit designs and is not included in Table 1.

MAINTENANCE

Vortex separators do not have any moving parts, and are therefore not maintenance intensive. However, wash downs are required following every CSO event to prevent odors. To accomplish this, some

TABLE 1: AVERAGE VORTEX PERFORMANCE CHARACTERISTICS FOR CSO APPLICATIONS

Unit Type	Location	Effluent Hydraulic Flow (MGD)	Solids Reduction	Solids Removal	Total Net Treatment Removal	Factor
Swirl	Washington, DC	10	24	38	12	1.7
Fluidsep	Tengen, Germany	11	47	54	7	1.2
Storm King	James Bridge, UK	7.5	39	53	14	1.7
Storm King	Columbus, GA	4.3	23	61	34	2.6

SOURCE: References 10, 11, 20, and 21

units have been designed to be self-cleansing. This may not be necessary for storm water treatment applications. Pretreatment

BMPs such as bar screens or street sweeping can be used to decrease the quantity of wastes reaching the vortex separators, but it is not required. Maintenance would be required for pretreatment and pumping equipment.

COSTS

The capital cost for vortex solids separator treatment facilities are dependant on site-specific characteristics. Commonly, vortex solids separators are used with other treatment technologies such as automatic bar screens, and disinfection. The capital cost for vortex solids separator treatment facilities in the U.S. varies between $3,000 and $5,250 per acre of drainage basin (1993 dollars). Typically the capital cost for installed vortex solids separator units without pretreatment is approximately $4,900 per million gallons of flow treated (1993 dollars).

Total costs of vortex units often include predesign costs, capital costs and operation and maintenance (O&M) costs. Foe example, predesign study costs for the Storm King are typically $20,000 (1993 dollars). Predesign costs for the Fluidsep, range between $25,000 and $100,000 (1993 dollars). There are no predesign study costs associated with the EPA Swirl Concentrator, because published settleability curves are used for the basis of design.

Vortex solids separator units do not generally require significant energy expenditures unless pumping is required. Operating expenses primarily include labor for wash down or energy costs for automatic wash down or bar screens. However some installations such as the Storm King unit in Surry Heath, England, do not have a sanitary or foul sewer line for disposing of collected solids. These facilities must collect its residuals in a collection zone or holding tank. The frequency for pumping out the collected residuals will be dependent on the amount of material collected per storm, the number of storm events and the size of the holding zone or tank. The Surry Heath facility is estimating the holding zone will require pump out every 2-3 years. The cost for periodic emptying and disposal of the collected residuals is estimated to be between $300-450 per cleaning (1993 dollars).

ENVIRONMENTAL IMPACTS

Improvements can often be observer in water quality or in the health of the ecosystem. For example, the Washington, D.C. CSO Abatement Program, which includes EPA Swirl Concentrators and upstream storage, has resulted in decreased oxygen demands in the receiving water. Fish have returned to the once oxygen-depleted water. Much of the improved receiving water quality is attributable due to a combination of the upstream storage, and the bar screens, disinfection, and operation of the vortex units.

For CSO applications the vortex solid separators must be washed down after each storm events to prevent objectionable odors. Odor control for some storm water applications and for residual storage facilities may also be required. Collected residuals from storm water applications have not evaluated. However, collected residuals should be evaluated for toxicity and metals content before disposal.

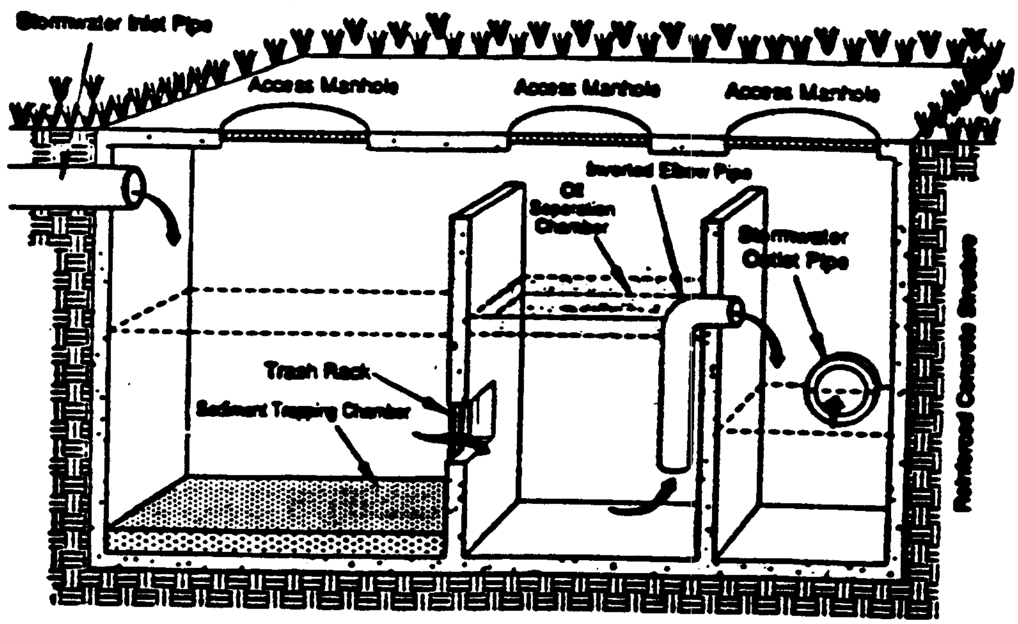
STORM WATER BMP: WATER QUALITY INLETS

DESCRIPTION

Water quality inlets (WQIs) consist of a series of chambers that allow sedimentation of coarse materials, screening of larger or floating debris, and separation of free oil (as opposed to emulsified or dissolved oil) from storm water. They capture only the first portion of runoff for treatment and are generally used for pretreatment before discharging to other best management practices (BMPs). A typical WQI, as shown in Figure 1 below, consists of a sediment chamber, an oil separation chamber and a discharge chamber. WQIs are also commonly called oil/grit separators or oil/water separators. WQIs can be purchased as a pre-manufactured unit or can be constructed on site.



SOURCE: Reference 3

FIGURE 1: PROFILE OF A TYPICAL WATER QUALITY INLET

COMMON MODIFICATIONS

The design of WQIs can be modified to improve their performance. Possible modifications include (1) an additional orifice and chamber that replace the inverted pipe elbow, (2) the extension of the second chamber wall up to the top of the structure, or (3) the addition of a diffusion device at the inlet. The diffusion device is intended to dissipate the velocity head and turbulence and distribute the flow more evenly over the entire cross-sectional area (API, 1990). Suppliers of pre-manufactured units (i.e., Highland Tank & Mfg., Jay R. Smith Mfg., etc.) can also provide modifications of the typical design for special conditions.

CURRENT STATUS

WQIs are widely used in the U.S.; however, recent studies indicate that the lack of regular maintenance adversely affect their performance. There is also some concern that, because the collected residuals contain hydrocarbon by-products, the residuals may be considered too toxic for conventional landfill disposal. Maintenance requirements and residual disposal, should be carefully evaluated in selecting a WQI. Possible alternatives to the WQI include sand filters, oil absorbent materials, and other innovative BMPs (i.e., Stormceptor System).

APPLICATIONS

WQIs are often used where land requirements and cost prohibit the use of larger BMP devices, such as ponds or wetlands. WQIs are also used to treat runoff prior to discharge to other BMPs. WQIs can be adapted to all regions of the country (Schueler, 1992), and are typically located in small, highly impervious areas, such as gas stations, loading areas or parking areas. Sites with high automotive related uses can be expected to have higher hydrocarbon concentrations than other land uses (MWCOG, 1993). Increased maintenance and residual disposal, due to these higher hydrocarbon concentrations from these areas, must be carefully evaluated before selecting a WQI for these applications.

LIMITATIONS

Two major constraints limit the effectiveness of WQIs. Theses constraints are (1) the size of the drainage area and (2) the activity within the drainage area. WQIs are generally recommended for drainage areas of 1 acre or less (Berg, 1991, NVPDC, 1992). Construction costs often become prohibitive for larger drainage areas. High sediment loads interfere with the ability of the WQI to effectively separate oil and grease from the runoff. Therefore, WQIs should not accept runoff from disturbed areas unless the runoff has been pretreated to reduce the sediment loads to acceptable levels.

WQIs are also limited by maintenance requirements and pollutant removal capabilities. Maintenance of underground WQIs can be easily neglected because the WQI is often "out of sight and out of mind." Regular maintenance is essential to ensuring effective pollutant removal. Lack of maintenance will often result in resuspension of settled pollutants. WQIs are most effective in removing heavy sediments and floating oil and grease. WQIs have demonstrated limited ability to separate dissolved or emulsified oil from runoff. WQIs are also not very effective at removing pollutants such as nutrients or metals, except where the metals are directly related to sediment removal.

PERFORMANCE

More than 95 percent of all WQIs operate as designed during their first 5 years. Very few structural or clogging problems or problems with the separation of the pollutants and water are experienced during that period. However, WQIs have a very poor record of pollutant removal due to a lack of regular clean-outs and the resuspension of the sediments (Schueler, 1992). The efficiency of oil and water separation in a WQI is inversely proportional to the ratio of the discharge rate to the unit's surface area (API, 1990). Due to the small capacity of the WQI, the discharge rate is typically very high and the detention time is very short, which can result in minimal pollutant settling. The average detention time in a WQI is less than 0.5 hour (MWCOG, 1993).

The WQI achieves slight, if any, removal of nutrients, metals and organic pollutants other than free petroleum products (Schueler, 1992). Grit and sediments are partially removed by gravity settling within the first two chambers. A WQI with a detention time of 1 hour may expect to have 20 to 40 percent removal of sediments.

The Metropolitan Washington Council of Governments (MWCOG) performed a long-term study to determine WQI performance and effectiveness. Monitoring of more than 100 WQIs indicated that less than 2 inches of sediments (mostly coarse-grained grit and organic matter) were trapped in the WQIs. Hydrocarbon and total organic carbon (TOC) concentrations of the sediments averaged 8,150 and 53,900 mg/kg, respectively. The mean hydrocarbon concentration in the WQI water column was 10 mg/L. The study also indicated that sediment accumulation did not increase over time, suggesting that the sediments become re-suspended during storm events (MWCOG, 1993). Although the design of the WQI effectively separates oil and grease from water, re-suspension of the settled matter appears to limit removal efficiencies. Actual removal occurs when the residuals are removed from the WQI (Schueler 1992).

DESIGN CRITERIA

Prior to WQI design, the site should be evaluated to determine if another BMP would be more cost-effective in removing the pollutants of concern. WQIs should be used where no other BMP is feasible. The site should be near a storm drain network so that flow can be easily diverted to the WQI for treatment (NVPDC, 1992). Construction activities within the drainage area should be completed and the drainage area should be revegetated so that the sediment loading to the WQI is minimized. Upstream sediment control measures should be installed to decrease the sediment loading.

WQIs are most effective for small drainage areas. Drainage areas of 1 acre or less are often recommended. WQIs are typically used in an off-line configuration (i.e., portions of runoff are diverted to WQI), but they can be used as an on-line unit (i.e., receive all runoff). Generally off-line units are designed to handle the first 0.5 inches of runoff from the drainage ares. Upstream isolation/diversion structures can be used to divert the water to the off-line structure (Schueler, 1992). On-line units receive higher flows that will likely cause increased turbulence and resuspension of settled material; thereby reducing WQI performance.

Chamber Design

Structural loadings should be considered in the WQI design (Berg, 1991). WQIs are available in pre-manufactured units or can be cast-in-place. Reinforced concrete should be used to construct below-grade WQIs. The WQIs should be water tight to prevent possible ground water contamination. The first and second chambers are generally connected by an opening covered by a trash rack or by a PVC or other suitable material pipe (Berg, 1991). If a pipe is used it should also be covered by a trash rack or screen. The opening or pipe between the first and second chambers should be designed to pass the design storm with out surcharging the first chamber (Berg, 1991). The design storm will vary depending on geographical location and is generally definite by local regulations.

When the combined length of the first two chambers exceeds 12 feet, the chambers are typically designed with the length of the first and second chamber being 2/3 and 1/3 of the combined length respectively. Each of the chambers should have a separate manhole to provide access for cleaning and inspection.

The State of Maryland design standards indicate that the combined volume of the first and second chambers should be determined based on 40 cubic feet per 0.10 acre draining to the WQI. In Maryland, this is equivalent to capturing the first 0.133 inch of runoff from the contributing drainage area. The combined volume includes the volume of the first and second chamber up to the top of the interior walls and the volume of the permanent pool (Berg, 1991).

Permanent pools within the chambers help prevent the possibility of sediment resuspension. The first and second chambers should have permanent pools with 4-foot depths. If possible, the third chamber should also contain a permanent pool (NVPDC, 1992).

In the standard WQI, an inverted elbow is installed between the second and third chamber. The elbow should extend a minimum of 3 feet into the second chamber's permanent pool in order to retain oil (NVPDC, 1992). The elbow should be capable of passing the design storm to prevent frequent discharge of accumulated oil. The size of the elbow or number of elbows can be adjusted to accommodate the design flow (Berg, 1991).

MAINTENANCE

WQIs should be inspected after every storm event to determine if maintenance is required. At a minimum each WQI should be cleaned at the beginning of each change in season (Berg, 1991). The required maintenance will be site-specific due to variations in sediment and hydrocarbon loading. Maintenance should include clean-out and disposal of the sediments and removal of trash and debris. The clean-out and disposal techniques should be environmentally acceptable and in accordance with local regulations. Since WQI residuals contain hydrocarbon by-products they may require disposal as a hazardous waste. Many WQI owners contract with waste haulers to collect and dispose of these residuals. Since WQIs can be relatively deep, they may be designated as confined spaces. Caution should be exercised to comply with confined space entry safety regulations in the event that entry into the WQI is required.

COSTS

The construction costs for WQIs will vary greatly depending on the size and depth required. The construction costs (in 1993 dollars) for cast-in-place WQIs range from $5,000 to $16,000, with the average WQI costing around $8,500 (Schueler, 1992). For the basic design and construction of WQIs, the pre-manufactured units are generally less expensive than those cast-in-place (Berg, 1991).

Maintenance costs will also vary greatly depending on the size of the drainage, the amount of the residuals collected, and the clean-out and disposal methods available (Schueler, 1992). The cost of residuals removal, analysis and disposal can be major maintenance expense, particularly if the residuals are toxic and are not suitable for disposal in a conventional landfill.

ENVIRONMENTAL IMPACTS

WQIs can effectively trap trash, debris, oil and grease, and other floatables that would otherwise be discharged to surface waters (Schueler, 1992). The 1993 MWCOG study found that pollutants in the WQI sediments were similar to those pollutants found in downstream receiving water sediments (the tidal Anacostia River). This information suggests that downstream sediment contamination is linked to contaminated runoff (MWCOG, 1993). A properly designed and maintained WQIs can be an effectively BMP for reducing hydrocarbon contamination in receiving water sediments.

WQIs generally provide limited hydraulic and residuals storage. Due to the limited storage, WQIs do not provide adequate storm water quantity control. The WQI residuals require frequent removal and may require disposal as a hazardous waste. The 1993 MWCOG study found that the residuals from WQIs typically contain many priority pollutants, including polyaromatic hydrocarbons, trace metals, pthalates, phenol, toluene, and possibly methylene chloride (MWCOG, 1993). During periods of high flow, the residuals may be resuspended and released from the WQI to surface waters.

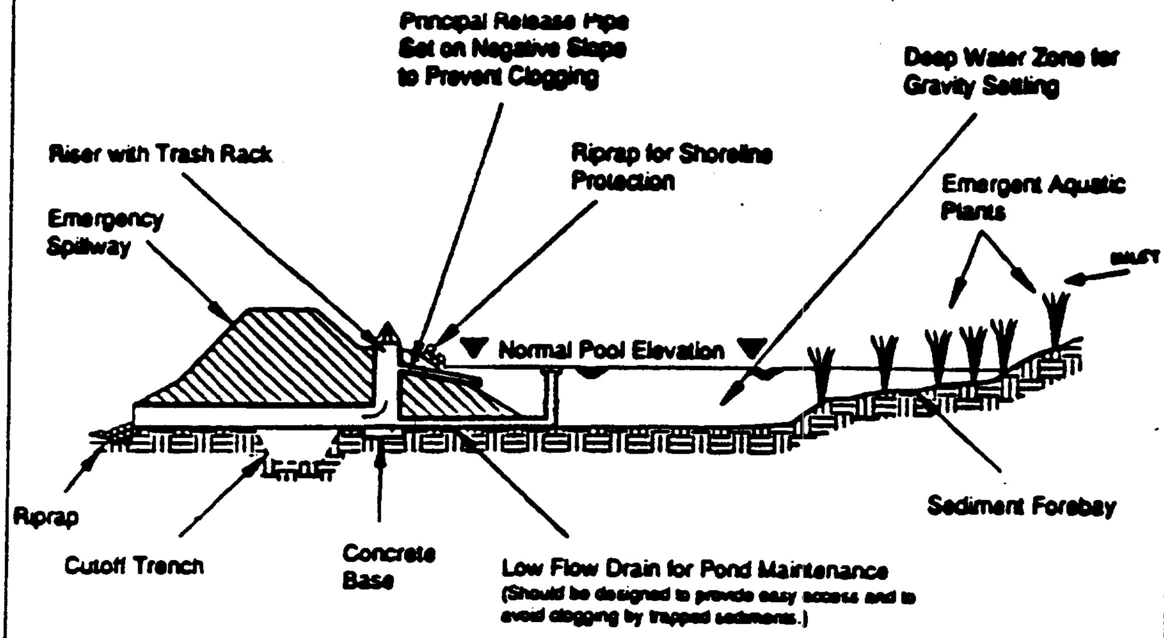
STORM WATER BMP: WET DETENTION PONDS

DESCRIPTION

Wet detention ponds provide both retention and treatment of contaminated storm water runoff. A typical wet detention pond is shown in Figure 1 below. A wet detention pond maintains a permanent pool of water where pollutant removal is achieved through physical, biological and chemical processes. Storm water runoff is detained in the pond until runoff from the next storm event mixes with and displaces some of the treated water before discharge to receiving waters. Discharge from the pond is controlled by a riser and an inverted release pipe.



SOURCE: Reference 2

FIGURE 1: TYPICAL LAYOUT OF A WET DETENTION POND

Wet detention ponds remove sediment, organic matter and metals by sedimentation and remove dissolved metals and nutrients through biological uptake. Effective pollutant removal can be achieved if the pond is properly designed and maintained (SEWPRC, 1991).

COMMON MODIFICATIONS

A typical wet pond may be enhanced with the addition of a sediment forebay, as shown in Figure 1, or by constructing shallow ledges along the edge of the permanent pool. Runoff passes through the sediment forebay where the heavier sediments drop out of suspension, while additional removal of lighter sediments occurs in the permanent pool. The shallow, peripheral ledges contain aquatic plants that trap pollutants as they enter the pond. Biological activity also increases due to the aquatic plants, and results in increased nutrient removal. Perimeter wetland areas can also be created that will aid in pollutant removal. The ledges also act as a safety precaution from accidental drowning and provide easy access for maintenance to the permanent pool.

Storm water quality control is achieved in the permanent pool, which is designed by either the eutrophication method or the solids settling method (Hartigan, 1988). Several models are available for both methods. The solids settling method accounts for pollutant removal through sedimentation, whereas the eutrophication method accounts for dissolved nutrient removal that occurs as a result of biological processes. Equations for the Walker eutrophication model are shown in Table 2 below. The solids settling method indicate that two-thirds of the sediment, nutrients and trace metal loads are removed by sedimentation within 24 hours. Theses projections are supported by the results of the EPA's 1993 National Urban Runoff Program (NURP) studies. However, other studies indicate that a hydraulic residence time (HRT) of 2 weeks is required to achieve significant phosphorus removal (MD, 1986). This longer HRT is similar to the HRT determined by the eutrophication method. In some cases, the HRTs calculated by the eutrophication method are up to three times greater than HRTs calculated by the solids settling method. These longer HRTs appear to be due to the slower reaction rates associated with the biological removal of dissolved nutrients. This results in a permanent pool that is approximately three times larger than the permanent pool calculated by solids settling models (Hartigan, 1988). Other design methods, such as sizing the permanent pool to collect a specific volume of runoff from the drainage area, have been tried with varying degrees of success, and are not described in this fact sheet.

TABLE 2: WALKER EUTROPHICATION MODEL

$$K2 = (0.056)(QS)(F)^{-1}/(QS + 13.3) \qquad (1)$$

$$R = 1+(1-(1+4N)^{0.5})/(2N) \qquad (2)$$

where:

K2	= Second order decay rate (m^3/mg-yr)
QS	= Mean overflow rate (m/yr) = Z/T

Z	= Mean depth (m)
T	= Average HRT (yr)
R	= Total P retention coefficient = BMP efficiency
N	= (K2)(P)(T)
P	= Inflow total P (ug/L)

SOURCE: Reference 3

Other key factors to be considered in the pond design are the volume and area ratios. The volume ratio, VB/VR, is the ratio of the permanent pool storage (VB) to the mean storm runoff (VR). The area ratio, A/As, is the ratio of the contributing drainage area (A) to the permanent pool surface area (As). Both ratios are considered important in the design of the pond and are correlated with treatment efficiencies. Larger VBs and smaller VRs provide for increased retention and treatment between storm events. Low VB/VR ratios result in poor pollutant removal efficiencies. The eutrophication model indicates that the VB/VR ratio should equal 4.0 for maximum efficiency (Hartigan, 1988). However, design standards for the State of Maryland set VB/VR equal to 2.5 (Hartigan, 1988). The area ratio is also an indicator of pollutant removal efficiency. Data from previous studies, indicates that area ratios less than 100 typically have better pollutant removal efficiencies (MD, 1986). A VB/VR of 4.0 is equivalent to a 2 week HRT assuming an average of 100 storm events per year (Hartigan, 1988). This can be determined using the formula VB/[(VR)(N)] = HRT, where N is the average number of storm events per year and HRT is expressed in years. A different VB/VR ratio will change the HRT. For example, in Maryland a VB/VR ratio equal to 2.5 is equivalent to a 9 day HRT (Hartigan, 1988).

One way to increase the HRT is to increase the depth of the permanent pool. However, the permanent pool depth should not exceed 20 feet. The optimal depth ranges between 3 and 9 feet for most regions, given a 2 week HRT (Hartigan, 1988). Ponds with shallower depths will have shorted HRTs. It is important to maintain a sufficient permanent pool depth in order to prevent the resuspension of trapped sediments (NVPDC, 1992). Conversely, thermal stratification and anoxic conditions in the bottom layer might develop if permanent pool depths are too great. Stratification and anoxic conditions may decrease biological activity. Anoxic conditions may also increase the potential for the release of phosphorus and heavy metals from the pond sediments (NVPDC, 1992).

In general, pond designs are unique for each site and application. Ponds should always be designed to complement the natural topography (NVPDC, 1992). The pond should be constructed with adequate slopes and lengths. While, a length-to-width ratio is usually not used in the design of wet detention ponds for storm water quantity management, a 2:1 length-to-width ratio is commonly used when water quality is of concern. In general, high length-to-width ratios (greater than 2:1) will decrease the possibility of short-circuiting and enhance sedimentation within the permanent pool. Baffles or islands can also be added within the permanent pool to increase the flow path (Hartigan, 1988). Shoreline slopes between 5:1 and 10:1 are common and allow easy access for maintenance, such as mowing and sediment removal (Hartigan, 1988). In addition, wetland vegetation is difficult to establish and maintain on slopes steeper than 10:1. Ponds should be wedge-shaped so that flow enters the pond and gradually spreads out. This minimizes the potential for zones with little or no flow (Urbonas, 1993).

The design of the wet pond embankment is another key factor to be considered. Proper design and construction of the embankments will prolong the integrity of the pond structure. Subsidence and settling will likely occur after an embankment is constructed. Therefore, during construction the embankment should be overfilled by at least 5% (SEWPRC, 1991). Seepage through the embankment can also affect the stability of the structure. Seepage can generally be minimized by adding drains, anti-seepage collars and core trenches. The embankment side slopes can be protected from erosion by using minimum side slopes of 2:1 and by covering the embankment with vegetation or rip-rap. The embankment should also have a minimum top width of 6 feet to ease maintenance.

Normal flows will be discharged through the wet pond outlet, which consists of a concrete or corrugated metal riser and barrel. The riser is a vertical pipe or inlet structure that is attached to the base with a watertight connection. Risers are typically placed in or adjacent to the embankment rather than in the middle of the pond. This provides easy access for maintenance and prevents the use of the riser as a recreation spot (e.g., diving platform for kids) (Schueler, 1988). The barrel is a horizontal pipe attached to the riser that conveys flow under the embankment.

Typically, flow passes through an inverted pipe attached to the riser, as shown in Figure 1, with higher flows will pass through a trash rack installed on the riser. The inverted pipe should discharge water from below the pond water surface to prevent floatables from clogging the pipe and to avoid discharging the warmer surface water. Clogging of the pipe could result in overtopping of the embankment and damage to the embankment (NVPDC, 1992). Flow is conveyed through the near horizontal barrel and discharged to the receiving stream. Rip-rap, plunge pools, or other energy dissipators should be placed at the outlet to prevent scouring and minimize erosion. Rip-rap also provides a secondary benefit of reaeration of the pond discharges.

The design and construction of the riser and barrel should consider the design storm and the material of construction. Generally, the riser and barrel are sized to meet the storm water management design criteria (e.g., to pass a 2-year or a 10-year storm event). In many installations the riser and barrel are designed to convey multiple design storms (Urbonas, 1993). The riser and barrel should be constructed of reinforced concrete rather than corrugated metal pipe to increase the life of the outlet. The riser, barrel and base should also have sufficient weight to prevent flotation (NVPDC, 1992).

In most cases, emergency spillways should be included in the pond design. Emergency spillways should be sized to safely pass flows that exceed the design storm flows. The spillway prevents pond water levels from overtopping the embankment, which could cause structural damage the embankment. The emergency spillway should be located so that downstream buildings and structures will not be negatively impacted by a spillway discharges. The pond design should include a low flow drain, as shown in Figure 1. The drain pipe should be designed for gravity discharge and should be equipped with an adjustable gate valve.

MAINTENANCE

Wet detention ponds function more effectively when they are regularly inspected and maintained. Routine maintenance of the pond includes mowing of the embankment and buffer areas and inspection for erosion and nuisance (e.g., borrowing animals, weeds, odors) problems (SEWPRC, 1991). Trash and debris should be routinely removed to maintain an attractive appearance and also to prevent the outlet from becoming clogged. In general, wet detention ponds should be inspected after every storm event. The embankment and emergency spillway should also be routinely inspected for structural integrity, especially after major storm events. Embankment failure could result in severe downstream flooding.

When any problems are observed during routine inspections, necessary repairs should be made immediately. Failure to correct minor problems may lead to larger more expensive repairs or even pond failure. Typically, maintenance includes repairs to the embankment, emergency spillway, inlet and outlet, removal of sediment and control of algal growth, insects and odors (SEWPRC, 1991). Large vegetation or trees that may weaken the embankment should be removed. Periodic maintenance may also include the stabilization of the outfall area (e.g., add rip-rap) to prevent erosive damage to the embankment and the stream bank. In most cases sediments removed from wet detention ponds are suitable for landfill disposal. However, where available, on-site disposal od removed sediments will reduce maintenance costs.

COSTS

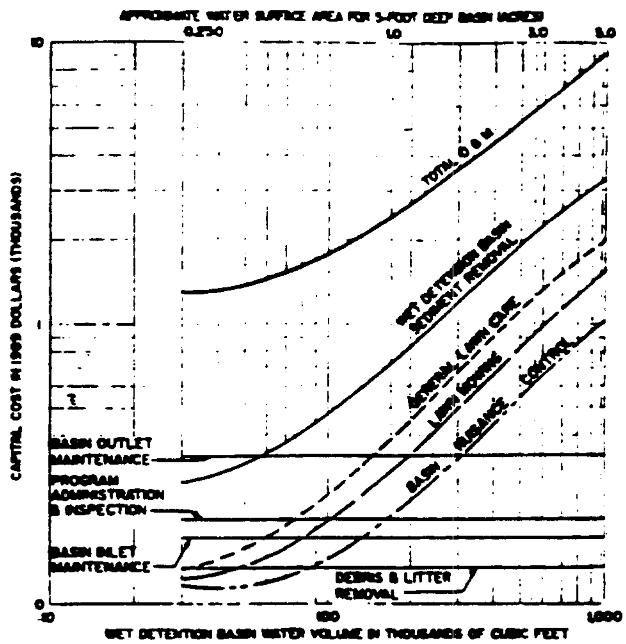
The total cost for a pond includes permitting, design and construction and maintenance costs. Permitting costs may vary depending on state and local regulations. Typically, wet detention ponds are less costly to construct in undeveloped areas than retrofitting into developed areas. This is due to the cost of land and the difficulty in finding suitable sites in developed areas. The cost of relocating of pre-existing utilities or structures is also a major concern in developed areas. The construction costs for wet detention ponds in 1989 for undeveloped areas are shown in Figure 2 below. These costs include mobilization and demobilization of heavy equipment, site preparation (e.g., clearing and excavation), site development (e.g., seeding and inlet construction) and contingencies (e.g., engineering and legal fees) (SEWPRC, 1991). Several studies have shown the construction cost of retrofitting a wet detention pond into a developed area may be 5 to 10 times the cost of constructing the same size pond in an undeveloped area.

Operation and maintenance costs in 1989 are presented in Figure 3 below (SEWPRC, 1991). Annual maintenance costs can generally be estimated at 3 to 5 percent of the construction costs (Schueler, 1992). Maintenance costs include the costs for regular inspections of the pond embankments, grass mowing, nuisance control, debris and liter removal, inlet and outlet maintenance and inspection, and sediment removal and disposal. Sediment removal costs can be decreased by as much as 50 percent if an on-site disposal areas are available (SEWPRC, 1991).

ENVIRONMENTAL IMPACTS

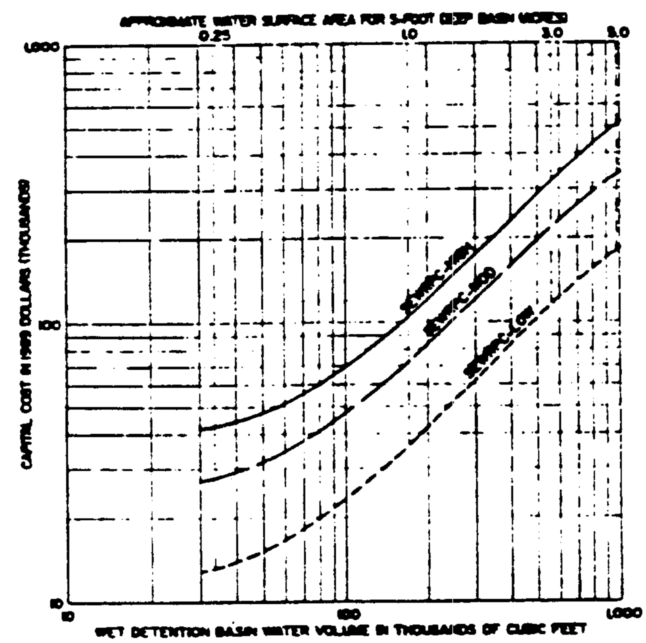
Wet detention ponds provide both storm water quantity and quality benefits. Benefits obtained from the use of wet detention ponds include decreased potential for downstream flooding and stream bank erosion. Water quality is also improved due to the removal of suspended solids, metals, and dissolved nutrients. In general, the positive impacts from a wet detention ponds will exceed any negative impacts from a pond, assuming the pond is properly designed and maintained.

TABLE 3: CONSTRUCTION COSTS (1989)



SOURCE: Reference 4

TABLE 4: OPERATIONS AND MAINTENANCE COSTS (1989)



SOURCE: Reference 4

However, wet detention ponds that are improperly designed, sited or maintained may have potential adverse affects on water quality, groundwater, cold water fisheries, or wetlands. Improperly designed or maintained ponds may result in stratification and anoxic conditions that can promote the resuspension of solids and the release of nutrients and metals from the trapped sediments. During construction, precautions should be taken to prevent damage to wetland areas. Ponds should also not be sited in areas where warm water discharges from the pond will adversely impact cold water fishery. The potential groundwater contamination should be carefully evaluated. However, studies to date indicate that wet detention ponds do not significantly contribute to groundwater contamination (Schueler, 1992).

Treatment within a pond can be enhanced through extending the detention time in the permanent pool. This allows for a more gradual release of collected runoff from a design storm over a specified time (Hartigan, 1988). This results in increased pollution removal as well as control of peak flows.

CURRENT STATUS

Wet detention ponds have been widely used throughout the U.S. for many years to treat of storm water runoff. Many of these ponds have been monitored to determine their performance. EPA Region V is currently performing a study on the effectiveness of 50 to 60 wet detention ponds. Other organizations, such as the Washington, D.C., Council of Governments (Wash COG) have also conducted extensive evaluations of wet detention pond performance (Schueler, 1992). Wet detention ponds provide the benefit of both storm water quantity and quality control. In general, a higher level of nutrient removal and better storm water quantity control can be achieved in wet detention ponds than can be achieved with other best management practices (BMPs), such as infiltration trenches or sand filters. However, proper maintenance is essential to maintaining these higher levels of treatment.

LIMITATIONS

Wet detention ponds must be able to maintain a permanent pool. Therefore, ponds should not be constructed in areas where there is insufficient precipitation or on soils that are highly permeable. In wetter regions, a small minimum drainage area may be adequate, where as, in more arid regions, a larger drainage areas may be required in order to ensure sufficient water to maintain the permanent pool. In some cases, soils that are highly permeable may be compacted or overlaid with clay blankets to make the bottom less permeable. Land constraints, such as small sites or highly developed areas, may also preclude the use of a pond. In addition, the local climate (i.e., temperature) may affect the biological uptake in the pond. With out proper maintenance, the performance of the pond will drop off sharply. Regular cleaning of the forebays is particularly important. Maintaining the permanent pool is also important in preventing the resuspension of trapped sediments. In most cases no specific limitations have been places on disposal of sediments removed from wet detention ponds. Studies to date indicate that pond sediments are likely to meet toxicity limits and can be safely landfilled (Schueler, 1992). Some states have allowed sediment disposal on-site, as long as the sediments are deposited away from the shoreline, preventing their reentry into the pond.

PERFORMANCE

The primary pollutant removal mechanism in a wet detention pond is sedimentation. Suspended pollutants, such as metals, nutrients, sediments, and organics, are partly removed by sedimentation. Other pollutant removal mechanisms include algal uptake, wetland plant uptake and bacterial decomposition (Schueler, 1992). Dissolved pollutant removal occurs as a result of biological and chemical processes (NVPDC, 1992).

The removal rates of conventional wet detention ponds (i.e., without the sediment forebay or peripheral ledges) are well documented and are shown in Table 1 below. The wide range in the removal rates is a result of varying hydraulic residence times (HRTs), which is further discussed in the Design Criteria section. Increased pollutant removal by biological uptake and sedimentation is correlated with increased HRTs. Proper design and maintenance also affect pond performance.

Studies have shown that more than 90 percent of the pollutant removal occurs during the quiescent conditions (i.e., the period between the rainfall events) (MD, 1986). However, some removal occurs during the dynamic period (i.e., when the runoff enters the pond).

TABLE 1: REMOVAL EFFICIENCIES FROM WET DETENTION PONDS

Parameter	Percent Removal	
	Schueler, 1992[1]	Hartigan, 1988[2]
Total Suspended Solid	50 - 90	80 - 90
Total Phosphorus	30 - 90	
Soluble Nutrients	40 - 80	50 - 70
Lead	70 - 80	
Zinc	40 - 50	
Biochemical Oxygen Demand or Chemical Oxygen Demand	20 - 40	

[1] hydraulic residence time varies
[2] hydraulic residence time of 2 weeks

DESIGN CRITERIA

Well designed and properly maintained ponds can function as designed for 20 years or more. Concrete risers and barrels have a longer life than corrugated metal pipe risers and barrels and are recommended for most permanent ponds (Schueler, 1992). The accumulation of sediments in the pond will reduce the storage capacity and cause a decline in performance. Therefore, the bottom sediments in the permanent pool should be removed every 2 to 5 years or as necessary. The design of the pond should allow easy access to the forebays for frequent sediment removal.

All local, state and federal permit requirements should be established prior to starting the pond design. Depending on the location of the pond, required permits and certifications may include wetland permits, water quality certifications, dam safety permits, sediment and erosion control plans, waterway permits, local grading permits, land use approvals, etc.(Schueler, 1992). Since many states and municipalities are still in the process of developing or modifying storm water permit requirements, the applicable requirements should be confirmed with the appropriate regulatory authorities.

Prior to designing the pond, a site should be selected that is able to support the pond environment. The cost effectiveness of locating a pond at that site should also be carefully evaluated. The site must have adequate base-flow from the groundwater or from the drainage area to maintain the permanent pool. Typically, underlying soils with permeability between 10^{-5} and 10^{-6} cm/sec will be adequate so that a permanent pool can be maintained. In addition, the pond should be located where the topography of the site allows for maximum storage at minimum construction costs (NVPDC, 1992). Land constraints to avoid include existing utilities (e.g., electric or gas) that would be costly to relocate and excavation of bedrock that would require expensive blasting operations.

The design of wet detention ponds should serve two functions: storm water quantity control and storm water quality control. Storm water quantity requirements are typically met by designing the pond to control post-development peak discharge rates to pre-development levels. Various routing models (i.e., Soil Conservation Service TR-20 or EPA SWMM) can be used to calculate the required storm water storage. Usually the pond is designed to control multiple design storms (e.g., 2- and/or 10-year storms) and safely pass the 100-year storm event. However, the design storm may vary depending on local conditions and requirements.

Storm Water Management Fact Sheet
Employee Training

DESCRIPTION

In-house employee training programs are established to teach employees about storm water management, potential sources of contaminants, and Best Management Practices (BMPs). Employee training programs should instill all personnel with a thorough understanding of their Storm Water Pollution Prevention Plan (SWPPP), including BMPs, processes and materials they are working with, safety hazards, practices for preventing discharges, and procedures for responding quickly and properly to toxic and hazardous material incidents.

APPLICABILITY

Typically, most industrial facilities have employee training programs. Usually these address such areas as health and safety training and fire protection. Training on storm water management and BMPs can be incorporated into these programs.

Employees can be taught through 1) posters, employee meetings, courses, and bulletin boards about storm water management, potential contaminant sources, and prevention of contamination in surface water runoff, and 2) field training programs that show areas of potential storm water contamination and associated pollutants, followed by a discussion of site-specific BMPs by trained personnel.

ADVANTAGES AND DISADVANTAGES

Advantages of an employee training program are that the program can be a low-cost and easily implementable storm water management BMP. The program can be standardized and repeated as necessary, both to train new employees and to keep its objectives fresh in the minds of more senior employees. A training program is also flexible and can be adapted as a facility's storm water management needs change over time.

Obstacles to an employee training program include:

- Lack of commitment from senior management.
- Lack of employee motivation.
- Lack of incentive to become involved in BMP implementation.

KEY PROGRAM COMPONENTS

Specific design criteria for implementing an employee training program include:

- Ensuring strong commitment and periodic input from senior management.
- Communicating frequently to ensure adequate understanding of SWPPP goals and objectives.
- Utilizing experience from past spills to prevent future spills.
- Making employees aware of BMP monitoring and spill reporting procedures.
- Developing operating manuals and standard procedures.

- Implementing spill drills.

IMPLEMENTATION

An employee training program should be an on-going, yearly process. Meetings about SWPPPs should be held at least annually, possibly in conjunction with other training programs. Figure 1 illustrates a sample employee training worksheet. Worksheets such as these can be used to plan and track employee training programs. Program performance depends on employees' participation and on senior management's commitment to reducing point and nonpoint sources of pollution; therefore, performance will vary among facilities. To be effective these programs need senior management's support

COSTS

Costs for implementing an employee training program are highly variable. Most storm water training program costs will be directly related to labor and associated overhead costs. Trainers can reduce costs by using free educational materials available on the subject of storm water quality.

Figure 2 can be used to estimate the annual costs for an in-house training program. Table 1 provides an example of how this worksheet can be used to estimate annual costs.

Storm Water Management Fact Sheet
Visual Inspection

DESCRIPTION

Visual inspection is a Best Management Practice (BMP) in which members of a Storm Water Pollution Prevention Team visually examine material storage and outdoor processing areas, the storm water discharges from such areas, and the environment in the vicinity of the discharges, to identify contaminated runoff and its possible sources.

In a visual inspection, storm water runoff may be examined for the presence of floating and suspended materials, oil and grease, discoloration, turbidity, odor, or foam; and storage areas may be inspected for leaks from containers, discolorations on the storage area floor, or other indications of a potential for pollutants to contaminate storm water runoff.

Visual inspections may indicate the need to modify a facility to reduce the risk of contaminating runoff.

APPLICABILITY

The U.S. EPA has recognized visual inspection as a baseline BMP for over 10 years. Its implementation, however, has been sporadic. Implementation may increase as more facilities develop Storm Water Pollution Prevention Plans. Implementation may also increase as facility management recognizes visual inspection to be effective both in protecting water quality and in reducing costs.

ADVANTAGES AND DISADVANTAGES

Visual inspections are an effective way to identify a variety of problems. Correcting these problems can improve the water quality of the receiving water.

Limitations associated with visual inspections include the following:

- Visual inspections are effective only for those areas clearly visible to the human eye.
- The inspections need to be performed by qualified personnel.
- To be effective, inspections must be carried out routinely. This requires a corporate commitment to implementing them.
- Inspectors need to be properly motivated to perform a thorough visual inspection.

KEY PROGRAM COMPONENTS

Visual inspections for signs of storm water contamination should be performed routinely. Flows should be observed during dry periods to determine the presence of any stains, sludge, odors, and other abnormal conditions.

Visual inspections should also be made at all storm water discharge outlet locations during the first hour of a storm event, once runoff has reached its maximum flow rate. Inspectors should examine the discharge for the presence of floating and suspended materials, oil and grease, discoloration, turbidity, foam, or odor.

Inspection frequency interval may be determined by the storm water discharge permit, by storm frequency, or by the potential risk from the site. Inspections should be made at least once a month in areas with frequent storms; inspections may be less frequent where storms are less frequent. Finally, inspection frequency may be based in part on the history of previous spills and leaks. Experienced personnel should evaluate the causes of previous accidents, assess the risks for future accidents, and determine an inspection schedule based on these risks.

Proper records of inspection results must be kept. The record for each inspection should include the date of the inspection, the names of the personnel who performed the inspection, and their observations.

Visual inspections of a facility should focus on the following key areas:

- Storage facilities.
- Transfer pipelines.
- Loading and unloading areas.
- Pipes, pumps, valves, and fittings.
- Tanks (including internal and external inspection of the tank for corrosion and inspection of its support or foundation for deterioration).
- Primary or secondary containment facilities.
- Shipping containers.

In addition, a visual inspection should include assessing the integrity of the storm water collection system; checking for leaks, seepage, and overflows from sludge and waste disposal sites; and ensuring that dry chemicals and dust from industrial areas is not exposed to wind or other elements that may move them into the runoff.

IMPLEMENTATION

A visual inspection BMP program should be incorporated into every storm water discharger's record keeping and internal reporting structure.

Outfall flow rates and the presence of oil sheens, floatables, coarse solids, color, and odors will probably be the most useful indicators of potential problems. Specific parameters to look for in completing a visual inspection include the following:

- Odor: Discharge odors can vary widely. Some may indicate the source of contamination. Industrial discharges may smell like a particular spoiled product, oil, gasoline, a specific chemical, or a solvent. For example, the decomposition of organic wastes in a discharge will release sulfide compounds, creating an intense smell of rotten eggs. Significant sanitary wastewater contributions will also cause pronounced and distinctive odors.
- Color: Color may indicate inappropriate discharges, especially from industrial sources. Industrial discharges may be any color. Dark colors, such as brown, gray, or black, are most common. For instance, flow contaminated by meat processing industries is usually a deep reddish-brown. Paper mill wastes (plating-mill wastes) are often yellow. Wash water from cement and stone working plants can cause cloudy discharges. Contamination from industrial areas may come from process waters (slug or continuous discharges); from equipment and work area wash water discharged to floor drains; or from spills washed into storm drains.
- Turbidity: Turbidity is often affected by the degree of gross contamination. Industrial flows can be cloudy (moderately turbid) or opaque (highly turbid). Undiluted industrial discharges, such as those coming from continual flow sources or intermittent spills, are often highly turbid. Sanitary wastewater is also often cloudy in nature.

- Floatable matter: A contaminated flow may also contain floatable solids or liquids. Identifying floatables can aid in finding the source of the contamination, because these substances are usually direct products or byproducts of the manufacturing process or the sanitary system. Examples of floatables of industrial origin are animal fats, spoiled food products, oils, plant parts, solvents, sawdust, foams, packing materials, and fuel.

- Deposits and Stains: Deposits and stains (residues) are any type of coating that remains after a non-storm water discharge has ceased. Deposits or stains usually are of a dark color and usually cover the area surrounding the storm water discharge. They often contain fragments of floatable substances, and, at times, take the form of a crystalline or amorphous powder. For example, contamination from leather tanneries often produces grayish-black deposits containing fragments of animal flesh and hair. Another characteristic example is the coating of white crystalline powder formed on sewer outfalls by nitrogenous fertilizer wastes.

- Vegetation: Storm water discharges often affect surrounding vegetation. Industrial pollutants often cause a substantial alteration in the chemical composition and pH of the discharge water, which can affect plant growth even when the source of contamination is intermittent. For example, nutrients from various food product wastes increase plant growth. In contrast, the discharge of chemical dyes and inorganic pigments from textile mills may decrease vegetation, as these discharges are often very acidic. In either case, even when the pollution source is gone, the vegetation surrounding the discharge will continue to show the effects of the contamination.

  In order to accurately judge if the vegetation surrounding a discharge is normal, the observer must take into account recent weather conditions, as well as the time of year. Increased or inhibited plant growth near storm water discharges, as well as dead and decaying plants, is often a sign of pollution. However, it is important to distinguish whether plant damage is caused by contamination or by the physical effects of increased flows, such as scour. This can be done by chemically analyzing the flow or by confirming its source through additional visual inspections.

- Structural Damage: Structural damage is also a sign of industrial discharge contamination. Cracked or deteriorated concrete or peeling surface paint at an outfall usually indicates the presence of severely contaminated discharges. Contaminants causing this type of damage are usually very acidic or basic and are usually of industrial origin. For instance, discharges from primary metal industries may cause structural damage because their batch dumps are highly acidic.

The effectiveness visual inspections in reducing storm water runoff contamination is highly variable and dependent upon site-specific parameters. These factors include inspectors' motivation level, the types of industrial activity occurring at the facility, and the facility's maintenance procedures. Because familiarity with facility operations is essential in performing effective visual inspections, the inspections should be assigned to qualified staff such as maintenance personnel or environmental engineers. Figure 1 provides a sample visual evaluation worksheet that can be used to record the results of the inspections.

COSTS

Costs for performing the visual inspection BMP are minimal and consist of direct labor and overhead costs for staff hours spent on training, planning inspections, inspecting, and completing follow up activities. Annual costs can be estimated using the example in Table 1. Figure 2 can be used as a worksheet to calculate the estimated annual cost for implementing a visual inspection program.

ECONOMIC ANALYSIS OF THE STORM WATER PHASE II PROPOSED RULE: INITIAL FINAL DRAFT

August 1,1997

U.S. Environmental Protection Agency
Office of Wastewater Management
401 M Street, SW
Washington, DC 20460

EXECUTIVE SUMMARY

This Economic Analysis (EA) includes the U.S. Environmental Protection Agency's (EPA) analysis of the national compliance costs and benefits, including monetized and non-monetized benefits, associated with the proposed phase II storm water regulation. A comparison of costs and benefits is also included. This EA also includes analyses for Executive Order 12866 for Regulatory Impact Analysis (RIA), the Regulatory Flexibility Act of 1980, the Small Business Regulatory Enforcement Fairness Act of 1996, Executive Order 12898 for Environmental Justice, the Unfunded Mandate Reform Act of 1995, and the Paperwork Reduction Act of 1995. The findings of these analyses are summarized in the following sections.

The proposed phase II storm water regulation has been developed pursuant to Section 402(p)(6) of the Federal Water Pollution Control Act (hereinafter referred to as the Clean Water Act [CWA]) and will serve as the final regulatory component in a phased program designed to control contaminated discharges associated with storm water runoff. Specifically, the phase II regulation will address contaminated storm water discharges from small municipal separate storm sewer systems (MS4s) and construction activities at small construction sites (sites disturbing greater than or equal to 1 acre and less than 5 acres). Existing phase I regulations currently address contaminated storm water discharges from medium and large municipalities, [1] construction activities at sites disturbing five acres or greater, and specified industrial activities (40 C.F.R. §122.26).

OPTIONS FOR IMPLEMENTING THE STORM WATER PHASE II PROGRAM

The proposed phase II storm water regulation has been developed pursuant to the requirements of CWA §402(p)(6) and is based on the findings of the Phase II Storm Water Report to Congress,[2] public and expert comments and testimony, other technical data and literature, and input from members of the Storm Water Phase II Federal Advisory (FACA) Subcommittee. EPA worked with the FACA Subcommittee for more than 18 months to develop the proposed phase II regulation.

[1] Phase I also provides authority to regulate municipalities that contribute to water quality impacts.

[2] *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress*. U.S. EPA, Office of Water, March 1995, EPA 833-K-94-002. The Storm Water Phase II Report to Congress includes the recommendations of the *Clinton Clean Water Initiative*.

Working with the FACA Subcommittee, EPA considered numerous alternative approaches and requirements for each of the basic components of the proposed regulation, including the structural approach to implementing the program, the scope of coverage of the proposed regulation, and substantive requirements applicable to each category of phase II sources, including waivers. Major alternatives to the basic program components included:

- Structuring the phase II program as a National Pollutant Discharge Elimination System (NPDES) permit-based program, a non-NPDES program, or a program that allows use of NPDES permits as well as other mechanisms (e.g., permit-by-rule)
- Designating *all* small municipal storm sewer systems (MS4s) as sources subject to the phase II regulation; designating only those small MS4s that meet specified criteria (e.g., census-designated urbanized area); or allowing the permitting authority to determine which small MS4s require phase II regulation
- Designating all land-disturbing construction sites not subject to phase I (i.e., under 5 acres) as sources subject to the phase II regulation (a variation provided for an exemption based on de minimis impact); those construction activities involving clearing, grading, or excavating greater or equal to 1 acre and less than 5 acres of land; or use of a local ordinance or state plan under which all construction- related sources of runoff pollution would have to be controlled to the greatest extent feasible
- Designating certain industrial or commercial activities not expressly subject to phase I (e.g., facilities that maintain, fuel, clean or rehabilitate two types of machinery, heavy industrial equipment and school buses) as sources subject to the phase II regulation
- Determining and defining those best management practices considered minimum measures for small MS4s (e.g., public education and outreach, public involvement, illicit discharges, construction site storm water discharge control, post-construction storm water management in new and re-development, pollution prevention/good housekeeping, evaluation and assessment)

EPA also examined providing exemptions or waivers for situations where there is no exposure of industrial materials to storm water, there exists a watershed plan or total maximum daily load (TMDL) that adequately addresses pollutants of concern, rainfall or erosion is limited, and storm water results in no impact on water quality.

Consideration of alternatives by the EPA and the FACA Subcommittee was an iterative process, one that started with a broad range of issues and worked toward acceptable specific alternatives within each program component. One result of this process is that the alternatives discussed in this EA tend to be distinguished by differences in the components of the proposed regulation (e.g., scope of coverage for small MS4s or small construction sites) rather than differences in the overall regulatory approach (e.g., NPDES versus non-NPDES). Where the FACA Subcommittee's recommendations to EPA reflect some agreement on a particular issue, this is reflected in the alternatives considered and the proposed regulation.

In cases where agreement was not reached by the FACA Subcommittee, EPA considered the numerous options presented and selected those that best satisfy the objectives of the phase II program. These objectives include the general goals of protecting water quality, providing sufficient flexibility to the permitting authority to focus on priority phase II sources within the relevant watershed, and achieving compatibility with the phase I program. Additional specific objectives include a desire for a single comprehensive program, the need for the program to be effectively enforced, an emphasis on public participation, the ability of the program to address all phase II sources, and efficient utilization of existing programs.

In addition to considering alternative approaches to specific components of the phase II proposed rule, EPA also worked with the FACA Subcommittee to combine these components into several distinct phase II regulatory options. Major regulatory alternatives addressed in this RIA include:

- No regulation of phase II sources (Status Quo)
- The final phase II rule promulgated on August 7, 1995 (60 FR 40230)
- An NPDES Permit/Partnership approach (Plan B)
- A flexible NPDES storm water program.

The proposed phase II regulation is based on the flexible NPDES program alternative. This alternative has evolved through several iterations to incorporate aspects of each of the other alternatives that best achieve the objectives of the storm water program. A primary characteristic of the proposed rule is the flexibility it offers both the permitting authority and small MS4s and small construction sites. A summary of the proposed phase II rule is provided in Exhibit ES-1.

EVALUATION OF NATIONAL COMPLIANCE COSTS

EPA developed detailed cost estimates for the incremental requirements imposed under the proposed phase II regulation and applied these estimates to the potentially regulated universe of phase II sources. Where necessary, simplifying assumptions were made to facilitate the analysis and to overcome data limitations. These assumptions were designed to be "conservative," that is, where uncertain of costs

Exhibit ES-1. Overview of Proposed Phase II Storm Water Regulation

Scope of Coverage	Regulates Small Municipalities (Population under 100,000): MS4s located in an incorporated place, county or other place under jurisdiction of a governmental entity and within a census-designated urbanized area. The permitting authority would be required to evaluate those small MS4s located in an incorporated place, county or other place under jurisdiction of a governmental entity and outside an urbanized area with a population density of greater than 1,000 people per square mile and a population greater than 10,000. These MS4s would be designated as phase II sources where they meet criteria that indicate the potential to result in significant water quality impacts. The permitting authority would be required to designate any incorporated place, county or other place under jurisdiction of a governmental entity that contributes substantially to the storm water pollutant loadings of a physically inter-connected MS4 regulated under an NPDES permit. Small Construction Sites: Discharges from construction activities that disturb greater than or equal to 1 acre and less than 5 acres, unless otherwise waived from certain program requirements. Sites disturbing less than 1 acre are also regulated if part of a larger common plan of development or sale.
Requirements	Small Municipalities (Population under 100,000): Each small MS4 would be required to obtain coverage under a NPDES permit. Permit would require that the small MS4 develop, implement, and enforce a storm water management program designed to reduce pollutants to the maximum extent practicable and protect water quality. Each small MS4 would be required to specify in their permit application or notice of intent to be covered under a general permit the best management practices that will be used in their storm water management program and measurable goals for six specified minimum control measures. These minimum measures include: public education and outreach, public involvement/ participation, illicit discharge detection and elimination, construction site storm water runoff control, post-construction storm water management in new development and re-development, and pollution prevention/good housekeeping for municipal operations. Small Construction Sites: Obtain coverage under a NPDES permit. Small construction site operators would be required to seek such permits under the phase I storm water requirements. General permit requirements under phase I include storm water pollution prevention planning, soil and erosion control, notice of intent, notice of termination, and municipal notification. The permitting authority could reference qualifying soil and erosion control measures.
Exemptions/Waivers	Storm water discharges from industrial facilities do not require a NPDES permit where owner or operator achieves and certifies no exposure of industrial materials or activities to storm water. Applicable to phase I and phase II. Not applicable to large or small construction sites, or individually designated sources. Permitting authority could authorize small construction sites to discharge subject to a general permit without submitting an NOI. Permit authority could waive regulation of a MS4 when the total population served by the MS4 is less than 1,000 people. The waiver may be provided if there are no water quality violations and no substantial contribution of pollutants to physically inter-connected and regulated MS4s. Permitting authority could waive requirements applicable to construction site disturbing 1 to 5 acres where waste load allocations (TMDL) addresses pollutants of concern; a comprehensive watershed plan addresses pollutants of concern; rainfall energy factor less than 2 during construction; or annual soil loss less than 2 tons per acre per year.
Other	Persons can petition the permitting authority to subject an MS4 to NPDES coverage. Permitting authority may designate other sources based on the potential for water quality impacts or significant contribution of pollutants.

EPA chose to be conservative by estimating higher, rather than lower, costs. EPA's approach for estimating costs for small MS4s involved:

- Identifying and characterizing the requirements of the proposed phase II regulation
- Applying cost data collected under the phase I storm water program for common program elements that represent incremental phase II requirements
- Developing minimum, mean, and maximum per capita costs for each of the six minimum measures required under the proposed phase II regulation
- Applying per capita costs to the potential universe of phase II municipalities for the first permit cycle
- Developing total and per capita cost estimates for the second and third permit cycles excluding certain first permit cycle costs (e.g., illicit connections) assumed completed during first permit cycle
- Developing other municipal costs (e.g., submittal of an application, record keeping, and reporting) from data previously developed under the phase I program.

EPA's approach for estimating costs for small construction sites involved:

- Identifying and characterizing the requirements of the proposed phase II regulation
- Developing an estimate of construction starts involving sites equal to or greater than 1 acre but less than 5 acres based on building permit data collected by the U.S. Bureau of the Census and then estimating the number of building permits issued on individual construction sites
- Determining the number of construction starts subject to incremental costs associated with the proposed phase II regulation through reviewing data on existing storm water requirements imposed by NPDES-authorized States on small sites
- Determining the fraction of starts where soil and erosion control is an incremental phase II cost based on a survey of local soil and erosion control programs
- Developing cost estimates for development of the storm water pollution prevention plan based on cost data from the phase I construction general permit
- Developing unit cost estimates for soil and erosion controls based on the control appropriate for small sites and applying these cost estimates to 21 scenarios in order to estimate the range of expected costs
- Developing cost estimates for the submittal of a notice of intent, notice of termination and notification to the local municipality based on cost data from the phase I construction general permit.

Exhibit ES-2. Summary of Major Cost Assumptions

Assumption	Potential Impact on Analysis
Estimated expenditures from large and medium sized municipal storm sewer systems (MS4s) were used to extrapolate the costs of minimum measures to phase II municipalities.	Potentially overstates the costs because phase II communities are smaller and do not have as many structures to maintain, systems to map, or connections to inspect for illicit discharges. Also, potentially understates per capita costs because smaller populations are required to finance public meetings, information packets, etc.
Not all phase II municipalities were expected to incur incremental costs for the minimum measures because many communities are already conducting regular maintenance of infrastructure and have storm water ordinances already in effect.	Potentially overstates costs. It is unknown what phase II communities are currently doing to control storm water discharges or what they may do before promulgation of a final phase II rule. Coastal communities will have some CZARA §6217 requirements that will need to be implemented prior to promulgation of the phase II rule.
Construction cost analysis includes Coastal Zone Act Reauthorization Amendments (CZARA) §6217 sites and does not take credit for soil and erosion controls that will be required in coastal counties prior to promulgation of the final phase II rule.	Overstates construction costs by including soil and erosion control costs in the analysis. Costs for storm water pollution prevention plans, notice of intent, and notice of termination are included in the analysis because they are required by the construction general permit but not the CZARA §6217 program.
Construction starts were estimated to increase 2.1 percent annually.	This assumption most likely over estimates the construction costs because the growth rate for construction starts fluctuates yearly and does not necessarily increase each year.
Distributing construction starts by size categories based on data collected from Prince George's County, Maryland.	Data may either under or over estimate the number of building permits issued for single-family homes occurring in developments greater than 5 acres. This will either over- or understate construction costs (i.e., there will be more, or less, single-family construction starts occurring on land disturbing less than 5 acres of land).
Use of general National Pollutant Discharge Elimination System permit.	The cost analysis assumes that municipalities, industrial facilities, and construction sites will apply for general permits. This may underestimate costs because some could apply for an individual permit. Phase II MS4s have the option to join together, if possible, or to request inclusion with an existing phase I MS4 permittee. If either of these occur on a widespread bases the municipal costs may be overstated.
Overlap with phase I requirements.	Whenever the phase II rule requires activities similar to phase I, such as permit conditions, the default was to use cost estimates developed for the phase I permits. This may overstate costs.
The number of starts were reduced by 15 percent annually to account for the construction waiver.	EPA estimates the number of construction sites that will apply for a waiver from the construction requirements of the phase II rule to range from 5 to 25 percent. The true number of sites which will be able to utilize the waiver is unknown, therefore, the 15 percent reduction may either under or overstate costs.
Construction cost off-set.	Potentially understates costs. Treating increases in the value of residential dwellings due to location near storm water ponds as a cost off-set may understate compliance costs for the construction industry.

R0010287

Major assumptions used in developing the cost estimates for small municipalities and small construction sites are summarized in Exhibit ES-2. In general, these assumptions tend to overstate rather than understate costs associated with the phase II regulation. For example, cost data drawn from phase I may overstate costs incurred by phase II sources because phase I sources must implement BMPs across a significantly larger spectrum of facilities, structures, and people. A second example is the inclusion of sites that may be subject to Coastal Zone Act Reauthorization Amendment (CZARA) requirements. CZARA requires coastal communities to implement management measures to address nonpoint source runoff from several specific types of activities, including construction activities in urban areas. By including construction sites potentially subject to these requirements, this analysis potentially overstates costs.

Exhibit ES-3 presents a summary of the estimated annual range of total annual costs imposed under the proposed phase II regulation and other major options considered. The range of values for each option includes the costs for compliance, which encompasses the paperwork requirements.

Exhibit ES-3. Summary of Total Annual Low-High Cost Estimates (Millions of 1997 Dollars)

	Status Quo	August 7, 1995 Final Rule	Plan B	September 30, 1996 Draft Proposed Rule	February 13, 1997 Draft Proposed Rule	Proposed Phase II Rule
Construction	$0	$270–$2,719	$225–$2,015	$153–$1,282	$17–$165	$17–$165
Municipal	$0	$632–$1,787	$350–$1,489	$94–$271	$94–$271	$94–$271
Industrial	$0	$1,218–$74,825	$0	$46–$2,632	$46–$2,632	$0
Total Cost	$0	$2,120–$79,331	$575–$3,504	$293–$4,185	$157–$3,068	$111–$436

Because the phase II proposed rule provides a significant degree of flexibility to the permitting authority and regulated phase II sources, the actual costs of implementing the proposed storm water phase II rule are highly dependent on how the program is implemented by the permitting authority and regulated phase II sources. To some extent, this flexibility is reflected in the broad ranges of costs. EPA believes that because of the significant flexibility provided by the proposed rule, the low to middle ranges of costs are most representative of the actual costs likely to be incurred. For example, in the municipal cost analysis, the maximum per capita estimate was driven by one municipality. The estimate for this municipality was viewed as an outlier and after it was removed from the data set, the maximum values approached the minimum values.

SOCIAL COSTS

The social costs of a proposed regulation include the costs imposed on the regulated community to achieve compliance with the proposed,[3] as well as the State and Federal costs of administering the regulation. Under the proposed phase II regulation, no compliance requirements have been deemed to require capital expenditure, however, EPA has included opportunity costs on the estimated total annual compliance cost for MS4s.

EPA estimated the cost to the Federal and State governments for administering the proposed regulation. The main component of this administrative cost category is the cost of labor and material resources for administering the municipal permit program (processing applications, reviewing storm water pollution prevention plans, reviewing municipal reports, and issuing permits) and for administering the construction program (Notice of Intent [NOI] and Notice of Termination [NOT] tracking).

EPA estimated unit costs for administrative function in the following areas:

- Incorporation of 401 certification into permits and revising storm water goals in non NPDES-authorized States;
- Permit application and issuance for municipalities including processing of applications, developing and issuing permits, reviewing the storm water pollution prevention plans, and reviewing the reports required of small regulated MS4s;
- NOI and NOT tracking for construction general permits; and
- Repermitting municipal sources.

Exhibit ES-4 presents the range of estimated social costs associated with the proposed storm water phase II regulation. The cost accounts have been separated to indicate the costs associated with information collection assessed pursuant to the Paperwork Reduction Act, as well as non-Paperwork Reduction Act compliance costs. Paperwork costs include applications, report preparation and generation, and record keeping. Non-paperwork compliance costs include items such as soil and erosion controls and public outreach activities.

[3] In this EA, this cost has been adjusted for the increase in property value of residential dwellings located around constructed ponds.

Exhibit ES-4. Estimated Total Annual Social Costs for the Proposed Storm Water Phase II Rule (Millions of 1997 $)

Social Cost Categories	Low Value	High Value
Total Annual Cost to Regulated Community for Compliance		
– Construction		
- PRA Costs	$26.0	$52.7
- Non PRA Costs	$81.0	$912.3
- Construction Cost Off-Set (negative cost)	-$90.0	-$800.0
– Municipalities		
- PRA Costs	$0.9	$2.1
- Non PRA Costs	$94.1	$269.3
Annual Opportunity Costs	$16.0	$46.2
Annual Unemployment Costs	$0.0	$0.0
Annual Costs for Administering the Proposed Regulation		
– Federal Costs		
- PRA Costs	$0.5	$1.3
- Non PRA Costs	$0.1	$0.4
– State Costs		
- PRA Costs	$2.4	$6.1
- Non PRA Costs	$0.4	$3.8
Estimated Total Annual Social Cost	$131.4	$494.2

Source: Exhibit 6-3

EVALUATION OF BENEFITS

Estimates of total annual monetized benefits associated with the phase II regulation were derived from an aggregate, "top-down" approach. This means that the underlying data and assumptions were geared to a national scale (e.g., national value of the commercial fishery, nationwide beach visit data). This approach was selected because research indicated that, given the variability of local situations and the scarcity of data on both local conditions and on extrapolation methods. A bottom-up approach is not feasible at this time. Nevertheless, information from more geographically-confined studies provided important data that support the benefit analysis. In addition, local and regional experiences also provided verification of some of the impacts and benefits that are estimated at a national level.

One consequence of the approach used to estimate total annual monetized benefits is that, unlike the cost analysis, the benefits analysis does not provide monetized estimates of the benefits associated with each phase II regulatory alternative.

Total annual monetized benefit estimates were derived using an approach in which the benefits of discrete, large-scale changes in water quality beyond present day conditions were estimated and then a share of those benefits was apportioned to the storm water phase II rule. To allocate water quality impacts to storm water runoff, data from the 1994 *National Water Quality Inventory* was used.[4] Prior to selecting these data for use in the analysis a comprehensive review of data sources and other analyses to identify sources that would meet three necessary criteria was used. The data source must provide information on a national level, address both coastal and interior water bodies, and provide comprehensive information on the contribution of storm water runoff to water quality impairment. The *Inventory* was the only national, comprehensive source of data on degrees and sources of water use impairment that addressed storm water runoff as well as other sources of water quality problems. Other data sources exist, such as the Clean Water Act Effects Model but they are limited in scope and coverage and could not provide a national benefits estimate.

The share of water quality improvement benefits attributed to phase II was based on the following approach. First, the maximum benefits obtainable after all non-CSO storm water impairments were reversed was estimated.[5] The benefits analysis identified numerous areas where controls on storm water runoff would have positive financial impacts on society through avoided costs or enhanced value or income. These include: enhanced commercial fisheries, avoided treatment costs, avoided water storage replacement costs, avoided navigational dredging costs, avoided damages from floatables, avoided flood damage and cleanup costs, and avoided streambank erosion. Similarly, the benefits analysis identified the following recreational benefits: enhanced opportunities for swimming, enhanced opportunities for fishing, reduced illness from consuming contaminated seafood, reduced illness from swimming in contaminated waters, enhanced opportunities for boating, and enhanced opportunities for other, non-contact recreation.

Exhibit ES-5 presents the range of total annual monetized benefits associated with controlling water impairments resulting from storm water discharges. This exhibit includes the estimated maximum total annual monetized benefit that could be attained by controlling discharges from storm water phase I and phase II sources and sanitary sewer overflows.

[4] This report is also known as the 305(b) Report to Congress.

[5] This includes discharges from storm water phase I sources, storm water phase II sources, and sanitary sewer overflows. This does not include combined sewer overflows.

Exhibit ES-5. Total Annual Monetized Storm Water Benefits (Thousands of 1997 $)

	Lower bound	Upper Bound
Financial Benefits	$165,800	$478,300
Recreational Benefits	$83,900	$551,900
Health Benefits	$3,873	$7,900
Total	$253,573	$1,038,100

Source: Exhibit 10-4.

After estimating maximum potential storm water control benefits, the share of storm water impairments that are attributable to sanitary sewer overflows and to phase I storm water sources, were estimated and removed. Finally, to account for the fact that any control will not be 100 percent effective, EPA estimated the effectiveness of the phase II storm water best management practices and applied these estimates to the total annual phase II monetized benefits. Due to the uncertainty regarding the rate of effectiveness of different best management practices and other related issues such as allocating benefits between other EPA Wet Weather Programs, EPA developed 3 scenarios to estimate phase II total annual monetary benefits.

Scenario 1 includes the following assumptions:

- When monetary benefits resulting from controlling sanitary sewer overflows and storm water pollutants overlap, 2/7 of the benefits should be attributed to sanitary sewers and 5/7 to storm water
- Municipal benefits were distributed 50:50 between phase I and phase II sources
- Construction benefits were split 40 percent for phase I sources and 60 percent for phase II sources
- EPA also determined that 100 percent of all benefits that can be attributed to industrial sources are phase I benefits
- EPA estimated the total monetized benefits if the storm water controls were 90 percent effective in removing or prohibiting storm water pollutants. This number is based on effective installation combined with monthly inspections. Ninety percent effectiveness is consistent with the maximum effectiveness of a properly installed silt fence. Silt fences are a low cost and commonly used best management practice at construction sites.

Scenario 2 includes the following assumptions:

- When monetary benefits result from controlling sanitary sewer overflows and storm water pollutants overlap that 2/7 of the benefits should be attributed to sanitary sewers and 5/7 to storm water

- Municipal benefits were distributed 50:50 between phase I and phase II sources

- Construction benefits were split 50:50 between phase I and phase II sources

- EPA also determined that 100 percent of all benefits that can be attributed to industrial sources are phase I benefits

- EPA estimated storm water benefits if the controls were 60 percent effective in prohibiting storm water contamination or in the removal of storm water pollutants. EPA believes that once the phase II permittees adopt and implement storm water best management practices the effectiveness of the practices will vary. The effectiveness will vary because permittees are not required to implement specific practices and the effectiveness between properly installed practices varies. Therefore, EPA suggests that the effectiveness of phase II storm water controls may be as little as 60 percent if controls are not properly installed and inspected.

Scenario 3 includes the following assumptions.

- EPA decided to split the benefit categories that overlap all wet weather programs (combined sewers, sanitary sewers, and storm water) based on total suspended solids (TSS). EPA has determined the benefits split should be as follows for these categories: 1 percent for sanitary sewer overflows, 3 percent for combined sewer overflows, and 96 percent for storm water.

- Municipal benefits were distributed 50:50 between phase I and phase II sources.

- Construction benefits were split 40:60 between phase I and phase II sources.

- It was determined that 100 percent of all benefits that can be attributed to industrial sources are phase I benefits.

- Total monetized benefits were estimated as if the storm water controls were 80 percent effective in removing or prohibiting storm water pollutants. Eighty percent effectiveness is consistent with the TSS removal efficiency goal of the CZARA program.

Exhibit ES-6. Summary of Total Annual Monetized Benefits from Implementation of the Proposed Phase II Storm Water Rule (Millions of 1997 $)

Benefits Category	Scenario 1 Annual Value	Scenario 2 Annual Value	Scenario 3 Annual Value
Financial Benefits	$83 - $265	$42 - $130	$71 - $226
Recreational Benefits	$35 - $228	$22 - $149	$31 - $202
Health Benefits	$1 - $3	$1 - $2	$2 - $4
Total	$119 - $495	$65 - $281	$104 - $431

Source: Exhibit 10-8.

Although this analysis identified and monetized significant benefits associated with the proposed phase II storm water regulation, it did not address all benefits associated with the proposed regulation since not all such benefits can be readily monetized. For example, the benefits of storm water runoff controls in protecting habitats and wildlife are not addressed in the estimates provided above. Hydromodification is addressed in the benefits analysis, but it is extremely difficult to estimate the monetized benefit from controlling sources on a large-scale basis.

COMPARISON OF COSTS AND BENEFITS/COST-EFFECTIVENESS

As discussed above, EPA was able to develop a partial monetary estimate of expected annual benefits for the storm water phase II proposed rule for financial benefits, recreational benefits, and health benefits. Summing the annual monetized benefits, for each of the scenarios, across these categories results in total annual monetized benefits ranging from approximately $66 million to $495 million (1997 $) annually for the proposed rule. This estimate of benefits understates the true value of storm water controls because it omits numerous mechanisms by which society is likely to benefit from reduced storm water pollution, such as improved aesthetic quality of waters, benefits to wildlife and to threatened and endangered species, option existence values, cultural values, tourism benefits, biodiversity benefits, and reduced siting costs for reservoirs.

Exhibit ES-7 presents a comparison of the estimated total annual monetized benefits with the total annual costs associated with the proposed storm water phase II regulation. Because EPA is uncertain of the exact total annual monetized benefit the benefits for each scenario has been compared to total annual costs. The net annual social benefits (social benefits less social costs) for the three benefits scenarios range from a low of negative $63.1 million in Scenario 2 to a high of negative $0.2 million in Scenario 1.

Exhibit ES-7. Comparison of Total Annual Monetized Benefits to Total Annual Costs for the Proposed Phase II Storm Water Rule (Millions of 1997 $)

Benefit Categories	Scenario 1 Value	Scenario 2 Value	Scenario 3 Value
Financial Benefits	$ 83.6 - $264.5	$42.1 - $130.5	$71.5 - $226.2
Recreational Benefits	$ 34.6 - $227.6	$22.8 - $149.4	$30.8 - $202.3
Health Benefits	$ 1.2 - $ 2.5	$0.8 - $ 1.6	$1.5 - $ 3.2
	$ 119.4 - $ 494.6	$ 65.7 - $ 281.5	$103.8 - $ 431.7
Cost Categories	Value	(Low- High)	
Compliance Costs		$ 112.0 - $ 437.0	
Opportunity Costs		$ 16.0 - $ 46.2	
Administration Costs		$ 3.4 - $ 11.6	
Total Monetized Costs		$ 131.4 - $ 494.8	
Net Monetized Benefits	$ (12.0) - $ (0.2)	$ (65.7) - $ (213.3)	$ (27.9) - $ (63.1)

Source: Exhibit 11-1.

EPA believes that there are several aspects of the storm water phase II rule that inherently encourage the selection of cost-effective practices. EPA structured the proposed storm water phase II rule to allow NPDES permitting authorities to develop specific programs that reflect the most cost-effective approach given regional and watershed-specific conditions. In addition, given the flexibility provided in this rule would allow regulated entities to select the most cost-effective storm water best management practice because it is in their economic interest to do so.

The proposed phase II storm water regulation has been structured to protect water quality through completing the phased storm water program while providing a maximum amount of flexibility to those affected by the program. In developing this proposed regulation, EPA has combined those provisions deemed most important by the Agency and stakeholders on the FACA Subcommittee, and has worked to achieve an approach that will be cost effective. Among the options considered, the proposed regulation would impose the lowest estimated costs on the regulated community and those agencies responsible for implementing the rule while achieving significant benefits. In addition, the flexibility provided under the proposed phase II regulation promotes efficient implementation. EPA believes these factors support the regulatory approach proposed.

REGULATORY FLEXIBILITY ANALYSIS

In compliance with the Regulatory Flexibility Act of 1980 (RFA) as amended by the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA), EPA analyzed the potential for the proposed phase II storm water regulation to have a significant economic impact on a substantial number of small entities. In identifying small entities potentially affected by the rule, EPA used the definitions of small businesses, municipalities, and nonprofit organizations established by the RFA and the Small Business Administration (SBA). Criteria for determining whether an impact is significant are established by EPA guidelines.

Based on data from the 1990 U.S. Census, EPA identified a total of 3,614 small municipalities subject to the proposed rule. In addition, 11 American Indian reservations are potentially affected. EPA identified 187,610 construction firms in SIC 15 with annual sales within applicable SBA size standards (between $0 and $17 million). However, it is not possible to distinguish which of these business are not involved in site development (and thus not subject to the proposed rule). The proposed rule does not apply to any nonprofit organizations.

EPA conducted screening analyses of the potential economic impact of the proposed rule on the identified small entities. For municipalities, EPA conducted a "revenue test." This test calculates total annual compliance cost as a percentage of total annual municipal revenues. EPA calculated total annual compliance cost based on mean costs ($2.69 per capita and $555 per municipality) and the population reported in the 1990 Census. EPA estimated annual revenues based on data from the 1992 Census of Governments, using state-specific estimates of annual revenue per capita for municipalities in three population size categories (fewer than 10,000, 10,000–25,000, and 25,000–50,000). EPA performed the revenue test for American Indian reservations using these same sources but adjusted the per capita revenue estimates.[6]

EPA conducted a "sales test" to evaluate the potential economic impact of compliance costs on small businesses. This test compares annual compliance cost as a percentage of total sales. Because the available data are not amenable to this calculation, EPA approximated the sales test by estimating

[6] Revenue per capita for tribal governments was not available. Therefore, EPA used the state-specific municipal per capita revenue estimates by size category and adjusted these estimates downward based on the ratio of per capita income on the reservation to per capita income for the state. EPA then multiplied the adjusted estimates of per capita revenue by the reservation population and conducted the screening analysis in the same manner as for municipalities (assuming annual compliance costs of $2.69 per capita and $555 per reservation).

compliance costs for single-family homes under various scenarios and comparing those costs with the median sale price of a single-family home. However, it is unlikely that the compliance costs will be borne by businesses developing construction sites and building and selling new single-family homes because they are able to pass regulatory costs on to buyers.

Based on criteria established for use in implementing the RFA and SBREFA, EPA does not expect the proposed phase II storm water rule to have a significant economic impact on a substantial number of small entities. The results of a revenue test for municipalities indicate that mean estimated compliance costs represent greater than 1% of estimated revenues for only 62 (or 1.7%) of the affected small municipalities, and greater than 3% of estimated revenues for only 4 (or 0.1%) small municipalities. Thus, the rule may be presumed not to have a significant economic impact on a substantial number of small entities (a Category 1 rule). A doubling of the estimated per capita portion of compliance costs does not change this potential classification. In addition, only a small number of Native American reservations are affected, which also does not change the potential classification.

EPA's approximation of a "sales test" for site developers and building contractors suggests that mean compliance costs will not exceed 1% of sales for a construction business that builds and sells typical single-family homes (the one exception is for homes built on sites between 4 and 5 acres, when the sales test ratio is estimated based on the median home price and including soil and erosion costs). In addition, as described above, these costs will most likely be passed on to the homebuyer. Indeed, EPA's analysis indicated that the potential increase in monthly mortgage payments may range from $0.79 to $13.51, which is relatively small compared to average monthly payments ranging from $900 to $1,500. Thus, a "pass through" of costs to home buyers appears feasible. These results suggest that the rule may be classified as Category 1 for building contractors as well.

ENVIRONMENTAL JUSTICE

Executive Order 12898 established a federal policy for incorporating environmental justice into federal agency missions by directing agencies to identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations. EPA ensured consideration of environmental justice concerns during the Phase II rulemaking by selecting a balanced FACA membership and specifically inviting a representative of the Environmental Justice Information Center to participate on the storm water phase II FACA subcommittee. Together, the FACA and EPA examined the potential impact of the proposed storm water phase II rule on low-income and minority populations, and worked to develop a proposed rule that would advance environmental justice.

Three aspects of the proposed storm water phase II regulation will promote environmental justice. First, the proposed rule would result in improvements in water quality in the areas around small municipalities and certain industries that impact water quality. These improvements will benefit all persons living in or using these areas, including minority populations and low-income populations. Second, the proposed rule would provide a high degree of flexibility to the NPDES permitting authority to address high priority contaminated storm water discharges based on community input and public participation. This ability to focus program requirements on priority needs or areas should serve as an additional tool to address environmental justice concerns. Finally, the proposed phase II regulation will promote environmental justice through its substantive requirements. The proposed regulatory language would specify that required public education and outreach programs required of small MS4s should be tailored to address the concerns of all communities, particularly minority and disadvantaged communities. In addition, the proposed regulatory language would specify that compliance with required public involvement and participation requirements should include efforts to engage all economic and ethnic groups.

UNFUNDED MANDATES

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA) establishes requirements for Federal Agencies to assess the effects of their regulatory actions on State, local and tribal governments and the private sector. UMRA requires EPA to:

- Identify the Federal law under which the rule is being promulgated
- Describe EPA's consultation with representatives of State, local, and tribal governments
- Identify regulatory alternatives
- Qualitatively and quantitatively assess the anticipated costs and benefits of the proposed rule
- Assess costs imposed on the economy and unemployment impacts, and
- Select the least costly, most-cost effective, or least burdensome alternative.

EPA has completed each of these requirements as presented specifically in Chapter 5 and generally throughout this EA. As discussed in Chapter 2, the phase II storm water regulation is required by § 402(p)(6) of the CWA, which requires that the phase II program must, at a minimum, establish priorities, establish requirements for State storm water management programs, and establish expeditious deadlines. This provision also provides that the program may include performance standards, guidelines, guidance, management practices, and treatment requirements, as appropriate.

In developing the proposed phase II regulation, EPA has taken numerous steps to obtain the input of representatives of State, local, and Tribal governments. EPA solicited public comments on alternative approaches to the phase II program in a *Federal Register* notice published on September 9, 1992 (See 57 *FR* 41344). Forty-three and 24 percent of the 130 comments received were from municipalities and State or Federal agencies, respectively. In addition, EPA held public and expert meetings in 1993 to assist in developing and analyzing options for identifying unregulated storm water sources and possible controls. Finally, EPA established the Urban Wet Weather Flows Federal Advisory Committee (FACA), which included a Storm Water Phase II Subcommittee. The balanced membership of the Storm Water Subcommittee included representatives from States, municipalities, and Indian Tribes, as well as the industrial and commercial sectors, agriculture, environmental groups, and public interest groups. EPA worked with the Storm Water Subcommittee for over 18 months in developing and refining options for the proposed phase II program.

Working with the FACA Subcommittee EPA considered several distinct regulatory options, which are discussed generally above and in detail in Chapter 3. Compliance cost estimates for these options are presented in Chapter 4 and low and high cost estimates for each option are presented above in Exhibit ES-3. Also, as summarized above and discussed in Chapters 7-10, EPA assessed the benefits of the proposed phase II regulation. Chapter 10 indicates the monetized benefits. The monetized benefits for three likely benefits scenarios are summarized in Exhibit ES-6 and the comparison of benefits to costs for the proposed phase II storm water rule are indicated in Exhibit ES-7.

For several reasons, EPA does not believe that this proposed rule will have a significant effect on the economy or upon unemployment. First, the proposed rule does not address industries involved in production, but rather small municipalities and small construction sites. Second, flexibility within the proposed rule will allow municipalities to tailor proposed phase II requirements to their needs and financial position. Finally, discussions with representatives within the construction industry indicate that construction costs are likely to be passed on to consumers. EPA believes that these same reasons will result in the proposed rule having minimal or no unemployment impacts.

Finally, as indicated in Exhibit ES-3, the proposed storm water phase II regulation would be the least costly alternative. As previously stated, the net annual social benefits (social benefits less social costs), for the three benefits scenarios, range from negative $0.2 million in Scenario 1 to negative $63.1 million in Scenario 3.

PAPERWORK REDUCTION

The Paperwork Reduction Act of 1995 requires EPA to assess the paperwork burden imposed on the regulated entities for the proposed storm water phase II rule. Within this EA, EPA has estimated the paperwork burden and costs for three permitting cycles, or 15 years. The average annual burden and cost for requirements directed by the Paperwork Reduction Act of 1995 are estimated to be approximately 2.1 million hours and $75.5 million for each year in the first permit cycle and approximately 2.0 million hours and $60.9 million for each year in the second and third permit cycles. Exhibit ES-8 indicates the estimated annual hourly burden and cost for those entities affected by the proposed storm water phase II rule.

Exhibit ES-8. Estimated Total Annual Paperwork Burden

Paperwork Requirement for:	First Permit Cycle		Second and Third Permit Cycles	
	Total Hourly Burden(thousands)	Estimated Annual Cost (millions)	Total Hourly Burden (thousands)	Estimated Annual Cost (millions)
Small Construction Sites	1,700	$52.0	1,700	$52.0
Small MS4s	106	$2.7	72	$1.9
Federal Government	48	$14.0	43	$1.3
State Governments	263	$6.8	219	$5.7
Annual Total	2,117	$75.5	2,034	$60.9

Note: The costs associated with the paperwork requirements have been included in the range of estimated costs in Exhibit ES-3.

PHASE I INDUSTRIAL NO EXPOSURE

The proposed storm water rule includes a provision which will allow phase I industrial establishments to certify that if they have no exposure of significant materials or industrial activities to storm water they can petition EPA for an exemption from the requirements of the storm water phase I rule. This provision is included in the phase II proposed storm water rule but is only applicable to phase I industrial establishments. Therefore, EPA has decided not to factor the costs savings associated with this exemption into the costs analysis for the phase II rule. Rather, the cost savings associated with this exemption will be addressed separately in a later version of this EA.

Enforceable State Mechanisms for the Control of Nonpoint Source Water Pollution

ELI Project #970300

Table of Contents

Page No.

Executive Summary

This study examined the laws of the fifty states, Puerto Rico, and the District of Columbia to identify and analyze enforceable mechanisms for the control of nonpoint source water pollution. An enforceable mechanism consists of a *standard* applicable to an identified entity or entities; a *sanction* such as a civil, criminal, or administrative penalty, loss of a license, and performance of required remedial action, but not mere loss of an incentive; and a *process*, either explicit or implied, for applying the standard and imposing the sanction.

The study found many enforceable mechanisms in state law, and also found that there is great variability in such authorities. In the absence of any federal legislative or regulatory norm, the states have exhibited great diversity in their legislation.

Standards are often supplied by a mixture of agriculture laws, forestry laws, fish and game laws, nuisance prohibitions, general water pollution discharge prohibitions, land use planning and regulation laws, and criminal laws. Also, many state authorities are watershed-based, or targeted solely upon critical areas, buffers, or particular impaired waters. In addition, state laws also often delegate standard setting, implementation, or enforcement duties to units of local government or conservation districts.

Because of this great variation in approach, it is not possible to quantify nonpoint authorities or to classify them in mutually exclusive categories. Moreover, because these laws operate together, it is necessary to understand each state's entire program in order to assess its potential for using an enforceable mechanism to deal with particular conduct in a particular place. For example, a state may address in its forestry law conduct that is addressed in another state by a soil and water conservation district law. Or a state may address agricultural activities in riparian buffer zones or critical areas in ways that it does not address similar activities that are located at greater distances from identified waters, while another state imposes similar requirements across all agricultural lands.

Some general observations emerge from the study.

First, nearly all of the states have some general statutory authority to deal with nonpoint source discharges that can be shown to result in water pollution. These "general discharge prohibition" authorities come in different forms, but most are parts of states' water pollution control laws. Careful scrutiny of these laws is essential in assessing their utility in controlling nonpoint source pollution. For example, in about half the states, water pollution control provisions superficially resemble the federal Clean Water Act's prohibition of the discharge of a pollutant without a permit, 33 U.S.C.

1311(a), but unlike the federal act can be applied to nonpoint source pollution because they lack the limitation in 33 U.S.C. 1362(12) that defines "discharge of a pollutant" as "from any point source."

General discharge prohibition laws come in two major types. One type prohibits the discharge of any substance (or pollutant, or waste) without a permit. This is broad authority and can serve either as the basis for adopting a permitting program by regulation or for enforcement against discharges in appropriate case-by-case settings. Some states with this type of authority have adopted explicit statutory or regulatory exemptions for agriculture or forestry activities. The definition of "waste" or "pollutant", if these terms are used rather than "any substance" in such provisions may present difficulties in controlling nonpoint discharges of sediments or properly applied agricultural chemicals in some states.

Even more states have provisions that simply prohibit the causing of "pollution," or causing or contributing to the exceedance of water quality standards. In these states, however, the difficulty of proving a direct link between a particular discharge and the condition of a waterbody can be substantial, or at least expensive absent ongoing and extensive monitoring. Nevertheless, these provisions allow states to impose sanctions and obtain compliance in relatively clear-cut cases. Provisions in state public health and penal codes and fish and game laws, typically enforced as petty criminal offenses, also may prohibit specific kinds of discharges that detrimentally affect public waters, cause nuisances, impair public health, or kill fish. Again, these require proof of a detrimental effect directly traceable to the operation in question before enforcement action may be taken.

The general discharge prohibitions primarily operate as back-up enforcement authorities, used when voluntary and incentive measures fail, or when no other authority exists in a given area. However, in some states they serve as the basis for the imposition of direct regulatory requirements upon nonpoint source dischargers. More states apply enforceable mechanisms to require operating standards and practices through targeted laws, such as erosion control laws, forest practices laws, and agricultural conservation laws.

Enforceable erosion and sediment control laws provide one significant area of control. Some of these programs are statewide in application, many are delegable to local governments or conservation districts. However, most of these programs exempt agriculture or at least normal agricultural activities; some exempt both agriculture and forestry. Thus, where these laws exist, and where they have coverage beyond simple NPDES stormwater permitting, they are usually directed at disturbance of earth for development or land conversion activities.

Forest practices laws play a role in establishing enforceable nonpoint source pollution controls in about a dozen states - primarily on the west coast and in New England - which have forestry laws with enforceable statewide standards. These states require the preparation and approval of harvest plans incorporating state standards or prescribed best management practices (BMPs). Other states regulate forest practices through erosion and sediment control laws. Even more common are forestry-related requirements establishing riparian buffer zones, limiting percentage of vegetation that may be removed near a waterway, special rules for timber operations in wetlands, and similar targeted requirements. While these approaches all rely on prescriptive enforceable requirements, another approach has been adopted by a handful of states. These do not require the enforceable implementation of particular standards statewide, but have instead adopted a "bad actor" authority that allows them to issue orders to halt particular logging operations that are actively discharging pollution.

Another approach with some relevance to forest sources of nonpoint source pollution is the increasing number of states that now require licensing of loggers and/or professional foresters. While licensing does not itself limit nonpoint source pollution, it can serve as a means to have timber operations designed and supervised properly, and assures familiarity of operators with BMPs.

Agriculture is the most problematic area for enforceable mechanisms. Many laws of general applicability, as noted above, have exceptions for agriculture. Where state laws exist, they often defer to incentives, cost-sharing, and voluntary programs. Nevertheless, about a fifth of the states have some statewide sediment requirements applicable to agriculture, often administered by local governments or soil and water conservation districts. Even more states (about a fourth) authorize individual soil and water conservation districts, as a matter of local option, to adopt enforceable "land use regulations" for the control of erosion and sedimentation. But most of these require approval by landowner referendum, with approval requiring a super-majority (ranging from 66 to 90 percent) in order for such regulations to become effective.

Enforceable regulation of agricultural nutrients presents a mixed picture. Enforceable authorities most commonly include concentrated animal feeding operation (CAFO) regulations similar to the federal requirements, but with variations on the number of animals, or with the addition of siting requirements. Some states have adopted "accepted agricultural practice" requirements, or nutrient regulations, that are enforceable. Most states have laws regulating fertilizers, but only to ensure content and efficacy: only a few have provisions that address misapplication of fertilizers or water pollution resulting from such application. Finally, a number of states have enforceable provisions allowing districts or agencies to order abatement of agricultural pollution. Several of these laws provide that abatement cannot be ordered unless state or federal cost-share money is provided to help pay for the required action.

In the context of both forestry and agriculture, states have in many different ways contrived mechanisms to make BMPs either enforceable or at least something more than voluntary by linking them to other enforcement mechanisms. There are at least five such approaches. Some laws, such as state comprehensive forest practices laws, make BMPs directly enforceable in connection with required plans and permits. Another approach makes BMPs enforceable, but only after the fact when a "bad actor" is causing pollution. A third approach makes BMPs the basis for an exemption from a regulatory program. For example, a law may provide that compliance with BMPs will allow a forestry operation not to need a permit under a critical areas program, or a farm not to comply with an erosion and sediment control law. Another approach makes compliance with BMPs a defense to a regulatory violation; such provisions include those that prohibit a state from taking action under a water pollution control statute against a farm that is implementing BMPs, whether or not the operation is causing pollution. Finally, a substantial number of states make compliance with agricultural BMPs a defense to nuisance actions.

Pesticide discharges are regulated indirectly by most states. Most states provide for state registration of pesticides, and for licensing of dealers and various classes of applicators (with typical exemptions for farmers applying pesticides to their own or neighbors' property). States typically have the ability to prohibit or restrict uses in areas where there is evidence of damage or harm. Some states have broad prohibitions of causing harm anywhere, but in most states these provisions do not cover "use" or application of pesticides, but only transport, storage, and disposal. Several states have prescribed responses if contamination is shown by state monitoring of waters or groundwaters.

Several other sources of nonpoint source pollution are subject to enforceable mechanisms. Onsite sewage disposal systems (septic tanks) are usually locally regulated by building codes and health officials. However, a significant number of states have adopted requirements at the state level and delegated administration to local governments. Only a small number of the state laws explicitly require the owner to maintain the proper functioning of the system. There are often special requirements in coastal areas for the construction and maintenance of such systems. Hydromodification, including drainage and stream alteration activities, is subject to a great deal of state regulation, some of which addresses nonpoint source impacts of the activity. Less explicit state law speaks to highways and certain other state agency activities, but some mechanisms exist there as well.

With respect to most of the issues described above, the most sophisticated state enforceable requirements appear to be arising on a targeted watershed basis. There are typically more explicit operating requirements and clearer enforcement authorities in the context of watershed protection areas, estuaries and coastal waters, wild and scenic rivers, and targeted impaired waters. This presents both a greater level of complexity for understanding state enforceable mechanisms and an opportunity for further work, research, and analysis. Federal decisionmakers can assist in the development of state enforceable authorities by undertaking studies of the effectiveness of these authorities in particular watersheds and with respect to particular impaired waters.

This report demonstrates the great diversity of state legislation imposing enforceable mechanisms. It identifies the kinds of responses that state and federal decisionmakers can draw upon in filling gaps and dealing with remaining water quality problems in the nonpoint source context.

Chapter One:

✲

Introduction

After 25 years of federal and state efforts under the federal Clean Water Act, nonpoint source pollution remains a significant problem. The Act's enforceable provisions are directed at discharges from point sources - regulating the discharge of pollutants to surface waters from pipes, outlets, and other discrete conveyances. In contrast to this enforcement approach, nonpoint source water pollution - polluted runoff - is addressed primarily through non-regulatory means under the Act.

Yet water pollution from nonpoint sources remains a substantial contributor to the impairment of waters across the nation. Various approaches have been used to control such pollution, including assistance to states from federal planning and grant programs under the Clean Water Act (e.g., 33 U.S.C. §§ 1288, 1329). Common strategies at the state level include watershed and land use planning, development of voluntary best management practices (BMPs), technical assistance programs, cost-sharing for implementation of prevention and control measures, and - the focus of this study - some enforceable mechanisms, including regulation and liability provisions.

State adoption of enforceable mechanisms has occurred largely in the absence of any direct federal requirement or mandate. But the federal Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) provided impetus to most coastal states to identify enforceable mechanisms applicable to activities causing or contributing to nonpoint source pollution in the coastal zone. 16 U.S.C. §§ 1455(d)(16), 1455b. The implementation of urban and industrial stormwater permitting by the states under the 1987 Water Quality Act has also resulted in some states taking a more comprehensive approach to sedimentation and polluted runoff beyond simply meeting the federal requirements. Acting independently, some states have adopted innovative programs or employed older pollution control authorities to control nonpoint source pollution. There is much activity, ferment, and interest in this area.

The Environmental Law Institute has examined what enforceable mechanisms the states have available to them, the scope of the existing mechanisms used by the states, and the general limitations and impediments that accompany some of these mechanisms, in order to inform the nation's policy decisions on the remaining nonpoint problem. This report summarizes the Institute's findings.

STATE LAW: DIVERSE AND CHANGING

It is important to recognize at the outset that both the existence and scope of legally enforceable measures vary widely among the states. Absent explicit federal requirements in the area, such variation is not only to be expected, but somewhat desirable as it provides an opportunity to assess alternative approaches.

Some states have attempted to achieve broad coverage over polluting activities in their enforceable nonpoint source control mechanisms, while many others have taken aim at specific problems. Still other states have little in the way of an articulated enforceable scheme, although even these generally have some statutory enforcement authorities that could be used to address particularly damaging discharges from nonpoint sources. It is fair to say that no state is entirely without any enforceable authority relevant to nonpoint source discharges. While some states have few such authorities, others have adopted a bewildering array of enforceable tools applicable to specific watersheds, specific activities, and specific effects on the environment. These are frequently paired with equally bewildering arrays of exemptions and exclusions.

Understanding what enforceable mechanisms exist is important -- both in order to structure federal and state programs that can improve and maintain the nation's water quality, and to operate fairly in addressing the respective responsibilities of point and nonpoint source dischargers for water quality improvement.

The task of understanding state enforceable controls is quite difficult because no two states have adopted anything like the same set of laws. And even when the laws appear quite similar, they often have varying definitions, enforcement mechanisms, and procedures. In more than one instance, even laws that use identical words can have quite different scopes because of minor changes in the wording of the relevant definitions. These variations, along with the widely varying complements of laws enacted by each state, make state-to-state comparisons of particular laws difficult. One state may address nonpoint source silvicultural discharges through its broad sediment control statute, while another may reach the same conduct through a forest practices law, a combination of watershed-specific laws, or a water pollution control statute that covers some forms of nonpoint discharges as well as point source discharges.

This extreme variability also has another lesson for the policymaker: state programs can only be understood whole. The mere compilation of a list of authorities does not reveal their interconnection, whether and how they can be used in practice given institutional and procedural constraints, or how programs delegated to counties, localities, or watershed districts can be evaluated in relation to apparently similar state programs that are not so decentralized. As a result, even this study - looking at numerous authorities across all of the states - necessarily gives an incomplete picture of the individual capacity of any one state.

Any research effort examining the states is also faced with rapidly changing information. There is more than the typical amount of flux in the many state laws that affect nonpoint source discharges. This is true for at least three reasons:

First, state legislatures typically respond to new and urgent problems. As new pollution problems are identified as important, or are elevated in importance as older problems are being solved, legislative responses become more likely. This is clearly the case with respect to such nonpoint source issues as animal waste (particularly with respect to siting issues), silvicultural practices affecting rivers and watersheds, biological effects such as *Pfiesteria piscicida*, impacts of suburban development, the cost of providing additional levels of treatment at publicly owned treatment works, and new interest in the recovery of river corridors. States are often the first line responders to the emergence of new problems or the ascendancy of older ones.

Second, state action is beginning to be affected by the CZARA-driven upgrades to nonpoint source programs in the coastal states. The "conditional approvals" given by the Environmental Protection Agency (EPA) and the National Oceanic and Atmospheric Administration (NOAA) to many of these programs will require states to seek new "enforceable mechanisms" or to demonstrate the utility of such existing mechanisms over the course of the next several years if their programs are to remain compliant and eligible for continued nonpoint source grant funding under the Clean Water Act and coastal zone funding under the Coastal Zone Management Act. A prior wave of modest enforceable nonpoint control mechanisms was launched by the stormwater permitting programs under the 1987 Water Quality Act. While many states simply implemented the requirements of the program, others took the initiative to add additional land use and sediment controls in implementing legislation.

Third, state action is beginning to be affected by the impact of judicial and EPA requirements for states to establish and implement Total Maximum Daily Loads (TMDLs) for their impaired waters. This task will require both better understanding of pollution sources in affected waterbodies, and development of effective state responses in requiring pollution prevention and controls. 33 U.S.C. § 1313(d).

Indeed, greater investment in the assessment of impaired waters in state biennial reports under 33 U.S.C. 1315(b) is also playing a role in the evolution of state nonpoint source authorities. These state assessments and improved technical tools and capacity, including the use of biological indices, are beginning to reveal the locations and scale of pollution problems only guessed at in prior decades. The identification of particular impaired waters can lead to political pressures at the state level to adopt control and abatement measures.

In sum, this area is one in which state laws are changing. At the same time, however, many of the laws that create enforceable duties for nonpoint source dischargers are quite old. As described below, some are the legislative codifications of centuries-old common law nuisance principles. Others are broad provisions in state clean water laws enacted in the 1960s and 70s that apply to nonpoint sources, but that may not have been implemented to their fullest extent by regulations or enforcement programs. Still others are state laws, such as planning and zoning laws, that have relevance to pollution-causing activities, but that were not originally drafted with pollution prevention effects in mind. This mixture of new laws and new implementation opportunities for older laws constitutes the complement of enforceable mechanisms available in most states.

This study is a snapshot of state laws at one time, taken with the knowledge and expectation that changes are continuing. The picture that emerges is intended to inform the broader discussion and to help lead to the development of effective approaches as states continue to make laws in this area.

RESEARCH APPROACH

Scope

This study examined the laws of the fifty states, Puerto Rico, and the District of Columbia. It did not examine tribal laws, nor the laws of individual cities or municipalities. However, to the extent to which duties and enforceable mechanisms were created by state law and delegated to political subdivisions, these state laws were examined.

It is necessary to define the scope of the study with respect to "nonpoint" source pollution because of the increasing overlap of this category with sources regulated under the point source (NPDES) provisions of the Clean Water Act. These areas of overlap have arisen, in part, as a result of decisions by Congress to expand the regulatory reach of the Clean Water Act incrementally -- primarily by bringing more categories into the point source permitting program.

The municipal and industrial stormwater program is the most significant of these potential overlaps. Section 402(p) of the Clean Water Act, 33 U.S.C. 1342(p), enacted in 1987, established a two-phase program. Under the first phase, NPDES permits (individual, general, or multi-sector or "group" permits) are required for stormwater discharges from municipal separate storm sewers serving populations greater than 100,000, and stormwater discharges from certain industrial activities including, initially, construction sites of five acres or larger. Permits may also be required case-by-case if a stormwater discharge is determined to violate a water quality standard or is a significant contributor of pollutants to the waters of the United States. The second phase will cover stormwater discharges from smaller metropolitan areas, smaller construction sites, light industry, and other activities. Obviously, not all earth-disturbing activities resulting in runoff are captured by the stormwater permitting program, and many such activities are regulated, if at all, by the states under other authorities. Because state authorities often cover both activities subject to stormwater permitting and other activities, this study attempted to include the general state authorities that appeared to cover these other activities, even if many also clearly fall within the § 402(p) universe.

A similar problem was presented by enforceable mechanisms dealing with agricultural sources of animal wastes. Large concentrated animal feeding operations (CAFOs) are regulated as point sources under the Clean Water Act, 33 U.S.C. 1362(14). Many states, accordingly, regulate these operations through amendments to their water pollution control regulations corresponding to 40 CFR 122.23 and 40 CFR Part 122, App. B. Such point source regulation is not within the scope of this study. This study focuses on state nonpoint source authorities affecting animal wastes that appear to have a different reach from the federal CAFO regulations.

Finally, section 401 of the Clean Water Act, 33 U.S.C. 1241, presents a related issue. That section requires states to certify whether an activity to be authorized under a federal license or permit will comply with adopted state water quality standards. If the state denies such certification, the federal license or permit may not be issued. Because all states are required to apply this authority, a state-by-state analysis was not undertaken. However, it should be noted that this authority is used by some states to address some forms of nonpoint source pollution, although the provision's applicability to nonpoint source discharges remains in some dispute, *see Oregon Natural Desert Association v. Thomas*, 940 F. Supp. 1534 (D. Ore. 1996) *appeal pending* (401 applies to nonpoint discharges).

In summary, this study examines state laws that cut across areas that are also subject to federal regulations or requirements, but focuses on state laws that do more than simply implement the federal requirements in order to highlight state actions that differ from mere conformance to federal requirements.

Enforceable Mechanism

"Enforceable mechanism" is defined narrowly for purposes of this study. The definition is designed to identify only those authorities that can impose an obligation upon an uncooperative discharger as completely as upon one that is cooperative. In consequence, the term is not identical to the term "enforceable policies and mechanisms" as defined in CZARA and interpreted in the guidance documents issued by EPA and NOAA for that program. In particular, the loss or recoupment of incentives for nonpoint source dischargers participating in voluntary programs is not deemed an "enforceable mechanism" for purposes of this study.

For purposes of this study an enforceable mechanism consists of a *standard* applicable to an identified entity or entities; a *sanction* such as a civil, criminal, or administrative penalty, loss of a license, and performance of required remedial action (but not mere loss of an incentive); and a *process*, either explicit or implied, for applying the standard and imposing the sanction. For example, the standard may be a provision that "no person" shall "discharge a pollutant so as to cause or contribute to a violation of water quality standards," while the sanction and process may include administrative or civil actions leading to penalties, cessation of the discharge, abatement, cost recovery, criminal fines and jail terms, or other remedies.

An enforceable mechanism is not limited to "regulatory" or permit-based regimes similar to the NPDES program. Indeed, mere liability for a clearly defined action is sufficient. Thus, the availability of injunctive relief and damages, or provisions for summary abatement and cost recovery, or the power to issue binding cease-and-desist orders qualify as enforceable mechanisms.

Study Methodology

The researchers developed a template identifying categories of state laws that affect activities that generate nonpoint source pollution. This template was developed to guide research that necessarily ranged across numerous titles of any state's legislation - from the criminal code to the public health code, from the environmental code to the agricultural code. The template's categories were based on prior state studies conducted by the Environmental Law Institute, on a review of the required CZARA management measures and a preliminary sampling of program submissions by coastal states under that law, and on the researchers' professional judgment.

The template was then used to guide a broad review of the state legislative codes for all fifty states, Puerto Rico and the District of Columbia. State laws were reviewed in their published and codified form, supplemented by some computer-assisted research. CZARA program submissions were also reviewed for those states participating in the CZARA process as a cross-check on the primary research.

In order to identify the principal state authorities, and to keep the study within manageable scope, the research was conducted upon state statutes. State regulations were consulted only where needed to clarify the jurisdiction conferred by state laws. Thus, for example, where a forest practices statute clearly created enforceable obligations, state regulations under that statute were not reviewed. Conversely, where a state statute was ambiguous on the enforceability of a program, the regulations were consulted, but only to the extent needed to understand the reach of the statute. Once a statute was identified as enforceable or potentially enforceable, no attempt was made to list all of its substantive requirements. Thus, for example, the study indicates the existence in various states of enforceable land use standards for erosion and sediment control, but it does not identify the specific buffer zone requirements, erosion rates, or control structures required by such programs.

For similar reasons, and because this was a study of *state* enforceable mechanisms, the study does not identify and discuss *local* ordinances and rules. Instead, the study identifies those state laws that create the enforceable authority in local governments, or that authorize delegation of the relevant enforceable statewide control programs to local governments.

Finally, because this study is intended to identify relevant legal authorities, it looks at the maximum possible uses of existing law for nonpoint source pollution control, rather than at state implementation practices. The study is aimed at answering the question: What kinds of existing tools do the states have available to them in the event that they need to control nonpoint source water pollution by enforceable means? Thus if a state has an applicable law that has remained unenforced - for policy reasons, lack of staff, absence of controlling judicial construction, failure to adopt regulations, or other reasons - the law is nevertheless included in this study.

GOALS OF THIS REPORT

This report provides an overview of the current legal landscape. It identifies the kinds of state laws that exist, the opportunities they present, and their limitations. The report is primarily intended to provide objective baseline information for policy makers and others wrestling with the need to control nonpoint sources of water pollution that have not, thus far, been amenable to other forms of control.

The report serves three major functions. First, it is intended to help guide *federal* legislation, regulation, and policymaking that may hereafter affect nonpoint source discharges. Such federal decisions may come in the context of Clean Water Act reauthorization, federal budgeting priorities, and components of other federal legislation including transportation, flood control, water projects, and agriculture. Administrative decisions informed by this report may include those regarding stormwater, state water quality standards, TMDL development, and other implementation issues. The report is intended to enable federal policymakers to draw upon state trends and experiments in selecting federal approaches, to identify general weaknesses or gaps in existing state approaches, and to identify useful state laws and programs that should not be inadvertently undermined by federal decisions to adopt new federal policies, requirements, and guidelines.

Second, the report is intended to identify potentially useful state approaches that can be *borrowed by other states* and used in drafting legislation. This function is intended to make the most of the states' functions as "laboratories" for innovation and experiment, enabling states to borrow from similar states with less risk and greater likelihood of legislative acceptance. Thus, the report is intended to assist states in improving their programs. At the same time, by establishing a baseline or "snapshot" of current state practice, the report can serve as the basis for future work analyzing trends and assessing effectiveness of various approaches. With baseline information, state mechanisms can be tracked for effectiveness in the future by others, and compared, leading to a better understanding of what works and why.

Third, the report identifies - indeed, in some cases, exhumes - state laws on the books that could be *used creatively* by individual state agencies and law enforcers (such as public health officers, district or states' attorneys, agency staff, and state attorneys general) to deal with specific nonpoint source problems. Some of the older fish and game authorities, public health and nuisance provisions, and other laws may provide ways to address - albeit imperfectly - some nonpoint problems without requiring agencies to go back to the legislature for new authority. While these laws cannot substitute for integrated nonpoint programs including enforceable mechanisms where necessary, they can be components of such programs and can bridge gaps in existing authorities.

The report finds that there are numerous legal authorities on the books that can be used to establish and enforce nonpoint source control requirements. It also finds that these authorities appear in different kinds of state laws, with many exemptions and limitations, and that - as a consequence - the availability of an enforceable authority to address any particular nonpoint source discharge may depend upon complex issues of interpretation, evidence, and process.

Chapter Two:

Discharge Prohibitions

Virtually all of the states have some enforceable statutory authority to deal generally with the subject of water pollution and activities on the land that may lead to such pollution. These authorities come in several forms. Many are parts of states' broad water pollution control laws. Provisions in public health and penal codes, typically enforced as petty criminal offenses, may prohibit specific kinds of discharges and substances that detrimentally affect public waters. Statutory nuisance and public health laws provide additional authorities where certain adverse effects can be proven. So does the common law of nuisance. And state fish and game protection laws frequently contain general provisions prohibiting pollution harmful to fish; or imposing liability for fish kills due to pollution events, not limited to point source pollution.

Although these were collected separately by source of law, these broad authorities discussed together below. The key issues in each statute are determining exactly what needs to be proven to demonstrate a "violation" of the law resulting in imposition of a sanction. Careful scrutiny of these laws is essential in assessing their utility in controlling nonpoint source pollution. For example, while various state water pollution control act provisions superficially resemble the federal Clean Water Act's prohibition of the discharge of a pollutant without a permit, 33 U.S.C. 1311(a), unlike the federal act many of these can be applied to nonpoint source pollution because they lack the limitation in 33 U.S.C. 1362(12) which defines "discharge of a pollutant" as "from any point source."

ELEMENTS OF THE GENERAL DISCHARGE PROHIBITION

Materials Discharged

The first issue in assessing the potential applicability of any discharge prohibition to any nonpoint discharge is to determine what materials are included in the prohibition. A law which prohibits the discharge of "wastes" without a permit may, for example, have some utility in regulating discharges of manure from stock raising operations or motor oil from suburban driveways, but be useless in addressing sediment discharges and be uncertain in addressing farm runoff containing pesticides. On the other hand, a similar state law prohibiting unpermitted discharges of "pollutants" may be limited by the need to show that the substance discharged either is on a list of pollutants or actually results in pollution of the receiving waters.

Complicating these definitional inquiries is the fact that states frequently do not define the same words in the same ways. For example, Fla. Stat. 403.031(12) defines "wastes" as "sewage, industrial wastes, and all other liquid, gaseous, solid, radioactive, or other *substances which may pollute* or tend to pollute any waters of the state." This definition, which is similar to definitions of "wastes" in a number of other states, clearly avoids the problem of a waste definition that excludes sediment and other non-discarded substances. But at the same time it raises problems of proof similar to those in state statutes prohibiting discharges of "pollutants" -- that an impact on the receiving waters may need to be shown in order for enforcement to occur. The broadest provisions found among the states prohibit the unpermitted discharges of "any substance" or any "organic or inorganic matter." (e.g., S.C. Code 48-1-90)

Another kind of common state statute, frequently found in public health laws, criminal laws, fish and game laws, or state environmental laws, actually lists materials that cannot be lawfully discharged - either at all, or without a permit - into the waters of the state or onto land adjacent to such waters. These lists typically include such specifics as offal, ashes, rubbish, paper, wood, sawdust, sludge, and other specific materials, only some of which are typical of nonpoint source pollution. Obviously, these provisions have only limited utility in the nonpoint source enforcement context. However, some state laws end these lists with a catch-all provision -- such as "anything else of an unsightly or unsanitary nature" (Ohio Rev. Stat. 1531.29) or "or substance in any form resulting from domestic, industrial, commercial, mining, agricultural, or governmental operations" (Fla. Stat. 403.413), or "any other article which might pollute the water" (Vern. Tex. Code Ann. Water 11.090).

Although such provisions may expand the reach of some narrow "list"-type statutes, the expansion may be limited by two common legal doctrines of statutory construction. The first is *noscitur a sociis*, which simply means that a word is interpreted in accordance with the words around it. Thus, for example, if the list contains only materials associated with industrial processes, but no agricultural materials, the catch-all provision will be interpreted to reach only industrial-type materials. Similarly, if all the listed materials are wastes or products of human action, the doctrine may constrain the use of the law in reaching sediment discharges. The second doctrine, which is similar but not identical, is *ejusdem generis*, which indicates that the last word or phrase in a series should be read as a subset or subcategory of the preceding terms rather than as a term with greater breadth. Of course, the doctrine of plain meaning can be invoked in opposition to these others. The upshot is that reliance on a broad catch-all phrase at the end of a list has some risks in an enforcement context depending on the substance at issue.

Prohibited Conduct

The second major issue in interpreting the general discharge prohibitions is to determine what conduct is covered by the law. Such provisions usually come in two forms: (1) prohibition of mere discharge (or discharge without permit) without requiring the state to demonstrate any effect on the receiving waters, and (2) prohibitions of discharges that have, or can be projected to have, adverse effects on receiving waters.

Connecticut law illustrates both types. For example, Conn. Gen. Stat. 22a-430(a), 22a-423, prohibits any person from discharging or maintaining any discharge of "any water, substance or material into the waters of the state without a permit for such discharge...whether or not such substance causes pollution." At the same time, Conn. Gen. Stat. 22a-427 prohibits any person from causing "pollution" of any of the waters of the state.

The typical type (1) prohibition states that the discharge of a material, substance, or waste into the waters of the state or onto the land where it may enter the waters of the state without a permit is unlawful. These provisions are typically the cornerstone of state NPDES programs for point source discharges, but they may also have some application to nonpoint discharges where state definitional limitations do not constrain such use. Approximately half the states have such provisions in their water pollution control laws without statutory provisions limiting them only to point source discharges.

The difficulties in applying type (1) prohibitions to nonpoint sources largely arise in two ways. First, a significant number of the states with such provisions have explicit statutory or regulatory exceptions for agriculture and/or forestry (e.g. Fla. Stat. 403.927, 314 Code Mass. R. 3.05; Alabama Admin. Code 335-6-6-.03). While these exceptions remove significant nonpoint sources from the scope of these provisions, the exceptions themselves demonstrate the reach of the provisions over nonpoint source activities that are not specifically excepted. The second difficulty is more complex. Where there is a prohibition on discharge without a permit, but no permit scheme has ever been established, is the prohibition enforceable? A number of states have resolved this issue - either by establishing explicit permit authorities, or alternative authorities, or by case law - but others have not. In general, use of type (1) prohibitions where no permit program exists for nonpoint source discharges is possible, and many states assert the right to use such prohibitions in after-the-fact enforcement actions against polluters. But after-the-fact enforcement in a limited number of cases may not provide the same kinds of environmental benefits as a clear regulatory program that operates in advance of pollution events.

The vast majority of states have a type (2) prohibition that is potentially applicable to nonpoint source pollution. The typical type (2) prohibition does not address the issuance of a permit or the lack thereof. It simply prohibits discharges causing an identifiable harmful effect on the receiving waters. Such provisions typically make it "unlawful for any person to cause pollution of any of the waters of the state" (e.g. Okla. Stat. tit. 27A 2-6-105; Neb. Rev. Stat. 81-1506). Some of these provisions may spell out what is meant by "pollution," or may require that the state prove that the discharge caused a violation of a water quality standard in order to enforce the provision (e.g., Miss. Code 49-27-29(2)(a)(ii)). Some state laws explicitly prohibit not only discharges that "cause" water quality standards to be violated, but also discharges that "contribute" to such conditions (e.g., N.Y. Env. Cons. L. 17-0501; Indiana Code 13-18-4-5).

Type (1) and (2) prohibitions found in state water pollution control laws are usually enforceable by the entire panoply of regulatory tools, including administrative orders, injunctions, civil penalties, criminal fines and sentences, and, in some cases, summary abatement and cost recovery.

In addition to these two types of general prohibitions found in water pollution control laws, there are other common prohibitions. Typically found in other parts of the state codes, these are usually directed at specific environmental harms beyond the mere exceedance of water quality standards or causing pollution. These include provisions limited to conduct that causes or threatens to cause pollution of a drinking water supply, that endangers public health, that causes a nuisance, or that results in the death of fish or other aquatic life. Using these provisions for enforcement requires proof of a particular kind of adverse effect. These provisions are typically enforceable as misdemeanor offenses with modest fines, some provision for jail time or imprisonment, and are often subject to abatement by injunction. To the extent to which these are petty criminal offenses, proof of wrongful intent (or at least reckless disregard) may be required.

Location of the Discharge

The last issue that arises with general prohibition statutes is whether the material actually must enter the water in order for a violation to exist. While type (1) provisions often have such a requirement, a significant number of states, although not a majority, contain provisions that prohibit the placement of materials where they are "likely to cause pollution" (e.g., Ark. Code Ann. 8-4-217(a)(1); N.D. Cent. Code 61-28-06) or "likely to enter the waters" (e.g., R.I. Gen. Laws 46-12-5(a)). Some states approach this problem a different way. For example, Connecticut authorizes issuance of an order where any person has created or is maintaining a condition "which reasonably can be expected to create a source of pollution to the waters of the state." Conn. Gen. Stat. 22a-432.

REVIEW OF STATE GENERAL DISCHARGE PROHIBITIONS IN WATER POLLUTION LAWS

This section summarizes the general prohibition authorities in the respective states and notes explicit limitations. It does not include state authorities that are explicitly limited to point sources - e.g. prohibitions of "discharge" where the state definition is limited to point sources. This summary is intended to illustrate the potential scope of these provisions. Obviously, issues of statutory construction, regulatory interpretations, typical practice, and state institutions will influence the actual application of the provisions. In effect, this section identifies the outer bounds of such authorities as they appear on the books.

It is important to recognize in this brief summary that states have other authorities available to them -- many discussed later in this report. Indeed, where states are employing explicit strategies under other authorities aimed directly at nonpoint sources, they may make little or no use of the authorities summarized in this section. The following summary is organized by EPA region.

As noted above, Connecticut prohibits both the discharge of any substance without a permit, and causing water pollution. Both provisions are potentially applicable to nonpoint sources. Conn. Gen. Stat. 22a-427, -430. Maine prohibits the discharge of any pollutant without a permit, but explicitly provides that this provision is not violated by any discharge that is in compliance with an approved agricultural erosion and sediment control plan, 38 Maine Rev. Stat. 413; Maine also prohibits any violations of water quality notwithstanding any permits or exemptions, but requires establishment of a mixing zone before enforcement of this provision against any source may occur. 38 Maine Rev. Stat. 451. Massachusetts prohibits discharge of a pollutant without a permit, 21 Mass. Gen. L. 42, but agricultural and silvicultural nonpoint source discharges are exempted by regulation. 314 Code Mass. R. 3.05. New Hampshire prohibits discharge of a waste without a permit, but also has a provision making it unlawful for any person to dispose of wastes in such manner that water quality standards will be violated. N.H. Rev. Stat. Ann. 485-A:12. Rhode Island prohibits the placement of any pollutant in a location where it is likely to enter the waters, and the placement of any solid waste or debris in the waters; but it only prohibits the "discharge [of] any pollutant" from a "point source" R.I. Gen. Laws 46-12-5. Vermont prohibits discharge of any substance without a permit, but expressly exempts the "proper application of fertilizer to fields and crops." 10 Vt. Stat. Ann. 1259.

New Jersey law prohibits discharge of pollutants without a permit or as otherwise authorized, N.J. Stat. Ann. 58:10-6; and also prohibits the placement of "deleterious" substances into the waters or where they can find their way into such waters, but exempts from the latter provision chemicals used in agriculture, forestry, horticulture, and livestock if done in an approved manner. N.J. Stat. Ann. 23:5-28. New York prohibits the direct or indirect discharge of any substance that "shall cause or contribute to" a condition in violation of water quality standards. N.Y. Env. Cons. L. 17-0501. Puerto Rico authorizes its state agency to forbid any discharges that do not have the appropriate permit. 12 P.R. Laws Ann. 1131(13)(A)(a), and also expressly prohibits direct or indirect discharge of any substance capable of polluting or leading to pollution in violation of water quality standards. 24 P.R. Laws Ann. 595.

Delaware requires a permit for any activity "which may cause or contribute to a discharge of a pollutant into any surface or ground water" 7 Del. Code 6003. The adopted implementing regulations appear limited to point source discharges to water and land, but the statute is not so limited and Delaware maintains that this authority also applies to nonpoint sources; indeed, Delaware's nonpoint programs rely in part upon this authority. District of Columbia law expressly authorizes the mayor to regulate and require permits for nonpoint source pollution. D.C. Code 6-926. Maryland law prohibits the discharge of a pollutant without a permit or other authorization and allows the imposition of permit requirements for activities that could cause or increase the discharge of pollutants. Md. Code Ann., Envir. 9-322, 9-323(b). Pennsylvania prohibits the discharge of any substance resulting in pollution, 3 Purdon's Stat. 691.401; Pennsylvania also has a provision prohibiting discharge without a permit, which it has used for nonpoint sources, but the provision applies only to industrial wastes, 3 Purdon's Stat. 691.301. Virginia law prohibits the discharge of wastes or any "noxious or deleterious substances" or the pollution of waters without a permit, Va. Code 62.1-44.5, as well as the placement of any substance which may contaminate or impair the lawful use or enjoyment of waters of the state except as permitted by law. Va. Code 62.1-194.1. West Virginia's general water pollution control law appears not to provide for the regulation or prohibition of nonpoint source discharges. W. Va. Code 22-11-8.

Alabama requires a permit for discharges of "pollution", Ala. Code 22-22-9(I)(3), but although the requirement is not limited to point sources, the regulations provide that a permit is not required for discharges "from non-point source agricultural and silvicultural activities." Ala. Admin. Code 335-6-6-.03(a). Florida law provides that causing pollution except as provided by law is prohibited, Fla. Stat. 403.161, and requires permits for discharges of waste that contribute to violation of water quality standards, Fla. Stat. 403.088, but further provides that agricultural activities (including all "normal and customary" farming and forestry operations), and agricultural water management systems, are authorized and do not require permits. Fla. Stat. 403.927.

Georgia expressly requires anyone seeking to "erect or modify facilities or commence or alter an operation of any type which will result in the discharge of *pollutants from a nonpoint source* into the water of the state, which will render or is likely to render such waters harmful to the public health, safety, or welfare, or harmful or substantially less useful for domestic, municipal, industrial, agricultural, recreational or other lawful uses, or for animals, birds or aquatic life" to obtain a permit. Georgia Rev. Stat. 12-5-30(b). Kentucky prohibits the discharge of any pollutant or substance that shall cause or contribute to water pollution "in contravention of any rule, regulation, permit, or order or...the statute" Ky. Rev. Stat. 224.70-110; the law further provides that if a violation is traceable to an agricultural operation, it shall be handled under the state's enforceable agricultural water quality act rather than under the stricter water pollution control act. Ky. Rev. Stat. 224.120(10).

Mississippi prohibits pollution of the waters of the state or placement of wastes where they are likely to cause pollution, defining "pollution" as contamination not "in compliance with a valid permit," Miss. Code Ann. 49-27-29(2)(a)(I), 49-17-5(1), but the regulations provide that no permit shall be required for agriculture and silviculture nonpoint source pollution. Miss. Wastewater Reg. - Gen. Req. B.5. Mississippi has another provision, not linked to permitting definitions, prohibiting the discharge of any "wastes" which reduce water quality below adopted water quality standards. Miss. Code Ann. 49-27-29(2)(a)(ii). North Carolina prohibits the discharge of wastes and certain other discharges without a permit, N.C. Gen. Stat. 143-215.1(a); of perhaps greater immediate utility in the nonpoint context is its authority to issue "special orders" to "any person...responsible for causing or contributing to any pollution of the waters of the state within the area for which standards have been established." N.C. Gen. Stat. 143-215.2. South Carolina prohibits the direct or indirect discharge, seepage, or drainage of any substance into the waters of the state except in compliance with a permit. S.C. Code 48-1-90. Tennessee has a general prohibition against any discharge causing "pollution" except as properly authorized, Tenn. Code Ann. 69-3-114, but the law does not apply to any nonpoint source discharges from "any agricultural or forestry activity." Tenn. Code 69-3-120(g).

Illinois prohibits any person from causing, threatening, or allowing the discharge of any "contaminants" that would cause or tend to cause water pollution, or that would violate regulations or standards adopted by the Pollution Control Board. 415 Ill. Cons. Stat. 5/12(a). While this provision is not expressly limited to point sources, a second provision, 415 Ill. Cons. Stat. 5/12(f), which prohibits the unpermitted discharge of contaminants (without requiring evidence of water pollution) is expressly limited to point source discharges. Indiana law provides that a person may not "cause, permit or suffer to be...drained, allowed to seep, or otherwise disposed into any waters...any organic or inorganic matter that causes or contributes to a polluted condition of any waters" in violation of adopted water quality standards. Indiana Code 13-18-4-5. Michigan prohibits the direct or indirect discharge of any substance that may be injurious to health, safety or welfare, uses of waters, riparian lands, and fish and wildlife. Mich. Cons. L. 324.3109(1). Although this section is codified in a chapter of the code entitled "point source pollution control", Michigan law provides that chapter headings are not part of the act and are not to be used to construe the scope of the act. Mich. Cons. L. 324.103.

Minnesota has a general requirement of notice to the state of water pollution events and requires reasonable attempts by the discharger to minimize or abate pollution caused thereby. Minn. Stat. 115.061. Furthermore, by regulation, Minnesota has provided that "no sewage, industrial waste or other wastes shall be discharged from either a point or nonpoint source into the waters of the state in such quantity or in such a manner alone or in combination with other substances as to cause pollution." Minn. Rules 7050.0210(13). Ohio's water pollution law prohibits causing pollution or placing any wastes where they cause pollution except in accordance with a permit, but exempts agricultural and silvicultural runoff and earthmoving activities subject to regulation under Ohio's nonpoint source control programs administered by soil and water conservation districts and local governments. Ohio Rev. Stat. 6111.04. These programs are discussed later in this report. The Ohio law also exempts runoff of excrement from domestic and farm animals, only some of which is subject to regulation under the referenced programs. Wisconsin law authorizes the state agency to issue orders for the abatement of nonpoint source pollution if the source is "significant" and impairs water quality. Wis. Stat. 281.20. The provision has limitations on its use to control pollution caused by animal waste and pollution from an agricultural source in a priority watershed, where other planning and implementation tools are to be used first.

Arkansas makes it unlawful for any person to cause pollution or place waste in a location where it is likely to cause pollution. Ark. Code Ann. 8-4-217(a). Louisiana prohibits any "activity" which results in the discharge of any substance to the waters of the state without the "appropriate permit, variance, or license." 30 La. Rev. Stat. 2075. It also prohibits the discharge of any substance that will tend to cause water pollution in violation of any provision. 30 La. Rev. Stat. 2076(A)(1). However, the law also provides that these and other provisions of the water pollution control law "shall not apply to any unintentional nonpoint-source discharge resulting from or in connection with the production of raw agricultural, horticultural, or aquacultural products." 30 La. Rev. Stat. 2076(A)(2).

New Mexico's water pollution law does not itself contain a prohibition applicable to nonpoint source water pollution, but rather authorizes the water quality control commission to adopt regulations "to prevent or abate water pollution in the state" and to require permits. N.M. Stat. Ann. 74-6-4. Thus, the availability of any enforceable authority depends entirely on the promulgation of specific regulatory requirements. Oklahoma law makes it unlawful for any person to cause water pollution or to place wastes in any location where they are likely to cause pollution. Ok. Stat. Ann. tit. 27A, 2-6-105. This provision is expressly interpreted to apply to nonpoint sources. Ok. Regs. 252:610-7-1. Texas prohibits the discharge of waste, including agricultural waste, into or adjacent to any waters, and prohibits any other act which causes pollution of any waters, except as authorized. Vern. Tex. Code Ann., Water Code 26.121(a). The law exempts agricultural and silvicultural discharges in compliance with a certified water quality management plan under Ag. Code 201.026.

Iowa prohibits "disposal" of a pollutant (defined as "waste") by discharge into the waters of the state except pursuant to a permit. Iowa Code Ann. 455B.186. Kansas prohibits the discharge or placement or flowage of "sewage" (defined as any substance that contains human or animal waste products or excrement or any wastes from domestic, manufacturing, or other forms of industry) into the waters of the state except pursuant to a permit. Kan. Stat. Ann. 65-164. The law also allows the attorney general to take action to secure abatement of "abatable pollution of the surface waters detrimental to the animal or aquatic life in the state." Kan. Stat. Ann. 65-171b. Missouri law prohibits causing pollution or placing any water contaminant where it is reasonably certain to cause pollution; it also prohibits the discharge of water contaminants which reduce the water quality below adopted water quality standards if not otherwise subject to effluent regulations. Mo. Rev. Stat. 644.051. Nebraska law makes it unlawful to cause water pollution or to place any wastes in a location where they are likely to cause water pollution, or to discharge wastes that reduce the water quality in the receiving waters below adopted water quality standards. Neb. Rev. Stat. 81-1506.

Colorado's water pollution control law authorizes the water quality control commission to adopt regulations relating to any "activity" that "does or could reasonably be expected to cause pollution of any state waters in violation of control regulations or...any applicable water quality standard." Colo. Rev. Stat. 25-8-205. With this authority, the state clearly may choose to regulate nonpoint sources of pollution; however, "control regulations related to agricultural practices shall be promulgated only if incentive, grant, and cooperative programs are determined by the commission to be inadequate and such regulations are necessary to meet state law or the federal act."

Colo. Rev. Stat. 25-8-205(5). Montana law makes it unlawful to cause water pollution or place any wastes "where they will cause pollution of any state waters." Mont. Code Ann. 75-5-605(a). However, the law exempts materials placed in connection with activities permitted by any other state or federal agency, 75-5-605(a), and expressly exempts from state nondegradation requirements those nonpoint sources existing on April 29, 1993, all new nonpoint sources that follow "reasonable land, soil, and water conservation practices," land application of manure, and use of agricultural chemicals if done in accordance with an agricultural ground water management plan. Mont. Code. Ann. 75-5-317(2).

North Dakota law makes it unlawful to cause water pollution or place any wastes where they are likely to cause water pollution. N.D. Cent. Code 61-28-06(1)(a). South Dakota has a similar provision. S.Dak. Codified L. Ann. 34A-2-21. In addition, any discharge of wastes (defined as any polluting "substances") that results in degradation of water quality is also prohibited. S.Dak. Codified L. Ann. 34A-2-22. Utah prohibits causing pollution that constitutes a menace to public health and welfare, is harmful to fish or wildlife, or impairs beneficial uses of water, and prohibits placement of waste where there is "probable cause" to believe it will cause pollution. Utah Code Ann. 19-5-107. Wyoming makes it unlawful to "cause, threaten or allow the discharge of any pollution or waste into the waters of the state" except as authorized by permit. Wyo. Stat. Ann. 35-11-301. The prohibition has been held to apply to polluting activities for which no permit was available.

Arizona law requires the Department of Environmental Quality to adopt a permit requirement for point sources, and for certain facilities likely to pollute aquifers, and a "program to control nonpoint source discharges of any pollutant or combination of pollutants into navigable waters." Ariz. Stat. 49-203.A. Its general prohibition law makes it a criminal offense to (with criminal intent) discharge substances to waters without a required permit or other "appropriate authority," or to violate a water quality standard. Ariz. Rev. Stat. 49-263.A. California law requires a "report of waste discharge" from any person proposing to discharge "waste." The regional water quality control board must then issue waste discharge requirements (WDRs) - essentially a permit. Cal. Water Code 13260. However, these requirements may be conditionally waived by the regional board. Cal. Water Code 13269. California uses these requirement by first seeking to abate nonpoint source pollution through nonregulatory means, but reserves the power to either grant a conditional waiver (to secure operational changes in a discharger) or to require the report of waste discharge and issue a WDR.

Hawaii prohibits the discharge of any pollutant to waters of the state except as authorized by law or permit. Hawaii Rev. Stat. 342D-50. Hawaii, moreover, has explicit authority to regulate nonpoint source pollution under a provision that allows the issuance of enforceable nonpoint source rules which may include "water quality standards for specific areas, types of nonpoint source discharge, or management measures." Hawaii Rev. Stat. 342E-3(a). Nevada's general pollution prohibition authority is expressly limited to point sources. Nev. Rev. Stat. 445A.465. However Nev. Rev. Stat. 455A.565 also allows the state to prescribe controls for nonpoint sources ("diffuse sources") to prevent degradation of high quality waters, but not for "normal...farming practices". And 455.570 allows regulation of nonpoint sources existing on Jan 1, 1979 that are "significantly causing or adding to water pollution in violation of a water quality standard" and for new nonpoint sources where they impair high quality waters.

Alaska law provides that "a person may not pollute or add to the pollution of the...water of the state." Alaska Stat. 46.03.710. Idaho has very limited jurisdiction over nonpoint sources. It defines "discharge" in its water pollution control act as not including "surface water runoff from nonpoint sources." Idaho Code 39-3602. Another provision states that nonpoint sources are not required to meet water quality standards other than those necessary to support designated uses, unless a TMDL is required to be developed. Idaho Code 39-3604. In the context of TMDLs for high-priority impaired waters, the law provides that "nothing in this section shall be interpreted as requiring best management practices for agricultural operations which are not adopted on a voluntary basis." Idaho Code 39-3610. Indeed, the only direct authority is a prohibition on new or expanded nonpoint activities which "can reasonably be expected to lower the water quality of an outstanding resource water," Idaho Code 39-3618, and these sources are entirely exempt from permitting or other regulation if they implement BMPs. Idaho Code 39-3620(6).

Oregon law prohibits any person from polluting waters of the state or placing any waste where it is "likely to escape or be carried into the waters of the state, and from discharging wastes into water if such discharge reduces water quality below the adopted standards. Ore. Rev. Stat. 468B.025(1). Washington prohibits the discharge of "any organic or inorganic matter that shall cause or tend to cause" water pollution. Wash. Rev. Code 90.48.080, and permits are required for disposal of material into the waters of the state. Wash. Rev. Code 90.48.160. However, the law does not authorize the adoption of a permit system for nonpoint sources or imposition of penalties for pollution arising from forest practices conducted in compliance with the state's forest practices law. Wash. Rev. Code 90.48.420.

The general prohibition authorities summarized above are typically used by states not to carry out a detailed regulatory approach to nonpoint source water pollution, but rather as "back-up" authority to other programs intended to control such pollution, or to deal with egregious cases in the absence of other programs. In many states, because of the absence of an implementation program, they may represent an unused tool in the toolbox; in others, they are an integral part of the state's approach. In general, these tools have some importance because they potentially link nonpoint source pollution control to the states' point source control authorities. And they typically provide a wider array of order, abatement, and penalty authorities than either focused nonpoint source programs or older nuisance or misdemeanor-type prohibitions.

DISCHARGE PROHIBITIONS OF NARROWER SCOPE

In addition to the general prohibitions found in most states' water pollution control laws, virtually every state has other - usually older - provisions prohibiting certain kinds of discharges deemed detrimental to the public health or welfare, fisheries, drinking water, or other interests identified by the legislature. Typically misdemeanor provisions, these may nevertheless serve in some instances the important role of providing an enforceable response to a nonpoint source pollution event, or in some cases, threatened pollution event.

Discharge of Listed Substances

Various statutes specifically list detrimental substances whose discharge into the waters of the state is prohibited. These provisions are found most often in public health laws, criminal laws, and fish and game laws. Sometimes they take aim primarily at "litter" that may enter the waters of the state. Other laws seem more concerned with disease-bearing wastes or substances. "Offal, filth, rubbish..." heads a typical list. West Virginia has a typical provision, making it an offense "to place, deposit, dump, or throw, or cause to be placed, deposited, dumped or thrown, any litter...garbage, refuse, trash, can, bottle, paper, ashes, carcass of any dead animal or part thereof, offal, or any other offensive or unsightly matter into any river, stream, creek, branch, brook, lake or pond, or upon the surface of any land within one hundred yards thereof, or in such location that high water or normal drainage conditions will cause any such materials to be washed into any [such waters]." The offense is defined as a misdemeanor punishable by fine of not less than $50 nor more than $500. W.V. Code 20-7-8. This study identified similar provisions in Connecticut, Maine, Massachusetts, New Hampshire, New York, Pennsylvania, Florida, Illinois, Indiana, Michigan, Minnesota, Ohio, Arkansas, Oklahoma, Texas, Iowa, and California, although undoubtedly other states have such provisions.

Discharge of Substances Harmful to Fish

Approximately half the states' fish and game codes contain provisions that prohibit the discharge of various substances that are, or that may be, harmful to fish. These provisions do not require proof of injury to fish, but focus on the nature of the substances discharged. This is usually clear from the nature of the prohibition, but it is spelled out explicitly in some laws - for example, "it is not necessary to prove that the violation has actually caused the death of, or damage to, any particular fish" 30 Pa.C.S.A. 2504. Some of these provisions are written quite broadly, while others are narrow.

For example, Kentucky's law provides: "No person shall place or cause to be placed in any public waters any substance that might injure, interfere with, or cause the waters to be unfit for the support of wildlife [including fish]" Ky. Rev. Stat. 150.460(1) (penalty of up to $500 and/or 6 months). Arkansas law provides that "it shall be unlawful for any person to deposit, throw, drop, or discharge in any manner in any of the waters of this state any substance, liquid, or gas or anything else that will or does intoxicate or stupefy or in any manner injure any fish therein, whether done for the purpose of catching or taking fish or not." Ark. Code Ann. 15-43-317. Rhode Island law provides: "No person shall place, deposit, or explode any substance injurious to the health or life of a fish in any stream or fresh water pond" R.I. Gen. L. 20-11-10. Far more narrowly, Vermont prohibits the deposit of "lime, creosote, coculus inducus or other drug or poison destructive to fish" 10 Vt. Stat. Ann. 4606(b). Given the principles of statutory construction discussed earlier in this chapter, it may be harder to apply this provision to many forms of nonpoint source pollution.

Although many states have provisions of this type, others have drafted them in such a way as to be useless for reaching nonpoint source discharges. For example, contrast Maine's prohibition on the use of any "explosive, poisonous or stupefying substance...for the purpose of taking or destroying any kind of fish." 12 Maine Rev. Stat. Ann. 7617.

State fish and game laws can also provide regulatory authority over pollution discharges in some cases. For example, Massachusetts has an unusual provision that allows the state fisheries agency to determine that a "prohibition or regulation of the discharge of waste or material from any source" is needed for particular inland waters because of the value of the fishery therein, leading to action by the pollution control agency. 131 Mass. Gen. L. 41.

Some states, such as New York and California, use fisheries protection provisions to control nonpoint source pollution of shellfish production areas. For example Cal.

Water Code 14950(d) provides that regional water quality boards "shall have primary responsibility for the protection of commercial shellfish harvesting from the effects of point and nonpoint pollution sources." Regulatory authority under the law arises once the area has been downgraded or restricted by the state's Department of Health Services, closed for more than 30 days per year for 3 previous years, or formally determined to be threatened. Cal. Water Code 14954. "Once the nature, sources, scope, and degree of the pollution affecting a commercial shellfish growing area have been determined, the regional board, with the advice of the local technical advisory committee, shall *order* appropriate remedial action, including the adoption of best management practices to abate the pollution affecting that area." Cal. Water Code 14956(a). However, Cal. Water Code 14956(b) provides that "if *agricultural* sources of pollution have been identified as contributing to the degradation of shellfish growing areas, the regional board shall *invite* members of the local agricultural community representing the type of agricultural discharge affecting the local shellfish growing area, the local resource conserve district, the local soil conservation service.....and affected shellfish growers to develop and implement appropriate short- and long-term remediation strategies that will lead to a reduction in the pollution affecting the commercial shellfish growing area."

Fish Kill Caused by Pollution

Many states also have provisions that prohibit fish kills or that allow enforcement responses to fish kills. Although some of these are simply broadly written prohibitions on killing fish without a valid fishing license, many others clearly proscribe nonpoint source and other discharges that result in harm to aquatic life.

Some of these provisions are similar to those described in the preceding section, but possibly may require proof of injury to fish, not simply discharge of an injurious substance. For example, Puerto Rico's law might be interpreted as falling within either category: "It is prohibited to throw or cause to be thrown or deposited into any...body of water...oils, acids, poisons, or any other substance which kills or destroys fish, crustacea, or mollusca." 12 P. R. Laws Ann. 61. Indiana's law prohibits drainage or placement of material into state waters that causes or contributes to a polluted condition such that "any fish life or any beneficial animal or vegetable life in any waters may be destroyed or propagation thereof prevented or injuriously affected." Indiana Code 13-1-3-8.

Other laws prohibit killing fish by depositing in any "public stream or body of water..any poison, poisonous substance...or other deleterious or poisonous matter" Ala. Code 9-11-93; or they provide that "No fish, other than migratory food fish of the sea in the marine and coastal district, shall be taken except by angling." N.Y. Env. Cons. L. 11-

1301(1)("taking" includes killing). States with potentially applicable fish kill laws include at least Massachusetts, New York, Puerto Rico, Maryland (where the harm is from sediment), Alabama, Indiana, Minnesota, New Mexico, Wyoming, and Arizona.

In addition to state laws prohibiting fish kills, including those caused by polluting substances that may be discharged from nonpoint sources, it is also worth noting other state provisions that create explicit liability to the state where an "unlawful" pollution discharge damages fish. These include New Hampshire, Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Kansas, South Dakota, California, Alaska, Oregon, Washington. Pennsylvania law provides: "The Commonwealth has sufficient interest in fish living in a free state to give it standing, through its authorized agencies, to recover damages in a civil action against any person who kills any fish or who injures any streams or stream beds by pollution or littering." 30 Pa.C.S.A. 2506(a). See N.C. Gen. Stat. 143-215.3 (similar)

Pollution of Drinking Water or Public Water Supply

About a fourth of the states have older provisions specifically aimed at preventing or criminalizing the pollution of a drinking water supply. Typical is Ok. Stat. tit. 11, 37-115: "No person...shall pollute or permit the pollution of the water supply of a municipality, or any stream, pond, spring, lake, or other water reservoir or groundwater aquifer, which is used or which is being held for use as a water supply by a municipality." Compare Minn. Stat. 144.35 "No sewage or other matter that will impair the healthfulness of water shall be deposited where it will fall or drain into any pond or stream used as a source of water supply for domestic use."

Nuisance and Public Health Provisions

All, or virtually all states have statutory provisions that provide for the abatement of nuisances, and many have additional public health provisions that may have some application to particular instances of nonpoint source pollution. The common law of nuisance also applies in every state. Nuisances are of basically two types: public nuisance and private nuisance. Public nuisance is the creation of a condition that causes injury to the public welfare, while private nuisance impairs the use and enjoyment of property. Nuisance is not a fault-based doctrine, but requires only proof of the adverse condition. Thus, even a condition that does not violate any law or regulation may still be abatable as a nuisance. Remedies for public nuisances are typically injunctions for abatement, or authority for a public entity to conduct summary abatement of the nuisance and recover its abatement costs, and/or the imposition of fines - reflecting the historic origins of public nuisance as a quasi-criminal action. Public nuisance actions may be brought by the state or, often, by any affected entity or person, while private nuisance actions are brought by adversely affected land owners.

Nonpoint source water pollution that impairs the usefulness of waters, adversely affects human health, or impairs the rights of others may be abatable under state nuisance laws. Two types of nuisances are generally addressed by state statutes - first, and more important for most nonpoint sources, are state provisions declaring water pollution to be a nuisance. Such legislative declarations limit the need to prove particular deleterious effects in order to secure relief. Second, are state provisions that provide for the abatement of conditions dangerous to public health or otherwise noxious or offensive to the senses.

Alabama law combines both approaches in one provision: "Any and all pollution is hereby declared to be a public nuisance and, if it creates, or is about to create, a health hazard, shall be subject to immediate control of the commission by order or injunction." Ala. Code 22-22-9(I)(4). This provision both declares water pollution a nuisance making it subject to injunctive relief by the state or any person, and declares that particular kinds of water pollution (health hazards) are subject to certain kinds of administrative relief and summary abatement action. Pennsylvania law provides a typical, but especially complete, version of the "water pollution as nuisance" provision: "The discharge of...any substance into the waters of this Commonwealth, which causes or contributes to pollution...or creates a danger of such pollution is hereby declared not to be a reasonable or natural use of such waters, to be against public policy and to be a public nuisance" and "shall be abatable in the manner provided by law or equity for the abatement of public nuisances." 3 Purdon's Stat. 691.3, 691.601. Minnesota's provision is given additional detail in state regulations, making its applicability to nonpoint discharges explicit: "No sewage, industrial waste or other wastes shall be discharged from either point or nonpoint sources into any waters of the state so as to cause any nuisance conditions, such as the presence of significant amounts of floating solids, scum...excessive suspended solids, material discoloration...undesirable slimes or fungus growths, aquatic habitat degradation, excessive growth of aquatic plants, or other harmful effects" Minn. Rules 7050.021.

Some laws more directly reflect the historic petty criminal nature of water pollution as a nuisance. Cal. Penal Code 374.4(a) provides: "Every person who...dumps or causes to be dumped, any waste matter into any bay, lagoon, channel, river, creek, slough, canal, lake, or reservoir, or other stream or body of water, or upon a bank, beach, or shore within 150 feet of the high water mark of any stream or body of water, is guilty of a misdemeanor" and imposes a fine of $100-1000. A few states have even older provisions, like Kentucky Rev. Stat. 438.060, which makes it a violation for any person to place or cause to be placed "in any stream, dam, pool or pond" any substance that renders the water "unfit for use or produces a stench," punishable by fine of not less than $10 nor more than $100 and/or imprisonment for 30 days to 6 months. Ohio Rev. Stat. 3767.13(C): "No person shall...corrupt or render unwholesome or impure, a watercourse, stream, or water." This is a misdemeanor punishable by up to 60 days and/or $500.

General nuisance law is typified by Minn. Stat. 561.01: "Anything which is injurious to health, or indecent or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property, is a nuisance." Some states have made the connection to public health abatement explicit. For example, Kansas's Secretary of Health and Environment and county boards of health can examine all "nuisances, sources of filth and causes of sickness"..."When such source is found to exist on any private property or upon any watercourse in the state" they have the power to order the owner to remove the nuisance within 24 hours. Failure to obey an order is punishable by a fine of $10 to $100. Kan. Stat. Ann. 65-159.

Nuisance laws are generally not preempted by state regulatory laws; however, a number of states have expressly enacted savings clauses to preserve public and private nuisance actions for abatement of water pollution (e.g., Ala. Code 22-22-9(o)).

Virtually every state has enacted "right to farm" legislation exempting agricultural activities (and in a few states, silvicultural activities) from abatement as a nuisance. These laws vary in the extent of the exemption. All of them are clearly aimed at preventing private nuisance actions occasioned by recent suburban dwellers encountering the odors and noise of normal farming operations, but some are broader and apply to public as well as private nuisance actions and to a wider array of conduct. Most also provide that the exemption from nuisance liability does not apply where the agricultural activity is conducted in violation of law, or negligently, or (in some cases) where the nuisance alleged is water pollution. The following selected state laws give an idea of the scope of these ubiquitous laws.

Delaware has a typical right to farm provision: "No agricultural or forestal operation...which has been in operation for a period of more than 1 year shall be considered a nuisance, either public or private, as the result of a changed condition in or about the locality where such...operation is located. This section shall not apply when the nuisance is determined to exist as the result of the negligent or improper operation...or when such operation is being operated in violation of state or federal law or any local or county ordinance." 3 Del. Code 1401.

New Hampshire agricultural operations cannot be found a nuisance if they were in operation for one year or more and were not a nuisance when operations commenced; however this exception does not apply if operations are "injurious to public health or safety" N.H. Rev. Stat. Ann. 432.33, nor if the nuisance results from "negligent or improper operation". N.H. Rev. Stat. Ann. 432.34. But operations "shall not" be found negligent or improper" if they are obeying all laws. Thus, New Hampshire agricultural operations are exempt from nuisance actions unless they create a public health hazard, or they are violating an explicit legal requirement. Michigan law provides that a farm operation is not a nuisance if it "conforms to generally accepted agricultural and management practices according to policy determined by the Michigan commission of agriculture" Mich. Cons. L. 286.473.

Idaho law goes farther by exempting not only agriculture but also agricultural processing operations and forestry activities from nuisance actions; the law also preempts local regulation of such activities, declares the right to conduct forest practices a "natural right" and has an exception only for "improper or negligent operation" - defined as operations not in compliance with law and adversely affecting public health and safety. Idaho Code 22-4501 and 38-1401.

New York exempts agricultural activities only from *private* nuisance actions, and subjects the exemption to various exceptions for increased activities and activities causing conditions dangerous to life or health. N.Y. Pub. Health L. 1300-c. California's right to farm nuisance exemption specifically provides that it "shall not invalidate " provisions of the state's Health and Safety Code, Fish & Game Code, Food & Ag. Code, or Porter-Cologne Water Quality Act that declare such an activity a nuisance "specifically defined or described in any of those provisions."

Some states' right to farm provisions specifically do not protect agricultural operations from nuisance claims based on water pollution. e.g., Hawaii Rev. Stat. 165-2, Ark. Code Ann. 2-4-106, Iowa Code Ann. 176B.11, N.D. Cent. Code 42-04-03.

ENFORCEMENT AND SANCTIONS

Most general discharge prohibitions under state water pollution control laws are enforceable by administrative orders, civil injunctions, civil penalties in the $10,000 to $25,000 range, criminal sanctions and other sanctions. This is why determining whether these authorities can be applied (particularly in the absence of an adopted permitting program for nonpoint sources) can be extremely important to a state effort.

Most of the discharge prohibitions based on other statutes are enforceable as petty criminal offenses and through abatement orders or injunctions.

These distinctions are important, not only because of their potential effectiveness in changing behavior, but also because they affect issues of process and issues of proof. For example, while proving that a discharge was of a "waste" or that it caused "pollution" presents one set of difficulties in a civil or administrative context, proving an offense in a criminal case (even in a magistrate's court) can present additional hurdles. Can the state show that the discharge was of a "deleterious substance" harmful to fish "beyond a reasonable doubt" and that the act occurred with the requisite intent? And is this even worthwhile if the sanction is $500? On the other hand, if an offense is criminal, even if petty, does this provide sufficient practical effect to bring about compliance and the deterrence of others? State discharge prohibitions come in many types, often presenting complex issues for prosecution or enforcement in the nonpoint source context.

PERFORMANCE OF URBAN STORMWATER

BEST MANAGEMENT PRACTICES

Introduction

Surface water quality degradation in urban and urbanizing areas is largely attributed to stormwater runoff (EPA 1993, Duda 1993, Bannerman et al. 1993). The hydroecological impacts on receiving waters from urban runoff pose a health risk from the rate at which they enter the system and the numerous types of pollutants associated with stormwater runoff (Klein 1979, Schueler 1987, Hall and Anderson, 1988). Table 1 highlights conventional, inorganic, and organic contaminants in urban stormwater and the ir risk to human and aquatic health (Makepeace et al. 1995). To control the quantity, and improve the quality of urban runoff in a cost-effective manner, best management practices (BMPs) have been widely implemented for over 20 years. Table 2 lists BMPs commonly practiced and the relative size of drainage basin for which they are designed.

Performance data on best management practices is needed to derive design criteria to ensure that they will effectively treat stormwater to desired target levels. Numerous studies on BMP performance document a wide range of pollutant removal capabilitie s for suspended solids, nutrients, bacteria, oxygen-demand, and a few heavy metals. Only recently has research begun to focus on the fate of organic contaminants in urban stormwater facilities (Helfield and Diamond 1997, Wren et al. 1997, Pitt et al. 1993). Despite the diversity of data sources on BMP performance, the predictive utility is surprisingly low as there is considerable variability amongst study site characteristics, pollutants studied, climatic factors and data quality (Tanner et al. 1998).

Given the variable nature of BMP monitoring studies, it is difficult to conclude specific criteria that could be applied to all situations to maximize their performance. Rather, research suggests design characteristics and environmental conditions that may affect BMP performance and should be considered when evaluating its pollutant removal capabilities. Further, it has been shown that desired pollutant reductions are not consistently achieved based on design expectations. The performance of BMPs is qu ite variable with detention facilities acting as a sink for some pollutants, while at times also as a net source for other constituents. Conclusions regarding the processes and mechanisms responsible for improving ambient water quality are inferred based on design elements of the BMP and an understanding of chemical cycling and fate. Most studies, however, are limited to monitoring input and output concentrations or mass loadings to determine BMP effectiveness.

Table 1. A selection of contaminants in urban stormwater and their risk to human and aquatic health.

(from Makepeace et al. 1995)[a].

Chemical	*Range (mg/L)*	*Risk*		*Chemical*	*Range (mg/L)*	*Risk*

[a] **Many of the results presented are based on preliminary findings of the NURP by Cole et. al. (1984).**

[b] **A problem is considered "major" if the upper contaminant concentration limit is ten times the regulation maximum allowable concentration (MAC) for drinking water quality or aquatic life guidelines. Minor problems are associated w ith upper concentrations between the MAC and ten times the MAC.**

Table 2. Types of Best Management Practices (BMPs) for urban stormwater (from Brix 1994, EPA 1993, Yu and Nawang 1993, Schueler et al. 1992).

Type	*Relative Size of Drainage Area*	*Description*
Constructed Wetland	Moderate to large	Intentionally created from non-wetland sites for sole purpose of wastewater or stormwater treatment. Types include: 1) free-floating macrophyte, 2) emergent macrophyte 3) submerged macrophyte.
Extended (Dry) Pond	Moderate to large	Outlet structure of dry pond is modified as a "retention outlet" that provides slow release of runoff from a 1-yr design storm, moderate to higher removal rates for particulates (40-70%), very low for dissolved pollutants.
Grassed Swales	Small	Shallow, vegetated ditch above watertable. It is used as an infiltration/filtration method to provide pretreatment before runoff is discharged to other treatment systems. Vegetative cover should never be shorter than 3-4 inches.
Infiltration Basin	Moderate	Impoundments that store runoff temporarily until it gradually infiltrates into the soil surrounding the basin. Infiltration basins should drain within 72 hours to maintain aerobic conditions. Runoff is pretreated to remove coarse sediment and prevent c logging.
Infiltration Trench	Moderate	Shallow excavated ditches with coarse substrate (sand, gravel) to allow infiltration to subsoil and groundwater. Some facilities are lined with fine fabric to prevent infiltration to groundwater.
Porous Pavement	Small	Thin layer of open-graded asphalt mixture on top of a deep-based filled with large-size crushed stone aggregate to serve as reservoir to detain stormwater. Stored runoff exfiltrates from the reservoir into the soil. A fine filter fabric may be used to prevent infiltration to groundwater. Limited data available on performance.
Vegetated Filter Strips	Small	Areas of vegetated cover designed to strictly treat low to moderate overland sheet flow. Used as pretreatment for other structural practices such as infiltration basins and trenches.
Water Quality Inlets	Small	Underground retention systems designed to remove solids. A basin is constructed 2-4 feet deep below an outlet pipe to collect sediment. Multiple-chamber systems may include an additional basin to filter fine sediment. Oil/grit separators can provide ad ditional treatment.
Wet Pond	Moderate to large	Permanent pool of water that temporarily stores runoff and allows particulate pollutants to settle out and dissolved pollutants to be removed by biological uptake or other decay processes. Stormwater is released at a controlled rate.

R0010342

Performance of Urban BMPs

A review of the research provides a range of removal efficiencies for a select suite of urban stormwater constituents, design characteristics, and processes attributed to promoting water quality improvement (Table 3). Design elements such as the r atio of stormwater pond to catchment area, pond geometry, and detention time are primary design considerations to ensure the BMP provides the desired level of pollutant removal. Such design features are typically designed to treat the volume of runoff g enerated from 1-yr and 2-yr storm events, rather than more frequent events (Allan et al. 1997). The physical-chemical environment of the BMP is also suggested to significantly affect effluent from wet detention basins. As an example, Borden et al. (1997) found that large seasonal differences in pollutant removal of both total and dissolved nitrogen and phosphorus species was attributed to thermal stratification. Turnover in the fall releases phosphorous that has accumulated in the anaerobic sediment in t he hypolimnion. Processes such as thermal dynamics of the pond, plant growth and senescence, and other physical, chemical and biological interactions, however, are not incorporated in modelling the design of BMPs. Such internal pond dynamics and the sen sitivity of chemical species to pH, redox potential, organic matter content, and available exchange sites dictate the dominant form and phase of the chemical, and thus pollutant removal.

Table 3. Factors affecting the performance of BMPs.

Design Characteristics	Detention time Storage volume Shape of BMP (length:width ratio of detention pond, slope, flow path obstructions, buffer width) Pond surface area relative to contributing catchment area Type of substrate/sediment; Auxiliary devices (e.g. baffles, sediment forebay) Presence of vegetation
Processes	Adsorption Sedimentation/resuspension Precipitation Complexation Degradation (photolysis, hydrolysis, volatization, biological) Biotic uptake

Environmental Conditions	Storm intensity, loading rate
	Drainage basin land cover
	Physical-chemical properties of BMP surface water
	Particle-size distribution and settling velocity
	Pre-storm water quality in BMP
	Thermal stratification

EPA (1993) and Brown and Schueler (1997) provide summaries of stormwater BMP effectiveness which include: extended wet detention ponds, wet ponds, stormwater wetlands, multiple pond systems, infiltration trenches, infiltration basins, porous pavement, sand filters, grassed swales, filter strips, and water quality inlets/oil grit separators. Dry detention ponds are another BMP but are designed for controlling peak flows rather than quality control. Appendix A provides a summary of BMP e ffectiveness based on work by Schueler et al. (1992) and additional research. An examination of factors contributing to the treatment of suspended solids, nutrient and heavy metals is provided. As the most common type of BMP studied is the wet detention p ond for a variety land use characteristics (e.g., suburban resident, commercial, rural), the data presented is biased towards this particular BMP facility.

Suspended Solids

BMPs are primarily designed to remove total suspended solids (TSS) and pollutants sorbed to particles. As such, gravitational settling is relied upon as the predominant process for pollutant removal. The effectiveness is illustrated by sediment accumul ation in wet detention ponds (e.g. 0.8cm/yr to 2 cm/yr) (Marsalek et al. 1997, Guo 1997, Allan et al. 1997). Studies report TSS load reductions for wet detention basins to be generally greater than 50%, but range from 20-98% (Borden et al. 1997, Schueler et al. 1992).

BMPs are primarily designed to remove total suspended solids (TSS) and pollutants sorbed to particles by sedimentation. Studies report TSS mass load reductions for wet detention basins to be generally greater than 50%, but range from 20-98% (Borden et al. 1997, Schueler et al. 1992). Another indicator of effectiveness is provided by the rate of sediment accumulation in BMPs that range from 0.8cm/yr to 2 cm/yr (Marsalek et al. 1997, Guo 1997, Allan et al 1997). The ability to treat TSS, however, is a function of particle-size distribution, storm intensity, loading rate, and geometry and age of BMP facility.

Particle-size distribution of the influent is shown to influence the treatment capabilities of a BMP (Ferrara and Witkowski 1983, Yu and Nawang 1993, Wu et al 1998b). Ferrara and Witkowski (1983)

generalize that as storm intensity increases the concen tration of TSS increases due to larger size fractions of TSS resulting in a greater removal efficiency. Based on research by Randall (1983), Allan et al. (1997) concludes BMP removal to be a function of influent concentration. Removal rates were poor whe n TSS concentration was less than 10mg/L and increased to a consistent percentage removal up to100 mg/L. However, research by Tanner et al. (1997) on sub-surface flow wetlands observed the greatest annual percent mass removal and lowest outflow concentrat ion to be generally associated with the lowest hydraulic loading rate. This conclusion did not apply to ammonium-nitrogen, total phosphorus and one sample of suspended solids. There was a lag-effect in the effluent concentration for nutrient species.

The sedimentation rate is also affected by pond geometry. If there is insufficient length-to-width ratio, the finer particles will not settle-out. Marsalek et al. (1997) observed sediment sorting in detention ponds draining a commercial complex, with c oarsest particles settling nearest the inlet (Marsalek et al. 1997). The available storage volume and hydraulic loading rate of runoff to the BMP further limit the effectiveness of sedimentation. Storms that produce a runoff volume greater than the stora ge volume of the BMP, or if sediment is allowed to accumulate and consequently reduce storage volume, short-circuiting within the pond will adversely affect BMP performance (Marsalek et al. 1997, EPA 1993, Martin 1988a). It is suggested that a minimum de tention time of 24-hours is necessary to ensure high removal rates for stormwater pollutants to allow for settling and biological uptake (Pitt et al. 1993, Yu and Nawang 1993, Schueler 1987). The age of the BMP facility is another factor contributing to BMP performance. Tanner et al. (1997) reported a decline in removal efficiencies with an increase in age of the BMP. TSS percent mass removal declined from 75-80% in the first year of operation to 55-70% by the 5th year.

Nutrients

Wet detention ponds and constructed wetlands can act as a sink, source or transformer of nutrients (Mitsch and Gosselink 1993). To improve stormwater quality polluted with excessive nutrient levels, BMP facilities are designed to provide sedimentation for particle-phase constituents and biological uptake for soluble nutrients (Martin 1988b). It has been found that the performance of BMPs for nutrient-enriched stormwater is unpredictable. This may be attributed to the complex nature of nutrient speciat ion, which is affected by seasonality, detention time, organic matter content, oxygen availability, and plant biomass. The most effective phosphorus removal mechanisms have been found to be adsorption, complexation, precipitation reactions with aluminium, iron, calcium and clay particles and by peat accretion (Brix 1994, Mann and Bavor 1993). Pond conditions amenable to nitrification-denitrification processes are most effective for nitrogen removal (i.e. aerobic vs anaerobic conditions/oxygen availability) (Brix 1994, Mitsch and Gosselink 1993). Further, similar to TSS, particle size distribution affects removal efficiencies of nutrients. The quality of the substrate and age of facility are also determinants of BMP performance.

Many studies report greater variability in BMP performance for nutrients than other constituents (Tanner et al. 1997, Yu et al. 1993, Martin 1988b, Mann and Bavor 1993). There is a range in removal efficiencies for particle and dissolved phases, as wel l as different species of nutrients. For example, Ferrara and Witkowski (1983) report a net export of TKN of 25.4% for the most intense storm (17.5mm) and a net gain by a wet detention facility of 23.9% for a less intense storm (10mm). A different pattern is found for TP in which there was a net reduction for the same storms of 48.6%

R0010345

and 30.9%, respectively. In another study using three methods to calculate BMP performance, Martin (1988b) reported a range in percent pollutant reduction for all species and phases of nutrients, from a net export of dissolved ammonia (i.e. 8-33%) to a reduction of 15-57% in dissolved phosphorus. Similarly, variable performance of nutrient species is observed for a pond/wetland system in Colorado in which there was a net expo rt (76%) of nitrate and an overall reduction of 19% for total nitrogen, and net reduction of 51% and 40% for total and dissolved phosphorus, respectively (Anon 1994).

It is indeterminate what factors contribute to the reduction of nutrients in stormwater runoff from the data collected in the studies. The variability of reduction for all particle size classes for TKN and TP does not appear to have a clear relationshi p between particle-size distribution and storm intensity (Ferrara and Witkowski 1983). The net export of pollutants may be attributed to the large proportion of pollutants associated with the soluble size fraction of solids (i.e. < 1µm). This was also observed for the effluent concentrations, which may suggest the soluble phase of nutrients are not being effectively treated in this wet detention basin. Mann and Bovar (1993) suggest that the type of substrate and age of facility affect pollutant remova l. The net export and gain of phosphorus was attributed to the 50% difference in sorption capacity of two types of gravel substrate in similar constructed wetland systems (i.e. 25.8 and 47.5 µg P/g substrate) (Mann and Bavor 1993). The decline in performa nce observed in the subsequent year was attributed to the saturation of phosphorus in the substrate. Similar reasons are provided for a 50% reduction in performance for total phosphorus for gravel-bed constructed wetlands (e.g. 35-75% to 15-38%) over a 5- yr period (Tanner et al. 1993). However, the standard error was large for these samples. The clogging of gravel substrate also contributes to reduced performance. Currently, long-term studies on a variety of BMPs are not available, nor are internal pond m easurements, to assess the longevity or treatment capacity.

Heavy Metals

BMPs generally have a positive impact on reducing total heavy metal pollutants from urban stormwater. Overall, studies report a moderate to high removal efficiency for wet detention basins, constructed wetland systems and combined pond-wetland systems (Schueler et al. 1992). Sedimentation is considered to be the predominant removal mechanism for heavy metals as it is assumed that pollutants in urban stormwater are largely sorbed to suspended sediments (Allan et al. 1997, Scholze et al. 1993). The co ncentration of heavy metals in sediments indicates the improvement BMPs have on stormwater quality (Marsalek et al. 1997).

Overall, characterization of BMP sediments (i.e. detention basins) indicates an accumulation of heavy metals associated with sedimentation rates ranging from 0.8cm/yr to 2 cm/yr (Marsalek et al. 1997, Guo 1997). Despite the strong ability of particula tes and organic matter to sequester heavy metals, Allan et al. (1997) found that TSS is not a good surrogate for other pollutants (Borden et al. 1997). This counters a design principle for BMPs that assumes an 80% removal of TSS will control other polluta nts, including heavy metals (EPA 1993). Further, the reliance on sedimentation to remove pollutants from the water column is not sufficient as data illustrates the presence of heavy metals in urban runoff in the dissolved-phase .

The results of performance studies reflect total metal concentration for a select number of pollutants. Pollutant removal efficiencies for wet detention ponds range from a net mass export of 17% to a reduction of 96% for Zn, an approximate reduction of 18-95% for Pb, generally >50% for Cu, and less the 0% to 51% for Cr. In a combined level spreader/vegetative buffer strip, a greater mass reduction in total Pb and Zn from runoff increased with filter length. An average mass loading reduction for thre e storm events of 25% and 51% was achieved for Pb and Zn respectively (Yu et al. 1993). For the largest storm (32.5mm) there was a net export of 55% and 16% of Pb at 6m and 21 m, respectively.

The benefits derived from improved water quality may be countered by adverse affects induced by sediment contamination. Further, cation-exchange capacity, and sensitivity to pH and Eh can affect the solubility of heavy metals, thus affecting the abili ty of sediments to sequester heavy metals from the water column. In a wet detention basin in Kingston, Ontario, Marsalek et al. (1997) found a suite of heavy metals to exceed the Ontario Lowest Effect Level (LEL) guidelines for the protection and manageme nt of aquatic sediment quality for 8 of the 10 metals sampled (i.e. Cd, Cr, Cu, Fe. Pb, Mn, Ni, and Zn). Arsenic and mercury were below the sediment LEL. These results reflect an average concentration of the top 18cm of sediment that has accumulated over a 9yr period (i.e. based on calculated sedimentation rate of 2cm/yr). Guo (1997) found that the concentration of heavy metal in the sediment generally decreased with depth and was correlated to percent organic content of the sediment (Guo 1997). The co ncentration of Pb, Zn and Cu decreased with depth and organic matter. The relationship was more consistent with organic matter than depth. The higher concentration of heavy metals in surficial sediments indicates a high risk to biota given the susceptibi lity of chemical speciation to changes in water quality. The mobilization of heavy metals from the sediment can be enhanced due to intermittent flooding which produces alternating periods of aerobic and anaerobic conditions. The change in the oxidized-sta te of an environment can alter the speciation of chemicals, and thus their bioavailability. For example, Marsalek et al. (1997) indicates the probability of a lower toxic form of Cr (Cr III) to be oxidized into a more toxic form of chromium, Cr (VI). In the same study, the proportion of heavy metals in a potentially mobile fraction was significant. Cadmium mobility also is increased during oxidized conditions under a range in pH values and has limited mobility during reducing conditions (Fergusson 1990).

Conclusions

The use of BMPs to control and treat urban stormwater runoff has become common practice in developing watersheds. Ordinances have been developed by local governments to dictate the use of BMPs for new development to protect surface water quality. To da te, studies on BMP effectiveness demonstrate a wide range of pollutant removal capabilities that range from a net export to more than a 90% reduction for a select suite of chemicals. Research indicates that performance is affected by specific design char acteristics, processes affecting chemical phase and speciation, and environmental conditions. However, it is difficult to interpret the pollutant removal efficiency of BMPs beyond generalities. Studies report only influent and effluent concentration and /or pollutant loading reductions, thus making it difficult to determine what specific factors are affecting BMP performance. Currently there is a lack of within-BMP monitoring of water quality and other media (e.g. sediment, vegetation) to provide a stro ng understanding of factors and processes that affect pollutant fate within a BMP. There is a particular lack of long-term monitoring of the processes responsible for export or detention of urban stormwater pollutants. There is a need to study the fate o f contaminants within the BMP and the interactions amongst media. For example, processes such as diffusion, turbulence, resuspension and bioturbation will affect the movement of chemicals across the sediment-water interface. Such processes are affected by physical-chemical properties such as temperature, pH, Eh, organic matter, etc.. Monitoring should also be expanded to include organic contaminants which are present in urban stormwater and pose health risks to humans and aquatic biota due to their persi stence in the environment and ability to transform into more harmful compounds (Makepeace et al. 1993, Helfield and Diamond 1997). Further, the variability in results is not only due to factors affecting BMP performance, but also the methods used to calcu late effectiveness and estimate flow for non-gaged BMPs.

Recommendations

- The long term performance of BMPs needs to be evaluated. The pollutant removal capabilities of BMPs are likely limited by a finite capacity of sediment/substrate to sorb and retain pollutants. The majority of studies reflect seasonal, short-term monit oring activities, and as such long-term performance of BMPs is uncertain (i.e. ≥ 5 yrs.). To date, research findings infer that the longevity of BMPs is linked to the ability of the substrate to assimilate pollutants (Mann and Bovar 1993, Tanner et al. 1997) and maintenance practices (Schueler et al. 1992).
- To more effectively manage BMPs, it is important to understand the specific process and interactions that cause the transformation, immobilization, and export of pollutants. The interactions amongst physical, biological and chemical processes need to be better understood. As an example, research on internal processes that affect chemical transformation and mobilization of particle-sorbed constituents in urban stormwater detention facilities is limited. The export of pollutants from BMPs indicates the release and/or transformation of pollutants within the BMP, yet the data presently available relies upon influent and effluent measurements to determine the effectiveness of the BMP facility. Such information on internal pond dynamics is necessary to imp rove upon effective BMP design and maintenance practices.
- The effect of an urban BMP needs to extend beyond water quality and include other media such as sediment, benthic invertebrates and vegetation. The reliance on sedimentation as the predominant design feature to remove pollutants from the water column, in addition to a lack of maintenance, results in contaminated sediments. The use of vegetation in wet detention ponds and constructed wetlands also introduces uncertain risk from the introduction of pollutants at low, but harmful concentrations. The cap acity of vegetation, bacteria and benthic invertebrates to accumulate and breakdown pollutants is not fully understood.
- The types of pollutants studied should be extended to include a more extensive array of priority pollutants such as hydrocarbons (e.g PAHs, pesticides) and inorganic pollutants. Helfield and Diamond (1997) and Makepeace et al. (1995) illustrate the r isk that may be induced by the presence of such chemicals in urban stormwater.
- The aggregation of data needs to be reported on a monthly and seasonal basis, rather than annual averages of pollutant removal. At this temporal scale, seasonal factors affecting BMP performance, such as thermal stratification of pond water and plant growth and senesce can be assessed.

Monterey Park, CA 91754
Phone 323.266.7500 • Fax 323.266.7600

ACKNOWLEDGEMENTS

This report, which is a first, statewide, to the author's knowledge, has not been possible without the support and involvement from:

- State Water Resources Control Board, Storm Water Unit for providing funding to perform the duties required to manipulate such a large volume of data. Special thanks to the State Board staff for making this project possible;
- Regional Board management, that was very supportive of this effort, and Dr. Xavier Swamikannu's constant assistance and advice;
- Santa Monica Bay Restoration Project for providing funding to accomplish this task. Special thanks to the SMBRP staff for making this project possible;
- And special thanks to the student assistants working on this project. Without their hard work and perseverance, this task could not be concluded:
  - Binh Phan,
  - Robert Tom, and
  - Jessica Huynh.

Again, many thanks to those contributing to the success of this project that can provide useful information in an area crucial to the progress of the Storm Water Program in improving water quality in our region.

Its substance reaches everywhere; it touches the past and prepares the future; it moves under the poles and wanders thinly in the heights of the air...

If there is magic on the planet, it is contained in water.

Loren Eiseley, Naturalist

EXECUTIVE SUMMARY

INTRODUCTION

In 1987 the **Clean Water Act** was amended by Congress to require the regulation of point source discharges of storm water from industry and from municipal separate storm sewer systems serving over 100,000 people. In 1990 the **U.S. Environmental Protection Agency (EPA)** promulgated regulations requiring, in part, **National Pollution Discharge Elimination System (NPDES)** permits for all storm water discharges associated with industrial activity. The regulations allow authorized states to issue general permits or individual permits to regulate storm water discharges. California is one of the authorized states to issue NPDES permits.

Consistent with Tier I, Baseline Permitting, of the U.S. EPA permitting strategy, the **California State Water Resources Control Board** issued a statewide **General Industrial Activities Storm Water Permit (General Permit)** on November 19, 1991, that applied to all storm water discharges requiring a permit except construction activity. The General Permit was reissued on April 17, 1997.

The nine California **Regional Water Quality Control Boards (Regional Boards)** have the responsibility of implementing and enforcing the statewide General Permit.

Some of the General Permit key requirements are:

- to prepare and implement a **Storm Water Pollution Prevention Plan (SWPPP)** by each regulated facility;

- the develop and implement a **Monitoring Program (MP)**;
- submit an **Annual Self-Monitoring Report (AR)** by July 1, each year the facility continues coverage under the permit.

BACKGROUND

Since the implementation of the storm water regulations, Los Angeles Regional Board embarked, with limited staff resources, in a sustained effort to administer and enforce the General Permit requirements. The Board staff also provided outreach, compliance support and guidance to the permittees and other interested stakeholders.

The Los Angeles metropolitan area is one of the most industrialized areas of the State and the nation. It is home to thousands of industrial and commercial facilities, ranging from petroleum refineries to aerospace corporations, from wastewater treatment plants to recycling facilities. In the region are also located some of the major harbors and airports in the country, military bases, transportation facilities and many other types of businesses. A recent report: *Effectiveness of Industrial Storm Water General Permitting Program* - October 1996, prepared by the **Water Environment Federation** for the US EPA, determined that California had over 10% of the total number of **Notices of Intent (NOIs)** filed nationwide. Under L.A. Regional Board's jurisdiction (covering most of L.A. and Ventura Counties), there were 2,457 industrial facilities covered by the General Permit, as of July 1, 1997. That represents 30% of the total number of NOIs filed in California (See Attachment 1). As a consequence, the number of NOIs filed in L.A. Region (excluding construction NOIs) is almost the same as that in the states of New Jersey and Wyoming combined, or more than the number of NOIs in Louisiana or Arizona (Source: US EPA NOIs database, June 1998, See Attachment 2).

One of the objectives of this staff report is to give an overview of the facilities' compliance performance. The second objective is to perform a brief analysis of the sampling results as reported by the permittees in their ARs. The analyzed data are presented in tables and graphs.

METHODS AND PROCEDURES

The main objectives of the monitoring program required by the General Permit are:

- to demonstrate compliance with the permit;
- aid in implementing the SWPPP; and,
- measure the effectiveness of the **Best Management Practices (BMPs)** in reducing or preventing pollutants in storm water discharges and authorized non-storm water discharges.

All facility operators (except for inactive mining operations) are required to:

1. Perform visual observations of storm water discharges and authorized non-storm water discharges.

2. Collect and analyze samples of storm water discharges. Analysis must include:

   - pH;
   - total suspended solids (TSS);
   - total organic carbon (TOC) or Oil and Grease;
   - specific conductance;
   - toxic chemicals, and other pollutants which are likely to be present in storm water discharges in significant quantities; and,
   - those parameters listed in **Table D** of the General Permit. The Table D parameters are those listed in the U.S. EPA Multi-Sector General Permit (See **Federal Register**/ Vol. 60, No. 189/ September 1995, page 50804-51319).

- Facility operators subject to Federal storm water effluent limitation guidelines in **40 CFR Subchapter N** must also sample and analyze for any pollutant specified in the appropriate category of 40 CFR Subchapter N.

The examination focused on:

- a cursory review of the ARs, to determine the overall level of compliance with the requirements of the General Permit, as self reported by the permittees,
- a limited statistical analysis of the **sampling analytical results (SAR)**, as reported by the facilities.

The following procedure was used to process the documents and enter the data:

- **First step** was to process the documents immediately upon receipt at the L.A. Regional Board and date stamp the ARs as received. In the process, thousands of documents were handled, summing up to over 15 cubic feet of records.

- **The second step** was to enter the date when the ARs were received into a database file containing the identification number of the facility.

- **The third step** was to sort the documents in the order of their **Waste Discharge Identification (WDID)** number, verify that each had a date stamp as a proof of the date when they were received and also, to confirm that the certification signature was existent. In case the certification signature was missing, the AR form was returned to the facility operator with a note to be signed by the proper facility representative. The ARs with missing certification signature were not processed until received with the proper signature present. The date when AR was received with the proper signature was logged in as the receiving date.

- **The fourth step** was to perform a cursory review of the ARs, verifying a limited range of compliance items:
    - any change of information (phone number, contact person, address, etc.);
    - AR was submitted by the deadline;
    - the facility has prepared a SWPPP and MP;
    - the required visual observations were performed;
    - required storm water runoff samples were taken and analyzed;
    - the mandatory annual site inspection/comprehensive evaluation was performed.

The reviewed items are also marked on a checklist form attached to the individual AR document. A sample checklist is attached to this report.

Next, a spreadsheet table of overall compliance was developed. The results of the review are entered in the table: ***Compliance Evaluation for 1996-97 Annual Reports, page 2-1***. The compliance data were not entered as separate records for each individual facility, instead a general tally for all facilities was developed.

Concomitant, the SAR data, as submitted with the ARs, were entered on a database file as separate records for each facility, for each storm event sampled. Depending on the number of existing outfalls, a facility may have more than one set of sampling data records for each storm event.

The SAR for the following parameters were entered in the database file:

- pH;
- Oil and Grease;
- Total Organic Carbon;
- Total Suspended Solids;
- Specific Conductance;

- Chemical Oxygen Demand;
- Biological Oxygen Demand;
- Total Chromium;
- Copper;
- Nickel;
- Zinc;
- Toluene;
- Xylene;
- Total Dissolved Solids.

More than 10,000 data values were entered in the file.

RESULTS

Compliance Evaluation for 1996-97 Annual Reports, page 2-1, presents a tabulated synthesis of the compliance items reviewed by February 28, 1998. The data shows a large percentage of the facilities, 55%, failed to submit the AR by the deadline. As a consequence, in concordance with the State and Regional Board progressive enforcement strategy, **442** Notices of Non-Compliance were issued, followed by **131** Notices of Violation. There was also a significant number of facilities, 105, which declared they did not prepare a SWPPP, mostly due to the claim that they recently applied for coverage under the General Permit.

The assessment shows that a significant percentage of facilities:

- 55% failed to take and analyze samples from the required two storm events,
- 32% did not take samples at all, and,
- 21% reported they have some type of non-storm water discharges present.

There was no attempt to determine if the samples were taken from a qualified storm event or when a discharge was present.

The **Group Monitoring Plan (GMP)** evaluation shows that the percentage of designated sampling facilities, taking samples in our Region, 18%, approaches the yearly percentage mandated by the General Permit: 20%.

Overall Sampling Results Analysis for 1996-97 Annual Reports, page 2-2, presents a synthesis of the SAR from the facilities submitting data as of January 1, 1998. There was no attempt to determine the quality control and quality assurance or the manner in which the samples were taken, handled and analyzed. For a limited number of reported values that seemed grossly out of range, or obviously wrong (as in the case of pH, values reported above 14), the facility operator was contacted for confirmation, to correct eventual typo errors. However, some of the results were confirmed as high as reported.

The values of the SAR were than compared with existing storm water **benchmark levels (BLs)**, (See Federal Register/ Vol. 60, No. 189/ September 1995, page 50826). The values of mean and median are computed for each parameter analyzed.

The data shows that a significant percentage of **SAR values** are outside or above BLs:

- for pH: 13%,
- for TSS: 27%,
- for SC: 29%.

The percentage of **facilities** reporting values outside or above BLs are also notable:

- for pH: 23%,
- for TSS: 27%,
- for SC: 29%.

For some parameters, there are a number of very low SAR values reported, uncharacteristic for typical values for common storm water runoff composition.

An attempt was made to present together the data from 1992-1993 and 1996-1997 seasons in: ***Combination of 1992-93 & 1996-97 Annual Reports Overall Analysis, page 3-1 and 3-2***. A brief analysis of the 1992-1993 SAR data was presented in the first ***Storm Report*** Newsletter issued by the Regional Board. It is important to note that the missing data from 1993 to 1996 can be made accessible in electronic format subject to availability of additional resources to perform the data entry task. Attached to the report there are a number of graphs organized by parameter and year, from page 4-1 to 5-5. There is another set of graphs organized by parameter, year and watershed, found at page 6-1 to 11-5. A third set of graphs, at page 12-1 to 12-6, are organized by **Standard Industrial Classification (SIC) Codes**, parameters and year, for 1996-1997 season only.

A brief review of the comparison do not show any dramatic improvement, percentage wise, in the number of samples reported outside or above the BLs, between 1992-1993 and 1996-1997 season. While the median values are within the BLs, the mean for TSS, SC and O&G are consistently above the BLs. As previously shown, there is a significant number of facilities reporting values above BLs and in addition a significant number of facilities still failed to take the required samples and analyze them, excluding GMP participants scheduled not to sample in a particular year or those previously obtaining an exemption from sampling from the Regional Board. The data available can not detect an overall trend or for any given parameter, due to the three year gap in recording.

The 1992-1993 season was the first year in which the permittees had to submit an AR with sampling results. There is a significant difference in the number of samples analyzed and number of facilities taking samples between 1992-1993 and 1996-1997:

an overall four to five fold increase can be noticed. This may be due to increased awareness about the requirements of the General Permit and constant compliance assistance and enforcement activities performed by the State and Regional Board staff.

Data for 1996-1997 season may be skewed upwards for some parameters due to a number of very high values. For a number of limited records, staff contacted the facility for confirmation, as stated before.

FINAL REMARKS

The brief analysis presented in this report was used to better prepare and plan the 1997-1998 season ARs review effort. The attempt to input all sampling results values in an electronic database will be continued in the future, subject to adequate, continued funding support. This data can make a significant contribution to various efforts under way in our region, to determine background levels of storm water runoff contribution to water quality impairments, trends and loads into the various regional watersheds. This gives RB staff an additional tool in the effort to determine the existence of any geographical or sector-wise "hot spots". The data can help in the process of determining **Total Maximum Daily Loads (TMDLs)** for various parameters, it can assist the municipalities' efforts to improve monitoring and control of diffuse pollution contributed from industrial sites into the municipal storm drain system. Also, a number of research projects under way, at prestigious universities in our area, can benefit from the accessibility to this database.

The availability of this data, with all inevitable constraints and unknowns, represents an important step forward in the endeavor to better understand and address complex diffuse pollution phenomena and their impact on aquatic systems. The research and interpretation of the data can be also expanded beyond the limited attempt of this report.

The greatest benefit is for the permittees themselves, since they can better quantify and evaluate their performance and they can direct their resources to address the real on-site issues in an economic, effective and efficient way.

Glossary of Terms

Best management practice (BMP): A practice or combination of practices that are determined to be the most effective and practicable (including technological, economic, and institutional considerations) means of controlling point and non-point source pollutants at levels compatible with environmental quality goals.

Constructed wetland: An artificial wetland system designed to mitigate the impacts of urban runoff.

Forebay: An extra storage space provided near an inlet of a wet pond or constructed wetland to trap incoming sediments before they accumulate in the pond.

Gabion: A rectangular basket or mattress made of steel wire in a hexagonal mesh. Gabions are generally subdivided into equal-sized cells that are wired together and filled with stones, forming a large, heavy mass used for shore protection.

Impervious area: A hard surface area (e.g., parking lot) that prevents or retards the entry of water into the soil, thus causing water to run off the surface in greater quantities and at an increased rate of flow.

Nonpoint source pollution: Water pollution caused by rainfall or snowmelt moving over and through the ground which carries pollutants. A nonpoint source is any source of water pollution that does not meet the legal definition of point source in section 502(14) of the Clean Water Act.

Nonstructural control: A practice that does not require construction of a facility to control urban runoff.

Premium: An additional charge for real estate property with an amenity such as a water view or a view of wooded land.

Receiving waters: Lakes, rivers, wetlands, coastal waters, and groundwaters that receive runoff.

Riprap: A protective layer or facing of quarrystone placed to prevent erosion, scour, or sloughing of an embankment or cliff.

Sediment: The product of erosion processes; the solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice.

Structural control: A practice that involves design and construction of a facility to mitigate the adverse impact of urban runoff, and often requires maintenance.

Urban runoff: The portion of precipitation, snowmelt, or irrigation water that does not naturally percolate into the ground or evaporate, but runs off the land into streams or other surface water. It can carry pollutants from the air and land into the receiving waters.

Wet pond: Pond for urban runoff management that is designed to detain urban runoff and always contains water.

FROM THEORY TO IMPLEMENTATION - FINDING ILLICIT CONNECTIONS

Barry Johnson, M.S., P.E., Camp Dresser & McKee
Dean Tuomari, Wayne County Department of Environment

The Rouge River National Wet Weather Demonstration Project (Rouge Project) began in 1992 by the Department of the Environment, Wayne County, Michigan. The Project is a United States Environmental Protection Agency (USEPA) grant funded comprehensive program to manage wet weather pollution to restore the water quality of the Rouge River, an urbanized tributary of the Detroit River in Southeast Michigan. The Rouge River has been designated as a significant source of pollution to the Great Lakes system.

The Rouge Project is designed to identify the most efficient and cost effective controls of wet weather pollution, while assuring maximum use of the resource. Combined sewer overflow (CSO) controls are being implemented in phases. Under Phase 1, six communities are separating their sewers and eight communities are constructing 10 retention treatment basins. A two-year evaluation study of the CSO control basins began on June 1, 1997. These results coupled with efforts to control storm water and other pollution sources in the watershed will provide the basis for the Phase 2 CSO control program on the remaining CSO sources in the watershed. The information gained from the evaluation of design storms and control technologies will be useful nationwide in determining cost effective CSO controls to meet water quality standards.

Innovative storm water control technologies are also being evaluated under the Rouge Project. A total of 60 pilot storm water management projects are being implemented throughout the watershed by 25 different communities and agencies. Categories of pilot storm water management projects currently underway include wetlands creation and restoration, structural practices such as grassed swales and detention ponds, illicit discharge elimination, erosion controls, stream bank stabilization and habitat restoration to name a few.

Innovative, readily transferable tools have been developed, employed by the Project, and are being shared with other cities and state agencies. These include a suite of computer models to simulate the water quality and quantity response of the Rouge River in response to wet weather events for existing and future conditions under various CSO and storm water runoff management alternatives; a comprehensive geographic information system (GIS); relational databases were designed and implemented to manage the wealth of data collected under the Project (DataView and Rouge Information Manager); and the use of a holistic watershed approach.

The Rouge Project in southeastern Michigan is a working demonstration of a watershed-wide approach to restoring and protecting an urban river system by using a cooperative locally based approach to pollution control. Innovative, readily transferable tools have been developed and employed by the Project. The environmental results of the Project are already very evident.

ABSTRACT

The Rouge River Watershed located in southeastern Michigan encompasses approximately 438 square miles. A primary objective of the Rouge Project is to demonstrate how to address and correct urban wet weather pollution problems. However, water quality objectives in the Rouge River Watershed will not be achieved unless illicit discharges are eliminated. The Rouge Project illicit connection program has utilized several methods to identify sources of illicit discharges, but first, a method to prioritize areas for detailed evaluations had to be developed. A GIS database was established to assist in this area.

Several methods were explored to identify illicit connections, however, this paper discusses five of those methods used to provide information to prioritize areas of the watershed for detailed investigation. Those include: *dye testing of plumbing* and *on-site sewage disposal systems*; *visual observations of manholes*, *outfalls* and *on-site sewage disposal systems*; *aerial photography*; *televising of storm sewers*; and *testing for ammonia, surfactants, E. coli* and *isotopes of hydrogen* and *oxygen*. Data collected suggested that there are 5,260 illicit discharges and at least 3,600 failing on-site sewage systems in the watershed. This data has been helpful in convincing municipalities to include an illicit discharge investigation and an on-site sewage maintenance program in their application for a storm water discharge permit.

KEYWORDS

Illicit discharges, on-site sewage, dye test, illicit connections

INTRODUCTION

Sampling and modeling of CSOs to the Rouge River in southeast Michigan indicates that when the CSOs are treated or eliminated, the river will not meet water quality standards. Investigations by municipalities have identified illicit connection problems. These sources of non-storm water pollutants into storm drainage systems are required to be investigated and eliminated as part of the voluntary National Pollutant Discharge Elimination System (NPDES) storm water permits for communities and as part of NPDES permits for storm water associated with industrial activities.

Considerable effort has been made since 1994 in the Rouge Watershed to locate and eliminate illicit connections. Published material suggested many possible ways to trace the sources of illicit connections. As part of the Rouge Project, methods to locate illicit connections have been evaluated. This paper presents the approaches used to locate areas with illicit discharges, and methods to locate illicit connections and results.

DISCUSSION

The Rouge River Watershed has a population of over 1.5 million people and has 43,520 businesses. Because of the size of the area, it was necessary to develop criteria to prioritize areas for investigation. One screening was done to eliminate businesses that were on combined sewer systems. This reduced the number of businesses to 22,467. Once developed, the criteria used was to identify areas of known water quality problems, to review complaints related to water quality, and to review water quality data and land use. Land use was of particular interest because the data were used to identify areas in communities that were used for business operations. Businesses were a priority based on findings in Washtenaw County (Schmidt, 1986). These findings indicated that 38 percent of the businesses tested were improperly connected to the storm sewer system. The highest percentage of illicit storm drain connections were detected at automobile-related facilities.

Water sample results were given more weight in residential areas in selecting areas for investigation because it is more convincing to the public and municipal employees that there is a problem. *E. coli* bacteria was found to be the most significant water quality problem in the residential areas. This could have resulted from on-site sewage disposal systems (OSDS), sanitary sewers, pet waste, wildlife, and illegal dumping. Census data from 1990 reported that there were over 18,000 OSDS in the Rouge Watershed. It was suspected that failing OSDS could be contributing to the bacterial problem in the watershed. This encouraged the development of a program to investigate non-residential operations, and OSDS in areas with high *E. coli* results and storm sewers. The data collected has been used to project illicit connections and their impact on water quality in each subwatershed in the Rouge River Watershed.

METHODOLOGY

First, dye testing was used to locate illicit connections in businesses. A method to prioritize the investigation was developed based on the Standard Industrial Classification (SIC) of businesses. Businesses were surveyed in the target areas and dye was placed into the plumbing fixtures to observe discharge locations. Storm and sanitary sewers in the business target areas were observed after dye was placed in the fixture.

Dye testing was also used to evaluate OSDS. Dye was placed in the septic tank and the surface water downstream from the property was checked for visual observation of the dye. If no dye was seen, a charcoal packet was placed in the stream to collect dye that was not visible. The charcoal packets were collected and taken to the laboratory for analysis.

In residential areas, a second and third method was used to help isolate sources of bacteria; water testing and visual observations. Visual observations were conducted on manholes, outfalls, and on-site disposal systems. Manholes and outfalls in areas that had reported high *E. coli* bacteria were also tested for ammonia, surfactants and *E. coli*. The manhole or outfall was photographed and the following were recorded: water color, staining on the structure, debris and odor.

A fourth method, consisted of television cameras in storm sewers which were used to show staining on the pipe, debris in the sewer, and the sewer lead location of a suspicious discharge. The fifth method was the use of aerial photography. It was believed that infrared photography could identify warm water discharges in the winter. These warm discharges would then be investigated for the source of the water. An analysis of the same area in the warm months might also allow concentrations of chlorophyl to be identified. The source of the nutrients that stimulated the chlorophyl might identify an illicit discharge.

RESULTS

Dye Testing

From 1987 through December of 1997, Wayne County dye tested approximately 3,340 businesses and industries for illicit connections to the storm sewer system. Approximately 8 percent of the 3,340 facilities inspected were found to have illicit connections and the elimination of these improper discharges has diverted raw sewage and other pollutants from the river to the wastewater treatment plant. If one illicit connection was found at a business, it usually resulted in finding others. An average of 2.5 improper connections were found at businesses that had an illicit connection.

The majority of illicit connections found in non-residential facilities were drains connected to storm sewers. Drains include floor drains, trench drains, interior catch basins, oil separators, machine process water and sump pumps. The categories of illicit connections found were: floor drains (46 percent), sinks (20 percent), horse washing-washing machines (15 percent), toilets (11 percent), and a variety of others (8 percent). **Figure 1** is a chart of these findings.

Another study, funded in the Oakland County portion of the Rouge Watershed included stream sampling for fecal coliform, *E. coli* bacteria, and benthic macroinvertebrates, along with dye testing of septic tanks.

a. Of the 49 surface water sampling sites, 43 percent had a daily geometric mean for *E. coli* bacteria of 1000 or more per 100 mL. of sample.
b. The macroinvertebrate study was done to indicate water quality of the streams in the survey area. A scale has been developed to rate macroinvertebrate and water quality. The results in the study area ranged from 7 which indicates poor water quality, to 20 which is considered good water quality.
c. Dye testing in 1994 found 52.3 percent of the homes tested had discharges to the river.
d. An optical brightener test was done at the river sites where dye was collected. These were all negative. The brightener test has been used to detect laundry waste in coastal areas.
f. Dye testing in 1995 found a 39.3 percent failure rate for OSDS in the communities surveyed.

Water Testing and Visual Observations

Hundreds of manholes and outfalls were tested for ammonia and photographic documentation and field data sheets were recorded at each manhole and outfall. Over 150 manhole locations and outfalls were identified to have over 1 ppm ammonia or visual evidence of suspicious discharges. Follow up sampling was done to relate *E. coli* levels with ammonia and surfactants at each manhole and outfall. Over 200 manholes and outfalls have been checked for ammonia, anionic surfactants and *E. coli*. Nineteen of the these had *E. coli* counts over 5000 per 100 mL.

A grant was funded by the Rouge Program Office to Wayne County to survey OSDS serving homes in one of the tributaries that drain to an area that was planned to be used for canoeing. Canoeing has been discouraged in most of the Rouge River due to the high *E. coli* bacteria counts. Through December 31, 1997, 427 homes have been visited and a visual survey of the property has been done to identify signs of OSDS problems. Ninety-three of the systems have been described as failing or potentially failing for a failure rate of 21 percent. Typical descriptions from the field notes are:

- Sewage backup in the home
- Gray water discharging to the ground surface
- Standing water on top of gravel seepage field
- Mushy area, associated with back end of apparent seepage field
- Illicit connection and undersized septic tank (100 gallons) drained by a trench type (long single perforated pipe) seepage field.
- Black sludge residue and toilet paper debris around surface of the septic tank covering
- Growth of cattails, wet marsh on the face of the downward sloping hill.

Visual observations from field crews and the public have identified significant improper discharges to the river. Two examples that field crews found and reported were:

- a team doing a habitat study found a combined sewer discharging during dry weather. The sewer maintenance personnel investigated this, corrected the problem and reported that the discharge gate had stuck in the open position.
- a team sampling outfalls noticed signs of sewage in the outfall. Tracing the flow upstream they found that a sewer contractor was by-passing the sanitary waste to the storm sewer so he could work on the sanitary.

Stable isotopes of oxygen and hydrogen have been used to determine the existence of illicit connections in a discharge. The study funded under this project found that the isotope signatures of groundwater, sanitary sewer water and tap water were significantly different. This signature allowed the discharges to be identified as having come from groundwater, precipitation or sanitary sewage. For further details of methods and findings refer to the paper "Identification of Illicit Connections in Storm Sewers: An Innovative Approach Using Stable Isotopes," by Suresh Sangal et. al.

Aerial, Infrared and Thermal Photography

The use of aerial, infrared and thermal photography to find illicit discharges is in the experimental phase. An examination of the aerial photo of a site with a known illicit discharge revealed thermal conditions that were too similar to other warm conditions to make it distinguishable.

Televising of Sewers

Several television tapes of storm sewers were reviewed. The tapes did not show the characteristic staining or debris that is seen when an illicit discharge has been occurring for some time. The storm sewer televised was newly constructed a year ago. The failure to observe sewage debris or detect an odor during the field work also helped support that there was no illicit discharge occurring when the sewer was being televised.

Results of One Detailed Investigation

A storm sewer relief drain was investigated to locate a pollution source. This 11 foot diameter storm sewer had been under suspicion for several years. In 1997, samples from manholes were taken upstream from the discharge point of the sewer. These samples were taken from the main pipe of the sewer and in laterals that connected to the sewer. One of the laterals that connects to the sewer had *E. coli* results of 8160 per 100 mL of sample. A confirmation sample a few days later showed 9600 *E. coli*. When the results were found at that level, additional samples were taken 5 days after the confirmed sample (9600) had been taken. The sample results going upstream in the storm sewer where the 8160 and the 9600 *E.coli* were found were: 12,560, 24,000, 160,000 and 9600 per 100 mL. These results indicate an increase and then a decrease as you move upstream. The manhole where the 160,000 result was the "hot spot." **Figure 2** shows a representation of the sewer and the test results.

The results were shared with the city which had the sewer televised. The television tapes did not show any suspicious connections. Plans were made to begin dye testing the homes next to the storm sewer. Before beginning the process of dye testing, a sample was taken to show current information. The results of that sample indicated less than 8 *E. coli* per 100 mL. in the sample. After discussion with the city, it was agreed to postpone the dye testing and instead inform the residents of the results of the sampling on their street. At this point it was felt that the high *E. coli* may have been due to dumping of waste into the sewer. A letter was prepared to ask residents to inform the city or county personnel of anything they may have knowledge about which would have resulted in the high *E. coli* counts. As a result of this investigation, dry weather sampling continues on a monthly basis at this location.

Other findings have included:

- The prioritization method for businesses was successful in locating illicit connections; it was not helpful in locating illicit discharges of *E.coli*.
- There was no definite correlation to date between field tests for ammonia, anionic surfactants (a test to detect detergents) and *E.coli*.
- Projections have been made of illicit connections for the Rouge Watershed based on these findings. The estimated number of potential illicit connections in the entire watershed is 5260. It is estimated that 51 million gallons of liquid would be discharged from these illicit connections. (Boerma, 1997)
- Eighteen percent (77) of the residences contacted indicated that they did not have an OSDS. They indicated that they were connected to the sewer. In most cases, the municipality had no record of the sewer connection and were not charging them.

CONCLUSION

Future areas to be checked will be developed based on complaints, a review of manhole and outfall sampling to determine contributing conveyances, and instream/in-sewer sampling to localize the sources. Results of the manhole sampling have found several that have *E. coli* results over 10,000 per 100 mL. Utilizing the Rouge Project GIS, maps have been prepared for tracking sampling of manholes and outfalls, and other data to illustrate results, and to help prioritize further investigations. These will be helpful in showing municipalities the areas that need to be investigated.

The future direction of illicit connection/discharges is to have each community in the Rouge Watershed commit to actively exploring illicit connections/discharges within their community. Grants and assistance from county agencies are available for communities. As part of an application for a general storm water permit from the State of Michigan under the NPDES program, a community is required to develop an Illicit Discharge Elimination Plan. The Rouge Project is assisting communities in the preparation of these applications. Elements of the Illicit Discharge Elimination Plan that are recommended to be included are: a legal basis for the program, how problem areas will be identified, how the sources will be pinpointed, and how to achieve correction and evaluation and reporting. **Figure 3** was developed to describe these elements to communities and suggest options for them to consider. Education is very important when developing an illicit discharge elimination plan. Reference is made to education development in the boxes below each element.

On-site sewage disposal systems contribute to surface water pollution. With over 18,000 of these in the watershed and average failure rates between 17 and 39 percent, there are a substantial number impacting surface water. Using a 20 percent failure rate, there would be 3600 OSDS failing in the watershed. Two hundred gallons (200) per day per OSDS would result in 720,000 gallons per day of sewage being discharged to the ground surface or directly to surface water each day. The discharge of this waste can be prevented if there is regular inspection and maintenance of OSDS.

The liquid waste discharged from illicit discharges is estimated to be 51 million gallons per year. This is a significant amount. This waste includes human waste, oil, grease, detergents, chemical and solids.

Clean Water & Oceans: Water Pollution: In Depth: Report
Stormwater Strategies
Community Responses to Runoff Pollution

May 1999

Top of Report

Chapter 2

THE CAUSES OF URBAN STORMWATER POLLUTION

Runoff pollution occurs every time rain or snowmelt flows across the ground and picks up contaminants. It occurs on farms or other agricultural sites, where the water carries away fertilizers, pesticides, and sediment from cropland or pastureland. It occurs during forestry operations (particularly along timber roads), where the water carries away sediment, and the nutrients and other materials associated with that sediment, from land which no longer has enough living vegetation to hold soil in place.

This report, however, focuses on runoff pollution from developed areas, which occurs when stormwater carries away a wide variety of contaminants as it runs across rooftops, roads, parking lots, baseball diamonds, construction sites, golf courses, lawns, and other surfaces in our cities and suburbs. The oily sheen on rainwater in roadside gutters is but one common example of urban runoff pollution.

This chapter discusses some of the causes of stormwater runoff and pollution, which are important to understand before adopting management strategies.

The United States Environmental Protection Agency (EPA) now considers pollution from all diffuse sources, including urban stormwater pollution, to be the most important source of contamination in our nation's waters. [1] While polluted runoff from agricultural sources may be an even more important source of water pollution than urban runoff, urban runoff is still a critical source of contamination, particularly for waters near cities -- and thus near most people. EPA ranks urban runoff and storm-sewer discharges as the second most prevalent source of water quality impairment in our nation's estuaries, and the fourth most prevalent source of impairment of our lakes. [2] Most of the U.S. population lives in urban and coastal areas where the water resources are highly vulnerable to and are often severely degraded by urban runoff.

Urban stormwater continues to impair the nation's waterways, 27 years after passage in 1972 of the law now known as the Clean Water Act. The main reason why urban stormwater remains such an important contributor to water pollution is the fact that in most areas, stormwater receives no treatment before entering waterbodies. The storm-sewer system merely collects the urban runoff and discharges it directly to the nearest river, lake, or bay.

Over the past 27 years, water pollution control efforts have focused primarily on certain process water discharges from facilities such as factories and sewage treatment plants,

R0010402

with less emphasis on diffuse sources. While these efforts have led to many water quality improvements, new efforts are now needed to address the remaining sources of water pollution, including urban runoff pollution.

Comprehensive stormwater regulation has been slow to develop (see box: "History of Stormwater Regulation in the United States"). Since 1992, cities with a population over 100,000, certain industries, and construction sites over 5 acres have had to develop and implement stormwater plans under Phase I of the National Pollutant Discharge Elimination System (NPDES) stormwater regulations. To date, states and the EPA have issued more than 260 permits affecting some 850 operators, including larger cities operating separate storm sewer systems, which requires them to develop stormwater management plans. A number of stormwater discharges from industrial activities are also subject to NPDES stormwater permit requirements.

In October 1999, EPA is expected to promulgate a rule requiring smaller municipalities, those with populations of fewer than 100,000 people located in urbanized areas (where population density is greater than 1,000 persons per square mile) to develop stormwater plans. Municipalities not in urbanized areas that have more than 10,000 residents and a population density greater than 1,000 persons per square mile will also have to develop stormwater plans if the state so designates. Under this so-called "Phase II" rule, the EPA and states will develop "tool boxes" from which the smaller local governments can choose particular stormwater strategies, including the strategies presented in this report, to develop their stormwater plans.

Stormwater must be distinguished from other urban sources of pollution largely caused by wet weather since each separate source is regulated differently. In addition to stormwater runoff, which is the focus of this study, there are two other significant sources of urban wet weather pollution: sanitary sewer overflows (SSOs) and combined sewer overflows (CSOs). SSOs occur when sanitary sewers, often because of leaks and cracks, become surcharged in wet weather and overflow, often through manholes or into basements. CSOs occur when flows into combined sewer system (systems that receive stormwater, sanitary sewer discharges from residences and businesses, and wastewater discharges from industrial facilities and transport it all through a single pipe) exceed the treatment and storage capacity of the sewer system and waste treatment facility. At that point, this combined waste stream overflows into creeks, rivers, lakes or estuaries through designated outfalls usually without treatment. CSOs and SSOs are more of a problem with older systems while stormwater is an issue for all metropolitan areas, especially growing areas. Moreover, while prevention programs can be very important to efforts to reduce CSOs and SSOs, structural changes are usually necessary. By contrast, much stormwater pollution can be *prevented* with proper planning in growing or redevelopment areas.

Remarkably, studies have shown that stormwater alone can be almost as contaminated as these sewage/stormwater mixtures.[3] Yet stormwater runoff remains to be regulated in most of the nation's populated areas. While many CSO and SSO control measures may overlap with stormwater pollution control measures, strategies that deal with stormwater specifically must be implemented if the quality of America's waterbodies is to improve. These strategies are the focus of this report.

HISTORY OF STORMWATER REGULATION IN THE UNITED STATES
The history of stormwater regulation began over 25 years ago. It has been in and out of the courts, Congress, EPA and is now in the hands of states and local governments.

1972: EPA issues exemptions from the federal Clean Water Act NPDES permit program for most sources of stormwater. NRDC sues EPA to require permits for all point sources, including urban storm sewers (applications by 1973 and permits by 1974).

1975–1977: The U.S. District Court finds that EPA exemptions are contrary to the

R0010403

Clean Water Act (NRDC v. Train).[a] This decision is upheld by U.S. Court of Appeals in 1977 (NRDC v. Costle).[b]

1980: EPA issues rules responding to the court's decision that exempt cities outside "urbanized areas from needing NPDES permits for their storm sewers." NRDC and industry sue EPA over the rules (NRDC v. EPA).[c]

1980–1990: During this period, EPA struggled with developing stormwater rules, and extends the stormwater permit deadlines for large cities until 1987 and 1989. EPA also issues "nonenforcement letters" informing cities that EPA would not take enforcement actions against cities with permit applications and proposes narrowing the definition of stormwater discharges. In 1983, EPA issues a final report on the Nationwide Urban Runoff Program. In 1984, NRDC and the states negotiated with EPA to reject narrowing coverage and revoke letters.

1987: In Clean Water Act amendments, Congress requires EPA to issue by 1989 "Phase I" rules addressing stormwater from cities with a population over 100,000 and from industrial sites, and to issue by 1992 "Phase II" rules for other significant sources of stormwater pollution.

1990: EPA promulgates "Phase I" NPDES stormwater regulations and extends compliance beyond those dates in the 1987 law. NRDC sues EPA for illegally extending deadlines and excluding certain sources from regulations (NRDC v. EPA).[d]

1992: A U.S. Court of Appeals ruling prohibits further stormwater dead-line extensions (NRDC v. EPA)[e] and invalidates certain provisions of the Phase I rule. EPA and the states issued initial general permits for storm-water discharges.

1992: Congress provides an additional extension to small cities for storm-water permit applications.

1995: EPA is sued for its failure to conduct study, file report, and issue regulations concerning Phase II stormwater pollutant sources (NRDC v. Browner).[f] EPA issues Report to Congress on "Storm Water Discharges Poten-tially Addressed by Phase II of the NPDES Storm Water Program." NRDC and EPA enter into consent decree requiring EPA to issue a final rule by March 1999 (later extended to October 1999) addressing both Phase II stormwater and Phase I issues remanded by the court. In 1996, EPA convenes a federal advisory committee.

1997: EPA issues draft Phase II stormwater rules.

The Water Cycle

To fully understand the stormwater pollution problem, it is helpful to step back and review the water cycle, also known as the hydrologic cycle. The water cycle is simply the constant movement of water from the sky to the ground and back again. The main components of the water cycle are precipitation, infiltration, evapotranspiration (evaporation and transpiration, the process by which plants release water they have absorbed into the atmosphere), surface and channel storage, and groundwater storage. As part of that cycle, when rainwater falls to the ground, or when snow or hail on the ground melt, that water may take several paths, as illustrated in Figure 2-1 (print report only).

While the magnitude of these effects varies across the country depending on the precipitation patterns, soil types and other factors, the underlying principles remain the same. [4] In a typical Midwestern undeveloped area, for example, with natural ground cover such as forests or meadows, a large fraction -- perhaps 50 percent -- of the water infiltrates the soil. Much of this water may remain near the surface from which it often resurfaces into lakes or streams. Other infiltrated water descends to a deeper level, perhaps recharging an underground aquifer used for drinking water. A significant share -- 40 percent in this example -- of the water returns to the atmosphere through evapotranspiration. Only a small amount of the water -- the remaining 10 percent, in this example -- typically remains on the surface of undeveloped land to run off into streams and other waterbodies.

Urbanization can dramatically alter this water cycle, increasing runoff and reducing, at times to almost zero, infiltration. This can completely alter the physical and chemical character of the receiving waterbody.

The Causes of Stormwater Pollution

The stormwater pollution problem has two main components: the increased volume and velocity of surface runoff and the concentration of pollutants in the runoff. Both components are directly related to development in urban and urbanizing areas. Together, these components cause changes in hydrology and water quality that result in a variety of problems including habitat loss, increased flooding, decreased aquatic biological diversity, and increased sedimentation and erosion, as well as affects on our health, economy, and social well-being. These consequences will be discussed in Chapter 3; the following is a discussion of the sources of these problems.

Table 2-1
Impacts from Increases in Impervious Surfaces

	Resulting Impacts				
Increased Imperviousness Leads to:	**Flooding**	**Habitat Loss (e.g., inadequate substrate, loss of riparian areas, etc.)**	**Erosion**	**Channel Widening**	**Streambed Alteration**

INCREASED VOLUME AND VELOCITY: THE IMPERVIOUS COVER FACTOR

Types of Impervious Cover

Some impervious cover, such as exposed rock or hardpan soil, is natural. Land development, however, greatly increases it. Human-made impervious cover comes in three varieties: rooftop imperviousness from buildings and other structures; transport imperviousness from roadways, parking lots, and other transportation-related facilities; and impaired pervious surfaces, also known as urban soils, which are natural surfaces that become compacted or otherwise altered and less pervious through human action. Examples of the hard soils include the base paths on a baseball diamond or a typical suburban lawn.

Transport imperviousness generally exceeds rooftop imperviousness in urban areas of the United States.[5] "Cumulative figures show that, worldwide, at least one third of all developed urban land is devoted to roads, parking lots, and other motor vehicle infrastructure. In the urban United States, the automobile consumes close to half the land area of cities; in Los Angeles the figure approaches two thirds."[6] The city of Olympia, Washington, also found that transport imperviousness constituted approximately

R0010406

two-thirds of total imperviousness in several residential and commercial areas.[7] This distinction is important because rainfall on transportation surfaces drains directly to a stream or stormwater collection system that discharges to a waterbody usually without treatment, whereas some roofs drain into seepage pits or other infiltration devices. Research has also found a strong relationship between curb density and overall imperviousness in residential areas suggesting that roads lead to the creation of other impervious surfaces.[8]

The creation of additional impervious cover also reduces vegetation, which magnifies the effect of the reduced infiltration. Trees, shrubs, meadows, and wetlands, like most soil, intercept and store significant amounts of precipitation. Vegetation is also important in reducing the erosional forces of rain and runoff. In one study, conversion of forest to impervious cover resulted in an estimated 29 percent increase in runoff during a peak storm event.[9]

Imperviousness Thresholds

Research has shown that when impervious cover reaches between 10 and 20 percent of the area of a watershed, ecological stress becomes clearly apparent.[10] After this point, stream stability is reduced, habitat is lost, water quality becomes degraded, and biological diversity decreases. Figure 2-3 (print report only) shows that as the amount of impervious surface in a watershed increases infiltration and evapotranspiration both drop substantially. As a result, more water, having nowhere else to go, runs off the surface picking up pollutants from activities occurring on the impervious surfaces.

To put these numbers into perspective, typical total imperviousness in medium-density, single-family home residential areas ranges from 25 percent to nearly 60 percent.[11] Total imperviousness at strip malls or other commercial sites can approach 100 percent.

Increased Volume of Runoff

The effect of impervious surfaces on the volume of stormwater runoff can be dramatic. For example, a 1-inch rainstorm on a 1-acre natural meadow would typically produce 218 cubic feet of runoff, enough to fill a standard size office to a depth of about 2 feet. The same storm over a 1-acre paved parking lot would produce 3,450 cubic feet of runoff, nearly 16 times more than the natural meadow, and enough to fill three standard size offices completely.[12]

On a larger scale, the effect is even greater. In a 620-square-mile portion of the watershed of the Des Plaines River in Illinois, in 1886, when agricultural or urban development covered 10 percent of the land area, the river's median annual discharge was 4 cubic feet per second. Today, when development covers approximately 70 to 80 percent of that same area, the median annual discharge has been 700 to 800 cubic feet per second, 175 to 200 times the earlier discharge level.[13]

Greater Stream and Runoff Velocity During Storm Events

Impervious surfaces increase the speed of runoff as it drains off the land. Unlike grassy meadows or forests, hard, impervious cover, such as parking lots and rooftops, offers little resistance to water flowing downhill, allowing it to travel faster across these surfaces.[14] In addition, the faster rate of runoff delivers more water in a shorter time to receiving waters than would occur under natural conditions. The increased velocity and delivery rate greatly magnifies the erosive power of water as it flows across the land surface and once it enters a stream.

Increased Peak Discharges

Increased imperviousness not only changes the volume of stormwater flows, but also the distribution of flows over time. When land is undeveloped, the initial stormwater flow following a rain event is relatively small, since the land absorbs and infiltrates much of the water. However, impervious cover forces rainwater or snowmelt to run off the land immediately, causing a sharp peak in runoff immediately following the rain event, as illustrated in Figure 1-5 (print report only). Impervious cover can double, triple, quadruple or even quintuple peak discharge.[15] Streams receiving these increased urban peak flows are described as "flashy," meaning that they are prone to sporadic and unstable discharges including flash floods or sudden high pulses of storm flows. An increase in peak flow can have significant impacts on the human and natural environment. Greater peak flows lead to increased flooding, channel erosion and widening, sediment deposition, bank cutting, and general habitat loss as discussed in Chapter 3.

Reduced Stream Base Flow

Because impervious cover reduces infiltration and forces stormwater to run off the land immediately, it also typically reduces the amount of groundwater available to recharge streams when there is no rain.[16] Hydrologists often refer to groundwater zones under urban areas as "starved" since they are not replenished. This groundwater-charged stream flow, known as base flow, can fall to 10 percent of the regional average when the level of imperviousness in the stream watershed reaches 65 percent.[17] Prolonged low flow can have a significant impact on aquatic life and, in some cases, a greater impact than extreme peak flows.[18] Reduced infiltration can also lead to shortages of drinking water supplies.

Decreased Natural Stormwater Purification Functions

Government flood control agencies often replace the beds of creeks, streams, and other drainage ways with concrete open channels, or completely replace those drainage ways with subsurface concrete storm drain lines. These changes degrade or eliminate habitat and dramatically alter hydrology. Channelizing, diking, and levying disconnects a river from its floodplain and reduces its ability to modify floods naturally. Similarly, this and other development fills, converts, or otherwise eliminates swamps, marshes and other wetlands. Eliminating these natural drainage ways reduces flow storage and detention and soil moisture maintenance and can increase overall flooding and erosion. In addition, natural streambeds and floodplains provide a hydrologic link between groundwater and surface water and can naturally clean waters. By capturing and slowing stormwater, these areas trap sediment, trace metals, and soluble forms of nutrients.[19] Studies have shown that wetlands can retain up to 100 percent of the metals present in water.[20] Wetlands reduce nitrogen discharges, both through the process of bacterial denitrification and through plant uptake, but less effectively reduce phosphorous when soils are saturated.

Similarly, other natural areas can reduce pollutant loads. One riparian forest in the Chesapeake Bay region removed 89 percent of the nitrogen and 80 percent of the phosphorus from runoff.[21] Forests also typically absorb 70 to 80 percent of atmospherically deposited nitrogen.[22] Trees and other plants stabilize the soil, giving it structure that prevents erosion, and reduce runoff by intercepting and storing precipitation. When rapid stormwater flows have already created erosion on bare soils, plants on downhill slopes slow those flows and allow sediment, as well as other pollutants, to settle onto the land rather than in a waterbody.

However, use of wetlands, streams, and other natural systems is not desirable unless stormwater is delivered at a rate at which pollutants can be assimilated. Natural wetlands, while playing an important role in managing the quality and quantity of runoff, should not be viewed as a sink for polluted runoff. While wetlands help remove pollutants from runoff, some pollutants can accumulate in wetlands or be converted to more potent forms, thereby degrading the natural ecosystem functions and values of these systems and impact the organisms living there.[23] Furthermore, the US EPA recommends protection for any wetland or riparian area which removes pollutants from runoff to coastal waters.[24] Therefore, use of these systems for stormwater management should be carefully considered, realizing that these systems need quality water delivered at an appropriate rate to function properly.

INCREASED DEPOSITION OF POLLUTANTS

The second aspect of urbanization that contributes to urban stormwater pollution is the increased discharge of pollutants. As human activity increases in a given area, the amount of waste material deposited on the land and in drainage systems increases. The principal contaminants of concern for stormwater fall into seven categories. The following table lists these categories and provides examples.

While all activities can be a source of some contaminants, certain activities are particularly large contributors. Industrial sites can be major sources of metals and organic chemicals. Feedlots are a large source of pathogens, nutrients, and BOD. Agricultural and timber operations discharge high quantities of sediment. This report focuses on those activities in urbanized and urbanizing areas, practices of homeowners, businesses, and government agencies that also contribute many of these contaminants.

TABLE 2-2
Categories of Principal Contaminants in Stormwater

Category	Examples
Metals	zinc, cadmium, copper, chromium, arsenic, lead
Organic chemicals	pesticides, oil, gasoline, grease
Pathogens	viruses, bacteria, protozoa
Nutrients	nitrogen, phosphorus
Biochemical oxygen demand (BOD)	grass clippings, fallen leaves, hydrocarbons, human, and animal waste
Sediment	sand, soil, and silt
Salts	sodium chloride, calcium chloride

Vehicle Use

Driving a car or truck contributes a number of different types of pollutants to urban runoff. Pollutants are derived from automotive fluids, deterioration of parts, and vehicle exhaust. Once these pollutants are deposited onto road and parking surfaces, they are available for transport in runoff to receiving waters during storm events. One landmark study estimated that cars and other vehicles contributed 75 percent of the total copper load to the lower San Francisco Bay through runoff.[25] Brake pad wear contributed 50 percent of the total load, and 25 percent came from atmospheric deposition -- the eventual settling of metals from tailpipe emissions onto the ground. Other car- and truck-related sources of metals include tire wear, used motor oil and grease, diesel oil, and vehicle rust.[26] Tire ware is a substantial source of cadmium and zinc; concentrations at outfalls often exceed acute toxicity levels. Engine coolants and antifreeze containing ethylene glycol and propylene glycol can be toxic and contribute high BOD to receiving waters.

Vehicle exhaust contributes the nutrient nitrogen to our nation's waters. Studies estimate that deposition of nitrogen from power plant and vehicle exhaust contributes 17 pounds per year of nitrogen and 0.7 pounds per year of phosphorus to a typical acre of land in the metropolitan Washington, DC, area.[27] In general, fossil fuel combustion is the largest contributor of nitrogen to the waters of the northeastern United States, and is a very large contributor elsewhere.[28]

Oil, grease, and other hydrocarbons related to vehicle use and maintenance also contaminate our waters. These come from disposal of used oil and other fluids on the ground or into storm drains, spills of gasoline or oil, and leaks from transmissions or other parts of automobiles and trucks. The stormwater discharge from one square mile of roads and parking lots can yield approximately 20,000 gallons of residual oil per year.[29] Runoff from residential car washing also contributes oil, grease, grit, and detergents to the stormwater system. Even gas vapor emitted when filling tanks can subsequently mix with rain, contributing significantly to polluted runoff.[30]

Roads and Parking Lots

In many communities, most impervious cover is related to the transportation system.[31] Material accumulates on these surfaces during dry weather conditions, only to form a highly concentrated first flush during storm events. One study found streets to be the impervious surface with the highest pollutant loads in most land use categories.[32] Another found that transportation related land uses have the second highest level of pollutant concentrations; only piped industrial sources were higher.[33]

Home Landscaping and Public Grounds Maintenance

Landscaping practices are another potential source of pollutants in urban runoff. Turf management chemicals including fertilizers used at home and on golf courses, cemeteries, and public parks can add nutrients to runoff.[34] Monitoring has shown a direct link between the chemicals found in lawn care products and urban water quality.[35] While there remain questions on some details of the contribution of turf management to receiving water quality, it is clear that the type, quantity, and timing of materials used make a significant difference.

One important variable is the quantity of chemicals being applied. Over or improper application at homes and other places is far too common.[36] Experts estimate that residential fertilizer use accounts for one-third of the excess nitrogen entering the Sarasota Bay watershed in southwest Florida.[37] Of particular concern is the application of fertilizers and pesticides just before an intense storm event, since they may not have had time to become fixed in the soil and thatch.

Similarly, harmful pesticides found in stormwater, such as chloropyrifos, 2,4-D, and diazinon come from golf courses, municipal parks, highway medians and roadsides, and residential lawns and gardens.[38] The percentage of pesticide lost in runoff can be large; one study found up to 90 percent of the herbicide 2,4-D was lost in runoff after being applied a few hours before a storm event.[39]

Since organic matter contains nutrients, raking autumn leaves or grass clippings into gutters or streets for municipal collection or otherwise facilitating the entry of these materials into the storm-sewer system also adds nutrient loads and oxygen-demanding substances to stormwater. Poorly maintained garden beds or lawns can be a source of sediment as well.

Table 2-4
Six Pesticides Found Frequently in Stormwater Samples

Pesticide Name	Human Health and/or Environmental Effects
2,4-D	Associated with lymphoma in humans; testicular toxicant in animals.
Chlorpyrifos	Moderately toxic to humans; neurotoxicant; can be highly toxic to birds, aquatic organisms, and wildlife.
Diazinon	Moderately toxic to humans; neurotoxicant; can be highly toxic to birds, aquatic organisms, and wildlife.
Dicamba	Neurotoxicant; reproductive toxicity in animals; association with lymphoma in some human studies.
MCPA (Methoxane)	Low toxicity to non-toxic in test animals, birds, and fish; suspected gastrointestinal, liver, and kidney toxicant.
MCPP (Mecoprop)	Slightly to moderately toxic; some reproductive effects in dogs; suspected cardiovascular, blood, gastrointestinal, liver, kidney, and neurotoxicant.

Construction Sites

Construction activity is the largest direct source of human-made sediment loads.[40] quot;Results from both field studies and erosion models indicate that erosion rates from construction sites are typically an order of magnitude larger than row crops and several orders of magnitude greater than rates from well-vegetated areas, such as forest or pastures.quot;[41] Since erosion rates are much higher for construction sites relative to other land uses, the total yield of sediment and nutrients is higher.[42] Studies indicate that poorly managed construction sites can release 7 to 1,000 tons of sediment per acre during a year, compared to 1 ton or less from undeveloped forest or prairie land.[43] Construction activity can also result in soil compaction and increased runoff.

Like nutrients, soil and sediment are, to a certain degree, a naturally occurring and functional component of all waterbodies. Yet human activities usually increase the amount of sediment entering our waterbodies to such an extent as to turn sediment into a water quality problem.

Illicit Sanitary Connections to Storm Sewers From Homes and Businesses

Illicit connections from toilets to storm sewer pipes can add pathogens to stormwater.[44] [45]

R0010412

Pathogens are viruses, bacteria, and protozoa harmful to human health. Coliform bacteria, which come from human waste, is commonly used as an indicator that harmful pathogens may be present in the water.[46] Studies have found high levels of coliform bacterial in stormwater.[47]

Illicit sanitary connections can also add nutrients such as nitrogen and phosphorus to stormwater. Human waste also contributes to bod. Leaking sanitary sewer lines located near storm sewer lines can pose the same problems as illicit connections.[48]

Septic Systems

Effluent from poorly maintained or failing septic systems can rise to the surface and contaminate stormwater.[49] Septic systems can be important sources of pathogens and nutrients, especially nitrogen, that are not effectively removed from the waste stream. Bathing beach and shellfish bed closures are frequently the result of septic system effluent. One study found that 74 percent of the nitrogen entering the Buttermilk Bay estuary in Massachusetts originated from septic systems.[50] Fecal coliform and BOD can be present in stormwater if the system is improperly sited, designed, installed, or maintained.

Illicit Industrial Connections to Storm Sewers

Businesses that illicitly connect pipes containing wastewater from industrial processes to the storm sewer system rather than to the sanitary sewers can add metals, solvents or other contaminants to stormwater. In Seattle, one industrial facility's discharge of lead to the storm sewer system resulted in sediment so contaminated that it could be sent to a smelter to be refined.[51] Floor drains, dry wells, and cesspools are also frequent sources of illicit industrial discharges and connections.

Uncovered Materials Stored Outside

Rain or melting snow can erode piles of bulk material, such as sand, loose topsoil, or road salt if left uncovered, adding sediment, salts or other pollutants to nearby waterbodies. Likewise, precipitation can wash contaminants off leaking or dirty objects left outdoors. For example, water quality monitoring showed that untreated runoff collected from auto recycling facilities near Los Angeles frequently exceeded EPA benchmark figures, for biochemical oxygen demand, nitrogen, oil and grease, phosphorus, and sediment.[52]

Street, Sidewalk, and Airport De-icing

In colder parts of the country, salts used to keep roads, parking lots and sidewalks free of ice often drain into our waterbodies as snow and ice melt and spring rain falls. While some salt and ice treatment is necessary to keep roads safe in winter, measures can be taken to reduce or prevent the impacts from de-icing. The principal salts used are sodium chloride and calcium chloride, although materials such as calcium magnesium acetate and other commercial products are also used.[53] Some municipalities spread sand to maintain road traction on snow and ice, and this sand eventually may increase sediment loads. Airports de-ice runways and planes, usually with glycol mixtures that can be both toxic to fish, wildlife, and humans and exert high BOD on receiving streams.

Landfills

Because the soil cover on landfills is not stabilized with vegetation or other retaining cover while the landfill is operational, soil can erode from landfills as it does from construction sites. Additionally, improperly maintained hazardous-waste landfills can allow toxic contaminants to reach or stay on the surface of the landfill, allowing stormwater to carry these pollutants to nearby waterbodies.

Pets and Wild Animals

Waste from domestic and wild animals is a source of pathogens, nutrients and BOD in stormwater.[54] The Northern Virginia Soil and Water Conservation District estimates that each day, dogs leave 180,000 pounds of waste on the ground in Fairfax County, Virginia, alone.[55] Waste from birds such as pigeons, geese, and gulls that are attracted to human activity can also be a problem. Wild geese that congregate in large numbers on cultivated turf adjacent to bodies of water also contribute to pathogen, nutrient and BOD loadings.[56]

Littering

Not only does stormwater frequently receive no treatment, it also often does not even have the benefit of simple filtering or screening for visible objects. As a result, paper cups, cigarette butts, virtually anything made of styrofoam, newspaper, and other materials that people toss on the ground are carried into storm sewer systems -- and eventually into lakes, streams, and oceans.

This list, exhaustive as it is, is incomplete. Galvanized roofs, unpaved roads, the dust that collects on paved streets, and countless other aspects of daily life in urban areas contribute to polluted runoff. The first step in stormwater management is not to memorize any particular list, but rather to recognize the breadth of opportunities for pollution prevention and the need to think holistically about the entire chain of human activities that affect runoff quantity and quality. The case studies presented in this report demonstrate a wide variety of effective and efficient strategies for addressing stormwater runoff at the source.

Report To Congress On The Phase II Storm Water Regulations

Report to Congress
on the
Phase II Storm Water Regulations

Table of Contents

I. INTRODUCTION

A. PURPOSE OF REPORT TO CONGRESS

EPA provides this Report to Congress in compliance with Section 431(a) of the Departments of Veterans Affairs and Housing and Urban Development and Independent Agencies Appropriations Act of 2000, Pub. L. No. 106-74 (1999) ("Appropriations Act"). The Appropriations Act directs the Administrator of the Environmental Protection Agency ("EPA") to submit two reports to the Committee on Environment and Public Works in the Senate and the Committee on Transportation and Infrastructure in the House of Representatives. The first of the reports is to address several issues related to EPA rulemaking to implement Section 402(p)(6) of the Clean Water Act ("CWA"). This rulemaking is also referred to as the Storm Water Phase II rule. Section 431(a) of the Appropriations Act directs the Administrator to submit a report containing:

> (1) an in-depth impact analysis on the effect the final regulations will have on urban, suburban, and rural local governments subject to the regulations, including an estimate of --
>
> > (A) the costs of complying with the 6 minimum control measures described in the regulations; and
> >
> > (B) the costs resulting from the lowering of the construction threshold from 5 acres to 1 acre;
>
> (2) an explanation of the rationale of the Administrator for lowering the construction site threshold from 5 acres to 1 acre, including --
>
> > (A) an explanation, in light of recent court decisions, of why a 1-acre measure is any less arbitrarily determined than a 5-acre measure; and
> >
> > (B) all qualitative information used in determining an acre threshold for a construction site;
>
> (3) documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000 (including an explanation of why the coverage of the regulation is based on a census-determined population instead of a water quality threshold); and
>
> (4) information that supports the position of the Administrator that the Phase II storm water program should be administered as part of the National Pollutant Discharge Elimination System under section 402 of the Federal Water Pollution Control Act (33 U.S.C. 1342).

Section 431(c) of the Appropriations Act directs EPA to publish the reports in the Federal Register for public comment. The Appropriations Act does not specify whether EPA should seek and respond to public comment on the reports prior to submitting them to the Committees. Section 431(a) does provide, however, that the Administrator shall not promulgate the Phase II rule until submitting the Section 431(a) report to the Committees. EPA is subject to a judicial consent decree in NRDC v. Browner, (D.D.C., Civ. No. 95-634 PLF) to take final action by October 29, 1999 on the Phase II rule proposed earlier. The Appropriations Act does not relieve EPA from the timing of this rulemaking obligation. Therefore, EPA will invite public comment on the Section 431(a) report after submitting it to the Committees. EPA will carefully review and evaluate comments received and determine whether the comments warrant further action regarding the October 29, 1999, final rule.

As noted above, on October 29, 1999, the Administrator of EPA will take final action on a notice of proposed rulemaking under CWA section 402(p)(6), 33 U.S.C. § 1342(p)(6). On January 9, 1998, at 63 Fed. Reg. 1536, EPA proposed to expand the National Pollutant Discharge Elimination System (NPDES) permitting program for storm water to apply to discharges from certain small municipal separate storm sewer systems (MS4s) and from construction activity generally disturbing between one and five acres of land surface. Although EPA designated for regulation discharges from these two categories, the rulemaking would also allow for waivers (for subsequent exclusion from regulation of certain sources in these categories) and designation (for subsequent inclusion of certain sources that fall outside of the categories). Waivers would be available based on criteria by which the NPDES permitting authority would determine a low potential for adverse water quality impact, and the permitting authority would designate additional sources on a localized basis when necessary to protect or remedy localized adverse water quality impacts.

Rulemaking under CWA section 402(p)(6) is to be based on a study that EPA was directed to provide to Congress under CWA section 402(p)(5). Section 402(p)(5) provides that:

> The Administrator, in consultation with the States, shall conduct a study for the purposes of -
>
> (A) identifying those stormwater discharges or classes of stormwater discharges for which permits are not required pursuant to [CWA sections 402(p)(1) and (p)(2)];
>
> (B) determining, to the maximum extent practicable, the nature and extent of pollutants in such discharges; and
>
> (C) establishing procedures and methods to control stormwater discharges to the extent necessary to mitigate impacts on water quality.

CWA section 402(p)(5) directed EPA to provide reports to Congress on the different components of this study. In proposing the regulations under CWA section 402(p)(6), EPA identified the reports to Congress comprising the study described in CWA section 402(p)(5), specifically, *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress* (U.S. EPA, 1995, EPA 833-K-

94-002). Today's report under section 431(a) of the Appropriations Act is a supplement to the study described in CWA section 402(p)(5).

B. PURPOSE OF THE PHASE II RULE

The Phase II rule would establish a cost effective, flexible approach for reducing environmental harm by storm water discharges from many point sources of storm water that are currently unregulated. Some of the costs of implementing the Phase II rule are discussed in Chapter II of this report. A summary of the rule's benefits are described below. EPA's Economic Analysis of the Final Phase II Storm Water Rule fully analyzes the costs and benefits expected from implementation of the rule.

The environmental harm currently caused by discharges from municipal separate storm sewer systems (MS4s) and construction activity is well documented:

- Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving water bodies.

- The National Urban Runoff Program (NURP) Study (U.S. EPA 1983) indicated that discharges from MS4s draining runoff from residential, commercial, and light industrial areas carried more than ten times the annual loadings of total suspended solids as did discharges from municipal sewage treatment plants that provide secondary treatment, and somewhat higher annual loadings of chemical oxygen demand (COD), total lead, and total copper.

- The National Water Quality Inventory (305(b)), 1996 report to Congress shows that urban runoff/storm sewer discharges affect 13% of impaired rivers, 21% of impaired lakes and 45% of impaired estuaries.

- Urban storm water runoff, sanitary sewer overflows, and combined sewer overflows have become the largest causes of beach closings in the United States in the past three years. A survey of coastal and Great Lakes communities found that more than 1,500 beach closings and advisories were attributable to storm water runoff in 1998 based on EPA data supplemented with additional data (Natural Resources Defense Council. 1998. "Testing the Waters Volume VIII-Has Your Vacation Beach Cleaned Up Its Act?" New York, NY). Recreational bathers are at the highest risk for contracting illnesses such as gastroenteritis, typhoid, dysentery, hepatitis, skin rashes, and respiratory infections.

- The MS4 program will address illicit discharges, which can contribute high levels of pollutants, including heavy metals, toxic substances, oil and grease, solvents, nutrients, viruses and bacteria into receiving water bodies.

- The NURP study found that pollutant levels from illicit discharges were high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health.

- Discharges from construction activity impact the biological, chemical, and physical integrity of receiving waters. A number of pollutants are preferentially absorbed onto particles found in fine sediment. Estimates indicate that 80 percent of the phosphorus and 73 percent of the Kjeldahl nitrogen in streams is associated with eroded sediment from construction and other activities.

- Sediment yields from smaller construction sites are as high as or higher than the 20 to 150 tons/acre/year measured from larger sites.

- Siltation is the largest cause of impaired water quality in rivers and the third largest cause of impaired water quality in lakes, according to the 305(b) Report to Congress.

The implementation of the six minimum measures identified for small MS4s should significantly reduce pollutants in urban storm water compared to existing levels and do so in a cost effective manner. Similarly, the implementation of best management practice ("BMP") controls at small construction sites should also result in a significant reduction in pollutant discharges and an improvement in surface water quality. EPA's Economic Analysis of the Final Phase II Storm Water Rule details the expected benefits from implementation of the rule. These benefits include:

- Enhanced Commercial Fishing: Commercial fisheries are a significant part of the nation's economy. In 1997, the commercial shellfish catch was worth $1.04 Billion and the finfish catch was worth $581 Million. 18% of surveyed estuary miles identified storm water as a significant source of impairment.

- Enhanced Recreational and Subsistence Fishing: The potential value of marine recreational fishing is $1.1 Billion to $11.3 Billion annually. Pollutants in storm water may result in eliminating or decreasing the numbers or size of sport fish or shellfish in receiving waters. In September 1996, there were 2,196 fish consumption advisories and about 25% of waters designated for fishing did not support that use.

- Enhanced Opportunities for Boating: Storm water controls offer benefits to boaters by reducing sediment and other pollutants in waters, increasing water clarity and enhancing the experience for boating users. EPA estimates that pollution reduction due to Phase II controls may result in 3,000 currently non-boatable miles of river becoming boatable.

- Enhanced Opportunities for Swimming: EPA estimates that Americans participated in 1.3 billion non-pool swimming days. EPA estimates that at least 28% of these trips are to either marine or fresh water that is impacted by runoff from Phase II sources. For example, in 1998, storm water runoff caused beach closures that resulted in the loss of an estimated 86,000 individual trips to beaches impacted by Phase II sources.

- Enhanced Opportunities for Noncontact Recreation: Activities like picnicking, jogging, biking, camping and hunting do not necessitate direct contact with water, but water quality affects the ability to enjoy these activities when in close proximity to water. Storm water controls reduce turbidity, odors, floating trash and other pollutants and allow waters to be used as focal points for recreation, enhancing the experience of current and future users.

- Enhanced Nonconsumptive Wildlife Uses: An estimated 76.1 million people participated in observing wildlife and waterfowl in 1991. Storm water controls that result in greater numbers or diversity of viewable wildlife species will produce benefits.

- Reduced Flood Damage: Storm water runoff controls may mitigate flood damage by addressing problems due to the diversion of runoff, insufficient storage capacity, and reduced channel capacity from sedimentation.

- Drinking Water Benefits: Storm water was identified as a major source of impairment in rivers, streams, lakes, reservoirs and ponds. Pollutants from storm water runoff, such as solids, toxic pollutants (including pesticides) and bacteria, may impose additional costs for treatment or even render the water unusable for drinking.

- Water Storage Benefits: Storm Water is a major source of impairment for reservoirs. The heavy load of solids deposited by storm water runoff can lead to rapid sedimentation of reservoirs and the loss of needed water storage capacity.

- Navigational Benefits: Storm water also delivers high sediment loads to rivers and harbors critical to navigation and commerce. Where waters are used for navigation, solids must be dredged and disposed of to maintain the utility of the waterway. An estimated 5% of these sediments (12.6 million cubic yards of material) is attributed to storm water runoff from roads and constructions sites. Storm water controls will reduce the rate and amount of sediment loadings.

- Reduced Illness from Consuming Contaminated Seafood: Storm water controls may reduce the presence of pathogens in seafood caught by commercial or recreational anglers. Researchers have estimated 2,700 cases of illness annually from raw or partially cooked contaminated seafood.

- Reduced Illness from Swimming in Contaminated Water: Epidemiological studies have indicated that swimmers in water contaminated by storm water runoff are more likely to experience illness than those that swim farther from a storm water outfall. By reducing illicit connections and other sources of pathogens in storm water, EPA estimates that up to 500,000 cases of illness will be avoided annually.

- Enhanced Aesthetic Value: When storm water affects the appearance or quality of a water body, the desirability of working, living, traveling or owning property near that water body is similarly affected. Improvements in water quality due to reductions in storm water pollution will result in benefits as these waters recover and become more desirable locations near which people want to live, work, travel or own property.

Thus, the rule will result in significant monetized financial, recreational and health benefits, as well as benefits that EPA has been unable to monetize.

II. IMPACT OF PHASE II RULE ON LOCAL GOVERNMENTS

This section responds to the Appropriations Act's direction to provide a report containing:

"(1) an in-depth impact analysis on the effect the final regulations will have on urban, suburban, and rural local governments subject to the regulations, including an estimate of-
(A) the costs of complying with the 6 minimum control measures described in the regulations; and
(B) the costs resulting from the lowering of the construction threshold from 5 acres to 1 acre;"

A. SUMMARY OF PHASE II RULE REQUIREMENTS

EPA conducted an in-depth impact analysis of the effect of the final Storm Water Phase II Rule on local governments. Two provisions of the Phase II rule are expected to result in compliance costs for local governments. These are the provision requiring certain municipalities to regulate discharges from their municipal separate storm sewer systems (MS4s) and the provision which extends the storm water construction program to cover sites between one and five acres in size. The analysis considers potential cost impacts to all local governments, including urban, suburban and rural governments, and provides insight into the differing situations of small or very small local governments. Based on this analysis, EPA determined that the Phase II rule is not expected to have a significant impact on a substantial number of local governments.

Municipal Storm Water Program:

The Phase II Rule would automatically designate for regulation discharges from small MS4s located in urbanized areas, and require that NPDES permitting authorities examine for potential designation, at a minimum, a particular subset of discharges from small MS4s located outside of urbanized areas. The MS4 provision would result in costs primarily for local governments in urbanized areas. An urbanized area is defined by the U.S. Census Bureau as an area with a population of at least 50,000 and a minimum average population density of more than 1,000 people per square mile. Thus, this rule would primarily affect suburban and urban local governments, because these MS4s are more likely to be located in urbanized areas. Rural local governments may be designated on a case-by-case basis if the permitting authority determines that they have a significant impact on water quality. The Phase I storm water program addressed runoff from "medium" and "large" MS4s, generally those discharges from governmental jurisdictions serving populations of 100,000 or more people. The Phase II Storm Water regulations will address discharges from smaller MS4s. The rule also would allow MS4s that are automatically designated because they are within an urbanized area to obtain a waiver from the otherwise applicable requirements if the discharges from small MS4s are not causing impairment of a receiving water body. Qualifications for the waivers vary depending on whether the MS4 serves a population under 1,000 or a population under 10,000.

Under the Phase II rule, a storm water discharge control program that meets the requirements of six minimum control measures would be administered within the jurisdiction of all regulated small MS4s. Small MS4 operators would design and administer the program, or would arrange with other government entities (including operators of nearby larger MS4s) to do so. These minimum control measures would consist of: public education and outreach on storm water impacts, public involvement/ participation, illicit discharge detection and elimination, construction site storm water runoff control, post-construction storm water management in new development and redevelopment, and pollution prevention/good housekeeping for municipal operations. The Agency provides an analysis of the costs to local governments of implementing the six municipal minimum control measures in Section B below.

Municipal Construction:

The 1990 Phase I rule required all operators of construction activity disturbing five or more acres of land surface to apply for an NPDES permit for any resulting point source discharges of storm water.[1] The construction provisions of the Phase II rule would extend similar requirements to construction projects that disturb between one and five acres of land. This provision would impose additional requirements on small construction projects of local governments, regardless of whether the local government is urban, suburban or rural. The rule excludes routine road maintenance from the definition of construction, thereby excluding many municipal public works projects. EPA expects that most new one to five acre road construction projects are likely to be built in conjunction with either larger development projects or State and Federal transportation programs and at least partially funded by these other sources. The Phase II rule would also provide waivers from coverage based on the potential to discharge storm water and cause a significant impact to water quality. EPA's analysis of construction starts concluded that the additional requirement for municipally constructed projects should not have a significant impact on a substantial number of the local governments subject to the regulation. EPA reports on its analysis of the costs to local governments of implementing the soil erosion control provisions for their construction sites between one and five acres in Section C below.

Regulatory Flexibility:

In promulgating Storm Water Phase II, EPA examined regulatory flexibility issues and potential cost impacts on small entities, including small local governments. In order to solicit input from potentially regulated small entities, EPA convened a Small Business Regulatory

---

[1] On December 18, 1991, Congress enacted the Intermodal Surface Transportation Efficiency Act (ISTEA), which postponed NPDES permit application deadlines for most storm water discharges associated with industrial activity at facilities that are owned or operated by small municipalities, including construction activity over five acres.

Enforcement Flexibility Act (SBREFA) Panel which included small local government representatives as well as other stakeholders. EPA conducted an analysis and determined that the rule was expected not to have a significant impact on a substantial number of small local governments or other small entities. However, in order to provide additional flexibility for small local governments, EPA included several programmatic options and potential waivers for small governments.

The rule would allow for a great deal of flexibility by providing various options for obtaining permit coverage and satisfying the required minimum control measures. For example, the NPDES permitting authority would be able to incorporate by reference qualifying State, Tribal, or local programs in a NPDES general permit and recognize existing responsibilities among different governmental entities for the implementation of minimum control measures. In addition, a regulated small MS4 could participate in the storm water management program of an adjoining regulated MS4 and could arrange to have another governmental entity implement a minimum control measure for them. The rule also provides potential waivers for MS4s serving a population less than 10,000 and also for construction projects not expected to significantly impair water quality. Therefore, Storm Water Phase II is not expected to have a significant impact on a substantial number of small local governments, and offers significant flexibility to those local governments in implementing provisions of the rule which may result in compliance cost impacts.

B. Impacts of the Municipal Minimum Control Measures on Local Governments

EPA estimated that the overall annual cost to local governments of implementing a storm water program based on the six minimum measures would be $297 million. EPA developed this estimate using actual program cost information from Phase II communities with existing storm water programs. The estimate assumes that all of the 5,040 Phase II designated municipalities would incur program costs and that costs are related to the size of the community served. Therefore, the Agency probably overestimates national costs because permitting authorities can waive permitting requirements for MS4s serving up to 10,000 people.

EPA conducted an in-depth analysis of the potential cost of complying with the six minimum measures on local governments in urbanized areas. These local governments are primarily urban and suburban, although a few rural governments may be designated by States to be included in the program based on potential water quality impacts. While the total regulatory costs associated with Phase II include all sizes of local government, EPA specifically considered the impacts to small local governments as required under the Regulatory Flexibility Act, as amended by the Small Business Regulatory and Enforcement Fairness Act. In preparing the analysis, EPA compared estimated annual compliance costs with annual municipal revenues for 4,455 small local governments (municipalities with fewer than 50,000 people) and evaluated cost-to-revenue ratios for indication of significant economic impacts. The results, which are reported in the economic analyses prepared for the proposed and final rules, led EPA to conclude that there would not be a substantial economic impact on a significant number of small governments; EPA expects even less of an impact on larger governments. Below is a summary of EPA's analysis.

Cost Analysis:

EPA estimated annual costs for the municipal programs based on a fixed cost component and a variable cost component. The fixed cost component included costs for the municipal application, record keeping, and reporting activities. On average, EPA estimated annual costs of $1,525 per municipality. Variable costs include the costs associated with annual operations for the six minimum measures. EPA reviewed cost data from existing Phase I storm water programs and cost data gathered from Phase II communities by the National Association of Flood and Storm Water Management Agencies (NAFSMA). These costs reflect the actual operating costs of program elements that are comparable to the six minimum measures for municipalities representing a wide range of population sizes. EPA estimated costs on a per household basis from both data sets. Annual mean costs per household are comparable across the data sets: $8.93 (NASFMA) and $8.85 (Phase I).

Total annual cost for each of the 4,455 municipalities was calculated as the sum of the $1,525 fixed cost and the urbanized area household estimate multiplied by the per household cost based on the NAFSMA data.[2] For example, a municipality with 5,000 households would have a total program cost of:

$$\$46,175 = \$1,525 + (5,000 * \$8.93).$$

Small Local Governments:

EPA estimated municipality revenues based on state-level revenue data collected by the U.S. Bureau of the Census 1992 Census of Governments. The Bureau of the Census reports municipal government revenues by population size for eight size categories including three used by EPA: less than 10,000, 10,000 to 24,999, and 25,000 to 49,999. For every state, EPA gathered the aggregate municipal revenue data and aggregate municipal population data reported by the Bureau of the Census for these three size categories.[3] EPA then divided revenue by population to obtain revenue per capita for each size category within each state. EPA merged this data set with the Phase II municipality population data set and multiplied the appropriate per capita revenue estimates by the Phase II urbanized area populations to obtain 4,455 estimates of annual municipal revenues.

---

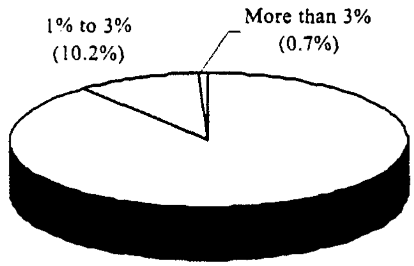
[2] Based on Census data, EPA used a conversion factor of 2.62 people per household to obtain household estimates for the Phase II communities.

[3] EPA did not adjust municipal revenue from their 1991 values to 1998 values, which is the unit of measure EPA used for costs. There is no standard adjustment factor for municipal revenues. Thus, the cost-to-revenue ratio probably overstates the cost impact.

Finally, EPA divided the 4,455 cost estimates by the 4,455 revenue estimates to obtain cost-to-revenue ratios. EPA categorized these ratios according to whether they were less than 1% (i.e., cost is less than 1% of revenue), between 1% and 3%, and greater than 3%. Figure A summarizes the results, showing that the cost-to-revenue ratios were less than 1% for 89% of the Phase II municipalities and greater than 3% for less than 1% of municipalities.

Under, the Phase II rule, the permitting authority could waive permitting requirements for systems serving less than 1,000 people. All of the municipalities with cost-to-revenue ratios that are greater than 3% have populations less than 1,000 people, and may qualify for a waiver. Consequently, the flexibility of the rule addresses any potentially significant adverse cost impacts. Because no Phase II municipality with a population of more than 6,000 had a cost-to-revenue ratio of more than 1%, EPA does not expect this provision will have significant economic impacts on the 585 municipalities with populations larger than 50,000.

Figure A. Summary of Cost-to-Revenue Ratios for 4,455 Phase II Municipalities with Populations Less than 50,000



C. COSTS OF THE SOIL EROSION CONTROL PROVISION ON LOCAL GOVERNMENTS

EPA's cost analysis for the soil erosion control provision multiplies cost estimates per construction site for soil erosion control measures and administrative costs by the number of construction sites potentially affected by the rule. EPA estimates that the rule would apply to approximately 110,223 currently unregulated construction starts per year (using 1998 estimates) out of a total of 528,499 construction starts. Annual costs associated with installing the soil erosion controls and completing permitting activities is estimated as $505 million. Less than 0.5% (< $500,000) is expected to accrue from local governments.

<u>Cost Analysis:</u>

Most soil erosion control costs would accrue to the private sector, primarily to dischargers in the construction industry. However, local governments may also incur soil erosion control costs for discharges from public works projects that disturb between one and five acres (costs borne either directly by the local government or indirectly through a contractor). Since routine road maintenance is excluded from coverage under Storm Water Phase II, those public works starts are excluded from analysis. EPA used the site-based estimates of soil erosion control costs that it developed for the economic analysis of the final rule and Bureau of Census construction start data to estimate the expected annual impact on local governments. Table A summarizes the two types of costs by site size that a construction company or public works department may incur.

Table A. Summary of Site-Based Soil Erosion Control Costs

Cost	1 Acre Site	3 Acre Site	5 Acre Site
Administrative [a]	$937	$937	$937
Soil Erosion Control BMPs [b]	$1,206	$4,598	$8,709
Total Cost	$2,143	$5,535	$9,646
Annualized Cost (7%)[c]	$202	$522	$910

Notes:
a. These activities would include costs to submit a notice of intent to be covered by a general permit, to notify the municipality, to develop a storm water pollution prevention plan, to retain records, and to file a notice of termination from a general permit.
b. BMPs (best management practices) costs are based on combinations of the following that differ across sites with different sizes, slopes, and soil types: silt fence, mulch, seed/mulch, stabilized entrance, stone check dam, earth dike, and sediment traps.
c. Annualized cost assumes a 20-year period and a 7% cost of capital. The capitalization factor is 0.09439.

<u>Small Local Governments:</u>

There are four categories of local governments which may experience costs of compliance associated with the Phase II rule. These are:

1) Phase I jurisdictions (subject to Phase II requirements for construction between one and five acres; already required to have a municipal storm water program),
2) Phase II jurisdiction above 50,000 population (subject to Phase II municipal and construction requirements),
3) Phase II jurisdictions below 50,000 population (subject to Phase II municipal and construction requirements; subject to SBREFA review), and
4) Jurisdictions that are not required to have a municipal storm water program under

Phase I or Phase II (subject to Phase II requirements for construction).

The greatest potential economic impact of the soil erosion control provision is expected to be on the third category, because they would incur soil and erosion control costs in addition to annual program costs for the six minimum measures, and because of their smaller size. Therefore, the analysis below focuses on the impacts on these small local governments.

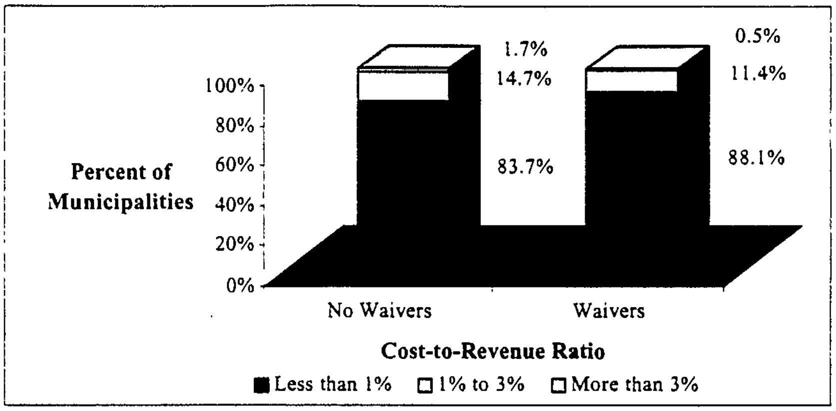
To evaluate the severity of potential impact, EPA used the Bureau of the Census construction start database to estimate the annual number of construction starts in Phase II municipalities that are classified by the Bureau of the Census as a "public works" start, excluding routine road maintenance. The data showed that 2% of municipalities are expected to have a 1-acre start, 2% are expected to have a 3-acre start and 1% are expected to have a 5-acre start. These results indicate that local governments would not incur soil and erosion control costs on an annual basis, because they would not necessarily have Phase II construction starts in any given year. As a conservative assumption (i.e., tending to overstate costs), EPA annualized the costs over a 20-year period, assuming a 7% cost of capital (see Table A). The 20-year assumption is conservative because it implies higher construction rates than the data suggest [i.e., 1-acre site (5%), 3-acre site (5%), and 5-acre site (5%)]. EPA then added the annualized values to obtain an annual cost of $1,634 per municipality for the soil erosion control provision.

Because the soil erosion control provision of the Phase II rule would apply to discharges from construction sites between one and five acres regardless of location, local governments other than Phase II designated municipalities could incur costs. EPA compared the annualized value across all site sizes of $1,634 to the national mean estimate of local government revenues. For the smallest municipality size category, the mean annual revenue was $1.4 million (1991 dollars; 1992 Census of Governments). The cost-to-revenue ratio for the smallest size category is well below 1%.

Finally, EPA then added the cost of complying with the Phase II soil erosion program for small construction to the cost-to-revenue ratios for the MS4 program discussed above to evaluate the combined impact on Phase II municipalities of the municipal minimum measures and soil erosion control costs that may be borne directly or indirectly (passed through from construction companies). Based on this revised cost-to-revenue analysis, the combined costs are not expected to have a significant economic impact on a substantial number of designated Phase II municipalities.

Figure B summarizes the cost-to-revenue impacts for all 4,455 Phase II municipalities with populations less than 50,000 (bar on left). Figure B also summarizes impacts for these Phase II municipalities assuming that the municipalities with populations below 1,000 are granted waivers so they incur soil erosion control costs as regulated small construction site dischargers but no program costs as small MS4 dischargers (bar on right). In either case, a vast majority of municipalities would not incur annual costs that are greater than 1% of revenues and fewer than 2% of municipalities would incur costs that are greater than 3% of revenues. Therefore, EPA concluded that the Phase II rule would not have a significant impact on potentially regulated small local governments.

Figure B. Summary of Cost-to-Revenue Ratios Revised to Include Soil Erosion Control Costs for 4,455 Phase II Municipalities with Populations under 50,000



* "No Waivers" estimates costs assuming (for the purpose of this analysis) that no small local governments with populations below 1,000 receive a waiver and, therefore, are subject to both the municipal and the soil erosion provisions of Phase II. Even if this were to occur, the potential impacts are not significant.

R0010433

III. RATIONALE FOR THE ONE ACRE CONSTRUCTION THRESHOLD

This section responds to the Appropriations Act's direction to provide a report containing:

"(2) an explanation of the rationale of the Administrator for lowering the construction site threshold from 5 acres to 1 acre, including --
(A) an explanation, in light of recent court decisions, of why a 1-acre measure is any less arbitrarily determined than a 5-acre measure; and
(B) all qualitative information used in determining an acre threshold for a construction site;"

BACKGROUND

In 1990, EPA promulgated the first phase of the NPDES permit application rules for storm water. (*National Pollutant Discharge Elimination System Permit Application Requirements for Storm Water Discharges*, 55 Fed. Reg. 47990 (Nov. 16, 1990), referred to as the "Phase I" rule). As directed under CWA section 402(p)(4)(A), the Phase I rule set forth the permit application requirements for storm water discharges "associated with industrial activity," including, applicability provisions defining the term "storm water discharge associated with industrial activity." Under CWA section 402(p)(2)(B), storm water discharges associated with industrial activity were excluded from the moratorium against permitting discharges composed entirely of storm water.

Among other things, the Phase I rule defined storm water discharge associated with industrial activity to include discharges from "construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale." 40 C.F.R. 122.26(b)(14)(x). In 1992, a court ruled that the five acre threshold used for defining construction activity as "industrial activity" was improper because EPA had failed to identify information to support its position that construction activities on less than five acres are non-industrial in nature.

The Phase II rule would regulate storm water discharges from additional smaller construction activities. The rule would regulate these construction-related storm water sources under CWA section 402(p)(6) to protect water quality rather than under CWA section 402(p)(2). Designation under 402(p)(6) gives States and EPA the flexibility to waive the permit requirement for construction activity that is not likely to impair water quality, and to designate additional sources below one acre that are likely to cause water quality impairment. Thus, the one acre threshold under the Phase II rule would not be an absolute threshold like the five acre threshold that applies under the Phase I rule. The one acre threshold is reasonable for accomplishing the water quality goals of CWA section 402(p)(6) because it results in 97.5% of the total acreage disturbed by construction being designated for coverage by the NPDES storm water program, while excluding from automatic coverage the numerous smaller sites that represent 24.7% of the total number of construction sites.

Rationale for Five Acre Threshold in the Phase I Rule

In the preamble to the Phase I rule, which regulates storm water discharges from construction activity disturbing five acres or more as "storm water discharges associated with industrial activity," EPA had explained that the construction industry should be subject to storm water permitting because at a high level of intensity, construction is equivalent to other regulated industrial activities. 55 Fed. Reg. 48033. The Phase I rule regulates storm water "associated with industrial activity." EPA had proposed that the Phase I regulations apply to construction site discharges from sites disturbing down to one acre. EPA increased the size threshold to five acres for the final rule.

After a judicial challenge to the Phase I regulations, the Ninth Circuit remanded the regulation to EPA for further proceedings. NRDC v. EPA, 966 F.2d 1292, 1306 (9th Cir. 1992). To support the increased threshold (from one to five acres), the Agency had explained that larger sites typically involve heavier equipment for removing vegetation and bedrock than smaller sites. 55 Fed. Reg. 48036. The court found that EPA's rationale for increasing the limit was inadequate because the Agency cited no information to support its perception that construction activities on less than five acres are non-industrial in nature. 966 F.2d at 1306. Thus, the Court focused on the relationship between the size threshold and the statutory reference to "industrial."

Rationale for One Acre Threshold in the Phase II Rule

In lowering the threshold to one acre in the Phase II rule, the Phase II rule would not regulate discharges from small construction site as "industrial activity." Instead, EPA interprets the text of CWA section 402(p)(6) as a basis to designate small construction site discharges as sources "to be regulated to protect water quality." EPA interprets this language as less restrictive than the terms "associated with industrial activity" for the purpose of establishing an applicability threshold that is based on size alone but which may be modified by permitting authorities to account for higher and lower threat sources. In addition to water quality considerations, the text of CWA section 402(p)(6) allows for designations based on considerations of administrative feasibility by specifying that the Agency has discretion to identify sources "to be regulated."

Though the Phase II rule would not regulate a discharge from a construction site below the five acre threshold as a "discharge associated with industrial activity," the Phase II rule nonetheless responds to the Ninth Circuit's direction to conduct further rulemaking on the matter of discharges from sites disturbing more than one acre (from the Phase I proposed rule) and from sites disturbing less than five acres (from the Phase I final rule). For discharges from sources in this category, which the Agency still believes present water quality concerns based on the potential for water quality impairment due to gross sediment runoff (among other pollutants), CWA section 402(p)(6) rather than CWA section 402(p)(2)(B) and (3) provides a more sensible basis to address the sources that threaten water quality. In light of the Agency's decision to regulate these sources down to one acre to protect water quality with controls similar to those applied to Phase I sources, EPA believes it is unnecessary to examine further whether sites below five acres are "associated with industrial activity."

EPA is regulating storm water discharges from construction activity disturbing between 1 and 5 acres because the cumulative impact of many sources, and not just a single identified source, is typically the cause for water quality impairments, particularly in relation to sedimentation-related water quality standards.

The one acre threshold provides an administrative tool for more easily identifying those sites that are identified for coverage by the rule (but may receive a waiver) and those that are not automatically covered (but may be designated for inclusion). Although all construction sites less than five acres could have a significant water quality impact cumulatively, EPA is automatically designating for permit coverage only those storm water discharges from construction sites that disturb land equal to or greater than one acre. Categorical regulation of discharges from construction below this one acre threshold would overwhelm the resources of permitting authorities and might not yield corresponding water quality benefits. Construction activities that disturb less than one acre make up, in total, a very small percentage of the total land disturbance from construction nationwide (about 2.5%).

In addition to the diminishing water quality benefits of regulating all sites below one acre, the Agency relies on practical considerations in establishing a one acre threshold and not setting a lower threshold. Regardless of the threshold established by EPA, a NPDES permit can only be required if a construction site has a point source discharge. A point source discharge means that pollutants are added to waters of the United States through a discernible, confined, discrete conveyance. "Sheet flow" runoff from a small construction site would not result in a point source discharge unless and until it channelized. As the amount of disturbed land surface decreases, precipitation is less likely to channelize and create a "point source" discharge (assuming the absence of steep slopes or other factors that lead to increased channelization). Categorical designation of very small sites may create confusion about applicability of the NPDES permitting program to those sites. EPA's one acre threshold reflects, in part, the need to recognize that smaller sites are less likely to result in point source discharges. Of course, the NPDES permitting authority could designate smaller sites (below one acre, assuming point source discharges occur from the smaller designated sites) for regulation if a watershed or other local assessment indicated the need to do so. The Phase II rule would include this designation authority at 40 CFR 122.26(a)(9)(i)(D) and (b)(15)(ii).

Though location-specific water quality studies would provide the ideal information base from which to make regulatory decisions, the Phase II rule establishes one acre as a default standard for regulation in the absence of location-specific studies. The rule does account for location-specific water quality information, however, for any deviation from the default standard through additional designations and waivers. The rule codifies the ability of permitting authorities to provide waivers for sites greater than or equal to one acre and designate additional discharges from small sites below one acre when location-specific information suggests that the default one acre standard is either unnecessary (waivers) or too limited (designations) to protect water quality.

OTHER QUALITATIVE AND QUANTITATIVE INFORMATION ON SIZE THRESHOLDS

EPA had difficulty evaluating the water quality consequences of designating specific size thresholds because, while generally proportional to the size of the disturbed site, the water quality threat posed by discharges from construction sites of differing sizes varies nationwide, depending on the local climatological, geological, geographical, and hydrological influences. In order to ensure improvements in water quality nationwide, however, the Phase II rule does not allow various permitting authorities to establish different size thresholds except based on the waiver and designation provisions of the rule. EPA believes that a national one acre threshold for automatic designation, coupled with procedures for waiving sites above one acre and for designating sites below one acre based on local water quality considerations, ensures protection against adverse water quality impacts from storm water discharges from small construction sites while not overburdening the resources of permitting authorities and the construction industry.

EPA believes that the water quality impact from small construction sites is as high as or higher than the impact from larger sites on a per acre basis. The concentration of pollutants in the runoff from smaller sites is similar to the concentrations in the runoff from larger sites. The proportion of sediment that makes it from the construction site to surface waters is likely the same for larger and smaller construction sites in urban areas because the runoff from either site is usually delivered directly to the storm drain network where there is no opportunity for the sediment to be filtered out.

The expected contribution of total sediment yields from small sites depends, in part, on the extent to which erosion and sedimentation controls are being applied. Because current storm water regulations are more likely to require erosion and sedimentation controls on larger sites in urban areas, smaller construction sites that lack such programs are likely to contribute a disproportionate amount of the total sediment from construction activities (MacDonald, L.H. 1997. Technical Justification for Regulating Construction Sites 1-5 Acres in Size. Unpublished report submitted to the U.S. Environmental Protection Agency, Washington). Smaller construction sites are less likely to have an effective plan to control erosion and sedimentation, are less likely to properly implement and maintain their plans, and are less likely to be inspected (Brown, W. and D. Caraco. 1997. Controlling Storm Water Runoff Discharges from Small Construction Sites: A National Review. Submitted to the U.S. Environmental Protection Agency, Office of Wastewater Management, Washington, DC. by the Center for Watershed Protection, Silver Spring, MD).

To confirm its belief that sediment yields from small sites are as high as or higher than the 20 to 150 tons/acre/year measured from larger sites, EPA gave a grant to the Dane County, Wisconsin Land Conservation Department, in cooperation with the USGS, to evaluate sediment runoff from two small construction sites. The first was a 0.34 acre residential lot and the second was a 1.72 acre commercial office development. Runoff from the sites was channeled to a single discharge point for monitoring. Each site was monitored before, during, and after construction.

The Dane County study found that total solids concentrations from these small sites are similar to total solids concentrations from larger construction sites. Results show that for both of the study sites, total solids and suspended solids concentrations were significantly higher during construction than either before or after construction. For example, preconstruction total solids concentrations averaged 642 mg/L during the period when ryegrass was established, active construction total solids concentrations averaged 2,788 mg/L, and post-construction total solids concentrations averaged 132 mg/L (on a pollutant load basis, this equaled 7.4 lbs preconstruction, 35 lbs during construction, and 0.6 lbs post-construction for total solids). While this site was not properly stabilized before construction, after construction was complete and the site was stabilized, post-construction concentrations were more than 20 times less than during construction. The results were even more dramatic for the commercial site. The commercial site had one preconstruction event, which resulted in total solids concentrations of 138 mg/L, while active construction averaged more than 15,000 mg/L and post-construction averaged only 200 mg/L (on a pollutant load basis, this equaled 0.3 lbs preconstruction, 490 lbs during construction, and 13.4 lbs post-construction for total solids). The active construction period resulted in more than 75 times more sediment than either before or after construction (Owens, D.W., P. Jopke, D.W. Hall, J. Balousek and A. Roa. 1997. "Soil Erosion from Small Construction Sites in Dane County, Wisconsin." Draft Report. USGS and Dane County Land Conservation Department, WI).

Construction start data indicates that excluding construction sites below one acre from coverage under the Phase II rule would exclude a significant percentage of sites from automatic coverage while only excluding a small percentage of the total acreage. As is indicated in Table B, by choosing a nationwide threshold of one acre, the Phase I and Phase II rules will together address 97.5% of the national disturbed acreage yet will only regulate 75.3% of the construction starts. The remaining construction starts (24.7% or 130,435 starts) each occur on less than one acre of disturbed land and together constitute only 2.5% of total acreage disturbed by construction.

Table B. Percentage of national disturbed acreage and construction starts addressed by regulating all construction above different thresholds

	percentage of national disturbed area controlled by regulating all sites:	number of construction starts addressed (percent of national total)
all sites	100 %	527,774 (100 %)
greater than 1.0 acres	97.5 %	397,309 (75.3 %)
greater than 2.0 acres	92.3 %	301,941 (57.2 %)
greater than 3.0 acres	87.8 %	253,224 (48.0%)
greater than 4.0 acres	83.7 %	221,471 (42.0 %)
greater than 5.0 acres	78.1 %	188,425 (35.7 %)

* Table includes all construction starts. It does not exclude starts already regulated by Phase I, equivalent State programs, or potential Phase II waivers.

A two acre threshold would have tripled the total number acres that would not be designated for permit coverage. A threshold below one acre would have significantly increased the number of sites regulated without significantly increasing the number of acres for which storm water controls would be required. Thus, the additional increment in water quality protection that would be achieved by a lower size threshold would have resulted in a disproportionately higher burden on the regulated community.

CONCLUSION ON ONE ACRE THRESHOLD

The Ninth Circuit concluded that EPA arbitrarily defined discharges "associated with industrial activity" when the Agency established the five acre size threshold, particularly in light of the Agency's proposal to establish the threshold at one acre. The Phase II one acre threshold is not arbitrary because (1) sediment loads from disturbed land surface cause adverse impacts on water quality, (2) as site size decreases, the likelihood that precipitation will create "discernible, confined, discrete conveyances" through channelization decreases, (3) the one acre threshold is not an absolute threshold because NPDES authorities can waive the threshold for sites (and during seasons) when there is a lower potential for a discharge that would impair water quality and can designate sources below the threshold where necessary to protect water quality on a localized basis, and (4) the number of additional sites that would be regulated by a threshold below one acre is disproportionately high relative to the total number of acres disturbed by those sites.

EPA recognizes that the size criterion alone may not be a perfect predictor of the need for regulation, but effective protection of water quality depends as much on simplicity in implementation as it does on the scientific information underlying the regulatory criteria. The default size criterion of one acre will ensure protection against adverse water quality impacts from storm water discharges from small construction sites while not overburdening the resources of permitting authorities and the construction industry to implement the program to protect water quality in the first place. Further, as noted above, NPDES permit authorities can designate sources below one acre where necessary to protect water quality in a particular area, or waive sites above one acre where NPDES permit coverage under the Phase II rule is not necessary to protect water quality.

IV. Storm Water Problems in Census Designated Urbanized Areas

This section responds to the Appropriations Act's direction to provide a report containing:

"(3) documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000 (including an explanation of why the coverage of the regulation is based on a census-determined population instead of a water quality threshold);

Background

In 1990, EPA promulgated the first phase of the NPDES permit application rules for storm water ("Phase I"). Phase I required NPDES permits for storm water discharges from large and medium municipal separate storm sewer systems generally serving populations of 100,000 or more. Areas with a combined sewer were not included in the total population served for Phase I.

This definition of large and medium MS4s for Phase I created so-called "donut holes." Donut holes are unregulated MS4s located within those urbanized areas that include systems covered by the Phase I storm water program, but are not currently addressed by the storm water program because the Phase I regulations specify applicability based on political jurisdiction. In other words, donut holes are geographic gaps in the existing NPDES storm water program's regulatory scheme. Storm water discharges from donut hole areas present a problem due to their adverse impacts on local waters, as well as by frustrating the attainment of water quality goals of neighboring regulated communities.

The storm water Phase II rule designates discharges from small MS4s located in urbanized areas for NPDES permit coverage. EPA adopted the Bureau of the Census definition of an urbanized area as comprising a place and the adjacent densely settled surrounding territory that together have a minimum population of 50,000 people. A permitting authority may designate additional small MS4s after the authority develops designation criteria and applies those criteria to small MS4s located outside of an urbanized area, in particular those with a population of 10,000 or more and a population density of at least 1,000 per square mile. The permitting authority may waive the requirement for a permit for any small MS4 serving a jurisdiction with a population of less than 1,000 unless storm water controls are needed because the MS4 is contributing to a water quality impairment. The permitting authority may also waive permit coverage for MS4s serving a jurisdiction with a population of less than 10,000 if all waters that receive a discharge from the MS4 have been evaluated and discharges from the MS4 do not significantly contribute to a water quality impairment or have the potential to cause an impairment. The Phase II rule also allows States with a watershed permitting approach to phase in coverage for MS4s in jurisdictions with populations under 10,000.

EPA's Rationale for Basing Regulation on Census-Determined Population Rather Than a Water Quality Threshold

EPA adopted the Bureau of the Census definition of "urbanized area" for the purposes of the Phase II rule. The existing storm water Phase I rule already covers discharges from MS4s with more than 100,000 population. Phase II would address the remaining MS4s in urbanized areas.

The Bureau of the Census defines an urbanized area as comprising a place and the adjacent densely settled surrounding territory that together have a minimum population of 50,000 people. The densely settled surrounding territory generally has at least 1,000 people per square mile. The Bureau of the Census definition of "urbanized area," adopted by EPA for the purposes of the Phase II rule, was published in the Federal Register (55 FR 42592, October 22, 1990).

EPA is using urbanized areas to automatically designate regulated small MS4s on a nationwide basis for several reasons:

(1) Water Quality Impacts from Urban Runoff

Studies and data show a high correlation between degree of development/ urbanization and adverse impacts on receiving waters due to storm water. See section A below for a full discussion of storm water impacts due to urban development.

(2) Addresses gaps in coverage

The blanket coverage within the urbanized area encourages the watershed approach and addresses the problem of "donut-holes," where unregulated areas are surrounded by areas regulated under Phase I.

(3) Pollution Prevention

This approach targets present and future growth areas as a preventative measure to help ensure water quality protection. Urbanized areas have experienced significant growth over the past 50 years. According to EPA calculations based on Census data from 1980 to 1990, the national average rate of growth in the United States during that 10-year period was more than 4 percent. For the same period, the average rate of growth within urbanized areas was 15.7 percent and the average for outside of urbanized areas was just more than 1 percent. Table C below illustrates the growth of urbanized areas for the past five Census (EPA, 1995). The new development occurring in these growing areas can provide some of the best opportunities for implementing cost-effective storm water management controls.

Table C. Growth of Urbanized Areas in the United States Between 1950 and 1990

Year	Number of Urbanized Areas	Population in Urbanized Areas (millions)			Land Area (sq. mi.)
		Total	Central Cities	Urban Fringe	
1950	157	69.2	48.4	20.9	19,728
1960	213	95.8	57.9	37.8	25,544
1970	273	120.7	65.1	55.6	35,081
1980	366	139.2	67.0	72.1	52,017
1990	405	160.4	79.7	80.7	61,520

(4) Simplified Designation and Coverage

The determination of urbanized areas by the Bureau of the Census allows operators of small MS4s to quickly determine whether they are included in the NPDES storm water program as a regulated small MS4.

Using urbanized areas as a basis for designation effectively targets resources to the most densely developed territory. The 405 urbanized areas in the United States cover only 2 percent of the total U.S. land areas yet contain approximately 63 percent of the nation's population.

Documentation of Water Quality Problems Due to Storm Water Runoff from Urbanized Areas

EPA has compiled a number of studies demonstrating that storm water runoff is generally a problem in urbanized areas. This information is divided into storm water impacts due to urban development (section A below) and other discharges to municipal storm sewers (section B below). The Appropriations Act specifically requested that this report provide "documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000." While 50,000 is the population threshold used by the Bureau of the Census for defining urbanized areas and EPA adopted the Census definition for the purpose of automatic designation in the Phase II rule, the studies below indicate that water quality impacts will occur in these areas and potentially in areas with lower population densities as well. The Phase II rule would allow the lower population density areas to be designated on a case by case basis.

A. Storm Water Impacts Due to Urban Development

EPA's 1995 Storm Water Phase II Report to Congress (EPA, 1995) and the Coastal Zone Management Measures Guidance (EPA, 1992) describe the impacts from urbanization. Urbanization impacts water quality principally through changes in hydrology and increases in pollutant loadings. Increases in population density and imperviousness due to urbanization can result in significant changes to stream hydrology including:

- increased peak discharges compared to predevelopment levels;
- increased volume of urban runoff produced by each storm in comparison to predevelopment conditions;
- decreased time needed for runoff to reach the stream, particularly if extensive drainage improvements are made;
- increased frequency and severity of flooding;
- reduced streamflow during prolonged periods of dry weather due to reduced level of infiltration in the watershed;
- greater runoff velocity during storms due to the combined effects of higher peak discharges, rapid time of concentration, and the smoother hydraulic surfaces that occur as a result of development.

An increase in imperviousness can also significantly decrease the amount of water infiltration, reducing groundwater recharge.

The types of pollutants found in urban runoff include sediment, nutrients, oxygen-demanding substances, pathogens, road salts, hydrocarbons, heavy metals, and toxics. In addition, thermal impacts from increased temperature of urban runoff and loss of riparian habitat can severely impair aquatic organisms that have finely tuned temperature limits.

1. Urbanization and Imperviousness

Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving waterbodies (U.S. EPA, 1992). Urban development increases the amount of impervious surface in a watershed as farmland, forests, and meadowlands with natural infiltration characteristics are converted into buildings with rooftops, driveways, sidewalks, roads, and parking lots with virtually no ability to absorb storm water. Storm water and snow-melt runoff wash over these impervious areas, picking up pollutants along the way while gaining speed and volume because of their inability to disperse and filter into the ground. What results are storm water flows that are higher in volume, pollutants, and temperature than the flows in less impervious areas, which have more natural vegetation and soil to filter the runoff (U.S. EPA, 1997. Urbanization and Streams: Studies of Hydrologic Impacts. EPA 841-R-97-009. Office of Water. Washington, DC).

Studies reveal that the level of imperviousness in an area strongly correlates with the quality of the nearby receiving waters. For example, a study in the Puget Sound lowland ecoregion found that when the level of basin development exceeded 5 percent of the total impervious area, the biological integrity and physical habitat conditions that are necessary to support natural biological diversity and complexity declined precipitously (May, C.W., E.B. Welch, R.R. Horner, J.R. Karr, and B.W. May. 1997. Quality Indices for Urbanization Effects in Puget Sound Lowland Streams, Technical Report No. 154. University of Washington Water Resources Series). Research conducted in numerous geographical areas, concentrating on various variables and employing widely different methods, has revealed a similar conclusion: stream degradation occurs at relatively low levels of imperviousness, such as 10 to 20 percent (even as low as 5 to 10 percent according to the findings of the Washington study referenced above) (Schueler, T.R. 1994. "The Importance of Imperviousness." Watershed Protection Techniques 1(3); May, C., R.R. Horner, J.R. Karr, B.W. Mar, and E.B. Welch. 1997. "Effects Of Urbanization On Small Streams In The Puget Sound Lowland Ecoregion." Watershed Protection Techniques 2(4); Yoder, C.O., R.J. Miltner, and D. White. 1999. "Assessing the Status of Aquatic Life Designated Uses in Urban and Suburban Watersheds." In Proceedings: National Conference on Retrofits Opportunities in Urban Environments. EPA 625-R-99-002, Washington, DC; Yoder, C.O and R.J. Miltner. 1999. "Assessing Biological Quality and Limitations to Biological Potential in Urban and Suburban Watersheds in Ohio." In Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers, Auckland, New Zealand). Furthermore, research has indicated that few, if any, urban streams can support diverse benthic communities at imperviousness levels of 25 percent or more. An area of medium density single family homes can be anywhere from 25 percent to nearly 60 percent impervious, depending on the design of the streets and parking (Schueler, 1994).

In addition to impervious areas, urban development creates new pollution sources as population density increases and brings with it proportionately higher levels of car emissions, car maintenance wastes, pet waste, litter, pesticides, and household hazardous wastes, which may be washed into receiving waters by storm water or dumped directly into storm drains designed to discharge to receiving waters. More people in less space results in a greater concentration of pollutants that can be mobilized by, or disposed into, storm water discharges from municipal separate storm sewer systems. A modeling system developed for the Chesapeake Bay indicated that contamination of the Bay and its tributaries from runoff is comparable to, if not greater than, contamination from industrial and sewage sources (Cohn-Lee, R. and D. Cameron. 1992. "Urban Stormwater Runoff Contamination of the Chesapeake Bay: Sources and Mitigation." The Environmental Professional, Vol. 14).

2. Large-Scale Studies and Assessments

In support of Phase II's regulatory designation of MS4s in urbanized areas, the Agency relied on broad-based assessments of urban storm water runoff and related water quality impacts, as well as more site-specific studies. The first national assessment of urban runoff characteristics was completed for the Nationwide Urban Runoff Program (NURP) study (U.S. EPA. 1983.

Results of the Nationwide Urban Runoff Program. Volume 1 - Final Report. Office of Water. Washington, D.C.). The NURP study is the largest nationwide evaluation of storm water discharges, which includes adverse impacts and sources, undertaken to date.

EPA conducted the NURP study to facilitate understanding of the nature of urban runoff from residential, commercial, and industrial areas. One objective of the study was to characterize the water quality of discharges from separate storm sewer systems that drain residential, commercial, and light industrial (industrial parks) sites. Storm water samples from 81 residential and commercial properties in 22 urban/suburban areas nationwide were collected and analyzed during the 5-year period between 1978 and 1983. The majority of samples collected in the study were analyzed for eight conventional pollutants and three heavy metals.

Data collected under the NURP study indicated that discharges from separate storm sewer systems draining runoff from residential, commercial, and light industrial areas carried more than 10 times the annual loadings of total suspended solids (TSS) than discharges from municipal sewage treatment plants that provide secondary treatment. The NURP study also indicated that runoff from residential and commercial areas carried somewhat higher annual loadings of chemical oxygen demand (COD), total lead, and total copper than effluent from secondary treatment plants. Study findings showed that fecal coliform counts in urban runoff typically range from tens to hundreds of thousands per hundred milliliters of runoff during warm weather conditions, with the median for all sites being around 21,000/100 ml. This is generally consistent with studies that found that fecal coliform mean values range from 1,600 coliform fecal units (CFU)/100 ml to 250,000 cfu/100 ml (Makepeace, D.K., D.W. Smith, and S.J. Stanley. 1995. "Urban Storm Water Quality: Summary of Contaminant Data." Critical Reviews in Environmental Science and Technology 25(2):93-139). Makepeace, et al., summarized ranges of contaminants from storm water, including physical contaminants such as total solids (76 - 36,200 mg/L) and copper (up to 1.41 mg/L); organic chemicals; organic compounds, such as oil and grease (up to 110 mg/L); and microorganisms.

Monitoring data summarized in the NURP study provided important information about urban runoff from residential, commercial, and light industrial areas. The study concluded that the quality of urban runoff can be affected adversely by several sources of pollution that were not directly evaluated in the study, including illicit discharges, construction site runoff, and illegal dumping. Data from the NURP study were analyzed further in the U.S. Geological Survey (USGS) Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States study (Driver, N.E., M.H. Mustard, R.B. Rhinesmith, and R.F. Middleburg. 1985. U.S. Geological Survey Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States. Report No. 85-337 USGS. Lakewood, CO). The USGS report summarized additional monitoring data compiled during the mid-1980s, covering 717 storm events at 99 sites in 22 metropolitan areas and documented problems associated with metals and sediment concentrations in urban storm water runoff. More recent reports have confirmed the pollutant concentration data collected in the NURP study (Marsalek, J. 1990. "Evaluation of Pollutant Loads from Urban Nonpoint Sources." Wat. Sci. Tech. 22(10/11):23-30; Makepeace, et al., 1995).[4]

America's Clean Water - the States' Nonpoint Source Assessment (Association of State and Interstate Water Pollution Control Administrators (ASIWPCA). 1985. America's Clean Water - The States' Nonpoint Source Assessment. Prepared in cooperation with the U.S. EPA, Office of Water, Washington, DC), a comprehensive study of diffuse pollution sources conducted under the sponsorship of the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) and EPA revealed that 38 States reported urban runoff as a major cause of designated beneficial use impairment and 21 States reported storm water runoff from construction sites as a major cause of beneficial use impairment. In addition, the 1996 305(b) Report (U.S. EPA. 1998. The National Water Quality Inventory, 1996 Report to Congress. EPA 841-R-97-008. Office of Water. Washington, DC), provides a national assessment of water quality based on biennial reports submitted by the States as required under CWA section 305(b) of the CWA. In the CWA 305(b) reports, States, Tribes, and Territories assess their individual water quality control programs by examining the attainment or nonattainment of the designated uses assigned to their rivers, lakes, estuaries, wetlands, and ocean shores. A designated use is the legally applicable use specified in a water quality standard for a watershed, waterbody, or segment of a waterbody. The designated use is the desirable use that the water quality should support. Examples of designated uses include drinking water supply, primary contact recreation (swimming), and aquatic life support. Each CWA 305(b) report indicates the assessed fraction of a State's waters that are fully supporting, partially supporting, or not supporting designated beneficial uses.

In their reports, States, Tribes, and Territories first identified and then assigned the sources of water quality impairment for each impaired waterbody using the following categories: industrial, municipal sewage, combined sewer overflows, urban runoff/storm sewers, agricultural, silvicultural, construction, resource extraction, land disposal, hydrologic modification, and habitat modification. The 1996 Inventory, based on a compilation of 60 individual 305(b) reports submitted by States, Tribes, and Territories, assessed the following percentages of total waters nationwide: 19 percent of river and stream miles; 40 percent of lake, pond, and reservoir acres; 72 percent of estuary square miles; and 6 percent of ocean shoreline waters. The 1996 Inventory indicated that approximately 40 percent of the Nation's assessed rivers, lakes, and estuaries are impaired. Waterbodies deemed as "impaired" are either partially supporting designated uses or not supporting designated uses.

The 1996 Inventory also found urban runoff/discharges from storm sewers to be a major source of water quality impairment nationwide. Urban runoff/storm sewers were found to be a source of pollution in 13 percent of impaired rivers; 21 percent of impaired lakes, ponds, and

---

[4] EPA notes that it is not relying solely on the NURP study to describe current water quality impairment. Rather, EPA is citing NURP as a source of data on typical pollutant concentrations in urban runoff. Recent studies have not found significantly different pollutant concentrations in urban runoff compared to the original NURP data (see Makepeace, et al., 1995; Marsalek, 1990; and Pitt, et al., 1995).

reservoirs; and 45 percent of impaired estuaries (second only to industrial discharges). In addition, urban runoff was found to be the leading cause of ocean impairment for those ocean miles surveyed.

In addition, a recent USGS study of urban watersheds across the United States has revealed a link between urban development and contamination of local waterbodies. The study found the highest levels of organic contaminants, known as polycyclic aromatic hydrocarbons (PAHs) (products of combustion of wood, grass, and fossil fuels), in the reservoirs of urbanized watersheds (U.S. Geological Survey (USGS). 1998. Research Reveals Link Between Development and Contamination in Urban Watersheds. USGS news release. USGS National Water-Quality Assessment Program).

Urban storm water also can contribute significant amounts of toxicants to receiving waters. Pitt, et. al. (1993), found heavy metal concentrations in the majority of samples analyzed. Industrial or commercial areas were likely to be the most significant pollutant source areas (Pitt, R., R. Field, M. Lalor, M. Brown 1993. "Urban stormwater toxic pollutants: assessment, sources, and treatability" Water Environment Research, 67(3):260-75).

3. Local and Watershed-Based Studies

In addition to the large-scale nationwide studies and assessments, a number of local and watershed-based studies from across the country have documented the detrimental effects of urban storm water runoff on water quality. A study of urban streams in Milwaukee County, Wisconsin, found local streams to be highly degraded due primarily to urban runoff, while three studies in the Atlanta, Georgia, region were characterized as being "the first documentation in the Southeast of the strong negative relationship between urbanization and stream quality that has been observed in other ecoregions" (Masterson, J. and R. Bannerman. 1994. "Impacts of Storm Water Runoff on Urban Streams in Milwaukee County, Wisconsin." Paper presented at National Symposium on Water Quality: American Water Resources Association; Schueler, T.R. 1997. "Fish Dynamics in Urban Streams Near Atlanta, Georgia." Technical Note 94. Watershed Protection Techniques 2(4)). Several other studies, including those performed in Arizona (Maricopa County), California (San Jose's Coyote Creek), Massachusetts (Green River), Virginia (Tuckahoe Creek), and Washington (Puget Sound lowland ecoregion), all had the same finding: runoff from urban areas greatly impair stream ecology and the health of aquatic life; the more heavily developed the area, the more detrimental the effects (Lopes, T. and K. Fossum. 1995. "Selected Chemical Characteristics and Acute Toxicity of Urban Stormwater, Streamflow, and Bed Material, Maricopa County, Arizona." Water Resources Investigations Report 95-4074. USGS; Pitt, R. 1995. "Effects of Urban Runoff on Aquatic Biota." In Handbook of Ecotoxicology; Pratt, J. and R. Coler. 1979. "Ecological Effects of Urban Stormwater Runoff on Benthic Macroinvertebrates Inhabiting the Green River, Massachusetts." Completion Report Project No. A-094. Water Resources Research Center. University of Massachusetts at Amherst.; Schueler, T.R. 1997. "Historical Change in a Warmwater Fish Community in an Urbanizing Watershed." Technical Note 93. Watershed Protection Techniques 2(4); May, C., R. Horner, J.

Karr, B. Mar, and E. Welch. 1997. "Effects Of Urbanization On Small Streams In The Puget Sound Lowland Ecoregion." Watershed Protection Techniques 2(4)).

Pitt and others also described the receiving water effects on aquatic organisms associated with urban runoff (Pitt, R.E. 1995. "Biological Effects of Urban Runoff Discharges" In Stormwater Runoff and Receiving Systems: Impact, Monitoring, and Assessment, ed. E.E Herricks, Lewis Publishers; Crunkilton, R., J. Kleist, D. Bierman, J. Ramcheck, and W. DeVita. 1999. "Importance of Toxicity as a Factor Controlling the Distribution of Aquatic Organisms in an Urban Stream." In Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers. Auckland, New Zealand).

In Wisconsin, runoff samples were collected from streets, parking lots, roofs, driveways, and lawns. Source areas were broken up into residential, commercial, and industrial. Geometric mean concentration data for residential areas included total solids of about 500-800 mg/L from streets and 600 mg/L from lawns. Fecal coliform data from residential areas ranged from 34,000 to 92,000 cfu/100 mL for streets and driveways. Contaminant concentration data from commercial and industrial source areas were lower for total solids and fecal coliform, but higher for total zinc (Bannerman, R.T., D.W. Owens, R.B. Dods, and N.J. Hornewer. 1993. "Sources of Pollutants in Wisconsin Stormwater." Wat. Sci. Tech. 28(3-5):241-59).

Bannerman, et al. also found that streets contribute higher loads of pollutants to urban storm water than any other residential development source. Two small urban residential watersheds were evaluated to determine that lawns and streets are the largest sources of total and dissolved phosphorus in the basins (Waschbusch, R.J., W.R. Selbig, and R.T. Bannerman. 1999. "Sources of Phosphorus in Stormwater and Street Dirt from Two Urban Residential Basins In Madison, Wisconsin, 1994-95." Water Resources Investigations Report 99-4021. U.S. Geological Survey). A number of other studies have indicated that urban roadways often contain significant quantities of metal elements and solids (Sansalone, J.J. and S.G. Buchberger. 1997. "Partitioning and First Flush of Metals in Urban Roadway Storm Water." ASCE Journal of Environmental Engineering 123(2); Sansalone, J.J., J.M. Koran, J.A. Smithson, and S.G. Buchberger. 1998. "Physical Characteristics of Urban Roadway Solids Transported During Rain Events" ASCE Journal of Environmental Engineering 124(5); Klein, L.A., M. Lang, N. Nash, and S.L. Kirschner. 1974. "Sources of Metals in New York City Wastewater" J. Water Pollution Control Federation 46(12):2653-62; Barrett, M.E, R.D. Zuber, E.R. Collins, J.F. Malina, R.J. Charbeneau, and G.H Ward., 1993. "A Review and Evaluation of Literature Pertaining to the Quantity and Control of Pollution from Highway Runoff and Construction." Research Report 1943-1. Center for Transportation Research, University of Texas, Austin).

4. Beach Closings/Advisories

Urban wet weather flows have been recognized as the primary sources of estuarine pollution in coastal communities. Urban storm water runoff, sanitary sewer overflows, and combined sewer overflows have become the largest causes of beach closings in the United States in the past three years. Storm water discharges from urban areas not only pose a threat to the ecological environment, they also can substantially affect human health. A survey of coastal and Great Lakes communities found that more than 1,500 beach closings and advisories where attributable to storm water runoff in 1998 (Natural Resources Defense Council. 1998. "Testing the Waters Volume VIII-Has Your Vacation Beach Cleaned Up Its Act?" New York, NY). Other reports also document public health, shellfish bed, and habitat impacts from storm water runoff, including more than 823 beach closings/advisories issued in 1995 and more than 407 beach closing/advisories issued in 1996 due to urban runoff (Natural Resources Defense Council. 1996. Testing the Waters Volume VI: Who Knows What You're Getting Into. New York, NY; NRDC. 1997. Testing the Waters Volume VII: How Does Your Vacation Beach Rate. New York, NY; Morton, T. 1997. Draining to the Ocean: The Effects of Stormwater Pollution on Coastal Waters. American Oceans Campaign, Santa Monica, CA). The Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay (Haile, R.W., et. al. 1996. "An Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay." Final Report prepared for the Santa Monica Bay Restoration Project) concluded that there is a 57 percent higher rate of illness in swimmers who swim adjacent to storm drains than in swimmers who swim more than 400 yards away from storm drains. This and other studies document a relationship between gastrointestinal illness in swimmers and water quality, the latter of which can be heavily compromised by polluted storm water discharges.

B. Other Discharges to Municipal Storm Sewers

In addition to runoff from storm events, municipal separate storm sewer systems may receive and ultimately discharge other materials introduced into the system. Non-storm water discharges to storm sewers come from a variety of sources, including:

- illicit connections and cross connections from industrial, commercial, and sanitary sewage sources
- leaking sanitary sewage systems
- malfunctioning on-site disposal systems (septic systems)
- improper disposal of wastes such as used oil, wastewater and litter
- spills
- infiltration of ground water contaminated by a variety of sources, including leaking underground storage tanks
- wash waters, lawn irrigation, and other drainage sources.

Studies have shown that discharges from MS4s often include wastes and wastewater from non-storm water sources. Federal regulations (§ 122.26(b)(2)) define an illicit discharge as "...any discharge to an MS4 that is not composed entirely of storm water...," with some exceptions. These discharges are "illicit" because municipal storm sewer systems are not designed to accept, process, or discharge such wastes. Sources of illicit discharges include, but are not limited to,: sanitary wastewater; effluent from septic tanks; car wash, laundry, and other industrial wastewaters; improper disposal of auto and household toxics, such as used motor oil and pesticides; and spills from roadway and other accidents.

Illicit discharges enter the system through either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the MS4 from cracked sanitary systems, spills collected by drain outlets, and paint or used oil dumped directly into a drain). The result is untreated discharges that contribute high levels of pollutants, including heavy metals, toxics, oil and grease, solvents, nutrients, viruses and bacteria into receiving waterbodies. The NURP study, discussed earlier, found that pollutant levels from illicit discharges were high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health. The study noted particular problems with illicit discharges of sanitary wastes, which can be directly linked to high bacterial counts in receiving waters and can be dangerous to public health.

Because illicit discharges to MS4s can create severe widespread contamination and water quality problems, several municipalities and urban counties performed studies to identify and eliminate such discharges. In Michigan, the Ann Arbor and Ypsilanti water quality projects inspected 660 businesses, homes, and other buildings and identified 14 percent of the buildings as having improper storm sewer drain connections. The program assessment revealed that, on average, 60 percent of automobile-related businesses, including service stations, automobile dealerships, car washes, body shops, and light industrial facilities, had illicit connections to storm sewer drains. The program assessment also showed that a majority of the illicit discharges to the storm sewer system resulted from improper plumbing and connections, which had been approved by the municipality when installed (Washtenaw County Statutory Drainage Board. 1987. Huron River Pollution Abatement Program).

In addition, an inspection of urban storm water outfalls draining into Inner Grays, Washington, indicated that 32 percent of these outfalls had dry weather flows. Of these flows, 21 percent were determined to have pollutant levels higher than the pollutant levels expected in typical urban storm water runoff characterized in the NURP study (U.S. EPA. 1993. Investigation of Inappropriate Pollutant Entries Into Storm Drainage Systems -- A User's Guide. EPA 600/R-92/238. Office of Research and Development. Washington, DC). That same document reports a study in Toronto, Canada, that found that 59 percent of outfalls from the MS4 had dry-weather flows. Chemical tests revealed that 14 percent of these dry-weather flows were determined to be grossly polluted.

Inflows from aging sanitary sewer collection systems are one of the most serious illicit discharge-related problems. Sanitary sewer systems frequently develop leaks and cracks, resulting in discharges of pollutants to receiving waters through separate storm sewers. These pollutants include sanitary waste and materials from sewer main construction (e.g., asbestos cement, brick, cast iron, vitrified clay). Municipalities have long recognized the reverse problem of storm water infiltration into sanitary sewer collection systems; this type of infiltration often disrupts the operation of the municipal sewage treatment plant.

The improper disposal of materials is another illicit discharge-related problem that can result in contaminated discharges from separate storm sewer systems in two ways. First, materials may be disposed of directly in a catch basin or other storm water conveyance. Second, materials disposed of on the ground may either drain directly to a storm sewer or be washed into a storm sewer during a storm event. Improper disposal of materials to street catch basins and other storm sewer inlets often occurs when people mistakenly believe that disposal to such areas is an environmentally sound practice. Part of the confusion may occur because some areas are served by combined sewer systems, which are part of the sanitary sewer collection system, and people assume that materials discharged to a catch basin will reach a municipal sewage treatment plant. Materials that are commonly disposed of improperly include used motor oil; household toxic materials; radiator fluids; and litter, such as disposable cups, cans, and fast-food packages. EPA believes that there has been increasing success in addressing these problems through initiatives such as storm drain stenciling and recycling programs, including household hazardous waste special collection days.

Programs that reduce illicit discharges to separate storm sewers have improved water quality in several municipalities. For example, Michigan's Huron River Pollution Abatement Program found the elimination of illicit connections caused a measurable improvement in the water quality of the Washtenaw County storm sewers and the Huron River (Washtenaw County Statutory Drainage Board, 1987). In addition, an illicit detection and remediation program in Houston, Texas, has significantly improved the water quality of Buffalo Bayou. Houston estimated that illicit flows from 132 sources had a flow rate as high as 500 gal/min. Sources of the illicit discharges included broken and plugged sanitary sewer lines, illicit connections from sanitary lines to storm sewer lines, and floor drain connections (Glanton, T., M.T. Garrett, and B. Goloby. 1992. The Illicit Connection: Is It the Problem? Wat. Env. Tech. 4(9):63-8).

V. RATIONALE FOR USING A NPDES APPROACH

This section responds to the Appropriations Act's direction to provide a report containing:

"(4) information that supports the position of the Administrator that the Phase II stormwater program should be administered as part of the National Pollutant Discharge Elimination System under section 402 of the Federal Water Pollution Control Act (33 U.S.C. 1342)"

EPA interprets Clean Water Act section 402(p)(6) as authorizing the Agency to develop a storm water program for Phase II sources either as part of the existing NPDES permit program or as a stand alone non-NPDES program such as a self-implementing rule. Although EPA believes that it has the discretion to not require sources regulated under CWA section 402(p)(6) to be covered by NPDES permits, the Agency has determined, for the reasons discussed below, that it is most appropriate to use NPDES permits in implementing the program to address the sources designated for regulation in Phase II. EPA believes that the NPDES program best achieves the goals of the Phase II rule for the following reasons:

- Applying an NPDES permit approach to Phase II sources allows for consistent regulation between larger MS4s and construction sites regulated under Phase I and smaller sources regulated under Phase II.
- Use of NPDES permits to regulate Phase II municipalities will allow co-permitting of small regulated MS4s with larger MS4s regulated under the existing Phase I storm water program.
- The use of NPDES permits is a familiar regulatory implementation vehicle that is well understood by State regulators and potential permittees.
- NPDES permits provide the flexibility to allow the use of general permits on a watershed basis, while also allowing site-specific controls to be developed on a case-by-case basis.
- NPDES permits allow incorporation by reference of existing State, Tribal and local programs.
- NPDES permit applications and NOIs provide important information to regulatory authorities and the public.
- NPDES permit procedures include beneficial processes for citizen participation and enforcement.
- NPDES permits are federally enforceable under the CWA.

- NPDES permit coverage provides "permit as a shield" legal protection to the permittee.

- NPDES permit coverage provides an established and predictable regulatory regime to avoid duplicative regulation under the Resource Conservation and Recovery Act and the Comprehensive Emergency Response, Compensation, and Liability Act, due to exclusions from regulation for facilities subject to NPDES permits.

In developing an approach for the Phase II rule, individual members of both the FACA Committee and the Storm Water Phase II FACA Subcommittee encouraged EPA to seek opportunities to integrate, where possible, the proposed Phase II requirements with existing Phase I requirements, thus facilitating a unified and "seamless" storm water discharge control program. EPA believes that using the NPDES framework is the best means of integrating the regulation of Phase II sources with the existing storm water program. The NPDES framework is already applied to regulated storm water sources and can be extended to the sources to be regulated in Phase II. This approach facilitates program consistency, public access to information, and program oversight.

Requiring Phase II sources to be covered by NPDES permits would help address the consistency problems currently caused by municipal "donut holes." Donut holes are gaps in program coverage where a small unregulated MS4 is located next to or within a regulated larger MS4 that is subject to an NPDES permit under the existing NPDES storm water program. The existence of such "donut holes" creates an equity problem because similar discharges may remain unregulated even though they cause or contribute to the same adverse water quality impacts. Using NPDES permits to regulate the unregulated discharges in these areas is intended to facilitate the development of a seamless regulatory program for the mitigation and control of contaminated storm water discharges in an urbanized area. For example, the Phase II rule would allow a newly regulated MS4 to join as a "limited" co-permittee with a regulated MS4 by referencing a common storm water management program. Such cooperation should be further encouraged by the fact that the minimum control measures to be required in the Phase II rule for regulated small MS4s are very similar to a number of the permit requirements for medium and large MS4s under the existing storm water program. The minimum control measures applicable to discharges from smaller MS4s under Phase II are described with slightly more generality than under the Phase I permit application regulations for larger MS4s, thus enabling maximum flexibility for operators of smaller MS4s to optimize efforts to protect water quality.

The Phase II rule would also apply NPDES permit requirements to construction sites below 5 acres that are similar to the existing requirements for those 5 acres and above. In addition, the rule would allow compliance with qualifying local, Tribal, or State erosion and sediment controls to meet the erosion and sediment control requirements of the general permits for storm water discharges associated with construction, both above and below 5 acres.

Incorporating the CWA section 402(p)(6) program into the NPDES program capitalizes upon the existing governmental infrastructure for administration of the NPDES program.

Moreover, much of the regulated community already understands the NPDES program and the way it works.

Another goal of the NPDES program approach is to provide flexibility in order to facilitate and promote watershed planning and sensitivity to local conditions. The following are some of the more significant examples of the flexibility provided by the NPDES approach:

- NPDES general permits may be used to cover a category of regulated sources on a watershed basis or within political boundaries.
- The NPDES permitting process provides a mechanism for storm water controls tailored on a case-by-case basis, where necessary.
- The NPDES permit requirements of a permittee may be satisfied by another cooperating entity.
- NPDES permits may incorporate the requirements of existing State, Tribal and local programs, thereby accommodating State and Tribes seeking to coordinate the storm water program with other programs, including those that focus on watershed-based nonpoint source regulation.

NPDES permits generally require an application or a notice of intent to trigger coverage. This information exchange assures communication between the permitting authority and the regulated community. This communication is critical in ensuring that the regulated community is aware of the requirements and the permitting authority is aware of the potential for adverse impacts to water quality from identifiable locations. The NPDES permitting process includes the public as a valuable stakeholder and ensures that the public is included and information is made publicly available.

Another concern for EPA and several of the individual FACA Subcommittee members was that the program ensure citizen participation. The NPDES approach ensures opportunities for citizen participation throughout the permit issuance process, as well as in enforcement actions. NPDES permits are also federally enforceable under the CWA.

EPA believes that the use of NPDES permits makes a significant difference in the degree of compliance with regulations in the storm water program. The Agency does not anticipate that a self-implementing rule would ensure the degree of public participation needed for the development, enforcement and revision of the storm water management program. Citizen suit enforcement has assisted in focusing attention on adverse water quality impacts on a localized, public priority basis. Citizens frequently rely on the NPDES permitting process and the availability of NOIs to track program implementation and help them enforce regulatory requirements.

NPDES permits are also advantageous to the permittee. The NPDES permit informs the permittee about the scope of what it is expected do to be in compliance with the Clean Water Act. As explained more fully in EPA's April 1995 guidance, Policy Statement on Scope of Discharge Authorization and Shield Associated with NPDES Permits, compliance with an NPDES permit constitutes compliance with the Clean Water Act (see CWA section 402(k)). In addition, NPDES permittees are excluded from duplicative regulatory regimes under the Resource Conservation and Recovery Act and the Comprehensive Emergency Response, Compensation and Liability Act under RCRA's exclusions to the definition of "solid waste" and CERCLA's exemption for "federally permitted releases."

Throughout development of the rule, State representatives sought alternatives to the NPDES approach for State implementation of the storm water program for Phase II sources. Discussions focused on an approach whereby States could develop an alternative program that EPA would approve or disapprove based on identified criteria, including that the alternative non-NPDES program would result in "equivalent or better protection of water quality." The State representatives, however, were unable to propose or recommend criteria for gauging whether a program would provide equivalent protection. EPA also did not receive any suggestions for objective, workable criteria in response to the Agency's explicit request for specific criteria (by which EPA could objectively judge such programs) in the preamble to the proposed rule.

EPA also considered suggestions that the Agency authorize Phase II to be implemented as a self-implementing rule, which would be a regulation promulgated at the Federal, State, or Tribal level to control some or all of the storm water dischargers regulated under the Phase II rule. Under this approach, a rule would spell out the specific requirements for dischargers and impose the restrictions and conditions that would otherwise be contained in an NPDES permit. It would be effective until modified by EPA, a State, or a Tribe, unlike an NPDES permit which cannot exceed a duration of five years. Some stakeholders believed that this approach would reduce the burden on the regulated community (e.g., by not requiring permit applications), and considerably reduce the amount of additional paperwork, staff time and accounting required to administer the proposed permit requirements.

EPA is sensitive to the interest of some stakeholders in having a streamlined program that minimizes the burden associated with permit administration and maximizes opportunities for field time spent by regulatory authorities. Key provisions in the Phase II rule would address some of these concerns by promoting a streamlined approach to permit issuance by, for example, using general permits for coverage of Phase II permittees and allowing the incorporation of existing programs. By adopting the NPDES approach rather than a self-implementing rule, the Phase II rule also allows for consistent regulation between larger MS4s and construction sites regulated under the Phase I rule and smaller sources regulated under Phase II.

EPA believes that it is most appropriate to use NPDES permits to implement a program to address Phase II sources. In addition to the reasons discussed above, NPDES permits provide a better mechanism than would a self-implementing rule for tailoring storm water controls on a case-by-case basis, where necessary. A self-implementing rule would not ensure the degree of public participation that the NPDES permit process provides for the development, enforcement and revision of the storm water management program. A self-implementing rule also might not have provided the regulated community the "permit shield" under CWA section 402(k) that is provided by an NPDES permit. Based on all these considerations, EPA declined to adopt a self-implementing rule approach and adopted the NPDES approach for Phase II sources.

EPA-833-F-99-020
October 1999

EPA REDUCING POLLUTED RUNOFF: THE STORM WATER PHASE II RULE

As part of the Administration's ongoing efforts to curb polluted runoff, the Environmental Protection Agency (EPA) is finalizing a new rule to control storm water runoff from smaller storm sewer systems in urbanized areas and smaller construction sites. The second half of EPA's effort to control storm water, the storm water Phase II rule will make approximately 3,000 more miles of rivers safe for boating and protect up to 500,000 people a year from illness due to swimming in contaminated waters. Improving controls on storm water runoff will also prevent thousands of annual beach closures, make fish and seafood safer to eat, and reduce the costs of drinking water treatment.

Storm water runoff is polluting our waterways. When it rains or snows, the water that runs off of city streets, parking lots, and construction sites can wash sediment, oil, grease, toxics, pathogens, and other pollutants into nearby storm drains. Once this pollution has entered the sewer system, it is discharged–untreated–into local streams and waterways. Known as storm water runoff, this pollution is a leading threat to public health and the environment today.

Improving controls on storm water runoff. New regulations being finalized by EPA, known as storm water Phase II, will reduce the impacts of storm water runoff through a strengthened, yet flexible and cost-effective, storm water program. Phase I of the storm water program, which was promulgated in November 1990, covered municipal storm sewer systems serving populations over 100,000, construction sites above five acres, and industrial activities.

Expanding permit requirements for municipal storm sewer systems. Building upon the existing storm water program, storm water Phase II requires municipal storm sewer systems serving populations under 100,000 that are located in urbanized areas to obtain a National Pollutant Discharge Elimination System (NPDES) permit under the Clean Water Act. This will result in storm water controls for approximately 5,040 additional municipalities across the country. Types of controls could include public education programs, storm sewer inspections for illegal connections, and ordinances to control construction site runoff.

Providing flexibility for municipalities. The Phase II rule takes a "best management practice" approach, providing municipalities with the flexibility to decide what these practices should be. Municipal Phase II storm water programs are to be composed of six minimum control measures, including:

- public education and outreach;
- public involvement and participation;
- illicit discharge detection and elimination;

- construction site storm water runoff control;
- post-construction storm water management; and
- pollution prevention, or "good housekeeping," for municipal operations.

Municipalities may be able to use existing programs to satisfy these control measures, thereby avoiding program duplication. The use of general, rather than individual, permits is encouraged. There is permitting flexibility for municipal storm sewer systems serving under 10,000 people, including waivers and permit phase-in options. In addition, to control environmental and public health impacts, unregulated facilities and activities that are causing water quality impairments may be brought into the program and required to obtain a storm water permit on a case-by-case basis.

Controlling impacts of development. Storm water Phase II requires operators of construction sites disturbing one to five acres to obtain an NPDES permit. Sediment, which runs off of construction sites at a rate of anywhere between 20 and 150 tons/acre/year, has been identified as the single largest cause of impaired water quality in rivers and the third largest cause of impaired water quality in lakes. The additional coverage provided under the storm water Phase II rule will ensure that sediment discharges from more than 97 percent of the land disturbed by construction activity will be controlled under a storm water permit. Types of controls could include filter fences, storm drain inlet protections, and temporary mulching and seeding of exposed land areas.

Providing incentives for industrial facilities. For those industrial facilities currently covered under Phase I of the storm water program, the new rule provides incentives to protect operations from storm water exposure. At least 70,000 industrial facilities may be able to take advantage of this new provision by adopting practices to protect their operations from exposure to storm water impacts, such as covering operations under a storm resistant shelter.

Targeting polluted runoff–an Administration priority. The new storm water Phase II rule is a key action under the Administration's Clean Water Action Plan. A primary goal of the Clean Water Action Plan is to strengthen controls for polluted runoff, the leading remaining cause of water pollution today.

*****

The storm water Phase II rule was proposed by EPA in January 1998 and received more than 500 comments during a 90 day comment period. EPA will provide a 'tool box' to facilitate implementation, including fact sheets, federal financing programs, guidance, training, research and additional support. Municipalities and construction sites will have up to three years and 90 days from the date the new rule takes affect to obtain a storm water permit. For more information on storm water Phase II, please call (202) 260-5816, e-mail your questions to sw2@epa.gov or visit EPA's website at http://www.epa.gov/owm/sw/phase2 on the Internet.

TABLE OF CONTENTS

SECTION 1: INTRODUCTION

SECTION 2: STORMWATER MANAGEMENT REQUIREMENTS

SECTION 3: STORMWATER BEST MANAGEMENT PRACTICES

List of Tables

List of Figures

SECTION 1: INTRODUCTION

1.1 Purpose

The purpose of the Stormwater Management Manual is to provide engineers, developers, property owners and managers, and interested citizens with information on stormwater management requirements, technical guidance on the methodology that can be used to meet the requirements, and guidelines for designing, implementing, and maintaining Best Management Practices (BMPs) that may be used in the City of Greensboro to improve the quality of surface waters, and minimize the stormwater runoff volume and discharge rates from developed areas. This manual will explain the need for stormwater management in Greensboro and describe the minimum design requirements and accepted methodology for meeting City ordinance requirements. The manual also includes a comprehensive review of the most effective BMPs currently used for stormwater management: which BMPs work best for different development scenarios, which BMPs may be implemented to meet different regulatory requirements, and those BMPs that can be used to receive credit on the stormwater utility fee. The manual provides design, installation, and maintenance guidelines for various BMPs to increase the options for stormwater BMPs and to improve BMP's water quality functionality, ease of maintenance, and longevity.

This manual is not intended to stifle creativity of the designer; rather the City encourages and is open to reviewing new procedures, techniques, and stormwater best management practices where they can be shown to be appropriate by the design professional. While the City intends to develop stormwater quantity and quality management master plans for all watersheds within the city limits to serve as guidance for drainage system and best management practice design, the responsibility for adequate and appropriate stormwater management control measures for a given site remains with the qualified design professional.

Because urban stormwater quantity and quality management is a relatively new practice, design guidelines will likely be changing in the future as the needs for each watershed and sub-watershed are determined in the master planning process, new technologies are developed based information obtained from long-term monitoring data, and changes occur in regulatory requirements. The City will strive to keep this manual updated to allow for increased flexibility and efficiency in stormwater management.

1.2 Need for Stormwater Management

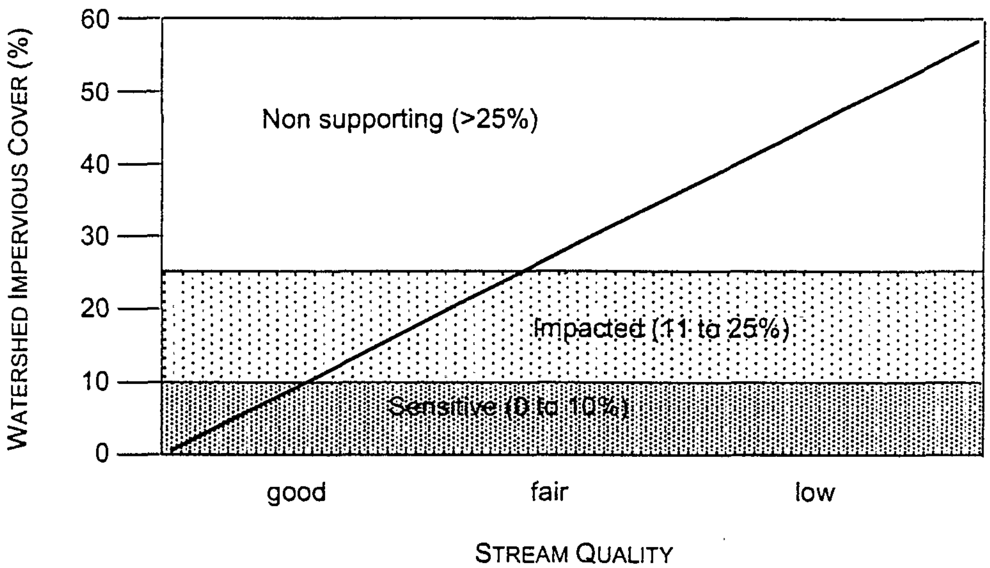
1.2.1 Effects of Urbanization on Watershed Hydrology and Pollutant Loading

Changes in the land use in Greensboro resulting from urbanization have affected the regional hydrology and pollutant loading in stormwater runoff. This has resulted in increased stormwater quantity and quality problems including:

⇨ degradation of overall water quality
⇨ floodplain expansion
⇨ increased flooding frequency
⇨ stream channel enlargement and erosion
⇨ changes in stream flow patterns (high storm flows, low dry weather flow)
⇨ loss of stream habitat
⇨ decline in stream biological function
⇨ property damage and safety concerns
⇨ unsightly stream channel conditions

Research has generally shown that impacts to surface waters are directly related to watershed imperviousness and that impacts can begin to be significant when the watershed reaches the threshold value of 10% imperviousness (Figure 1.1).

Figure 1.1: Relationship Between Impervious Cover and Stream Quality



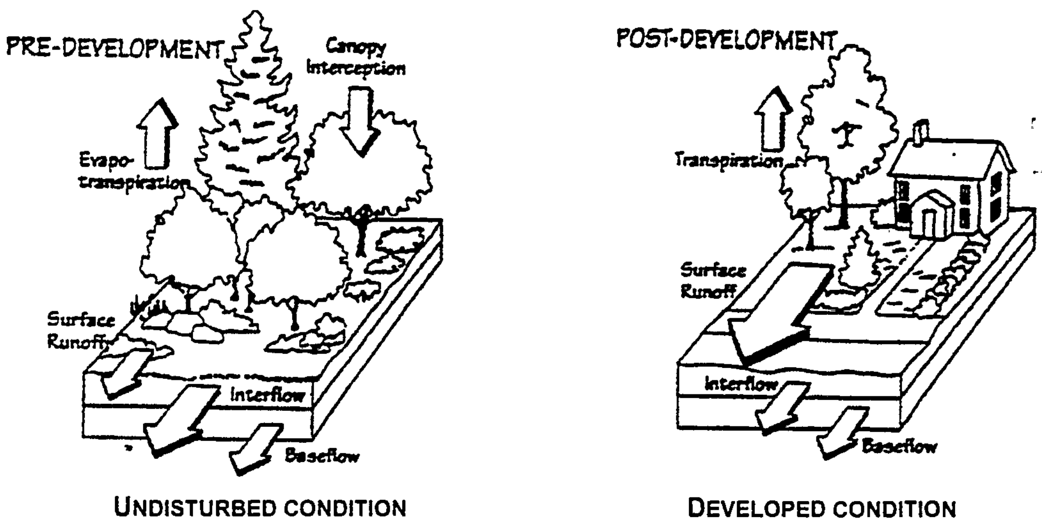
SOURCE: SCHUELER

Watershed Hydrology

Undisturbed areas have vegetation and organic topsoil that intercept precipitation and a natural topography that consists of small depressions that store precipitation and allow a significant fraction of precipitation to infiltrate into the ground. As these areas are developed, the vegetation and organic topsoil are stripped away, the complex natural topography is graded to uniform slopes, the soil is tightly compacted by heavy construction equipment, and impervious areas such as streets, sidewalks, parking lots, and buildings cover the landscape. As a result, much less water has a chance to infiltrate into the soil and therefore, the quantity of stormwater runoff drastically increases after the site is developed (Figure 1.2).

To manage the higher rates and larger volumes of runoff, drainage systems have historically been designed to remove the stormwater from developed areas as quickly as possible. This practice adequately served its purposes during the early days of Greensboro's development. However, the recent urbanization and corresponding increased runoff has produced drastic changes to stream channel geometry, stream hydrology, and floodplain expansion.

Figure 1.2: Changes in Water Balance due to Urbanization

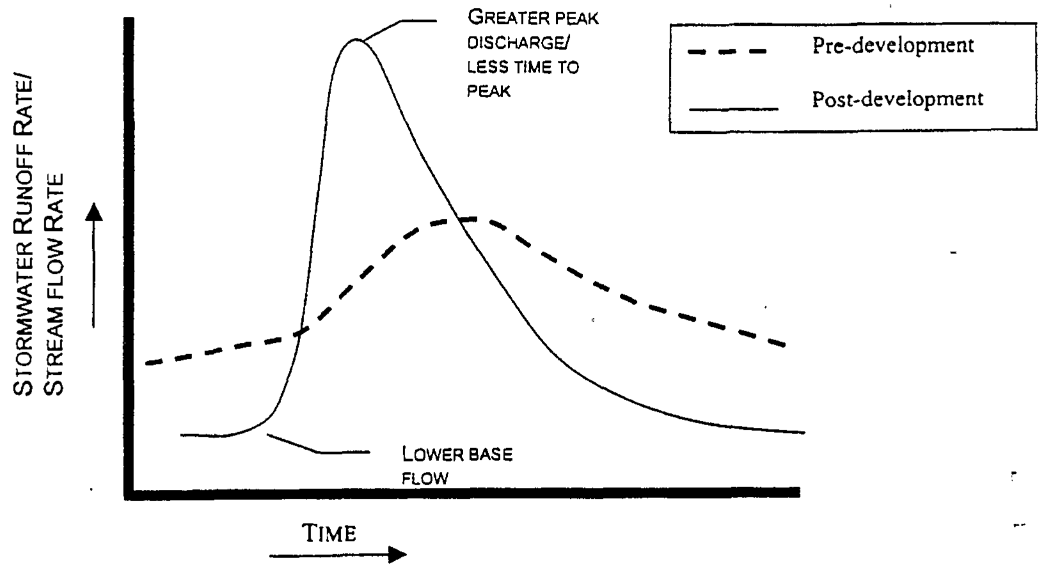


Source: CONTROLLING URBAN RUNOFF, METROPOLITAN WASHINGTON COUNCIL OF GOVERNMENTS

As higher flowrates are experienced in streams (Figure 1.3), streams naturally increase their cross sectional area to accommodate the increased flow. The stream will deepen and widen, often resulting in high vertical banks that are unstable. As the watershed continues to urbanize, the stream will continue to erode away its channel banks and bottom.

Stream erosion contributes to water quality problems by increasing the sediment loading in the stream flow which increases turbidity, degrades aquatic habitat, and fills in slow moving surface waters more rapidly. Also, eroded banks have created unsightly conditions and, in some cases, damage to adjacent public and private property, as well as a potential safety hazard.

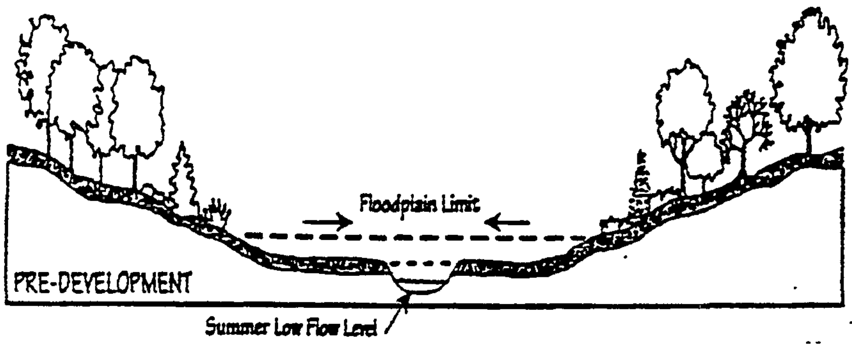
Figure 1.3: Changes in Hydrology due to Urbanization



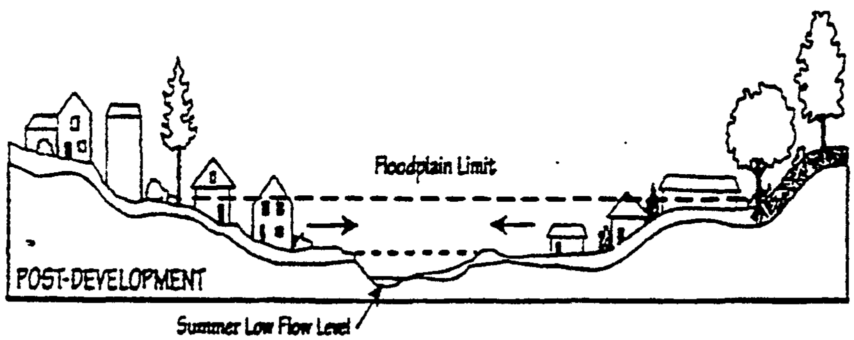
As previously stated, in urban areas the majority of precipitation is converted to surface runoff that quickly discharges to the stream. Thus, the infiltration of precipitation into the soil is significantly reduced which results in lower groundwater (base) flow. The base flow supplies streams with steady flow during dry periods. This reduction in base flow may cause streams that used to be normally wet during the year to "dry up" and only convey runoff during and shortly after a rain storm event. The aquatic habitat in the stream section may not be able to survive. In larger urban streams the quantity and depth of stream flow during dry periods will generally be less, which may impact the diversity of fish habitat and their ability of passage.

In addition, the increased stream flow volumes and rates associated with stormwater from urbanized areas tends to produce more frequent floods and cause expansion of the floodplain. For example, areas that were previously flooded only once during five years may flood every year, or even several times each year. Also, areas that were previously not flooded now may be within the floodplain and those properties in the floodplain will experience higher flood levels, as shown in Figure 1.4.

Figure 1.4: Changes in Floodplain due to Urbanization



PRE-DEVELOPMENT FLOODPLAIN



POST-DEVELOPMENT FLOODPLAIN

Pollutant Loading

In addition to the changes in watershed hydrology, urbanization has adversely impacted surface water quality through pollution transported by stormwater runoff. According to EPA's report to Congress, urban runoff is the number two source of pollution in lakes and estuaries and the number three source of pollution in rivers (Horsely, 1997). Examples of pollution associated with urban stormwater runoff are shown in Table 1.1.

The City has performed monitoring studies to determine the effects that urbanization has on pollutant loading in stormwater runoff. The studies included collecting runoff samples from different land use areas within the City of Greensboro and determining the concentration of various pollutants. Table 1.2 summarizes some of the monitoring data collected between April 1995 and October 1998.

Table 1.1: Examples of Pollution in Urban Runoff	
POLLUTANTS	**EXAMPLES**
Floatables	Litter such as paper cups and plastic bags
Bacteria	Leaking sanitary sewers; septic tanks; animal wastes
Oil and grease	Vehicle drippings; improper disposal
Nutrients	Fertilizers; sanitary sewer leaks
Pesticides	Outdoor applications
Metals	Vehicle parts wear (brakes, tires, engine parts), paint
Thermal impacts	Runoff from impervious surfaces; loss of stream canopy

TABLE 1.2: POLLUTANT EVENT MEAN CONCENTRATIONS (MG/L) FOR DIFFERENT LAND USES IN GREENSBORO			
POLLUTANT	**COMMERCIAL[1]**	**RESIDENTIAL[2]**	**OPEN[3]**
Cadmium	0.0009	0.0003	0.0003
Copper	0.02	0.01	0.003
Lead	0.02	0.024	0.005
Zinc	0.22	0.01	0.02
Ammonia Nitrogen	0.65	0.51	0.50
Biochemical Oxygen Demand 5-Day (BOD)	33.92	20.79	6.25
Chemical Oxygen Demand (COD)	99.79	86.26	33.13
Nitrate	1.48	0.76	0.19
Dissolved Phosphorus	0.38	0.31	0.26
Total Phosphorus	0.66	0.35	0.29
Total Dissolved Solids (TDS)	120	98	90
Total Suspended Solids (TSS)	157	87	45
Total Kjeldahl Nitrogen (TKN)	2.1	1.46	0.53

[1] Heavy Commercial Land Use – 90% imperviousness
[2] Residential/Institutional Land Use – 50% imperviousness
[3] Open Park/Undisturbed Land Use – 2% imperviousness

From Table 1.2 it can be seen that pollutant concentrations generally increase as urbanization intensifies.

Urbanization has major impacts on the hydrology of watersheds in the City and the quality of our limited water resources. For this reason, it is crucial that stormwater BMPs be implemented to help offset the impacts of development through proper management of pollutant sources and stormwater runoff.

1.2.2 Stormwater Management Regulations and Policies

To address the adverse effects of urbanization on water quality, Federal, State and local regulations have been adopted to protect the quality of surface waters. In the past, regulations targeted point source discharges such as effluent from wastewater treatment facilities, but now regulations also require pollution control of stormwater runoff.

NPDES Discharge Permits

With the Clean Water Act, the EPA mandated that it is illegal to discharge any pollutant to "waters of the United States" without a National Pollutant Discharge Elimination System (NPDES) Permit.

Industrial Stormwater Permit
Stormwater runoff from "Industrial Activities" is considered a discharge that is illegal without an NPDES Permit. Generally, the Industrial NPDES Permit requires certain industries to develop and implement a Stormwater Pollution Prevention Plan (SWPPP), which includes various BMPs to minimize pollution to surface waters.

Municipal Stormwater Permit
The City of Greensboro and other municipalities with a population over 100,000 (Phase I cities) are required to obtain a NPDES Municipal Separate Storm Sewer System (MS4) Discharge Permit. The Permit requires the development and implementation of a Storm Water Quality Management Program (SWQMP) to control the discharge of pollutants from the municipal separate storm sewer system to the maximum extent practicable. The City of Greensboro established the Storm Water Services Division to administer and manage this program. Storm Water Services is responsible for monitoring of water quality in streams, stormwater master planning, providing public environmental education, implementation of capital improvement projects, and other activities aimed at improving the quality of our surface waters and management of stormwater runoff.

To fund the Storm Water Services Division, a stormwater utility fee is assessed on all properties within city limits. Residential properties are assessed a flat rate, while non-residential properties are assessed a fee based on the amount of impervious area that exists on the property.

Water Supply Watershed Protection Requirements

The City of Greensboro utilizes and depends on a series of lakes on the Reedy Fork Creek in the northern region of the city for its drinking water supply. Due to rapid development in the watershed of the water-supply lakes, Guilford County and subsequently the City adopted a Water Supply Watershed Protection Ordinance in the mid 1980s to protect the Reedy Fork (Greensboro) watershed (refer to Appendix A for maps showing the Greensboro watershed). There are other protected drinking water supply watersheds besides the Reedy Fork watershed where a portion of the watershed is within the jurisdictional boundaries of the City. A portion of High Point, Randleman Lake, and Burlington watersheds are regulated by the City of Greensboro.

In the early 1990s, the State of North Carolina adopted regulations that set forth minimum watershed management requirements to protect drinking water supplies and required local governments to adopt and enforce these regulations within their water supply protection ordinance. In 1999, the State set forth new regulations for increased protection of the Upper and Lower Randleman watersheds. These regulations were adopted in the City's ordinance in December 1999 (see Appendix A). The State regulations serve to protect water supply reservoirs and their watersheds by imposing restrictions on "new development" in the following ways:

- ⇨ **limits on built-upon area**
- ⇨ **use of stormwater BMPs**
- ⇨ **protection of buffers along streams and lakes**

To enforce these regulations, the City requires that before any new development or re-development activities begin on a site located within a protected water supply watershed, a *Watershed Development Plan* must be submitted to the City for approval. The Watershed Development Plan, when required, should be incorporated into the *Stormwater Management Plan* as described in the following section.

The Watershed Development Plan must show that built-upon surfaces do not exceed the maximum percentage of built-upon area allowed. Built-upon area includes all impervious surfaces but also includes some areas that are partially impervious (e.g. gravel areas, dirt roads, etc.). The amount of built-upon area that is allowed on new development sites in a particular watershed depends on the classification of the watershed.

For "high density" development sites, the Watershed Development Plan must show how structural BMPs will be implemented to improve the quality of runoff from the site. The structural BMPs must be proven facilities and at a minimum meet the design criterion of

85% removal of total suspended solids (TSS) from runoff resulting from the first one inch of rainfall.

For "low density" development sites in the General Watershed Area, the Watershed Development Plan must indicate that the site design will minimize impacts to the environment. A passing score on the "General Watershed Area Performance Scoresheet" is required before a "low density" development can be approved for watershed protection. Low density development in the watershed critical area has different requirements.

The Watershed Development Plan must also show buffers along streams that are required to be protected. The type of streams that are required to be protected and the development activity that is allowed in the buffer may differ in each watershed.

This manual gives guidance on site design techniques to reduce impacts to the water-supply watersheds, and design criteria for structural BMPs to meet the requirements for high-density development. For items required on the Watershed Development Plan refer to Section 2. For more information on specific regulations in the water supply watersheds, refer to Section 2 of this manual and the City's water supply watershed protection ordinance, which can be viewed online at *www.ci.greensboro.nc.us.*

Storm Water Management Ordinance

Chapter 27 of the City Code of Ordinances is the Storm Water Management Ordinance. The main objective of this ordinance is to provide enforcement authority to meet the City's municipal NPDES Permit and associated SWQMP.

Another key objective of this ordinance is to protect properties from potential stormwater quantity and quality problems. Potential problems include increased flooding and drainage problems due to inadequate or lack of conveyance systems and excessive stream bank erosion/channel widening due to increased runoff from developed areas.

On March 16, 1999 and April 4, 2000, the City Council adopted amendments to Chapter 27 of the Greensboro Code of Ordinances (Section 27-22) to control the adverse effects of increased stormwater runoff associated with newly developed or redeveloped sites. The revised ordinance requires all new development within the city limits to submit a *Stormwater Management (SWM) Plan.*

The SWM Plan must show stream buffers along all open (1) perennial streams and (2) drainage channels draining an area greater than 50 acres. The SWM Plan must also include an *offsite stormwater conveyance system analysis* that shows the effects the development will have on the downstream properties including a determination if the development will cause or increase quantity or quality problems. If the analysis shows that negative impacts will result, stormwater management improvements including structural and/or non-structural BMPs are to be implemented to minimize the impact.

Section 2 of this manual provides basic technical guidance including suggested analysis and design procedures to meet the requirements of the City of Greensboro's stormwater management ordinance. The information provided in this manual is not intended to be exhaustive, but rather to represent a concise collection of established, technically sound, and efficient means to produce stormwater management plans that may include non-structural and/or structural facilities to satisfy requirements of the City's stormwater quantity management ordinance. The ordinance provides flexibility for the City to work with developers and engineers to provide stormwater management facilities to minimize the adverse downstream impacts of stormwater runoff, but does not require the proliferation of facilities that may provide minimal benefit to the citizens of Greensboro and/or the public drainage system.

Stormwater Utility Credit Policy

A stormwater utility fee is assessed on all properties within city limits. Since the main goals of the City are to reduce the amount of pollutants that are discharged to surface waters and to minimize stream and property damage associated with increased flowrates, the City offers credit on the stormwater utility fee to those who implement approved stormwater BMPs on-site.

This manual provides guidelines for BMPs to be considered to receive credit. Refer to the City's *Stormwater Utility Credit Policy* for more information regarding credit opportunities, including the actual credit that can be awarded for implementation of BMPs.

SECTION 2: STORMWATER MANAGEMENT REQUIREMENTS

2.1 City of Greensboro Stormwater Master Plans

It is the intent of the City of Greensboro to produce stormwater management master plans that will guide public and private development projects on various quantity and quality aspects of stormwater management for all of the major sub-watersheds in the city. Where such master plans are available and approved by the City Council, site development projects are to conform to the stormwater management guidance and standards available in said master plans.

2.2 Stormwater Management Plan

A Stormwater Management (SWM) Plan is required:

⇨ for all new development and redevelopment projects in the corporate limits and extraterritorial jurisdiction of the City, unless otherwise exempt.
⇨ to be approved by the City Technical Review Committee prior to site plan or preliminary subdivision plat approval. It is preferred that the SWM Plan be submitted with the site plan or preliminary subdivision plat. For projects located in water-supply watershed areas, a Watershed Development Plan should be incorporated into the Stormwater Management Plan.
⇨ to be approved prior to obtaining a grading or building permit
⇨ to contain all items in section 2.2.1 below.

Site designers are encouraged to develop *comprehensive SWM plans* for the proposed development, including stormwater quantity and quality controls, non-structural and/or structural improvements, and pollution prevention programs for the site. Any proposed measures which go beyond the requirements of Ordinance Section 27-22 may qualify for credits under the City's Stormwater Utility Fee Crediting Program. In addition, most quantity control facilities provided under the requirements of Section 27-22 should qualify for the fee crediting program, at reduced incentive rates compared to more comprehensive plans.

2.2.1 Stormwater Management/Watershed Development Plan Components

The following information is required on all Stormwater Management (SWM) Plans:

<u>General Information</u>

1. Watershed Location of Proposed Site Development: Note the <u>watershed</u> (i.e., North Buffalo Creek, South Buffalo Creek, Horsepen Creek) and <u>sub-watershed</u> names (i.e., North Buffalo Creek Sub-Watershed 1, North Buffalo Creek Sub-Watershed 2), as applicable, for the

proposed site development. Note water-supply watershed name (i.e., Greensboro Watershed) and water-supply watershed designation (i.e., WS-III, WS-IV, WCA), as applicable.

2. Council-Approved Watershed Master Plan Available? – "Yes" or "No"

3. Show existing built-upon area, if any, and note the amount.

4. Show the proposed built-upon area and note the amount.

5. Note the maximum amount of built-upon area (per watershed development restrictions, stormwater control design, etc.)

6. Show the proposed disturbed (site development) area and note the amount.

7. Note on-site soil type(s) and the hydrologic group(s).

8. Show existing and proposed stormwater conveyance system (pipes, channels, swales, catch basins,etc.) layout and applicable easements. Label pipe size, material, elevations, slopes and structure types (grate inlet, manhole, etc.)

9. Label the amount of off-site drainage area and runoff quantities that discharge onto site.

10. Engineer's Certification of Stormwater Quantity Control.

10. Engineer's Certification of Stormwater Quality Control (for high-density development in designated water-supply watershed area).

11. If the site was previously approved or part of a subdivision that was previously approved by the City or County for stormwater management or watershed development, provide the name of the plan and the date that the plan was approved.

Stormwater Management Study – Analysis of Off-site System

12. Map showing the limits of the off-site study. Within the limits the map should show:
    - topography
    - stormwater conveyance system
    - properties and structures adjacent to the conveyance system
    - the total drainage area at the downstream limit of the study (at least 10 times greater than the site development area).

13. Attributes of the off-site stormwater conveyance system including: structure types, materials, slopes, significant elevations, etc.

14. Provide supporting hydrologic and hydraulic calculations.

Stream Buffer and Related Information

15. Show the location of all streams and drainageways that require buffers.

16. Show the buffers and where measured from (that is, top of bank, top of steep slopes adjacent to stream, or edge of wetlands).

17. Label the dimensions and restrictions within the buffer (that is, To Remain Undisturbed, 50% impervious, vegetated, etc.)

18. Show the location of jurisdictional waters and wetlands.*

*The U.S. Army Corps of Engineers and the N.C. Division of Water Quality regulate wetlands and waters of the United States through the 404 Corps Permit and 401 State Water Quality Certification process. The City encourages the protection and enhancement of wetlands and surface waters to promote improved water quality and water quantity management, as well as fish and wildlife biota and habitat preservation, and other benefits to local comprehensive watershed management. *Site designers/developers are responsible for obtaining all applicable Local, State, and Federal permits/certifications/approvals as necessary for proposed site development activities.*

19. Indicate proposed location of proposed stream crossing(s) showing the proposed grading and overall stream impact (includes culvert and outlet protection length). (Alternative analysis may be required by the City to reduce and /or mitigate impacts).

FEMA Regulated Floodway/Floodplain Information

20. Show designated FEMA-regulated floodway and floodplain boundaries on property and note the 100-year Base Flood Elevation (BFE), as applicable.

21. If the site is located within a FEMA Special Flood Hazard Area (SFHA):
    -note the finished floor/floodproofing elevations of all structures.
    -note that no encroachment/development into FEMA-regulated floodway will be made*.
    -If a FEMA-designated Floodway/plain does not exist on the property/parcel, note the nearest distance to a FEMA-designated floodway, if within 2000 feet.

* In general, encroachment into a FEMA-regulated floodway is not permitted unless the developer performs a FEMA No-Rise Certification and/or Conditional/Letter of Map Revision Application and receives approval from the City of Greensboro (Local Floodplain Administrator) and FEMA officials. Questions regarding development procedures within FEMA designated floodplains may be directed to the City's Storm Water Services Division, Technical Support Section.

Low Density General Watershed Development Information

22. Provide completed watershed scoresheet.

23. For each factor where points are claimed, the requirements of that factor must be clearly depicted on the plans (for example, if 20 points for factor 7, "stream buffer along drainageways" are claimed, the plans need to show a 50' buffer on each side of the creek,the areas to remain wooded, and note the total buffer area amount and the wooded area amount).

Watershed Development in WCA (Watershed Critical Area)

24. Show location of natural slopes greater than 15% which are adjacent to streams and drainageways. These areas and jurisdictional wetlands must remain undisturbed and either dedicated as drainageway and open space or platted as a water quality conservation easement (WQCE).

26. Note that drainage will be provided by means of open vegetated channels.

27. Note the intended land use and SIC Industry Code.

28. Show location of proposed storage tank(s) and indicate material to be stored. A secondary containment system must be constructed for the tank(s) and approved by the City.

Stormwater Control BMP Information

29. Indicate the type(s) of non-structural and/or structural stormwater control best management practices (BMPs) that are proposed.*

    *If proposing to use *existing* on-site or off-site controls, provide information to demonstrate that the controls have been approved by the City and can continue to meet quantity/quality control requirements.

30. If proposing to use off-site stormwater controls, indicate the location and owner(s) of the controls and provide information to demonstrate that the property owner will assist in maintaining the controls.

31. If proposing to use a public owned regional stormwater management facility, provide information to demonstrate that the municipality accepts participation from the property owner.

32. Show the location of the proposed stormwater controls and the location of the inlets and outlets to the control.

33. Show and label the access easement to stormwater control from the street R-O-W and the

D.M.U.E. around the facility.

34. Show the approximate size, configuration, and hydraulic structures for the stormwater control/improvement (with calculations).*

*This may be done in lieu of submitting full construction design, details, and calculations for *preliminary subdivision plans only.* No grading permit will be issued *or* recordation of any lot can occur until the construction plans have been approved for the stormwater control(s) that handle runoff from that lot. *Site plans must include construction drawings for review and approval.*

35. Provide applicable maintenance agreements for proposed stormwater controls.

36. Note: The engineer's certification of completion will be required prior to the final plat or certificate of occupancy. The stormwater control is to be inspected to ensure it is functioning as designed and has full design volume prior to issuance of the final certificate of occupancy.

37. Note: The property owner (or homeowner's association) is responsible for maintaining the stormwater control(s) according to the approved maintenance plan and direction of the City of Greensboro.

38. Note: The City of Greensboro and their assigns have right to access the stormwater control(s) for inspections or maintenance, as necessary.

Stormwater Control/Improvement Construction Plans

39. Layout of stormwater control, grading, and significant components (for example, primary outlet structure(s), dam, filter bed depth, bottom drain, etc.).

40. Cross section of proposed SWM improvements showing the elevations of significant components and storage allocations (e.g. sediment storage, peak reduction storage, etc.).

41. Details and material specifications of all significant components of the stormwater control.

42. Provide Engineer's Statement of Pond and Dam Safety (if dam construction is proposed).

43. Provide hydrologic and hydraulic analysis/calculations, water quality and other pertinent calculations for design of the stormwater control.

44. Provide an inspection/maintenance plan for reference by the owner for long-term maintenance needs.

45. Provide the construction sequence for completing the stormwater control.

2.3 Stream Protection Requirements

City Ordinance Sections 27-22 and 30-7 have provisions to help protect and preserve stream channels and floodplains from excessive disturbance and encroachment. The watershed master plans, currently under development, will identify sensitive floodplain areas and may require additional conditions for development and/or buffers within floodplain/ floodprone areas in order to provide protection for citizens from identified existing/future flood risks and/or to meet other objectives within the stakeholder-driven watershed master plans.

2.3.1 Stream Channelization/Piping Restrictions

Generally, no perennial or intermittent stream is to be piped without first obtaining approval from the Technical Review Committee and other applicable city, state and federal permits and certifications. **Perennial streams within a designated water supply watershed and intermittent streams within the Upper and Lower Randleman Lake Watersheds may not be channelized or piped** except where street, driveway and utility crossings and other activities are permitted by the ordinance and are shown to be necessary and impacts are minimized.

2.3.2 Stream Buffers

Stream buffer requirements are summarized in the following tables. Stream buffers are most effective when the buffer remains in an undisturbed state. Therefore, it is encouraged that disturbance be minimized in the entire stream buffer, not just the portion that is required to remain undisturbed. Where the buffer is disturbed, it should be promptly stabilized, re-planting a dense cover of strong rooted grass, plants and trees.

<u>Citywide (excluding Randleman Lake Watershed)</u>

There are four cases within the City, not including the portion of the city inside the Randleman Lake Watershed, where stream buffers are required:

CASE 1: Drainageways draining an area equal to or larger than 50 acres (non-perennial)
CASE 2: Perennial streams (as defined by this manual)*
CASE 3: Perennial streams (on "Watershed Map", "low density" development)
CASE 4: Perennial streams (on "Watershed Map", "high density" development)

*The buffer requirements for Case 2 do not apply to perennial streams that are shown on the "Watershed Map".

Table 2.1: Stream Buffer Requirements (Cases 1-4)				
CASE	MINIMUM WIDTH (each side)	UNDISTURBED	NO BUILT-UPON SURFACE (vegetated)	BUILT-UPON LIMIT OF 50% (no occupied structures allowed)
1	50'	First 15'	N/A	Next 35'
2	50'	First 15'	N/A	Next 35'
3	30'	N/A	Entire 30'	N/A
4	100'	N/A	Entire 100'	N/A

For cases 1 and 2, stream buffers are to be measured from one of the following: (1) the top of the stream bank, or (2) the top of steep slopes adjacent to the stream, or (3) the edge of contiguous wetlands. For cases 3, 4 the stream buffers are to be measured from the top of the stream bank.

Randleman Lake Watershed

The Randleman Lake regulations, including stream buffer requirements, were adopted by the NC Environmental Management Commission in the Spring of 1999 and incorporated into the City's Development Ordinance effective January 1, 2000. The regulations require *riparian* buffers to be maintained on all perennial and intermittent streams in the upper and lower Randleman Lake watersheds. For more information on this buffer requirement including the different zones of the riparian buffer, refer to Ordinance Section 30-7.

Table 2.2: Randleman Lake Watershed Stream Buffer Requirements					
STREAM	Density	MINIMUM WIDTH (each side)	ZONE 1	ZONE 2	ZONE 3
Intermittent	Low	50'	First 30'	Next 20'	N/A
	High	50'	First 30'	Next 20'	N/A
Perennial	Low	50'	First 30'	Next 20'	N/A
	High	100'	First 30'	Next 20'	Last 50'

2.4 Stormwater Quality and Quantity Control

Stormwater quality and quantity control are required by Ordinance Sections 30-7 and 27-22. They are required as follows:

1. **Stormwater Quality Control (Sec 30-7):**
   Applicable to high density development in designated water-supply watershed areas. *Required to* provide structural control that removes 85% Total Suspended Solids (TSS) from the runoff from the first one (1) inch of rainfall.

2. **Stormwater Quantity Control (Sec 27-22):**
   Applicable to all new development sites within the City that increase the net built-upon area of the site by more than 400 square feet.
   Required to minimize off-site flooding, drainage and erosion problems.

The stormwater management (SWM) plan must indicate that these minimum control requirements are met, where applicable. An "ideal site SWM Plan" in most cases is one in which the complete pre-developed stormwater runoff characteristics of the site are maintained in the post-developed conditions, including emulation of the pre-developed runoff hydrographs and pollutant runoff characteristics, and is consistent with an approved watershed master plan. Low-impact developments which incorporate non-structural and/or structural stormwater management practices promote improved urban stormwater management programs and minimize adverse downstream impacts. This concept is increasingly referred to as "sustainable development" from a stormwater and watershed management viewpoint.

2.4.1 Quality Control for High Density Development in Water Supply Watershed Areas (Ordinance Section 30-7)

Section 30-7 requires an "engineered" stormwater quality control to improve the quality of stormwater runoff from new high density development sites. The stormwater quality control must be an acceptable structural BMP as shown in Table 3.2, of this Manual. The requirements and guidelines for designing these BMPs are presented in Section 3.4.

The engineer's certification of stormwater quality control, which is provided in Table 30-7-1-5 of the City's Ordinance, is required for proposed high density developments.

2.4.2 Quantity Control (Ordinance Section 27-22)

Section 27-22 requires a hydrologic and hydraulic engineering analysis to evaluate off-site impacts due to increased stormwater runoff from new development and/or redevelopment sites within city limits. Where problems are determined, it is the developer's responsibility to provide stormwater improvements to minimize the problems.

Site Analysis

1. Evaluate the peak runoff from the property for the pre-development (existing) conditions (Q_1) during a 24-hour rainfall sequence with a recurrence interval of both 2 years and 10 years (where runoff discharges from the property at more than one location, evaluate each location). The 24-hour rainfall sequences for the 2 and 10 year recurrence storms, depth-duration-frequency table, and intensity-duration-frequency table, for the Greensboro area are provided in Appendix C. The rainfall values in the 24-hour rainfall sequence are based on "Type II distribution" (applicable to the Greensboro area, as excerpted from NWS TP-40 and HYDRO-35) of the 24 hour rainfall of 3.5 inches and 5.1 inches for 2- and 10-year recurrence rain storms, respectively.

2. Evaluate the peak runoff from the property for the post-development conditions (Q_2) during a 24-hour rainfall sequence with a recurrence interval of both 2 years and 10 years (where runoff discharges from the property at more than one location, evaluate each location).

3. Evaluate the peak runoff value(s) for post-development conditions (Q_2) and compare that to the pre-development conditions (Q_1) for both the 2-year and 10-year recurrence storms, 24-hour rainfall sequence. If either of the post-development peak flows are greater than the pre-development peak flows, the designer must perform a preliminary and/or detailed hydrologic and hydraulic analysis of the off-site stormwater conveyance system to indicate downstream impacts of any increased stormwater flows to determine if stormwater management improvements are necessary, or provide on-site stormwater control improvements that reduce post-development flows of the 2-year and 10-year recurrence storms, 24- hour rainfall sequence to the pre-development condition, or participate in an approved downstream regional SWM facility, if available.

Off-site Analysis

For new development sites where on-site controls are not provided to reduce post-development flows to pre-development flows, an off-site analysis will be required, unless otherwise exempt. Where on-site quantity controls are provided to reduce post-development flows to pre-development flows, an off-site analysis may generally not be required, provided that conditions in an approved watershed master plan are satisfied. In some cases, however, it is possible that on-site stormwater controls may exacerbate system-wide drainage problems, and thus the designer should verify that the SWM Plan does not create new problems downstream. Therefore, it is recommended that an off-site analysis be performed prior to sizing a quantity control improvement to reduce post-development rates to pre-development rates as the analysis may indicate that different on-site stormwater controls are needed for the given development (other than those developed based on a site-specific analysis only) or that minimal stormwater control measures are required for the site.

Downstream Limits of Analysis: In determining downstream effects from the proposed site development or redevelopment activity, hydrologic and hydraulic engineering studies shall extend downstream to a point where the proposed site development or redevelopment represents less than ten (10) percent of the total drainage area or watershed. This point is referred to as the "10% point."

For example, a 5-acre site located near the headwaters of a drainage basin is proposed for sustainable development of which 4 acres are proposed to be disturbed (that is, the runoff will increase on 4 acres of the site after it is developed). The 4 acres drain to one location before discharging from the site. The downstream limit of analysis would be where the contributory watershed equals 40 acres. In general, the area of interest for analysis is the property / site itself, the drainage exit point of the property, and each component (channel, pipe, culvert, overland flow etc.) of the downstream system to the 10% point in the watershed, at a minimum.

Design Storm Events for Analysis: The studies shall be based on an analysis of both 2- and 10-year design storm events.

Analysis Criteria: The analysis should examine whether the design storm events of interest cause or increase flooding, drainage, or erosion problems on off-site property. In determining downstream effects from the proposed development, studies shall extend downstream to the 10% point and should include:

a) routing of peak flows to the 10% point within the watershed using accepted hydraulic/hydrologic methods described in Section 2.4.3, and

b) if peak flow calculations indicate that adjacent development(s) might be adversely impacted by the proposed development, then hydraulic step-backwater calculations (Corps of Engineers' computer models HEC-2 or HEC-RAS are recommended where detailed hydraulic analysis is required) shall be performed and flood elevations determined for the areas impacted. *Detailed hydrologic and hydraulic engineering studies can be costly, thus the Guidance Manual recommends detailed studies only where peak flow hydrograph routing analysis indicates that drainage / flooding problems might be present.*

Land Use Conditions: Hydrologic / hydraulic studies should utilize the following land use conditions for analysis:

- use existing conditions for downstream areas of interest
- for development of watershed hydrographs (off-site drainage areas), existing conditions land use is the minimum requirement, but future land use conditions are recommended for a conservative analysis
- the effects of upstream stormwater detention facilities can be considered in the analysis only if such structures (i.e., regional facilities) have been accepted for maintenance by the City or otherwise approved by the City.

Implementation of Stormwater Control Improvements

Where it is determined that the development of the said site does contribute to flooding, drainage or soil erosion problems at any location between the proposed development site and the 10 percent downstream point then stormwater quantity control improvements must be implemented. Improvements may consist of:

1. On-site peak reduction – The developer may choose to use nonstructural approaches such as natural or engineered swales, depressions in the land and other natural approaches, or structural approaches such as detention structures, extended detention facilities, and alternative Best Management Practices (BMPs) with provisions for stormwater quantity control. *A combination of nonstructural and structural approaches is encouraged.*

2. Off-site peak reduction – The developer may use an off-site publicly or privately owned facility where: the facility is functional (within 2 years for proposed public facilties); the owner/entity has accepted stormwater runoff from the site; it can be demonstrated that the facility is sized to handle the increased flow; the owner has participated and/or implemented a maintenance agreement for use of the facility; it is demonstrated that there are no quantity problems between the site and the off-site facility.

3. Improvements to the downstream stormwater conveyance system – Where it is determined that the best solution is to upgrade the downstream system, this may be done provided that the downstream property owner where the improvements will be made grants a temporary construction easement and the improvement will not cause other problems downstream. The site developer is to coordinate with the City on all proposed downstream improvements.

Design Storm Events: The improvements shall be evaluated based on both 2- and 10-year 24-hour design storm events.

Method for Design: The designer should demonstrate that the proposed improvements are sufficient to minimize downstream problems. Hydraulic/hydrologic methods presented in Section 2.4.3 should be used to evaluate the proposed improvement. An example of an evaluation of a detention facility is provided in Appendix D.

Land Use Conditions: For site specific design of SWM control structures / facilities, use fully developed land use conditions for the site and existing land use conditions for any upstream areas draining to or through the facility (future land use conditions are recommended, however, for a conservative analysis).

Additional Stormwater Management for Public Benefits

Where the Enforcement Officer determines that additional storage capacity in a stormwater management facility beyond that required for on-site stormwater management is necessary in order to enhance or provide for the public health, safety, and general welfare, to correct undesirable existing drainage or flooding conditions or to provide greater protection for future development, the Enforcement Officer may:

1. require that the applicant grant necessary easements over, through or under the applicant's property to provide access to or drainage for such a facility;

2. require that the applicant attempt to obtain from the owners of property where the proposed stormwater management facility is to be located, any easements necessary for the construction and maintenance of same (and failing the acquisition of such easement(s) the City may, at its option, assist in such matter by purchase, condemnation, dedication or otherwise, and subject to item 3 below, with any cost incurred thereby to be paid by the City); and/or

3. participate financially in the construction of such facility or improvement to the extent that such facility or improvement exceeds the required on-site stormwater management determined by the Enforcement Officer.

To implement this provision, both the City and owner/developer must be in agreement with the proposed stormwater management facility that includes additional storage capacity and jointly develop a cost sharing plan which is agreeable to all parties involved.

2.4.3 Hydraulic/Hydrologic Methods

The following hydraulic/hydrologic methods are accepted by the City for use to address quantity and quality requirements.

Hydrologic Methods (hydrograph formulation and peak flow estimation)

- NRCS (Natural Resources Conservation Service, U.S. Department of Agriculture) hydrologic methods (formerly known as the SCS, Soil Conservation Service) are preferred and acceptable for all applications. NRCS methods include those contained in the TR-55 publication and corresponding computer program.

    - The hydrograph formulation methodology presented in Chapter 5 – Tabular Hydrograph method is the preferred method. A summary of this method is given in Appendix D.

    - Runoff flood peaks for small catchment areas or subwatersheds (approximately 50 acres or less) may be determined using the methodology presented in Chapter 4 of

TR-55. However, as pointed out under Limitations in Chapter 4, if a hydrograph is needed or watershed subdivision is required, the Tabular Hydrograph method given in Chapter 5 should be used.

- The NRCS routines applied within the US Army Corps of Engineers computer models HEC-1 and HEC-HMS are preferred and acceptable for most applications. (The Corps of Engineers HEC-1 / HEC-HMS models are preferred over the NRCS TR-20 model, however, since Corps models will be used by the City in watershed modeling and master planning.)

- The Rational Method, Qp = C I A, is acceptable for determining peak runoff from drainage areas of 200 acres or less.

- The "Small Watershed Method" developed by Dr. H.R. Malcom, PE, NC State University, Raleigh, NC, is acceptable for most hydrologic analyses on small watersheds, based on Malcom's procedures.

- Other hydrologic analysis methods may be allowed if the designer demonstrates that the alternatives are appropriate for the intended purpose.

Detention Storage Estimation Methodologies:

- The Storage-Indication (Puls method) is an acceptable method for routing hydrographs through a reservoir of any size. This method is incorporated into the US Army Corps of Engineers HEC-HMS and NRCS TR-20 computer models.

- The "Chainsaw Routing" method developed by Dr. H.R. Malcom, PE, NC State University, Raleigh, NC, is acceptable for most reservoir routing analyses on small reservoirs, as deemed appropriate by the designer based on Malcom's procedures. The procedure and an example of an application of this method are given in Appendix D.

- TR-55 (Chapter 6) and Dr. H.R. Malcom's "Preliminary Design" (given in Appendix E) present methods to give the designer an approximate estimate of the storage required to provide the desired detention. These methods are good for preliminary design, but are to be followed up with an acceptable reservoir routing method for final design.

- Other reservoir routing analysis methods may be allowed if the designer demonstrates that the alternatives are appropriate for the intended purpose.

Hydraulic Methodologies (Open and closed conveyance analysis):

- Where step-backwater hydraulic computations are required for open stream channels including bridges and culvert roadway crossings, the US Army Corps of Engineers HEC-2 or HEC-RAS models are preferred and recommended for most applications. Where significant closed conduits represent the stormwater conveyance system, EPA's SWMM model is recommended, if a detailed hydraulic analysis is required for development of the SWM Plan.

- For simple hydraulic analyses, where applicable, the Manning's Equation and other hydraulic relationships (e.g., Hydraulic and Energy Grade Line calculations) may be applied where appropriate assumptions for use are satisfied and the results will be conservative.

- Other hydraulic analysis methods may be allowed if the designer demonstrates that the alternatives are appropriate for the intended purpose.

2.4.4 Engineer's Certification Note of Stormwater Quantity Control

For new development plans within the city limits of Greensboro, one of the following certification notes should be made.

1. The development shown on this plan is consistent with the provisions contained on the preliminary plan/site plan ____(name of plan)______, which was approved prior to July 1, 1999 and which approval has not lapsed, as specified in Section 30-6-12 of the Greensboro Development Ordinance, and therefore is exempt from compliance with Section 27-22 of the Stormwater Management Ordinance.

2. The net increase in built-upon area is less than 400 square feet, therefore, this development is exempt from subsection (g)(2) "Quantity Control Requirements" of Section 27-22 of the Stormwater Management Ordinance.

3. The stormwater management study included with this plan indicates that there will be no downstream flooding, drainage, or erosion problems as a result of the proposed development between the point where the runoff discharges from the property to where the site development area represents less than 10% of the total drainage area. Therefore, no quantity control improvement is proposed.

4. The stormwater management study included with this plan indicates that there will be downstream flooding, drainage, or erosion problems associated with this development. The proposed stormwater management improvement(s) indicated on this plan is (will be) designed to minimize increased flooding, drainage and erosion problems from occurring between the point where the runoff discharges from the property to where the site development area represents less than 10% of the total drainage area.

5. The stormwater control structure(s) shown on this plan is (will be) designed to reduce the post-development 2-year 24 hour storm event and the 10-year 24 hour storm event to pre-development rates.

2.5 Modifications to Stormwater Requirements

2.5.1 Water-Supply Watershed Protection (Chapter 30)

Ordinance Section 30-9-11, Modifications, describes the procedures for obtaining a modification to the water supply watershed standards of Chapter 30-7.

2.5.2 Stormwater Management Control (Chapter 27)

A modification shall only be granted after a written request is submitted by the applicant to the Enforcement Officer containing, site plan descriptions and drawings, detailed hydrologic and hydraulic engineering analysis and an explanation of the reasons a variance is warranted. The request should clearly indicate that the modification is in general harmony with the general purpose and intent of the Ordinance, and by granting the modification the public safety and welfare have been assured. Separate written modification requests shall be required if there are subsequent additions, expansions, or modifications which would alter the approved stormwater runoff characteristics of a proposed site development or redevelopment activity receiving a modification.

<u>Stream Protection Requirements</u>

A modification to the requirements of Section 27-22 (f) may be granted by the Enforcement Officer if it can be demonstrated that all alternatives to avoid and/or minimize impacts to the stream channel or buffer has been evaluated and proven to be infeasible.

<u>Quantity Control Requirements</u>

A modification to the quantity control requirements of Section 27-22 (g) may be granted by the Enforcement Officer if it can be shown by detailed hydrologic and hydraulic engineering studies and analysis which are acceptable to the Enforcement Officer that one of the following applies:

1. the installation of stormwater management facilities would have insignificant effects on downstream flood peaks; or
2. stormwater management facilities are not needed to protect downstream developments and the downstream drainage system has sufficient capacity to receive any increase in runoff; or
3. it is not necessary to install stormwater management facilities to control developed peak discharge rates at the exit to a proposed development or redevelopment and installing such facilities would increase flood peak discharge rates at some downstream locations; or
4. the Enforcement Officer determines that stormwater management facilities are not needed to control developed peak discharge rates and that installing such facilities would not be in the best public interest.

Quantity control requirements may not be waived if the Enforcement Officer determines that not controlling downstream flood peak discharge rates would increase known flooding or drainage problems, or exceed the capacity of the downstream drainage conveyance system at any point between the exit of a proposed site development or redevelopment and the 10 percent downstream point.

3.1 Overview of Stormwater BMPs

BMPs can generally be classified into two categories: (1) Pollution Prevention BMPs and (2) Runoff/Pollution Control BMPs. An overview of these two categories are discussed below.

3.1.1 Pollution Prevention BMPs

Pollution prevention BMPs are **activities** that are implemented to control pollution **at the source** by preventing pollutants from commingling with stormwater runoff. Pollution prevention BMPs are often much less expensive and more effective than BMPs which manage stormwater after pollutants have migrated into the runoff. Implementing pollution prevention BMPs is very important to improving the quality of our surface waters and overall environment.

The pollution prevention BMPs presented in this manual are beneficial for reducing pollutants in stormwater runoff. The City promotes pollution prevention BMPs that are relatively easy to implement and, in many cases, required by other environmental regulations for specific types of properties (for example, NPDES requirements for permitted industrial sites). Some facilities in Greensboro should already be implementing these practices. If a facility is not employing these practices at this time, the pollution prevention BMPs presented generally require only relatively minor efforts to implement and can provide significant stormwater pollution reduction.

Pollution prevention BMPs can be utilized to meet industrial NPDES requirements and to receive credit on the stormwater utility fee. Because most of these practices are easy to implement and effective in promoting a cleaner, healthier environment, the City encourages all businesses and interested citizens to use these practices.

The following pollution prevention BMPs are discussed in Section 3.2 of this manual:

- ⇨ Employee education
- ⇨ On-site refuse management
- ⇨ Stormwater system maintenance
- ⇨ Paved area sweeping
- ⇨ Used oil recycling
- ⇨ Covering
- ⇨ Spill containment
- ⇨ Soil erosion control

This list of BMPs is not intended to be exhaustive, but rather to give some of the most effective BMPs for preventing pollution of stormwater runoff from developed areas.

3.1.2 Stormwater Quality/Quantity Control BMPs

Stormwater quality/quantity control BMPs are site design/planning practices, improvements, facilities, etc., that serve to reduce the total volume of runoff generated, reduce peak runoff discharge rates, and provide surface water quality protection by minimizing impacts to environmentally sensitive areas and removing pollutants from stormwater runoff. These BMPs can be non-structural/site development BMPs or structural BMPs.

Non-Structural BMPs

Non-structural BMPs can be defined as **techniques incorporated in site design/planning** to promote low-impact development. These BMPs may be used to reduce the volume of runoff generated, reduce runoff discharge and provide partial pollutant removal. These practices are relatively inexpensive to implement, with the major cost usually being land area. But, with thoughtful site design, these practices can improve the stormwater management and aesthetic value of the development.

These stormwater BMPs can be implemented to help meet requirements for "low density" development in water-supply watershed areas and to reduce the amount of impervious area that is required to be treated for "high density" development. These BMPs can be incorporated in the site design to reduce stormwater runoff quantity and prevent adverse effects on the downstream property and receiving streams. Non-structural BMPs can be used to receive credit on the stormwater utility fee.

The following non-structural BMPs, which have been observed to be effective, are discussed in Section 3.3 of this manual:

- ⇨ Open vegetated conveyances
- ⇨ Stream buffers
- ⇨ Disconnect rooftop drainage
- ⇨ Clustering/Conservation of natural areas
- ⇨ Grass paving
- ⇨ Natural infiltration

Structural BMPs

Structural BMPs can be defined as **"engineered stormwater management facilities"** that can be designed to improve the quality of stormwater runoff and reduce stormwater runoff rates and/or volumes. These BMPs are designed to capture surface runoff from developed areas and improve the quality of the runoff from the site by removing pollutants through processes such as sedimentation, plant uptake, filtration, microbial activity, etc.

Structural BMPs are generally the costliest of the various BMPs to implement and to maintain. Most potential BMP owners are generally aware of the initial construction costs and land allocation that is required for structural BMPs, but some do not fully understand or appreciate the responsibility and costs associated with the maintenance of stormwater BMPs. This manual presents design, installation, and maintenance guidelines for each structural BMP.

This manual describes each structural BMP and provides design guidelines to make the BMP as efficient as possible in removing pollutants. The manual points out which BMPs are acceptable to use to meet water supply watershed protection regulations for high density development and the associated minimum design requirements. The manual describes each BMP's ability to incorporate peak flow reduction and their credit potential toward the stormwater utility fee. The manual also provides guidelines on selecting the best BMP for certain site conditions.

The following structural BMPs are discussed in Sections 3.4, 3.5, and 3.6 of this manual. Section 3.4 presents BMP selection guidelines, regulatory considerations and design information for each structural BMP. Section 3.5 provides general installation guidelines, while Section 3.6 provides inspection and maintenance guidelines for each structural BMP.

- ⇨ Grass swales
- ⇨ Filter strips
- ⇨ Dry detention basins
- ⇨ Wet detention ponds
- ⇨ Stormwater wetlands
- ⇨ Bioretention areas
- ⇨ Sand filtration facilities
- ⇨ Proprietary stormwater treatment facilities

3.2 Pollution Prevention BMPs

3.2.1 Employee Education

Description

Employee education programs are designed to educate employees on the proper operational practices to minimize the potential for on-site pollutants to contact stormwater runoff. Through education, employees become more aware of potential stormwater pollutants, runoff characteristics, spill control measures, and methods to minimize off-site migration of polluted stormwater runoff from commercial and industrial properties. As a result, it is one of the easiest to implement and most beneficial pollution prevention BMPs available. In addition, a proper employee education program outlines methods by which employees can also reduce potential for stormwater pollution at their individual residences.

Applicability

Every commercial, and industrial or related facility that stores materials outside or is involved with receiving or shipping materials can benefit from employee education programs regarding on-site stormwater management practices.

Employee education programs are required by federal law under *40 CFR Part 112 - Oil Pollution Prevention Regulations* and *40 CFR Part 122, 123, and 124 - National Pollutant Discharge Elimination System Regulations for Storm Water Dischargers.* As a result, all facilities conforming to these regulations should already be performing employee education.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, organizations must meet the minimum criteria outlined in Table 3.1. For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

City of Greensboro Public Education Outreach

The City of Greensboro is committed to educate citizens on environmental awareness issues. The Storm Water Services Division, as part of its municipal NPDES permit, has developed educational programs to inform citizens on ways they can help protect the quality of Greensboro's streams and lakes. The City has produced several television and radio ads.

Table 3.1: Summary of Employee Education Requirements

ACTIVITY	DESCRIPTION	FREQUENCY	DOCUMENTATION
Employee Briefings	Education sessions for all employees regarding proper water quality and environmental protection activities.	30 min./quarter	Submit programs with agenda to SWS for approval prior to briefings.
Employee Surveys	Conduct written surveys of each employee per EPA regulations	Once annually	Submit summary of survey responses in Annual Report.
Post/Distribute Information	Post and/or distribute periodic stormwater information provided by Storm Water Services.	As received	Verify posting of Annual Report.

campaigning surface water quality protection. The City has also produced informational videos, brochures, etc., on various environmental topics for a wide range of audiences, including industries, businesses, schools and interested citizens.

The City also has helped form several volunteer groups to help educate citizens on water quality issues and to encourage citizens to get involved in cleaning up the City's surface waters. These groups include:

Environmental Business Partners
This program is setup to create a partnership with the City government and local businesses in order to provide the community with environmental/stormwater information.

"Green Heroes" (Includes Adopt-A-Stream, Adopt-A-Street, and Adopt-A-Park)
This program consists of volunteer groups that periodically remove litter along the stream section that they have adopted.

"Drain Markers" Program
This program involves placing the drain markers on storm water inlets that read "Don't Dump – Drains to Lakes and Creeks"

The City has also set up an "Environmental Helpline" (373-2812) to take calls on pollution problems from spills to excessive erosion problems from construction sites and to answer questions.

If you have an interest in obtaining any informational material, participating in the volunteer groups or have any other questions regarding environmental issues, please contact the Helpline.

3.2.2 On-Site Refuse Management

Description

On-site refuse management programs include specific operating practices designed to minimize the potential for on-site litter and debris. The goal for these types of programs is to limit the amount of floatables and debris collecting in stormwater runoff and discharging off-site. In addition, on-site refuse management programs entail good housekeeping practices and help maintain a clean facility appearance.

Applicability

Commercial and industrial facilities can benefit from an active on-site refuse management program. Many facilities already employ such a program either formally or informally as part of good housekeeping efforts to maintain a clean, aesthetically pleasing business environment.

Litter reduction and recycling activities are essential to improving solid waste management. Nearly 65% of the City's landfill waste comes from local commercial and industrial businesses. Recycling programs can save landfill space, and because the City of Greensboro services recycling dumpsters free of charge, they can save business owners money.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, organizations must develop and implement an on-site refuse management plan which focuses on litter reduction, recycling, and proper disposal and storage. Organizations wishing to receive credit for on-site refuse management, must prepare and submit an on-site refuse management plan. The plan should include the following items at a minimum:

1. A litter reduction program encouraging staff to properly dispose of waste materials. This program should outline the appropriate disposal options for all waste, including hazardous and non-hazardous and general solid waste material.
2. A comprehensive on-site waste material recycling program. This program should include all materials that could be reused or reclaimed either on-site or through the use of contractors of vendors. This may include paper wastes, waste treatment solids, and other materials.
3. Maintain area of refuse container covers designed to eliminate exposure to the environment (i.e. wind, rain, snow, etc.).

For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

City of Greensboro Solid Waste Management

The City's Solid Waste Management Division offers twice-a-week garbage service as well as recycling service up to four times per week to its business customers. Business owners are responsible for providing city-approved trash and recycling dumpsters.

Businesses may recycle the following materials in the Recycle Greensboro program:

Office and computer paper	**Newspapers**	**Tin cans**	**Chipboard**
Plastic soda bottles	**Magazines**	**Empty aerosol cans**	
Plastic milk or water jugs	**Aluminum cans**	**Corrugated cardboard**	

The City does **NOT** allow the following to be disposed at the City landfill:

Aluminum cans	**Yard waste**	**Tires**
Lead batteries	**Large appliances**	
Anti-freeze	**Fluorescent bulbs**	

The Solid Waste Management Division publishes the *Business Waste Line* and *"One Man's Trash"* which includes articles such as profiles on recycling programs of local businesses, easy and effective things businesses can do to reduce waste, and updates on the City's collection services. *Business Waste Line* is published twice a year and *"One Man's Trash"* is published quarterly and sent to local businesses.

If you have any questions concerning the City's refuse and recycling program, or would like help setting up a recycling program for you business please contact the City of Greensboro Solid Waste Management Division at 335-5444.

3.2.3 Stormwater System Maintenance

Description

On-site stormwater system maintenance entails property owners or management regularly maintaining the stormwater system on their property. Often, it is very effective for individual facilities to periodically clean out on-site stormwater structures to assist in the City's effort in maintaining the stormwater system. By regularly maintaining on-site storm sewer systems and open channel conveyances, a facility may reduce the amount of sediment and other pollutants that can potentially migrate into the City's storm sewer system and downstream receiving waters. This helps the City meet the pollutant reduction goals associated with its federal National Pollutant Discharge Elimination System (NPDES) Stormwater Permit. Also, periodic cleanings of the stormwater infrastructure can prevent water back ups in the system and potential damage from flooding due to a clogged system.

Applicability

Sites that have stormwater conveyances (pipe system, open channel, and water bodies) on their property that drain the runoff from the site are responsible for maintaining the conveyances. Storm sewer conveyances that cross through private property but receive public runoff, will be maintained by the City of Greensboro. However, inlet structures that collect runoff from private property are the maintenance responsibility of the property owner, even if the structure is connected to a publicly maintained storm sewer pipe.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, organizations must prepare and submit an on-site stormwater system maintenance plan. This plan must meet the following minimum criteria:

1. Catch basins (e.g. curb inlets, grate inlets, etc.) and outfalls must be cleaned a minimum of 2 times per year.
2. Curb and gutter systems must be cleaned a minimum of 4 times per year.
3. Other implemented structural BMPs must be routinely maintained and inspected on an annual basis (minimum).

For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

City of Greensboro "SWIMS" Program

The City Storm Water Services Division is currently in the process of inventorying the storm sewer infrastructure and open channel conveyance systems in the city limits. The inventory includes public and private storm sewer systems (pipe diameter size is 12 inches or greater), open channels, and ponds and lakes.

Attribute information, such as structure depth, structure condition, etc, along with location information is gathered for each structure in the system (e.g. pipe, curb inlet). The City will use this information along with a Geographical Information System (GIS) to develop a proactive program termed the Stormwater Infrastructure Management System ("SWIMS"). This program will optimize maintenance of public storm sewer systems by specifying which structures need immediate repairs or cleaning before further problems occur. The program will also allow the City to predict which structures need to be cleaned more frequently based on data collected in the field and the associated land uses.

3.2.4 Paved Area Sweeping

Description

A paved area sweeping program can significantly reduce sediment and other potential pollutants from migrating into the City's waterways. Paved areas are a source of various pollutants (especially hydrocarbons and heavy metals emitted by vehicles). Small pollutants attach to sediment; and when it rains, the sediment, along with the attached pollutants, flow with the stormwater runoff to the nearest waterway. By employing a regular paved area sweeping program, a facility can dramatically reduce the amount of sediment entering the stormwater runoff. This not only helps the City maintain clean waterways but also improves general housekeeping efforts at individual facilities.

Applicability

Essentially, every commercial and industrial facility that has paved areas can employ a sweeping program. Commercial and industrial facilities with large parking lots often receive the most benefit from paved area sweeping. In addition, it is often more cost effective to sweep large paved areas as compared to small paved areas. Many industries may already be employing routine paved area sweeping to comply with their NPDES Storm Water Permit.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, organizations must develop, submit, and document implementation of a detailed paved area sweeping management plan. The plan should include at a minimum: sweeping frequency, name of sweeping contractor, sediment and debris disposal method, and areas regularly swept. All paved areas must be swept a minimum of once every two weeks. For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

City of Greensboro Paved Area Cleaning Program

The City of Greensboro Street Cleaning Division is responsible for periodically cleaning major and secondary public roads and public parking lots. The City uses a street sweeper that is equipped with a vacuum to pick up loose debris once it is swept to the curb. This prevents the debris from entering the storm sewer system.

3.2.5 Used Oil Recycling

Description

Petroleum-based products are one of the major pollutants found in many urban surface waters. One of the major contributors is improperly managed used oil. Therefore, a used oil recycling program employed at facilities that utilize oil in their operations can be extremely beneficial with respect to improving stormwater runoff quality. Many facilities that utilize oil should already have a used oil recycling practice in place as it has become relatively convenient and cost effective.

Applicability

Commercial and industrial facilities that use oil in its operations can employ a used oil recycling program. There are many commercial vendors that collect used oil and haul it to a commercial recycling facility. This significantly reduces the amount of effort required by facilities to employ used oil recycling. Furthermore, by using a reputable used oil recycling company, a facility can reduce its potential liability regarding used oil contamination.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, organizations must meet the following minimum criteria:

1. Offer and maintain an on-site, used oil recycling collection area.
2. Utilize a registered commercial oil recycling company to collect, haul, and recycle the used oil, as necessary.
3. Provide annually to Storm Water Services copies of all manifests for used oil collection performed each year.
4. Display City of Greensboro Used Motor Oil Recycling informational material in clearly visible and frequented on-site locations.

For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

City of Greensboro Household Hazardous Collection Center

Russell and Meiorin conducted a study (1985) of household practices and found that 11 percent of homeowners who change their motor oil disposed of it directly to street drains and another 14 percent disposed of it on the ground (Horsely and Witten).

The City of Greensboro, Guilford County, and ECOFLO, Inc. provide a service to collect household hazardous waste from all households in Guilford County (no commercial or business waste is accepted). The Household Hazardous Waste Collection Center is located at 2750 Patterson Street, Greensboro.

3.2.6 Covering

Covering includes protecting certain areas of a facility from contact with precipitation. Covering dramatically reduces the contact of precipitation on potential stormwater pollutant sources, thereby reducing the pollutant levels in stormwater runoff from a particular property. Covering can include a building, canopy, or other structure that directs rainfall away from areas of concern. Areas at a facility that are commonly covered in some form are stockpile areas, hazardous material storage areas, maintenance areas (i.e. motor vehicle), and loading/unloading areas.

<u>Applicability</u>

Covering is a common practice employed by many commercial and industrial facilities. The City recognizes that constructing coverings for large outdoor storage areas may not be cost effective for some facilities and other BMPs may be utilized.

<u>Storm Water Utility Credit</u>

To be eligible for stormwater utility credit for implementation of this BMP, covering must be employed at all hazardous and petroleum-based material storage areas and any area that entails maintenance activities. Organizations must meet the following minimum criteria:

1. All hazardous and petroleum-based materials must be covered and protected from stormwater contact.
2. A spill control and response plan must be developed and submitted to Storm Water Services for all hazardous and petroleum-based materials stored on-site.
3. All maintenance activities must be performed under covered areas.
4. A site sketch with the covered areas must be submitted to the Storm Water Services Division with the credit application before final approval of a covered area can be granted.

3.2.7 Spill Containment

<u>Description</u>

Spill containment BMPs are provisions incorporated to prevent spilled materials which are potentially hazardous from migrating outside storage areas. The containment may be a dike or pit (for example, a concrete or steel berm) constructed around individual storage containers or a storage area. The dike or pit will may have drain pipes with valves to allow "clean" stormwater to discharge from the containment area; however, the valve is kept shut under normal conditions in cases of a leak or spill.

If the area to be contained is a large area with a storm drainage network, it may be appropriate to construct a basin at the storm sewer outfall. The basin can be designed to trap floating materials through the use of a skimmer baffle, as shown in Figure 3.1.

It is preferred, if possible, that storage areas of significant materials be covered to prevent rainfall from entering the containment area.

Applicability

If a facility uses hazardous or petroleum-based materials (i.e. chemicals, wastes, oils, etc.) and stores them outside, they should employ spill containment around their storage areas. In many cases, however, if facilities do store hazardous materials outside, federal law *(40 CFR Part 112 - Oil Pollution Prevention Regulations* and *40 CFR Part 264 - Hazardous Waste Regulations)* require such facilities to have spill containment for these areas.

Stormwater Utility Credit

To be eligible for stormwater utility credit for implementation of this BMP, all hazardous and petroleum-based materials that are stored outside must have spill containment. Organizations wishing to receive credit for spill containment must meet the following minimum criteria:

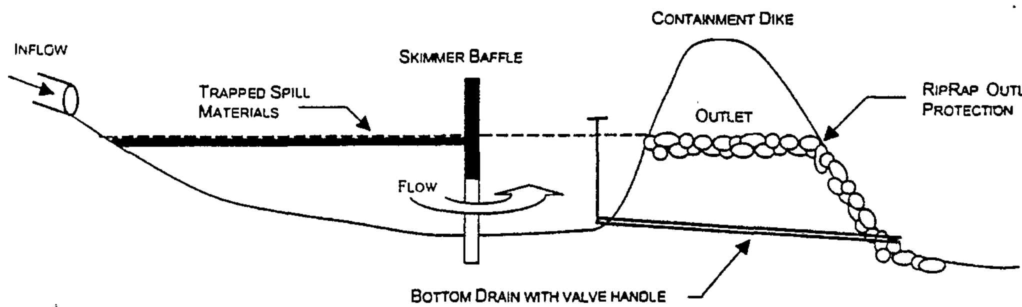
1. All spill containment facilities must be capable of containing 110 percent of the volume of the largest container in the applicable storage area. For example, if the largest container in a storage area is a 55-gallon drum, the spill containment storage area must have at least 61 gallons (55 x 110%) of volume.
2. For storage areas that contain potentially hazardous materials that dissolve in water or otherwise do not float, a spill containment structure must be provided with a valve. The valve must remain closed during normal facility operation. In the event of a rainfall event, the collected stormwater must be visually inspected (sight and smell) for any potential contamination. If no potential contamination is visible, the containment valve may be opened and the collected stormwater discharged. Any contaminated stormwater must be disposed in a proper manner.
3. For storage areas that contain potentially hazardous material that floats on water (e.g. oil), a structure using a skimmer baffle as shown in Figure 3.1 or other trapping provision may be used.
4. A site plan detailing the storage areas and spill containment must be submitted to Storm Water Services.
5. Display easily visible signage indicating a hazardous material storage area.
6. Implement a regular inspection program (once per week minimum) for all spill containment areas.
7. Document all inspection and maintenance activities associated with spill containment facilities (Inspection and maintenance log should be available for City review at any time).

For more information regarding credit opportunities, refer to the City's *Stormwater Utility Credit Policy* document.

Spill Containment for City of Greensboro Hugh Medford Service Center

The City of Greensboro has constructed a spill containment structure to protect potential spill areas at its Service Center. The structure is a wet basin with a skimmer baffle that traps floating material at the surface (as shown in Figure 3.1). For more information, contact the Storm Water Services Division.

Figure 3.1: Example Spill Containment Structure for Floatable Material



3.2.8 Erosion and Sedimentation Control

Description

Soil erosion has a major impact on the quality of surface waters. Erosion increases the sediment loading to surface waters causing adverse impacts such as increased turbidity, reduced light penetration, clogging of gills/filters of fish and aquatic invertebrates, and reduced spawning. Other impacts of increased sediment loading occur in low flow receiving waters, such as slow moving meandering streams, ponds and lakes, where the sediment has a chance to settle out. Impacts include smothering of aquatic habitat, more rapid filling of impoundments, increasing the need for costly cleanouts and decreasing the aesthetic value (Schueler, 1987).

The greatest amount of soil erosion occurs during development construction and related land disturbance, where grading activities expose the soil. Soil erosion can also occur on developed sites where pervious areas are not well stabilized (for example, sparse grass cover), and in urban streams where increased flow velocities due to increased runoff has eroded the stream banks, and other places where runoff has been concentrated and the conveyance system is not adequately protected to resist erosion.

Applicability

For all land disturbance activities erosion and sedimentation controls are to be implemented to prevent excessive sediment transport via stormwater runoff. After construction, it is important that property owners periodically inspect the facility grounds to check for any erosion problems or areas where earth is exposed due to poor grass cover or landscape cover.

City of Greensboro Soil Erosion and Sedimentation Control

Through the Soil Erosion and Sedimentation Control Act of 1973 and the City's National Pollution Discharge Elimination System (NPDES) Stormwater Permit, the City of Greensboro enforces sedimentation and erosion controls on all new commercial and residential projects. For sites where land disturbances are greater than one (1) acre, a grading permit is required by City Ordinance. For sites where land disturbances are less than one (1) acre, no grading permit is required; however, the City will still manage and enforce erosion control on the site.

Refer to the City's Soil and Sedimentation Control Section Standards of Practice for more information on the City's regulations, policies, and procedures. Or, contact the Field Services Section of the Storm Water Services Division at 373-2812.

3.3 Non-Structural BMPs

3.3.1 Open Vegetated Conveyance

Description

Open vegetated conveyances may be used instead of curb and gutter (where permitted) and hard piping to convey stormwater runoff where feasible. Open vegetative conveyances may be channels, swales, and, where runoff is in the form of sheet flow, any vegetated area that accepts runoff. Vegetated conveyances help to improve water quality by providing partial pollutant removal as the water is filtered by the vegetation and an opportunity for a portion of the water to infiltrate into the soil. They can also improve stormwater runoff quantity management by reducing the velocity of the flow through the conveyance and providing some infiltration into the soil.

Applicability

Vegetated conveyance systems can best be incorporated into moderate to low density development where land area is available and where the land surface is gently sloping (5% maximum). The site soils must be able to withstand erosion and a dense cover of strong rooted vegetation, such as tall fescue grass, must be established within the conveyance. Vegetated conveyances usually work best when the conveyance is "cut" into existing soils.

A benefit of using open vegetated conveyances is that they can save on construction costs by eliminating the need for stormwater sewer systems.

Open vegetated conveyances may be used for the following:

⇨ *Stormwater conveyance in the watershed critical area.* Section 30-7-3.2 (2) (a) states that drainage shall be provided by means of open channels. Subsection (b) states that the drainage shall have protected channels.

⇨ *Scoring points on the "scoresheet" for low density development in the General water-supply watershed area.* Use of open vegetated conveyances will provide more points than piped conveyances (Factor #10). Also, vegetated conveyances that are used and are designed to resist soil erosion (10-year event), will classify as "protected drainageways" on the scoresheet (Factor #5).

⇨ *To provide stormwater quantity control.* Vegetated conveyance systems can provide temporary retention to reduce stormwater discharge rates. A hydrologic-hydraulic analysis will have to be performed to determine the design that will provide the desired reduction (for more information on design guidelines, see Section 3.4.6, Grass Swales, and section 3.4.7, Filter Strips).

⇨ *Credit towards the stormwater utility fee.* Using vegetated conveyances instead of "hard" conveyances and are designed according to the guidelines given below, will be eligible for credit as specified in the *Stormwater Utility Credit Policy* document.

Planning and Design Guidelines

To improve its effectiveness as a stormwater BMP, open vegetated conveyance systems should be used in gently sloping areas to promote shallow, low velocity flow. This will maximize the channel filtering surface, and facilitate sedimentation and infiltration while increasing the travel time to the discharge point.

Channels and swales should be designed to promote shallow flow (i.e. trapezoidal). Conveyances designed with narrow cross sections will have higher velocities and deeper flow depths which allows for less pollutant removal, increased erosion potential, and higher quantity of flow at the discharge point.

The bottom width should be wide enough to maintain a shallow flow but narrow enough to prevent small rills from forming in the bottom during low flows.

Generally the side slopes should not be steeper than 3H:1V. The slopes should be flat enough to maximize the contact surface area (the water with vegetation) and prevent bank erosion while steep enough to reasonably contain the flow.

The permissible velocity for vegetated conveyances should be limited to prevent erosion within the channel. The permissible velocity varies depending on the soil type, the vegetation type, how well the conveyance is maintained, etc. Generally, the velocity should not exceed 4 ft/sec within the channel (10 year storm), for velocities greater than this, check dams may need to be constructed within the channel to slow the velocity.

It is recommended that the lining of open conveyances be a dense cover of erosion resistant grass, such as tall fescue. For channels and swales where relatively steep slopes exist (greater than 3:1), it may be beneficial to plant trees along the top of the slope. Tree roots will provide additional stabilization to the channel banks. It may be necessary to use temporary matting to get the grass established or to use sod.

3.3.2 Stream Buffers

Description

Stream buffers may be implemented along streams, drainageways, and impoundments. The function of the buffers are to:

- ⇨ protect the overall stream quality by providing shading for the stream and provide wildlife habitat;
- ⇨ remove pollutants from stormwater runoff through infiltration and filtering of stormwater runoff from adjacent land areas;
- ⇨ help attenuate flow rates from developed areas;
- ⇨ provide a set back from the stream to prevent damage to structures or improved property due to flooding or changes in the stream channel.

The most effective stream buffers for protecting the overall quality of the stream are those that are left undisturbed including a tree line maintained along the stream bank.

Applicability

All major streams, drainageways, and water bodies should have buffer protection.

Stream buffers must be provided for the following:

Meet water-supply watershed and stormwater management requirements. Refer to Section 2.3 of this Manual for more information.

Stream buffers may be provided for the following:

⇨ *Scoring points on the scoresheet for low density development in the General water-supply watershed area.* Points on the scoresheet can be granted for buffers placed on drainageways and jurisdictional streams (Factor #7).

⇨ *Reduce the stormwater runoff that a site generates.* Stream buffers can serve to reduce the runoff rates that flow into the buffer. The actual reduction depends of the quantity of flow entering the buffer, the flow source (e.g. pipe discharge, sheet flow), the width of the buffer, buffer ground cover, etc.

⇨ *Credit towards the stormwater utility fee.* Properties that implement stream buffers according to City requirements and the guidelines below will be eligible for credit as specified in the *Stormwater Utility Credit Policy* document.

Planning Design Guidelines and Requirements

Stream buffers, at a minimum, are required to be implemented on both sides of (1) perennial streams, as defined by this Manual, and (2) drainage channels draining an area equal to or larger than 50 acres. In the Randleman Lake Watershed, buffers on intermittent streams are required as well.

3.3.3 Disconnect Rooftop Drainage

Description

Disconnecting rooftop drainage can reduce the runoff flow rates from developed areas. Disconnecting means that runoff from rooftops will not be directed to storm drainage systems but rather be directed toward pervious surfaces where it can filter through the grass or other landscape material, or infiltrate into the soil.

Applicability

This practice is applicable mostly for low density residential or commercial developments (less than 50% impervious). Disconnection is not applicable where the volume of runoff from rooftops will cause erosion or problems to adjacent downstream properties.

Disconnection practices may be used for the following:

⇨ *Scoring points on the scoresheet for low density development in the General water-supply watershed area.* Points on the scoresheet can be granted for dispersing flow instead of concentrating it (Factor #5). To receive points, the rooftop should disconnected as specified below (along with other impervious areas).

⇨ *Provide stormwater quantity control.* Disconnection of impervious areas can increase the time it takes for runoff to travel to the site outfall (increase time of concentration) and may allow a portion of the runoff to infiltrate into the soil. The effect that disconnection has on stormwater quantity depends on many factors, such as the storm event, the amount of impervious area that is being disconnected, whether the flow is concentrated or not, the soil type, the type of cover on the pervious surface, and the distance from where the runoff is "disconnected" to the nearest downstream area of imperviousness, stormwater conveyance system, or site outfall.

⇨ *Credit towards the stormwater utility fee.* Properties that disconnect rooftop drainage according to the guidelines below, will be eligible for credit as specified in the *Stormwater Utility Credit Policy* document.

Planning and Design Guidelines

Downspouts from rooftops should discharge to gently sloping, well vegetated or landscaped areas (mulched areas do a good job in storing and dispersing water as long as the inflow velocity is not great). Erosion control devices, such as splash blocks may be needed at the roof downspout discharge.

Rooftops should provide a downspout for every 5000 square feet of rooftop to reduce the erosion potential at the discharge location. The minimum distance between downspout discharge and the next impervious surface shall be 10 feet.

3.3.4 Clustering/Conservation of Natural Areas

Description

Clustering is a land development practice which can be implemented to concentrate development away from environmentally sensitive areas such as streams, wetlands, mature forests, etc. Because the idea of clustering is to compact development in one location, it will also reduce the amount of roadways, sidewalks and drives required compared to development that sprawls over the entire land area.

Applicability

Clustering and conversation of natural areas should be practiced at least to some extent for all developments, not only to reduce the impacts to our natural resources by minimizing disturbance and percentage impervious, but also to maintain some of the natural beauty of the site.

Clustering and conservation may be used for the following:

⇨ *Scoring points on the scoresheet for low density development in the General water-supply watershed area.* Points for clustering (Factor #1) can be received based on the criteria listed in the water-supply watershed ordinance (Chapter 30). Points can also be earned for conservation of stream buffers (Factor #7) and for conservation or re-creation of wooded areas (Factor #11). Also, by reducing built-upon surfaces, points may be gained for built-upon area (Factor #2).

⇨ *Protection of fragile areas in the watershed critical area.* The City ordinance requires development to conserve fragile areas in the undisturbed state. Fragile areas are steep slopes (>15%) lying adjacent and parallel to streams and drainageways, and wetlands.

⇨ *Reduction of stormwater utility fee.* Clustering and conservation practices are designed to reduce the impervious areas required for the site. Because the stormwater utility is based on impervious surfaces, the fee will be reduced for the site.

⇨ *Other considerations.* Reducing the amount of impervious area reduces the volume of runoff required to be treated by structural BMPs thus reducing the cost and size of the BMPs. Concentrating development away from environmentally sensitive areas will also reduce the amount of time and expense to get federal and state permits for impacts to jurisdictional waters.

Planning and Design Considerations

Concentrate development on the flattest part of the land away from environmentally sensitive areas such as steep slopes, streams, and wetlands. This will not only reduce the impacts to these areas but may reduce the amount of earth moving necessary.

Minimize the width of streets (in accordance with City standards).

Minimize the number of parking spaces and reduce the size of parking stalls and parking aisle widths (in accordance with City standards).

Reduce the amount of overflow parking to the minimum needed.

Take inventory and preserve mature trees and forests.

3.3.5 Grass Paving

Description

Grass paving technology allows for the reduction of paved areas by implementing grass paving in areas that are infrequently used such as fire lanes, overflow parking, golf cart paths, etc. A variety of grass paving units are available on the market. Grass paving units are designed to carry vehicular loading and may be composed of different type materials. The pavers are usually covered with sod to make these areas practically indistinguishable from other grassed areas.

Grass paving provides water quality benefits by allowing stormwater to infiltrate into the underlying soils and by filtering of the stormwater as it flows through the grass.

Applicability

Grass pavers can provide a more aesthetically pleasing site and reduce the "sea of asphalt" look. Grass paving should not be used for frequently traveled or parked in areas, since damage could be done to the grass and the grass needs sunlight to survive.

Grass paving may be used for the following:

⇨ *Scoring points on the scoresheet for low density development in the General water-supply watershed area.* Points can be received for "Other Measures" (Factor #12) for use of grass paving. Sites that incorporate 5% of their total impervious surface as grass paving will receive 10 points for this category.

⇨ *Reduce the runoff generated by a site.* Grass pavers can reduce the runoff volume generated and extend the time of concentration. Some units may provide enough infiltration to be considered a pervious cover; check with the manufacturer for more information on the runoff characteristics of the grass paving.

⇨ *Reduction of stormwater utility fee.* Grass paving is not considered an impervious surface (see note below) as it pertains to the fee, therefore the fee will be less.

⇨ *Credit towards the stormwater utility fee.* Sites that incorporate grass paving into their site, will be eligible for credit as specified in the *Stormwater Utility Credit Policy* document.

*Note: Grass paving units are considered by the State and the City to be built-upon area, as it pertains to water-supply watershed regulations.

Design Considerations

Grass paving should not be used in high traffic areas or where vehicles will be permanently parked for long periods of time which may affect the growth of grass.

Refer to the manufacturer's guidelines for proper design considerations, installation, and maintenance of grass paving.

3.3.6 Natural Infiltration

Description

Natural infiltration is a method in which an undisturbed land area covered with natural vegetation accepts runoff from new development and infiltrates the runoff into the soil. Natural infiltration areas should only be used where the soils have a moderate to high infiltration rate (that is, soils in hydrologic group A or B). The area should be in the forested condition with the land surface covered by leaves, needles, and organic matter and should only be used for passive recreation, such as hiking.

Applicability

A natural infiltration area, that meets the design criteria below, may be used a stormwater quality control in the Watershed Critical Area (WCA) where the built-upon area is 6% or less in the Lower Randleman WCA or is 12% or less in any other WCA.

Design Considerations

The following equation is to be used to determine the size of the natural infiltration area (Source: Guilford County Water Quality Protection Manual):

$$A = (KTI)/[(cd - K)$$

Where

A = Natural infiltration area required
K = 0.5 (runoff, inches)
T = Site area
I = Built-upon area ratio (Built-upon area/T)
c = Effective water capacity, in./in. (water/soil)
d = Depth of soil A horizon, in. (determined from table 3.2)

TABLE 3.2: SUITABLE SOIL TYPES FOR NATURAL INFILTRATION

SOIL TYPE	c in/in	d in	HYDROLOGIC GROUP
Appling sandy loam	.25	6	B
Cecil, Madison sandy loam	.25	4	B
Enon, Vance, Helena, fine sandy loam and sandy loam	.17	4	B
Cecil, Enon, Madison, Coronaca and Mecklenburg sandy clay loam and clay loam	.14	4	B or C

SOURCE: GUILFORD COUNTY WATER QUALITY PROTECTION MANUAL

The runoff from areas to be treated should flow into the natural infiltration area as sheet flow and with a non-erosive velocity.

The natural infiltration area is to have the following characteristics:

1. Appropriate soils – high or moderate infiltration rates, low erosion potential, well drained (not in wetland or floodplain)

2. Mature forest cover (the calculated natural infiltration area (A) is to be doubled where a mature forest cover is not present)

3. Slopes not exceeding 10% (where slope exceeds 10% an additional 10% is to be added to the calculated natural infiltration area (A))

4. Remain permanently undisturbed – the natural infiltration area is to be covered by a water quality conservation easement (WQCE)

3.4 Structural BMPs

3.4.1 Introduction

The selection and design guidelines set forth by the City are provided to aid the design engineer in planning and designing the appropriate BMP relative to its function, ease of maintenance, aesthetics, and safety. The design engineer is responsible for designing stormwater BMPs to function properly for each specific site. The City will not be responsible for systems designed according to these guidelines which do not function properly; and will require failed systems to be replaced.

Table 3.3 compares the pollutant removal and peak flow rate reduction efficiency rating of the structural BMPs and notes whether the BMP is acceptable to use to meet the water-supply watershed requirements for high density development. The table also shows the stormwater credit "potential" that each BMP may be able to provide, which is based on its pollutant removal

Table 3.3: Structural BMP Control Efficiency Rating

STRUCTURAL BMP	POLLUTANT REMOVAL CAPABILITY (acceptable method under 30-7-1.12(B)(1)?)	APPROPRIATE FOR PEAK REDUCTION OF 2-YEAR, 10-YEAR STORMS?	STORMWATER UTILITY CREDIT POTENTIAL
Grass swales	2 (No)	2 (maybe feasible for small drainage areas – incorporate check dam(s))	2
Filter strips	2 (No)	2 (maybe feasible for small drainage areas – incorporate check dam at end)	2
Dry detention basins (w/ extended detention)	3 (No)	5	3
Wet detention ponds	4.5 (Yes)	4.5	4.5
Stormwater wetlands	4.5 (Yes)	3	4
Bioretention areas	4.5 (Yes)	1 (usually designed to capture first flush – may be feasible for very small sites	3
Sand filtration facilities	4.5 (Yes)	1	3
Proprietary stormwater treatment facilities	Varies (Depends – monitoring study may be req'd-see Sect. 5.13)	0-1 (most proprietary facilities that will meet watershed requirements are designed to capture the first flush	3

***Note: Scale of 1 through 5**
Where **1** represents limited efficiency/potential and **5** represents excellent efficiency/potential

and peak flow rater reduction capability. The credit potential shown in Table 3.3 is based on general cases. In some cases the BMPs may be able to provide more credit opportunity, for example, incorporating peak flow rate reduction in a bioretetention area that controls a small site.

****NOTE:** The minimum water quality requirements associated with the design of BMPs acceptable to meet water supply watershed requirements are noted by italicized text in the individual BMP sections.*

3.4.2 Structural BMP Selection Guidelines

Once the stormwater control objective has been decided, it is important to select the best BMP for the specific site. This section provides guidance on selecting structural BMPs that best meet certain site characteristics, community acceptance issues, and land uses. Each of the structural BMPs presented in this manual (except for proprietary stormwater treatment facilities) are compared in the following matrices. Again, this section is to provide general guidance; the design engineer should examine the site-specific case thoroughly before deciding on a BMP design.

Site Suitability

Table 3.4 shows some of the main site characteristics that are usually considered when determining which BMPs to be used. The *drainage area* category refers to, generally, the most appropriate BMP to use for certain drainage area sizes. For example, wet detention ponds seem to maintain a permanent pool when it has a larger drainage area

Table 3.4: BMP Site Suitability

Structural BMP	Drainage Area (Acres)	Space Consumption	Site Slope	Soils	Ground Relief B/W Inlet & Outlet
Grass swales	5 max	MED	4% or less	Erosion resistant; permeable	0.5 – 1 feet
Filter strips	Depends[1]	MED			0.5 – 1 ft
Dry detention basins (w/ extended detention)	Full range	MED	15% or less	Erosion resistant; compactable	3 to 6 ft
Wet detention ponds	10 min	HI		Compactable; impermeable	5 to 8 ft
Stormwater wetlands	20 min	HI	5% or less	Impermeable; topsoil for plants	5 to 8 ft
Bioretention areas	5 max	MED	10% or less	"Made" Planting Soil	5 to 7 ft
Underground Sand Filter	1-2 max	NONE – LO		Not restrictive	5 to 7 ft
Perimeter Sand Filter	1-2 max	LO			3 to 5 feet
Surface Sand Filter	5 max	MED			5 feet

[1] The drainage area to the filter strip is limited by the length of surface to be treated –100 feet.

(especially when there is a groundwater source), but most certainly can be used drainage areas smaller than 10 acres. Also, it is usually easier to manage sand filter facilities that have smaller drainage areas, but a larger site may choose to implement several facilities or a combination of different BMPs. The *space consumption* category refers to the relative amount of land space that is taken up by the BMP, including associated dams, benches and embankments. The *ground relief between inlets and outlets* category refers to the elevation difference between the inlet and outlet outfalls. For example, runoff from parking lot that is treated by a bioretention BMP first drops 6 inches from the parking lot to a gravel spreader, then flows down through 3 inches of mulch, 4 feet of "made" planting soil and 6 inches of gravel underdrain, and discharged. In this example, the runoff has to "drop" a little more than 5 feet from the inlet to outlet to be treated.

Community Acceptance

Table 3.5 shows various community and property owner issues that should be considered before selecting a BMP. These issues are important because the property owner will be fully responsible and liable for the BMP that is constructed.

Table 3.5: Community Acceptance

STRUCTURAL BMP	EASY TO MAINTAIN?	SAFE?	RELATIVELY ECONOMICAL[1]?	AESTHETICALLY PLEASING?	PROVIDES HABITAT?
Grass swales	☺	☺	☺	☺	☹
Filter strips	☺	☺	☺	☺	☹
Dry detention basins (w/ extended detention)	☺	😐	☺	😐	😐
Wet detention ponds	☺	😐	😐	😐	☺
Stormwater wetlands	😐	☹	😐	😐	☺
Bioretention areas	☹	☺	😐	☺	😐
Underground Sand Filter	☹	☺	☹	☺	☹
Perimeter Sand Filter	☹	☺	☹	☺	☹
Surface Sand Filter	☹	😐	☹	😐	☹

☺ = Yes 😐 = Maybe ☹ = No

Relatively Economical is based on the construction costs per drainage area treated. It does not take into account land costs.

Land Uses

Table 3.6 shows suggested structural BMPs for various land uses. It is important to note the proximity of residences or to the BMP, the desired aesthetic value, property owner's ability to maintain the BMP, land availability and costs, pollutant sources to the BMP, etc.

Table 3.6: Suggested BMP for Various Land Uses						
STRUCTURAL BMP	SINGLE FAMILY	MULTI-FAMILY	LOW DENSITY COMMERCIAL	HIGH DENSITY COMMERCIAL	LOW DENSITY INDUSTRIAL	HIGH DENSITY INDUSTRIAL
Grass swales	✓	✓	✓		✓	
Filter strips	✓	✓	✓		✓	
Dry detention basins (w/ extended detention)	✓	✓	✓	✓	✓	✓
Wet detention ponds	✓	✓	✓	✓	✓	✓
Stormwater wetlands					✓	✓
Bioretention areas	✓ (for individual home sites)		✓	✓		
Underground				✓		
Perimeter			✓	✓		
Surface			✓			

3.4.3 Control Volumes

Water Quality Volume (WQV)

The Water Quality Volume (WQV) is the storage needed within a structural BMP to control the "first flush" of runoff during a storm event. Studies have generally shown that the highest pollutant concentrations are found in the initial runoff period or "first flush." The State of North Carolina and City of Greensboro designate the "first flush" to be the runoff volume from the first 1.0 inch of rainfall over the drainage area to the structural BMP. The WQV may be calculated (Schueler, 1987) as follows.

$$\mathbf{WQV} = \frac{\mathbf{1.0 * R_v * DA}}{\mathbf{12}}$$

Where;

WQV = Water Quality Volume (in acre-feet)

$\mathbf{R_v}$ = Volumetric Runoff Coefficient (Schueler 1987) = **0.05 + 0.009(I)**

where **I** = percent impervious cover of the drainage area

DA = Drainage Area to BMP (in acres)

Quantity Control Storage Volumes

Refer to Section 2.4.2 of this manual for guidance on determining quantity control storage volumes.

3.4.4 Stormwater Utility Credit

Credit will be granted for sites that construct structural BMPs to treat runoff. The credit will be based on the BMPs pollutant removal and peak flow reduction efficiency. Organizations wishing to receive credit for installation of structural BMPs should follow the guidelines presented in this manual. For more information on credit opportunities refer to the City of Greensboro *Stormwater Utility Credit Policy Manual.*

3.4.5 Regulatory Considerations

The following State and Federal regulations need to be considered when designing structural BMPs.

Dam Safety

Structural BMPs designed to impound water pose a potential hazard to downstream citizens and property. Because structural BMPs are mostly used in urbanized areas or rapidly growing areas, such as in Greensboro, potential hazards related to water impoundments and dams are increased.

The State of North Carolina Dam Safety Law of 1967 [as Amended through 1995] provides for the certification and inspection of dams in the interest of public welfare with respect to reducing the risk of failure to dams. The rules, which are provided in the North Carolina administrative Code Title 15A, Subchapter 2K (see Appendix F), entitled "Dam Safety," state that "no person shall begin the construction of any dam until at least 10 days after filing with the Department a statement concerning its height, impoundment capacity, purpose, location and other information required by the Department." It is important to note that the department requires notification for the construction of *any* dam even if the dam may be "exempt" from the State's regulation.

The Regulations (N.C.G.S 143-215.25A (a) (6)) exempts a dam "that is less than 15 feet in height or that has an impoundment capacity of less than 10 acre-feet, *unless the Department determines that failure of the dam could result in loss of human life or significant damage to property below the dam.*" If the failure of a dam could result in the loss of human life or significant property damage the dam is classified as a High Hazard (Class C) structure. Although many structural BMP dams that are constructed in Greensboro are smaller than the size criteria for State regulation, the fact that they are being constructed in an urban or developing area could potentially have significant impacts to human life and property. Table 3.7 shows the quantitative guidelines used by the State Dam Safety Office for dam hazard classification.

To help ensure that stormwater BMP dams have met the State Dam Safety regulations and that the dams have been designed with public health, safety, and welfare in mind the **Engineer's Statement of Pond and Dam Safety** (Figure 3.2) is required for dams proposed to be constructed for stormwater BMPs that temporarily or permanently store water.

Table 3.7: Dam Hazard Classification

HAZARD CLASSIFICATION	CRITERIA	QUANTITATIVE GUIDELINES
LOW	Interruption of Road Service, Low Volume Roads	Less than 25 Vehicles per Day
	Economic Damage	Less than $30,000
INTERMEDIATE	Damage to Highways, Interruption of Service	25 to Less than 250 Vehicles per Day
	Economic Damage	$30,000 to Less than $200,000
HIGH	Loss of Human Life*	Probable Loss of 1 or More Human Lives
	Economic Damage	More than $200,000
		250 Vehicles per Day at 1000 Feet Visibility
		100 Vehicles per Day at 500 Feet Visibility
		25 Vehicles per Day at 200 Feet Visibility

*Probable Loss of Human Life Due to Breached Roadway or Bridge on or Below the Dam

NOTE: Cost of dam repair and loss of services should be included in economic loss estimate if the dam is a publicly owned utility, such as a municipal water supply dam.

Figure 3.2: Engineer's Statement of Pond and Dam Safety

ENGINEER'S STATEMENT OF POND AND DAM SAFETY

The stormwater pond and dam shown on this plan satisfies requirements of the North Carolina State Dam Safety Law of 1967 [As Amended Through 1995] and the Rules and Regulations as presented in the North Carolina Administrative Code Title 15A, Subchapter 2K - Dam Safety. Even in the case where the dam shown on this plan is determined by the State to be exempt from the above noted Dam Safety requirements, I, as the qualified design engineer, state that the pond and dam are designed to be safe and adequate for the protection of public health, safety, welfare, and downstream property. I understand that this statement as the design engineer shall not relieve the owner or operator of the pond and dam from the legal duties, obligations, and liabilities arising from such ownership or operation.

Jurisdictional Streams and Wetlands

It is the intent in most cases to design stormwater management devices to remove pollutants before they have a chance to enter "waters of the United Sates." Stormwater BMPs should be constructed outside of perennial streams and natural wetland areas unless no practical alternative exists. Also, natural or existing lakes, ponds, and wetlands should not be considered for stormwater BMP retrofits until Federal and State Permits for such purpose have been obtained. The US Army Corps of Engineers (ACE) requires that all impacts to jurisdictional waters and wetlands be reported to their office. Depending on the impact, the US ACE and NC Division of Water Quality (DWQ) may require the applicant to obtain permits, prepare environmental documents, mitigate for the impact, etc. For Greensboro, the contacts are the US ACE Raleigh Regulatory Field Office at 919-876-8441 and NC DWQ Winston-Salem Division Office at 336-771-4608.

Required Stream Buffers

Stream buffers protect the overall quality of the stream, by achieving pollutant removal as runoff flows through the buffer, by providing shade for the stream and habitat for wildlife. Stream buffers are required for certain streams within the City (refer to the City ordinance section 30-7, water-supply watershed districts, ordinance section 27-22, stormwater management control, and Section 2.3 of this manual for more information on buffer requirements). Although stormwater BMPs may be allowed in required stream buffers, other alternative locations should be examined. Whenever there is a practical alternative, structural BMPs should not be placed in stream buffers, but if encroachment into the stream buffer is needed, the amount of stream buffer area that is impacted and the distance between the impact and the stream should be minimized. Also, consideration should be given to the design of the BMP discharge to prevent erosion in the buffer zones and of stream banks.

FEMA Floodway/Floodplain

Placement of structures including stormwater structural BMPs within a designated 100-year floodplain as shown on FEMA's Flood Insurance Rate Map (FIRM), is strongly discouraged. In the event of a large flood, floodwaters could cause significant damage to the BMP. No structural BMP will be allowed in the designated "floodway" without submitting a "Certification of No Rise" to the City for approval, a "Conditional Letter of Map Revision" or a "Letter of Map Revision" is obtained from FEMA and all applicable federal and state permits have been obtained. Structures placed in the floodplain should be appropriately constructed to prevent damage from floodwaters. Refer to Chapter 30-7-5 Flood Damage Prevention, for more information regarding this subject.

3.4.6 Grass Swales

Description

Grass swales are gently sloping waterways or channels that are densely covered with erosion-resistant grasses and designed to slowly convey stormwater runoff. The grass swale is similar to the vegetated conveyance presented in Section 3.3.1 (Non-structural BMPs), but with additional provisions to improve its stormwater management functionality.

In the past, open channels were used for the sole purpose of conveying stormwater runoff, but by incorporating certain design parameters, grass swales can provide modest quality and quantity control. Swales help to improve water quality by providing partial pollutant removal through the filtering action of the grass, particle settling by reduced velocity, and infiltration into the soil. Grass swales can also improve stormwater runoff quantity management by reducing the velocity of the flow through the conveyance and providing some infiltration into the soil.

Applicability

Due to their limited pollutant removal capability, grass swales are not an acceptable BMP for meeting the requirements for "high density" development in the water-supply watershed. However, use of grass swales which are designed according to the guidelines presented in this section can be awarded credit on the stormwater utility fee. Also, grass swales in some cases can attenuate the peak flow rate from developed areas and can be used to meet stormwater management requirements. Typically, swales can be designed to control smaller storms (such as the 1-year or 2-year) and smaller sites (5 acres or less).

Grass swales can best be incorporated into moderate to low density development where land area is available and where the land surface is gently sloping (5% maximum), and the drainage area is relatively small (1 to 2 acres). The in situ soils must be able to withstand erosion and a dense cover of strong rooted grass must be established within the swale. Grass swales resist erosion better when the are "cut" into the natural ground.

Design Guidelines

For grassed swales to meet City regulations, a 15' access easement will be required from the public street right-of-way to the grassed swale. A maintenance easement shall be placed over the swale and shall extend 15' beyond the top of the side slopes.

Cross section geometry: To improve their effectiveness as a stormwater BMP, grass swales should be constructed with a wide cross section (for example, trapezoidal, or parabolic) and in gently sloping areas to promote shallow, low velocity flow. This will maximize the channel filtering surface, and facilitate sedimentation and infiltration while increasing the travel time to the discharge point. Swales that are designed with narrow cross sections tend to have higher velocities and deeper flow depths which allows for less pollutant removal, increased erosion potential, and higher quantity of flow at the discharge point.

WQV storage: The WQV should be discharged within 6 to 24 hours. The water quality volume should be temporarily detained in the grass swale and released over 24 hours (48 hours maximum). The maximum depth of the water quality volume storage within the swale should be 1.5 feet.

Flow Velocity: The velocity for 2-year storm should not exceed 2 feet per second within the swale.

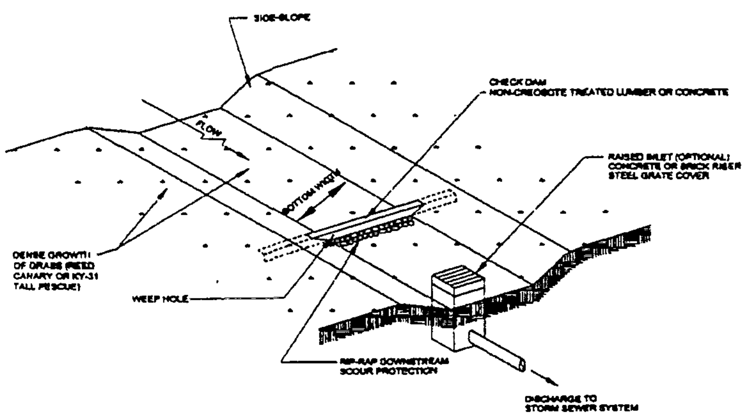
Bottom width: The bottom width should be within the range of two to eight feet. The two feet minimum allows for construction considerations wide enough to maintain a shallow flow but narrow enough to prevent small rills from forming in the bottom during low flows.

Side slopes: The side slopes should be flatter than 4H:1V. The slopes should be flat enough to maximize the contact surface area and prevent bank erosion while steep enough to reasonably contain the flow.

Longitudinal slope: The longitudinal slope should be less than 5%. The slope should allow for sufficient drainage and uniform flow while preventing excessive velocity. For slopes greater than 2%, check dams should be utilized at the specified intervals.

Check dams: A control to increase the stormwater management efficiency of vegetative swales, is to construct check dams spaced at suitable intervals and perpendicular to the flow direction. Check dams may be constructed with treated timber, gabions, or rip rap. For quality credit, check dam spacing is such that the top of a check dam is at the same

Figure 3.3: Example of Grass Swale



elevation as the toe of the check dam immediately upstream. For example, a swale that has a 4% slope and check dams that are two feet high, would have a spacing of every 50 feet. A hydrologic-hydraulic study will have to be performed to determine the spacing and discharge rates of the check dams needed to meet quantity reduction **requirements.**

Capacity: The swale should be designed to adequately convey the 10 year storm event in a non-erosive manner or provide an overflow as shown in Figure 3.3.

3.4.7 Filter Strips

Description

Filter strips are similar to grass swales, with the exception that strips are designed to receive runoff from impervious or pervious areas in the form of sheet flow. The filter strip is usually the same or greater width than the area it is treating and a spreading device (such as a gravel diaphragm) is placed between the runoff area and the filter strip to help distribute the runoff evenly. The filter strip may be a replanted forested area or a densely grassed area (see Figure 3.4). The filter strip may also be a natural undisturbed area where the land characteristics meet the design criteria below.

Filter strips, like swales, provide modest pollutant removal efficiency through the filtering action of the grass and infiltration into the soil.

Filter strips slightly reduce peak flows by reducing velocity and providing some infiltration into the soil. A check dam can be used at the end of the filter strip to provide additional peak reduction and direct the discharge to a conveyance system, if desired.

Applicability

Filter strips are best utilized in low density developments (single and multi-family) where the contributing drainage area is small, relatively flat (less than 5%), and will drain through overland flow. Filter strips can treat runoff from parking lots, roads, or pervious areas that receive chemical treatment such as golf courses. The area to be treated should flat across its width so runoff will be evenly distributed across the filter strip.

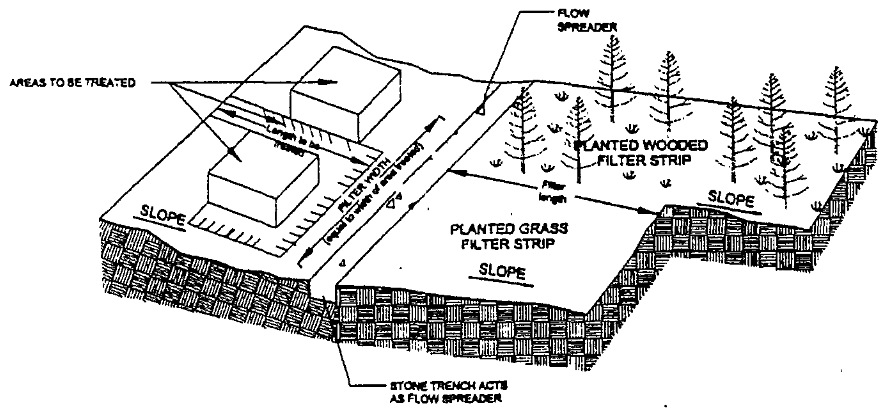
ue to their limited pollutant removal capability, filter strips are not an acceptable BMP for meeting the requirements for "high density" development in the water-supply watershed. However, filter strips can be effective when used as pretreatment for other BMPs such as bioretentDion. Filter strips also do a good job in protecting water resources such as streams, wetlands and lakes.

Design Guidelines

For vegetated filter strips used to meet City regulations (water-supply watershed or stormwater management), a 15' wide access easement will be required from the public street right-of-way to the filter strip. A maintenance easement shall be placed over the filter strip and extend 15' beyond its perimeter.

Length (direction of flow): The length of filter strip should be at least 50 feet. The length of 50 feet will give the runoff time to be filtered or intercepted by the vegetation and allow some infiltration. After 100 feet of run it is probable that the sheet flow will begin to channelize.

Figure 3.4: Example of Filter Strip



Width: The filter strip width should be the same width of the area that it is treating (see diagram). Runoff should enter the filter strip as uniform, low velocity sheet flow. A pea gravel diaphragm or level spreader may be required to uniformly distribute and dissipate the energy of incoming flow.

Longitudinal Slope: The longitudinal slope of the filter strip should be between 1 to 6%. The strip should be sloped enough to provide positive drainage but not too much to exceed the erosion tolerance of the vegetation. The designer should note what type ground cover and soil type that will be used when designing the slope of the filter strip.

Vegetation: The filter strip can be planted with a variety of species but should incorporate a dense cover of strong rooted grass, plants and trees. A mixed, dense, **native** grass species is the most low maintenance, sustainable, effective forms of vegetation cover for reducing runoff volume and pollutant loads (study findings - Texas State Soil and Water Conservation Board Bulletin No 97-1). Where natural areas are used as filter strips, the existing natural vegetation usually provides effective treatment.

Treatment Area: Areas to be treated by the filter strip should be graded uniformly with a longitudinal slope of 5% or less. The maximum length of impervious area that can be treated is 100 feet.

Flow Spreader: A gravel diaphragm (trench) should be used to separate the area to be treated from the filter strip. The trench shall be used to dissipate the energy of incoming runoff and maintain sheet flow. The filter strip should exactly meet the elevation of the level spreader to help prevent the chance of channelization (Schueler, 1987).

Optional Check Dam: For increased quantity control a check dam be placed at the end of the filter strip for temporary storage. The check dam can also provide a means to concentrate discharge at one location (e.g. to a yard inlet) once it passes over the filter strip.

3.4.8 Dry Detention Basins

Description

A dry detention basin is a stormwater temporary storage basin that does not have a permanent pool. Dry basins receive stormwater runoff and temporarily stores (or details) it for a short period of time as the captured water is slowly released. Dry detention basins can be incorporated in underground chambers, athletic fields, open spaces, etc, and therefore, is relatively easy to fit into a site.

Dry detention basins are best used for reducing stormwater runoff peak flow rate to an acceptable rate. Because dry detention basins have a tendency to re-suspend accumulated sediments, they are not the best choice for water quality protection. However, by providing "extended detention" (WQV is discharged over 24 hours), dry detention basins can provide modest pollutant removal, mainly of coarse sediments.

Applicability

The dry detention basin is ideal for reducing flow rates of small and large storm events. Dry detention basins can be sized to support small to large size drainage areas. Therefore, this BMP can be effective to meet the requirements of the quantity control requirements of the stormwater management ordinance.

Dry detention basins do not have the pollutant removal capability of wet detention ponds and are **not** considered an acceptable stormwater BMP to meet the requirements for high-density development in water-supply watershed areas. However, dry detention basins with extended detention do a decent job in settling out coarse particles. Therefore, sites that incorporate extended detention of the WQV and the design guidelines below are eligible for quality credit as specified in the *Storm Water Utility Credit Policy* document .

Also, dry detention basins may be used as part of a "treatment train," for example, as the pretreatment (sedimentation) basin to the surface sand filtration facility.

General Guidelines

Avoid placing these structures in environmentally sensitive areas such as streams and wetlands.

Though dry detention basins impound water temporarily, associated dams should be constructed in accordance with NC Dam Safety Regulations. Careful attention should be paid to dam design and the downstream present and future use.

For dry detention basins used to meet City regulations, a 15' wide access easement will be required from the public street right-of-way to the dry basin. A maintenance easement shall be placed over the basin and extend 15' beyond its embankments (or outer edge for concrete chambers). Underground chambers will need an adequate amount of access doors/manholes for periodic maintenance, such as sediment removal.

The embankment slopes for open basins should be flatter than 3H:1V slope for safety and ease of maintenance. Suitably designed vertical concrete walls may be used instead of earth embankments for open dry detention basins. In this case, it is recommended that a safety fence or other device be constructed around basin perimeter to prevent accidents.

Design Guidelines

For design methodology on meeting stormwater management regulations, quantity control, please refer to section 2.4.2.

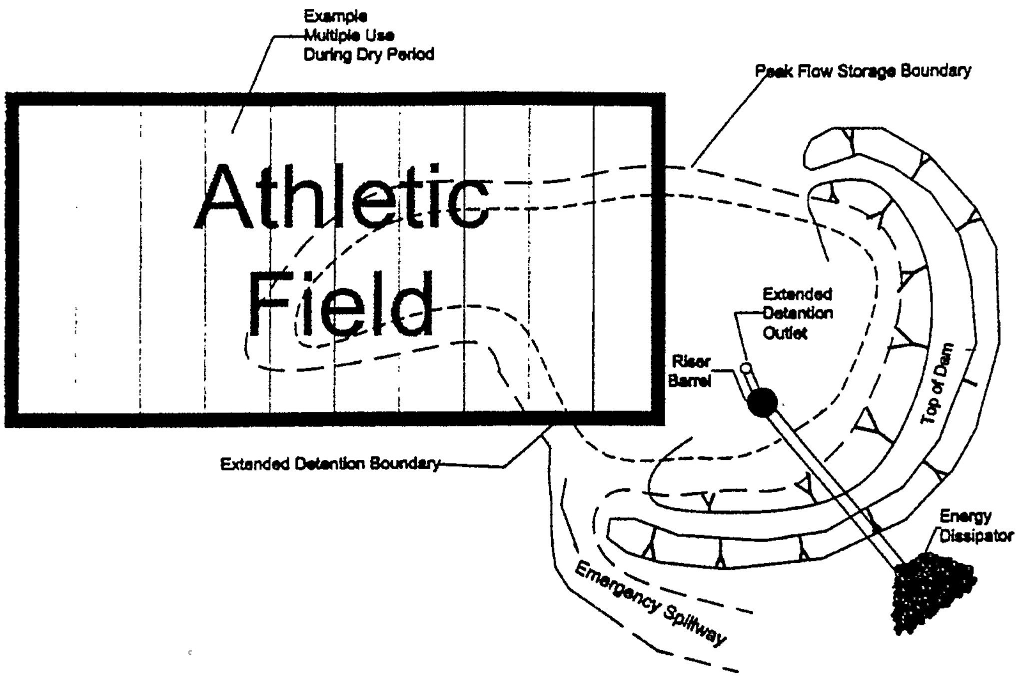
Dry detention basin should temporarily store the WQV for 24 hours or more.

The efficiency of sedimentation basins to settle suspended solids is based mainly on the surface loading rate (outflow divided by basin surface area) and is relatively independent of the depth of the basin. The following equation may be used to size a sedimentation basin with an efficiency of settling particle sizes larger than 20 microns. It was derived by the Washington State Department of Ecology from the Camp Hazen Equation (Schueler, 1996):

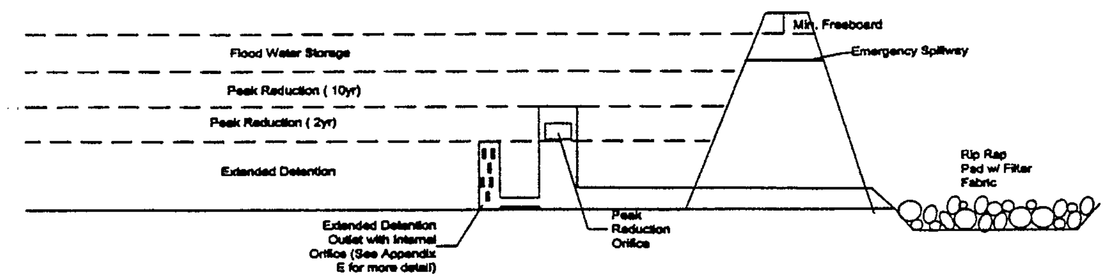
$$As = -(Qo/w) * Ln(1-E)$$

Where
- As = Sedimentation basin surface area (sq. ft)
- E = Trap Efficiency - target 90% (equation uses decimal format)
- w = Particle settling velocity (for 20 micron silt particle = 0.0004 ft/sec)
- Qo = rate of outflow (WQV divided by detention time, usually 24 hours)

Figure 3.5: Example of Dry Detention Basin



PLAN



PROFILE

R0010526

Low flow Orifice(s)
Low flow orifices are designed to slowly release the volume stored in the basin. The release device may be a perforated riser, pipe with attached orifice plate, or a skimming device. With any of these orifices trash protection must be considered (see Appendix H for examples of trash protection devices).

Spillways
Aboveground dry detention basins should have spillways designed to safely pass up to the 100-year storm event, at a minimum. Riser/barrel assemblies, concrete chutes, or rip rap lined channels may be used to pass larger storm events. Open channel spillways must not be placed in the fill section of earth dams. The spillways must have provisions to prevent erosion of the receiving conveyance.

3.4.9 Wet Detention Ponds

Description

In Greensboro, the wet detention pond is currently the most commonly used BMP for meeting water-supply watershed protection requirements. This stormwater BMP improves stormwater quality primarily by detaining stormwater runoff for an extended period of time (usually 2 to 5 days) to allow pollutants that are suspended in the runoff to settle out. During a storm event, runoff enters the pond and replaces the "treated" water in the permanent pool that has been detained in the permanent pool from the previous storm event(s). As runoff enters the pond, its velocity is significantly reduced allowing suspended pollutants to begin settling. Many pollutant particles found in stormwater runoff are very small in size and, because smaller particles settle slower than larger particles, the pond is designed to provide adequate detention time so smaller particles have a chance to settle out.

The components of the wet detention pond that help increase the pond's pollutant removal efficiency are the permanent pool, temporary pool, and forebay. The permanent pool prevents particles that have settled to the pond bottom from re-suspending when runoff flows into the pond. The temporary pool is storage above the permanent pool that is designed to control the WQV. To increase the detention time of the runoff, the temporary pool is slowly released through low flow orifice(s). A separate smaller pond, called a forebay, is placed upstream of the main pond to trap a majority of the coarser fractions of suspended solids in the runoff before it enters the main pond.

Applicability

The wet detention pond is effective in removing pollutants and can be used to meet water supply watershed regulations. It also can be easily adapted to provide quantity control for storms larger than the water quality storm event, require less periodic maintenance than other structural BMPs, and if desired can provide an amenity to a property such as "lakefront" residential property, wildlife habitat and fountain pools. The wet detention pond BMP is most applicable for large industrial and commercial facilities and residential subdivisions.

Wet detention ponds, based on findings from the City's periodic BMP inspection program, seem to function better when the pond is larger and receives flow from a larger drainage area. This may be attributed to several factors, such as, in larger drainage areas there is usually a better chance for seasonal or permanent surface or groundwater flow into the pond as opposed to smaller drainage areas. This flow may help the permanent pool to be "flushed" more often (as opposed to only during storm events), which may help to prevent undesirable conditions from developing (for example, stagnate water, fluctuating permanent pool elevation, etc.). It is suggested that owners of smaller properties cooperate to construct and maintain one relatively large pond to serve several properties, rather than several individual smaller ponds. Although the City generally recommends a drainage area of 10 acres or more, wet detention ponds may be used for smaller drainage areas.

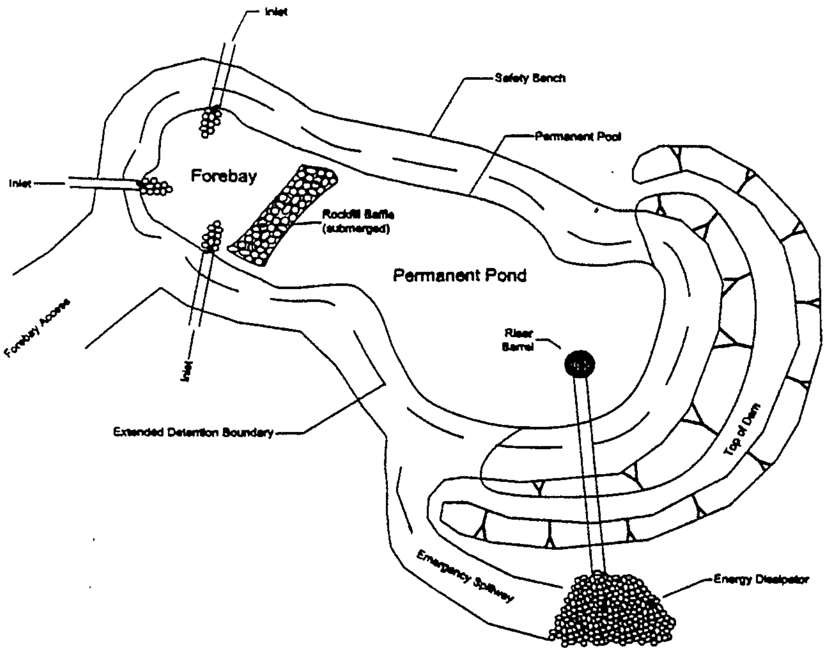
Wet detention ponds have a higher tolerance for runoff with significant sediment concentration than the other BMPs. Therefore, wet detention ponds are the best BMPs to use in large developments where construction will take place in phases or in residential development where site disturbance will occur for a significant period after the BMP is installed. Also, properties where the land may remain fully or partially unstabilized or if there are sources of sediments on the property (e.g. stock yards, gravel/dirt areas, construction equipment storage, etc.) the wet detention pond is a good choice.

General Guidelines

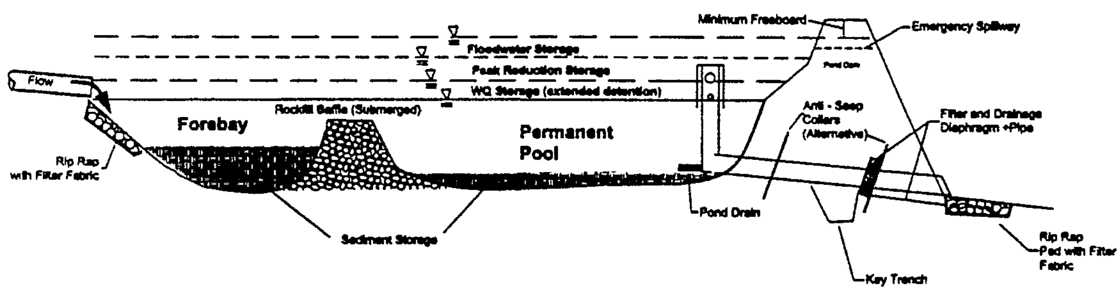
Placement of ponds in jurisdictional waters may require Federal and State Permits. It is suggested that ponds not be placed in perennial streams, whenever possible. Also, wet detention ponds used to meet water-supply watershed regulations will be required to be designed to treat the total drainage area to the pond, on-site and off-site, per the City's water-supply watershed ordinance. That means, if the property owner of a 10 acre site decides to place a wet detention pond in a perennial stream that drains 75 acres, the pond must be sized to control 75 acres of drainage area including the existing development within the drainage area in addition to the 10 acre site. However, the property owner may be able to recoup costs by allowing new development in the off-site drainage area to use the pond to control built-upon area in exchange for financial participation.

When designing the dam and spillways, existing and potential future downstream development should be considered. Avoid placing the dam upstream of highly developed or traffic areas whenever possible. The discharge from the spillways should be directed to a conveyance system that can adequately handle the flow or if no conveyance is present, the discharge should be directed away from existing development.

Figure 3.6: Example of Wet Detention Pond



PLAN



PROFILE

R0010529

The pond should be easily accessible for maintenance. A 15' wide access easement shall be provided from the public street right-of-way to the pond. A drainage maintenance and utility easement (DMUE) shall be paced over the pond and extend 15' beyond the embankments. The access easement should be kept easily accessible for maintenance.

For ease of maintenance and safety, the pond embankments should be sloped to a maximum of 3H:1V with flatter slopes preferred. A 10-15' bench (max. slope 10%) placed around the pond near the normal pool surface, is strongly encouraged. This bench will allow machinery gain closer access to the pond during cleanouts. This break in the grade will be a safety amenity and can make the pond more aesthetically pleasing.

The pond surface area shall have a minimum 2:1 length to width ratio, with 3:1 preferred. *The distance between the inlets and outlets should be maximized to increase the pollutant removal capability of the pond.*

It is encouraged to create a pond that fits within the natural contours of the land but care should be taken to prevent "dead storage zones" (areas outside the flow path between the inlet and outlet) within the pond. "Dead storage zones" are areas outside the flow path from the inlets to the outlets. Generally, the pond should be narrower at the inlet forebay area and become wider at the outlet. Whenever possible one forebay should be created and all pond inlet pipes discharge to the forebay area.

The bottom of the pond should be slightly sloped from the upstream end to the downstream end. This will allow the pond and captured sediments to drain better when cleanouts are necessary.

It is encouraged where appropriate to use educational signs at the pond describing the function of the pond and the purpose it serves.

Design Guidelines

Sediment Storage: Storage is to be allocated for sediment accumulation between cleanouts. *Recommended 0.125 inches depth over the drainage area with approximately 75% of this volume be allocated to the forebay.*

Minimum Average Permanent Pool depth: 3 feet.
The average permanent pool depth is the average depth of the permanent pool over the entire pond including the forebay. The permanent pool is measured from the top of the sediment storage to the invert of the low flow orifice that releases the WQV.

Permanent Pool Surface Area: See Table 3.8:

Table 3.8: Wet Detention Pond Permanent Pool Surface Area to Drainage Area Ratio (Percent)							
BUILT-UPON PERCENT	**AVERAGE PERMANENT POOL DEPTH (FT)**						
	3.0	**4.0**	**5.0**	**6.0**	**7.0**	**8.0**	**9.0+**
10	0.59	0.49	0.43	0.35	0.31	0.29	0.26
20	0.97	0.79	0.70	0.59	0.51	0.46	0.44
30	1.34	1.08	0.97	0.85	0.70	0.64	0.62
40	1.73	1.43	1.25	1.03	0.90	0.82	0.77
50	2.00	1.73	1.50	1.33	1.09	1.00	0.92
60	2.39	2.03	1.66	1.51	1.29	1.17	0.10
70	2.75	2.27	1.96	1.79	1.48	1.35	1.29

Interpolation and extrapolation may be necessary to determine the appropriate surface area to drainage area ratios.

Temporary pool volume: water quality volume (WQV).

Temporary pool draw down time: 2 to 5 days.

Principal Spillway Capacity: 10 year 24 hour storm event.

Emergency Spillway Capacity: Minimum 100 year 24-hour rain storm event (design to be consistent with the NC Dam Safety Requirements).

Dam freeboard: NC Dam Safety requires a one (1) foot minimum freeboard above the maximum flood pool elevation during the spillway design flood. The City encourages the designer to maximize the freeboard to the extent practicable.

Pond Inlets

Inverts for inlet pipes should be at the elevation of the normal pool to allow the pool to dissipate the energy of the inflow to prevent erosion along the embankment slope. Inlets should be designed to discharge to the pond perpendicular to the pool surface to minimize potential erosion problems to the side embankment. Rip rap pads should be underlain with a gravel/sand filter or geotextile fabric which should extend from the pipe invert to the pond bottom.

Forebay

A forebay shall be provided for all inlets to the pond. The forebay area is to be located at the upstream area of the pond. *The forebay is separated from the rest of the pond by a barrier or baffle, which may be constructed of earth, rip rap, or gabions. The forebay serves to trap coarse sediments and minimize their migration into the main pond. Collecting the sediment in this one area makes it easier to clean out, since machinery will not have to go into the entire pond, which can be very expensive.*

The forebay baffle should extend to one foot below the normal pool elevation or above. The baffle material may be earth, rip rap, etc. If earth baffles are used, provisions should be included to allow the forebay to drain out with the rest of the pond to facilitate sediment removal from the forebay. This could include a rip rap check dam in a section of the earth baffle or a perforated riser pipe connecting the forebay to the main pond.

It is recommended that approximately 75% of the required sediment storage be allocated to the forebay. To minimize the resuspension of settled particles, the depth of water in the forebay (between the permanent pool elevation and top of sediment storage) should be at least 2 feet and the average velocity for the 2-year storm peak flow rate (peak flow divided by average cross sectional area of forebay) should be less than 1.0 fps.

An access to the forebay for future sediment cleanouts is to be provided. It is recommended that the access have a maximum slope of 15-20% extending from the top of the embankment to the toe. This access will allow construction equipment to get down in the forebay and will minimize disturbance to the vegetation.

Pond Dam

Notification of the proposed dam construction is to be made to the NC Dam Safety Office.

A concrete retaining wall may be used for the pond dam, but it shall not include more than 50% of the pond perimeter.

For earth dams, the top width of the dam should be 10 feet minimum.

For earth dams, a cutoff trench should be excavated and filled with highly impervious and well compacted material. Incorporating a chimney drain or drainage blanket should be considered to reduce the potential for seepage problems.

For large ponds that have a considerable fetch, wave action during storms should be considered in the freeboard.

Treatment Orifices

Low flow orifice(s) shall be used to slowly release of the water quality volume over a period of 2 to 5 days. Additional low flow orifice(s) or other appropriate provisions may be incorporated above the temporary pool to provide peak flow reduction. Refer to Appendix F for the preferred method for calculating the orifice drawdown time.

The low flow orifices are to be protected from clogging up with floating debris using a trash guard. The trash guard should be durable and secure and should extend at least six inches below the normal pool surface. A common method when using a riser/barrel is to extend the principal spillway trash rack assembly below the normal pool. When the low flow orifice will be placed in a concrete dam or spillway, an inverted or submerged orifice can be used or a half aluminum pipe bolted to the concrete (see Appendix H for example trash protection devices).

Principal Spillway
The principal spillway should be a riser/barrel, concrete free fall weir, or concrete chute with capacity to handle the 10-year 24 hour rain storm event, at a minimum. Of the available options for the riser/barrel material such as reinforced concrete, ductile iron, PVC, or corrugated aluminum piping, reinforced concrete (where the joints are sealed watertight) and ductile iron pipes (being rigid pipes) are preferable for this application. A flexible pipe, such as corrugated aluminum piping may experience distortion of its cross-sectional shape during compaction of the soil around it and result in internal soil erosion problems potentially leading to failure of the embankment around and above the pipe.

Riser/barrel assemblies should be equipped with a trash rack and an anti-vortex device and should be properly anchored to resist buoyancy forces.

A "filter and drainage diaphragm" or anti-seep collars should be used to prevent piping along the barrel within the earth fill, with the diaphragm being the preferred method (see Appendix J for NRCS design guidelines).

Appropriate energy dissipation should be used at the spillway exit to prevent erosive velocities for up to the 10-year peak discharge rate, at a minimum. Every effort should be made to discharge in defined conveyances and parallel to the existing flow to prevent bank erosion. Downstream channels may need to be modified and lined with rip rap to prevent erosion of the channel. Modifications to the downstream channel should be minimized as much as possible to prevent excessive disturbance in the channel.

Emergency Spillway
The emergency spillway should be designed to safely convey discharges resulting from storms up to the 100-year 24 hour storm, at a minimum. The spillway should be located where it will not adversely affect downstream property such as roadways and building structures. The emergency spillway may be incorporated into the principal spillway where accommodating the emergency spillway elsewhere is not feasible for the given site characteristics.

The emergency spillway should be cut into existing soils outside the fill section of the dam. The emergency spillway may be grass lined, when velocities permit, or lined with **rip rap, concrete, or other erosion resistant materials. Grass lined spillways are to be planted with a dense cover of erosion resistant grasses.**

Pond Drain
A pond drain is to be provided to drain the pond for routine maintenance or structural repairs in an emergency situation. It is recommended that the pond drain be designated to have the discharge capability to completely drain the pond in less than 48 hours, in the event of an emergency posed by impending failure of the pond dam. The upstream slope of the pond dam should be designed to be flat enough to prevent slope failure due to "quick drawdown" of the pond (NC Dam Safety Code specifies a factor of safety of 1.25) in an emergency. Care should be taken to minimize transport of settled sediment from the pond during draining.

3.4.10 Stormwater Wetlands

Description

Constructing wetlands to treat stormwater is an attempt to reproduce the excellent pollutant removal capability of natural wetlands. Stormwater wetlands remove pollutants primarily through physical filtration and settling, by biological processes of wetland plants, and bacteria in the substrate. The stormwater wetland BMP is, in some respects, similar in design to the wet detention pond. The major difference is the creation of varying depth zones in the shallow marsh area of the wetland to support emergent wetland vegetation. Because consideration must be paid to creating various depth zones and establishing a plant community that can thrive in the different zones, designing, constructing, and maintaining stormwater wetlands is more complex than wet detention ponds.

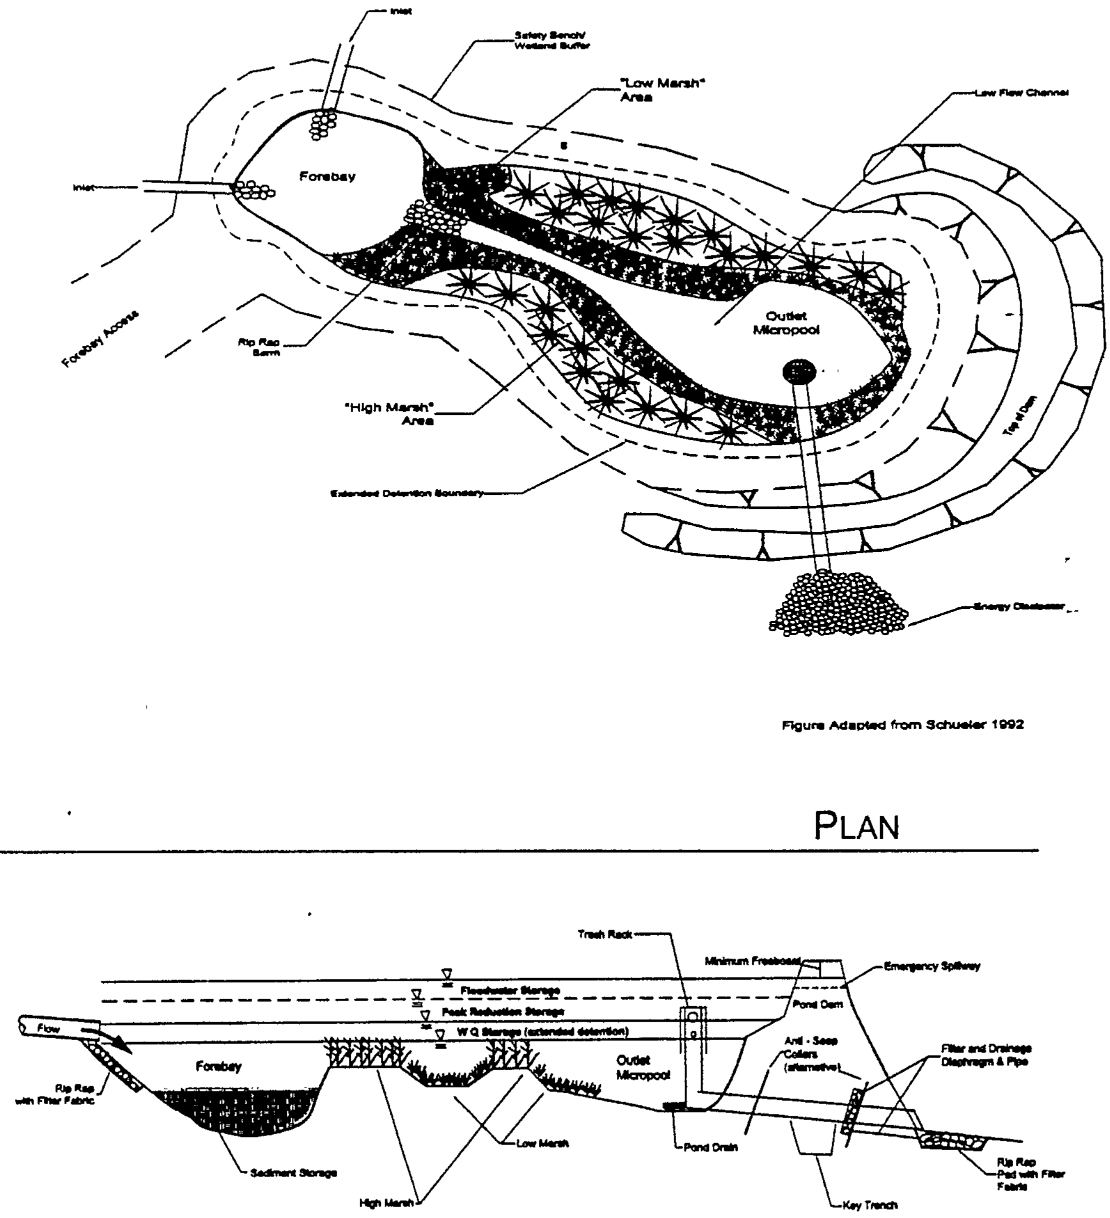
Although stormwater wetlands are modeled after natural wetlands, they have many differences. Generally, natural wetlands are self-maintaining while stormwater wetlands will not exist without human care (Schueler 1992). Because stormwater wetlands are located in the urban setting and do not contain natural wetland soils conducive to wetland plant growth, stormwater wetlands do not possess the diversity of wildlife and plant community that natural wetlands possess.

Applicability

Sustaining a moisture condition where the wetland plantings can survive is crucial to making stormwater wetlands successful. Therefore, stormwater wetland BMPs should be used for larger drainage areas (greater than 20 acres). It is also recommended to determine the water table elevation and examine the water balance to determine if the wetland can survive during dry weather. Permanent access to an irrigation supply may be necessary to sustain the wetland if the water balance in the wetland is insufficient.

Because wetland areas will attract a diverse wildlife and plant life, using the stormwater wetland for treatment in the urbanized and residential setting should be carefully considered. A wetland buffer as shown in Figure 3.7, is recommended to protect the wetland habitat and shield nearby land uses from potential nuisances (Schueler, 1992).

Figure 3.7: Example of Stormwater Wetland



Natural wetland areas will not be allowed to be converted to stormwater wetlands without the regulating approval of the US Army Corps of Engineers (US ACE) and the NC Division of Water Quality (NC DWQ). The removal of wetland soils and vegetation from natural wetlands to provide a "seedbank" for a stormwater wetland BMP is prohibited without consultation with the US ACE and NC DWQ. Once stormwater wetlands are created, they may become the jurisdiction of the US ACE and NC DWQ. Filling in or modification to the stormwater wetlands once they are established may be illegal without a permit.

Peak reduction storage may be incorporated into the wetland design above the temporary water quality volume storage if the plants proposed can sustain submergence for the required inundation period.

General Guidelines

Placement of wetlands in jurisdictional waters may require federal and state permits. It is suggested that wetlands not be constructed in perennial streams. As required for all BMPs used to meet water-supply watershed regulations, stormwater wetlands will be required to treat the total drainage area to the wetland, on-site and off-site.

When designing the dam and spillways, existing and potential future downstream development should be considered. Placing the dam upstream of highly developed or traffic areas should be avoided whenever possible. The discharge from the spillways should be directed to a conveyance system that can adequately handle the flow or if no conveyance is present, the discharge should be directed away from existing development.

The wetland should be easily accessible for maintenance. A 15' wide access easement shall be provided from the public street right-of-way to the wetland. A drainage maintenance and utility easement (DMUE) shall be paced over the wetland and extend 15' beyond the top of embankments. The access easement should be kept easily accessible for maintenance.

For ease of maintenance and safety, the wetland embankments are not to be steeper than 3H:1V with flatter slopes preferred. A 10-15' bench (max. slope 10%) placed around the wetland near the normal pool surface elevation, is encouraged. This bench will allow machinery gain closer access to the pond during cleanouts. This break in the grade will be a safety amenity and can make the wetland more aesthetically pleasing.

The wetland shall have a minimum 2:1 length to width ratio, with 3:1 preferred. *The distance between the inlets and outlets are to be maximized to increase the flowpath of the wetland.* The flowpath can be increased through use of internal berms and shelves used to create the varying depth zones within the wetland (Schueler, 1992).

It is encouraged to create a wetland that fits within the natural contours of the land but care should be taken to prevent "dead storage zones" (areas outside the flow path between the inlet and outlet) within the wetland. "Dead storage zones" are areas outside the flow path from the inlets to the outlets. Generally, the wetland should be narrower at the inlet forebay area and become wider at the outlet. Whenever possible one forebay should be created and all wetland inlet pipes discharge to the forebay area.

Creating a complex microtopography (varying depth zones) within the wetland will increase the pollutant removal efficiency of the wetlands (Schueler, 1992). These depth zones can be classified into the deep water zone, which consists of the forebay and outlet micropool, and the shallow water zone, which consists of the high marsh, and low marsh. Designing the wetland with various depth zones will help to prevent the wetland from being taken over by a dominant plant species (such as cattails).

To increase the aesthetic value of the wetland area, a wetland buffer should be established around the perimeter of the wetland. To promote a greater and more diverse wildlife habitat, a wetland buffer should consist of a variety of trees, shrubs, and plants (Schueler, 1992). The amount of open grass areas should be limited to prevent an overpopulation of geese. The buffer will also serve to distance adjacent residences/businesses from the wetland area.

It is encouraged where appropriate to use educational signs at the pond describing the function of the pond and the purpose it serves.

Treatment Sizing Criteria

Target Permanent Pool Depth Zone Allocation (based on surface area of the wetland)

Shallow water zone: 70%
35% - "high marsh" 0 to 9 inches depth
35% - "low marsh" 9 to 18 inches depth
Deep water zone: 30%
15-20% - forebay – 4 to 6 feet deep – sediment storage to be allocated to forebay
10-15% - outlet micropool – 4- 6 feet deep

Extended Detention storage: WQV

Extended Detention draw down time: 48 hrs

Wetland Surface Area/Drainage Area Ratio: see table 3.9

Table 3.9: Wetland Permanent Pool Surface Area to Drainage Area Ratio

PERCENT BUILT-UPON	10	20	30	40	50	60	70
SA/DA	0.59	0.97	1.34	1.73	2.00	2.39	2.75

Principal Spillway Capacity: 10 year 24 hour rain storm event

Emergency Spillway Capacity: Minimum 100 year 24-hour rain storm event (design to be consistent with the NC Dam Safety Requirements).

Dam freeboard: NC Dam Safety requires a one (1) foot minimum freeboard above the maximum flood pool elevation during the spillway design flood. The City encourages the designer to maximize the freeboard to the extent practicable.

Shallow Water Zones

The shallow water zone (0-18 inches depth) is designed to promote growth of emergent plantings. The shallow water zone should be sized to be approximately 70% of the wetland surface area. Half of this 70% should be designated as high marsh (0-9 inches depth) and the other half as low marsh (9-18 inches depth). Variations in depth will allow for a diversity of emergent wetland species to thrive. Generally, the bottom elevation across the width of the wetland should remain level to promote sheet flow and to prevent short circuiting and creating stagnant areas or dead zones.

Deep Water Zone

The deep water zone consist of the forebay and the outlet micropool. The function of these components are described below.

Forebay

The forebay serves to reduce incoming velocity which promotes initial settling of sediment, minimizing the amount of suspended sediment that enters the wetland area. The forebay serves to spread the flow equally over the width of the wetland. The forebay is to be separated from the remaining wetland by an earthen berm that is no lower than one foot below the normal pool. Sediment cleanout may be needed approximately every 5-10 years (depending on the condition of the drainage area).

Inlets are to discharge into the forebay. Inverts for inlet pipes should be at the elevation of the normal pool to allow the pool to dissipate the energy of the inflow to prevent erosion along the embankment slope. Inlets should be designed to discharge to the pond perpendicular to the pool surface to minimize potential erosion problems to the side embankment. Rip rap pads should be underlain with a gravel/sand filter or geotextile fabric which should extend from the pipe invert to the pond bottom.

An access to the forebay for future sediment cleanouts is to be provided. It is recommended that the access have a maximum slope of 15-20% extending from the top of the embankment to the toe. This access will allow construction equipment to getdown in the forebay and will minimize disturbance to the vegetation.

Outlet Micropool

The outlet micropool is required to allow adequate depth for the extended detention release outlet to function properly and to allow a drain to be installed low enough to drain the wetland. The outlet micropool should be 4 to 6 feet deep. The deep pool areas can be used to stock mosquito fish to help control the mosquito population.

Wetland Plantings

A wetland planting plan is to be developed as part of the wetland design. Selecting the proper plant species and planting locations is an important part in creating a successful stormwater wetland BMP. A wetland planting plan should be prepared by a qualified landscape architect and wetlands ecologist as part of the design of the wetland.

Plantings should be spaced at 3 feet at a minimum. If the wetland is not 50% to 75% established after the first growing season, reinforcement plantings will be needed.

Suitable planting soil shall be specified in wetland planting area. The soil should have adequate texture and organic matter to retain moisture for plant growth. A soil analysis should be performed on the soil before it is placed in the wetland.

Appropriate species must be selected for the high and low marsh areas and the wetland edge. Careful attention should be paid to the inundation tolerance of the plantings along with the depth of water experienced in extended detention. A well planned wetland will utilize a variety of emergent, submergent, and floating wetland plants as well as buffer trees and plantings.

It is suggested that various species of plantings be utilized to maximize plant diversity and increase the probability that the wetland plant growth will be successful. Examples of wetland plantings that may be used for stormwater wetlands and there inundation tolerance are listed in Appendix G.

Wetland Pond Dam

Notification of the proposed dam construction is to be made to the NC Dam Safety Office.

A concrete retaining wall may be used for the pond dam, but it shall not include more than 50% of the pond perimeter.

For earth dams, the top width of the dam should be 10 feet minimum.

For earth dams, a cutoff trench should be excavated and filled with highly impervious and well compacted material. Incorporating a chimney drain or drainage blanket should be considered to reduce the potential for seepage problems.

Treatment Orifices

Low flow orifice(s) shall be used to slowly release of the water quality volume over a period of 48 hours. Additional low flow orifice(s) or other appropriate provisions may be incorporated above the temporary pool to provide peak flow reduction. Refer to Appendix F for the preferred method for calculating the orifice drawdown time.

The low flow orifices are to be protected from clogging up with floating debris using a trash guard. The trash guard should be durable and secure and should extend at least six inches below the normal pool surface. A common method when using a riser/barrel is to extend the principal spillway trash rack assembly below the normal pool. When the low flow orifice will be placed in a concrete dam or spillway, an inverted or submerged orifice can be used or a half aluminum pipe bolted to the concrete (see Appendix H for examples or trash protection).

Principal Spillway

The principal spillway should be a riser/barrel, concrete free fall weir, or concrete chute with capacity to handle the 10-year 24 hour rain storm event, at a minimum. Of the available options for the riser/barrel material such as reinforced concrete, ductile iron, PVC, or corrugated aluminum piping, reinforced concrete and ductile iron pipes (being rigid pipes) are preferable for this application. A flexible pipe, such as corrugated aluminum piping may experience distortion of its cross-sectional shape during compaction of the soil around it and result in internal soil erosion problems potentially leading to failure of the embankment around and above the pipe.

The spillway should be equipped with a trash rack and an anti-vortex device.

Riser/barrel assemblies should be properly anchored to resist buoyancy forces.

A "filter and drainage diaphragm" or anti-seep collars should be used to prevent piping along the barrel within the earth fill, with the diaphragm being the preferred method (see Appendix J for NRCS design guidelines).

Appropriate energy dissipation should be used at the spillway exit to prevent erosive velocities for up to the 10-year peak discharge rate, at a minimum. Every effort should be made to discharge in defined conveyances and parallel to the existing flow to prevent bank erosion. Downstream channels may need to be modified and lined with rip rap to prevent erosion of the channel. Modifications to the downstream channel should be minimized as much as possible to prevent excessive disturbance in the channel.

Emergency Spillway

The emergency spillway should be designed to safely convey discharges resulting from storms up to the 100-year 24 hour storm, at a minimum. The spillway should be located where it will not adversely affect downstream property such as roadways and building structures. The emergency spillway may be incorporated into the principal spillway where accommodating the emergency spillway elsewhere is not feasible for the given site characteristics.

The emergency spillway should be cut into existing soils outside the fill section of the dam. The emergency spillway may be grass lined, when velocities permit, or lined with rip rap, concrete, or other erosion resistant materials. Grass lined spillways are to be planted with a dense cover of erosion resistant grasses.

Wetland Pond Drain

A pond drain should be provided to drain the wetland for routine maintenance or structural repairs in an emergency situation. It is recommended that the pond drain be designated to have the discharge capability to completely drain the pond in less than 48 hours, in the event of an emergency posed by impending failure of the dam. The upstream slope of the pond dam should be designed to be flat enough to prevent slope failure due to "quick drawdown" of the pond (NC Dam Safety Code specifies a factor of safety of 1.25) in an emergency. Care should be taken to minimize transport of settled sediment from the pond during draining.

3.4.11 Bioretention Areas

Description

The bioretention BMP is a relatively new concept. Prince George's County, Maryland was one of the first communities in the United States to use and promote bioretention to treat stormwater runoff (1987). This BMP was designed to mimic natural forest ecosystem with a combination of soil filtration and plant uptake. The bioretention area, which includes a planting soil layer, mulch, plantings, and an underdrain system, is designed to appear as a landscaped or natural area giving this BMP a very appealing image. Stormwater runoff enters the bioretention area and is temporarily stored in a shallow pond on top of the mulch layer. The ponded water then slowly filters downward through the made planting soil and is absorbed through the plantings. As the excess water filters through the system, it is collected by an underdrain pipe and discharged to a storm conveyance system.

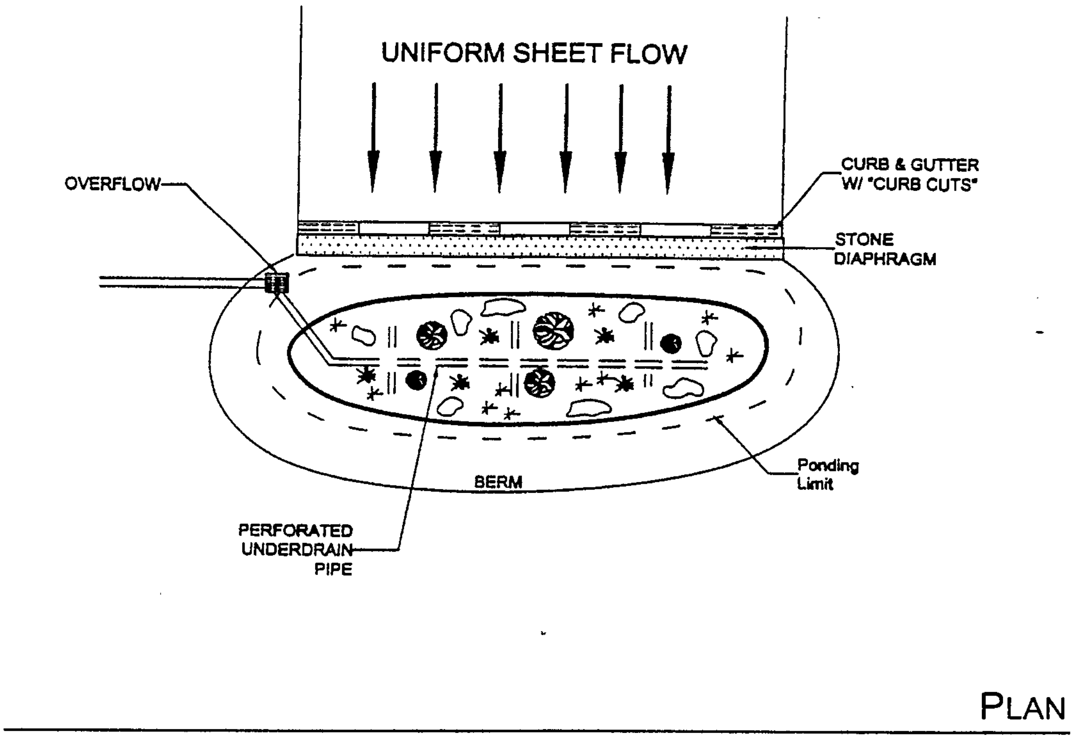
Applicability

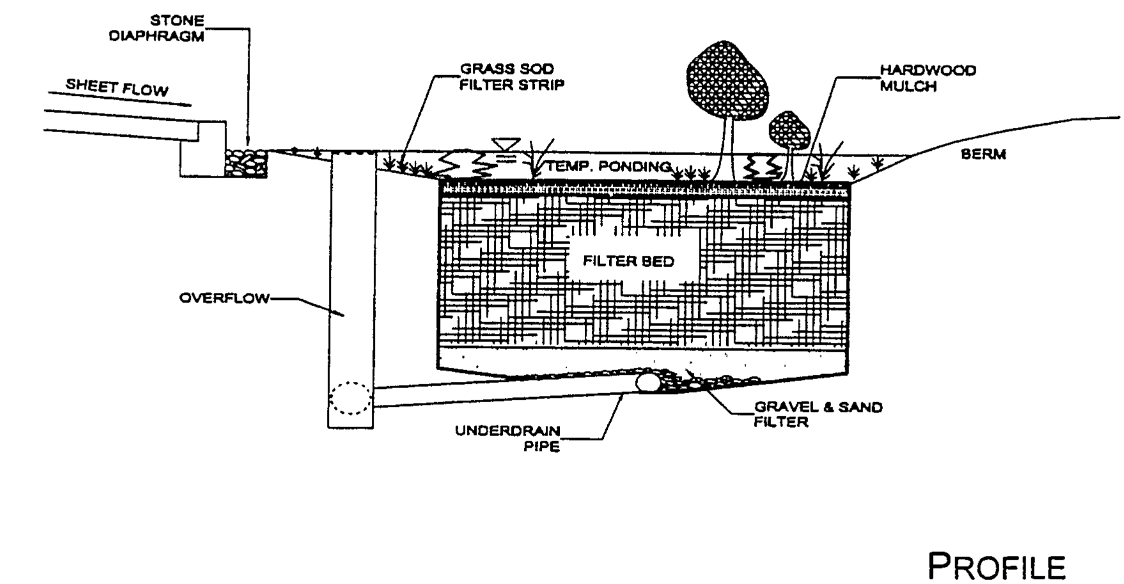
Bioretention areas work well on smaller sites, where stormwater runoff rates are low and aesthetics are important. Bioretention areas can be implemented to treat parking lot runoff, individual residential home sites, and small commercial facilities.

Bioretention areas can be used to save costs in other site development areas. For example, bioretention areas usually accept stormwater runoff as sheet flow; therefore, the designer can use bioretention to reduce the amount of storm sewer needed for the project. Bioretention areas also can also be incorporated as part of the required landscaping buffer.

The drainage area to individual bioretention cells should be relatively small (1 to 2 acre drainage area) and well stabilized to prevent excessive debris and sediment from collecting in the bioretention area. Keeping smaller drainage areas to the bioretention

Figure 3.8: Example of Bioretention Area





areas will make it easier to manage the pollutants that enter the cell during and after construction. For larger drainage area sites, a bioretention area consisting of multiple cells can be installed.

Constructing bioretention areas for large residential developments to meet water-supply watershed regulations is discouraged, except in cases where multiple cells are provided on the site, each receiving drainage from a small area. The City's water-supply watershed (Ch. 30) ordinance requires stormwater BMPs to be constructed before the certificate of compliance can be issued on the first house. Housing developments may sometimes require several years to build out, therefore, it is that much more difficult to implement aggressive erosion control over that period. Special attention is needed to manage the runoff from each individual lot while construction is taking place especially where there are different subcontractors doing the grading, house construction, road construction, etc, who may not be aware of the presence or function of the cells. Sediment that does escape the construction area can quickly clog the bioretention area, severely reducing or eliminating its filtering capacity.

Also careful consideration should be given where bioretention areas will be used to treat larger sites where construction takes place in phases. It may be desired by the developer to initially construct a wet detention pond BMP and after construction is complete, modify the pond to a bioretention cell. If this practice is desired, the developer should consult with the City.

Because bioretention systems are sensitive to fine sediments, they should not be placed on sites where the contributing drainage area will not be completely stabilized or is periodically being disturbed.

General Criteria

Bioretention areas work best when constructed off-line, capturing only the water quality volume, and excess runoff is diverted away from the BMP.

Bioretention areas should be designed to fit into the natural topography and complement surrounding landscaping.

Bioretention areas can be of any reasonable shape to fit the cell around tree conservation areas, driveways, etc. In order to establish a well planted bioretention area, the minimum width of the bioretention should be 10 feet.

The bioretention area should be easily accessible for maintenance. A 15' wide access easement shall be provided from the public street right-of-way to the bioretention area. A drainage maintenance and utility easement (DMUE) shall be paced over the bioretention area and extend 15' beyond its perimeter. The access easement should be kept easily accessible for maintenance.

Design Guidelines

*Bioretention Filter Bed Surface Area: 10% * Rv * Drainage Area (for 6" ponding depth)*
This formula is based on the sizing guidelines (which are based on the experience) of Prince George's County which specifies that the bioretention surface area should be 5% to 7% of the drainage area multiplied by the runoff coefficient based on infiltrating precipitation events of 0.5 to 0.7 inches occurring over a six hour period. In Greensboro, the BMP is required to control the **one inch rainfall (WQV).**

Ponding Depth: 6 inches maximum

Hardwood shredded mulch layer: Approximately 3 inches deep

Planting soil layer: 4 feet minimum

Plantings: 3 species of each trees, shrubs, and herbaceous species

Planting density: 1000 stems/acre minimum

Pretreatment
Pretreatment is necessary to reduce incoming velocities, spread flow over the bioretention area, and provide some removal of coarse suspended sediments. The pretreatment may be a gently sloping grass sod filter strip or a grass swale along the upstream side of the cell. A gravel diaphragm, landscape stone, or other energy dissipator should be used to reduce incoming energy of runoff from impervious areas and areas of concentrated flow, and to help spread the flow over the bioretention area.

Bioretention Filter Bed
The filter bed surface must be level to allow for uniform ponding over the cell. The maximum ponding depth should be specified at a maximum of 6 inches to allow the cell to drain within a reasonable time and to prevent long periods of inundation of the plantings.

The planting soil provides a medium for physical filtration for the stormwater runoff plus a source of water and nutrients for the plant life. *This soil should have adequate permeability (0.5 ft/day) and organic content to support plant life.* The City currently recommends the planting soil to be 50% sand, 20% leaf mulch, and 30% topsoil. The maximum clay content should be 10% or less. The recommendation is based on the satisfactory results obtained from the use of this mixture in Prince George's County, Maryland.

The soil should also have the following characteristics (State of NC BMP manual):

PH range: 5.5 – 6.5
Organic Matter: 1.5 – 3.0%
Magnesium: 35 lbs/acre

Phosphorus (p2O5): 100 lbs/acre
Potassium (K2O): 85 lbs/acre
Soluble salts: not to exceed 500 ppm

Mulch Layer
The mulch layer provides an environment for plant growth by reducing erosion of the planting soil bed, maintaining moisture, trapping fine sediments before it seals the planting soil surface, and allowing for the decomposition of organic matter (Schueler, 1996). Studies have been shown by Prince George's County that the mulch layer plays an important role in pollutant removal, and shredded hardwood mulch should be applied liberally.

Hardwood mulch or chips should be used because they resist floatation better than other landscape covers. Optimum age of the mulch is 12 months. The mulch should be very clean, free of weeds, soil, roots, plastic, etc.

Bioretention Plantings
A bioretention area landscape plan shall be prepared and include the type and number of plantings, their planting location, installation guidelines, and post-installation inspection and maintenance guidelines.

Consult with a landscape professional to help decide which species are best suited for the landscape and for installation guidelines. Table 3.10 shows commonly used bioretention plantings.

The proper selection of bioretention plantings is key to establishing a successful bioretention BMP. Factors such as inundation tolerance, drought, sun exposure, etc. should be considered to provide successful plantings. Using a variety of plantings (trees, shrubs, grasses) is recommended for a natural appearance and a higher chance for successful growth. The plantings should be placed in a random fashion and can be placed along the banks of the cell.

A minimum of 3 species of each trees, shrubs, and herbaceous plantings should be specified with a minimum planting density of 1000 stems/acre. A higher planting density may be desired for landscaping purposes. Figure 3.9 shows various planting zones for the bioretention area.

Underdrain System
The native soils in Guilford County do not generally allow for adequate infiltration. Therefore, all bioretention cells shall have an underdrain system placed beneath the planting soil. The underdrain may consist of perforated piping with a gravel jacket. Geotextile fabric should be placed at the bottom of the excavated cell to prevent clay from getting into the pipe. The pipe should be a sturdy pipe, such as Schedule **40** PVC and should be placed on top of the fabric. A run of pipe should be spaced every 10 feet and the bottom of the cell should have a positive slope toward the pipe. The

longitudinal slope should have an approximate grade of 0.5% and should connect to a storm sewer system or outfall to a channel in a non-erosive manner.

Non-perforated piping should be connected to the underdrain piping and extend to the surface of the planting soil for cleanouts.

Table 3.10: Examples of Plant Species Suitable for Bioretention

TREES	SHRUBS	HERBACEOUS SPECIES
Acer rubrum Red Maple	*Aesculus pariviflora* Bottlebrush Buckeye	*Andropogon virginicus* Broomsedge
Betula nigra River Birch	*Aronia arbutifolia* Red Chokeberry	*Eupatorium perpurea* Joe Pry Weed
Juniperus virginiata Eastern Red Cedar	*Fothergilla gardenii* Fothergilla	*Hemerocalis spp* Day Lily
Koelreuteria paniculata Golden Rain Tree	*Hamemelis virginiana* Witch Hazel	*Iris pseudacorus* Yellow Iris
Nyssa sylvatica Black Gum	*Hypericum densiflorum* Common St. Johns Wort	*Lobelia cardinalis* Cardinal Flower
PLATANUS ACERIFOLIA London Plane-Tree	*Ilex glabra* Inkberry	*Panicum virgatum* Switchgrass
Platanus occidentalis Sycamore	*Ilex verticillata* Winterberry	*Pennisetum alopecuroides* Fountaingrass
Quercus palustris Pin Oak	*Juniperus horizontalis* Creeping Juniper	*Rudbeckia laciniata* Greenhead Coneflower
Quercus phellos Willow Oak	*Lindera benzoin* Spicebush	*Scirpus cyperinus* Woolgrass
Salix nigra Black willow	*Myrica pennsylvnica* Bayberry	*Vernonia noveboracensis* New York Ironweed

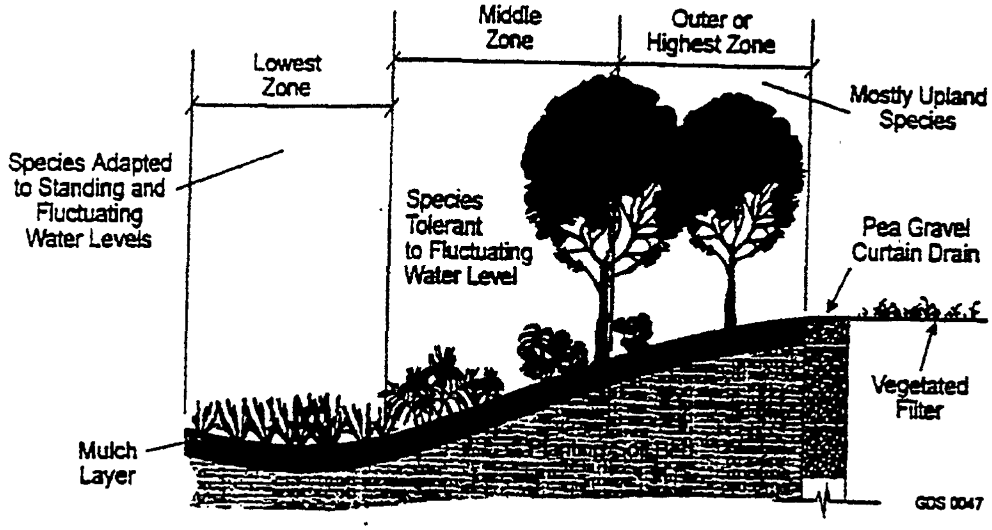
Figure 3.9: Example Planting Zones for Bioretention Areas



SOURCE: COURTESY OF THE MARYLAND DESIGN MANUAL LOIDERMAN ASSOCIATES

Bioretention Overflow

An overflow bypass should be used to pass storms larger than the water quality volume away from the bioretention area. If the bioretention area collects sheet flow, such as from a parking area, a catch basin at the elevation of the normal pool can be placed in the parking lot. When the ponding limit in the bioretention area is exceeded, the stormwater runoff will be routed through the catch basin to the storm sewer inlet. To prevent the water quality volume from being flushed out of the bioretention cell before it has time to be treated, the overflow should be located on the upstream side of the bioretention area.

The same concept should apply to flows that enter via swale or pipe. Once the maximum ponding limit has been exceeded, a diversion should be placed within the vicinity of the inflow area to divert the extra runoff will be diverted away from the cell.

3.4.12 Sand Filtration Facilities

Description

Sand filtration systems used for stormwater treatment work similar to those that are used in the drinking water purification process. These systems remove pollutants through sedimentation, filtration, and microbial activity within the sand. Stormwater filtration systems consist mainly of a pretreatment, or sedimentation basin, and the filter area. Runoff first enters the sedimentation basin where the runoff velocity is reduced allowing larger pollutant particles to drop out. When the stormwater exits the sedimentation area it is spread evenly over the filter bed where it then flows downward through the filter. As the stormwater flows through the filter, the filtration media trap and absorb pollutants present in the stormwater. Sand filtration systems are beneficial when land space is scarce or expensive, because they can be designed to be placed underground or to border the perimeter of a parking lot or other impervious surface.

Applicability

Sand filtration facilities are best used for smaller sites (5 acres or less) where the percent imperviousness and the land value is high. Also, the facilities should be used on sites where the drainage area to the facility will remain well stabilized after the construction phase to prevent excess sediment and debris from prematurely clogging the filter. It is recommended that individual sand filtration facilities be sized to treat relatively small drainage areas (1 to 2 acres or less). By implementing several facilities on a site, this will prevent the entire site from being untreated if one filter facility happens to get clogged.

The cost of the construction of concrete underground sand filtration facilities is high in relation to other BMPs and the maintenance burden for the owner can be quite substantial. However, because the BMP can be placed underground, the construction and maintenance costs may be offset by the save in land space.

To prevent loose debris such as grass clippings, landscape debris, etc from entering the facility, it is highly recommended that sand filtration facilities treat only runoff from impervious surfaces. It is a good idea to implement pollution prevention BMPs, such as paved area sweeping and covering, to minimize the sediment and other pollutants that enter the BMP.

Sand filtration BMPs differ from bioretention, in the fact that the hydraulic head above the filtration bed can be significantly higher than the 6 inches allowed for bioretention. Thus a smaller filter bed surface area will be required.

There are three basic sand filtration BMP types: (1) underground sand filter, (2) perimeter sand filter, and (3) surface sand filter. The underground BMP is ideal to treat stormwater in the ultra-urban environment where land costs are high. The perimeter sand filter and surface sand filter are good to treat parking lot runoff.

Description of Various Sand Filter Types

Underground Sand Filter
There are several different configurations for a sand filtration facility placed in an underground basin. The most widely known type is the District of Columbia (DC) sand filter developed by Mr. Hung V. Truong of the D.C, Environmental Regulation Administration. This type BMP is designed for use in the ultra-urban setting where the drainage area is small (less than one acre). The DC facility consists of three chambers: a wet sedimentation chamber, sand filtration chamber, and outlet chamber (see Figure 3.10).

The wet sedimentation chamber serves to dissipate the incoming velocity and settle out grit. The sedimentation chamber also has a submerged orifice that serves to trap floating debris and prevent it from entering the sand filtration chamber. Mr. Truong points out that the sedimentation chamber can be replaced by a commercial hydrodynamic BMP (see section 3.4.13, Proprietary Stormwater Treatment Facilities). The sand filtration chamber consists of the 24 inch sand bed layer underlain by a gravel bed with perforated PVC drain pipes. An optional layer of geotextile (plastic filter cloth) liner can be placed on top of the sand bed to prevent debris from getting into the sand layer. The outlet chamber collects the effluent from the underdrain pipes, and flow from the by-pass pipe when the volume of the basin is exceeded.

Perimeter Sand Filter (Delaware Sand Filter)
The perimeter sand filter was originally developed by Mr. Earl Shaver of the Delaware Department of Natural Resources and Environmental Control. This type of facility was primarily intended to border the perimeter of parking lots and treat the runoff from it. The facility consists of two parallel concrete chambers; a wet sedimentation chamber and a sand filtration chamber (see Figure 3.11). Runoff in the form of sheet flow flows into the wet sedimentation chamber where the energy is dissipated, flow is dispersed, and coarse sediments drop out. The flow then overflows into the sand filtration chamber where it percolates through the sand medium and is collected by an underdrain system. An overflow weir should be implemented to safely bypass storms larger than the water quality volume.

Surface Sand Filter (SSF)
The City of Austin, Texas first developed and used sand filtration systems for treating stormwater runoff (see Figure 3.12). The sand filter can be placed in a concrete or earth basin. A sedimentation basin is needed to pretreat the incoming runoff and to bypass larger storm events. The City of Austin found that it was important to size the sedimentation chamber to remove suspended solids to prevent excessive sediment loading on the sand filtration chamber. Since the SSF is an open basin, it will generally cost less than the other enclosed sand filter types and is usually practical to treat a larger drainage area.

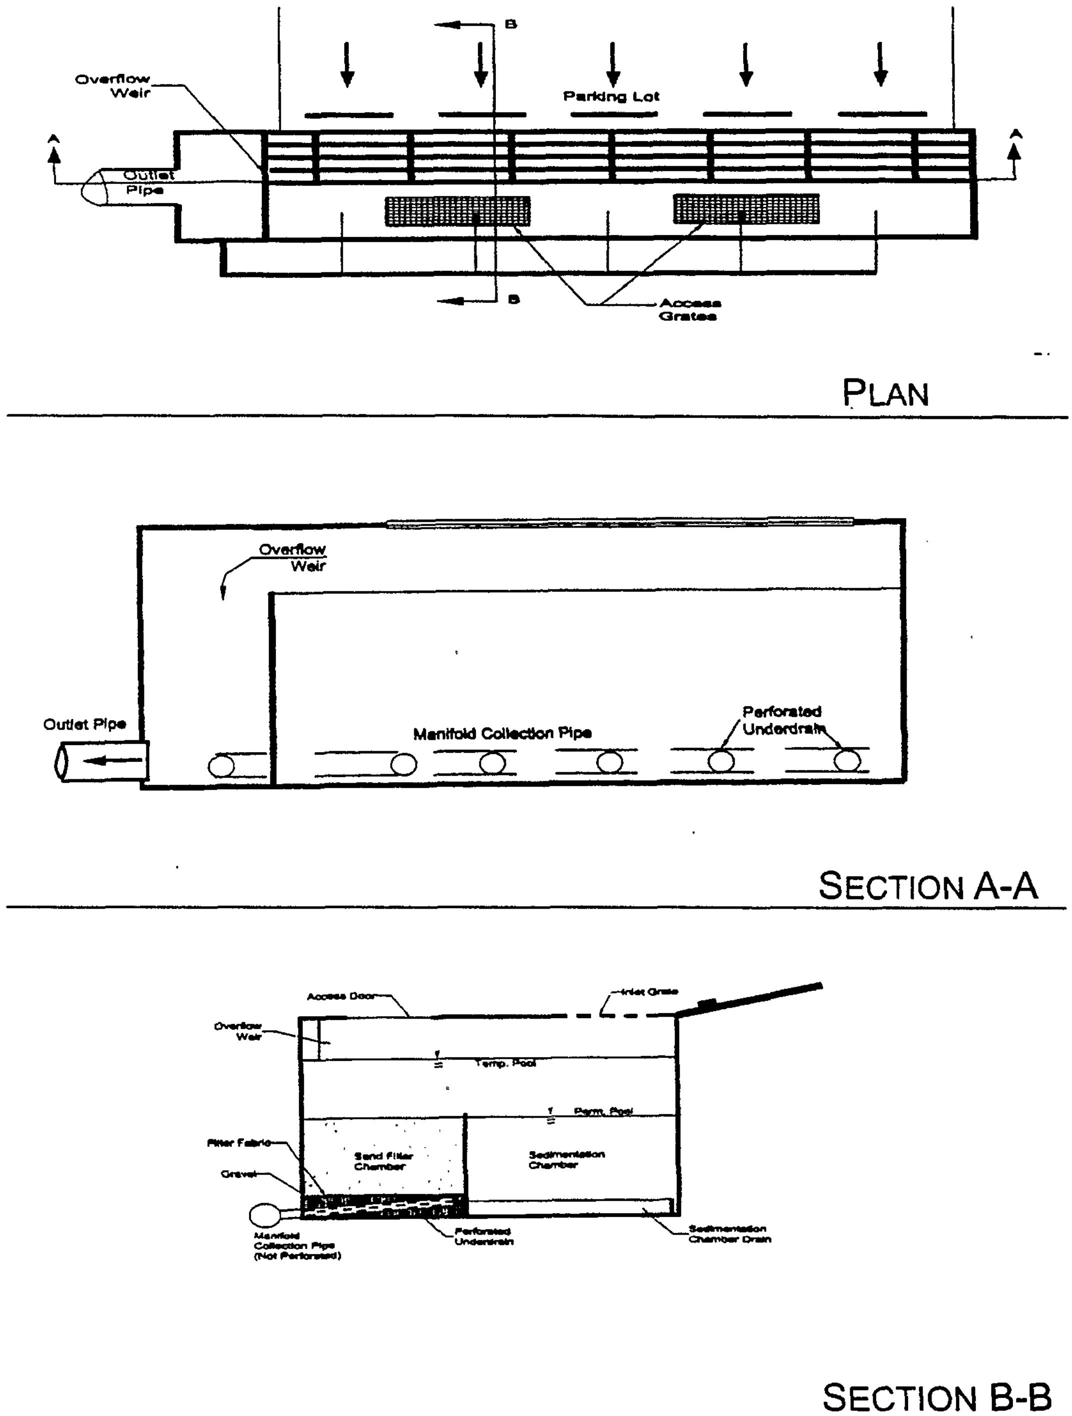

Figure 3.12: Example of Surface Sand Filter

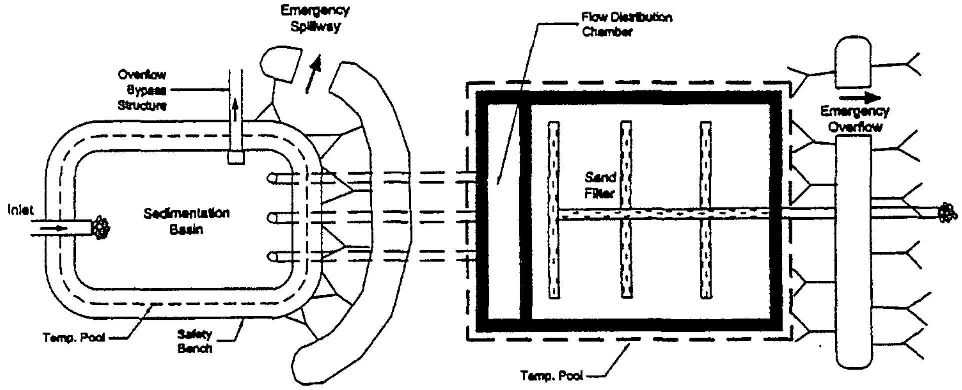
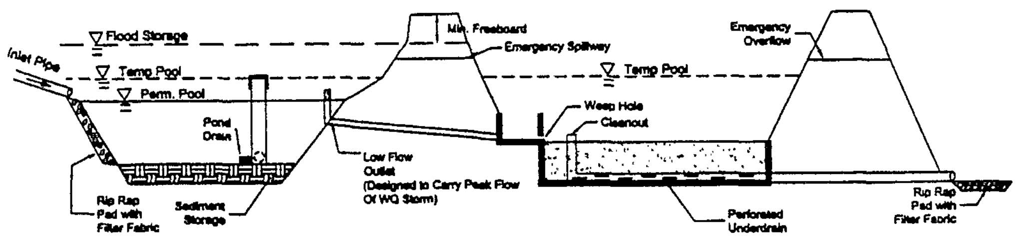


PLAN



PROFILE

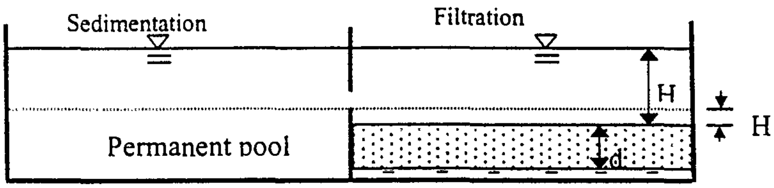
R0010552

Design Guidelines

Entire facility should hold 75% of water quality volume (Schueler, 1996).
The volume may be allocated to the filter chamber and the sedimentation chamber (wet pool in sedimentation chamber may be included in the allocation). The justification for providing storage for a reduced portion of the WQV is that sand is a relatively permeable material (as compared to other filtering materials) and the filter bed is continually filtering water during the duration of the storm event. It is estimated that the median rain storm event for this region will take longer than 6 hours for the first one inch of rainfall to occur.

Sand Filter bed area (A_f): The required surface area for a sand filtration facility is determined from the following equation. The typical sand filter is designed to function as shown in Figure 3.13.

Figure 3.13: Sand Filter Schematic



$$A_f = \frac{(d)(A)[ln(H_1+d)-ln(H_2+d)]}{(k)(T)-(d)[ln(H_2+d)-ln(d)]}$$

For the specific case where $H_2 = 0$: $$A_f = \frac{(d)(A)[ln(H_1+d)-ln(d)]}{(k)(T)}$$

Where,

T = time required for the water quality volume to filter through the sand bed in days [40 hours or 1.67 days is recommended maximum (Schueler, 1996)].
A = total surface area in ft^2 (sand filter + sediment chamber)
A_f = surface area of the sand filter in ft^2
H_1 = maximum water depth above filter bed in feet (should not exceed 5 feet)
H_2 = height of invert of sediment chamber outlet above top of sand filter bed in ft.
d = the depth of filter material in feet [18 inches minimum (1.5) feet]
k = coefficient of permeability for sand bed in ft/day [3.5 ft/day (Schueler, 1996)]
ln = natural logarithm

At a minimum, the sedimentation chamber surface area be equal to the surface area of the sand filter bed. The equation used for sizing the surface area of the dry detention basin (Section 3.4.8) may be used to as a guideline for sizing the surface area of the sedimentation chamber.

Sedimentation Chamber

The efficiency of sedimentation chamber to settle suspended solids is based on the surface loading rate (outflow divided by basin surface area) and is relatively independent of depth. However, it is recommended that the sedimentation chamber remain wet and have a depth of 2 to 3 feet to minimize particle resuspension due to turbulence (Schueler, 1996).

To improve the removal efficiency of the sedimentation chamber, it is recommended that the sedimentation basin be designed to detain at least 50% of the water quality volume and be slowly released over a period of several hours. Providing this detention will allow more coarse sediments to settle out, which will help to prevent premature clogging of the sand bed.

Commercial hydrodynamic BMPs may also be considered to use to provide initial sedimentation instead of gravity settling chambers.

Sand Filter Chamber

Provisions should be made to distribute the flow from the sedimentation chamber uniformly across the sand filter chamber. The underground DC sand filter type and the perimeter Delaware sand filter type use overflow weirs along the width of the sand filter to accomplish this. When the flow from the sedimentation basin is outlets by pipe flow, a flow distribution chamber should be incorporated (see Figure 3.12).

The sand bed should be a minimum of 18 inches depth and the top of the bed should be completely level. The sand should be clean ASTM C-33 medium aggregate concrete sand.

For underground sand filter facilities, a 5 feet minimum height clearance should be provided between the top of the sand bed and the bottom of the slab to provide clearance for future maintenance.

It is recommended to use a dewatering valve placed just above the sand bed layer to drain the facility should the sand bed become clogged (see Figure 3.10).

Underdrain System

An underdrain system shall be used to collect water that has percolated through the sand filter. The preferred pipe is 6 inch perforated schedule 40 PVC piping placed in an 8 to 10 inch gravel jacket. Although some designs call for filter fabric between the gravel bed and sand layer, the City believes that this fabric could present a clogging problem, and recommends that a three inch layer of pea gravel be used instead. To ensure adequate drainage, the bottom of the chamber should be sloped toward the underdrain pipes which should be spaced approximately 10 feet along the filter bed. The underdrain may discharge to a main collector pipe or to an outlet chamber.

Overflow
Sand filtration facilities should be placed off-line (divert runoff from storms greater than the one inch rainfall before entering the facility) whenever possible. A by-pass structure can be used to direct flow away from the filtration facility once the treatment volume has been exceeded.

For on-line facilities, an overflow should be placed in the sediment chamber and be designed to carry the 10 year design storm at a minimum. The overflow needs to placed as far upstream of the filtration bed as possible to prevent the initial WQV from being flushed out by the subsequent runoff (see Figure 3.12).

Access for Sand Filtration Facilities
A 15' wide access easement shall be provided from the public street right-of-way to the sand filtration and pretreatment areas. A drainage maintenance and utility easement (DMUE) shall be paced over the entire facility and extend 15' beyond its perimeter. The access easement should be kept easily accessible for maintenance.

For sand filtration facilities that are underground, adequate access shall be provided into the facility for inspection and maintenance. It is preferred that large aluminum or steel doors be placed to access the sand filtration chamber. Steps will need to be provided for the underground facility. Also observation manholes or doors should be provided for underground overflow chamber and the sedimentation chamber. Maintenance to the underground sand filtration facility will involve entering a confined space and the appropriate provisions should be made to comply with OSHA confined space requirements.

3.4.13 Proprietary Stormwater Treatment Facilities

Description

The need for urban BMPs that are more efficient in pollutant removal and present less impact to development has spawned the introduction of innovative stormwater BMP technology. These technologies usually combine the processes of settling, filtration, and various biological processes into one controlled system housed in a modular unit. By combining different processes, these BMPs can be designed to focus on removing many different type pollutants and higher concentrations of these pollutants than conventional BMPs.

Applicability

Proprietary stormwater treatment facilities apparently possess several beneficial attributes which make these BMPs a potential viable solution for future use in this area. For example, units can be usually be placed almost anywhere on a site where it can receive concentrated flows, such as from a storm drainage structure. Also, many of the innovative proprietary BMPs are relatively safe because the stormwater is treated inside the unit, and is not open to the environment like a stormwater pond or wetland. Another benefit is that only minimal on-site construction is necessary since the units are usually assembled before they reach the site.

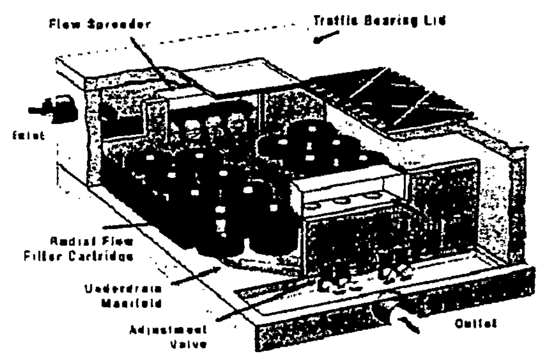
There may be several proprietary BMPs on the market that may be able to the quality control requirments for water-supply watershed protection, such as StormFilter™ by Stormwater Management®, Portland Oregon (1-800-548-4667 *or www.stormwatermgt.com*), StormTreat™ by StormTreat™ Systems, Sandwich Massachusetts (1-508-833-1033 or *www.stormtreat.com*) and Stormceptor®, manufactured by CSR Hydro Conduit, Thomasville, North Carolina (1-800-475-6302 or *www.csrstormceptor.com*) . Proprietary systems may be used to treat runoff in water-supply watersheds as long as they are designed to treat the first inch of rainfall and are proven to provide 85% TSS removal. *For application to meet water-supply watershed protection requirements, the City will require the owner to monitor (upon installation) the pollutant removal efficiency for proprietary systems that have not been used and proven in the City before. The City may be able to offer technical assistance with the monitoring requirements. If satisfactory results are found, the system may be used and no other monitoring studies will be required for subsequent installations within the City. If unsatisfactory results are found, the system must be replaced with an approved facility that meets the TSS removal requirement.*

Example Proprietary BMPs:

StormFilter™

The StormFilter™ facility provides treatment through rechargeable cartridges that are filled with a variety of filter media such as the CSF® media (see Figure 3.14). Captured stormwater flows through these cartridges which trap and absorb pollutants. StormFilter™ units may be cast-in-place, precast, and linear. The units typically consist of an inlet bay that serves to remove heavy suspended solids, a flow spreader for dispersing the flow uniformly to the cartridge bay , the cartridge bay, and the outlet bay. This system can also incorporate an overflow device to bypass larger storm events. The company will specify the type filter material required in order to achieve the desired pollutant removal.

Figure 3.14: Schematic of StormFilter™

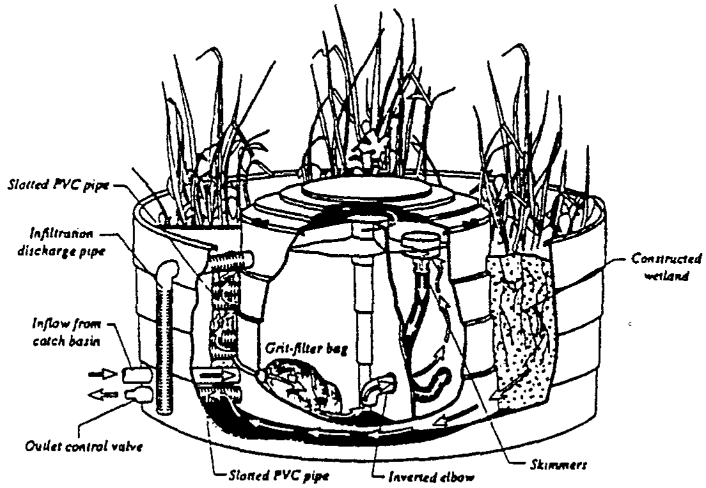


SOURCE: STORMWATER MANAGEMENT®

StormTreat™

The StormTreat™ facility provides treatment in a 9.5 foot diameter modular tank and treats runoff through sedimentation, filtration and constructed wetlands uptake (see Figure 3.15). The system is installed off-line and receives flow from an oversized catch basin that is designed to divert larger storms. The inflow is piped into a sedimentation chamber where large sediment is removed by a grit-filter bag and a series of skimmer devices. The sedimentation chamber is equipped with an inverted elbow to trap floatables. The water is then discharged to the subsurface of a gravel substrate "wetland." The wetland is comprised of a gravel substrate planted with bulrushes and other wetland plants (Horsely, 1998). Monitoring of this BMP is reported to have shown that it can achieve around 98% TSS removal when sized according to design criteria (Massachusetts Strategic Environmental Partnership).

Figure 3.15: Schematic Cross Section of StormTreat™ System



SOURCE: STORMTREAT™ SYSTEMS, INC

Other Proprietary BMPs

Other propriety systems may be available for stormwater treatment, such as hydrodynamic type BMPs such as Stormceptor®, Continuous Deflective separation (CDS) units by CDS Technologies and Storm King® by H.I.L. Technology. For use in the water-supply watershed areas, monitoring studies must indicate that the system can meet the TSS removal requirement of 85%. Even where certain BMPs may not be able to meet this requirement alone, many of these technologies could provide excellent pretreatment in a treatment series with another BMP such as a sand filter.

R0010557

3.5 Structural BMP Installation Guidelines

3.5.1 Introduction

Proper installation of stormwater BMPs and associated devices is crucial in creating a successful BMP. The following sections are provided to give some general guidelines on the installation of BMPs and construction timing.

Where BMPs are constructed to meet City regulations, the City will inspect the BMP to ensure that it is constructed according to plan and is functioning properly before the ownership responsibility is turned over to the property owner. The water-supply watershed (Ch. 30) ordinance and the 1999 stormwater management (Ch. 27) ordinance require that stormwater control facilities be substantially complete, have full design volume, and otherwise functioning properly prior to plat recordation or occupancy permit is granted for the property. The following sections describe specifically what aspects of BMP the City will inspect to approve the installation.

3.5.2 Grass Swales, Filter Strips

General Installation Guidelines

Rough graded swales and filter strips should be used to convey water during construction. Final grading should be done at the latest stage of construction possible to grade out erosion gulleys and to prevent excessive sediment from depositing within the permanent grass cover.

The drainage area to swales and filter strips should be stabilized (seeded with straw cover) at the same time as the swales and filter strips are.

It is recommended that swales be sodded or lined with erosion resistant temporary matting to allow a dense grass cover to be established. The sod should be securely fastened to the ground to keep them in place.

When check dams are used at the end of filter strips, a channel or swale should be constructed between the filter strip and check dam to route the flow to the spillways. The swale should be sodded or lined with temporary erosion resistant matting to allow a dense vegetation to establish.

Wood check dams should be pressure treated (rot resistant). The wood should be embedded several feet into the sideslopes.

Gravel trenches should be placed at the same time as the final grading of the filter strip is done. This is to prevent the excess sediments that runoff during the construction phase from prematurely filling the voids in the rock.

Installation Inspections by the City of Greensboro

The City will check to ensure that the BMP is constructed according to design, including proper slopes, dimensions, etc. The City will inspect to ensure that there are no current erosion problems and that the BMP is protected from potential erosion problems, such as use of temporary matting. The City will also inspect to make sure that there is no excessive sediment accumulation within the swale or filter strip.

3.5.3 Dry Detention Basins, Wet Detention Ponds

General Installation Guidelines

Dry detention basins and wet detention ponds may be used as sedimentation basins during construction as long as the construction sediment is removed and the design volume is restored prior to turning the maintenance responsibilities over to the property owner(s).

If a riser/barrel assembly is used, ensure that the soil is well compacted around the barrel and anti-seep collars (if used) to minimize weak zones and planes that become pathways for excessive seepage.

Riprap pads should not be just "dumped" and spread out at the end of pipe, but rather placed in the ground where the top of the rock is even with the adjacent grade. Geotextile fabric or sand and gravel bedding should be placed under all riprap protection. The filter fabric should be properly secured into the soil according to the manufacturer's specifications.

When constructing a dam on a stream, the loose material in the stream bed and banks should be removed prior to filling. This loose material can provide a path for excess seepage if not thoroughly cleaned out.

Installation Inspections by the City of Greensboro

Once construction on site is complete and areas draining to the pond are stabilized, the City will determine if the pond needs to have sediment removed. If construction sediment accumulation is not accounted for in the plans, dredging will be required when there is noticeable amounts of sediment accumulation on the pond bottom. If construction sediment is accounted for in the plans, dredging will be required when construction sediment levels exceed the design construction sediment allocation.

3.5.4 Stormwater Wetlands

General Installation Guidelines

The wetland should be initially graded approximately 6 inches below the final elevations. Grading should be conducted within acceptable tolerance limits in order to ensure sheet flow, prevent excessive velocities, prevent dead zones, and allow for proper planting depths as designed. It may be necessary to modify the wetland planting plan to correspond with the actual depth zones created in the field.

If the wetland bottom is above the water table elevation it is important to have a very low permeable soil layer for the wetland foundation to prevent the wetland from drying up in between rain events. The soil foundation should be compacted thoroughly at the appropriate moisture content to reduce infiltration. In some instances it may be necessary to install impermeable liners below the wetland area.

To better ensure success of the wetland, it is important that nutrient rich topsoil be added to the excavated wetlands (Schueler, 1992). It may be desirable to "disc up" the ground before adding the topsoil to incorporate the topsoil into the in situ soil. The final grading (use machinery that will not heavily compact topsoil) should be completed to ensure the proper depth zones. After the final grading, temporary ground cover should be established to reduce excessive erosion.

Riprap pads should not be just "dumped" and spread out at the end of pipe, but rather placed in the ground where the top of the rock is even with the adjacent grade. Geotextile fabric or sand and gravel bedding should be placed under all riprap protection. The filter fabric should be properly secured into the soil according to the manufacturer's specifications.

To get the soils thoroughly saturated, the wetland soils should be inundated for a period of time before the plantings are introduced.

A wetland specialist should be consulted regarding plantings. The construction of the wetland should coincide with the appropriate planting season for the species selected.

It is a general misconception that the plantings will have to be completely inundated to be able to survive. The water levels should gradually be increased to get the plantings accustomed to inundation (Hammer, 1997).

Unstablized areas of construction sites produce high concentrations of sediment loads even with conventional erosion control practices. Fine grading, adding topsoil, and plantings should not be completed until the drainage area of the wetland has been permanently and completely stabilized. If the wetland is utilized to meet water-supply watershed regulations, the wetland must be **completed in its entirety,** including planting, before the Certificate of Occupancy (C.O.) is issued.
If it is impossible for the site to be stabilized before the C.O. is desired, the wetland must be initially constructed as a wet detention pond. The wet detention pond may later be converted to the wetland after the site has been stabilized.

Installation Inspections by the City of Greensboro

The City of Greensboro needs to inspect the final grades of the wetland prior to planting and to ensure that all sediment has been cleaned out from the forebay area. The City will again inspect the site after the plantings have been planted prior to the maintenance responsibility being turned over to the property owner.

3.5.5 Bioretention Areas

General Installation Guidelines

Sediment transported by stormwater runoff from construction areas will quickly clog the surface of the bioretention cell. **The planting soil material and underdrain system should not be placed until the site has been completely stabilized and paved areas draining to the cell are flushed to remove loose sediment (must be controlled by an erosion control device).**

Once grading of the site is completed, pervious areas within the drainage area should be immediately seeded to allow time for grass to establish before the planting soil material is placed. Pervious areas draining to bioretention areas should be inspected periodically after seeding to ensure that a dense cover is established and that they are not disturbed by construction equipment.

The City strongly recommends that the filter material be placed at the latest stage of construction possible. If the bioretention cell is utilized as a sediment pit during construction, the cell must be completely mucked out before placing the planting soil material and the underdrain system. When the cell has been excavated, it is recommended that the design engineer should inspect the cell to assess the compactability of the underlying soil to ensure that the soil provides a stable foundation for the cell.

A geotextile fabric should be placed between the bottom of the cell and the underdrain system.

The bioretention planting soil is to be placed in one to two foot lifts and loosely compacted (tamp with back hoe). The soil surface should be level to promote uniform ponding.

The plantings for the bioretention area should be installed according to the bioretention landscape plan.

If any surrounding areas are disturbed during the installation of the bioretention cell, the cell must be protected from sedimentation from these areas. One way to protect the cell is to place a temporary silt fence around the cell. The developer is responsible for protecting the bioretention area from runoff from any subsequent construction activities that take place on-site.

Rip rap pads should not be just "dumped" and spread out at the end of pipe, but rather placed in the ground where the top of the rock is even with the adjacent grade. Geotextile fabric or sand and gravel bedding should be placed under all riprap protection. The filter fabric should be properly secured into the soil according to the manufacturer's specifications.

Installation Inspections by the City of Greensboro

The City of Greensboro needs to inspect the site before the filter materials are placed. All land disturbance and site stabilization activities are to be completed before the City inspects the site. After the filter material is placed, the City will test the initial draw down time and performance of the bioretention system.

3.5.6 Sand Filtration Facilities

General Installation Guidelines

Because the sediment in the runoff from construction areas will quickly clog the surface of the sand filter bed, the filter bed and filter underdrain system should not to be placed until the site has been completely stabilized and paved areas draining to sand filter are flushed.

Sediment is to be removed from the sedimentation and filtration chambers before placement of the filter material.

The City strongly recommends that the filter material be placed at the latest stage of construction possible. The developer is responsible for protecting the sand filter once the filter is placed from any subsequent construction activities that take place on-site.

The sand bed should be completely level to promote uniform ponding.

Installation Inspections by the City of Greensboro

The City of Greensboro is required to inspect the site before the filter material is placed in the chamber. All land disturbance and site stabilization activities are to be completed before the City inspects the site. Once the material is placed, the City will fill the structure with water to allow the City to monitor the filtration rate and draw down time.

3.5.7 Proprietary Stormwater Treatment Facilities
Follow the manufacturer's specifications for installing proprietary stormwater BMPs. The City will inspect to ensure that the BMPs are installed according to the specifications and is functioning as designed.

3.6 Structural BMP Maintenance and Inspection Guidelines

3.6.1 Introduction

The purpose of this section is to provide owners of structural BMPs with guidelines to help maintain the BMPs. It is often the case that owners do not fully understand what the BMP on their property is designed to do, much less how to properly maintain it. With different and more complex stormwater BMPs being introduced, it is even more crucial that owners know about the maintenance required for a particular BMP before they decide on one to implement. For owners to appreciate the need for maintenance, it is important that owners are aware that BMPs provide value to the quality of our surface waters and in many cases can be an amenity to their property.

Periodic inspections and maintenance are key factors in preserving the functionality of structural stormwater BMPs. Stormwater BMPs are not self maintaining systems, and over time the efficiency of structural BMPs to remove pollutants will diminish. Trapped sediments and other pollutants can potentially reduce the volume capacity of the BMPs, decrease filtration rates for filtering BMPs, and damage plantings used for treatment. The following guidelines are provided for the benefit of owners of structural BMPs to help ensure that the BMP will continue to meet the objectives they were designed for.

Besides inspecting and maintaining components in which a BMP's water quality functionality is to be sustained, attention must also be paid to the structural components to sustain its hydraulic functionality as well. Minimizing the risk of hydraulic malfunction (potentially leading to structural failure) is essential, especially for larger impondment structures such as wet detention ponds, since the majority of the stormwater BMPs in Greensboro are located in urbanized settings, where structural failure may jeopardize downstream life and property.

Maintenance is also important to prevent the decline in the appearance of the BMP. Unhealthy conditions (such as noxious vegetation, stagnant water, etc.) may occur within and around the BMP, which may affect the aesthetics and economic value of the surrounding property.

3.6.2 BMP Maintenance Requirements

The City's water-supply watershed (Ch 30) ordinance and the 1999 stormwater management (Ch 27) ordinance require that BMPs which are constructed to meet these requirements must be maintained by the property owner or owners' association. The BMPs must be maintained to continue to function to meet the regulations it was designed for. The City has the authority to inspect these BMPs periodically and require the BMP owner to perform maintenance activities, when necessary.

The City, as required by the State, will conduct periodic inspections of structural BMPs implemented for water-supply watershed protection. The City will advise the owner of recommended and required maintenance actions needed to maintain BMP functionality.

The design engineer and developer should be responsible for providing BMP owners with inspection and maintenance guidelines and educating them on it.

3.6.3 General Maintenance Guidelines

Dam Safety *(This section is applicable to all above ground BMPs that utilize a dam to permanently or temporarily retain or detain water).*

Preserving the structural integrity of the dam of a pond BMP is important in protecting downstream life and property. There are at least four aspects of the dam that require specific attention: (1) *assessment of hazard potential* due to changes in downstream development; (2) *seepage*; (3) *dam material problems*; and (4) *vegetation growth* on the dam embankments

Assessment of Hazard Potential
Before any dam is constructed, the design engineer is responsible for notifying the NC State Dam Safety Office of the proposed dam. If the dam falls under State Dam Safety jurisdiction, the dam must be constructed, maintained and operated according to their design and construction guidelines. Even if the dam does not fall under the NC Dam Safety Office's jurisdiction, the dam should be designed and constructed in accordance with current good engineering practice. The City has requirements concerning the maintenance of dams associated with required BMPs.

As new development occurs downstream of the BMP, the chance of significant property damage or danger to human life may increase if catastrophic failure of the dam occurs. Although the dam may be initially exempt from regulation by the State, the owner is responsible for reporting to the State Dam Safety Office downstream development that may affect the hazard classification of the dam.

Seepage
The downstream side of the dam should be inspected regularly for evidence of significant seepage. Seepage can emerge anywhere below the normal pool elevation, including the downstream slope of earth dams, areas beyond the toe of the dam, and around the spillway or pond outlet conduit. Indications of significant seepage include areas where the soil is saturated or where there is a flowing "spring" or leak. If "sinkholes" in the dam embankment are noticed, or if constant flowing water is noticed on the downstream side of the dam, then seepage has become excessive and professional engineering advice should be sought immediately to avert a major structural problem or a catastrophic failure of the dam.

Dam Material Problems
For earth dams, pronounced cracks on the embankment surface indicate the first stages of potential dam failure. Transverse cracks (running perpendicular to the embankment face)

R0010564

generally indicating differential settlement of the dam, can provide pathways for excessive seepage. Longitudinal cracks (running parallel to the embankment face) may be due to inadequate compaction of the dam during construction or shrinkage of the clay (desiccation) in the top of the embankment during prolonged dry conditions. These cracks may eventually lead to slope failure such as sliding or sloughing.

For reinforced concrete dams, the concrete should be checked for pronounced cracking, leakage from the joints, and displacement (noticeable leaning or bulging). Also, excessive seepage, leakage, or springs just downstream of the concrete dam could be indicative of potential seepage-related "piping" problems under the dam.

If such problems or other structural problems are observed, professional engineering advice should be sought.

Vegetative Growth
Trees and other woody vegetation are <u>not</u> permitted on the top slopes or dam embankments. Large root systems from woody vegetation can weaken the dam structure and provide seepage pathways. Thick vegetative cover can also provide a haven for burrowing animals such as the groundhog. These animals can create a network of burrows in the dam embankments that can significantly weaken the dam, by creating seepage paths, which may eventually lead to dam failure. Mowing of the dam embankments should occur, at a minimum, once every 6 months to prevent woody vegetation growth and cover for burrowing animals.

<u>Reduction of Pollutants Entering BMPs</u>

Stormwater BMPs are not 100% efficient in removing pollutants; therefore, when the amount of pollutants into the BMP is higher, the amount of pollutants discharged from the BMP will be higher. Also, increased amounts of pollutants to the BMP will increase the maintenance required to keep the BMP functioning properly. Maintenance to BMPs can be very expensive.

Pollution prevention activities
To assist the stormwater pond in stormwater quality enhancement, every effort should be made to reduce the pollutant load entering the pond system. Pollution prevention BMPs described in Section 3 of this manual should be implemented along with the following efforts:

- ⇨ Outside trash dumpsters should be kept covered, and the area around the dumpster should be kept neat and clean.
- ⇨ Chemicals, petroleum products and other pollution sources (such as machinery) should be stored in a covered area away from possible stormwater contact. Spent chemicals are to be properly disposed or recycled.
- ⇨ Fertilizers and pesticides should be used conservatively on the property grounds. Excessive amounts of these chemicals can be washed away with stormwater runoff increasing the nutrient load to the pond.

⇨ Chemicals such as copper sulfate used to inhibit algae growth in the water quality pond degrade water quality. Since the pond's main function is to enhance water quality, these chemicals should not be used. Rather, reducing the amount of fertilizer application and ensuring that the pond outlets are properly functioning so the pool is flushed periodically will help to deter algae growth.

⇨ Trash and vegetative floatables (grass clippings, leaves, limbs, etc.) should be cleaned from the pond surface and surroundings periodically to promote a healthy, aesthetically pleasing environment, and to prevent blockage of the pond outlets. Studies have shown that people are less likely to litter ponds that are aesthetically pleasing and support wildlife.

Stabilization of BMP drainage area

The area draining to the BMP pond should remain stabilized to prevent excessive sediment from entering the BMP facility. When the bare soil is directly exposed to precipitation the sediment concentration in runoff is much higher than for soil that is stabilized. A stabilized area is covered by impervious surfaces (pavement, buildings), grass cover, landscaped cover (mulch, pine straw), etc.

For filtration practices such as sand filtration facilities and bioretention, maintaining a stabilized drainage area is especially important. Eroded sediment can quickly "seal" the filtration bed, drastically decreasing its filtration capacity.

3.6.4 Grass Swales, Filter Strips

<u>Grass Cover</u>

After initial seeding, the grass should be watered, as needed.

The grass should be mowed periodically (usually when mowing the rest of the property). To maintain the filtering capability of the grass, it should not be mowed to close to the ground (three to four inches minimum).

The ground should be inspected to make sure there is dense growth on all portions of the control device. Bare spots or areas where there is sparse grass cover should be reseeded. It may be necessary to use a temporary erosion resistant matting or to use sod to repair these areas.

As always for grassed areas, fertilizers and pesticides should not be over-applied. Refer to product directions for correct application quantity.

The grass used should be erosion resistant and can tolerate frequent inundation (standing water). Tall fescue is an appropriate choice.

<u>Erosion Problems</u>

The inlet and outlet areas, side slopes (swales), and the rest of the conveyance area should be inspected for erosion problems.

Where water discharges from a pipe and where the stormwater runs off impervious area onto pervious area, there may be erosion problems. The BMP should have riprap protection at the end of pipes and a gravel trench at the edge of impervious areas to help prevent erosion. These devices should be inspected to ensure they are functioning properly. If erosion is noticed in within the rip rap pad or along the edges of the pad, more rock may be needed or it may have been improperly placed (no geotextile liner or improper placement of liner, rip rap not well graded, etc.) If the rock or gravel is displaced downstream, a larger size rock or gravel should be used.

Rill erosion (small channels or gulleys in the ground) is a common problem found in these control devices where the water runoff is naturally trying to channelize. Rill erosion can be repaired by filling in the rills with suitable (clayey) soils and reseeding. It may be necessary to use a temporary erosion resistant matting or to use sod to repair these areas.

Sediment Build-up

Because these BMPs are designed to slow stormwater flows down, sedimentation of coarse particles will occur. Over time the sediment level within the bottom of the swale or filter strip will increase, especially at the upstream area. Sediment will need to be removed periodically (once build-up exceeds one to two inches) from the BMP.

3.6.5 Dry Detention Basins, Wet Detention Ponds, Stormwater Wetlands

The following items should be inspected/maintained on a quarterly basis. These items are in addition to any NC Dam Safety requirements for dams regulated by that agency.

Buffer Vegetation

Strong rooted grasses that have a high tolerance for erosion should be planted on embankments around the pond. Good grass cover should be maintained around the pond perimeter to prevent excessive sediment from entering the pond. The following should be used as guidelines for maintaining buffer vegetation.

- ⇨ To sustain the structural integrity of the dam, no trees or woody vegetation should be allowed on the dam embankments or top of dam. These areas should be mowed on a quarterly basis.
- ⇨ To preserve the hydraulic capacity of the pond system and to prevent runoff from backing up, inlet and outlet areas should be kept clear of heavy vegetation.

⇨ To provide easy access to the pond, the maintenance access around the pond should be free of trees and mowed on a periodic basis.

⇨ Trees and brush, if desired, are acceptable on pond embankments other than the dam.

Erosion Problems

Unsuitable fill material, inadequate compaction, and/or poor stabilization of earth structures can result in accelerated erosion where high runoff velocities exist. High velocities usually occur on steep pond embankments, at pond inlet and outlet discharge areas, and where the water is constricted to channel flow. The entire pond area should be inspected quarterly for signs of erosion, paying special attention to the following areas:

Embankments

If pond embankments are not kept well vegetated with grasses, rill erosion (small channels formed in the embankment due to poor grass cover) may occur. Rill erosion can be repaired by filling the small channels with suitable soil, compacting, and seeding. It may be necessary to install temporary erosion control (such as hay bales) along heavily eroded areas to allow the repaired areas to stabilize. It is especially important to inspect for and immediately repair any erosion on the dam embankments.

Pipe Inlet and Outlet areas

Where erosion causes the undercutting of the downstream end of pipe, the undercut should be stabilized immediately to prevent the end pipe section from "breaking" off. Eroded areas should be filled with good compactable soil and covered with geotextile and riprap.

Open Channel Flow

Eroded areas should be seeded/sodded and protected with temporary velocity dissipation (such as excelsior matting, straw bales, etc.) If erosion continues, a more robust lining should be used.

Blockage of Outlets

Wet extended detention ponds are designed for the water to exit the pond through the low flow orifice(s), the principal spillway, and the emergency spillway. It is important to check all three outlets for blockage that would impair the pond's water quality and hydraulic functionality.

Low Flow Orifice(s)

Unless an inverted orifice is used, some type of trash guard is to be maintained over the low flow orifice(s) to prevent clogging. When the orifice becomes clogged the water level rises to the principal spillway elevation and the benefits associated with temporary storage and its gradual release are lost. To preserve "extended detention" the low flow orifice should be inspected for blockage **twice a month and after large storms.**

Principal and Emergency Spillway
Principal and emergency spillways are designed to safely convey larger than one inch storms that produce runoff which exceed the water quality volume of the BMP. If these spillways are blocked so they do not operate at full capacity, the risk of dam overtopping or other uncontrolled releases may result. To ensure the hydraulic capacity of the spillways, the spillways should be inspected for blockage **twice a month and after large storms.**

If a riser/barrel is used for the principal spillway, a trash rack is to be maintained on the riser. Vegetative growth in the riser should be removed promptly so that the design capacity of the spillway is maintained. Also, the outlet area where the barrel projects from the fill should be clear of tree limbs, sediment accumulation, etc.

Sediment Accumulation

To preserve the BMP's pollutant removal capability, sediment must be removed in areas where the capacity of the design sediment storage volume has been exceeded.

Dry Detention Basin
The sedimentation in dry detention basins will generally not be as much as in wet detention ponds or stormwater wetlands. Sediment accumulation will be less noticeable in dry basins that are open and have a vegetated bottom and embankments. Dry detention basins that have extended detention (24 hours or greater), will have more sedimentation. Sediment should be removed when the detention storage capacity is reduced or when aesthetics is a concern.

Wet Detention Pond
The forebay helps to improve the removal efficiency of the pond system by trapping the majority of coarser suspended solids behind the baffle. When sediment deposition in the forebay exceeds the designed sediment storage capacity for the forebay, the forebay must be dredged. An indication of when the forebay sediment capacity is exceeded is when sediment bars are visible near the inlet discharge or when the sediment level at the inlet to the pond is less than one foot below the normal pool surface (the elevation of the pool is at the bottom of the low flow orifice). Typically, forebays will need to be dredged every 5 to 10 years.

Depth measurements relative to the normal surface elevation (bottom of water quality orifice) should be taken at several locations around the pond. The sediment is to be removed when the measured depth is less than the design permanent pool depth. If a forebay is used at the inlet area of the pond and is regularly dredged, the frequency of dredging the entire pond could be greatly reduced.

Wetland
The forebay helps to trap the majority of suspended solids to prevent the sediment from entering the wetland area and suffocating the plantings. When sediment deposition in the forebay exceeds its designed sediment storage capacity, the forebay must be dredged. It may be necessary to drain down the wetland to measure the

depth of sediment deposited. It is projected that the wetland forebay will need dredging every 3 to 5 years.

Sediment accumulation should be monitored in the wetland area as well. A layer of peat will form in the wetland at a rate of 0.5 inches per year (Hammer 1997). When sediment deposition equals six inches or more the sediment should be removed. The wetland plantings that are destroyed during the cleanout are to be replaced.

Sediment from most sources is usually not hazardous or contaminated, however, it is very "soupy" and is difficult to manage. It is good idea to provide a storage area near the BMP to place sediment once it is dredged to allow it to dry. If desired, sediment may be land applied and seeded. If land applied on-site, it should be within the drainage area to the BMP so sediment that runs off can be recaptured.

Wetland Vegetation

It is likely that a portion of the initial plantings will not survive the first growing season due to factors such as the quality of the plantings, selection of plantings, variable water levels, lack of water, etc. Therefore, it will most likely be necessary for the owner to add additional plantings during the initial development stage of the wetland. Over the long term, drought or other factors may cause a portion of the wetland plantings to die off and need replacement.

Proper Water Balance

An important step to developing a successful wetland system is to ensure that the water balance in the wetland is appropriate to support plant life. The wetland must be able to sustain water and to provide a certain level of inundation after storm events. If the wetland is not sustaining an adequate water balance adjustments will be need to be made to the outflow rates. The slow release outlet should be equipped with a valve to control the water levels in the wetland.

It may be necessary to periodically irrigate the wetland if the wetland is unable to sustain a water level that is conducive to wetland plant growth.

3.6.6 Bioretention Areas

Paved Sweeping Program

A paved area sweeping program should be implemented for all properties that utilize bioretention BMPs. Sweeping paved areas on a periodic basis will help extend the life of the BMP by reducing the pollutant load and debris that enters it. Debris shall be swept away from the pretreatment component (filter strip, channel, or chamber).

Mowing/Landscaping Activities

Mowing/landscaping activities on the property should to be conducted in such a way to prevent lawn and plant clippings as well as eroded sediment from entering the bioretention cell. One way to prevent clippings from entering the cell is to use mulching mowers or bag and remove clippings, especially in areas that drain to the filter.

Minimum Inspection/Maintenance Requirements

The following inspection/maintenance activities should be conducted on a **quarterly** (i.e., 4 times per year) basis, unless noted otherwise.

Overall bioretention area

(a) Accumulated paper, trash, and debris should be removed from the bioretention area.
The bioretention area should remain clear of trash and debris to preserve the draw down rate and stormwater treatment function of the cell. The type of debris removed should be noted and their possible sources identified. Efforts should be made to reduce the amount of the debris entering the bioretention area.

(b) Observe the filtration performance of the cell (every six months at a minimum).
If the drawdown time of the filter bed is greater than the design drawdown time corrective maintenance is needed. Corrective maintenance to restore proper drawdown time and stormwater treatment performance of the filter bed includes:

1. Clean out the underdrain system.

2. Remove mulch and top few inches of planting soil and replace.

   The clogged material should be replaced with new material of the original specifications. Contaminated soil should be removed and disposed of at an approved site (landfill). Instead of replacing the top layer of planting soil, it may be possible to aerate or cultivate the first few inches to restore the draw down capacity of the cell.

3. If appropriate draw down time cannot be restored the owner will be required to remove and replace the filter bed and under drain system.

Pretreatment

(a) Inspect energy dissipators for proper functionality.
Energy dissipators (pea gravel diaphragm, riprap pads, check dams, etc) that are used to slow down and spread the runoff before it enters the bioretention cell should be inspected for proper functionality. Sediment build-up should be removed. Once the

voids become substantially filled with sediment, the rock must be removed, cleaned (away from bioretention area) and placed back in its original location. Larger rock or other measures may be required if the rock is being carried away by high water flows.

(b) Inspect sedimentation/diversion chambers (if applicable) for sediment build-up and blockage.

The sedimentation/diversion chamber should be cleaned out when sediment levels exceed the design level (12 inches accumulation depth is to be used if no design level is given). The sludge should be removed and disposed of at an approved site (landfill). All inlets and outlets to the chamber should be inspected for blockage.

(c) Inspect filter strips and channels for bare areas, rill or channel erosion.

A robust grass cover for the pretreatment areas must be maintained. Bare areas and eroded areas should be seeded or sodded immediately.

Plantings

(a) Replace plantings that are dead, diseased, or otherwise have failed to establish.

If replacing plantings frequently, the planting soil may need to be tested. Make sure that the plantings used are to able withstand the bioretention environment (i.e. frequent inundation).

(b) Pruning and weeding the bioretention cell may be aesthetically desired.

Make sure that all loose vegetation is removed from the bioretention cell so as not to interfere with the functionality of the cell.

Mulch Layer

(a) Inspect the cell for proper mulch cover.

Mulch needs to be reapplied in areas where erosion has displaced the mulch (mulch just may need spreading out). It will be necessary to replace the mulch layer every year when the mulch decays. The thickness of mulch should be approximately 3 inches.

Planting soil

(a) Test the pH of the soil (annually)

To keep plantings healthy, the planting soil shall be tested once a year to determine if the pH is in the acceptable range. If the pH is low than lime should be applied; if the pH is high then iron sulfate can be used.

(b) Test the toxicity of the soil (as needed, approximately once every 5 years)

After a few years of service, the quantity of heavy metals and other pollutants that is collected by the cell may reach toxic levels impairing plant growth and the effectiveness of the cell. If the toxic levels are too high, the soil will need to be replaced.

Outlet

(a) Verify that there is discharge from the underdrain when water is ponded in the cell. When the water level is above the filter bed, check the outlet area to ensure that the bioretention cell is functioning. If there is no discharge from the outlet, the system is nonfunctional and corrective maintenance is needed immediately to restore draw down.

(b) The overflow structure should be inspected to ensure it is not blocked with debris and is functioning properly.

(c) Inspect for and fix erosion problems at the outlet areas
The downstream areas from the outlets of the bioretention area should be checked to ensure there is no erosion. Eroded areas should be revegetated. An energy dissipator, if not already in place, may be needed if erosion continues to occur.

3.6.7 Sand Filtration Facilities

Paved Area Sweeping Program

A paved area sweeping program is recommended for all properties that utilize a sand filter. Sweeping paved areas on a periodic basis will help to extend the life of the filter by reducing the pollutant load and debris entering the filter. Sweeping should be done in such a manner as to prevent debris from entering inlets leading to the sand filter.

Mowing/Landscaping Activities

Mowing/landscaping activities on the property should be conducted in such a way to prevent lawn and plant clippings as well as eroded sediment from entering the filter facility. One way to prevent clippings from entering the facility is to use mulching mowers or to bag and remove clippings, especially in areas that drain to the filter.

Minimum Inspection/Maintenance Requirements

The following inspection/maintenance activities should be conducted on a **quarterly** (i.e., 4 times per year) basis, unless noted otherwise.

Overall Sand Filter Facility

(a) Accumulated paper, trash, and debris are removed from the filtration facility.
Large debris should be removed from each chamber within the sand filter facility to preserve the draw down rate and stormwater treatment function of the filter. Note the type debris is removed and identify possible sources. Efforts should be made to reduce the amount of the debris entering the filtration facility.

(b) Check to verify that there are no signs of cracking or deteriorating concrete (every 6 months at a minimum).
Check for signs of pronounced cracking in the concrete and other structural problems that may present a hazard to the public (especially underground filters that carry vehicle loading).

Sedimentation Chamber

(a) Check to verify that the perforated pipe or low flow orifice (if applicable) is clear of debris.
Some systems use low flow orifices or perforated pipes to slowly distribute water from the sedimentation chamber to the filtration chamber. To assure the capacity of the filter, these components are to be inspected quarterly and unclogged as necessary.

(b) Measure the sediment depth at several locations in the sedimentation chamber (every 6 months at a minimum)
The sedimentation chamber should be cleaned out when sediment levels exceed the design level (12 inches is to be used if no design level is given). The sludge should be disposed at an approved site (landfill). If the sedimentation chamber utilizes a submerged weir to trap floatables, any oil on the surface must be removed separately and recycled before the chamber is pumped.

Filtration Chamber

(a) Monitor the performance of the filter bed (every six months at a minimum).
If the draw down time of the filter bed is greater than twice the initial design drawdown time corrective maintenance is needed. Corrective maintenance to restore proper draw down time and stormwater treatment performance of the filter bed includes:

1. Clean out the under drain system.
2. Replace the top layer of the sand filter bed

Accumulated sediment on top of the sand bed and the top layer of discolored sand should be scraped off. The removed sand should be replaced with new sand of the original specifications. The sediment and contaminated sand should be disposed at an approved site (landfill).

If a filter fabric/screen is used on top of the sand layer, replace it with a new fabric/screen of the original specifications. If gravel is used on top of the filter fabric/screen, rinse the gravel well and reuse. The sediment rinsed from the gravel should be collected. The used filter/screen and collected sediment is to be disposed at the landfill. Before replacing the fabric/screen, be sure to check to see if the sand layer is contaminated.

3. If appropriate draw down time cannot be restored the owner will be required to remove and replace the filter bed and under drain system.

If the filter bed is not draining at all, the stagnated water must be released by the dewatering valve or pumped out before corrective maintenance can be done to the sand bed. If oil is present on the surface it should be removed separately and recycled.

Outlet Chamber/Outlets

(a) Check to verify that the outlet is discharging when water is present in the filtration chamber.
When the water level is above the filter bed, check the outlet area to ensure that the sand filter is functioning. If there is no discharge from the outlet, the system is nonfunctional and corrective maintenance is needed immediately to restore draw down.

(b) Check to verify that there is no erosion at the outlet areas.
The downstream areas from the outlets of the sand filter should be checked to ensure there is no erosion taking place. Eroded areas should be revegetated. A velocity dissipator, if not already in place, may be needed if erosion continues to occur.

3.6.8 Proprietary Stormwater Treatment Facilities

Consult with the manufacturer for proper inspection/maintenance specifications. Most manufacturers have prepared a detailed Operation and Maintenance manual and provide maintenance services. The City of Greensboro requires that the owner follow the maintenance requirements for these systems and provide documentation of all inspections and maintenance activities performed.

Access / Maintenance Easement: Refers to the required access and maintenance easement to a structural stormwater management improvement or facility from the public Right-of-Way (R.O.W.) and includes the Drainage Maintenance and Utility Easement (D.M.U.E.) around the improvement or facility.

Alternative Structural Best Management Practice: Typically facilities other than dry detention and wet detention pond facilities designed to reduce the pollutant loading of stormwater runoff and in some cases reduce the stormwater runoff discharge rate. The City encourages the implementation of alternative and innovative best management practices, where appropriate.

Anti-Seep Collar: A metal plate or other device that connects to the outside of a structure that extends through a dam and serves to redirect seepage pathways to minimize the quantity of seepage along the structure.

Anti-Vortex Device: A device placed in a outlet riser structure to prevent a vortex, or whirlpool, from occurring when the outlet is acting as an orifice.

Baffle: A berm or barrier made of earth, rock, etc., or other diversion used to direct flow or trap sediments within a structural BMP.

Best Management Practice (BMP): An activity, design or planning technique, or structural device that is used singularly or in combination to protect the quality of receiving surface waters, reduce the volume of stormwater runoff generated, and/or reduce the stormwater runoff discharge rate.

Bioretention Area: A structural BMP that removes pollutants in stormwater runoff through filtration and plant uptake. The bioretention BMP consists of a "made" planting soil layer, mulch, plantings, and an underdrain system.

Bioretention Area Landscape Plan: Plan required for City approval of this BMP for water-supply watershed protection, which shows the plant types, quantity, and location.

Building Certificate of Compliance: Permit issued by the City Building Inspections Department that signifies that the building is in compliance and may be occupied.

Built-Upon Area: Term used in City Ordinance Section 30-7, Water-Supply Watershed Districts, and Section 27-22, Stormwater Management Control. Defined as impervious or partially impervious cover including buildings, pavement, gravel areas, recreation facilities, such as tennis courts, etc.

Catch Basins: Structures, which are connected to storm sewer pipe, used to collect stormwater runoff from the land surface, such as roads and parking lots.

Channel: Man-made or naturally formed conveyance that is well defined and may convey stormwater runoff, intermittent, or perennial streams.

Check Dam: A dam placed within a conveyance such as a swale or channel to slow the velocity of flow or temporarily detain the flow.

Chimney Drain: A seepage control device used in earth dams.

Clustering: As it pertains to stormwater BMP, site development practice where development is concentrated away from environmentally sensitive areas and the amount of impervious surfaces is reduced as a result of concentrating the development in one place as opposed to spreading out over the entire site.

City of Greensboro Stormwater Master Plan: A comprehensive stormwater management master plan that is to include all major watersheds and sub-watersheds in the City. The master plan for a given watershed/sub-watershed will guide the development of on-site and/or off-site stormwater management facilities and practices to meet stormwater quantity and quality management goals, in addition to environmental and watershed restoration objectives, as determined by a group of representative stakeholders.

Conservation or Floodplain Easements: Easements provided along environmentally sensitive areas and/or major streams that have mapped floodplains.

Dam Hazard Potential: An estimate of the extent of damage that a dam would do if it were to fail. The hazard potential is classified by the State Dam Safety Office as low, intermediate, or high.

Dam Safety Regulations: Regulations (Dam Safety Law of 1967 and Administrative Code Title 15A Subchapter 2K) regarding the construction, repair, alteration, or removal of a dam. These regulations are enforced by the NC Dam Safety Office, Land Quality Section.

Dam: A structure and appurtenant works erected to impound or divert water, as defined by the Dam Safety Law of 1967.

Dead Storage Zones: Term used to describe areas within pond BMPs (wet detention ponds, stormwater wetlands) that are not within the flow path between the inlet and outlet. These areas may be created where the BMP is an irregular shape and/or where the pond width goes back and forth between narrow and wide.

Deep Water Zone: One of the depth zones in the stormwater wetland BMP. The deep water zone, which consists of a forebay and outlet micropool, comprises approximately 30% of the wetland surface area and is usually 4-6 feet deep.

Depth Zones: Tem used to describe the varying depths within a stormwater wetland BMP. The depth zones include the deep water zone, which consists of forebay and outlet micropool, and a shallow water zone, which consists of the low marsh, and high marsh.

Detention: Temporarily storing water and slowly releasing it.

Development: Any manmade change to real estate, including buildings or other structures, mining, dredging, filling, grading, paving, excavation, or drilling operations; or storage of equipment or materials (from Water-supply watershed (Chapter 30) Ordinance).

Disconnection: Directing stormwater runoff from impervious surfaces to pervious surfaces to provide water quality improvement through contact with pervious cover, allow infiltration, and decrease peak discharge, before the runoff is discharged from the property or into a conveyance system.

Drainageways: Usually refers to areas where the topography forms a small "valley" that is not well defined and conveys stormwater runoff to streams or other water bodies.

Dry Detention Basin: A structural BMP that does not have a permanent pool but temporarily stores stormwater runoff and slowly releases it. This BMP has moderate pollutant removal capability but can provide an excellent means for reducing peak discharge rates.

Energy dissipator: A device such as rip rap pad, block baffles, etc. that is placed downstream of an pipe or channel outfall to reduce the velocity of the flow.

Enforcement Officer: City stormwater staff responsible for reviewing plans for compliance with the stormwater management requirements of this Ordinance.

Erosion: The wearing down or removal of land surface by flowing water, wind, ice, etc.

Extended Detention: To detain water for an extra length of time to achieve better pollutant removal efficiency (usually 24 hours or more).

FEMA: Acronym for the Federal Emergency Management Agency. This agency regulates development activities in designated floodplain areas.

FEMA Certificate of No Rise: Certification with supporting technical data that states that there will be no increase in flood levels as a result of a project that develops in the floodway.

FEMA Conditional Letter of Map Revision (CLOMR): FEMA's approval of the proposed changes to an effective FIRM for proposed placement of fill or other physical measures that result in changes to the floodplain elevation or floodway.

FEMA Flood Insurance Rate Map (FIRM): Map in which FEMA has delineated both the special flood hazard areas and the risk premium zones.

FEMA Floodplain: Area along designated streams that have the potential to flood during the 100-year storm event.

FEMA Floodway: Area along designated streams that must be reserved in order to discharge the base flood without cumulatively increasing the water surface elevation more than a designated height (for Greensboro, one (1) foot) (as defined by FEMA).

FEMA Letter of Map Revision (LOMR): FEMA's modification to an effective FIRM based on the placement of fill or other physical measures that result in changes to the floodplain elevation or floodway.

Fetch: Refers to the length across the surface of a pond, lake or reservoir, in which wind may act upon.

Filter and Drainage Diaphragm: A sand and gravel layer placed around a structure that extends through a dam, to capture seepage and safely convey it to the downstream side of the dam.

Filter Strip: A structural BMP that is designed to receive stormwater runoff that is in the form of sheet flow. The strip is a uniformly graded piece of land that is slightly sloped to provide positive drainage. The filter strip is densely planted with grass, which filters the stormwater as it flows across the strip.

First Flush: Term to describe the initial quantity of runoff from developed areas. It is generally accepted that the majority of pollutants are washed off by the initial runoff.

Floatable: Any material that floats on water such as oil, wood, leaves, paper or plastic litter, etc.

Floodplain: The area adjacent to the stream that is subject to flooding when the stream overtops its banks during storm events (usually associated with the area inundated by the 100 year storm event).

Flow Spreader: A device that takes flow that is concentrated or overland flow and spreads the flow to create sheet flow. The flow spreader may be a gravel diaphragm or trench.

Forebay: A feature in the wet detention pond and stormwater wetland. The forebay is placed at the inlet area of the pond and is separated from the rest of the pond by a baffle. The forebay serves to trap coarse sediments from the inflow to minimize accumulation in the remaining portion of the pond and wetland area, making sediment cleanouts easier and minimizing disturbance.

Freeboard: The difference between the maximum elevation of the water level during a specified storm and the top of impoundment or conveyance structure in which the water is contained.

Geographic Information System (GIS): An innovate computer system used to visualize, query, and analyze data that is spatial in nature.

Grass Paving: A technology that incorporates paver units that allow grass to grow between and is able to support vehicular loading. This technology was designed mainly to provide a developers a more aesthetically pleasing option to asphalt or concrete pavement, but also can provide benefits to stormwater management. Grass pavers are generally placed in areas that are infrequently used areas such as fire lanes, overflow parking, access roads, etc.

Herbaceous Plant: A plant whose stem above ground does not become woody.

High Marsh: Term to describe one of the depth zones in the stormwater wetland BMP. The high marsh has a depth of 0 to 9 inches and comprises approximately 35% of the wetland surface area.

High-Density Development: Term used in the City's Water-Supply Watershed Protection Ordinance. Defined as development where the built-upon area or density (single family detached homes) or the built-upon area (all other development) exceeds the applicable limits specified in the ordinance.

Hydrologic / Hydraulic Analysis: For purposes of this manual, hydrologic analysis involves procedures and techniques to estimate the transformation of precipitation or rainfall into surface stormwater runoff in terms of runoff volume and/or runoff rate. Hydraulic analysis generally refers to hydraulic engineering procedures and techniques to evaluate the storage and outflow (discharge) characteristics of stormwater runoff with respect to engineered structural stormwater facilities or improvements, analysis of closed conduit drainage systems, and/or a hydraulic backwater analysis necessary for determination of floodwater elevations for an open channel segment.

Hydrology: An earth science that encompasses the occurance, distribution, movement, and properties to the water of the earth.

Impervious surfaces: Generally man-made hard surfaces that are placed over natural soils or surfaces that do not allow infiltration of stormwater into the soils, or that greatly reduce the amount of infiltration, including building rooftops, pavement, paved or gravel roads/driveways/sidewalks/parking areas, and paved recreational areas.

Infiltration: Percolation of water into the ground.

Intermittent Streams: Refer to the definition in Ordinance Section 30-2-2.2.

Jurisdictional Streams/Wetlands: Streams and wetlands that are under the jurisdiction of the US Army Corps of Engineers.

Length to Width Ratio: Term used to describe the geometry of the stormwater BMP surface. Generally for pond BMPs (wet detention ponds, stormwater wetlands), the BMPs pollutant removal efficiency increases as the flow path between the inlets and outlets increases, therefore, for these BMPs the length to width ratio is defined as the length of the flow path to the width of the flow path.

Licensed Professional Engineer: A Professional Engineer (P.E.) duly licensed by the appropriate State Board in the State of North Carolina.

Low Flow Orifice: Outlet works that releases detained water to a desirable discharge rate or detention time.

Low-Density Development: Term used in the City's Water-Supply Watershed Protection Ordinance. Defined as development where the density (single family detached homes) or the built-upon area (all other development) does not exceed the applicable limits specified in the ordinance.

Maintenance Plan: Short-term and long-term inspection and maintenance activities that are generally necessary to maintain the functionality and safety of stormwater management facilities.

Microtopography: Term used to describe the varying depth zones within a stormwater wetland BMP. Microtopography is important in establishing a diverse wetland plantings, and extending the flow path between the inlet and outlet.

Municipal Separate Storm Sewer System (MS4) Discharge Permit: NPDES Stormwater Permit, that is required for municipalities with a population over 100,000 (Phase I). The Permit requires these municipalities to develop and implement a Stormwater Quality Management Program (SWQMP) to control the discharge of pollutants from the municipal separate storm sewer system to the maximum extent practicable.

New Development: Any land disturbance activity occurring on undisturbed land that results in vegetation/tree removal, grading, filling, placement of impervious surfaces or that otherwise decreases the infiltration capacity of the land.

Non-Structural BMPs: Techniques incorporated in site design/planning to reduce the volume of runoff generated, reduce runoff discharge rates and provide partial pollutant removal.

NPDES: Acronym for the EPA's National Pollutant Discharge Elimination System.

(One Hundred) 100-Year Storm: The precipitation volume or intensity that is has a 1% probability of being equaled or exceeded during a given year.

Open Vegetated Conveyance: Any ditch, channel, swale or flat strip of land that is covered with vegetation (forest, unmaintained growth, grass, or landscape covering) and conveys stormwater runoff.

Outfall: The end of a stormwater conveyance, such as a pipe, swale, channel, etc. where the flow is discharged to another conveyance system.

Outlet Micropool: Term to describe one of the deep water zones within a stormwater wetland BMP. The outlet micropool is a pool around the outlet to allow the low flow orifice and pond drain to operate properly.

Owner's Association: An association of property owners established when there is more than one owner of a permanent structural stormwater management facility or improvement. The association will be responsible for the obligations, liabilities, and maintenance activities associated with stormwater management improvement ownership.

Perennial Streams: Streams, and lakes and ponds along them, that are indicated as being perennial 1) on the most recent version of the US Geological Survey 1:24000 scale (7.5 minute quadrangle) topographic maps, 2) on the most recent version of the Soil Survey map developed by the USDA – Natural Resource Conservation Service, or 3) by an examination of site-specific evidence by the City Storm Water Services Division using criteria approved by the NC Division of Water Quality. However, if the above-mentioned map indicates an area as a perennial stream but the Storm Water Services Division finds no perennial water body actually exists on the ground, that area shall not be deemed a perennial stream. Ponds and lakes created for animal watering, crop irrigation, or other agricultural uses that are not part of a natural drainageway are not streams. If the City of Greensboro develops a detailed stream network map covering one or more watersheds, then within the watersheds covered by that map perennial streams shall thenceforth be as shown by that map.

Perimeter (Delaware) Sand Filter: A type of sand filtration facility developed in Delaware where the facility is placed underground along the perimeter of impervious areas such as parking lots.

Pollutant Loading: The quantity of pollutants that are discharged to surface waters by means of stormwater runoff, discharge of non-stormwater, or groundwater contamination.

Pollutant: Substances or chemicals that are harmful or degrade the quality of surface waters and associated habitat, such as sediment, nutrients, bacteria, chemicals, etc.

Pollution Prevention BMPs: Activities implemented to control pollution at the source by preventing pollutants from commingling with stormwater runoff.

Post-development peak discharge rates, 2-year: The peak flow rate of stormwater runoff that results from a land area *after* it is developed or redeveloped during a precipitation event based on an amount of precipitation that has a 50% probability of being equaled or exceeded in a given year.

Post-development peak discharge rates, 10-year: : The peak flow rate of stormwater runoff that results from a land area *after* it is developed or redeveloped during a precipitation event based on an amount of precipitation that has a 10% probability of being equaled or exceeded in a given year.

Pre-development peak discharge rates, 2-year: The peak flow rate of stormwater runoff that results from a land area *before* it is developed or redeveloped during a precipitation event based on an amount of precipitation that has a 50% probability of being equaled or exceeded in a given year.

Pre-development peak discharge rates, 10-year: The peak flow rate of stormwater runoff that results from a land area *before* it is developed or redeveloped during a precipitation event based on an amount of precipitation that has a 10% probability of being equaled or exceeded in a given year.

Proprietary Stormwater Treatment Facilities: Patented structural BMPs that have been developed to remove pollutants in stormwater runoff.

Public Waters: Surface stormwater runoff from (City-owned) public lands such as streets, parks, parking lots, etc.

Receiving Waters: Surface waters that receive stormwater runoff or groundwater seepage.

Redevelopment: Any land disturbance activity occurring on previously developed land that results in vegetation/tree removal, grading, filling, placement of impervious surfaces or otherwise decreased infiltration and retention capacity of the land.

Regional Stormwater Management Facility: A structural management practice established by one or more local governments for the purpose of managing stormwater from multiple properties.

Riser/barrel: An pond outlet works that consists of a vertical, standpipe (riser) on the upstream side of the dam to control the water level, connected to a pipe (barrel) that runs through the dam and discharges on the downstream side.

Runoff/Pollution Control BMPs: Site design/planning practices, or structural facilities that serve to reduce the total volume of runoff generated, reduce peak runoff discharge rates, and provide surface water quality improvement by minimizing impacts to environmentally sensitive areas and by removing pollutants from stormwater runoff.

Safety Bench: A recommended feature for all stormwater BMPs that have a permanent pool. The safety bench is a flat or gently sloped area around the permanent pool elevation and serves to separate the pool from the embankment.

Sand Filtration Facility: A structural BMP that removes pollutants in stormwater runoff through sedimentation and filtration. The sand filtration facility consists of sedimentation chamber/basin and sand filter chamber. There are three main designs: the underground or DC sand filter, perimeter or Delaware Sand Filter, and surface sand filter.

Scoresheet: Refers to the scoresheet provided in Section 30-7-1.11 of the Greensboro Code of Ordinances. Developments in the General Watershed Area that are classified as low density may be approved by the City for watershed protection if they have a passing score on the scoresheet.

Seepage: As it pertains to dam seepage, flow of water through the dam, foundation, or ground from the upstream side of the dam to the downstream side.

Sedimentation: The process of suspended particles settling out in slow moving receiving waters.

Sedimentation Chamber: The portion of a structural BMP (such as sand filtration facility) that is designed to settle out coarse sediments.

Shallow Water Zone: Term to describe one of the depth zones in the stormwater wetland BMP. The shallow water zone, which consists of the low marsh and high marsh, comprises approximately 70% of the wetland surface area and has a depth of 0 to 18 inches.

Sheet Flow Runoff: Runoff that is overland flow and is not concentrated into a conveyance system.

Skimmer Baffle: Baffle used in a structural BMP or spill containment structure, designed to trap floatable material, such as oil, litter, gasoline, leaves, etc. Usually consists of a sheet of metal or plastic or concrete wall that placed across the control structure and extending below the permanent pool trapping floatables on the upstream side of the baffle.

Spillway: Outlet works designed to discharge water during a storm event from a water body once it reaches a certain elevation.

Stabilization (Site): Condition where the soil is no longer exposed. For filtration BMPs it is crucial that the site is stabilized before placement of the filter material, which includes completion of paving and landscaping (seeding with straw and/or mulch).

Storm Sewer: Structures associated with collecting stormwater and conveying it subsurface to a downstream outfall. Structures include pipe, catch basins, and junction structures (manholes).

Storm Sewer Design Manual: Refers to the guidance manual developed by the City Engineering Division for storm sewer system design.

Storm Water Management Ordinance: Chapter 27 of the Greensboro Code of Ordinances provides Storm Water Services with the legal authority to administer the City's NPDES Stormwater Permit. Section 27-22 of this Ordinance, adopted by City Council in 1999, sets forth the stormwater management control requirements for new development.

Storm Water Services: Division under the City of Greensboro Environmental Services Department. Responsible for implementation and enforcing the City's Municipal Separate Storm Sewer System Discharge Permit and development of a comprehensive stormwater management program for the City.

Storm Water Utility Fee: Fee that is assessed to all City of Greensboro properties to fund the Storm Water Services Division. Residential properties are charged a flat rate, while the fee for non-residential properties is based on the amount of impervious surface that is on the property.

Stormwater: Precipitation.

Stormwater Conveyance System: System used to convey stormwater runoff to downstream receiving waters. The conveyance system may include storm sewer, open channels/swales, structural BMPs, etc.

Stormwater Infrastructure Management System (SWIMS): A proactive program developed by the City of Greensboro to optimize maintenance of the public storm sewer system through use of the information gathered by stormwater infrastructure and conveyance system inventory, land use data, and other sources.

Stormwater Management Control: Typically, a structural device used to manage the quality and/or quantity of stormwater runoff.

Stormwater Management Manual: Provides requirements and guidance for meeting the requirements of Ordinance Section 30-7, Water Supply Watershed Development, and Section 27-22 of the Storm Water Management Ordinance.

Stormwater Management Improvement: A stormwater management control, non-structural/structural BMP, upgrade to existing conveyance system, etc., implemented to reduce negative stormwater impacts associated with development.

Stormwater Management Plan: This plan is required for all proposed new development or redevelopment by Section 27-22 of the Greensboro Code of Ordinances, Stormwater Management Control Requirements. The plan must address the requirement specified in the ordinance and be prepared in accordance with the guidelines of the Stormwater Management Guidance Manual., such as engineering analysis of impacts to downstream storm sewer systems and property as a result of increased runoff, measures to control increased runoff to prevent flooding, drainage, or erosion problems, and buffers along streams and major drainageways.

Stormwater (Watershed) Master Plan: A comprehensive stormwater management master plan that is to include all major watersheds and sub-watersheds in the City. The master plan for a given watershed/sub-watershed will guide the development of on-site and/or off-site stormwater management facilities and practices to meet stormwater quantity and quality management goals, in addition to environmental and watershed restoration objectives, as determined by a group of representative stakeholders.

Stormwater Pollution Prevention Plan (SWPPP): Requirement of the NPDES Industrial Stormwater Permit. Details stormwater BMPs and other practices to eliminate discharge of pollutants from industrial facilities via stormwater runoff.

Stormwater Quality Management Program (SWQMP): Requirement of the municipal NPDES Stormwater Permit. Details activities that the City will implement to control the discharge of pollutants from the municipal separate storm sewer system to the maximum extent practicable, including, but not limited to, public education and awareness, stormwater runoff and stream monitoring, storm sewer and conveyance system inventory, identification of illicit discharges and improper disposals, and erosion and sedimentation control.

Stormwater Runoff: Rainfall that does not infiltrate into the ground and flows as surface water.

Stormwater Runoff Discharge Rate: The volumetric rate of runoff that leaves a particular area of interest over a specified time interval.

Stormwater Utility Credit Policy: City of Greensboro policy to issue credit to properties that implement on-site stormwater BMPs designed to reduce the discharge of pollutants to surface waters, and minimize stream and property damage by decreasing flowrates. The BMPs eligible for credit are referred to in this manual and the Stormwater Utility Credit Policy document.

Stormwater Utility Fee: Fee charged to all properties to fund the City Storm Water Services division. The fee is a flat fee for single family detached residential homes and based on the amount of impervious surfaces for other residential and non-residential properties.

Stormwater Wetlands: A structural BMP that consists of a permanent pool, temporary pool, and varying depth zones (microtopography) to establish wetland plantings.

Stream Buffers: Land along streams, drainageways, and other water bodies, which are provided to protect the quality of the surface waters, and minimize structure or improved property damage due to flooding or changes in the stream channel (for example, widening, deepening or meandering).

Stream: Natural body of concentrated flowing water in a natural low area or natural channel on the land surface (NC Division of Water Quality).

Structural BMPs: Defined as "engineered" stormwater management facilities designed to improve the quality of stormwater runoff and reduce stormwater runoff rates. They use processes such as sedimentation, plant uptake, filtration, microbial activity, etc. to remove pollutants from stormwater runoff. They can use the storage to control stormwater runoff to also help reduce peak discharges.

Sub-Basin (Sub-Watershed) Master Plan: A plan that identifies existing and potential future stormwater quality and quantity problems for a designated drainage basin within the city through hydrologic/ hydraulic and water quality/pollutant load modeling utilizing data collected on the City's land use, topography, surface water conveyance system, monitoring activities, etc., and identifies potential on-site and regional solutions to address the issues in a holistic and stakeholder driven manner.

Surface Sand Filter: A type of sand filtration facility where the facility is placed above ground.

Surface Waters: Refers to water that exists on the surface of the earth, such as streams, ponds, lakes, springs, wetlands, stormwater runoff from precipitation events, etc.

Swales: Man-made or natural open conveyance of stormwater runoff that is usually designed to convey or treat stormwater runoff has relatively flat side slopes and a wide bottom, as opposed to well defined channels or ditches.

Technical Review Committee (TRC): A committee consisting of representatives from various City of Greensboro departments that are responsible for reviewing and approving proposed development activities within the City's jurisdiction.

(Ten) 10-Year Storm: The precipitation volume or intensity that is has a 10% probability of being equaled or exceeded during a given year.

Time of concentration: As it refers to hydrology, the time required for 100 percent of a tract of land to contribute to the runoff at the outlet.

Trash rack: A device placed on outlet (pipe or box) spillways to prevent the outlet from being clogged with large debris.

(Two) 2-Year Storm: The precipitation volume or intensity that is has a 50% probability of being equaled or exceeded during a given year.

Underdrain System: A system of perforated pipes placed under the filter beds of filtering BMPs which serves to collect the filtered water and discharge it to the stormwater conveyance system.

Underground (DC) Sand Filter: A type of sand filtration facility, developed by Washington DC, where the facility is placed underground.

Underground Oversized Stormwater Sewer System: Underground chamber or pipe system used to provide temporary storage (dry detention) to reduce post-development peak runoff rates.

Urbanization: Development of land for use as commercial, industrial, residential, and/or other land uses associated with city growth. Urbanization causes increases in impervious surfaces, which in turn causes a decrease in surface water quality.

Water Balance: As it relates to structural BMPs, the net presence of water considering precipitation, dry weather flow, storage, evaporation and infiltration. For stormwater wetlands, it is very important to have a water balance that can sustain the plantings.

Water Quality Volume (WQV): The storage needed within a structural BMP to control the "first flush" of runoff during a storm event. The "first flush" is designated by the NC Division of Water Quality and City of Greensboro as the first inch of rainfall.

Watershed: Land area that contributes surface runoff to any point of interest.

Watershed Map: As it pertains to Section 2.2 of this manual, the Guilford County Designated Water Supply Watershed Map, dated June 30, 1991

Watershed Protection Plan: Plan required when developing, disturbing, or subdividing land that is in the City's water-supply watershed area. The plan must meet the requirements of the Water-Supply Watershed Protection Ordinance.

Water-Supply Watershed Protection Requirements (Ordinance): Requirements set forth to protect the City's water-supply lakes and watershed, such as limits on built-upon surfaces, use of stormwater BMPs, and buffer protection of lakes and streams.

Water-Supply Watershed: The land area that drains to a water source. Usually associated with water sources for treatment and distribution of drinking water.

Designated Water-Supply Watershed: Water-supply watersheds that are designated by the NC Environmental Management Commission for protection by their regulations.

Watershed Critical Area: The area designated around a water-supply reservoir, that is restricted further from development activities and land use than the General water-supply watershed area.

Watershed General Area: The area that is within a designated water-supply watershed area that is not watershed critical area.

Wet Detention Pond: A structural BMP that is used to remove pollutants from stormwater runoff and, if desired, provide peak reduction. The pond consists of a permanent pool; a temporary pool, which is designed to be above the permanent pool, to store the water quality volume; and a forebay, which is constructed at the inlet area to trap larger sediments.

Wetland Planting Plan: Plan required for City approval of this BMP for water-supply watershed protection, which shows the planting types, quantity, and location.

Storm Water Phase II Compliance Assistance Guide

R0010593

Compliance Guide Notice

The statements in this document are intended solely as guidance to aid regulated entities in complying with the Storm Water Phase II final rule. The guidance is not a substitute for reading the regulation and understanding all its requirements as it applies to your facility. This guidance does not constitute rulemaking by the EPA and may not be relied on to create a substantive or procedural right or benefit enforceable, at law or in equity, by any person. EPA may decide to update this guide without public notice to reflect changes in EPA's approach to implementing Storm Water Phase II or to clarify and update text. To determine whether EPA has revised this document and/or to obtain copies, go to EPA's web site at www.epa.gov/owm/sw/phase2.

1.0 INTRODUCTION

After reading this introduction, you should know whether you need to use this guide, what the guide covers, and where to get the latest information on the regulation.

The U.S. Environmental Protection Agency (EPA) published the regulation entitled "National Pollutant Discharge Elimination System - Regulations for Revision of the Water Pollution Control Program Addressing Storm Water Discharges" (*Federal Register*, Volume 64, Number 235, pages 68722-68852) on December 8, 1999 as required by Section 402(p) of the Clean Water Act (CWA). This guide explains how to tell if you are subject to the regulation and what to do if you are required to comply.

1.1 Who should use this guide?

This new rule regulates storm water discharges from two categories:

First, the rule covers storm water discharges to certain ***municipal separate storm sewer systems*** (MS4s). Public entities which operate these MS4s, such as cities, counties, States, and the Federal government, could be regulated under this rule. MS4 operators should read section 4 for more information.

Second, the rule also covers storm water discharges from ***construction activity*** generally disturbing between 1 and 5 acres. A construction operator could include the site owner, developer, contractor, or subcontractor. Construction site operators should read section 5 for more information.

The storm water Phase II final rule also provide regulatory relief for certain ***industrial facilities*** (currently permitted under EPA's storm water regulations) where storm water runoff is not exposed to industrial activities. Operators of industrial facilities interested in the no exposure exclusion should read section 6.

1.2 What Does this Guide Cover?

The purpose of this guide is to help the regulated community comply with the Storm Water Phase II Rule. This guide answers the following basic questions:

- Why is the Storm Water Phase II Rule important?
- Am I subject to the Storm Water Phase II Rule?
- What must I do to comply with the Storm Water Phase II Rule?

1.3 How Do I Use this Guide?

This guide is organized into seven major sections plus three appendices.

Section 1.0	Introduces you to this guide and the Storm Water Phase II Rule. Describes basic types of entities regulated so you can determine if you are affected by the rule.
Section 2.0	Provides background on why the Storm Water Phase II Rule is needed. Topics such as the environmental impacts of storm water and why storm water should be controlled are discussed. The history of the NPDES Storm Water program is briefly described.
Section 3.0	Delivers an overview of the Storm Water Phase II requirements. The basic components of the program are described and schedules and timelines are highlighted.
Section 4.0	Gives step-by-step procedures for operators of small MS4s to determine if they are subject to the regulation and provides information on how to demonstrate compliance.
Section 5.0	Gives step-by-step procedures for operators of small construction activities to determine if they are subject to the regulation and provides information on how to demonstrate compliance.
Section 6.0	Provides a discussion of how the Rule affects industrial facilities, including which industrial facilities are covered, and an explanation of the No Exposure exclusion and how to determine if you qualify.
Section 7.0	Documents the Compliance Assurance Process - Discusses how EPA will determine compliance, what happens if you or EPA discovers noncompliance, and the legal status of the guide.
Appendices	Provides additional references and where to go for more information on storm water.

1.4 Where Can I Get More Information on the Storm Water Phase II Rule?

Additional information on the NPDES storm water Phase II rule, including a series of fact sheets and a full copy of the final rule, can be found on EPA's web pages at http://www.epa.gov/owm/sw/phase2.

Compliance assistance will be covered in Section 7 of the guide. One source for compliance assistance and information on the rule is the Local Government Environmental Assistance Network (LGEAN). LGEAN is one of EPA's compliance assistance centers and can be found on the web at www.lgean.org or contacted by phone at 1-877-TO-LGEAN.

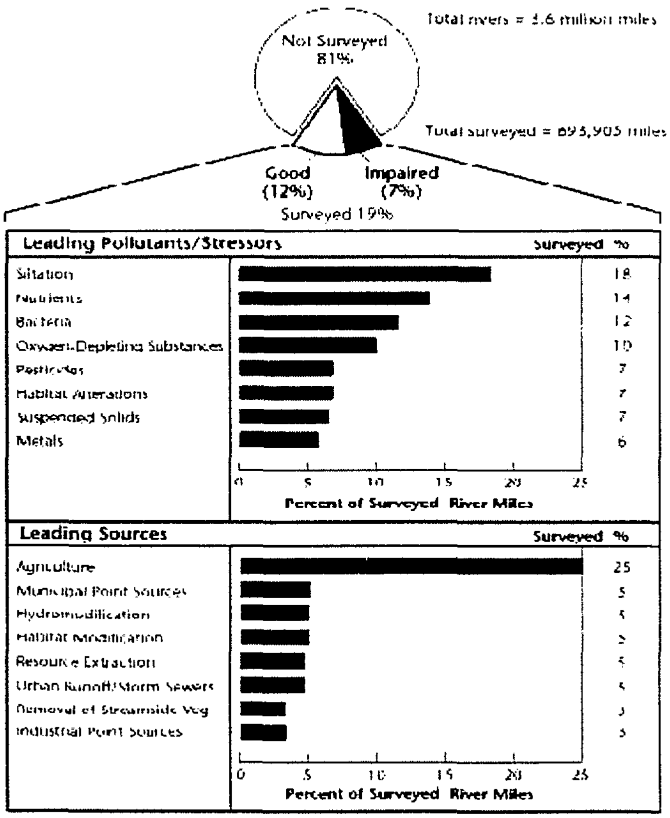
2.0 BACKGROUND

After reading section 2, you should understand the environmental impacts of storm water and the history of the storm water program, including existing regulations to control storm water (Phase I).

2.1 What are the Environmental Impacts from Storm Water Discharges?

Storm water runoff from lands modified by human activities can harm surface water and, in turn, cause or contribute to an exceedance of water quality standards by changing natural hydrologic patterns, accelerating natural stream flows, destroying aquatic habitat, and elevating pollutant concentrations and loadings. Such runoff may contain high levels of contaminants, such as sediment, suspended solids, nutrients (phosphorus and nitrogen), heavy metals, pathogens, toxins, oxygen-demanding substances (organic material), and floatables (U.S. EPA. 1992. *Environmental Impacts of Storm Water Discharges: A National Profile.* EPA 841-R-92-001. Office of Water. Washington, DC). After a rain, storm water runoff carries these pollutants into nearby streams, rivers, lakes, estuaries, wetlands, and oceans. Individually and combined, these pollutants impair water quality, threatening designated beneficial uses and causing habitat alteration and destruction.

SURVEYED River Miles: Pollutants and Sources



NOTE: Percentages do not add up to 100% because more than one pollutant or source may impair a river segment

The 1996 305(b) Report (U.S. EPA. 1998. The National Water Quality Inventory, 1996 Report to Congress. EPA 841-R-97-008. Office of Water. Washington, DC), provides a national assessment of water quality based on biennial reports submitted by the States as required under CWA section 305(b) of the CWA. In the CWA 305(b) reports, States, Tribes, and

R0010598

nonattainment of the designated uses assigned to their rivers, lakes, estuaries, wetlands, and ocean shores. The 1996 Inventory indicated that approximately 40 percent of the Nation's assessed rivers, lakes, and estuaries are impaired.

The 1996 Inventory also found urban runoff/discharges from storm sewers to be a major source of water quality impairment nationwide. Urban runoff/storm sewers were found to be a source of pollution in 13 percent of impaired rivers; 21 percent of impaired lakes, ponds, and reservoirs; and 45 percent of impaired estuaries (second only to industrial discharges). See Figures 2-1 and 2-2 for an illustration of the pollutants and sources of pollution for both rivers and estuaries. In addition to these waterbodies, urban runoff was found to be the leading cause of ocean impairment for those ocean miles surveyed.

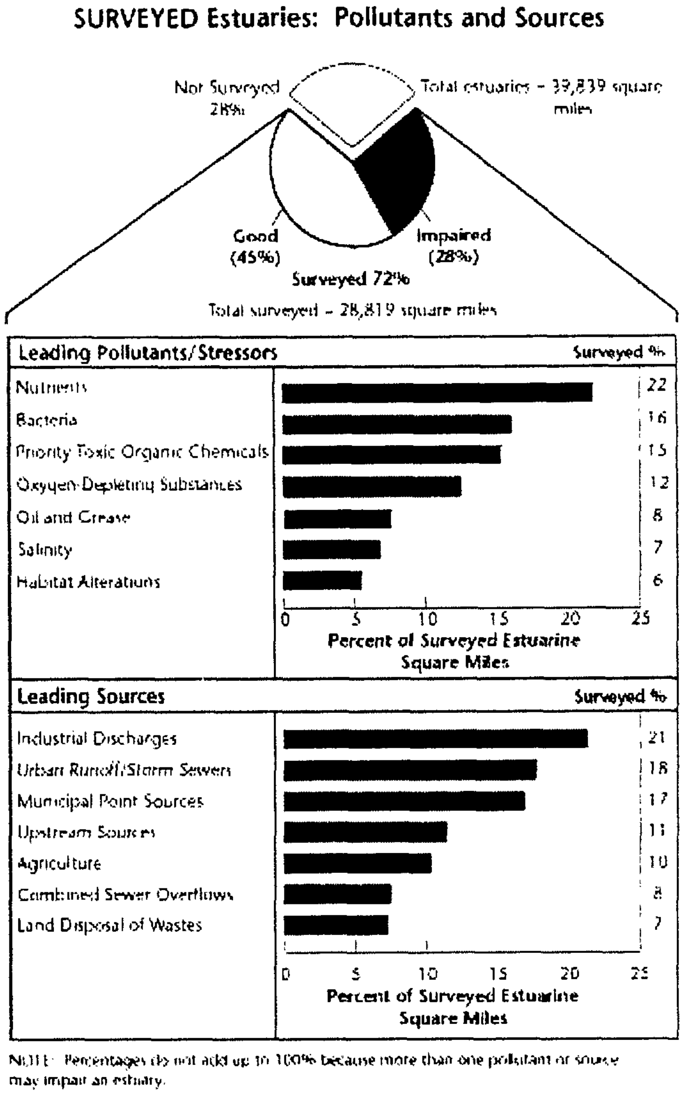


Figure 2-2. Pollutants and Sources in surveyed Estuaries (EPA, 1998)

Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving waterbodies (U.S. EPA, 1992). Urban development increases the amount of impervious surface in a watershed as farmland, forests, and meadowlands are converted into buildings with rooftops, driveways, sidewalks, roads, and parking lots with virtually no ability to absorb storm water. Storm water and snow-melt runoff wash over these impervious areas, picking up pollutants along the way while gaining speed and volume because of their inability to disperse and filter into the ground (see Figure 2-3 which illustrates the increased runoff resulting from increased impervious area). The resulting storm water flows are higher in volume, pollutants, and temperature than the flows in less impervious areas, which have more natural vegetation and soil to filter the runoff (U.S. EPA, 1997. *Urbanization and Streams: Studies of Hydrologic Impacts*.

R0010599

EPA 841-R-97-009. Office of Water. Washington, DC).

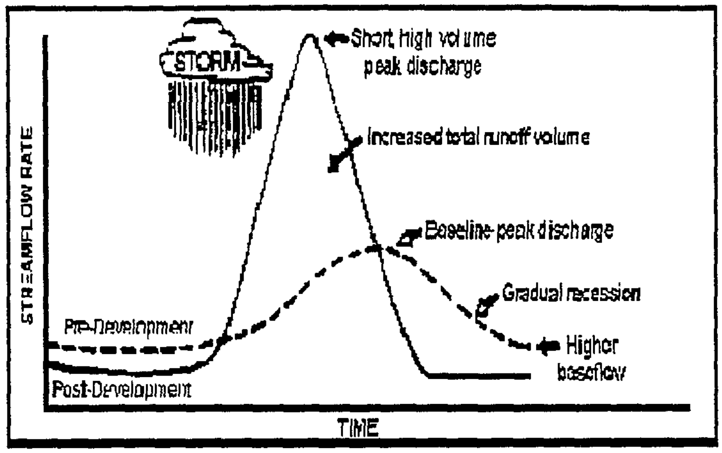

Figure 1. Impacts of urbanization on stream flow (Schueler, 1987).

In addition to the pollutants picked up by storm water runoff before it enters a storm drain, studies have shown that discharges from a storm drain system often include wastes and wastewater from non-storm water sources, referred to as illicit discharges. These discharges are 'illicit' because municipal storm sewer systems are not designed to accept, process, or discharge such wastes. Sources of illicit discharges can include sanitary wastewater illegally connected to the storm drain system; effluent from septic tanks; car wash, laundry, and other industrial wastewaters; improper disposal of auto and household toxics, such as used motor oil and pesticides; and spills from roadways.

Illicit discharges enter the system through either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the MS4 from cracked sanitary systems, spills collected by drain outlets, and paint or used oil dumped directly into a drain). The result is untreated discharges that contribute high levels of pollutants, including heavy metals, toxics, oil and grease, solvents, nutrients, viruses and bacteria into receiving waterbodies.

2.2 Summary of EPA's Storm Water Program

In 1972, Congress amended the Federal Water Pollution Control Act (commonly referred to as the Clean Water Act (CWA)) to prohibit the discharge of any pollutant to waters of the United States from a point source unless the discharge is authorized by an NPDES permit. The NPDES program is designed to track point sources and require the implementation of the controls necessary to minimize the discharge of pollutants. Initial efforts to improve water quality under the NPDES program primarily focused on reducing pollutants in industrial process wastewater and municipal sewage. These discharge sources were easily identified as responsible for poor water quality.

As pollution control measures for industrial process wastewater and municipal sewage were implemented and refined, it became increasingly evident that more diffuse sources of water pollution were also significant causes of water quality impairment. Specifically, storm water runoff was found to be a major cause of water quality impairment.

In 1987, Congress amended the CWA to require implementation, in two phases, of a comprehensive national program for addressing storm water discharges. The first phase of the program, commonly referred to as "Phase I," was promulgated on November 16, 1990 (55 FR 47990). Phase I requires NPDES permits for storm water discharge from a large number of priority sources including medium and large municipal separate storm sewer systems ("MS4s") generally serving populations of 100,000 or more and several categories of industrial activity, including construction activity that disturbs five or more acres of land.

The Phase I permits for municipal separate storm sewer systems mostly covere larger cities, and require them to develop a storm water management program, track and oversee industrial facilities regulated under the NPDES storm water program, conduct some monitoring, and submit periodic reports.

The operators of construction activities disturbing greater than 5 acres have been required to obtain NPDES permit coverage since 1992. General permits for large construction activity require construction operators to develop and implement a storm water pollution prevention plan to control erosion, sediment and other wastes on the site.

The Phase I industrial storm water program also regulates the following industrial sectors:

- facilities subject to EPA storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards
- heavy manufacturing facilities
- mining/oil and gas
- hazardous waste faciliites
- landfills
- recycling facilities
- steam electric power
- transportation facilities
- sewage treatment plants
- construction activity (described above), and
- light manufacturing facilities.

The second phase of the storm water program, which this guide addresses, requires permits for storm water discharges from certain small municipal separate storm sewer systems and construction activity generally disturbing between 1 and 5 acres. See Figure 2-4 for a summary of the federal storm water permit requirements under Phases I and II.

Figure 2-4. Summary of Federal Permit Requirements Under the NPDES Storm Water Program

	Municipal Separate Storm Sewer Systems (MS4s)	Construction Activity	Industrial Activity
Requirements in Effect Now (Phase I)	**Medium and Large MS4s** (§ 122.26(d)) • Storm Water Management Program: - Public education and outreach - Public participation efforts - Illicit discharge detection and elimination program - Construction and post-construction runoff control program for all construction activity (no size threshold) - BMPs to reduce pollutants from industrial, commercial, and residential areas • Track/oversee industrial facilities regulated under the NPDES storm water program • Conduct analytical and visual monitoring of MS4 discharges • Submit periodic program assessment reports	**Category (x) Construction Activity (5+ Acres)*** <u>CGP</u>: • Storm Water Pollution Prevention Plan (SWPPP) - Site description - Description of BMPs for erosion and sediment, post-construction storm water management, and other controls - Self-evaluation and reporting **Category (x) is one of the categories of "storm water discharges associated with industrial activity." Temporarily excluded from permitting: Category (x) construction activity operated by a municipality of <100,000 (ISTEA moratorium).*	**Ten Categories of Industrial Activity (Categories (i)-(ix),(xi))*** <u>MSGP</u>: • SWPPP - Site evaluation -Description of appropriate storm water management BMPs - Self-evaluation, monitoring, and reporting • If discharging into a medium or large MS4, notify the MS4 operator **Temporarily excluded from permitting: Industrial activity operated by a municipality of <100,000, except for power plants, airports, and uncontrolled sanitary landfills (ISTEA moratorium).*
Requirements that Will Be in Effect by 2003 (Phase II)	**Regulated Small MS4s** (§ 122.34 outlined here, but may choose permit coverage under § 122.26(d) instead) • Storm Water Management Program: - Public education and outreach - Public participation efforts - Illicit discharge detection and elimination program - Construction runoff control program for construction activity disturbing 1 acre or greater - Post-construction runoff control program for construction activity disturbing 1 acre or greater - Good housekeeping/pollution prevention for municipal operations • Conduct assessment of identified BMPs and measurable goals for each minimum control measure • Submit annual program assessment reports	**Small Construction Activity (≤1 and <5 Acres)** • Expected to be similar to Category (x) Construction Activity requirements above --- **Category (x) Construction Activity Operated by a Municipality of < 100,000** • Same requirements as for Category (x) Construction Activity above	**Industrial Activity Operated by a Municipality of <100,000*** • Same requirements as for Ten Categories of Industrial Activity above **Does not include: Power plants, airports, and uncontrolled sanitary landfills*

R0010602

3.0 REGULATION REQUIREMENTS

After reading section 3.0, you should understand the basic components and requirements of the Storm Water Phase II Rule and the rule's compliance schedule/timeline. This information is meant to serve as a basis for understanding the details of the Rule as discussed in further sections of this guidance.

3.1 What Does The Storm Water Phase II Rule Require?

This regulation can be divided into three main components, each with distinct requirements, affecting three types of entities. These components and the requirements for each are summarized below.

Regulated Small MS4s (see section 4.0)

A certain subset of operators of small MS4s (primarily those located in urbanized areas) are required to implement programs and practices to control polluted storm water runoff from the jurisdiction serviced by the MS4. The operator must design its storm water management program to satisfy applicable CWA water quality requirements and technology standards. The program must include the development and implementation of best management practices (BMPs) and measurable goals for the following six minimum measures, and include evaluation and reporting efforts:

- Public education and outreach,
- Public participation/involvement,
- Illicit discharge detection and elimination,
- Construction site runoff control,
- Post-construction runoff control, and
- Pollution prevention/good housekeeping for municipal operations.

Two waivers from coverage are available for small MS4s brought into the program by the Phase II regulation.

Small Construction Activity (see section 5.0)

All construction operators disturbing more than 1 acre and less than 5 acres are required to apply for an NPDES storm water permit for small construction activity. EPA already regulates construction activity disturbing more than 5 acres. A construction operator is usually the developer or landowner, but can also be the contractor or another party responsible for the operational control of erosion and sediment control practices on site.

Unlike the requirements for regulated small MS4s, the requirements for small construction activity (primarily activity disturbing between 1 and 5 acres of land) are not detailed in the Phase II regulation. Rather, the requirements are left to the discretion of the NPDES permitting authority when it develops the small construction activity permit. EPA expects the permit for small construction activity to be similar to the existing storm water general permits for large construction activity regulated under the Phase I program. EPA's existing Construction General Permit includes requirements to:

- Submit a Notice of Intent (NOI);
- Develop and implement a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP includes erosion and sediment controls, controls on waste at the site, self-inspection/monitoring, and reporting efforts; and
- Submit a Notice of Termination (NOT) when permit coverage is no longer necessary.

Two waivers from coverage are available for small construction activity.

Industrial Activity (see section 6.0)

Eleven categories of industrial activity are regulated under Phase I of the NPDES Storm Water Program. Under the Phase II Rule, no new categories of industrial activity are designated into the storm water program. The Rule does, however, include a revised no exposure exclusion that is available to all regulated categories of industrial activity (except category (x) - large construction activity) if the facility operator can certify that storm water runoff is not exposed to industrial activities.

Also, this regulation further extends the deadline to obtain permit coverage for those industrial activities operated by municipalities with populations of less than 100,000 that were temporarily exempted from permitting under the Intermodal Surface Transportation Enforcement Act (ISTEA) of 1991.

3.2 What Is the Phase II Rule's Compliance Schedule/Timeline?

The Phase II Final Rule was published in the *Federal Register* on December 8, 1999 (64 *FR* 68722). The following table lists milestones for EPA, the NPDES permitting authorities, and the regulated community under this program.

Storm Water Phase II Program Compliance Timeline

ACTIVITY	DEADLINE
Conditional No Exposure Exclusion option available in States where EPA is the NPDES permitting authority	February 7, 2000
Submission of No Exposure Certification	Every 5 years
EPA issues a menu of BMPs for small MS4 programs	October 2000
EPA issues a model general permit for small MS4s	October 2000
EPA issues guidance on measurable goals for small MS4 programs	October 2001
NPDES permitting authority determines designation of small MS4s located outside of an urbanized area that serve a jurisdiction with a population of 10,000 and population density of 1,000	By December 9, 2002; or by December 8, 2004 if apply designation criteria on a watershed basis under a comprehensive watershed plan
NPDES permitting authority determines waivers for regulated small MS4s in urbanized areas	By December 9, 2002
NPDES permitting authority issues general permits for regulated small MS4s and small construction activity	By December 9, 2002
Operators of regulated small MS4s and small construction activity designated by the rule must obtain permit coverage	By March 10, 2003
Operators of regulated small MS4s and small construction activity designated by NPDES permitting authority must obtain permit coverage	Within 180 days of notice
Temporarily exempted municipal operators of industrial activity must obtain permit coverage (ISTEA moratorium)	By March 10, 2003
The NPDES permitting authority may phase in coverage for small MS4s serving jurisdictions with a populations less than 10,000 on a schedule consistent with a State watershed permitting approach	Completion of phase-in by March 8, 2007
The regulated small MS4s must fully implement their storm water management programs	By the end of the first permit term – typically a 5-year period
Re-evaluation of the Phase II small MS4 regulations by EPA	By December 2012
NPDES permitting authority determination on a petition for designation of a non-regulated storm water discharger	Within 180 days of receipt

4.0 REGULATED SMALL MS4S

After reading section 4.0, you should understand what an MS4 is, which operators of MS4s are subject to the Phase II small MS4 regulations (including who may be waived from coverage), the small MS4 permit options, and the permit requirements for a small MS4 storm water management program. The discussion of these elements concludes with a step-by-step review of the process for compliance with the small MS4 program and possible funding options. Special concerns regarding Federal and State-operated small MS4s are also addressed.

4.1 MS4 DEFINITIONS

EPA's National Pollutant Discharge Elimination System (NPDES) storm water permitting program labels municipal separate storm sewer systems (MS4s) as either "small," " medium," or "large" for the purposes of regulation. The definitions of each are included herein. The Phase I storm water program covers medium and large MS4s. The Phase II storm water regulation covers a certain subset of small MS4s, known as "regulated small" MS4s. Regulated small MS4 coverage under the rule is discussed in section 4.2.

4.1.1 What is an "MS4"?

What constitutes a municipal separate storm sewer system (MS4) is often misinterpreted and misunderstood. The term MS4 does not solely refer to municipally-owned storm sewer systems, but rather is a term of art with a much broader application that can include, in addition to local jurisdictions, State departments of transportation, universities, local sewer districts, hospitals, military bases, and prisons. An MS4 also is not always just a system of underground pipes – it can include roads with drainage systems, gutters, and ditches. The regulatory definition of an MS4 is provided in the text box below.

According to 40 CFR 122.26(b)(8), "***municipal separate storm sewer*** means a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains):

(i) Owned or operated by a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State law)...including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the Clean Water Act that discharges into waters of the United States.

(ii) Designed or used for collecting or conveying storm water;

(iii) Which is not a combined sewer; and

(iv) Which is not part of a Publicly Owned Treatment Works (POTW) as defined at 40 CFR 122.2."

4.1.2 What is a "large" MS4?

A ***large* MS4** is any MS4 located in an incorporated place or county with a population of 250,000 or greater as of the 1990 Census. The Phase II Final Rule revised the original large MS4 definition (found in the 1990 Phase I regulations) by freezing it as of the 1990 Census so that no new large MS4s could be automatically designated based on the 2000 Census, or any subsequent Census. Listings of incorporated places and counties with populations of 250,000 or greater as of the 1990 Census are included in the revised Appendices F and H to Part 122, found in the Phase II Final Rule.

4.1.3 What is a "medium" MS4?

A ***medium* MS4** is any MS4 located in an incorporated place or county with a population between 100,000 - 249,999 as of the 1990 Census. The Phase II Final Rule revised the original medium MS4 definition (found in the 1990 Phase I regulations) by freezing it as of the 1990 Census so that no new medium MS4s could be automatically designated based on the 2000 Census, or any subsequent Census. Listings of incorporated places and counties with populations between 100,000 - 249,999 as of the 1990 Census are included in the revised Appendices G and I to Part 122, found in the Phase II Final Rule.

> **Important Note:** Many MS4s in areas below 100,000 in population have been individually brought into the Phase I program by NPDES permitting authorities. Such already regulated MS4s are considered Phase I MS4s and are not required to develop a Phase II program.

4.1.4 What is a "small" MS4?

A ***small* MS4** is any MS4 that is not already regulated under the Phase I storm water program. Unlike the definitions of medium and large MS4s, the definition of a small MS4: 1) is not dependant on a population threshold, and 2) includes Federally-owned systems, such as military bases and veterans hospitals.

4.2 COVERAGE: Who Is Subject to the Phase II Final Rule?

4.2.1 Are All Small MS4s Covered by the Phase II Final Rule?

No. The universe of small MS4s is quite large since it includes every MS4 except for the approximately 900 medium and large MS4s already regulated under the Phase I storm water program. Only a select sub-set of small MS4s, referred to as ***regulated* small MS4s**, are covered by the Phase II Final Rule, either through automatic nationwide designation by the rule or designation on a case-by-case basis by the NPDES permitting authority.

4.2.2 How Is A Small MS4 Designated as a Regulated Small MS4 under Phase II?

A *small* MS4 can be designated as a *regulated small* MS4, and thereby be subject to the Phase II rule, in any one of the three ways explained in the following subsections.

4.2.2.1 Automatic Nationwide Designation by the Rule

The Phase II Final Rule requires "automatic" nationwide coverage of all operators of small MS4s that are located within the boundaries of a Bureau of the Census-delineated "urbanized area" (UA) based on the latest decennial Census. This doesn't just include municipal operators of small MS4s, but also universities, highway departments, and any other operator of a storm sewer system that is located fully or partially within the UA. **Refer to section 4.3 for more information on how to determine if a particular small MS4 is located within a UA.**

> **Important Note:** Only the portion of the small MS4 that is located within the UA boundaries is regulated under Phase II. For example, if a county operates a small MS4 that serves the whole county but only half of the MS4 falls within the UA boundary, then the county must obtain permit coverage (and implement a storm water management program) only for the half of the MS4 in the UA.

Once a small MS4 is designated into the program based on the UA boundaries, it cannot be waived from the program if in a subsequent UA calculation the small MS4 is no longer within the UA boundaries. An automatically designated small MS4 remains regulated unless, or until, it meets the criteria for a waiver. See section 4.4 for more information on waivers from coverage for regulated small MS4s in urbanized areas.

An operator of a small MS4 located outside of a UA boundary may be designated as a regulated small MS4 if the NPDES permitting authority determines that the small MS4's discharges cause, or have the potential to cause, an adverse impact on water quality. See sections 4.2.2.2 and 4.2.2.3 below for more information on designations by the permitting authority.

Preamble of the Phase II Final Rule: Appendix 6

A listing of governmental entities that are located either fully or partially within a UA according to the 1990 Census can be found in Appendix 6 to the Preamble of the Phase II Final Rule. The list is a general geographic reference intended to help operators of small MS4s determine whether or not they are located in a UA and, consequently, required to comply with the regulation; it is not a list of all Phase II regulated MS4s and it may contain errors. For example, the list does not include small MS4 operators such as colleges and universities, Federal prison complexes, and State highway departments located within a UA.

4.2.2.2 Potential Designation by the NPDES Permitting Authority — Required Evaluation of 10,000/1,000 Areas

The Phase II Final Rule requires the NPDES permitting authority to develop a set of designation criteria and apply them, *at a minimum*, to all small MS4s located outside of a UA that serve a jurisdiction with a population of at least 10,000 and a population density of at least 1,000 people/square mile. The permitting authority is required to *evaluate* such small MS4s but is not required to *designate* them into the program unless they meet the designation criteria.

Recommended Designation Criteria

EPA recommends in the Phase II regulations that the NPDES permitting authority use a balanced consideration of the following designation criteria on a watershed or other local basis:

- ✔ Discharge to sensitive waters;
- ✔ High population density;
- ✔ High growth or growth potential;
- ✔ Contiguity to a UA;
- ✔ Significant contributor of pollutants to waters of the United States; and
- ✔ Ineffective protection of water quality concerns by other programs.

Preamble of the Phase II Final Rule: Appendix 7

A listing of governmental entities located outside of a UA that have a population of at least 10,000 and a population density of at least 1,000 people per square mile, can be found in Appendix 7 to the Preamble of the Phase II Final Rule. Similar to Appendix 6, the list is a geographic reference only – it is not a list of regulated entities and it may contain errors. Operators of small MS4s located within a listed area could be examined by their NPDES permitting authority for potential designation into the Phase II program. Furthermore, the NPDES permitting authority reserves the right to designate for regulation any small MS4 that is contributing pollutants to waters of the United States, whether or not its jurisdiction is found in Appendix 7.

Deadline for Designation

The NPDES permitting authority is required to designate small MS4s meeting the designation criteria by December 9, 2002, or by December 8, 2004 if a comprehensive State watershed plan is in place and the criteria are being applied on a watershed basis.

4.2.2.3 Potential Designation by the NPDES Permitting Authority — Physically Interconnected

The Phase II Final Rule requires the NPDES permitting authority to designate any small MS4 located outside of a UA that contributes substantially to the pollutant loadings of a *physically interconnected* MS4 that is permitted by the NPDES storm water program. This means the other MS4 could be a large, medium, or regulated small MS4.

Small MS4s located right outside the boundary of an urbanized area are the ones most likely to meet this criterion for designation and, therefore, should make an effort to become aware of whether they discharge pollutants directly into a regulated MS4. The sooner a small MS4 operator is prepared for potential designation and implementation of the Phase II program, the better.

> ***Physically interconnected*** means that one MS4 is connected to a second MS4 in such a way that it allows for *direct* discharges into the second system.

Deadline for Designation

The final rule does not set a deadline for designation of small MS4s meeting this criterion.

4.3 URBANIZED AREAS: What Are They and How Does a Small MS4 Operator Determine If It Is Located in One?

As discussed in section 4.2, the Phase II Final Rule covers all small municipal separate storm sewer systems (MS4s) located within an "urbanized area" (UA). Based on the 1990 Census, there are 405 UAs in the United States that cover 2 percent of total U.S. land area and contain approximately 63 percent of the Nation's population. These numbers include Puerto Rico — the only U.S. Territory with UAs.

UAs constitute the largest and most dense areas of settlement. UA calculations delineate boundaries around these dense areas of settlement and, in doing so, identify the areas of concentrated development. UA designations are used for several purposes in both the public and private sectors. For example, the Federal Government has used UAs to calculate allocations for transportation funding, and some planning agencies and development firms use UA boundaries to help ascertain current, and predict future, growth areas.

4.3.1. What Is the Definition of an Urbanized Area (UA)?

The Bureau of the Census determines UAs by applying a detailed set of published UA criteria (see 55 *FR* 42592, October 22, 1990) to the latest decennial census data. Although the full UA definition is complex, the Bureau of the Census' general definition of a UA, based on population and population density, is provided below.

> An ***urbanized area*** (UA) is a land area comprising one or more places – central place(s) – and the adjacent densely settled surrounding area – urban fringe – that together have a residential population of at least 50,000 and an overall population density of at least 1,000 people per square mile. It is a calculation used by the Bureau of the Census to determine the geographic boundaries of the most heavily developed and dense urban areas.

UA Facts:

- The basic unit for delineating the UA boundary is the census block. Census blocks are based on visible physical boundaries, such as the city block, when possible, or on invisible political boundaries, when not. An urbanized area can comprise places, counties, Federal Indian Reservations, and minor civil divisions (MCDs - towns and townships).

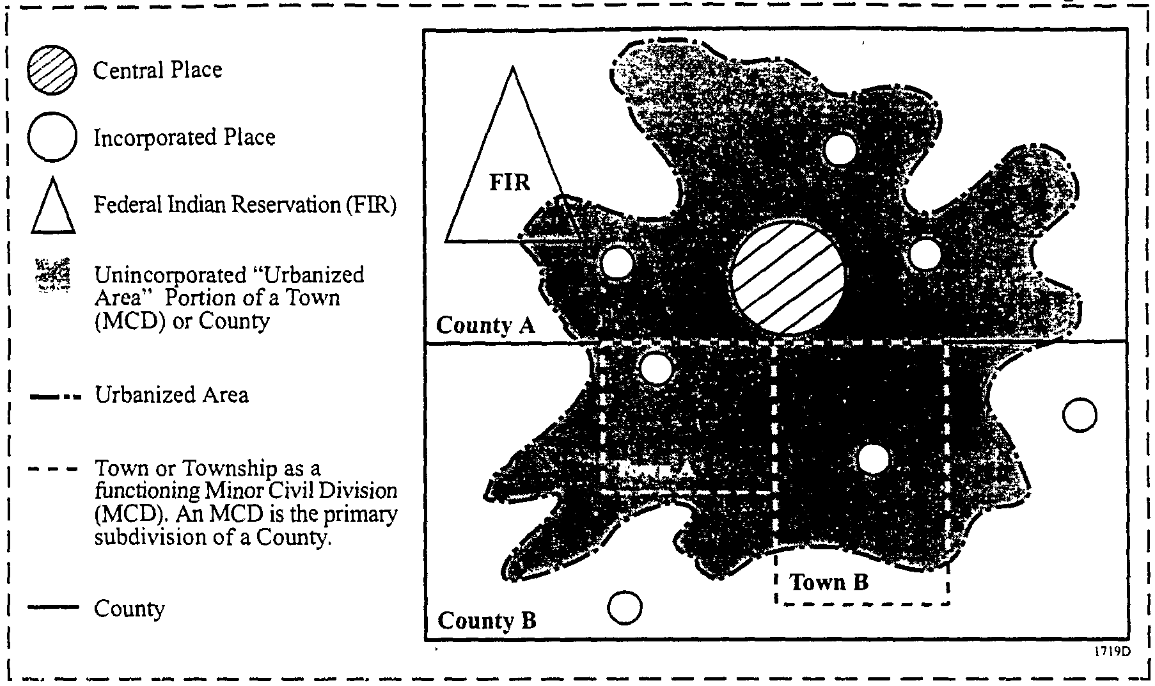
- A UA can include governmental entities of every population size: 200; 7,000; 15,000; 30,000, 200,000; or 3 million! Entities with small populations are commonly found in the urban fringe of the UA.

- Before the time of permit issuance (by December 9, 2002), new UA calculations based on the 2000 Census should be published. The regulated small MS4 universe then will be based on these new calculations.

4.3.2. What Does A UA Look Like?

The drawing below (see Figure 4-1) is a simplified UA illustration that demonstrates the concept of UAs in relation to the Phase II Final Rule. This "urbanized area" includes within its boundaries incorporated places, a portion of a Federal Indian reservation, an entire MCD, a portion of another MCD, and portions of two counties. Any and all operators of small MS4s located within the boundaries of the UA are covered under the Phase II Final Rule, regardless of political boundaries. Operators of small MS4s located outside of the UA are subject to potential designation into the Phase II MS4 program by the NPDES permitting authority, as explained in section 4.2.

Figure 4-1



4.3.3 How Can An Operator of a Regulated Small MS4 Determine If It Is Located Within a UA?

Operators of small MS4s can determine if they are located within a UA, and therefore covered under the Phase II storm water program, through the following two steps:

— STEP 1 —

Refer to a listing of incorporated places, MCDs, and counties that are located entirely or partially within a UA. Such a listing, based on the 1990 Census and including only those entities not regulated under Phase I, can be found in Appendix 6 to the Preamble of the Phase II Final Rule. If a small MS4 is located in a listed incorporated place, MCD, or county, then the operator of the small MS4 should follow step (2) below. It is important to note that Appendix 6 is general guidance only and may contain errors. For this reason, even if a particular small MS4 isn't located in a listed area, EPA recommends that the small MS4 operator follow Step 2.

— STEP 2 —

Some operators of small MS4s may find that they are located within an

R0010613

entity listed in Appendix 6 but not know if their systems are within the urbanized portion of the listed entity, or they are not on the list but want to confirm their status as recommended above. In such cases, they should contact one or more of the following institutions for more detailed information on the location of UA boundaries:

- ❑ **The State or NPDES Permitting Authority**

Storm Water Coordinators: The NPDES permitting authority may be the State or the U.S. EPA Region. The Storm Water Coordinators for each U.S. EPA Region are listed in Section 8. These regional contacts can assist with UA information and provide the names of State storm water contacts.

State Data Centers: Each State's Data Center receives listings of all entities that are located in UAs, as well as detailed maps and electronic files of UA boundaries. The Bureau of the Census web site includes a list of contact names and phone numbers for the Data Center in each State at www.census.gov/sdc/www.

State Planning/Economic/Transportation Agencies: These agencies typically use UAs to assess current development and forecast future growth trends and, therefore, should have detailed UA information readily available to help determine the UA boundaries in any given area.

- ❑ **County or Regional Planning Commissions/ Boards**

As with State agencies, these entities are likely to have detailed UA data and maps to help determine UA boundaries.

- ❑ **The Bureau of the Census**

Urbanized Areas Staff: 301 457-1099

Web Site: www.census.gov
The site provides information on purchasing UA maps and electronic files for use with computerized mapping systems. Obtain free UA cartographic boundary files (Arc/Info export format) for Geographical Information System (GIS) use at: www.census.gov:80/geo/www/cob/ua.html.

UA Maps: Detailed UA maps are available for purchase with a $25 minimum order ($5 per map sheet). Each map sheet measures 36 by 42 inches. For prices and a listing of UAs, visit www.census.gov/mp/www/geo/msgeo12.html. Order from the Department of Commerce, Bureau of the Census (MS 1921), P.O. Box 277943, Atlanta, GA 30384-7943 (Phone: 301 457-4100; Toll-free fax: 1-888-249-7295).

- ❑ **U.S. EPA**

EPA is currently modifying a web-based geographic program called *Enviromapper* for use in determining UA boundaries. This program will allow users to enter a location (by name, zip code, or street address) and see a map that will show if the location is within a UA boundary. EPA is committed to using Enviromapper to create a tool that, someday, will be the only tool necessary to determine the location of UA boundaries. Information about *Enviromapper* will be available at www.epa.gov/owm/phase2.

4.3.4 How Will the Year 2000 Census Affect the Determination of Status as a Regulated Small MS4?

The listing of incorporated places, MCDs, and counties located within UAs in the United States and Puerto Rico, found in Appendix 6, is based on the 1990 Census. New listings for UAs based on the 2000 Census are scheduled to be available by August of 2001. Once the official 2000 Census listings are published by the Bureau of the Census, operators of small MS4s located within the revised boundaries of former 1990 UAs, or in any newly defined 2000 UAs, become regulated small MS4s and must develop a storm water management program.

Any additional automatic designations of small MS4s based on subsequent census years is governed by the Bureau of the Census' definition of a UA in effect for that year and the UA boundaries determined as a result of the definition.

Once a small MS4 is designated into the Phase II storm water program based on the UA boundaries, it can not be waived from the program if in a subsequent UA calculation the small MS4 is no longer within the UA boundaries. An automatically designated small MS4 will remain regulated unless, or until, it meets the criteria for a waiver.

4.4 WAIVERS: Which Regulated Small MS4s May Obtain a Waiver From Coverage?

Two waiver options are available to operators of regulated small MS4s in urbanized areas if the NPDES permitting authority determines that their discharges do not cause, or have the potential to cause, water quality impairment.

> **Important Note:** The waivers are granted by the NPDES permitting authority, the operator of the regulated small MS4 can not determine for itself that it meets the waiver criteria. If the permitting authority is not proactive in assessing small MS4s for potential waivers, an operator may petition for a waiver assessment.

If a permitting authority decides to grant waivers, it is required to do so by December 9, 2002 to coincide with the expected date of the small MS4 permit issuance. The permitting authority is also required to periodically review any waivers granted to small MS4 operators to determine whether any information required for granting the waiver has changed. Minimally, such a review needs to be conducted once every five years. The waiver options are described in the following two subsections.

Deadline for Waivers

The NPDES permitting authorities are required to make their waiver determinations by March 9, 2002 to coincide with the expected issuance of their small MS4 general permit. If the permit authority chooses to phase in permit coverage based on a comprehensive watershed plan (see section 4.5.2.2), then regulated small MS4s may be waived on the same schedule. The phase-in of permit coverage and waivers is to be completed no later than March 8, 2007.

4.4.1 Option 1: Less than 1,000 Population in a UA

The first waiver option applies where:

(1) the jurisdiction served by the system is less than 1,000 people;

(2) the system is not contributing substantially to the pollutant loadings of a physically interconnected regulated MS4; and

(3) if the small MS4 discharges any pollutants identified as a cause of impairment of any water body to which it discharges, storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established "total maximum daily load" (TMDL) that addresses the pollutant(s) of concern.

> ***TMDLs*** are water quality assessments that determine the source or sources of pollutants of concern for a particular waterbody, consider the maximum amount of pollutants the waterbody can assimilate, and then allocate to each source a set level of pollutants that it is allowed to discharge (i.e., a "wasteload allocation"). Small MS4s that are not given a wasteload allocation would meet the third criterion above.

The third criterion of this waiver option need only be met if the small MS4 is discharging into a impaired water body and the discharge contains a pollutant or pollutants that are the cause of the impairment (i.e., the "pollutants of concern").

4.4.2 Option 2: Less than 10,000 Population in a UA

The second waiver option applies where:

(1) the jurisdiction served by the system is less than 10,000 people;

(2) an evaluation of all waters of the U.S. that receive a discharge from the system shows that storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established TMDL that addresses the pollutant(s) of concern or an equivalent analysis; and

(3) it is determined that future discharges from the small MS4 do not have the potential to result in exceedances of water quality standards.

> ***Pollutants of Concern*** include biochemical oxygen demand (BOD), sediment or a parameter that addresses sediment (such as total suspended solids, turbidity or siltation), pathogens, oil and grease, and any pollutant that has been identified as a cause of impairment in any water body to which the MS4 discharges.

This waiver option differs from the first option in that: 1) it applies to a larger jurisdiction size (up to 10,000 rather than 1,000), 2) it requires a determination that the discharges are not affecting the receiving water body, whether the water body is impaired or not (in the first option an assessment is only necessary if the water body is impaired and the MS4 is discharging a pollutant of concern), 3) the determination must be based on a TMDL <u>or</u> an equivalent analysis (the first option does not allow for an equivalent analysis), and 4) an assessment of the impacts of future discharges must be performed (no such assessment is necessary under the first option).

4.5 PERMITTING OPTIONS: What Permitting Choices are Available?

The Storm Water Phase II Final Rule requires operators of a particular subset of small MS4s in urbanized areas to obtain National Pollutant Discharge Elimination System (NPDES) permit coverage because their storm water discharges are considered "point sources" of pollution. All point source discharges, unlike nonpoint sources such as agricultural runoff, are required under the Clean Water Act (CWA) to be covered by federally enforceable NPDES permits. Those MS4s already permitted under the NPDES Phase I storm water program, even MS4s serving less than 100,000 people, are not required to be permitted under the Phase II storm water program.

NPDES storm water permits are issued by an NPDES permitting authority, which may be an NPDES-authorized State or a U.S. EPA Region in non-authorized States. Once a permit application is submitted by the operator of a regulated small MS4 and a permit is obtained, the conditions of the permit must be satisfied (i.e., development and implementation of a storm water management program) and periodic reports must be submitted on the status and effectiveness of the program. This section addresses the flexible permit options the Phase II regulations allow for the regulated small MS4 operator, as well as for the permitting authority. The permit requirements are discussed in section 4.6.

4.5.1 For Regulated Small MS4 Operators

4.5.1.1 The Types of Permit Coverage Available

Unlike the Phase I program that requires individual permits for medium and large MS4s, the Phase II approach allows operators of regulated small MS4s to choose from as many as three permitting options as listed below. Each NPDES permitting authority reserves the authority to determine, however, which options are available to the regulated small MS4s in their jurisdiction.

1) General Permits

- General permits are strongly encouraged by EPA. The Phase II program has been designed specifically to accommodate a general permit approach.

- General permits prescribe one set of requirements for all applicable permittees. General permits are drafted by the NPDES permitting authority, then published for public comment before being finalized and issued.

- A Notice of Intent (NOI) serves as the application for the general permit. The regulated small MS4 operator complies with the permit application requirements by submitting an NOI to the NPDES permitting authority that describes the storm water management plan, including best management practices (BMPs) and measurable goals. The operator has the flexibility to develop an individualized storm water program that addresses the particular characteristics and needs of its system, provided the requirements of the general permit are satisfied.

- For general permit coverage, the regulated small MS4 operator must follow the Phase II permit application requirements (see section 4.6.2).

2) Individual Permits

- Individual permits are required for Phase I medium and large MS4s, but not recommended by EPA for Phase II program implementation.

- Individual permits prescribe a particular set of requirements for a particular permittee or a group of co-permittees. Individual permits require the submission of a more comprehensive permit application than an NOI that is submitted under a general permit. Once the permit application is received, an individual permit is drafted by the NPDES permitting authority, then published for public comment before being finalized and issued.

- The Phase II rule allows a regulated small MS4 to submit an individual application for coverage under either the:

- Phase II MS4 regulation (see § 122.34 of the Phase II rule), or
- Phase I MS4 regulation (see 40 CFR §122.26(d)).

3) Modification of an Existing Phase I Individual Permit – A Co-Permittee Option with Medium and Large MS4s

The operator of a regulated small MS4 could participate as a limited co-permittee in a neighboring Phase I MS4's storm water management program by seeking a modification of the existing Phase I individual permit. As a limited co-permittee the small MS4 operator would be responsible for compliance with the permit's conditions applicable to its jurisdiction.

Note: A list of Phase I medium and large MS4s can be obtained from the EPA Office of Wastewater Management (OWM) or downloaded from the OWM web site.

The permittee must comply with the applicable terms of the modified Phase I individual permit rather than the minimum control measures in the Phase II Final Rule.

4.5.1.2 Co-permittee with Another Operator of a Regulated Small MS4

Section 4.5.1.1 explained the permitting option of a modification of an existing Phase I individual permit in order to be a co-permittee with a medium or large MS4. Regulated small MS4 operators may also choose to share responsibilities for meeting the Phase II program requirements with another regulated small MS4 operator under a general or individual permit. Those operators choosing to do so may submit jointly an NOI or individual permit application that identifies who will implement which minimum measures within the area served by the MS4s.

4.5.1.3 Relying on Another Entity to Satisfy One or More of the Minimum Control Measures

Under either a general or individual permit, the Phase II small MS4 permittee has the option of relying on other entities that are already performing one or more of the minimum control measures to implement the measure(s) on the permittee's behalf. This is only allowable where the existing control measure, or component thereof, is at least as stringent as the Phase II rule requirements (under § 122.34(b)) and the other entity has agreed to the arrangement.

For example, a county may already have an illicit discharge detection and elimination program in place and may allow an operator of a regulated small MS4 within the county's jurisdiction to rely on the county program instead of formulating and implementing a new program. In such a case, the permittee would not need to implement the particular measure, but would still be ultimately responsible for its effective implementation. For this reason, EPA recommends that the permittee enter into a legally binding agreement with the other entity. If the permittee chooses to rely on another entity, they must note this in their permit application and subsequent reports.

Note: Also, the other entity does not necessarily need to be a governmental entity. For example, a permittee could rely on a non-profit organization that is performing public education efforts on environmental issues to satisfy the public education and outreach minimum measure.

A Phase II permittee also has the option to rely on another entity to satisfy all of the permittee's small MS4 permit obligations – but only if the other entity is a governmental entity permitted under the NPDES storm water program. Should this option be chosen, the permittee must note this in its NOI, but does not need to file the otherwise required periodic reports on the status of the program. Again, it is important to note that the permittee would remain ultimately liable under the small MS4 permit. This option is particularly beneficial for operators that serve a low population, have limited resources or legal authority, or are surrounded by an NPDES regulated municipality. For example, let's assume a college campus or a veteran's hospital are operators of small MS4s and they are located in the middle of a Phase II regulated city. Negotiating with the city to implement the storm water management program for them in their jurisdictions could be a cost-effective and less burdensome option than for each to implement their own programs.

4.5.2 For the NPDES Permitting Authority

4.5.2.1 Alternative Options for Writing Permit Requirements

Two permitting options tailored to minimize duplication of effort by the regulated small MS4 permittee can be incorporated into the general or individual permit by the NPDES permitting authority:

1) Recognizing Another Governmental Entity's Program

The permitting authority can recognize in a small MS4 permit that another governmental entity is responsible under an NPDES permit for implementing any or all of the minimum control measures. In such a case, responsibility for implementation of the measure(s) would rest with the other governmental entity, thereby relieving the small MS4 permittee of its responsibility to implement that particular measure(s). See Table 4-1 for examples of both this option and the following option.

R0010620

STORM WATER PHASE II RULE SMALL MS4 FLEXIBLE PERMITTING OPTIONS

	Referencing a QUALIFYING LOCAL PROGRAM (QLP)	RECOGNIZING an NPDES-Regulated Entity	RELYING on Another Entity	CO-PERMITTEE with an NPDES-Regulated Entity
NPDES PERMITTING AUTHORITY Responsibilities	• PA assesses local, State, and Tribal NPDES and non-NPDES programs to determine if their requirements are equivalent to one or more Phase II minimum measures for regulated small MS4s • PA chooses whether to reference a QLP in small MS4 permit. Requires permittee to follow requirements of QLP rather than new permit requirements. • PA does not need to notify the administrator of the QLP or obtain permission since referencing the QLP has no bearing/no affect on the administrator.	• PA assesses entities that are, or will be, performing the equivalent of 1 or more of the small MS4 minimum measures under an NPDES permit. • PA chooses whether to recognize such an entity in a small MS4 permit.	N/A	N/A
SMALL MS4 OPERATOR Responsibilities	• The operator should already be complying with any QLP referenced in the permit. • Compliance with the QLP is considered compliance with the NPDES permit; therefore operator held liable if doesn't comply with the QLP.	• Operator has no responsibility to perform the measure(s) that is being done by the recognized entity. • Not held liable if the other entity fails to perform the measure effectively; however, PA may then require the operator to implement the measure itself.	• Operator chooses, under its own permit, whether to rely on another entity to implement 1 or more minimum measure on its behalf can be a non-NPDES regulated entity. • Operator notes in NOI or indiv. permit application that it is relying on another entity to implement a measure. • Remain liable if other entity fails to perform the measure effectively.	• Operator chooses whether to be a co-permittee with another regulated MS4 and submits a single NOI or individual permit application • The operators determine who will do what and include this information in the permit application
EXAMPLES	The QLP in the small MS4 permit could be a State program that requires MS4 operators to detect & eliminate illicit discharges into their systems.	A county doing educational outreach for the whole county under a Phase I NPDES permit could be recognized, thereby relieving all small MS4s in the county from having to have their own educational outreach programs.	1. An environmental group is doing educational outreach on the impacts of storm water runoff. 2. A county is already implementing a construction runoff control program under a Phase I NPDES permit.	

2) Referencing a Qualifying Local Program

The NPDES permitting authority can include conditions in a small MS4 permit that direct a permittee to follow the requirements of an existing qualifying local program rather than the requirements of particular minimum control measure(s). A qualifying local program is defined as a local, State or Tribal municipal storm water program that imposes requirements that are equivalent to those of the Phase II MS4 minimum measures (as found in § 122.34(b) of the rule). Unlike in Option 1 above, under this option the permittee remains responsible for the implementation of the minimum measure through its compliance with the qualifying local program.

4.5.2.2. Alternative Option for Permit Coverage: Phase-in Coverage for Regulated Small MS4s with Populations under 10,000

Permitting authorities may phase-in permit coverage for regulated small MS4s serving jurisdictions with a population under 10,000 on a schedule consistent with a State watershed permitting approach. Under this alternative option, the permitting authority must develop and implement a schedule to phase-in permit coverage for approximately 20 percent annually of all regulated small MS4s that qualify, completing the phase-in schedule in no more than five years. In such a case, the regulated small MS4 operators would be notified by the permitting authority concerning the operator's deadlines for permit coverage.

Deadlines for Phase-In
- Permitting authorities are required to have their phase-in schedule approved by the USEPA Regional Administrator no later than December 10, 2001.
- Under the phase-in option, all regulated small MS4s are required to have coverage under an NPDES permit no later than March 8, 2007.

4.6 REQUIREMENTS: What Requirements Are Regulated Small MS4s Subject To?

A regulated small MS4 operator is required to submit a permit application and obtain coverage under a NPDES storm water permit. Under the permit, the operator will be required to develop and implement a storm water management program that includes six minimum control measures, evaluation/assessment and reporting efforts, and recordkeeping, as described herein. This section begins by highlighting the standards an operator must meet to ensure compliance with the Phase II regulations.

4.6.1 Applicable Standards

A Phase II small MS4 operator must design a storm water management program so that it:

- ❑ Reduces the discharge of pollutants to the "maximum extent practicable"

(MEP);

- ❑ Protects water quality; and
- ❑ Satisfies the appropriate water quality requirements of the Clean Water Act.

The standard of MEP is the same standard applied to Phase I medium and large MS4 programs. There is no regulatory definition of MEP in order to allow the permitting authority and regulated MS4s maximum flexibility in their interpretation of it as appropriate.

Compliance with the technical standard of MEP requires the successful implementation of approved BMPs. The Phase II Final Rule considers narrative effluent limitations that require the implementation of BMPs and the achievement of measurable goals as the most appropriate form of effluent limitations to achieve the protection of water quality, rather than requiring that storm water discharges meet numeric effluent limitations.

EPA intends to issue Phase II NPDES permits consistent with its August 1, 1996, Interim Permitting Approach policy, which calls for BMPs in first-round storm water permits and expanded or better tailored BMPs in subsequent permits, where necessary, to provide for the attainment of water quality standards. In cases where information exists to develop more specific conditions or limitations to meet water quality standards, these conditions or limitations should be incorporated into the storm water permit. Monitoring is not required under the Phase II Rule, but the NPDES permitting authority has the discretion to require monitoring if deemed necessary.

4.6.2 Permit Application Requirements

The permit application requirements differ depending on the type of permit chosen. The following subsections describe the applicable requirements for each type of permit option allowable under the Phase II regulation.

Deadline for Submission of Permit Application

The deadline for submission of each type of permit application is the same – it must be done no later than March 10, 2003 unless the NPDES permitting authority chooses to phase-in permit coverage on a watershed basis and establishes other deadlines (see section 4.5.2.2).

4.6.2.1 General Permit Under Phase II Regulations

Operators of regulated small MS4s are required to submit in their NOI the following information:

❑ Best management practices (BMPs) for each of the six minimum control measures:

❶ Public education and outreach on storm water impacts
❷ Public participation/involvement
❸ Illicit discharge detection and elimination
❹ Construction site storm water runoff control
Post-construction storm water management in new development/ redevelopment
❻ Pollution prevention/good housekeeping for municipal operations

❑ Measurable goals for each minimum control measure (i.e, narrative or numeric standards used to gauge program effectiveness);

❑ Estimated months and years in which actions to implement each measure will be undertaken, including interim milestones and frequency; and

❑ The person or persons responsible for implementing or coordinating the storm water program.

The operator of a regulated small MS4 has the flexibility to determine the BMPs and measurable goals, for each minimum control measure, that are most appropriate for the system. The chosen BMPs and measurable goals, submitted in the permit application, become the required storm water management program; however, the NPDES permitting authority can require changes in the mix of chosen BMPs and measurable goals if all or some of them are found to be inconsistent with the provisions of the Phase II Final Rule. Likewise, the permittee can change its mix of BMPs if it determines that the program is not as effective as it could be. Section 4.6.2 fully describes the minimum control measures, including sample BMPs and measurable goals for each, while section 4.6.3 describes the permit requirements concerning evaluation/assessment and recordkeeping activities.

4.6.2.2 Individual Permit Under the Phase II Regulation

For individual permit coverage under Phase II, the regulated small MS4 operator must follow the requirements of 40 CFR § 122.21(f) and the Phase II permit application requirements as described in section 4.6.2.1 above. The operator must also provide an estimate of the square mileage served by the system and any additional information requested by the NPDES permitting authority. A storm sewer map that satisfies the requirements of § 122.34(b)(3)(i) of the Phase II rule will satisfy the map requirements of § 122.21(f)(7).

4.6.2.3 Individual Permit Under the Phase I Regulation

For individual permit coverage under Phase I, the regulated small MS4 operator must follow the permit application requirements detailed at 40 CFR § 122.26(d). The operator must submit both Part 1 and Part 2 of the application requirements in §§ 122.26(d)(1) and (2) by March 10, 2003. The operator would not need to submit the information required by §§ 122.26(d)(1)(ii) and (d)(2) regarding legal authority unless it wanted the permitting authority to take that information into account when developing the individual permit.

4.6.2.4 Modification of an Existing Phase I Individual Permit

Under this permit option, the operator of a regulated small MS4 must follow Phase I permit application requirements in § 122.26(d), with some exclusions, rather than Phase II permit application requirements. The operator would not need to follow the application requirements of §§ 122.26(d)(1)(iii) and (iv) and (d)(2)(iii) – *discharge characterization.* The operator may satisfy the requirements in §§ 122.26(d)(1)(v) and (d)(2)(iv) – *identification of a management program* – by referring to the Phase I MS4's storm water management program.

EPA Recommendations

In referencing a Phase I's MS4's storm water management program, the operator should briefly describe how the existing plan will address discharges from the small MS4 or would need to be supplemented in order to adequately address the small MS4 discharges. The small MS4 operator should explain their role in coordinating storm water pollutant control activities in their MS4 service area and detail the resources available to accomplish the plan.

If a small MS4 is considering this option, it should find out when the Phase I MS4's permit is scheduled for renewal and become thoroughly familiar with the Phase I MS4's permit conditions. This co-permitting approach will be most successful if both MS4s have had thorough discussions of their storm water programs and if the small MS4 submits it's application at the time that the Phase I MS4 is submitting its reapplication.

4.6.2 Program Requirements: The Six Minimum Control Measures

If coverage is obtained under a general permit or an individual permit under the Phase II regulations, the operator of a regulated small MS4 is required to implement a storm water management program that includes, at a minimum, the six minimum control measures described in the following subsections. As you read these subsections, keep in mind that the operator has a great deal of flexibility in determining the best management practices they will use to accomplish each measure. The rule allows the operators to chose the BMPs and measurable goals for each measure as appropriate for their particular MS4 service area – as long as the chosen BMPs and measurable goals result in effective control of pollutants in storm water runoff. Otherwise, the permitting authority may require changes in the chosen mix of BMPs and measurable goals to result in a more effective program.

4.6.2.1 Public Education and Outreach on Storm Water Impacts

Why Is Public Education and Outreach Necessary?

An informed and knowledgeable community is crucial to the success of a storm water management program since it helps to ensure the following:

Greater support for the program as the public gains a greater understanding of the reasons why it is necessary and important. Public support is particularly beneficial when operators of small MS4s attempt to institute new funding initiatives for the program or seek volunteers to help implement the program; and

Greater compliance with the program as the public becomes aware of the personal responsibilities expected of them and others in the community, including the individual actions they can take to protect or improve the quality of area waters.

What Is Required?

To satisfy this minimum control measure, the operator of a regulated small MS4 must:

- ❑ Implement a public education program to distribute educational materials to the community, or conduct equivalent outreach activities about the impacts of storm water discharges on local waterbodies and the steps that can be taken to reduce storm water pollution; and

- ❑ Determine the appropriate best management practices (BMPs) and measurable goals for this minimum control measure. Some program implementation approaches, BMPs (i.e., the program actions/activities), and measurable goals are suggested below.

What Are Some Guidelines for Developing and Implementing This Measure?

Three main action areas are important for successful implementation of a public education and outreach program:

➊ *Forming Partnerships*
Operators of regulated small MS4s are encouraged to enter into partnerships with other governmental entities to fulfill this minimum control measure's requirements. It is generally more cost-effective to use an existing program, or to develop a new regional or state-wide education program, than to have numerous operators developing their own local programs. Operators also are encouraged to seek assistance from non-governmental organizations (e.g., environmental, civic, and industrial organizations), since many already have educational materials and perform outreach activities.

❷ *Using Educational Materials and Strategies*
Operators of regulated small MS4s may use storm water educational information provided by their State, Tribe, EPA Region, or environmental, public interest, or trade organizations instead of developing their own materials. Operators should strive to make their materials and activities relevant to local situations and issues, and incorporate a variety of strategies to ensure maximum coverage. Some examples include:

Brochures or fact sheets for general public and specific audiences;

Recreational guides to educate groups such as golfers, hikers, paddlers, climbers, fishermen, and campers;

Alternative information sources, such as web sites, bumper stickers, refrigerator magnets, posters for bus and subway stops, and restaurant placemats;

A library of educational materials for community and school groups;

Volunteer citizen educators to staff a ***public education task force;***

Event participation with educational displays at home shows and community festivals;

Educational programs for school-age children;

Storm drain stenciling of storm drains with messages such as "Do Not Dump - Drains Directly to Lake;"

Storm water hotlines for information and for citizen reporting of polluters;

Economic incentives to citizens and businesses (e.g., rebates to homeowners purchasing mulching lawnmowers or biodegradable lawn products);and

Tributary signage to increase public awareness of local water resources.

❸ *Reaching Diverse Audiences*
The public education program should use a mix of appropriate local strategies to address the viewpoints and concerns of a variety of audiences and communities, including minority and disadvantaged communities, as well as children. Printing posters and brochures in more than one language or posting large warning signs (e.g., cautioning against fishing or swimming) near storm sewer outfalls are methods that can be used to reach audiences less likely to read standard materials. Directing materials or outreach programs toward specific groups of commercial, industrial, and institutional entities likely to have significant storm water impacts is also recommended. For example, information could be provided to restaurants on the effects of grease clogging storm drains and to auto garages on the effects of dumping used oil into storm drains.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are intended to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, should reflect the needs and characteristics of the operator and the area served by its small MS4. Furthermore, they should be chosen using an integrated approach that fully addresses the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following measurable goals:

Target Date	Activity
1 year............	Brochures developed (bilingual, if appropriate) and distributed in water utility bills; a storm water hotline in place; volunteer educators trained.
2 years..........	A web site created school curricula developed; storm drains stenciled.
3 years..........	A certain percentage of restaurants no longer dumping grease and other pollutants down storm sewer drains.
4 years..........	A certain percentage reduction in litter or animal waste detected in discharges.

4.6.2.2 Public Participation/Involvement

Why Is Public Participation and Involvement Necessary?

EPA believes that the public can provide valuable input and assistance to a regulated small MS4's municipal storm water management program and, therefore, suggests that the public be given opportunities to play an active role in both the development and implementation of the program. An active and involved community is crucial to the success of a storm water management program because it allows for:

Broader public support since citizens who participate in the development and decision making process are partially responsible for the program and, therefore, may be less likely to raise legal challenges to the program and more likely to take an active role in its implementation;

Shorter implementation schedules due to fewer obstacles in the form of public and legal challenges and increased sources in the form of citizen volunteers;

A broader base of expertise and ***economic benefits*** since the community can be a valuable, and free, intellectual resource; and

A conduit to other programs as citizens involved in the storm water program development process provide important cross-connections and relationships with other community and government programs. This benefit is particularly valuable when trying to implement a storm water program on a watershed basis, as encouraged by EPA.

What Is Required?

To satisfy this minimum control measure, the operator of a regulated small MS4 must:

- ❑ Comply with applicable State, Tribal, and local public notice requirements; and
- ❑ Determine the appropriate best management practices (BMPs) and measurable goals for this minimum control measure. Possible implementation approaches, BMPs (i.e., the program actions and activities), and measurable goals are described below.

What Are Some Guidelines for Developing and Implementing This Measure?

Operators of regulated small MS4s should include the public in developing, implementing, and reviewing their storm water management programs. The public participation process should make every effort to reach out and engage all economic and ethnic groups. EPA recognizes that there are challenges associated with public involvement. Nevertheless, EPA strongly believes that these challenges can be addressed through an aggressive and inclusive program. Challenges and example practices that can help ensure successful participation are discussed below.

Implementation Challenges

The best way to handle common notification and recruitment challenges is to know the audience and think creatively about how to gain its attention and interest. Traditional methods of soliciting public input are not always successful in generating interest, and subsequent involvement, in all sectors of the community. For example, municipalities often rely solely on advertising in local newspapers to announce public meetings and other opportunities for public involvement. Since there may be large sectors of the population who do not read the local press, the audience reached may be limited. Therefore, alternative advertising methods should be used whenever possible, including radio or television spots, postings at bus or subway stops, announcements in neighborhood newsletters, announcements at civic organization meetings, distribution of flyers, mass mailings, door-to-door visits, telephone notifications, and multilingual announcements. These efforts, of course, are tied closely to the efforts for the public education and outreach minimum control measure.

In addition, advertising and soliciting for help could and should be targeted at specific population sectors, including ethnic, minority, and low-income communities; academia and educational institutions; neighborhood and community groups; outdoor recreation groups; and business and industry. The goal is to involve a diverse cross-section of people who could offer a multitude of concerns, ideas, and connections during the program development process.

Possible Practices (BMPs)

There are a variety of practices that could be incorporated into a public participation and involvement program, such as:

Public meetings/citizen panels allow citizens to discuss various viewpoints and provide input concerning appropriate storm water management policies and BMPs;

Volunteer water quality monitoring gives citizens first-hand knowledge of the quality of local water bodies and provides a cost-effective means of collecting water quality data;

Volunteer educators/speakers who can conduct workshops, encourage public participation, and staff special events;

Storm drain stenciling is an important and simple activity that concerned citizens, especially students, can do;

Community clean-ups along local waterways, beaches, and around storm drains;

Citizen watch groups can aid local enforcement authorities in the identification of polluters; and

"Adopt A Storm Drain" programs encourage individuals or groups to keep storm drains free of debris and to monitor what is entering local waterways through storm drains.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are intended to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, would greatly depend on the needs and characteristics of the operator and the area served by its small MS4. Furthermore, they should be chosen using an integrated approach that fully addresses the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following measurable goals:

Target Date	Activity
1 year............	Notice of a public meeting in several different print media and bilingual flyers; citizen panel established; volunteers organized to locate outfalls/illicit discharges and stencil drains.
2 years..........	Final recommendations of the citizen panel; radio spots promoting program and participation.
3 years..........	A certain percentage of the community participating in community clean-ups.
4 years..........	Citizen watch groups established in a certain percentage of neighborhoods; outreach to every different population sector completed.

4.6.2.3 Illicit Discharge Detection and Elimination

What Is An "Illicit Discharge"?

Federal regulations define an illicit discharge as "...any discharge to an MS4 that is not composed entirely of storm water..." with some exceptions. These exceptions include discharges from NPDES-permitted industrial sources and discharges from fire-fighting activities. Illicit discharges (see Table 4-2) are considered "illicit" because MS4s are not designed to accept, process, or discharge such non-storm water wastes. It is important to note that "illicit" does not mean "illegal." Not every illicit discharge is necessarily a prohibited illegal discharge.

Why Are Illicit Discharge Detection and Elimination Efforts Necessary?

Discharges from MS4s often include wastes and wastewater from non-storm water sources. A study conducted in 1987 in Sacramento, California, found that almost one-half of the water discharged from a local MS4 was not directly attributable to precipitation runoff. A significant portion of these dry weather flows were from illicit and/or inappropriate discharges and connections to the MS4.

Table 4-2

Sources of Illicit Discharges
Sanitary wastewater
Effluent from septic tanks
Car wash wastewaters
Improper oil disposal
Radiator flushing disposal
Laundry wastewaters
Spills from roadway accidents
Improper disposal of auto and household toxics

Illicit discharges enter the system through either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the MS4 from cracked sanitary systems, spills collected by drain outlets, or paint or used oil dumped directly into a drain). The result is untreated discharges that contribute high levels of pollutants, including heavy metals, toxics, oil and grease, solvents, nutrients, viruses, and bacteria to receiving waterbodies. Pollutant levels from these illicit discharges have been shown in EPA studies to be high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health.

What Is Required?

Recognizing the adverse effects illicit discharges can have on receiving waters, the final rule requires an operator of a regulated small MS4 to develop and implement an illicit discharge detection and elimination program. This program must include the following:

- ☐ A storm sewer system map, showing the location of all outfalls and the names and location of all waters of the United States that receive discharges from those outfalls;

R0010631

- ❑ Through an ordinance, or other regulatory mechanism, a prohibition (to the extent allowable under State, Tribal, or local law) on non-storm water discharges into the MS4, and appropriate enforcement procedures and actions;
- ❑ A plan to detect and address non-storm water discharges, including illegal dumping, into the MS4;
- ❑ The education of public employees, businesses, and the general public about the hazards associated with illegal discharges and improper disposal of waste; and
- ❑ The determination of appropriate best management practices (BMPs) and measurable goals for this minimum control measure. Some program implementation approaches, BMPs (i.e., the program actions/activities), and measurable goals are suggested below.

Does This Measure Need to Address All Illicit Discharges?

No. The illicit discharge detection and elimination program does not need to address the following categories of non-storm water discharges or flows unless the operator of the regulated small MS4 identifies them as significant contributors of pollutants to its MS4:

- ❑ Water line flushing
- ❑ Landscape irrigation
- ❑ Diverted stream flows
- ❑ Rising ground waters
- ❑ Uncontaminated ground water infiltration
- ❑ Uncontaminated pumped ground water
- ❑ Discharges from potable water sources
- ❑ Foundation drains
- ❑ Air conditioning condensation
- ❑ Irrigation water
- ❑ Springs
- ❑ Water from crawl space pumps
- ❑ Footing drains
- ❑ Lawn watering
- ❑ Individual residential car washing
- ❑ Flows from riparian habitats and wetlands
- ❑ Dechlorinated swimming pool discharges
- ❑ Street wash water.

What Are Some Guidelines for Developing and Implementing This Measure?

The objective of the illicit discharge detection and elimination minimum control measure is to have regulated small MS4 operators gain a thorough awareness of their systems. This awareness allows them to determine the types and sources of illicit discharges entering their system, and establish the legal, technical, and educational means needed to eliminate these discharges. Permittees could meet these objectives in a variety of ways depending on their individual needs and abilities, but some general guidance for each requirement is provided below.

The Map

The storm sewer system map is meant to demonstrate a basic awareness of the intake and discharge areas of the system. It is needed to help determine the extent of discharged dry weather flows, the possible sources of the dry weather flows, and the particular waterbodies these flows may be affecting. An existing map, such as a topographical map, on which the location of major pipes and outfalls can be clearly presented would demonstrate such an awareness.

EPA recommends collecting all existing information on outfall locations (e.g., review city records, drainage maps, storm drain maps), and then conducting field surveys to verify locations. It probably will be necessary to walk (i.e., wade through small receiving waters or use a boat for larger waters) the streambanks and shorelines for visual observation. More than one trip may be needed to locate all outfalls.

Legal Prohibition and Enforcement

EPA recognizes that some permittees may have limited authority under State, Tribal or local law to establish and enforce an ordinance, or other regulatory mechanism, prohibiting illicit discharges. In such a case. the permittee is encouraged to obtain the necessary authority, if at all possible. Otherwise, the NPDES permitting authority assumes responsibility for implementation of this component of the minimum measure, yet the permittee would remain ultimately responsible for the quality of its MS4 discharge. Model ordinances, including examples of amendments to local codes or existing ordinances, will be provided in the Phase II storm water guidance for regulated small MS4s, which is part of EPA's planned implementation "tool box" for the rule.

The Plan

The plan to detect and address illicit discharges is the central component of this minimum control measure. The plan is dependant upon several factors, including the permittee's available resources, size of staff, and degree and character of its illicit discharges. EPA envisions a plan similar to the one recommended for use in meeting Michigan's general storm water NPDES permit for small MS4s. As guidance only, the four steps of a recommended plan are outlined below:

➊ **Locate Problem Areas**
EPA recommends that priority areas be identified for detailed screening of the system based on the likelihood of illicit connections (e.g., areas with older sanitary sewer lines). Some methods that could be used to locate problem areas include: public complaints; visual screening; water sampling from manholes and outfalls during dry weather; and use of infrared and thermal photography.

➋ **Find the Source**
Once a problem area or discharge is found, additional efforts usually would be

necessary to determine the source of the problem. Some methods that could be used to find the source of the illicit discharge include: dye-testing buildings in problem areas; dye- or smoke-testing buildings at the time of sale; tracing the discharge upstream in the storm sewer; employing a certification program that shows that buildings have been checked for illicit connections; implementing an inspection program of existing septic systems; and using video to inspect the storm sewers.

❸ **Remove/Correct Illicit Connections**
Once the source is identified, the offending discharger should be notified and directed to correct the problem. Education efforts and working with the discharger can be effective in resolving the problem before taking legal action.

❹ **Document Actions Taken**
As a final step, all actions taken under the plan should be documented. Doing so would illustrate that progress is being made to eliminate illicit connections and discharges. Documented actions should be included in the required annual reports and include information such as: the number of outfalls screened; any complaints received and corrected; the number of discharges and quantities of flow eliminated; and the number of dye or smoke tests conducted.

Educational Outreach

Outreach to public employees, businesses, property owners, the general community, and elected officials regarding ways to detect and eliminate illicit discharges is an integral part of this minimum measure that will help gain support for the permittee's storm water program. Suggested educational outreach efforts include:

- Developing ***informative brochures, and guidances*** for specific audiences (e.g., carpet cleaning businesses) and school curricula;
- Designing a program to ***publicize and facilitate public reporting*** of illicit discharges;
- ***Coordinating volunteers*** for locating, and visually inspecting, outfalls or to stencil storm drains; and
- Initiating ***recycling programs*** for commonly dumped wastes, such as motor oil, antifreeze, and pesticides.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are intended to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, should reflect the needs and characteristics of the operator and the area served by its small MS4. Furthermore, they should be chosen using an integrated approach that would fully address the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following measurable goals:

Target Date	Activity
1 year...........	Sewer system map completed; recycling program for household hazardous waste in place.
2 years..........	Ordinance in place; training for public employees completed; a certain percentage of sources of illicit discharges determined.
3 years..........	A certain percentage of: illicit discharges detected; illicit discharges eliminated; and households participating in quarterly household hazardous waste special collection days.
4 years..........	Most illicit discharge sources detected and eliminated.

The educational outreach measurable goals for this minimum control measure could be combined with the measurable goals for the Public Education and Outreach minimum control measure.

4.6.2.4 Construction Site Storm Water Runoff Control

Why Is The Control of Construction Site Runoff Necessary?

Polluted storm water runoff from construction sites often flows to MS4s and ultimately is discharged into local rivers and streams. Of the pollutants listed in Table 4-3, sediment is usually the main pollutant of concern. Sediment runoff rates from construction sites are typically 10 to 20 times greater than those of agricultural lands, and 1,000 to 2,000 times greater than those of forest lands. During a short period of time, construction sites can contribute more sediment to streams than can be deposited naturally during several decades. The resulting siltation, and the contribution of other pollutants from construction sites, can cause physical, chemical, and biological harm to our nation's waters. For example, excess sediment can quickly fill rivers and lakes, requiring dredging and destroying aquatic habitats.

Table 4-3

Pollutants Commonly Discharged From Construction Sites
Sediment
Solid and sanitary wastes
Phosphorous (fertilizer)
Nitrogen (fertilizer)
Pesticides
Oil and grease
Concrete truck washout
Construction chemicals
Construction debris

What Is Required?

The Phase II Final Rule requires an operator of a regulated small MS4 to develop, implement, and enforce a program to reduce pollutants in storm water runoff to their MS4 from construction activities that result in a land disturbance of greater than or equal to one acre. The small MS4 operator is required to:

- ❑ Have an ordinance or other regulatory mechanism requiring the implementation of proper erosion and sediment controls, and controls for other wastes, on applicable construction sites;

R0010635

- ❑ Have procedures for site plan review of construction plans that consider potential water quality impacts;

- ❑ Have procedures for site inspection and enforcement of control measures;

- ❑ Have sanctions to ensure compliance (established in the ordinance or other regulatory mechanism);

- ❑ Establish procedures for the receipt and consideration of information submitted by the public; and

- ❑ Determine the appropriate best management practices (BMPs) and measurable goals for this minimum control measure. Suggested BMPs (i.e., the program actions/activities) and measurable goals are presented below.

What Are Some Guidelines for Developing and Implementing This Measure?

Further explanation and guidance for each component of a regulated small MS4's construction program is provided below.

Regulatory Mechanism

Through the development of an ordinance or other regulatory mechanism, the small MS4 operator needs to establish a construction program that requires controls for polluted runoff from construction sites with a land disturbance of greater than or equal to one acre. Because there may be limitations on regulatory legal authority, the small MS4 operator is required to satisfy this minimum control measure only to the maximum extent practicable and allowable under State, Tribal, or local law. If an operator is unable to establish an enforceable construction program due to a lack of legal authority, and is unsuccessful in trying to obtain the necessary authority, the NPDES permitting authority would then assume responsibility.

EPA intends to develop a model ordinance that a small MS4 operator could use as a basis for its construction program. Alternatively, amendments to existing erosion and sediment control programs, or other ordinances, can also provide the basis for the program.

Site Plan Review

The small MS4 operator is required to include in its construction program requirements for the implementation of appropriate BMPs on construction sites to control erosion and sediment, as well as waste at the site. To determine if a construction site is in compliance with such provisions, the small MS4 operator should review the site plans submitted by the construction site operator before ground is broken.

Site plan review aids in compliance and enforcement efforts since it alerts the small MS4 operator early in the process to the planned use or non-use of proper BMPs and provides a way to track new construction activities. The tracking of sites is useful not only for the small MS4 operator's recordkeeping and reporting purposes, which will be required activities under their NPDES storm water permit (see Fact Sheet 2.9), but also for members of the public interested in ensuring that the sites are in compliance.

Inspections and Penalties

Once construction commences, the BMPs should be in place and the small MS4 operator's enforcement activities should begin. To ensure that the BMPs are properly installed, the small MS4 operator is required to develop procedures for site inspection and enforcement of control measures to deter infractions. Procedures could include steps to identify priority sites for inspection and enforcement based on the nature and extent of the construction activity, topography, and the characteristics of soils and receiving water quality. Inspections give the MS4 operator an opportunity to provide additional guidance and education, issue warnings, or assess penalties. To conserve staff resources, one possible option for small MS4 operators could be to have these inspections performed by the same inspector that visits the sites to check compliance with health and safety building codes.

Information Submitted by the Public

A final requirement of the small MS4 program for construction activity is the development of procedures for the receipt and consideration of public inquiries, concerns, and information submitted regarding local construction activities. This provision is intended to further reinforce the public participation component of the regulated small MS4 storm water program and to recognize the crucial role that the public can play in identifying instances of noncompliance.

The small MS4 operator is required only to *consider* the information submitted, and may not need to follow-up and respond to every complaint or concern. Although some form of enforcement action or reply is not required, the small MS4 operator is required to demonstrate acknowledgment and consideration of the information submitted. A simple tracking process in which submitted public information, both written and verbal, is recorded and then given to the construction site inspector for possible follow-up would suffice.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are intended to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, should reflect the needs and characteristics of the operator and the area served by its small MS4. Furthermore, they should be chosen using an integrated approach that fully addresses the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following measurable goals:

Target Date	Activity
1 year...........	Ordinance or other regulatory mechanism in place; procedures for information submitted by the public in place.
2 years..........	Procedures for site inspections implemented; a certain percentage rate of compliance achieved by construction operators.
3 years..........	Maximum compliance with ordinance; improved clarity and reduced sedimentation of local waterbodies.
4 years..........	Increased numbers of sensitive aquatic organisms in local waterbodies.

Am I Correct in Thinking that Construction Sites Are Already Covered Under the NPDES Storm Water Program?

Yes. EPA's Phase I NPDES storm water program requires operators of construction activities that disturb five or more acres to obtain a NPDES construction storm water permit. General permit requirements include the submission of a Notice of Intent and the development of a storm water pollution prevention plan (SWPPP). The SWPPP must include a site description and measures and controls to prevent or minimize pollutants in storm water discharges. The Phase II Final Rule similarly regulates discharges from smaller construction sites disturbing equal to or greater than one acre and less than five acres.

Even though all construction sites that disturb more than one acre are covered nationally by an NPDES storm water permit, the construction site runoff control minimum measure for the small MS4 program is needed to induce more localized site regulation and enforcement efforts, and to enable operators of regulated small MS4s to more effectively control construction site discharges into their MS4s.

To aid operators of regulated construction sites in their efforts to comply with both local requirements and their NPDES permit, the Phase II Final Rule includes a provision that allows the NPDES permitting authority to reference a "qualifying State, Tribal or local program" in the NPDES general permit for construction. This means that if a construction site is located in an area covered by a qualifying local program, then the construction site operator's compliance with the local program would constitute compliance with their NPDES permit. A regulated small MS4's storm water program for construction could be a "qualifying program" if the MS4 operator requires a SWPPP, in addition to the requirements summarized in this fact sheet.

The ability to reference other programs in the NPDES permit is intended to reduce confusion between overlapping and similar requirements, while still providing for both local and national regulatory coverage of the construction site. The provision allowing NPDES permitting authorities to reference other programs has no impact on, or direct relation to, the small MS4 operator's responsibilities under the construction site runoff control minimum measure profiled in this fact sheet.

Is a Small MS4 Operator Required to Regulate Construction Sites that the Permitting Authority has Waived from the NPDES Construction Program?

No. If the NPDES permitting authority waives requirements for storm water discharges associated with small construction activity (see § 122.26(b)(15) of the Phase II rule), the small MS4 operator is not required to develop, implement, and/or enforce a program to reduce pollutant discharges from such sites.

4.6.2.5 Post-construction Storm Water Management in New Development/ Redevelopment

Why Is The Control of Post-Construction Runoff Necessary?

Post-construction storm water management in areas undergoing new development or redevelopment is necessary because runoff from these areas has been shown to significantly effect receiving waterbodies. Many studies indicate that prior planning and design for the minimization of pollutants in post-construction storm water discharges is the most cost-effective approach to storm water quality management.

There are generally two forms of substantial impacts of post-construction runoff. The first is caused by an increase in the type and quantity of pollutants in storm water runoff. As runoff flows over areas altered by development, it picks up harmful sediment and chemicals such as oil and grease, pesticides, heavy metals, and nutrients (e.g., nitrogen and phosphorus). These pollutants often become suspended in runoff and are carried to receiving waters, such as lakes, ponds, and streams. Once deposited, these pollutants can enter the food chain through small aquatic life, eventually entering the tissues of fish and humans. The second kind of post-construction runoff impact occurs by increasing the quantity of water delivered to the waterbody during storms. Increased impervious surfaces interrupt the natural cycle of gradual percolation of water through vegetation and soil. Instead, water is collected from surfaces such as asphalt and concrete and routed to drainage systems where large volumes of runoff quickly flow to the nearest receiving water. The effects of this process include streambank scouring and downstream flooding, which often lead to a loss of aquatic life and damage to property.

What Is Required?

The Phase II Final Rule requires an operator of a regulated small MS4 to develop, implement, and enforce a program to reduce pollutants in post-construction runoff to their MS4 from new development and redevelopment projects that result in the land disturbance of greater than or equal to 1 acre The small MS4 operator is required to:

- ☐ Develop and implement strategies which include a combination of structural and/or non-structural best management practices (BMPs);

- ❑ Have an ordinance or other regulatory mechanism requiring the implementation of post-construction runoff controls to the extent allowable under State, Tribal or local law;
- ❑ Ensure adequate long-term operation and maintenance of controls;
- ❑ Determine the appropriate best management practices (BMPs) and measurable goals for this minimum control measure.

What Is Considered a "Redevelopment" Project?

The term "redevelopment" refers to alterations of a property that change the "footprint" of a site or building in such a way that the disturbance of equal to or greater than 1 acre of land results. The term does not include such activities as exterior remodeling. Because redevelopment projects may have site constraints not found on new development sites, the rule provides flexibility for implementing post-construction controls on redevelopment sites that consider these constraints.

What Are Some Guidelines for Developing and Implementing This Measure?

This section includes some sample non-structural and structural BMPs that could be used to satisfy the requirements of the post-construction runoff control minimum measure. It is important to recognize that many BMPs are climate-specific, and not all BMPs are appropriate in every geographic area. Because the requirements of this measure are closely tied to the requirements of the construction site runoff control minimum measure (see Fact Sheet 2.6), EPA recommends that small MS4 operators develop and implement these two measures in tandem. Sample BMPs follow.

❑ **Non-Structural BMPs**

- **Planning and Procedures.** Runoff problems can be addressed efficiently with sound planning procedures. Master Plans, Comprehensive Plans, and zoning ordinances can promote improved water quality by guiding the growth of a community away from sensitive areas and by restricting certain types of growth (industrial, for example) to areas that can support it without compromising water quality.
- **Site-Based Local Controls.** These controls can include buffer strip and riparian zone preservation, minimization of disturbance and imperviousness, and maximization of open space.

❑ **Structural BMPs**

- **Storage Practices.** Storage or detention BMPs control storm water by gathering runoff in wet ponds, dry basins, or multichamber catch basins and slowly releasing it to receiving waters or drainage systems. These practices both control storm water volume and settle out particulates for pollutant removal.

- **Infiltration Practices**. Infiltration BMPs are designed to facilitate the percolation of runoff through the soil to ground water, and, thereby, result in reduced storm water quantity and reduced mobilization of pollutants. Examples include infiltration basins/trenches, dry wells, and porous pavement.

- **Vegetative Practices**. Vegetative BMPs are landscaping features that, with optimal design and good soil conditions, enhance pollutant removal, maintain/improve natural site hydrology, promote healthier habitats, and increase aesthetic appeal. Examples include grassy swales, filter strips, artificial wetlands, and rain gardens.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are intended to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, should reflect needs and characteristics of the operator and the area served by its small MS4. Furthermore, the measurable goals should be chosen using an integrated approach that fully addresses the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following goals:

Target Date	Activity
1 year............	Strategies developed that include structural and/or non-structural BMPs.
2 years..........	Strategies codified by use of ordinance or other regulatory mechanism.
3 years..........	Reduced percent of new impervious surfaces associated with new development projects.
4 years..........	Improved clarity and reduced sedimentation of local waterbodies.

4.6.2.6 Pollution Prevention/Good Housekeeping for Municipal Operations

Why Is Pollution Prevention/Good Housekeeping Necessary?

The Pollution Prevention/Good Housekeeping for municipal operations minimum control measure is a key element of the small MS4 storm water management program. This measure requires the small MS4 operator to examine and subsequently alter own actions to help ensure a reduction in the amount and type of pollution that (1) collects on streets, parking lots, open spaces, and storage and vehicle maintenance areas and is discharged into local waterways; and (2) results from actions such as environmentally damaging land development and flood management practices or poor maintenance of storm sewer systems.

While this measure is meant primarily to accomplish the goal of improving or protecting the quality of receiving waters by altering the performance of municipal or facility operations, it also can result in a cost savings for the small MS4 operator, since proper and timely maintenance of storm sewer systems can help avoid repair costs from damage caused by age and neglect.

What Is Required?

Recognizing the benefits of pollution prevention practices, the rule requires an operator of a regulated small MS4 to:

- Develop and implement an operation and maintenance program with the ultimate goal of preventing or reducing pollutant runoff from municipal operations into the storm sewer system;
- Include employee training on how to incorporate pollution prevention/good housekeeping techniques into municipal operations such as park and open space maintenance, fleet and building maintenance, new construction and land disturbances, and storm water system maintenance. To minimize duplication of effort and conserve resources, the MS4 operator could use training materials that are available from EPA, their State or Tribe, or relevant organizations;
- Determine the appropriate best management practices (BMPs) and measurable goals for this minimum control measure. Some program implementation approaches, BMPs (i.e., the program actions/activities), and measurable goals are suggested below.

What Are Some Guidelines for Developing and Implementing This Measure?

The intent of this control measure is to ensure that existing municipal, State or Federal operations are performed in ways that will minimize contamination of storm water discharges. EPA encourages the small MS4 operator to consider the following components when developing their program for this measure:

Maintenance activities, maintenance schedules, and long-term inspection procedures for structural and non-structural controls to reduce floatables and other pollutants discharged from the separate storm sewers;

Controls for reducing or eliminating the discharge of pollutants from areas such as roads and parking lots, maintenance and storage yards (including salt/sand storage and snow disposal areas), and waste transfer stations. These controls could include programs that promote recycling (to reduce litter), minimize pesticide use, and ensure the proper disposal of animal waste;

Procedures for the proper disposal of waste removed from the separate storm sewer systems and the areas listed in the bullet above, including dredge spoil, accumulated sediments, floatables, and other debris; and

- ***Ways to ensure that new flood management projects assess the impacts on water quality*** and examine existing projects for incorporation of additional water quality protection devices or practices. EPA encourages coordination with flood control managers for the purpose of identifying and addressing environmental impacts from such projects.

The effective performance of this control measure hinges on the proper maintenance of the BMPs used, particularly for the first two bullets above. For example, structural controls, such as grates on outfalls to capture floatables, typically need regular cleaning, while non-structural controls, such as training materials and recycling programs, need periodic updating.

What Are Appropriate Measurable Goals?

Measurable goals, which are required for each minimum control measure, are meant to gauge permit compliance and program effectiveness. The measurable goals, as well as the BMPs, should consider the needs and characteristics of the operator and the area served by its small MS4. The measurable goals should be chosen using an integrated approach that fully addresses the requirements and intent of the minimum control measure. An integrated approach for this minimum measure could include the following measurable goals:

Target Date	Activity
1 year...........	Pollution prevention plan (the new BMPs and revised procedures) completed; employee training materials gathered or developed; procedures in place for catch basin cleaning after each storm and regular street sweeping.
2 years..........	Training for appropriate employees completed; recycling program fully implemented.
3 years..........	Some pollution prevention BMPs incorporated into master plan; a certain percentage reduction in pesticide and sand/salt use; maintenance schedule for BMPs established.
4 years..........	A certain percentage reduction in floatables discharged; a certain compliance rate with maintenance schedules for BMPs; controls in place for all areas of concern.

4.6.3 Program Requirements: Evaluation/Assessment & Reporting

If coverage is obtained under a general permit or an individual permit under the Phase II regulations, the operator of a regulated small MS4 is required to comply with the evaluation/assessment and reporting requirements summarized in this section.

Frequency of Reports

Reports must be submitted annually during the first permit term – permit terms are typically a 5-year period. For subsequent permit terms, reports must be submitted in years 2 and 4 only, unless the NPDES permitting authority requests more frequent reports. Reports do not need to be submitted if the operator of the regulated small MS4 is relying on another entity to satisfy all permit obligations (see section 4.5.1.3)

Required Report Content

The reports must include the following:

- ❑ The status of compliance with permit conditions, including an assessment of the appropriateness of the selected BMPs and progress toward achieving the selected measurable goals for each minimum measure;
- ❑ Results of any information collected and analyzed, including monitoring data, if any;
- ❑ A summary of the storm water activities planned for the next reporting cycle;
- ❑ A change in any identified best management practices or measurable goals for any minimum measure; and
- ❑ Notice of relying on another governmental entity to satisfy some of the permit obligations (if applicable – see section 4.5.1.3).

A Change in Selected BMPs

If, upon evaluation of the program, improved controls are identified as necessary, permittees should revise their mix of BMPs to provide for a more effective program. Such a change, and an explanation of the change, must be noted in a report to the NPDES permitting authority.

Recordkeeping Requirements

Records required by the NPDES permitting authority must be kept for at least 3 years and made accessible to the public at reasonable times during regular business hours. Records need not be submitted to the NPDES permitting authority unless the permittee is requested to do so.

4.7 SMALL MS4 PROGRAM COMPLIANCE PROCESS: What Do I Need to Do To Comply?

Sections 4.1 through 4.6 of this guidance have provided a details on who's covered and what's required under the Phase II regulations for regulated small MS4s. Now that you are familiar with the Phase II program, this section walks you through the process, from beginning to end, that an operator of a regulated small should take to comply with the regulation. This step-by-step "walk-through" references the appropriate sections of the guidance along the way as a means for understanding how the information in sections 4.1 through 4.6 fits together.

The last page of this section includes a permitting decision tree to help operators of MS4s determine if they need an NPDES storm water permit. By starting in the upper left hand corner, an operator can follow the decision tree to determine if they fall under Phase I or Phase II, and if they are eligible for a waiver.

Step 1: Determine if you are an operator of an MS4 (see section 4.1.1).

Step 2: As an operator of an MS4, determine if you are an operator of a small MS4 (see section 4.1.4).

Step 3: As an operator of a small MS4, determine if you are an operator of a regulated small MS4 (see section 4.2). You need to find out if you are:

A. Automatically designated by the rule

- First, determine if your system is located partially or fully within an urbanized area (See section 4.3),
- Second, determine if you may qualify for a waiver (waivers are at the discretion of the permitting authority). If you qualify for a waiver, stop here. (See section 4.4)

B. Potentially designated by the NPDES permitting authority

- Determine if your system, located outside of a UA, may fit the criteria for potential designation. Since designations are at the discretion of the permitting authority, a final determination is made by the permitting authority and not the small MS4 operator. If designated, continue with Step 4.

Step 4: Read Phase II Rule and guidance materials to get a sense of the permitting options (see section 4.5) and program requirements (see section 4.6).

Step 5: Determine which neighbors are regulated as Phase I MS4s (refer to list on the EPA web site) or Phase II MS4s (refer to Appendix 6 and maps of your UA). This information will be used to base your decision as to whether to:

- Be a co-permittee with another regulated MS4. (See section 4.5.1.2)
- Rely on another regulated MS4 for partial or full implementation of the minimum measures on your behalf. (See section 4.5.1.3)

Step 6: Determine if programs similar to one or more of the minimum measures is already being performed by another entity. This information will be used to decide whether you wish to rely on another entity for partial implementation of the minimum measures on your behalf. (See section 4.5.1.3)

Step 7: Determine which permit option to choose (depends on which are made available by the your NPDES permitting authority) (See section 4.5.1)

- General permit under the Phase II regulation
- Individual permit under the Phase I or Phase II regulation
- Modification of a Phase I individual permit (Co-permittee with a large or medium MS4)

In determine which option to choose, think about...

— If you wish to be a co-permittee and share responsibilities based on information from Step 5

— If, instead of the co-permittee option, you wish to have own permit but rely on another entity for implementing a measure or measures based on information from Steps 5 & 6.

Step 8: Begin planning and development of your storm water management program

- Use menu of BMPs as a guide (provided by EPA or the permitting authority). The EPA web site will also have references and links to helpful guidance on every facet of a storm water management program for MS4s.

- Meet with staff who will be responsible for implementing the storm water management program (may be a multi-departmental team). Task them with:
  - — Assessing the storm water management characteristics and needs of the area served by the regulated small MS4.
  - — Determining appropriate BMPs and measurable goals
  - — Determining who will be responsible for what under the program

- Form a citizen advisory panel to help develop the program and give them similar tasks as those given to the staff.

- Meet with local Phase I and Phase II MS4 operators to discuss co-permittee status or sharing of resources, such as: hiring one enforcement inspector for multiple areas, co-sponsoring household hazardous waste collection events, or sharing a street sweeper, recycling truck, illicit discharge detection cameras, or any other equipment. (Note: Nothing listed here is required by the Phase II rule -- they are only examples)

- Meet with other entities that you may rely on to implement one or more of the minimum measures to discuss the arrangement and any legal agreements.

Step 9: **A. Under a General Permit:**

1) Once a general permit is issued, read it carefully. You may not be

required to implement every minimum measure due to the permitting authority recognizing or referencing other similar programs (see section 4.5.2.1). For this reason, before the permit is issued (which is expected to be no later than December 9, 2002) follow Step 8 but only do a preliminary storm water management program until the final permit requirements are know. Once the permit is issued, if you have chosen this option you will need to make final decisions on the following issues and complete the development of your storm water management plan:

- Do you want to be a co-permittee with another regulated small MS4?
- Do you want to rely on another entity for some or all of the permit requirements?
- Which BMPs and measurable goals will you use for each minimum measure you will be implementing?

2) Fill out an NOI in accordance with the Phase II regulation. (See section 4.6.2.1)

B. Under an Individual Permit (new or modified):

If you have chosen one of the individual permit options (i.e., under Phase II, under Phase I, or modified existing Phase I), you will need to continue efforts in Step 8, as applicable, and complete development of your permit application in accordance with the Phase II regulation. (See sections 4.6.2.2 through 4.6.2.4)

Step 10: Submit your NOI under a general permit or your individual permit application to the NPDES permitting authority by March 10, 2003; unless your NPDES permitting authority phases-in permit coverage and establishes alternative deadlines (see section 4.5.2.2).

Step 11: Implement your storm water management program in accordance with applicable standards (see section 4.6.1). The Phase II rule allows you up to five years to fully implement your program, although the exact timeframe is at the discretion of the your NPDES permitting authority.

Step 12: Write annual reports in your first permit term assessing the effectiveness of BMPs and if measurable goals were met, and submit the reports to your NPDES permitting authority. You may change the mix of BMPs originally selected if you find that such a change is necessary to ensure a more effective program. This step, as required in the Phase II regulations at § 122.34(g) and described in section 4.6.3, is not applicable if you sought coverage under an individual permit under the Phase I regulations or under a modification of an existing Phase I MS4 permit.

Step 13: Be aware that you may need to take over implementation of a minimum control measure if you are relying on another entity for its implementation and the other entity fails to perform it effectively. This is why EPA encourages a legally-binding agreement when choosing to rely on another entity. Also, the permitting authority may chose to change your mix of BMPs and measurable goals as submitted in you permit application if it determines that your program is not effectively controlling pollutant discharges.

4.8 FEDERAL AND STATE-OPERATED REGULATED SMALL MS4S: Unique Program Implementation Issues

In addition to local government jurisdictions, small MS4s include certain Federal and State-operated MS4s. Federal facilities were not designated for regulation by the NPDES Phase I storm water program for MS4s. The Phase II Final Rule, however, includes the "United States" in the definition of a small MS4, thereby including Federal MS4 operators in the NPDES Phase II storm water program. Federal and State-operated small MS4s can include universities, prisons, hospitals, roads (i.e., departments of transportation), military bases (e.g., State Army National Guard barracks), parks, and office buildings/complexes.

The small MS4 program, largely designed with municipally-operated small MS4s in mind, raises a number of implementation issues for Federal and State operators of regulated small MS4s who must obtain an NPDES permit that requires the development and implementation of a storm water management program that includes the six minimum control measures. This section highlights potential implementation issues related to the minimum control measures, and then discusses the implementation options included in the rule that may help resolve these issues.

4.8.1 What Are Some Implementation Concerns?

This section profiles the three most common implementation issues raised in the public comments submitted regarding Federal/State implementation of the small MS4 program.

How Does the Final Rule Account for Unique Characteristics?

Federal and State small MS4s possess a number of characteristics that set them apart from their municipal counterparts. For example, whereas municipally-operated MS4s largely serve resident populations, many Federal or State-operated MS4s, such as medical clinics and departments of transportation (DOTs), do not. Other types of Federal and State MS4s, such as military bases, prisons, and State universities, serve populations that are different from a typical municipal population. Their unique characteristics might lead Federal or State MS4 operators to question either the need to implement the entire suite of minimum control measures or their ability to comply fully with their Phase II storm water permit. The flexibility within the minimum measures allows Federal and State MS4s to develop a storm water program that comprises the minimum measures in a way that makes sense for their circumstances.

What If the Operator Lacks Legal Authority?

Three of the minimum control measures (illicit discharge detection and elimination, and the two construction-related measures) require enforceable controls on third party activities to ensure successful implementation of the measure. Some Federal and State operators, however, may not have the necessary legal regulatory authority to adopt these enforceable controls in the same manner as do local governments.

For example, a State DOT that is responsible for the portions of its roads running through urbanized areas may not have the legal authority to impose restrictions on, and penalties against, illicit (i.e., non-storm water) discharges into its MS4 if the source of the discharge is outside the DOT's right-of-way or jurisdiction. As in the case of local governments that lack such authority, State and Federal MS4s are expected to utilize the authority they do possess and to seek cooperative arrangements.

How Can the Program Be Implemented in Areas Where There Are Multiple Regulated Entities?

Since the final rule provides automatic coverage of all small MS4s within an urbanized area, regardless of political boundaries, coverage of multiple governments and agencies in a single area is likely. For example, a city government that operates a small MS4 within an urbanized area must obtain permit coverage alongside the county, State, and Federal DOTs if they all operate a portion of the roads (i.e., MS4s) in the city. All four entities are responsible for developing a storm water management program for their MS4s (or portions thereof) within the urbanized area. EPA encourages State and Federal small MS4 operators to establish cooperative agreements with cities and counties in implementing their storm water programs.

4.8.2 Are There Implementation Strategies that Help Facilitate Program Implementation?

This section offers two hypothetical strategies for resolving the implementation issues raised above. The best solution may include a creative combination of strategies.

STRATEGY #1
A Focus on Choosing Appropriate BMPs

The final rule requires the permittee to choose *appropriate* best management practices (BMPs) for each minimum control measure. In other words, EPA expects Phase II permittees to tailor their storm water management plans and their BMPs to fit the particular characteristics and needs of the permittee and the area served by its MS4. Therefore, the Federal or State operator of a regulated storm sewer system can take advantage of the flexibility provided by the rule to utilize the most suitable minimum control measures for its MS4. Below is an example of tailored activities and BMPs that

Federal or State operators can implement for each measure:

- **Public Education and Outreach**. Distribute brochures and post fliers to educate employees of a Federal hospital about the problems associated with storm water runoff and the steps they can take to reduce pollutants in storm water discharges. For example, employees could be advised against carelessly discarding trash on the ground or allowing their cars to leak oil/fluids in the parking lot.

- **Public Participation/Involvement**. Provide notice of storm water management plan development and hold meetings at which employees of a Federal office complex are encouraged to voice their ideas and opinions about the effort. Request volunteers to help develop the plan.

- **Illicit Discharge Detection and Elimination**. Develop a map of the storm sewer system on a military base. Perform visual dry weather monitoring of any outfalls to determine whether the storm sewer system is receiving any non-storm water discharges from the base. If a dry weather flow is found, trace it back to the source and stop the discharge. Should a Federal military base identify an illicit discharge, the source of which is traced to the boundary of its system, the Federal operator should refer the discharge to the adjoining regulated MS4 for further action.

- **Construction Site Runoff Control**. Require the implementation of erosion and sediment controls, and control of waste, for any Federal or State DOT road construction. The DOT would review site plans for proper controls, perform inspections, and establish penalties in the construction contract if controls are not implemented. If construction is done directly by the regulated DOT instead of a private contractor, the DOT could be penalized by the NPDES permitting authority for non-compliance with its small MS4 permit in the event that controls are not properly implemented.

- **Post-Construction Runoff Control**. Require the implementation of post-construction storm water controls for any new construction on the grounds of a prison. This can be required as part of a construction contract, instituted as internal policy, and considered during site plan review.

- **Pollution Prevention/Good Housekeeping for Municipal Operations**. Train maintenance staff at a State university to employ pollution prevention techniques whenever possible. For example, routinely pick up trash/litter from the university grounds, use less salt on the parking lots and access roads in the winter, perform any maintenance of university vehicles under shelter only, limit pesticide use to the minimum needed, use vegetative buffer strips in the parking lots to filter runoff, and keep dumpster lids closed.

STRATEGY #2
Working with Other Entities

There may be instances when the Federal or State permittee has limited capabilities to satisfy one or more of the minimum control measures. As discussed above, the permittee may lack the proper legal authority to enforce controls (although it should try to obtain the necessary legal authority if at all possible).

In the case of limited capabilities, the permittee can work with neighboring operators of regulated small MS4s, preferably on a watershed basis, to form a shared storm water management program in which each permittee is responsible for activities that are within individual legal authorities and abilities. The final rule allows the permittee to rely on other entities, with their permission, to implement those minimum measures that the permittee is otherwise unable to implement. Three examples are:

- A State DOT with limited regulatory legal authority can reference a local sewer district's illicit detection and elimination program in its permit application, provided the program sufficiently addresses illicit discharges into the DOT's storm sewer system.
- The permittee or NPDES permitting authority can reference such programs as coastal nonpoint pollution control programs, State or local watershed programs, State or local construction programs, and environmental education efforts by public or private entities.
- The permittee can become a co-permittee with a neighboring Phase I MS4 through a modification of the Phase I MS4's individual permit. This may be the most logical and preferable option for those Federal and State entities located in close proximity to Phase I MS4s.

Choosing to work with other governmental entities as a co-permittee, or referencing parts of each other's plans, can help resolve issues that may arise where multiple regulated jurisdictions exist in the same area. Permittees can avoid duplicative efforts, as well as territorial or regulatory disputes, by working together to implement the storm water program.

Suggested Steps for Working with Other Entities

(1) Identify the boundaries of the urbanized area.

(2) Identify the operators of storm sewer systems or portions of the systems within the urbanized area such as local, State, Tribal or Federal governments or other entities.

(3) In seeking permit coverage:

Identify where another entity's program may satisfy one or more minimum control measure. If a program has requirements that are equivalent to a minimum control measure's required elements, the operator of the regulated small MS4 may reference the program in its permit application, provided the other entity gives it permission to do so. While such an arrangement relieves the operator from performing the minimum measure itself, the operator remains ultimately responsible for the measure's effective implementation.

OR

Team with an operator of a Phase I MS4 and become a co-permittee on its existing Phase I individual permit.

4.9 FUNDING OPTIONS

Possibly the biggest challenge for an operator of a regulated small MS4 in implementing a storm water management program is finding funding for the program. Funding is needed to maintain the staff, equipment and materials necessary to develop and implement an effective program. Adequate funding is critical to the success of the program but attaining it can be difficult as many other important programs compete for the same limited revenues from a general fund. Therefore, the operator of a regulated small MS4 will need to consider alternative funding options. This section provides brief introductions to some of the various funding options currently in use across the country. The following information on funding options was written by the American Public Works Association (AWPA) as part of their Storm Water Phase II workshops:

Debt Financing: Typically used for capital-intensive projects, local governments can issue debt to finance storm water management programs and facilities. Revenue bonds - or bonds that rely on ongoing source of revenue may be used. Alternatively, a general obligation bond can be issued which are backed by the full faith and credit of your municipality (based on your ability to generate revenues though taxes and other fees).

Grants and Loans: Federal, State, or Regional grant or loan funds may be available for some elements of the storm water program, depending on the BMP's selected and the location. Grants and loans are usually applicable to specific projects and not on-going activities, such as operation and maintenance.

Users /Utility Fees: Utility services charges are rates billed to customers for providing storm water management services. The service charges may be flat rates, or variable rates based on classes of customers. Utility service charges may represent a dedicated source of funding and an ongoing method of funding some or all storm water management programs.

Special Assessment: Properties can be assessed annually to fund storm water management programs. Often, special assessments are used to fund a special district or authority that can implement all or portions of a region's storm water management program.

Local Improvement Under this type of funding system, individual properties benefitted by storm water projects are assessed to fund the project. Some states require special enabling legislation to establish this type of special benefits district.

General Fund: General fund monies are used for may storm water programs. If storm water programs are funded from your General Fund, the programs are at risk in each budget cycle. In addition, in order to increase funding levels for your program, other local government services may be affected or a general tax increase may be required.

Inspection Fees: Plan review and inspection fees allows the community to recover some or all of the direct cost associated with performing design reviews for pre and post construction BMP's.

Developer Fees: The developers construct needed facilities as a condition of development and bear associated costs.

Alternative Fees: Instead of constructing on-site facilities to meet development requirements, developers may be given the option of paying a comparable fee to be used by the local government to build regional facilities that are designed to meet the same objectives as the developer-constructed on-site mitigation.

Connection Fees: A one time charge assessed at the time of development to recover a proportionate share of the cost of existing facilities and planned future facilities. The applicability depends upon legislation in each state.

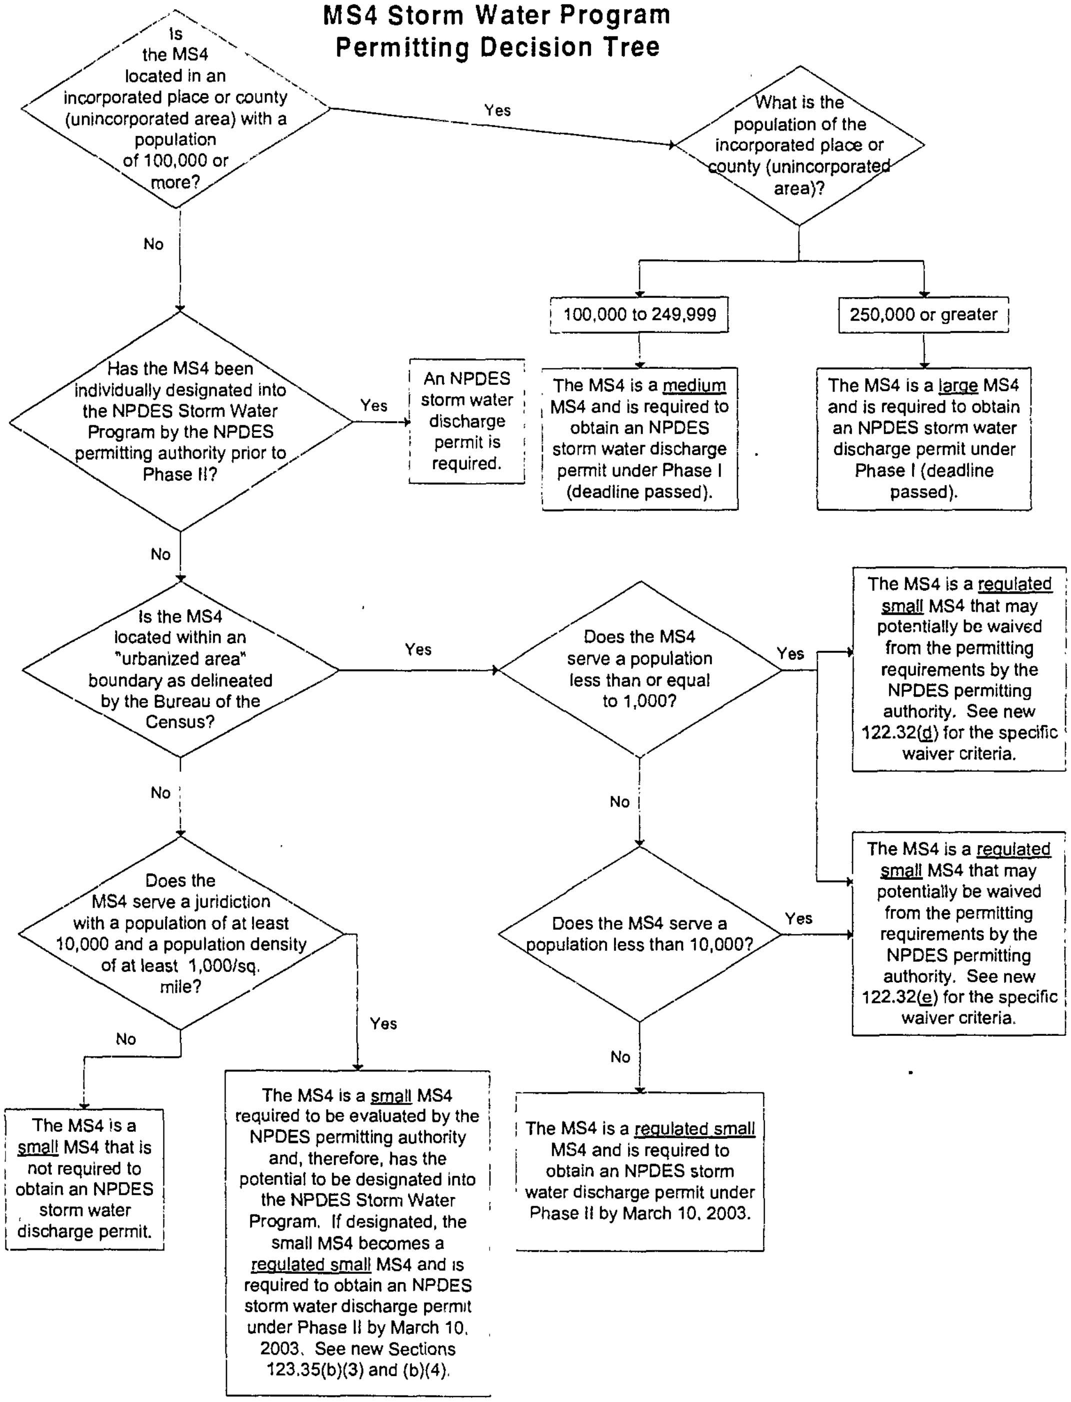
MS4 Storm Water Program Permitting Decision Tree



1. See Appendices F, G, H, and I to Part 122 (as revised by the Phase II Final Rule) for the list of incorporated places and counties (unincorporated areas) with a population of 100,000 or greater. If the MS4 is located in a listed entity, then the answer to this question is "Yes" and the MS4 is covered under the Phase I MS4 program as a medium or large MS4.

5.0 SMALL CONSTRUCTION ACTIVITY

After reading Section 5.0, you should understand what type of construction activity is subject to the Phase II small construction activity regulations (including who may be waived from coverage), who is considered an operator of small construction activity, the permit options and requirements for small construction activity, and the interaction of the NPDES storm water program for construction with the NPDES storm water program for regulated MS4s. The discussion of these elements concludes with a step-by-step review of the process for compliance with the Phase II regulations for small construction activity.

5.1 COVERAGE: Who Is Subject to the Phase II Rule?

The NPDES Storm Water Program defines construction activities as "small" and "large" for the purposes of regulation. The Phase I storm water program covers large construction activity. The Phase II storm water regulation covers small construction activity. To understand who is covered under the Phase II Rule, it is necessary to understand who is already covered under the Phase I Rule. Toward this end, this section provides a definition of the type of construction activity covered by Phase I and Phase II, as well as other definitions essential to understanding the construction component of the NPDES Storm Water Program.

5.1.1 What Type of Construction Activity Is Covered Under the Phase I Regulations?

The Phase I Rule identifies eleven categories of industrial activity in the definition of "storm water discharge associated with industrial activity" that must obtain an NPDES storm water discharge permit (see section 6.1). Category (x) of this definition includes construction activity (including clearing, grading and excavation) that results in ***a total land disturbance of 5 acres or greater***. Disturbances of less than 5 acres are also regulated under category (x) if they are part of a "larger common plan of development or sale" with a planned land disturbance of 5 acres or greater. Phase I construction activity is commonly referred to as "large"

Construction activities can include road building, construction of residential houses, office buildings, industrial sites, or demolition.

Land Disturbance means exposed soil due to clearing, grading, or excavation activities.

Larger common plan of development or sale describes a situation in which multiple construction activities are occurring, or will occur, on a contiguous area.

An operator is the person or persons that has either operational control of construction project plans and specifications, or day-to-day operational control of activities necessary to ensure compliance with storm water permit

R0010656

construction activity. The Phase I rule requires all operators of large construction activity to obtain an NPDES storm water discharge permit before discharging storm water runoff to a municipal separate storm sewer system or waters of the United States.

5.1.2 What Type of Construction Activity Is Covered Under the Phase II Regulations?

In 1992, the Ninth Circuit court remanded for further proceedings the portion of EPA's Phase I storm water regulation related to category (x) construction activity (NRDC v. EPA, 966 F.2d at 1292). EPA responded to the court's decision by designating under Phase II storm water discharges from construction site activities that ultimately will result in a ***land disturbance of equal to or greater than 1 and less than 5 acres*** as "storm water discharges associated with *small construction* activity" (see § 122.26(b)(15)). The Phase II rule requires all operators of small construction activity to obtain an NPDES storm water discharge permit before discharging storm water runoff to a municipal separate storm sewer system or waters of the United States.

Construction activities disturbing less than 1 acre are also included in Phase II of the NPDES storm water program if they are part of a larger common plan of development or sale with a planned disturbance of equal to or greater than 1 acre and less than 5 acres, or if they are designated by the NPDES permitting authority. The NPDES permitting authority or EPA Region may designate construction activities disturbing less than 1 acre based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants to waters of the United States.

The definition of small construction activity does not apply where the construction operator can certify to one of two waivers – see section 5.2 for more information on waiver options.

5.1.3 What is meant by the terms "land disturbance," "larger common plan of development or sale," and "operator" of a construction site?

The definitions of "land disturbance," "larger common plan of development or sale," and "operator" of a construction site are key in understanding coverage under the NPDES Storm Water Program for construction activity. These definitions originate from the NPDES storm water general permit for large construction activity.

- **Land disturbance** refers to exposed soil resulting from activities such as clearing, grading and excavating.

- **Larger common plan of development or sale** is a contiguous area where multiple separate and distinct construction activities are occurring under one plan (e.g., the operator is building on three half-acre lots in a 6-acre development). The "plan" in a common plan of development or sale is broadly defined as any announcement or piece of documentation (including a sign, public notice or hearing, sales pitch, advertisement, drawing, permit application, zoning request, computer design, etc.) or physical demarcation (including boundary signs, lot stakes, surveyor markings, etc.) indicating that construction activities may occur on a specific plot.

- **An operator** of a construction site is the person (or persons) responsible for obtaining coverage under an NPDES storm water permit for construction activity, and complying with the permit requirements. An operator is the person or persons that meet either of the following criteria:

  - Has operational control of construction project plans and specifications, including the ability to make modifications to those plans and specifications; or

  - Has day-to-day operational control of those activities at a project which are necessary to ensure compliance with a storm water pollution prevention plan (SWPPP) for the site or other permit conditions (e.g., they are authorized to direct workers at a site to carry out activities required by the SWPPP or comply with other permit conditions).

  There may be more than one party at a site responsible for "operational control." Depending on the project and the distinction between the parties' (e.g., owner's vs. developer's) responsibilities, there can either be a single party acting as a site operator needing permit coverage or there can be two (or more) operators who may share permit responsibilities. In cases where there are two or more operators , both parties will need permit coverage if they choose to keep the responsibilities as described in the above bullets separate, or they choose to separately maintain operational control for different portions of the site, etc. In such cases both operators should obtain permit coverage as co-permittees by co-submitting separate Notice of Intent forms, and should share in meeting permit conditions (e.g., generating the storm water pollution prevention plan, performing inspections, etc.). The option to have one sole operator who is willing to assume complete responsibility / liability for all permit requirements still exists and, in many cases, may be the less overall burdensome way to comply with storm water requirements.

  There are other instances where parties conduct earth disturbing activities at a site but do not need their own permit coverage. Examples for whom this may apply include a subcontractor who is under the supervision of the operator, or an entity that is neither a subcontractor nor has operational control (e.g., a utility line installer).

  Additional information on the responsibilities of operators can be found in Part III.E of EPA's NPDES Construction General Permit, published on February 17, 1998 (63 FR 7858). Part II of the fact sheet contained in the NPDES Construction General Permit also provides answers to common questions regarding roles and responsibilities of different parties involved on a construction site.

Important note: NPDES-authorized States may use a different definition of "operator" than the one provided above.

5.2 WAIVERS: Which Small Construction Activity Sites May Obtain a Waiver From Coverage?

Under the Phase II Rule, NPDES permitting authorities have the option of providing a waiver from Phase II coverage and requirements to operators of small construction activity who certify to one of two conditions:

- Low predicted rainfall potential (i.e., activity occurs during a negligible rainfall period), where the rainfall erosivity factor ("R" in the Revised Universal Soil Loss Equation [RUSLE]) would be less than 5 during the period of construction activity.
- A determination that storm water controls are not necessary based on either:

    (A) A "total maximum daily load" (TMDL) that address the pollutant(s) of concern for construction activities; **OR**

    (B) For nonimpaired waters that don't require TMDLs, an equivalent analysis that determines allocations for small construction sites for the pollutants of concern or determines that such allocations are not needed to protect water quality based on consideration of instream concentrations, expected growth in pollutant concentrations from all sources, and a margin of safety.

Pollutants of concern include sediment or a parameter that addresses sediment (such as total suspended solids, turbidity, or siltation) and any other pollutant that has been identified as a cause of impairment of a receiving waterbody.

The intent of these waiver provisions (see §§ 122.26(b)(15)(A) and(B)) is to waive only those sites that are highly unlikely to have a negative effect on water quality. Therefore, before applying for a waiver, operators of small construction activity are encouraged to consider the potential water quality impacts that may result from their project and to carefully examine such factors as proximity to water resources and sensitivity of receiving waters. Small construction activities disturbing less than 1 acre that are designated by the permitting authority are not eligible for these waivers.

5.2.1 Waiver 1: The Rainfall Erosivity Factor Waiver

The Rainfall Erosivity Factor waiver is based on the potential for a construction activity to occur in an area, or during a certain period of time, where there is low predicted rainfall potential and, therefore, less likelihood of causing impacts. This waiver is time-sensitive and is dependent on when during the year a construction activity takes place, how long it lasts, and the expected rainfall and intensity during that time. It creates an incentive for construction site operators to build during the dry part of the year.

How would an operator qualify for, and certify to, this waiver?

To qualify for this waiver, the construction site operator must determine the value of the rainfall erosivity factor (R factor) in the Revised Universal Soil Loss Equation (RUSLE) and then certify to the permitting authority that the value of the factor is less than 5 during the period of construction. The RUSLE is a refinement of the Universal Soil Loss Equation (USLE), which is a method developed by the U.S. Department of Agriculture to measure soil loss from agricultural lands at various times of the year on a regional basis. The R factor varies based on location and time period during the year.

A construction site operator will need site-specific data to calculate the values for rainfall erosivity using the RUSLE. The rainfall erosivity factor is determined in accordance with Chapter 2 of *Agriculture Handbook Number 703, Predicting Soil Erosion by Water: A Guide to Conservation Planning With the Revised Universal Soil Loss Equation (RUSLE).* This handbook is no longer in print but Chapter 2 can be obtained from EPA's web site or by contacting EPA's Water Resource Center.

5.2.1 Waiver 2: The Water Quality Waiver

The Water Quality waiver consists of: 1) a component for small construction sites that will discharge to an impaired waterbody where total maximum daily load (TMDL) assessments have been performed, and 2) a component for small construction sites that will discharge to non-impaired waters where an analysis equivalent to the TMDL assessments have been performed.

For impaired waters where technology-based controls required by NPDES permits are not achieving State water quality standards, the CWA requires implementation of the TMDL process.

> The **TMDL process** establishes the maximum amount of pollutants a waterbody can assimilate before water quality is impaired, then requires that this maximum level not be exceeded. A TMDL assessment determines the source or sources of a pollutant of concern, considers the maximum allowable level of that pollutant for the waterbody, then allocates to each source or category of sources a set level of the pollutant that it is allowed to discharge into the waterbody. Allocations to point sources are called

A TMDL is developed for each pollutant that is found to be contributing to the impairment of a waterbody or a segment of a waterbody. To allow a waiver for construction activities, a TMDL would need to address sediment, or a parameter that addresses sediment such as total suspended solids, turbidity, or siltation. Additional TMDLs addressing common pollutants from construction sites such as nitrogen, phosphorus, and oil and grease also may be necessary to ensure water quality protection and allow a waiver from the NPDES storm water program. More information on TMDLs can be found at http://www.epa.gov/owow/tmdl/.

Non-impaired waterbodies do not require TMDL assessments. However, construction site operators that discharge to non-impaired waterbodies are still eligible for this waiver. A construction site operator is eligible for a waiver if an analysis equivalent to a TMDL assessment is conducted for the pollutants of concern and it is determined through this analysis that small construction sites would not have to control their contribution of pollutants of concern to the waterbody to protect water quality. The analysis may also determine that allocations are not needed to protect water quality based on consideration of variables including existing in-stream concentrations; expected growth in pollutant contributions from all sources; and a margin of safety. In this situation, the construction site operator also qualifies for a waiver.

How would an operator qualify for, and certify to, this waiver?

EPA expects that when TMDLs, or equivalent analyses are completed, there may be a determination that certain classes of sources, such as small construction sites, would not have to control their contribution of pollutants of concern to the waterbody in order for the waterbody to be in attainment with water quality standards (i.e., these sources were not assigned wasteload allocations). In such a case, to qualify for the Water Quality waiver, the operator of the construction site would need to certify that its construction activity will take place, and the storm water discharges will occur, within the area covered either by the TMDLs or equivalent analysis. A certification form would likely be provided by the NPDES permitting authority.

5.3 PERMIT OPTIONS

The Storm Water Phase II Rule requires operators of small construction activities to obtain National Pollutant Discharge Elimination System (NPDES) permit coverage because their storm water discharges are considered "point sources" of pollution. Point source pollutant discharges, unlike nonpoint sources such as agricultural runoff, are required under the Clean Water Act (CWA) to be covered by federally enforceable NPDES permits.

NPDES storm water permits are issued by an NPDES permitting authority, which may be an NPDES-authorized State or a U.S. EPA Region in non-authorized States (see *Appendix A* for a list of U.S. EPA Regions). Once a permit application is submitted by the operator of a small construction activity, the conditions of the permit must be satisfied (i.e., implementation of a storm water pollution prevention plan). This section addresses the permit options under the Phase II regulations for operators of small construction activity, as well as for the permitting authority. The permit requirements are discussed in Section 5.4.

5.3.1 For Operators of Small Construction Activity: What Types of Permit Coverage Are Available?

Similar to the Phase I program for large construction activity, the Phase II approach allows operators of small construction activities to choose between two permitting options. Each NPDES permitting authority has the discretion, however, to determine which options are available to operators of small construction activities in their jurisdiction.

1) General Permits

General permits are strongly encouraged by EPA for small construction activity. EPA anticipates that the existing general permit for large construction activity will serve as a model for small construction activity general permits.

General permits prescribe one set of requirements for all applicable permittees. General permits are drafted by the NPDES permitting authority, then published for public comment before being finalized and issued.

A Notice of Intent (NOI) serves as the application for the general permit. Under the Phase II Rule, NPDES permitting authorities have the discretion to not require submittal of an NOI under a general permit for small construction activity.

Small construction operators must submit an NOI and obtain coverage under a general permit by March 10, 2003 or an earlier date set by the permitting authority (if this option is available).

2) Individual Permits

NPDES permitting authorities may deny coverage under general permits and require operators to submit an individual NPDES permit application based on information such as water quality data.

In the event that an NPDES permitting authority decides to issue an individual construction permit for small construction activity, operators are subject to the individual application requirements found at 40 CFR §122.26(c)(1)(ii).

For any discharges of storm water associated with small construction activity identified in §122.26(b)(15) that are not authorized by a general permit, an individual permit application must be submitted to the permitting authority by

March 10, 2003.

5.3.2 For the NPDES Permitting Authority

5.3.2.1 Alternative Option for Writing Permit Requirements: Referencing a Qualifying State, Tribal or Local Erosion and Sediment Control Program

Under §122.44(s) of the Phase II Rule, permitting authorities have the flexibility to develop permit conditions that incorporate by reference qualifying State, Tribal, or local erosion and sediment control programs into permits for large and small construction activity.

To be considered a qualifying State, Tribal, or local program, the program must require construction site operators to:

- Implement appropriate erosion and sediment control BMPs;
- Control waste such as discarded building materials, concrete truck washout, chemicals, litter, and sanitary waste at the site that may cause adverse impacts to water quality;
- Submit a site plan for review that incorporates consideration of potential water quality impacts; and
- Develop and implement a storm water pollution prevention plan (SWPPP) containing elements similar to those required by other NPDES construction storm water permits.

In addition to these elements, a qualifying program for large construction activities must also include any additional requirements necessary to achieve the applicable technology-based standards of "Best Available Technology" (BAT) and "Best Conventional Technology" (BCT) based on the best professional judgment of the permit writer.

> **Important Note:** Not all the construction programs administered by NPDES-permitted MS4s would qualify. A primary reason for this is because NPDES-permitted MS4s are not obligated under their permit to require construction operators to develop a SWPPP.

Should a State, Tribal, or local program include one or more, but not all, of the elements listed above, the NPDES permitting authority can reference the program in the permit, provided it also lists the missing element(s) as a condition in the permit.

5.3.2.2 Permit Application: Optional Use of NOIs

Under the Phase II Rule, EPA is providing NPDES permitting authorities with the discretion to not require NOIs under a general permit for discharges from small construction activity, if desired. EPA does, however, recommend the use of NOIs for tracking permit coverage and prioritizing inspections and enforcement. This alternative option does not apply to general permits for large construction activity.

5.4 PERMIT REQUIREMENTS

The Phase II Rule requires operators of small construction sites, nationally, to obtain an NPDES permit and implement practices to minimize pollutant runoff. The Phase II Rule directs permitting authorities to develop and issue permits for small construction activity no later than December 9, 2002. Operators of small construction activity will be required to obtain permit coverage by March 10, 2003, or an earlier date set by the permitting authority. However, operators may have to comply with local, State, or Tribal construction runoff control programs (see section 4.6.2.4 for information on the Phase II small MS4's construction program).

For the Phase II small construction program, EPA has taken an approach similar to Phase I where the program requirements are not fully defined in the rule but rather in the NPDES permit by the NPDES permitting authority. EPA recommends that the NPDES permitting authorities use their existing Phase I NPDES construction general permits as a guide to developing their Phase II construction permits. In doing so, the Phase II requirements would be similar to the Phase I requirements described in subsection 5.4.2, although the applicable standards for small construction activity are different as outlined in subsection 5.4.1.

5.4.1 Applicable Water Quality Standards

Unlike the technology-based standards of BAT and BCT that are applicable to large construction activity, an operator of small construction activity is required to design its pollutant control plan so that it:

- Protects water quality (under CWA section 402(p)(6)); and
- Satisfies the appropriate water quality requirements of the CWA.

The water quality standards for large and small construction activity are different because they were designated into the NPDES storm water program under two separate sections of the CWA with differing standards Practically, though, the standard for small construction activity would be substantively the same as the standard for large construction activity.

5.4.2 Potential Small Construction Activity Permit Requirements

EPA currently has only one type of permit available for construction activity operators, the NPDES Construction General Permit. This permit provides coverage to large construction activities only. EPA expects any general permit for small construction activity to be very similar to the CGP. To gain familiarity with the CGP, the three main elements of the CGP are included below.

> **Important note:** This section on the CGP requirements is included for informational purposes only in order to provide a sense of what the permit requirements for small construction activity may be – these are not the requirements for small construction activity.

5.4.2.1 Notice of Intent

A complete and accurate NOI must be submitted to the NPDES permitting authority. An NOI includes general information and a certification that the activity will not impact endangered or threatened species. This certification is unique to EPA's NOI and is not a requirement of most NPDES-delegated State's NOIs.

An NOI must be postmarked at least two days prior to commencement of any work on site (if the operator has control over plans and specifications) or two days prior to commencement of the operator's portion of the work (if the operator has only day-to-day operational control).

5.4.2.2 Storm Water Pollution Prevention Plan (SWPPP)

The most important requirement of the CGP is the construction storm water pollution prevention plan (SWPPP) that includes the appropriate BMPs to minimize the discharge of pollutants from the site. The CGP requires at least one SWPPP for each construction project or site.

The construction site operator, or operators, must develop the SWPPP prior to submitting the NOI to obtain permit coverage. Unlike the NOI and other reporting forms, the operator(s) does not submit the SWPPP to the permitting authority. Instead, the SWPPP remains onsite and made accessible according to the requirements described in the CGP.

The SWPPP comprises several elements:

- **Site description.** This will contain a description of potential pollutant sources and other information.
- **Controls (BMPs).** This part of the SWPPP must clearly describe not only the controls, but also the timing and responsible permittee for implementing the controls in the following categories:
    - Erosion and Sediment Controls
    - Storm Water Management Controls

- Other Controls

- **Inspections.** Another critical element of the SWPPP is regular inspections of disturbed areas of the site that has not been stabilized; exposed materials storage areas; structural controls; and vehicle entrances and exits.

- **Maintenance.** The SWPPP also requires that operators perform maintenance on the controls (BMPs) to ensure they are in effective operating condition.

- **Signatures.** The SWPPP must be signed by at least one of the persons responsible for submitting an NOI for the project.

- **Accessibility.** The CGP requires the operator(s) to retain a copy of the SWPPP at the construction site or other local location accessible to the permitting authority.

More information on the construction SWPPP requirements can be found in the CGP, published on February 17, 1998 (63 *FR* 7858, p. 7906). EPA has also issued a construction general permit for Regions IV and VI. Contact your EPA Regional office or State environmental agency for information on construction permits in your State. In addition, EPA published a construction SWPPP guidance in a document entitled *Storm Water Management for Construction Activities: Developing Storm Water Pollution Prevention Plans and Best Management Practices* (EPA 832-R-92-005, September 1992).

5.4.2.3 Notice of Termination (NOT)

A completed Notice of Termination (NOT) must be submitted to the NPDES permitting authority within 30 days after one or more of the following conditions have been met:

- Final stabilization has been achieved on all portions of the site for which the permittee is responsible;

- Another operator/permittee has assumed control over all areas of the site that have not been finally stabilized; or

- For residential construction only: temporary stabilization of a lot has been completed prior to transference of ownership to the homeowner, with the homeowner being made aware of the need to perform final stabilization.

5.5 INTEGRATION OF NPDES PROGRAM FOR CONSTRUCTION WITH NPDES PROGRAM FOR MS4S

There is often confusion about the interaction between the NPDES Storm Water Program for construction activity, which has been the topic of discussion in this section, and the construction runoff control program implemented by NPDES-regulated MS4s, which was the topic of discussion in section 4.6.2.4.

- These are two separate and distinct construction programs.

- A construction operator is subject to requirements under BOTH programs if it is located in an NPDES-regulated MS4's jurisdiction.

The NPDES Storm Water Program for Construction is administered by the NPDES permitting authority, either the State or an EPA Regional Office.

- This program requires the construction site operator to seek coverage under an NPDES storm water discharge permit for construction. The current permit, the Construction General Permit, requires the operator to submit an NOI, develop a SWPPP, and comply with other applicable NPDES storm water discharge permit requirements.

- The Construction General Permit (CGP) currently only applies to large construction activity disturbing greater than 5 acres. Permits for small construction activity will be issued by each NPDES permitting authority by December 9, 2002.

The NPDES Storm Water Program for MS4s: MS4 Construction Runoff Control Programs are administered by the MS4 operator. The MS4 operator's NPDES storm water discharge permit requires it to establish requirements to control storm water discharges from construction activity and new development and redevelopment.

- Regulated small MS4s must control 1 acre and above.

- Medium and large MS4s have no particular size thresholds that they must control – differs among MS4s

- The specific requirements of the construction programs will vary among MS4s. An MS4 permit typically does not specify that the MS4 operator must require a SWPPP or that a permit application be submitted.

5.6 SMALL CONSTRUCTION ACTIVITY COMPLIANCE PROCESS: What Do I Need To Do To Comply?

Sections 5.1 through 5.5 of this guidance have provided details on who's covered, who may be waived, and what may be required under the Phase II regulations for small construction activity. Now that you are familiar with the Phase II program, this section walks you through the process, from beginning to end, that an operator of a small construction activity should take to comply with the regulation. This step-by-step "walk-through" assumes the issuance of a general permit for small construction activity that is similar to the CGP. Remember, the general permit for small construction activity may have different requirements, timeframes, and deadlines than what is noted here. Repeat the steps for each individual construction site.

The last page of this section includes a permitting decision tree to help operators of construction activity determine if they need an NPDES storm water permit. By starting in the upper left hand corner, an operator can follow the decision tree to determine if they fall under Phase I, Phase II, or are eligible for a waiver.

Step 1: Determine if your construction site will discharge storm water runoff into a MS4 (see section 4.1.1 for definition) or to waters of the United States. If so, proceed to Step 2. If not, stop here.

> ***Waters of the United States*** include interstate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation, or destruction of which would affect or could affect interstate or foreign commerce. (Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA are not waters of the United States.) A complete definition can be found at 40 CFR 122.2.

Step 2: Determine if your construction site's storm water discharge will meet the definition of a "storm water discharge associated with small construction activity." If so, proceed to Step 3. If not, stop here. (See section 5.1.2)

Step 3: If your site meets the definition of small construction activity, determine if it qualifies for a waiver from the permit requirements. If so, stop here. If not, proceed to Step 4. (See section 5.2)

Step 4: Obtain and read the applicable storm water discharge permit for small construction activity (or the CGP until the small construction permit has been issued to get a sense of the upcoming permit requirements). The small construction permit should be issued by the NPDES permitting authority by December 9, 2002. (See section 5.4.2 for potential requirements)

Step 5: Determine which parties are considered *operators* and, therefore, are responsible for complying with the requirements described in the storm water permit for small construction activity (See section 5.1.3)

Step 6: Develop a SWPPP. (See section 5.4.2.2)

- SWPPPs must be developed prior to submitting the NOI.
- You do not need to submit the SWPPP to your NPDES permitting authority, however, it should be accessible to the public.

Step 7: Complete and submit an NOI. (See section 5.4.2.1)

- Your NPDES permitting authority may or may not require a NOI. If so, the Phase II regulation requires that you submit your NOI no later than March 10, 2003 (or 90 days after the NPDES permitting authority issues the permit, whichever comes first).
- Submit a completed NOI to your NPDES permitting authority two days prior to beginning work at the construction site.

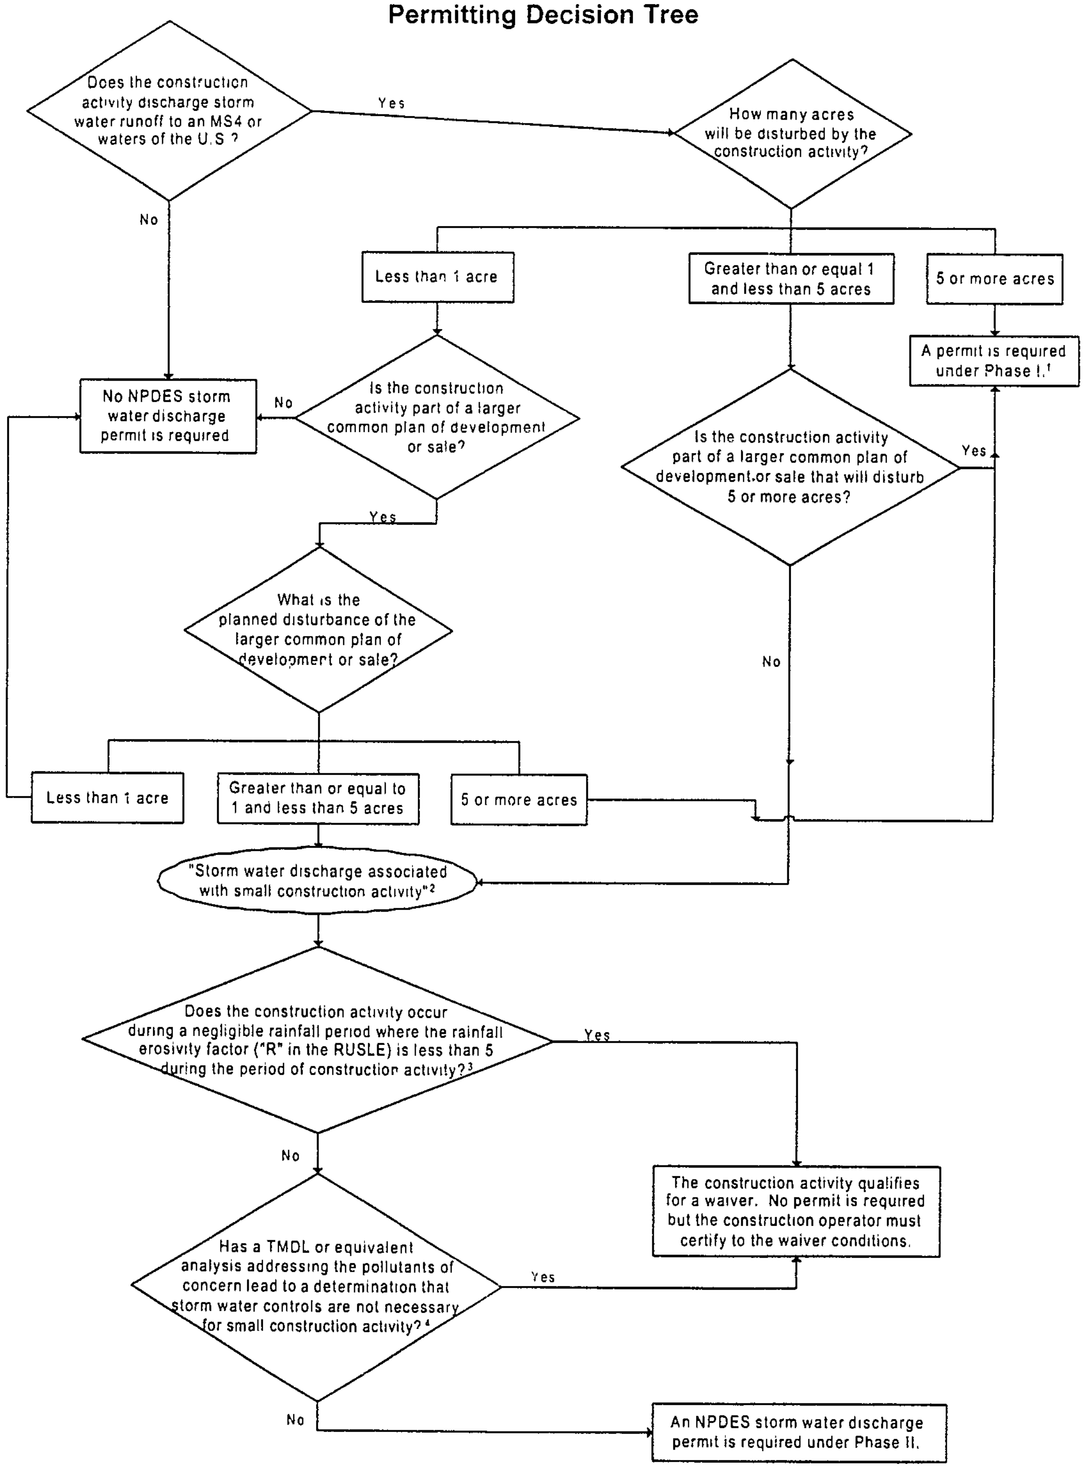
Step 8: Implement the SWPPP.

- Includes generation of inspection reports that are to be kept on-site.

Step 9: Complete and submit an NOT. (See section 5.4.2.3)

- Submit a completed NOT to your NPDES permitting authority within 30 days after one or more of the appropriate conditions have been met.

Construction Activities Storm Water Program Permitting Decision Tree



1. Construction activity disturbing, or part of a planned disturbance of five or more acres is a "storm water discharge associated with industrial activity" under category (x). See 40 CFR 122.26(b)(14)(x)
2. See new 122.26(b)(15) for the definition of "storm water discharge associated with small construction activity."
3. See new 122.26(b)(15)(i)(A) for more details
4. See new 122.26(b)(15)(i)(B) for more details.

R0010670

6.0 INDUSTRIAL ACTIVITY

After reading section 6.0, you should understand the basic components and requirements of the Phase II regulations as they affect the categories of industrial activity covered by the Phase I regulations. Phase II revises the original Phase I industrial no exposure exemption and also sets a new deadline for permit coverage for the municipally-owned industrial activity that had been temporarily exempted from storm water permit coverage.

6.1 PHASE I INDUSTRIAL ACTIVITY: What Industrial Activities are Covered by Phase I of EPA's Storm Water Program?

The 1990 storm water regulations for Phase I of the federal storm water program identify eleven categories of industrial activities under the definition of a "storm water discharge associated with industrial activity" that must obtain a National Pollutant Discharge Elimination System (NPDES) permit. The categories contain industries listed either by reference to an industry's Standard Industrial Classification (SIC) code, or by a short narrative description of the activity found at the industrial site (see text box at right for more detailed descriptions). For facilities that match the SIC codes or description in one of the categories, only those that have a storm water discharge to a *municipal separate storm sewer system (MS4)* or *waters of the United States* are required to seek permit coverage. The NPDES permit requirements vary between individual and general permits, but in general involve the development of a storm water pollution prevention plan based upon site assessments, monitoring and reporting data on storm water discharges, and mitigating any possible effects of discharges on endangered species and national historic properties (for EPA issued permits).

Storm Water Discharge Associated with Industrial Activity (40 CFR 122.26(b)(14)(i) - (xi))

- Facilities subject to storm water effluent limitation guidelines; new source performance standards, or toxic pollutant effluent standards under 40 CFR Subchapter N.
- "Heavy" industrial facilities with SIC codes listed in 40 CFR 122.26(b)(14)(ii), (iii), and (vi)
- "Light" industrial facilities with SIC codes listed in 40 CFR 122.26(b)(14)(xi), which conduct the activities specified in that sections.
- Hazardous waste treatment, storage, or disposal facilities.
- Landfills, land application sites, and open dumps that receive or have received industrial waste.
- Steam electric power generating facilities.
- Sewage treatment works.
- Construction activity (including clearing, grading, and excavation) disturbing five or more acres of land, or less than five acres of land if it is part of a larger common plan of development or sale of five acre or greater.

R0010671

Under the Phase I regulations, operators of facilities within category eleven (xi), commonly referred to as "light industry," were exempted from the definition of "storm water discharge associated with industrial activity," and the subsequent requirement to obtain an NPDES permit, provided their industrial materials or activities were not "exposed" to storm water. This Phase I no exposure exemption from permitting was limited to those facilities identified in category (xi), and did not require category (xi) facility operators to submit any information supporting their no exposure claim.

In 1992, the Ninth Circuit court remanded to EPA for further rulemaking the no exposure exemption for light industry after making a determination that the limited exemption was arbitrary and capricious. The result was a revised no exposure exemption (now an "exclusion") as part of the Phase II regulation.

6.2 PHASE II NO EXPOSURE EXCLUSION: What is the Conditional No Exposure Exclusion for Industrial Activity as Revised by this Regulation?

The intent of the no exposure provision is to provide a simplified method for complying with the Clean Water Act to all industrial facilities that are entirely indoors. This includes facilities that are located within a large office building, or at which the only items permanently exposed to precipitation are roofs, parking lots, vegetated areas, and other non-industrial areas or activities.

As revised in the Phase II regulation, if a condition of No Exposure exists at a Phase I industrial facility, then permits will not be required for storm water discharges from these facilities. All industrial facilities that have no exposure of materials to storm water, including the "light industrial" facilities, must submit a certification to the permitting authority. The facility must certify that a condition of No Exposure exists at its facility and either maintain a condition of no exposure or obtain a permit. The following subsections discuss who is eligible for the revised no exposure exclusion, the definition of no exposure, and the requirement to submit a written certification of no exposure in place of a permit application.

6.2.1 Who is Eligible to Qualify for the No Exposure Exclusion?

The Phase II Conditional No Exposure Exclusion represents a significant expansion in the scope of the original no exposure provision in terms of eligibility. Now, all Phase I industrial categories with a condition of no exposure, except for construction activity, are eligible for the no exposure exclusion. The exclusion from permitting is available on a facility-wide basis only, not for individual outfalls

6.2.2 What is the Definition of No Exposure?

The Phase II regulatory definition of no exposure is as follows:

> ***No exposure*** means all industrial materials and activities are protected

by a storm resistant shelter to prevent exposure to rain, snow, snowmelt, and/or runoff. Industrial materials or activities include, but are not limited to, material handling equipment or activities, industrial machinery, raw materials, intermediate products, by-products, final products, or waste products.

A storm resistant shelter is not required for the following industrial materials and activities:

- Drums, barrels, tanks, and similar containers that are tightly sealed, provided those containers are not deteriorated and do not leak. "Sealed" means banded or otherwise secured and without operational taps or valves;
- Adequately maintained vehicles used in materials handling;
- Final products, other than products that would be mobilized in storm water discharges (e.g., rock salt).

The term "storm-resistant shelter," as used in the no exposure definition, includes completely roofed and walled buildings or structures, as well as structures with only a top cover but no side coverings, provided material under the structure is not otherwise subject to any run-on and subsequent runoff of storm water.

While the intent of the no exposure provision is to promote a condition of permanent no exposure, certain machinery, such as trucks, may become temporarily exposed to rain and snow while passing between buildings. Adequately maintained mobile equipment (e.g., trucks, automobiles, forklifts, trailers, or other such general purpose vehicles found at the industrial site that are not industrial machinery, and that are not leaking contaminants or are not otherwise a source of industrial pollutants) also can be exposed to precipitation or runoff. Such activities alone would not prevent a facility from certifying to no exposure. Similarly, trucks or other vehicles awaiting maintenance at vehicle maintenance facilities that are not leaking contaminants or are not otherwise a source of industrial pollutants, would not be considered exposed.

EPA recognizes that there are circumstances where permanent no exposure of industrial activities or materials is not possible and, therefore, under such conditions, materials and activities could be sheltered with temporary covers (e.g., tarps) between periods of permanent enclosure. The No Exposure provision does not specify every such situation, but NPDES permitting authorities can address this issue on a case-by-case basis.

The Phase II regulation also addresses particulate matter emissions from roof stacks/vents. If regulated by, and in compliance with, other environmental protection programs (i.e., air quality control programs) and not causing storm water contamination, they are considered not exposed. Particulate matter or visible deposits of residuals from roof stacks and/or vents not otherwise regulated (i.e., under an air quality control program) and evident in storm water outflow are considered "exposed." Likewise, visible "track out" (i.e., pollutants carried on the tires of vehicles) or windblown raw materials are considered "exposed." Leaking pipes containing contaminants exposed to storm water are deemed "exposed," as are past sources of storm water contamination that remain onsite. General refuse and trash, not of an industrial nature, is not considered exposed as long as the container is completely covered and nothing can drain out holes in the bottom, or is lost in loading onto a garbage truck. Industrial refuse and trash that is left uncovered, however, is considered "exposed."

6.2.3 What Do I Need To Know About Certifying to a Condition of No Exposure?

In order to obtain the Conditional No Exposure exclusion, you will have to submit written certification that your facility meets the definition of "no exposure," even if you are a category (xi) facility operator. The Phase II Rule included as an appendix to the preamble a four-page No Exposure Certification form to be used for this purpose in areas where EPA is the NPDES permitting authority. EPA's certification form uses a series of yes/no questions which you must answer regarding the your industrial activity. You may certify to no exposure if you can answer "no" to all of the questions.

> **Important note:** EPA's No Exposure Certification form applies only in areas where EPA is the NPDES permitting authority. Where a State is the NPDES permitting authority, the State will issue its own form. Since most aspects of EPA's form are also regulatory requirements as to what must be included within a written certification of no exposure, you may expect the State forms to be very similar to EPA's.

The Certification form serves two purposes: 1) as an aid to help you in determining whether you have a condition of No Exposure at your facility or site, and 2) as the necessary written certification of No Exposure, provided you are able to answer all the questions in the negative.

- ❑ If, after you have completed the form, you find that you answered "yes" to one or more of the questions about possible exposure, you must make the appropriate changes at the facility if you still wish to apply for the conditional exclusion. These changes must remove the particular material, process, or activity at the facility or site from exposure to storm water.

- ❑ If, after completing the form, you find that you were able to check "no" to every question, you qualify for the no exposure exclusion and must sign and submit the form to your NPDES permitting authority.

Certification Facts:
- The certification must be completed and submitted to your permitting authority once every 5 years, and can only be done so if the condition of no exposure continues to exist at the facility.
- The Certification must be provided for each facility qualifying for the no exposure

exclusion.

- The form is non-transferable. If a new operator takes over your facility, they must complete, sign, and submit a new form to claim the no exposure exclusion when they assume control over the operations of the facility.

6.2.4 Are There Any Concerns Related to Water Quality Standards?

Yes. An operator certifying that its facility qualifies for the conditional no exposure exclusion may, nonetheless, be required by the permitting authority to obtain permit authorization. Such a requirement would follow the permitting authority's determination that the facility's discharge is likely to have an adverse impact on water quality.

Many efforts to achieve no exposure can employ simple good housekeeping and contaminant cleanup activities such as moving materials and activities indoors into existing buildings or structures. In limited cases, however, industrial operators may make major changes at a site to achieve no exposure. These efforts may include constructing a new building or cover to eliminate exposure or constructing structures to prevent run-on and storm water contact with industrial materials and activities. Major changes undertaken to achieve no exposure, however, can increase the impervious area of the site, such as when a building is placed in a formerly vegetated area. Increased impervious area can lead to an increase in the volume and velocity of storm water runoff, which, in turn, can result in a higher concentration of pollutants in the discharge, since fewer pollutants are naturally filtered out.

The concern of increased impervious area is addressed in one of the last questions on the Certification form, which asks, "Have you paved or roofed over a formerly exposed, pervious area in order to qualify for the no exposure exclusion? If yes, please indicate approximately how much area was paved or roofed over." This question is intended to aid the NPDES permitting authority in assessing the likelihood of such actions interfering with water quality standards. Where this is a concern, the facility operator and its NPDES permitting authority should take appropriate actions to ensure that water quality standards can be achieved.

6.2.5 Industrial Program Compliance Process: What Do I Need To Do To Obtain the No Exposure Exclusion and Comply with Applicable Requirements?

Sections 6.1 through 6.2.4. of this guidance have provided information necessary to understand the conditional no exposure exclusion. Now that you are familiar with the no exposure exclusion, this section walks you through the process, from beginning to end, that an operator of industrial activity will need to take to comply with the Phase II regulation. This step-by-step "walk-through" assumes the issuance of a no exposure certification form that is similar to EPA's form. Remember, a State's certification form may have different requirements and deadlines than what is noted here. Repeat the steps for each individual facility or site.

Step 1: Determine if your industrial activity meets the definition of a "discharge associated with industrial activity." If so, proceed to Step 2. If not, stop here. (See section 6.1)

- If you are a regulated industrial operator, you need to **either** apply for a storm water permit, **or** submit a no exposure certification, in order to be in compliance with the NPDES storm water regulations. Any storm water permit you may currently hold becomes null and void once a completed conditional no exposure certification form is submitted

Step 2: Obtain the no exposure certification form from your NPDES permitting authority. Determine if your regulated industrial activity meets the definition of " no exposure" and qualifies for the exclusion from permitting. If it does, proceed to Step 3. If not, stop here and obtain industrial storm water permit coverage (probably through the multi-sector general permit or similar permit).

- The conditional no exposure exclusion option is currently available only for facilities in areas where EPA is the NPDES permitting authority. In all other areas, where the State is the NPDES permitting authority, the facility operators will need to wait until the State makes the option available.

Step 3: Submit the certification form to your NPDES permitting authority -- a new form must be submitted once every 5 years.

- Be aware that even when you certify to no exposure, your NPDES permitting authority still retains the authority to require you to apply for an individual or general permit if it has determined that your discharge is contributing to the violation of, or interfering with the attainment or maintenance of, water quality standards, including designated uses.

Step 4: Submit a copy, upon request, of the certification form to the municipality in which the facility is located.

Step 5: Allow your NPDES permitting authority or, if discharging into a municipal separate storm sewer system, the operator of the system, to (1) inspect the facility and (2) make such inspection reports publicly available upon request.

Step 6: Maintain a condition of no exposure.

- The no exposure exclusion is conditional and not an outright exemption. Therefore, if there is a change in circumstances that causes exposure of industrial activities or materials to storm water, the you are required to comply immediately with all the requirements of the NPDES Storm Water Program, including applying for and obtaining a storm water discharge permit.

- Failure to maintain the condition of no exposure or obtain coverage under an NPDES permit can lead to the unauthorized discharge of pollutants to waters of the United States, resulting in penalties under the CWA.

6.3 ISTEA MORATORIUM: How Has this Regulation Affected the Municipally-Operated Industrial Activity Subject to the Intermodal Surface Transportation Enforcement Act (ISTEA) Moratorium?

Provisions within ISTEA temporarily delayed the deadline for Phase I industrial activities operated by municipalities with populations of less than 100,000 people to obtain an NPDES storm water discharge permit. Congress delayed the permitting deadline to allow small municipalities additional time to comply with NPDES requirements. This moratorium on permitting did not apply to power plants, airports, and uncontrolled sanitary landfills operated by small municipalities.

The Phase II Rule slightly extended this temporary exemption from permitting and set a deadline of no later than March 10, 2003 for all ISTEA-exempted municipally-operated industrial activities to obtain NPDES permit coverage. Of course, like any other regulated industrial activity, these municipally-operated industrial activities are eligible to qualify for the no exposure exclusion from permitting if a condition of no exposure exists. Municipal-operators must follow the same procedures outlined in Section 6.2.4 in order to obtain an exclusion from permitting.

Many of the small municipalities that will now have to obtain permit coverage for their industrial activity will also have to obtain permit coverage for their small MS4 (see section 4.0) and small construction activity (see section 5.0). The Phase II regulation deadlines for industrial, small MS4, and small construction permit coverage are all the same – no later than March 10, 2003 – to allow the NPDES permitting authority to issue one individual permit that covers all three components if it chooses to do so.

7.0 THE COMPLIANCE ASSURANCE PROCESS

After reading section 7, you should understand how EPA will determine compliance, what happens if you or the EPA discovers noncompliance, and where to go for compliance assistance information.

7.1 How Will EPA Determine Compliance?

EPA employs several approaches to monitor compliance with its environmental regulations, including both EPA-initiated and facility-initiated methods.

1. **Inspections** – EPA may conduct periodic inspections at facilities subject to this regulation. Inspections may be initiated by disclosures to EPA, randomly selecting facilities, or a variety of targeting methods. Inspections may be used, for instance, to monitor recordkeeping requirements, visit sites where storm water controls should be in place, and/or verify that facilities have permits.

2. **Permits, Records, and Reports** – Permits are not required for small construction sites and regulated small MS4s for up to three years and 90 days from the effective date of the final rule. After general permits are issued, the NPDES permitting authorities intend to use the data in storm water permit applications, construction waiver certifications, storm water pollution prevention plans (SWPPPs), no exposure certifications, records, and reports (as required by the Phase II regulation) to set appropriate permit conditions and track discharges covered by a storm water permit. Compliance and enforcement authorities will use the information to assess the regulated entity's level of compliance.

3. **Review of No Exposure Certifications** – Operators of industrial facilities that are eligible for a no exposure exclusion from the NPDES permitting requirements may prepare, and submit for review, a no exposure certification. NPDES authorities will use the information contained in the certification in determining compliance with the no exposure provisions. This information will particularly assist in determining compliance with the no exposure certification in conjunction with complaints from the public.

4. **Self-audit and Self Disclosure** – Facilities have the primary responsibility for ensuring that they are in continuous compliance. EPA encourages the facility to take advantage of EPA's Audit Policy, Small Business Policy, or Small Community Policy (these will be discussed in more detail in section 7.2).

   In addition to this document, to aid in determining whether it is in compliance, the facility might use a document currently being developed by EPA entitled "Protocol for Conducting Environmental Compliance Audits under the Storm

Water Program." This protocol, which is a part of a set containing other statute-specific audit protocols, is a tool to assist and encourage businesses and organizations to perform environmental audits and disclose violations in accordance with EPA's Audit Policy. The protocol provides guidance on key requirements, defines regulatory terms, gives an overview of the federal laws affecting a particular environmental management area, and includes a checklist for review of the facility: EPA anticipates making the document available for public use in summer 2000. To see a sample of protocols that have been completed under other statutes (RCRA, EPCRA, CERCLA), visit the Internet site: http://es.epa.gov/oeca/ccsmd/profile.html.

7.2 If I Discover a Violation, How Can I Work With The Agency to Correct It?

EPA promotes environmental compliance by providing incentives. By participating in compliance assistance programs or voluntarily disclosing violations and promptly correcting violations, businesses may get penalty waivers or reductions. EPA has three policies that potentially apply to entities regulated by the Storm Water Phase II Rule. These policies do not apply if an enforcement action has already been initiated.

Audit Policy. The first of these policies is *"Incentives for Self-Policing: Discovery, Disclosure, Correction and Prevention of Violations"* (60 FR 66706), known as the "Audit Policy". EPA initiated this policy to provide entities of all sizes with incentives to voluntarily discover and promptly disclose and correct violations of environmental regulations. For a more detailed description of the Audit Policy, visit the Internet site at: www.epa.gov/oeca/polguid/polyguid1.html.

Small Business Policy. EPA's *"Policy on Compliance Incentives for Small Business"* was developed to help small businesses with 100 or fewer employees achieve environmental compliance by creating benefits for businesses that make a good faith effort to comply with environmental regulations before a government agency discovers a violation or otherwise takes an enforcement action. The Policy currently provides incentives, such as penalty waivers or penalty reduction, for businesses that participate in on-site compliance assistance programs or conduct environmental audits to discover, disclose, and correct violations. The Policy is presently being modified to broaden when and how a small business can take advantage of the Policy. Revisions are expected in spring of 2000. Please see www.epa.gov/oeca/polguid or contact Ginger Gotliffe (202-564-7072) for more information.

Small Community Policy. The *"Policy on Flexible State Enforcement Responses to Small Community Violations"* (November 1995) promotes alternative strategies for communities to achieve environmental and economic goals. States are encouraged to use multimedia compliance assistance and prioritize compliance issues to address specific needs of their small communities. As long as states work within the parameters of the Policy, EPA will generally defer to their decision to waive part or all of the penalty for a small community's environmental violations. This approach allows small communities to apply their limited resources to fixing their environmental problems, rather than to paying penalties. The policy applies to communities generally comprised of fewer than 2,500 residents. In the context of the Storm Water Phase II Rule, small MS4s that are not eligible for waivers from their regulatory requirements would be most likely to take advantage of this policy. For a more detailed description of the Small Communities Policy, visit the Internet sites: www.epa.gov/oeca/scpolcy.html or www.epa.gov/oeca/ccsmd/mun.html.

7.3 Where Can I Go for Compliance Assistance on the Storm Water Phase II Rule?

The permitting authority is the leading source for information on the Storm Water Phase II Rule. EPA is also developing a "tool box" to assist States, Tribes, municipalities, and other parties involved in the Phase II program. This tool box will facilitate implementation of the storm water program in an effective and cost-efficient manner. The tool box is available on EPA's web page at http://www.epa.gov'owm/sw/phase2 and consists of the following eight major components:

- Fact Sheets
- Guidance Documents
- Menu of BMPs
- Training and Outreach Efforts
- Information Clearinghouse
- Technical Research
- Support for Demonstration Projects
- Compliance Monitoring/Assistance Tools

In addition, EPA provides widely available compliance assistance through the establishment of national compliance assistance centers, in partnership with industry, academic institutions, and other federal and state agencies. Centers have been established that provide services for several industries that contain many small businesses. Compliance assistance centers offer a range of communications services, including Web sites, e-mail groups, fax-back systems, and telephone assistance lines. Each Center is targeted to a specific sector and explains relevant federal environmental regulations. For instance, local governments can use the services of the Local Government Environmental Assistance Network (LGEAN). LGEAN is a "first-stop shop" providing environmental management, planning, and regulatory information for local government elected and appointed officials, managers, and staff. It provides 24-hour access to regulatory and pollution prevention information, message boards, regulatory updates, grants and information, and more. It is a good source for compliance assistance information on the Storm Water Phase II Rule.

For more information on EPA's compliance assistance centers, please contact Tracy Back (202-564-7076). You can access all the centers through www.epa.gov/oeca/mcfac.html or individually at:

EPA's Compliance Assistance Centers

Center	Phone	Web Address
Local Government Environmental Assistance Network (LGEAN)	1-877-TO-LGEAN	www.lgean.org

7.4 If the Agency Discovers a Violation, What Might Be Its Response?

To maximize compliance, EPA implements a balanced program of compliance assistance, compliance incentives, and traditional law enforcement. EPA knows that small businesses which must comply with complicated new statutes or rules often want to do the right thing, but may lack the requisite knowledge, resources, or skills. Compliance assistance information and technical advice helps small businesses to understand and meet their environmental obligations. Compliance incentives, such as our Small Business Policy, encourage persons to voluntarily discover, disclose, and correct violations before they are identified by the government. EPA's strong law enforcement program protects all of us by targeting persons who neither comply nor cooperate to address their problems.

EPA uses a variety of methods to determine whether regulated entities are complying, including inspecting facilities, reviewing records and reports, and responding to citizen complaints. If we learn an entity is violating the law, EPA (or a State, if the program is delegated) may file an enforcement action seeking penalties of up to $27,500, per violation, per day. While the statutory maximum penalty is currently $27,500, it may be increased periodically based on inflation in accordance with the Debt Collection Improvement Act of 1996. The proposed penalty in a given case will depend on many factors, including the number, length, and severity of the violations, the economic benefit obtained by the violator, and its ability to pay. EPA has polices in place to ensure penalties are calculated fairly. These policies are available to the public. In addition, any company charged with a violation has the right to contest EPA's allegations and proposed penalty before an impartial judge or jury.

EPA recognizes that we can achieve the greatest possible protection by encouraging businesses and organizations to work with us to discover, disclose, and correct violations. That is why we have issued Audit, Small Business, and Small Community policies to eliminate or reduce penalties for small and large entities which cooperate with EPA to address compliance problems. To help the regulated community in understanding their requirements for compliance with the rule, EPA provides compliance assistance through its regional offices, Office of Enforcement and Compliance Assurance at Headquarters, and national compliance assistance centers partners.

ABBREVIATIONS:

BAT	Best Available Technology Economically Achievable (applies to non-conventional and toxic pollutants)
BCT	Best Conventional Pollutant Control Technology (applies to conventional pollutants)
BMP	Best Management Practice
BPJ	Best Professional Judgment
BPT	Best Practicable Control Technology Currently Available (generally applies to conventional pollutants and some metals)
CFR	Code of Federal Regulations
CGP	Construction General Permit
COD	Chemical Oxygen Demand
CSO	Combined Sewer Overflow
CWA	Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972)
CZARA	Coastal Zone Act Reauthorization Amendments
D.O.	Dissolved Oxygen
DMR	Discharge Monitoring Report
ELG	Effluent Limitations Guidelines
EPA	Environmental Protection Agency
FR	Federal Register
MEP	Maximum Extent Practicable
MS4	Municipal Separate Storm Sewer System
MSGP	Multi Sector General Permit
NOI	Notice of Intent
NOT	Notice of Termination
NOV	Notice of Violation
NPDES	National Pollutant Discharge Elimination System
NPS	Non-point Source
O&M	Operation and Maintenance
OW	Office of Water
OWM	Office of Wastewater Management
PA	Permitting Authority
POTW	Publicly Owned Treatment Works
SIC	Standard Industrial Classification
SWPPP	Storm Water Pollution Prevention Plan
TMDL	Total Maximum Daily Load
TSS	Total Suspended Solids
UA	Urbanized Area

DEFINITIONS:

Best Available Treatment(BAT)/Best Control Technology (BCT): A level of technology based on the very best (state of the art) control and treatment measures that have been developed or are capable of being developed and that are economically achievable within the appropriate industrial category.

Best Management Practices (BMPs): Activities or structural improvements that help reduce the quantity and improve the quality of storm water runoff. BMPs include treatment requirements, operating procedures, and practices to control site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

Category (xi) facilities: Specific facilities classified as light industry with equipment or materials exposed to storm water.

Clean Water Act (Water Quality Act): (formerly the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972). Public law 92-500; 33 U.S.C. 1251 et seq.; legislation which provides statutory authority for the NPDES program. Also know as the Federal Water Pollution Control Act.

Conveyance: The process of water moving from one place to another.

Discharge: The volume of water (and suspended sediment if surface water) that passes a given location within a given period of time.

Erosion: When land is diminished or worn away due to wind, water, or glacial ice. Often the eroded debris (silt or sediment) becomes a pollutant via storm water runoff. Erosion occurs naturally but can be intensified by land clearing activities such as farming, development, road-building, and timber harvesting.

Excavation: The process of removing earth, stone, or other materials from land.

General Permit: A permit issued under the NPDES program to cover a certain class or category of storm water discharges. These permits reduce the administrative burden of permitting storm water discharges.

Grading: The cutting and/or filling of the land surface to a desired slope or elevation.

Illicit Connection: Any discharge to a municipal separate storm sewer that is not composed entirely of storm water and is not authorized by an NPDES permit, with some exceptions (e.g., discharges due to fire fighting activities).

Industrial Activity: Any activity which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant.

Large Municipal Separate Storm Sewer System (MS4): An MS4 located in an incorporated place or county with a population of 250,000 or more, as determined by the latest U.S. Census

Light Manufacturing Facilities: Described under Category (xi) of the definition of "storm water discharges associated with industrial activity." [40 CFR 122.26(b)(14)(xi)] Under the Phase I NPDES Storm Water Program, these facilities were eligible for exemption from storm water permitting requirements if certain areas and activities were not exposed to storm water. As a result of the Phase II Final Rule, these facilities must now certify to a condition of no exposure.

Maximum Extent Practicable (MEP): A standard for water quality that applies to all MS4 operators regulated under the NPDES Storm Water Program. Since no precise definition of MEP exists, it allows for maximum flexibility on the part of MS4 operators as they develop and implement their programs.

Medium Municipal Separate Storm Sewer System (MS4): MS4 located in an incorporated place or county with a population of 100,000 or more but less than 250,000, as determined by the latest U.S. Census.

Municipal Separate Storm Sewer System (MS4): A publically-owned conveyance or system of conveyances that discharges to waters of the U.S. and is designed or used for collecting or conveying storm water, is not a combined sewer, and is not part of a publicly-owned treatment works (POTW).

Multi-Sector General Permit (MSGP): An NPDES permit that regulates storm water discharges from eleven categories of industrial activities.

No exposure: All industrial materials or activities are protected by a storm resistant shelter to prevent exposure to rain, snow, snowmelt, and/or runoff. Industrial materials or activities include, but are not limited to, material handling equipment or activities, industrial machinery, raw materials, intermediate products, by-products, final products, or waste products. Material handling activities include the storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product or waste product.

Non-authorized States: any State that does not have the authority to regulate the NPDES Storm Water Program.

Non-point Source (NPS) Pollutants: Pollutants from many diffuse sources. NPS pollution is caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up and carries away natural and human-made pollutants, finally depositing them into lakes, rivers, wetlands, coastal waters, and even our underground sources of drinking water.

Notice of Intent (NOI): An application to notify the permitting authority of a facility's intention to be covered by a general permit; exempts a facility from having to submit an individual or group application.
