6. The Permittee shall provide training on the requirements of the development construction and development planning sections of this permit to all construction inspection staff and other staff directly involved in construction activities. Training should be completed by December 30, 1999, and conducted annually thereafter. All new staff should be trained within six

months after their employment start-date.

F. Permittee Public Agency Activities

1. Requirements under the development planning and development construction sections of this Order shall apply to all applicable public agency development and construction projects.

2. The Permittee shall routinely conduct trash collection along, on and/or in water bodies under its jurisdiction.

3. Catch basin maintenance, under Permittee's jurisdiction, shall include:

   a. All catch basins will be cleaned out and inspected one time between May 1 and September 30 of each year; and,

   b. All catch basins that are at least 40% full of trash and debris between October 1 and April 30, shall be cleaned-out.

4. The Permittee shall develop a database on inlet maintenance, which at a minimum, includes a record of catch basin clean-outs to include: the quantity, predominant types, and likely sources of trash removed.

   a. All open channels will be cleaned at least once between May 1 and September 30 of each year. A database record of the of the amount of trash removed shall be maintained.

5. Curbed streets shall be swept a minimum of twice per month.

6. Street saw-cutting and paving is prohibited during a storm event of 0.25 inches or greater (except during emergency conditions).

7. Discharge of untreated runoff from temporary or permanent street maintenance waste storage areas is prohibited.

8. For vehicle maintenance and repair facilities, the discharge of untreated storm water runoff to the storm drain system from toxic or hazardous material storage areas, fueling areas, and repair/maintenance areas is prohibited.

9. All vehicle/equipment wash areas must be self-contained, or covered, or equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer. This provision does not apply to fire fighting vehicles.

10. Discharge of untreated storm water runoff from any toxic or hazardous material storage areas, including waste storage and handling areas, is prohibited.

11. For new public agency developments 25% of all required landscaping areas must be vegetated with xeriscape vegetation.

12. The routine application of pesticides, herbicides, and fertilizers during the wet season is prohibited. The Permittee's Stormwater Task Force shall develop a protocol for the non-routine application of pesticides, herbicides, and fertilizers.

13. Uncovered parking lots with greater than 25 parking spaces, will be swept at least monthly. By October 1, 2000 the Permittee shall develop and implement an uncovered parking lot washing program.

14. Discharge of liquids from concrete truck washouts into storm drains, open ditches, streets or catch basins is prohibited.

15. The Permittee shall train Permittee employees (whose jobs or activities directly affect storm water quality, or those who respond to questions from the public) regarding the requirements of the storm water management program. This includes maintenance, construction, planning, and inspection personnel.

G. Public Information and Participation

1. Telephone numbers for reporting clogged catch basin inlets, illicit discharges, dumping and general storm water management information will be listed in the government pages of the telephone book.

2. A storm water brochure must be provided with every building permit application. The brochure must include:

   a. A listing of contractor and developer storm water management training programs available in the area. (This list must be updated annually on the Permittee's website address);
   b. A list of all requirements of this order related to development and redevelopment projects; and,
   c. The list of development planning and development construction BMPs.

3. The Permittee shall insure that a minimum of 1.5 million impressions per year are made on the general public about storm water quality via print, local TV access, local radio or other appropriate media (in addition to the schoolchildren and industrial/commercial education outreach required below).

4. The Permittee shall distribute outreach materials to the general public, and targeted audiences such as schools, community groups, contractors and developers, at the appropriate public counters and at public events.

5. The Permittee shall provide the Long Beach Unified School District with materials, including but not limited to, videos, live presentations, brochures,

and other media, necessary to educate a minimum of 50% of all school children (K-12) every two years on storm water pollution. This requirement can be accomplished through cooperative efforts with other agencies.

6. Industrial/ Commercial Educational Program

   a. The Permittee shall implement an industrial/commercial educational site visit program. Site visits will occur once every two years at all Phase I industrial facilities, vehicle repair shops, vehicle body shops, vehicle parts (excluding parts retail stores with no outside storage) and accessory facilities, gas stations, restaurants, and additional industrial/ commercial facilities identified as priorities by the Regional Board Executive Officer or the Permittee. During the educational site visit, the Permittee shall:

      i. Consult with a representative of the facility to explain applicable storm water regulations;

      ii. Distribute and discuss applicable BMP and educational materials, including information regarding the codes, regulations, ordinances, and permits applicable to the category of the facility. Specific BMP brochures shall be developed and distributed for each major type of industry. In the case of Phase I facilities, notify the facility of specific requirements under the Statewide Industrial General Permit including that such facilities must file an Notice of Intent (NOI) with the State Water Resources Control Board and that a Storm Water Pollution Prevention Plan (SWPPP) must be available on the site;

      iii. Conduct a site walk-through, when requested by the owner/operator, to provide consultation on recommended BMPs; and

   b. The Permittee shall provide an annual update of the database of industrial/commercial facilities to Los Angeles County and the Regional Board Executive Officer. The database format shall include at a minimum:

      - Facility name
      - Site Address
      - Watershed Management Area
      - Applicable SIC code(s); and
      - NPDES storm water permit coverage status, if applicable

      i. The list of facilities identified within the Permittee's jurisdiction shall include, at a minimum:

         - All industrial groups regulated under Phase I of the Federal storm water program (40 CFR 122.26; Phase I Facilities);

         - Motor vehicle repair shops, motor vehicles body shops, motor vehicle parts and accessories facilities (excepting those with no outside materials storage), gas stations, and restaurants; and

- Additional SIC industrial/commercial facilities identified as priorities by the Permittee or the Regional Board Executive; and
- Number of facility visitations reported to the Executive Officer a list of visited facilities on an annual basis.

H. Five Year Public Education Strategy

1. The Permittee shall participate in the Five Year Public Education Strategy implemented by the Los Angeles County Department of Public Works pursuant to Board Order No. 96-054 by representation in the of the Los Angeles County Department of Works Educational Sub-committee.

I. Inlet/ Catch-basin Stenciling Program

1. All storm drain inlets and catch basins owned and operated by the Permittee must be stenciled with prohibitive language to discourage illegal dumping. In addition, signs with prohibitive language discouraging illegal dumping must be posted along channels and creeks. The Permittee is responsible for the maintenance of the posted signs. The_Permittee shall maintain storm drain sign legibility.

J. Parking Lot Study

1. The Permittee shall conduct a representative survey of privately-owned parking lots of more than 10 spaces exposed to storm water runoff to determine the amount of pollutants generated by these sources and the measures taken to remove litter by the lot operators. The Permitee shall report the results of this survey by July 15, 2000. The survey shall be accompanied by recommendations necessary to effectively reduce the contribution of storm water pollution constituents from these sources and a plan for their implementation.

K. Total Maximum Daily Loads [40 CFR 130.7]

1. The Permittee shall modify the LBSWMP to comply with waste load allocations developed and approved pursuant to the process for the designation of Total Maximum Daily Loads (TMDLs) for impaired water-bodies.

II. Standard Provisions

A. Public Review

1. All documents submitted to the Regional Board in compliance with the terms and conditions of this Permit shall be made available to members of

the public pursuant to the Freedom of Information Act (5 U.S.C. Section 5.52 (as amended) and the Public Records Act (California Government Code Section 6250 *et seq.*)

2. All documents submitted to the Executive Officer for approval shall be made available to the public for a 30-day period to allow for public comment.

B. Monitoring [40 CFR 122.41(j)]

1. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity;

2. The Permittee shall retain records of all monitoring information, including all calibration and maintenance monitoring instrumentation, copies of all reports required by this Order, and records of all data used to complete the Report of Waste Discharge and application for this Order, for a period of at least five(5) years from the date of the sample, measurement, report, or application. This period may be extended by request of the Regional Board or EPA at any time and shall be extended during the course of any unresolved litigation regarding this discharge;

3. Records of monitoring information shall include:

   a. The date, exact place, and time of sampling or measurements;

   b. The individual(s) who performed the sampling or measurements;

   c. The date(s) analyses were performed;

   d. The individual(s) who performed the analyses;

   e. The analytical techniques or methods used; and

   f. The results of such analyses;

4. All sampling, sample preservation, and analyses must be conducted according to test procedures under 40 CFR Part 136, unless other test procedures have been specified in this Order; and,

5. All chemical, bacteriological, and bioassay analyses shall be conducted at a laboratory certified for such analyses by an appropriate governmental regulatory agency.

C. Reporting

1. The Annual Storm Water Permit Report and Assessment shall contain the following completed declaration:

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted.

Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility, of a fine and imprisonment for knowing violations.

Executed on the ___ day of _________ , 19_,

at ____________________________.

(Signature) ___________________ (Title)________________________"

2. The Annual Monitoring Report shall contain both tabular and graphical summaries of the monitoring data obtained during the previous year. In addition, the Permittee shall discuss the compliance record and the corrective actions taken or planned which may be needed to bring the discharge into full compliance with the waste discharge requirements.

3. Monitoring Program Reporting shall be consistent with the following standard requirements where applicable:

   a. The Permittee shall file with the Board technical reports on self monitoring work performed according to the detailed specifications contained in the Monitoring Program as directed by the Executive Officer;

   b. In reporting the monitoring data, the Permittee shall arrange the data in tabular form so that the date, the constituents, and the concentrations are readily discernable. The data shall be summarized to demonstrate compliance with waste discharge requirements and, where applicable, shall include results of receiving water observations;

   c. Each monitoring report must affirm in writing that "all analyses were conducted at a laboratory certified for such analyses by the Department of Health Services or approved by the Executive Officer and in accordance with current EPA guideline procedures or as specified in this Monitoring Program";

   d. Each report shall contain the following completed declaration:

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted.

Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility, of a fine and imprisonment for knowing violations.

Executed on the ___ day of ________, 19__,

at _________________________.

(Signature)_______________(Title)_________________";

e. If no flow occurred during the reporting period, the monitoring report shall so state;

f. For any analyses performed for which no procedure is specified in the EPA guidelines or in the monitoring and Reporting Program, the constituent or parameter analyzed and the method or procedure used must be specified in the monitoring report; and

g. The Executive Officer may make modifications to the approved monitoring program as deemed necessary.

D. Duty to Comply [40 CFR 122.41(a)]

1. The Permittee must comply with all of the terms, requirements, and conditions of this order. Any violation of this order constitutes a violation of the Clean Water Act, its regulations and the California Water Code, and is grounds for enforcement action, Order termination, Order revocation and reissuance, denial of an application for reissuance; or a combination thereof.

2. A copy of these waste discharge specifications shall be maintained by the Permittee so as to be available at all times to Permittee employees and members of the public.

3. Any discharge of wastes at any point(s) other than specifically described in this Order is prohibited, and constitutes a violation of the Order.

E. Duty to Mitigate [40 CFR 122.41 9d]

1. The Permittee shall take all reasonable steps to minimize or prevent any

discharge that has a reasonable likelihood of adversely affecting human health or the environment.

F. Inspection and Entry [40CFR 122.41(I)

1. The Regional Board, USEPA, and other authorized representatives shall be allowed:

   a. Entry upon premises where a regulated facility is located or conducted, or where records are kept under conditions of this Order;

   b. Access to copy any records that are kept under the conditions of this Order;

   c. To inspect any facility, equipment (including monitoring and control equipment), practices, or operations regulated or required under this Order; and

   d. To photograph, sample, and monitor for the purpose of assuring compliance with this Order, or as otherwise authorized by the Clean Water Act and the California Water Code.

G. Proper Operation and Maintenance [40 CFR 122.41 (e)]

1. The Permittee shall at all times properly operate and maintain all facilities and systems of treatment and control including sludge use and disposal facilities (and related appurtenances) that are installed or used by the Permittee to achieve compliance with this Order. Proper operation and maintenance includes adequate laboratory controls and appropriate quality assurance procedures. This provision requires the operation of backup or auxiliary facilities or similar system that are installed by a Permittee only when necessary to achieve compliance with the conditions of this Order.

H. Signatory Requirements [40 CFR 122.41]

1. Except as otherwise provided in this Order, all applications, reports, or information submitted to the Regional Board shall be signed by the Director of Public Works or City Engineer under penalty of perjury.

I. Reopener and Modification [40 CFR 122.41(f)]

1. This Order may only be modified, revoked, or reissued, prior to the expiration date, by the Regional Board, in accordance with the procedural requirements of the Water Code and Title 23 of the California Code Regulations for the issuance of waste discharge requirements, and upon prior notice and hearing, to:

a. Address changed conditions or new information identified in the required reports or other sources deemed significant by the Regional Board;
b. Incorporate applicable requirements or statewide water quality control plans adopted by the State Board or amendments to the Basin Plan;
c. Comply with any applicable requirements, guidelines, and/or regulations issued or approved pursuant to CWA Section 402(p); and/or
d. Consider any other federal, or state laws or regulations that became effective after adoption of this Order.

2. After notice and opportunity for a hearing, this Order may be terminated or modified for cause, including, but not limited to:

a. Violation of any term or condition contained in this Order;
b. Obtaining this Order by misrepresentation, or failure to disclose all relevant facts; or
c. A change in any condition that requires either a temporary or permanent reduction or elimination of the authorized discharge.

3. This Order may be modified, revoked and reissued, or terminated for cause.

4. The filing of a request by the Permittee for a modification, revocation and re-issuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any condition of this Order.

5. This Order may be modified to make corrections or allowances for changes in the permitted activity listed in this section, without following the procedures at 40 CFR Part 122.25, if processed as a minor modification. Minor modifications may only:

a. Correct typographical errors
b. Require more frequent monitoring or reporting by the Permitee.

J. Severability

1. The provisions of this permit are severable; and if any provision of this permit or the application of any provision of this permit to any circumstance is held invalid, the application of such provision to other circumstances and the remainder of this permit shall not be affected.

K. Duty to Provide Information [40 CFR 122.41 (h)

1. The Permittee shall furnish, within a reasonable time, any information the Regional Board or US EPA may request to determine whether cause exists for modifying, revoking and reissuing, or terminating this Order. The Permittee shall also furnish to the Regional Board, upon request, copies of records required to be kept by this Order.

L. Twenty-four Hour Reporting

1. The Permittee shall report any noncompliance that may endanger health or the environment. Any information shall be provided orally within 24 hours from the time the Permittee becomes aware of the circumstances. A written submission shall also be provided within five days of the time the Permittee becomes aware of the circumstances. The written submission shall contain a description of the noncompliance and its cause; the period of noncompliance, including exact dates and times and, if the noncompliance has not been corrected, the anticipated time it is expected to continue; and steps taken or planned to reduce, eliminate, and prevent reoccurrence of the noncompliance.

   The following shall be included as information that must be reported within 24 hours under this paragraph:

   a. Any unanticipated bypass release that exceeds any effluent limitation in the Order;

   b. Any condition upset that exceeds any effluent limitation in the Order; or

   c. Violation of a maximum daily discharge limitation for any of the pollutants listed in this Order to be reported within 24 hours.

   The Regional Board may waive the above-required written report on a case-by-case basis.

M. Bypass [40 CFR 122.41(m)]

1. Bypass (the intentional diversion of waste streams from any portion of a treatment facility) is prohibited. The Regional Board may take enforcement action against the Permittee for bypass unless:

   a. Bypass was unavoidable to prevent loss of life, personal injury or severe property damage. (Severe property damage means substantial physical damage to property, damage to the treatment facilities that causes them to become inoperable, or substantial and permanent loss of natural resources that can reasonably be expected to occur in the absence of a bypass. Severe property damage does not mean economic loss caused by delays in production.);

   b. There were no feasible alternatives to bypass, such as the use of auxiliary treatment facilities, retention of untreated waste, or maintenance during normal periods of equipment down time. This condition is not satisfied if adequate back-up equipment should have been installed in the exercise of reasonable engineering judgement to prevent a bypass that could occur during normal periods of equipment downtime or preventive maintenance;

c. The Permittee submitted a notice at least ten days in advance of the need for a bypass to the Regional Board; or

d. The Permittee may allow a bypass to occur that does not cause effluent limitations to be exceeded, but only if it is for essential maintenance to assure efficient operation. In such a case, the above bypass conditions are not applicable. The Permittee shall submit notice of an unanticipated bypass as required.

N. Upset [40 CFR 122.41(n)]

1. A Permittee that wishes to establish the affirmative defense of an upset in an action brought for non compliance shall demonstrate, through properly signed, contemporaneous operating logs, or other relevant evidence that:

   a. an upset occurred and that the Permittee can identify the cause(s) of the upset;

   b. the permitted facility was being properly operated by the time of the upset;

   c. the Permittee submitted notice of the upset as required; and

   d. the Permittee complied with any remedial measures required.

No determination made before an action for noncompliance, such as during administrative review of claims that non-compliance was caused by an upset, is final administrative action subject to judicial review.

In any enforcement proceeding, the Permittee seeking to establish the occurrence of an upset has the burden of proof.

O. Property Rights [40 CFR 122.41 (h)]

1. This Order does not convey any property rights of any sort, or any exclusive privilege.

P. Enforcement

Violation of any of the provisions of this NPDES permit or any of the provisions of this Order may subject the violator to any of the penalties described herein, or any combination thereof, at the discretion of the prosecuting authority; except that only one kind of penalty may be applied for each kind of violation.

1. The California Water Code provides that any person who violates a waste discharge requirement or a provision of the California Water Code is subject to civil penalties of up to $5,000 per day, $10,000 per day, or $25,000 per day of

violation, or when the violation involves the discharge of pollutants, is subject to civil penalties of up to $10 per gallon per day or $25 per gallon per day of violation; or some combination thereof, depending on the violation, or upon the combination of violations.

2. The Federal Clean Water Act (CWA) provides that any person who violates a permit condition or any requirement imposed in a pretreatment program implementing sections 301, 302, 306, 307, 308, 318 or 405 of the CWA is subject to a civil penalty not to exceed $25,000 per day of such violation. Any person who willfully or negligently violates permit conditions implementing these sections of the CWA is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both. Any person who knowingly violates permit conditions implementing these sections of the CWA is subject to a fine of not less than $5,000, or more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or by both.

3. The Clean Water Act provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, or other document submitted or required to be maintained under this Order, or who knowingly falsifies, tampers with, or renders inaccurate any monitoring device or method required to be maintained under this act, shall upon conviction, be punished by a fine of not more than $10,000 per violation, or by imprisonment for not more than 2 years per violation, or by both.

Q. Need to Halt or Reduce Activity not a Defense [40 CFR 122.41(c)

1. It shall not be a defense for a Permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this Order.

R. Other Information

1. Should the Permittee discover that it failed to submit any relevant facts or that it submitted incorrect information in a report, it shall promptly submit the missing or correct information.

2. The Permittee shall report all instances of non-compliance not otherwise reported at the time monitoring reports are submitted.

3. The Permittee shall mail a copy of each monitoring report to:

INFORMATION TECHNOLOGY
CALIFORNIA REGIONAL WATER QUALITY
CONTROL BOARD - LOS ANGELES REGION
320 W. 4TH STREET, SUITE 200
LOS ANGELES, CA 90013

A copy of the monitoring report shall also be mailed to:

REGIONAL ADMINISTRATOR
ENVIRONMENTAL PROTECTION AGENCY
REGION 9
75 Hawthorne Street
San Francisco, CA 94105

S. Definitions

1. "Construction" means constructing, clearing, grading, or excavation that results in soil disturbance. Construction includes structure tear-down. It does not include routine maintenance to maintain original line and grade, hydraulic capacity, or original purpose of facility, nor does it include emergency construction activities required to immediately protect public health and safety.

2. "Development construction projects" are those projects constructed on privately and publicly owned land outside the public street right of way. For projects constructed within the public street right of way, refer to Section 2, Municipal Construction Activities.

3. "Discretionary project" is a project which requires the exercise of judgement or deliberation when the public agency or body decides to approve or disapproves a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statues, ordinances, or regulations.

4. "Environmentally Sensitive Areas" means an area designated as an Area of Special Biological Significance by the State Water Resources Control Board or an area designated as a significant natural area by the California Resources Agency or an area designated as an area of Ecological Significance by the County of Los Angeles.

5. "Grab sample" is defined as any individual sample collected in a short period of time not exceeding 15 minutes. "Grab samples" shall be collected during normal peak loading conditions for the parameter of interest, which may or may not be during hydraulic peaks. It is used primarily in determining compliance with "daily maximum" limits and the "instantaneous maximum" limits.

6. "Hazardous substance" is a material defined under 40 Code of Federal Regulations (CFR) § 302. These are categorized as either "listed" or "unlisted" hazardous substances. Listed hazardous substances are certain items of solid waste that exhibit characteristics identified in 40 CFR § 261.2 through 261.24. Examples of hazardous substances include any substance or chemical product for which one or more of the following applies:

   - A material safety data sheet (MSDS) is required
   - The substance is listed as radioactive by the Nuclear Regulatory Commission

- The substance is listed as hazardous by the U.S. Department of Transportation
- The material is listed in Labor Code § 6382(b)

The above four categories are described in the California Health and Safety Code, Division 20, Chapter 6.95, Hazardous Materials Release Response Plans and Inventory.

7. "Illicit Connection" is any man-made conveyance that is connected to the storm drain system without a permit or through which prohibited non-storm water flows are discharged, excluding roof-drains and other similar type connections. Examples include channels, pipelines, conduits, inlets, or outlets that are connected directly to the storm drain system.

8. "Illicit Discharge" is any discharge to the storm drain system that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illicit discharge includes all non storm-water discharges except discharges pursuant to an NPDES permit, discharges that are identified in Part 2 of this order, and discharges authorized by the Regional Board Executive Officer.

9. "Illicit Disposal" is any disposal, either intentionally or unintentionally, of material(s) or waste(s) that can pollute storm water or urban runoff.

10. "Median" of an ordered set of values is the value which the values above and below is an equal number of values, or which is the arithmetic mean of the two middle values, if there is no one middle value.

11. "Ministerial" [approval] describes a government decision involving little or no personal judgement by the public official as to the wisdom or manner of carrying out the project. The public official merely applies the law to the facts as presented but uses no special discretion or judgement in reaching a decision. A ministerial action involves the use of fixed standards or objective measurements, and the public official cannot use personal, subjective judgement in deciding whether or how the project should be carried out. [Section 15369 of CEQA Guidelines]

12. "Non-Storm Water Discharge" means discharge other than storm water runoff or snow melt.

13. "Potable water sources" means flows from drinking water storage, supply and distribution systems including flows from system failures, pressure releases, system maintenance, well development, pump testing, fire hydrant flow testing; and flushing and dewatering of pipes, reservoirs, vaults, and wells.

14. "Priority pollutants" are those constituents referred to in 40 CFR 401.15 and listed in the EPA NPDES Application Form 2C, pp. V-3 through V-9.

15. "Sidewalk Washing" means pressure washing of paved pedestrian walkways with only water and properly disposing of all debris collected.

16. "Source Control BMPs" are activities, plans, policies, management practices and maintenance procedures, which are designed to control pollutants from entering the storm drain system.

17. "Square feet" for commercial development means total impermeable area including parking area.

18. "Storm water discharges associated with industrial activity" is defined at 40 CFR § 122.26(b)(14)(i) through (xi), and refers to eleven categories of activities required to obtain a National Pollutant Discharge Elimination System (NPDES) permit for storm water discharges.

19. "Toxic pollutant" means any pollutant listed as toxic under section 307(a)(1) of the Clean Water Act or under 40 CFR 122, Appendix D.

20. "Upset" means an exceptional incident in which there is unintentional and temporary noncompliance with effluent limitations because of factors beyond the reasonable control of the Permittee. An upset does not include noncompliance to the extent caused by operational error, improperly designed treatment facilities, inadequate treatment facilities, lack of preventive maintenance, or careless or improper action.

21. "Water Quality Standards and Water Quality Objectives" applicable to the Permittee include those contained in the Los Angeles Regional Water Quality Control Plan (Basin Plan), the California Ocean Plan, the National Toxics Rule, and other state or federally approved surface water quality plans. Such plans are used by the Regional Board to regulate all discharges, including storm water discharges.

22. "Wet Season" means the calendar period beginning October 1 through April 15.

23. "Wet Weather" means a storm event that generates runoff 0.10 inches or more over a 24-hour period.

This Order expires on June 29, 2004. The Permittee must submit a complete Report of Waste Discharge (ROWD) in accordance with Title 23, California Code of Regulations, not later than 180 days in advance of such date as application for reissuance of waste discharge requirements.

I, Dennis A. Dickerson, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of an Order adopted by the California Regional Water Quality Control Board, Los Angeles Region, on June 30, 1999.

STORM WATER MONITORING PROGRAM

CITY OF LONG BEACH

A. Monitoring Plan

The Permittee shall prepare, maintain, and update, if necessary, a monitoring plan which shall include at a minimum, the following:

1. Quality control, quality assurance, data collection, storage and analyses, and detection limits;
2. All sample collection, handling, storage, and analyses in accordance with 40 CFR 136;
3. Location of monitoring stations, constituents, and sampling frequency;
4. Targeted monitoring indicators (e. g., ecosystem, biological diversity, in stream toxicity, habitat, chemical, sediment, stream health) chosen for monitoring;
5. Statistical methods used to design studies, conduct sampling, and interpret data;
6. A description of the role and responsibilities of all the participants in monitoring studies
7. A description of computer software and modeling programs that will be utilized to assess data, interpret information; and
8. A general description of how data are intended to be utilized for feedback into the storm water management program.

An up-to-date Monitoring Plan shall be submitted to the Regional Board Executive Officer, when so requested.

B. Monitoring Program

1. The following monitoring program is designed to meet the objectives as stated in this Order:

   a. Beginning Year 1, the Permitee will monitor and test for mass emissions and toxicity at three representative storm drain sites, utilizing end of pipe outfall testing.

   b. In Year 1, the Permitee will monitor one receiving water body (Alamitos Bay) and conduct water column testing for bacteria and toxicity near the dry-weather diversion storm drain outfall.

   c. In Year 2, the Permitee will monitor one receiving water body (Alamitos Bay) and report on the effectiveness of the dry weather diversion on water quality.

d. Beginning Year 3, the Permittee will monitor and test for mass emissions and toxicity at a site on Los Cerritos Channel

e. In Years 3 through 5, the Permitee proposes to co-fund plume, benthic and toxicity studies, based on "fair share" participation as designated by the Los Angeles Regional Water Quality Control Board (Regional Board) for receiving waters in the Los Angeles River and San Gabriel River watersheds.

g. The Permittee will monitor mass emission stations according to the following schedule provided there are sufficient storm events during the season:

Storm Season	Number of Stations	Number of Events/Storm Season
1999-2000	Three	Two dry-weather, four wet-weather
2000-2001	Three	Two dry-weather, four wet-weather
2001-2004	Four + n	Two dry and four wet-weather + n

n is to be determined by "fair share" allocation in Year 3.

2. Mass Emission Station Monitoring

a. The Permittee shall monitor a total of four mass emission stations: three stations (Dominguez Gap, Bouton Creek and Alamitos Bay) beginning the 1999-2000 monitoring season and the fourth (Los Cerritos Channel) beginning in the Year 2000-2001 monitoring season. Additional monitoring for the Los Angeles River and San Gabriel River watersheds is dependent on "fair share" allocation by the Regional Board. The Permittee will monitor up to six station events per year including dry weather sampling.

b. All samples for mass emissions monitoring may be taken with an automatic sampler or equivalent except for the following constituents: (i) pathogen indicators and (iii) oil and grease. These constituents must be collected as grab samples, unless the Regional Board approves an alternative method after request. The samplers shall be set to monitor storms totaling 0.25 inches or greater of rainfall. The constituents to be analyzed are listed on page C-5 through C-9.

c. If a constituent is not detected at the method detection limit (MDL) for its respective test method listed on pages C-5 though C-9 in more than 75 percent of the first 48 sampling events, it will not be further analyzed unless the observed occurrences show concentrations greater than state water quality standards. The Permittee will also conduct annual confirmation sampling for non-detected constituents at each station for as long as the station is monitored.

3. Receiving Waters Study

a. The Permittee will conduct one receiving water study during the 1999-2000 and 2000-2001 monitoring season to evaluate the effectiveness of dry weather diversion.

b. The Permittee proposes, in Years 3 through 5, in conjunction with other "fair share" participants, to fund a study of receiving waters for Los Angeles River and San Gabriel River watersheds. The purpose of the study will be to study the impacts, if any, of storm water/non-storm water discharges on the beneficial uses of the Los Angeles River/ San Pedro Bay and San Gabriel River. The study may include the following distinct components:

i. Plume Study:

- Map the spatial and temporal structure of the runoff plumes and as it flows into the bay or estuary following strong winter storms.
- Examine the interaction between the runoff plume and ocean processes as they affect the advection, dispersion, and mixing of the plume.
- Evaluate the impact of storm runoff plumes on beneficial uses of the coastal ocean.
- Characterize the optical properties of the suspended particulate material ("SPM") and dissolved organic material ("DOM") associated with runoff sources.
- Examine the effects of DOM and SPM on the water column optics and the distribution of nutrient concentrations, as the same may affect phytoplankton productivity.
- Assist in establishing appropriate locations for benthic study stations.

ii. Benthic Study:

- Water quality (dissolved oxygen, salinity, density, temperature, light transmissivity and pH).
- Sediment grain size, sediment organic concentrations and sediment contaminant concentrations.
- The structure of the benthic invertebrate community.

iii. Water Column Toxicity Study:

- Multiple specie (mysid, sea urchin, ceriodaphnia) bioassays.
- Phase I TIE tests.

iv. Sediment Toxicity Study:

- Amphipod survival bioassays of sediment samples from stations (including reference sites).
- Multi-species bioassays will be conducted for chronic toxicity in sediment samples from sampling stations, plus 1 reference site.

- Chemical analysis of multi-species growth test tissue samples will be conducted for organics and metals.

- Phase I TIE tests using sea urchin fertilization of interstitial water will be conducted for samples from stations identified to be toxic in amphipod survival bioassays.

4. Toxicity Identification Evaluation Procedure

   a. The Permittee will conduct Phase 1 TIE on dry weather samples when two consecutive dry weather samples from the same monitoring station show toxicity.

   b. The Permittee will conduct Phase 1 TIE on wet weather samples when three consecutive wet weather samples from the same monitoring station show toxicity.

   c. The Permittee will, once the cause(s) of toxicity has been determined, discuss separately in the Annual Monitoring Report, the following:

      i. the potential sources of the pollutant(s) causing toxicity,
      ii. proposed special studies to verify the sources(s) of the pollutant(s) causing toxicity
      iii. proposed special studies to identify BMPs to reduce the pollutant(s) causing toxicity
      iv. proposed changes to the LBSWMP to reduce the pollutants causing toxicity, and
      v. follow-up monitoring to demonstrate that toxicity has been removed.

   The Regional Board Executive Officer may direct the Permittee to submit the above report earlier than the scheduled Annual Monitoring Report.

LIST OF CONSTITUENTS IN MONITORING PROGRAM AND ANALYTICAL METHODS

CONSTITUENTS	USEPA METHOD	DETECTION LIMIT
Conventional Pollutants		(mg/L)
Oil and Grease	1664

ANNOUNCEMENT

NPDES–DEVELOPMENT PLANNING FOR STORMWATER MANAGEMENT

On July 15, 1996, the Regional Water Quality Control Board (RWQCB), Los Angeles Region, adopted Order No. 96-054 ("Permit"). Under the Permit, the County of Los Angeles is designated as the Principal Permittee and the 85 incorporated cities as co-Permittees. In February 2000, the RWQCB adopted a Resolution that established Standard Urban Stormwater Mitigation Plan (SUSMP) criteria for priority projects for the Permittees described in Part A and Part B of the attached table.

The primary objectives are to:

- Effectively prohibit non-stormwater discharges, and
- Reduce the discharge of pollutants from stormwater conveyance systems to the maximum extent practicable

The Los Angeles County Department of Public Works (DPW) is responsible for the implementation of SUSMP requirements in the County unincorporated areas (excluding the Antelope Valley area) and all County-owned facilities. Development and redevelopment projects falling into either Parts A or B of the attached table will be required to obtain SUSMP approvals. Details of facilities and measures that mitigate impacts to water quality must be shown on improvement plans and reviewed as part of those plans.

Information regarding the preparation of SUSMP is available on our website (*link to* SUSMP Plan on www.888CleanLA.com).

SUSMP pertaining to new subdivisions will be reviewed by DPW's Land Development Division. Please call Steve Burger at (626) 458-4943 with any questions (Monday through Thursday).

SUSMP for single-lot developments will be reviewed by DPW's Building and Safety Division. Please contact Mitch Miller at (626) 458-6390 with any questions pertaining to these developments (Monday through Thursday).

In addition, SUSMP for non-residential projects will be reviewed by DPW's Environmental Programs Division. Related questions should be directed to the Industrial Waste Unit of Environmental Programs Division at (626) 458-3517 (Monday through Thursday).

Attachment: SUSMP Project Types, Characteristics and Activities, Parts A and B.

SUSMP Project Types, Characteristics, and Activities
Part A. Type of Proposed Project:
A 10+ home subdivision
A 100,000+ square-foot commercial development[1, 2]
An automotive repair shop (SIC codes 5013, 5014, 5541, 7532-7534, and 7536-7539)[3]
A retail gasoline outlet
A restaurant (SIC code 5812)[4]
A hillside-located single-family dewelling[5]
Parking lots 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to stormwater runoff
Location within or directly adjacent to or discharging directly to an environmentally sensitive area

Part B. Project Characteristics or Activities:
Automotive or Equipment Repair and/or Maintenance
Automotive or Equipment Washing or Cleaning Area(s)
Gas Station or Fuel Dispensing
Outdoor Material or Waste Handling or Storage
Chemical handling and/or storage of petroleum products, paints, solvents, concrete, or hazardous waste?
Outdoor Equipment or Product Fabrication including welding; cutting; sawing; metal fabrication; assembly; application of paints, coatings, or finishes; pre-cast concrete fabrication, etc.
Outdoor Areas for Equipment or Machinery Repair and/or Maintenance
Dry Cleaning Factory
Food Service
Food Processing Plant
Animal Slaughtering
Animal Confinement, Pet Care Facilities, Stables, Kennels, etc.
10 or More Dwelling Units
Hillside Location[5]

[1] "100,000 Square Foot Commercial Development" means any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas.

[2] "Commercial Development" means any development on private land that is not heavy industrial or residential. The category includes, but is not limited to: hospitals, laboratories and other medical facilities, educational institutions, recreational facilities, plant nurseries, multi-apartment buildings, car was facilities, mini-malls and other business complexes, shopping malls, hotels, office buildings, and public warehouses and other light industrial complexes.

[3] "Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

[4] "Restaurant" means a stand-alone facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption (SIC code 5812).

[5] "Hillside" means property located in an area with known erosivesoil conditions, where the development contemplates grading on any natural slope that is 25 percent or greater.

Re: Petition to Correct Deficiencies or Withdraw EPA Approval; Delegated Clean Water Act Authority; Storm Water, Los Angeles Regional Water Quality Control Board (40 C.F.R. § 123.64)

Dear Administrator Browner and Regional Administrator Marcus:

Enclosed please find the Natural Resources Defense Council's formal petition to commence proceedings to withdraw EPA approval of the delegated NPDES storm water program administered by the Los Angeles Regional Water Quality Control Board ("Water Board").

By any objective measure, the Water Board has failed to control storm water and urban runoff in the Los Angeles region, thereby creating what is increasingly recognized as one of the worst runoff pollution problems in the nation. As demonstrated in our petition, the Water Board's failure violates the Clean Water Act, EPA regulations, and the express terms of EPA's NPDES Memorandum of Agreement with the State of California.

By correcting the extreme deficiencies that currently exist in the Water Board's storm water program, there is a great opportunity to improve the environment and reduce public health risks that impact tens of millions of people who use the Santa Monica Bay, San Pedro Bay, the Ventura County coastline, and many adjacent waters. We hope that EPA and the State of California will seize this opportunity to bring this program into compliance with the law, thereby benefiting the more than ten million residents of the

Counsel for Petitioner
Natural Resources Defense Council

CAROL BROWNER, ADMINISTRATOR
UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

In Re Petition of NATURAL RESOURCES DEFENSE COUNCIL for Correction of Legal Deficiencies or Withdrawal of Storm Water Program Administered by Los Angeles Regional Water Quality Control Board	PETITION FOR CORRECTION OF LEGAL DEFICIENCIES OR WITHDRAWAL OF EPA APPROVAL; MEMORANDUM OF POINTS AND AUTHORITIES IN SUPPORT THEREOF [40 C.F.R. §123.64]

Introduction

The Natural Resources Defense Council, Inc., a non-profit environmental organization with over 400,000 members, including 80,000 in California, hereby petitions the Administrator of the United States Environmental Protection Agency to require the immediate correction of legal deficiencies or withdraw EPA approval of the Los Angeles Regional Water Quality Control Board's (hereafter "RWQCB" or "Regional Board") National Pollution Discharge Elimination System Storm Water Permit Program ("Storm Water Program"). 40 C.F.R. § 123.64(b)(1). This petition is brought on the grounds that the State of California, by and through the RWQCB, is not administering the Storm

Water Program in accordance with the provisions of. <u>inter alia</u>, 33 U.S.C. § 1342 and 40 C.F.R. Parts 122 and 123, and that the program meets the criteria for withdrawal of approval as set forth in 40 C.F.R. § 123.63. By any objective measure. the RWQCB's Storm Water Program is wholly inadequate to implement the Clean Water Act or to control polluted urban runoff.

This failure has enormous consequences for the region and its residents. Urban storm water runoff. one of the largest sources of pollution to the coastal and other receiving waters of the nation. is a particularly severe problem in the Los Angeles region. Pollutants conveyed in storm water and urban runoff (collectively referred to herein as "storm water") now constitute the number one source of pollution to Santa Monica Bay and the rest of the region's waterways. Consequently, storm water pollution, which not only harms the environment but has been shown in Los Angeles to cause serious human health impacts, is the most severe water quality problem facing the region. In fact. the severity of the storm water problem in Southern California is such that many experts believe it is the worst problem of its kind in the nation.

However. rather than making storm water a priority during the nearly ten years it has bee.. in charge. the RWQCB has let its storm water permit program fall to such a level that it is completely ineffective and unable to make any significant impact on the problem. While the Board recently has shown signs of shifting its policy stance by adopting strong new development standards. even the best policies are an insufficient response when the regulatory structure to implement them—and other aspects of the program—are entirely missing. In this regard. ***NRDC's Petition demonstrates that the Regional Board inexplicably devotes the least amount of resources to its worst water quality problem: polluted runoff.***

Because of its legal inadequacy and objective ineffectiveness. EPA must withdraw the State's authority. vested in the Regional Board. to oversee the Storm Water Program in Los Angeles unless these deficiencies are corrected within ninety days. 40 C.F.R. § 123.64(b)(8)(iii).

By way of general summary, the major failures of the RWQCB's Storm Water Program include the following:[1]

First. and most fundamentally. the RWQCB has failed to take basic steps consistent with organizing and sustaining an adequate Storm Water Program, starting with the most critical—providing for an adequate level of staffing—through and including the most mundane (yet essential). such as maintaining information. files, and records on its own activities.

Second. the RWQCB has failed to exercise control over the activities required to be regulated under the storm water program. It has failed to issue permits to hundreds, if not thousands. of entities that require them; it has issued a legally defective permit to municipal governments; and it has repeatedly failed to meet deadlines associated with permit implementation.

Third. the RWQCB has failed to inspect and monitor activities subject to the storm water permit program. There are approximately 3,500 active industrial entities in the region subject to the general industrial storm water permit[2] and, by some credible estimates, upwards of 10,000 facilities that should be permitted.[3] Yet. at its current pace. it would take the RWQCB nearly 35 years to perform industrial site inspections at each facility in the region.

Fourth, in part because there have been very few substantive inspections by the RWQCB. the RWQCB has been unable to discover actual permit and other Clean Water Act storm water violations that cause pollution of regional waters. In fact, the vast majority of all formal enforcement actions[4] taken by the RWQCB for storm water violations in the last three years were

---

[1] Each of these general claims is substantiated in the sections that follow. These claims, and those contained in the substantive sections of this Petition, *infra*, constitute NRDC's allegations. pursuant to 40 C.F.R. Section 123.63(b)(1).

[2] General Industrial Storm Water Permit Statistics November 1999, at 1 (Los Angeles Regional Water Board 1999).

[3] Heal the Bay, *Omission Accomplished: The Lack of a Los Angeles Regional Water Board Enforcement Program, 1992-1997*, at 21 (January 1999) (citing to UCLA Quarterly Progress Report # 3 to California State Water Resources Control Board, August 15, 1996).

[4] The RWQCB implements a "progressive enforcement approach" to address noncompliance. A "Level I" action is typically a written notice to comply which is sent to the violator. A "Level II" action is typically a second letter to a violator issued by the Executive Officer alerting them to the possibility of more stringent action. It may also include

for failing to submit required forms and information—such as failure to submit an annual report or failure to file an NOI.[5] The RWQCB rarely if ever takes formal enforcement action against entities on the basis of inadequate storm water practices or violations of receiving water objectives. The RWQCB's failure in this regard means that meaningful storm water enforcement action in Southern California is almost entirely the purview of environmental organizations. specifically NRDC and the Santa Monica BayKeeper.

Fifth. as a result of the matters summarized above. the RWQCB has failed to protect and restore regional waters. including world-famous local beaches. riparian habitats. and other coastal resources. as required by the Clean Water Act. In fact. storm water discharges in the region consistently violate the Clean Water Act, a fact which is known to the RWQCB. In the end. the acute toxicity and pathogenic content of regional storm water discharges is the most basic and important proof of this severe problem.

I. Legal Standard

A. The Clean Water Act Sets Standards for Delegated Programs and Provides for EPA Withdrawal of Approval When These Standards are not Satisfied.

The Clean Water Act provides that "[a]ny state [NPDES] permit program under this section shall at all times be in accordance with this section and guidelines promulgated pursuant to this section." 33 U.S.C. § 1341(c)(2). In order to assure that any state program is at all times consistent with the Clean Water Act, the Administrator of EPA may withdraw approval of the program if it does not meet established criteria. The power to withdraw approval of a state permit program is granted to the Administrator by 33 U.S.C. § 1342(c)(3). It provides, in pertinent part:

> Whenever the Administrator determines after public hearing that the State is not administering a program approved under this section in

---

a Time Schedule Order. A "Level III" action is "formal" enforcement. specifically the issuance of a Cease and Desist Order or the imposition of Administrative Civil Liability against a violator. *Id* at 7-9.

[5] *See Quarterly Report of Violations and Enforcement Actions*. January 1997 through June 1999 (RWQCB).

> accordance with the requirements of this section, he shall so notify the State and, if appropriate corrective action is not taken within a reasonable time, not to exceed ninety days, the Administrator shall withdraw approval of such program . . . .

The criteria the Administrator is to use in determining whether to withdraw approval of the state permit program are set forth in 40 C.F.R. § 123.63. This part provides that the administrator may withdraw program approval in a number of circumstances, which may be summarized as follows: when the state program fails to exercise control over activities required to be regulated, including <u>failure to issue permits</u>; when there is repeated issuance of <u>permits which do not conform to requirements</u>; when the State's <u>enforcement program fails to comply with requirements</u>; when the State's <u>program fails to adequately inspect and monitor</u> activities subject to regulation.

Further, a state program may be withdrawn where it otherwise fails to comply with the terms of the Memorandum of Agreement ("MOA") under which all state programs are authorized. 40 C.F.R. § 123.63. The Administrator must look to the terms of the MOA to determine whether the State has carried out its duties as set forth in the MOA. In the case of the MOA between U.S. EPA and California, specific Regional Board duties are enumerated, including:

> a. Regulating all discharges subject to the NPDES and pretreatment programs, except those reserved to EPA, in conformance with Federal and State law, regulations, and policy;
>
> b. Maintaining technical expertise, administrative procedures and management control, such that implementation of the NPDES and pretreatment programs consistently conforms to State laws, regulations and policies;
>
> c. Providing technical assistance to the regulated community to encourage voluntary compliance with program requirements;

d. Assuring that no one realizes an economic advantage from noncompliance;

e. Maintaining an adequate file at the appropriate Regional Board Office for each permittee;

f. Comprehensively evaluating and assessing compliance with schedules. effluent limitations. and other conditions in permits:

h. Taking timely and appropriate enforcement actions in accordance with the CWA, applicable federal regulations, and State law: [and]

i. [Conducting] compliance inspections to determine the status of compliance with permit requirements. including sampling and non-sampling inspections.

B. The Clean Water Act Provides Specific Procedures By Which Any Person Can Petition the Administrator to Correct Program Deficiencies or Withdraw Approval.

EPA regulations provide that "the Administrator may order the commencement of withdrawal proceedings on his or her own initiative or in response to a petition from an interested person alleging failure of the State to comply with the requirements of this part . . . ." 40 C.F.R. § 123.64(b)(1). The word, "Person", is broadly defined to include any "individual or organization having an interest in the subject matter of the proceeding."

II. Factual Background: The Regional Board's Failure to Adequately Regulate Storm Water Pollution Has Created the Worst Water Quality Problem in the Region, and One of the Worst Polluted Runoff Problems in the United States.

The ability of the Regional Board to meet its overall obligation to effectively manage and implement the Clean Water Act is inextricably linked with its ability to combat urban runoff and storm water pollution. In simple terms, the goals and the requirements of the Clean Water Act cannot be, and will not be, achieved in Southern California until and unless urban runoff and storm water pollution are effectively regulated.

This direct connection is a result of the predominant role runoff plays in contributing pollutants to receiving waters, degrading many of these waters, and impairing beneficial uses. The sheer volume of polluted runoff; the relative significance of runoff pollution compared to other sources of water pollution; as well as the causes and effects of runoff on human health and the environment are now well-understood in Southern California. These documented facts demonstrate the considerable negative impact on people and the environment that continues today as a result of the Regional Board's inadequate efforts and oversight.

A. <u>Polluted Runoff is the Largest Source of Water Pollution in Los Angeles.</u>

Research has demonstrated that storm water is the largest single source of water pollution in Southern California.[6] As the Southern California Coastal Water Research Project has reported, not only does storm water discharged to Santa Monica Bay contain high quantities of individual pollutants, but it also contains many different pollutants—including those of the greatest concern.[7] These pollutants include a toxic soup of hydrocarbons, pathogens, pesticides, sediment, nutrients and heavy metals. "Urban runoff now represents a larger percentage of the load for pollutants such as zinc, and surpasses loadings from wastewater treatment facilities for pollutants such as lead." *Id.*

---

[6] *See, e.g.*, EPA's National Urban Runoff Program (U.S. EPA, 1983); Gersberg, R.M., *Impact of Urban Runoff on Santa Monica Bay and Surrounding Ocean Waters* (1995); *State of the Bay 1998, Executive Summary* (Santa Monica Bay Restoration Project, Mar. 17, 1998) ("*State of the Bay*").

[7] *Santa Monica Bay Restoration Plan* (Santa Monica Bay Restoration Project, August 1994) ("*Bay Plan*") at ES-8; *see, also, id.* at 3-1 ("storm water [and] urban runoff is known to contribute significantly to [12 of the 19] pollutants of concern . . . .").

Indeed, in the past three decades, mass emissions of urban runoff-borne pollutants have increased dramatically in Southern California; this trend has continued during the 1990s, the period in which the Regional Board has been regulating most sources of polluted runoff in the Los Angeles area.[8] In particular, discharges of pollutants such as copper, nickel, nitate, zinc, phosphorous, and ammonia have grown significantly in runoff, while the amount of each pollutant has fallen in wastewater discharged from publicly-owned treatment works. Indeed, the United States Environmental Protection Agency itself recently has recognized that polluted runoff is the leading cause of impairment in the Los Angeles Region. *See Heal the Bay & Santa Monica BayKeeper v. Browner*, Case No. C98-4825 SBA, Amended Consent Decree at 2.

B. Southern California's Polluted Runoff Problem is Among the Worst in the Nation.

The storm water pollution discharged to Southern California's rivers, streams, and ultimately the ocean is not only significant relatively—that is, compared to other local pollutant sources—but also in comparison to storm water discharged in other regions. UCLA researchers have determined that Southern California is impacted by more storm water pollution than "90% of the other urbanized areas in the United States." Stenstrom & Strecker, *Sources of Storm Drain Sources of Contaminants to Santa Monica Bay* (1994) ("Stenstrom & Strecker") at 37; see generally *Los Angeles Times* (September 6, 1999).

1. Polluted Runoff-Related Public Health and Environmental Impacts are Serious and Numerous.

As a general matter, the United States Environmental Protection Agency has observed that storm water pollution and dry weather urban runoff are "increasingly important contributors of use impairment as discharges of industrial process wastewaters and municipal sewage plants

[8] "Changes in Contaminant Inputs to the Coastal Ocean." Southern California Coastal Water Research Project

R0008658

come under increased control. . . ." 55 Fed. Reg. 47990, § I (Nov. 11, 1990). Storm water harms coastal waters in part because it contains most, if not all, of the pollutants of greatest concern.[9] In Southern California, research now has demonstrated a variety of serious public health and environmental impacts.

a. Runoff-Related Health Risks at Local Beaches

Perhaps the most significant impact of storm water pollution affects one of the "major recreational beneficial uses of the Bay," swimming.[10] The documented presence of human pathogens in the surf zone of local beaches degrades water quality to such an extent that it is often unsafe for human contact. In fact, due to storm water pollution, many Santa Monica Bay beaches are unsafe for swimming during the rainy season, and many beaches remain unsafe even during dry weather. Because the beaches of Santa Monica Bay attract some 40 to 50 million recreational visits from both residents and tourists each year, the magnitude of this problem is considerable.[11]

These conditions, which are not limited to times when the beaches are officially closed, have been traced directly to urban runoff.[12] A 1995 epidemiological study conducted by the Santa Monica Bay Restoration Project and University of Southern California researchers

(1998).

[9] *The Quality of Our Nation's Water: 1994 Report to Congress* (Washington: U.S. EPA, 1995) at 25.

[10] *Bay Plan* at ES-11.

[11] *Bay Plan* at ES-14 and *Bay Plan Update* (Santa Monica Bay Restoration Project, July, 1997) at 34; *State of the Bay*.

[12] Official Department of Health advisories to avoid ocean contact for 72 hours following a storm are often issued. See *Testing the Waters 1999: A Guide to Water Quality at Vacation Beaches* at 33-34 (147 closures or advisories issued in Los Angeles County during 1998) (NRDC, 1999).

examined the health effects of swimming near storm drain outfalls in Santa Monica Bay.[13] The study found that people who swam directly in front of these storm drains experienced substantially more fevers, chills, ear discharge, vomiting, and similar maladies than those who swam 100 or 400 yards away from the outlets.

b. Runoff-Related Toxicity Impairs Streams and Marine Coastal Environments.

Recent studies indicate that storm water discharge plumes in the Los Angeles area are acutely toxic to marine organisms, and the plumes are detectable miles from discharge points.[14] Because storm water has a freshwater base, it does not mix easily with the ocean's saltwater medium. Consequently, plumes of storm water often remain intact within coastal waters for multiple days. Satellite pictures display enormous plumes of contaminated storm water stretching as far as the Channel Islands, miles off of the Ventura County coastline.[15]

c. Runoff Has Other Demonstrated Negative Impacts in the Marine Environment.

Research focused on Southern California waters also has confirmed additional negative impacts caused by polluted runoff, including impacts related to the growth of marine plants. Recently, researchers have observed phytoplankton blooms known as "red tides" near Malibu Creek and on the boundary of storm water plumes. Storm water inputs stimulate these blooms.[16] In Southern California, researchers also have observed that "high concentrations of . . . particles

[16] Bay, Jones, and Schiff, *Study of the Impact of Stormwater Discharge on the Beneficial Uses of Santa Monica Bay*, Executive Summary (SCCWRP, 1999).

in stormwater plumes may have an adverse impact on marine plants by reducing light penetation." *Id.* Storm water plumes reduced the depth at which photosynthesis can occur. and these impacts can occur with even the smallest storms. *Id.*

2. Polluted Runoff Problems Are Increasing in Regional Waters.

Finally. the overall volume of storm water running into coastal waters has increased steadily over the last century.[17] Storm water volume increases with population growth and with urbanization. both of which continue at a rapid pace in Southern California.[18] This fact means that in order to meet requirements to reduce storm water pollution in local waters, the Regional Board must reduce the amount of pollution discharged in absolute terms at a sufficient rate such that additional loadings related to regional growth.do not outstrip reductions made in established urban areas.

III. Legal Argument: The Storm Water Program in Los Angeles Violates Federal Law and Regulations.

The storm water problem is a complex one. and the different areas of the Storm Water Program that are designed to address it. such as outreach assistance to permittees. review of annual permit reports, and industrial site inspections. are interrelated to such an extent that if there is a lapse or a failure in one area of the program. then the other areas of the program will suffer was well. If. for example. inspections are not carried out or are superficial. Clean Water Act violations may never be discovered, and the end result will be more pollution entering the

[17] *Bay Plan Update* (Santa Monica Bay Restoration Project, July. 1997).

[18] This is. in large part. due to the fact that expanding populations modify land uses. replacing natural "sinks" with impervious surfaces. such as roads and buildings. Because rainwater cannot penetrate these surfaces. they create increased runoff. which then flows to the ocean in greater velocities and volumes.

region's waterways. Likewise, if industrial entities that should be permitted are not, the result is not only unregulated discharges of pollution but also the loss of needed permit-related fees that, if collected, would support staff activities and promote program adequacy.

NRDC demonstrates in the sections that follow that the RWQCB's Storm Water Program is not only inadequate in virtually every respect, but that individual programmatic failings are magnified in light of other inadequacies, with the end result being a program that is ineffective. Simply put, the RWQCB's efforts to control the largest source of water pollution in Southern California largely have failed; the program violates 33 U.S.C. §§ 1341 *et seq.* and accompanying regulations.

A. Insufficient Resources and Staffing for the Storm Water Program is the Root Cause of the Program's Illegality and a Fundamental Reason Why EPA Must Withdraw Approval.

When the United States Congress enacted the Clean Water Act, it recognized the fundamental importance of assuring that adequate resources were allotted by States to carry out the Act. Congress stated that:

> The objective of this Act will be met only if the States have vigorous and adequate pollution control programs. . . . [T]here are many states with serious deficiencies in the quality of their program, often caused by a serious inadequacy in the level of funding and manpower.

U.S. Code Cong. and Adm. News at 3685 (P.L. 92-500 §106) (1972).

The concern expressed by Congress, while couched in general terms, provides a perfect description of, and explanation for, the root problem that has hobbled the RWQCB's Storm Water Program: it is severely understaffed and under-funded. The magnitude of this problem becomes evident when (1) the number of legally-required program tasks and elements are considered; (2) the RWQCB's existing storm water staffing levels are compared to those that the

State itself has admitted are required; and (3) existing staffing levels are compared to other RWQCB water quality programs. to which substantially more resources are allotted in many cases. As the analysis below demonstrates. the Storm Water Program is structurally incapable of functioning at current staffing levels—and RWQCB staff know it and have complained about it.

1. A Legally Adequate Storm Water Program Must Have a Number of Separate Elements.

The Clean Water Act regulates two main types of storm water dischargers. and thus there are two main programmatic elements that comprise the storm water program: industrial (which includes construction sites) and municipal. *See* 33 U.S.C. § 1342(p)(3)(A)-(B). Each of these subprograms has many essential tasks which are connected. These tasks include: program development. including developing a storm water work plan and coordinating with other state and federal agencies; public outreach. including responding to general inquiries and conducting presentations and workshops; reviewing permit applications and issuing permits: reviewing annual reports and storm water management plans ("SWPPs"): conducting compliance inspections and monitoring: and initiating and carrying out enforcement actions. See id.; see also 33 U.S.C. § 123.63.

The staff resources necessary to complete these tasks are significant, as SWRCB and RWQCB documents indicate. Consider the following examples:

A single, adequate inspection of an industrial facility takes an average of 12 hours to complete, including drafting reports and related administrative tasks. Hence. to perform one annual inspection of each industrial entity subject to the General Industrial Storm Water Permit alone would take over 25 full-time staff.[19]

The RWQCB must conduct annual report reviews for every active storm water permittee in the region. Each review takes an average of 4 hours.[20] This means that approximately 14,000 hours—or about 8 full-time staff—are required just to perform adequate plan reviews each year.

---

[19] Personal communication with Regional Water Board Executive Staff (October 27, 1999).

Oversight and review of pollution reduction plans ("SWPPs")—the basic facility blueprints for storm water compliance—is also an essential task. The RWQCB estimates that at least 2.5 full-time staff would be necessary in order to review SWPPs submitted by industrial facilities.[21]

Municipal inspections are also a critical element of an adequate program. But cities are large, and adequate inspections of each municipal program would take nearly forty hours, when all required tasks are tabulated, according to RWQCB staff. Given the approximately 100 municipal entities subject to the Los Angeles County and the Ventura County municipal storm water permits, it would take nearly 3 full-time staff simply to conduct one annual inspection of each permittee.[22]

2. The State Allots Grossly Insufficient Resources to the Storm Water Program.

Given the number of tasks that Board staff is expected to complete, coupled with the magnitude of the caseload for the region, the State of California recognized that the Los Angeles Regional Water Quality Control Board would need a significant number of dedicated professional staff to carry out the program in a manner that is minimally effective. In 1994 the State undertook a planning exercise to identify the number of full-time staff necessary to carry out the program in the Los Angeles for each of the following five years:[23]

\\

\\

[20] Personal communication with Regional Water Board Executive Staff (October 27, 1999).

[21] *Work Plan for Storm Water—Industrial Permit Activities* (SWRCB 1994).

[22] Personal communication with Regional Water Board Executive Staff (October 27, 1999).

[23] *Five Year Work-Plan* (State Water Resources Control Board) at Table A-3

Fiscal Year	*Number of Full-time (FY) Staff*
1994-1995:	5.59
1995-1996:	7.74
1996-1997:	13.19
1997-1998:	16.65
1998-1999:	21.37

While these figures show that the State itself calculated that slightly over 21 full-time RWQCB staff would be necessary to implement the Storm Water Program, actual staffing levels have never exceeded 5.59 full-time staff.[24] Stated as a fraction of the staff the State itself claims are necessary. the RWQCB has only one person for every set of tasks that require four people to accomplish. Viewed from a different perspective. it takes the RWQCB staff four years to accomplish the amount of work that should be completed each and every year.

3. According to Assessments Prepared by the State Itself, Virtually Every Aspect of The Storm Water Program is Under-Funded and Inadequate.

The fundamental consequence of the failure to fund the program is that the Storm Water Program operates on a shoestring—and worse. Core elements such as issuance of permits. permit implementation, facility inspections. and enforcement activities all suffer significantly (each of these issues is discussed in following sections below). But these are simply the most noticeable program failures. State documents reveal that almost every task deemed by the State itself to be worthy of inclusion on staffing allocation assessments—such as SWPP review,

[24] Staff Report on Storm Water Discharges Associated Industrial Activities prepared for 12/14/98 Board hearing. at

outreach and education, group monitoring oversight and non-filer investigation—receive either no funding or a small fraction of the minimum funding deemed necessary. *See Los Angeles Regional Board Activities Under the Storm Water Program* (SWRCB, 1997); *see also Watershed Management Initiative Chapter* at 24-26 (Table 1) (listing storm water program elements as "underfunded" or "unfunded"). EPA itself has asserted that the Regional Board's storm water program is "severely underbudgeted." *EPA NPDES Program Implementation Review—Final Report Los Angeles Regional Water Quality Control Board at 29* (EPA, October 1999).

This lack of resources, and its effect on the quality of the storm water program, has not gone unnoticed by RWQCB staff, and consequently, by management. For example, in an e-mail dated March 25, 1998, one storm water staffer commented to Board management on the critical resource problem:

> I was asked many times what we can do to improve the SW program. I think we have to face reality first, recognize it, and then adjust expectations to the reality: if we are not able to receive resources matching the workload, [then] the expectations should be far less than what other regions are doing. Also, send this message out to the public, State Board, US EPA and demand some support.[25]

In another e-mail dated April 8, 1998, RWQCB staff emphasized that the resource limitations have resulted in the deconstruction of the Storm Water Program: "As I see it, we started with a SW [storm water] unit, five years ago, and now we dismantled it to pieces." This staff member concluded by noting that:

> The program does not need fixing—there is no program to start with ... Unless the Stormwater issues are really elevated to an important status level, there is nothing to be fixed. It is only patching work.[26]

2. (Regional Water Board).

[25] Correspondence from Dan Radulescu to Wendy Phillips (March 25, 1998).

[26] Correspondence from Dan Radulescu to Wendy Phillips (April 8, 1998).

4. The Storm Water Program Suffers To a Greater Degree Than Other Regional Board Programs.

Not only are the resources provided to the Storm Water Program insufficient as measured against the level identified as necessary by the State Water Resources Control Board, but the small number of personnel assigned to the Storm Water Program is sharply contrasted with the number of personnel assigned to other programs. For example, the Underground Storage Tank program has 24 full-time staff.[27] The "traditional," point source NPDES program has even more full-time employees assigned to it. *Id.* Yet, with 4 to 5 staff assigned to storm water, the RWQCB is attempting to carry out a program that is arguably far more complex—and and a far more significant cause of water pollution in the region.

5. Conclusion

Given the enormous level of work required by the storm water program and the low level of staff and resources allocated to it, it is clear that the Regional Board is not operating the storm water program at a level that comes close to meeting the requirements imposed by law. This failure to operate the program, and lack of control over the activities covered by it, meets the criteria for withdrawal of approval under 40 C.F.R. § 123.63(a)(2).

B. The Regional Board Has Failed to Exercise Control Over the Activities Required to be Regulated by the Clean Water Act's Storm Water Provisions.

As a condition of EPA approval, the Clean Water Act requires that any state storm water program maintain control over those basic activities that are the subject of regulation under the Act. 40 C.F.R. § 123.63(a)(2)(i); MOA at 6. With respect to the Storm Water Program, these include issuing permits to entities that require them: issuing legally adequate permits; and

[27] *Regional Water Quality Control Board Organizational Chart* (January, 2000).

providing sufficient staff resources to allow for timely implementation of permit requirements (specifically including those permit programs that must be separately approved by the Executive Officer before taking effect). Id.

The Regional Board has failed with respect to each of these requirements.

1. The Regional Board Has Failed to Issue Permits to Thousands of Illegal Dischargers

First, the Regional Board has failed to issue permits to thousands of industrial entities throughout Southern California who are now discharging runoff illegally without a Clean Water Act permit. According to numerous independent studies in the Los Angeles area, the approximately 3,500 facilities now enrolled under general permit coverage are only a fraction of those who are required to comply. In its report, "*Omission Accomplished*," the environmental group Heal the Bay demonstrated that, using conservative assumptions, as many as 10,000 industrial facilities in the Los Angeles region should be, but are not, enrolled under the general industrial storm water permit.[28] Other estimates of the number of facilities operating illegally without a discharge permit are as much as three times higher. While there may be some uncertainty about the number of non-complying facilities, the fact that the Regional Board has to "regulate tens of thousands of facilities" not currently under permit is beyond doubt.[29]

While each facility has a legal duty to comply in the first instance, the Regional Board has the overall responsibility to assure that "all discharges subject to NPDES . . . programs [are regulated] in conformance with Federal and State law, regulations, and policy." MOA at 6. The

[28] Heal the Bay, *Omission Accomplished: The Lack of a Los Angeles Regional Water Board Enforcement Program, 1992-1997*, at 23 (January 1999).

[29] *Fact Sheet, Industrial Storm Water Program, Los Angeles Region*, at 1 (RWQCB, 1998); Correspondence from Dennis Dickerson, RWQCB, to Mike Schulz, Associate Director, EPA Region IX at 9 (November 4, 1998) ("we admit that there are a large number of non-filers within the Region . . . .").

sheer number of facilities operating without a permit, year after year, demonstrates the Regional Board's neglect of its legal obligation. Under these circumstances, EPA's duty to suspend Regional Board authority in light of the RWQCB's failure to "exercise control over activities required to be regulated . . . . including failure to issue permits," could not be more clearly invoked. 40 C.F.R. § 123.63(a)(2)(i).

2. <u>The Regional Board's Most Important Permit Is Legally Flawed.</u>

Second, the Regional Board has failed to assure that its single most important storm water permit, the Los Angeles Municipal Storm Water Permit ("LA Municipal Permit"), meets basic legal mandates and EPA policy. This omission may be related to the fact that the Regional Board has admitted that its permit development activities are "underfunded" and it is able to "deal with only some of [the] issues on the table." *Watershed Management Initiative Chapter* at 24 (Table 1) (RWQCB, 1998).

Specifically, the LA Municipal Permit does not contain legally adequate provisions regarding the obligation of dischargers to meet water quality standards. The LA Municipal Permit provides that discharges will be deemed to be in compliance with water quality standards as long as the permittee has implemented the Permit in a complete and timely manner. *LA Municipal Permit* at 12 ("Receiving Water Limitations").

This provision continues today in force notwithstanding EPA's repeated objection to similar permit language and its issuance of legally adequate, "model" water quality standard provisions in 1999. Significantly, EPA-approved language includes the following absolute prohibition absent from the LA Municipal Permit: "discharges . . . that cause or contribute to the violation of water quality standards or water quality objectives (collectively WQSs) are prohibited." *See, e.g., NPDES Permit for the Santa Margarita Watershed* (Permit No. CA 0108766) at 4 (April 28. 1999); *see also, correspondence from Alexis Strauss, Director Water Division, EPA Region IX to Loretta Barsamian, Executive Officer, San Francisco Regional Water Quality Control Board* (March 17, 1999) (setting forth EPA objections).

By failing to include important permit conditions in its most significant storm water permit, the Regional Board has failed to maintain "technical expertise, administrative procedures and management control such that implementation of the NPDES .. program[] consistently conforms to State laws, regulations and policies." MOA at 6. It has further failed to regulate major dischargers in conformance with applicable laws and policies. Id. On this basis, EPA must withdrawal program approval. 40 C.F.R. § 123.63(a)(4).

3. The Regional Board Has Failed to Effectively Oversee Permit Implementation.

Third, the Regional Board has failed to assure that significant storm water permits, particularly the LA Municipal Permit, are implemented in a timely fashion. Board staff repeatedly failed to exercise management control and oversight sufficient to approve model programs required under the terms of the LA Municipal Permit, thereby substantially delaying implementation of the critical core permit programs designed to reduce runoff pollution.

The LA Municipal Permit included requirements for the subsequent approval of nearly a half dozen model programs to educate the public and control pollutants associated with development and redevelopment, public agency activities, and illicit connections and illegal discharges. See, e.g., *LA Municipal Permit* at 26, 32, 42. The structure of the permit is such that the approval of each model program by the Executive Officer of the RWQCB serves as the "trigger" after which each of the 85 permittees must implement their own individual program. based upon the approved model program. See *LA Municipal Permit* at 26. As such, a failure to approve a model program in a timely fashion has the direct of effect of hamstringing permit implementation.

This is precisely what occurred since July 1996, when the current LA Municipal Permit was adopted by the Regional Board. As the following table demonstrates. RWQCB staff almost immediately lost control of the implementation process, ultimately approving each model program many months (and sometimes years) after applicable permit deadline:

Model Program	*Permit Deadline*[30]	*EO Approval Date*[31]
Public Agency	December 1, 1997	October 21, 1998
Illicit Connection/ Illicit Discharge	March 31, 1997	March 23, 1999
Development Planning		
Program	January 30, 1998	February 11, 1999
BMP List	January 30, 1998	April 22, 1999
SUSMPs	June 30, 1998	January 26, 2000
Development Construction	September 30, 1997	April 22, 1998
Public Education	July 30, 1997	December 1, 1997

[30] *LA Municipal Permit* at 26, 36, 38, 42; *see also Management Report, July '99-September '99* at 12-13 (LARWQCB).

[31] *See* Correspondence from Dennis Dickerson to Interested Parties (February 10, 1999) (IC/ID); *see generally Management Report, July '99-September '99* at 12-13 (RWQCB).

Demonstration of Legal Authority	November 28, 1996	July 5, 1998

According EPA itself, these failures "severely hindered" progress under the storm water permit. *EPA NPDES Program Implementation Review—Final Report Los Angeles Regional Water Quality Control Board at 29* (EPA, October 1999). The delayed approval of these programs underscores that the Regional Board's resource-related inability to oversee implementation of the storm water program extends not only to requirements imposed by federal or state law, but also to those that it designs, such as the model program requirements.

C. <u>The Regional Board Has Failed to Inspect Most Industrial Storm Water Dischargers.</u>

The failure to inspect and monitor storm water dischargers is an enumerated basis for program withdrawal. <u>See</u> 40 C.F.R. § 123.63(a)(3)(iii). This requirement is underscored in the MOA between EPA and the State, which provides specifically that the "Regional Boards shall conduct compliance inspections to determine the status of compliance with permit requirements, including sampling and non-sampling inspections."

Inspection of industrial facilities, construction sites, and municipal entities is a basis for program withdrawal because it is critical to program success. In addition to discovering violations of permits that may be causing pollution to enter waterways illegally, inspections enable Board personnel to meet with facility operators and review permit obligations and measures necessary to prevent pollution. Without an adequate inspection program, it is extremely difficult for RWQCB to determine whether dischargers are complying with permit terms, and thus whether the Storm Water Program is functioning as intended. This is especially true because unlike traditional point sources, who are required to submit detailed monitoring reports regularly, most storm water permittees do not submit similar data.

As discussed below, the Regional Board's storm water inspection program is totally inadequate EPA has identified the need for increased "field presence" by the Regional Board. but given that inspection and program review activities are "under to unfunded," only a "small percent of permitted businesses are inspected." *EPA NPDES Program Implementation Review—Final Report Los Angeles Regional Water Quality Control Board at 29* (EPA. October 1999); *Watershed Management Initiative Chapter* at 24-26 (Table 1) (RWQCB, 1998).

Consequently. the Regional Board staff has conducted only <u>four</u> audits of municipal storm water permittees in Los Angeles County. Furthermore, RWQCB staff annually conduct inspections of only an extremely small percentage of the industrial entities covered under the General Industrial and Construction Permits. Indeed. the Regional Board's failure to inspect industrial facilities is a special factor contributing to storm water pollution in Southern California because this region is the most heavily industrialized in the State of California.[32]

1. <u>The Regional Board's Municipal Storm Water Inspection Program is Virtually Non-Existent</u>.

The State of California's *Storm Water Program Five Year Work Plan* specifies that, beginning in July 1994, "municipal [storm water] programs will be evaluated annually through offsite and onsite audits." *Storm Water Program Five Year Work Plan* at V-9 (State of California. 1994) ("Work Plan"). The Work Plan further specifies the inspection elements required annually for each municipal discharger:

> Onsite audits occur at municipal facilities or sites within the drainage area of a municipality's storm drain system. and consist of interviews of municipal program managers and personnel, review of records, meetings to review offsite-audit

[32] *Watershed Management Initiative Chapter* at 7 (RWQCB. May 15. 1998).

> findings. and inspection of specific projects or actions (e.g.. drop-inlet cleaning. construction-site inspection. control measure effectiveness study) conducted by a municipality. . . . The following activities are included in this task:
>
> (a) Conduct offsite audit:
> (b) Conduct onsite audit;
> (c) Implement appropriate follow-up action.

The requirement of annual inspections is consistent with U.S. EPA mandates, which require an annual inspection of all major dischargers. and at least one inspection every five years for all "minor" discharges. *See State Water Board's Responses to Legislative Analyst's Office Questions* at 6 (October 8. 1998); *Storm Water Five Year Workplan* at VI-15 (SWRCB, 1994) (treating industrial entities as minor storm water dischargers).

Notwithstanding this requirement. RWQCB records show that only four "site visits" to Los Angeles area municipal dischargers (the cities of Pomona. Lynwood. Inglewood. and Santa Monica) and only 17 visits to Ventura County permittees have taken place since 1996. *See L.A. Municipal Storm Water Permit Key Tasks* at 1 (RWQCB 1998): *see also Performance Tracking Reports* (RWQCB, 2000).[33] To put this number in perspective. over a period of three years. the RWQCB should have conducted one annual audit of each of the 95 municipal permittees (for a total of 285 audits). and each audit should have included offsite and onsite components. Even assuming that each of the RWQCB's 21 "site visits" met established requirements (as set forth above). the RWQCB's municipal inspection activity in Los Angeles and Ventura Counties is 7% of the required level.

---

[33] Some RWQCB documents state that 3 audits were conducted. *Performance Tracking Reports* (RWQCB. 2000).

2. <u>The Regional Board's Industrial Inspection Program is Totally Inadequate.</u>

As noted. U.S. EPA requires site inspections of major dischargers on an annual basis and all others at least once every five years. Even assuming that each permitted industrial discharger and construction site in the Los Angeles area were considered a "minor" (instead of "major") discharger. the RWQCB must conduct inspections of at least twenty percent of all enrolled entities every year to meet minimum requirements.[34]

Records show that Regional Board staff have not completed anywhere near the minimum required number of inspections. even if it is assumed for the sake of analysis that the most easily achieved standard applies—one inspection per facility every five years. From June 1996 through June 1999. the Regional Board conducted a total of only 858 inspections, which represents approximately 24% of the 3,558 permitted industrial facilities.[35] Hence. the Regional Board's rate of inspection is *at least* three times slower than legally adequate.

Moreover. according to staff, many of these inspections were in response to a Notice of Termination (a submittal that indicates that a facility is closing). Overall, 384 of the reported three-year total of 859 inspections (nearly 45%) were related to facility closure—when polluting activities putatively have ceased. The table below sets forth the minuscule number of *compliance* inspections that the Regional Board claims were conducted at all industrial sites (including construction) in each of the last three full years (for which data is available):

---

[34] The State. however. committed in 1994 to conducting an initial inspection visit to every new industrial discharger over a three-year period beginning in 1996. *See Stormwater Program Five Year Workplan* at VI-18 to VI-19 (SWRCB 1994). The RWQCB has failed to meet this program task.

[35] *General Industrial Storm Water Permit Statistics November 1999*, at 1 (RWQCB). *See also List of Industrial Storm Water Permittees*, available at www. swrcb.ca.gov/html/indpmt.html (SWRCB): *See List of Active Construction Storm Water Permittees*, available at www.swrcb.ca.gov/html/cnstrpmt.html (SWRCB). These lists are updated daily. and so total counts vary over time.

Year	*Number of Facilities Inspected*[36]	*Percent of All Enrolled Facilities*
1996-1997	50 facilities	1.4%
1997-1998	123 facilities	3.4%
1998-1999	302 facilities	8%

For fiscal year 1999-2000, Board staff indicated that 454 inspections of industrial facilities are planned, due to a one-time funding increase.[37] Even this level of effort amounts to barely 13% of currently enrolled industrial facilities, still far short of the most lenient inspection rate standard. Moreover, through the end of 1999, Regional Board staff had only conducted 49 inspections, making it all but impossible for them to come anywhere close to their goal.[38]

Yet, even this picture of inadequacy does not fully capture the extent of the problem. According to numerous independent studies in the Los Angeles area, the facilities now enrolled under general permit coverage are only a fraction of those that should be complying but are not. As noted above, as many as 10,000 or more facilities should be enrolled under a general storm water permit; at the RWQCB's average annual rate of inspection it would take the Regional Board nearly 35 years to inspect every ones of these facilities.[39]

---

[36] *General Industrial Storm Water Permit Statistics November 1999*, at 1 (Los Angeles Regional Water Board 1999); personal communication with Xavier Swaminkannu (January 2000). NOTE: Throughout this petition, NRDC bases its analysis on data provided pursuant to Public Records Act requests transmitted to the RWQCB, SWRCB, and EPA. NRDC believes that the data provided regarding inspections overstates RWQCB inspection efforts due to poor record-keeping and the lack of a single, consistent data gathering system employed by the RWQCB. In all, NRDC spent over two months attempting to decipher, with the help of RWQCB staff, the precise level of RWQCB inspection activity, and we believe that it is simply impossible to say exactly how many inspections were actually conducted. Nevertheless, we are reporting the data currently available to us. The only error, therefore, that could be introduced into our analysis by the RWQCB's record-keeping would be one that casts RWQCB activities in overly *positive* light. NRDC reserves the right to supplement or revise inspection data based on further discovery.

R0008676

3. Summary

Given these facts, the criteria for EPA's withdrawal of approval under 40 CFR § 123.63 (a)(3)(iii) and (a)(4) for failure to inspect and monitor activities subject to regulation easily has been met. Not only has the RWQCB failed to inspect the vast majority of facilities under its control, it has wholly failed to implement the terms of the MOA between EPA and the State, an agreement which provides that "the Regional Boards shall conduct compliance inspections to determine the status of compliance with permit requirements, including sampling and non-sampling inspections." MOA at § IV.B.1.

D. The Regional Board Rarely Enforces Storm Water Laws and Regulations.

In order for a law or regulation to achieve its goals, it must induce compliance. Compliance with the law will only result if there is an effective enforcement program to induce it. Accordingly, the failure to act on violations of the Clean Water Act, including non-compliance with permits and other program requirements, is grounds for withdrawal of state programs. 40 C.F.R. § 123.64. Unfortunately, while the RWQCB has increased its enforcement of storm water violations in 1999, overall the storm water enforcement program is still inadequate. The Regional Board itself states that its enforcement program is "underfunded" and, as a result, it is only able to conduct "[m]inimal administrative review and enforcement" and deal with "major non-compliance." *Watershed Management Initiative Chapter* at 24-26 (Table 1) (RWQCB, 1998). As demonstrated below, this "enforcement" program in no way encourages compliance with the law, nor is it consistent with the applicable requirements.

1. Minimum Standards for Enforcement.

When EPA delegated NPDES authority within the Los Angeles area to the State, the Regional Board became the chief enforcement agency for "NPDES permit requirements," including those applicable to storm water dischargers. MOA at 38. The RWQCB is required under the terms of the MOA between EPA and the State to take "timely and appropriate enforcement actions in accordance with the CWA, applicable Federal regulations, and State Law." MOA at 6. Finally, in this respect, the Regional Board must assure "that no one realizes an economic advantage from noncompliance." *Id.*

Pursuant to the MOA, additional enforcement policy is set through California's Administrative Procedures Manual ("APM"). MOA at 2. The APM provides that "*violations of . . . applicable statutory or regulatory requirements should result in a prompt enforcement response against the discharger.*" APM at 5 (italics in original). The APM also provides that any incidence of toxicity should be brought to the attention of the RWQCB for possible enforcement action. *Id.* With respect to failure to obtain permit coverage, the APM states that such a violation is "significant." *Id*

2. <u>The RWQCB Takes Very Few Enforcement Actions Against Storm Water Dischargers.</u>

In all, "[c]ompliance assurance and enforcement outputs in the Storm Water Program are <u>very low</u> relative to the number of regulated facilities." *Compliance Assurance and Enforcement Strategy* (SWRCB, 1998) (emphasis added). This finding is especially true of the Los Angeles RWQCB. During the period from January 1997 through June 1999, despite the over 3,558 enrolled industrial and construction facilities in the region, and the approximately 100 additional municipal dischargers, the RWQCB brought only 37 formal enforcement actions (denoted by the Board as "Level 3" actions) for violations of storm water regulations. *See Quarterly Report of Violations and Enforcement Actions* (January 1997-June 1999).[40]

[40] During preparation of this Petition, Petitioners sought enforcement totals for the second half of 1999. Those

3. Formal Enforcement Action Pursued by the RWQCB Concerns Reporting Requirements and Only Extends to Certain Types of Dischargers.

While the small number of formal enforcement actions taken by the RWQCB indicates that the enforcement program is depressed, even this figure does not capture the degree of inadequacy. As the chart below illustrates, entire sectors of storm water dischargers do not receive any formal enforcement attention at all:

Formal Enforcement by Category and Type, January 1997-June 1999

	Municipal	*Industrial*	*Construction*
Formal Enforcement (discharge/BMP-related):	NONE	NONE	3
Formal Enforcement (reporting-related):	1	33	NONE

As the chart shows, the Regional Board only took 3 formal enforcement actions for the most substantive violations (such as for unlawfully discharging runoff or failure to implement BMPs) during the entire period for all discharger categories combined.[41] The RWQCB took no formal enforcement actions during the period against industrial dischargers for the most substantive violations. Similarly, the RWQCB took one formal enforcement action against municipal dischargers for any type of violation. The RWQCB took only five informal enforcement actions (Level I or Level II) against municipal dischargers. *See Id.* (January 1997-June 1999 Reports).

summaries had not yet been compiled. Pers. Comm Wendy Phillips (January 13, 2000). Note also that of the formal (Level III) enforcement actions brought by the Board for the six years from 1991 through 1997, only two were for violations of storm water permit requirements, of which one was for a violation of an industrial permit, the other being for construction storm water violations. *See Omission Accomplished* at 21 (Heal the Bay, 1998).

[41] These actions were taken against three construction firms: RCS Development Company/Western Pacific Housing (ACL No. 99-007), Beazer Homes Southern California (ACLs 99-012), and Shea Homes (CAO No. 99-008). *See Id.* (April-June 1999).

4. <u>The RWQCB Must Greatly Increase the Level of Enforcement Activity to Stem Violations of the Clean Water Act.</u>

General analyses by the State of California and the RWQCB confirm the impression that the miniscule number of enforcement actions described above is failing to compel compliance with the Clean Water Act.

In a general statewide review, the California Environmental Protection Agency ("California EPA") itself concluded in 1999 that "the number of water quality violations is unacceptably high and that there is a significant gap between the number of enforcement actions needed and the number taken." *Compliance Assurance and Enforcement Initiative* at 9 (SWRCB, September 1999). California EPA further conducted an analysis of 986 violations, representing a five percent sample. It found that:

> the review team determined that these violations should have resulted in a total of 248 enforcement actions, including 167 informal actions and 81 formal actions. Of the needed enforcement, only 68 informal and 8 formal actions were actually taken. . . . Projecting the results . . . indicates that there are approximately 21,000 violations per year . . . .

<u>Id.</u>

Within the Los Angeles Region, the RWQCB staff recently completed one of the first specific studies of non-compliance within the Storm Water Program. Staff examined one sector of industrial storm water permittees, the auto dismantling industry, in order to determine "whether auto salvage yards have complied substantially with the federal storm water regulations for industrial activities." *Storm Water Pollution in the Auto Dismantling Industry: Evaluation of Compliance with the California General Industrial Storm Water Permit* at 2 (Draft, January 2000) ("Compliance Evaluation").

The answer to this question is a resounding "No." As a point of departure, staff noted that compliance of permitted facilities of all types within the industrial storm water segment was "not well characterized." Id. at 5. After conducting document reviews and site visits, the RWQCB's preliminary findings include: (i) "[s]ite inspection revealed BMPs not fully implemented"; (ii) "25% of facility operators did not know what a SWPPP was"; (iii) "[m]ajority of SWPPPs were not site-specific"; and (iv) "enforcement actions on [only] 10% of facilities who failed to submit SWPPP by deadline." Compliance Evaluation at 23.

Further, the vast majority of SWPPPs reviewed by staff were judged to be inadequate or totally missing certain information. *Id.* at 24-25, 27. Monitoring programs were adjudged to be totally inadequate in five of six categories. *Id.* at 26, 28. Not surprisingly, sampling conducted at the facilities within the evaluation showed exceedances "for all constituents (TSS, SC, O&G, Al, Cu, Fe, Pb, and Zn) except for Ph." *Id.* at 40, 45. Concentrations of metals were particularly high. Id.

This evaluation serves to confirm that the RWQCB is not compelling compliance in this industrial segment. Moreover, by implication these findings strongly suggest that the RWQCB is not compelling compliance in any of the other industrial segments subject to the regulation under the industrial storm water permit. In fact, given that the auto dismantling industry has been subject to a prolonged, well-publicized citizen enforcement effort by the Santa Monica BayKeeper, the high levels of non-compliance identified by the RWQCB actually may be statistically lower than in many other industrial segments, who have not been subject to any serious enforcement effort

\\

\\

5. <u>RWQCB Staff Have Failed to Formally Notify the Board that Storm Water Discharges to Santa Monica Bay and Other Receiving Waters Are Acutely Toxic.</u>

As noted above. the Southern California Coastal Water Research Project has found that storm water discharges in Southern California often are acutely toxic. even when diluted ten to one. These findings. however. never have been formally presented to the RWQCB as a basis for enforcement action, contrary to the express requirements of the Administrative Procedures Manual. APM at 5 ("toxicity").

6. <u>Summary</u>

In all. the RWQCB's enforcement program is inadequate where it exists and. with respect to municipal and industrial dischargers. it remains virtually non-existent. especially when it comes to stopping unlawful discharges and enforcing BMP implementation. As statewide and regional analyses by the State itself show. countless violations of law are not subject to any enforcement. and programmatic compliance. as a consequence, remains spotty at best.

These conditions are precisely those for which withdrawal of EPA approval was designed. *See* 40 CFR § 123.63(a)(3) (withdrawal approval where there has been a failure to act on violations of permits or other program requirements); *see also* MOA at 6 (responsibility of the RWQCB to assure that no one realizes an economic advantage from noncompliance and to take timely and appropriate enforcement actions). EPA must. therefore, withdrawal approval of the Regional Board's Storm Water Program on this enumerated basis/

\\

\\

F. Continuing Storm Water-Related Violations of the Clean Water Act Demonstrate the Overall Failure of the Storm Water Program and the Need for EPA to Withdraw Approval.

This Petition has demonstrated that the Storm Water Program in the Los Angeles area is inadequate in virtually every respect. In the end, however, one of the most serious indictments of this program is the chemical and biological characteristics of storm water discharges in the region. As demonstrated above, scientific investigations by independent agencies and organizations have established two fundamental facts. First, in Southern California runoff is often acutely toxic in freshwater and marine environments, even when diluted substantially. Second, in Southern California runoff conveys human pathogens to waterways which are heavily used for contact recreation. Studies show that exposure to runoff or these runoff-contaminated waters dramatically increases the incidence of certain illnesses. *See supra* at 6-11.

These conditions are not merely regrettable, they are illegal. The Clean Water Act prohibits the discharge of toxic contaminants in toxic amounts. It further prohibits the discharge of disease-causing microbes and viruses and the impairment of affected beneficial uses, such as swimming in the ocean. In fact, the Act affirmatively requires that beneficial uses of waters—such as habitats for fish or as recreational resources for people—be protected and maintained. *See* 33 U.S.C. § 1251(a); (objective of the Clean Water Act is "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters"); 33 U.S.C. § 1251(a)(3) ("it is the national policy that the discharge of toxic pollutants in toxic amounts be prohibited"); 40 C.F.R. § 122.44 (probibiting discharges which "cause, have the reasonable potential to cause, or contribute to" a violation of a water quality standard"); *Water Quality Control Plan for the Los Angeles Region*, Chapters 2 and 3 (providing that "all waters shall be maintained free of toxic substances [in toxic concentrations]" and designating recreation as a beneficial use of coastal waters): *California Ocean Plan* (Water Quality Control Plan, Ocean Waters of California) at 2 (bacterial characteristics, water-contact standards) (SWRCB. 1997).

The scientifically-demonstrated attributes of the storm water problem is. in the final analysis. the ultimate "proof in the pudding" of the RWQCB's failure to implement a legally adequate Storm Water Program. The truth is plain: storm water discharges in the region violate the Clean Water Act on a regular, predictable. and ongoing basis. In turn. these indisputable facts show specifically that the RWQCB is. among other things. (1) unlawfully failing to regulate discharges in a manner consistent with state and federal law. (2) unlawfully failing to maintain management control sufficient to assure that storm water discharges meet applicable laws, regulations, and policies, and. most generally. (3) unlawfully failing in its duty to implement the most basic elements of the Clean Water Act. *See* MOA §§ I.C.3 and IV.B.1 (regional board duties).

Under these circumstances. the Administrator must assure that such deficiencies are immediately corrected or the State's authority to oversee the Clean Water Act Storm Water Program in Los Angeles must be revoked.

IV. <u>Conclusion</u>

For all of the reasons set forth above. NRDC respectfully requests that the Administrator commence withdrawal proceedings pursuant to 40 C.F.R. § 123.64(b)(1). Further, each of the aforementioned legal inadequacies must be corrected within ninety days, and a legally adequate storm water program must be implemented in Los Angeles within this period. If this does not occur. the Administrator must withdraw EPA authority from the Los Angeles Storm Water Program. With respect to the specification of the precise characteristics of a legally adequate program. NRDC reserves the right to further brief this issue after further discovery. *See* 40 C.F.R. § 123.64(a)(3)(D) ("Motions"). NRDC further reserves the right to supplement the facts and legal arguments contained herein.

Respectfully Submitted.

Subject: swimming pools & training -Reply

New Jersey has a General Discharge to Surface Water Permit for swimming poool discharges that acts like a permit-by-rule in that discharges are allowed as long as certain requirements are met, e.g. the water must have sat in the pool for at least 48 hours so that the chlorine has a chance to dissapate. If anyone wants a copy of the permit let me know.

On the Navy presentations I am still confused - is this in addition to the regional traing sessions or are these the regional training?

Barry Chalofsky

CONDITIONS FOR AUTHORIZATION UNDER THE NJPDES DISCHARGE TO SURFACE WATER GENERAL PERMIT FOR SWIMMING POOL DISCHARGES (NJ0128589)

The New Jersey Pollutant Discharge Elimination System (NJPDES) Discharge to Surface Water (DSW) General Permit for Swimming Pool Discharges authorizes the discharge of water containing de minimis amounts of pollutants as specified below, without the submittal of a NJPDES permit application or request for authorization and without an individual permit or other written notification of authorization from the Department of Environmental Protection (Department), as of the effective date of this general permit. A de minimis discharge of pollutants for purposes of this general permit is defined as water, which complies with all of the conditions, specified in this permit. The entity responsible for the work, which results in a discharge authorized by this permit, is required to certify that the proposed discharge(s) will comply with all of the conditions of this permit. The certifying entity must maintain a copy of this certification on-site and where it is impractical to maintain on-site, must provide a copy to the Clerk of the municipality where this discharge activity will occur or occurs. However, no submittal to the Department is required. Conditions for discharges authorized by this general permit are further specified below. Questions or comments regarding this permit should be directed to Jim Grob of the Division of Water Quality at (609) 292-4860.

PURPOSE AND SCOPE

The New Jersey Water Pollution Control Act (N.J.S.A.58:10A), also known as the state Clean Water Act, requires that all discharges of pollutants into waters of the state be in conformance with a valid NJPDES permit. This permit has been developed to authorize discharges to surface water which are essentially clean yet may contain detectable levels of regulated pollutants. These discharges are not directly associated with industrial processes, site remediation activities or sanitary sewerage systems, and are of a temporary, short-term, non-continuous nature, yet require regulation by the Federal and State statutes and regulations, in accordance with 33 U.S.C. 1251 et seq. at 1972 P.L. 92-500, the Federal Water Pollution Control Act as amended (the federal Clean Water Act), N.J.S.A. 58:10A et seq., and N.J.A.C. 7:14A 1.1 et seq. The Department has determined that these types of discharges are appropriately controlled under a general permit, and is issuing this general permit in accordance with 40 CFR §122.28 and §123.25 and N.J.A.C. 7:14A-6.13, thereby exempting this class of discharges from obtaining individual NJPDES/DSW permits. These types of discharges are similar in nature because of their low probability of containing pollutants (other than the pollutants specified below), the relatively infrequent nature of the discharge, and the relatively low concentration of pollutants present in the discharges. Pollutants that may be present in these discharges are specified below and include filterable or dissolved solids, suspended solids, and chlorine and chlorine related compounds. This General Permit requires that these discharges be subject to Best Management Practices (BMPs) to minimize if not eliminate any environmental impact that may otherwise result from the discharge. This permit operates under the premise that if appropriate BMPs are implemented prior to discharge; no negative or negligible environmental impact should result from the discharge. If appropriate BMPs are not employed and the discharge causes adverse environmental impacts to the receiving waters, the discharge is in violation of this permit and the entity authorizing the activity and certifying compliance with the requirements of this general permit.

There are no requirements to file with the Department in order for a discharge to be authorized by this permit. The company or entity conducting the activity which will result in a surface water discharge to be authorized by this permit must execute a certification stating that the discharge will comply with all applicable conditions of this permit, in addition to providing specific information about the discharge itself. This certifying agent will also be responsible for ensuring that the discharge meets all applicable requirements of this general permit during the discharge event. (Specific information regarding the required certification is found in Section C of this permit. Certification forms are available from the Division of Water Quality.) The company or entity authorizing the work must maintain the original copy of the certification. A copy of this certification must be maintained on site during the discharge event. Where it is not practical to keep a copy on site, a copy must be maintained in the business office of the certifying agent and provided to the clerk in the town or municipality where the discharge activity is occurring.

The discharges from the draining of and filter backwash from municipal, commercial, or other non-residential swimming pools which use chlorine may be eligible for authorization by this permit:

Discharges eligible for authorization under this permit may be discharged to all surface waters of the State of New Jersey (State), directly and via storm sewers, except for waters categorized as FW1, as defined in N.J.A.C. 7:9B-1.15.

Schedúled multiple short-term discharges occurring over a period of time are eligible for authorization under this permit. In these instances the Department requires the certification to include a schedule of occurrence of all of the discharges. If a discharge cited above exceeds a short-term nature due to unforeseen circumstances and it becomes necessary to extend the duration of the discharge, the certifying agent may submit a written request to the Department for a determination of eligibility to be authorized by or to continue to be authorized by this permit.

The Department may authorize other (multiple) discharges that are short-term in nature but which will occur over a period of time under this general permit upon written approval. The agent should submit a request to the Department to be authorized under this permit and include an estimated discharge schedule. Other similar types of planned, non-continuous short-term discharges may qualify for coverage under this permit on a case-by-case basis based upon individual written approval by the Department.

Discharges resulting from filter backwash operations (other than swimming pools using chlorine) are required to obtain authorization under another general or individual NJPDES permit. Questions regarding discharges, which are similar to the discharges, listed above but which are not specified, or questions regarding the eligibility of any discharge by this general permit, should be directed to the Division of Water Quality at (609) 292-4543 so that a permit determination can be made.

Incidental discharge to ground waters of the State which may result from a discharge authorized by this permit, such as from overland flow on the way to the storm sewer or surface water conveyance, are also authorized under this general permit.

EXCLUSIONS

Discharges **specifically excluded** from authorization under this permit include:

- all discharges of industrial process wastewater including contact and non-contact cooling water,
- sanitary sewer flushing,
- discharges from domestic, publicly or privately owned, and industrial treatment works (except for potable water storage tank overflow),
- combined sewer overflow,
- sanitary sewer overflow,
- all stormwater discharges,
- discharges associated with site remediation activities, including water from well construction and development,
- contaminated water from monitoring well construction and development or capping,
- discharges from water and wastewater treatment system bench scale and pilot testing,
- discharges resulting from filter backwash operations (except from swimming pools meeting the requirements set forth in this permit),
- draining of and filter backwash from municipal, commercial, or other non-residential swimming pools which use pool chemicals other than chlorine,
- water used to clean and rinse storage tanks, natural gas pipelines, or other vessels,
- contaminated waters resulting from construction dewatering activities,
- discharges resulting from water main breaks and water distribution system infrastructure failures, and
- emergency discharges of polluted waters.
- dewatering from construction activities from commercial industrial development such as gasoline stations, auto repair shops, brownfields development, etc.

A. <u>GENERAL CONDITIONS</u>

1. This permit is revocable, or subject to modification or change at any time, pursuant to the applicable regulations, when in the judgment of the New Jersey Department of Environmental Protection such revocation, modification or change is deemed necessary.

2. The issuance of this permit shall not be deemed to affect or restrict in any way action by the Department of Environmental Protection of the State of New Jersey on any future application.

3. This permit does not waive the requirement to obtain other Federal, State or local government consent or approvals when necessary. No work shall be undertaken until such time as all other required approvals and permits have been obtained. This permit does not grant permission to use publicly or privately owned storm sewers or conveyances.

4. The Department reserves the right to require the certifying agent to apply for an individual or other general NJPDES permit if deemed appropriate, or the certifying agent may request exclusion from coverage under this general permit by applying for an individual or other general NJPDES permit.

5. Representatives of the Department shall have the right to enter and inspect any area associated with a discharge authorized under this permit.

B. WATER QUALITY REQUIREMENTS

1. The discharge shall not contain toxic pollutants in toxic amounts, as defined under 33 U.S.C. 1251 et seq., the Federal Water Pollution Control Act, or N.J.S.A. 58:10A-1 et seq., the New Jersey Water Pollution Control Act, or other pollutants, including temperature and pH, in mass, concentration, or other measures of degree which could cause adverse impacts or be detrimental to the natural aquatic biota, or which could cause instream exceedances of applicable Federal or New Jersey Surface Water Quality Standards criteria (N.J.A.C. 7:9B-1.14 et seq.) of the receiving water.

2. The discharge shall not cause or result in erosion to the area of the discharge or the surrounding stream banks. Adequate dewatering structures and velocity dissipation devices should be used when necessary to prevent and minimize erosion, stream scouring, and increases in turbidity or any other potential damage to the receiving waters and its environs. Dischargers may refer to "Standards for Soil Erosion and Sediment Control in New Jersey", as promulgated by the State Soil Conservation Committee and N.J.A.C. 2:90-1.3 et. seq. In addition, the regional Soil Conservation District office (organized by county) may be contacted for guidance on soil erosion control.

3. The discharger shall take into account the conveyance capacity of the discharge outlet structure and/or conveyance structure prior to discharge and shall manage or control the flow of the discharge accordingly. The discharge shall not cause or create downstream flooding conditions.

4. The discharge shall not contain any scum, foam or other residual matter.

5. The following pollutant-specific guidelines and requirements shall be employed, when necessary, to comply with the terms of this general permit. Best Management Practices (BMP) appropriate to the type of discharge shall be employed at all times.

   Suspended Solids

   The discharger shall minimize the amount of suspended solids or turbidity in the discharge to the maximum extent practical. If the discharge contains suspended solids, BMPs shall be utilized to reduce or eliminate the levels prior to discharge to receiving waters. These BMPs can include everything from increased retention time up to and including filtration devices (such as hay bales).

   Other Solids

   There shall be no discharge of floating solids in other than trace amounts. The discharger shall use appropriate BMPs to eliminate floating debris, floatable or settleable solids, including construction or maintenance-related dirt, rust, or scale present in the waters prior to discharge.

   Chlorinated Discharges

The discharger shall take measures to reduce or eliminate any residual chlorine contained in the discharge. Swimming pool water may only be authorized under this permit if the level of chlorine has been effectively dissipated or reduced to prevent deleterious impacts to aquatic life or degradation of the surface water quality of the receiving waters. Contained chlorinated discharges (e.g., swimming pool water) shall be retained, after receiving the last dosing of chlorine, for a minimum of seven days, (or until such time that analysis indicates the level of chlorine to be non-detectable,) such that the chlorine level is reduced or dissipated through aeration or other means, prior to discharging these waters. A pool chlorination kit can be used to confirm that there is no detectable level of chlorine in the water prior to discharge.

Swimming Pool Filter Backwash

Only swimming pool filter backwash that meets all applicable requirements of this permit, including those set forth in this paragraph, are authorized by this permit. Whenever possible, discharges of swimming pool filter backwash shall be directed to the sanitary sewer. If disposal into a sanitary sewer system is not an option, the following measures must be taken prior to discharging the filter backwash into a storm sewer or to a surface water body. The swimming pool filter water shall be retained, until such time that the chlorine has dissipated, prior to discharging. The water used to backwash the filter should also be retained or discharged over a grassy area so those solids settle out and can be removed or are filtered out prior to discharging the water. Solids, residue, or sediment shall not be discharged to a waterway and shall be removed (i.e., discharged to a publicly owned treatment works (POTW), disposed of as solid waste, etc.) prior to discharging the filter backwash water to the receiving waterbody.

C. CERTIFICATION BY AGENT

1. The company or entity authorizing the activity which will result in the discharge to be authorized by this permit, must designate an agent. The agent will be responsible for ensuring that the discharge complies with all applicable requirements of this permit and must certify this compliance in writing.

2. A certification legally executed by the designated agent shall be maintained by the entity authorizing the work. A copy of the certification shall be kept on site. Where this is impractical, a copy shall be kept at the business office of the designated agent and a copy of this certification should be sent to the clerk in the town or municipality in which the discharge will occur. (The discharger is not required to submit a copy of the certification to the Department.) This certification shall be available so that it may be provided to a Department representative, or other person or persons, upon request. The certification shall contain all of the following information (printed or typed):

    a) Name of entity authorizing the work (company, town or municipality) resulting in the discharge to surface water. Name and title of a principal officer in the company or of a specified official in the town or municipality other than the designated agent and the business address and telephone number of same;

    b) Name and title of designated agent, affiliation, address and telephone number;

c) The scheduled date(s) of the discharge event(s);

d) Source of the water being discharged (e.g., filter backwash, pool draining) and nature of the discharge;

e) approximate quantity or flow rate, as appropriate, of the discharge;

f) approximate duration of the discharge;

g) location(s) (street name(s) or street address (as appropriate), municipality, and county) of the discharge;

h) the receiving waters to which the discharge is directed, including the method of transport (i.e., via storm sewer, ditch, tributary, etc.); and

i) Best Management Practices to be used (including any chemical dechlorination agents).

j) The certification shall state specifically: "I, the undersigned, certify under penalty of law that the information provided in this document is true, accurate and complete. I maintain full responsibility for this discharge and its compliance with all applicable requirements as set forth in the NJPDES/DSW General Permit for Swimming Pool Discharges, NJ0128589. I am aware that there are significant civil and criminal penalties for submitting false, inaccurate or incomplete information, including fines and/or imprisonment. I certify that Best Management Practices appropriate to the discharge have been employed. I have no prior knowledge which would deem this discharge ineligible for coverage under this permit." The certification shall be signed and dated both by the designated agent and by the person listed above who is representing the entity authorizing the work.

Certification forms are available from the Division of Water Quality.

3. If this certification is not made as specified above, or cannot be produced upon request of a Department or other government or jurisdictional representative, the discharger may be subject to enforcement actions. The certifying agent should maintain the certification for 90 days following the last discharge event authorized by this certification pursuant to this general permit.

4. The Department reserves the right to require the discharger to cease discharging and obtain an individual or other general NJPDES permit or to utilize other alternate disposal methods. The Department reserves the right to enforce all applicable NJPDES regulations should there be a suspected or confirmed violation of the conditions of the General Permit for Swimming Pool Discharges or of the Federal or New Jersey Water Pollution Control Act. Discharges which are not conducted in accordance with all applicable conditions of this permit and

which therefore may result in adverse environmental impacts, including, but not limited to, a fish kill, may subject the authorizing entity to enforcement actions, including penalties.

Subject: Re: swimming pools & training

Region 6 has recognized swimming pool discharges as a potential problem. We've sent a mailing to about 1700 pool contractors in the State of Texas reminding them that discharges to waters of the US without a permit is a violation of 301 of the CWA. We've also told MS4's to keep an eye on these discharges and to try to eliminate these discharges. Some people balked and said that it was hard to stop. Told them to apply as a group for a general permit to TNRCC (State Agency) as a possible solution. However, without some type of NPDES permit, its a violation and I might enforce on it if they continue. Thats it from Region 6!

  >-----------------------------------------------------|
```

I received a question today about chlorinated swimming pool discharges. The caller said that many swimming pools have a pipe that discharges a small amount to the street daily. In addition, there are the large discharges from emptying a pool.

Since addressing illicit discharges is a requirement for medium & large MS4s, I am wondering how States, Regions, and MS4s have addressed this issue. Do any States have policies on this issue or has it been ignored?

On another matter- we are getting close to finalizing the first training sessions that we are setting up with the Navy. We will have info. on the web site once we know for sure but we expect the training sessions for this year to be in New Orleans, Seattle, San Diego, Denver, Hartford, and

Jacksonville. We would like to involve both other regulators and the regulated community in this training. Therefore, I am looking for suggestions of speakers. Some possibilities are phase I MS4s with good programs that could share their experience of developing a storm water program; military representatives with industrial permits that have been looking at how to address their phase II municipal requirements; storm water agencies that are developing joint a program that covers different entities, and of course, State and Regional coordinators.
If you would like to volunteer yourself or have suggestions, please let me know. Priorities are people in or near the above mentioned cities but I would appreciate suggestions from other areas as well. You can either respond to the list or e-mail me directly at bell.wendy@epa.gov

Subject: FW: swimming pools & training

> Swimming pools are a difficult issue .Obviously, pools have high levels of chlorine -- and sometimes other chemicals -- that can be extremely toxic to aquatic organisms. A direct discharge to the storm sewer, without a permit, is illegal.

> For private homeowners, we have a policy that we encourage them to let the water sit for 3-5 days before discharging. This allows much of the chlorine to dissipate. Additionally, we encourage homeowners to run the water across a lawn or long driveway to provide additional opportunity for chlorine to leave the water.

> For commercial pools (hotels, health clubs, schools, etc.) the volumes are larger, and they can rarely allow the water to sit, untreated, for that length of time. We encourage them to discharge to the sanitary sewer, but I know that some municipalities have begun to prohibit these discharges; it's probably a sewer capacity issue for them. A swimming pool discharge is comparable to a cooling water discharge, all of which have an NPDES permit and are required to meet a chlorine limit. Some other states have a general permit for swimming pool discharges; that would be ideal for us, too, but I've never heard it discussed here. (Obviously, again, it's a resource issue for us.) So, in summary, I believe that many commercial-size pools around the state are inappopriately discharging to the storm sewer, in lieu of better options and/or guidance from us.

> A couple of additional notes:
> There are probably two activities that go on with swimming pools.
> 1. draining the whole or most of the pool down. Large volume, maybe once or twice a year.
> 2. backwash of filters. every few days or so, much smaller volume.
> both of these activities probably have high chlorine in the water at levels that are toxic to aquatic life.

Re: Natural Resource Defense Council Petition for Correction of Legal Deficiencies or Withdrawal of EPA Approval

Dear Administrator Browner and Regional Administrator Marcus:

This office represents the County of Los Angeles ("County") and its Department of Public Works. As principal permittee over the Los Angeles Municipal Storm Water Permit, the County is an interested person in the above-referenced petition.

As you know, should the EPA decide to initiate withdrawal proceedings, there are relatively short time frames specified in the federal regulations to seek participation in the proceedings.

The County may wish to move for intervention or other appropriate method of participation if withdrawal proceedings are initiated. It is imperative that the County receive timely notice concerning your decision in this matter. The County requests that it be placed on the service list to receive all notices or correspondence served on the parties to the petition.

We understand that pursuant to federal regulations, "an informal investigation" is underway to determine whether cause exists to initiate withdrawal proceedings. The County requests that it be kept informed of the status of the investigation and, to the extent possible, be allowed to participate in the process to protect its interests.

Notices and correspondence should be addressed to:

Peter J. Gutierrez
Senior Deputy County Counsel
652 Kenneth Hahn Hall of Administration
500 West Temple Street
Los Angeles, CA 90012

Thank you for your attention to this matter.

Very truly yours,

LLOYD W. PELLMAN
County Counsel

Dear Mr. Dickerson:

MUNICIPAL STORMWATER PERMIT NO. CAS614001--ORDER NO. 96-054
COUNTYWIDE STORMWATER MANAGEMENT PLAN
REPORT OF EFFECTIVENESS

In the Los Angeles County Municipal National Pollutant Discharge Elimination System Permit, Part 2.VII.C.2, the Principal Permittee, in consultation with the Permittees, shall, not later than July 31, 2000, prepare and submit a report on the assessment of the effectiveness of the CSWMP components (except that identified in C.1.). Enclosed, as required, is the Countywide Stormwater Management Plan (CSWMP) Report of Effectiveness for your review.

As you know, the model programs were only recently approved so there was limited feedback on detailed items, but the feedback that was received was very beneficial for determining which program management techniques are preferred.

If you have any questions, please contact Tim Piasky at (626) 458-5969, Monday through Thursday, 7:00 a.m. to 5:30 p.m.

Very truly yours,

HARRY W. STONE

FINAL REPORT

LOS ANGELES COUNTY
CSWMP REPORT OF EFFECTIVENESS

July 31, 2000

Prepared by

Los Angeles County Department of Public Works
900 South Fremont Avenue
Alhambra, California 91803

INTRODUCTION

This report was prepared in response to NPDES Permit Section VII.C.2 requiring an assessment on the effectiveness of the CSWMP components. To assess the effectiveness of the Countywide Storm Water Management Plan (CSWMP) components, the County distributed a survey to the Permittees. The questions were grouped into six categories:

- Program Management
- Illicit Connections and Illicit Discharges
- Development Planning
- Development Construction
- Public Agency Activities
- Public Information and Participation

Thirty-nine cities responded to the survey.

PROGRAM MANAGEMENT

This section of the survey received much attention. It includes 17 questions regarding how Permit responsibilities should be issued and which groups should be involved in meetings. A summary of the responses to each question within this section follows.

1. *How would you prefer the next Permit be developed?*

Twenty-eight of the responding cities are in favor of a Countywide Permit. Six cities prefer a Watershed Permit and three cities prefer a COG or sub-watershed Permit. None of the cities were in favor of maintaining their own Permit.

2. *Do you want the County to continue as Principal Permittee?*

Thirty-six of the responding cities prefer to have the County continue as the Principal Permittee, or at least retain certain functions, such as program leadership in Monitoring, Public Education, Reporting, and Administration. Only one city does not want the County to continue as Principal Permittee.

3. *Are you satisfied with current Principal Permittee responsibilities?*
4. *Should other Principal Permittee responsibilities be added?*

Thirty-two of the responding cities find current Principal Permittee responsibilities adequate. Four cities recommend adding to the County's responsibilities, namely taking the lead in developing and implementing a new Countywide trash monitoring program to satisfy trash TMDL and Notice to Meet and Confer (NTMC) requirements. One city would like the monitoring program to be coordinated with local efforts.

5. *Are you satisfied with current Permittee responsibilities?*
6. *Should other Permittee responsibilities be added?*

Thirty-five of the responding cities agree current Permittee responsibilities are adequate. Three cities are open to having responsibilities added to city duties, and one would like to see responsibilities removed. Added responsibility suggestions include monitoring, cost sharing, help in distributing information, and negotiating directly with the Regional Board. The suggested responsibility removal is TMDL monitoring.

7. *Were the WMC meetings successful?*

The opinion of the success of WMC meetings is generally positive, mainly as an informational forum. Five cities disagree, emphasizing that there is room for improvement.

8. *What was the most useful aspect of the WMC meetings?*

The most useful aspects of the WMC meetings:

Developing watershed direction
Discussing common issues
Sharing information and ideas
Pooling resources
Receiving EAC updates
Obtaining new information
Having a dedicated time to coordinate activities

9. *What could be improved at the WMC meetings?*

Suggestions for improvements at the WMC meetings:

Chair should be large city rather than an outside contractor
Follow through on action items
Start on time
Stick to the agenda
Present an education topic or invite guests
Respond to Watershed issues
Participation of all cities
Focus on one or two issues per meeting

Acquire grant funding
Propose projects
Meet less frequently
Ensure Regional Board attends consistently
More leadership by County
Have more invited guests from other watershed stakeholders

10. Should the WMC set goals?

Opinions are split as to whether the WMC should set goals (20 responding cities are for, 13 against). There is a slight favoritism toward setting goals such as monitoring, participation, and uniformity. Those against believe the Permit defines WMC goals and that adding goal-setting would add bureaucracy.

11. Should the WMC be included in the next Permit?

Thirty cities wish to continue WMC meetings. Two cities are against continuing WMC meetings, with one of the cities recommending a COG-based Committee.

12. Were the EAC meetings successful?

Cities that attend EAC meetings basically agree that they are successful.

13. What was the most useful aspect of the EAC meetings?

Useful aspects of the EAC meetings:

Allowing Permittees to quickly voice concerns to the Regional Board
Hearing other watershed opinions
Learning of new means to comply with the Permit
Sharing information and resources
Providing leadership on issues

14. What could be improved at the EAC meetings?

Improvements could be made to the EAC meetings by:

Distributing minutes faster and to more City Management
Negotiating solutions (reducing combativeness)
Including watershed chairs
Sharing more specific experiences

15. *Would you support one large group watershed meeting immediately followed by individual watershed meetings?*

Twenty-eight cities are in favor of a large group watershed meeting followed by individual watershed meetings. Pros are large scale problem solving and the ability to address specific issues that are not recognized in smaller group meetings. Cons are the time involved, scheduling, and attendance for multi-watershed Permittees. If this type of meeting is put into place, most cities feel the larger group should meet less frequently than once a month.

16. *How often should the groups meet?*

Most cities (24) would like to see watershed meetings continue on a monthly basis. If the group watershed meeting is added, it could meet quarterly. Other suggestions include meeting once a month with both groups, holding watershed meetings semimonthly or quarterly, and holding watershed meetings more frequently at the beginning of the new Permit.

17. *Should the public review process be modified?*

Generally, cities are satisfied with the public review process. Seven cities suggested modifications. Suggestions to modify the process:

Commission a third party to summarize each opinion at public hearings
Exclude public review of permit submittals
Develop technical work groups

ILLICIT CONNECTION AND ILLICIT DISCHARGES

The Illicit Connections and Illicit Discharges (IC/ID) Model Program has been received well, although some cities feel it is too early in the program to comment.

18. *Has the Illicit Connections and Illicit Discharges Model Program been successful so far?*
19. *What are the biggest successes of the program?*

The most noted success of the IC/ID program is greater awareness among the public and city staff members. Other successes include behavioral changes, code enforcement clarity and development of a Public Hot Line program for receiving, responding, tracking and reporting public complaints.

20. *What are the biggest failures of the program?*

Failures of the IC/ID program:

Identifying, responding, enforcing, and documenting all IC/IDs due to resource limitations
Lack of standardized enforcement procedures

21. *How could the program be improved?*

Suggestions to improve the program:

Increase funds to hire more staff
Hire County people to do IC on a contract basis
Establish fire truck washing as a conditionally exempted discharge
Recognize non-stormwater connections and address them
Provide uniform guidelines for washing impervious surfaces
Standardize enforcement and spill response procedures
Enforce pro-actively
Introduce more outreach
Improve documentation

22. *Should any of the exempted or conditionally exempted discharges be dealt with as illicit connections or illicit discharges?*

In general, cities do not want to deal with exempted or conditionally exempted discharges as IC/IDs. Three cities disagree. The items suggested for IC/ID are homeowner wash water, street washing, fire fighting, dechlorinated swimming pool discharges, and individual car washing.

23. *Have there been any noticeable improvements from the program?*

Noted improvements from the IC/ID program include:

Increased public awareness
Increased public reporting
Fewer sewage overflows and grease interceptor problems
Improved sawcut slurry vacuuming
Decreased illicit discharges from Industrial/Commercial sites

DEVELOPMENT PLANNING

The Development Planning Model Program is rather new. Almost one third of the cities feel it is too early to comment on the success of this program. Cities that commented generally feel the program is succeeding.

24. *Has the Development Planning Model Program been successful?*

The program is viewed as successful by 18 of the responding cities. Sixteen cities found it too early to judge. Noted downfalls of the program include:

Resistance to implement BMPs due to aesthetic reasons
Disapproval of Regional Board SUSMPs

25. *How could the program be improved?*

Suggestions for improvement include:

Make the program clear and sensible
Condense and clarify the program
Support the August 1999 Permittee-submitted SUSMPs
Develop standards
Enforce consistently
Reject the Regional Board's SUSMPs
Enhance brochures
Simplify and expedite the approval process for the SUSMP and BMPs
Make Regional Board requirements consistent and feasible
Allow cities greater flexibility
Increase harvesting requirements
Implement on a widespread basis
Conduct follow-up training for city staff
Tailor program for local soil and relief conditions
Acquire more information regarding the effectiveness of all BMPs
Exclude non-discretionary projects

26. *Which BMPs have been successful and why?*

Different BMPs have worked for different cities. However, there is still limited information to develop effectiveness opinions. Generally, cost-effective BMPs that can be readily implemented for a project without significantly interfering with other project aspects are the most successful. BMPs that have been successful on a limited basis include:

Reducing impervious surfaces

Requiring large percentage of lot area to be landscaped
Incorporating trash container areas
Implementing basic housekeeping practices
Education
Introducing CDS units and Jensen Stormwater Interceptors
Incorporating catch basin protection and runoff protective measures
Building dry gravel wells, pits, trenches, permeable paving, french drains
Using treatment control devices and post-construction management plans

27. Which BMPs have not been successful and why?

Due to the short time that BMPs have been being implemented, there was a limited response as to which BMPs have not been successful. More will be understood about the successfulness of various BMPs as the results of these recently installed BMPs become available. However, it was noted by one city that redevelopment is actually hindered due to the expense of incorporating BMPs. The reason some BMPs failed is due to maintenance, cost, aesthetics, and physical constraints. Some of these include:

Catch basin inserts
Fossil filters
Detention basins
Planters
Maximizing pervious surfaces

28. Have there been any noticeable improvements?

There is a consensus that the program is making improvements, although they are difficult to quantify. Ten cities noted improvements. Improvements as a result of the Development Planning Model Program:

Increased awareness in permit applicants
Increased runoff collection
Appreciation of city efforts by local entities

DEVELOPMENT CONSTRUCTION

Again, this program is too new for all the cities to comment on.

29. Has the Development Construction Model Program been successful?

All of the cities that gave a definitive response (31) feel the program is successful. Its main benefits are increased awareness and BMP implementation.

30. *How could the program be improved?*

Suggested improvements for the program:

Improve coordination of inspections between the Regional Board and City Staff
Improve document clarity
Provide BMP training for inspectors and developers
Improve enforcement
Increase the involvement from the Regional Board on 5+ acre projects
Need reference information from the Regional Board

31. *Which BMPs have been successful and why?*

Sand bags and other containment methods (silt fences, k-rail, berms, and gravel bags) are the most successful BMPs. Favored BMPs are generally useful, cost effective, easily understandable, and maintainable. Other successful BMPs include street sweeping, retention ponds, vegetated areas, and storm drain inlet protection.

32. *Which BMPs have not been successful and why?*

Although there were considerably more BMPs noted for successfulness, there are aspects that need improvement. The downside of sand bags is their natural deterioration and possible failure. A negative aspect of silt fences is their maintenance. The use of hay as a method for preventing intrusion of surface water into catch basins is adverse, because the hay tends to collapse quickly under high flow conditions. The BMPs reducing the tracking of dirt from construction sites to streets was noted as impractical and ineffective. Training and scheduling BMPs posed a problem due to the unpredictability of rainfall. Contractor compliance is a main concern that can impede the success of any BMP.

33. *Have there been any noticeable improvements from the program?*

Through inspectors cognizance and enforcement of BMPs, contractor awareness and compliance have improved. Other noted improvements of the program include agency coordination, construction site erosion control, and trash reduction.

PUBLIC AGENCY ACTIVITIES

34. *Has the Public Agency Activities Model Program been successful so far?*

The Public Agency Activities Model Program received a positive response. All responding cities, except for two, agree it has been successful so far. Awareness and street cleanliness have been very positive aspects of the program.

35. *How could the program be improved?*

Improvements can be made to the program by:

- Expanding and increasing education and training
- Reducing record keeping
- Modifying the Annual Report questionnaires
- Clarifying the document by adding Development Planning/Development Construction requirements
- Ensuring County flood control crew compliance
- Increasing Regional Board enforcement of their general permits
- Renaming the program to "Municipal Agency Programs"
- Adding operations such as refuse collection and water production

36. *Which activities should be added to the program?*

Suggested additions to the program are more training materials and better data-tracking systems.

37. *Which activities should be removed from the program?*

The emergency procedure was recommended for removal. It was also suggested that the dry weather flow diversion be moved to a separate program.

38. *Have there been any noticeable improvements from the program?*

Improvements from the program include:

- Cleaner streets, catch basins, and city facilities
- Increased awareness
- Staff involvement
- Equipment procurement

PUBLIC INFORMATION AND PARTICIPATION

39. *What has been the effectiveness of the industrial/commercial educational program?*

The industrial/commercial educational program received a mixed review. Responses ranged from finding the program moderately effective to a huge success. Positive aspects noted were increased knowledge, awareness and compliance. However, compliance was problematic for other cities.

40. What has been your experience in submitting site visit data to the County?

There was a mixed response to data submittal as well. The majority of cities found submitting to the County difficult, while others responded positively. Editing and formatting data were noted complications using the SiteViz program. County staff was helpful to many cities encountering these difficulties.

41. What is the database software of preference for your City?

Preferred City database software includes Microsoft products such as Access and Excel. FileMaker Pro was also noted as a preference over SiteViz. However, the majority of cities (33) support Microsoft products currently or will soon.

42. What kind of benefits have come from the program?

As with other programs, the main benefits reported are public awareness and education. Other positive aspects of the program are:

Improved business operations
Enhanced communication with businesses
Improved permit compliance

43. What is the main issue involved when managing the program?

Many issues faced when managing the program revolve around the SiteViz database. Data entry is time consuming, tedious, and requires specialized training. Other factors impeding program management are:

Changing ingrained polluting habits
Coordinating with the County
Finding staff time to conduct and document the program
Getting the most accurate business information
Coordinating all departments
Deciphering inspector reports

44. What data should be added or removed from the industrial/commercial educational program databases?

Suggestions for modifying the database:

Add State IDs for sites with State General Industrial Storm Water Permits
Add a field to recommend a follow-up
Add a field for narrative comments

- Remove codes
- Remove one of the two date fields
- Limit the activities assessment list to checkmark fields
- Allow multiple values in one field rather than multiple fields with one value
- Focus on the 14 categories in the Countywide program guidance
- Improve the Health Department's performance
- Clarify the PPD rating process
- Add procedure for adding and deleting businesses from the database

45. *What sites should be added to the educational site visits?*

Many of the sites that were suggested to include on educational site visits involve vehicle maintenance or sales. Other sites that may benefit from site visits are:

- Schools
- Hospitals
- Nurseries
- Contractor yards
- Business Parks
- Shopping centers
- Carpet cleaners
- Pool service businesses
- Dry-cleaning establishments with onsite facilities
- Veterinary clinics/animal hospitals
- Hotels/Motels
- Residential care facilities
- Parking lots
- Trailer parks

It was also suggested to discontinue visits to certain vehicle supply wholesale distributors, sweatshops, out of home businesses and out of business sites.

46. *What information should be added to the educational site visits?*

To make the site visits more useful, inspectors could discuss current trash and litter issues, product substitution (for pollution prevention), State Law AB 2019 concerning non-filers, and the 5-Year Education Strategy. Improvements could also be made by developing more industry specific BMPs.

CONCLUSIONS

The CSWMP is still in its infancy and thus it is premature at this time to accurately measure its effectiveness, however it has been determined to be an effective tool for increasing stormwater pollution awareness and prevention.

RECOMMENDATIONS

The items listed, throughout this evaluation, as potential improvements to a respective Program should be studied further, such that final results and recommendations can be included in the submittal of the ROWD and WMAPs to the RWQCB by Febuary 1, 2001.

PREVENTION

Storm Water/Urban Runoff Public Education Program

Five-Year Storm Water Public Education Strategic Analysis

Submitted by:
Los Angeles County
Department of Public Works
July 31, 2000

R0008714

TABLE OF CONTENTS

INTRODUCTION

The 1996 National Pollutant Discharge Elimination System Municipal Storm Water Permit requires that the County of Los Angeles, as Principal Permittee, conduct a five-year public education program. A budget of $5.2 million for five years was allocated for the public education program. As the Program enters its fifth and final year, it has become recognized as a model pollution prevention public education program among municipalities on a regional and statewide basis.

At the time of the Permit's inception, the County and the 85 Permittee cities did not have a clear picture of who among the County's diverse population to target for public education, and what messages were needed to motivate significant behavior change. Moreover, all parties acknowledged that a $5.2 million budget was extremely limited for a public education program of this complexity, necessitating that funds be allocated judiciously. The conclusion was that, while not mandated, financial support would need to be solicited from Permittees to leverage limited resources and extend the Public Education Program's media reach.

After a full year of information gathering, original quantitative and qualitative research and consensus-building with Permittees, the County's public relations contractors, Rogers & Associates, with their lead subcontractors Harris & Company and Larry Walker Associates, submitted the Five-Year Public Education Plan to the Regional Water Quality Control Board (RWQCB) on July 30, 1997 and received approval to proceed.

We are now completing Year Four of the five-year Permit period and Year Three of the Five-Year Public Education Plan. The final qualitative research report on the public education program will be available in June 2001. However, interim research studies, anecdotal information, public/private partnerships and media coverage have been included in this report to offer RWQCB a "snapshot" of how the Public Education Plan has faired to date -- and what steps should be taken to advance the effort in the new permit period.

Following is a brief analysis of public relations activities from Years One through Four and recommendations for Year Five public education outreach efforts and the new permit's public education component.

The Five-Year Public Education Program was designed to be:

- Grounded in research
- Broad-based with an overarching approach
- Flexible, adaptable, and cost-effective
- Accessible, providing simple, everyday actions that will make a difference
- Integrated and coordinated
- Results-oriented

Overall Program Goals and Strategies

At the outset, the County of Los Angeles identified seven primary program goals aimed at reducing storm water pollution:

- Reduce the amount of storm water / urban runoff pollution ~~in Los Angeles~~ County.
- Build bridges and forge partnerships that integrate County, city and jurisdictional programs, appropriately mix educational outreach with technical understanding and leverage resources.
- Improve general understanding of storm water / urban runoff pollution and its prevention methods.
- Incorporate storm water activities into other County environmental education programs by the end of the second year of implementation.
- Move existing County BMPs under the storm water pollution prevention program umbrella by August 1998.
- Integrate the County storm water overarching theme into a minimum of 35%* of the Permittee programs by August 1998 and 50%* by August 2000.
- Increase *awareness* of storm water pollution prevention messages among the adult population to 83%* in five years.

* *Note:* These percentage goals will be measured on a countywide basis.

To reach these core objectives, the Public Education Program identified and recommended eight key programmatic strategies – designed to work synergistically, leverage resources and expand the Program's potential reach and impact.

Strategy 1: Overarching Approach
Develop a unified overall public education approach, "look" and message(s) that promote Los Angeles County's overall storm water / urban runoff goals to set the tone and feel for the overall public education program. This approach helps all target audiences identify the program and its pollution prevention messages.

Strategy 2: Partnerships
Build bridges and forge partnerships that are conducive to maximum leverage of resources and that integrate: (1) County, city and jurisdictional programs and (2) the public and private sectors.

Strategy 3: Unified Pollution Prevention Efforts
Create synergy by unifying multiple pollution prevention efforts (such as recycling, proper household hazardous waste and used oil disposal recycling) under a single, all-encompassing agenda rather than conducting individual, splinter programs. Link all programs to the impact they have on storm water pollution under "Project Pollution Prevention."

Overall Program Goals and Strategies cont.

Strategy 4: Segment and Target Specific Audiences

Prioritize audiences and activities within each audience that will target the greatest potential polluters who (1) are the most likely to adopt change in their personal and professional behaviors, and (2) that will result in the highest pollutant removals in the most cost-effective manner.

Identify as primary targets those people who are most likely to attempt pollution prevention activities and to repeat their usage if the experience is positive, simple and convenient. While no one will be ignored, downgrade to a secondary level of importance those people who would not, for a variety of reasons, try to change their habits and behaviors and those people who have a minimal level of impact on storm water pollution.

Strategy 5: Simple, "How-To" Instructions Incorporated Into Everyday Routines

Develop specific guidelines supported by simple tasks and concise "how-to" or "tips" instructions that will motivate Los Angeles County residents and businesses to use pollution prevention actions in their "everyday" routines.

Strategy 6: Monitoring and Evaluation

Establish a monitoring and evaluation system to: (1) measure the effectiveness of the program by assessing the number of people who show increased awareness, intent and/or actions in reducing storm water/urban runoff pollution; and (2) ensure program components and outreach efforts are adjusted and enhanced on a regular basis in relation to what is working and what isn't in the various communities and target audiences.

Strategy 7: Implement Countywide Programs and Supplement with Local Programs

Develop an overall program with individual activities that impact pollution on a countywide basis. Utilize overarching materials for all audiences that are developed and implemented by the County, yet are supportable and supplemented on a local basis in a manner that meets Permit minimum requirements, is cost effective and efficient.

Strategy 8: Multiple Audience Impact

Wherever possible, develop program materials and activities that can be implemented and will have impact on more than one audience at a time.

Using Research to Develop the Program

In order to lay the groundwork for implementing these eight-core strategies, identify target audiences and set goals, comprehensive, multi-phased research was conducted.

◆ ***Issues, Pollutants and Materials Report***

The first research report, *Issues, Pollutants and Materials Report,* was a compilation of: (1) existing research on target audiences and public education programs in Los Angeles County; (2) an analysis of storm water public education model programs throughout the country; and (3) a review of existing information and analysis of pollutants of concern. In this report, several overall challenges became apparent and have served as the impetus in formulating research and monitoring questions and methods.

These overall challenges were:

- Discovering exactly what motivates or influences behavior change in each target audience;
- Deciding who to target within each audience segment;
- Prioritizing audiences to maximize the budget;
- Addressing the County's vast ethnic, cultural, geographical and socioeconomic diversity; and
- Demonstrating that the education effort has helped to reduce storm water / urban runoff pollution.

Segmentation Research

Based on these challenges, it was decided that a segmentation study would offer the best approach for arriving at answers.
The two primary objectives for the Segmentation Study conducted in February 1997 were:

Objective 1 Segment Los Angeles County residents for the purpose of directing limited County and Permittee resources toward those residents who pose the *greatest threat* to storm water quality and who represent the *greatest opportunity* to respond to a public education program.

Objective 2 Provide a baseline measurement of residents' current storm water-related practices and habits.

Prior to conducting this segmentation study, it was hypothesized that all Los Angeles County residents are not equally responsible for storm water pollution, or at least may differ in the type of pollution they are contributing. An analysis of the collected data supports this hypothesis that different groups of residents differ significantly in terms of: (1) the amount of pollution they contribute; (2) their demographics and lifestyles; and (3) their attitudes related to storm water pollution and the likelihood of changing their behaviors.

Using Research to Develop the Program cont.

♦ ***Methodology Overview***

Total number of interviews:	1191 among Los Angeles County residents
Timeframe of interviews:	February 8 - March 23, 1997
General population sample:	- Countywide random sampling - Selected by random digit phone numbers - Established for gender and age based on census data
Participants were screened for these criteria:	- 16 years or older - Must be a permanent resident of Los Angeles County and have lived here for more than six months
Surveys were conducted in language of preference:	- English - Mandarin - Spanish - Korean - Cantonese - Vietnamese
Recent immigrant segments:	- Latino (sample = 101), Asian (sample = 101) - Residents who moved to the County from another country - Lived in County at least six months, but less than five years - Speak Spanish, Cantonese, Mandarin, Korean or Vietnamese most often at home

Segmentation is the result of a cluster analysis performed by a computer filtering and sorting the total population based on their survey answers by attitudinal and behavioral variables. The segments/groups are reflective of those residents who are most/least likely to change behavior and who have more or less damaging behavior by volume[1]. The residents characterized as "Neat Neighbors," "Fix It Foul-Ups," and "Rubbish Rebels" are the three segments that were identified as the primary targets of the Five-Year Public Education Program.

We learned from the segmentation that overall, Los Angeles County residents are interested in and concerned about local water quality. They are also willing to change many of their behaviors that contribute to storm water pollution.

Unfortunately, even with their high overall level of concern, many residents are unknowingly engaging in practices that threaten storm water quality. Additionally, although the County's indicators of concern and potential compliance are positive, not all residents are equally concerned about or willing to change their behaviors in order to improve storm water quality. By segmenting the population, however, a clearer picture emerges of who should be targeted with limited resources and how best to reach them.

[1] Estimated volumes of pollution created by pollution-causing behaviors were derived from the self-reporting activities recorded in the segmentation study. For example, if 1.09 million people self-reported dropping one cigarette butt per day on the ground.

R0008720

Using Research to Develop the Program cont.

Target Audiences

From the segmentation analysis, two groups of Los Angeles County residents emerged as most promising in terms of allocating public education resources:

"Neat Neighbors"
(primary target)
50% of County's population

Because of their numbers in the population and because of their desire to 'do the right thing,' "Neat Neighbors" will likely heed the program's messages and even small, but widespread changes in these residents' habits will positively impact the County's storm water quality.

"Fix It Foul-Ups"
(primary target)
13% of County's population

"Fix It Foul-Ups" contribute disproportionately to storm water pollution through their do-it-yourself activities. However, they have good intentions and are very receptive to modifying their pollution-causing behaviors. They can be effectively reached through do-it-yourself channels.

To effectively promote behavior change among the primary target audiences -- Neat Neighbors and Fix It Foul-Ups -- the Program needed to tap into their desire to 'do the right thing' and provide them 'how-to' information about alternative, anti-polluting behaviors. These residents were likely to be affected by credible messages that imply that a change in their behavior will help protect children, keep their neighborhoods from smelling and preserve the environment for the future.

Total Population Reached Based on Segmentation Recommendations

Neat Neighbors	50%	72% of Los Angeles County residents receive messages using two different communications campaigns
Fix It Foul-Ups	13%	
Rubbish Rebels	9%	
	72%	
Concerned Non-Contributors	20%	Additional 20% gained from spillover of Neat Neighbor/Fix It campaign (92% total)
	20%	
Prove-It-To-Me Polluters	5%	8% considered non-targets due to low polluting behavior or low number (100% total)
Preoccupied Polluters	3%	
	8%	

Status of Results/Achievements

Once target audiences were confirmed, focused goals were set, and key messages were developed, the County initiated a comprehensive and multi-faceted public education program. In order to effectively reach the target 83% of County residents with pollution prevention messages and bring about measurable behavioral change, the Program employed a strategic mix of communications tactics, which included:

- Paid advertising (radio, print, outdoor and transit shelter)
- Nontraditional advertising (movie slides, radio promotions, coffee jackets)
- Media relations (broadcast and editorial coverage)
- Partnerships with corporations, retailers, nonprofit organizations, community-based organizations and trade associations
- Participation in high-profile special events
- Strategic outreach to schools and businesses
- Collaboration with synergistic DPW programs and local city efforts
- Specialized "Project Pollution Prevention" Program collateral and premiums

Just as program strategies and goals were founded on research, research was used as a critical monitoring tool throughout the duration of the Program – to help evaluate its effectiveness on an ongoing basis and modify strategies where appropriate.

Interim "Touchbase" Tracking Study – July 1998

In July 1998, an interim tracking research study was completed assessing the near-term impact of the Program against the May 1997 baseline segmentation study. The "touchbase" was specifically designed to assess the effectiveness of the January-June 1998 paid media advertising campaign and to provide recommendations for improving the overall effectiveness of the media campaign for 1999. Based on the "touchbase" study, the storm water program was proven to be: (1) communicating accurately; (2) perceived by Los Angeles County residents to be delivering important messages; (3) successful in changing attitudes; and (4) starting to positively impact behaviors.

According to the touchbase study, the Program and Media Campaign appeared to be most successful in their first six months in *getting residents to understand the connection that what goes into the streets, goes into the ocean.* Residents also understood that the water from storm drains goes to the ocean *untreated.* In the baseline study, residents were asked about their level of concern about issues of concern facing Los Angeles County. At that time, residents ranked crime, quality of public schools, air pollution, smog and pollution of the ocean, lakes, and rivers as their top four concerns, in that order. One year later, the ranking shifted – and *the only issue that increased in concern was pollution of the ocean, lakes and rivers* – moving from the fourth priority issue to the third priority issue.

Status of Results/Achievements cont.

Pollution Volumetrics – Total Number of Occurrences Per Month
Target audience exposed to media advertising campaign for six months (January – June 1998)

Pollution-causing behaviors with significant changes between 1997 and 1998	**1997**	**1998**	**Difference**
Allow paper or trash to blow into the street	692,194	565,585	-126,609
Drop a cigarette butt on the ground	1,094,297	807,978	-286,319
Empty a car ashtray into the street	168,928	69,275	-99,653
Wash off paint brushes under an outdoor faucet	195,399	126,510	-68,889

Pollution volumetrics – an estimate of the number of people in the County engaging in polluting activities – extrapolated from the research showed significant changes in polluting behaviors between 1997 and 1998 with the following representative activities:

- Allowing paper or trash to blow into the street, down from about 692,000 times per month in May 1997 to about 565,000 times per month in June 1998
- Dropping a cigarette on the ground, down from about one million butts per month in 1997 to about 800,000 butts per month in 1998
- Emptying a car ashtray into the street, down from about 168,000 time per month in 1997 to about 69,000 times in 1998
- Washing off paint brushes under an outdoor faucet, down from about 195,000 to about 126,000

Final Segmentation Study – June 2001

A final segmentation study will be conducted in June 2001 – at the culmination of the five-year program – to assess the overall effectiveness of the Program and to provide detailed recommendations for the next permit's public education component. The survey sample size and demographics will mirror the May 1997 baseline study and will be designed to comprehensively measure awareness levels and polluting behaviors among all target audience segments.

Topline public education recommendations are provided in this report, based on all anecdotal and field experience, qualitative and quantitative research conducted to date. Final program recommendations will be submitted upon completion of the Year Five segmentation study.

Status of Results/Achievements cont.

"Snapshot" of Public Education Program Results – select results through June 2000

In addition to the measurable behavior change identified in the two interim segmentation studies (July 1998 and July 2000), public education program activities have been "quantified," whenever possible, to capture the Program's reach and depth. Media campaign tactics have been strategically recommended and executed to garner maximum impressions (number of times audience hears campaign message) and to leverage limited media advertising resources. In most primary areas of activity, additional value in marketing dollars has been secured – meaning pro bono advertising, media and corporate partnerships were secured that would have otherwise cost the Program significant budget resources.

Program Activity	Added Value/Impact
Advertising – Traditional	♦ Countywide media campaign (radio, print, billboards and transit shelters) ***reached upwards of 86% of the target audience*** during its first two years and ***leveraged more than $1,985,000*** in pro bono media placements. ♦ The third annual media advertising campaign ran from April to July 2000.
Advertising – Nontraditional	♦ Nontraditional advertising venues–including Project Pollution Prevention-imprinted movie theater slides, coffee jackets, and Countywide radio promotions–generated ***upwards of 28,000,000 impressions.***
Media Relations	♦ Print and electronic media placements secured to date– including media campaign launch, interim segmentation study results, El Nino and Earth Day tie-ins, and diversion system coverage--are ***valued at an estimated $712,000*** and generated ***upwards of 87,000,000 impressions.***
Corporate Partners	♦ Program partners secured to date – including COSTCO, CSK/Kragen, Chevron, Brita, Petco, City of Los Angeles and Initiative Media – have generated an ***estimated $3,808,000 in additional value.***
Special Events	♦ Participation in more than 25 Los Angeles County special events (County Fair, Earth Faire, etc.) has reached an ***estimated total attendance of 860,000.***
Business Outreach	♦ Los Angeles County Health Dept. restaurant rating system trainings – including storm water BMPs – ***reached 50,000 County restaurant workers.*** ♦ Specialized automotive repair BMPs video and manual reached ***up to 19,000 automotive repair students.***
School Education Grades: K-6	♦ Environmental Defenders Program reached ***more than 1,000,000 students*** at ***1,500 Los Angeles County schools*** through assembly events and through community events.
School Education Grades: 7-12	♦ Generation Earth Program includes a service learning curriculum and projects for students, field studies, radio campaign, a battle of the schools competition, community events for students and teachers, concerts and the internet www.generationearth.com
Used Oil Program	♦ Regional Used Oil Media Campaign – Annual media campaign (radio, print and outdoor advertisement) with proper disposal/recycling messages for the Rubbish Rebel/do-it-yourselfer demographic providing them with straight forward information on how and where to recycle used motor oil and filters.

Getting Results:
What it Takes to Make Social Marketing Programs Work

Social marketing campaigns, unlike public awareness campaigns, are designed to bring about behavioral change utilizing a variety of mutually reinforcing communications strategies. The mandate to "normalize" or "denormalize" a specific social behavior is challenging on many levels, and the most successful campaigns are those that have been focused in their efforts and well financed – allowing for sustained saturation of consistent messages through multiple outreach venues.

The intended targets of such programs must pass through several stages on their road to behavior change. In the case of storm water pollution, the County aims to guide ten million residents from a vastly diverse population base – from awareness of the issue and polluting behaviors, to acknowledgment that they are contributing to the problem through their actions, to the adoption of pollution prevention practices in their daily life. Given the challenges implicit in developing new social "norms" and the particular complexities of the storm water issue, this complete shift to a pollution prevention mindset and lifestyle will take many years – and only then, if there has been a consistently high level of message exposure among residents. Without prolonged, consistent reach and frequency *and* significant long-term budget, a social marketing campaign has little chance of meeting its formidable objectives.

To understand what it does take to achieve success on this level, we will refer to a movement widely regarded as the leader in the social marketing arena – the tobacco control movement. This model social marketing campaign should be reviewed by the RWQCB as it develops the new permit in its entirety, and the public education component, specifically.

The tobacco control movement – illustrated in this case by the Los Angeles County Tobacco Control Program and its parent program, the California Tobacco Control Program (established under Proposition 99) -- has achieved overwhelming success in "denormalizing" and modifying a variety of smoking behaviors. After ten years of sustained public education, and new laws regarding the use of tobacco in public places, the number of smokers has plummeted from 24% in 1988 to 18% in 2000 across the state, including Los Angeles County. This represents just one of many successes, which include reduced incidence of smoking among youth, lowered case rates of lung and other cancers, and increased protection from secondhand smoke.

In analyzing California's tobacco control movement, it is important to note:

- That the movement has achieved these successes through the combined efforts of many multi-media campaigns – designed and implemented by local health departments, community coalitions and organizations, voluntary health organizations, regional, statewide and federal projects
- That the movement has a simple message that links smoking, disease and death and is able to put a face on the consequences of this behavior
- That the movement is able to focus efforts against an "external" enemy (the tobacco industry)
- That the movement has been in full swing for ten years and has benefited from high-profile legislation and extensive media coverage throughout its history
- And that the media campaign has been well funded in order to meet its objectives

Getting Results:
What it Takes to Make Social Marketing Programs Work cont.

COMPARATIVE LOS ANGELES COUNTY PROGRAM BUDGETS STORM WATER VS. TOBACCO CONTROL PROGRAM		
Annual Program Budgets	**Storm Water/Urban Runoff Program**	**Los Angeles County Tobacco Control**
Advertising Budget	$400,000 [2]	$390,000 [3]
Other Source Contributions	$450,000 (City of Los Angeles and Permittee contributions) [2]	$5,500,000 [4]
Subtotal	**$850,000 per year**	**$5,890,000 per year**
Public Relations Budget	$800,000 [2]	$500,000 [3]
Other Source Contributions	NA	$750,000 [4]
Subtotal	**$800,000 per year**	**$1,250,000 per year**
Total Annual Program Funds:	**$1,650,000 per year**	**$7,140,000 per year**

In the simplest terms, the funding levels outlined above are key to understanding the success of the tobacco control movement. Los Angeles County Tobacco Control's annual combined PR/advertising budget is just under $1 million. However, the state's overarching public education program directs more than $6 million per year specifically to Los Angeles County – nearly 25% of its annual operating budget. Because the state's high-profile advertising and public education campaigns provide "umbrella" coverage of key campaign messages across and within the state's key markets, the Los Angeles County program is able to strategically direct its monies to very specific outreach needs within the community. Add to this a ten-year track record, a steady stream of support among key stakeholders in the public health arena, and highly publicized legislative victories, and it becomes clear that significant and lasting behavioral change is precipitated by a finely-tuned mix of resources and strategies.

Juxtaposed against this is the Los Angeles County Storm Water Public Education Program. To our credit, with only three years of program implementation at limited spending levels, the Program has seen some measurable success in modifying the polluting behaviors of Los Angeles County residents. However, in order to have a substantial and long-term impact on the region's pollution levels, the Program needs dramatically increased funding levels over a prolonged period of time. Current program dollars are only enough to purchase advertising during a 3-4 month period each year. Due to rising media costs (radio advertising costs increased 20% between 1999 and 2000) and static public education dollars, the Stormwater Program has actually received less media value (decreasing reach and frequency) for its money each year. Now add to this lack of an overarching statewide or federal pollution prevention advertising/public education campaign, "optional" funding contributions from Permittees and other Municipal NPDES permit holders within the Los Angeles media market, and a very complex issue without a universal "enemy" or "face," and it becomes clear that the Storm Water Public Education Program is in need of significant funding. The State and Federal Government along with the private sector must step to the plate and become actively and financially involved to assure the continual success of the Program.

[3] *Avg. advertising and public relations budgets for L A County Tobacco Control Program since 1997*
[4] *Approximate percentage of annual contributions to target LA County from the California Tobacco Control Program (Prop 99); total advertising/PR budget of $25,000,000*

Recommendations to Date

As noted, this report captures and analyzes Los Angeles Storm Water Public Education Program activities conducted through Year Four of the Permit -- June 2000. Utilizing all available qualitative and quantitative research, field/anecdotal experience and knowledge gleaned from other synergistic DPW programs and social marketing campaigns, the County has presented the chronology of the Five-Year Public Education Program, its strategic underpinnings and achievements to date.

The Permit has recently completed Year Four, but only Year Three of Public Education Program implementation. As outlined in the Five-Year Public Education Plan and under the current NPDES Permit, public education will be implemented through June 2001 and a final segmentation study will be conducted at the culmination of the program. Thus, results garnered through 2001 should be carefully reviewed, as they will provide a more complete picture of the effectiveness of the Five-Year Public Education Plan and will provide a strong foundation on which to base future program recommendations.

Based on results to date, we recommend the following elements be implemented to effectively conduct the public education and outreach program:

1. **Public Education Programs should continue** - As supported by research, we believe that eighty-three percent (83%) of Los Angeles County's population can be reached with key pollution prevention messages through a single, integrated, multi-faceted communications campaign which focuses on a desire to "do the right thing" and provide "how to" information about alternative, anti-polluting behaviors. Working in concert with the Permittees, the County's Public Education Program adopted the "problem/solution" - oriented approach and reinforced it with strong visual cues and an identifying "signature" look and feel--"Project Pollution Prevention."

   Through a strategic and cost-effective combination of educational outreach tools and activities, the comprehensive Public Education Program has shown measurable increases in awareness among target audiences after three years of implementation. The Program has seen increases both in knowledge base (about the impacts of storm water pollution and potential solutions to reduce the problem), and in behaviors (by encouraging the adoption of appropriate solutions).

   Through a unified and coordinated effort between the County and Permittees, an integrated Public Education Program can continue to:

   - Change the mindset of a large, diverse population while educating target audiences about solutions to storm water pollution;
   - Create synergy by using an overarching campaign approach, "look" and tone, and by unifying multiple pollution prevention efforts;
   - Impact more than one audience at a time with a single communications campaign;
   - Build bridges and forge partnerships that integrate city and jurisdictional programs; and
   - Document and prove that the educational outreach efforts result in behavioral change and reduced pollution -- in all communities within Los Angeles County.

R0008727

Recommendations to Date cont.

2. **Research should continue to play a major role in the development and execution of the new public education program.** Research has proven to be a critical component of the current Storm Water Public Education Program. Upfront, it enabled the Media Campaign to segment and prioritize target audiences and allocate limited budget resources accordingly. At key benchmarks, interim research enabled the Media Campaign to monitor its effectiveness, evaluate communications tactics and modify strategies to achieve optimal results. Raising the bar in the new public education program – both in terms of reaching numeric goals and judiciously allocating increased dollars – will require continuous monitoring and evaluation.

3. **Additional funds from various sources should be allocated to the Public Education Program** – Interim Tracking Study results (July 1998) indicated that the media campaign was: communicating accurately; perceived by Los Angeles County residents to be delivering important messages; successful in changing attitudes; and was starting to impact behaviors. Because Los Angeles is a cluttered and expensive media market, a significant increase in funding and coordination is required to consistently build upon public education program results and deliver media messages with optimal reach and frequency.

   Unlike the Los Angeles County tobacco control program (previously noted), the Storm Water Public Education Program does not benefit from any statewide media campaign "spillover,"-- nor statewide budget dollars earmarked for Los Angeles County, nor a high-profile, multi-media campaign conveying complementary messages.

   In order to effectively convey the Program's complex messages and maintain consistent visibility throughout the program year – and not just during specific seasonal "windows,"--the program under the new permit needs to receive ***3-5 times the current annual program budget.***

   This is clearly beyond the means of the few local governments now supporting the effort. All Permittees, the State and the Federal Government need to pitch-in and contribute to the long-range success of the Program.

Recommendations to Date cont.

4. **Specific funds should be allocated to paid advertising and should reflect rising media costs.** Of the total public education program budget, ***approximately 70% per year should be earmarked for paid media.*** Paid media is the venue where we can best pinpoint target audiences, control placement, reach and frequency of the outreach, and can ensure consistent exposure to proven messages.

   Advertising costs are rising exponentially in the LA media market. To lend perspective, *radio advertising costs increased 20% between 1999 and 2000, while public education dollars remained consistent.* What that means is that instead of increasing the reach of program messages among County residents annually, program dollars were actually able to buy less and less advertising time each year, with total target audience reach also decreasing annually. To match anticipated cost increases, paid advertising allocations should range between 65% - 75% of the total annual program budget between Year One and Year Five.

   As delineated in the Program's core strategies, unified efforts are necessary to meet the program's challenging objectives. One collective media buy – coordinated by the County and supplemented by all parties -- will provide the County as a whole with the most strategic use of limited dollars and a media campaign most likely to achieve success.

5. **Final public education recommendations should be based on Year Five segmentation study findings.** The final segmentation should be utilized as the comprehensive benchmark of the Program's effectiveness and serve as the critical foundation for public education recommendations under the new permit. Given that the public education program has only enjoyed less than three years of implementation, the final full year of program activity (and its subsequent measurement) is expected to play a significant role in developing future educational strategies.

Data from the final segmentation study will be analyzed to determine the following additional items:

- **The effectiveness of advertising creative concepts and materials** – dependent on findings, new creative concepts and messages may be recommended to maximize media impact.
- **Confirmation on the *extent* to which an increase in funds *specifically allocated towards paid advertising* is recommended.**
- **The need to allocate funds towards business outreach** -- given that this audience is reached to a great degree through general public/residential outreach efforts and the industrial/commercial education site visit program.

Storm Water Public Education Program Overview

The following section is broken down by fiscal year and category of activity. Supporting this overview are representative samples of the education activities. Work was performed under ten categories of activities.

Activity	Five-Year Plan (Section 4)
1. Graphic Design/Advertising	General Public/Residents, Activities 1, 2, 4, 5, 8; Businesses, Activities 1, 6; Public Agency Employee, Activity 2
2. Corporate Partnerships	General Public/Residents, Activities 6, 9; Businesses, Activity 4
3. Media Relations and News Bureau	General Public/Residents, Activity 3; Businesses, Activity 5; Public Agency Employee, Activity 4
4. Special Events	General Public/Residents, Activity 10
5. Trade Show Displays	General Public/Residents, Activity 7
6. Tips Cards and Other General Public Collateral Materials	General Public/Resident. Activities 2, 5; Public Agency Employee, Activity 2
7. Business Outreach Materials	Businesses, Activities 1, 2
8. Training/Workshops	Businesses, Activities 3, 4; 8; Public Agency Employee, Activities 1,2, 3
9. Bulletins	Public Agency Employee, Activity 4
10. Research	Section 5, Five-Year Public Education Plan

Year One (1996 - 1997) Highlights

Research and Development of Five-Year Plan

- Developed ***Public Education Advisory Committee***, an ad hoc committee of various Permittee and County representatives, assembled to provide constructive input into the development of the ***Five-Year Public Education Plan*** and elicit buy-in from Permittee cities. Facilitated meetings throughout the fiscal year.

- Developed ***Initial Five-Year Public Education Plan – Part One***, detailing situation analysis, goals and objectives for the four primary target audiences: general public/residential; commercial/industrial and new development/ construction; K-12 school children; and public agencies.

- Developed ***Research Report on Issues, Pollutants and Materials***. The report served as a resource for reviewing and assessing the individual and collective efforts of Los Angeles County, 85 Permittees and some of the nation's leading storm water / urban runoff prevention programs. Focus areas in the report included: complex issues surrounding storm water / urban runoff prevention efforts; the prioritization of pollutants of concern, land uses and associated target audiences; specific materials and programs being implemented throughout the country; and overall recommendations on how to proceed in developing the ***Five-Year Public Education Plan.***

- Developed ***Initial Five-Year Public Education Plan – Part Two***, detailing overall strategies and public education tactics.

- Developed ***Residents and Industry Storm Water Awareness, Practices and Communications Report***. Report detailed focus group findings on current levels of awareness, knowledge and concern about storm water pollution; current usage of BMPs; reactions to potential program messages, creative materials and outreach strategies.

- Developed two-volume ***Public Employee Trainers' Manual*** (Volume One: Municipal Activities; Volume Two: Construction). Manuals were developed to provide Permittees with training materials for educating appropriate Permittee employees regarding compliance with applicable storm water permits. Conducted three training sessions for public agency employees.

- Conducted ***Los Angeles County Segmentation Study*** to define target audiences, quantify polluting behaviors and provide a strategic foundation for the ***Five-Year Public Education Plan's*** goals, objectives, messages, strategies and outreach tactics. Study identified three primary target audience segments around which to strategically and cost-effectively focus public education efforts. Segments, characterized as "Neat Neighbors," "Fix-It Foul-ups," and "Concerned Non-Contributors," were defined as the largest contributors to storm water pollution and those most likely to change behaviors, and represent approximately 83% of LA County's 10 million residents.

Year One (1996 - 1997) Highlights - cont.

Research and Development of Five-Year Plan

- Conducted presentations on ***Segmentation Study*** results, creative concepts and scenarios within the ***Five-Year Public Education Plan*** to the Public Education Advisory Committee and WMA Committees.

- Developed first three BMP posters for Site Visit Program and began distribution.

Special Events

- Attended the Los Angeles County Fair and other community events.

Year Two (1997 - 1998) Highlights

Research and Development of Five-Year Plan

- Developed final ***Five-Year Public Education Plan*** for review and approval by the *Public Education Advisory Committee, WMA Committees*, and ultimately, the *RWQCB*.

- Conducted ***Interim "Touchbase" Tracking Study*** following six-month implementation of the advertising campaign. Study indicated that the media campaign proved to be: (1) communicating accurately; (2) perceived by LA County residents to be delivering important messages; (3) successful in changing attitudes; and (4) starting to impact behaviors.

Graphic Design/Advertising

- Developed and produced letterhead package, including the ***Channel Bulletin*** and media release letterhead, and ***The Report*** covers.

- Developed ***Project Pollution Prevention*** logo and made available to Permittees via the Internet (www.freethmoroz.com).

- Developed and planned Countywide media buy in accordance with the ***Segmentation Study***.

- Tested media messages through mall intercept studies done in partnership with the City of Los Angeles.

- Conceptualized and produced ***Now You Know*** media campaign in accordance with the ***Segmentation Study*** and mall intercept results. Creative materials utilizing the ***Now You Know*** theme, included radio spots, print ads, and bus shelter poster designs.

- Paid media campaign leveraged **$1,085,000 in pro bono outdoor and radio placements**.

Media Relations

- Secured print and electronic media stories garnering **upwards of 22,766,000 impressions** at a **value of $162,439.**

- Developed ***Guide to Storm Water Media Relations***, a comprehensive resource manual to assist Permittees in executing local media relations campaigns: conducted workshop for Permittees in conjunction with the distribution of the media guide.

- Developed and distributed Spanish and English radio PSAs.

Year Two (1997 - 1998) Highlights - cont.

Corporate Partnerships

- Confirmed partnerships with Metro Display Advertising, Eller Media, Vista Metropolitan Outdoor Media, Worldwide Pet Supply Association, LA County Police Canine Association, PETCO, CrazyDog, Doggie Walk Bags at an **estimated value of $2.7 million.**

- Implemented training partnership with County of Los Angeles Health Services Department for restaurant worker storm water BMP training. Upwards of 50,000 businesses were identified for training over the next fiscal year.

Business Outreach

- Developed ***Businesses and Industries for a Clean Environment*** overview brochure.

- Finalized copy and design of 18 BMP fact sheets, technically specific and researched among target audience.

- Conducted an auto repair workshop with the California Dept. of Toxic Substances Control and the LA Urban League Toyota Training Center.

- Developed ***Southeastern Targeted Opportunities to Prevent Pollution (STOPP) Business Outreach Pilot Program***, detailing site visit reports, recommendations for business outreach (to auto repair shops and restaurants) and preparations for public workshops.

- Conducted ***Auto Mechanics Clean Business Fair***, an entertainment-oriented education event for automotive repair shop managers and employees hosted by County inspector David Dolphin and KTNQ/KLVE Spanish-language radio celebrity, Humberto Luna.

- Developed ***Project Pollution Prevention (PPP) Automotive Repair Workshop Report,*** detailing the ***Auto Mechanics Clean Business Fair.***

- Conducted ***Clean Business Expo*** for restaurants in conjunction with California Department of Toxic Substances Control, California Restaurant Association, and Bell Gardens Merchants and Commerce Association.

- Developed and distributed a series of topical small space ads for Permittee use (available on disk and via the Internet).

R0008734

Year Two (1997 - 1998) Highlights - cont.

Special Events

- Attended County special events (including Earth Fest '98, and Los Angeles County Fair). **Estimated attendance: 258,000.**

Bulletins

- Developed seven ***Channel Bulletins*** and distributed to Permittees, Public Education Advisory Committee and special interest mailing list.

Year Three (1998 - 1999) Highlights

Research

- Compiled results of ***Interim "Touchbase" Tracking Study***; produced and distributed research report to RWQCB, Public Education Advisory Committee, SCAG, SMBRP, County and Permittees.

Graphic Design/Advertising

- Conceptualized and produced new radio, print and outdoor media campaign reflecting 1998 interim evaluation results. Creative materials using the ***Warning Sign*** theme, included radio commercials, print ads, bus shelter poster designs and movie theatre slides.

- Paid advertising campaign leveraged **$900,000 in pro bono outdoor and radio placements.**

- Distributed ad launch materials to Permittees, Board of Supervisors and RWQCB.

- Secured advertising space on the screens of four high-traffic movie theaters coinciding with summer blockbuster season **(860,000 impressions)** and highlighted in the AMC Magazine's July issue **(circulation 100,000).**

- Secured advertising space on the back of grocery receipts in four high-traffic County stores for eight weeks, garnering **325,000 impressions**.

Tips Cards and Other General Public Collateral Materials

- Produced pesticide and fertilizer tips cards with PPP branding; produced used oil tips cards in conjunction with Chevron; produced recycling tips cards in conjunction with COSTCO.

- Produced interactive storm water pollution prevention game to increase participation at special events.

Corporate Partnerships

- Confirmed partnerships with Chevron, COSTCO, Petco, LA County Arboretum, Southern California Veterinary Medicine Association, and Doggie Walk Bags, garnering an **estimated 2,775,000 impressions** at a **value of $136,066**.

R0008736

Year Three (1998 - 1999) Highlights - cont.

Media Relations

- Secured print and electronic media stories garnering **8,530,000 estimated impressions** at a **value of $157,030.**
- Secured media coverage regarding County storm water diversion systems in the *Los Angeles Times* (front page), *Beach Reporter*, *Daily Breeze* and *Long Beach Press-Telegram.* **Estimated impressions: 1,500,000.**
- Secured ad launch coverage in *Adweek*, *Daily Breeze*, *News-Pilot*, KFWB-AM and KCSN-FM. **Estimated impressions: over 500,000.**
- Secured County panelists and coordinated storm water program on Century *Cable's Bill Rosendahl Show.* **Estimated impressions: 404,000.**
- Developed and distributed five template media releases to all Permittees.
- Produced two audio news releases (general storm water pollution prevention and lawn and gardening care). **Estimated impressions: 1,075,000.**

Special Events

- Attended ten County special events (including Earth Faire, Los Angeles County Fair, America's Family Pet Expo, Long Beach Home and Garden Show). **Estimated attendance: over 250,000.**

Business Outreach

- Conducted meetings with the Building Industry Association regarding the new State Construction Permit.
- Conducted educational site visits.

Bulletins

- Developed four ***Channel Bulletins*** and distributed to Permittees, Public Education Advisory Committee and special interest mailing list.

R0008737

Year Four (1999 – 2000) Highlights

Graphic Design/Advertising

- Secured and coordinated four-week radio promotion with KIIS FM, ***2000 Superbowl Storm Water Sweep,*** including: partnerships with Universal Studios, Pepsi and Popeye's Chicken; four weeks of on-air spots and announcements. Website postings, interactive phone messages and promotions at live remotes; and a station-sponsored beach clean-up and picnic, wherein more than 2,200 pounds of trash was collected along Santa Monica Beach. **Estimated impressions: 22,567,000.**

- Secured advertising space on the screens of five high-traffic movie theaters coinciding with holiday blockbuster season **(1,106,700 impressions)** and highlighted in the AMC Magazine's November issue **(circulation 100,000).**

- Secured advertising space on the back of grocery receipts in four high-traffic County stores for 12 weeks. **Estimated impressions: 975,000.**

- Produced two additional radio ads. "Encounter Group" and "Salute."

- Annual Countywide media campaign aired from April into July 2000 and has not been evaluated to date.

- Distributed media campaign materials to Permittees, Board of Supervisors and RWQCB.

Media Relations

- Secured print and electronic media stories garnering **53,892,100 estimated impressions** at a **value of $310,604.**

- Secured media coverage on less toxic/alternative products, used oil recycling centers and HHW Roundups, including four live feature segments on the *KTLA Morning* News and two segments on *KTLA Pacesetters*. **Estimated impressions: upwards of 2,120,000 at a value of $80,000.**

- Secured media coverage on launch of five new underground storm water diversion systems. in conjunction with Heal the Bay. the City of Long Beach and the American Lung Association. **Estimated impressions: upwards of 3,000,000 at a value of $22,000.**

Year Four (1999 - 2000) Highlights - cont.

Tips Cards and Other General Public Collateral Materials

- Produced 65,000 customized coffee jackets imprinted with PPP messages, and secured distribution at 31 County coffeehouses. **Estimated impressions: 1,296,000.**

- Produced 10,000 customized magnets – focused on used automotive fluid recycling – imprinted with PPP and CSK/Kragen logos. Initial distribution took place at the Toyota/Long Beach Grand Prix.

- Produced 7,500 general pollution prevention tips cards imprinted with PPP and Brita logos. Initial distribution took place at Earth Faire 2000.

- Produced 20,000 customized shop towels (10,000 English, 10,000 Spanish) – focused on used automotive fluid recycling – imprinted with PPP messages and logo, and developed in conjunction with the City of Los Angeles and CIWMB. Initial distribution took place at Eagle One Nationals.

Corporate Partnerships

- Confirmed partnerships with CSK/Kragen, Brita. American Lung Association, City of Los Angeles and CIWMB garnering **an estimated value of $66,000.** Note: partnership with high-profile corporate and nonprofit entities such as Kragen, Brita and American Lung contributed considerable added value to the Program, though one that is not quantifiable in traditional advertising/marketing dollars. The Program benefited significantly from these affiliations via their significant "brand equity," increased credibility among target audience segments and greatly expanded program visibility and reach.

Special Events

- Attended six County special events (including the Los Angeles County Fair, Latin Business Association Expo, Toyota/Long Beach Grand Prix, Earth Faire, Cinco de Mayo at Whittier Narrows and Eagle One Nationals); **estimated attendance: over 500,000.**

Business Outreach

- Developed and distributed specialized automotive repair BMP workbooks and videos to 319 automotive instructors at targeted high schools. ROP programs. adult vocational schools, community colleges (potentially **reaching upwards of 19,000 students**).

Bulletins

- Developed three ***Channel Bulletins*** and distributed to Permittees and special interests.

VENTURA COUNTY MUNICIPAL STORM WATER NPDES PERMIT (BOARD ORDER No. 00-108; NPDES PERMIT No. CAS004002) – LETTER OF TRANSMITTAL

Dear Mr. Pratt, et al:

We are pleased to send you the final municipal storm water permit for the Ventura County (attached), which was adopted by the Regional Board at its meeting on July 27, 2000, pursuant to Division 7 of the California Water Code. Board Order No. 00-108 serves as your permit, under the National Pollutant Discharge Elimination System (NPDES), for storm water discharges and urban runoff within Ventura County, and will expire on July 27, 2005.

The Order requires the Ventura County Flood Control District, herein referred to as the Principal Co-Permittee, and other Co-Permittees to implement the NPDES Permit No. CAS004002, including the Monitoring and Reporting Program, Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP), and Ventura Countywide Stormwater Quality Management Plan (SMP). The first Annual Storm Water Report and Assessment, for the period July 1, 1999 through July 27, 2000, is due on October 1, 2000. The first Annual Monitoring Report is due July 15, 2001.

Once again, we wish to thank you and your staff for their participation and assistance during the development and adoption of the permit for the Ventura County. Should you have any questions, please do not hesitate to call me at (213) 576-6605 or Dr. Xavier Swamikannu at (213) 576-6654.

Sincerely,

Dennis A. Dickerson

MONITORING AND REPORTING PROGRAM

ATTACHMENT

STATE OF CALIFORNIA

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
LOS ANGELES REGION

ORDER NO. 00-108 NPDES PERMIT NO. CAS004002
WASTE DISCHARGE REQUIREMENTS
FOR
MUNICIPAL STORM WATER AND URBAN RUNOFF DISCHARGES
WITHIN
VENTURA COUNTY FLOOD CONTROL DISTRICT,
COUNTY OF VENTURA, AND THE CITIES OF VENTURA COUNTY

FINDINGS

The California Regional Water Quality Control Board, Los Angeles Region (hereinafter called the Regional Board), finds that:

Permit Parties

1. Ventura County Flood Control District (VCFCD), the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks (hereinafter referred to separately as Co-permittees and jointly as the Discharger) have joined together to form the Ventura Countywide Storm Water Quality Management Program to discharge wastes under waste discharge requirements contained in Order No. 94-082, adopted by this Board on July 27, 2000. The Discharger discharges or contributes to discharges of storm water and urban runoff from municipal separate storm sewer systems (MS4s), also called storm drain systems, into receiving waters of the Santa Clara River, Ventura River, Calleguas Creek, and other coastal watersheds within Ventura County.

2. The Regional Board may require a separate National Pollutant Discharge Elimination System (NPDES) permit for any entity that discharges storm water into coastal watersheds of Ventura County. Such entity can be any State or Federal agency, State or Federal facility, real estate development, waste disposal facility, special district, private interest, etc. Pursuant to 40 CFR 122.26(a), the Regional Board will give these entities the option to become a Co-permittee, after obtaining the concurrence of the Co-permitees, or obtain an individual storm water discharge permit.

Nature of Discharge

3. Storm water discharges consist of surface water runoff generated from various land uses in all the hydrologic drainage basins which discharge into waters of the State. The quality of these discharges varies and is affected by hydrology, geology, land

use, season, and sequence and duration of hydrologic events. The primary pollutants of concern currently identified by the Program for these discharges are total and fecal coliform, mercury, polyaromatic hydrocarbons (PAHs), DDT and their by-products, diazinon, sediment/total suspended solids (TSS), chlorpyrifos, copper, lead, thallium, bis(2-ethylhexyl) phthalate, and phosphorous.

4. In general, the substances that are found in urban storm water runoff can harm human health and aquatic ecosystems. In addition, the high volumes of storm water discharged from MS4s in areas of urbanization can significantly impact aquatic ecosystems due to physical modifications such as bank erosion and widening of channels. It is anticipated that, due to the nature of storm water events (i.e., large volumes of water and high velocities) that there will be short-term, reversible impacts to beneficial uses that are not directly related to water quality.

5. Water quality assessments conducted by the Regional Board identified impairment, or threatened impairment, of beneficial uses of water bodies in the Ventura Coastal Watersheds. These impairments include many of the pollutants of concern identified by the program. These impairments are identified on the Federal 303(d) list of impaired water bodies.

Permit Background

6. The Discharger has filed a report of waste discharge (ROWD) and has applied for renewal of its waste discharge requirements and an NPDES permit to discharge wastes to surface waters. The ROWD includes the Ventura Countywide Storm Water Quality Management Plan (hereinafter called Ventura County SMP) which describes in detail all group activities and entity-specific activities. The Ventura County SMP also describes management measures that are included and how they are organized; it lists tasks required to accomplish the measures, the schedule for implementation, and specific goals. The schedule and tasks are projected for the 5-year permit period. An outline of the Ventura County SMP is presented in Attachment B. The Implementation chapter of the Ventura County SMP consists of the following elements:

   a. Program management
   b. Programs for residents
   c. Programs for industrial/commercial businesses
   d. Programs for land development
   e. Programs for construction sites
   f. Programs for Co-permittee facility maintenance, and
   g. Programs for illicit discharge control

   The Ventura County SMP is implemented by the Co-permittees with general funds, and/or Benefit Assessment Program funds.

7. The Ventura Countywide Storm Water Quality Management Program also includes the Storm Water Monitoring Plan. To date, the monitoring program has consisted of land-use based monitoring combined with receiving water monitoring and modeling. The Discharger intends to sign an agreement to participate in the Regional Monitoring

Program established for Southern California municipal programs under the guidance of the Southern California Coastal Water Research Project.

8. The Regional Board has reviewed the ROWD and has determined it to be complete under the reapplication policy for MS4s issued by the USEPA on July 1996. The Regional Board finds that the Permittee's proposed Storm Water Management Plan is acceptable at this time, and when fully implemented, is expected to be consistent with the statutory standard of Maximum Extent Practicable (MEP).

Permit Coverage

9. The area subject to permit requirements includes all areas within the boundaries of the cities as well as unincorporated areas of Ventura County defined as urban by the U.S. Census Bureau (Figure 1). Municipal storm drain systems in this area discharge either directly into the Pacific Ocean or one of five major water bodies:

Water Body	Receives Municipal Storm Drain Discharges from:
Ventura River	City of Ojai, City of San Buenaventura (part), unincorporated Ventura County (part)
Santa Clara River	City of Fillmore, City of Oxnard (part), City of San Buenaventura (part), City of Santa Paula, unincorporated Ventura County (part)
Calleguas Creek	City of Camarillo, City of Moorpark, City of Simi Valley, City of Thousand Oaks (part), unincorporated Ventura County (part)
Malibu Creek	City of Thousand Oaks (part), unincorporated Ventura County (part)
Bays/ Estuaries	City of Oxnard (part), City of Port Hueneme, City of San Buenaventura (part)

10. The Co-permittees are separate legal entities and have the authority to develop, administer, implement, and enforce storm water quality management programs within their own jurisdiction. The Ventura County SMP defines certain storm water discharge requirements that apply to the Discharger, and others that apply to specific Co-permittees. Each Co-permittee is responsible for compliance with relevant portions of this permit within their jurisdiction.

11. VCFCD is the Principal Co-permittee for permit implementation while the remaining entities, including the County of Ventura and the ten cities, are designated as Co-permittees. The following Implementation Agreement exists between the Principal Co-permittee and the Co-permittees:

As the Principal Co-permittee, VCFCD will:

a. Coordinate permit activities;
b. Establish uniform data submittal format;
c. Set time schedules;
d. Prepare regulatory reports;
e. Forward information to the Co-permittees;

f. Arrange for public review;
g. Secure services of consultants as necessary;
h. Implement activities of common interest;
i. Develop/prepare/generate all materials and data common to all Co-permittees;
j. Update Co-permittees on Regional Board and US Environmental Protection Agency (USEPA) regulations;
k. Arrange for collection and payment of annual permit renewal fee; and,
l. The Principal Co-permittee shall convene all Management Committee and Subcommittee meetings.

All Co-permittees will:

a. Comply with the requirements of the permit within their own jurisdictional boundaries;
b. Prepare and provide to the Principal Co-permittee permit-required submittals;
c. Develop programs to address:
   - Implementation of controls to reduce pollution from commercial, industrial, and residential areas;
   - Implementation of structural/non-structural controls on land development and construction sites;
   - Implementation of controls to reduce pollution from maintenance activities;
   - Elimination of illegal connections, including discouragement of improper disposal, encouragement of spill prevention and containment, and implementation of appropriate spill response;
   - Inspection monitoring and control programs for industrial facilities; and,
   - Implementation of public awareness and training programs.

d. Co-permittees shall be represented at Management Committee Meetings;
e. There are currently five subcommittees which were developed during the first permit cycle: Residents, Businesses/Illicit Discharges, Planning and Land Development, Construction, and Co-permittee Facilities Maintenance. The Management Committee will assign subcommittee attendance requirements in proportion to Co-permittee population. Co-permittees shall be represented at all assigned subcommittee meetings, and,
f. Within its own jurisdiction, each Co-permittee is responsible for adoption and enforcement of storm water pollution prevention ordinances, implementation of self-monitoring programs and Best Management Practices (BMPs), and conducting applicable inspections. Based upon a countywide model, each Co-permittee, except the City of Simi Valley, has adopted a Storm Water Quality Ordinance applicable to their jurisdiction. This is in addition to 'the

'Control of Water Quality, Soil, Erosion and Sedimentation of New Agricultural Hillside Developments' adopted by the Board of Supervisors of the County of Ventura on March 20, 1984. The Principal Co-permittee is responsible for the preparation and submittal of progress and annual reports to the Regional Board.

12. This permit is intended to develop, achieve, and implement a timely, comprehensive, cost-effective storm water pollution control program to minimize pollutants to the maximum extent practicable in storm water discharges from the permitted area in Ventura County to the waters of the United States.

Federal and State Regulations

13. The Water Quality Act of 1987 added Section 402(p) to the Federal Clean Water Act (CWA). This section requires the U.S. Environmental Protection Agency (EPA) to establish regulations setting forth NPDES requirements for storm water discharges. The first phase of these requirements was directed at municipal separate storm drainage systems (MS4) serving a population of 100,000 or more and storm water discharges associated with industrial activities, including construction activities. Other dischargers, including municipalities with a population of less than 100,000, for which the U.S. EPA Administrator or the State determines that the storm water discharge contributes to a violation of a water quality standard, or is a significant contributor of pollutants to waters of the United States, may also be subject to NPDES requirements. On November 16, 1990, EPA published these final regulations in the Federal Register under Part 122 Code of Federal Regulations.

14. The CWA allows the EPA to delegate its NPDES permitting authority to states with an approved environmental regulatory program. The State of California is a delegated State. The Porter-Cologne Water Quality Control Act (California Water Code) authorizes the State Water Resources Control Board (State Board), through the Regional Boards, to regulate and control the discharge of pollutants into waters of the State and tributaries thereto.

15. Section 6217(g) of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) requires coastal states with approved coastal zone management programs to address non-point pollution impacting or threatening coastal water quality. CZARA addresses five sources of non-point pollution: agriculture, silviculture, urban, marinas, and hydromodification. This NPDES permit addresses the management measures required for the urban category, with the exception of septic systems. The Regional Board addresses septic systems through the administration of other programs.

16. The State Water Resources Control Board adopted a revised Water Quality Control Plan for Ocean Waters of California (Ocean Plan) on July 23, 1997. The Ocean Plan contains water quality objectives for the coastal waters of California.

17. This Regional Board adopted a revised Water Quality Control Plan (Basin Plan) for the Los Angeles Region on June 13, 1994. The Basin Plan, which is incorporated into this Order by reference, specifies the beneficial uses of Ventura County water

bodies and their tributary streams and contains both narrative and numerical water quality objectives for these receiving waters. The following beneficial uses are identified in the Basin Plan and apply to all or portions of each watershed covered by this Permit:

a. Municipal and domestic supply
b. Agricultural supply
c. Industrial service supply
d. Industrial process supply
e. Ground water recharge
f. Freshwater replenishment
g. Navigation
h. Hydropower generation
i. Water contact recreation
j. Non-contact water recreation
k. Ocean commercial and sport fishing
l. Warm freshwater habitat
m. Cold freshwater habitat
n. Preservation of Areas of Special Biological Significance
o. Saline water habitat
p. Wildlife habitat
q. Preservation of rare and endangered species
r. Marine habitat
s. Fish migration
t. Fish spawning
u. Shellfish harvesting

18. To facilitate compliance with federal regulations, the State Water Resources Control Board (State Board) has issued two statewide general NPDES permits: one for storm water from industrial sites [NPDES No. CAS000001, General Industrial Activities Storm Water Permit (GIASP)] and the other for storm water from construction sites [NPDES No. CAS000002, General Construction Activity Storm Water Permit (GCASP)]. The GCASP was issued on August 20, 1992. The GIASP was reissued on April 17, 1997. Facilities discharging storm water associated with industrial activities and construction projects with a disturbed area of five acres or more are required to obtain individual NPDES permits for storm water discharges, or be covered by these statewide general permits by completing and filing a Notice of Intent (NOI) with the State Board. The USEPA guidance anticipates coordination of the state-administered programs for industrial and construction activities with the local agency program to reduce pollutants in storm water discharges to the MS4.

19. The State Board, on October 28, 1968, adopted Resolution No. 68-16, "Maintaining High Quality Water" which established an anti-degradation policy for State and Regional Boards.

20. The State Board, on June 17, 1999, adopted Order No. WQ 99-05, which specifies standard receiving water limitations language to be included in all municipal storm water permits issued by the State and Regional Boards.

21. California Water Code (CWC) Section 13263(a) requires that waste discharge requirements issued by Regional Boards shall implement any relevant water quality control plans that have been adopted; shall take into consideration the beneficial uses to be protected and the water quality objectives reasonably required for that purpose; other waste discharges; and, the need to prevent nuisance.

22. California Water Code Section 13370 *et seq.* requires that waste discharge requirements issued by the Regional Boards comply with provisions of the Federal Clean Water Act and its amendments.

<u>Public Notification</u>

23. This action to adopt and issue waste discharge requirements and an NPDES permit for this discharge is exempt from the provisions of the California Environmental Quality Act (CEQA), Chapter 3 (commencing with Section 21100) of Division 13 of the Public Resources Code in accordance with Section 13389 of the California Water Code.

24. The Regional Board has notified the Discharger and interested agencies and persons of its intent to issue waste discharge requirements for this discharge, and has provided them with an opportunity to submit their written views and recommendations.

25. The Regional Board, in a public hearing, heard and considered all comments pertaining to the discharge and to the tentative requirements.

26. This Order shall serve as a National Pollutant Discharge Elimination System (NPDES) Permit, pursuant to Section 402 of the Federal Clean Water Act, or amendments thereto, and shall take effect on August 11, 2000 provided the Regional Administrator of the EPA has no objections.

IT IS HEREBY ORDERED that the Ventura County Flood Control District, the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks, in order to meet the provisions contained in Division 7 of the California Water Code and regulations adopted thereunder, and the provisions of the Clean Water Act, as amended, and regulations and guidelines adopted thereunder, shall comply with the following:

PART 1 - DISCHARGE PROHIBITIONS

A. The Co-permittees shall, within their respective jurisdictions, effectively prohibit non-storm water discharges into the MS4 (storm drain systems) and watercourses except where such discharges:

   1. Are covered by a separate individual or general NPDES permit; or

R0008751

2. Meet one of the conditions below:

   a. Not identified as a source of pollutants:

      1. Flows from riparian habitats or wetlands;
      2. Diverted stream flows;
      3. Natural springs;
      4. Rising ground waters;
      5. Uncontaminated ground water infiltration [as defined at 40 CFR 35.2005(20)]; or;

   b. Not identified as a source of pollutants, subject to conditions:

      6. Water line flushing;
      7. Discharges from potable water sources;
      8. Foundation drains;
      9. Footing drains;
      10. Air conditioning condensate;
      11. Water from crawl space pumps;
      12. Reclaimed and potable irrigation water;
      13. Dechlorinated swimming pool discharges;
      14. Individual residential car washing;
      15. Sidewalk washing;
      16. Discharges or flows from emergency fire fighting activities.

   If any of the above categories of non-storm water discharges (Part I, A.2.b) are determined to be a source of pollutants by the Regional Board Executive Officer, the discharge need not be prohibited if the Co-permittee implements appropriate BMPs to ensure that the discharge will not be a source of pollutants. Notwithstanding the above, the Regional Board Executive Officer may impose the prohibition in consideration of anti-degradation policies.

   The Discharger may, for any of the above non-storm water categories, require BMPs deemed necessary to ensure that the discharge will not be a source of pollutants.

   c. The Regional Board Executive Officer may authorize the discharge of additional categories of non-storm water, after consideration of anti-degradation policies and upon presentation of evidence that the non-storm water discharge will not be a source of pollutants. This evidence may include the implementation of BMPs to control pollutants.

3. Discharges originating from federal, state, or other facilities which the Discharger is pre-empted by law from regulating.

PART 2 - RECEIVING WATER LIMITATIONS

A. Discharges from the MS4 that cause or contribute to the violation of water quality standards or water quality objectives are prohibited.

B. Discharges from the MS4 of storm water, or non-storm water, for which a Discharger is responsible, shall not cause or contribute to a condition of nuisance.

C. The Discharger shall comply with the permit through timely implementation of control measures and other actions to reduce pollutants in the discharges in accordance with the Ventura County SMP and other requirements of this permit including any modifications. The Ventura County SMP shall be designed to achieve compliance with receiving water limitations. If exceedance(s) of water quality objectives or water quality standards persist, notwithstanding implementation of the Ventura County SMP and other requirements of this permit, the Discharger shall assure compliance with discharge prohibitions and receiving water limitations by complying with the following procedure:

   1. Upon a determination by either the Discharger or the Regional Board that discharges are causing or contributing to an exceedance of an applicable water quality standard(s), the Discharger shall promptly notify and thereafter submit a report to the Regional Board that describes BMPs that are currently being implemented, and additional BMPs that will be implemented, to prevent or reduce any pollutants that are causing or contributing to the exceedances of water quality standards. This report may be included with the Annual Storm Water Report and Assessment, unless the Regional Board directs an earlier submittal. The report shall include an implementation schedule. The Regional Board may require modifications to the report.

   2. Submit any modifications to the report required by the Regional Board within 30 days of notification.

   3. Within 30 days following the approval of the report, the Discharger shall revise the Ventura County SMP and monitoring program to incorporate the approved, modified suite of BMPs, implementation schedule, and any additional monitoring required.

   4. Implement the revised Ventura County SMP and monitoring program according to the approved schedule.

D. So long as the Discharger complies with the procedures set forth above and is implementing the revised Ventura County SMP, the Discharger does not have to repeat the procedure for continuing or recurring exceedances of the same water quality standard(s) unless directed by the Regional Board to develop additional BMPs.

PART 3 - STORM WATER QUALITY MANAGEMENT PLAN IMPLEMENTATION, MONITORING, AND REPORTING

A. General Requirements

1. The Discharger shall, at a minimum, adopt and implement the elements of the Ventura County SMP that are consistent with the terms of this permit.

   Additionally, modifications to the Ventura County SMP made during the term of the permit including those made in accordance with Part 3. B. of this permit shall be implemented.

2. The Ventura County SMP shall, at a minimum, comply with applicable requirements of 40 CFR 122.26(d)(2). The Ventura County SMP shall be implemented so as to reduce the discharges of pollutants in storm water to the maximum extent practicable. The Ventura County SMP is described in Attachment B.

3. Each Co-permittee shall be responsible for implementation of relevant portions of the Ventura County SMP within its jurisdictional boundaries. The Principal Co-permittee shall be responsible for program coordination as described in Section 1 of the Ventura County SMP as well as compliance with relevant portions of the permit within its jurisdiction.

B. Modifications

1. The Discharger shall modify the Ventura County SMP adopted with this Order to make it consistent with the requirements herein. The revised Ventura County SMP will be submitted to the Regional Board Executive Officer for approval no later than January 27, 2001].

2. The Regional Board Executive Officer may approve changes to the Ventura County SMP, except as noted in Part 3 B.1, either:

   a. Upon petition by the Discharger or interested parties, and after providing for and considering public comment, or,

   b. As deemed necessary by the Regional Board Executive Officer following notice to the Discharger, and after providing for and considering public comment.

The Discharger shall modify the Ventura County SMP, at the direction of the Regional Board Executive Officer, to incorporate regional provisions. Such provisions may include watershed-specific requirements for watersheds shared by the Discharger with other MS4 programs.

C. Legal Authority

1. Co-permittees shall possess the necessary legal authority to prohibit non-storm water discharges and control the contribution of pollutants to the storm drain system from storm water discharges, including, but not limited to:

   a. A prohibition on illicit discharges and illicit connections and a requirement for removal of illicit connections;

      i. Prohibit the discharge of wash waters to the MS4 when gas stations, auto repair garages, or other types of automotive service facilities are cleaned;
      ii. Prohibit the discharge of runoff to the MS4 from mobile auto washing, steam cleaning, mobile carpet cleaning, and other such mobile commercial and industrial operations;
      iii. Prohibit the discharges of runoff to the MS4 from areas where, repair of machinery and equipment which are visibly leaking oil, fluid or antifreeze, is undertaken;
      iv. Prohibit the discharge of runoff to the MS4 from storage areas of materials, containing grease, oil, or other hazardous substances, and uncovered receptacles containing hazardous materials;
      v. Prohibit the discharge of chlorinated swimming pool water and filter backwash to the MS4;
      vi. Prohibit the discharge of untreated runoff from the washing of toxic materials from paved or unpaved areas to the MS4;
      vii. Prohibit washing impervious surfaces in industrial/commercial areas which results in a discharge of untreated runoff to the MS4, unless specifically required by State or local health and safety codes; and
      viii. Prohibit the discharge from washing out of concrete trucks, pumps, tools, and equipment to the MS4.

   b. A prohibition on spills, dumping, or disposal of materials other than storm water ;

      i. Litter, landscape debris and construction debris;
      ii. Any state or federally banned pesticide, fungicide or herbicide;
      iii. Food wastes; and
      iv. Fuel and chemical wastes, animal wastes, garbage, batteries, and other materials which have potential adverse impacts on water quality.

   c. A mechanism to control, through interagency agreement, the contribution of pollutants from one portion of the MS4 to another portion of the MS4;

d. A requirement for compliance with conditions in ordinances, permits, contracts, or orders; and,

e. The ability to carry out all inspections, surveillance and monitoring procedures necessary to determine compliance and non-compliance with permit conditions, including the prohibition on illicit discharges to the MS4.

2. Each Co-permittee shall adopt, no later than July 27, 2001, an agency-specific storm water and urban runoff ordinance or amend an existing one if necessary, based on the countywide model (Appendix A of the Ventura County SMP) to be able to enforce all requirements of the permit.

D. Annual Storm Water Report and Assessment

1. The Discharger shall submit, by October 1 of each year beginning the Year 2001, an Annual Storm Water Report and Assessment documenting the status of the general program and individual tasks contained in the Ventura County SMP, as well as results of analyses from the monitoring and reporting program CI 7388. The Annual Storm Water Report and Assessment shall cover each fiscal year from July 1 through June 30, and shall include the information necessary to assess the Discharger's compliance status relative to this Order, and the effectiveness of implementation of permit requirements on storm water quality. The Annual Storm Water Report and Assessment shall include any proposed changes to the Ventura County SMP as approved by the Management Committee.

   The Discharger shall submit, by October 1, 2000, the Annual Report for the period July 1, 1999 through July 27, 2000 documenting the status of the general program up to permit reissuance and the results of analyses from the monitoring and reporting program.

2. Storm Water Management Program Budget

   a. The Discharger shall prepare annually a storm water budget update on resources applied to the storm water program. This budget report shall include an annual update identifying the storm water budget for the following year using [estimated percentages and written explanations where necessary], for the specific categories noted below:

      i. Program management
      ii. Illicit connections/illicit discharge
      iii. Development planning/development construction
      iv. Construction inspection activities
      v. Public Agency Activities
         - Operations and Maintenance
         - Municipal Street Sweeping

- Fleet and Public Agency Facilities
- Landscape and Recreational Facilities

vi. Capital Costs
vii. Public Information and Participation
viii. Monitoring Program
ix. Other

Co-permittees, in addition to the Benefit Assessment budget, shall report any supplemental dedicated budgets, if any, for the same categories.

E. Storm Water Monitoring Report.

1. The Discharger shall submit a Storm Water Monitoring Report on July 15, 2001 and annually on July 15 thereafter. The report shall include:

   a. Status of implementation of the monitoring program as described in the attached Monitoring and Reporting Program, CI-7388.

   b. Results of the monitoring program; and

   c. A general interpretation of the significance of the results, to the extent that data allows.

F. Modification

1. The Regional Board Executive Officer or the Regional Board consistent with 40 CFR 122.41 may approve changes to the Ventura County Monitoring Program, after providing the opportunity for public comment, either:

   a. By petition of the Permittee or by petition of interested parties, after the submittal of the Annual Monitoring Program Report. Such petition shall be filed, not later than 60 days after the Annual Monitoring Program Report submittal date, or

   b. As deemed necessary by the Regional Board Executive Officer following notice to the Permittee.

PART 4 – SPECIAL PROVISIONS

The Ventura County SMP submitted by the Discharger is an integral and enforceable component of the permit.

Changes to Storm Water Quality Management Plan may be made as follows:

It is anticipated that the storm water quality management program, as delineated in the Ventura County SMP may need to be modified, revised, or amended from time-to-time in response to changed conditions, and to incorporate more effective approaches to pollutant control. Minor changes to the Ventura County SMP may be made at the direction of the Regional Board Executive Officer. Minor changes requested by the Discharger shall become effective upon written approval of the Regional Board Executive Officer. If proposed changes constitute a major revision in the overall scope of effort of the program, such changes must be approved by the Regional Board as permit amendments. The Discharger shall implement the Ventura County SMP on July 27, 2000, and for the duration of this permit.

Requirements of the permit shall take effect on August 11, 2000 provided the US EPA Regional Administrator has no objections.

A. Programs for Residents

1. Co-permittees shall identify staff who will serve as the public reporting contact person(s) for reporting clogged catch basin inlets and illicit discharges/dumping, and general storm water management information within 6 months of permit issuance, and thereafter include this information, updated when necessary, in public information, the government pages of the telephone book, and the annual report as they are developed/published. The designated contact staff will be provided with relevant storm water quality information including current resident program activities, preventative storm water pollution control information and contact information for responding to illicit discharges/illegal dumping.

2. Co-permittees shall mark storm drain inlets with a legible "no dumping" message. In addition, signs with prohibitive language discouraging illegal dumping must be posted at designated public access points to creeks, other relevant water bodies, and channels by July 27, 2002.

3. Each Co-permittee shall conduct educational activities within its jurisdiction and participate in countywide events.

4. Each Co-permittee shall distribute outreach materials to the general public and school children at appropriate public counters and events. Outreach material shall include information such as proper disposal of litter, green waste, and pet waste, proper vehicle maintenance techniques, proper lawn care, and water conservation practices.

5. The Discharger shall insure that a minimum of 2.1 million impressions per year are made on the general public about storm water quality via print, local TV access, local radio, or other appropriate media.

B. Programs for Industrial/Commercial Businesses

1. Each Co-permittee shall implement an industrial/commercial educational site inspection program.

2. Co-permittees shall inspect automotive service and food service facilities in its jurisdiction once every two years. During site visits, Co-permittees shall:

   a. Consult with a representative of the facility to explain applicable storm water regulations;

   b. Distribute and discuss applicable BMP and educational materials; and,

   c. Conduct a site walk-through to inspect for, at a minimum, evidence of illicit discharges and storm water educational programs for employees.

3. Co-permittees shall revisit automotive and food service facilities where evidence of illicit discharge is found within six months of the inspection. If necessary, Co-permittees will begin enforcement action to remove sources of illicit discharges.

4. Based on Pollutants of Concern source identification, additional target businesses may be identified to be included in the inspection program. Co-permittees shall report on the types and proposed actions to be taken in regard to the additional target businesses in annual reports.

5. No later than July 27, 2002, each Co-permittee shall conduct a site visit and complete a site visit check-list provided by the Regional Board, and distribute educational program materials to facilities identified as subject to the State Board General Industrial Permit. Thereafter, material will be redistributed once every two years. These industrial facilities shall be notified of specific requirements contained in the Statewide Industrial General Permit including: that such facilities must file an Notice of Intent (NOI) with the State Board, and that a Storm Water Pollution Prevention Plan (SWPPP) must be available on the site. Educational materials shall also include information describing illicit discharges. The information shall include: types of discharges prohibited, how to prevent illicit discharges, what to do in the event of an illicit discharge, and the array of enforcement actions the facility may be subject to, including penalties that can be assessed. The Co-permittee shall note on the site-visit check-list if an NOI has been submitted and if a SWPPP is available on site.

6. Co-permittees shall provide an annual update of the inspected automotive service, food service, and other targeted facilities, and the facilities identified as Phase I industrial facilities to this Regional Board in the annual report. The database shall include at a minimum; facility name, site address, applicable SIC code(s), and NPDES storm water permit coverage.

7. Co-permittees shall train their employees in targeted positions (whose jobs or activities directly affect storm water quality, or those who respond to questions from the public), including inspection staff, regarding the

requirements of the storm water management program by January 27, 2001, and annually thereafter.

C. Programs for Planning and Land Development

1. The Discharger shall implement the approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) (Attachment A) no later than January 27, 2001. The SQUIMP shall address conditions and requirements for new development and significant redevelopment. At a minimum, appropriate elements of the SQUIMP will be included as project requirements for the following development categories:

   a. Single-family hillside residences;
   b. 100,000 square foot commercial developments;
   c. Automotive repair shops;
   d. Retail gasoline outlets;
   e. Restaurants;
   f. Home subdivisions with 10 or more housing units;
   g. Locations within, or directly adjacent to or discharging directly to an environmentally sensitive area; and,
   g. Parking lots of 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to storm water runoff.

2. The Discharger shall no later than July 27, 2002, prepare a technical manual which shall include:

   a. specifications for treatment control BMPs and structural BMPs based on the flow-based and volume-based water quality design criteria for the purposes of countywide consistency, and
   b. criteria for the control of discharge rates and duration.

   Notwithstanding the requirement that the BMP design criteria be incorporated into a technical manual, the criteria shall be effective as of July 27, 2000. The technical manual criteria shall be consistent with, and must not be less stringent than the design criteria in the SQUIMP, and shall be subject to approval by the Regional Board Executive Officer.

3. The Discharger shall identify no later than January 27, 2001, specific environmentally sensitive areas in Ventura County for the application of SQUIMP requirements, based on the Regional Board's Basin Plan and CWA Section 303 (d) Impaired Water-bodies List, and submit the list to the Regional Board Executive Officer for approval. Once approved, this list will supplement the state designations included in the definition of "Environmentally Sensitive Areas".

4. Co-permittees shall make appropriate modifications to their internal planning procedures for preparing / reviewing CEQA documents, and for linking storm water quality mitigation conditions to legal discretionary project approvals.

linking storm water quality mitigation conditions to legal discretionary project approvals.

5. Co-permittees shall train their employees in targeted positions (whose jobs or activities are engaged in development planning) regarding the requirements of the SQUIMP no later than January 27, 2001, and annually thereafter.

6. The Permittee shall include watershed and storm water management considerations in the appropriate elements of the Permittee's General Plan whenever said elements are significantly rewritten. Appropriate elements include, but are not limited to, water quality protection, development goals and policies, open space goals and policies, preservation of and integration with natural features, and water conservation policies.

D. Programs for Construction Sites

1. Co-permittees shall require the preparation, submittal, and implementation of a Storm Water Pollution Control Plan (SWPCP) prior to issuance of a grading permit for construction projects that meet one of the following criteria:

   a. Will result in soil disturbance of one acre or more in size;
   b. Is within or discharging directly to or directly adjacent to an environmentally sensitive area or,
   c. Is located in a hillside area.

2. Co-permittees shall prepare and implement a SWPCP on Co-permittee construction projects, as required above.

3. The SWPCP shall include appropriate construction site BMPs selected from documents such as the California Storm Water BMP Handbook, the Caltrans Storm Water Quality Handbook, Ventura County Stormwater Quality Standard Sheet, EPA database and American Society of Civil Engineers (ASCE) database. In addition, Co-permittees shall ensure the following minimum requirements are met, to the maximum extent practicable, at construction sites regardless of size:

   a. Sediments generated on the project site shall be retained using structural drainage controls;

   b. No construction-related materials, wastes, spills, or residues shall be discharged from the project site to streets, drainage facilities or adjacent properties by wind or runoff;

   c. Non-storm water runoff from equipment and vehicle washing and any other activity shall be contained at the project site;

d. Erosion from slopes and channels will be eliminated, by implementing BMPs, including, but not limited to, limiting of grading scheduled during the wet season, inspecting graded areas during rain events, planting and maintenance of vegetation on slopes, and covering erosion susceptible slopes.

4. The SWPCP must include the rationale used for selecting or rejecting BMPs. The project architect, or engineer of record, or authorized qualified designee, must sign a statement on the SWPCP to the effect:

"As the architect/engineer of record, I have selected appropriate BMPs to effectively minimize the negative impacts of this project's construction activities on storm water quality. The project owner and contractor are aware that the selected BMPs must be installed, monitored, and maintained to ensure their effectiveness. The BMPs not selected for implementation are redundant or deemed not applicable to the proposed construction activity."

The landowner shall sign a statement to the effect:

"I certify that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system or those persons directly responsible for gathering the information, to the best of my knowledge and belief, the information submitted is true, accurate, and complete. I am aware that submitting false and/or inaccurate information, failing to update the SWPCP to reflect current conditions, or failing to properly and/or adequately implement the SWPCP may result in revocation of grading and/or other permits or other sanctions provided by law."

The SWPCP certification shall be signed by the landowner as follows:

(1) For a corporation: by a responsible corporate officer which means (a) a president, secretary, treasurer, or vice president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision-making functions for the corporation, or (b) the manager of the construction activity if authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures;

(2) For a partnership or sole proprietorship: by a general partner or the proprietor; or

(3) For a municipality or other public agency: by an elected official, a ranking management official (e.g., County Administrative Officer, City Manager, Director of Public Works, City Engineer, District Manager), or the manager of the

construction activity if authority to sign SWPCPs has been assigned or delegated to the manager in accordance with established agency policy.

5. Co-permittees shall require proof of filing a Notice of Intent for coverage under the State General Construction Activity Storm Water Permit prior to issuing a grading permit for all projects requiring coverage under the state general permit.

6. Co-permittees shall inspect sites with SWPCPs for storm water quality requirements during routine inspections a minimum of once during the wet season. For inspected sites that have not adequately implemented their SWPCP, a follow-up inspection to ensure compliance will take place within 2 weeks. If compliance has not been achieved, and the site is covered under the State General Construction Activity Storm Water Permit, the Regional Board shall be notified. Co-permittees shall develop and implement a checklist for inspecting storm water quality control measures at construction sites by January 27, 2001.

7. Co-permittees shall discuss storm water controls at construction sites and distribute educational materials targeted to the construction community during meetings, inspections, and as appropriate.

8. Co-permittees shall train employees in targeted positions (whose jobs or activities are engaged in construction activities including construction inspection staff) regarding the requirements of the storm water management program by January 27, 2001, and annually thereafter.

E. Public Agency Activities

Corporation Yards

1. The Principal Co-permittee shall develop a model SWPCP for corporation yards and the Co-permittees shall implement the minimum requirements of the SWPCP in all corporation yards by July 27, 2002. Thereafter, Co-permittees shall inspect corporation yards on an annual basis.

2. Co-permittees shall prohibit the discharge of untreated storm water runoff to the storm drain system from toxic or hazardous material storage areas no later than January 27, 2001.

3. Co-permittees shall prohibit the discharge of untreated storm water runoff to the storm drain system from fueling areas, and repair/maintenance areas for vehicle maintenance and repair facilities no later than July 27, 2001.

4. Co-permittees shall require that all vehicle/equipment wash areas must be self-contained, or covered, or equipped with a clarifier, or other

pretreatment facility, and properly connected to a sanitary sewer. This provision does not apply to fire fighting vehicles.

Other Facilities

5. Co-permittees shall inspect and clean the catch basins, open drainage facilities, and detention/retention basins at least one time each year prior to the wet season. At any time, any catch basin that is at least 40% full of trash and debris shall be cleaned out. All reinforced concrete open channels shall be cleaned at least once each year prior to the wet season.

6. Co-permittees shall conduct street sweeping on curbed public streets in their permitted area according to the following schedule:

   a. A monthly average not less than 4 times per month in high traffic downtown areas;
   b. A yearly average of not less than 6 times per year in moderate traffic collector streets, and residential areas;
   c. In addition, Co-permittees will sweep continuously bermed public streets once per year prior to the rainy season.

7. Co-permittees shall prohibit street saw cutting and paving during a storm event of 0.25 inches or greater (except during emergency conditions).

8. Co-permittees shall prohibit discharge of untreated runoff from temporary or permanent street maintenance material and waste storage areas.

9. The Discharger shall develop a standardized protocol for the routine and non-routine application of pesticides, herbicides (including preemergents), and fertilizers within one year after permit adoption.

   There shall be no application of pesticides or fertilizers during the following conditions:

   a. During rain events;
   b. Within one day of a rain event forecasted to be greater than 0.25 inches except for application of preemergent herbicides;
   c. After a rain event where water is leaching or running or,
   d. When water is running off-site.

   The Discharger shall ensure that staff applying pesticides are either certified by the California Department of Food and Agriculture, or are under the direct supervision on-site of a certified pesticide applicator.

10. Co-permittees shall train their employees in targeted positions (whose jobs and activities affect storm water quality) regarding the requirements of the storm water management program no later than January 27, 2001, and annually thereafter.

11. Co-permittees shall routinely conduct trash collection along, or in improved open channels within their jurisdiction.

12. The Discharger shall encourage the establishment of voluntary programs for the collection of trash in natural stream channels.

F. Programs for Illicit Discharges / Illegal Connections

1. Co-permittees shall investigate the cause, determine the nature and estimated amount of reported illicit discharge/dumping incidents, and refer documented non-storm water discharges/connections or dumping to an appropriate agency for investigation, containment and cleanup. Appropriate action including issuance of an enforcement order that will result in cessation of the illicit discharge, and/or elimination of the illicit connection, shall take place within six months after the Co-permittee gains knowledge of the discharge/connection.

2. Each Co-permittee shall train its employees in targeted positions, as defined by the Ventura County SMP, on how to identify and report illicit discharges by January 27, 2001, and annually thereafter.

3. Automotive, food facility, construction and Co-permittee facility site inspection visits shall include distribution of educational material that describes illicit discharges and provides a contact number for reporting illicit discharges.

4. New information developed for Phase I industrial facility educational material shall include information describing illicit discharges. The information shall include: types of discharges prohibited, how to prevent illicit discharges, what to do in the event of an illicit discharge, and the array of enforcement actions the facility may be subject to, including penalties that can be assessed.

G. Total Maximum Daily Loads [40 CFR 130.7]

1. The Permittee shall modify the Ventura County SMP to comply with waste load allocations developed and approved pursuant to the process for the designation and implementation of Total Daily Maximum Loads (TMDLs) for impaired water bodies.

H. Stormwater Quality Urban Impact Mitigation Plan

1. The terms and requirements in the Storm Water Quality Urban Impact Mitigation Plan (SQUIMP) may be amended by the Regional Board Executive Officer to conform with the State Board's decision in: In Re: *The Consolidated Petitions of Cities of Bellflower et al. (Review of January 26, 2000, Action of the Regional Board and its Executive Officer Pursuant to*

Board Order No. 96-054) or any subsequent ruling on the matter by a court of law.

2. Requirements for new development and significant redevelopment in environmentally sensitive areas shall be incorporated into enforceable documents such as land development guidelines and city ordinances no later than July 27, 2001.

a. Requirements of the SQUIMP as they relate to the supplemental list of "Environmentally Sensitive Areas" identified based on the Regional Board's Basin Plan and the CWA Section 303(d) Impaired Water-bodies List shall take effect no later than July 27, 2001.

b. Requirements of the Stormwater Quality Urban Impact Mitigation Plan for state designations of "Environmentally Sensitive Areas" shall take effect no later than January 27, 2001.

I. PART 5 - DEFINITIONS

A. The following are definitions for terms applicable to this Order:

1. **"Anti-degradation policies"** means the *Statement of Policy with Respect to Maintaining High Quality Water in California* (State Board Resolution No. 68-16) which protects surface and ground waters from degradation. In particular, this policy protects waterbodies where existing quality is higher than that necessary for the protection of beneficial uses including the protection of fish and wildlife propagation and recreation on and in the water.

2. **"Applicable Standards and Limitations"** means all State, interstate, and federal standards and limitations to which a "discharge" or a related activity is subject under the CWA, including "effluent limitations,"water quality standards, standards of performance, toxic effluent standards or prohibitions, "best management practices," and pretreatment standards under sections 301, 302, 303, 304, 306, 307, 308, 403 and 404 of CWA.

3. **"Automotive Repair Shop"** means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

4. **Best Management Practices (BMPs)** are methods, measures, or practices designed and selected to reduce or eliminate the discharge of pollutants to surface waters from point and nonpoint source discharges including storm water. BMPs include structural and nonstructural controls, and operation and maintenance procedures, which can be applied before, during, and/or after pollution producing activities.

5. **"CWA"** means the Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972) Public Law 92—500, as amended by Public Law 95—217, Public Law 95—576, Public Law 96—483 and Public Law 77—117, 33 U.S.C. 1251 et seq.

6. **"Construction"** means constructing, clearing, grading, or excavation that results in soil disturbance. Construction includes structure teardown. It does not include routine maintenance to maintain original line and grade, hydraulic capacity, or original purpose of facility, nor does it include emergency construction activities required to immediately protect public health and safety.

7. **"Co-permittee"** shall mean any of the following public entities; the Ventura County Flood Control District (VCFCD), the County, or the City of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, or Thousand Oaks. Each Co-permittee is responsible for compliance with the terms of the NPDES Permit.

8. **"Designated Public Access Points"** means any pedestrian, bicycle, equestrian, or public vehicular point of access to jurisdictional channels in the area of Ventura County subject to permit requirements.

9. **"Development"** shall mean any construction, rehabilitation, redevelopment or reconstruction of any public or private residential project (whether single-family, multi-unit or planned unit development); industrial, commercial, retail and other non-residential projects, including public agency projects; or mass grading for future construction.

10. **"Directly Adjacent"** means situated within 200 feet of the contiguous zone required for the continued maintenance, function, and structural stability of the environmentally sensitive area.

11. **"Director"** shall mean the Director of Public Works of the County and Person(s) designated by and under the Director's instruction and supervision.

12. **"Directly Discharging"** means outflow from a drainage conveyance system that is composed entirely or predominantly of flows from the subject, property, development, subdivision, or industrial facility, and not commingled with the flows from adjacent lands.

13. **"Discharge"** when used without qualification means the "discharge of a pollutant."

14. **"Discharge of a Pollutant"** means: Any addition of any "pollutant" or combination of pollutants to "waters of the United States" from any "point source" or, Any addition of any pollutant or combination of pollutants to the waters of the "contiguous zone" or the ocean from any point source other than a vessel or other floating craft which is being used as a means of transportation. The term discharge includes additions of pollutants into waters of the United States from: surface runoff which is collected or channeled by man; discharges through pipes,

sewers, or other conveyances owned by a State, municipality, or other person which do not lead to a treatment works; and discharges through pipes, sewers, or other conveyances, leading into privately owned treatment works. This term does not include an addition of pollutants by any "indirect Discharger."

15. **"Effluent limitation"** means any restriction imposed by the Regional Board on quantities, discharge rates, and concentrations of "pollutants" which are "discharged" from "point sources" into "waters of the United States," the waters of the "contiguous zone," or the ocean.

16. **"Environmental Protection Agency"** or **"EPA"** means the United States Environmental Protection Agency.

17. **"Environmentally Sensitive Areas"** means an area "in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which would be easily disturbed or degraded by human activities and developments" (California Public Resources Code § 30107.5). Areas subject to storm water mitigation requirements are : areas designated as an Area of Special Biological Significance (ASBS) by the State Water Resources Control Board, an area designated as a significant natural resource by the California Resources Agency, or an area identified by the Discharger as environmentally sensitive for water quality purposes, based on the Regional Board Basin Plan and Clean Water Act Section 303(d) Impaired Water-bodies List for the County of Ventura.

18. **"Facility or Activity"** means any NPDES "point source" or any other facility or activity (including land or appurtenances thereto) that is subject to regulation under the NPDES program.

19. **"Hillside"** means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is 25% or greater and where grading contemplates cut or fill slopes.

20. **"Illicit Connection"** shall mean any man-made conveyance that is connected to the storm drain system without a permit or through which prohibited non-storm water flows are discharged, excluding roof-drains and other similar type connections. Examples include channels, pipelines, conduits, inlets, or outlets that are connected directly to the storm drain system.

21. **"Illicit Discharge"** means any discharge to the storm drain system that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illicit discharge includes all non storm-water discharges except discharges pursuant to an NPDES permit, discharges that are identified in Part 1 of this order, and discharges authorized by the Regional Board Executive Officer.

22. **"Infiltration"** means the downward entry of water into the surface of the soil.

23. "**MS4**" see Municipal Separate Storm Sewer System.

24. **"Municipal Separate Storm Sewer System"** means a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels, or storm drains) owned by a State, city, town or other public body, that is designed or used for collecting or conveying storm water, which is not a combined sewer, and which is not part of a publicly owned treatment works. Commonly referred to as an "MS4".

25. **"National Pollutant Discharge Elimination System (NPDES)"** means the national program for issuing, modifying, revoking and reissuing, terminating, monitoring and enforcing permits, and imposing and enforcing pretreatment requirements, under sections 307, 402, 318, and 405 of CWA. The term includes an "approved program."

26. **"NPDES"** means National Pollutant Discharge Elimination System.

27. **"New Development"** means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.

28. **"Non-Storm Water Discharge"** means discharge other than storm water runoff or snowmelt.

29. **"Parking Lot"** means land area or facility for the parking of commercial or business or private motor vehicles.

30. **"Permit"** means an authorization, license, or equivalent control document issued by EPA or an "approve State" to implement the requirements of 40 CFR Parts 122, 123, and 124. "Permit" includes an NPDES "general permit" (§ 122.28). Permit does not include any permit which has not yet been the subject of final agency action, such as a "draft permit" or a "proposed permit."

31. **"Pollutants of Concern"** means a prioritized list of pollutants identified in the Ventura County SMP as requiring additional investigation.

32. **"Potable Water Sources"** means flows from drinking water storage, supply and distribution systems including flows from system failures, pressure releases, system maintenance, well development, pump testing fire hydrant flow testing; and flushing and dewatering of pipes, reservoirs, vaults, and wells.

33. **"Priority Pollutants"** are those constituents referred to in 40 CFR 401.15 and listed in the EPA NPDES Application Form 2C, pp. V-3 through V-9.

34. **"Rain Event"** means any rain event greater than 0.1 inch in 24 hours.

35. **"Redevelopment"** means, but is not limited to, the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; land disturbing activities related with structural or

impervious surfaces. Redevelopment that results in the creation or addition of 5,000 square feet or more of impervious surfaces is subject to the requirements for storm water mitigation. If the creation or addition of impervious surfaces is fifty percent or more of the existing impervious surface area, then storm water runoff from the entire area (existing and additions) must be considered for purposes of storm water mitigation. If the creation or additions is less than fifty percent of the existing impervious area, then storm water runoff from only the addition area needs mitigation.

36. **"Regional Administrator"** means the Regional Administrator of the Regional Office of the Environmental Protection Agency or the authorized representative of the Regional Administrator.

37. **"Restaurant"** means a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption (SIC Code 5812).

38. **"Side Walk Washing"** means pressure washing of paved pedestrian walkways with average water usage of 0.006 gallons per square foot, with no cleaning agents, and properly disposing of all debris collected, as authorized under Regional Board Resolution No. 98-08.

39. **"Site"** means the land or water area where any "facility or activity" is physically located or conducted, including adjacent land used in connection with the facility or activity.

40. **"Source Control BMP"** means any schedules of activities, prohibitions of practices, maintenance procedures, managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

41. **"SQUIMP"** shall mean the Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan. The SQUIMP shall address conditions and requirements of new development.

42. **"State General Permit"** shall mean a permit issued by the State Water Resources Control Board or the Regional Board pursuant to 40 CFR § 122 and 123 to regulate a category of point sources. The term State General Permit includes but is not limited to the General Permit for Stormwater Discharges Associated with Construction Activity and the General Industrial Activities Stormwater Permit and the terms and requirements of both. In the event the EPA revokes the in-lieu permitting authority of the State Water Resources Control Board, then the term State General Permit shall also refer to any EPA administered stormwater control program for industrial, construction, and any other category of activities.

43. **"Storm Water"** shall mean "Stormwater".

44. **"Storm Water Pollution Prevention Plan"** shall mean a plan, as required by a State General Permit, identifying potential pollutant sources and describing the design, placement and implementation of BMPs, to effectively prevent non-stormwater Discharges and reduce Pollutants in Stormwater Discharges during activities covered by the General Permit.

45. **"Stormwater"** shall mean any surface flow, runoff, and/or drainage associated with rainstorm events and/or snowmelt.

46. **"Stormwater Pollution Control Plan (SPCP)"** shall mean a plan identifying potential pollutant sources from a construction site and describing proposed design, placement and implementation of BMPs, to effectively prevent non-stormwater Discharges and reduce Pollutants in Stormwater Discharges to the Storm Drain System, to the maximum extent practicable, during construction activities.

47. **"Stormwater Quality Management Plan"** shall mean the Ventura Countywide Stormwater Quality Management Plan, which includes descriptions of programs, collectively developed by the Co-permittees in accordance with provisions of the NPDES Permit, to comply with applicable federal and state law, as the same is amended from time to time.

48. **"Structural BMP"** means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both treatment control BMPs and source control BMPs.

49. **"Total Maximum Daily Load (TMDL)"** means the amount of pollutant, or property of a pollutant, from point, nonpoint, and natural background sources, that may be discharged to a water quality-limited receiving water. Any pollutant loading above the TMDL results in a violation of applicable water quality standards.

50. **"Treatment"** means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media absorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

51. **"Treatment Control BMP"** means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media absorption or any other physical, biological, or chemical process.

52. **"Upset"** means an exceptional incident in which there is unintentional and temporary noncompliance with the permit limit because of factors beyond the reasonable control of the permittee. An upset does not include noncompliance to the extent caused by operational error, improperly designed treatment facilities, inadequate treatment facilities, lack of preventive maintenance, or careless or improper maintenance.

53. **"Water Quality Standards and Water Quality Objectives"** applicable to the Permittee include those contained in the Los Angeles Regional Water Quality Control Plan (Basin Plan), the California Ocean Plan, the National Toxics Rule, the California Toxics Rule, and other state or federally approved surface water quality plans. Such plans are used by the Regional Board to regulate all discharges, including storm water discharges.

54. **"Waters of the State"** means any surface water or groundwater, including saline waters, within boundaries of the state.

55. **"Waters of the United States or Waters of the U.S."** means:

a. All waters that are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide;
b. All interstate waters, including interstate "wetlands";
c. All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, "wetlands," sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation, or destruction of which would affect or could affect interstate or foreign commerce including any such waters:
1. Which are or could be used by interstate or foreign travelers for recreational or other purposes;
2. From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or
3. Which are used or could be used for industrial purposes by industries in interstate commerce;
d. All impoundments of waters otherwise defined as waters of the United States under this definition;
e. Tributaries of waters identified in paragraphs (a) through (d) of this definition;
f. The territorial sea; and
g. "Wetlands" adjacent to waters (other than waters that are themselves wetlands) identified in paragraph (a) through (f) of this definition.

Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA (other than cooling ponds as defined in 40 CFR 423.22(m), which also meet the criteria of this definition) are not waters of the United States. This exclusion applies only to man-made bodies of water, which neither were originally created in waters of the United States (such as disposal area in wetlands) nor resulted from the impoundment of waters of the United States. *[See Note 1 of this section.]* Waters of the United States do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for the purposes of the Clean Water Act, the final authority regarding Clean Water Act jurisdiction remains with US EPA.

56. **"Watercourse"** shall mean any natural or artificial channel for passage of water, including the VCFCD jurisdictional channels included in the List of Channels

within the Comprehensive Plan of the VCFCD, as approved by the Board of Supervisors of the VCFCD on October 4, 1993, and any amendments thereto.

57. **"Wet Season"** means the calendar period beginning October 1 through April 15.

58. **"Whole Effluent Toxicity"** means the aggregate toxic effect of an effluent measured directly by a toxicity test.

PART 6 – STANDARD PROVISIONS

A. The Discharger shall comply with all provisions and requirements of this permit.

B. Should the Discharger discover that it failed to submit any relevant facts or that it submitted incorrect information in a report, it shall promptly submit the missing or correct information.

C. The Discharger shall report all instances of non-compliance not otherwise reported at the time monitoring reports are submitted.

D. This Order includes the attached Monitoring and Reporting Program, and Storm Water Quality Urban Impact Mitigation Plan, which are a part of the permit and must be complied with in the same manner as with the rest of the requirements in the permit.

E. Public Review

1. All documents submitted to the Regional Board in compliance with the terms and conditions of this Permit shall be made available to members of the public pursuant to the Freedom of Information Act (5 U.S.C. Section 552 (as amended) and the Public Records Act (California Government Code Section 6250 *et seq.*).

2 All documents submitted to the Executive Officer for approval shall be made available to the public for a 30-day period to allow for public comment.

F. Duty to Comply [40 CFR 122.41(a)]

1. The Discharger must comply with all of the terms, requirements, and conditions of this Order. Any violation of this order constitutes a violation of the Clean Water Act, its regulations and the California Water Code, and is grounds for enforcement action, Order termination, Order revocation and reissuance, denial of an application for reissuance; or a combination thereof.

2. A copy of these waste discharge specifications shall be maintained by the Discharger so as to be available during normal business hours to Discharger employees and members of the public.

3. Any discharge of wastes at any point(s) other than specifically described in this Order is prohibited, and constitutes a violation of the Order.

G. Duty to Mitigate [40 CFR 122.41 (d)]

The Discharger shall take all reasonable steps to minimize or prevent any discharge that has a reasonable likelihood of adversely affecting human health or the environment.

H. Inspection and Entry [40 CFR 122.41(i)]

The Regional Board, USEPA, and other authorized representatives shall be allowed:

1. Entry upon premises where a regulated facility is located or conducted, or where records are kept under conditions of this Order;

2. Access to copy any records that are kept under the conditions of this Order;

3. To inspect any facility, equipment (including monitoring and control equipment), practices, or operations regulated or required under this Order; and,

4. To photograph, sample, and monitor for the purpose of assuring compliance with this Order, or as otherwise authorized by the Clean Water Act and the California Water Code.

I. Proper Operation and Maintenance [40 CFR 122.41 (e)]

The Discharger shall at all times properly operate and maintain all facilities and systems of treatment and (and related appurtenances) that are installed or used by the Discharger to achieve compliance with this Order. Proper operation and maintenance includes adequate laboratory controls and appropriate quality assurance procedures. This provision requires the operation of backup or auxiliary facilities or similar system that are installed by a Discharger only when necessary to achieve compliance with the conditions of this Order.

J. Signatory Requirements [40 CFR 122.41(k)]

Except as otherwise provided in this Order, all applications, reports, or information submitted to the Regional Board shall be signed by the Director of Public Works, City Engineer, or authorized designee under penalty of perjury.

K. Reopener and Modification [40 CFR 122.41(f)]

1. This Order may only be modified, revoked, or reissued, prior to the expiration date, by the Regional Board, in accordance with the procedural requirements of the Water Code and Title 23 of the California Code of Regulations for the issuance of waste discharge requirements, and upon prior notice and hearing, to:

   a. Address changed conditions identified in the required reports or other sources deemed significant by the Regional Board;

   b. Incorporate applicable requirements or statewide water quality control plans adopted by the State Board or amendments to the Basin Plan;

   c. Comply with any applicable requirements, guidelines, and/or regulations issued or approved pursuant to CWA Section 402(p); and/or,

   d. Consider any other federal, or state laws or regulations that became effective after adoption of this Order.

2. After notice and opportunity for a hearing, this Order may be terminated or modified for cause, including, but not limited to:

   a. Violation of any term or condition contained in this Order;

   b. Obtaining this Order by misrepresentation, or failure to disclose all relevant facts; or,

   c. A change in any condition that requires either a temporary or permanent reduction or elimination of the authorized discharge.

3. This Order may be modified, revoked and reissued, or terminated for cause.

4. The filing of a request by the Discharger for a modification, revocation and re-issuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any condition of this Order.

5. This Order may be modified to make corrections or allowances for changes in the permitted activity listed in this section, following the procedures at 40 CFR Part 122.63, if processed as a minor modification. Minor modifications may only:

   a. Correct typographical errors, or

   b. Require more frequent monitoring or reporting by the Permittee.

L. Severability

The provisions of this permit are severable; and if any provision of this permit or the application of any provision of this permit to any circumstance is held invalid, the application of such provision to other circumstances and the remainder of this permit shall not be affected.

M. Duty to Provide Information [40 CFR 122.41(h)]

The Discharger shall furnish, within a reasonable time, any information the Regional Board or USEPA may request to determine whether cause exists for modifying, revoking and reissuing, or terminating this Order. The Discharger shall also furnish to the Regional Board, upon request, copies of records required to be kept by this Order.

N. Twenty-four Hour Reporting[1]

1. The Discharger shall report any noncompliance that may endanger health or the environment. Any information shall be provided orally within 24 hours from the time the Discharger becomes aware of the circumstances. A written submission shall also be provided within five days of the time the Discharger becomes aware of the circumstances. The written submission shall contain a description of the noncompliance and its cause; the period of noncompliance, including exact dates and times and, if the noncompliance has not been corrected, the anticipated time it is expected to continue; and steps taken or planned to reduce, eliminate, and prevent reoccurrence of the noncompliance.

2. The Regional Board may waive the required written report on a case-by-case basis.

O. Bypass [40 CFR 122.41(m)][2]

Bypass (the intentional diversion of waste streams from any portion of a treatment facility) is prohibited. The Regional Board may take enforcement action against the Discharger for bypass unless:

1. Bypass was unavoidable to prevent loss of life, personal injury or severe property damage. (Severe property damage means substantial physical damage to property, damage to the treatment facilities that causes them to become inoperable, or substantial and permanent loss of natural resources that can reasonably be expected to occur in the absence of a

---

[1] This provision applies to incidents where effluent limitations (numerical or narrative) as provided in this Order or in the Ventura County SMP are exceeded, and which endanger public health or the environment.

[2] This provision applies to the operation and maintenance of storm water controls and BMPs as provided in this Order or in the Ventura County SMP.

bypass. Severe property damage does not mean economic loss caused by delays in production.);

2. There were no feasible alternatives to bypass, such as the use of auxiliary treatment facilities, retention of untreated waste, or maintenance during normal periods of equipment down time. This condition is not satisfied if adequate back-up equipment should have been installed in the exercise of reasonable engineering judgment to prevent a bypass that could occur during normal periods of equipment downtime or preventive maintenance;

3. The Discharger submitted a notice at least ten days in advance of the need for a bypass to the Regional Board; or,

4. The Discharger may allow a bypass to occur that does not cause effluent limitations to be exceeded, but only if it is for essential maintenance to assure efficient operation. In such a case, the above bypass conditions are not applicable. The Discharger shall submit notice of an unanticipated bypass as required.

P. Upset [40 CFR 122.41(n)][3]

1. A Discharger that wishes to establish the affirmative defense of an upset in an action brought for non compliance shall demonstrate, through properly signed, contemporaneous operating logs, or other relevant evidence that:

   a. An upset occurred and that the Discharger can identify the cause(s) of the upset;

   b. The permitted facility was being properly operated by the time of the upset;

   c. The Discharger submitted notice of the upset as required; and,

   d. The Discharger complied with any remedial measures required.

2. No determination made before an action for noncompliance, such as during administrative review of claims that non-compliance was caused by an upset, is final administrative action subject to judicial review.

3. In any enforcement proceeding, the Discharger seeking to establish the occurrence of an upset has the burden of proof.

Q. Property Rights [40 CFR 122.4(g)]

This Order does not convey any property rights of any sort, or any exclusive privilege.

---

[3] *Supra*. See footnote number 2.

R. Enforcement

1. Violation of any of the provisions of the NPDES permit or any of the provisions of this Order may subject the violator to any of the penalties described herein, or any combination thereof, at the discretion of the prosecuting authority; except that only one kind of penalties may be applied for each kind of violation. The Clean Water Act provides the following:

Criminal Penalties

a. *Negligent Violations*
The CWA provides that any person who negligently violates permit conditions implementing sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

b. *Knowing Violations*
The CWA provides that any person who knowingly violates permit conditions implementing sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

c. *Knowing Endangerment*
The CWA provides that any person who knowingly violates permit conditions implementing sections 301, 302, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than $250,000, or by imprisonment for not more than 15 years, or both.

d. *False Statement*
The CWA provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed of required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than two years, or by both. If a conviction is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment

of not more than four years, or by both. (See section 309(c)(4) of the Clean Water Act.)

Civil Penalties:

a. The CWA provides that any person who violates a permit condition implementing sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed $27,500 per day for each violation.

2. The California Water Code provides that any person who violates a waste discharge requirement provision of the California Water Code is subject to civil penalties of up to $5,000 per day, $10,000 per day, or $25,000 per day of violation; or when the violation involves the discharge of pollutants, is subject to civil penalties of up to $10 per gallon per day or $25 per gallon per day of violation; or some combination thereof, depending on the violation or combination violations.

S. Need to Halt or Reduce Activity not a Defense [40 CFR 122.41(c)]

It shall not be a defense for a Discharger in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this Order.

T. This Order may be modified, revoked, or reissued, prior to the expiration date as follows:

1. To address changed conditions identified in the required technical reports or other sources deemed significant by the Regional Board;

2. To incorporate applicable requirements or statewide water quality control plans adopted by the State Board, or amendments to the Basin Plan;

3. To comply with any applicable requirements, guidelines, or regulations issued or approved under Section 402(p) of the CWA, if the requirement, guideline, or regulation so issued or approved contains different conditions or additional requirements not provided for in this Order. The Order as modified or reissued under this paragraph shall also contain any other requirements of the CWA then applicable; or,

4. Any amendments under the Clean Water Act.

U. Regional Board Order No. 94-082 is hereby rescinded.

V. This Order expires on July 27, 2005]. The Discharger must submit a Storm Water Quality Management Plan in accordance with Title 23, California Code of Regulation, not later than 180 days in advance of such date as application for reissuance of waste discharge requirements.

State of California
CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
LOS ANGELES REGION

MONITORING AND REPORTING PROGRAM NO. CI 7388

FOR

STORM WATER MANAGEMENT/URBAN RUNOFF DISCHARGES
FOR
VENTURA COUNTY FLOOD CONTROL DISTRICT,
COUNTY OF VENTURA, AND THE CITIES OF VENTURA COUNTY

NPDES PERMIT NO. CAS004002

I. Program Reporting Requirements

A. The Discharger shall submit, by October 1, 2000, the Annual Storm Water Report and Assessment for the period July 1, 1999, through July 27, 2000 documenting the status of the general program up to permit reissuance and the results of analyses from the monitoring and reporting program.

B. The Discharger shall submit, by October 1 of each year beginning the year 2001, an Annual Storm Water Report and Assessment documenting the status of the general program and individual tasks contained in the Ventura County SMP, and an integrated summary of the results of analyses from the monitoring program described under *II. Monitoring Requirements*.

The Annual Storm Water Report and Assessment shall include any proposed changes to the Ventura County SMP as approved by the Management Committee. The Annual Storm Water Report and Assessment Report shall cover each fiscal year from July 1 through June 30. At a minimum, the annual report will include the following:

Program Management

1. A comparison of program implementation results to performance standards established in the Ventura County SMP;

2. Status of compliance with permit requirements including implementation dates for all time-specific deadlines. If permit deadlines are not met, the Discharger shall report the reasons why the requirement was not met, how the requirements will be met in the future, including projected implementation date;

3. An assessment of the effectiveness of Ventura County SMP requirements to reduce storm water pollution. This assessment will be based upon the specific

record-keeping information requirement in each major section of the permit, monitoring data, and any other data the Discharger has, or is aware of that provides information on program effectiveness. Beginning in the Year 2003, to the extent data collected in monitoring requirements included herein allows, the discharger shall include an analysis of trends, land use contributions, pollutant source identifications, BMP effectiveness, and impacts on beneficial uses.

4. An analysis of the data to identify areas of the Program coverage which cause or contribute to exceedances of water quality standards or objectives, predominate land uses in these areas, and potential sources of pollutants in those areas;

5. Discussion of the compliance record and the corrective actions taken or planned that may be needed to bring the discharge into full compliance with the waste discharge requirements.

Programs for Residents

6. Number of storm drain inlets and signs in the Co-permittees' systems that are marked or posted with a no dumping message. Percent of total system marked/signed;

7. Description of activities on distributing brochures, community outreach efforts, public communication efforts and educational programs in schools including an estimate of the number of impressions per year made on the general public about storm water quality via print, local TV access, local radio presentations, meetings or other appropriate media;

Programs for Industrial / Commercial Businesses

8. Number of automotive, food facility and industrial facilities targeted under the program. During the past year, the number of industrial and commercial site visits conducted and the number of outreach contacts made and the number of industrial facilities the Co-permittees have identified that have failed to file an NOI;

9. An annual update of a database of industrial/commercial facilities identified as subject to the State Board General Industrial Permit. The database shall include at a minimum: facility name, site address, SIC code, and NPDES storm water permit coverage status, if applicable;

10. The percentage of targeted staff trained annually;

Programs for Planning and Land Development

11. The percentage of total development projects reviewed for storm water and conditioned to meet SQUIMP requirements in the previous year;

12. The scheduled date of significant rewrite of the Co-permittees' General Plan;

13. Description of activities on distributing brochures, outreach efforts, communication efforts including an estimate of the number of contacts made to the land development community about storm water quality via print, meetings or other appropriate venues.

14. The percentage of targeted staff trained annually;

Programs for Construction Sites

15. Number of construction projects requiring SWPCPs in the past year and the percentage of projects in categories requiring submittal of a SWPCP for which SWPCPs were completed;

16. Number and type of enforcement actions, applicable to storm water enforcement, taken at construction sites during the past year;

17. Description of the outreach program to the construction community and assessment of its effectiveness; This assessment should include a discussion of the number of inspections, site visits, or other meetings conducted;

18. The percentage of targeted staff trained annually;

Programs for Illicit Discharge and Illegal Connection Control

19. Number of reports of illicit discharges that Co-permittees responded to, percentage that were identified as actual illicit discharges, and percentage of the actual illicit discharges where the incident was either cleaned up, referred to another responsible agency and/or follow up/education with the discharger was conducted;

20. For groups of identified illicit discharge types where the probable causes for the discharge can be identified, report probable causes and the actions taken to prevent similar discharges from occurring;

21. Number of illicit connections identified in the past year;

22. Number of illicit connections eliminated in the past year;

23. Number and type of enforcement actions for storm water illicit discharges and/or illicit connections taken in the past year;

24. A summary from records on illicit discharges and connections which includes

type of material, type of source, date of initial inspection, enforcement action taken, date of follow-up inspection, date of conclusion/clean up/removal/ follow up/education;

Programs for Facilities Maintenance

25. A summary which at a minimum includes the quantity, predominant types and likely sources of trash removed from catch basin inlets;

26. A summary of the total curb miles of streets swept annually and the percentage of total curb miles swept annually as a function of total curb miles;

27. The percentage of targeted staff trained annually; and,

Pollutants of Concern

28. A progress report on sources of Pollutants of Concern (POCs), BMPs for their control, and implemented BMP effectiveness.

B. The Discharger shall submit a Storm Water Monitoring Report on July 15, 2001, and annually on July 15, thereafter. The report shall include:

1. status of implementation of the monitoring program;
2. results of the monitoring program;
3. a general interpretation of the results;
4. both tabular and graphical summaries of the monitoring data obtained during the previous year; and

The Discharger shall submit, by October 1, 2000, the results of analyses from the monitoring and reporting program for the period July 1, 1999 through July 27, 2000 together with the Annual Report for the same period.

C. All applications, reports, or information submitted to the Regional Board shall be signed and certified pursuant to EPA regulations 40 CFR 122.41 (k). Each report shall contain the following completed declaration:

> "I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted.
>
> Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for

submitting false information, including the possibility, of a fine and imprisonment for knowing violations.

Executed on the __ day of ________, 19__,

at ________________________.

(Signature)________________(Title)__________________";

Co-permittee submittals to the Principal Co-permittee shall also be signed and certified pursuant to EPA regulations 40 CFR 122.41 (k).

D. The Discharger shall mail the original of each annual report to:

INFORMATION TECHNOLOGY
CALIFORNIA REGIONAL WATER QUALITY
CONTROL BOARD - LOS ANGELES REGION
320 W. 4TH STREET, SUITE 200
LOS ANGELES, CA 90013

A copy of the annual report shall also be mailed to:

REGIONAL ADMINISTRATOR
ENVIRONMENTAL PROTECTION AGENCY
REGION 9
75 Hawthorne Street
San Francisco, CA 94105

II. Monitoring Requirements

A. The Discharger shall implement the Countywide Monitoring Plan, as described in Chapter 6 of the Report of Waste Discharge (ROWD), which addresses discharge characterization (outfall monitoring), receiving water and watershed monitoring. To achieve this, the Discharger shall:

1. Conduct land use monitoring as shown in the summary table shown below:

Monitoring Station	Minimum Number Events (per year)	Sample Type	Constituents[1]
A-1, Wood Road	1[2]	Automated composite and grab samples	Metals Organics Conventional Inorganics Microbiological Toxicity and TIEs[3]
R-1, Swan St.[3]	3 Per Permit Term	Automated composite and grab samples	Metals Organics Conventional Inorganics Microbiological Toxicity and TIEs[3]
I-2, Ortega St. [3]	3 Per Permit Term	Automated composite and grab samples	Metals Organics Conventional Inorganics Microbiological Toxicity and TIEs[3]

1 The list of specific constituents, analytical methods, detection limits, and holding times is included in Attachment to the Monitoring and Reporting Program No. 7388.
2 A maximum of 5 events shall be monitored during the permit term.
3 Toxicity monitoring shall occur during at least one storm per year until baseline information has been collected, and then be discontinued. A Toxicity Identification Evaluation (TIE) shall be performed when acute toxicity results are greater than 1 TUa. Freshwater acute toxicity test shall be conducted on the most sensitive of the two species - Fathead minnow and Ceriodaphnia.

2. Conduct receiving water and watershed monitoring:

   a. For Revolon Slough the following monitoring program shall be implemented:

Monitoring Station	Minimum Number of Events (per year)	Type of Sample	Constituents[1]
W-3, La Vista Drain	1[2]	Automated composite and grab samples	Metals Organics Conventional Inorganics Microbiological Toxicity and TIEs[3]
W-4, Revolon Slough @ Wood Road	1[2]	Composite and grab samples	Metals Organics Conventional Inorganics Microbiological Toxicity and TIEs[3]

1 The list of specific constituents, analytical methods, detection limits, and holding times is included in Attachment to the Monitoring and Reporting Program No. 7388.
2. A maximum of 5 events shall be monitored during the permit term.
Toxicity monitoring shall occur during at least 1 storm event a year until baseline information has been collected, and then be discontinued. A Toxicity Identification Evaluation (TIE) shall be performed when acute toxicity results are greater than 1 TUa. Freshwater acute toxicity test shall be conducted on the most sensitive of the two species - Fathead minnow and Ceriodaphnia.

b. The Discharger shall participate as part of the Federal 205(j) grant non-point source grant study of the Calleguas Creek watershed;

c. The Principal Co-permittee shall participate in appropriate water quality meetings of watershed management planning, including the Santa Clara River Enhancement and Management Plan, the Calleguas Creek Watershed Management Plan, and the Steelhead Restoration and Recovery Plan;

d. The Discharger shall participate with the Southern California Coastal Water Research Project (SCCWRP) in storm water studies, as set forth in the signed Memorandum of Agreement.

e. The Discharger shall participate in the development and implementation of volunteer monitoring programs in the Ventura Coastal watersheds.

f. The Discharger shall develop a work plan for an instream bioassessment monitoring program and submit it to the Regional Board Executive Officer for approval no later than January 27, 2001. On approval by the Regional Board Executive Officer, the Discharger shall implement the instream bioassessment monitoring program, and submit the results with the Annual Monitoring Report. The bioassessment program shall include an analysis of the community structure of the instream macroinvertebrate assemblages in urban runoff-impacted stream segments at experimental sites. The Discharger shall make all efforts to locate such sites in the Ventura River, but if they are not available then the Discharger may consider other watersheds.

g. The Discharger shall monitor a total of three mass emission stations to establish baseline conditions and load estimates, for the Ventura River and Calleguas Creek, beginning with the 2000-2001 monitoring season, and for the Santa Clara River beginning with the 2001-2002 monitoring season. Up to six station events per year, including a minimum of two dry weather samples must be monitored. All samples for mass emissions may be taken with an automatic sampler except for the following constituents: (i) pathogen indicators; and (ii) oil and grease. The constituents to be analyzed and their detection limits are listed in Attachment 1. If a constituent is not detected at the method detection limit (MDL) for its respective test in more than 75 percent of the first 48 sampling events, it will not be further analyzed unless the observed occurrences show concentrations greater than state water quality standards. The Discharger will also conduct annual confirmation sampling for non-detected constituents at each station for as long as the station is monitored. Chronic toxicity tests shall be

conducted using the most sensitive marine species for two wet weather events (preferably the first significant storm and one other event) and one dry weather flow sample per monitoring season. Toxicity Identification Evaluations (TIEs) shall be conducted when toxicity manifests in:
(1) two consecutive wet weather samples , or;
(2) any dry weather flow sample.

h. An update of the Watershed Management Model (WMM) may be required by the Regional Board Executive Officer based on the needs of TMDL development. The Regional Board will assist the Discharger in identifying fund sources to assist in the implementation of this requirement, if invoked.

B. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

C. The Discharger shall retain records of all monitoring information, including all calibration and maintenance of monitoring instrumentation, copies of all reports required by this Order, and records of all data used to complete the Report of Waste Discharge and application for this Order, for a period of at least five(5) years from the date of the sample, measurement, report, or application. This period may be extended by request of the Regional Board or EPA at any time and shall be extended during the course of any unresolved litigation regarding this discharge.

D. Records of monitoring information shall include:

1. The date, exact place, and time of sampling or measurements;

2. The individual(s) who performed the sampling or measurements;

3. The date(s) analyses were performed;

4. The individual(s) who performed the analyses;

5. The analytical techniques or methods used; and,

6. The results of such analyses.

E. All sampling, sample preservation, and analyses must be conducted according to test procedures under 40 CFR Part 136, unless other test procedures have been specified in this Order.

F. All chemical, bacteriological, and bioassay analyses shall be conducted at a laboratory certified for such analyses by an appropriate governmental regulatory agency.

G. If no flow occurred during the reporting period, the monitoring report shall so state.

H. For any analyses performed for which no procedure is specified in the EPA guidelines or in this Monitoring and Reporting Program, the constituent or parameter analyzed and the method or procedure used must be specified in the monitoring report.

I. Whenever feasible, all MDLs shall be less than California Toxic Rule and Ocean Plan standards. If this is not feasible, the Discharger shall use analytical methods with the lowest MDL.

J. The Regional Board Executive Officer or the Regional Board, consistent with 40 CFR 122.41, may approve changes to the Monitoring and Reporting Program, after providing the opportunity for public comment, either:

a. By petition of the Discharger or by petition of interested parties after the submittal of the Annual Monitoring Program Report. Such petition shall be filed not later than 60 days after the Annual Monitoring Program Report submittal date, or
b. As deemed necessary by the Regional Board Executive Officer following notice to the Discharger.

III. Program Evaluation

A. All Co-permittees shall perform a self-audit to verify implementation of the Ventura County SMP through January 1 of each year and report the results of the self-audit to the principal Co-permittee by February 1, 2001, and annually thereafter.

B. All Co-permittees shall submit program evaluation results, in a standardized format, to the principal Co-permittee by August 1, 2001, and annually thereafter.

The above monitoring and reporting program, or subsequent modification thereto, shall become effective when Order No. 00-108 is adopted. All reports shall be signed by a responsible officer or duly authorized representative (as specified in 40 CFR Section 122.22) of the Discharger and submitted under penalty of perjury.

Ordered by:

Dennis A. Dickerson
Executive Officer

Date: July 27, 2000

R0008791

VENTURA COUNTYWIDE URBAN RUNOFF AND STORM WATER NPDES PERMIT

STORM WATER QUALITY URBAN IMPACT MITIGATION PLAN

BACKGROUND

The Ventura Countywide Stormwater Quality Management Program (Ventura Program) was established pursuant to Section 402(p) of the Federal Clean Water Act, which requires that all point source discharges of pollutants into waters of the United States, including discharges from municipal storm drain systems, be regulated by a National Pollutant Discharge Elimination System (NPDES) permit. On August 22, 1994 the California Regional Water Quality Control Board, Los Angeles Region (Regional Board), issued NPDES permit CAS063339 (Permit) to the Ventura County Flood Control District (VCFCD), the County of Ventura, and the cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks for discharges from municipal storm drain systems in Ventura County. On February 11, 1999 these twelve agencies, the Co-permittees, submitted a Stormwater Quality Management Plan (1999 Plan) in accordance with Title 23, California Code of Regulation and as required by Permit. The 1999 Plan served as application for reissuance of waste discharge requirements and presented activities designed to advance the municipal storm water program that the Co-permittees implemented during the first five-year permit term. The 1999 Plan included a program for development planning. The Regional Board accepted the 1999 Plan, however, delayed reissuance of the Permit. On March 8, 2000, the Regional Board approved a final Standard Urban Storm Water Mitigation Plan (SUSMP) for Los Angles County and the Cities in Los Angeles County. Subsequently, at the request of the Regional Board, the Co-permittees prepared the Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) to be consistent with SUSMP requirements and will be modifying the 1999 Plan to include the modified requirements.

The requirement to implement a program for development planning is based on, federal and state statutes including: Section 402 (p) of the Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 ("CZARA"), and the California Water Code. The Clean Water Act amendments of 1987 established a framework for regulating storm water discharges from municipal, industrial, and construction activities under the NPDES program. The primary objectives of the municipal storm water program requirements are to:

1. Effectively prohibit non-storm water discharges, and

2. Reduce the discharge of pollutants from storm water conveyance systems to the Maximum Extent Practicable (MEP statutory standard).

The SQUIMP was developed as part of the municipal storm water program to address storm water pollution from new development and redevelopment by the private sector. This SQUIMP contains a list of the minimum required Best Management Practices (BMPs) that shall be used for a designated project. Additional BMPs may be required by ordinance or code adopted by the Co-permittees and applied generally or on a case by case basis. The Co-permittees are required to implement the requirements set herein in their own jurisdictions. Developers shall incorporate appropriate SQUIMP requirements into the project plans for the projects covered by the SQUIMP requirements. Each Co-permittee will approve the project plan as part of the development plan approval process.

All projects that fall into one of eight categories are identified in the Ventura Countywide Municipal Permit as requiring SQUIMPs. These categories are:

- Single-Family Hillside Residences
- 100,000 Square Foot Commercial Developments
- Automotive Repair Shops
- Retail Gasoline Outlets
- Restaurants
- Home Subdivisions with 10 or more housing units
- Location within or directly adjacent to or discharging directly to an environmentally sensitive area
- Parking lots with 5,000 square feet or more impervious parking or access surfaces or with 25 or more parking spaces and potentially exposed to storm water runoff

The SQUIMP requirements shall take effect not later than January 27, 2001 for projects identified herein that have not received development/planning permit approval or been deemed complete for processing prior to July 27, 2000..

DEFINITIONS

"100,000 Square Foot Commercial Development" means any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas.

"Automotive Repair Shop" means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

"Best Management Practice (BMP)" means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

"Commercial Development" means any development on private land that is not heavy industrial or residential. The category includes, but is not limited to: hospitals, laboratories and other medical facilities, educational institutions, recreational facilities, plant nurseries, multi-apartment buildings, car wash facilities, mini-malls and other business complexes, shopping malls, hotels, office buildings, public warehouses and other light industrial complexes.

"Designated Public Access Points" means any pedestrian, bicycle, equestrian, or vehicular point of access to jurisdictional channels in the area of Ventura County subject to permit requirements.

"Directly Adjacent" means situated within 200 feet of the contiguous zone required for the continued maintenance, function, and structural stability of the environmentally sensitive area.

"Directly Connected Impervious Area (DCIA)" means the area covered by a building, impermeable pavement, and/ or other impervious surfaces, which drains directly into the storm drain without first flowing across permeable land area (e.g. lawns).

."Directly Discharging" means outflow from a drainage conveyance system that is composed entirely or predominantly of flows from the subject, property, development, subdivision, or industrial facility, and not commingled with the flows from adjacent lands.

"Environmentally Sensitive Area" means an area "in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which would be easily disturbed or degraded by human activities and developments" (California Public Resources Code § 30107.5)

Areas subject to storm water mitigation requirements are: areas designated as an Area of Special Biological Significance (ASBS) by the State Water Resources Control Board, an area designated as a significant natural resource by the California Resources Agency, or an area identified by the Discharger as environmentally sensitive for water quality purposes, based on the Regional Board Basin Plan and Clean Water Act Section 303(d) Impaired Water-bodies List for the County of Ventura.

"Hillside" means property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is twenty-five percent or greater.

"Infiltration" means the downward entry of water into the surface of the soil.

"New Development" means land disturbing activities; structural development, including construction or installation of a building or structure, creation of impervious surfaces; and land subdivision.

"Parking Lot" means land area or facility for the temporary parking or storage of motor vehicles used personally, for business or for commerce with an impervious surface area of 5,000 square feet or more, or with 25 or more parking spaces.

"Redevelopment" means, but is not limited to, the expansion of a building footprint or addition or replacement of a structure; structural development including an increase in gross floor area and/or exterior construction or remodeling; replacement of impervious surface that is not part of a routine maintenance activity; land disturbing activities related with structural or impervious surfaces. Redevelopment that results in the creation or addition of 5,000 square feet or more of impervious surfaces is subject to the requirements for storm water mitigation. If the creation or addition of impervious surfaces is fifty percent or more of the existing impervious surface area, then storm water runoff from the entire area (existing and additions) must be considered for purposes of storm water mitigation. If the creation or additions is less than fifty percent of the existing impervious area, then storm water runoff from only the addition area needs mitigation.

"Restaurant" means a stand-alone facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812).

"Retail Gasoline Outlet" means any facility engaged in selling gasoline and lubricating oils.

"Source Control BMP" means any schedules of activities, structural devices, prohibitions of practices, maintenance procedures, managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

"Storm Event" means a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather.

"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both Treatment Control BMPs and Source Control BMPs.

"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

"Treatment Control BMP" means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

CONFLICTS WITH LOCAL PRACTICES
Where provisions of the SQUIMP requirements conflict with established local codes, (e.g., specific language of signage used on storm drain stenciling), the Co-permittees may continue the local practice and modify the SQUIMP to be consistent with the code, except that to the extent that the standards in the SQUIMP are more stringent than those under local codes, such more stringent standards shall apply.

SQUIMP PROVISIONS APPLICABLE TO ALL CATEGORIES

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

The Discharger shall control the post-development peak storm water runoff discharge rates to maintain or reduce pre-development downstream erosion, and to protect stream habitat.

2. CONSERVE NATURAL AREAS

If applicable, the following items are required and shall be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- Concentrate or cluster Development on portions of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants.
- Promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

3. MINIMIZE STORM WATER POLLUTANTS OF CONCERN

Storm water runoff from a site has the potential to contribute oil and grease, suspended solids, metals, gasoline, pesticides, and pathogens to the storm water conveyance system. The development shall be designed so as to minimize, to the maximum extent practicable, the introduction of pollutants of concern that may result in significant impacts, generated from site runoff of directly connected impervious areas (DCIA), to the storm water conveyance system. Pollutants of concern consist of any pollutants that exhibit one or more of the following characteristics: current loadings or historic deposits of the pollutant are impacting the beneficial uses of a receiving water, elevated levels of the pollutant are found in sediments of a receiving water and/or have the potential to bioaccumulate in organisms therein, or the detectable inputs of the pollutant are at concentrations or loads considered potentially toxic to humans and/or flora and fauna. The storm water pollutants of concern currently identified by the Program are total and fecal coliform, mercury, PAHs, DDT and byproducts, diazinon, sediment/TSS, chlorpyrifos, copper, lead, thallium, bis(2-ethylhexyl)phthalate, and phosphorous. The program may amend the list of pollutants of concern as additional information becomes available.

In meeting this specific requirement, "minimization of the pollutants of concern" will require the incorporation of a BMP or combination of BMPs best suited to maximize the reduction of pollutant loadings in that runoff to the Maximum Extent Practicable. Those BMPs best suited for that purpose are those listed in the *Ventura Countywide Stormwater Quality Management Program's Land Development Guidelines*; *California Storm Water Best Management Practices Handbooks*; *Caltrans Storm Water Quality Handbook: Planning and Design Staff Guide*; *Start at the Source (1999) by Bay Area Stormwater Management Agencies Association*, *Manual for Storm Water Management in Washington State*; *The Maryland Storm Water Design Manual*; *Florida Development Manual: A Guide to Sound Land and Water Management*; Denver *Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices* and *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, USEPA Report No. EPA-840-B-92-002, as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question. However, it is possible that a combination of BMPs not so designated may, in a particular circumstance, be better suited to maximize the reduction of the pollutants.

Examples of BMPs that can be used for minimizing the introduction of pollutants of concern generated from site runoff are identified in Table 2. All BMPs for development planning recommended in one of the above references may be used, subject to the criteria set in this SQUIMP.

4. PROTECT SLOPES AND CHANNELS

Project plans shall include BMPs consistent with local codes and ordinances and the SQUIMP to decrease the potential of slopes and/or channels from eroding and impacting storm water runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes
- Utilize natural drainage systems to the Maximum Extent Practicable
- Control or reduce or eliminate flow to natural drainage systems to the Maximum Extent Practicable

- Stabilize permanent channel crossings
- Vegetate slopes with first consideration given to native or drought tolerant species
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion, with the approval of all agencies with jurisdiction, e.g., the U.S. Army Corps of Engineers and the California Department of Fish and Game

5. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the storm water conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins within the project area shall be stenciled with prohibitive language (such as: "DON'T DUMP! DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.
- Signs and prohibitive language and/or graphical icons, which prohibit illegal dumping, shall be posted at designated public access points along channels and creeks within the project area.
- Legibility of stencils and signs shall be maintained.

6. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Outdoor material storage areas refer to storage areas or storage facilities solely for the storage of materials. Improper storage of materials outdoors may provide an opportunity for toxic compounds, oil and grease, heavy metals, nutrients, suspended solids, and other pollutants to enter the storm water conveyance system. Where proposed project plans include outdoor areas for permanent storage of materials that may contribute pollutants to the storm water conveyance system, the following Structural or Treatment BMPs are required:

- Materials with the potential to contaminate storm water shall be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.
- The storage area shall be paved and sufficiently impervious to contain leaks and spills.

- The storage area shall have a roof or awning to minimize collection of storm water within the secondary containment area.

7. PROPERLY DESIGN TRASH STORAGE AREAS

A trash storage area refers to an area where a trash receptacle or receptacles are located for use as a repository for solid wastes. Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas shall meet the following Structural or Treatment Control BMP requirements (individual single family residences are exempt from these requirements):

- Trash container areas shall have drainage from adjoining roofs and pavement diverted around the area(s).
- Trash container areas shall be screened or walled to prevent off-site transport of trash.

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons why water quality controls will not function as designed or systems to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included or is required to include, Structural or Treatment Control BMPs in project plans, the Co-permittee shall require that the applicant provide verification of maintenance provisions through such means as may be appropriate, including, but not limited to legal agreements, covenants, CEQA mitigation requirements and/or Conditional Use Permits.

For all properties, the verification will include the developer's signed statement, as part of the project application, accepting responsibility for all structural and treatment control BMP maintenance until the time the property is transferred and, where applicable, a signed agreement from the public or private entity assuming responsibility for Structural or Treatment Control BMP maintenance. The transfer of property to a private or public owner shall have conditions requiring the recipient to assume responsibility for maintenance of any Structural or Treatment Control BMP included in the sales or lease agreement for that property. The condition of transfer shall include a provision that the property owners conduct maintenance inspection of all Structural or Treatment Control BMPs at least once a year and retain proof of inspection. For residential properties where the Structural or Treatment Control BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance shall be included in the projects conditions, covenants and restrictions (CC&Rs). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what storm water management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Co-permittee can provide. The transfer of this information shall also be required with any subsequent sale of the property.

If Structural or Treatment Control BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the appropriate public agency. Structural or Treatment Control BMPs proposed for transfer shall meet design standards adopted by the public entity for the BMP installed and should be approved by the appropriate public agency prior to installation.

9. DESIGN STANDARDS FOR STRUCTURAL OR TREATMENT CONTROL BMPs

Structural or Treatment Control BMPs selected for use at any project covered by this SQUIMP shall meet the design standards of this Section unless specifically exempted.

Volume-based and flow-based design standards may be used separately or in combination to equivalent treatment of storm water discharges. Volume-based criteria should be used in the sizing of detention/retention or infiltration structures; flow-based criteria should be used on swales, catch basin devices, or wetlands. Other, BMP-specific criteria may be applicable. Project applicants should refer to the *Ventura Countywide Storm Water Quality Management Program Land Development Guidelines* for further information.

Volume-based Post-construction Structural or Treatment Control BMPs shall be designed to mitigate (infiltrate or treat) storm water runoff from either:

1. the volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in *California Stormwater Best Management Practices Handbook – Industrial/ Commercial,* (1993), the *Ventura Countywide Stormwater Quality Management Program Land Development Guidelines*, or

2. the 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998)*, or

3. the volume of runoff produced from a 0.75 inch storm event, prior to its discharge to a storm water conveyance system, or

4. the volume of runoff produced from a historical-record based reference 24-hour rainfall criterion for "treatment" that achieves approximately the same reduction in pollutant loads achieved by the 85th percentile 24-hour runoff event,

OR

Flow Based Post-Construction Structural or Treatment Control BMPs shall be sized to handle the flow generated from either:

1. 10% of the 50-year design flow rate, or
2. a flow that will result in treatment of the same portion of runoff as treated using volumetric standards above, or
3. a rain event equal to at least 0.2 inches per hour intensity, or
4. a rain event equal to at least two times the 85th percentile hourly rainfall intensity for Ventura County

Limited Exclusion

Where the land area for development or redevelopment is less than 5,000 square feet, restaurants are excluded from the numerical Structural or Treatment Control BMP design standard requirement only.

10. PROVISIONS APPLICABLE TO INDIVIDUAL PRIORITY PROJECT CATEGORIES

REQUIREMENTS

A. 100,000 SQUARE FOOT COMMERCIAL DEVELOPMENTS

1. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays shall include the following:

- Repair/maintenance bays shall be indoors or designed in such a way that does not allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

The activity of vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include, in the project plans, an area for washing/steam cleaning of vehicles and equipment. The area in the site design shall be:

- Self-contained and/or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

B. RESTAURANTS

1. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

The activity of outdoor equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include in the project plans an area for the washing/steam cleaning of equipment and accessories. This area shall be:

- Self-contained, connected to a grease interceptor, and properly connected to a sanitary sewer.
- If the wash area is to be located outdoors, it shall be covered, paved, have secondary containment, be connected to a grease interceptor and be connected to the sanitary sewer.

C. RETAIL GASOLINE OUTLETS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. The project plans shall include the following BMPs:

- The fuel dispensing area shall be covered with an overhanging roof structure or canopy. The canopy's minimum dimensions shall be equal to or greater than the area within the grade break. The canopy shall not drain onto the fuel dispensing area, and the canopy downspouts shall be routed to prevent drainage across the fueling area.
- The fuel dispensing area shall be paved with Portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area shall have a 2% to 4% slope to prevent ponding, and shall be separated from the rest of the site by a grade break that prevents run-on of storm water to the extent practicable.
- At a minimum, the concrete fuel dispensing area shall extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

D. AUTOMOTIVE REPAIR SHOPS

1. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the storm water conveyance system. Therefore, design plans, which include fueling areas, shall contain the following:

- The fuel dispensing area shall be covered with an overhanging roof structure or canopy. The cover's minimum dimensions shall be equal to or greater than the area within the grade break. The cover shall not drain onto the fuel dispensing area and the downspouts shall be routed to prevent drainage across the fueling area.
- The fuel dispensing areas shall be paved with Portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.
- The fuel dispensing area shall have a 2% to 4% slope to prevent ponding, and shall be separated from the rest of the site by a grade break that prevents run-on of storm water.
- At a minimum, the concrete fuel dispensing area shall extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays shall include the following:

- Repair/maintenance bays shall be indoors or designed in such a way that does not allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all wash-water, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, an Industrial Waste Discharge Permit should be obtained.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

The activity of vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include, in the project plans, an area for washing/steam cleaning of vehicles and equipment. This area shall be:

- Self-contained and/or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer or to a permitted disposal facility.

4. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water

- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited

E. PARKING LOTS

1. PROPERLY DESIGN PARKING AREA

Parking lots contain pollutants such as heavy metals, oil and grease, and polycyclic aromatic hydrocarbons that are deposited on parking lot surfaces by motor vehicles. These pollutants are directly transported to surface waters. To minimize the offsite transport of pollutants, the following design criteria are required:

- Reduce impervious land coverage of parking areas
- Infiltrate runoff before it reaches the storm drain system
- Treat runoff before it reaches the storm drain system

2. PROPERLY DESIGN TO LIMIT OIL CONTAMINATION AND PERFORM MAINTENANCE

Parking lots may accumulate oil, grease, and water insoluble hydrocarbons from vehicle drippings and engine system leaks.

- Treat to remove oil and petroleum hydrocarbons at parking lots that are heavily used (e.g. fast food outlets, lots with 25 or more parking spaces, sports event parking lots, shopping malls, grocery stores, discount warehouse stores)
- Ensure adequate operation and maintenance of treatment systems, particularly sludge and oil removal, and system fouling/plugging prevention control

11. WAIVER

A Co-permittee may, through adoption of an ordinance or code incorporating the treatment requirements of the SQUIMP, provide for a waiver from the requirement if impracticability for a specific property can be established. A waiver for impracticability shall be granted only when all other Structural or Treatment Control BMPs have been considered and rejected as infeasible. Recognized situations of impracticability include, (i) extreme limitations of space for treatment on a redevelopment project, (ii) unfavorable or unstable soil conditions at a site to attempt infiltration, and (iii) risk of ground water contamination because a known unconfined aquifer lies beneath the land surface or an existing or potential underground source of drinking water is less than 10 feet from the soil surface. Any other justification for impracticability shall be separately petitioned by the Co-permittee and submitted to the Regional Board for consideration. The Regional Board may consider approval of the waiver justification or may delegate the authority to approve a class of waiver justifications to the Regional Board Executive Officer. The supplementary waiver justification becomes recognized and effective only after approval by the Regional Board or the Regional Board Executive Officer. A waiver granted by a Co-permittee to any development or redevelopment project may be revoked by the Regional Board Executive Officer for cause and with proper notice upon petition.

If a waiver is granted for impracticability, the Co-permittee shall require the project proponent to transfer the savings in cost, as determined by the Co-permittee, to a storm water mitigation fund operated by a public agency or a non-profit entity to be used to promote regional or alternative solutions for storm water pollution in the watershed.

12. LIMITATION ON USE OF INFILTRATION BMPs

Three factors significantly influence the potential for storm water to contaminate ground water. They are (i) pollutant mobility, (ii) pollutant abundance in storm water, (iii) and soluble fraction of pollutant. The risk of contamination of groundwater may be reduced by pretreatment of storm water. A discussion of limitations and guidance for infiltration practices is contained in, *Potential Groundwater Contamination from Intentional and Non-Intentional Storm water Infiltration, Report No. EPA/600/R-94/051, USEPA (1994).*

The distance of the groundwater table from the infiltration BMP may also be a factor determining the risk of contamination. A historic high water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic except in cases where groundwater basins are unconfined. Unconfined groundwater basins and vulnerable unconfined aquifers are areas that have been identified by the County of Ventura Public Works Agency, Water Resources Division and the Regional Board as areas where the application of infiltration BMPs should be limited to those that provide pre-treatment to ensure groundwater is protected from pollutants of concern.

Infiltration BMPs are not recommended for areas of industrial activity or areas subject to high vehicular traffic (25,000 or greater average daily traffic (ADT) on main roadway or 15,000 or more ADT on any intersecting roadway) unless appropriate pretreatment is provided to ensure groundwater is protected and the infiltration BMP is not rendered ineffective by overload.

13. ALTERNATIVE CERTIFICATION FOR STORM WATER TREATMENT MITIGATION

In lieu of conducting detailed BMP review to verify Structural or Treatment Control BMPs adequacy, a Co-permittee may elect to accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria established herein. The Co-permittee is encouraged to verify that certifying person(s) have been trained on BMP design for water quality, not more than two years prior to the signature date. Training conducted by an organization with storm water BMP design expertise (e.g., a University, American Society of Civil Engineers, American Society of Landscape Architects, American Public Works Association, or the California Water Environment Association) may be considered qualifying.

TABLE 2

EXAMPLE BEST MANAGEMENT PRACTICES (BMPs)

The following are examples of BMPs that can be used for minimizing the introduction of pollutants of concern that may result in significant impacts, generated from site runoff to the storm water conveyance system. (See Table 1: Suggested Resources for additional sources of information):

- Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths shall still comply with regulations for the Americans with Disabilities Act and other life safety requirements.
- Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.
- Comply with all zoning and applicable ordinances to minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.
- Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).
- Use open space development that incorporates smaller lot sizes.
- Reduce building density.
- Comply with all zoning and applicable ordinances to reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.
- Comply with all zoning and applicable ordinances to reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.
- Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas, and avoid routing rooftop runoff to the roadway or the storm water conveyance system.
- Biofilters including vegetated swales and strips
- Extended/dry detention basins
- Infiltration basin
- Infiltration trenches or vaults
- Wet detention basins/wet ponds
- Constructed wetlands

TABLE 2 (Continued)

- Catch basin inserts
- Continuous flow deflection/separation systems
- Storm drain inserts
- Media filtration
- Bioretention facility
- Foundation planting
- Catch basin screens
- Normal flow storage/separation systems
- Clarifiers
- Filtration systems
- Primary waste water treatment systems
- Dry Wells[1]
- Cistern

1 The proponent must ensure that this BMP complies with all applicable federal, state, and local requirements for siting, construction, operation and maintenance.

SUSMP REQUIREMENTS AS PART OF CEQA MITIGATION MEASURES

Dear Ms. Phillips:

The City Planning Department has incorporated the Standard Urban Stormwater Mitigation Plan (SUSMP) requirements into their existing CEQA Mitigation Measures. As a result, SUSMP requirements are now imposed not only on the nine (9) Planning Priority Projects but also as appropriate on all other discretionary projects.

Under the CEQA process, all discretionary projects undergo a review to determine if they may have any significant adverse impact on the environment, including impacts from stormwater discharges. If a potentially significant impact is determined, appropriate BMP(s) must be incorporated into the design plans prior to the project applicant obtaining a building or grading permit. Currently, the Stormwater Management Division staff review the design plans of all projects having stormwater mitigation measures to ensure that the proposed BMPs are properly sized.

Should you have any questions, please call me at 213-847-6346 or Wing Tam at 213-847-5225.

Sincerely,

Gary Lee Moore

COMMENTS: Please review the attached letters. The first is from Dr. Fannin, I believe that there is not much more to be said. This letter is great. The second is from Los Angeles County Fire Department Management. We may find that this is may be the most expedient way to answer this question. We will maintain an active Ad Hoc committee status until we have an answer from the Public Works or there is a need to take this question to the State level. Thanks for your participation. As a "responder" I feel better that agency reps like you are dedicated to address issues such as this one.

COUNTY OF LOS ANGELES - DEPARTMENT OF HEALTH SERVICES
PUBLIC HEALTH

DISEASE CONTROL PROGRAMS

August 1, 2000

Dennis Dickerson
California Regional Water Quality
Control Board
Los Angeles Region
320 W. 4th Street, Suite 200
Los Angeles, CA 90013

Dear Sir:

I am Shirley L. Fannin, M.D.; Director of Disease Control Programs for Public Health in Los Angeles County. My job includes describing and tracking the communicable diseases which affect the citizens of Los Angeles and preventing outbreaks of those diseases to the greatest extent possible.

I recently attended an ad hoc committee meeting convened by the Los Angeles County Hazardous Materiels Coordinating Committee to address the issue of cleanup of blood and other human tissue at accident sites or accidental spills. Your employee, Dr. Xavier Swammikannu asked that I put my recommendations for an exception to the storm drain discharge requirements in the washdown of accidental blood/tissue spills in writing for the consideration of your Board.

The subject we discussed at the meeting was washdown of an accident site where blood had been spilled. This generally occurs on the streets or in other public places following a vehicle or pedestrian accident, or when a container holding blood spills onto the pavement or ground.

In Los Angeles County, we have encountered these situations regularly and proceed with clean-up by washing down the contaminated surface with a lot of water. Some agencies have used chemicals such as chlorine prior to washdown to inactivate potential viruses which might be present in the blood. I have not recommended this. The runoff would either soak onto the soil or be carried to a storm drain.

My recommendations to the fire department or others responsible for clean up have been based on the following considerations:

1. The greatest safety for cleanup personnel and the safety of the public. The amount of blood at the scene of one of these accidental spills is usually small, less than a unit of blood, or 750 cc. It generally spreads thinly over the surface it covers, and like any liquid quickly flows into

cracks and crevices of the surface it is on. If the blood is cleaned up directly by a person, there is a risk of spatter exposure to the mouth or eyes or direct exposure through cuts on the hands or exposed surfaces of the body. The likelihood of complete cleanup is small since any liquid could spread widely throughout the accident scene. The action of water on blood is to immediately destroy the blood cells and to dilute the material contained inside them rapidly. The likelihood of survival of biologic agents associated with the blood is minuscule. The actions of road chemicals on such agents would also be to destroy them or render them harmless. Allowing the runoff to drain into a storm sewer would not be a health hazard either at the accident scene or further down the drain. It certainly would not be a problem at the ocean drain site.

The biologic agents which concern most people on a theoretic basis are HIV virus, Hepatitis B virus, and Hepatitis C virus. These are the most likely viruses to be present in blood in California citizens. None of these viruses reproduce outside a living human cell. The HIV virus is a fragile virus and is inactivated by numerous chemicals, heat , and light. In fact, a 1:10 dilution of household bleach is adequate to inactivate the virus under most conditions. Hepatitis C virus is probably the most prevalent virus in the blood of Califonians. It is present in between 0.5% to 2%) people in the US and Europe. The risk at an accident scene for encountering Hepatitis C would be no greater than 2:100 on average. The second most prevalent virus would be Hepatitis B. In California, the risk of encountering Hepatitis B contaminated blood at an accident site would be approximately 5:1,000. The risk of blood at an accident being contaminated with HIV virus would be approximately 1:1,000 or less on an average.

2. Increased effectiveness and efficiency of cleanup. Because the blood spreads and splatters the most rapid and effective clean up will be a washdown. This will prevent undue delays of freeway traffic and the long waiting periods necessary to call special cleaning squads. It will also remove the visible remains of the accident much faster thus preventing citizen concern from escalating.

3. Cost savings to the fire department, highway patrol, and CalTrans employees. It will decrease the cost of accident investigation and cleanup by decreasing the cleanup time for major injury accidents and eliminate the need for special cleanup units. .

4. Demonstration to the public that such visible blood is not a reason for undue concern if handled properly. Treating a blood spill as if it were a class 4 contamination gives the wrong message concerning risk to the public. In addition, the use of plain water would not unecessarily add increased amounts of chemicals to the runoff water. This will further decrease the burden of runoff water contamination on the storm drain system, keeping chemical contaminants to an unavoidable minimum.

I am an active supporter of efforts to protect the environment of the Santa Monica Bay and all Coastal waters. My Department has been an active participant in evaluating storm drain runoff into the Bay and we monitor it carefully. Though there is no likelihood of sterile effluent from storm drains, we still need to assure the community that we are watching those drains and minimizing the products of civilization which get into them. My recommendations are made in the spirit of these activities.

If there is any further information I can provide, please let me know. I can be reached at (213)240-7728, FAX (213)202-5980, e-mail sfannin@dhs.co.la.ca.us.

Sincerely yours,

Shirley L. Fannin MD

LOS ANGELES, CALIFORNIA 90063-3294

(323) 881-2401

P. MICHAEL FREEMAN
FIRE CHIEF
FORESTER & FIRE WARDEN

November 30, 2000

Harry W. Stone, Director
Los Angeles County Department of Public Works
900 South Fremont Avenue
Alhambra, CA 91803

Dear Mr. Stone:

SUBJECT: **MITIGATION OF RESIDUAL BLOOD RELEASES**

Our Department is requesting your assistance in addressing an issue that continually surfaces during public agency responses to trauma scenes involving mitigation of residual blood from victims.

The Los Angeles County Board of Supervisors established the Hazardous Materials Coordinating Committee (HMCC) to "facilitate information sharing among government and private agencies for the coordinated influence and development of legislation, policies and procedures to assure comprehensive protection of communities from hazardous materials." The HMCC is chaired by our Department and includes representatives from several government agencies.

A Trauma Scene Management Subcommittee was established to address the mitigation of residual blood releases. This ad-hoc Committee is focused on the health and safety issues that responders, victims, and the environment may face at trauma scenes in public areas. The following agencies are Committee members: The Los Angeles County Department of Health Services (DHS), Los Angeles City Fire Department, Los Angeles County Sanitation Districts, Los Angeles Sheriff's Department, Office of Public Safety, Long Beach Department of Health and Human Services, Pasadena Fire Department, Cal Trans, City and County Department's of Public Works, Coroner's Office, and the Regional Water Quality Control Board.

Members of this Committee recently met with staff from the State Department of Health Services, Medical Waste Management Program, and were advised that the 1998 Trauma Scene Waste Management Act did not apply to public agencies. An inquiry to the Federal Environmental Protection Agency (EPA) Region 9 and their Office of Solid Waste and Emergency Response produced no documents that address this issue on the Federal level. The EPA suggested that this should be resolved at the regional level.

R0008826

The HMCC has received a letter from Dr. Shirley Fanin, Medical Director, Disease Control Programs, Los Angeles County DHS, that indicates the most rational method of protecting the health of responders and the public is the practice of washing down residual blood. A copy of this letter is enclosed for your review. Discussions with Mr. Rod Kubomoto of your Watershed Management Division led us to believe that this approach may be consistent with the limits and exemptions of the Los Angeles County National Pollutant Discharge Elimination System (NPDES) permit. We present this issue to you as the administrator of the County NPDES permit to resolve with the State Regional Water Quality Control Board (Los Angeles Region) as part of the permitting process.

Your assistance in addressing this important issue will be of great benefit to the public agencies of Los Angeles County. Also, your direction on this matter will greatly influence the way that first responders across the region prepare and respond to trauma scenes.

If you have any further questions, please call me or have your staff contact Michael Wilkinson, Acting Deputy Fire Chief, Prevention Bureau, at (323) 881-2461 or William Jones, Chief, Health Hazardous Materials Division, at (323) 890-4043.

Sincerely yours,

for P. MICHAEL FREEMAN

Dennis A. Dickerson
Executive Officer
California Regional Water Quality Control Board,
Los Angeles Region
320 West 4th Street, Suite 200
Los Angeles, CA 90013

Dear Mr. Dickerson:

The letter is in follow up to our meeting on October 5, 2000 concerning the NRDC Petition to Withdraw the NPDES storm water permit program administered by the Los Angeles Regional Board. One of the NRDC's principal concerns with the Regional Board's program is the alleged absence of an effective program for controlling pollutants in storm water discharges from industrial facilities. NRDC also recognizes, however, that the root of the problem is the lack of adequate staffing at the Regional Board to implement the program. At the October 5 meeting, we suggested that the upcoming MS4 permit reissuance for Los Angeles County require that the MS4 permittees provide more assistance to the Regional Board in this regard. We also indicated that we would provide this letter of support to the Regional Board for such requirements.

EPA's storm water permit application regulations of November 16, 1990 (55 Fed. Reg. 47990) set forth the permit application requirements for industries and municipalities and also provide guidance concerning the implementation of the program over the longer term. The storm water regulations envision a cooperative effort on the part of the NPDES permitting authority and permitted MS4s in the implementation of the industrial storm water program (55 Fed. Reg. 47997). The regulations at 40 CFR 122.26(d)(2)(iv)(C) also specifically require that MS4 permittees develop and implement controls on industrial sources which discharge into the storm sewer system, including:

> "a description of a program to monitor and control pollutants in storm water discharges to municipal systems from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities that are subject to Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA), and industrial facilities that the municipal permit applicant determines are contributing a substantial pollutant loading to the municipal storm sewer system."

The current MS4 permit for Los Angeles County requires "educational visits" by MS4 personnel to assist industrial/commercial facilities in complying with local ordinances and prohibitions. We understand that the intent of this particular requirement was to provide time for the permittees to gain experience in controlling pollutants in storm water discharges from these facilities. Now that the permittees have had five years to gain such experience, we recommend that the next permit explicitly require that the permittees require compliance with local ordinances and implement an effective enforcement program to ensure compliance. For industrial facilities, such a requirement would be fully consistent with EPA regulations at 40 CFR 122.26(d)(2)(iv)(C). We also believe that the Regional Board's extension of the program to commercial facilities is consistent with EPA regulations at 40 CFR 122.26(d)(2)(iv)(A); however, NRDC's concerns are primarily related to industrial facilities.

Since the intent and requirements of local MS4 ordinances are usually similar (but perhaps less detailed) to the requirements of the State's general NPDES permit for industries, the above recommendation should significantly assist the Regional Board in more effectively controlling pollutants in storm water discharges from industrial (and commercial) facilities. As noted above, NRDC's concerns with the Regional Board's program are fundamentally resource-related, and by utilizing the resources of the MS4 permittees more effectively, this should help to address NRDC's concerns.

It should also be noted that the above recommendation would be nothing new for California MS4 permits. For example, the MS4 permits issued in 1996 for Orange and Riverside Counties already include explicit requirements for enforcement of local ordinances for storm water pollution control. Detailed enforcement requirements for local ordinances have also been proposed by the San Diego Regional Board for the upcoming reissuance of the San Diego County MS4 permit.

Should you have any questions regarding this matter, please call me at (415) 744-1860, or refer your staff to Eugene Bromley of the CWA Standards and Permits Office at (415) 744-1906.

Sincerely,

Alexis Strauss
Director, Water Division

City Council Meeting 12-19-2000 Santa Monica, California

ORDINANCE NUMBER 1995 (CCS)
(City Council Series)

AN ORDINANCE OF THE CITY COUNCIL
OF THE CITY OF SANTA MONICA
ADDING CHAPTER 8.108 TO THE SANTA MONICA MUNICIPAL CODE
WHICH ADOPTS SANTA MONICA AMENDMENTS
TO THE CALIFORNIA BUILDING STANDARDS CODE
RELATING TO GREEN BUILDING STANDARDS

WHEREAS, on June 8, 1999, the City Council adopted Ordinance Number 1945 (CCS), which adopts the California Building Standards Code, Santa Monica amendments to the California Building Standards Code; and other technical codes; and

WHEREAS, Health and Safety Code Sections 18938 and 17958 provides that the California Building Standards Code establishes building standards for all occupancies throughout the State; and

WHEREAS, Health and Safety Code Section 18941.5 provides that the City may establish more restrictive building standards if they are reasonably necessary due to local climatic, geological or topographical conditions; and

WHEREAS, the City Council has considered the 1998 edition of the California Building Standards Code, which incorporates by reference the 1996-1997 editions of the Technical Codes, and all of the referenced standards, tables, matrices and appendices of each of these codes therein; and

WHEREAS, based upon the findings contained in the Resolution adopted concurrently with this Ordinance, the City Council has found that certain modifications and additions to the California Building Standards Code are reasonably necessary based upon local climatic, topographical and geological conditions; and

WHEREAS, Public Resource Code Section 25402.1(h)(2) says that a local enforcement agency may adopt more restrictive energy standards when they are cost-effective and approved by the Energy Commission; and

WHEREAS, the City hired a private consultant to conduct a cost study of the proposed changes and said study demonstrated the cost effectiveness of these changes; and

WHEREAS, the State Energy Commission approved the proposed standards on September 20, 2000;

NOW, THEREFORE, THE CITY COUNCIL OF THE CITY OF SANTA MONICA DOES ORDAIN AS FOLLOWS:

SECTION 1. Chapter 8.108 is hereby added to the Santa Monica Municipal Code to read as follows:

CHAPTER 8.108 GREEN BUILDING STANDARDS

8.108.010 Purpose.

The green building design and construction standards established in this chapter are intended to reduce human exposure to noxious materials; conserve non-renewable energy and scarce materials; minimize the ecological impact of energy and materials used; use renewable energy and materials that are sustainably harvested; and protect and restore local air, water, flora and fauna. These standards will help protect the health of building occupants; improve employee productivity; use energy, water and materials more efficiently; incorporate recycled-content building materials; and increase the durability, ease of maintenance, and economy of building operations.

8.108.020 Scope.

The provisions of this chapter shall apply to all new buildings, and existing buildings whose repair, alteration or rehabilitation costs exceed 50 percent of their replacement cost as determined by Section 8.84.040 except (a) one-and-two-family dwellings and their accessory structures and (b) qualified historic buildings as defined in the State Historic Building Code (Title 24, Part 8).

8.108.030 Compliance Methods.

(a) Except as provided in subsections (b) and (c) of this Section, the envelope, space-conditioning, lighting and service water-heating systems of all buildings subject to the provisions of this chapter shall be designed, constructed and installed to use no more source energy from non-renewable sources than the allowable energy budget calculated in accordance with the performance approach set forth in Chapter 8.36 and reduced in accordance with Section 8.108.040.

(b) Multi-family residential buildings that are three stories or less in height may use the prescriptive approach set forth in Chapter 8.36 for the envelope, space-conditioning, lighting and service water-heating systems if these buildings also meet the following requirements:

(1) all windows and glass patio doors are equipped with double-glazed, low-emissivity glazing, with center- of-glass U-value not more than 0.32 Btu/(hr.sq.ft. deg. F.), and Solar Heat Gain Coefficient not more than 0.37;

(2) fixed lighting fixtures installed within the dwelling units have a combined average efficacy of not less than 40 lumens per watt;

(3) water heaters have a minimum energy factor of 0.60; and

(4) space cooling appliances (if installed) have a Seasonal Energy Efficiency Ratio (SEER) of not less than 12.

(c) When building designs, materials or devices cannot be adequately modeled by the performance approach, alternate calculation methods may be used when approved by the California Energy Commission pursuant to their administrative regulations for exceptional methods.

8.108.040 Reductions in Allowable Energy Budgets.

Allowable energy budgets shall be the allowable energy budget determined in accordance with Chapter 8.36 and reduced by the following factors for the occupancy types shown in Table 8.108-A. Required reduction factors for occupancies not shown in Table 108-A shall be determined by the Building Officer for the most similar energy consuming use.

Table 8.108-A

Required Reduction Factors for Allowable Energy Budgets

Multi-family residences	20%
Hotels and motels	25%
Commercial and institutional offices	25%
Light industrial	25%
Retail	20%

When determining compliance with the percentage reduction, alternate calculation methods that consider energy savings in addition to those recognized in Chapter 8.36 may be used when approved by the Building Officer. These savings may include, but are not limited to, efficiency of fan systems with motors less than twenty-five horsepower and garage ventilation controls.

8.108.050 Use of Recycled Construction Materials.

All new buildings subject to the provisions of the chapter shall be built with a minimum of four major construction materials that have a post-consumer recycled content that meets the Environmental Protection Agency (EPA) recycled content guidelines as set forth in the Comprehensive Guideline for Procurement of Products Containing Recovered Materials (CPG) and the Recovered Materials Advisory Notices (40 CFR Part 247), or any successor publication. Building and Safety Division shall maintain copies of the most recent guidelines issued by the EPA. Major construction materials are those materials that serve a structural, partitioning or finishing function throughout the building or cover more than one-half of the floor, roof or wall surfaces.

8.108.060 Additional Mandatory Features for All Buildings.

(a) Solar Water Heating. Solar collectors shall be the primary source to heat swimming pool water and to preheat industrial process water, including but not limited to, car washes and laundries.

(b) Pipe Insulation. All hot water distribution and recirculating system piping shall be thermally insulated from the heater to the end-use fixtures. Pipe insulation shall have R-value equal to R-4 for piping 2 inches or less in diameter and R-6 for larger piping. The R-value specified shall not be exceeded.

(c) Heat Traps. Heat traps shall be provided on the inlets and outlets of non-circulating hot water heaters and tanks to reduce the buoyancy-induced flow of hot water through the piping. Bent piping for heat traps shall have a minimum external diameter of twelve inches.

SECTION 2. Section 8.36.010 of the Santa Monica Municipal Code is amended to read as follows:

8.36.010. Adoption.

That certain document entitled "California Energy Code, 1998 Edition," which is Part 6 of Title 24 of the California Code of Regulations, as published by the California Building Standards Commission and the International Conference of Building Officials is hereby adopted as the Energy Code of Santa Monica, subject to the provisions of Chapter 8.108 Green Building Standards.

SECTION 3. Any provision of the Santa Monica Municipal Code or appendices thereto, inconsistent with the provisions of this Ordinance, to the extent of such inconsistencies and no further, are hereby repealed or modified to that extent necessary to effect the provisions of this Ordinance.

SECTION 4. If any Section, subsection, sentence, clause, or phrase of this Ordinance is for any reason held to be invalid or unconstitutional by a decision of any court of any competent jurisdiction, such decision shall not affect the validity of the remaining portions of this Ordinance. The City Council hereby declares that it would have passed this Ordinance, and each and every Section, subsection, sentence, clause, or phrase not declared invalid or unconstitutional without regard to whether any portion of the Ordinance would be subsequently declared invalid or unconstitutional.

SECTION 5. The Mayor shall sign and the City Clerk shall attest to the passage of this Ordinance. The City Clerk shall cause this ordinance, or a summary thereof to be published once in the official newspaper within 15 days after its adoption. This Ordinance shall be effective 30 days after its adoption.

APPROVED AS TO FORM:

MARSHA JONES MOUTRIE
City Attorney

Adopted and approved this 19th day of December, 2000.

Michael Feinstein, Mayor

State of California)
County of Los Angeles) ss.
City of Santa Monica)

I, Maria M. Stewart, City Clerk of the City of Santa Monica, do hereby certify that the foregoing Ordinance No. 1995 (CCS) had it's introduction on December 5, 2000, and was adopted at the Santa Monica City Council meeting held on December 19, 2000, by the following vote:

Ayes:	Council members:	Holbrook, O'Connor, McKeown, Genser, Katz, Mayor Pro Tem Bloom, Mayor Feinstein
Noes:	Council members:	None
Abstain:	Council members:	None
Absent:	Council members:	None

From: Dennis Dickerson
To: Dan Radulescu; Dennis Dasker; Wendy Phillips; Xavier Swamikannu
Date: 1/10/01 4:11PM
Subject: Today's EAC Mtg

This notes will range several topics

TMDL Zero trash appears to be the big issue for the cities. Were there any way to modify or rephrase it would go a long way to reduce controversy.

Any mtg on the permit/TMDL with enviro groups they are asking to be participants

Asking that we post TMDL comment response on the web

TMDL I committed that we should get any change sheet or response to comenmts out not later than two days before the mtg.

NTMC comment that we appeared to stray from our commitment early on not to link NTMC to the TMDL, i.e., monitoring They want a mtg to discuss the NTMC letter and our outlook. Wendy, pls arrange.

Suggestion that I support that we establish after the TMDL is adopted a standing TMDL implementation working group

I requested that they offer a review/overview of the ROWDs that are submitted early on. Feb 14 is tentative date Invite enviros - mtg not intended to debate but just present their viewpoint

Rouge River National Wet Weather Demonstration Project

Wayne County, Michigan

Evaluation of On-Line Media Filters in the Rouge River Watershed TASK PRODUCT MEMORANDUM

Nonpoint Work Plan No. URBSW5, Task No. 3

Authors: Razik Alsaigh, Jeff Boerma, Amy Ploof & Louis Regenmorter

ACKNOWLEDGMENTS

We would like to thank Paul Geisert (Aqua-Net, Inc,), Henry Happel (Suntree Isles), Paul Renberg (Sonoco), Jorge R. Sainz (Geotechnical Marine), and Joseph B. H. Smith (Foss Environmental) for their assistance in this demonstration project.

The Rouge River National Wet Weather Demonstration Project is funded, in part, by the United States Environmental Protection Agency (EPA) Grant #X995743-01, 02, 03 and 04 and #C995743-01. The views expressed by individual authors are their own and do not necessarily reflect those of EPA. Mention of trade names, products, or services does not convey, and should not be interpreted as conveying, official EPA approval, endorsement, or recommendation.

Rouge River National Wet Weather Demonstration Project

MISSION STATEMENT

The mission of the Rouge River National Wet Weather Demonstration Project is to demonstrate effective solutions to water quality problems facing an urban watershed highly impacted by wet weather and develop potential solutions and implement projects which will lead to the restoration of water quality in the Rouge River. The project will address both conventional and toxic pollutants to:

- provide a safe and healthy recreational river resource for present and future generations;
- re-establish a healthy and diverse ecosystem within the Rouge River Watershed;
- protect downstream water resources such as the Detroit River and Lake Erie; and
- help ensure compliance with federal, state and local environmental laws which protect human health and the environment.

This will be accomplished through the development, implementation and financial integration of technical, social and institutional frameworks leading to cost-efficient and innovative watershed-based solutions to wet weather problems. This watershed-based national demonstration project will provide other municipalities across the nation facing similar problems with guidance and potentially effective solutions.

PREFACE

The Rouge River and its watershed are a primary source of pollution to the Great Lakes. The Clean Water Act of 1972 intended to make waterways "fishable and swimmable" by 1972. Although that goal has not been reached, great progress has been made in improving water quality in most waterways. The Rouge River Remedial Action Plan (RAP) provided a basis for which The Rouge River National Wet Weather Demonstration Project (Rouge Project) efforts were created: it identified the major sources of pollution and measured the relative contributions of each. The RAP is the continuing foundation for the Rouge Project and presents a framework for addressing the problems within the Rouge River by looking beyond treatment and focusing instead on prevention methods.

The Rouge Project was established under the initial Rouge Grant 1 from the United States Environment Protection Agency, Region 5, and enabled Wayne County to initiate a comprehensive watershed-wide pollution-control approach that addresses combined sewer overflow (CSO), stormwater management, and other nonpoint source controls through the application of innovative technologies, progressive financial and institutional arrangements, and creative public involvement and education programs.

Rouge Grant 2 provides the framework for the progression and implementation of Project goals as Wayne County continues its mission to develop potential solutions and implement projects which will lead to the restoration of water quality in the Rouge River. The Project will address both conventional and toxic pollutants to:

- provide a safe and healthy recreational river resource for present and future generations;
- re-establish a healthy and diverse ecosystem within the Rouge River Watershed;
- protect downstream water resources such as the Detroit River and Lake Erie; and
- help ensure compliance with federal, state, and local environmental laws which protect human health and environment.

This will be accomplished through the development, implementation, and financial integration of technical, social, and institutional frameworks leading to cost-efficient and innovative watershed-based solutions to wet weather problems. This watershed-based national demonstration project will provide other municipalities across the nation facing similar problems with guidance and potentially effective solutions.

Under Rouge Grant 2, the Rouge Project will build on lessons learned from Grant 1 efforts and focus on further integration of the goals of the overall Mission. To this end, Rouge Grant 2 concentrates on the following key Project areas:

- **Watershed Management** will continue under Rouge Grant 2 with the development and evaluation of wet weather and stormwater alternatives, the planning of long-term monitoring programs, and the ongoing efforts to enhance instream water quality, monitor rain and flow levels, interpret data analysis, and present recommendations.

- **Nonpoint Source Pollution Control** will provide for the stormwater management, permit applications, and development of financial and institutional alternatives for wet-weather watershed management in concert with enhanced efforts to establish institutional partnerships. Toward the goal of institutional partnering, several community projects will be undertaken with watershed communities. Additional efforts include the inventory of wetlands and measurement of pollutant loads from abandoned dumps and air deposition with possible remediation of some sites.

- **CSO Construction Coordination** will continue to monitor the construction of CSO demonstration projects established under Grant 1. Additional planning and assistance will allow project coordinators to make additional recommendations on the design criteria of future CSO abatement facilities.

- **Public Involvement and Information** will reach and interact with more stakeholders, institutions, and regulatory agencies, thus fostering a renewed understanding and continued commitment to reducing pollution, and continuing the transfer of watershed management approaches beyond the project. It will be the central mechanism for transmittal of the Project's Decision Support System tools, processes, and information necessary for sustaining a watershed management support system directly to varied audiences both within and outside the Rouge watershed.

Additional information on the Rouge River Project is available from many sources, including the Wayne County Department of Environment (WCDOE), the Rouge Program Office (RPO), and the Rouge Project website at http://www.rougeriver.com.

ABSTRACT

This report describes the performance of the on-line media filter demonstration pilot project for the period of October 1995 to June 1997. This best management practice (BMP) uses storm sewer inserts to filter sediments and absorb hydrocarbon products from storm sewer runoff before it reaches surface waters. These inserts were applied as a demonstration project in the Cities of Livonia and Westland, Michigan. These BMPs were recommended to evaluate the costs and benefits of low cost, inlet insert type devices for use in existing urban areas. Four devices were tested as part of this demonstration. The sediments and hydrocarbons collected by the four devices were measured and the results of the four devices were assessed. The operation and maintenance (O&M) considerations, capital cost, and estimated O&M costs are also addressed. All four filters performed well during the 19 month evaluation period and were relatively easy to maintain. The results of this demonstration show that the best filter depends on the conditions at the site and the objective of its installation.

LIST OF TABLES

LIST OF FIGURES

1.0 INTRODUCTION.

Urban stormwater has been extensively studied over the past 15-20 years and is recognized as a major source of pollution to many of the nations waterways. The 1989 Rouge River Remedial Action Plan (RAP) and 1994 Rouge RAP Update identified stormwater and/or nonpoint source pollution as a major contributor to flow, suspended solids, biochemical oxygen demand, nutrients, and trace contaminants and identified nonpoint source pollution as a major concern in the upper and middle reaches of all branches of the Rouge River (SEMCOG; 1989, 1994). One of the primary goals of the Rouge River National Wet Weather Demonstration Project (Rouge Project) is to implement pilot stormwater pollution control programs to test their applicability to southeast Michigan and nationwide. Data derived from the pilot storm water pollution control projects will be utilized by the Rouge Subwatershed advisory groups during development of management plans for the seven Rouge subwatersheds.

The purpose of this report is to describe the performance evaluation of the on-line media filter demonstration project for the period of October 1995 to June 1997. This demonstration project is structural BMP #8 as described in the Rouge Project document "Interim Final Report for the 319 Grant (RPO-NPSO1A-TR02.01)."

2.0 BEST MANAGEMENT PRACTICE (BMP) DESCRIPTION AND APPLICATION IN THE ROUGE WATERSHED.

2.0 BEST MANAGEMENT PRACTICE (BMP) DESCRIPTION AND APPLICATION IN THE ROUGE WATERSHED. This BMP uses storm sewer inserts to filter sediments and absorb hydrocarbon products from storm water runoff before it reaches surface waters. These BMPs are suitable for small impervious drainage areas. Storm sewer inserts were examined in the Rouge Watershed for the possibility of retrofitting existing small urban drainage areas as a means to provide water quality benefits. These devices are applicable for use in gas stations, small convenience stores, and small parking lots and they have a relatively low cost.

These inserts were applied as a demonstration project in the Cities of Livonia and Westland, Michigan. They are the only structures of this kind presently in use in the Rouge Watershed. Filter inserts have been used elsewhere in the U.S., most notably in the states of Florida and Washington.

3.0 ROUGE PILOT BMP PROJECT DEMONSTRATION ACTIVITIES.

The Rouge Program Office (RPO) recommended these BMPs for pilot demonstration in order to evaluate the costs and benefits of low cost, inlet insert type devices for use in existing urban areas in the Rouge Watershed. The information from these devices will be used to determine if existing storm sewer design criteria should be modified and if retrofit of existing catch basins with these devices is a viable, cost effective pollution management option for implementation watershed-wide. Four of these devices were tested as part of this demonstration.

3.1 SITE CHARACTERISTICS.

This pilot BMP was tested for a period of 19 months at two gas station sites: one at Schoolcraft and Merriman Roads in Livonia, Michigan and one at Ford and Newburgh Roads in Westland, Michigan. *Figure 3-1* contains site plans for both locations. Two catch basins (M1 and M2) were monitored at the Livonia site and five catch basins (N1, N2, N3, N4, and N5) were monitored at the Westland site. Each filter was installed within the catch basin and not within the sewer pipe, so the flow through the filters was only from the gas station tributary areas. The drainage areas for the two catch basins at the Livonia site are 0.16 acres for M1 and 0.60 acres for M2. The drainage areas for the five catch basins at the Westland site are 0.064 acres for N1, 0.048 acres for N2, 0.125 acres for N3, 0.049 acres for N4, and 0.033 acres for N5. The tributary area to all media filter devices was composed entirely of gas station property and is considered 100 percent impervious. Both locations (Livonia and Westland) had a very similar environment with respect to the type and frequency of traffic and both had a convenience store at the site.

3.2 DESIGN CHARACTERISTICS.

The catch basin insert type units selected for this BMP evaluation are presently manufactured and marketed by vendors throughout the United States and Canada. Many of the vendors are located in Florida and Washington due to the interest of local municipalities in this type of water quality improvement retrofit. Several vendors were contacted and four units were chosen for assessment:

- *Hydro-Cartridge®:* by Geotechnical Marine Corporation; Hialeah Gardens, Florida.
- *StreamGuard™:* by Foss Environmental; Seattle, Washington.
- *Gullywasher™:* by Aqua-Net Incorporation Seattle; Washington.
- *Grate Inlet Skimmer Box:* by Suntree Isles Incorporation; Cape Canaveral, Florida.

The chosen devices were selected because they are easy to install, did not require construction and were compatible with the catch basins at the gas station sites available to the Rouge Project for testing these devices.

The objective of these devices is to provide a unit that can be installed in existing storm water catch basins by simply lifting the catch basin manhole cover, inserting the unit, and replacing

Figure 3-1
Site Plans for On-line Media Filter Evaluation

Figure 3-1a: Livonia Site Plan

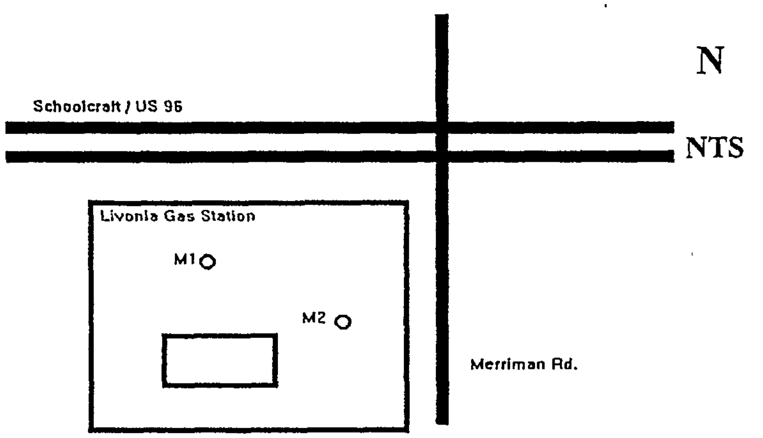

Figure 3-1b: Westland Site Plan

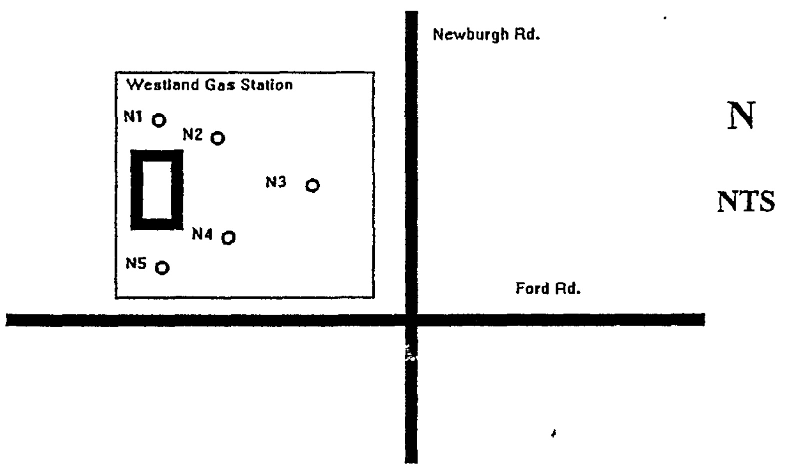

the cover to its original position. Units are sized to fit the existing catch basins. These units consist of materials and structures to capture solids and absorbent media to capture oil products. Overflow outlets are also provided to allow flow through for large runoff events. The design for each of these units is briefly explained in the following paragraphs.

3.2.1 **Hydro-Cartridge®**. The Hydro-Cartridge® is a fiberglass filter with an oil absorbing media. Two types of media were tested in this study, Woolzorb™ and Rubberizer™. This filter uses standing water to slow the flow through the filter allowing oil to separate to the top and sediment to settle at the bottom of the filter. Hydrocarbon polymer pillows are positioned at the top of the filter to absorb hydrocarbons. A sketch of the Hydro-Cartridge® is included in *Appendix A*.

3.2.2 **StreamGuard™**. The StreamGuard™ is a fabric filter bag that hangs in the storm inlet from the lid of the catch basin. It is held in place by the weight of the inlet cover on the inlet structure. This filter uses standing water to reduce the flow velocity and allow sediment to settle out. This filter also has one-half inch diameter holes on the side near the top of the device to allow storm water to overflow the filter. Oil absorbing media is positioned in the center of the filter to absorb hydrocarbons as storm water flows through the filter. A sketch of the StreamGuard™ is included in *Appendix A*.

3.2.3 **Gullywasher™**. The Gullywasher™ is a metal basket with cellulose filter media on the bottom and sides of the basket. Storm water flows into an aluminum funnel and enters a basket filled with cellulose material that hangs below the funnel. During large storm events, the basket will overflow. A sketch of the Gullywasher™ is included in *Appendix A*.

3.2.4 **Grate Inlet Skimmer Box**. The Grate Inlet Skimmer Box is a fiberglass filter with oil absorbing media. The Grate Inlet Skimmer Box has two filter parts: the first is a ring around the top of the filter that contains the oil absorbing media, and the second is a bucket with screened holes on the sides and bottom and open overflow holes at top. Storm water entering the filter first enters the top ring flow around a "boom" of oil absorbing media and drop into the bucket section. The bucket section is designed to hold the runoff from the first part of a large storm or from an entire small storm and slowly release the storm water to the storm sewer through screens. If the storm is large, the bucket fills up and drains through overflow holes at the top. A sketch of the Grate Inlet Skimmer Box is included in *Appendix A*.

3.3 **INSTALLATION CONSIDERATIONS.** Four devices were obtained from vendors and all four were installed at the sites. The only structural revision to the sites that was required was the purchase of one new manhole cover with an indent on the bottom side. The indent was necessary to allow the grate inlet skimmer box fit properly. The installation of these devices was performed by the RPO team and consisted of removing the catch basin cover, setting the device into the manhole, and reinstalling the catch basin cover.

The StreamGuard™ was the easiest to install. It is a fabric bag that can fit almost any inlet shape or size. The other three devices were also easy to install, but precise measurement of the inlet opening, rim configuration, and cover type were needed to ensure their proper fit. The Gullywasher™ required minor hammering due to the tight fit of this device on several of the inlets.

3.4 OPERATION AND MAINTENANCE CONSIDERATIONS. An important considerations of these insert devices is the maintenance required to ensure that the filters effectively capture sediment and absorb oil. A device may be excellent at capturing sediments and oils, but if it requires very frequent maintenance it may become impractical. The four devices used in this demonstration project functioned properly with only monthly maintenance based on the existing environmental conditions. For the purposes of this demonstration, a monthly basic maintenance schedule was chosen to assess the maintenance requirements of these devices for long-term use in a gas station environment. In only one instance, when the Hydro-Cartridge® froze in cold weather, was immediate attention necessary during the 19 month assessment period.

The RPO team performed the following operation and maintenance (O&M) activities in accordance with the standard operating procedures described in *Appendix B*.

1. Each filter was checked weekly in the field, preferably just after a rain event.
2. Sediment and organic materials were removed monthly from the filters. A sieve analysis was performed on the material removed.
3. Filter media samples were analyzed for oil and grease content on a monthly basis.

It should be noted that the maintenance schedule will vary depending on where these devices are used and the amount of hydrocarbons, sediment, or debris generated from the drainage area. The observations included in this report are related to the function of these devices in a gas station drainage area environment in southeast Michigan.

O&M procedures for each of the four filter types are detailed in the following sections.

3.4.1 Hydro-Cartridge®. The Hydro-Cartridge® is a fiberglass device molded to fit the catch basin. Installing the device requires only removal of the catch basin lid, inserting the device, and replacing the lid. During operation the filter fills with water making its removal more difficult. For maintenance, the full filter must be lifted out of the catch basin and generally required two persons. Initially, removal of the filter was relatively difficult, but became easier with increased familiarity with the device. Use of a vactor truck is likely to make clean-up of these filters easier.

This filter performed well during the 19-month evaluation period, with one exception. During a period when temperatures were below 10°F for about seven days, the standing water in the filter froze and the catch basin became plugged. A storm event occurred while the surface of the standing water in the device was frozen, causing storm water runoff to pond and flood an area of 12 feet by 20 feet and one foot in depth. This incident led to the filter being removed until warmer weather. This filter could be modified to work effectively in cold weather by adding several relief holes above the standing water surface to allow for a secondary path for the runoff if the standing water in the device froze. These holes would be plugged in the summer and unplugged in the winter. If this filter is modified it is expected that very little maintenance will be required throughout the year. The exchange of the absorbent pillow or pads is easy and consists of tying and untying a string.

3.4.2 **StreamGuard™.** The StreamGuard™ is a fabric filter basket held in a catch basin by being pinched between the lid and rim of the catch basin. This configuration makes the process of removing the filter difficult initially, but becomes relatively easy with experience. The advantage of this filter's design is that it can be cut to fit a variety of different catch basins. The versatility of the StreamGuard™ enabled installation at two different catch basins using the same filter size. The filter is thrown away once it is no longer useful, therefore, no time is spent cleaning it for reuse. Once the installation and removal techniques are mastered, this filter is easy to maintain.

3.4.3 **Gullywasher™.** The Gullywasher™ is a metal basket filled with cellulose booms designed to fit a specific catch basin size. When the cellulose booms are dry the filter is easy for one person to install and remove. When the cellulose booms are wet the filter becomes much heavier, but is still manageable for one person. Booms are constructed of plastic netting filled with cellulose. This plastic netting sometimes catches on the metal basket causing an inconvenience when loading or unloading the booms from the basket. Maneuvering the used cellulose booms out of the filter and putting in the new media makes this filter somewhat more difficult to maintain than the StreamGuard™ or Hydro-Cartridge®.

3.4.4 **Grate Inlet Skimmer Box.** The Grate Inlet Skimmer Box is relatively easy to maintain except for screens located in the main bucket. The oil absorbing media is simply lifted out for disposal and new media is installed. Decaying leaves and debris plugged the screens making them difficult to keep clear, even with use of a wire brush. Two different filters with different screen configurations were used and both experienced the plugging of the screens. The filter was easy to maintain except for this problem. A vactor truck could also be a great help to clean this device.

3.5 **HYDROLOGICAL CONDITIONS.** During the period of October 11, 1995 - June 5, 1997 the cumulative precipitation was 48.45 inches as recorded at the Wayne County rain gauge located at Merriman Road South of Ann Arbor Trail and at the Detroit Metropolitan Airport rain gage. *Table 3.1* outlines the hydrological conditions at the gas stations for the study period. *Table 3.1* shows the total amount of rain for a given month and the maximum amount of rain that fell in a one hour period. The time period each filter was in place is also indicated. During the winter months of November through March for both 1995-1996 and 1996-1997, the precipitation was mainly snow with some rain and the ground was generally frozen.

Table 3.1
Summary of Hydrological Conditions in the Rouge Watershed: October 11, 1995 - June 6, 1997[1]

Time Period	Temperature and Precipitation				Type of Insert			
	Avg. Temp. (F)	No. of Events	Total (inches)	Max. (inches per hour)	Hydro-Cartridge®	Stream Guard™	Gully-washer™	Grate Inlet Skimmer Box

1 Source: National Weather Service Data for Detroit Metropolitan Airport (10/11/95-8/9/96). Wayne County Rain Gauge at Merriman Road, South of Ann Arbor Trail (8/9/96-6/5/97).

* October only includes data from October 11, 1995 through the end of the month.

N.A. indicates data are not available.

> indicates the filter was installed on the date written ahead of the marker.

< indicates the filter was removed on the date written behind the marker.

In indicates the filter was installed.

N.I. indicates the filter was not installed.

3.6 ASSESSMENT OF BENEFITS. The Rouge Project standard operating procedure (SOP) for field assessment of these devices "On-line Media Filter: Field Installation, Maintenance and Evaluation" (RPO/CDM-FLD-0629) is included as *Appendix B*.

All four filters were in use for more than one year. The Hydro-Cartridge® and Skimmer Box were in use from mid October 1995 until June 5, 1997, at the Livonia location. The StreamGuard™ was installed February 9, 1996 and the Gullywasher™ was installed March 25, 1996 at the Westland location; both were removed June 5, 1997. There was only one instance of a plugged filter backing up storm water flow, and during that event there were no complaints from the gas station managers regarding the devices. All of these devices removed sediment and oils from stormwater, although certain units were more effective than others. *Table 3.2* through *Table 3.5* document the data collected for these devices. *Table 3.6* summarizes the data by catch basin for the two sites. Sediment data evaluation comments were based on data collected from December 11, 1996 to May 9, 1997 and all oil data evaluation comments were based on data from August 9, 1996 to March 31, 1997.

The laboratory performed the oil and grease extraction of the samples in compliance with EPA SWA46 Method 9071 "Oil and Grease Extraction Method for Sludge Samples." The method used is to recover low levels of oil and grease by chemically drying a wet sludge sample and then extracting via the Soxhlet apparatus. This method is used when relatively polar, heavy petroleum fractions are present, or when the levels of nonvolatile greases challenge the solubility limit of the solvent. This method is suitable for biological lipids, mineral hydrocarbons, and some industrial waste waters. This method is not recommended for measurement of low-boiling fractions that volatilize at temperatures below 7 C.

The sediment analysis was performed in accordance with industry accepted methods. The samples were delivered to the lab in buckets. The lab dried the entire sample in the bucket to determine the dry weight of material trapped in the filer. The dry material was then tested for organic content by the loss on ignition test. If the dry material was found to have less than 75 percent organics, a sieve analysis was performed on the recovered material.

3.6.1 Sediment Removal and Retainage. All of the devices tested removed and retained sediment from stormwater runoff. As shown in *Table 3.7*, the Gullywasher™ was the most effective of the four devices tested at removing sediment. The Gullywasher™ was six times as effective at removing sediment than the next most effective device, the StreamGuard™ (6.60 pounds of sediment captured per 1,000 gallons of water filtered to 1.11 pounds of sediment captured per 1,000 gallons of water filtered). Fabric filters such as the StreamGuard™ and the Gullywasher™ retained a larger amount of sediment than rigid fiberglass filters. The Gullywasher™ is considered a fabric filter because the metal basket is just a means of holding the cellulose filter. The StreamGuard™ retained nearly three times the amount of the sediment as the Skimmer Box or Hydro-Cartridge®.

Percent Silt	13.1	17.5	15.3	8.9	31.4	11.1	17.8	13.1	17.3
Oil Analysis									
Oil Captured (mg/Kg)	65,000	71,500	68,000	8,300	10,700	10,200	4,200	10,400	8,000
Oil Captured / Gallons Filtered ((mg/KG) / 1,000 gallons)	3,100	7,300	5,200	1,900	5,400	2,300	1,200	5,900	3,300

Notes:
(1) Gallons Filtered is estimated as the drainage area multiplied by the rainfall.
(2) All numbers in this table are averages of the monitoring periods shown in *Table 3.2* through *Table 3.5*.

The sediment collected at each catch basin was analyzed by the lab to estimate the composition of the sediment collected. As shown in *Table 3.6*, the sediment consisted of approximately the same composition ratios at both the Westland and Livonia sites. Organics made up about 20 percent of the sediment collected. The remainder of the sediment was approximately 5 percent gravel, 80 percent sand, and 15 percent silt. The sediment collected by each of the four devices was also analyzed to determine if the filters captured the same composition of sediment. As shown in *Tables 3.2 - 3.5* the sediment collected by the four devices consisted of approximately the same composition ratios.

3.6.2 **Oil Removal and Absorption.** The four devices removed and absorbed oil from the runoff. Of the four devices tested, the Hydro-Cartridge® removed the most oil per gallon of stormwater filtered. As shown in *Table 3.8*, the Hydro-Cartridge® removed nearly two times more oil than the next most effective tested device, the StreamGuard™ (9,700 mg/Kg of oil per 1,000 gallons to 5,000). The design of the Hydro-Cartridge® allows it to temporarily hold several gallons of oil from a spill. The base of the filter is always full of water and thus if oil entered the filter, it would float on the standing water and would not pass through the filter, even in wet weather. This feature enabled the Hydro-Cartridge® to perform the best between the four tested filters at handling oil.

The Hydro-Cartridge®and StreamGuard™devices absorbed oil than the Skimmer Box and Gullywasher. The difference could be due to the retained water slowing the flow and enabling oil to collect on the media, or that a better oil absorbing media was used. The Skimmer Box and Gullywasher™ both used a cellulose media, while the Hydro-Cartridge® and StreamGuard™ both used other materials as their media. This may suggest that the other materials used were more effective at removing oil than the cellulose media. In summary, filters that retain storm water appear to allow more oil absorption and absorbing material other than the cellulose media appear to absorb more oil.

3.6.3 **Summary of Benefits.** All on-line quality devices evaluated by the Rouge Project demonstrated stormwater sediment and oils removal benefits. The four devices were all relatively easy to maintain. During the 19 month evaluation period no complaints were received from the gas station managers regarding these devices.

The results of the four devices for the average amount of sediment removed per gallon of water are listed in *Table 3.7*. The results of the four devices for the average amount of oil removed per gallon of water are listed in *Table 3.8*. The selection of device and media should be made based on the pollutant you are interested in controlling. The results of this demonstration show that the best filter depends on the conditions at the site and the objective of its installation.

Table 3.7
On-line Quality Devices Sediment Removal Summary

Device	Average Sediment Captured / Gallon Filtered (lbs/ 1,000 gallons)
Gullywasher™	6.60
StreamGuard™	1.11
Grate Inlet Skimmer Box	0.39
Hydro-Cartridge®	0.19

Table 3.8
On-line Quality Devices Oil Adsorption Summary

Device	Average Oil Captured / Gallon Filtered ((mg/Kg) / 1,000 gallons)
Hydro-Cartridge®	9,700
StreamGuard™	5,000
Gullywasher™	2,100
Grate Inlet Skimmer Box	700

3.7 **CAPITAL AND O&M COSTS.** Capital costs for each of these media filters are listed below (as of 1995). Operation and maintenance (O&M) costs were also estimated for sites similar to the gas stations monitored during this evaluation.

3.7.1 **Hydro-Cartridge®.** The Hydro-Cartridge® is a fiberglass structure with media inserts. The fiberglass structure costs around $700 to $800 each depending on the size of the catch basin. The media inserts are about $9 each. At sites similar to the gas stations monitored during this evaluation, we estimate it would be necessary to replace the media inserts approximately every three months. The actual amount of time before the inserts need to be replaced will vary depending on the specific site conditions.

3.7.2 **StreamGuard™.** The StreamGuard™ is a fabric insert with a cost of $40 to $80 each depending on the design of the filter, the quantity ordered, and if the insert has oil absorbing media. At sites similar to the gas stations monitored during this evaluation, we estimate it would be necessary to replace the StreamGuard™ approximately every two months. The actual amount of time before the inserts need to be replaced will vary depending on the specific site conditions.

3.7.3 **Gullywasher™**. The Gullywasher™ is an aluminum basket with cellulose media. The cost of the basket decreases as the quantity of similar baskets ordered increases. This is due to tooling costs for each differently dimensioned storm inlet. The cost of a basket when ordering 100 or more baskets is approximately $440 each. The cost of the cellulose media is approximately $60 per basket. These prices also depend on the size of the filter and the quantity ordered. At sites similar to the gas stations monitored during this evaluation, we estimate it would be necessary to replace the cellulose media approximately every three months. The actual amount of time before the inserts need to be replaced will vary depending on the specific site conditions.

3.7.4 **Grate Inlet Skimmer Box.** The Skimmer Box is a fiberglass filter with replaceable filter media. The fiberglass structure costs around $475 each depending on the size of the catch basin. The media inserts are about $25 each. At sites similar to the gas stations monitored during this evaluation, we estimate it would be necessary to replace the media inserts approximately every three months. The actual amount of time before the inserts need to be replaced will vary depending on the specific site conditions.

3.7.5 **Summary of Capital Costs**. The following table shows a summary of the costs, estimated for 1995, for the various four tested devices.

Table 3.9
On-line Quality Devices Capital Cost Summary
(1995 costs)

Device	Hydro-Cartridge®	Stream Guard™	Gullywasher™	Grate Inlet Skimmer Box
Structure	$700 - $800	n/a	$440	$475
Media	$9	$40 - $80	$60	$25
Approximate Media Replacement Interval	every three months	every two months	every three months	every three months
Estimated First Year Capital Cost	$736-$836	$240-$480	$680	$575

3.7.6 **O&M COSTS.** The O&M of the devices by the RPO team consisted of a weekly site visit to ensure the devices were operating correctly and a monthly clean out of sediment, organic materials, and changing the oil absorbing materials. The amount of time spent for a typical weekly site visit was relatively short, about 10 minutes. This gave the two person RPO team adequate time to ensure that the devices were functioning as designed. The monthly clean out of the filters took approximately 30 minutes per device. The clean out was performed as described in the SOP included as *Attachment B*. The RPO team also took samples of the media during these visits, so clean out time should be less than the one indicated above without sampling activities. Also, the weekly visits can be reduced to by-weekly and the monthly clean out visits can be reduced to by-monthly.

The devices were all relatively easy to maintain and with experience became even easier. Maintenance of the devices could be performed by city maintenance personnel or comparable staff. The current wage for a two person crew in this area of work is about $40 per hour. For a typical catch basin, the weekly site visits can be reduced to bi-weekly or less and the monthly clean out visits can be reduced to bi-monthly. Then, for a typical two month period with O&M consist two site visits and a one monthly clean out, approximately one hour per device would be spent on O&M activities. The O&M cost for one year would be approximately $240 per device. The actual amount of time needed to for O&M will very depending on how frequent each site generates sediment or oil.

Disposal cost for dry material range from $10 - $20 per cubic yard. Disposal cost will be reduced if a dewatering/drying area is available.

4.0 CONCLUSIONS.

Four on-line media filter devices were monitored for a 19 month period at two gas station sites in southeast Michigan. These devices were monitored to evaluate the costs and benefits of low cost, inlet insert type devices for use in existing urban areas in the Rouge Watershed. The Capital costs for the four devices were reasonable, and all devices were easy to operate and maintian. All four filters demonstrated the ability during the 19 month monitoring period to remove some debris, sediment, and oil without causing storm water backup. (With one exception when one filter froze and runoff ponded; this ponding could be prevented with some modifications to the filter.)

The results of this demonstration show that the best filter depends on the conditions at the site and the objective of its installation.

- In terms of amount of sediment removed and retained per gallon of stormwater filtered, the Gullywasher™ was the most effective, retaining six times the amount of sediment as the next most effective device.
- In terms of oil absorption and removal per gallon of stormwater filtered, the Hydro-Cartridge® was the most effective, retaining almost two times the amount of oil as the next most effective device.
- In terms of O&M, all devices were easy to operate and maintain. The Hydro-Cartridge® and StreamGuard™ were the easiest to maintain.
- In terms of Capital cost for the device, the StreamGuard™ had the lowest cost at $40-$80 because the only part is the filter itself. The Gullywasher™ and the grate inlet skimmer box both cost less ($440 and $475) than the Hydro-Cartridge® at $700-$800.
- In terms of cost of insert replacements, the cost varied considerably among the filters. The lowest priced is the Hydro-Cartridge® at $9 each while the costs for the skimmer box, Gullywasher™ and StreamGuard™ were $25, $60, and $40-$80, respectively.
- In terms of first year Capital cost, the lowest cost is the StreamGuard™ at $240-$480. The grate inlet skimmer box, Gullywasher™, and Hydro-Cartridge® were $575, $680, and $736-$836, respectively.
- In terms of labor O&M time, it is estimated that a two person crew would spend approximately one hour per two month period maintaining and checking each device. In southeast Michigan, the personnel cost for maintaining the devices for one year is approximately $240 per device.

HYDRO-CARTRIDGES®

STORM DRAIN FILTRATION SYSTEM

A SAINZ DESIGN

Hydro-Cartridges is the latest environmental fiberplastic product developed by our company, directed to help our communities in the task of improving storm drainage systems and the protection of the delicate aquifer. Its design allows its use in new or already existing storm drainage, giving it retrofitting characteristics, saving expensive improvements elasticity in accordance with each situation.

Hydro-Cartridges is a very simple and flexible concept with a rugged construction aimed to last and perform its duties any time.

Hydro-Cartridges also can be used by environmental enforcing agencies as a valuable tool to monitor and control dangerous situations

StreamGuard™...THE FUTURE OF INLET PROTECTION

Description

A StreamGuard™ Type II Catch Basin Filter (CBF) consists of a specially designed, nonwoven polypropylene felt filter bag which is suspended in the catch basin using a nonwoven polypropylene felt fabric "boot". *StreamGuard*™ units can be quickly installed in most catch basins by simply removing the catch basin grating, placing the filter in the basin opening, and replacing the grating. The weight of the grating holds the catch basin filter in place, even when full. There are four (4) *StreamGuard*™ models to choose from: oil and sediment (OS), industrial (IND), sediment (S) and trash (T).

Operation

The *StreamGuard*™ Type II-OS has been specially designed to remove oil, grease, and sediment from stormwater runoff. The unit differs from the sediment only unit in that it has a measured amount of specially modified hydrophobic and oleophilic polypropylene oil absorbent in the bag. Every major component of the *StreamGuard*™ Type II-OS (the felt fabric bag, felt fabric "boot" and special oil-absorbent media) attracts oil like a magnet. As water enters the catch basin inlet, it is directed into the filter bag. Contaminants are initially filtered from the runoff by the boot, and then the bag and absorbent media where oil, grease and sediment are captured. Soon this felt cloth is masked over and then the bag operates in the "normal" mode with the bag ¾ full of water. This gives the oil-absorbing media more time to capture the oil and grease, also allowing the sediment to drop directly into the sediment trap zone (see drawings on reverse side). Water flow is down through the oil-absorbing media and then through the flow holes back up to the overflow pockets where it is released to the catch basin. During the peak storm periods, emergency overflow openings allow the unit to be bypassed at a rate of up to 200 gallons per minute (the industrial unit does not have this overflow mechanism).

Maintenance

Maintaining *StreamGuard*™ CBFs is a quick and inexpensive procedure; replacement frequency depends on sediment/oil loading and runoff volume. The maintenance interval can be as often as weekly at busy construction sites for the sediment (S) only unit. For use in parking lot applications the oil and sediment (OS) unit is an excellent choice. Frequency of replacement is very site dependant; a good rule of thumb is to replace the filter every 3-5 inches of rainfall. For industrial (IND) applications with heavier sediment and oil loads, more frequent maintenance may be required. The *StreamGuard*™ is disposable, so maintenance of the units is as simple as removing the used unit (using the handy retrieval strap attached to the boot) and installing a new one. In all cases it is recommended that a monitoring program be put into place after the installation of any catch basin filter.

Disposal

Disposal of the material accumulated in the *StreamGuard*™ catch basin filters (CBFs), and the filters themselves is dependent on the nature of the pollutants being collected. At some sites, the Type II-OS CBFs could contain up to 50 percent oil (dry weight basis). In certain industrial applications, the accumulated sediment may contain other contaminants (e.g., heavy metals) and should be managed in accordance with local, state and federal regulations. In all cases, the generator is responsible for the proper characterization and disposal of the waste.

Applications

StreamGuard™ Catch Basin Filters provide a cost-effective BMP for removal of oil, grease, sediment and floatables at *industrial facilities, car and truck washing locations, construction sites, steam cleaning operations, parking lots, ports, marinas, shipyards, airports, intermodal rail yards, service stations, truck stops, shopping malls and many other sites where sediment, oil, trash and floatables can enter storm water drainage systems.*

Specifications

Type II-OS (oil and sediment)

Construction material: polypropylene
Maximum overflow rate: 200 GPM (except IND model)
Absorbent Material: Polypropylene (oleophilic)
Optimum filtration rate: 10 GPM (Type OS)
Boot adapter dimensions:
Nominal depth: 24"

Note: Boot adapter may be trimmed to size for a neat appearance

Stormwater Services Corporation (SSC) expressly warrants this product to be free from defects in material and workmanship. Except as specifically provided above, SSC makes no representation or warranty, either expressed or implied, with respect to the Catch Basin Filter, including its performance, merchantability, or fitness for a particular purpose. In no event will SSC be liable for any lost profits or consequential or special damages.

TECHNICAL DATA

*** WILL FIT ANY SIZE GRATE*

*** NO TOOLS REQUIRED FOR INSTALLATION*

*** ALTERATION OF EXISTING INLETS NOT REQUIRED*

*** CONTAINS OVERFLOW DRAINS SO UNIT NEVER OVERFLOWS EVEN IF IT IS NEVER CLEANED*

*** COMES COMPLETE WITH A 100% PERIMETER SKIMMER WITH TRASH SCREEN ATTACHED WHICH CAN BE REMOVED OR REPLACED WITH NO TOOLS REQUIRED*

*** ALSO AVAILABLE WITH UNIT IS AN ABSORBENT OIL COLLECTOR RING WHICH CAN BE ADDED OR REMOVED WITH NO TOOLS REQUIRED*

*** THE OIL COLLECTOR RING IS 100% AROUND THE INSIDE PERIMETER OF THE GRATE WHICH ALLOWS 90% OF ALL WATER ENTERING THE UNIT FROM ALL DIRECTIONS TO PASS THROUGH AND AROUND THE OIL COLLECTOR ENSURING THAT MOST OF THE OIL IS COLLECTED IN THE MEMBRANE*

*** UNIT CONTAINS AN INTERNAL DRAINAGE SYSTEM FITTED WITH A FILTER SILT SCREEN WHICH ALLOWS ALL REMAINING WATER THAT DID NOT GO UP AND THROUGH THE SKIMMER TO BE FILTERED AND DRAINED OUT, PREVENTING MOSQUITO BREEDING*

*** BECAUSE OF THE WAY THE UNIT IS CONSTRUCTED WITH THE REMOVABLE OIL TRAY AND TRASH SKIMMER, IT IS VERY ADAPTABLE TO NEW ITEMS OR REQUIREMENTS AT THE PRESENT TIME AND IN THE FUTURE*

APPENDIX B
STANDARD OPERATING PROCEDURE FOR ON-LINE MEDIA FILTERS

THE ROUGE RIVER PROJECT
A WORLD CLASS EFFORT
BRINGING OUR RIVER BACK TO LIFE

Online Media Filters: Field Installation, Maintenance and Evaluation

Standard Operating Procedure

RPO/CDM-FLD-0629

1.0 Scope and Application

This Standard Operating Procedure (SOP) defines how catch basin filters will be maintained and evaluated in the field. The results from the maintenance and evaluation activities will be used to estimate: (1) the cost of maintaining these filters; and (2) their effectiveness in removing pollutants from stormwater runoff entering the inlet.

2.0 Method Summary

Different types of catch basin filters and filter media will be field tested to qualitatively assess how they perform at removing sediment and oil from stormwater runoff. The maintenance requirements of each type of filter will be assessed. Catch basin filters will be installed in seven catch basins at two gas stations. One station is located at the intersection of Merriman and Schoolcraft in the City of Livonia and the other is at the intersection of Newburgh and Ford Road in Westland. During the evaluation period, the following items will be recorded for various types of filters: 1) all sediment captured by the filter will be weighed and recorded; 2) comments and observations about the oil absorbing characteristics; 3) a record of the time needed to maintain the filter; and 4) and rainfall from an on-site rain gage.

3.0 Safety, Restrictions, and Limitations

3.1 Safety

The primary safety concerns related to this survey are traffic and exposure to contaminated runoff. Traffic safety pertains to insuring that field personnel maintaining the catch basin filters minimize traffic obstructions and are not struck by cars entering or exiting from the gas stations. This will be prevented by the placement of traffic cones around the catch basin where work is being performed. In no case should field personnel leave the catch basin without first replacing the lid. Field personnel must be aware of the potential for exposure to contaminated water or sediments. Latex gloves should be worn at all times, and no food should be ingested without first washing hands with soap and water. Confined space entry will not be allowed.

3.2 Restrictions and Limitations

Field personnel shall be sensitive to the business needs and requests of the gas station manager and employees. Maintenance work should be done between the hours of 10:00-11:00 a.m. or 2:00 - 4:00 p.m. when traffic volume is lower. Any requests or restrictions made by the station manager or employees will be adhered to whenever possible.

4.0 Equipment and Materials

The required equipment is listed below:

-Rain gage
-Small water pump for water removal
-Small shovel for sediment removal
-Five gallon buckets for sediment and filter collection
-scale for weighing sediment
-manhole pick / crowbar
-extension cord to plug in pump
-traffic cones
-gloves for handling filter
-30 gallon plastic trash container

5.0 Procedures

5.1 Informing Gas Station Employees

Each time field personnel go to the gas station for either maintenance or installation of the filters, the field personnel must identify themselves to the employees of the gas station and state the purpose of the visit. After the work has been completed, employees of gas station will be told that the visit is over and field personnel are leaving the site.

5.2 Rain Data

Before any filter evaluations are performed a non-recording rain gage must be installed onsite at the gas station. The rain gage will be installed at a location where there are no obstructions overhead. Once a suitable location for the rain gage has been identified, field personnel must receive permission from the gas station manager to install the rain gage.

Throughout the portion of the year when temperatures remain above freezing (>0°C), a record of rainfall will be kept by observing the rain gage installed at the gas station. Field personnel must check the gage after each event to determine the amount of rain that occurred during the specific event. This rain data will be recorded on Form 219 that is attached to this SOP. The gage must be read as soon as possible after each rain event to ensure accurate records. Evaporation can impact the results if the readings are not performed until sometime later.

Once the air temperatures are consistently below freezing, a record of rainfall volume will be maintained by accessing rainfall data from heated rain gages located in the watershed. The nearest heated rain gages are located either in Oakland County or at Metro Airport. Call Tim Brown at (810) 452-9194 to get rain data from heated rain gages in Oakland County.

5.3 Catch Basin Filter Installation and Removal

Catch basin filters are designed to hang down, inside of the catch basin. When installing the filter, field personnel should make sure that the filter is installed as prescribed by the manufacturer (refer to the attached manufactures's instruction). Both the filter and the catch basin need to be inspected prior to installation. If either structure is found to be damaged, an assessment of it's functionality needs to be performed. There should be a tight seal between the filter and the catch basin rim to avoid water bypassing the filter. Field personnel should make certain that the catch basin is functional after the filter has been installed. The lid should be firmly in place and flush with the surrounding pavement. Care should be exercised when removing the filter to prevent damaging the filter or losing any sediment that has been trapped in the filter. Once a filter is removed, the catch basin lid should be immediately replaced.

5.4 Maintenance & Monitoring

When monitoring the various types of catch basin filters, there are three items of importance:

1. The volume of water that has flowed through the filter
2. The amount of sediment caught in the filter
3. The performance of the oil absorbing media

The amount of flow through the filter will be monitored by observations during rain events. The amount of sediment captured by the filter will be determined by removing the sediment from the filter, drying the sediment and weighing it. The performance of the oil absorbing media will be evaluated by visual observation.

Initially, the filter should be checked during every rainfall of five hundredths of an inch (0.05") or more. Field personnel should inspect the site to see if the filter is draining properly and take photographs if any unique situation occurs. Unique situations would be items such as drainage during heavy downpours or ponding around the catch basin during light rain fall.

The filter should be checked for sediment buildup and, the oil absorbing media should be inspected. Initially the filter should be inspected on the next dry working day after every rain event. Inspections will be performed less often once it is established how often maintenance needs to be performed.

The sediment can be left in the filter as long as the sediment does not block the filter's operation. If the sediment causes the filter to back up, the filter should be removed and cleaned out. Water may need to be pumped out of filter to remove sediment. Removing sediment can also require the removal of the filter from the catch basin. Sediment that is removed needs to be dried and weighed.

Drying the sediment will be performed by placing the sediment in five gallon buckets. The buckets will be kept open and allowed to dry at a Wayne County location to be arranged by Lou Regenmorter. Once the sediment is dry, it will be weighed and recorded.

Whenever checking for sediment, the oil absorbing media should also be inspected. If the media appears saturated with oil or there is a heavy film of oil inside the filter that the media is failing to remove, the media should be changed. Any observations or changes in the absorbing media need to be documented in the field notes.

When a visit is made to inspect or maintain the filters a record of the visit must be documented on Form 220 attached to this SOP. General field notes should be made for each visit.

5.5 Specific Maintenance & Monitoring

5.5.1 StreamGuard™ made by FOSS Environmental Services Co.

The StreamGuard™ filter is a fabric filter. It is a sack designed to hang down inside of the catch basin. It is secured by inserting the top of the filter between the catch basin lid and rim. The filter is designed to funnel storm water into the sack. The water flows out small flow holes in the sides during lower storm flow or out overflows near the top of the filter during high storm flow. An oil absorbing media is placed in the sack to collect oil carried in with the stormwater. The filter has a removal strap to be used to pull the filter out of the catch basin.

This filter is installed by removing the catch basin lid placing the filter in the catch basin and replacing the lid. The catch basin rim should be wiped clean of dirt and grit before the filter is placed inside. It is important for the top edge of the filter to completely cover the rim of the catch basin to prevent bypassing and provide maximum holding power. Once the lid is replaced any part of the filter fabric outside of the catch basin shall be trimmed to a uniform length of about two inches.

The StreamGuard™ filter will be removed by pulling the catch basin lid off and pulling the filter out. It is very important to either hang on to the filter-removal strap or secure the strap to the catch basin lid when removing the catch basin lid. If the removal strap is not secured the filter will fall into the catch basin. It may take two people to remove this filter. The first time the filter is removed, two people should perform the removal. After the first removal, field personnel can determine if two people are necessary for future filter removals.

The StreamGuard™ filter can be cleaned for reuse. Any sediment that has been collected should be removed and weighed to evaluate the performance of the filter. When a filter is removed, the sediment should be carefully dumped into a bucket. Some of the sediment may be pulled out of the filter by hand if necessary. It is important not to get the oil filter media in with the sediment. The oil absorbing media may need to be removed by hand set aside and replace after sediment is removed. When cleaning the filter it is more important not to lose any sediment, than it is to get all the sediment out of the filter. Once the filter is cleaned out and the oil absorbent media replaced, the filter can be placed back inside the catch basin.

5.5.2 Hydro-Cartridge® made by Geotechnical Marine Corp.

The Hydro-Cartridge® is a fiberglass filter that is inserted inside of a catch basin to remove sediment and oils from the stormwater runoff that enters the basin. The filter slows the flow of stormwater, allowing: (1) oil to separate and float to the top of the standing water in the filter; and (2) sediments to settle to the bottom of the filter.

The Hydro-Cartridge® hangs from the rim of the catch basin. Installation of the Hydro-Cartridge® is performed by removing the catch basin lid, cleaning the dirt and grit off the catch basin rim, placing the filter in the catch basin with the filter's top edge resting on the rim, and replacing the catch basin lid.

The Hydro-Cartridge® has a oil absorbing media that will require regular maintenance. The oil absorbing media is located at the top of the filter (refer to the attached manufacturer's document). The media will be removed and replaced when oil is visible on the surface of the standing water in the filter or the media appears saturated. Field personnel will use their best judgement and experience to determine when the media needs to be changed.

The Hydro-Cartridge® will collect sediment in the bottom of the filter and will require cleaning. The sediment that collects at the bottom of the filter will be measured from the ground surface during each site visit. After the filter is installed, the depth from the catch basin lid to the bottom of the filter will be measured. Each time the field personnel check on the filter, a depth measurement should be taken from the rim to the surface of the sediment. The difference in the depth to the filter bottom and the depth to the surface of the sediment equals the depth of the sediment. This depth should be noted in the field notes.

When the sediment reaches a depth of three inches above the bottom of the filter or when the filter begins to backup, the sediment will be removed. The filter will have to be removed from the catch basin to remove the sediment. First, the water in the filter will have to be pumped out. When pumping the water out, it is important not to pump out any sediment or oil if possible; the end of the pump tube should be kept below the surface of the water but above the sediment. If this is impossible, the field personnel will have to pump water into a container such as a 30 gallon trash barrel. After the sediment has been removed from the filter, the water in the barrel can be poured back into the filter insuring that no sediment left the filter without being weighed.

Once the filter is empty of water, it will be removed from the catch basin. The sediment is then removed and placed in a five gallon bucket for weighing. When removing sediment it is more important not to lose any sediment than it is to get all the sediment out of the filter. The filter should be replaced as described in the installation process.

5.5.3 Grate Inlet Skimmer Box made by Suntree Isles, Inc.

The Grate Inlet Skimmer Box is a fiberglass catch basin filter. The filter has two main parts; a skimmer tray with oil absorbing media and a box with screen filters. During a storm, runoff will first flow into the skimmer tray where oil absorbing media removes any oil carried along with the stormwater. The stormwater then overflows into a box located under the skimmer. The box has screen covered holes along the sides and bottom. The screens filter out sand and other debris from the stormwater. If the stormwater flow exceeds the capacity of the screens the top of the box has holes with no screens which allows the water to bypass the filter and overflow.

The Grate Inlet Skimmer Box is installed inside the catch basin. Installation of the Grate Inlet Skimmer Box is performed by removing the catch basin lid, cleaning the dirt and grit off the catch basin rim, placing the filter in the catch basin, resting the top edge on the rim, and replacing the catch basin lid.

The filter is visited after each rain event. The oil absorbing media should be removed and replaced when the media appears saturated with oil. Field personnel will have to use their best judgement and experience to determine when the media needs to be changed.

The Grate Inlet Skimmer Box will collect sediment in the bottom of the filter box. This box will require periodic cleaning. The sediment that collects at the bottom of the filter will be measured from this surface. After the filter is first installed, the depth from the catch basin lid to bottom of filter with no sediment is measured. Each time the field personnel checks on the filter, the depth to the sediment should be taken. When the sediment reaches a depth of three inches above the bottom of the filter or when the filter begins to backup, the sediment should be removed.

To remove the sediment, the filter will have to be removed from the catch basin. The sediment will be remove and placed in a five gallon bucket for weighing. When removing sediment it is more important not to lose any sediment than it is to get all the sediment out of the filter. The filter should be replaced as described in the installation process.

5.5.4 Gullywasher™ made by Aqua-Net, Inc.

The Gullywasher™ is an aluminum basket which holds filter media. The cylindrical basket hangs from a tray which rests in the catch basin lid. The basket is made of wire mesh with an open top and wire mesh bottom. Inside the basket is a second wire mesh cylinder that divides the center of the basket from the outside of the basket. The filter media is placed in the space between the center area and outside edge. Filter media is also placed in the bottom of the center portion of the basket. The filter media is an absorbent packed in plastic mesh booms or bags. The basket is hung with four cable straps to a tray. The tray is designed to hold the basket under the catch basin lid, and to funnel the stormwater into the center of the basket. During heavy flow, storm water will bypass the filter between the top of the wire basket and the bottom of the tray.

The Gullywasher™ is installed inside the catch basin. Installation of the Gullywasher™ is performed by removing the catch basin lid, cleaning the dirt and grit off the catch basin rim, placing the filter into the catch basin by means of the installation straps, resting the top edge on the rim, and replacing the catch basin lid.

The filter will be visited during rain events as often as possible. When the filter backs up and overflows instead of filtering the storm water, the filter media will need to be changed. Field personnel will determine when the filter media needs to be changed.

There are several steps that must be taken to monitor the amount of sediment the Gullywasher™ captures. Before the filter is installed the media should be soaked and placed into the basket. The basket and wet media will be weighed prior to installation. When the time comes to change the media the filter, the basket and media should again be weighed. The difference of the before and after weight will be the amount of sediment captured.

To change the Gullywasher™ media, the filter will have to be removed from the catch basin. Removal of the Gullywasher™ is performed by removing the catch basin lid, attaching the installation straps to the Gullywasher™ tray, and pulling the filter out of the catch basin. Removal will be done by two people the first time. Field personnel can decide if two people are needed on future removals.

Once the Gullywasher™ is out of the catch basin, the filter media can be changed. The filter media will be gently removed from the basket and placed in bags, and the bags containing the filter media will be marked with the time and date removed. New filter media will be placed in the Gullywasher™ and the filter will be replaced as described above.

6.0 Filter and Sediment Collection

6.1 Oil Absorbent Material

All the filters are designed with an absorbent media that collects oil and gasoline. The oil absorbent media should be collected and stored after it is saturated and can no longer be used in the filter. Every time the oil absorbent media is removed from a device it should be placed in a five gallon bucket or plastic bags with the following information included with the material: date removed, date installed, and reason why it was removed. If there is no reason to store the used filters, a means of disposing of the filters will be arranged by the field personnel through Wayne County Department of Environment.

6.2 Sediment Collection

Sediment collected from catch basins filters will be collected and stored in five gallon buckets. Sediment from each type of filter system will be kept in separate buckets. Each bucket must be labeled to identify which filter it came from and the date removed. Once the buckets of sediment are dried and weighed it may not be necessary to keep the sediment. Sediment disposal should be arranged by the field personnel through Wayne County Department of Environment.

7.0 Field QA/QC

Field QA/QC procedures will include calibration of the scale used to weigh sediment accumulations. Field crews will document all calibration and maintenance activities, observations, field measurements and cleaning in either field logbooks or on Forms 219 and 220. Since no laboratory analyses will be performed under this SOP, laboratory QA/QC procedures are not applicable.

8.0 Computations, Documentation, and Reporting

All field notes will be made on Forms 219 and 220. A report summarizing the maintenance and effectiveness of each catch basin filter will be made from field notes.

EXECUTIVE SUMMARY

This report summarizes and evaluates Best Management Practices (BMPs) that are potentially appropriate for Retail Gasoline Outlets (RGOs). This report also summarizes and evaluates several studies that characterized the chemical quality of storm water runoff from RGOs. These prior studies are important because they provide a basis for evaluating and recommending appropriate BMPs for RGO applications.

Based on the results of several storm water studies, it does not appear that the water quality of storm water runoff from properly operated and maintained RGOs is appreciably different than water quality from a number of other sources, including parking lots and roads. Additionally, in most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand are below the NPDES storm water permit limitations established by several states for vehicle-related activities.

Properly operated and maintained RGOs may currently be implementing a variety of BMPs to reduce storm water contaminant concentrations. Two basic categories of BMPs are presented in this paper. The first category consists of practical pollution prevention measures. These are the basic, common operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that involve installation of equipment to reduce contaminant concentrations in storm water runoff.

Practical pollution prevention measures are appropriate for RGOs because they are simple, cost effective, and protective of storm water quality. In contrast, the storm water treatment BMPs are less appropriate for RGOs because they are ineffective or unproven for treatment of low contaminant concentrations and are relatively expensive to install and maintain.

STORM WATER BEST MANAGEMENT PRACTICES FOR RETAIL GASOLINE OUTLETS

SECTION 1.0 – INTRODUCTION

1.1 General

Storm water Best Management Practices (BMPs) are practices used to prevent or reduce the pollution of surface waters caused by storm water runoff. This report summarizes and evaluates BMPs that are potentially appropriate for Retail Gasoline Outlets (RGOs). This report also summarizes and evaluates several studies that characterized the chemical quality of storm water runoff from RGOs. These prior studies are important because they provide a basis for evaluating and recommending appropriate BMPs for RGO applications.

The Western States Petroleum Association (WSPA) commissioned this study in response to existing and anticipated regulation of storm water discharges from RGOs. In some cases, municipal ordinances require owners and operators of RGOs to implement BMPs that may not have beneficial effects on storm water quality. Additionally, the required BMPs may not be consistent between municipalities, causing compliance difficulties for RGO owners and operators. The information in this report is based on a variety of sources, including an extensive literature search and review; discussions with numerous researchers regarding on-going and unpublished studies; a review of local, state, and federal regulations; and a review of storm water BMPs currently utilized by WSPA members.

1.2 Background

In 1972, the Federal Water Pollution Control Act (also known as the Clean Water Act, or CWA) was amended to provide that any discharge of pollutants from a point source to waters of the United States is effectively prohibited unless it is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Although this technically prohibits discharge of pollutants in storm water, the focus at that time was on the bigger problems of industrial waste and sewage treatment.

As more significant sources of water pollution were brought under control, the impact of pollutants in storm water began to receive greater attention. Water quality studies conducted in the 1970s and 1980s identified urban runoff as a diffuse, or nonpoint, source of pollution. In response to these studies, the 1987 amendments to the Water Quality Act added Section 402(p). This section established a comprehensive, two-phased approach for the U.S. Environmental Protection Agency (EPA) to follow in addressing storm water discharges. Five types of storm water discharges are covered under the Phase I program. Dischargers within these five categories, listed below, were required to obtain permit coverage before October 1, 1992:

a. A discharge for which a permit has been issued prior to February 4, 1987.
b. A discharge associated with industrial activities.
c. A discharge from a municipal separate storm sewer system serving a population of 250,000 or more.
d. A discharge from a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000.
e. A storm water discharge determined by the EPA Administrator or the State to contribute to a violation of a water quality standard or to be a significant contributor of pollutants to the Waters of the United States.

Storm water discharges from commercial facilities, such as RGOs and parking lots associated with other commercial operations, are not included under the Phase I regulations. However, Phase II regulations now being promulgated are expected to increase the number and type of dischargers required to obtain NPDES permit coverage for storm water discharges. EPA, in a draft Phase II report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits but are proposed for regulation in Phase II. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees.

In addition to potential regulation under state and federal programs, RGOs are likely to be regulated by local municipalities. Municipalities, as part of their mandated storm water management programs, are required to monitor and control pollutants in storm water discharges from their municipal storm drainage systems. Methods of control may include regulating storm water discharges from facilities, including RGOs, that are identified by municipalities as contributors of pollutants to the municipal storm drain system.

1.3 Water Quality of Storm Water Discharges from RGOs

To evaluate the BMPs appropriate for use at RGOs, it is necessary to develop an understanding of the types and concentrations of chemicals typically found in storm water runoff from RGOs. For this reason, summaries of three recent studies that characterized the water quality of storm water discharges from RGOs are included in this report. These studies are described in the following subsections.

1.3.1 WSPA/API RGO AND COMMERCIAL PARKING LOT STUDY

A WSPA/API storm water runoff study (WSPA/API, 1994) was conducted on six retail gasoline outlets (RGOs) and four commercial parking lots. The objective of the study was to characterize simulated storm water runoff from RGOs and compare the results with simulated runoff from commercial parking lots and published urban "background" values. The analytical results from this study are presented in Table 1.

The WSPA/API study was conducted on RGOs that were "normally operated and maintained." For the purposes of that study, "normally operated and maintained" signifies that the RGOs utilize Best Management Practices (BMPs) to minimize the buildup of potential storm water contaminants on exposed areas. These BMPs include regular sweeping of exposed areas, regular site inspections, and standardized spill response procedures. All of the RGOs were high-volume retailers, and three conducted on-site vehicle maintenance or repair services.

The study demonstrates that for the constituents analyzed, median event mean concentrations (EMCs) of chemicals in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by the National Urban Runoff Program (NURP). Furthermore, for the constituents analyzed, no significant differences were found between median EMCs of runoff from RGO pump islands and driveways. These results indicate that fueling activities at normally operated and maintained RGOs do not contribute significant additional concentrations of chemical constituents to storm water runoff.

1.3.2 DISCRETE LAND USE TYPES STUDY

Another recent study (Shepp, 1995) investigated the petroleum hydrocarbons and general water quality characteristics associated with four discrete land uses in the Washington D.C. Metropolitan Area. The monitored sites included a parking lot where cars typically are parked for relatively long periods; a parking lot for a commercial convenience store, where short-term parking occurs; a street; and an RGO. Details were not provided regarding the throughput or BMPs used at the RGO monitored for the study, however; the station is described as a "gas and go" style facility, providing no automotive service or maintenance. Samples were collected from 26 storm events for the longer-term parking lot, 14 storm events for the short-term parking lot, 9 storm events for the street, and 13 storm events for the RGO. The mean results, which are summarized in Table 2, indicate that the mean hydrocarbon concentration in runoff from the convenience commercial store is substantially higher than the closely grouped mean values for the RGO, longer term parking lot, and street. Similar results were reported for the majority of the other parameters measured.

1.3.3 ACTION PLAN DEMONSTRATION PROJECT

Sacramento County's Action Plan Demonstration Project (Uribe and Associates, 1994) characterized storm water runoff from RGOs and evaluated the use of mobile high-pressure washing as a BMP. The report presents the analytical results of storm water samples collected over two consecutive wet seasons from three RGOs in Sacramento County.

The Sacramento County project selected high-volume (more than 200,000 gallons per month), self-service RGOs with convenience markets and without automobile repair service bays for the study.

The initial analytical program for the collected samples included analyses for oil and grease, total suspended solids, metals (13 EPA priority pollutant metals plus aluminum and iron), polycyclic aromatic hydrocarbons (PAHs), and petroleum hydrocarbons. However, some of the metals, petroleum hydrocarbons, and PAHs were consistently not detected in samples collected from the first three storm events. On the basis of these results, the following parameters were selected for the remainder of the study:

- oil and grease
- total suspended solids
- heavy metals (cadmium, chromium, copper, lead, and zinc)

The analytical results from the study are presented in Table 3. The results of the study indicated that regular high-pressure washing of pavement surfaces at RGOs actually caused an increase in the concentrations of certain pollutants in storm water discharges.

1.4 Evaluation of RGO Storm Water Runoff Studies

The results of the three RGO storm water runoff studies described in the preceding subsections are summarized in Table 4. For comparison, Table 4 also presents the effluent limitations contained within draft or final NPDES storm water permits from several states that have promulgated effluent limitations for industrial facilities engaged in vehicle-related activities. Also presented are the mean concentrations for residential and commercial land uses from NURP (1983), a comprehensive study conducted from 1978 through 1983 with funding and guidance provided by EPA. The results of NURP provide insight on what can be considered background levels for urban runoff.

As summarized in Table 4, the mean concentrations of total suspended solids, lead, copper, and zinc in runoff from RGOs are generally below the background levels established by the results of NURP. Additionally, in most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand are below the limitations established for a number of NPDES permits, including storm water discharge limitations established for transportation-related industrial facilities located in Missouri, Alabama, Oregon, and Louisiana. On this basis, it appears that the concentrations of chemical constituents in storm water discharges from properly operated and maintained RGOs are below background concentrations and are generally below levels that require additional controls or treatment, as established by the effluent limitations developed for storm water discharges from sites where vehicle fueling, maintenance, and repair occur.

However, it should be noted that the preceding conclusions are based on the mean concentrations from samples collected from a total of ten RGOs. The analytical results for individual RGOs and storm events are variable, as would be expected based on typical variability in RGO age, construction, throughput, and management practices. The variability in analytical results for oil and grease and total suspended solids is illustrated on the histograms presented as Figure 1. In some cases, the results exceed the background concentrations established by NURP and/or the effluent limitations developed for vehicle-related sites. The variability in analytical results shown on this figure suggests that there may be cases where concentrations of specific chemical constituents in storm water discharges from RGOs are above levels where additional controls may be required. However, the histograms also indicate that the majority of the results are below concentrations where additional controls may be required, suggesting that, in most cases, the BMPs implemented at properly operated and maintained RGOs are effective and sufficient for preventing storm water pollution.

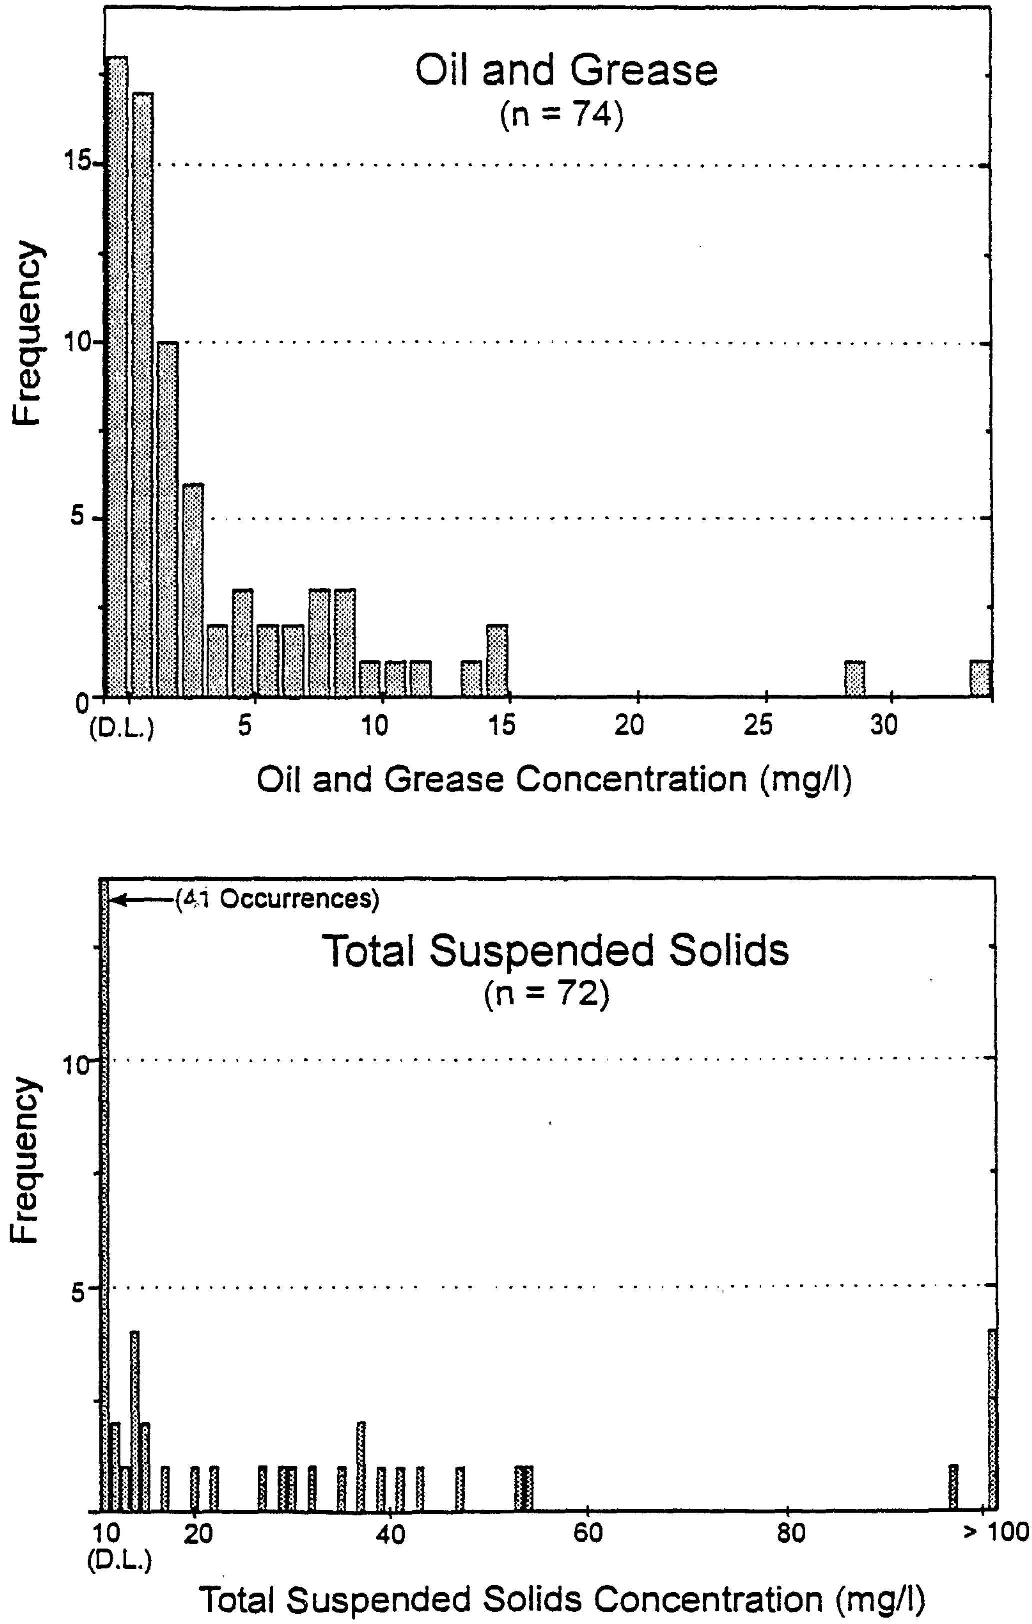

Figure 1 - Histograms of Mean Results for Oil & Grease and Total Suspended Solids from Three Recent Studies Characterizing Storm Water Runoff from RGOs

SECTION 2.0 -- BEST MANAGEMENT PRACTICES FOR RGOs

2.1 General

As described in Section 1.4 of this report, storm water discharges from RGOs contain concentrations of oil and grease, total suspended solids, heavy metals, and other constituents. Although the concentrations of these constituents from properly operated and maintained RGOs are often no higher than from other land uses, such as parking lots and streets, there may be a requirement to minimize pollutant loading of storm water through implementation of BMPs.

Two basic categories of BMPs are described in this report. The first category consists of practical pollution prevention measures. These are the basic, everyday operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that usually involve installation of equipment to treat storm water. The storm water treatment BMPs described in this report are limited to on-site treatment devices applicable to relatively small sites that lack the room necessary for traditional urban BMPs such as extended dry detention basins or wet ponds.

The first category of BMPs, pollution prevention measures, are preferred over storm water treatment BMPs because they are relatively simple and cost effective. The results of a recent survey of several WSPA/API member companies, representing several thousand RGOs across the western United States, indicated that the types of pollution prevention and source control practices that are described in this report are already being used at many RGOs. This approach for preventing pollution is endorsed by EPA as one of the best means of pollution control. In fact, the Pollution Prevention Act of 1990 set forth a national policy that:

> "...pollution should be prevented or reduced at the source whenever feasible; pollution that cannot be prevented should be recycled in an environmentally safe manner, whenever feasible; pollution that cannot be prevented or recycled should be treated in an environmentally safe manner whenever feasible; and disposal or other release into the environment should employed only as a last resort and should be conducted in an environmentally safe manner."

The second category of BMPs are storm water treatment measures. Storm water treatment may require a fairly significant capital outlay, along with operational and maintenance expenses, and may not result in an appreciable improvement in storm water quality. Treatment of storm water discharges from RGOs is problematic for two reasons. First, as characterized in Section 1.4 of this report, storm water discharges from RGOs typically carry relatively low concentrations of contaminants. The efficiency and removal rates for many structural BMPs at such low influent concentrations are questionable. Second, storms are often short-duration events with relatively high intensities. It is often difficult to effectively treat the necessary amount of rainfall that discharges from a 100 percent impervious RGO without storing a large volume of water. Creating on-site storage for the necessary volume of storm water runoff often is the most costly item in the overall BMP system (Bell & Nguyen, 1995). Nevertheless, structural BMPs may be required for sites where it has been demonstrated that operational practices are not sufficient to control pollutants. In addition, some municipalities require the installation of structural BMPs for new developments or significant remodels. The specific requirements vary greatly between jurisdictions, and it is recommended that owners and operators contact individual municipalities for specific requirements.

A description of practical pollution prevention measures and storm water treatment BMPs are described in the following sections.

2.2 Practical Pollution Prevention Measures Suitable for RGOs

The following are proactive practical pollution prevention measures that can be effective for all RGOs. The intent of these pollution prevention measures is to control pollutants to the extent that the treatment of storm water is unnecessary. A summary of these practical pollution prevention measures is presented in Table 5.

2.2.1 USING SPILL CONTAINMENT & OVERFILL PREVENTION EQUIPMENT

Using spill and overfill equipment for Underground Storage Tanks (USTs) can effectively reduce fuel spills during UST filling activities. Federal regulations have made installation of spill and overfill equipment mandatory for all RGO USTs installed after December 1988. For RGO USTs installed prior to December 1988, federal regulations will not require spill and overfill equipment until 1998; however, local and/or state regulations may require earlier installation. In addition, fuel pump shut-offs, including automatic shut-offs at each pump and a manual shut-off inside the building, are effective for preventing or minimizing the size of spills.

Proper maintenance of the spill containment equipment is required to ensure proper product delivery. The required maintenance includes regular removal of accumulated debris, water, and product.

2.2.2 POSTING SIGNS WARNING AGAINST "TOPPING OFF"

"Topping off" fuel tanks during fueling can lead to spills, which can potentially contribute hydrocarbon pollutants to storm water runoff. Posting high visibility signs, warning against "topping off" can be effective for minimizing these types of spills.

2.2.3 USING "HOLD OPEN" LATCHES ON DISPENSER NOZZLES

Proper use of "hold open" latches on dispenser nozzles can facilitate automated gasoline fueling and can minimize spills caused by improper fueling methods, including use of fixed objects such as gas caps, wallets, pieces of wood, etc., to keep dispenser latches open. It should be noted that "hold open" latches may not be allowed by local fire departments and may increase the potential for spills caused by customer drive-offs unless used in conjunction with break-away hoses.

2.2.4 PROVIDING CANOPIES AND USE OF CONCRETE FOR FUELING AREAS

Providing canopies over fueling areas can reduce storm water pollution caused by direct precipitation onto fueling areas. However, canopies may not be necessary for RGOs with effective good housekeeping and spill response procedures.

Portland Cement Concrete (PCC) can be used instead of asphaltic concrete in fuel areas. This is advantageous because asphalt soaks up fuel, or can be slowly dissolved by fuel, engine fluids, and other organic liquids. Over time, the asphalt itself can become a source of storm water pollutants.

2.2.5 AVOIDING STORM WATER RUNON

RGOs should be graded to prevent storm water runon to fuel islands and outdoor maintenance areas. Runon can also be prevented by installing berms, curbs, or valley gutters to redirect the runoff. It is also possible to redirect roof gutter downspouts so that they drain away from the fueling and maintenance areas.

2.2.6 MAINTENANCE PROCEDURES FOR EXISTING OIL & GREASE SEPARATORS AND OTHER TREATMENT BMPS

Any structural BMP, including oil and grease separators, drainage sumps, and catch basins, should be maintained regularly. This reduces the potential for re-suspension and transport of settled particulates, which can be a source of storm water pollutants. Proper maintenance of oil/grit separators includes periodic sediment clean out.

2.2.7 AVOIDING RGO WASH DOWNS

As described in Section 1.3.3 of this report, a study to evaluate the use of high-pressure washing as a storm water BMP was conducted for Sacramento County (Uribe and Associates, 1994). The results of the study indicated that regular high-pressure and high-temperature washing of pavement surfaces at RGOs can actually cause an increase in the concentrations of certain pollutants in storm water discharges. In addition, discharges to the street or storm drain system that result from RGO washdowns is prohibited by many municipalities. As an alternative, fuel dispensers should be regularly cleaned using a damp cloth or mop. Mop water should be discharged to a mop sink connected to the sanitary sewer. However, check with your local sewer authority regarding permitting or other requirements for mop water discharges to the sewer system.

2.2.8 SWEEPING EXPOSED AREAS

Regular sweeping of exposed areas, using hand brooms and/or vacuums, can be an effective storm water BMP. Sweeping may be most effective when conducted immediately prior to the wet season and forecasted rain events. Studies show that routine sweeping is effective in reducing concentrations of total suspended solids, particulate heavy metals, and hydrocarbons bound to particulates. In addition, pollutant removal rates are shown to vary directly with the frequency of sweeping. A street sweeping study in San Jose revealed approximate removal rates of 50 percent for heavy metals and total suspended solids when streets were swept once or twice a day (NVPDC, 1992). However, a significant reduction to less than 5 percent removal was observed when the frequency of sweeping dropped to once or twice a month (Pitt, 1979).

2.2.9 ELIMINATING NON-STORM WATER DISCHARGES AND ILLICIT CONNECTIONS

Non-storm water discharges and illicit connections are potentially significant sources of storm water pollution. An example of a non-storm water discharge is the wash water from vehicle or pavement washing that is discharged to the street or storm drain system. This type of discharge is prohibited by many municipalities. Examples of illicit connections are indoor drains or sinks that discharge to the storm drain instead of the sewer system. These illicit connections are also prohibited by most municipalities, and it is recommended that all RGOs be inspected to confirm that all illicit connections are eliminated.

2.2.10 STANDARDIZING SPILL RESPONSE PLAN

A standardized spill response plan ensures that spills are promptly detected, contained as necessary, and properly cleaned up. An effective plan provides a well-defined set of spill response procedures and establishes a training program to educate all employees about the procedures. Typical spill response techniques at RGOs include using shop rags for small spills and using absorbent materials such as vermiculite, sawdust, or cat litter for larger spills. In addition, there are commercially available adsorbent materials that can be recycled. Used shop rags should be stored in a closed bin for recycling by a cleaning service. Separate wet/dry vacuums also can be used for larger motor oil and antifreeze spills. Due to their potential flammability, spilled gasoline, solvents, or other volatile liquids should be removed using absorbent materials. Depending on the type of spill, the used absorbent materials may have to be disposed of as a hazardous waste.

2.2.11 TRAINING EMPLOYEES

Employee training is a key component of pollution prevention. Routine employee training can take the form of distinct BMP training programs or incorporating BMP training into existing employee safety or other general training sessions. An effective training program emphasizes routine employee observations of product deliveries to USTs and frequent inspections of self-serve fueling areas and other customer-related operations. RGOs with maintenance and/or repair facilities should also emphasize routine employee shop inspection to ensure that operations do not adversely impact storm water.

2.2.12 PROVIDING OVERHEAD COVERAGE OF VEHICLE MAINTENANCE AND REPAIR AREAS

Conducting vehicle maintenance and repair activities under canopies or inside buildings is an effective pollution prevention measure. Overhead coverage includes use of temporary roofs, permanent roofs, sheds, or indoor facilities. Overhead coverage prevents direct storm water contact with the maintenance area, which can potentially contribute automotive waste fluids to the storm water runoff.

2.2.13 PREVENTING DISCHARGES WHEN CHANGING FLUIDS

Preventing spills and other discharges in exposed maintenance and repair areas is an effective storm water BMP. A drip pan can be placed under a vehicle while disconnecting hoses, unscrewing filters, or removing other parts to capture the automotive fluids. However, if fluids are leaked onto exposed surfaces, proper spill response procedures should be performed, as described in Section 2.2.9 of this report.

2.2.14 USING PARTS CLEANING STATIONS

Using a self-contained parts cleaning station can prevent parts cleaning wash-off from contacting storm water. Parts cleaning wash-off can contain cleaning solvents, along with oil residues from the parts. Drip pans, drain boards, and drying racks can be installed as part of the cleaning station for drainage of parts cleaning wash-off into appropriate recycling or disposal equipment.

2.2.15 COLLECTING AND STORING FILTERS, WASTE OIL, AND OTHER FLUIDS

Proper collection and storage of oil filters, waste oil, and other fluids such as transmission fluid, degreasers, antifreeze, hydraulic fluid, and various cleaning solvents is an effective BMP. In addition, recycling these materials can significantly reduce the disposal costs associated with hazardous wastes. Many commercial recycling facilities pick up the wastes on site, but typically accept only separated wastes. Unseparated wastes are harder to recycle, and therefore, increase overall treatment costs. Used oil filters and fluids should be stored in covered drums. If the drums are stored in exposed areas, the drum exterior should be routinely checked for contaminants and wiped clean, if necessary.

2.3 Storm Water Treatment BMPs

In the event that the practical pollution prevention measures described above are determined to be insufficient, or in areas where additional controls are mandated, it may be necessary to install storm water treatment devices. Descriptions of the available treatment methods for RGO storm water runoff are provided in the following subsections. A summary of these treatment BMPs are included in Table 5. The BMPs described below are limited to those that can be used in urban areas where almost 100 percent of the surface is covered with structures or pavements, and where there is insufficient space available for relatively large structural storm water quality management facilities such as extended dry detention or wet ponds. The information presented is based on a review of published and unpublished studies, discussions with researchers with studies in progress, review of literature provided by manufacturers, and discussions with personnel from numerous regulatory agencies. The descriptions provide the approximate initial installation and yearly maintenance costs. Specific design information is not included in this report; however, references that provide sufficient design level information are cited and a list of useful references is attached to this report.

2.3.1 VEGETATIVE BUFFER AREAS

2.3.1.1 BMP Description

A vegetative buffer area (VBA), also referred to as a biofilter, is a nonstructural BMP designed to remove particulate pollutants by filtration through grass and infiltration through soil. According to U.S. EPA (1991), a VBA is designed as a permanent, maintained strip of planted or indigenous vegetation located between non-point sources of pollution and receiving water bodies to remove or mitigate the effects of non-point source pollutants such as nutrients, pesticides, sediments, and suspended solids. VBAs that are used as storm water conveyance systems usually are called grass swales. A schematic of a typical grass swale is presented as Figure 2.

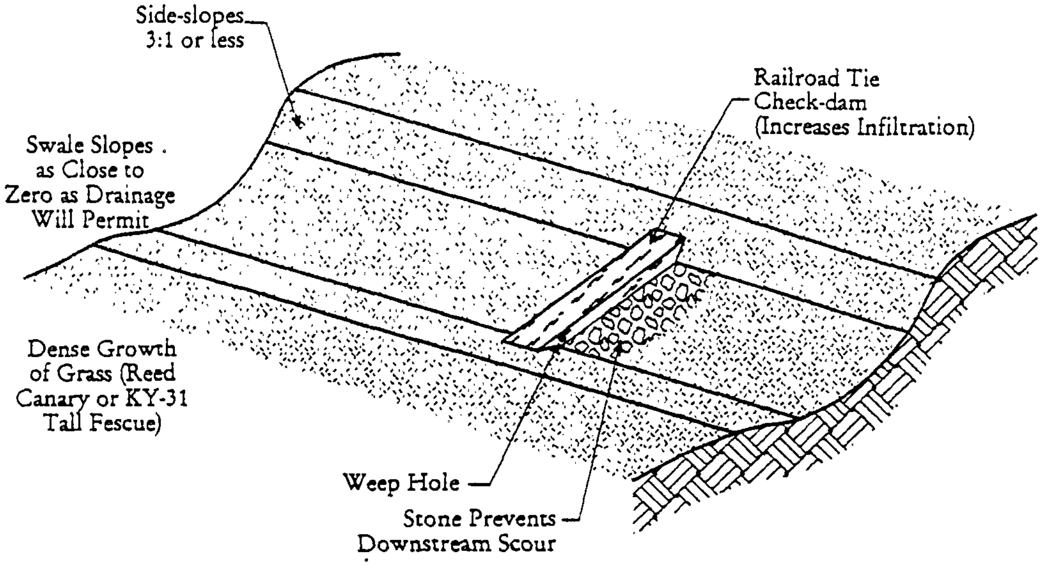

Figure 2 - Schematic of a Typical Grass Swale (MWCOG, 1987)

2.3.1.2 BMP Discussion

The vegetation in a VBA acts to filter and settle out particulate sediment and attached pollutants. The reduction in runoff velocity within the vegetated areas enhances the amount of settling and infiltration that occurs. Nutrient uptake, adsorption, and infiltration mechanisms may decrease the pollutant load entering the natural waterways. The reduced runoff velocity also lessens the potential for resuspension of particles as the flow travels toward the waterway (NVPDC, 1992). Results of modeling studies indicate that VBAs are somewhat effective in removing particulates, although settling is not optimized. VBAs are less effective in removing soluble nutrients (MWCOG, 1987).

Several methods have been proposed to size VBAs (Horner, 1988; FHWA, 1989; IEP, 1991; Tollner, et al., 1976). Using the method of Horner (1988) and assuming a 2-year event, a 3% slope, and a 4-inch grass height, the VBA area required to treat a 1/2 acre impervious site ranges between 400 and 650 square feet (Camp Dresser & McKee et. al., 1993). Typical design lengths for grass swales range from 100 to 200 feet (Horner, 1988). Studies have shown that swales are most effectively used on sites with a minimal amount of impervious cover, where peak discharge is less than 5 cubic feet per second (cfs) and velocities are less than 5 feet per second (fps). For these reasons, VBAs may not be a practical on-site BMP for RGOs.

Because VBAs rely on infiltration, fuel leaks or spills may potentially contaminate subsurface soils and, in some cases, groundwater. Even if discharges from leaks and spills can be avoided, metals and other contaminants may accumulate in the subsoils. As with the other infiltration BMPs, there may be waste discharge permitting requirements for VBAs (Camp Dresser & McKee et. al., 1993).

2.3.1.3 Range of Costs

According to MWCOG (1992), construction costs for a typical grass swale may range from $5 to $15 per linear foot, depending on the swale dimensions, grass type, and other possible characteristics. Maintenance costs for swales are estimated to be fairly low. Typical maintenance includes replacement of non-vegetated areas, periodic sediment removal, routine inspections, mowing, watering, and chemical applications.

2.3.2 POROUS PAVEMENT

2.3.2.1 BMP Description

Porous pavements use infiltration to control storm water runoff. This BMP is applicable as a substitute for conventional asphalt pavement on parking areas and low-traffic-volume roads, provided that the grades, subsoil characteristics, and groundwater table conditions are suitable for such use. In general, the grades should be very gentle to flat, the subsoil should have at least moderate permeability ($f \geq 0.27$ in/hr), and the depth to groundwater should be 2 to 4 feet (State of Maryland Department of the Environment). As indicated on Figure 3, porous pavements usually are layered systems, consisting of a porous asphalt surface overlying two layers of aggregate base course. The upper base course layer is designed as a filter layer, and the lower layer serves as a reservoir. A typical porous pavement asphaltic concrete mixture has approximately 16 percent voids, as opposed to conventional asphaltic concrete, which has 3 to 5 percent voids (NVPDC, 1992). The design of the actual porous pavement system is a function of several factors, including the load-bearing capacity of the subgrade, the expected traffic volume, and the storage capacity of the reservoir course layer. In turn, the storage capacity of the reservoir course layer is designed with respect to the depth to bedrock and the high water table, design storm, design method, allowable detention time, and existing subsurface soil infiltration rates. For sites with relatively pervious subgrade conditions, a porous pavement may allow infiltration of approximately 60 to 90 percent of the storm water runoff, depending on the rainfall intensity, existing subsurface conditions, and the actual design method used (MWCOG, 1987).

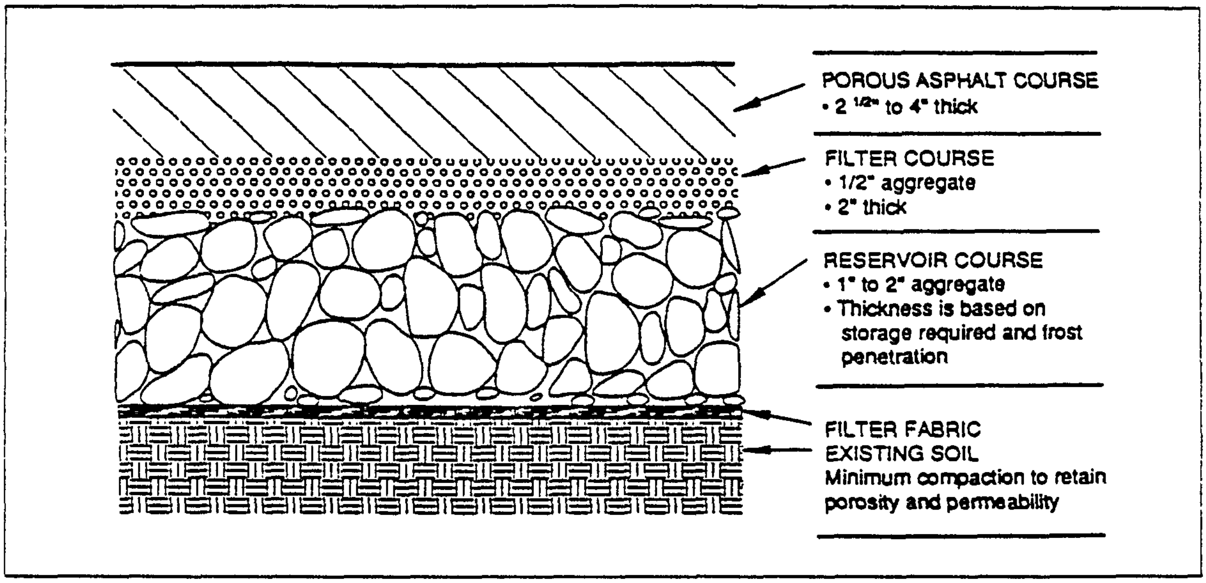

Figure 3 - Schematic of a Typical Porous Pavement (NVPDC, 1992)

2.3.2.2 BMP Discussion

Porous pavements may be an effective storm water BMP for some applications, however, because porous pavements are designed to allow rapid infiltration of storm water into subsurface soils, there is a significant potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. Also, depending on the types and concentrations of contaminants in the storm water discharge, metals and other contaminants may potentially accumulate in the subsoils. For these reasons, the use of porous pavements at RGOs is discouraged. Other problems associated with porous pavements are the high probability of pavement pore clogging from larger sized particulates and the absence of effective techniques to mitigate significant clogging that may occur. According to MWCOG (1992), 75 percent of all porous pavement systems surveyed in Maryland have partially or totally clogged within five years. For this reason, pretreatment of storm water to remove particulates often is recommended. Other disadvantages of porous pavements include the high level of required construction workmanship, the reduced strength of the pavement system, and the necessity of frequent inspections and maintenance after construction. Also, waste discharge permits may be required for infiltration BMPs, including porous pavements (Camp Dresser & McKee et. al., 1993).

2.3.2.3 Range of Costs

In general, a porous asphalt system may cost as much as 50 percent more than a conventional asphalt section and the necessary materials may be difficult to obtain in some regions of the country. An average additional construction cost over conventional asphaltic pavement was calculated by MWCOG (1987) for a 1-acre porous pavement BMP parking lot, using an 18-inch-thick reservoir course. The calculated construction cost was $75,054 greater than the cost of a conventional pavement section. This estimate did not include costs for initial site testing or pretreatment structures. Routine maintenance of porous pavements may constitute one to two percent of the initial construction costs (MWCOG, 1992).

2.3.3 INFILTRATION TRENCHES

2.3.3.1 BMP Description

An infiltration trench is a shallow excavation filled with a coarse stone medium to create an underground reservoir. The infiltration trench is designed to collect, store, and slowly exfiltrate storm runoff, relying on native subsurface biological, chemical, and physical pollutant removal mechanisms for treatment. A schematic of a typical infiltration trench is presented as Figure 4. The depth of the trench typically ranges from 2 to 10 feet, and the stone medium typically consists of washed aggregate with diameters of 1.5 to 3 inches (State of Maryland Department of the Environment). Infiltration trenches are only suitable for sites with relatively permeable subsurface conditions. It usually is recommended that an infiltration trench be installed at sites in conjunction with a pretreatment device (such as a filter strip, sump basin, or oil/grit separator) to remove particulate matter.

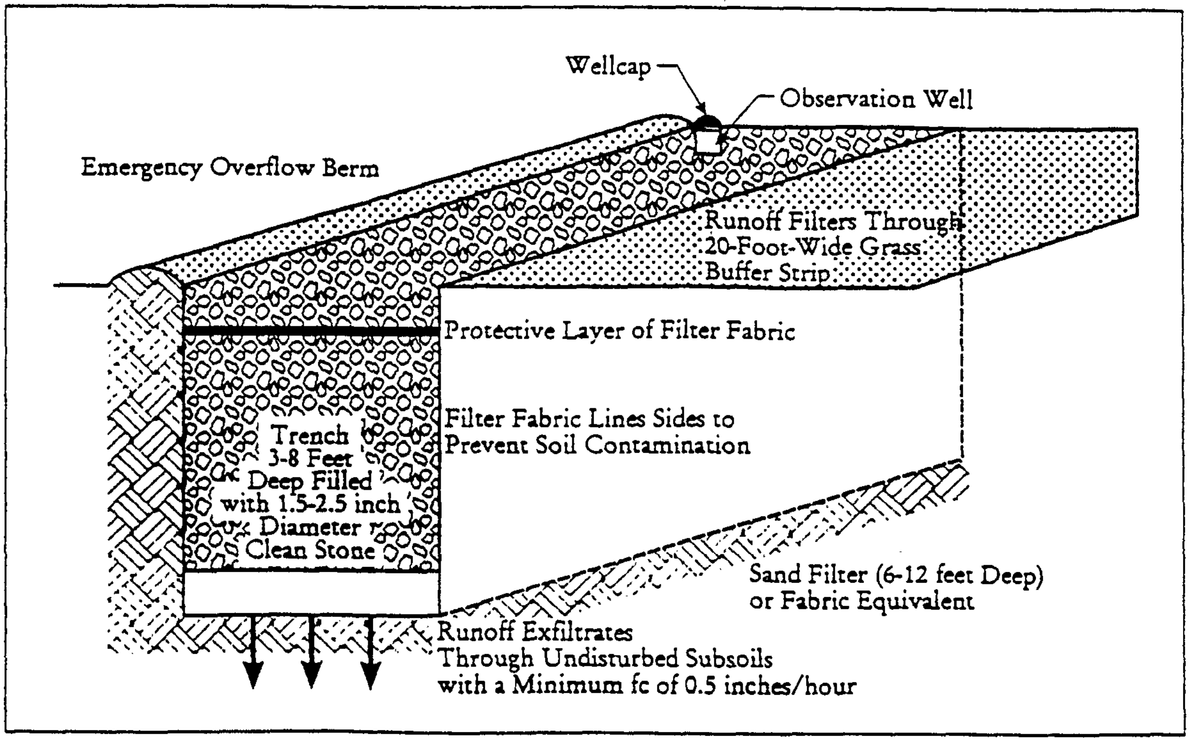

Figure 4 - Schematic of a Typical Infiltration Trench (MWCOG, 1987)

2.3.3.2 BMP Discussion

Where conditions are suitable, an infiltration trench is an adaptable BMP that effectively eliminates discharges containing soluble and particulate pollutants. However, as with other infiltration systems, trenches are not intended to trap coarse sediments and pretreatment is often necessary.

As with porous pavements, infiltration trenches are designed to allow rapid infiltration of storm water into subsurface soils. For this reason, there is a potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. RGOs that use infiltration trenches should be provided with a drainage sump equipped with a shut-off valve that can contain spills prior to discharge into the infiltration trench. In addition, depending on the types and concentrations of contaminants in the storm water discharge, metals and other contaminants may accumulate in the subsoils. There may also be waste discharge permitting requirements associated with use of infiltration trenches (Camp Dresser & McKee et. al., 1993).

Several studies of existing infiltration trenches have revealed high failure rates. A study by Galli (1992) indicated that less than half of the nearly 50 infiltration trenches surveyed were working as designed. Another study indicated that less than one-third still functioned after five years (Schueler, 1994). Failure of infiltration trenches usually is the result of clogging, which can be caused by a variety of factors, including inadequate pretreatment devices and/or an unsatisfactory subsurface location (including poor soil infiltration rates and close proximities to bedrock and/or water table).

2.3.3.3 Range of Costs

The construction cost of infiltration trenches is dependent on the excavation, stone fill, filter cloth, and inlet and outlet pipe costs. Construction costs of trenches with storage volumes ranging from 100 to 10,000 cubic feet range from $1,000 to $10,000 (Wiegand et. al., 1986). Operation and maintenance costs for infiltration trenches range from 5 to 15 percent of the capital cost of the facility, with an average cost of 9 percent (NVPDC, 1992). Also, possible replacement or rehabilitation of infiltration trenches may be required every ten years, and the cost of this may be equal to the initial construction cost (MWCOG, 1992).

2.3.4 SEPARATORS

2.3.4.1 BMP Description

The terms oil/grit separator, oil/water separator, oil and grease trap, and water quality inlet are often used interchangeably to describe treatment devices commonly installed to remove separate-phase hydrocarbons and, in some cases, sediment from storm water runoff. These devices are adaptations of the American Petroleum Institute (API) separator. A schematic of a separator is presented as Figure 5. The separator usually is a long basin with multiple chambers or vaults, typically installed below grade. The devices can be fairly easily fitted into an existing drainage system. The separator is designed to slow water flow which promotes settling of particulates and stratifies the flow to enhance phase separation. In this manner, the heavier particulates settle out, and the oil and grease rise for removal and disposal.

Another type of separator, called the coalescing plate interceptor (CPI) separator has a more advanced design. The CPI separator contains closely spaced plates, which enhance removal efficiencies. These are common for treating oil-bearing industrial wastewater, but, because they are typically designed to treat low flow rates with relatively high concentrations of oil, they are not typically used for treating storm water. A CPI separator generally achieves a greater removal efficiency than an API-type separator, but is more costly to purchase and operate.

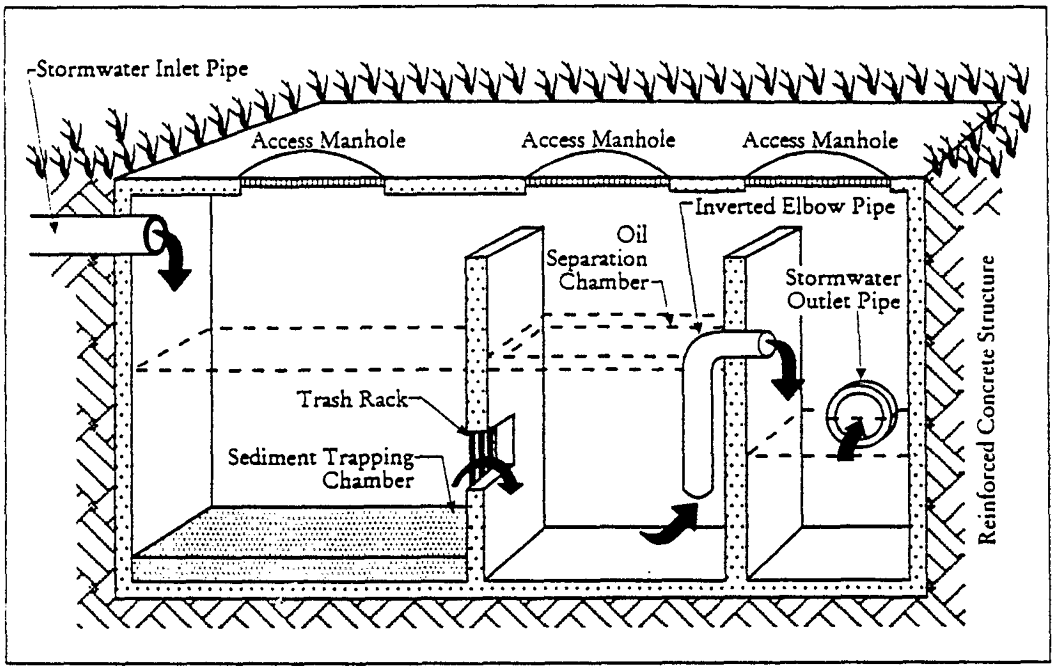

Figure 5 - Schematic of a Typical Oil/Grit Separator (NVPDC, 1992)

2.3.4.2 BMP Discussion

Although separators are commonly used, and are required in certain municipalities, recent research suggests that they are not appropriate as a storm water BMP. Separators are fairly costly to install and maintain, and most designs do not operate effectively with the low oil and grease concentrations typically found in properly operated and maintained RGOs. These devices are moderately effective for removing coarse-grained particulates along with hydrocarbons adsorbed onto particulates, but are typically not effective for removing fine-grained particulates or dissolved contaminants (NVPDC, 1992; MWCOG, 1987).

One significant problem with the use of separators as a storm water BMP is that the devices are typically designed as on-line systems with limited storage capabilities. This results in short detention times, which can cause significant re-suspension and discharge of pollutants. The

Northern Virginia BMP Handbook (1992) states that the average detention time of a conventional oil/grease separator system is barely more than one hour. Galli (1992) also demonstrated that the detention time within separators frequently is less than 30 minutes during storms. According to the California BMP Manual (Camp Dresser & McKee et. al., 1993), to provide the detention times necessary to effectively treat the majority of runoff resulting from a moderate storm event at a 1/2 acre paved site, a separator 57 feet long is required.

Alternative system designs treat the runoff only from the first approximate 0.06 to 0.12 inch of runoff and bypass the remainder for direct discharge. Although this methodology is somewhat effective in reducing the re-suspension of pollutants, it is ineffective for treating the volume of storm water customarily recommended or required. In Virginia, the Water Quality Volume (WQV), which is the minimum quantity of storm water that must be treated, is 0.5 inch. To store and effectively treat the volume of storm water that would result from this amount of rainfall, the separators would have to be significantly larger than those currently used at most sites.

In addition to alternative designs that bypass peak storm water discharges, several vendors currently offer innovative alternate designs that appear to significantly reduce the potential for re-suspension. However, these devices still rely on phase separation for removal of oil and grease, and have not been demonstrated effective for reducing the relatively low oil and grease concentrations typical of RGOs.

Maintenance is another factor that should be considered when evaluating separators. To function as designed, these devices require regular and frequent clean-out of trapped sediments to minimize re-suspension. The standing pool of water contained within the first chamber, along with the floating oil, must be periodically pumped out and replaced with clean water. Some commercial oil recyclers may accept this material for recycling; otherwise, it must be handled as hazardous waste. The maintenance requirements for separators have been termed the "Achilles heel" of existing separator technology. One study conducted in Maryland (Schueler, 1993) found not a single separator system out of more than 100 inspected that had ever been maintained. According to Schueler (1994), this poor track record is the result of several factors, including: a lack of outside companies that perform the required maintenance; a lack of enforcement by regulators; the expense associated with maintenance; and the actual or perceived toxicity of the trapped sediments, resulting in limited options for safe and economical sediment disposal.

2.3.4.3 Range of Costs

The purchase and installation costs for a standard API-type system ranges from approximately $5,000 to $15,000 depending on the size and location of the facility (NVPDC, 1992). In general, separator systems are costly on a runoff volume treated basis, averaging three to four times the unit cost of other BMPs such as trenches or sand filters (MWCOG, 1992). Maintenance costs are estimated to range from $1,000 to $2,000 per site each year (Schueler, 1994).

2.3.5 SAND FILTERS

2.3.5.1 BMP Description

Sand filters are a type of structural BMP that relies on sedimentation and sand filtration to remove total suspended solids, hydrocarbons, and heavy metals. Sand filter technology is rapidly advancing, and a number of sand filter designs are currently available. A schematic of one design, the D.C. Sand Filter, is presented as Figure 6. The D.C. Sand Filter is a three-chamber gravity-flow system. The first chamber and a portion of the second chamber contain a permanent pool, which traps grit and floating material, including oil and grease. The remaining portion of the second chamber contains a 24-inch-thick sand filter underlain by a layer of filter fabric, gravel, and collector pipes. Storm water entering the structure causes the pool to rise and overflow onto the filter. The water percolates through the sand and into the underdrain system. The water then enters a clearwell and is discharged through a connector pipe. Depending on the depth of the sand filter installation and the elevation of the street, storm drain, or other conveyance, it may be necessary to use a sump pump to discharge the treated storm water.

The D.C. Sand Filter is designed as an off-line system that treats only the initial discharge or water quality volume (WQV) from a storm event. The WQV typically used is the volume of runoff from the first 0.5 inch of rainfall. For a 1/2-acre, entirely impervious RGO, the WQV is approximately 900 cubic feet of water. A flow splitter is normally used to divert the remainder of the discharge for direct discharge. The WQV must be stored until it can be processed through the sand filter. To store and treat this volume of storm water, the underground vault needs to be 10 feet deep, 10 feet wide, and 23.5 feet long (City of Alexandria).

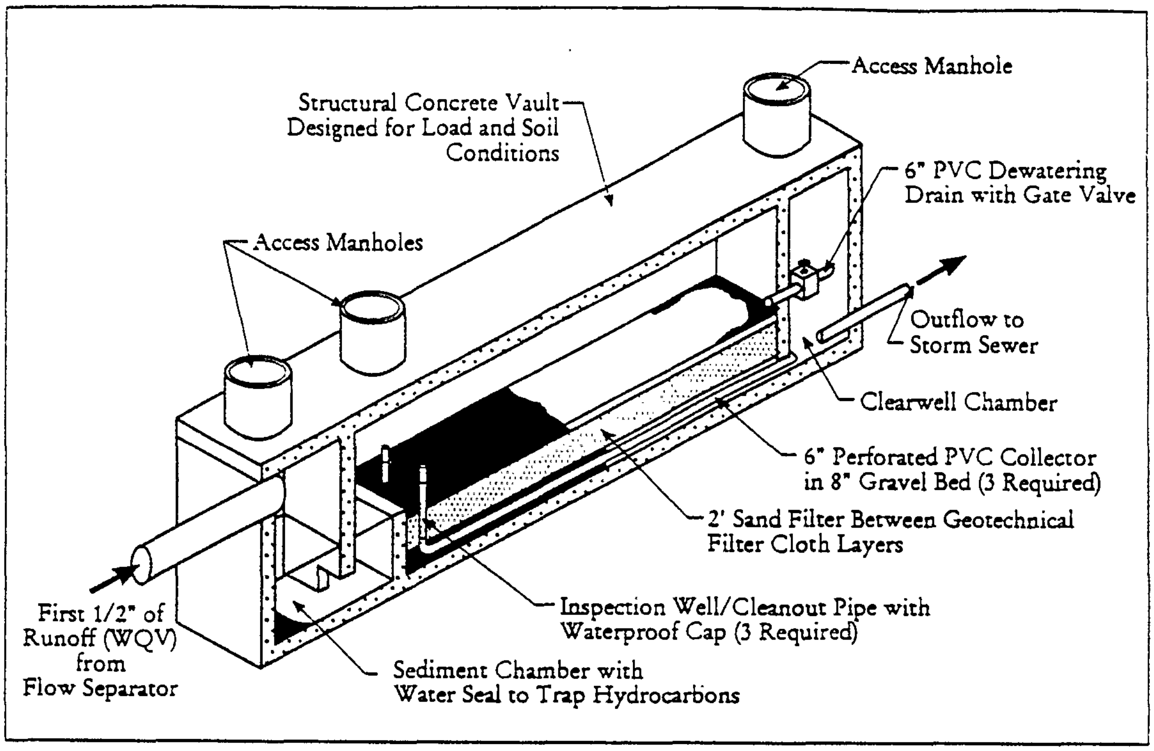

Figure 6 - Schematic of a D.C. Sand Filter (City of Alexandria, 1995)

A schematic of another type of sand filter, the Delaware Sand Filter, is presented as Figure 7. This filter consists of two parallel chambers connected by closely spaced notches in the top of the connecting wall. The filter is normally installed in-line. The first chamber is a sedimentation chamber with a permanent pool. Storm water flows into the first chamber through steel grates that cover the top of the chamber. As storm water enters the system, the permanent pool overflows through the weir notches into the second chamber, which contains an 18-inch-thick sand filter. The storm water percolates through the filter and is discharged through a filter fabric-covered grate located at the downhill end of the filter chamber. In some cases, a gravel bed and collector pipe are placed below the sand filter. The Delaware Sand Filter is designed to accept discharge until it has reached the capacity of the sedimentation chamber. The remaining storm water volume overflows and is discharged without treatment.

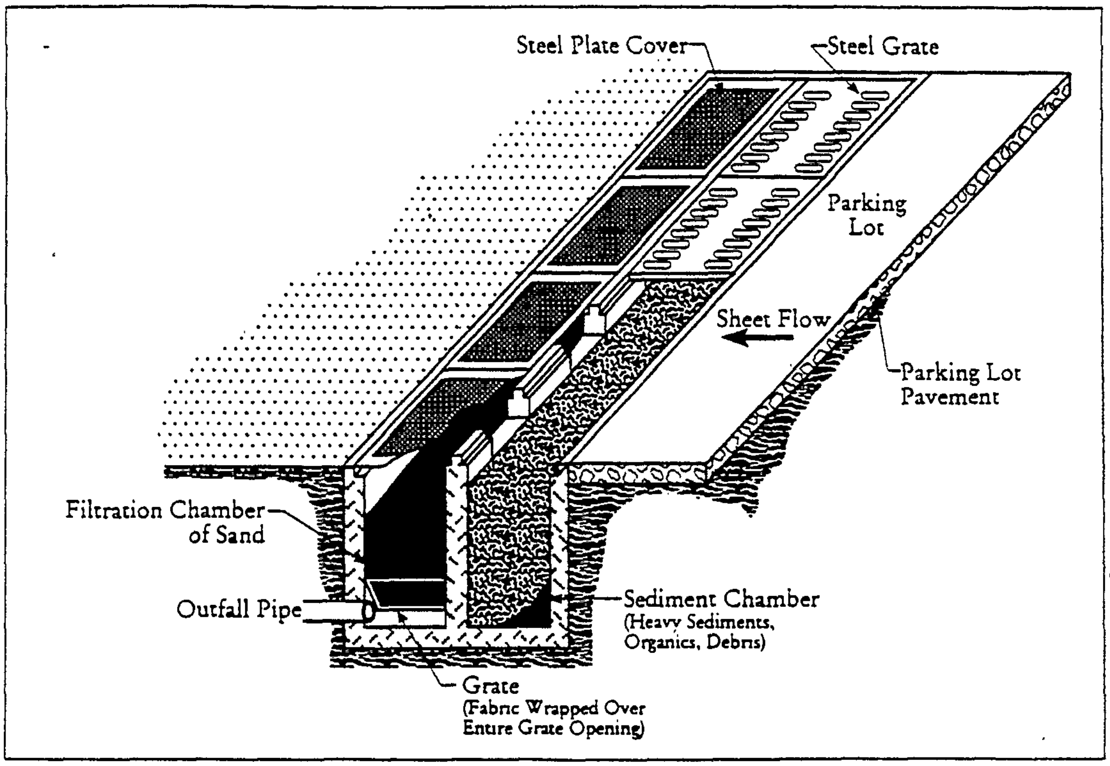

Figure 7 - Schematic of a Delaware Sand Filter (Bell & Nguyen, 1995)

2.3.5.2 BMP Discussion

Several studies have evaluated the performance of sand filters for treating storm water (City of Austin, 1991; Bell & Nguyen, 1995; Horner, 1994). The results of these studies indicate that sand filters are effective in removing particulate pollutants such as total suspended solids, lead, zinc, organic carbon, and organic nitrogen, with removal efficiencies generally exceeding 75 percent. These studies have not provided information regarding capabilities for removing dissolved metals. In some cases this could be significant, because dissolved metals are more mobile and toxic than particulate metals. The studies do indicate that sand filters can discharge nitrate and total dissolved solids, resulting in effluent concentrations of these constituents that are actually higher than influent concentrations. The net increase in nitrate concentrations suggests that nitrification may be occurring in the filter media. The net increase in total dissolved solids concentrations has been attributed to preferential leaching of cations from organic matter trapped on the surface of the sand (Schueler, 1994).

Sand filters appear to be prone to clogging, particularly in areas where high concentrations of suspended solids are present in storm water. Clogging problems are greatly reduced in areas that are completely impervious. The sedimentation chambers are also prone to freezing when used in colder climates. One significant concern with vault filters, such as the D.C. Sand Filter, is the buildup of potentially explosive gases within the vault and the determination that the vault is considered a "confined space," requiring special health and safety procedures for entry.

Routine maintenance is a fundamental requirement for the proper functioning of sand filters. In general, maintenance operations for sand filters include periodic excavation and replacement of the top layer filter media, regular removal of trash and other larger-sized debris, and routine visual inspections of the overall filter unit, particularly after storm events. Specific recommended maintenance for D.C. Sand Filter units include semi-annual pumping and refilling of the first chamber permanent pool, and replacement of the top two to three inches of sand or overlaying layers of geotechnical cloth every three to five years (Bell & Nguyen, 1995). The disposal of used sand filter media can be an additional maintenance burden if it is classified as a hazardous waste material.

2.3.5.3 Range of Costs

Construction costs for sand filters range from approximately $10,000 to $20,000 per impervious acre treated (Schueler, 1994). Maintenance costs for sand filters have been estimated to be approximately 5 percent of the construction cost per year (MWCOG, 1992), with the required maintenance operations including raking, disposal of contaminated sand, and trash and debris removal.

2.3.6 COMPOST FILTERS

2.3.6.1 BMP Description

Compost filters are similar to sand filters, except they use compost instead of sand for the filter media. Filtration through compost provides filtration, ion exchange, molecular adsorption, and biodegradation for pollutant removal. Currently, leaf compost is the most widely used compost media in storm water compost filters. A suitable compost has maturity, low contaminant levels, and high humic acid content and permeability (Schueler, 1994). Filtration through compost is a patented process. The patent holder, CSF Treatment Systems, has developed a drop-in compost storm water filter unit that is sized for small impervious sites such as RGOs. A schematic of a drop-in unit is presented in Figure 8. The drop-in unit is a three-chamber system. The first chamber collects and disperses the flow over the filter media. The second chamber contains an energy dissipator, a scum baffle, the compost filter media, and an overflow route. As storm water enters the second chamber, the design flow is filtered through the media, collected by a perforated underdrain system, and then discharged through a connector pipe. If the design storm is exceeded, overflow into the third chamber will occur and storm water will be discharged without treatment. Depending on the depth of the compost filter installation and the elevation of the street, storm drain or other conveyance, it may be necessary to use a sump pump to discharge the treated or bypassed storm water.

The drop-in unit is an in-line storm water treatment structure. It is typically installed below grade and its pre-cast concrete vaults range from a 6-foot by 12-foot to an 8-foot by 18-foot configuration. These vaults can be connected in series or parallel, depending on the design flow rate. Single drop-in units are rated to treat storm water discharges between 0.28 and 0.64 cubic feet per second. The drop-in filter is sized to handle a maximum of 2.5 gallons per minute per square foot of filter surface area (CSF, 1995).

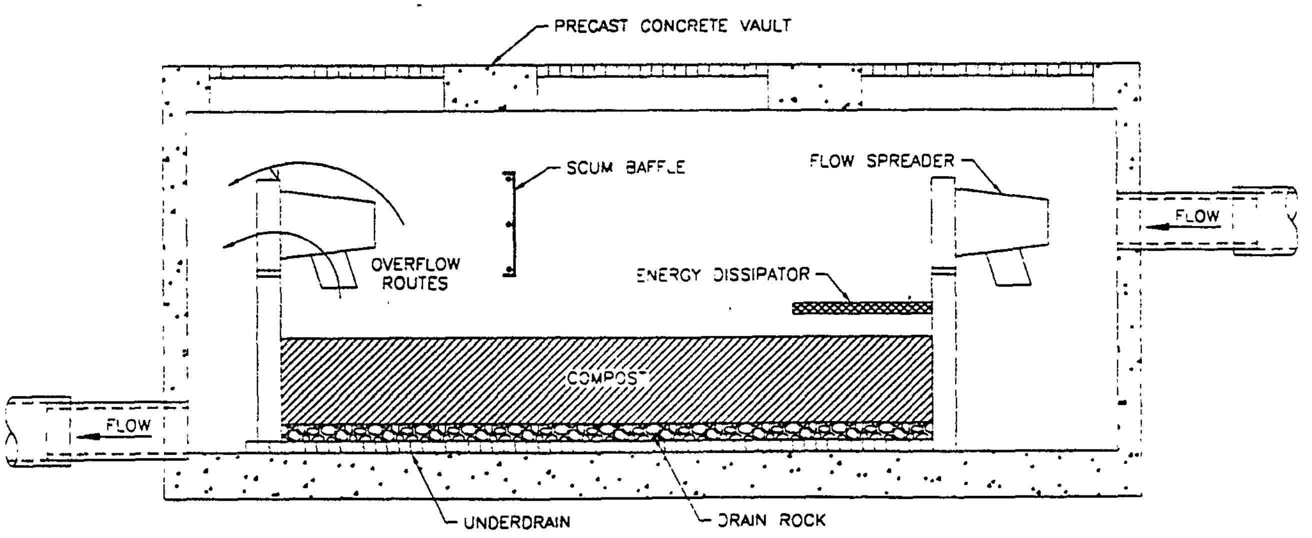

Figure 8 - Schematic of a Drop-In Compost Filter Unit (CSF, 1995)

2.3.6.2 BMP Discussion

A limited number of compost filters have been installed to date, and there is limited independent data regarding the actual performance. Based on results provided by the manufacturer, the drop-in CSF unit averages approximately 90 percent removal for total suspended solids, and ranges from 85 to 95 percent metals removal. The drop-in unit has also shown high efficiencies in removal of hydrocarbons and oil and grease at the low concentrations (5 to 10 ppm) typical of RGO operations. Average removal rates for hydrocarbons and oil and grease at these concentrations are approximately 80 percent. The Snohomish County (Washington) Surface Water Management Agency, which considers the compost filter to be an experimental BMP, has recently installed two compost filters. The performance of these filters will be monitored over the next wet season.

Some deficiencies of the compost filter system include the potential for a net increase in the concentrations of certain pollutants, including orthophosphorous, organic nitrogen, and total dissolved solids, in the compost filter discharge. The increase in orthophosphorous concentrations may be due to the inability of compost to perform anion exchange of soluble phosphorous, and the increase in organic nitrogen may suggest the occurrence of nitrification within the filter media. The increase in total dissolved solids may be explained through possible cation leaching processes within the compost filter media.

2.3.6.3 Range of Costs

In the northwest, initial costs for drop-in units designed for small sites such as RGOs range between $17,000 and $25,000 (CFS, 1995). For drop-in units, the manufacturer recommends that the compost media be replaced annually. The cost of this maintenance procedure should range from $800 to $1,200 per year (CFS, 1995). According to information provided by the manufacturer, the used compost can be directly landfilled as a non-hazardous waste.

2.3.7 CATCH BASIN INSERTS

2.3.7.1 BMP Description

Catch basin inserts are filtering devices that can be inserted into existing catch basins. Catch basin insert types include felt bags, tray(s), or "lobster trap" filters. A tray configuration is presented as Figure 9. Catch basin inserts are designed to remove suspended solids, trace metals, and hydrocarbons through mechanical straining, particle settling, and physical adsorption processes.

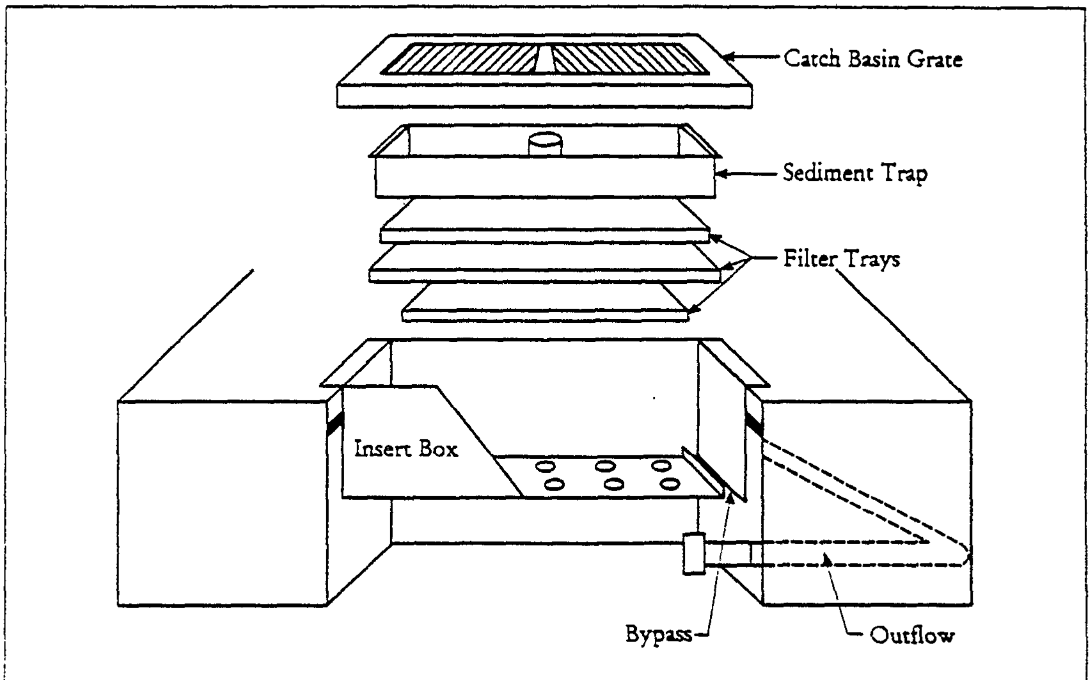

Figure 9 - Schematic of a Catch Basin Insert Tray (McPherson, 1992)

2.3.7.2 BMP Discussion

Results of one study on filter inserts indicates that filter inserts are nominally effective in removing fine sediment and associated pollutants and somewhat more effective in removing coarse material and debris (Interagency Catch Basin Insert Committee, 1995). There is little information regarding the effectiveness for hydrocarbons at the low inflow concentrations typical of properly operated and maintained RGOs. The available data does suggest, however, that removal efficiencies for hydrocarbons are low at low inflow concentrations and somewhat higher for high inflow concentrations. Clogging appears to be a potential problem with filter inserts, even on sites that are completely paved. In addition, preliminary indications are that the filters may require frequent replacement or cleaning.

2.3.7.3 Range of Costs

One vendor listed initial costs ranging from $1,600 to $3,200 for a three-tray filter with a flow rate capacity of 180 gpm. Annual maintenance costs for this three-tray system ranged from $6 to $520, depending on the frequency of maintenance and the respective filter media used. Disposal costs also need to be considered, and can vary considerably depending upon the classification of the used filter material waste.

SECTION 3.0 -- CONCLUSIONS

Based on the results of several storm water studies, it appears that the contaminant levels in storm water runoff from properly operated and maintained RGOs are not appreciably different from those of many other similar sources, such as parking lots and streets. In most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand in storm water runoff from RGOs are below the NPDES storm water permit limitations set by several states for vehicle-related activities.

Properly operated and maintained RGOs may currently be implementing a variety of BMPs to reduce storm water contaminant concentrations. Two basic categories of BMPs are presented in this paper. The first category consists of practical pollution prevention measures. These are the basic, common operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that involve installation of equipment to reduce contaminant concentrations in storm water runoff.

Practical pollution prevention measures are appropriate for RGOs because they are simple, cost effective, and protective of storm water quality. In contrast, the storm water treatment BMPs are less appropriate for RGOs because they are ineffective or unproven for treatment of low contaminant concentrations and are relatively expensive to install and maintain.

Table 5
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Using Spill Containment & Overfill Prevention Equipment	Prevents spills caused by overfilling USTs.	Federally required by 1998, already required in some areas.	Initial costs - high O&M costs - moderate	Suitable for RGOs.
Posting Signs Warning Against "Topping Off"	Minimizes spill occurrences by reminding employees and customers not to top off tanks.	None	Initial costs - low O&M costs - low	Suitable for RGOs.
Installing dispenser "hold open" latches	Minimizes spill occurrences by automating fuel dispensing.	Prevents use of fixed objects such as gas caps, wallets, pieces of wood, etc. to keep dispenser latches open. Can increase potential for spills caused by customer drive-offs unless used in conjunction with break away hoses. May not be allowed by local fire departments.	Initial costs - low to moderate O&M costs - low	Suitable of RGOs.
Providing Canopies and Use of Concrete for Fueling Areas	Canopies over fueling areas can minimize contact of storm water with potential pollutants. Portland Cement Concrete pavements are less prone to soak up fuel than asphaltic concrete.	Canopies also shield customers from sun and rain.	Initial costs - high O&M costs - low to moderate	Suitable for RGOs.
Avoiding Storm Water Runon	Reduces contact of storm water with fueling and maintenance areas.	Should be considered in the initial design of an RGO. Difficult to retrofit in most cases.	Initial costs - low (Initial costs for retrofit can be high) O&M costs - low	Suitable for RGOs.
Maintaining Existing Oil & Grease Separators and other treatment BMPs	The pollutant removal capabilities of oil & grease separators and other treatment BMPs can be maximized by conducting regular sediment cleanout.	Disposal of sediments removed must be properly managed.	Initial costs - N/A O&M costs - low to moderate	Suitable for RGOs with existing structural BMPs.

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Avoiding RGO Wash Downs	Discharges from RGO wash downs may violate local municipal ordinances and may introduce pollutants to the storm drain system.	Discharges to the sanitary sewer from RGO wash downs may require permits.	Initial costs - low O&M costs - low	Suitable for RGOs.
Sweeping Exposed Areas	Removes particulates thereby reducing the concentrations in storm water runoff.	BMP also enhances RGO appearance.	Initial costs - low O&M costs - low to moderate	Suitable for RGOs.
Eliminating Non-Storm Water Discharges and Illicit Connections	Can eliminate potentially significant sources of storm water pollution.	Discharges from floor drains or other sources to the sanitary sewer may require permits.	Initial costs - low to moderate O&M costs - low	Suitable for RGOs.
Standardizing Spill Response Plans	Eliminates a potential source of storm water pollution by ensuring that spills are promptly detected, contained as necessary, and properly cleaned up.	Employees should be trained to properly implement the spill response plan.	Initial costs - low O&M costs - low	Suitable for RGOs.
Training Employees	Ensures that inspections and spill response procedures are properly conducted by employees.	Training program should emphasize routine inspections and standardized spill response procedures.	Initial costs - low O&M costs - low	Suitable for RGOs.
Providing Overhead Coverage of Vehicle Maintenance and Repair Areas	Prevents direct storm water contact with potential storm water pollution sources.	None	Initial costs - low to high O&M costs - low to moderate	Suitable for RGOs.
Preventing Discharges When Changing Fluids	Eliminates a potential source of storm water pollution.	Recycling fluids when possible can reduce disposal costs.	Initial costs - low O&M costs - low	Suitable for RGOs.

R0008936

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Using Parts Cleaning Stations	Prevents parts cleaning wash-off from contacting storm water.	Recycling fluids when possible can reduce disposal costs.	Initial costs - low to moderate O&M costs - moderate	Suitable for RGOs.
Collection and Storage of Oil Filters, Waste Oil, and Other Fluids	Minimizes contact of storm water with potential pollutants.	Used oil filters and automotive fluids should be stored in covered drums. The exterior of drums stored in exposed areas should be wiped clean on a routine basis.	Initial costs - low O&M costs - low	Suitable for RGOs.
Catch Basin Inserts	Filters storm water using devices that are inserted into existing catch basins.	Filter inserts appear to be nominally effective in removing fine sediment and associated pollutants and somewhat more effective in removing coarse material and debris. There is little information regarding the effectiveness for hydrocarbons at the low inflow concentrations typical of properly operated and maintained RGOs. The available data does suggest, however, that removal efficiencies for hydrocarbons are low at low inflow concentrations and somewhat higher for high inflow concentrations. Clogging appears to be a potential problem and frequent replacement may be necessary.	Initial costs - low to high O&M costs - low to high	May prove to be suitable for RGOs, but additional study is necessary to confirm effectiveness with low hydrocarbon inflow concentrations. Use may not be warranted where practical pollution prevention measures effectively control pollutants.
Sand Filters	Relies on sedimentation and filtration through sand to remove total suspended solids, hydrocarbons, and heavy metals.	Effective for removing particulate pollutants. Limited data regarding effectiveness for removing dissolved pollutants. May cause an increase in concentrations of nitrates and total dissolved solids.	Initial costs - high O&M costs - moderate	May be suitable for RGOs but may not be warranted where practical pollution prevention measures effectively control pollutants.

R0008937

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Compost Filters	Relies on sedimentation and filtration through compost to remove total suspended solids, hydrocarbons, and heavy metals.	Still considered to be an experimental BMP by many regulators and there is limited independent data regarding pollutant removal capabilities. Results provided by the manufacturer indicate a 90 percent removal for total suspended solids, 80 percent removal for hydrocarbons, and 85 to 95 percent removal for metals. The net export of orthophorous, organic nitrogen, and total dissolved solids may be problematic.	Initial costs - high O&M costs - moderate to high	May prove to be suitable for RGOs but additional independent study is necessary to confirm effectiveness. Use may not be warranted where practical pollution prevention measures effectively control pollutants.
Vegetative Buffer Areas	Removes particulate pollutants by filtration through grass and infiltration through soil.	Requires a fairly large surface area which may be problematic for highly urbanized areas and retrofits. Studies have indicated that vegetative buffer areas are somewhat effective for removing particulates and less effective in removing soluble nutrients. Because vegetative buffer areas rely on infiltration, there is a potential to contaminate subsurface soil and, in some cases, groundwater.	Initial costs - moderate to high O&M costs - low to moderate	Not suitable for most RGOs as detailed in BMP considerations.
Infiltration Trenches	Collects, stores, and slowly exfiltrates storm water runoff into subsoils.	For sites with permeable subsoils, an infiltration trench can effectively eliminate storm water discharges containing soluble and particulate pollutants. However, use at RGOs is problematic because of the significant potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. Studies have indicated high failure rates caused by clogging.	Initial costs - moderate to high O&M costs - moderate to high	Not suitable for most RGOs as detailed in BMP considerations.

R0008938

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Porous Pavement	Specially designed pavements allow infiltration of approximately 60 to 90 percent of the storm water runoff.	Use is limited to sites with relatively pervious subgrade conditions. Use at RGOs is problematic because of the significant potential for fuel leaks or spills to contaminate subsurface soils and groundwater. Studies also indicate a significant problem with clogging.	Initial costs - high O&M costs - moderate to high	Not Suitable for RGOs.
Separators	Designed to slow water flow which promotes settling of particulates and stratifies flow to enhance phase separation.	Most designs do not operate effectively with the low oil and grease concentrations typical of properly operated and maintained RGOs. Limited ability to remove fine-grained particulates and trace metals. On-line systems with insufficient detention times may cause re-suspension of pollutants.	Initial costs - high O&M - moderate	Not suitable for RGOs.

[1] Basis for cost estimates: Initial costs, Low: < $999, Moderate: $1000 to $5,000, High: $5000+; Operation and maintenance costs; Low: < $499 per year, Moderate: $500 to $999 per year, High: $1000+ per year

[2] Suitability determination based ability of BMP to effectively reduce concentrations of contaminants in storm water discharges from properly operated and maintained RGOs.

Acknowledgments

Sacramento County would like to thank the parent corporations, owners/operators, and station managers from Arco, Chevron, and Shell for their participation in this study. Their cooperation and assistance is greatly appreciated.

The County also wishes to acknowledge the assistance of the staff and member companies of the Western States Petroleum Association, who helped identify suitable stations for the study, and facilitated their participation.

The County would also like to thank Mr. Mark McIntyre of Easy-Clean Systems for donating mobile cleaning services including the use of the Vacu-boom.

Funding for this project was provided by a grant from the U. S. Environmental Protection Agency through the San Francisco Estuary Project, with additional funding from the Sacramento County Water Resources Division.

Executive Summary

This report summarizes the findings of the Demonstration of Gasoline Fueling Station Best Management Practices project. The project is an "Action Plan Demonstration Project" (APDP) funded in part by a grant awarded by the U. S. Environmental Protection Agency (U.S. EPA) through the San Francisco Estuary Project to the County of Sacramento (County). The purposes of the study were to characterize storm water runoff from gasoline fueling stations, demonstrate the effectiveness of pollution prevention technologies or best management practices (BMPs) in reducing pollutant loadings from gasoline fueling station runoff, and to disseminate information on effectiveness and costs to a wide audience.

The basic project design involved a two year study in which:

- during the first wet season (1992/93), samples of sheet flow runoff from three gas stations were collected prior to BMP implementation and analyzed in the laboratory for a variety of pollutants (Phase 1);
- best management practices were developed and implemented during the following dry season (Phase 1); and
- the following wet season (1993/94), after BMP implementation, runoff samples were collected and analyzed for the purpose of comparing pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness (Phase 2).

The growing body of published studies and storm water monitoring data continues to indicate that vehicles are one of the most significant sources of storm water pollutants and that areas where service of vehicles is conducted may be of particular concern. Fueling station discharges may be regulated in the future, so cost-effective BMPs will be very important not only in pollution reduction, but regulatory compliance as well.

The initial work on Phase 1 included the selection of three representative gasoline fueling stations whose owners/operators were willing to participate in the BMP demonstration program. Runoff samples from six storms were collected at each of the three stations during the 1992/93 wet season. Multiple samples were collected manually from sheet flow to represent a flow-weighted composite sample of approximately the first 0.30 inch of rainfall. Climatological data were also compiled

R0008943

throughout the first wet season to aid in interpreting the storm water runoff results. The major classes of constituents analyzed in Phase 1 were:

Oil & Grease,
Total suspended solids,
Heavy metals (thirteen priority pollutant metals, aluminum, and iron),
Polycyclic aromatic hydrocarbons, and
Petroleum hydrocarbons.

After the first three storms, constituents not found in detectable concentrations or those found significantly below levels of concern were no longer included in the analyses, thereby allowing the analyses to focus on indicator pollutants. These pollutants were present in relatively high concentrations and were thought to be representative of the other pollutants on-site. The following pollutants were selected as indicators:

Oil & Grease,
Total suspended solids, and
Heavy metals (cadmium, chromium, copper, lead, and zinc)

Runoff water quality data from the first wet season of this study appeared comparable to results from recent related studies. Regressions of the pre-BMP data versus four rainfall parameters were performed: rainfall intensity during the period of sampling, cumulative precipitation to date, days since last storm of 0.10 inch or greater, and days since last storm of 0.25 inch or greater. This was done for each station individually and for the pooled data set. Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters showed the most consistent relationship to be between log concentration and days since last storm >0.25 inch, particularly for zinc. This result indicated that pollutant buildup occurs during dry periods, and runoff concentrations reflect the length of the buildup period.

The selection process for best management practices included all the potential BMPs applicable to the stations given the physical limitations of the sites. Off-site BMPs (e.g., detention pond, wetlands) were not considered because the scope and budget did not allow for these to be tested. Best management practices were selected using a semi-quantitative scoring method based on cost and perceived effectiveness in reducing pollutants. A suite of BMPs was selected to implement at each station that focuses on the areas with the greatest potential to generate pollutants (e.g., air/water supply area, fueling area, drive through area) as opposed to areas with less pollution potential (e.g., roof drains).

The following BMPs were selected for implementation at each station:

- Mobile Cleaning,
- Litter Control,
- Public Notices,
- Storm Drain Stenciling,
- Spill Cleanup Materials, and
- Employee Training.

The selected BMPs were implemented in the summer of 1993. Post-BMP runoff samples from the 1993-94 wet season were collected and analyzed to compare pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness.

Based on observations by project personnel and best professional judgment about the efficacy of source controls, it is highly likely that of the six BMPs implemented at the gas stations, the one BMP with the most significant chance to affect runoff quality was mobile high pressure water cleaning. The combined effect of the other five source controls was not likely to have a significant impact on the sources of pollution at the stations, namely, high volume vehicle traffic and leaks and spills of vehicle fluids. Consequently, the study can be considered in large part a pilot test of mobile cleaning as a best management practice.

When all the data from the pre-BMP condition is combined and compared against all the post-BMP condition data, the only statistically significant difference in the pre- to post-BMP concentrations was for oil and grease, and it was higher after the BMPs were implemented. For the event mass loading comparisons, no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs.

Although visual observations by the field crew confirmed that a significant amount of pollutants were removed with each cleaning, it is likely that the cleanings may have made more pollutants "available" for washoff in the next event, either storm or cleaning, by freeing up pollutants and allowing them to redeposit on the pavement surface. Potential reasons for this observation include:

- High pollutant deposition
- Rough surface texture
- Heavy pollutant buildup
- Incomplete washoff after cleaning

All-in-all, it appears that this pilot test of mobile cleaning asphalt surfaces, at high sales volume gas stations, near busy intersections on major streets, was probably a worst case scenario for this potential best management practice. The cost of mobile cleaning the fueling stations used for this study was estimated to be about $600 per station washdown which is equivalent to $1,300 per acre of paved surface. Therefore, the cost of mobile cleaning a significant amount of the areas in a watershed exposed to vehicle traffic, on a regular basis, would be quite high.

Since the results were inconclusive, this study cannot recommend the implementation of the mobile cleaning BMP on a large scale. However, field observations and study results seem to indicate that, given the right conditions, mobile cleaning may have the potential to remove sources of storm water pollution. It is clear from this study and others that it is not just gas station runoff, but runoff from any area where vehicles travel, park, or are serviced that is of concern. Recommendations are made for further investigation of BMPs for impervious areas exposed to vehicle traffic.

1.0 Introduction

1.1 Purpose and Scope

This report summarizes the findings of the Demonstration of Gasoline Fueling Station Best Management Practices project. The project is an "Action Plan Demonstration Project" (APDP) funded in part by a grant awarded by the U. S. Environmental Protection Agency (U.S. EPA) through the San Francisco Estuary Project to the County of Sacramento (County). The purposes of the study were to characterize storm water runoff from gasoline fueling stations, demonstrate the effectiveness of pollution prevention technologies or best management practices (BMPs) in reducing pollutant loadings from gasoline fueling station runoff, and to disseminate information on effectiveness and costs to a wide audience.

The basic project design involved a two year study in which:

- during the first wet season (1992/93), samples of runoff were collected prior to BMP implementation and analyzed in the laboratory for a variety of pollutants (Phase 1);
- best management practices were developed and implemented during the following dry season (Phase 1); and
- the following wet season (1993/94), after BMP implementation, runoff samples were collected and analyzed for the purpose of comparing pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness (Phase 2).

The scope of study was developed after a review of previous studies of storm water runoff. Information was obtained from a literature review and from discussions with researchers at agencies and in academia. Although no study was found that focused solely on runoff from gasoline fueling stations, several studies provided guidance for sample collection methodology and described pollutants typically found at gas stations.

1.2 Project Strategy

Approach

The project was conducted in two phases. The work in Phase 1 (first wet and dry seasons) consisted of identifying the pollutant loading from three representative gasoline fueling stations by collecting and analyzing runoff samples. Additionally, Phase 1 included selecting and implementing BMPs at the gas stations with the intent of reducing those pollutants found in the runoff water samples.

Specific tasks in Phase 1 included a literature review, gas station selection, sampling design, water quality monitoring and analysis, BMP selection and implementation, and public participation. This phase of the work culminated with the development of a Phase 1 Report (Sacramento County, 1993a) summarizing the completed tasks and associated findings.

The work in Phase 2 (second wet season) consisted of determining the effectiveness of the implemented BMPs in reducing pollutant loading by re-sampling the selected gas stations after BMP implementation and analyzing the results. The Phase 2 work culminates with the development of this comprehensive final report summarizing all the completed tasks, associated findings, results, and cost estimates to implement the BMPs on a basinwide scale.

Applied Science

As the term "Action Plan Demonstration Project" implies, this study was conducted as an applied science project, as opposed to a basic research project. This is an important distinction to make, because it influenced the project study design. The primary goal of this project was to demonstrate the effectiveness of BMPs in reducing storm water pollutants generated at gas stations. The most critical factor in demonstrating BMP effectiveness is the need to establish a sufficient database to show statistically significant differences between the pre- and post-control measure implementation. Without this, any conclusions will be judged and received with some hesitation. Such a database is difficult to develop because of the variability among storms (quantity, duration, intensity, etc.) and the variability among sites (runoff characteristics, activities located on-site, etc.).

The ability to discern statistically significant differences between two data sets hinges not only on the variability within each of the two data sets, but also on the number of data points in each set. When data variability is likely to be high, as in this case, it is necessary to have either correspondingly large data sets or a relatively large difference in their average values to demonstrate a statistically significant difference. The project team therefore advocated an approach that emphasized maximum production of useful data.

In practical terms, this approach meant the collection and analysis of samples from the maximum number of storms in each of the two wet seasons. To accomplish this within the available budget, it was necessary to focus the analyses on indicator pollutants. These pollutants were known or expected to be present in relatively high concentrations, and to be representative of the other pollutants on-site. By focusing on a subset of the expected pollutants, money was spent where it could produce the most useful data. As discussed more specifically in section 4, Monitoring, the selection of indicator pollutants was based on both the literature review and the sample results from the first three storms.

Another way to maximize the statistical validity of pre- and post-BMP comparisons is to maximize the difference in the pre- and post-BMP data. To effect this, the project team implemented a full suite of BMPs at each station, as opposed to implementing one BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results.

Characterization of gas station runoff was also a goal of the project. Given the applied science emphasis and practical constraints on project funding, a detailed, comprehensive characterization of all possible constituents in gas station runoff was not feasible. The runoff characterization therefore also focused on a limited list of key constituents.

2.0 Background

This section describes the scientific and regulatory background to the project.

2.1 Literature Review

The objective of the literature review was to collect, compile, and review the existing information on toxic pollutant loads associated with storm water runoff from gas stations. This information was used to support subsequent project tasks. Two independent approaches were used to conduct the review: on-line database searching on DIALOG to find published information, and telephone contacts to find any additional published information. The on-line database search showed that very little had been published on the topic of storm water runoff from service stations. The most closely related studies were conducted in Europe, but most of these efforts studied wastewater, and none focused strictly on storm water. However, valuable information was obtained through discussions with researchers (Sacramento County, 1992a).

2.2 Regulatory Impetus

As a result of published studies and monitoring data from municipalities, there is growing support for regulation of fueling station discharges, both sanitary as well as storm water. The growing body of storm water monitoring data continues to indicate that vehicles are one of the most significant sources of storm water pollutants and that areas where service of vehicles is conducted may be of particular concern. In fact, several agencies, including the City of Palo Alto Regional Water Quality Control Plant (RWQCP) and the County of Orange Environmental Management Agency, have recently passed new ordinances that regulate discharges from vehicle service facilities, including fueling stations (Palo Alto RWQCP, 1993; County of Orange, 1993). These agencies require the implementation of BMPs such as secondary containment, spill controls, and employee training, to comply with their ordinances.

At the national level, bills drafted to reauthorize the Clean Water Act are focusing on vehicle service facility discharges, particularly storm water runoff. In addition, U.S. EPA has been developing options for Phase II of the federal storm water regulations, that generally include increased regulation of vehicle service facilities, including fueling stations. The overall impression from this evidence is that fueling station discharges will be regulated, and so cost-effective BMPs will be very important in not just pollution reduction, but regulatory compliance as well.

3.0 *Monitoring Plan*

This section describes issues related to the constituents that were analyzed, the quality assurance and quality control aspects of the study design, and the sampling site selection process, including gasoline fueling station selection and sampling point determination. In addition, the sampling program design is provided, including weather monitoring, storm selection, sample collection, and sample handling procedures.

3.1 Constituents

The identification of constituents to analyze focused on the constituents generally thought to be present at fueling stations. Information on the likely pollutants from vehicles and vehicle traffic were obtained from a number of sources (Shaheen, 1975; Federal Highway Administration, 1984; City of Puyallup, 1988; Pitt and Field, 1990; Sacramento County, 1992b; Washington Department of Ecology, 1992; Wisconsin Department of Natural Resources, 1992). Based on a review of these studies, the major classes of constituents analyzed in the pre-BMP phase were:

- Oil & Grease,
- Total suspended solids,
- Heavy metals,
- Polycyclic aromatic hydrocarbons, and
- Petroleum hydrocarbons.

For each constituent analyzed (see Table 3.1), the EPA test method, detection limit, sample type, sample bottle, maximum holding times, and preservative are listed. Samples were not filtered before analysis.

Based on the results from the first three storms of Phase 1, constituents not found in detectable concentrations or those found significantly below levels of concern were no longer included in the analyses after the third storm, thereby allowing the analyses to focus on pollutants regularly found in significant concentrations (i.e., indicators). This action was consistent with the project's applied science approach (see section 1, Introduction).

1 Event = storms events sampled
2 C = composite
3 B = borosilicate
4 7/40 = 7 days for extraction and 40 days for analysis
5 (D) = Analyzed for dissolved concentration for one storm event each season.

The following pollutants were selected as indicators and were analyzed in samples from all twelve storms (6 pre- and 6 post-BMP):

- Oil & Grease;
- Total suspended solids; and
- Heavy metals -
  - Cadmium,
  - Chromium,
  - Copper,
  - Lead, and
  - Zinc.

The same suite of parameters that were analyzed in the environmental samples were also analyzed in the Quality Control (QC) samples (field duplicate, field blank, laboratory duplicate, matrix spike and matrix spike duplicate samples).

3.2 Quality Assurance / Quality Control

A Quality Assurance Project Plan (QAPP) (Sacramento County, 1993b) was prepared for the project using guidance from the *Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans*, (U.S. EPA, 1983). The QAPP presented specific information including data quality objectives, data use objectives, procedures, organization, functional activities, and specific quality assurance (QA) and quality control activities for the project.

QA/QC Sample Collection and Handling

Strict adherence to the sampling protocols described in section 3.4 is the most important QA/QC measure to be followed in the field. Documentation of consistency in sampling and analytical procedures is important for the validation of any sampling effort. As a part of field QA/QC, the chain-of-custody for each sample was strictly maintained. Sampling points for both Field QC samples and Laboratory QC samples were located at the same point that environmental sample collection took place.

Field QC Samples

Two types of field QC samples were used for Phase 1 and 2: field duplicate samples (duplicates) and field bottle blank samples (blanks). The objective of collecting duplicates was to obtain a check on sampling and analytical precision. The objective of collecting blanks was to check for cross-contamination during sample collection, shipment, and laboratory handling.

Field duplicate samples were collected in the field using the same sample collection methodology and sampling procedures as those used for collecting environmental samples. The procedure consisted of filling two 5 liter composite sample bottles, one for the environmental sample and one for the duplicate. Each time a 1 liter aliquot was collected and poured into the first 5 liter composite bottle, a second 1 liter aliquot was collected immediately thereafter and poured into the second 5 liter composite bottle. Both composite bottles remained on ice and were covered with screw-on caps, except during sample introduction. A discussion of sampling procedures is presented in section 3.4.

Blanks were collected concurrently with the environmental samples. Contaminant free water sufficient for the specified QA/QC analyses, a separate 1 liter glass bottle, and a separate 5 liter composite bottle were brought into the field along with the environmental sample containers. Each time a runoff sample was collected at the sampling point, an aliquot of contaminant-free water was poured into the separate 1 liter bottle and then into the separate 5 liter composite bottle. Both 5 liter bottles (environmental and blank composites) remained on ice and were covered with screw-on caps, except during sample introduction.

Both duplicates and blanks were labeled, packaged and sealed in the same manner as the environmental samples. The duplicate and blank samples were submitted blind to the laboratory along with the environmental samples. Because one environmental composite sample from each gas station was collected and delivered to the laboratory for each storm event, the sample was uniquely identified by station name and date. The identity of blank and duplicate samples was disguised.

Laboratory QC Samples

Matrix spike and matrix spike duplicate analyses of field samples were conducted as a quality control check. In addition, laboratory duplicates and method blanks were analyzed as part of the laboratory's routine in-house protocols. A complete discussion of the laboratory QA/QC program is provided in the QAPP (Sacramento County, 1993b).

QA/QC Sample Collection and Analysis Frequency

Due to the unpredictable and uncontrollable nature of storms, the frequency of collecting QA/QC samples deviated from the recommended U.S. EPA (1980) collection frequency for duplicates of "one sample per week or 10% of all field samples, whichever is greater," and for blanks "one blank per day." The collection frequency for this particular project was driven by storm events. Thus, QA/QC samples were collected on an event basis for each storm sampled. One field duplicate and one field blank were collected and analyzed for each event. One matrix spike, one matrix spike duplicate, and one laboratory duplicate was collected and analyzed for each event. QA/QC samples were collected at each of the three gas stations on a rotating basis.

3.3 Sampling Site Selection

The selection of sampling sites was a two step, sequential process. The first step was identifying three gas stations with appropriate characteristics whose owners/operators were willing to participate in the study. After the sites were identified, the actual sampling points were selected.

Station Selection

The goal of the site selection process was to select three representative gasoline fueling stations whose owner/operators were willing to participate in the BMP demonstration program. The following general principles were followed in this process:

- Maximize statistical validity of pre- and post-BMP comparisons.
- Select stations that are representative of those in Sacramento County.
- Select similar sites; minimize variability that may confound pre-and post-BMP comparisons.

As noted above, one of the guiding principles in site selection was to select sites that enhanced the ability to distinguish between pre- and post-BMP implementation. To this end, the project team originally expected to select stations that have automotive service bays. During the course of the site selection process, however, it became apparent that the major oil companies are phasing out the traditional service stations that provide a mix of gasoline sales and automotive repair services, and replacing them with the modern self service/convenience store facility.

The site selection process also strove to identify stations that are representative of gasoline service stations in Sacramento County. Lists of existing retail gasoline operations in Sacramento County were obtained from the records of public agencies during the site selection phase of the project. The major oil companies operating retail gasoline outlets in Sacramento were contacted individually. A meeting of the Western

States Petroleum Association's (WSPA) Environmental Management Subcommittee was attended by a member of the consultant team. From these contacts, information was obtained regarding the types of stations which represent typical gasoline stations currently in operation in Sacramento County. This information was used in the selection of gas station sites.

The typical station is now a self service gasoline retailer with a convenience market and without automobile repair service bays. Furthermore, older stations providing repair services are being renovated and converted to the self service/convenience market type of station. This type of station was therefore selected as most representative of gasoline retail stations in Sacramento County, and the selected gas stations all conform to this set of characteristics.

Given the ongoing changes in the oil industry, it was also considered important to select stations operating under companies that appear to be stable in the Sacramento market, to provide some security that the selected stations would still be in operation at the conclusion of the project. The project team selected one station from each of the three leading gasoline retailers in Sacramento County. This decision increased the representativeness of the program and added credibility to the results.

The three selected stations were located in fairly close geographical proximity to one another (2 miles) (see Figure 3.1), and all receive an average of 19 to 20 inches of annual rainfall. The stations were located in the suburban Citrus Heights / Fair Oaks area of northeastern Sacramento County. The sites are within the Arcade Creek watershed, a 25,000 acre mixed use watershed which drains to the Sacramento River via the Natomas East Main Drainage Canal, and then into the San Francisco Bay Delta/Estuary.

All three stations were high volume gasoline retailers (over 200,000 gallons per month) that emphasized self service gasoline sales. All three stations were situated at busy, signalized intersections along major arterial roadways. Station X was the parent oil company's highest volume retail station in Sacramento County. All three stations had convenience markets; none provided automotive repair services or had automobile service bays. Station Z had a car wash, but most of the runoff from this activity flowed away from the sample collection point. Figures 3.2, 3.3, and 3.4. show the facility layout for each of the three stations.

Besides the representativeness of the selected stations, the other key selection criteria involved the selection of similar stations, to minimize station-to-station variability in the runoff chemistry data and maximize the statistical validity of the pre- and post-BMP comparison. The selected stations had the following characteristics in common:

- Geographic location (similar precipitation and atmospheric deposition)
- Local setting (land uses, traffic patterns)
- Quantity of gasoline sold (high volume sales)
- Station layout and design
- Mix of services (e.g., convenience store)
- Existing BMPs and on-site treatment

Stations also were chosen where samples could be collected effectively, safely, and securely, and where the collected runoff would include only runoff from the gasoline station, uncomplicated by runoff from off-site. Finally, and in practical terms most importantly, stations were selected where the owner/operator has pledged their full cooperation.

Sampling Points

In essentially all cases, collection of storm water runoff that includes only service station runoff requires collection of samples on the service station property. Therefore, oil company approval was required before physical modifications could be made to the site to accommodate sample collection. The WSPA members, representing the three gasoline station retail outlets, agreed to allow these physical modifications to be made.

Statistical techniques were used to determine the number of sampling locations and storm events that should be included in the project, subject to the project's budgetary, logistic, and practical constraints. The statistical methods included an ANOVA model used in conjunction with statistical power analysis, a sampling plan design tool (Cohen, 1988). This analysis concluded that a 50% change in runoff concentrations due to BMP implementation would produce a statistically significant difference in pre- and post-BMP runoff characteristics, assuming three gas stations with one sampling point and six storms each for both the pre- and post-BMP sampling.

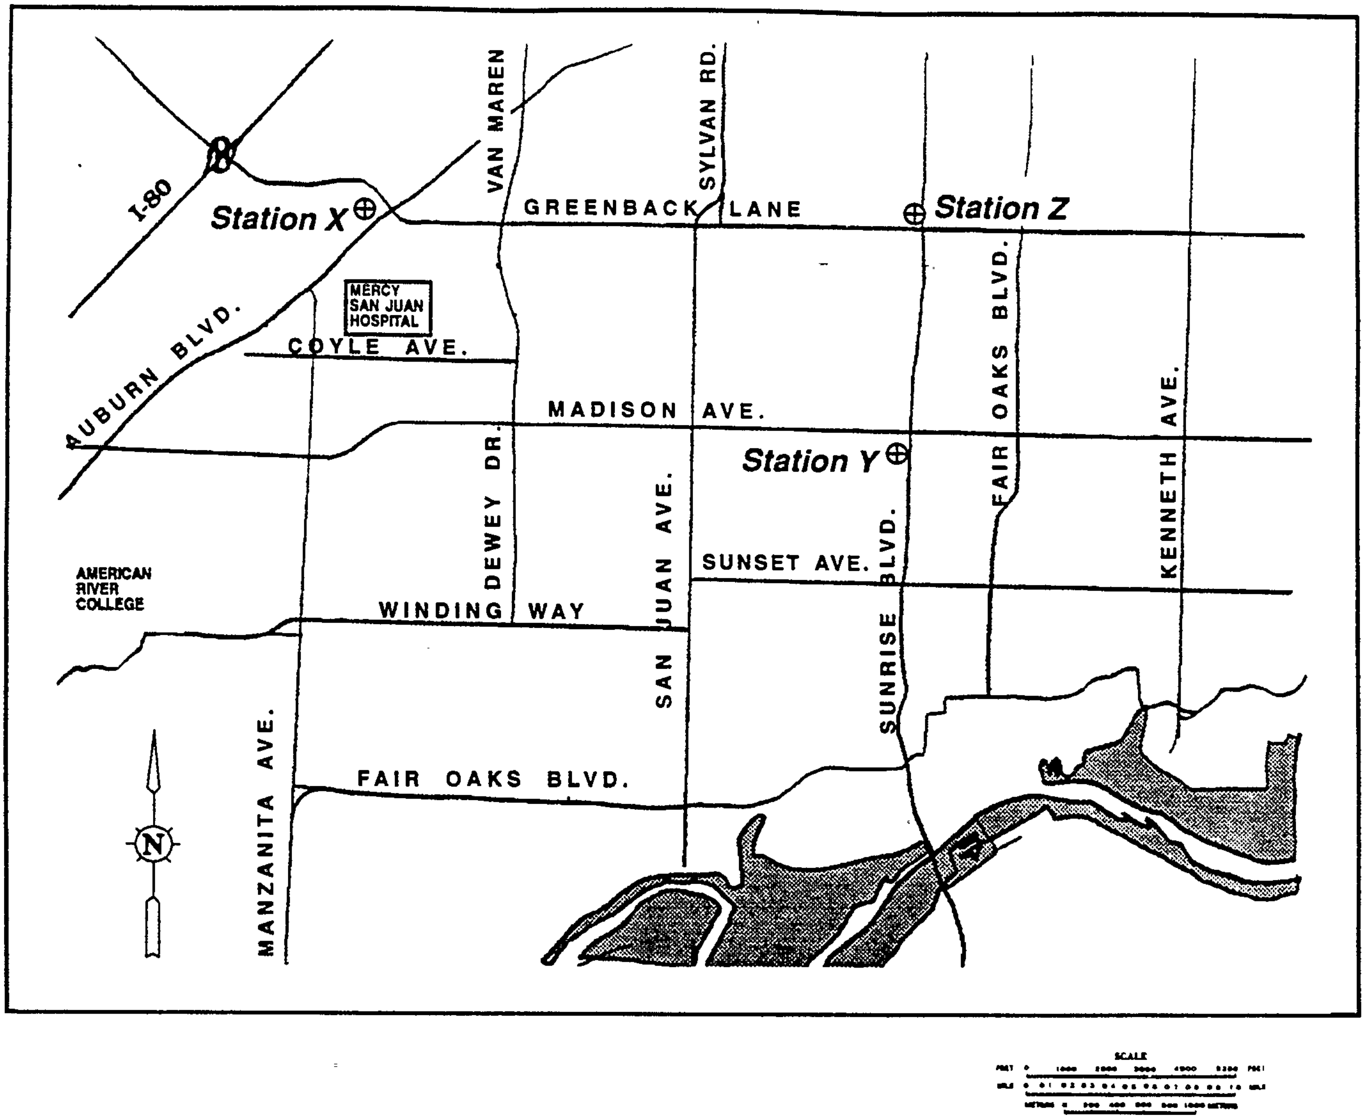

Figure 3.1

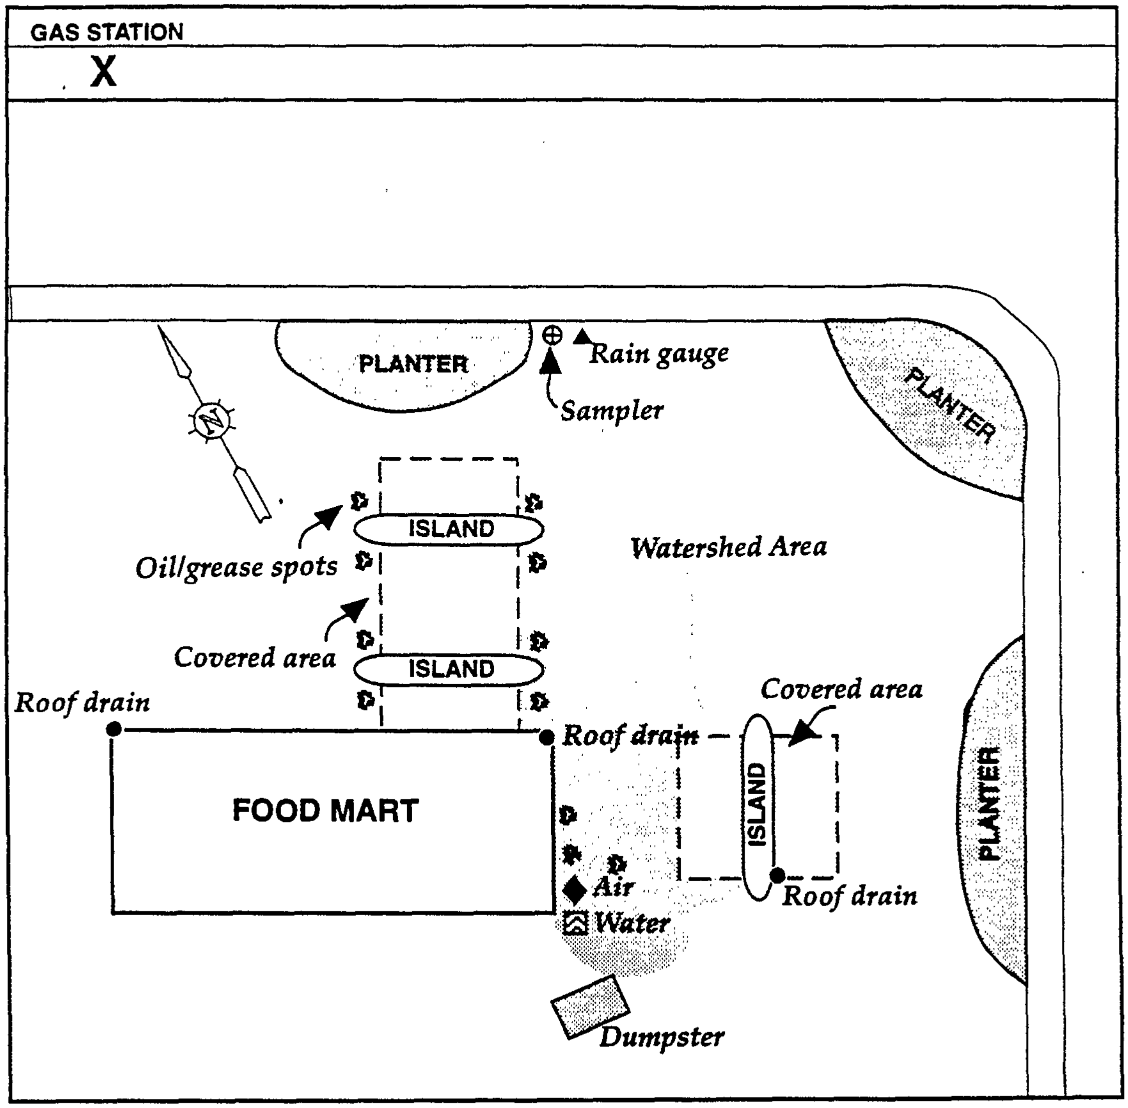
GASOLINE FUELING STATIONS

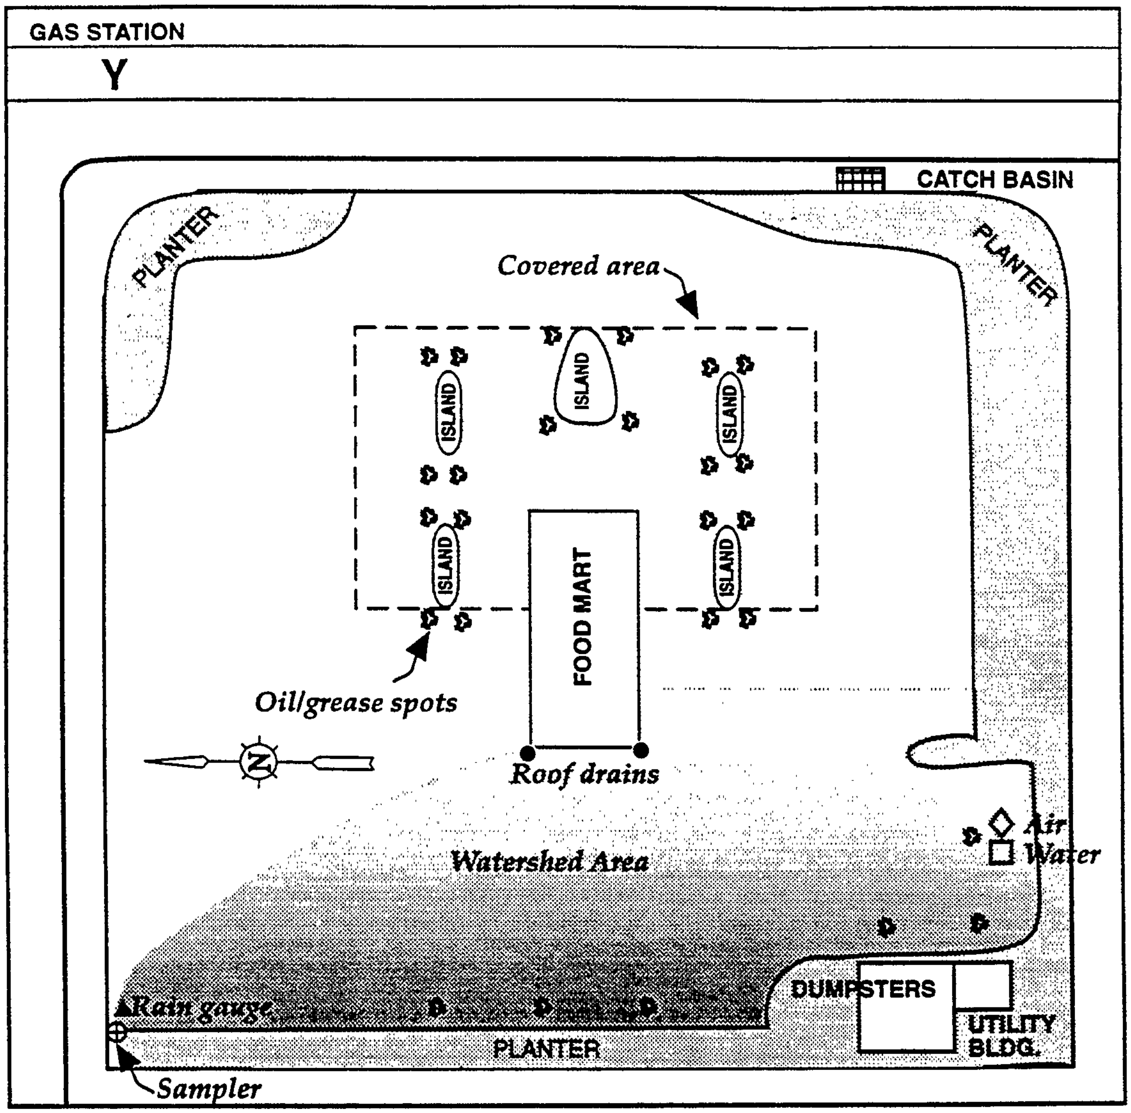
Vicinity Map

Figure 3.2



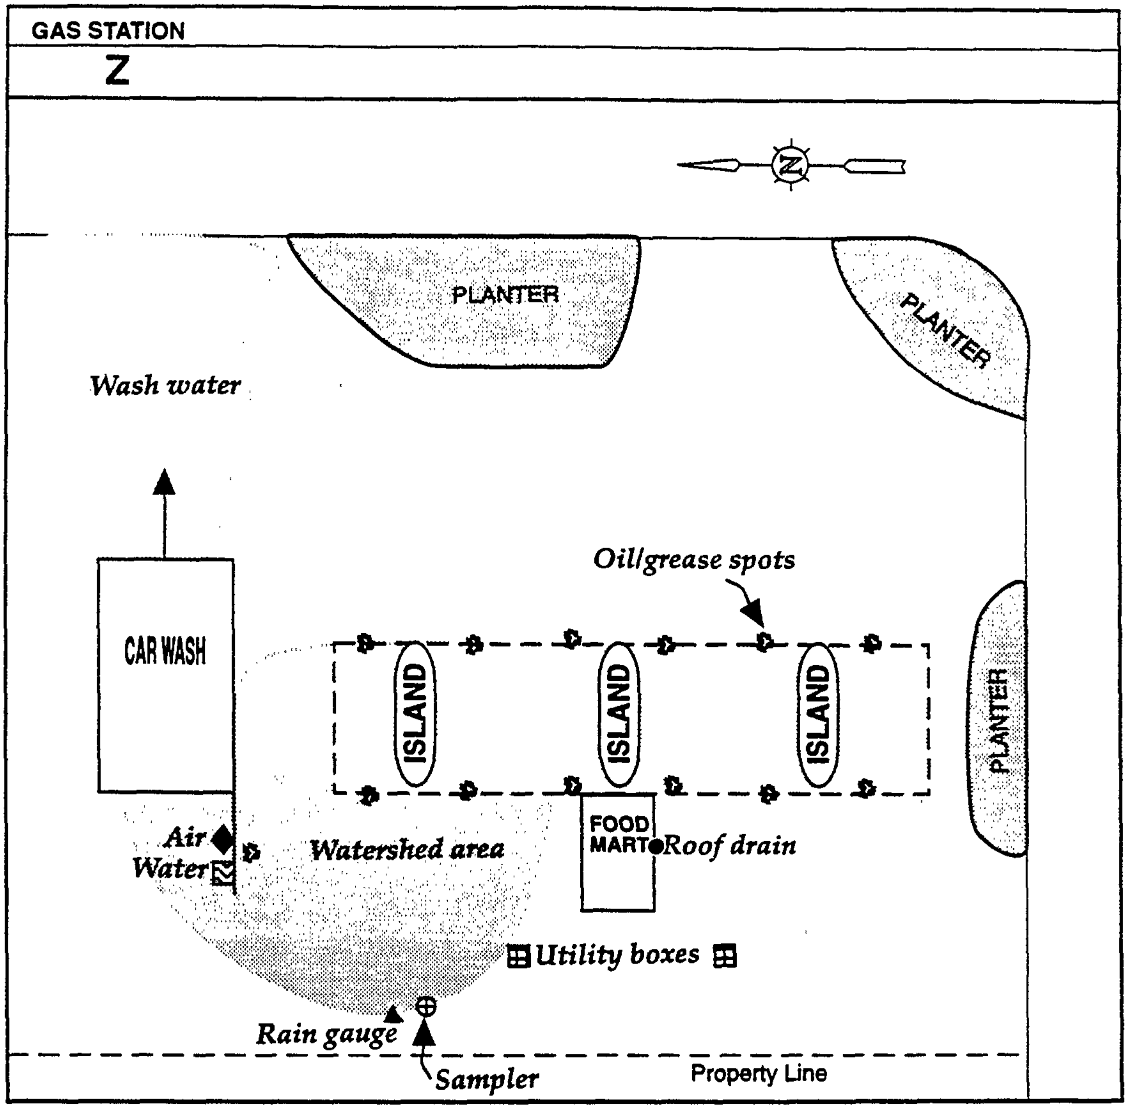
R0008964

Figure 3.3



R0008965

Figure 3.4



R0008966

Given the expressed wish of the participating oil companies for the project to have a minimal impact on station operations (i.e., no interference with traffic flow or services), and the project's budgetary constraints (the cost of sampling manpower and monitoring station installation); the selection of one representative sampling point at each gas station was considered adequate. Safety of field sampling personnel was also a factor in sampling point selection. Sampling points were chosen based on the following criteria:

- Minimum intrusion of off-site runoff co-mingling with the sample
- Minimum interruption of station operation
- Maximum safety for sampling crews
- Consistency among gas stations
- Locations receiving runoff representative of gasoline fueling stations, including runoff from fueling areas and air and water supply service areas

At each of the three gas stations, a sampling point was selected where station runoff left the property, where the runoff stream at the sampling point drained a significant portion of the property, and where the runoff stream at the sampling point included drainage from fueling areas and auxiliary services (especially air and water supply areas). These sampling points were selected after careful site inspection and dry weather flow testing (observation of drainage patterns by allowing water to flow from a garden hose onto the areas of interest). Subsequent storm sampling experience at the gas stations confirmed that the sampling points received runoff representative of the gas stations.

Samples were collected at each of the three selected gas stations from the sampling points indicated in Figures 3.2, 3.3, and 3.4.

3.4 Sampling Program Design

Weather Monitoring

Weather was monitored during this project to maximize the likelihood of "capturing" six storms each season, to minimize false starts, and to ensure that the sampling equipment and team was prepared in sufficient time to collect runoff samples. The incoming storms were monitored using the Weather Network on-line weather database system, as well as direct telephone contacts with Weather Network and National Weather Service forecasters. The project team accessed Weathernet's on-line database via modem through an account established for this project, thereby providing live access to Weather Network forecasters available around the clock during impending storm events.

Storm Selection

Using Weathernet information and a "phone tree," the Field Sampling Coordinator kept the project team informed as to the likelihood of sampling. As a storm approached, the Field Sampling Coordinator made a recommendation to the rest of the project team as to whether the storm was likely to be large enough for the purposes of this study. Only storms predicted to provide sufficient runoff to be sampled were selected.

Storm Events

Storm water monitoring programs in Sacramento County typically have restricted sampling events to storms expected to produce over 0.5 inch of rainfall within a 24-hour period, to achieve sufficient runoff to collect adequate samples. This guideline was adopted for the current project as well. In an average rainfall year, Sacramento County receives approximately 19-20 inches of precipitation in the area of the selected gas stations. In recent drought years (1986/87-1991/92), the annual rainfall has totaled significantly less. Given that some precipitation will occur during storms which do not meet the 0.5 inch / 24-hour intensity criteria, and given that it was not possible to predict the annual precipitation in advance, six was considered to be the number of storms that could reasonably be expected to be sampled within a wet season.

Sample Collection

Sheet flow samples were collected manually (without the use of sampling equipment) by placing a 1 liter glass bottle below grade at a sampling point (monitoring station). As shown in Figure 3.5, the monitoring station consisted of a 12 inch inside diameter by 18 inch deep reinforced concrete pipe (RCP) placed in the pavement at each location. A 3/8 inch aluminum plate was bolted in-place over the hole when sampling was not taking place. The plate was removed before sampling began.

At each station a 1 liter glass sample bottle was used to collect water for all the constituent analyses, and a 5 liter borosilicate glass bottle was used for compositing the 1 liter aliquots. During sampling, sheet flow runoff flowed over the lip of the RCP and was collected directly into the 1 liter sampling bottle. Continuous bailing was performed to keep the water level in the hole sufficiently below the mouth of the bottle to prevent cross-contamination of the collected sample. The individual 1 liter sample aliquots were composited immediately into the 5 liter borosilicate glass bottle.

Samples were flow weighted by collection at intervals based on a pre-determined increment of rainfall volume, equal to 0.05 inches. To accomplish this, rain gauges were used to measure rainfall volume during storm sampling. The same type of gauge was placed at each of the three stations during the sampling period to provide site-specific data. The gauges were placed in an open area on-site, away from the influence of structures or trees. The rain gauges were checked periodically, depending on the rainfall intensity, and the amount of rain in each gauge was recorded during the sampling period to yield rate information as well as total rainfall data. Upon initiation of runoff sufficient to permit sample collection, a 1 liter sample was collected every 0.05 inches of measured rainfall until the composite bottle contained 5 liters of sample.

Sample collection was initiated by the Field Sampling Coordinator. Each station had dedicated staff who covered that station for the duration of the sampling period. All field observations were recorded, including storm characteristics, runoff characteristics, activities on-site, irregularities or difficulties in the sampling procedure, the time each grab sample was taken, and unusual qualities of the runoff sample.

Sample Handling

The composite container was field preserved at approximately 4^{o} Centigrade by storage in a cooler containing ice. The filled composite sample containers were maintained on ice until delivery to the analytical laboratory. Delivery to the lab occurred within 24 hours of the completion of sampling. The composite containers remained closed with a screw on cover containing a Teflon Seal. Upon delivery to the lab, the composite was split by laboratory personnel into aliquots for the specified analyses, and preserved accordingly (see Table 3.1). Prior to pouring off aliquots from the composite for analyses, the composite sample was thoroughly shaken to ensure that representative samples were obtained.

Rainfall Monitoring

In addition to the on-site rain gauges used to measure rainfall during the sample collections, rainfall data were accessed from the closest Sacramento County ALERT system rain gauges. Figure 3.6 shows the location of three ALERT rain gauges in the vicinity of the three gas stations. The gauges are designated by numbers and nearby street names.

Rain Gauge Locations

R0008971

4.0 *Best Management Practices (BMPs)*

This section describes the selection and implementation of best management practices designed to reduce gas station runoff pollution.

4.1 Selection

The selection of best management practices was based on a review of appropriate BMPs described and used elsewhere for vehicle-related activities (SCVNPSPCP, 1992; U.S. EPA, 1992; Palo Alto RWQCP, 1993; California SWQTF, 1993; County of Orange, 1993). As part of Phase 1, BMPs were selected based on their effectiveness, practicality, and cost by using a semi-quantitative scoring method (Sacramento County, 1993a). The following six BMPs were selected and implemented:

- Mobile High Pressure Water Cleaning
- Public Notices
- Litter Control
- Storm Drain Stenciling
- Spill Cleanup Materials
- Employee Awareness

The above list includes all of the BMPs applicable to the stations given the physical limitations of the sites. The selected best management practices were either low in cost, and/or high in perceived effectiveness in reducing pollutants. A "potential for disruption" criterion helped guide the selection toward BMPs that were acceptable to the station owners/operators. The BMPs tended to focus on the areas of the stations with the greatest potential to generate pollutants (e.g., air/water supply area, fueling area, drive through area) as opposed to areas with less pollution potential (e.g., roof drains, landscaping). On-site treatment control BMPs were not selected because of their high relative cost and disruption to operations. Off-site BMPs (e.g., detention pond, wetlands) were not considered because the scope and budget did not allow for these to be tested. Therefore, all of the best management practices selected for implementation were source controls.

One way to maximize the statistical validity of pre- and post-BMP comparisons is to maximize the difference in the pre- and post-BMP data. To effect this, the project team implemented the full suite of BMPs at each station, as opposed to implementing one

BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results. The need to implement a suite of BMPs is especially important with source controls, because there are a variety of pollutant sources, each requiring a best management practice. If treatment controls had been a more viable approach, it's possible that fewer BMPs would have been necessary to produce a reduction in pollutants.

4.2 Implementation

Having selected the BMPs, the project team worked with the station owners/operators to gain their final approval and to implement the BMPs. The following discussions provide some detail on the actual implementation of each of the selected best management practices.

Mobile High Pressure Water Cleaning - The entire drainage area used in Phase 1, particularly the air/water supply, fueling, and drive through areas, was cleaned an average of about twice per month using a high pressure (3,000 psi) and high temperature (210^{o}F) mobile cleaning unit (Figure 4.1). The wash water generated was collected using a "Vacu-boom," a portable, runoff collection system (Figures 4.2 and 4.3). The "Vacu-boom" includes a hollow, flexible snake that is connected to a high power wet vacuum unit. The apparatus enables sheet flow to be captured and conveyed to a sanitary sewer inlet.

Several concerns were identified and resolved before using the mobile cleaning system including: 1) potential asphalt erosion caused by the high temperature of the water, 2) wash water disposal, 3) safety of the cleaning operator and the equipment, and 4) disruption of normal station operations. To reduce the potential for erosion of the asphalt, the operator avoided persistent spraying in one area to avoid heating up the asphalt surface. Wash water disposal was handled by discharging into the sanitary sewer system via a cleanout or rest room connection. The safety and disruption issues were addressed by conducting cleaning operations late at night during slower business hours and by supplying the operator and assistant with safety orange cones and an orange vest for increased visibility.

Figure 4.1 Mobile Cleaning System

Figure 4.2 Vacu-boom

R0008974

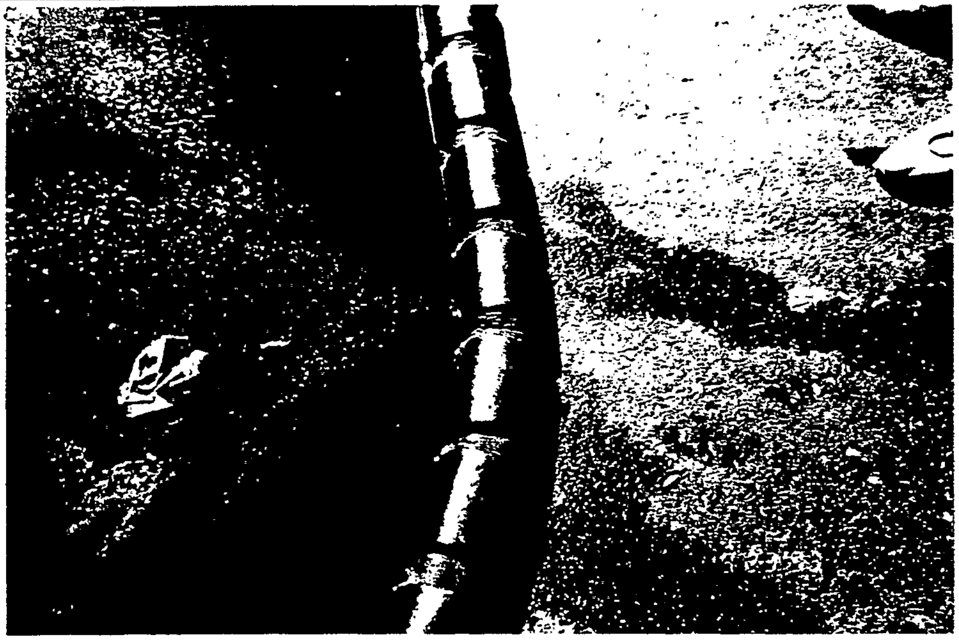

Figure 4.3 Wash water collected by Vacu-boom

The objective of the mobile cleaning BMP was to free the pollutants from the asphalt surface using high temperature and high pressure water and to transport the pollutants, in water suspension, to the Vacu-boom apparatus. The method of application that appeared to be the most effective was to initially wet the asphalt surface over the entire drainage area to the point of saturation without creating any significant runoff. The mobile cleaning took place starting from the furthest upstream point in the drainage area and working down in a back and forth line to the furthest downstream point. By initially wetting the surface, the waste stream from the mobile cleaning was able to freely travel down to the Vacu-boom without the water being "used up" in the wetting of dry asphalt. Water quality samples of the waste stream were originally going to be taken to determine the type and amount of pollutants being removed in the mobile cleaning BMP. However, since the Vacu-boom wet vacuum contained copper and brass fittings and components, project staff decided that the results would not be reliable and therefore abandoned the idea.

Table 4.1 presents data on the mobile cleanings performed during the project. The information presented in Table 4.1 relates the mobile cleaning number, dates of mobile cleaning, the stations cleaned, and the days since the previous cleaning with the storm number, the storm date, the number of days since the last cleaning, and the number of cleanings since the last storm sampled. The drainage areas at the three stations were mobile cleaned a total of ten times between late October 1993 and late March 1994.

To further explain Table 4.1, starting with the first column, the first cleaning occurred on 10/27/93 for stations Y and Z, and on 11/4/93 for station X. The second cleaning occurred on 11/9/93 for all three stations which resulted in 5 days since the last cleaning for station X and 13 days since the last cleaning for stations Y and Z (fourth column). The first storm (fifth column) was sampled on 11/29/93 (sixth column) which was 20 days since the last cleaning (seventh column) that was done on 11/9/93. The drainage areas at all the stations were mobile cleaned twice prior to this storm (eighth column).

Table 4.1 Mobile Cleaning/Sampled Storm Information

Mobile Cleaning Data				Sampled Storm Data			
Mobile Cleaning Number	Date of Mobile Cleaning	Station(s)	Days Since Previous Cleaning	Storm Number	Storm Date	Number of Days Since Last Cleaning	Cleanings Since Last Storm Sampled
1 1	10/27/93 11/4/93	Y and Z X					
2	11/9/93	All	5 (X), 13 (Y/Z)	1	11/29/93	20	2
3	12/5/93	All	26	2	12/11/93	6	1
4	12/23/93	All	18				
5	1/10/94	All	18	3	1/24/94	14	2
6	1/26/94	All	16	4	2/6/94	11	1
7	2/9/94	All	14	5	2/17/94	8	1
8	2/23/94	All	14				
9	3/9/94	All	14				
10	3/23/94	All	14	6	4/8/94	16	3

Public Notices - Signs educating the public about good housekeeping practices and what to do in the event of a spill were displayed in the air/water supply area. One sign requested that the gas station attendant be notified should a spill occur and the other sign requested that litter be properly disposed (Figure 4.4).

Litter Control - To supplement the litter control sign, the project team monitored the presence of trash receptacles in the air/water supply area (Figure 4.4).

Storm Drain Stenciling - The public is usually unaware that storm drains flow directly to a creek, river, or a bay. Storm drain stenciling conveys the message that the water that flows into the catch basin goes directly to the local rivers. The on-site, and nearby off-site storm drain inlets were stenciled to increase public awareness (Figure 4.5).

Spill Cleanup Materials - To ensure that spilled fluids are promptly removed, cleanup materials must be readily available. All three stations keep spill cleanup materials on-site. The station managers were also encouraged to, not only keep the spill materials readily available, but also to train employees in the proper use of the spill materials.

Employee Awareness - All three stations and their parent corporations have employee training programs that include material and waste management practices. This training was supplemented, as necessary, to assist the project team in understanding the conditions at each station. Because the team could not be at each of the stations most of the time, the employees were encouraged to use log sheets to record significant events (e.g., spills) that could help to interpret study results. However, the use of log sheets to monitor spills outside the fueling areas was difficult to implement because the limited staff found at these type of stations usually did not have the time to make observations.

Figure 4.4 Public Notices

Figure 4.5 Storm Drain Stenciling

5.0 *Results*

This section describes the results of the first (pre-BMP) and second (post-BMP) year's wet season's measurements, including drainage area estimates, climatological data, runoff sample analyses, and graphs.

5.1 Drainage Area Estimates

For each of the stations, the area draining to the collection point was less than the total area of the station (see Figures 4.2-4.4). Measurements of the drainage area to the sample collection point were made based on site plans provided by the County of Sacramento and field measurements, including field flow (hose) trials, made by the project team. A planimeter was used to determine the watershed areas depicted in Figure 3.2 through 3.4. The estimated dimensions of the drainage areas are provided in Table 5.1.

As shown in Table 5.1, there are several ways to calculate the area draining to the sample collection point. The project team is using the exposed paved area plus the roof drainage area (row 6 in Table 5.1) to represent the "sample area," or area draining to the collection point. This area excludes the *covered* paved drainage area because runoff normally does not flow through this area. One difference between the stations is the percent of roof area draining to the collection point, with station X having significantly more roof drainage area (29%) than either of the other two stations (Y = 4% and Z = 0%).

5.2 Sampling Results

Climatological Results

Climatological data were compiled throughout both wet seasons to aid in interpreting the storm water runoff results. These data included areawide rainfall totals from Sacramento County ALERT system rain gauges, inter-event times (time between significant storms), and rainfall intensity data recorded during sampling. Rainfall data collected at the three ALERT gauges were used to calculate the cumulative precipitation for the 1992-93 (Figure 5.1) and 1993-94 wet seasons (see Figure 5.3). Figures 5.2 and 5.4 show the daily precipitation totals for the 1992-93 and 1993-94 wet seasons, respectively.

Table 5.1 Drainage Area Estimates

	Area		Station X (sq. ft.)	Station Y (sq. ft.)	Station Z (sq. ft.)
1	**Exposed Paved Drainage Area**		**2,826**	**3,794**	**2,844**
2	Covered Paved Drainage Area (1)	+	222	149	887
3	Total Paved Drainage Area (2)	=	3,048	3,943	3,731
4	**Roof Drainage Area**	+	**1,150**	**168**	**0**
5	Total Paved + Roof Drainage Area	=	4,198	4,111	3,731
6	**Exposed Paved + Roof Drainage Area (3) = Sample Area (Row 1 + Row 4)**		**3,976**	**3,962**	**2,844**
7	Roof Drainage as Percent of Sample Area		29%	4%	0%
8	Area of Gas Station (4)		20,809	18,358	30,423
9	Sample Area as Percent of Gas Station Area		19%	22%	9%

(1) Covered paved drainage area is a potential source of pollutants but runoff normally does not flow through this area.

(2) Total paved drainage area is the sum of the exposed drainage area and the covered drainage are (covered by an overhang).

(3) Excludes covered paved drainage area.

(4) Area of gas station includes buildings, landscaping, and other facilities but excludes adjacent streets and sidewalks.

All four plots of precipitation data show when the six pre-BMP and six post-BMP sampling events took place.

Once collected, the ALERT system rainfall data allowed for the calculation of the time between sampled storms (inter-event time). The determination of inter-event time depends on the definition of a "significant" storm. Consistent with U.S. EPA storm water regulations (40 CFR 122.26), the project team used 0.10 inches of rain as the significant storm threshold. Table 5.2 presents the inter-event data for both wet seasons.

* = Weighted average of three closest rain gauges
** = Average of Chicago and Van Maren Cripple rain gauges

Because 1992-93 (pre-BMP) was a relatively wet year in California, with frequent storms occurring on a regular basis throughout the winter, the inter-event times were fairly short, ranging from 2 to 9 days. In 1993-94 (post-BMP), about half as much rain fell as compared to 1992-93 (approx. 13 inches versus approx. 26 inches). The inter-event times in 1993-94 reflected the drier winter, ranging from 0 up to 33 days. Because a 0.10 inch storm does not always produce a significant volume of runoff (depending on duration and intensity), inter-event times based on the previous storm of 0.25 inches or greater were also evaluated for both years.

As discussed in section 3.4, Sampling Program Design, rain gauges were used to measure rainfall volume at the three gas stations during storm sampling. The same type of gauge was placed at each of the three stations during the sampling period to give site-specific data. The gauges were placed in an open area on-site, away from the influence of structures or trees. The rain gauges were checked periodically, depending on the rainfall intensity, and the amount of rain in each gauge was recorded during the sampling period to yield rate information as well as total rainfall data.

Table 5.3 presents information for both wet seasons on observed rainfall and the period of observation as recorded during sample collection, and the calculated rainfall intensity. The intensity shown is simply the quotient of the measured rainfall divided by the total time of observation, which corresponds to the amount of time required to collect the composite sample. For the most part, the differences in the rainfall intensities represent the inherent variability caused by the geographic separation of the stations.

Runoff Water Quality Results

QA/QC Evaluation

On a quarterly basis, a review of the QA/QC program was conducted, fulfilling the requirement for such a review as described in the Quality Assurance Project Plan (Sacramento County, 1993b). The quality control data from the storms indicated that the data quality objectives, as measured by the project specific numerical goals (Sacramento County, 1993b), were generally met during the second wet season. Specifically, precision, expressed as relative percent difference, was within the goals of +/- 20% for oil & grease and metals, and within +/- 10% for TSS, except for one storm (February 17 = +11%). Percent spike recovery values were all within the 80-120% accuracy goal for metals, and 70-130% for oil & grease. In addition, the collection of samples from all six storms exceeded the completeness goal of four storms for the season.

The qualitative system audits performed during this period indicated that the measurement systems were used appropriately and that the sampling and analysis activities matched those presented in the QAPP. The performance audit data described above indicate that data of known and defensible quality were produced. During the second wet season, there was one analytical result from a field duplicate in the third storm that did not match well with its corresponding environmental sample. With this exception, no other significant QA problems occurred during the 1993-94 monitoring.

Runoff Water Quality Data

Table 5.4 presents the pre-BMP (1992-93) runoff data for analytes detected in at least 75% of analyzed samples (i.e., indicators, nickel, aluminum, and iron). Table 5.5 presents the post-BMP (1993-94) data for the indicator analytes. As expected for storm

For both data sets (1992-93 and 1993-94) and for nearly all of these analytes, the number of samples was equal to or greater than five, except for chromium at station Z (n = 4) in 1992-93, and chromium at station Y (n = 3) in 1993-94. In order to increase the statistical validity of the chromium results, a distributional method was used to establish a maximum likelihood value for the non-detect results. The method used is outlined in Appendix A.

For example, the calculated values for the 1992-93 non-detected chromium values were 1.02 ug/L and 1.67 ug/L. These values were higher than the analytical detection limit, indicating a data gap between the detected values and the non-detected values. Given that the chromium values calculated to replace the non-detected values were actually slightly greater than the detection limit, it was concluded that it would be reasonable to replace the two non-detected values with the detection limit (1.0 ug/L).

Also for the 1992-93 data set, this same method was used to determine values for non-detect results on oil & grease (December 10 storm) and chromium (January 6 storm) at station X. In both cases, the values calculated to replace the non-detected values were actually slightly greater than the detection limit. So it was deemed reasonable to replace the two non-detected values with their respective detection limits (0.5 mg/L - oil & grease; 1.0 ug/L - chromium).

Appendix B presents plots of pollutant concentrations versus station for all six post-BMP storms. Where applicable, the plots include water quality objectives (SWRCB, 1991) for comparison. This comparison is very conservative because it does not consider the fate of the pollutants (e.g., adsorption) and the fact that the samples were collected upstream of the storm drain system, as well as the receiving waters for which these objectives are developed (SWRCB, 1991).

Appendix B also presents plots of post-BMP pollutant concentrations versus storm for the three stations. As in the case with the previous plots, where applicable, the plots include water quality objectives (SWRCB, 1991) for comparison. Again, this comparison is very conservative because of the reasons outlined above. As was the case with the first year's data, pooled mean concentrations of copper, lead, and zinc (Table 5.5) exceeded California Inland Surface Waters Plan water quality objectives based on a Sacramento River hardness value of 59 mg/L as $CaCo_3$.

Comparison to Related Studies

Table 5.6 presents some of the pre-BMP runoff water quality data from this study along with data from recent characterization studies. These studies have focused in whole or in part on vehicle-related sources. The studies vary in sample size (n=4 to 18), sample type (composite, grab), waste stream type (sheet flow runoff, simulated runoff, oil/grit separator water), and activity area (gas stations, fueling islands, oil/grit separators, parking, streets, vehicle service, driveways). So direct comparisons among studies is not possible. However, it does appear that the pre-BMP results from this study are comparable to results from other studies.

6.0 *Data Analysis*

This section describes the first and second year's data analysis, including a determination of which distribution plots (normal or log-normal) best fit the data, estimation of mass loads, analysis of station-to-station and pre- to post-BMP differences, evaluation of seasonal trends, and evaluation of high pressure water cleaning.

6.1 Descriptive Statistics

Descriptive statistics (mean, median and standard deviation) for each year for each constituent, for each station individually, and for all three stations combined, are presented in Table 6.1.

Table 6.1 Descriptive Statistics

6.2 Determination of Best Fit Distributions

The initial data analysis step involved testing the runoff water quality data to determine whether the data better fit a normal or log-normal distribution. The data were plotted using both a normal scale and a log scale for the y-axis, in each case plotted with a normal probability distribution for the x-axis. By fitting a regression line to the data plot, it can be determined how well the data fit a normal or log-normal distribution. Only those constituents with four or more detected values at each station were included in this analysis. Those constituents were total suspended solids, oil & grease, cadmium, chromium, copper, lead, and zinc. The analysis was completed for each year of data separately for each gas station, and then for the data from all three stations combined.

As discussed in section 5.2, Sampling Results, non-detected data were replaced with the appropriate values before plotting so that the true number of data points could be used on each plot. In each case the curve-fitting function in Kaleidagraph™ was used to determine the equation of the line that fit the data most closely. Kaleidagraph™ reports an "R" value, which is an indication of how well the line approximates the actual data. Curves with "R" values close to 1.0 fit best.

Plots for Data Grouped by Constituent and Station

For the pre-BMP condition, the log-normal distribution fit the majority of the data best for the individual stations. In the case of cadmium and lead, the log-normal plots had higher "R" values than the normal plots for each sampling location, indicating that the log-normal curves fit best. In the case of chromium, copper, total suspended solids, and zinc, the station Y and Z curves fit best on the log-normal plot, but the curves for X fit slightly better on the normal plot. The station X and Y curves for oil and grease also fit best on the normal plot.

Plots for Data Grouped by Constituent Only (All Stations Combined)

For the pre-BMP data, for each of the seven constituents evaluated, when the data from all three stations were combined, the log-normal curves fit best. Each of the "R" values was greater than 0.93, indicating that the curves fit the data fairly well.

For the post-BMP data, log-normal distributions provided the best curve fits for the combined data sets for all constituents tested.

Assumption of Log-normal Distribution

Based upon the preceding analysis of the distributional characteristics of the data, the log-normal curves best fit the data overall for the constituents examined in this study. The regression analysis (sections 6.5 and 6.6) therefore assumes that the data are generally log-normally distributed. The distribution plots are shown in Appendix C.

6.3 Estimation of Event Mass Loads

For each constituent and station, event mass loads (EMLs) were estimated for each storm event monitored. The EMLs were calculated from the product of the measured pollutant concentration and the estimated runoff flow volume through the gas station monitoring site drainage area. The runoff flow volume for each storm was calculated from the estimated surface area draining to the monitoring site (as described in section 5.1), and the rainfall volume measured at the ALERT system rain gauge nearest the site. The estimated mass loads for the pre-BMP and post-BMP storm events are shown in Tables 6.2 and 6.3.

6.4 Analysis of Station-to-Station Differences and Pre- to Post-BMP Differences

Statistical analyses were conducted to determine whether runoff water quality differed from station-to-station during the study, and whether post-BMP runoff quality differed from pre-BMP runoff quality.

T-tests were used to evaluate the differences in gas station runoff water quality among the stations in each of the two years of the project, and also to evaluate the differences in runoff quality between the pre-BMP and post-BMP conditions. For the station-to-station comparisons, the tests were done by pairs of stations (X:Y, Y:Z, X:Z). A robust form of the paired, two-tailed Student's t-test was used. This test compares the means of two data sets, but does not assume that the variances of the populations from which the data sets are drawn are equal. The paired sample test is appropriate for data sets where the observations are in paired sets, as in this study.

The t-test evaluates the relative difference in mean values between two data sets. The test is set up to test what is called the "null hypothesis"; that is, the hypothesis that there is no significant difference between the two data sets. Technically, the t-test determines the probability of error associated with rejecting the null hypothesis. This is essentially equivalent to the probability of error (known as the "p" value) associated with accepting the hypothesis that there is a significant difference between two data sets.

The key measure produced by the t-test is the probability (p) value. A significant difference is considered to exist between the data sets when the p-value is less than or equal to 0.05, which indicates that the probability of error associated with rejecting the null hypothesis (or with accepting the alternative hypothesis that the data sets are different) is less than five percent.

Station-to-Station Differences - Pre-BMP Monitoring

The t-test p-values produced by the station-to-station comparisons of runoff pollutant concentrations for the pre-BMP condition (1992-93 monitoring) are shown in Table 6.4. In two instances, the p-value was small enough (<0.05) to warrant further investigation. The variances for these two instances were very large in comparison to the means, however, which indicates that the difference was likely an artifact rather than a significant difference. All of the other values indicate no statistically significant differences among the gas stations for the baseline monitoring, using the log-transformed values. These results allowed the data to be "pooled" or combined into a larger data set for evaluations of rainfall-related effects, and allowed the pooling of the data from the three stations in the pre-BMP analyses.

Table 6.4 p-Value Matrix; Paired t-tests
Pre-BMP (1992/93) Concentration Data

	Station Group		
Constituent	X/Y	Y/Z	X/Z
Total suspended solids	0.542	0.434	0.101
Oil & grease	0.232	0.936	0.112
Cadmium	0.349	0.345	0.155
Chromium	0.938	0.029	0.365
Copper	0.116	0.960	0.423
Lead	0.259	0.328	0.865
Zinc	0.002	0.329	0.884

Station-to-Station Differences - Post-BMP Monitoring

The t-test p-values produced by the station-to-station comparisons of runoff pollutant concentrations for the post-BMP condition (1993-94 monitoring) are shown in Table 6.5. As with the pre-BMP monitoring data, the t-test results indicate that no significant differences can be determined in post-BMP runoff water quality from one station to another. No p-values below 0.05 were obtained from the comparisons of the various station pairs. These results allowed the data to be "pooled" or combined into a larger data set for evaluations of rainfall-related effects, and allowed the pooling of the data from the three stations in the post-BMP analyses.

Table 6.5 p-Values; Paired t-tests Post-BMP (1993/94) Concentration Data*

Constituent	**X/Y**	**X/Z**	**Y/Z**
TSS	0.357	0.143	0.085
Oil and Grease	0.265	0.684	0.468
Cadmium	0.832	0.321	0.243
Chromium (ND values replaced)	0.894	0.441	0.307
Copper	0.274	0.167	0.164
Lead	0.200	0.172	0.225
Zinc	0.102	0.677	0.129

Table 6.6 p-Values; Paired t-tests Post-BMP (1993/94) Event Mass Data*			
	Station Group		
Constituent	**X/Y**	**X/Z**	**Y/Z**
TSS	0.347	0.100	0.107
Oil and Grease	<u>0.032</u>	0.498	<u>0.024</u>
Cadmium	0.108	0.184	0.063
Chromium (ND values replaced)	<u>0.032</u>	0.226	<u>0.042</u>
Copper	0.169	0.054	0.074
Lead	0.708	0.126	0.157
Zinc	<u>0.028</u>	0.445	<u>0.050</u>

* These values are the two-tail p-values from the paired t-tests performed on data for each pair of stations in the study. Each value represents the probability of error in accepting the hypothesis that there is a significant difference in the samples taken at two different gas stations.

Table 6.7 p-Values; Paired t-tests Pre-BMP (1992/93) Concentrations vs. Post-BMP (1993/94) Concentrations				
	Station			
Constituent	X	Y	Z	All
TSS	0.305	0.732	0.160	0.316
Oil and Grease (ND values replaced)	0.257	0.326	0.282	<u>0.045</u>
Cadmium	0.278	0.895	0.254	0.541
Chromium (ND values replaced)	0.342	0.614	0.494	0.770
Copper	0.313	0.453	0.172	0.121
Lead	0.390	0.798	0.185	0.259
Zinc	0.260	0.601	0.867	0.835

For the post-BMP monitoring, the EMLs were also tested for station-to-station differences. Significant differences were observed both between stations X and Y, and between stations Y and Z, for chromium, zinc, and oil and grease (see Table 6.6).

Pre-BMP to Post-BMP Differences

The lack of statistically significant differences in pollutant concentration data among the three stations for both years permits grouping of the data from the three stations in the pre- and post-BMP analyses, as well as use of the combined data sets in evaluations of rainfall-related effects for each year.

T-tests were again used to compare the pre-BMP monitoring results to those of the post-BMP conditions. The tests were run for each station individually and for data from the three stations combined, in each case comparing the pre-BMP data to the post-BMP data. The comparisons were done for both concentrations and mass loadings.

The results of the concentration data comparisons are shown in Table 6.7. A significance level of p=0.05 was again used to determine whether statistically significant differences exist. The only statistically significant difference in the pre- to post-BMP comparisons was found in the combined stations data sets for oil and grease. For the EML comparisons (Table 6.8), no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs. A complete set of the paired t-test results is presented in Appendix D.

Table 6.8 p-Values; Paired t-tests
Pre-BMP (1992/93) Masses vs. Post-BMP (1993/94) Masses

	Station			
Constituent	X	Y	Z	All

Copper	0.176	0.601	0.093	0.110
Lead	0.510	0.458	0.182	0.248
Zinc	0.173	0.775	0.908	0.508

6.5 Evaluation of Seasonal Trends

Regression analysis was used to evaluate the effects of precipitation patterns on gas station runoff chemistry for each of the two study years. A regression analysis provides an evaluation of the best-fit line drawn through a data plot. The "p" value indicates the likelihood that the observed relationship is due to chance. A p-value of ≤ 0.05 is generally considered to indicate a statistically significant relationship. The "r" value indicates the relative "goodness of fit", or strength of the relationship. An r value of 1 equals a perfect positive correlation between the data points; -1 equals a perfect negative correlation.

For the pre-BMP data, regressions were performed on the runoff concentration data vs. four rainfall parameters: rainfall intensity during the period of sampling, cumulative precipitation to date, days since last storm of 0.1" or greater, and days since last storm of 0.25" or greater.

For the post-BMP runoff concentration data, additional precipitation parameters were added: sampled storm depth (volume), intensity of storm (overall intensity during the entire storm event, from the ALERT rain gauge data), and elapsed rainfall before start of sampling. For the post-BMP event mass data, regressions were run on a smaller subset of precipitation parameters: cumulative precipitation to date, and days since last storm of 0.25" or greater.

The regressions were run for each station individually and for the combined stations data set. The log-transformed pollutant concentration values were used in all cases.

Pre-BMP Concentration Data

The statistically significant regression relationships for the pre-BMP data are shown in Table 6.9. The highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter. Four different constituents at station Y (chromium, lead, zinc, and TSS) and one constituent at station Z (zinc) were significantly correlated with this parameter. For the pooled data set (all stations combined), chromium and zinc were again significantly correlated with this parameter, although the r values were relatively low.

For the "days since last storm >0.10 inch" parameter, the station X regression of cadmium concentration was statistically significant, and had a fair r value, but the slope is negative, indicating that cadmium concentration decreases as the inter-event time gets longer, which is counterintuitive. It is likely that this result was an artifact due to chance. The pooled zinc data set was positively correlated with days since last storm >0.10 inch, although the r value was marginal.

At station Z, cadmium, lead, and zinc showed decreasing concentrations in relation to increasing rainfall intensity, which is plausible due to the diluting effect of more intense rainfall. For the pooled data set, oil and grease showed a similar inverse relationship to intensity, but the r value was weak.

Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters indicated that zinc (and possibly other metals) appeared to exhibit a build-up effect during dry periods at the fueling stations. Zinc concentration tended to decrease as the inter-event time decreased.

Table 6.9 Significant* Regressions
Rainfall Parameters vs. Concentrations**
Pre-BMP (1992/93) Monitoring

Station	Independent Variable	Dependent Variable**	"r" value
Y	Days Since Last Storm >0.25"	Chromium	0.84

Note: p-values below 0.05 are shaded and **bold**.

Post-BMP Concentration Data

The regression results for the concentration data are shown in Table 6.10. The statistically significant regression relationships are indicated by shading. Plots of the significant regressions are presented in Appendix E. There were several significant relationships but, as was the case with the pre-BMP data, the highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter. All five metal constituents and oil & grease, both at station Z and for the pooled data set (all stations combined), were significantly correlated with this parameter. Only TSS did not show any significant correlation with the "days since last storm >0.25 inch" parameter.

Concentrations of three of the five metals and oil & grease, in the pooled data set, were also significantly correlated with the "days since last storm >0.10 inch" parameter. Pooled data set concentrations of TSS showed statistically significant regression relationships with two parameters, elapsed rainfall before start of sampling and sampled storm depth. Both these parameters relate to volume of the sampled storm.

Post-BMP Event Mass Load Data

The regression results for the event mass load data are shown in Table 6.11. The statistically significant regression relationships are indicated by shading. Plots of the significant regressions are presented in Appendix F. In contrast to the post-BMP concentration data, there were no statistically significant regression relationships with the parameter "days since last storm of 0.25" or greater."

6.6 Evaluation of Effects of Mobile Cleaning

Despite the result, discussed in pre- to post-BMP Differences (section 6.4) that, overall, gas station runoff quality was not significantly different after implementation of BMPs, there were statistically significant regression relationships ($p \leq 0.05$) between both the post-BMP concentration and event mass load data, and the "days since last cleaning" parameter. The pooled concentration data set for two metals, cadmium and lead, showed a significant correlation with "days since last cleaning." The event mass load data showed a number of statistically significant regression relationships with the "days since last cleaning" parameter. The pooled data sets for three metals (cadmium, chromium, and zinc) and oil & grease showed that the event mass loads of these constituents decreased with decreasing number of days since last cleaning.

Table 6.11 Regression p-Values (Post-BMP)

Event Mass Loadings

7.0 *Discussion and Recommendations*

This section discusses the results of Phase 1 and Phase 2 and makes recommendations for further research.

7.1 Discussion

One of the goals of the project was to compare pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness. As discussed in section 4, Best Management Practices, the project team implemented the full suite of BMPs at each station, as opposed to implementing one BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results.

Based on observations by project personnel and best professional judgment about the efficacy of source controls, it is highly likely that of the six BMPs implemented at the gas stations, the one BMP with the most significant chance to affect runoff quality was mobile high pressure water cleaning. The combined effect of the other five source controls:

public notices,
litter control,
storm drain stenciling,
spill cleanup materials, and
employee awareness,

seems likely to have a much less significant impact on the primary sources of pollution at the stations, namely, high volume vehicle traffic and leaks and spills of vehicle fluids. In addition, some of the other source controls (litter control, spill cleanup, and employee training) were in place, to some extent, during the pre-BMP period. Consequently, the study can be considered in large part a pilot test of mobile cleaning as a best management practice. The discussion of BMP effectiveness therefore focuses on mobile cleaning.

Climatological Differences

In discussing the differences between the pre-BMP and post-BMP data, it is important to note the large difference in the climatology of the two wet seasons. In 1993-94 (post-BMP), about half as much rain fell compared to the pre-BMP wet season (1992-93) (approx. 13 inches versus approx. 26 inches). Because 1992-93 (pre-BMP) was a relatively wet year in California, with frequent storms occurring on a regular basis throughout the winter, the inter-event times were fairly short, ranging from 1 to 8 days. The inter-event times in 1993-94 reflected the drier winter, ranging from 1 to 34 days. Average inter-event time for pre-BMP sampling events was four days, compared to over nine days for post-BMP samples. As discussed below, both pre-BMP and post-BMP runoff quality was significantly affected by the inter-event time period (number of days since last storm).

Research by others including Pitt (1987), indicates that rain depth and intensity significantly affect particulate residue washoff from impervious surfaces. Normal rains, up to about one inch, typically remove only about 10-20 percent of the particulate residue on a surface. So it is possible that during the post-BMP wet season, when total rainfall was one-half of the pre-BMP wet season, that relatively less particulate residue was washed off the asphalt surfaces at the gas stations by storm events.

Summary of Pre-BMP to Post-BMP Differences

When all the data from the pre-BMP condition is combined and compared against all the post-BMP condition data, the only statistically significant difference in the pre- to post-BMP concentrations was for oil and grease, and it was higher after the BMPs were implemented. For the event mass loading comparisons, no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs.

However, these results must be interpreted in light of the sample size data variability and climatological effects, as follows:

1. Although the sample size for both years (n=18, 3 stations x 6 storms) is reasonable, given the logistical challenges of storm water monitoring; statistically, it is a relatively small sample size, particularly considering the inherently large variability in storm water data.

2. A review of the data from both years (Tables 5.4 and 5.5) confirms the high degree of variability in the pooled data. Standard deviations were generally as large as the means.

Effects of Climatology on Pre-BMP and Post-BMP Concentration Data

Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters indicated that zinc (and possibly other metals) appeared to exhibit a buildup effect during dry periods at the fueling stations. Zinc concentration tended to decrease as the inter-event time decreased. Similarly, for post-BMP data, the highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter (all five metal constituents and oil & grease), and with the "days since last storm >0.10 inch" parameter (three of the five metals and oil & grease).

This buildup or accumulation effect has been documented in other studies (U.S. EPA, 1979; U.S. EPA, 1985; Pitt and McLean, 1986) for particulates. It appears from this study that many of the heavy metals and oil & grease exhibit a similar effect. These data also seem to indicate that the accumulation of these pollutants translates into higher concentrations in the runoff, that is, that what accumulates tends to wash off.

For the post-BMP data, the only constituent that did not show any significant correlation with either of the "days since last storm" parameters was TSS. The concentration of total suspended solids in runoff did not increase with increasing time between significant storms. The potential explanations for this result are discussed below in relation to the effects of mobile cleaning.

Effects of Mobile Cleaning on Concentration and Mass Load Data

Although overall gas station runoff quality was not significantly different after implementation of BMPs, the length of time between cleanings and sampled storm events seems to have affected runoff quality. There were statistically significant regression relationships ($p \leq 0.05$) between both the post-BMP concentration and event mass load data for some metals and oil & grease, and the "days since last cleaning" parameter. This result appears to parallel the correlations found between the post-BMP concentration data and the "days since last storm" parameters. It seems that, in general, measured runoff concentrations for some metals and oil & grease increase with increasing time since the previous "washoff" event, whether that event was natural (storm) or artificial (cleaning).

In contrast to metals and oil & grease, the post-BMP concentrations and event mass loads of total suspended solids in runoff did not increase with increasing time between cleanings. Again, this result appears to parallel the correlations found between the post-BMP TSS concentration and load data and the "days since last storm" parameters. There are a couple of potential explanations for these results in relation to the effects of mobile cleaning.

One potential reason that post-BMP TSS concentrations and loads did not increase with increasing time between either storms or cleanings is that the cleanings were effective at removing available particulate residue and possibly even reducing the total residue lodged in the spaces of the asphalt surface. It is possible that the cleanings were much more effective at removing TSS, which did not exhibit a buildup effect, than in removing oil & grease and heavy metals, which did show an accumulation effect. It is likely that oil & grease have a strong affinity for asphalt surfaces because of the similarities in their chemical composition. This affinity would make the separation of oil & grease from asphalt difficult, even under the high pressure and temperature conditions created by the cleanings. As for the heavy metals, although they have been shown to be bound to particulates, it is likely that a significant amount of metals are also bound to oil & grease.

Another potential reason that post-BMP TSS data did not correlate with the "days since last ..." parameters may relate to the fact that the post-BMP concentrations of TSS showed statistically significant regression relationships with two completely different parameters than the other constituents: elapsed rainfall before start of sampling and sampled storm depth. Both these parameters relate to volume of the sampled storm. This result is consistent with the research of Pitt (1987), discussed previously, that indicates that rain depth and intensity significantly affect residue washoff from impervious surfaces, and that the accumulation of particulates on paved surfaces does not necessarily translate into those particulates being washed off by storm runoff. This study's results may indicate that, when total rainfall was significantly reduced during the post-BMP wet season, very little particulate residue was washed off the asphalt surfaces at the gas stations by storm events.

The point could be made that although total rainfall was significantly reduced during the post-BMP wet season, it would seem that the ten mobile cleanings that took place during this time would have, in a sense, "made up for" the lower frequency and volume of storms, and washed off much of the particulates. However, the timing of the cleanings was such that they may have had little impact on TSS buildup. Although the mobile cleanings occurred interspersed throughout the wet season (see Figure 5.4), only the last two mobile cleanings occurred after a significant storm (greater than 0.1 inch) and before the sampled storm (#6), and therefore, shortened the number of days, and presumably the TSS accumulation, since a significant event, either storm or cleaning.

Effectiveness of Mobile Cleaning

Although visual observations (see Figure 4.3) confirmed that a significant amount of pollutants were removed with each cleaning, it is likely that the cleanings may have made more pollutants, particularly oil & grease, "available" for washoff in the next event, either storm or cleaning, by freeing up pollutants and allowing them to redeposit on the pavement surface. There are several reasons for this observation.

1. Pollutant deposition - The asphalt at gas stations, particularly the high sales volume stations used in this study, is subject to very high pollutant deposition rates. The sources include not only the vehicles themselves traveling over the surface for routine services (e.g., fueling), but episodic sources like fluid spills in the air/water supply area, and local sources like the resuspension and deposition of airborne pollutants from vehicles stopping at the intersections and traveling on the major streets adjacent to the stations. The net effect is an essentially continuous deposition of pollutants at such locations. The cleaning effort may not have been sufficient for the level of pollutant deposition occurring at the gas stations.

2. Surface texture - Asphalt is a relatively rough and porous surface. Because of its texture, it has innumerable miniature storage spaces that receive and detain pollutants as they are deposited on its surface. These spaces act as pollutant sources when it rains or when the surface is cleaned. The ability of high pressure cleaning to efficiently remove pollutants from porous surfaces is questionable.

3. Pollutant buildup - A relatively long-term buildup of pollutants may have occurred on the outside pavement surfaces of these stations because of the significantly reduced volumes of rain that fell during the six year drought period preceding the study. In addition, because of drought restrictions, the use of water to clean asphalt surfaces at these stations was prohibited by local ordinance during much of this period. The high pressure cleanings may have loosened up the long-term buildup of pollutants which otherwise would not have been available for washoff during normal rainfall conditions.

4. Water accumulation before runoff - Because of the innumerable miniature storage spaces in asphalt, a significant amount of water must fall, in the case of a storm, or be applied, in the case of a cleaning, before these spaces are "filled" and runoff occurs. Observations by the mobile cleaning crew confirmed that the asphalt had to be wetted first before actual cleaning could start. This phenomena means that when cleaning time is restricted, as it was at the stations because of high traffic volumes, it is difficult to tell if the spray application rate is sufficient to overcome the necessary wetting and create a constant sheet flow toward the wash water collection device.

5. Incomplete washoff after cleaning - The mobile cleaning crew reported that although visual observations indicated that the cleanings removed a significant amount of pollutants, they also probably left behind a significant amount for a couple of reasons:
   a) The asphalt seemed to contain more pollution than the crew had time to remove.
   b) The limited coverage of the cleaning wand meant that even when the crew was able to remove significant quantities of the pollutants from the asphalt and suspend them in the sheet flow, as soon as the wand was moved to another area, pollutants started settling out of the sheet flow back into the asphalt, resulting in a redistribution rather than removal of some pollutants.

   It's likely that some of the pollutants left behind or redistributed were previously not available to be washed off, but were made available by mobile cleaning to be washed off in the next significant storm.

All-in-all, it appears that this pilot test of mobile cleaning asphalt surfaces, at high sales volume gas stations, near busy intersections on major streets, was probably a worst case scenario for this potential best management practice. The cost of mobile cleaning used by the fueling stations for this study was estimated to be about $600 per station per wash down, which is equivalent to $1,300 per acre of paved surface. Therefore, the cost of mobile cleaning a significant portion of the areas in a watershed exposed to vehicle traffic, on a regular basis, would be quite high.

Because the results were inconclusive, this study cannot recommend the implementation of the mobile cleaning BMP on a large scale. However, field observations and study results seem to indicate that, given the right conditions, mobile cleaning may have the potential to remove sources of storm water pollution. The discussion below provides some ideas on the focus of future studies.

7.2 Recommendations for Conduct of Future Studies

Monitoring results for the pre- and post-BMP study showed that constituent concentrations in runoff from the fueling stations are similar to those found in storm water monitoring data on streets, parking lots, driveways, oil/grit separators, and other areas that have significant exposure to vehicle traffic. In this study, the potential for interference with gas station activities and the resulting disruption to business constrained implementation of mobile cleaning. Because runoff from other areas significantly exposed to vehicles is likely to be representative of gas stations, it may be more appropriate to conduct future investigations of source control effectiveness on paved surfaces exposed to vehicle traffic that are not subject to the logistical constraints at high volume fueling stations. The discussion below is intended to provide insight on how to improve investigations of BMP effectiveness.

Existing Source Controls

Because existing source controls such as spill cleanup, litter control ,and employee education were being implemented at the fueling stations on a regular basis in the pre- and post-BMP study periods, their effectiveness could not be quantified. However, their ability to prevent potential sources of contamination is high and should be emphasized in all commercial and industrial areas where outdoor spills may occur.

New Construction Source Controls

Methods of source control not used in this study because of the high costs of retrofit include those that could normally be built as part of new facility construction. These BMPs include isolating runoff, redirecting runoff from areas with high pollution potential, or substituting cement for asphalt because it is easier to clean. Many of these best management practices may be cost-effective over the long-term in reducing storm water pollution.

Further Study of Mobile Cleaning

In this study, the potential for interference with gas station activities precluded extensive quantitative monitoring of the mobile cleaning method itself. Application rates varied over the drainage areas because of traffic, operator judgment, and time constraints. To reduce variability, a controlled application could be done by monitoring the amount and rate of application of high pressure/high temperature water. Other parameters to monitor might be use of soaps and detergents, use of different cleaning apparatus, and application on different pavement surfaces (e.g., cement concrete).

Because of the high cost of mobile cleaning, its practical use may be limited to spot cleaning specific areas with evidence of spills or staining such as behind restaurants, around vehicle service areas, and on heavily stained areas of parking lots. The important elements of mobile cleaning are that it be preventative and that the wash water be collected and disposed of properly.

Improvement in Pre- and Post-BMP Study Design

One of the advantages of this study's two-year time frame was that it allowed ample time after the pre-BMP monitoring to select and implement best management practices before the post-BMP monitoring began. The disadvantages of this time span were that climatological and site conditions changed between the pre-BMP and post-BMP monitoring. One alternative to this method is to conduct the study in the same wet season by monitoring a large number of vehicle traveled areas and service facilities of similar characteristics for the first few storms to verify that the data can be pooled, and then to implement the BMPs at some sites for the remaining storms to achieve a direct comparison on a per storm basis. This method may reduce climatological differences and differences in sites that occur from year to year. However, it would be necessary to statistically account for the effects of seasonal variation on runoff quality.

Use of Larger Watershed Treatment Controls

This study has attempted to demonstrate the effectiveness of BMPs, and source controls in particular, in reducing pollutant loadings from gasoline fueling station runoff. It is clear from this study and others that it is not just gas station runoff, but runoff from any area where vehicles travel, park, or are serviced that is of concern. Unfortunately, this description includes most of the area in urban watersheds and much of the area in suburban watersheds. The success and the practicality of implementing all but the most restrictive source controls (e.g., product reformulations - unleaded gasoline) over such a large area is questionable. In addition, measuring the effectiveness of less restrictive source controls is complicated by the inherent variability in runoff data. As a result, regional treatment such as detention basins, which have been used successfully elsewhere, may warrant a closer look in California.

8.0 Public Participation

This section describes the public participation process for the project. One of the goals of the project is to disseminate the results to a wide audience. To effect this goal, three presentations were made as part of the Phase 1 effort. The first presentation was an open house hosted by Sacramento County, a second presentation was made to WSPA at the beginning of the project, and, near the end of Phase 1, a third presentation was made to the American Public Works Association (APWA) California Stormwater Quality Task Force, a consensus building group of about 100 representatives from regulatory agencies, municipalities, industry, construction, and consulting firms.

A final presentation was made after Phase 2, also to the APWA California Stormwater Quality Task Force. Members of the project team presented preliminary results from the analysis of the post-BMP data as part of a larger presentation on monitoring results from a number of projects statewide, including the WSPA study of gas stations and parking lots (WSPA, 1993).

Appendix A

Distributional Method to Determine Non-detect Values

Distributional Method to Determine Non-detect Values

Example: Chromium concentration at station Z, December 10, 1992 and January 6, 1993.

1. Assign ranks to each of the results in ascending order of concentration, beginning with the two non-detected values. The first non-detected value was rank one and the greatest concentration (7.4 ug/L) was assigned a rank of 6.

2. Assign probabilities to each value in the data set using the Hazen (1930) method:

   $p_i = (i - 0.5 / n) * 100\%$

   where i is the rank of the given data point, p_i is the probability assigned to the i^{th} data point, and n is the number of data points.

3. Create a probability plot with the percent probability along the x-axis and the concentration on a log scale along the y-axis.

4. Using the curve fitting function of Kaleidagraph™, generate an exponential curve that closely matches the actual data curve:

   concentration = $2.6757e^{0.69726z}$

   where z is the standard normal deviate, or Z-statistic, corresponding to the specific cumulative probability (in percent).

5. Use the equation just derived, calculate values for the same probabilities as the original data points. The points with 8.33% and 25.00% probability correspond to the on-detected values.

6. The calculated values for the non-detects were 1.02 ug/L and 1.67 ug/L. These values were higher than the analytical detection limit, indicating a data gap between the detected values and the non-detected values.

7. Replace the non-detected values with the detection limit. (1.0 ug/L) since the values calculated to replace the non-detected values were actually slightly greater than the detection limit.

GEOMATRIX

TABLE OF CONTENTS

EXECUTIVE SUMMARY

This report presents the results of a two-part study of constituents present in simulated storm water runoff from six retail gasoline outlets (RGOs) and four commercial parking lots. The objective of the study is to characterize storm water runoff from RGOs and to compare the results with runoff from commercial parking lots and published urban "background" values. The study was funded by the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API).

The study demonstrates that for the constituents analyzed, median event mean concentrations (EMCs) in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by the National Urban Runoff Program. Furthermore, there are no significant differences in median EMCs in runoff from RGO pump islands and driveways for the constituents analyzed. These results indicate that fueling activities at normally operated and maintained RGOs do not contribute additional significant concentrations of measured constituents in storm water runoff.

In 1987, Section 402(p) was added to the Clean Water Act to establish a framework for addressing storm water discharges under the National Pollutant Discharge Elimination System (NPDES) program. Storm water discharges from commercial facilities, such as RGOs and parking lots, are not included under the initial regulations. However, regulations are now being promulgated that are expected to increase the number and types of dischargers required to obtain NPDES permit coverage for storm water discharges. EPA, in a report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees.

This study used a simulated rainfall method to induce runoff from representative RGO and parking lot test sites. The RGO and commercial parking lots used as test sites provide a variety of site and operational conditions. Simulated runoff was collected at two areas within each test site. These areas include pump islands and driveways at RGOs and high-use and moderate-use areas within commercial parking lots. Both discrete and composite runoff samples were collected during the 45-minute test. The collected samples were analyzed in accordance with appropriate EPA methods for a variety of constituents including California Code of Regulations Title 26 Metals, total suspended solids, oil and grease, total petroleum hydrocarbons as gasoline (TPHg), and benzene, toluene, ethyl benzene, and total xylenes (BTEX).

GEOMATRIX

RESULTS OF A RETAIL GASOLINE OUTLET AND COMMERCIAL PARKING LOT STORM WATER RUNOFF STUDY

1.0 INTRODUCTION

This report presents the results of a two-part study of simulated storm water runoff from six retail gasoline outlets (RGOs) and four commercial parking lots. Part I was conducted by Hart Crowser and characterized simulated storm water runoff from five RGOs. Part II was conducted by Geomatrix Consultants, Inc. (Geomatrix) and characterized simulated storm water runoff from four commercial parking lots and one RGO. The study was funded by the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API).

1.1 Objective

The objective of this study is to characterize storm water runoff from RGOs and to compare the results with runoff from commercial parking lots and published urban "background" values.

1.2 Background

In 1972, the Federal Water Pollution Control Act (also known as the Clean Water Act or CWA) was amended to provide that any discharge of pollutants from a point source to Waters of the United States is effectively prohibited unless it is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Although this technically prohibits the discharge of pollutants in storm water, the focus at that time was on the bigger problems of industrial waste and sewage treatment.

As more significant sources of water pollution were brought under control, the impact of pollutants in storm water became more noticeable. Water quality studies conducted in the 1970s and 1980s identified urban runoff as a diffuse, or nonpoint source of pollution. In response to these studies, the

1987 amendments to the Water Quality Act added Section 402(p). This section established a comprehensive two-phased approach for the U.S. Environmental Protection Agency (EPA) to follow in addressing storm water discharges. Five types of storm water discharges are covered under the Phase I program. Dischargers within these five categories, listed below, were required to obtain permit coverage before October 1, 1992:

A) A discharge for which a permit has been issued prior to February 4, 1987;

B) A discharge associated with industrial activities;

C) A discharge from a municipal separate storm sewer system serving a population of 250,000 or more;

D) A discharge from a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000; or

E) A storm water discharge determined by the EPA Administrator or the State to contribute to a violation of a water quality standard or to be a significant contributor of pollutants to the waters of the United States.

Discharges from commercial facilities, such as RGOs and parking lots, are not included under the Phase I regulations. However, Phase II regulations now being promulgated are expected to increase the numbers and types of dischargers that are required to obtain NPDES permit coverage for storm water discharges. EPA, in a draft Phase II report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees. It should be noted that, according to the EPA draft Phase II report, the list of potential permittees was created using limited reliable data on storm water problems associated with Phase II sources nationwide. In order to provide data regarding storm water runoff from potential Phase II facilities, WSPA and API commissioned this study.

1.3 Other Studies

This study utilized the results from a recently published RGO runoff study titled *Action Plan Demonstration Project, Demonstration of Gasoline Fueling Station Best Management Practices, Phase 1 Report* (September, 1993), prepared by Uribe & Associates and Larry Walker Associates for the County of Sacramento, Water Resources Division. Another storm water runoff study used for the WSPA/API study described herein is the *Final Report of the Nationwide Urban Runoff Program* (December 30, 1983) prepared by the Water Planning Division of EPA. These storm water studies are described in the following sections.

1.3.1 Sacramento County's Action Plan Demonstration Project

Sacramento County's Action Plan Demonstration Project characterized storm water runoff from RGOs and identified potential best management practices (BMPs) to reduce storm water runoff pollution. EPA provided funding of the study by a grant through the San Francisco Estuary Project and the Sacramento County Water Resources Division. The report presents the analytical results of samples collected from storm water runoff from three RGOs in Sacramento County.

The Sacramento County project selected high-volume (over 200,000 gallons per month), self-service RGOs with convenience markets and without automobile repair service bays for the study. The selected RGOs are located less than 2 miles apart.

Within each RGO, a single representative sampling point was selected where station runoff leaves the property and includes drainage from the fueling and auxiliary services areas. Uribe collected samples during six storm events during the 1992/93 wet season. For five of the storms, the sample collection procedure consisted of placing a 1 liter sampling bottle into a below-grade concrete sump. A portion of the storm water discharge flowed over the lip of the sump directly into a sampling bottle. Samples were collected in this manner for each 0.05 inch increment of measured rainfall. The samples were composited immediately into a 5-liter borosilicate bottle until the 5-liter bottle was filled. The one exception to this sample collection method occurred during the first storm event, when only grab samples were collected.

The initial analytical program for the collected samples included analyses for oil and grease, total suspended solids, metals (13 EPA priority pollutant metals plus aluminum and iron), polycyclic aromatic hydrocarbons (PAHs), and petroleum hydrocarbons. However, some of the metals, petroleum hydrocarbons, and PAHs were consistently not detected in samples collected from the first three storm events. On the basis of these results, the following parameters were selected for the final three sampling events:

- oil and grease
- total suspended solids
- heavy metals (cadmium, chromium, copper, lead, and zinc)

Pertinent results of Sacramento County's Action Plan Demonstration Project are discussed in Sections 3 and 4 of this report.

1.3.2 National Urban Runoff Program

The National Urban Runoff Program (NURP) was conducted from 1978 through 1983 with funding and guidance provided by EPA. NURP characterized the chemicals present in discharges from separate storm sewers that drain residential, commercial, and light industrial areas. NURP included 28 projects across the nation, conducted separately at the local level, but centrally reviewed, coordinated, and guided. The overall objective of the program was to collect information from a national perspective that could be used to characterize urban runoff, assess the impact of non-point source urban runoff on the quality of the receiving waters, and assist decision makers in developing control measures to limit its impact. The results of NURP provide insight on what can be considered background levels for urban runoff.

The resultant NURP data represent a cross section of regional climates, land use types, and ground surface conditions. The sites sampled during NURP included 81 sites that were unaffected by hydraulic devices, such as detention basins, that would modify runoff. A total of more than 2300 separate storm events were sampled from these sites during the project. Samples collected from these sites were tested for the following standard pollutants:

- total suspended solids
- biochemical oxygen demand
- chemical oxygen demand
- total phosphorus
- soluble phosphorus
- total Kjeldahl nitrogen
- nitrite and nitrate as N
- heavy metals (copper, lead, and zinc)

Pertinent results of NURP are discussed in Sections 3 and 4 of this report.

2.0 WSPA/API PART I AND PART II STORM WATER RUNOFF STUDIES

This section describes both parts of the WSPA/API runoff study. Part I, conducted by Hart Crowser, characterized simulated storm water runoff from five RGOs. Part II, conducted by Geomatrix, characterized simulated storm water runoff from four commercial parking lots and one RGO.

2.1 Literature Search

As part of this WSPA/API study, Hart Crowser conducted a literature search to assess whether analytical results from prior RGO runoff studies were available for this study. The search was conducted using the Dialog Information Database and included a search of the following databases:

NTIS (National Technical Information Service)
COMPENDEX (Engineering Information Inc.)
APILIT (American Petroleum Institute)
Pollution Abstracts/Cambridge Scientific Abstracts
Water Resources Abstracts
WATERNET (American Water Works Association)
CA SEARCH (Chemical Abstracts)

The database search did not disclose prior RGO storm water runoff studies.

2.2 Selection of RGOs and Test Sites

In selecting the RGOs to be used for the study, the following characteristics were evaluated for a number of potential RGO sites:

- monthly throughput
- site location
- anticipated level of use by commercial vehicles
- age and general appearance
- types of ancillary services provided including on-site vehicle service, car washes, or convenience stores
- on-site drainage patterns and adjacent property usage.

On the basis of this evaluation, six RGOs, all located in Southern California, were selected for the study. The six RGOs provide a representative cross section of typical RGOs in Southern California. Site characteristics for each RGO are summarized in Table 1. Each of the selected RGOs was considered "normally operated and maintained". For the purposes of this study, "normally operated and maintained" signifies that the RGOs utilize Best Management Practices (BMPs) to minimize the buildup of potential storm water contaminants on exposed areas. These BMPs include regular sweeping of exposed areas, regular site inspections, and standardized spill response procedures.

Hart Crowser and Geomatrix conducted the simulated rainfall application and sample collection at a pump island and driveway approach area within each RGO. These areas were selected to provide results that are representative of discharge from the entire RGO. A summary of pavement types and conditions of each test site location is presented in Table 2.

A simulated gasoline spill was performed at RGO 5 to provide data regarding the effectiveness of standardized spill response procedures. One quart of regular unleaded gasoline from a pump nozzle was discharged onto the pump island pavement. Absorbent material was applied to the spill after one minute. The absorbent material was then swept up after it appeared to have absorbed the spilled liquid, and the simulated runoff test was conducted.

2.3 Selection of Parking Lots and Test Sites

Commercial parking lots for the second part of the study were evaluated using the following criteria:

- site use
- relative parking duration
- traffic and parking volume
- pavement type, condition, and visual appearance
- cleaning methods and frequency
- on-site drainage patterns.

On the basis of this evaluation, Geomatrix and WSPA selected four commercial parking lots, all located in Southern California, for the study. The selected parking lots were associated with a grocery store, bank, office complex, and restaurant.

Simulated rainfall was applied and samples were collected at two locations at each of the four parking lots for a total of eight test sites. The test locations included one high-use and one moderate-use parking area. The high-use area was generally closer to the commercial facility entrance, and was occupied more frequently than the moderate-use area. Each of the parking lots used scheduled sweeping as a good housekeeping BMP. Parking lot test locations, conditions, and BMPs are summarized in Table 3.

2.4 Testing Methodology

To minimize test variability caused by differing rainfall intensities and durations, both parts of the WSPA/API runoff study used a simulated rainfall method to induce runoff from the study sites. The water-dispensing system and sampling procedures were identical for both the RGO and commercial parking lot sites. The water-dispensing system was designed to apply water uniformly over the test area and create sheet flow.

During the test, potable water was distributed uniformly over an approximate 400-square-foot area using a network of perforated 1-inch-diameter, schedule 80 polyvinyl chloride (PVC) pipes elevated approximately 4 feet above the pavement surface. A schematic of the simulated rainfall system is shown on Figure 1.

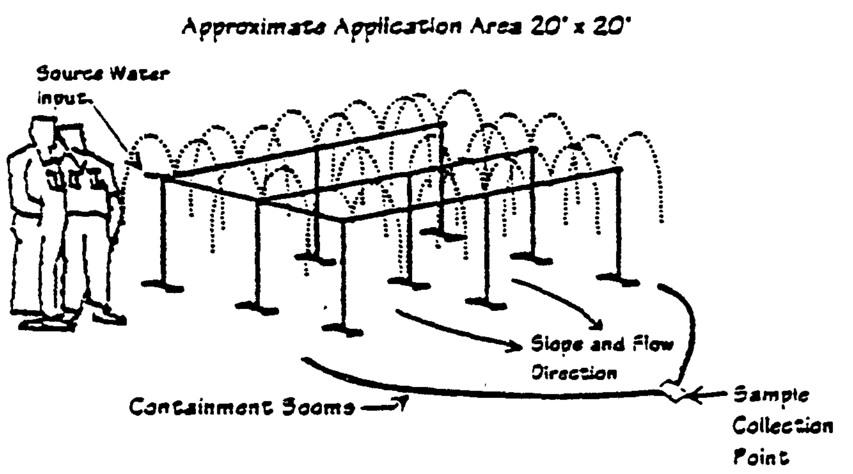

Figure 2. Schematic of Simulated Rainfall System

The water was applied at a rate of approximately 2.0 gallons per minute (gpm) for the duration of the 45-minute test. This rate represents a rainfall rate of approximately 0.008 inch per minute or 0.12 inch every 15 minutes over the test application area.

The runoff from the simulated rainfall application was channeled by gravity and sand-filled polyethylene tubing containment berms to a collection point. The runoff was diverted into a stainless steel collection trough and was pumped into a poly-lined 55-gallon steel drum.

2.5 Sampling Procedures

Sampling procedures for both Part I and II studies follow the sampling protocol established by SW-846, "Test Methods for Evaluating Solid Waste" (including surface and groundwater).

The following samples were collected at each test site.

- A discrete grab sample from the collection trough every 15 minutes during the 45 minute test
- One composite sample from the runoff pumped into the 55-gallon drum.

In addition to these samples, a background sample of the on-site water supply was collected at the point of discharge from the simulated rainfall application apparatus, and a duplicate oil and grease sample was collected at each test site. Samples were obtained using cleaned sampling equipment and were placed into laboratory-supplied and certified "clean" sampling containers. Collected samples were labeled, placed on ice in a cooler, and maintained under proper chain-of-custody procedures. A trip blank sample was included in each of the sample coolers used for this study.

2.6 Analytical Testing

GTEL Environmental Laboratories, a state-certified analytical laboratory located in Torrance, California analyzed samples from RGOs 1 through 5. Del Mar Analytical, a state-certified laboratory located in Irvine, California analyzed samples from RGO 6 and all four parking lots.

Laboratory analyses were conducted in accordance with appropriate EPA methods. The constituents, analytical test methods, and detection limits used for the WSPA/API study are listed in Table 4.

2.7 Quality Assurance and Quality Control

Both parts of the WSPA/API study described herein developed and implemented field and laboratory quality assurance/quality control (QA/QC) procedures. Field QA/QC includes following strict sampling protocols as specified in the project work plans and standard operating procedures. These procedures include an evaluation of cross-contamination through the analysis of trip blanks. Laboratory QA/QC addressed the following:

- Accuracy (analysis of matrix spike recoveries on each batch of samples and regular analysis of certified samples)
- Precision (analysis of matrix spike duplicates)
- Contamination (analysis of method and filter blanks)
- Holding Time (specified holding times associated with each chemical method)
- Certified Methods of Analysis (EPA or State certified methods of analysis).

3.0 RESULTS AND DISCUSSION

The following sections present the results of the WSPA/API simulated runoff study and provide summaries of analytical data from Sacramento County's Action Plan Demonstration Project and NURP. Also presented are data plots that provide comparisons between the pump islands and driveway RGO results and between RGOs, parking lots, and NURP.

3.1 Analytical Results

The analytical results of simulated runoff samples collected from RGOs as part of this study are summarized in Tables 5a and 5b. These tables present the results of both the Part I study conducted by Hart Crowser (RGOs 1 through 5) and the Part II study conducted by Geomatrix (RGO 6). Tables 6a and 6b summarize the results of laboratory analyses of simulated runoff samples from commercial parking lots. Tables 7 and 8, respectively, summarize the results from Sacramento County's Action Plan Demonstration Project and median concentrations reported in NURP.

3.2 Data Comparisons

This report compares analytical data from the WSPA/API RGOs and parking lots, the Action Plan Demonstration Project, and NURP using a series of box plots, Figures 3 through 24. Box plots are a simple and useful method of data comparison because they effectively describe the characteristics of single groups of data and reveal differences between groups. The components of a typical box plot are presented on Figure 2. Shown on this figure are the 25th and 75th percentiles of the data, which form the top and bottom of the box. Therefore, by definition, 25 percent of the data have a value equal to or less than the bottom line of the box, and 75 percent have a value equal to or less than the top of the box. The middle horizontal line within the box is the median, or 50th percentile (one-half of the data values are equal to or less than the median, and one-half are equal to or greater). Lines (called whiskers) extend vertically from the top and bottom of each box to the maximum and minimum data values.

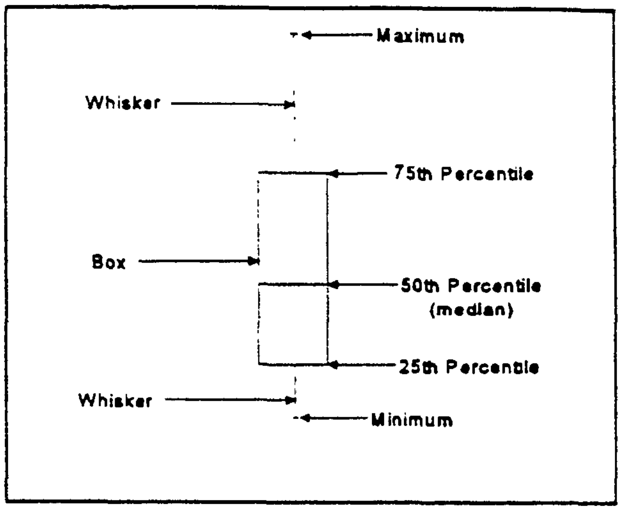

Figure 2. Components of a Typical Box Plot

In many cases, the boxes shown on Figures 3 through 24 are collapsed into a single horizontal line without a whisker extending to the minimum value. The principal reason for the shape of these plots is the presence of a large number of non-detect values in the data set. When this occurs, a single horizontal line is drawn at the detection limit, and the whisker and box segments below the reporting limit are masked.

Although Hart Crowser and Geomatrix collected and analyzed both discrete and composite samples for this study, only the composite results are used for comparison purposes in this report. Composite results are normally considered more meaningful than individual discrete results when evaluating pollutant loading in storm water discharges. It should be noted that the composite sampling methodology used for the WSPA/API study is equivalent to the event mean concentration (EMC) reported in NURP (EPA, 1983), which is defined as the total constituent mass discharged divided by the total runoff volume. In addition, the flow weighted sampling method used for the Action Plan Demonstration Project (Uribe, 1993) provides an estimate of EMC. To provide consistency in comparisons between these studies, the EMC will be used when describing composite discharge concentrations for the remainder of this report.

The following sections discuss comparisons between the pump island and driveway results from the WSPA/API RGOs, and between the RGOs, parking lots, and NURP.

3.2.1 Comparison of Results from RGO Pump Islands and Driveways

Figures 3 through 9 present box plots that compare EMC results between the pump islands and driveways from the WSPA/API RGOs for total suspended solids, oil and grease, total petroleum hydrocarbons as gasoline (TPHg) and benzene, toluene, ethyl benzene, and total xylenes (BTEX). On the basis of these box plots, there is no significant difference in median EMCs in runoff from pump islands and driveways for these constituents. In each case, the median EMCs from pump islands and driveways are either at or very near the detection limit. Toluene, ethyl benzene, and total xylenes were detected more frequently in samples from pump islands, primarily the result of the simulated spill on the RGO 5 pump island. However, the EMCs of these chemicals were significantly below the Maximum Contaminant Levels (MCLs) for drinking water established by EPA and California Department of Health Services (Marshack, 1993).

3.2.2 Comparison of Results from RGOs, Parking Lots, and NURP

Figures 10 through 24 present box plots that compare the EMC results for RGOs and parking lots. The median EMC results from NURP are also presented on the data plots for total suspended solids, copper, lead, and zinc (Figures 10, 20, 22, and 24, respectively). On the basis of these box plots, there is no significant difference in median EMCs between RGOs and parking lots for these constituents. In addition, the box plots for total suspended solids, copper, and zinc indicate that for these constituents, there is no significant difference in median EMCs between RGOs, parking lots, and background runoff levels established by NURP. The box plots for lead, Figure 22 indicate that the median and range of EMCs from RGOs and parking lots are significantly less than the background values reported in NURP.

4.0 CONCLUSIONS

The results of this study demonstrate that for the constituents analyzed in this report, median EMCs in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by NURP. Furthermore, there are no significant differences in median EMCs in runoff from RGO pump islands and driveways for the constituents analyzed. In all cases, the fueling related constituents (TPHg and BTEX) from pump islands were either not detected or below applicable Maximum Contaminant Levels (MCLs). These results indicate that fueling activities at normally operated and maintained RGOs do not contribute additional significant concentrations of measured constituents in storm water runoff.

Disclaimer

The statements and conclusions of this guide are those of the California Stormwater Quality Task Force (Task Force) and not necessarily those of the State of California. The mention of commercial products, their source, or their use in connection with material reported herein is not to be construed as either an actual or implied endorsement of such products.

The guide was produced and published by the California Stormwater Quality Task Force, an advisory body of municipal agencies regulated by the storm water program. This guide is not a publication of the State Water Resources Control Board or any Regional Water Quality Control Board, and none of these Boards has specifically endorsed the contents thereof. The purpose of this guide is to assist municipal agencies and retail gasoline outlets subject to storm water regulations, in attaining compliance with such regulations. This guide is not specifically intended for use in geographic areas not subject to federal or state storm water regulations, or at facilities that do not discharge storm water either directly to surface waters or indirectly, through municipal separate storm drain systems. Implementation of these best management practices can not be construed as compliance with all other applicable regulations, including local requirements.

Introduction

This guide represents the work of the California Stormwater Quality Task Force's (SWQTF) Retail Gasoline Outlet Work Group. The Work Group formed in May 1996 and met on a regular basis to review and discuss appropriate best management practices for fueling and other closely related activities likely to be found at retail fueling operations. Representatives from industry, municipalities, and regulatory agencies participated. Best management practices (BMPs) from throughout California, and elsewhere, were reviewed and considered for inclusion in this guide. The Work Group worked in the tradition of the SWQTF by raising and discussing issues in an open forum, and working to reach consensus on each issue. The Work Group worked in parallel and communicated with State and Regional Board staff responsible for storm water permit compliance.

These best management practices were developed with retail gasoline outlets primarily in mind, and may or may not have applicability to other facility types (e.g., cardlocks, bulk plants, fleet operations). The need for and application of these BMPs to other facility-types should be carefully reviewed on a case-by-case basis. During the development of this guide, storm water and wastewater issues were addressed together to avoid cross-media transfers of waste. In addition, the potential of these BMPs to affect other environmental media/regulations (e.g., hazardous waste) was considered before their inclusion in this guide.

Regulatory Context

The Federal Clean Water Act, as amended in 1987, and the State Porter-Cologne Act are the principle regulations for control of storm water pollutants. There are, however, other regulations that deal with the control of storm water pollutants. Examples include the Federal Coastal Zone Act Reauthorization Amendments of 1990, and the State Hazardous Waste Source Reduction and Management Review Act. The 1987 amendments to the Federal Clean Water Act added section 402(p) which establishes a framework for regulating municipal, industrial, and construction storm water discharges under the National Pollutant Discharge Elimination System (NPDES) program. On November 16, 1990, the USEPA published final regulations that establish application requirements for storm water permits from five classes of discharges (Phase 1) including storm water associated with industrial activity (industrial storm water) that discharges either directly to surface waters or indirectly through municipal separate storm drain systems. Municipalities with a population over 100,000 or those that have been determined to be a significant contributor of pollutants are also required to obtain a NPDES storm water permit.

As part of its storm water management program, a municipality is required to develop a program to monitor and control pollutants in storm water discharges from its municipal system. These programs must include structural and source control measures to reduce pollutants from runoff from commercial and industrial areas. Thus it is important for commercial and industrial facilities located within municipalities to realize that there may be municipal requirements on storm water discharges from their facilities.

In addition to the storm water requirements, both the Federal Clean Water Act and the State Porter-Cologne Act require the control of pollutants in wastewater discharges. The Porter-Cologne Act requires the development of Basin Plans for drainage basins in California. These basin plans are used in turn to identify more specific controls for discharges (e.g., wastewater treatment plant effluent). The basin plans are implemented through the NPDES program. Many municipalities, being subject to both storm water and wastewater regulations, will develop water quality protection programs that deal with both types of discharges in a coordinated and integrated way.

Purpose and Intent

The purpose of this guide is two-fold. First, to be a compilation of peer-reviewed best management practices for fueling and other closely related activities found at retail fueling operations. Second, to be a reference for municipalities, regulators, and facility owners and operators.

The intent of the SWQTF is that these best management practices serve as a "default" set of BMPs for use throughout California. Municipalities and retail gasoline outlets that have not yet adopted best management practices for these activities should give these practices strong consideration. Municipalities and retail gasoline outlets that do have and use BMPs should compare their current practices with those presented here. Substantive differences should be identified and re-evaluated. Successful implementation of these BMPs depends on a partnership between municipalities, regulators, and facility owners and operators. Each has a role to play:

- Municipalities should become familiar with these BMPs and incorporate them into their water quality protection programs, as appropriate.
- Regulators and inspectors should use these or similar BMPs to measure the pollution prevention efforts of facilities.
- Facility owners and operators should become familiar with these BMPs, teach their employees about them, and ensure that they are used on-site.

How to Use the Best Management Practices

Coverage - These best management practices cover three activities or areas:

- Fuel dispensing
- Air/water supply
- Outdoor waste receptacles

Retail gasoline outlets will have every combination of these activities/areas on-site, including other activities not covered by this guide. For example, a facility may have a fuel dispensing area, air/water supply area, indoor service bay, but no outdoor waste receptacles. These BMPs cover the first two areas but not the indoor service bay. Best management practices for the indoor service bay may be found elsewhere. The inclusion of best management practices for air/water supply areas is not intended to suggest that air and/or water must be supplied by retail gasoline outlets in geographic areas not otherwise required to do so.

Design - The design of this guide is purposely different from many BMP lists that are designed as a menu of BMPs from which the facility owner/operator, and the inspector, may choose some but not necessarily all BMPs. These BMP lists are designed so that if the activity/area is on-site, each numbered BMP listed below the activity should be implemented. For some BMPs, as described below, several implementation options are provided. The best management practices are meant to be implemented, monitored, and maintained on a year round basis. The guide also makes an important distinction between existing facilities and new or substantially remodeled facilities. A definition of new or substantially remodeled is also provided. The Work Group used these design elements to help clarify and unify expectations.

Options - Several of the best management practices provide facility owners and operators options for compliance. For example, one best management practice is:

- Minimize the possibility of storm water pollution from outside waste receptacles by doing at least one of the following:

a. use only watertight waste receptacle(s) and keep the lid(s) closed, or
b. grade and pave the waste receptacle area to prevent run-on of storm water, or
c. install a roof over the waste receptacle area, or
d. install a low containment berm around the waste receptacle area, or
e. use and maintain drip pans under waste receptacles.

It is the intent of these BMPs that a) through e) are options. Effective implementation of at least one of these options, chosen by the facility owner/operator, should be deemed implementation of this best management practice.

Other BMPs - The Work Group considered other BMPs not listed here including:

- Oil/water separators
- Catch basin inserts

The evidence reviewed by the Work Group indicated that the effectiveness and efficiency of these and other BMPs not listed was insufficient for them to pass peer review and therefore these BMPs can not be generally recommended for use statewide. There may be situations in which these BMPs would be effective and efficient (as evidenced by research), and therefore appropriate, but these situations should be the exception, not the rule. Members of the SWQTF are conducting studies on these and other BMPs. If that research shows that a particular BMP is effective and efficient, the SWQTF will consider adding it to this guide.

Best Management Practices

Existing Facilities

Fuel Dispensing Areas

1. Maintain fuel dispensing areas using dry cleanup methods such as sweeping for removal of litter and debris, or use of rags and absorbents for leaks and spills. Fueling areas should never be washed down unless the wash water is collected and disposed of properly.
1. Fit underground storage tanks with spill containment and overfill prevention systems meeting the requirements of Section 2635(b) of Title 23 of the California Code of Regulations.
1. Fit fuel dispensing nozzles with "hold-open latches" (automatic shutoffs) except where prohibited by local fire departments.
1. Post signs at the fuel dispenser or fuel island warning vehicle owners/operators against "topping off" of vehicle fuel tanks.

Facility - General

1. "Spot clean" leaks and drips routinely. Leaks are not cleaned up until the absorbent is picked up and disposed of properly.
1. Maintain and keep current, as required by other regulations, a spill response plan and ensure that employees are trained on the elements of the plan.
1. Manage materials and waste to reduce adverse impacts on storm water quality.
1. Train all employees upon hiring and annually thereafter on proper methods for handling and disposing of waste. Make sure that all employees understand storm water discharge prohibitions, wastewater discharge requirements, and these best management practices. Use a training log or similar method to document training.
1. Label drains within the facility boundary, by paint/stencil (or equivalent), to indicate whether they flow to an oil/water separator, directly to the sewer, or to a storm drain. Labels are not necessary for plumbing fixtures directly connected to the sanitary sewer.
1. Inspect and clean if necessary, storm drain inlets and catch basins within the facility boundary before October 1 each year.

Outdoor Waste Receptacle Area

1. Spot clean leaks and drips routinely to prevent runoff of spillage.
1. Minimize the possibility of storm water pollution from outside waste receptacles by doing at least one of the following:

a. use only watertight waste receptacle(s) and keep the lid(s) closed, or
b. grade and pave the waste receptacle area to prevent run-on of storm water, or
c. install a roof over the waste receptacle area, or
d. install a low containment berm around the waste receptacle area, or
e. use and maintain drip pans under waste receptacles.

Air/Water Supply Area

1. Minimize the possibility of storm water pollution from air/water supply areas by doing at least one of the following:

a. spot clean leaks and drips routinely to prevent runoff of spillage, or
b. grade and pave the air/water supply area to prevent run-on of storm water, or
c. install a roof over the air/water supply area, or
d. install a low containment berm around the air/water supply area.

New or Substantially Remodeled Facilities

The elements listed below should be included in the design and construction of new or substantially remodeled facilities.

Fuel Dispensing Areas

R0009142

1. Fuel dispensing areas must be paved with portland cement concrete (or, equivalent smooth impervious surface), with a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of storm water to the extent practicable. The fuel dispensing area is defined as extending 6.5 feet from the corner of each fuel dispenser or the length at which the hose and nozzle assembly may be operated plus 1 foot, whichever is less. The paving around the fuel dispensing area may exceed the minimum dimensions of the "fuel dispensing area" stated above.
1. The fuel dispensing area must be covered, and the cover's minimum dimensions must be equal to or greater than the area within the grade break or the fuel dispensing area, as defined above. The cover must not drain onto the fuel dispensing area.

Outdoor Waste Receptacle Area

1. Grade and pave the outdoor waste receptacle area to prevent run-on of storm water to the extent practicable.

Air/Water Supply Area

1. Grade and pave the air/water supply area to prevent run-on of storm water to the extent practicable.

Substantially Remodeled Facilities

One of the following criteria must be met before a facility is deemed to be substantially remodeled and the design elements described above are required to be included in the new design and construction:

- the canopy cover over the fuel dispensing area is new or is being substantially replaced (not including cosmetic/facial appearance changes only) and the footing is structurally sufficient to support a cover of the minimum dimensions described above, or
- one or more fuel dispensers are relocated or added in such a way that the portland cement concrete (or, equivalent) paving and grade break or the canopy cover over the fuel dispensing area do not meet the minimum dimensions as defined above. Replacement of existing dispensers or underground storage tanks do not, by themselves, constitute a substantial remodel.

Special note on the paving BMP (#1 only) addressing Fuel Dispensing Areas under New or Substantially Remodeled Facilities

This best management practice is not specifically intended to apply to facilities that install a new canopy where no canopy existed.

Special note on the canopy BMP (#2 only) addressing Fuel Dispensing Areas under New or Substantially Remodeled Facilities

This best management practice is not specifically intended to apply to facilities that:

- are located in geographic areas not subject to federal or state storm water regulations
- do not discharge storm water either directly to surface waters or indirectly, through municipal separate storm drain systems
- do not add fuel dispensers
- replace, relocate, or add fuel dispensers within the parameters described in the BMP
- increase their throughput of fuel dispensed without modifying their equipment
- make only cosmetic or facial appearance changes to their existing canopy

For the purposes of the waste receptacle area and air/water supply area BMPs only, the facility is considered substantially remodeled if the area around the waste receptacle area or air/water supply area is being regraded or repaved.

Help

For assistance with implementation of these best management practices, municipal staff or facility owners and operators should contact their local storm water program representative, Regional Board or State Board storm water contact, or the Stormwater Quality Task Force.

PETROLEUM HYDROCARBONS IN STORMWATER RUNOFF FROM RETAIL GASOLINE STATIONS

ABSTRACT

This paper presents a detailed study of the presence of petroleum hydrocarbons, Benzene, Toluene, Ethylbenzene, Xylene, and MTBE in stormwater runoff that originates from Retail Gasoline Stations in Orange County, California. Background information presented here includes: the physical and environmental characteristics of petroleum hydrocarbons in surface and subsurface waters. Geologic and climatic characteristics of the Orange County, California region and other previous studies done in the region and a brief overview of regions stormwater regulatory requirements. This study also investigates the effectiveness of required and proposed structural Best Management Practices (BMPs) for all new and renovated retail gasoline stations in the county utilizing field observations during actual storm events for the 1997-1998 rainy period.This study concludes with 4 sampling events in which stormwater runoff was collected from the stations parking lot, the intake and outlet of the stations clarifier system (S11 Requirement) and tested for the presence of petroleum hydrocarbons. The samples tested were all found to be well below applicable Maximum Contamination Levels (MCLs). The samples all lacked measurable differences (all < 0.5 ppm) for BTEX and (all < 0.5 ppm) for MTBE indicating that there was no measurable difference in petroleum hydrocarbons for stormwater entering and exiting these stations clarifiers as well as the stations surrounding parking lots. These conclusions also reflect similar conclusions from a previous study in the region where stormwater samples were collected and analyzed from retail gasoline stations and compared with commercial parking lots.

ACKNOWLEDGMENTS

I would like to give special appreciation to Dr. Prem Saint, Professor of Geological Studies at California State University, Fullerton for his technical and academic advisement during this project. Also, appreciation is given to Richard Boone, Storm Water Supervisor at the Orange County Public Facilities and Resources Department for his insightful technical assistance and review. I would also like to thank Tim Simpson, Vice President and Principal Engineer at Geomatrix Consultants for his assistance during my sampling procedures and for his help in my research portion of this study and Ron Wilkniss, South Coast issues Coordinator at the Western States Petroleum Association. Also, I would like to thank Judy Mason, Environmental Health and Safety Coordinator at Atlantic Richfield Corporation for her assistance during the site selection process. I would also like to thank Karen Ashby, Environmental Resources Specialist and Mel Newman, Meteorologist at the Orange County Public Facilities and Resources Department for their assistance with the sampling and meteorological data in chapter 6.

LIST OF TABLES

LIST OF FIGURES

1.0) INTRODUCTION

In the first half of this century deterioration of water quality due to urbanization and urban sources was associated with point sources from industrial and commercial operations and with domestic sewage. As more significant sources of water pollution were brought under control, the impact of pollutants in storm water began to receive greater attention. However, not until the 1970s was it realized that a significant portion of pollution from urban and urbanizing areas originated from nonpoint diffuse sources such as construction and washoff from impervious surfaces such as streets and parking lots. Urban nonpoint sources have been identified as a major cause of pollution of surface-water bodies by the US EPA (Vladimer, Novotny, and Olem 1994, 439).
In the 1988 Report to Congress (U.S. EPA, 1990) it was stated that urban stormwater runoff is the fourth most extensive cause of the impairment of the water quality of the nation's rivers and the third most extensive source of water quality impairment of lakes.

Urbanization usually increases the impervious area of a watershed, which increases storm-runoff rates and, subsequently, total volume of storm runoff. Associated with storm runoff are properties and constituents that can cause the degradation of water quality locally and in receiving waters downstream. Because of concerns about the effects of urban runoff on water quality, the Water Quality Act of 1987 contains provisions that specifically address stormwater run off discharges. The U.S. Environmental Protection Agency, under section 319 of the Water Quality Act of 1987, requires that states " assess the nature and extent of nonpoint sources of pollution." In addition to potential regulation under state and federal programs, local municipalities, as part of their mandated storm water management programs, are required to monitor and control pollutants in storm water discharges from their municipal storm drainage systems. Methods of control may include storm water discharges from facilities, that the municipality determines are contributing pollutants to the municipal storm drain system.

As urbanization increases so do new sources of urban stormwater runoff. One of the areas of concern are retail gasoline outlets (RGOs) or gas stations. It has long been suspected that RGOs are a contributor of inorganic and organic pollutants to both surface and subsurface waters nationwide. The extent of the contribution of these pollutants to the nations receiving waters is still not fully understood and is an ongoing topic of debate. This report is intended to help provide a basis for evaluating and recommending appropriate Best Management Practices (BMPS) for modern RGOs through site observations and sample data analysis.

1.1) Geochemistry of Petroleum Hydrocarbons

The term petroleum is derived from the Latin derivative petra for rock and oleum for oil. Current usage defines petroleum as any hydrocarbon mixture of natural gas, condense, and crude oil. The composition may vary with the location and age of an oil field, and may be depth dependent within an individual well. Crude oils are commonly classified according to their respective distillation residues, which reflect the relative contents of three basic hydrocarbon structural types: paraffins, naphthenes, and aromatics. Aromatic hydrocarbons usually comprise less then 15% of a total crude oil, although they often exceed 50% in heavier fractions of petroleum (Testa and Stephen 1991, 28). The aromatic fraction of petroleum is the most important environmental group of hydrocarbon chemicals and contains at least one benzene ring comprised of six carbon atoms in which the fourth bond of each carbon atom is shared throughout the ring. The aromatics are unsaturated, allowing them to react with hydrogen and other elements in the ring. Benzene is known as the parent compound of the aromatic series and, along with toluene, ethylbenzene, and the three isomers of xylene (ortho, meta, and para) are major constituents of gasoline (Table 1.1). These constituents will be referred to as the BTEX hydrocarbons.

CONSTITUENT	**PERCENTAGE**
Benzene	0 - 4.9%
Cumene	0 - 4%
Cyclohexane	0 - 3%
Di-isopropyl Ether	0 - 16%
Ethanol	0 - 10%
Ethylbenzene	0 - 4%
Ethyl tert-Butyl Ether	0 - 16%
Hexane	0 - 8%
Tert-Amly Ethyl Ether	0 - 16%
Tert-Amly Methyl Ether	0 - 16%
Methyl tert-Butyl Ether	0 - 16%
Toluene	0 - 20%
Trimethylbenzenes	0 - 5%
Xylenes	0 - 18%

Table 1.1 Constituents of a typical unleaded gasoline on the market today varies from manufacturer and brand (Citgo Petroleum Corporation 1997).

1.2) BTEX Hydrocarbons in Gasoline

The principal method for separating crude oil into useful products is through distillation. Boiling points of hydrocarbons generally increase with an increase in the number of carbon atoms that comprise the compound. As a crude sample or any hydrocarbon blend, is heated in increasing increments, the hydrogen compounds having a boiling point at or below the current temperature volatilizes. The remaining hydrocarbon compounds in the sample will not volatilize until the temperature is raised to their respective boiling points The range of boiling temperatures are from high to low, divided into the following product types: residue, heavy gas-oil, light gas-oil, kerosene, naphtha, gasoline, and butanes. The crude source has a definite effect on the composition of all refined products (Testa and Stephen 1991, 29). The BTEX constituents contained in gasoline and their respective physical properties are presented in Tables 1.2.

BENZENE	
Boiling Point	175-177.8 F @ 760 mmHg
Specific Gravity	0.882 - 0 .886 @ 60 F

Tables 1.2. Selected physical properties for BTEX and MTBE hydrocarbons (Ashland Chemical Company 1996).

1.3) Hydrocarbon Degradation Processes

Degradation processes include biodegradation as well as chemical and physical degradation via mechanisms such as oxidation, waterwashing, and inspissation (the evaporation of the lighter constituents of petroleum), leaving the heavier residual behind . Degradation processes tend to destroy paraffins, to remove the light ends, and to oxidize the remaining fractions of the product (Testa and Stephen 1991, 33). During biodegradation, aromatics are susceptible to microbial decomposition, including the BTEX hydrocarbons and the gasoline additive MTBE. Over 30 genera and 100 species of various bacteria, fungi, and yeast exist that metabolically utilize one or more kinds of hydrocarbons (Testa and Stephen 1991, 33). The order in which hydrocarbons are oxidized depends on numerous factors. However, in general smaller carbon molecules up to C20 are consumed before larger ones. Degradation processes exist in both surface and subsurface waters and their influence on the presence and fate of BTEX and MTBE found there cannot be ignored.

1.4) BTEXs Toxicity and Health Concerns

We have been releasing harmful materials since humans first gathered to form societies. In the last 100 years we have begun to generate an astonishing variety of chemicals with various potentials for harm to ecosystems and human health. Particularly since the end of world war 2 , the production and release of such materials has risen tremendously (Devinny and others 1990). Modern cities are built on the assumption that separate systems for wastewater collection are best. Sewage from homes and industries is collected in an enclosed system and treated, while the much larger amount of clean rain water is collected in an open system such as street gutters, storm sewers, and man made channels. These smaller urban systems are channeled to rivers, lakes, retention basins, reservoirs, or the ocean. Runoff from urbanized regions contain significant quantities of contaminants that provide pathways for potential human exposure. For example, rivers carrying stormwater runoff from urban areas are often sites for recreational uses such as swimming, fishing, and boating. Lakes and reservoirs serve similar purposes and are often used as a source for drinking water and groundwater recharge, another valuable drinking water supply. Ultimately, urban stormwater runoff reaches the ocean where its effect can degrade resources such as fisheries, estuaries, and public beaches.

An obvious first question about the composition of gasoline is "what dangers does it pose to public health ?" The question is important in the legal and regulatory sense, because chemicals which are not legally classified as hazardous are subject to very little regulation. Federal law considers chemicals hazardous if they are ignitable, corrosive, reactive, toxic, or radioactive. A summary of some of the hazardous characteristics for the BTEX constituents and some other common chemicals are listed in Table 1.3

CHEMICAL	TOXICITY	PERSISTENCE	IGNITABILITY	REACTIVITY	VOLATILITY
ACETONE	2	1	3	0	3
BENZENE	3	1	3	0	3
CHLOROFORM	3	3	0	0	3
ETHYLBENZENE	2	1	3	0	1
METHANE	1	1	3	0	3
NITRIC ACID	3	0	0	0	3
PARATHION	3	3	1	2	0
TOLUENE	2	1	3	0	2
XYLENE	2	1	3	0	1

Table 1.3. Characteristic values of BTEX and some other common hazardous industrial chemicals, 0= none, 1=low, 2=med, 3=high (Devinny and others 1990).

A study was done that ranked the threats presented by a chemicals toxicity according to a more complex criteria. The threat associated with a given chemical is rated by its frequency of occurrence. Data on the frequency of occurrence was gathered from reports of sampling programs at 32 sites. Benzene and Toluene topped the list (Table 1.4).

TOXIC COMPOUND	FREQUENCY OF OCCURRENCE
1. Benzene	.688
2. Toluene	.656
3. Methylene Chloride	.594
7. Ethylbenzene	.500
7. Xylenes (total)	.500
16. Vinyl Chloride	.375
17. PCBs (total)	.344
18. Acetone	.313
20. Dialkylphthalates (total)	.281

Table 1.4 Toxic compounds listed in order of frequency of occurrence (Devinny and others 1990).

Each chemical is also assigned a rating for toxicity and another for persistence. This combined Hazard Rating ranged from 3 for slightly toxic and nonpersistent chemical to an 18 for a highly toxic and nondegradable chemical. For example, PCBs which are highly toxic and difficult to degrade received an 18. Acetone, which is much less toxic and readily degraded, received a 6. Multiplying the frequency of occurrence by the hazard rating produced an overall ranking of threat to public health. When this is done, BTEX constituents in gasoline are ranked with some other commonly found hazardous chemicals in table 1.5 (Hallstedt et al 1986).

TOXIC COMPOUND	FREQUENCY X HAZARD RATING
1.Chloroform	9.00
1. Trichloroethane	9.00
3. Methylene Chloride	8.91
4. Benzene	8.25
5. Tetrachloroethylene	7.97
6. Toluene	7.99
8. Trichloroethene	7.50
9. PCBs (total)	6.19
11. Xylenes (total)	6.00
14. Naphthalene	5.25
18. Carbon Tetrachloride	4.50
18. Ethylbenzene	4.50
18. Vinyl Chloride	4.50

Table 1.5. Toxic compounds listed in order of frequency and hazard rating (Devinny and others 1990).

The State of California enacted Proposition 65, formally known as the Safe Drinking Water and Toxic Enforcement Act as of 1986 (Health and Safety Code, Chapter

6.6, Sections 25249.5 through 25249.13), was enacted as a ballot initiative in November, 1986. Among other things, it was intended by its authors to protect California citizens and the States drinking water sources from chemicals known to cause cancer, or birth defects or other reproductive harm, and to inform the citizens about exposures to such chemicals. Proposition 65 requires the Governor to publish by March 1, 1987 and to update at least annually, a list of chemicals known to the State to cause cancer or reproductive toxicity. As of September 1, 1996, 580 chemicals have been listed: 420 carcinogens and 160 reproductive toxicants. The California Environmental Protection Agency's Office of Environmental Health Hazard Assessment (OEHHA) is designated by the Governor as the lead agency for proposition 65 implementation.

The State of California relies upon information that already exists in the scientific literature when determining the threat of a chemical. A chemical is listed if the "state's qualified experts" consisting of an independent panel of scientists and health professionals, appointed by the Governor, find that the chemical has been clearly shown to cause cancer or birth defects or other reproductive harm. In addition, a chemical can be listed if it has been classified as a carcinogen or as a reproductive toxicant by an organization that has been designated as "authoritative". Examples include the World Health Organization and the International Agency for Research on Cancer. For purposes of Proposition 65, a substance is required to be labeled or identified as a carcinogen or as a reproductive toxicant by an agency of the state or federal government. A summary for BTEX and MTBE with regards to Proposition 65 and State drinking water standards are presented in table 1.6 (Cal EPA 1997).

CHEMICAL	LISTED AS CARCINOGEN	LISTED AS REPRODUCTIVE TOXIN	STATE MCL FOR DRINKING WATER
BENZENE	YES	YES	0.001 MG/L
TOLUENE	YES	YES	0.15 MG/L
ETHYLBENZENE	YES	YES	0.75 MG/L
XYLENE	YES	YES	1.75 MG/L
MTBE	NA	NA	NA

Table 1.6. Chemicals known to the State of California to cause cancer and/or reproductive toxicity (Cal EPA 1997).

1.5) VOCs in Surface and Subsurface Waters

When VOCs enter a moving body of water such as a gutter, channel or river, chemical and physical changes begin to take place. It is known that BTEX and MTBE can volatalize from water. Their half-lives in rivers, streams and aqueducts can be greater than one day. They travel distances range from about 1 km for shallow streams to more then 900 km for deeper rivers (Pankow and others 1996, 936). No one single factor can describe a VOC's half-life; factors that affect these volatilization rates include: water velocity, water depth, water temperature, wind speed, and air temperature. No single volatilization rate characterizes the loss process from rivers and streams. Studies have shown that in deep and slow moving channels, MTBE volatilizes at rates similar to those for the BTEX compounds. But, in shallow and faster moving channels, MTBE volatilizes at rates that are significantly slower then those for BTEX compounds (Pankow and others, 1996, 921).

In a 4 year study by the United States Geological survey, stormwater samples were collected in 16 cities and metropolitan areas with a population greater then 100,000 were analyzed for BTEX, MTBE, and other constituents (Figure 1.1). The cities are required by the Clean Water Act to obtain permits for stormwater discharged from municipal separate storm-sewer systems into surface waters. Concentrations of 62 VOCs were measured in 592 stormwater samples taken between 1991 through 1995. MTBE was the seventh most frequently detected VOC in urban stormwater. (Table 1.7) (Detzer and others 1996).

VOC	Minimum detected concen-tration (µg/L)	Maximum detected concen-tration (µg/L)	Median detected concen-tration (µg/L)	Fre-quency of detection (percent)
Toluene	0.2	6.6	0.3	23.2
Total xylene	0.2	15	0.4	17.5
Chloroform	0.2	7.0	0.7	13.4
Total trimethyl-benzene	0.2	15	0.3	12.4
Tetrachloro-ethene	0.2	42	0.6	8.0
Naphthalene	0.2	5.1	0.3	7.4
MTBE	0.2	8.7	1.5	6.9
Dichloro-methane	0.2	13	0.3	5.9
Bromo-dichloro-methane	0.2	2.8	0.6	5.8
Ethylbenzene	0.2	2.0	0.3	5.0

Table 1.7. VOCs in stormwater study (Detzer and others 1996).

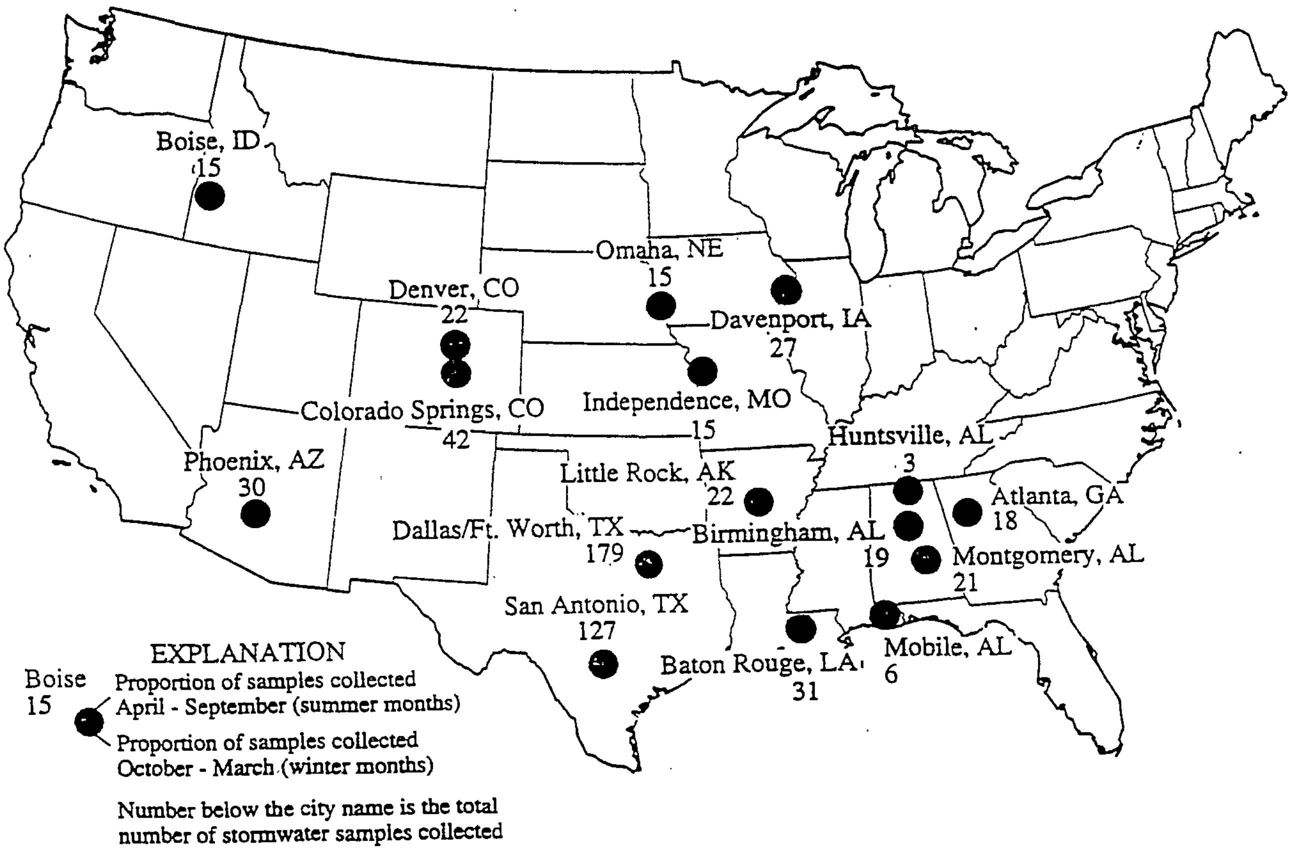

Figure 1.1. Stormwater sampling sites in the U.S. Number of stormwater samples taken from metropolitan areas with a population greater then 100.000 (Detzer and others 1996).

Petroleum derived hydrocarbons are regularly released into surface waters in proportion to surrounding urbanization and technological development. Sources of hydrocarbons to urban surface waters include: accidental spills, deliberate dumping of waste oil and fuels, emissions from engines during normal operations (primarily uncombusted exhaust hydrocarbons and crankcase drippings), fallout from atmospheric particles, spillage of refined products during refining and transportation, natural seepage and erosion of sedimentary rocks, and natural biogenic sources (Stenstrom, Silverman, and Bursztynsky 1983, 59). During a study of the Richmond California Watershed the most significant single identified factor that effects oil and grease pollution in urban runoff is land use. Runoff from commercial properties and parking areas contained an oil and grease concentration nearly three times higher than runoff from residential property. For the Richmond Watershed, controlling approximately ten percent of the land use could result in a 50% decrease in hydrocarbon emission (Stenstron, Silverman, and Bursztynsky 1983, 70).

Oil and grease pollution were found to be independent of all storm characteristics, with the exception of total rainfall. Rate of rainfall, days between storm events, and length of storms had no significant effect on oil and grease concentration, although there was an indication of a modest "first flush" effect (Stenstron, Silverman, and Bursztynsky 1983, 63). Monoaromatic hydrocarbons have been found regularly in bay water and in fish and shellfish tissue. Studies have also reported that monoaromatics may be contributing to the decline of the striped bass (Monroe Saxatites) and other fisheries in the bay. Thus the relatively high levels of oil and grease found in urban runoff in this study, and the potential for introduction of aromatics, may indicate that stormwater is a significant pollution contributor to San Francisco Bay (Stenstron, Silverman, and Bursztynsky 1983, 70).

Another important water resource at risk to possible storm water runoff contamination is groundwater. Here biological activity plays a very important role to one of the United States most valuable natural resources. Biological transformations often provide the predominant decay pathways in water and soil, and the complete mineralization of an organic molecule in water and soil is almost always a consequence of microbial activity
(Squillace and others 1996, 4). Water solubility is probably the most important chemical property affecting the partitioning of BTEX VOCs between water and subsurface solids or soils. In general, BTEXs low solubility's in water indicate a strong partitioning to the organic carbon associated with the subsurface solids. However, the VOC MTBE, a gasoline additive to gasoline to fight air pollution is highly soluble in water compared to the BTEX compounds. In fact, the solubility of pure liquid MTBE in water is about 50,000 Mg/L where as the next most soluble component of the BTEX constituents is benzene, which has a solubility of 1780 Mg/L (Mackay and others 1992, 3722).

In waters, BTEX compounds readily undergo biological transformations, however most studies have indicated that MTBE does not biodegrade easily under various environmental conditions. Because MTBE tends to stay in the water and not sorb to subsurface solids, it can move to the ground water at almost the same velocity as the recharge water. Once MTBE is in the groundwater it can move at virtually the same velocity as the water (Squillace and others 1996, 5). In a USGS National Water Quality Assessment Program, MTBE was the second most frequent detected VOC in groundwater sampled from 210 shallow wells and springs in 8 urban areas (Squillace and others 1996, 1). Data from the previous study also showed that in shallow urban groundwater, MTBE generally was not found with BTEX compounds, which are commonly associated with gasoline spills. This disassociation causes uncertainty as to the source of MTBE (Squillace and others 1996, 1721). The infrequent concurrent detection of MTBE with BTEX compounds suggest that point source leaks are not the principal source of MTBE detected in urban groundwater, although the lack of association does not completely rule out point source spills as a potential source. MTBE plumes originating from point source gasoline spills would generally occupy a larger proportion of the subsurface compared to BTEX compounds and concentrations of MTBE at the leading edge of the plume would be small but would be expected to increase with time. Therefore, if the small concentrations of MTBE detected in shallow urban groundwater originated from gasoline spills, then generally one would expect the concentrations of MTBE and detection's of BTEX compounds to increase with time at these same wells. MTBE plumes will generally occupy a larger portion of the subsurface compared to BTEX compounds for three reasons: (1) MTBE is persistent in aerobic and anaerobic groundwater, (2) MTBE can occur in large concentrations in gasoline as compared to BTEX, (3) MTBE dose not sorb to aquifer material and is more mobile in groundwater then other BTEX compounds based on field data and physical and chemical properties, solubility, and vapor pressure (Squillace and others 1996, 1727).

2.0) PHYSICAL SETTING OF THE STUDY AREA IN ORANGE COUNTY, CA

The study area covers the area of Orange County in Southern California. It is a classic Mediterranean type climate with dry summers and moderately wet winters. The area receives less than 14 inches of rainfall in a typical year, ranging from an average of 12 annually in the Costa Mesa area to more then 25-30 inches on the upper slopes of the Santa Ana Mountains. During the winter months, rains in the latter area are often accompanied by light snow fall above the 4000 feet. Rain falls in the County on the average of 35 days a year. Nearly four-fifths of the County's precipitation occurs between December and March. Orange County's 782 square mile area has a somewhat rectangular shape (Figure 2.1). The long northwest-southeast axis stretching from La Habra in the northwest of the County to San Clemente is about 40 miles in length, while the width is about 20 miles. Most of the County's urbanization is centered on the relatively smooth lowland plain stretching northwesterly from the vicinity of Irvine past Santa Ana, Garden Grove and Buena Park into neighboring Los Angeles County. The central lowland of the County is comprised of the Downey and Tustin Plains. Alluvial deposits of sand, mud and other sediments deposited over thousands of years by the Santa Ana, Los Angeles and San Gabriel Rivers have resulted in the Downey Plain. The Tustin Plain on the other hand, was formed by alluvial deposits from Santiago Creek and other smaller rivers flowing from the southern part of the Santa Ana Mountains. Plano Trabuco, although smaller then the above described Plains, is abruptly located a thousand feet above sea level south of O'neill Park between Trabuco Arroyo and Tijeros Canyon.

Orange County has three main mesas. which are along the northern portion of the coastline.Thousands of years ago the mesas were uplifted into one continuos ridge along the Newport Inglewood Fault. In time, streams cut through the ridge and formed three separate mesas, Bolsa Chica mesa, Huntington Beach Mesa, upon which most of the city of Costa Mesa is located. The foothills of the County are believed to have been elevated and formed by continuing earth movements. Rising to an elevation of 1400 feet are the Punte Hills in the northern part of the County. Southeast extensions of these hills are called the Chino Hills

LAND FORMS

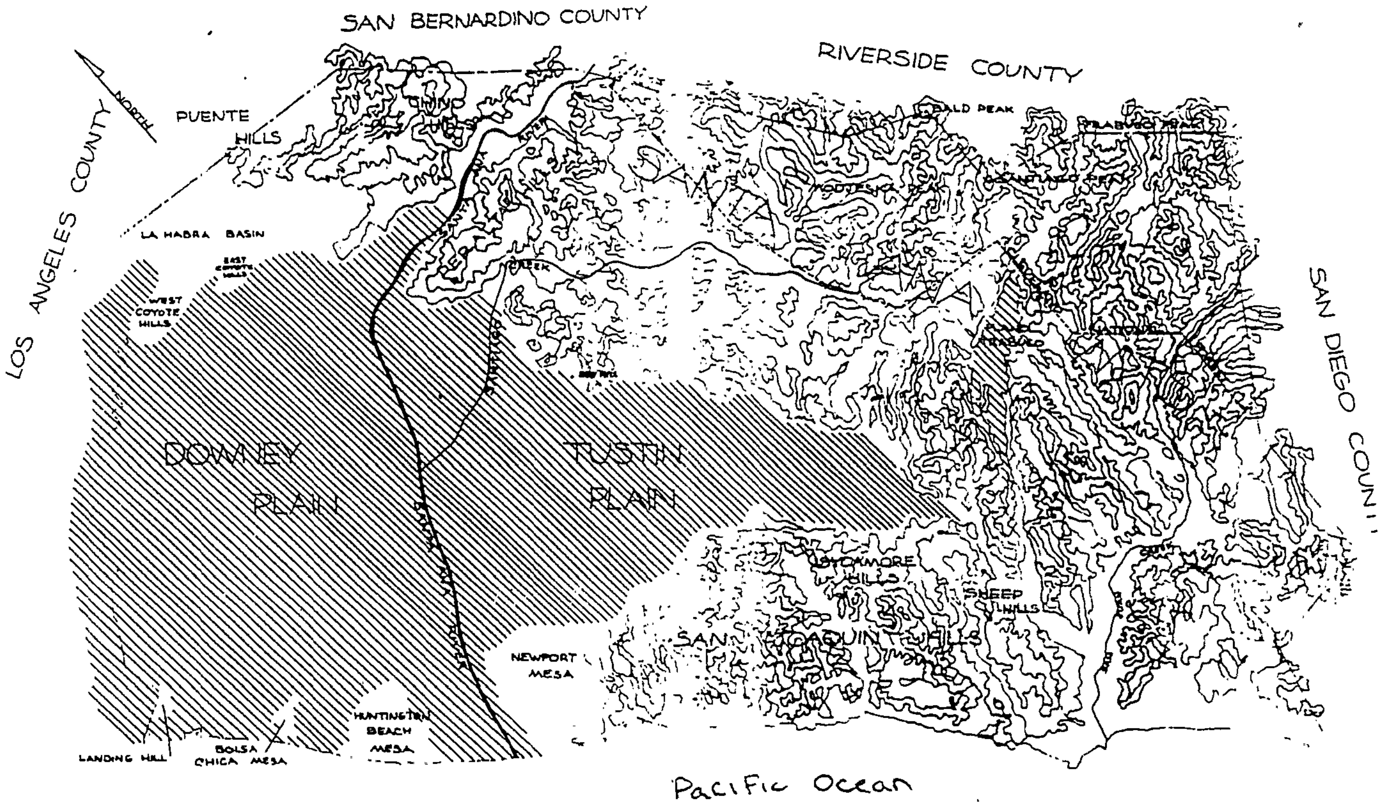

Figure 2.1. Orange Countys physiographical area (Orange County Planning Department 1971).

and reach 1780 feet. Separated from the Punte Hills by the La Habra Basin, the Coyote Hills rise 600 feet before descending into the Santa Ana Basin. Another belt of hills, reaching 1100 feet and running parallel to the coast in the south, are known as the San Joaquin Hills. These hills are composed of marine sediments and deposits of rock, boulders and gravel millions of years old. Several streams cut through the San Joaquin Hills creating small canyons perpendicular to the Coast. Over the years, the streams in these canyons have left sand and gravel deposits on their floors and have formed the beaches that meet the Pacific. The Santa Ana Mountains, rising to a height of over one mile, frame the northeast border of the County. Uplifted many millions of years ago along

R0009169

the Elsinore Fault and tilted toward the Coast, these mountains, such as Old Sattleback, 5496 feet and Santiago Peak, 5687 feet are visible throughout the County (Orange County Planning Department 1971).

Today around seventy-five percent of California's population (about 21 million people) live in the southern half of the state. Therefore, the heavily populated and semi-arid Southern California region must import the majority of its water supply. Imported water accounts for sixty-five percent of the Southern California supplemental water supply with the balance coming from local ground water sources. The water demand is met by surface water supplied by two primary aqueducts that bring water to the sprawling Southern California area from snowpack and rivers in the Northern region of the state and the seven state Colorado River Basin area (Figure 2.2).

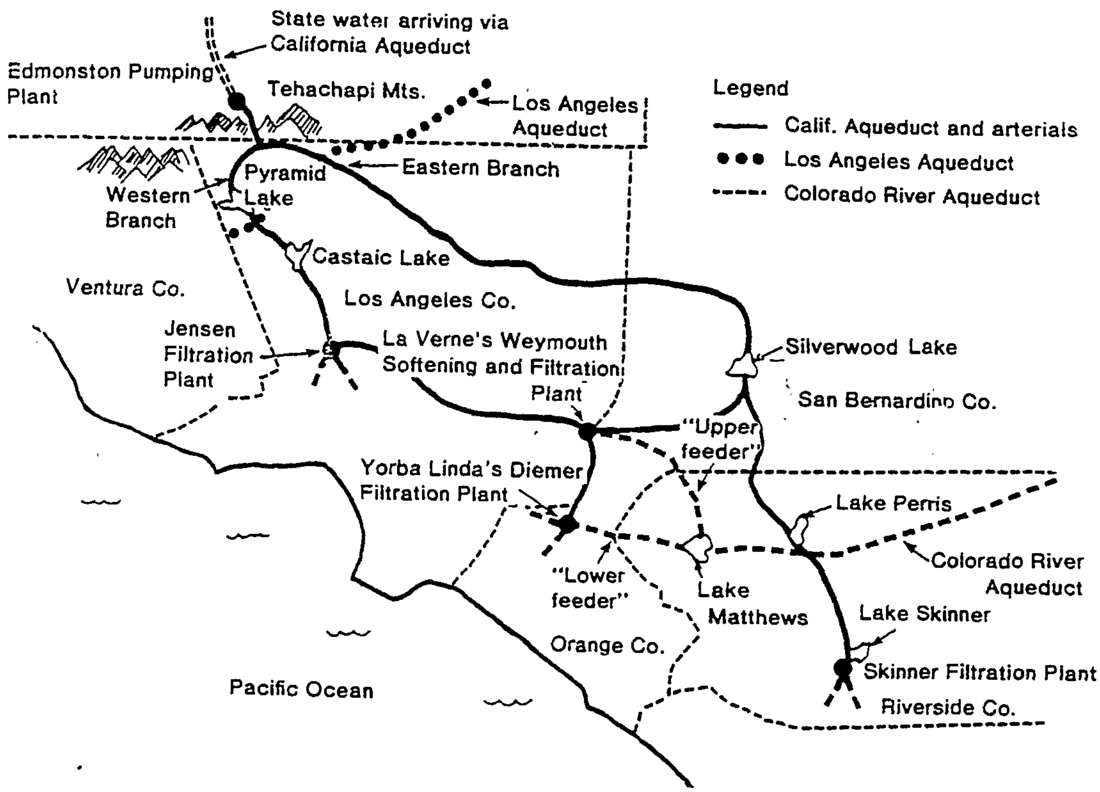

Figure 2.2. The major aqueducts of Southern California (Parratt 1985).

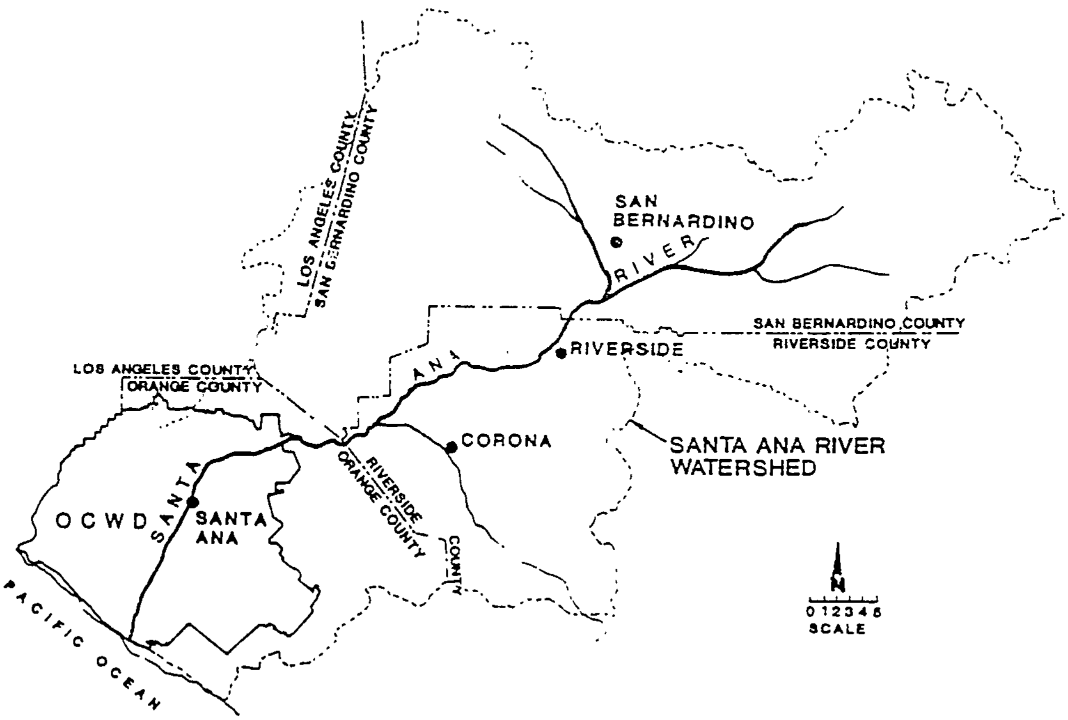
R0009170

Today, Orange County is one of the fastest developing urban regions in the United States. Within its boundaries lies a huge natural underground reservoir of water. In fact, this underground reservoir, or aquifer system is so important to the region that the Orange County Water District was formed by the State of California in 1933 to protect and manage this valuable subterranean water supply. The needs of this area must be met while ensuring that the groundwater supply does not become depleted or contaminated. A legal right to all the water that flows into Orange County in the Santa Ana River has been granted to the Orange County Water District, which owns about 1,200 acres of land in and near the river channel. With a drainage area of nearly 2500 square miles, the Santa Ana River is the largest coastal stream in Southern California (Figure 2.3), transversing through San Bernardino and Riverside counties before entering the south coastal plain. In the channel area is a region called the Forebay Region (Figure 2.4). The soil in this area is very permeable and water can seep into the aquifers. These are primarily used to percolate or recharge the aquifer. Bulldozers and earthmovers have transformed this part of the Santa Ana River into a series of ponds with sand berms for sides, these help to hold water and allow it to percolate through the ground here and "recharge" the groundwater basin.To satisfy the huge water demand of the region both stormwater runoff and imported water are diverted to this region to help recharge the aquifer below.

The effects of VOCs entering the the underground aquifer by stormwater runoff would probably be most profound in the forebay region. But VOC data from monitoring wells throughout the region do not show this to be the case. During my personal interview with Orange County Water District hydrologist Roy Herndon, he noted, we have been monitoring for BTEX VOCs for many years and have observed some detectable levels in the shallow aquifers here, but no detectable levels in the deeper primary aquifers (Herndon 1998).



SANTA ANA RIVER WATERSHED

3.0) OVERVIEW OF REGULATORY REQUIREMENTS

The Federal Clean Water Act, as amended in 1987, and the State Porter-Cologne Act are the principal regulations for control of storm water pollutants. Other regulations that deal with the control of storm water pollutants include: the Federal Coastal Zone Act Reauthorization Amendments of 1990, and the State Hazardous Waste Source Reduction and Management Review act. Under the Federal Clean Water Act stormwater discharges are regulated under the National Pollutant Discharge Elimination System (NPDES) program. The United States Environmental Protection Agency requires permits for the discharge either directly to surface waters or indirectly through municipal separate storm drain systems. Municipalities with a population exceeding one hundred thousand or those that have been determined to be a significant contributor of pollutants are required to obtain a NPDES storm water permit. These municipalities are required to develop a management plan to monitor and control pollutants in storm water discharges from its municipal system. Commercial and industrial facilities located in these municipalities that have storm water discharges from their facilities may be required to monitor and control pollutants that may be present in their storm water discharges (Stormwater Quality Task Force 1997, 2-3).

Pursuant to Article 11, Sec.7 of the State Constitution, which authorizes Orange County to exercise the police power of the state by adopting regulations promoting the public health, public safety and general prosperity, and in compliance with the conditions of the National Pollution Discharge Elimination System Permit (NPDES Permit), a Water Quality Ordinance was adopted. The purpose of this Water Quality Ordinance is to prescribe regulations as mandated by the Clean Water Act [33 usc sec.1251 et seg., as amended] "to effectively prohibit non-storm water discharges into the storm sewers and to reduce the discharge of pollutants from human activities that may result in undesirable discharges of pollutants, which eventually may be deposited in the waters of the United States". This ordinance is dedigned to improve water quality by controlling the pollutants which enter the storm water discharge system throughout Orange County (Office of County Counsel, Orange County 1997, Article 1).

3.1) BMP Selection

As written in the Drainage Area Management Plan (DAMP) candidate non-point sources (NPS) control measures have been selected from review of technical literature, review of existing NPS programs, and input from consulting firms and municipalities already involved in NPS control program implementation. As required by terms of Orange County's municipal NPDES Permits, consideration was given to:

"Structural Controls include: first flush diversion, detention and retention basins, infiltration trenches and basins, porous pavement, oil and grease separators, grass swales, swirl concentrators, and engineering and design modification of existing structures".

"Non-Structural Controls include: programs to educate the public on proper disposal of hazardous and toxic wastes, regulatory approaches, street sweeping, facility maintenance, and detection and elimination of illicit connections and illegal dumping".

Each new development will be required to implement appropriate "routine" structural BMPs and appropriate non-structural BMPs in keeping with the size and type of development, to minimize the introduction of pollutants into the stormwater discharge system. 'Routine" structural BMPs are economical, practicable, small scale measures which can be feasibly applied at the smallest unit of development. A wide variety of documents from other jurisdictions, including the state BMP manuals, as well as a number of new development BMP plans approved in the unincorporated area (plus a number of cities) were identified as having been reviewed. Later "special" structural BMPs may be installed to address specific water quality problems identified in the watershed planning process. "Special" structural BMPs are "engineered facilities designed to address specific pollutant problems identified in the watershed planning process, runoff management plan, CEQA process, or similar watershed planning". Thus, there will be the future need to revisit these requirements at an as-yet unspecified date or frequency. (Drainage Area management Plan 1993).

3.2) Orange County Discharge Permit Procedures

On application, the owner of property or the operator of any facility, which property or facility is not otherwise subject to the requirements of a State General Permit or a National Pollution Discharge Elimination System Permit. The permits regulate stormwater discharges. The Director, Public Facilities and Resources Department or his/her designee, may issue a permit authorizing the release of non stormwater discharges to the stormwater drainage system if: "the discharge of material or constituents is reasonably necessary for the conduct of otherwise legal activities on the property, and the discharge will not cause a nuisance, impair the beneficial uses of receiving waters, or cause any reduction in established water quality standards".

The applicant shall provide all information requested by the director, Public Facilities and Resources Department or his/her designee, for review and consideration of the application, including but not limited to specific detail as to the activities to be conducted on the property, plans and specifications for facilities located on the property, identification of equipment or processes to be used on site and other information as may be requested in order to determine the constituents, and quantities thereof, which may be discharged if permission is granted. The permit may include terms, conditions and requirements to ensure compliance with the objectives of this ordinance and as necessary to protect the receiving waters, including but not limited to:

a) Identification of the discharge location on the property and the location at which the discharge will enter the storm water discharge system;

b) Identification of the constituents and quantities thereof to be discharged into the stormwater drainage system;

c) Specification of pollution prevention techniques and structural or non structural control requirements as reasonably necessary to prevent the occurrence of potential discharges in violation of this Ordinance;

d) Requirements for self monitoring of any discharge.

e) Requirements for submission of documents or data, such as technical reports, production data, discharge reports, self monitoring reports and waste manifests.

f) Other terms and conditions appropriate to ensure compliance with the provisions of this Ordinance and the protection of receiving waters.

The permit shall be granted or denied by the director, Public Facilities and Resources Department or his/her designee, no later then 60 days following the completion and acceptance of the application as determined by the Director, Public Facilities and Resources Department or his/her designee. The applicant shall be notified in person or by first class mail, postage prepaid, of the action taken.

4.0) GAS STATION SITE SELECTION AND OBSERVATIONS

I compiled a list of stations built in Orange County that I could feasibly sample during storm events. These stations had to be subject to the latest BMPs required by the County of Orange and most importantly the S11 requirement. There was no one list of these stations compiled by the county, therefore it required visiting various cities and meeting with their planners. After compiling a list of about 20 candidate sites, I personally visited each and found only 9 employing the S11 requirement. From this list of 9, I chose 5 that I felt I could regularly visit during storm events from December, 1997 through May, 1998.

4.1) Site Observations

My main goal now was to visit each of these 5 stations during as many stormevents as possible and study the movement of stormwater runoff from each. I was interested in how certain BMPs actually work in the field, the BMPs included:

1) Canopies size and design.

2) The grading of the surrounding parking lot and fuel dispension area.

3) The type of clarifier used and its drain location, (S11 Requirement).

My next objective was to develop and test a possible sampling plan that would work at each of the 5 candidate sites. I decided to develop a sampling plan utilizing the clarifier and to test its effectiveness. Since the clarifier is built and located in a way as to intercept spilled gasoline before it reaches the storm water drainage system, it seemed like a logical place to sample for the possible presence of VOCs leaving these sites. This involved taking a sample from the stormwater inlet of the clarifier and another sample from the outlet and having those samples analyzed for possible difference in the presence of VOCs.

Each site consists of the following areas:

- Fuel Dispension Area: the area where the pumps are located. This is usually a concreted region sometimes referred to as the island. It is usually that region that is covered by the rain canopy (see Figure 4.9, page 43).
- Parking lot: the area that is around the fuel dispension area. This is usually the asphalted region and includes the driveways into the site and that lead to the fuel dispension area (see Figure 4.12, page 48).
- Drain: this is usually a barred grate in the ground located in the fuel dispension area or parking lot where stormwater runoff is channeled to. Under this barred grate exists a box like area usually a couple of feet wide and a couple of feet deep where stormwater collects and is treated or leads to a treatment box, before it is released to the street or storm water collection system (see Figure 4.7, page 39).
- Exit Port: this is usually located on the street and is usually just a couple of holes in the curb where water that has been treated by the clarifier is released to the gutter. Some stations have underground pipes from the clarifier to a storm drain. (see Figure 4.8, page 40).

4.2) Site A

Location: Yorba Linda, Ca.

Legend:

Cd - Drain to clarifier

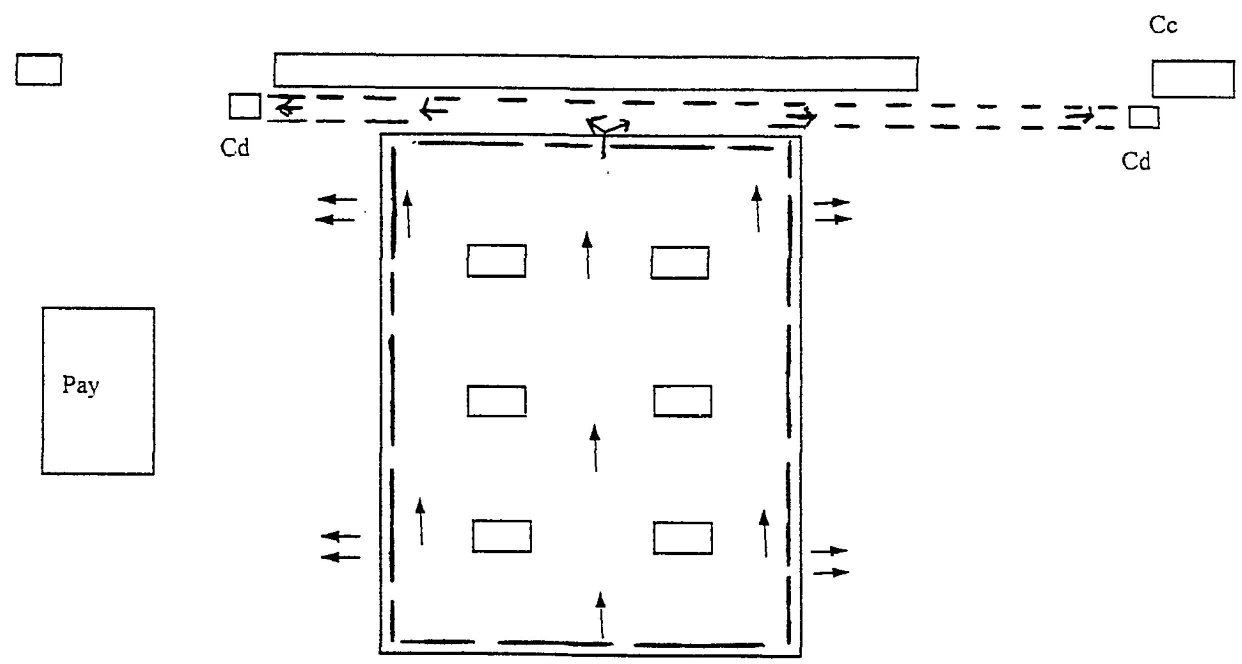
Cc - Exit port from clarifier, located on the street.

Single arrows - runoff that originates from fuel dispension area.

Double arrows - runoff that originates from surrounding parking lot area.

Small black dashed lines - graded gullies that channel stormwater runoff.

Large black dashed lines - canopy outline in relation to fuel dispension area



Grading: This stations parking lot is graded in asphalt and did a good job in keeping stormwater from flowing onto the fuel dispension area. This station is built on a large lot that is also occupied by a block of small stores and thus the station has an unusually large parking lot on its west side. During storm events this large parking lot area produces a lot of runoff that flows in to the clarifier, either by design or accident. The fuel dispension area is concrete and is graded to cause any possible flow to move down to a gully that leads to the clarifier drain. This gully and drain are located outside of the protective canopy and exposed to direct rain fall. In fact, the drains are located approximately 100 feet away in the parking lot area (Figure 4.1).

Canopy: The canopy here is a single rectangular design that ends just inside the outer edges of the fuel dispension area. During all storm events I have witnessed here the outer 2-5 feet of the fuel dispension area usually gets wet to the point of producing a flow The outer edge of the canopy produces drippings that land on the outer edge of the fuel dispension area (Figure 4.2).

Clarifier: This station uses two drains. The drains are located at the east and west sides of the fuel dispension area. The two drains are connected by a gully that intercepts any flow that comes from the fuel dispension area. The drains themselves are easily accessible by lifting up a steel grate that is approximately 2 feet by 2 feet. The drain depth is about 3 feet, but an upper metal screen makes sampling more difficult during low flow conditions. The outlet consists of two exit port holes in the curb at the gutter.

Comments: This station was built or renovated at an unknown time. It is a high volume outlet with a mini mart. I have visited this station 6 times during varying storm event intensities and have noted the following observations.

1) This station has by far the most visible sheens in the parking lot and flowing on top of water that was moving in the gullies (Figure 4.3).

2) The condition of the grading in the parking lot allowed for a lot of puddles to form.

3) The canopy allowed for rainfall to land on the outer 2-5 feet of the fuel dispension area.

4) The clarifier and the exit port at the curb (Figure 4.4) were easy to sample.

Figure 4.1. Parking lot stormwater gully in Yorba Linda. This drain carries fuel dispension area runoff to the clarifier is located in the parking lot and thus intercepts alot of parking lot runoff as well as direct rainfall. The puddles and gullies visible get splashed through by cars and thus drip more water on to the fuel bay dispension area (January 30, 1998).

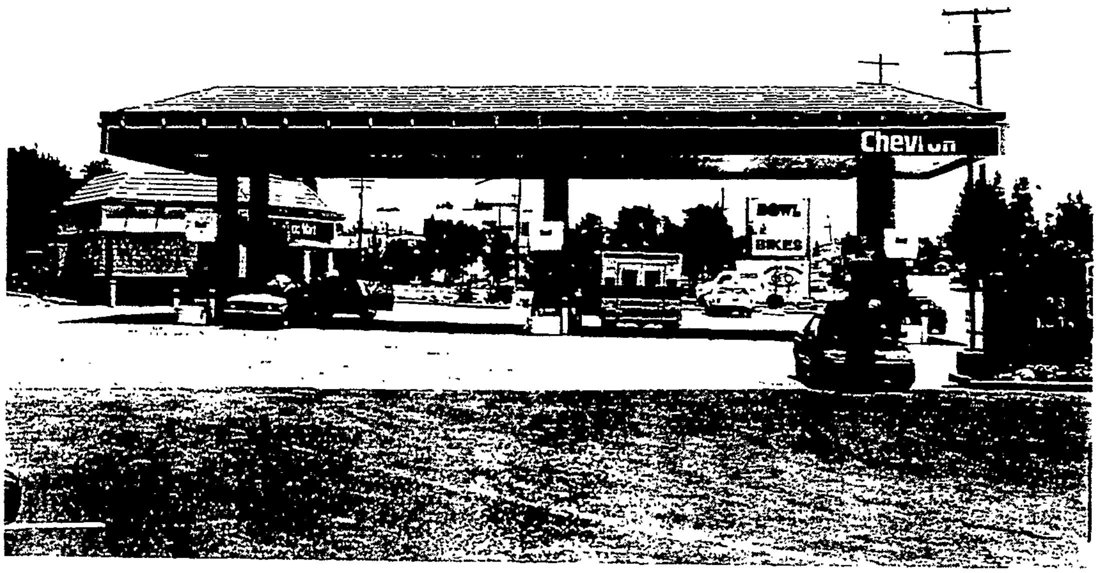


Figure 4.2. Rain canopy in Yorba Linda. Canopies with tall sides provide surface areas where rainwater builds up and can drip down onto the fuel dispension area (January 30, 1998).

Figure 4.3. Gasoline sheen in stormwater gully. A gasoline sheen is visible in a gully that transports stormwater from the fuel dispension area to the clarifier for treatment. During intense rain, clarifiers with drain locations such as these get quickly overwhelmed if parking lot runoff is not channeled away from drain (January 30, 1998).

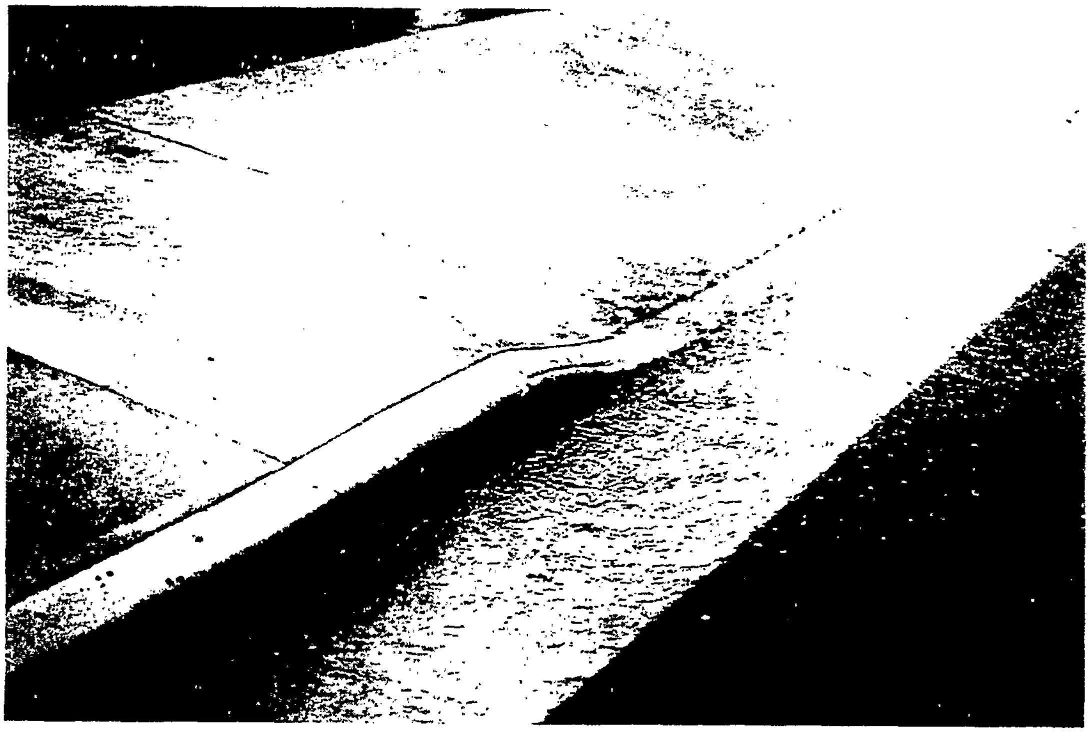

Figure 4.4. Stormwater release site at street. After stormwater is treated in the clarifier it is released to the street by 3 holes drilled in the curb. During more intense rainfalls it was sometimes necessary to block the gutter flow with sandbags to get a sample (January 30, 1998).

Location: Anahiem, Ca.

Legend:

Cd - Drain to clarifier

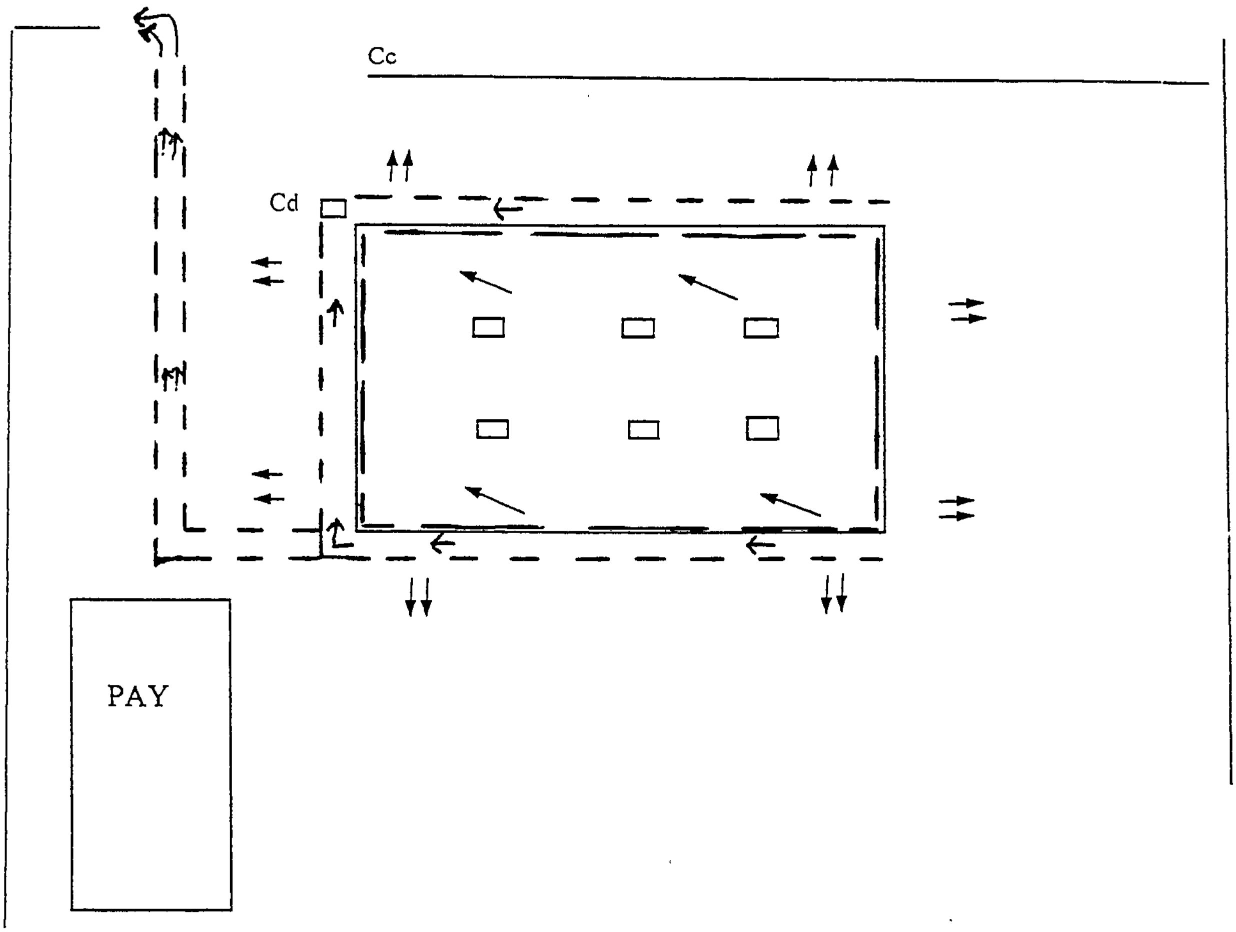
Cc - Exit port from clarifier, located on the street.

Single arrows - runoff that originates from fuel dispension area.

Double arrows - runoff that originates from surrounding parking lot area.

Small black dashed lines - graded gullies that channel stormwater runoff.

Large black dashed lines - canopy outline in relation to fuel dispension area



R0009186

Grading: This station employs gullies in the parking lot that intercept parking lot runoff and channels it to the curb. This system worked very well in keeping any flows from reaching the fuel dispension area. In fact, I have been here during some heavy downpours and did not observe any parking lot runoff flow on to the fuel dispension area (Figure 4.5).

The fuel dispension area is graded to cause any flow can originates there to move towards the gullies that run along the edges of fuel bay dispension area. The gullies and the drain are located just outside of the protective canopy and thus receive a lot of direct rainfall. (Figure 4.6).

Canopy: The canopy here is a single rectangular design that ends just above the outer edges. The outer 2-5 feet of the fuel dispension area received a lot of direct rainfall. This canopy had a lot of build up that dripped from the edges and lands on the edge of the fuel dispension area.

Clarifier: The drain to the clarifier is located at the northwest corner of the fuel dispension area edge and is connected by a gully that runs along two sides of the fuel dispension area. The drain itself is about 2 feet by 2 feet and the cover can be lifted up to get inside. The bottom is about 3 feet deep and a pipe is visible about midway up that appears to run underground to an exit port located on the curb in the gutter. A metal ring filter runs around the outside of the drain, but the middle is wide open and easy to sample by just submerging the sample bottle (Figure 4.7). The exit port is a single hole in the curb that produces a fast flow that is also easy to sample (Figture 4.8).

Comments: This station is the newest of my candidate sites and opened approximately February 15, 1998. It is a high volume outlet with a mini mart in a prime location. I have visited this station during 5 storm events and have noted the following observations.

1) The grading and use of gullies in the parking lot to keep stormwater from entering the fuel dispension area was among the best I have seen. There are no puddles that form in the parking lot area.

2) The use of gullies along the edge of the fuel dispension area to channel runoff to the clarifier would be very useful in the event of a major gasoline spill on the fuel

dispension area. Other wise it appeared the exposure of these gullies to direct rainfall just served to dilute the runoff from the fuel dispension area before reaching the clarifier. I also noticed that oncoming cars tended to splash through these gullies and bring water back on to the fuel dispension area. Departing cars also appear to splash through these gullies and carry fuel dispension area runoff into the parking lot and streets.

3) I have observed sheens moving on water in gullies during the entire times I have been at this station.

4) The majority of the water that reached the fuel dispension area appeared to be coming from direct rain and runoff that driped from the edge of canopy that fell on the edge of the fuel dispension area. The rest originated from customers cars.

5) As of this writing, I have not been able to get detailed information from the RGO on the type of clarifier being used at this site. When you look into the drain the water falls through a metal filter and fills the drain until the level reaches a pipe that goes underground and is released at the curb. I am assuming there must be a clarifier somewhere underground between the drain and the curb, otherwise this system would do little more then physically remove larger floating debris from the runoff before it is released to the stormwater drainage system. There is a large planter and I have been to other stations that have an access in the planter for maintenance of such an underground device, but the planter here does not appear to have anything like that.

Figure 4.5. Parking lot stormwater gully in Anahiem. This gully collects parking lot runoff and channels it to the street. Even during heavy downpours these channels keep runoff from the surrounding parking lot area from flowing on to the fuel dispension area (February 3, 1998).

Figure 4.6. Stormwater gullies leading to clarifier drain.This fuel dispension area is graded so as to allow any flow that originates there to move into these surrounding gullies. These gullies lead to the drain in the middle of the picture, where it is treated before it is released at the street (February 3, 1998).

Figure 4.7. Close up of drain to clarifier. With the barred cover swung open you can see the screen filter that surrounds the center of this clarifier. This style of clarifier is easy to take a sample from (February 3, 1998).

Figure 4.8. Exit port at street for releasing stormwater from clarifier. This is a typical exit port for treated water coming from the clarifier. The sand bag makes sampling easier and less of a chance for contamination from gutter flow. During heavy gutter flows, I have had to use as many as 5 bags to get a sample (February 3, 1998).

4.4) Site C:

Location: Anahiem, Ca.

Legend:

Cd - Drain to clarifier

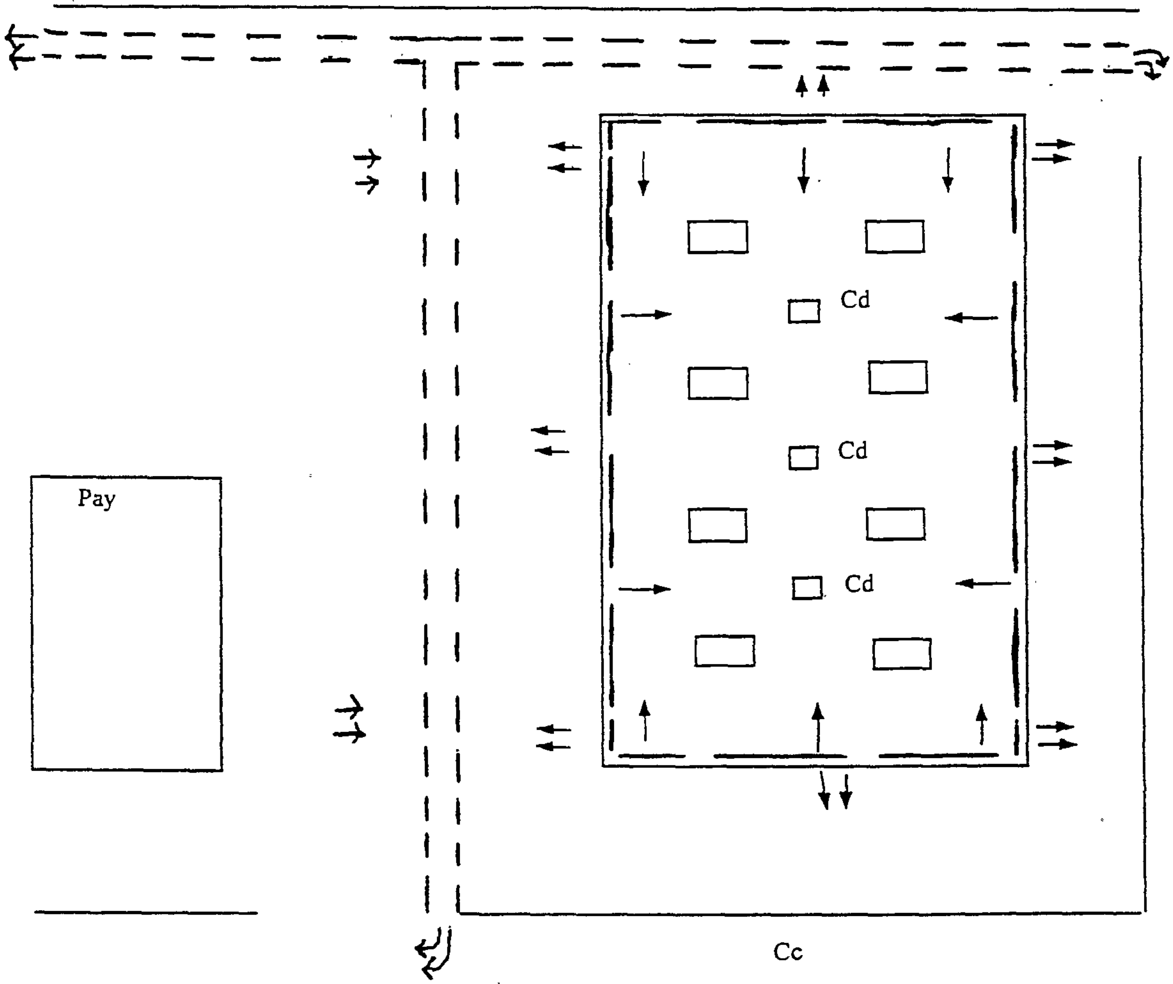
Cc - Exit port from clarifier, located on the street.

Single arrows - runoff that originates from fuel dispension area.

Double arrows - runoff that originates from surrounding parking lot area.

Small black dashed lines - graded gullies that channel stormwater runoff.

Large black dashed lines - canopy outline in relation to fuel dispension area



Grading: The parking lot is paved with asphalt and the grading does an excellent job of keeping stormwater from flowing on to the fuel dispension area. The parking lot uses gullies to channel away parking lot runoff to the street.The fuel dispension area is cement and graded to cause any flow that originates there to flow toward the center of the fuel dispension area. In the center of the fuel dispension area were three small drains that collected any spills or stormwater that occured on the fuel dispension area (Figure 4.9).

Canopy: The canopy here is a single rectangular "zigzag. design that ends just above the outer edges of the fuel dispension area. I have only observed light to medium strength storm events at this station and the outer 2-5 feet of the fuel dispension area received more rain fall than both sites A and B. Drippings from the outer edge of the canopy that landed on the edge of the fuel dispension area were also heavy. The reason for this is because of the way the design leaves gaps over the fuel dispension area. (Figure 4.10).

Clarifier: This station uses a system that employs 3 drains in the middle of the fuel dispension area. At the time of this writing I have not been able to get any information on the type of clarifier used and I have not been able to locate any possible exit ports in the curb along the adjacent streets. It is possible this location has a tank or an underground clarifier that holds or releases treated runoff from the fuel dispension area directly to the storm water drainage system underground.

Comments: This station opened approximately March 1, 1998 and is the second newest of my candidate sites. It is a high volume outlet with a mini mart in a busy location. I have visited this station three times during storm events and have noted the following observations:

1) The grading here is so effective I have never observed any runoff from the parking lot to flow on to the fuel dispension area. I have observed no standing puddles of water at this station.

2) The fuel dispension area grading and the positioning of the drains here worked excellent.

3) I have observed some moving sheens in the parking lot gullies, but I believe it was less then those at site B which has a very similar grading and gully design.

4) The storms I have observed here were not as strong as some of the others I have seen at other stations and the storms did not produce slanted rainfall that I have seen

during accomaning strong winds But the "zigzag" canopy design allows vertical rainfall to land on the fuel dispension area.

5) The overall design here (with regards to keeping stormwater off the fuel dispension area), worked excellent.Unfortunately the lack of access to the drain here makes it very difficult to get any kind of sample. If there is an underground exit port to the storm water drainage system, it might be to difficult to sample the water exiting the clarifier.

Figure 4.9. Fuel Dispension Area in Placentia. This station uses a 3 drain configuration in the center of the fuel dispension area. The fuel dispension area is graded to cause any kind of spill or stormwater flow to move to its center. This keeps the drains out of direct rainfall and far away from flows that originate in the surrounding parking areas (February 22, 1998).

Figure 4.10. Rain canopy in Anahiem. The "zigzag" design of this canopy may be stylish, but it allows way to much direct rainfall on to the fuel dispension area even during mild rainfall events (February 22, 1998).

4.5) Site D:

Location: Laguna Hills, Ca.

Legend:

Cd - Drain to clarifier

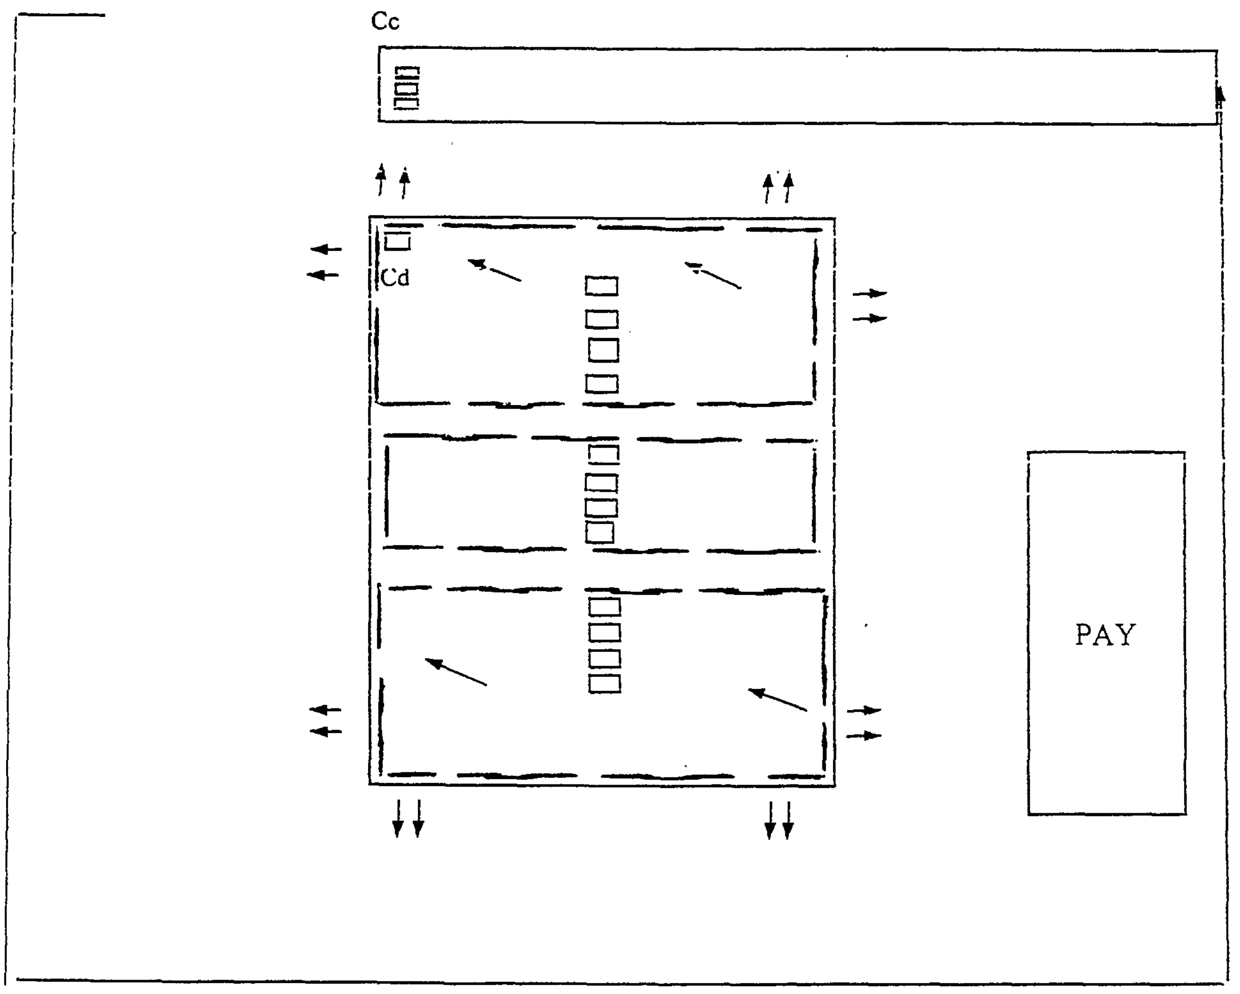
Cc - Exit port from clarifier, located on the street.

Single arrows - runoff that originates from fuel dispension area.

Double arrows - runoff that originates from surrounding parking lot area.

Small black dashed lines - graded gullies that channel stormwater runoff.

Large black dashed lines - canopy outline in relation to fuel dispension area



R0009197

Grading: The stations parking lot is graded in asphalt and does an excellent job of keeping stormwater from flowing on to the fuel dispension area. This parking lot also utilizes a single gully that channels stormwater runoff to the street (Figure 4.11).
The fuel dispension area is cement and graded so as to cause any flow that originates their to travel to the northeast corner to the drain location.

Canopy: this station uses a canopy that consists of three separate square canopies. This leaves open gaps between the canopies that allows direct rainfall on to the fuel dispension area. This also appeared to provide more edge surfaces to allow for more dripping from the sides of the canopies that land on the edges of the fuel dispension area. These canopies are also narrower then most I have observed and allow a lot of rainfall to directly land on the fuel dispension area (Figure 4.12).

Clarifier: This station has a 1300 gallon oil/water separator box, which is a three compartment sand and grease interceptor and sample box. There is a shut-off valve on the outlet pipe to restrict flow to the storm water drainage system. The first compartment captures all the stormwater runoff from the fuel dispension area. Sand will settle to the bottom of this compartment and liquid will flow freely into the second compartment. As enough liquid collects here, it will be forced into the sample box or third compartment. This system is located in the North planter (Figure 4.13)

Comments: This station was renovated in the mid 90s. It is a high volume outlet with a mini mart in a prime location. I visited this station three times during storm events and have noted the following observations:

1) This station makes use of 3 separate canopies that allows by far the most direct rainfall to land on the fuel dispension area. Its narrower design also allowed even the slightest of slanted rainfall to land as far in as to hit the pumps themselves. The 3 stage canopy also allowed for a lot of unnecessary drippings from all the extra edges present

2) This station uses a 3 stage clarifier that is installed in the planter. The drain in the fuel dispension area is small and utilizes small holes in a steel plate that is not easily removable (Figure 4.14). Since there is no access to the inside of this drain it would be necessary to some how cover it and allow a pooling to build up and take my sample when enough stormwater is present. But, because of the poor design of the canopy here (with

respect to keeping rainfall off the fuel dispension area) stormwater builds up fast on the fuel dispension area compared to other stations with a drain located under the canopy

3) This station seemed to employ the more sophisticated clarifier system I have seen, but as of this writing have not been able to gain access to the inside of the system. It appears that this system drained directly into a storm drain right on the street. Just above the storm drain and across the side walk is a steel cover with barred holes and a very noticeable stain coming from it and leading to the gutter (Figure 4.15).

Figure 4.11. Parking lot grading in Laguna Hills. The grading in this parking lot utilizes a gully to channel stormwater to the street. The steeper inclines around the fuel dispension area help keep parking lot runoff from flowing on to the fuel dispension area (March 4, 1998).

Figure 4.12. Rain canopy in Laguna Hills. This 3 stage canopy design contains more surface area on its sides then a single rectangular type, thus the fuel dispension area receives more stormwater in the form of drippings. Its narrow design also allows more rainfall even at the slightest slant to penetrate deep in to the fuel dispension area (March 4, 1998).

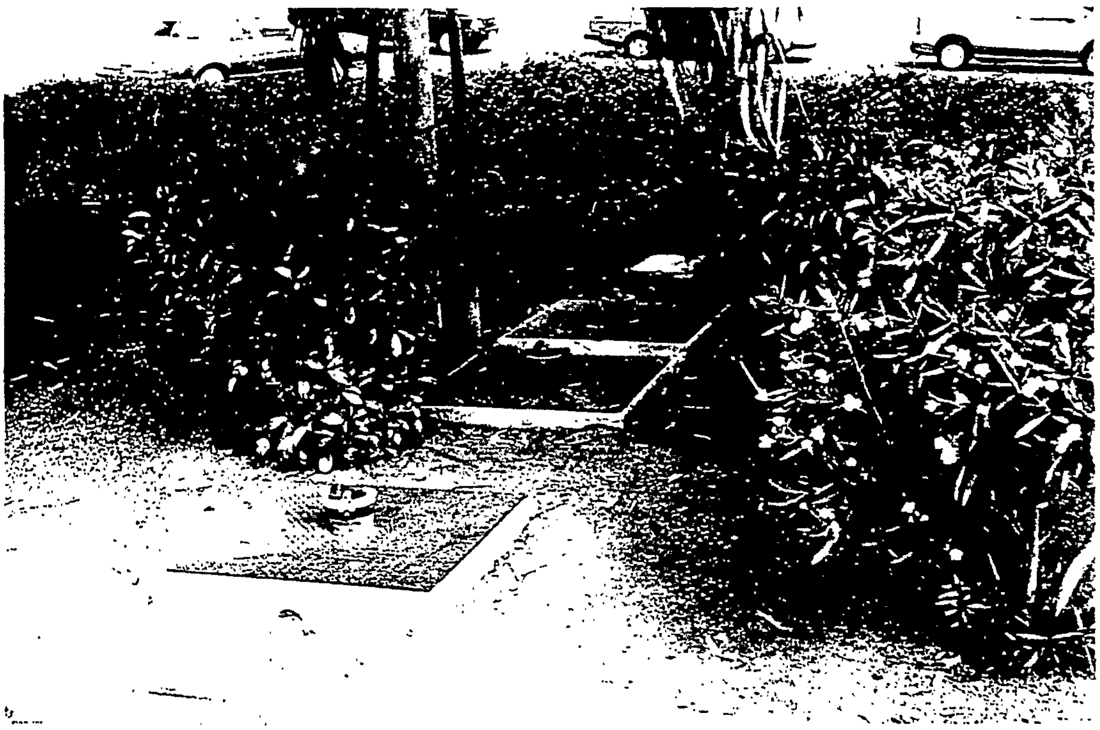


Figure 4.13. Stormwater treatment system in Laguna Hills. This stations 3 stage clarifier is located in the north planter. (March 4, 1998).

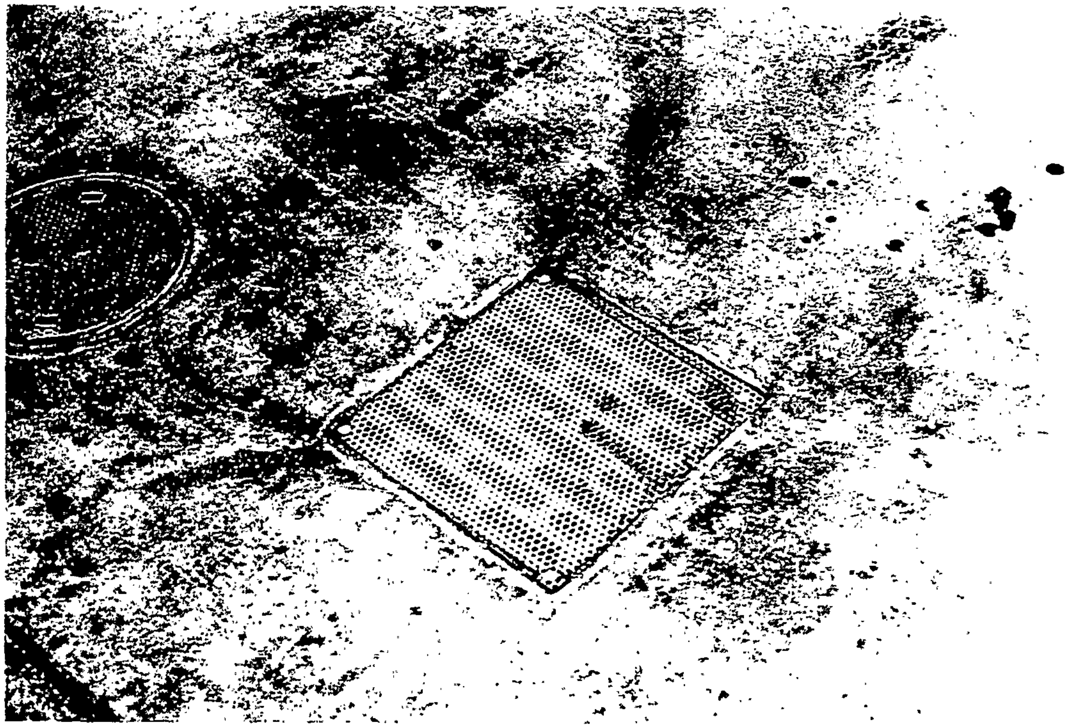

Figure 4.14. Drain to clarifier in Laguna Hills. This drain to the clarifier is located on the northwest corner of the fuel dispension area just under the corner of the protective canopy. Its small design could make sampling difficult if I cannot gain access to the inside. (March 4, 1998).

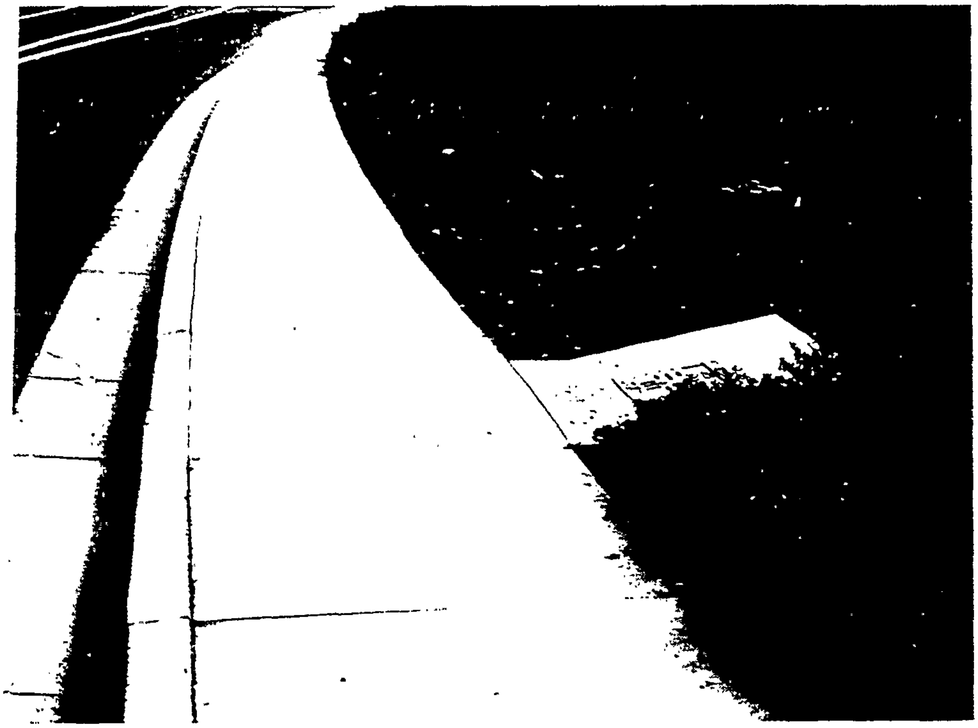

Figure 4.15. Exit port for treated stormwater. Water is released at the street after being treated in the clarifier, a stain on the sidewalk is obvious. (March 4, 1998).

4.6) Site E:

Location: El Toro, Ca.

Legend:

Cd - Drain to clarifier

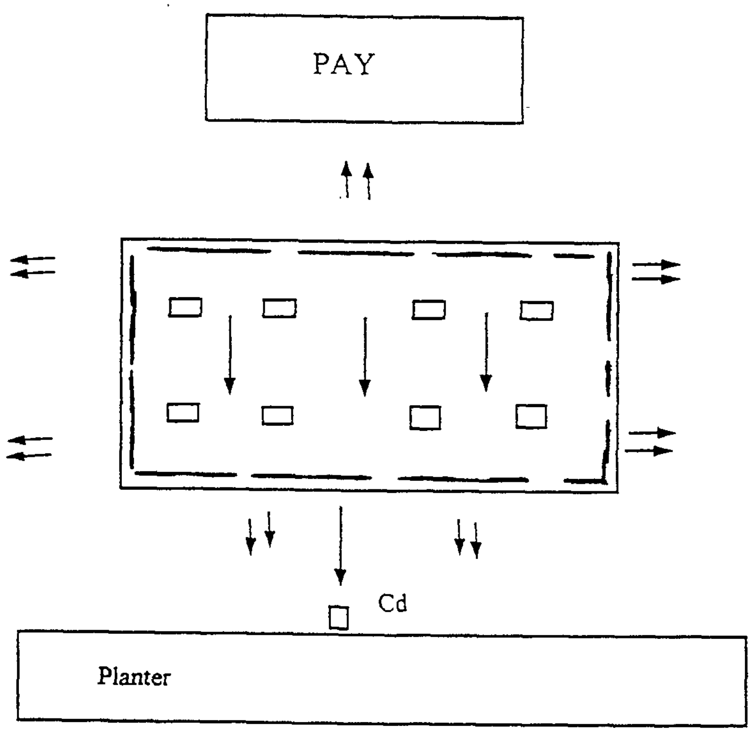
Cc - Exit port from clarifier, located on the street.

Single arrows - runoff that originates from fuel dispension area.

Double arrows - runoff that originates from surrounding parking lot area.

Small black dashed lines - graded gullies that channel stormwater runoff.

Large black dashed lines - canopy outline in relation to fuel dispension area



Grading: The parking lot is graded in asphalt and in a way that does an average job of keeping stormwater flow off the fuel dispension area. This station is located on a large corner and has a larger then usual parking lot. I have also observed some puddling in this parking lot.

The fuel dispension area is cement and is graded so as to cause any flow that originates their to move to the west end of the fuel dispension area to a drain that is located at a planter curb. Under this drain is a holding tank (Figure 4.16).

Canopy: The canopy here is of a single rectangular design that ends just above the outer edges of the fuel dispension area. I have observed some drippings from the outer edges of this canopy that land on the fuel dispension area. The outer 2-5 feet of the fuel dispension area collected a fair amount of stormwater from direct rainfall.

Clarifier: This station employs a 550 gallon underground tank that collects stormwater runoff from the fuel dispension area. The drain is located across the parking lot and consists of a metal barred grate that leads to the tank. The drain would not be that hard to sample but, I was not sure how I would get an exit sample or access to the inside of the tank.

Comments: This station opened or was renovated at an unknown date. It is a high volume outlet with a mini mart in a busy location. I have visited this site 2 times during storm events and have noted the following observations:

1) Any runoff from the fuel dispension area crossed an uncovered portion of the parking lot before it reaches the drain to the holding tank (Figure 4.17). This allowed direct rainfall and parking lot runoff to mix with fuel dispension area runoff, thus causing a dilution effect.

2) The holding tank design did not work well here. I have visited this location twice during stormevents and the tank is always full and overflowing to the stormwater drainage system (Figure 4.18). I have also visited this station 1 time during clear weather and the tank was still full with a noticeable sheen across the top (Figure 4.19).

Figure 4.16. View of Fuel Dispension Area in El Toro.This fuel dispension area uses a grading to the center that drains to the curb in front of the planter. Under the planter is a 550 gallon holding tank (March 24, 1998).

Figure 4.17. View of rain canopy in El Toro. From this angle, you can see how water from the fuel dispension area runs down to the curb where a drain is located. The last 30-40 feet of the grade is not under the protective canopy and gets a dilution effect, this also causes the tank to fill up very quickly and overflow to the street (March 24, 1998).

Figure 4.18. Drain leading to underground stormwater storage tank in El Toro. This drain to the 550 gallon tank was always full and overflowing during every stormevent I observed here. There is an access to the tank in the planter that can be used to pump out contaminated water. (March 24, 1998).

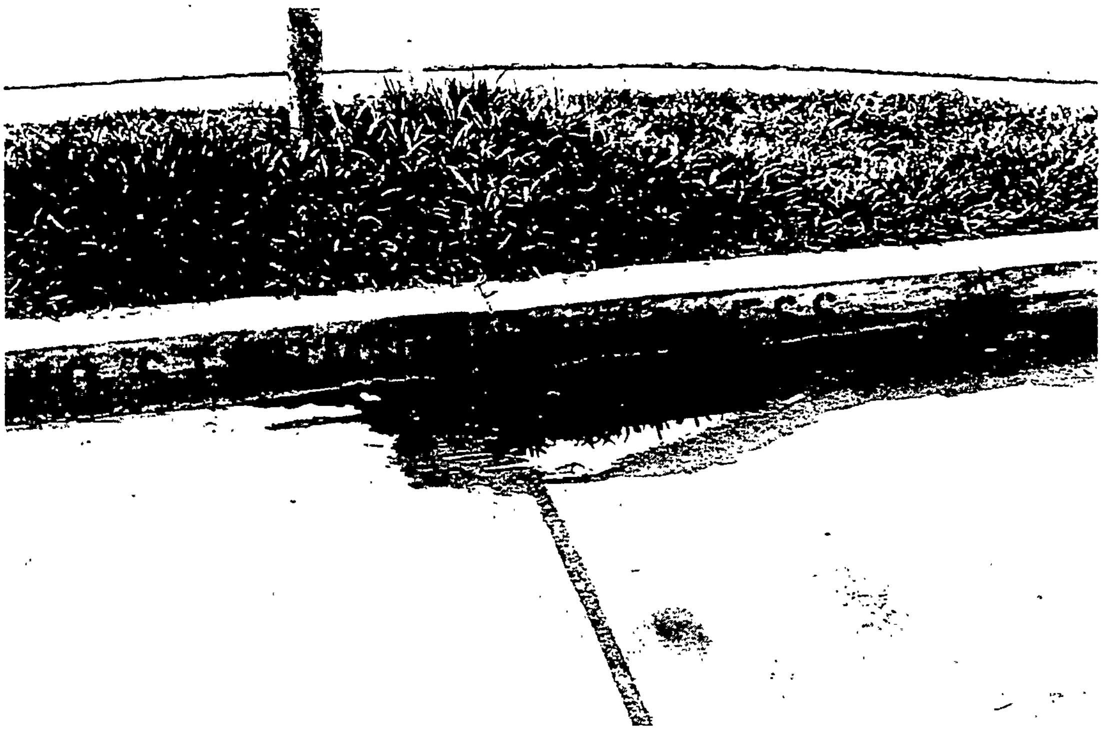


Figure 4.19. Drain to underground stormwater storage tank in El Toro. Close up of the drain to underground 550 gallon tank. When the tank is full of water from fuel dispension area it runs off to the street. (March 24, 1998).

4.7) Disscussion

Gasoline is regularly spilled during the refueling process or leaked from any vehicle on the fuel dispension area. I have come to the conclusion that the best way to reduce the amount of VOCs that originate from RGOs and enter the storm water drainage system is to minimize the accessibility of the fuel dispension area to stormwater from all possible sources. For modern high volume RGOs the major contributors of stormwater to the fuel dispension area include:

1) Rainfall that lands directly on the uncovered outer edge of the fuel dispension area during storm events.

2) Rainfall that lands on the canopy or sides of the canopy and drops on to the outer edge of the fuel dispension area.

3) Grading techniques that allow parking lot runoff to flow on to the fuel dispension area.

4) Grading techniques that allow for standing puddles of water in the parking lot area and/or the use of gullies adjacent to the entrance and exit ends of the fuel dispension area, that cars splash on to the fuel dispension area.

5) Stormwater that is brought on to the fuel dispension area by vehicles to be refueled.

I will now elaborate on each of the above 5 major contributors of stormwater to the fuel dispension area that I have been studying from December, 1997 through May, 1998.

1) None of the stations I have been observing during storm events had a canopy that totally protected the fuel dispension area even during light rain with a straight vertical fall. During heavy rains with strong winds, fuel dispension areas become so saturated, so fast, that some of the clarifier drains get totally overwhelmed and overflow. In fact, just a light wind can carry rainfall so far in to the fuel dispension area that the pumps are hit with direct rain fall at times. The best canopies I have seen are the single flat rectangular type. I would recremmend one that extends 5 feet "beyond" the outer most edge of the fuel

dispension area on all 4 sides. The use of "zigzag" and "multiple section" canopies might be stylish but allow acess direct rainfall to land on the fuel dispension area.

2) Canopies also drip stormwater from their edges on to the fuel dispension area, even during light vertical rainfall dripping edges sometimes land as far in as 2-5 feet from the outer edge. I have noticed that edges with tall vertical sides drop considerable more drippings then sides that are short with a sharp edge.

3) I have observed at some of my candidate sites the use of grading in the parking lot that does an excellent job of keeping stormwater from flowing on to the fuel dispension area. The most effective of my candidate sites make use of gullies located in the parking lot that channel stormwater runoff to the street.

4) I have observed that cars that drive through parking lot puddles before they pull up to be refueled tend to drip a lot more water on to the fuel dispension area. Gullies that are located at the edges of the fuel dispension area designed to carry fuel dispension area runoff to the clarifier drain, tend to get this water splashed back on to the fuel dispension area by on coming and departing cars.

5) Out of all the sources of stormwater to the fuel dispension area, the most difficult to control will probably be stormwater brought on by refueling vehicles. I have logged many hours at many different stations during many storm events of varying intensities peering out the window of my vintage 70s six pack camper and have found the best stations have no standing water or gullies that cars can splash through on the way up to the fuel dispension area. Furthermore it might be advantageous to have incoming cars approach the fuel dispension area from the direction that crosses the longest section of parking lot area to allow water slashed up under the car from the gutter at the street entrance to drip off some before they pull on to the fuel dispension area.

I have also noted one interesting common feature for all 5 of my stations. Storm events that occur during daylight hours are the best times to observe sheens that appear on standing and moving water. I have observed as many sheens in the parking lot area as I have that appear to originate from the fuel dispension area. This seems strange when you consider the many differences between these stations. For example, sites A and B have been open only 2-3 months, site A utilizes 2 clarifiers with drains located well out into the parking lot and 2 use drains located on the fuel dispension area. Another interesting observation I have made is that the duration or intensity of the storm event dose not seem to affect the amount of sheens visible, they seem to always be present in about the same quantity.

So where is all this fuel coming from and why does it seem to be so evenly spread across the entire station property ? I have been watching for sheens at all of the stations since I first began this project (sites A, D, E). I have been observing sites B and C since they opened, February and January respectively, I did not expect to see a lot of sheens as a result, but sheens were always present at these stations as well.

I have a suspicion that all of these sheens showing up are a result of incoming vehicles pulling up on a stormwater saturated fuel dispension area then departing and carrying water contaminated fuel on their tires and fenderwells to the surrounding parking lot area. There for, I think that minimizing the accessibility of the fuel dispension area to stormwater may be worth further study and offer the following suggestions:

1) The use of single rectangular type canopies and the extension of the edges over the fuel dispension area at least 5 feet on all 4 sides.

2) The use of grading that keeps stormwater from the surrounding parking lot area from flowing on to the fuel dispension area. If gullies are to be used to channel water off the property .they should be routed as far away from the fuel dispension area as possible.

3) If a clarifier is to be used, the fuel dispension area should be graded in a manner so as to cause any flow that originates there to move to the center and empty into a drain or drains located at the center of the fuel dispension area This eliminates the need for gullies along the outside of the fuel dispension area and still affords containment of large spills on the fuel dispension area.

The following map gives an approximation of the location of the previous 5 sites used in this study. As requested by the owners and associated groups the names and exact locations of my study sites are kept confidential.

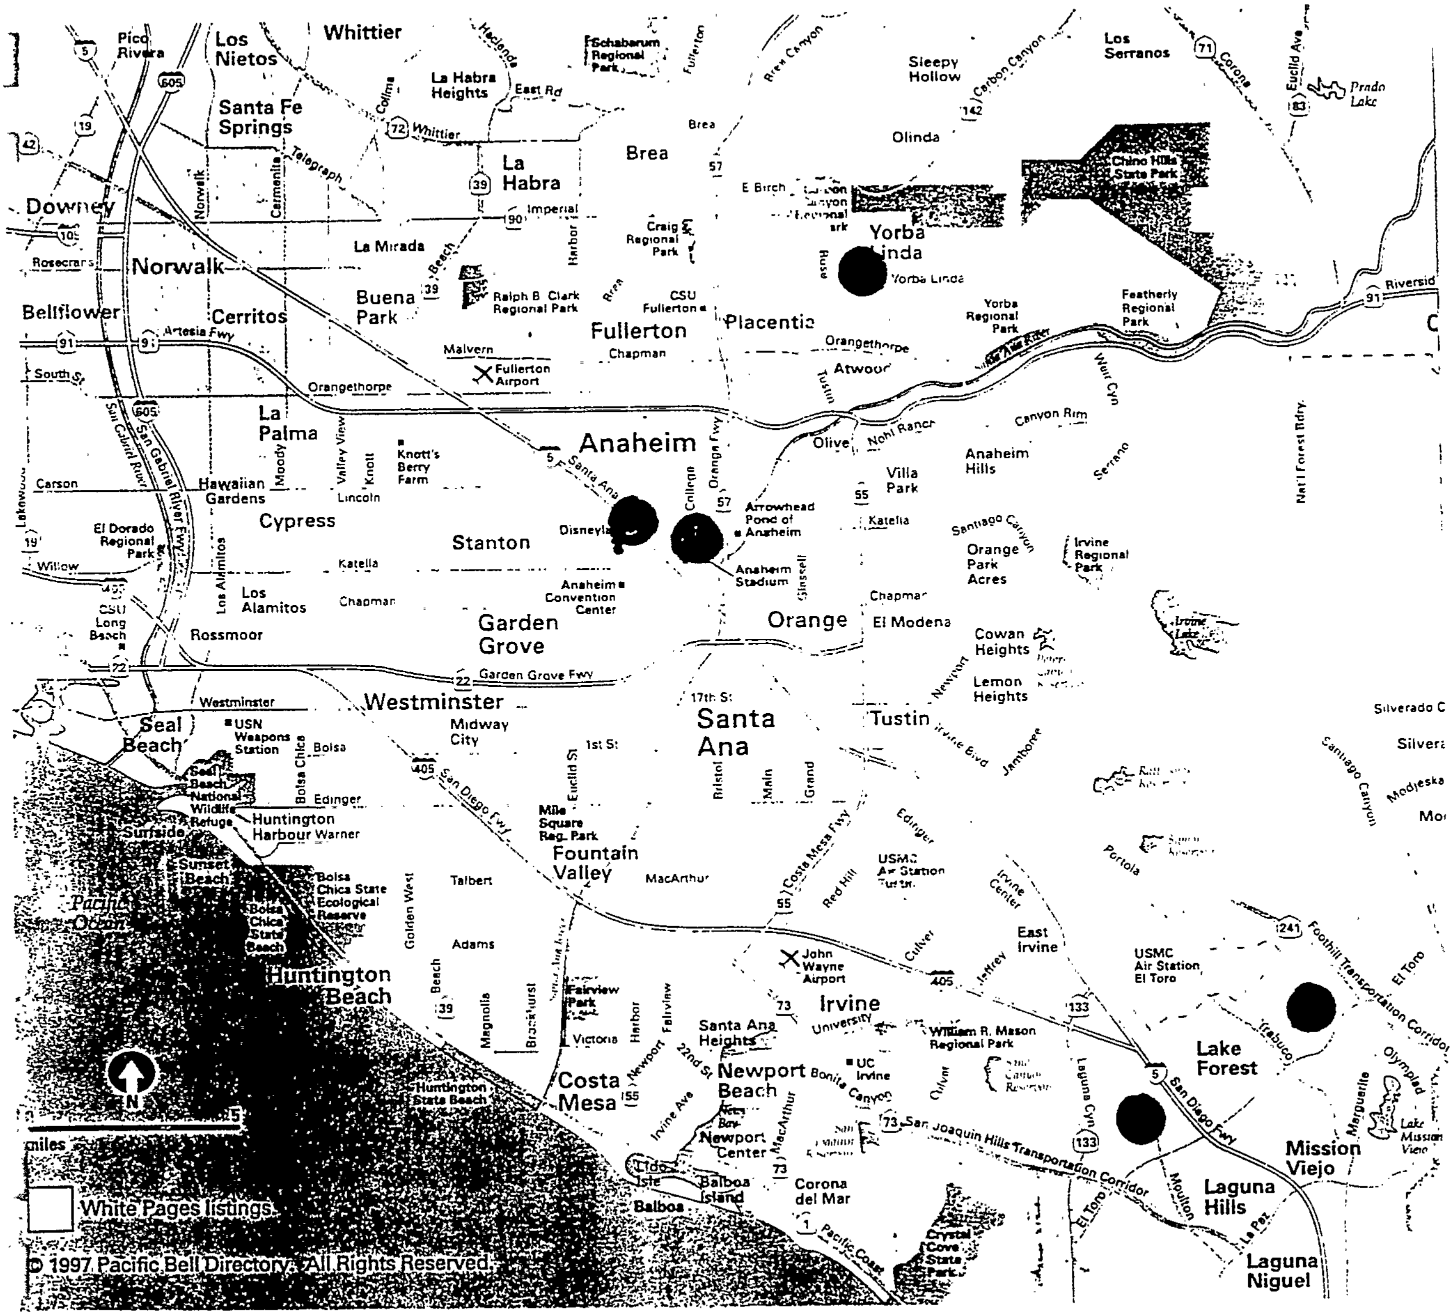

Figure 4.20. Red rings indicate approximate location of sites used in this study.

R0009213

5.0) SIMULATED STORMWATER STUDY AT A GASOLINE STATION

A literature search was conducted using the California State University Library and the University of California Library. I also conducted a search on the internet. I found no studies available for stormwater runoff that originates from RGOs. What information and studies I could find are summarized here.

A study conducted on Southern California RGOs entitled Results of a Retail Gasoline Outlet and Commercial Parking Lot Storm Water Runoff Study was prepared by Geomatrix Consultants (Geomatrix 1994). This report presents the results of a simulated storm water runoff from six RGOs and four commercial parking lots. This study was conducted for the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API). This study has two parts. Part 1, conducted by Hart Crower, characterized simulated storm water runoff from 5 RGOs. Part 2, conducted by Geomatrix, characterized simulated storm water runoff from four commercial parking lots and one RGO. Six RGOs, all located in southern California, were selected for this study. The six RGOs provide a representative cross section of typical RGOs in Southern California. Site characteristics for each RGO are summarized in Table 5.1.

Hart Crower and Geomatrix conducted a simulated rainfall application and sample collection at a pump island and driveway approach area within each RGO.
The water was applied at a rate of approximately 2 gallons per minute for the duration of a 45 minute test. This rate represents a rainfall rate of approximately 0.008 inch per minute or 0.12 inch every 15 minutes. The area used was approximately 400 square feet and the method of applying the water consisted of a network of perforated 1 inch pipe

Characteristic	RGO 1	RGO 2	RGO 3	RGO 4	RGO 5	RGO 6
Age of Facility	New	New	Older	Older	Older	Older

Table 5.2. Summary of retail gasoline outlet test locations and surface conditions for WSPA/API storm water runoff study. (Geomatrix 1994).

Commercial parking lots were selected for the second part of this study. Geomatrix and WSPA selected four commercial parking lots, all located in the Southern California. Simulated rainfall was applied and samples were collected at 2 locations at each of the 4 parking lots for a total of eight test sites. The test locations included one high-use and one moderate-use parking area. The high-use area was generally closer to the commercial facility entrance, and was occupied more frequently than the moderate-use area. Each of the parking lots used scheduled sweeping as a good housekeeping BMP. Parking lot test locations, conditions, and BMPs are summarized in Table 5.3.

Test Site	Site Use	Location and Traffic/Parking Condition	Traffic/Parking Frequency	Pavement Type and Condition	Best Management Practices
TS-1	Grocery Store Parking Lot	Near Store Entrance	High Volume of Traffic/Parking Spaces Normally Occupied During Business Hours	Asphaltic Concrete, Good Condition	Daily Sweeping
TS-2	Grocery Store Parking Lot	Located in Perimeter Parking Area	Moderate Traffic Volume/Area Used For Overflow Parking, Spaces Only Used During Peak Periods	Asphaltic Concrete, Good Condition	Daily Sweeping
TS-3	Bank Parking Lot	Near Bank Entrance/Parking	High Volume of Traffic/Parking Spaces Normally Occupied	Asphaltic Concrete, Good Condition	Daily Sweeping
TS-4	Bank Parking Lot	Located in Perimeter Parking Area	Moderate Traffic Volume/Spaces Only Used During Peak Periods	Asphaltic Concrete, Good Condition	Daily Sweeping
TS-5	Office Complex Parking Lot	Near Office Entrance	High Volume of Traffic/Parking Spaces Normally Occupied	Asphaltic Concrete, Good Condition	Daily Sweeping
TS-6	Office Complex Parking Lot	Located in Perimeter Parking Area	Moderate to High Traffic Volume/Spaces Normally Filled During Business Hours	Asphaltic Concrete, Slightly Degraded Condition	Daily Sweeping
TS-7	Restaurant Parking Lot	Near Restaurant Entrance	High Traffic Volume/Parking Spaces Normally Occupied During Business Hours	Asphaltic Concrete, Moderately Degraded Condition	Sweeping Every Other Day, Occasional Washdown
TS-8	Restaurant Parking Lot	Located in Perimeter Parking Area	Moderate to High Traffic Volume	Asphaltic Concrete, Moderately Degraded Condition	Sweeping Every Other Day, Occasional Washdown

Table 5.3 Summary of parking lot test locations, conditions, and best management practices for WSPA/ API storm water runoff study. (Geomatrix 1994)

Sampling procedures for both Part 1 and Part 2 follow the sampling protocol established by SW-846, "Test Methods for Evaluating Solid Wastes". The results from the simulated runoff from RGOs are presented in Tables 5.4.

Island: Fuel dispension area.

A simulated gasoline spill was performed at RGO 5 to provide data regarding the effectiveness of standardized spili response procedures. One quart of regular unleaded gasoline from a pump nozzle was discharged onto the pump island pavement. Absorbent material was applied to the spill after one minute. the absorbent material was then swep. up after it appeared to have absorbed the spilled liquid, and the simulated runoff test was conducted.To minimize test variability caused by differing rainfall intensities and duration, both parts of the study used a simulated rainfall method to induce from the study sites. The water dispensing system and sampling procedures were identical for both the RGO and commercial parking lot sites. The water dispensing system was designed to apply water uniformly over the test area and create sheet flow. The resuits from the simulated runoff from parking lots are presented in Tables 5.5.

Tables 5.5, BTEX data from parking lot study (Geomatrix 1994).

The authors of this paper concluded that for the constituents analyzed in this report, median event mean concentrations (EMCs) in storm water runoff from normally operated and maintained RGOs are no higher then those in runoff from commercial parking lots. In all cases, the fuel related constituents from pump islands were either not detected or below applicable Maximum Contaminant Levels (MCLs). These results indicate that fueling activities at normally operated and maintained RGOs do not contribute additional significant concentrations of measured constituents to storm water runoff (Geomatrix 1994, 13).

6.0) SAMPLING AND ANALYSIS DURING WINTER 1997/1998

The main focus of this CSUF sampling study was to evaluate the effectiveness of the S11 Motor Fuel Concrete Area Interruptable Drainage requirement. In the sites chosen there existed an underground clarifier or filter system that had a drain entry that collected stormwater from the fuel dispension area and an exit usually to the gutter along the street. The collected samples were analyzed for the presence of BTEX hydrocarbons.

6.1) Site Criteria

The following is a summary of the criteria used for my sampling sites.

- RGO was a modern high volume station located in Orange County California, built or renovated after June 1 1996.
- RGO was equipped with all the currently required BMPs.
- RGO was equipped with a clarifer (S11 requirement) with an inlet (drain) and an outlet (exit port) that could be sampled. The use of an underground tank or car wash system can not be utilized.

6.2) Qualifying Storm Event

Stormwater samples were collected and analyzed during as many storm events as possible. I used forecast information from the National Weather Service and the various radio and television news networks to plan my sampling trips. I also utilized the meteorological services at the Orange County Public Facilities and Resources Department ALERT stations to help forecast potential qualifying storm events. For the proposed study plan a qualified storm event was defined as an event that:

- Produced a "significant stormwater discharge" (a continuous discharge of stormwater for approximately one hour or more).

Was preceded by at least two working days of dry weather.

6.3) SAMPLING METHOD

In order to evaluate the effectiveness of the clarifiers which continually circulate stormwater for the entire duration of the storm event, I used a time weighted composite method. This method consisted of at least 4 sets and as many as 8 sets of manual samples collected at 15 minute intervals. The first of the 4-8 sets were collected within the first 30 minutes of discharge from a qualifying storm event as defined in section 4.2. In certain cases that samples could not be taken within the first 30 minutes, then sampling began when a continuous discharge begins, provided that the reason(s) for the delay was documented.This study plan includes a detailed account of each storm event sampled.

6.4) Sampling Procedure and Quality Control

When a candidate storm was forecast for the Orange County area, I went to the site to be sampled and waited for the rain to start. When the rain began, I waited 30 minutes or until enough runoff was flowing into the clarifier and out its exit port to the street to sample. The sampling sites consisted of the following:

- Fuel Dispension Area: the area where the pumps are located. This is usually a concrete region sometimes referred to as the island. It is usually that region that is covered by the rain canopy.
- Parking lot: the area that is around the fuel dispension area. This is usually the asphalt region and includes the driveways into the site and that lead to the fuel dispension area.
- Drain: this is usually a barred grate in the ground where stormwater runoff is channeled to. An underground pipe connects this drain to the clarifier where the water undergoes treatment before it is released to the street. This drain is usually located on/or near the fuel dispension area.
- Exit Port: this is usually located on the street and is usually just a couple of holes

in the curb where water that has been treated by the clarifier is released to the gutter.

I normally set up 2-5 sandbags in the gutter up gradient of the exit port in the curb.This deflected the gutter flow away from the exit ports and allows a sample to be taken without the possible contamination from other waters. During heavier storm episodes, gutter flows became so large that sampling was impossible due to the high levels of gutter flow. Indeed, in many storm events the exit ports were completely under water.The sand and bags were discarded after each sampling episode to prevent the possibility of cross contamination. I also used medical latex gloves and changed them after each sample was taken to prevent the possibility of cross contamination. The drain that was sampled was deep enough to totally submerge the 40 ml vial. Exit ports required a slight tilt of the vial, but could usually be totally filled without having to add water manually in some manner. When topping off of the vial was required, I used the cap as a dip inside the port and filled the vial.

As samples were collected at the site, they were placed in an ice chest and cooled to 4 degrees C. The samples were collected in 40 ml amber vials with septum caps. The vial was filled just to overflowing to ensure that there were no bubbles entrapped within the collection vial. They were then transferred to the lab as soon as possible.The volatile organic compounds were analyzed on a Sentex Scentograph Plus 2 gas chromatogragh (GC). This GC is owned and operated by the Orange County Public Facilities and Resources Department. The GC is equipped with a purge and trap system, a micro argon ionization detector (MAID) and a 30m VOCOL capillary column. A calibration standard was run after every third sample to ensure that the instrument is operating properly. All samples were also sent out to a certified laboratory.

6.5) Data Analysis

The first sample taken was labeled Cd. This sample was taken from the drain that collects stormwater runoff and allows it to enter the clarifier. The second sample taken was labeled Cc. This sample was taken at the exit port and represented water that had been treated by the clarifier and released to the street that eventually leads to the stormwater collection system. Sample Cd was compared with sample Cc for a measurable difference in the presence of BTEX constituents. I also took a background sample from the clarifier drain before storm water began to flow in. This gave me an idea of what was present in the clarifier before the storm event begins. This sample was labeled Cb and is a background sample. I was also interested in what is present in the parking lot and took a sample here at the beginning of each storm event and I took another sample when I was finished sampling at each site. These samples were labeled Cp. The amount of rain the sample sites received was measured by the County's ALERT system. This system is made up of 90 stations across the County. Each of sites that was sampled is located near at least 2 of these stations. Table 6.1 gives the locations, types and names of all Orange Countys active ALERT stations.

6.6) Sampling Event 1 on March 25, 1998

I arrived at site A, (see pages 28 -33) at 3.30 am during a light rain. Around 4 am I set up 3 new sand bags in the gutter to deflect flow away from outlet ports in the curb. By 4.30 am enough stormwater runoff was present to begin sampling. During the first hour enough stormwater was flowing to take 4 sets of samples with no problems. The drain at this location was shallow and made it impossible to submerge my sample bottle. I tilted the sample bottle and filled it to about 80% full and let the water flowing in fill it the rest of the by putting the bottle under the falling water. The exit port required that I tilt the bottle in the hole and fill it about 80% full. I then use the cap as a bucket by filling it in the hole and pouring it slowly into the sample bottle.

Table 6.1. Orange Counties active ALERT stations.

I observed many moving sheens of fuel at this station on many observations in the past and this time I observed just as many on this trip alone. During the second hour rain was starting to vary in its intensity. Enough water was still flowing to take 4 more sets of samples. Sheens of fuel were still present in the gullies and surrounding parking lot areas. Customer traffic has increased and I counted 37 vehicles this hour.This station had a grading design that works well at keeping parking lot stormwater runoff from moving on to the fuel dispension area. I observed none during this event. The canopy did not totally cover the fuel dispension area and even in this light consistent rain the west end of the fuel dispension area was wet about 4 feet in and a small flow was moving down to the gully that leads to the drain. The cars that were pulling up to refuel were bringing water on to the fuel dispension area but it was not enough to create a flow down to the drain. This station was designed in a way that water that reaches the fuel dispension area flows down gradient to a gully that travels about a 100 feet across the parking lot and empties into the drain. The drain therefore intercepts a lot of parking lot water and direct rainfall. The consistent presence of observed moving sheens was a bit surprising even after 2.5 hours of rain and I also noticed a strong turpentine and metallic smell from my hands and gloves. In fact, even after 48 hours in my garage the sand bags still had that strong smell. The results of this sampling are presented in Table 6.2.

6.7) Sampling Event 2 on March 31, 1998

Arrived at the site B, (see pages 34-40) at 4 pm during a light rain. At 6.45 pm I took a sample from the drain before runoff begins to trickle in. Parking lot runoff in gully was flowing enough to take a sample .The drain here was easy to sample, and it was deep enough to totally submerge sample bottle. At the curb at the exit port, I tilted the sample bottle in the exit port and filled it to about 80% and used the cap as a scoop inside the port to fill the rest of the way.

Light rain turns to medium intensity rain and the outer 4-5 feet of the fuel dispension area was wet enough on all 4 sides to start a trickle flow moving toward the gullies that lead to the drain. The edge of the canopy was dropping a lot of water on to the edge of the fuel dispension area. I did observe moving sheens in the gullies until it got dark. The lighting here made it very difficult to observe possible sheens at night. In fact, the logo colors of this franchise that was painted on the canopy reflected in a manner that they look like sheens on the wet surfaces. This station was by far the busiest one I have been to. But I did not see as many sheens here as I did at site A. The strong metallic turpentine smell was present here but, not near as strong as site A. The results of this sampling are presented in Table 6.4.

6.8) Sampling Event 3 on April 11, 1998.

I arrived at site B (see pages 34-40) around 10.30 am. A light rain began to fall around 10.45 am. I set up two sand bags at the curb to deflect off any possible gutter flow from the exit port at the curb. At 11 am enough flow was moving from the parking lot area to the gully that carries it to the street to take a sample (Cp). I also took my background sample from the clarifier drain (Cb) before any flow began to trickle in at 11 am. By 11.15 am enough runoff was trickling into the clarifier drain (Cd) and out of the exit port at the street (Cc) to begin sampling. Rain is light but steady during the duration of the storm event. But by 12 pm, rain had lightened up considerably and the storm was starting to break up. Runoff flow started to decrease and by 12.30 pm was no longer trickling into the clarifier drain. I took my second parking lot sample and left. This was the first time I had been able to sample or observe this station in the daylight hours. I have observed more sheens of fuel moving throughout the property and most of which were seen in both the parking lot and fuel dispension area gullies. I also observed sheens flowing in the street gutter that did not appear to be originating from this stations property. I also did not smell that strong turpentine metallic odor that I had experienced at other sites in my study. The results of this sampling are presented in Table 6.8.

6.9) Sampling Event 4 on May 12, 1998

I arrived at the site B (see pages 34-40) at 2 pm during a light rain. At 2.15 pm I took a sample from the drain (Cb) before runoff began to trickle in. Parking lot runoff in gully was flowing enough to take a sample (Cp).The drain here was easy to sample (Cd), and it was deep enough to totally submerge sample bottle. But, this time I allowed the bottle to fill by collecting water that was flowing downward into the drain. This storm was stronger than the previous two I had sampled here and water is cascading down into the drain for the entire sampling event. At the curb at the exit port (Cc). I tilted the sample bottle in the exit port and filled it to about 80% and used the cap as a scoop inside the port to fill to the top. This time it took 3 sand bags to deflect the gutter flow enough to avoid contamination.

Light rain turned to medium intensity rain and the outer 4-5 feet of the fuel dispension area was wet enough on all 4 sides to start a trickle flow moving toward the gullies that lead to the drain. This storm had strong winds associated with its rainfall and at times was blowing rainfall on to the pumps. I had also noticed that flow from the fuel dispension area was flowing into the gullies that channels stormwater to the street.The edge of the canopy is dropping a lot of water on to the edge of the fuel dispension area. I did observe moving sheens in the gullies during the entire event.This station was still by far the busiest one I have been to. But I did not see as many sheens here as I did at site A. The strong metallic turpentine smell was present here but, not as strong as site A. The results of this sampling are presented in Table 6.8.

6.10) Discussion

All my samples taken from the drain to the clarifiers were less then 0.5 ppb and all the samples from the exit port were less then 0.5 ppb, well below applicable Maximum Contaminant Levels (MCLs). This would indicate either the clarifier was not working properly or the BTEX levels were below the clarifiers capacity to separate them out.The samples were taken from a modern Retail Gasoline Outlet built in the current year (1998) and subject to all the current Best Management Practices. Furthermore I took samples from a separate location in the stations parking lot before and after each sampling event and those samples were also less then 0.5 ppb, well below applicable MCLs. The constant presence of visible gasoline sheens from the fuel dispension area and parking lot area were suspect, but the data indicates that there was no measurable difference between the two and more importantly, both were well below applicable MCLs.

7) CONCLUSIONS

I have spent the last 8 months studying articles, books, internet sites, and other studies done on stormwater runoff and petroleum hydrocarbons. I have also visited numerous Retail Gasoline Outlets during storm events ranging from mild to extreme.I have carefully observed stormwater movement and how the structural Best Management Practices perform in the field under real world conditions. I have conducted my own sampling on three separate occasions and had those samples tested at a certified lab for the presence of BTEX hydrocarbons. My literature review focused on studies done on the presence of petroleum hydrocarbons taken from various locations such as channels, rivers, streams from many cities across the U.S and the common consensus is that BTEX hydrocarbons are almost always present in samples, but they are usually in low concentration levels. Here in Orange County, California the Orange County Water District operates one of the most modern and admired systems in the world. This region is also one of the most heavily developed urban, industrial, commercial, and automobile dependent regions in the country. A system of monitoring wells provides data on the regions water quality year round and other water agencies perform similar monitoring. BTEX hydrocarbons have been found in high concentration levels in shallow aquifers here but, the deeper primary drinking water aquifers are well below applicable MCLs.The main reason for this is BTEXs affinity to biodegradion. My studies have indicated that most of the data still points toward leaking underground fuel tanks as the primary source of this contamination. The one possible exception could be the gasoline additive MTBE. It has begun to rise in concentration levels in various locations throughout California, but because MTBEs use is somewhat new to the region, there is not much data on its presence and has stirred new debate about its routes of entry to the regions surface and subsurface waters.

My study of the structural BMPs required for all new and renovated gas stations, brings me to the conclusion that the best way to keep spilled gasoline out of the stormwater system is to keep the spilled fuel from being carried from the fuel dispension area to the surrounding parking area where it can then enter the stormwater system. This means either intercepting and treating stormwater runoff as it leaves the fuel dispension area with a clarifier (S11 Requirement) or minimizing the amount of stormwater that gets onto the fuel dispension area or both. All the stations used in this study employed the "both" scenario. My observations of the use of a clarifier at my five stations yielded the following:

1) The stations I studied all used a different type of system. I never got any designs, prints, or specifics about the clarifier systems used but I carefully inspected all five sites and found only one clarifier system that seemed to mechanically treat for BTEX hydrocarbons (see page 49). Two stations used a system that appears as a collection pit with a two inch plastic pipe leading from the side of the pit and then underground across to the curb where it releases water at the street (see pages 39 & 40). Another station used an underground 550 gallon holding tank (see page 46).

2) The locations of the drains were an important part of the system. When the drain is located outside the protective cover of the canopy such as sites A and E, they overflow. When the drain is located on the edge of the fuel dispension area or connected with gullies, excess water accumulated in them as well, sites B and D.

3) When excess stormwater from unnecessary sources such as gullies, direct rainfall, and parking lot runoff reached the drain a dilution effect occurs. The only drain location that I felt minimized all sources of possible unnecessary stormwater entry was site C (see page 43).

4) Another problem I observed was a lack of clarifier maintenance. I visited site E in early November of 1997 and the tank was full and overflowing to the street. I visited it again three more times in the next three months and it was still full. I also observed site B from the first day it opened. During the first storm event I observed in January, I placed a penny in the debris trap. I sampled the station for the last time in May and the penny was still there.

I believe it would be better to improve upon the use of structural BMPS such as an enlarged canopy with sharp edges that extends at least five feet over the fuel dispension area on all four sides. Grading that effectively keeps any parking lot runoff from flowing on to the fuel dispension area. The need for a clarifier could then be more affectivly studied.

In the Sampling portion of my study (chapter 6) the drain and the exit port of the clarifier were sampled for the presence of BTEX hydrocarbons. I also took a sample from the surrounding parking lot area. When the samples were tested the data showed that there was no measurable differences between all three sampled areas. All were less then 0.5 ppb for BTEX and 10 ppb for MTBE. Furthermore, all these samples were well below applicable MCLs. These conclusions also reflex similar conclusions from a previous study in the region where stormwater samples were collected and analyzed from retail gasoline stations and compared with commercial parking lots (chapter 5).

I believe there is one other important comment in regards to the lack of a measurable difference in BTEX hydrocarbons from the drain and the exit port of the clarifier. For sampling events 2, 3, and 4 of this study. The stormwater entering the drain to the clarifier received direct rainfall and drippings from the edges of the canopy. This could have had a dilution effect on the fuel dispension area runoff entering the drain and been partially responsible for the less then 0.5 ppb readings from the analysis. The same 0.5 ppb readings at the exit port were probably well below what the clarifier was capable of treating. The parking lot sample was taken well away from the fuel dispension area, but may have been affected by direct rainfall as well.

Related subjects for further study:

The effectiveness of non structural Best Management Practices: this study focused on evaluating the effectiveness of structural Best Management Practices and sampling for the presence of petroleum hydrocarbons by utilizing the stations clarifier system (S11 requirement). See appendix C for a list of currently required structural Best Management Practices and appendix B for a list of currently required non structural Best Management Practices.

The first flush effect: the wet season for the Orange County California region was accompanied by one of the strongest El Nino events in recent history. Areas of Orange County received an average rainfall of approximately 30 inches. My sampling did not begin until March of 1998 This was well into the rainy season for this region. The extended forecast for the next season in Orange County is for a possible La Nina effect (the opposite of an El Nino effect). A sampling of the first storm event of the next rainy season and a few of the following stormevents may yield different results than the results I got by sampling the late season storm events.

APPENDIX A

Definitions (pursuant to RGOs)

1) "County" shall mean the County of Orange, California.

2) "Co-Permittee" shall mean the County, the Orange County Flood Control District, and all the municipalities within Orange County which are responsible for compliance with the terms of the NPDES permit.

3) "DAMP" shall mean the Orange County Drainage Area Management Plan, as the same may be amended from time to time.

4) "Development Project Guidance" shall mean Damp Chapter 7 and the Appendix there to, entitled Best Management Practices (BMPs) for new development including non-residential construction projects and all subsequent amendments thereto. This includes all Retail Gasoline Outlets.

5) "Discharge" shall mean any release, spill, leak, pump, flow, escape, leaching (including subsurface migration or deposition to groundwater), dumping or disposal of any liquid, semi-solid or solid substance.

6) "pollutant" shall mean any liquid, solid, or semi solid substance or combination thereof, included and not limited to:

a) Artificial materials (such as floatable plastics, wood products or metal shavings, trash and paper wastes.

b) Petroleum and related hydrocarbons (such as fuels, lubricants, surfactants, waste oils, solvents, coolants and grease.

c) Metals and non-metal compounds (such as lead, cadmium, zinc, copper, chromium and nickel) with characteristics which cause an adverse effect on living organisms.

d) Substances having a ph less then 6.5 or greater then 8.6, or unusual coloration, turbidity or odor.

7) "Renovation" shall mean the rehabilitation or reconstruction of a retail structure, for which either a discretionary land use approval, grading permit, building permit or non-residential plumbing permit is required.

8) "Storm Water Drainage System" shall mean street gutter, channel, storm drain, constructed drain, lined diversion structure, wash area, inlet, outlet to other facility, which is a part of a tributary to the county-wide stormwater runoff system and owned, operated, maintained or controlled by the County of Orange, the Orange County Flood Control District or any Co-Permittee City, and used for the purpose of collecting, storing, transporting, or disposing of stormwater (Office of County Council Orange County, Article 1).

APPENDIX B

Required Non-Structural BMPs for RGOs

N2. Activity Restrictions: If a Property Owners Association (POA) is formed, conditions, covenants, and restrictions shall be prepared by the developer for the purpose of surface water quality protection. Alternatively, use restrictions may be developed by a building operator through lease terms, ect.

N4. BMP Maintenance: Identification of responsibility for implementation of each non structural BMP and scheduled cleaning of all BMP structural facilities.

N5. Title 22 CCR Compliance: Compliance with Title 22 of the California Code of Regulations and relevant sections of the California Health and Safety Code regarding hazardous waste management, to be enforced by County Environmental Health on behalf of the State.

N6. Local Industrial Permit Compliance: Provides for clean storm water discharge from fuel dispensing areas, and requires permission to discharge industrial waste to public properties.

N7. Spill Contingency Plan: Prepared by building operator for use by specific types of building or suite occupancies (County Environmental Health has provided a list to the County Plan Check, as an example), and which mandates stockpiling of cleanup materials, notification of responsible agencies, disposal of cleanup materials, documentation, ect. An Accident Spill Plan is needed for restaurants, warehouses or grocery stores.

N8. Underground Storage Tank Compliance: Compliance with State regulations dealing with underground storage tanks, enforced by County Environmental Health on behalf of the State.

N9. Hazardous Materials Disclosure Compliance: Compliance with County and comparable City ordinances typically enforced by respective fire protection agency.

N10. Uniform Fire Code Implementation: Compliance with Article 80 of the Uniform Fire Code enforced by fire protection agency.

N11. Common Area Litter Control: For development with POAs, the POA will be required to implement trash management and litter control procedures in the common areas aimed at reducing pollution of drainage water. The Associations may contract with their landscape maintenance firms to provide this service during regularly scheduled maintenance, which should consist of litter patrol, emptying of trash receptacles in common areas, and noting trash disposal violations by homeowners or businesses and reporting the violations to the association for investigation.

N12. Employee Training: Education program (see N1) as it would apply to future employees of individual businesses. Developer either prepares manuals for initial purchasers of business site or for development that is constructed for an unspecified use makes commitment on half of POA to prepare.

N14. Common Area Catch Basin Inspection: For developments with POAs and privately maintained drainage systems, require the association to have privately owned catch basins inspected and, if necessary, cleaned prior to the storm system, no later then October 15th each year.

N15. Street Sweeping Private Streets and Parking Lots: For developments with POAs and privately streets and parking lots, require the streets and parking lots be swept prior to the storm season, no later than October 15th each year. Also applicable to developments with no POAs.

APPENDIX C

Required Routine Structural BMPs for RGOs.

S6. Trash Container (Dumpster) Areas: Trash container (dumpster) areas to have drainage from adjoining roofs and pavements diverted around the areas, and:

A. For trash container associated with fuel dispensing, vehicle repair/maintenance, and industry, such areas are to be roofed over or drained to a water quality inlet (see S16), engineered infiltration/filtration system, or equally effective alternative.

B. For trash container areas associated with restaurants and warehouse/grocery operations such areas are to be screened or walled to prevent off site transport of trash.

S9. Motor Fuel Dispensing Area Canopy: Areas used for fuel dispensing shall be paved with concrete (no use of asphalt). Concrete surfacing to extend 6.5 feet from the corner of each fuel dispenser in any direction. This distance may be reduced to or the maximum length that the fuel dispensing hose and nozzle assembly may be operated in any direction plus one foot. In addition, the fuel dispensing area shall be graded and constructed so as to prevent drainage flow either through or from the fuel dispensing area (also see S11).

S10. Motor Fuel Dispensing Area Canopy: All motor fuel concrete dispensing areas are to have a canopy structure for weather protection, extending over the motor fuel concrete fuel dispensing area as defined in No. 9.

S11. Motor Fuel Concrete Dispensing Area Interruptable: Drainage: The concrete motor fuel dispensing area will be graded and constructed so as to drain to an underground clarifier/sump/tank equipped with a shut off valve that can stop the further draining or stormwater or spilled material there from into the street or storm drain system. Spills will be immediately cleaned up according to spill contingency plan.

S13. Catch Basin Stenciling: Phrase "No Dumping Drains To Ocean", to be stenciled on catch basins to avert the public to the destination of pollutants discharged into stormwater.

S16. Water Quality Inlets: Water Quality inlets designed to remove free phase liquid petroleum compounds, grease, floatable debris, and settleable solids can be used in the following applications: S6, S8, S14.

(Orange County NPDES Clean Stormwater Program)

CONCENTRATIONS OF SELECTED CONSTITUENTS IN RUNOFF FROM IMPERVIOUS SURFACES IN FOUR URBAN CATCHMENTS OF DIFFERENT LAND USE

by

Florence I. Rabanal and Thomas J. Grizzard
Occoquan Watershed Monitoring Laboratory
Virginia Tech Department of Civil Engineering
Manassas, Virginia 22110

ABSTRACT

Urban stormwater has been identified as a major contributor of various pollutants to the surface waters of the nation. Recent efforts to determine the sources of these pollutants have included investigations into the effects of land use on stormwater quality, particularly in runoff from impervious surfaces. A fifteen month field study of urban stormwater runoff was begun in September, 1992 in the Washington, D.C. metropolitan area, with the primary objective of investigating the nature of urban runoff from impervious surfaces in different urban land uses. Four small catchments, including an office parking area, a commercial fueling station, a fast food restaurant parking lot, and a single family residential street were included in the study. Passive runoff sampling equipment was used to collect flow-composited stormwater samples for a total of 123 events. Stormwater runoff samples were analyzed for 17 constituents, including nutrients, aggregate organic materials, and trace metals. Samples were characterized in terms of event mean concentrations (EMCs) Where possible, EMCS were compared to data from the Nationwide Urban Runoff Program.

INTRODUCTION

In the United States, studies of the significance of urban stormwater runoff have been included in efforts to improve water quality for over two decades. The most widely cited of these was undertaken nearly twenty years ago when the Environmental Protection Agency (EPA) established the Nationwide Urban Runoff Program NXJRP (EPA, 1983). During the 5 year study, runoff data from 29 different cities and 2300 storm runoff events was compiled and analyzed. A comprehensive national study of similar magnitude has not been performed since NURP. However, stormwater runoff, associated water quality impacts, and monitoring needs continue to be studied and identified.

This paper describes an 18 month study which began in September, 1992 in the Washington Metropolitan area. Four field monitoring stations were constructed and installed to collect flow-weighted stormwater runoff samples from urban catchments of different land uses. A total of 123 events were sampled and analyzed for selected constituents.

STUDY METHODS

All four monitoring stations were constructed in catchments located within a 16 km radius of the Capitol Building in Washington, D.C., and were located either in the District of Columbia or the nearby Maryland suburbs. The catchments were selected so that all of the drainage area consisted of impervious surfaces. In addition, the catchments were chosen to represent different land use types, including a daily parking lot, a gasoline station fueling pad, a residential street, and a fast-food chain restaurant parking lot.

Station HL10 The field site for HL10 was located on the grounds of the United States (U.S.) National Arboretum in the northeast quadrant of the District of Columbia The monitored portion of the staff parking lot drained 1300 square meters (m'), and was constructed primarily of bituminous concrete with a portland cement concrete curb and gutter. The surrounding area was lightly wooded with a variety of ornamental shrubs.

Station HL20 Station HL20 was located at a gasoline station near U.S. Route 1 in Laurel, Maryland. The 883 m2 catchment consisted of a fueling area canopy, convenience store roof, portland cement concrete fueling pads, and bituminous concrete driveways.

Station HL30 The field site for station HL30 consisted of a block of residential street located in northeast Washington, D.C.. A stable residential neighborhood and elementary school surrounded the 650 m2 drainage area. The slope was approximately 15%, with bitutninous concrete paving and portland cement concrete curb and gutter.

Station HL40. Station HL40 received stormwater runoff from a fast food chain restaurant parking lot located in Takoma Park, Maryland. The site drainage area was 502 m2, consisted of a bituminous concrete surface, and included a solid waste storage and pickup area. The slope of the parking area was found to be approximately 10 percent.

Monitoring Station Design and Installation. Each station was designed to accommodate a 0.15 m type-H flume mated to a Model N-l Coshocton Wheel (USDA, 1979) fitted with a multi-slot splitting device, which provided a runoff collection volume of 1/1000th of the generated flow. The sample thus collected during a runoff event was continuously composited and flow-weighted, thereby taking on the constituent concentration characteristics of the entire storm flow. The analytical results of such a sample may then be expressed as Event Mean Concentrations (EMCs) for the constituents of interest. The EMC, or some other statistic from a distribution of observed EMCS, **are**

taken as basic descriptors of urban stormwater runoff, and are commonly employed in comparisons of stormwater characteristics between sites. Roth tipping bucket and wedge rain gages were used for measurements of total catchment precipitation for each event.

Sample Collection. Staff monitored National Weather Service (NWS) radio reports to determine the probability of a suitable storm event. If a storm was likely to occur, the sites were prepared for sampling. After a storm event, runoff samples were collected and transported to the laboratory for further analysis.

Analytical Program and Methods. Collected samples were analyzed for 17 constituents, using commonly accepted methods (APHA, 1992; EPA, 1983 & 1986). All analyses were conducted in accordance with a formal quality assurance program, including where appropriate, the following activities:

- Instrument calibration curve
- Duplicate analysis to assess precision
- Matrix spike to measure recovery
- Field and trip blank analysis

Statistical Analysis. In order to determine the similarities and/or differences in characteristics of runoff from the impervious surfaces in the monitored catchments, a non-parametric statistical method was employed. Nonparametric, or distribution free, methods are commonly used in the analysis of data from populations which are not normally distributed, or whose underlying distributions are simply unkown. It is commonly found that rainfall-runoff datasets are not normally distributed, and further, that nonpoint pollution export characteristics that arise from catchment response to rainfall inputs are similarly non-normal. For this reason, the Kruskal-Wallis test for differences between sample statistics drawn from multiple was performed on each constituent data sets (Sokal and Rohlf, 1969). The null hypothesis, Ho, for this current study was that no significant difference existed between constituent EMCS in stormwater runoff from the impervious surfaces sampled.

RESULTS AND DISCUSSION

EMCS were determined for each constituent and used in the determination of summary statistics, including minimum (MIN), maximum (MAX), and median (MED), which are shown in Table 1. The results from the Kruskal-Wallis test have also been presented in Table 1. Where the null hypothesis was rejected, the table block corresponding to the appropriate constituent abbreviations has been highlighted, indicating that at the 0.05 significance level, at least one of the runoff EMC populations was different from the others. Comparisons of observed EMC statistics to those reported in the NURP dataset (EPA, 1983) for residential, commercial, and mixed urban land uses have been presented in the discussion where appropriate.

In general, the analytical and statistical results for all stations were thought to have been greatly influenced by site physical characteristics. Each station appeared to have distinct physical features that influenced the incident rainfall volume and intensity, thereby affecting the ultimate constituent concentrations. For example, tree foliage surrounding HL10 while not affecting total rainfall, reduced its impact energy by interception. Similarly, the fueling canopy at HL20 was found to reduce rainfall impact energy, and also to direct flow to a limited portion of the overall catchment surface.

The physical site characteristics thought to influence runoff flow rates at HL30 and HL40 were somewhat different than the previous station pair HL10 and hl20) The catchment drainage areas for hl30 and HL40 displayed relatively steep slopes, of 9% and 10% respectively. It is likely that this caused higher runoff veloticities, and the resulting increase in kinetic energy was sufficient to detach and suspend more particulate matter.

Sediment and Turbidity. As may be seen by the distribution of summary values in Table 1, turbidity and TSS EMCs were generally low. The median turbidity EMCs ranged from 4.0 NTU at HIJO to 13.0 NTU at HL30 The TSS median EMCS displayed a similar trend, with the lowest observed at HL10 (1.0 mg/L) and the highest at HL30 (43 mg/L).

Comparisons of TSS EMCSto thosfrom NURP EPA 1983)are shown inFigure l,and it may be seen that the current study values were much lower. In interpreting this, it must be remembered that NURP catchments generally contained both pervious and impervious surfaces, whereas the current study surfaces were completely impervious.

Nutrients. As shown in Table 1, median EMC values for OP were generally low at all four stations, ranging from 0.03 to 0.06 mg/L. The site with the lowest vehicular activity and lowest slope exhibited the lowest TP EMC (0.05 mg/l)while the remaining three stations had EMC values ranging from 0.15 to 0.37 mg/L.

Median NH,+-N EMCS ranged from 0.03 mg/L at HL20 to 0.28 mg/L at HL10 The corresponding values for TKN were substantially higher, with the lowest at HL10 (0.72 mg/L), and the greatest at HL30 (2.24 mg/L). Stations HL10 and HL20 had lower values of median TKN EMC, but conversely, also displayed higher values of median OX-N EMCS.

Comparisons of the TP median EMCS to NURP values showed mixed results, with stations HL30 and HL40 comparing well with the residential and mixed land use NURP (EPA, 1983) characterizations, respectively, as illustrated in Figure 2. The median EMC TP values for HL10 and HL20 were lower than those reported from NURP. The higher concentrations observed at HL30 and HL40 were thought to be due to a combination of steep slopes and also were affected by detergent washing practices on the lot at HL40

It should be noted that TP median EMCS from the current study, with the exception of HL10 all exceeded the EPA water quality criterion of 0.05 mg/L (1986) for the prevention of nuisance plant growth in streams and flowing waters.

comparisons of nitrogen median EMC values to those from NURP (EPA, 1983) were limited to TKN and OX-N, as shown in Figures 3 and 4. As shown in Figure 3, median TKN EMC values for the current study were slightly higher than those reported from NURP for the residential catchment (HL30), and for the fast food parking lot (HL40) when compared to the NURP commercial site data. Roth the HL10 and HL20 TKN EMCS were lower than any of the reported NURP values. The median JZMCS at HL30 and HL40 were at sufficiently high concentrations to possibly contribute some significant nitrogenous oxygen demand (NOD) in ultimate receiving waters.

Aggregate Organic Matter. Results from measurements of organic matter are presented in Table 1, and may be seen to display differing trends with respect to the median EMCs The highest median EMCs for COD were observed at HL20 (55.3 mg/L) and HL30 (53.2 mg/L). The highest median EMCS for TOC and DOC were observed at HL30 and HL40. Finally, the highest median EMCS for oil and grease were observed at HL20 and HL40.

The observed differences in occurrence of the highest median EMC values for aggregate organic measurements were thought to be largely due to analytical methods and site physical characteristics. Generally, the EMC values for all aggregate organic measurements from HL10 were lower than those from the other stations, and this may be largely explained by the low slope and the relatively low vehicular density. COD and organic carbon EMC values were quite similar at the remaining three stations. When the oil and grease measurement was used to estimate organic strength, however, a somewhat different comparison emerged. Stations HL20 and HL40 were observed to have EMC values substantially above those for HL10 and HL30. This was very likely due to the presence of higher concentrations of petroleum hydrocarbons in the runoff from the gasoline station, and of oils and greases from food preparation in the runoff from the solid waste handling area of the fast food parking lot. In addition, at the latter site, the parking lot was periodically cleaned with a high pressure water flow, which probably moved organic matter downslope and into closer proximity to the stormwater drain.

Limited organic measurements in the NURP (EPA, 1983) database made it possible to only conduct a comparison of EMC values for COD, as shown in Figure 5. In general, the median COD EMCS for the current study were less than those reported for NURP for all land use types. This may be due to the previously mentioned differences in catchment types. In the current study, the catchments were completely impervious, while the NURP catchments contained both pervious and impervious areas. It may, therefore, be speculatedthatsomeoftheobserved COD concentrations in the NURP database were due to organic matter originating from the pervious portion of the catchment.

A general depiction of the organic strength of the stormwater was provided by the current study results. In order to obtain a better assessment of the potential impact on the oxygen resources of a receiving water body, it would be necessary to have some degradation rate measurements. It should be noted, however, that all the COD EMCB were in a range that would be of some legitimate concern with respect to anticipated oxygen depletion.

Trace Metals. The extractable cadmium (Cd) dataset was highly censored, with more than half of the values at all sites were found to lie below the method quantitation limit (QL) of 1.0 µg/L. Because of this, the median station EMCS for the cadmium analyses presented in Table 1 may be seen to not only be identical, but also equal to the QL. The presence of cadmium in stormwater runoff is generally thought to be related to industrial activities, and the low level of such activity in the subject catchments may partially explain the low observed EMCS for cadmium.

The highest median EMC value for chromium was computed at HL20 (9.65 ug/L), and the lowest at HL10 (2.3 µg/L). The greater vehicular traffic density and associated brake wear probably contributed to the higher values observed at HL20. None of the median EMC values exceeded either the chronic or acute freshwater criteria (EPA, . 1986).

The highest median EMC for copper was found at HL30 (18.1 µg/L), and the lowest at HL10 (4 µg/L). The computed median EMCs at all stations either closely approached or exceeded the freshwater chronic exposure criterion. The median EMCs at HL20, HL30, and HL40 also exceeded the acute exposure criterion for copper (EPA, 1986). Because the area has little industrial activity, it may be speculated that the principal sources of copper in runoff from the stations monitored were related to vehicle operation.

Lead concentrations in urban stormwater have been historically associated with fossil fuel combustion (space heating and internal combustion engines), tire wear, and lubricating oils and greases. As would have been expected from knowledge of the vehicular associations of the potential sources, the highest median EMCS for lead were observed at stations HL20 (14.0 µg/L) and HL30 (14.8 µg/L). At HL20, the sources may be logically attributed to high traffic densities, and concentrated sources. At HL30, however, the higher EMCS may have been related to more effective removal of particulates in runoff from the higher slopes. The lowest value, which was observed at HL10 (5.4 µg/L), was consistent with the low site slope and vehicular traffic When compared with the freshwater chronic and acute water quality criteria, the median lead EMC values exceeded the former at all stations, and approached the latter at HL20 and HL30 (EPA, 1983).

The high median EMC values of zinc (Zn) shown in Table 1 illustrate the ubiquity of the metal in the environment. The greatest value was observed at HL30 (212 µg/L), and the lowest at HL10 (79 mg/L). Given that zinc concentrations in stormwater have also been related to vehicular activities, it was surprising that the highest value was not observed at HL20 (159 µg/L), where traffic flow and activity was greatest. It was probable that the slightly larger value observed at HL30 was again an artifact of high catchment slope, and not land use. The median EMC values for zinc were less than the chronic water quality criterion at HL10, and exceeded both the chronic and acute water quality criteria at HL20, HL30, and HL40 (EPA, 1986).

Comparisons of the current study median EMCS to those from NURP have been presented in Figures 6,7, and 8 for the trace metals copper, lead, and zinc, respectively. In general, the median EMC values reported for copper and lead in the current study were significantly less than those reported by NURP. In the case of lead, this is explained by the almost complete transition to unleaded fuels in the years since NURP. The reasons for the lower observed copper concentrations are less clear. In the case of zinc, the median EMC values for the current study were observed to be comparable to those reported in NURP, with the possible exception of HL10, which displayed zinc EMC values that were substantially lower than those in the NuRp data (EPA, 1983).

SUMMARY

Physical site characteristics played a key role in determining the runoff quantity and EMCs of the constituents monitored. Because of the dramatic slope differences between catchments, it was often difficult to isolate the effects of land use on constituent EMCs

Stormwater runoff EMCs from the impervious urban surfaces monitored were compared to those reported from NURP (EPA, 1983) and the following general observations made:

Suspended sediment EMCS were generally lower than those previously reported in the NURP database. This was speculated to be related to influences of detached material from pervious surfaces in the NURP catchments.

With the eXCeptiOn Of the lOW aCtiVityflOW slope she at HL10, TP EMUS from this study had similar ranges to those reported from similar land uses in NURP. All TP EMCS were at concentrations above those desired in free flowing receiving waters.

EMCS for nitrogen forms in the current study were similar to those reported in the NURP data. Reduced nitrogen (TKN) form EMCS were sufficiently high to raise some question with respect to exertion of NOD in receiving waters.

Aggregate organics EMCS from the current study were generally found to be lower than those reported in NuRp. However, concentrations of COD were still sufficiently high raise some question about exertion of oxygen demand in receiving waters.

Trace metals EMCS were found to exceed either chronic or acute water quality criteria in the cases of copper, lead, and zinc. In the case of copper, EMCS from the current study were generally found to be lower than those reported in NURP. For lead, the same observation was made, and was concluded to be a result of the almost complete elimination of leaded motor fuel use in the U.S. For zinc, EMCS from the current study were found to be comparable to those reported in NURP.

PREFACE

Knowledge of the characteristics of highway runoff (concentrations and loads of constituents and the physical and chemical processes which produce this runoff) is important for decision makers, planners, and highway engineers to assess and mitigate possible adverse-impacts of highway runoff on the Nation's receiving waters. In October, 1996, the Federal Highway Administration and the U.S. Geological Survey began the National Highway Runoff Data and Methodology Synthesis to provide a catalog of the pertinent information available; to define the necessary documentation to determine if data are valid (useful for intended purposes), current, and technically supportable; and to evaluate available sources in terms of current and foreseeable information needs. This paper is one contribution to the National Highway Runoff Data and Methodology Synthesis and is being made available as a U.S. Geological Survey Open-File Report pending its inclusion in a volume or series to be published by the Federal Highway Administration. More information about this project is available on the World Wide Web at http://mass1.er.usgs.gov/fhwa/runwater.htm

A Review of Semivolatile and Volatile Organic Compounds in Highway Runoff and Urban Stormwater

By Thomas J. Lopes *and* Shannon G. Dionne

Abstract

Many studies have been conducted since 1970 to characterize concentrations of semivolatile organic compounds (SVOCs) in highway runoff and urban stormwater. To a lesser extent, studies also have characterized concentrations of volatile organic compounds (VOCs), estimated loads of SVOCs, and assessed potential impacts of these contaminants on receiving streams. This review evaluates the quality of existing data on SVOCs and VOCs in highway runoff and urban storm–water and summarizes significant findings. Studies related to highways are emphasized when possible. The review included 44 articles and reports that focused primarily on SVOCs and VOCs. Only 17 of these publications are related to highways, and 5 of these 17 are themselves review papers. SVOCs in urban stormwater and sediments during the late 1970's to mid-1980's were the subject of most studies.

Criteria used to evaluate data quality included documentation of sampling protocols, analytical methods, minimum reporting limit (MRL) or method detection limit (MDL), quality-assurance protocols, and quality-control samples. The largest deficiency in documenting data quality was that only 10 percent of the studies described where water samples were collected in the stream cross section. About 80 percent of SVOCs in runoff are in the suspended solids. Because suspended solids can vary significantly even in narrow channels, concentrations from discrete point samples and contaminant loads estimated from those samples are questionable without information on sample location or how well streamflow was mixed. Thirty percent or fewer of the studies documented the MRL, MDL, cleaning of samplers, or use of field quality-control samples. Comparing results of different studies and evaluating the quality of environmental data, especially for samples with low concentrations, is difficult without this information.

The most significant factor affecting SVOC concentrations in water is suspended solids concentration. In sediment, the most significant factors affecting SVOC concentrations are organic carbon content and distance from sources such as highways and power plants. Petroleum hydrocarbons, oil and grease, and polycyclic aromatic hydrocarbons (PAHs) in crankcase oil and vehicle emissions are the major SVOCs detected in highway runoff and urban stormwater.

The few loading factors and regression equations that were developed in the 1970's and 1980's have limited use in estimating current (1998) loads of SVOCs on a national scale. These factors and equations are based on few data and use inconsistent units, and some are independent of rainfall. Also, more cars on the road today have catalytic converters, and fuels that were used in 1998 are cleaner than when loading factors and regression equations were developed.

Comparisons to water-quality and sediment-quality criteria and guidelines indicate that PAHs, phenolic compounds, and phthalates in runoff and sediment exceeded U.S. Environmental Protection Agency drinking-water and aquatic-life standards and guidelines. PAHs in stream sediments adjacent to highways have the highest potential for adverse effects on receiving streams.

Few data exist on VOCs in highway runoff. VOCs were detected in precipitation adjacent to a highway in England, and chloromethane, toluene, xylenes, 1,2,4-trimethylbenzene, and 1,2,3-trichloropropane were detected in runoff from a highway in Texas. In urban stormwater, gasoline-related compounds were detected in as many as 23 percent of the samples. Land use could be the most significant factor affecting the occurrence of VOCs, with highest concentrations of VOCs found in industrial areas. Temperature is another factor affecting the occurrence and concentrations of VOCs. Urban land surfaces are the primary nonpoint source of VOCs in stormwater. However, the atmosphere is a potential source of hydrophilic VOCs in stormwater, especially during cold seasons when partitioning of VOCs from air into water is greatest. Tetrachloroethene, dichloromethane, and benzene were the only VOCs detected in stormwater that exceeded U.S. Environmental Protection Agency drinking-water standards.

INTRODUCTION

Runoff from highways and urban areas has long been recognized as a source of contaminants that could affect the Nation's water resources. Federal, State, and local agencies and universities have conducted or sponsored research since about 1970 to characterize runoff quality, estimate contaminant loads, and assess impacts on receiving streams. Sampling protocols, analytical methods and detection limits, and quality-assurance/quality-control (QA/QC) protocols have improved during this time. In addition, new contaminants are being released into the environment, more is known about their toxic effects, and water-quality criteria for contaminants have been established or changed. In light of these changes, highway-runoff and urban-stormwater studies need to be periodically reviewed for quality of data and whether the results address current water-quality issues.

Semivolatile organic compounds (SVOCs) and volatile organic compounds (VOCs) are two groups of contaminants that have been measured in runoff from highways and urban areas. SVOCs are operationally defined as solvent-extractable organic compounds that can be determined by gas chromatography/mass spectrometry (GC/MS) (Furlong and others, 1996). Examples of SVOCs include phthalates, phenols, and polycyclic aromatic hydrocarbons (PAHs). Smith and others (1988) reviewed the sources of several types of SVOCs and processes affecting their fate and distribution in surface water. SVOCs are present in many products, including plastics, dyes, and disinfectants, and PAHs are produced by burning gasoline, oil, wood, and other fuels. SVOCs typically are hydrophobic and by definition have a moderate tendency to volatilize (Karickhoff and others, 1979; Lucius and others, 1989). These properties control how SVOCs are distributed among air, water, and soil when released into the environment. Because they are hydrophobic and moderately volatile, SVOCs preferentially distribute into organic phases, such as tissue and sediments containing organic carbon (Witkowski and others, 1987; Smith and others, 1988).

SVOCs are an environmentally significant group of contaminants because they may accumulate to concentrations that will adversely affect aquatic organisms. Benthic organisms that live in contaminated sediment are most affected because sediments have the largest fraction of SVOCs; however, organisms that feed on benthic species also may be affected. Adverse effects could include mortality, reduced fecundity, and inhibited or abnormal growth. Recently, scientists have become aware of compounds that disrupt the endocrine system and reproduction of fish, reptiles, and mammals (Colborn and others, 1993). Endocrine disruption occurs when a compound either mimics natural hormones or blocks their function. Certain phthalates and PAHs are among the organic compounds that cause endocrine disruption, although their effect is weaker than the effect of some pesticides. In a national survey, concentrations of phenols in bottom sediment were found to correlate with concentrations of 11-ketotestosterone in male carp at an alpha-level of 0.05, suggesting these SVOCs also could cause endocrine disruption (Goodbred and others, 1997).

VOCs are operationally defined as organic compounds that can be extracted from water by purging with an inert gas, then trapped and determined by GC/MS (Connor and others, 1998). VOCs are present in many products including fuels, solvents, refrigerants, paints, adhesives, and deodorants. VOCs also are present in vehicle exhaust and chlorinated water. In contrast to SVOCs, VOCs can be either hydrophobic or hydrophilic, have a high tendency to volatilize, and distribute preferentially into air because of their volatility.

VOCs have low aquatic toxicity (Rowe and others, 1997). Except for spills, concentrations found in highway runoff and urban stormwater are too low to cause a toxic response in aquatic species. However, VOCs in highway runoff and urban stormwater could enter drinking-water supplies and have chronic effects on the consumers. For example, ground water in Tucson, Arizona, was contaminated with low concentrations of VOCs in urban stormwater (Pritt and others, 1996).

Objectives and Scope

The objectives of this review are to evaluate the quality of existing data on SVOCs and VOCs and to summarize significant findings. This is not an exhaustive review of all studies that contain information on SVOCs and VOCs, but a review of studies that focused primarily on SVOCs and VOCs in highway runoff, urban stormwater, precipitation, and sediments. Studies related to highway runoff are emphasized when possible. Measures of extractable organic compounds, such as petroleum hydrocarbons and oil and grease, are included in the discussion of SVOCs, but pesticides and polychlorinated biphenyls are not within the scope of this report.

A total of 44 articles and reports published between 1976 to 1998 were reviewed. Only 17 of these publications were related to highways, and 5 of these 17 are themselves review papers. SVOCs in urban stormwater and sediments were the subjects of most studies.

Criteria for Data Quality

Studies done since 1970 are useful if they were documented such that the quality, interpretations, and limits of the data can be qualified. Documentation should be able to answer several important questions, such as: Where, when, and how were samples collected? What analytical methods were used to identify and quantify contaminants, and what was the minimum reporting limit (MRL) or method detection limit (MDL)? What QA/QC steps were taken to assure data are representative, accurate, and precise? These questions comprise the criteria for evaluating the quality of existing data.

MONITORING TRACE ORGANIC CHEMICALS

Because of their physical and chemical properties, different samplers and sampling procedures are needed for SVOCs and VOCs. SVOCs can be sampled using a variety of samplers because analyte loss during sampling is not a significant issue. The choice and use of a sampler depends on sampling objectives and logistical considerations. For example, discrete point samplers are adequate for obtaining occurrence data, but do not obtain accurate concentrations of SVOCs unless the stream is well mixed and suspended solids are evenly distributed in the stream cross section. The best techniques to obtain accurate data are equal-width-increment (EWI) and equal-discharge-increment (EDI) sampling using samplers that collect depth-integrated samples (Wells and others, 1990). However, these sampling techniques are difficult in flashy runoff from urban areas and highways, which is why automatic samplers commonly are used in stormwater studies. Regardless of the sampler type, the sampler should be made of noncontaminating materials. Generally, metal and glass are the best materials for sampling trace concentrations of organic compounds. Teflon is the preferred material when metal and glass cannot be used, such as for sampling lines for automatic samplers.

In contrast, analyte loss during sampling is a significant issue for VOCs because of their volatility. Three types of samplers and sampling techniques are used to collect VOC samples, all three of which collect discrete point samples. If point sources are not nearby, point sampling for VOCs is not as significant an issue as for SVOCs because VOCs are mostly in the dissolved phase and not sorbed to sediments (Rathbun, 1998). The two most common sampling techniques are to manually dip a 40-mL (milliliter) glass vial directly into the stream or to obtain a sample with another container and then transfer the water to a vial. Vials are then quickly sealed with a Teflon-lined septum cap.

Dipping a vial directly into the stream eliminates potential contamination from sampling equipment. However, this technique is limited to the length of the sampler's arm and can be hazardous during high-flow conditions. A stainless steel and copper sampler (Shelton, 1997) is more versatile and safer than dip sampling because it collects samples at greater depths and can be suspended from bridges. Sample water is collected directly into sample vials, which are sealed when the sampler is retrieved from the stream. Laboratory and field testing has shown that this sampler collects accurate data (Gregory Delzer, U.S. Geological Survey, written commun., 1997). VOCs should not be collected using automatic samplers with peristaltic pumps that do not quickly seal vials because the negative pressure created by the pumps and volatilization from open vials can bias sample results. Recently, ISCO Inc. developed the model 6100 automatic sampler for sampling VOCs in streams. This sampler uses a positive-displacement pump and quickly seals vials. Laboratory testing of this sampler indicates it produces accurate data with less than 2 µg/L (micrograms per liter) of carryover between samples (Gregory Delzer, written commun., 1997).

Preservation of water samples for analysis of SVOCs and VOCs depends on laboratory requirements. SVOC samples usually are chilled at 4°C. VOC samples usually are chilled and may be acidified to a pH of less than 2 using hydrochloric acid. Some laboratories require addition of ascorbic acid to VOC samples if free chlorine is present.

GC/MS is the most accurate method of identifying and quantifying most SVOCs and VOCs. Even if laboratories use the same analytical method, they may report varying MRLs and MDLs that can create difficulties in data interpretation (Cole and others, 1984). MRLs and MDLs can vary because of the sample matrix, study objectives require different values, and analytical methods improve with time. For example, MRLs and MDLs that meet current regulatory requirements may be satisfactory for compliance monitoring. However, organic compounds in stormwater commonly occur at concentrations below water-quality criteria (Makepeace and others, 1995), so regulatory requirements may be inadequate to determine if compounds are present, to estimate loads, to identify causal factors and emerging problems, and to use data in the future if water-quality criteria are lowered. The National Water-Quality Laboratory of the U.S. Geological Survey (USGS) reports SVOCs in water as low as 5 µg/L (Fishman, 1993), SVOCs in sediment as low as 50 µg/Kg (micrograms per kilogram) (Furlong and others, 1996), and VOCs in water as low as 0.05 µg/L (Connor and others, 1998). Extraction and recovery efficiencies are lower for SVOCs than for VOCs, which is why SVOCs have higher MRLs and MDLs. Extraction and recovery efficiencies less than 90 percent are common for compounds that sorb to sediments (Furlong and others, 1996), whereas extraction and recoveries for most VOCs are 95 percent or greater (Connor and others, 1998).

Results of water-quality studies can form the basis of or alter agency policies and have significant economic and social implications. Studies should be supported by a QA/QC plan to ensure that these results are based on quality data. QA is the precautionary actions used to prevent systematic bias. Examples of QA are using noncontaminating materials and sample containers, cleaning equipment, preserving samples soon after collection, and shipping samples overnight. QC includes the steps used to check that QA is effective and to evaluate variability due to random error. Examples of QC are equipment blank samples to ensure that equipment is clean, replicates to assess sample variance and analytical precision, and samples spiked with analytes to evaluate analyte degradation and recovery. QC samples generally comprise 10 to 15 percent of all samples. The QA/QC plan usually is an unpublished document, but should be briefly described with study results. For large studies, the QA/QC plan often is a published document, such as that by Mueller and others (1997).

Sample Collection

Documentation of sample collection should include where, when, and how highway runoff and urban stormwater samples were collected. Documenting sample location is important so sampling can be repeated to evaluate apparent anomalies and to define changes with time. All studies answered the question of where samples were collected (table 1, at back of report), although the level of detail varied. Some studies provided maps showing precise sample locations; however, most studies included generalized maps or described sample locations. An extreme case of generalizing was Line and others (1997), who only stated that samples were collected in North Carolina.

Studies included in this review were conducted in the United States (fig. 1) and in Canada, Germany, Japan, Norway, Spain, Switzerland, and the United Kingdom. Most studies in the United States were conducted along the northeast coast and in southern states where population densities are greatest. Few studies have been conducted in the Great Lakes region and the central and western states.

Seventeen studies were related to SVOCs and VOCs in highway runoff or in rain, snow, and sediment near highways. Ten of the 17 studies related to highways were in the United States (Wiland and Malina, 1976; Zawlocki and others, 1980; Gupta, 1981; Hoffman and others, 1983, 1984, 1985; Hoffman and Quinn, 1987; Latimer and others, 1990; Barrett and others, 1993; Baldys and others, 1997); four were in England (Butler and others, 1984; Johnston and Harrison, 1984; Harrison and Johnston, 1985; Hewitt and Rashed, 1990); and one was in each of Canada (Boom and Marsalek, 1988), Norway (Gjessing and others, 1984), and Germany (Stotz, 1987). PAHs were the topic of most highway-related studies.

The priority pollutant monitoring project of the Nationwide Urban Runoff Program (NURP) had the widest geographic distribution and is the most frequently cited study of organic contaminants in urban stormwater. The U.S. Environmental Protection Agency's (USEPA) priority pollutants, including SVOCs and VOCs, were monitored in 15 cities in 14 states (Cole and others, 1984). Concentrations of the priority pollutants were measured in 86 stormwater samples collected from drainage basins with residential, commercial, or industrial land use.

Marsalek and Schroeter (1988) conducted a study similar to NURP in 12 Canadian cities in the Great Lakes region. Up to 125 stormwater and sediment samples from 81 sites with residential, commercial, industrial, or transportation land use were analyzed for 50 priority pollutants, including PAHs and chlorinated benzenes.

A set of independent urban stormwater studies conducted by the USGS comprise another type of study with a wide geographic distribution. In 1991, USEPA required cities with a population of 100,000 or more to monitor stormwater quality and obtain municipal National Pollutant Discharge Elimination System (NPDES) permits. The USGS monitored stormwater from drainage basins with residential, commercial, or industrial land use in 16 of these cities in 11 states (Delzer and others, 1996). Most of these

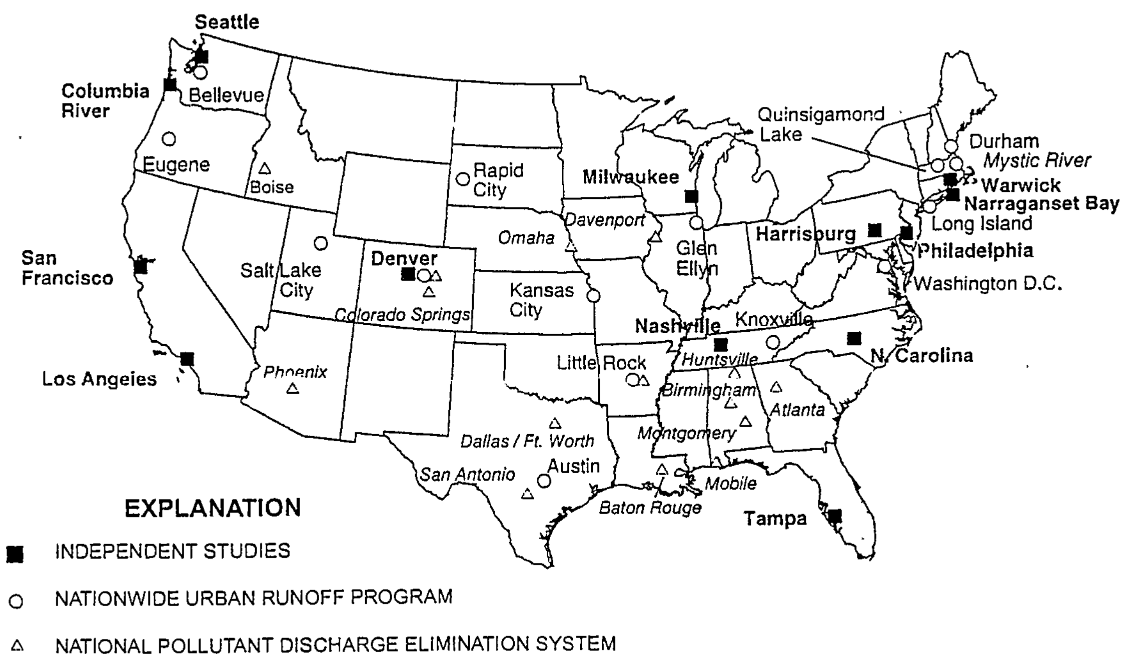

Figure 1. Cities in the United States where semivolatile and volatile organic compounds have been studied in highway runoff and urban stormwater.

cities are in southern and central states (fig. 1). A total of 642 stormwater samples were analyzed for up to 210 properties and constituents, including the priority pollutants. VOC data were compiled to characterize the occurrence of VOCs in stormwater (Delzer and others, 1996) and identify nonpoint sources (Lopes and Bender, 1998). Data on SVOCs and other contaminants that were measured in stormwater samples were not compiled.

Documenting when samples were collected is necessary to know if unusual weather occurred during the respective studies and to determine if state-of-the-art sampling and analytical methods were used. The question of when samples were collected was answered in about 84 percent of the studies. The majority of data were collected during the late 1970's to mid-1980's, including data related to highway runoff. Only 20 percent of studies, most of which were NPDES studies, collected data after 1990. Typically, the time between data collection and publication was about 2 to 4 years, although Latimer and others (1990) was published 10 years after data were collected. Studies that did not report when data were collected were published between 1982–91; therefore, data probably were collected prior to the mid-1980's.

The validity and comparability of data depend on several criteria, including documented sampling protocols. Description of the sampling protocol should include information on the type and material of the sampler; where in the stream cross section samples were collected; if discrete or composite samples were analyzed; and if whole water, suspended solids, or filtrates were analyzed. Most studies provided some, but none provided all information on the sampling protocol.

About 80 percent of studies reported the type of sampler. Water samples were collected with buckets, bottles, trays, cans, storage tanks, drums, and automatic samplers. Snow and sediment were sampled with corers, trowels, ponar samplers, jars, and lysimeters. Atmospheric deposition and rain were sampled with funnels. Line and others (1997) collected samples for VOCs with automatic samplers that were not designed for these contaminants; therefore, volatilization from sample water probably biased results.

About 60 percent of studies reported the sampler material. Most samplers were made of metal or glass, which are good materials to use for sampling organic contaminants. Studies that used flow splitters and samplers made of fiberglass and plastics included Zawlocki and others (1980), Gjessing and others (1984), Johnston and Harrison (1984), and Harrison and Johnston (1985). Sorption to these materials may have biased the SVOC and VOC data of these studies. Hewitt and Rashed (1990) conducted a study in the same area as Johnston and Harrison (1984) and Harrison and Johnston (1985) and may have used the same equipment, but there is insufficient information to determine this from the article. Seven studies used automatic-pumping samplers. Three NPDES studies (Lopes and others, 1995; von Guerard and Weiss, 1995; and Baldys and others, 1998) noted that sampling lines were made of Teflon. The other studies did not document the sampler-line material.

The largest deficiency in documenting data quality was that only 10 percent of studies described where water samples were collected in the stream cross section, if streamflow was well mixed, or if equal-width increment or depth-integrated techniques were used. The representativeness of discrete point samples and interpretations based on those data, especially load estimates, are questionable without this information. Sample location could have affected results because SVOC concentrations depend on suspended solids concentrations (Hunter and others, 1979; Hoffman and Quinn, 1987; and Barrett and others, 1993). Suspended solids concentrations can have significant horizontal and vertical variations (Horowitz and others, 1989) even in channels less than 5 ft wide (Edwards and Glysson, 1986). Samplers do not need to be sophisticated devices like electronically activated point samplers to obtain representative samples. However, the water samplers used in these studies and lack of information on flow conditions suggest most studies sampled surficial streamflow along the streambank. Stream velocity and suspended sediment concentrations typically are lowest along the banks, so point samples collected along the streambanks may result in biased (low) contaminant concentrations and load estimates. This may not be a significant issue in stormwater drainages where streamflow usually is fast and shallow.

About 90 percent of studies described whether samples were discrete or composite samples. About 70 percent of studies that described sampling methods manually collected discrete water samples. Eight studies composited stormwater samples, but two of these studies did not document whether these were time-weighted or flow-weighted composites. Composite samples were obtained using cone or churn splitters (Lopes and others, 1995; von Guerard and Weiss, 1995) and a flow splitter (Zawlocki and others, 1980). Other studies did not describe how samples were composited. About 90 percent of studies described whether bottom-sediment samples were point samples or composites and the depth interval of bottom sediment that was sampled. Most samples were point samples collected from the upper 10 centimeters of bottom sediment. Ellis and others (1985) and Brown and others (1985) composited surficial bottom-sediment samples from several sites. Gavens and others (1982) and Butler and others (1984) sieved bottom sediment and Hoffman and others (1984) sieved suspended solids for a consistent grain size among samples. Comparing bottom-sediment concentrations is difficult because most studies did not analyze for organic carbon, which is the most common way of normalizing organic contaminant concentrations in sediments.

About 90 percent of studies described whether whole-water samples were analyzed or if suspended solids and filtrates were analyzed separately. Unless stated otherwise, it was assumed that whole-water samples were analyzed. About 30 percent of studies separated suspended solids and analyzed the filtrate, solids, or both. Separation was done by filtration with glass fiber filters or by centrifugation.

Analytical Methods and Minimum Reporting and Detection Limits

Documenting the analytical methods, MRLs, and MDLs is important to use data from different studies for a common objective. About 90 percent of studies described the analytical method for contaminant identification and quantitation. Gas chromatograph/flame-ionization detection (GC/FID) was the most commonly used analytical method. GC/MS was used to identify analytes or confirm GC/FID results in about 30 percent of the studies. About 30 percent of studies documented analytical precisions and recoveries. Generally, precision was less than 25 percent and recoveries were greater than 80 percent.

About 30 percent of studies, most of which were conducted in the 1990's, documented the MRL or MDL. The MRL is the lowest concentration that can accurately be quantified. The MDL is the lowest concentration that the method can detect. For studies done in the 1980's, Brown and others (1985) reported an MRL of 1 µg/L for petroleum hydrocarbons, Schondorf and Herrmann (1987) reported MDLs ranging from 0.03 to 0.15 ng/L (nanograms per liter) for PAHs, Zawlocki and others (1980) reported an MRL of 100 µg/L for a variety of SVOCs, and Boom and Marsalek (1988) and Marsalek and Schroeter (1988) reported an MRL of 0.05 µg/L for PAHs. Except for Zawlocki and others (1980), these limits compare well with current (1998) limits of the U.S. Geological Survey. The high MRLs ranging from 5 to 100 µg/L used by Line and others (1997) could explain why few SVOCs and VOCs were detected in stormwater from industrial sites.

Quality Assurance and Quality Control

The validity and use of data depend on documenting the procedures used to ensure that high-quality data were collected. Most studies described some precautionary action to ensure sample integrity, but few studies described thorough QA/QC procedures. Only Cole and others (1984) described a QA/QC plan, although they were unable to evaluate the effectiveness of the plan for NURP.

As previously noted, about 60 percent of studies used noncontaminating materials such as glass and metal. However, only 30 percent of studies documented that equipment was cleaned before sampling or that samples were preserved. Chilling samples at 4°C was the most commonly used method for preserving samples. Infrequently described precautionary steps included use of Teflon-lined or metal lids, covering jars with aluminum foil, homogenizing samples before splitting into equal portions, slowly melting snow samples to minimize volatilization, sampling in well-mixed parts of a storm drain, shipping samples overnight, and using nitrogen to filter samples for SVOCs. Studies that retrieved samples up to 2 weeks after collection without chilling were Johnston and Harrison (1984) and Harrison and Johnston (1985). Latimer and others (1990) left samples at room temperature for up to 2 days before analysis. Line and others (1997) used automatic samplers for VOCs and retrieved and chilled samples sometimes hours after they were collected.

Both laboratory and field QC samples are needed to evaluate sample and analytical quality. About 30 percent of studies reported analyzing laboratory QC samples and 15 percent analyzed field QC samples.

Laboratory QC samples included blanks, lab-split duplicates, surrogate recoveries, and performance-evaluation samples. Four studies reported using laboratory blanks and surrogate recoveries to correct environmental concentrations. The use of field QC samples became prevalent after most of the studies in this review were conducted. Except for NURP, the only studies that reported analyzing field QC samples were conducted in the 1990's. Field QC samples included equipment blanks, trip blanks, replicates, and spikes. Evaluating the quality of environmental data, especially low concentrations, is difficult because few studies collected QC data and documented that samplers were cleaned.

SUMMARY OF STUDY RESULTS

Most highway-runoff and urban-stormwater studies were conducted to address regional or local issues. However, results from all studies could provide useful qualitative information to answer some general questions of national importance. For example, do certain SVOCs and VOCs occur more frequently and at higher concentrations in particular regions of the country? If so, do factors such as climate affect occurrence and concentrations of these compounds? What are the sources of SVOCs and VOCs? Can loads of SVOCs be estimated on a national scale? Could SVOCs and VOCs have an adverse effect on water resources? These questions are the focus of this summary.

Semivolatile Organic Compounds

SVOCs were the subjects of most highway runoff and urban stormwater studies. Much has been learned about these compounds, especially the extractable organic compounds and polycyclic aromatic hydrocarbons (PAHs).

Occurrence

Characterizing the occurrence of SVOCs in highway runoff and urban stormwater for the entire United States is not possible because few studies reported detection frequencies or were conducted in the Great Lakes region and the central and western states. Studies that reported detection frequencies are Cole and others (1984), Boom and Marsalek (1988), Marsalek and Schroeter (1988), Lopes and others (1995), von Guerard and Weiss (1995), and Baldys and others (1998). SVOC concentrations vary by several orders of magnitude, which is typical of stormwater quality (table 7 at back of report). Table 7 was compiled assuming that unknown sample types and samples described as sediment samples, but reported in milligrams per liter or nanograms per liter, were whole-water samples. Thirty SVOCs were measured but not detected in stormwater (table 2, at back of report).

Total oil and grease and hydrocarbon concentrations in runoff ranged from less than 1 to 480 milligrams per liter (mg/L) (table 7). In suspended sediment, bottom sediment, and soils, oil and grease and hydrocarbon concentrations ranged from 8 to 507,000 micrograms per gram (μg/g). The highest concentrations in water and solid phases were associated with highways and industrial land use.

Studies that analyzed petroleum hydrocarbons and oil and grease for the classes of organic compounds that comprise these measurements were Zawlocki and others (1980), Eganhouse and Kaplan (1981b), Brown and others (1985), Fam and others (1987), Hoffman and Quinn (1987), Marsalek and Schroeter (1988), and Barrett and others (1993). Comparing results is difficult because fractions were separated using non-standard procedures (Hoffman and Quinn, 1987). Most extractable organic compounds in stormwater are aliphatic compounds and, except for polar compounds, about 80 percent or more are in the solid phase. The high solubilities of polar compounds, such as phenols, ketones, and alcohols, explain the large percentages measured in filtrates. Generally, aromatic compounds, phenolic compounds, PAHs, alcohols, and ketones comprise less than 1 percent to about 15 percent of the extractable organic compounds.

Concentrations of individual PAHs in runoff ranged from less than 1 to 120 μg/L. Highest concentrations were associated with industrial land use; few data exist for individual PAHs in highway runoff. In solid phases, concentrations of individual PAHs ranged from less than 1 to 200 μg/g. Of the few studies that reported total PAH concentrations, the maximum concentrations were 18,210 μg/L in whole water and 1,100 μg/g in solid phases. The maximum detection frequency of PAHs in both urban stormwater and snow was 90 percent. Most PAHs were detected in less than 25 percent of samples (Cole and others, 1984;

Boom and Marselak, 1988; Marsalek and Schroeter, 1988; Lopes and others, 1995; von Guerard and Weiss, 1995; and Baldys and others, 1998).

Johnston and Harrison (1984) tentatively identified 2-chlorophenol and 2,4-dichlorophenol in bulk deposition adjacent to a highway. Baldys and others (1997) detected phenolic compounds at concentrations between 1 and 16 µg/L in 90 percent of highway runoff samples. Phenolic compounds were detected in 15 percent or less of urban stormwater samples from NURP (Cole and others, 1984), 55 percent for urban stormwater samples from Phoenix (Lopes and others, 1995), and were not detected in urban stormwater samples from Colorado Springs (von Guerard and Weiss, 1995) and Dallas-Fort Worth (Baldys and others, 1998). When detected, concentrations of phenolic compounds in urban stormwater generally were less than 20 µg/L.

Related Factors

Of the factors that affect SVOC concentrations in water, the most significant is suspended solids concentration. About 80 percent or more of SVOCs in stormwater are associated with the solid phase due to the hydrophobic character of these contaminants (Hunter and others, 1979; Zawlocki and others, 1980; Eganhouse and Kaplan, 1981a; Brown and others, 1985; Hoffman and Quinn, 1987; and Barrett and others, 1993).

Organic carbon content is the most significant factor affecting SVOCs in the solid phase (Butler and others, 1984; Ellis and others, 1985; and Witkowski and others, 1987). Mineral particles are less effective at sorbing nonionic SVOCs (Witkowski and others, 1987), thus grain size does not appear to be a significant factor affecting SVOC concentrations in sediments unless small grains have an organic coating (Witkowski and others, 1987; Gavens and others, 1982). In contrast, trace-element concentrations in sediments are strongly correlated with grain size because ionic elements adsorb to small particles that have charged surfaces (Horowitz and Elrick, 1987).

Sorption of SVOCs to solids is reflected in the high concentration of SVOCs in the initial runoff from a storm and correlation between concentrations of solids and SVOCs throughout a storm (Hunter and others, 1979; Stenstrom and others, 1984; Brown and others, 1985; Hoffman and others, 1984, 1985; and Hoffman and Quinn, 1987). The initial runoff, commonly called first flush, can have concentrations of suspended solids and sorbed SVOCs that are several factors higher than concentrations in composite samples. Suspended solids concentrations typically decrease during a storm due to flushing of particles that accumulated on the land surface (Novotny, 1995).

Land use also affects SVOC concentrations. Most studies found higher SVOC concentrations in runoff, snow, and bottom sediment from highways or industrial areas compared to residential and commercial areas (Hoffman and others, 1983, 1984; Hoffman and Quinn, 1987; Evans and others, 1990; Latimer and others, 1990; Bomboi and Hernandez, 1991; and Baldys and others, 1998). For example, PAH concentrations in snow near highways and a steel plant were similar, and PAHs were more frequently detected and concentrations were higher than NURP stormwater data (Boom and Marsalek, 1988). Gjessing and others (1984) found PAHs in snow up to 50 meters from a highway, the furthest of all contaminants they measured, and that PAHs were fractionated during atmospheric transport. Johnston and Harrison (1984) found PAHs in rain up to 70 meters from a highway and that concentrations decreased with distance. Butler and others (1984) found that PAH concentrations in bottom sediment decreased with distance from highways.

Storm characteristics, such as rainfall intensity and volume of runoff, are important factors affecting SVOC concentrations and loads in stormwater and sediments. As rainfall intensity increases, stream velocity and sediment-carrying capacity increase, resulting in increased SVOC concentrations in stormwater (Hoffman and Quinn, 1987; Barrett and others, 1993). In bottom sediment, Evans and others (1990) found that PAH concentrations weakly correlated with monthly rainfall and that concentrations increased about 4 to 30 days after a storm. Gupta (1981) observed higher concentrations of oil and grease in highway runoff and Prahl and others (1984) observed higher PAH concentrations in atmospheric particulates during winter compared to summer months. Schondorf and Herrmann (1987) found that freezing can concentrate organic compounds in water. During thaws, soluble organic compounds elute in the first and last parts of the melt and that about 90 percent of PAHs elute with the particulates during the last 20 percent of the melt. These observations indicate that concentrations and loads of SVOCs could vary seasonally.

Not all studies found a relation between storm characteristics and SVOC concentrations and loads. Stenstrom and others (1984) found no correlation between oil and grease concentrations and streamflow rates, total rainfall, time since beginning of storm, rainfall intensity, or antecedent dry days. Hunter and others (1979), Herrmann (1981), and Hoffman and others (1984) found that SVOC concentrations did not correlate with antecedent conditions. Zawlocki and others (1980) found no correlation between SVOC loads and rainfall, traffic volume, or runoff volume, although they noted that traffic volume during the storm had a greater effect than rainfall.

Conclusions have been mixed whether highway surface type significantly affects SVOC concentrations (Barrett and others, 1993). Gupta (1981) measured oil and grease concentrations from paved surfaces that were 20 times greater than from grass-covered surfaces, but concluded that land use was the most important factor. Strenstrom and others (1984) measured oil and grease concentrations 25 times greater from parking lots compared to residential areas. Wakeham and others (1980) concluded that PAHs in street dust were from asphalt. Zawlocki and others (1980) noted that higher suspended solids concentrations occurred in highway runoff at a site with a median barrier and side railings compared to another site without these features. Other variables, such as traffic volume and drainage, may be more important factors affecting SVOC concentrations than surface type (Stotz, 1987; Barrett and others, 1993).

Sources

Crankcase oil and vehicle emissions were consistently identified as the primary source of SVOCs in stormwater (Hunter and others, 1979; Zawlocki and others, 1980; Stenstrom and others, 1984; Brown and others, 1985; Hoffman and Quinn, 1987; Fam and others, 1987; Yamane and others, 1990; Latimer and others, 1990; and Bomboi and Hernandez, 1991). The significance of PAHs in automobile emissions is indicated by concentrations in sediment, snow, and rain that decrease with distance from highways (Butler and others, 1984; Johnston and Harrison, 1984; Gjessing and others, 1984; Harrison and Johnston, 1985; and Hewitt and Rashed, 1990).

Emission of most PAHs from automobiles is directly related to their concentration in gasoline (Westerhold and others, 1988). Naphthalene and its alkylated homologues comprise about 0.5 percent by weight of gasoline (Canadian Petroleum Institute, 1994); 13 other PAHs occur in gasoline at less than 0.01 to 54 mg/L (Westerhold and others, 1988). About 95 percent of PAHs in gasoline are decomposed during gasoline combustion. However, in gasoline with low PAH content, a large percentage of the PAHs emitted are formed during combustion, including 70 to 80 percent of cyclopenta[*cd*]pyrene and benzo[*b*&*k*]fluoranthene. Gasoline exhaust contains about 1 to 2 parts per million of phenol and o-cresol (Lucius and others, 1989) and is a possible source of phenolic compounds in stormwater.

Load Estimates

Estimates of SVOC loads and mass balances have been made on different scales to evaluate the relative importance of different sources and transport mechanisms. For example, Edwards (1983) estimated that forest and agricultural fires comprise 75 percent of the annual global release of PAHs. Hoffman and Quinn (1987) estimated 470,000 tons per year of petroleum hydrocarbons are released to waters of the United States and that up to 50 percent of this amount could be discharged in urban stormwater. Bjorseth and Ramdahl (1985) estimated that automobile emissions comprise one-third of the 6,000 tons of PAHs emitted each year in the United States. In contrast, Edwards (1983) estimated that automobiles, buses, and trucks comprise only 1.6 percent of benzo(a)pyrene emissions in the United States. The difference could be because Bjorseth and Ramdahl (1985) did not correct for catalytic converters, which were in about 50 percent of cars.

At a regional scale, Hoffman and others (1983, 1984) estimated hydrocarbon and PAH loads to Narraganset Bay, and Marsalek and Schroeter (1988) estimated SVOC loads to the Great Lakes. Estimates by Hewitt and Rashed (1990) and Stotz (1987) indicated that 30 percent or less of the PAHs emitted along highways is transported in runoff and the remainder is dispersed. Other estimates have been made at a local scale (Butler and others, 1984; Gjessing and others, 1984; Johnston and Harrison, 1984; Harrison and Johnston, 1985; Boom and Marsalek, 1988; and Hewitt and Rashed, 1990).

Few regression equations or loading factors have been developed for SVOCs compared to other constituents such as suspended solids and nutrients.

Most equations and factors were based on few data and have little statistical power and large uncertainties, especially for regional and national application. Also, studies reported loading factors with inconsistent units so comparisons are difficult or with units that limit their application (table 3, at back of report). For example, Hoffman and Quinn (1987), Stotz (1987), and Barrett and others (1993) report loading factors that are independent of rainfall and, therefore, apply only to areas with climates similar to their study areas. Gupta (1981) estimated loads from highways using regression equations for runoff, pollutant build-up and wash-off, and loads of suspended solids. Correlations between other contaminants and suspended solids were used to convert loads of suspended solids into loads of the other contaminants. However, conversion equations were developed for individual sites and have only site-specific application. Marsalek and Schroeter (1988) used a procedure similar to Gupta (1981) to estimate loads to the Great Lakes.

Using study results to develop equations and factors of SVOC loads and concentrations at a national level, particularly from highways, is not possible because ancillary information was not documented, raw data were rarely reported, laboratory reporting levels varied, and few studies were related to SVOCs from highways. In addition, vehicles emit fewer SVOCs and VOCs today than when most studies were conducted (U.S. Environment Protection Agency, 1996a). The lower emissions are probably due to catalytic converters and to the use of cleaner-burning fuels. Gasoline-powered cars without catalytic converters emit 25 times more total aerosol PAHs in comparison to cars with catalytic converters, and diesel trucks emit 7 times more PAHs than cars with catalytic converters (Rogge and others, 1993). Therefore, the few loading factors that are available in the literature probably have limited application for estimating current loads of SVOCs and VOCs.

Comparison to Water-Quality and Sediment-Quality Standards and Guidelines

The potential for SVOCs to adversely affect water resources can be made by comparing SVOC concentrations in urban stormwater, snowmelt, and sediment to water-quality and sediment-quality standards and guidelines. Makepeace and others (1995) and Boom and Marsalek (1988) concluded that certain PAHs, phenol, *m*- and *p*-cresols, pentachlorophenol, and phthalates in stormwater were a concern for drinking water and aquatic life. Of the PAHs, total PAH, acenaphthene, fluoranthene, and benzo(a)pyrene in urban stormwater exceeded drinking-water standards of the United States, Canada, and World Health Organization (WHO). Concentrations of fluoranthene in stormwater exceeded acute and chronic aquatic regulation values of the United States.

For this report, SVOC concentrations in sediments were compared to recently developed sediment-quality guidelines (U.S. Environmental Protection Agency, 1996b) as another assessment of their potential adverse effects. No single set of sediment-quality guidelines is universally accepted in the United States. Therefore, the method of USEPA (1996b) was used to determine an upper threshold concentration for selected SVOCs above which there is a high probability of adverse effects on aquatic life. However, guidelines do not exist for all SVOCs detected in urban stormwater and upper threshold concentrations may be over- or under-protective depending on site-specific conditions.

Briefly, USEPA (1996b) used several sets of sediment-quality guidelines that were developed using different methods and have considerable inconsistencies among them. Rather than select one set of guidelines over another, USEPA (1996b) used all available sediment guidelines for a contaminant to classify sites into one of three tiers based on the probability of adverse effects on aquatic life. Tier 1 sites have a high probability of adverse effects on aquatic life, Tier 2 sites have an intermediate probability of adverse effects on aquatic life, and Tier 3 sites have no indication of adverse effects on aquatic life. USEPA (1996b) used lower threshold guidelines, above which adverse effects occasionally occur, to define the Tier 2/Tier 3 boundary, and upper threshold guidelines, above which effects may be frequent or severe, to define the Tier 1/Tier 2 boundary. For a site to be designated as Tier 1, the measured contaminant concentration at that site must exceed at least two of the upper threshold guidelines for that contaminant.

The guideline used in this comparison was the Tier 1/Tier 2 boundary concentration (table 4, at back of report). The upper threshold values used were (1) the effects range-median (Long and Morgan, 1991; Long and others, 1995); (2) the apparent effects threshold-high (Barrick and others, 1988); (3) the probable effect level used by the Florida Department of

Environmental Protection (1994); (4) the probable effect level used by the Canadian Council of Ministers of the Environment (1995); (5) the USEPA sediment-quality criterion (U.S. Environmental Protection Agency, 1996b); and (6) the USEPA sediment-quality advisory level (U.S. Environmental Protection Agency, 1996b).

In the future, guidelines for PAHs are likely to change to PAH mixtures because PAHs typically co-occur in the environment. Testing and modeling is being conducted to determine the toxicity of PAH mixtures in sediment, which will form the basis for sediment-quality criteria for PAH mixtures (U.S. Environmental Protection Agency, 1998).

About 70 percent of surface-soil samples near a highway exceeded upper threshold concentrations of benz(a)anthracene, benzo(a)pyrene, chrysene, or pyrene, or of more than one of these PAHs, indicating adverse effects are probable (Butler and others, 1984). About 60 percent of bottom sediments from an urban stream exceeded upper threshold concentrations of fluoranthene, anthracene, pyrene, or benzo(a)pyrene, or of more than one of these PAHs (Ellis and others, 1985). Other studies had samples that exceeded upper threshold values, but the percentage of exceedence is unknown. For example, particulates in vehicle emissions and in the atmosphere exceeded upper threshold concentrations of benzo(a)pyrene (Prahl and others, 1984; Bjorseth and Ramdahl, 1985). Suspended sediments and street dust from highways and commercial areas exceeded upper threshold concentrations of fluoranthene, phenanthrene, pyrene, acenapthlyene, and benzo(a)pyrene (Hoffman and others, 1984 and 1985; Marsalek and Schroeter, 1988).

Volatile Organic Compounds

Few studies have been done on VOCs in highway runoff and urban stormwater. This summary of VOCs is mostly from the National Urban Runoff Program (NURP) and National Pollutant Discharge Elimination System (NPDES) studies.

Occurrence

Harrison and Johnston (1985) and Baldys and others (1997) were the only studies of VOCs in highway runoff. Harrison and Johnston (1985) sampled 2-week composites of atmospheric deposition at three sites near a highway in England. A total of 48 compounds were identified and quantified on a relative basis. Toluene and C_2-alkylbenzene were the major components in atmospheric deposition. No variation with distance from the highway was observed. Twenty-one highway runoff samples were collected at four sites between 1992-94 and analyzed for VOCs and other contaminants in the Dallas–Fort Worth area (Baldys and others, 1997). Chloromethane, toluene, xylenes, 1,2,4-trimethylbenzene, and 1,2,3-trichloropropane were detected in about 5 to 28 percent of samples at concentrations between 0.2 and 4.0 μg/L.

Most of the data on VOCs were collected during the NURP and NPDES studies. Together, these studies provide information on the occurrence of VOCs in most regions of the United States. For the NURP, the most frequently detected VOCs were dichloromethane, naphthalene, and chloroform, detected in 10 to 12 percent of all samples (Cole and others, 1984). In contrast, the most frequently detected VOCs for NPDES studies were toluene, xylenes, chloroform, and trimethylbenzene, detected in 12 to 23 percent of all samples (table 5, at back of report) (Delzer and others, 1996). A lower MRL for the NPDES studies could account from the greater frequencies of detection. Comparing VOC detections among regions of the United States may be possible using the NURP and NPDES data, but would be difficult because of the different reporting limits. Most detected concentrations of VOCs in urban stormwater for the NURP and NPDES studies were less than 10 μg/L and ranged from 0.2 to 43 μg/L.

The prevalence of gasoline-related compounds in NPDES data compared to NURP data probably is because stormwater was sampled closer to its source at NPDES monitoring sites and because the NURP did not measure xylenes, trimethylbenzenes, methyl *tert*-butyl ether (MTBE). MTBE and other ether oxygenates are added to gasoline to reduce vehicle emissions and enhance octane ratings. MTBE usage as an octane enhancer started about 1979. The use of MTBE to produce cleaner burning gasoline increased considerably during the late 1980's. In 1996, 17.6 billion pounds of MTBE were produced, making it the VOC with the third highest production (Chemical and Engineering News, April 8, 1996). MTBE's widespread use, high solubility, and resistance to degradation (Squillace and others, 1997) could account for its frequent occurrence in urban stormwater (Delzer and others, 1996) and in shallow urban ground water (Squillace and others, 1996).

Related Factors

Land use could be the most significant factor affecting the occurrence of VOCs. Lopes and Bender (1998) found that concentrations of gasoline-related and chlorinated VOCs were significantly higher in industrial areas as compared to commercial and residential areas and that MTBE was detected more frequently in commercial areas. Most VOCs have industrial applications (Pankow and Cherry, 1996), which probably is why concentrations were higher in industrial areas. The frequent detection of MTBE in commercial areas could be from spills at gas stations, which typically are located in commercial areas. Line and others (1997) infrequently detected VOCs in first-flush samples from industrial sites in North Carolina; sampling methods and high MRLs could account for the few detections.

Temperature is a significant factor affecting the occurrence of VOCs. A study by von Guerard and Weiss (1995) observed that more detections of VOCs occurred during snowmelt than during storm runoff. For all NPDES data, MTBE, benzene, xylenes, and 1,2,4-trimethylbenzene were detected more frequently during winter than summer (Delzer and others, 1996; Lopes and Bender, 1998). This higher detection of VOCs could be caused by the increased partitioning of VOCs from air into precipitation or slower volatilization from stormwater during cold months.

Sources

Lopes and Bender (1998) concluded that urban land surfaces are the primary nonpoint source of VOCs in stormwater. Most VOC concentrations in NPDES samples were higher than those in equilibrium with concentrations measured in urban air, indicating the atmosphere was not the source. VOCs associated with certain products, such as gasoline, frequently occurred together, and concentrations were significantly correlated and different among urban land uses. Model results indicated that VOC concentrations near the reporting limits evolved by volatilization. The primary source of VOCs probably was spills and VOCs sorbed to organic particulates and impervious surfaces, although partitioning between precipitation and VOCs in the atmosphere could be a source for MTBE.

The seasonal detection of some VOCs suggests that the atmosphere could be a nonpoint source. Measurements by Kawamura and Kaplan (1983), Pankow and others (1984), Harrison and Johnston (1985), Ligocki and others (1985), and Adachi and Kobayashi (1994) support the hypothesis that the atmosphere near highways and urban areas is a source of VOCs, although concentrations in precipitation were less than or equal to 0.2 μg/L. Concentrations of MTBE in precipitation estimated from concentrations in air range from less than 1 to about 4 μg/L (Squillace and others, 1996). These estimated concentrations of MTBE are why Squillace and others (1996) hypothesized precipitation could be a major source of MTBE detected in shallow urban ground water. Pankow and others (1997) demonstrated that MTBE and other VOCs in the atmosphere can be transported in recharge into sandy aquifers.

Comparison to Water-Quality Standards

From the NURP data, Makepeace and others (1995) concluded that tetrachloroethene, dichloromethane, and benzene could be a concern if stormwater entered drinking-water supplies. For the NPDES data, Delzer and others (1996) found that concentrations of MTBE in urban stormwater were less than the lower limit of the USEPA draft lifetime health advisory of 20 μg/L. Other VOCs detected in NPDES samples were compared to drinking-water standards (U.S. Environmental Protection Agency, 1996c) in table 6 (at back of report) because VOCs have low aquatic toxicities (Rowe and others, 1997) and primarily are a threat to drinking-water supplies. Less than 0.5 percent of NPDES samples exceeded drinking-water standards of dichloromethane and tetrachloroethene, similar to the NURP study (Makepeace and others, 1995).

INFORMATION NEEDS

This review has shown that highways can be major sources of SVOCs detected in water and sediment. However, there is insufficient information to determine if highways are sources of VOCs or to estimate loads and concentrations of SVOCs and VOCs from highways. Nationally consistent data are needed to (1) characterize the regional occurrence and concentrations of SVOCs and VOCs in highway runoff, (2) determine which are the most important factors affecting runoff quality, (3) estimate contaminant loads and concentrations on regional and national scales, and (4) identify water resources that potentially are affected.

A strategy is needed so that the distribution of information adequately represents factors affecting highway runoff in the United States. This strategy should define regions that have different values of factors that are expected to significantly correlate with water and sediment quality. For example, streams in drainage basins with residential and commercial land use are being monitored in regions with significantly different climate (Lopes and Price, 1997) because urban stormwater quality is significantly correlated with mean annual precipitation (Driver and Tasker, 1990). Other factors, such as highway-surface type, drainage, and traffic load, could be incorporated into this plan to develop a similar strategy for highways.

Information that is needed includes chemical data on SVOCs and VOCs in runoff, precipitation, and sediment to characterize their occurrence and ranges in concentrations. PAHs, oil and grease, and petroleum hydrocarbons are the primary classes of SVOCs associated with highway runoff. However, phenolic compounds and VOCs are in vehicle exhaust and could also be in highway runoff, precipitation, and sediment along highways. Parameters that could be related to chemical concentration, such as pH, dissolved oxygen, and total organic carbon, should also be measured. These data should be collected using appropriate procedures and materials and documented in a QA/QC plan.

Factors that are significantly related to water quality need to be characterized to estimate contaminant loads and concentrations from unmonitored sites and to identify potentially affected water resources. Factors that clearly affect concentrations and loads of SVOCs in highway runoff include suspended solids and organic carbon concentrations, total rainfall, rainfall intensity, traffic loads, and how runoff is drained. It is unclear if the type of surface has a significant effect, how much temperature affects concentrations and loads of SVOCs, and if surrounding land use has an effect. These and other factors may affect VOCs in highway runoff and precipitation. Relations between water quality and significant factors can be characterized by statistical analysis of ancillary data associated with monitoring sites and storms. From these relations, techniques similar to those of Driver and Tasker (1990) can be developed to estimate constituent loads and concentrations in highway runoff throughout the United States.

Geographic information on factors included in the estimation techniques can be used to obtain a national distribution of estimated contaminant loads and concentrations. These estimates and geographic information on water resources, including ground water, could then be used to determine which water resources could be adversely affected by highways. Ground water that is shallow and is used or has the potential of being used for drinking water could be affected by water-soluble compounds like MTBE.

Deterministic studies and modeling are also needed to understand the physical and chemical processes controlling highway-runoff quality, contaminant transport and fate, and impacts on biological and drinking-water resources. For example, Hewitt and Rashed (1990) and Stotz (1987) found that 70 percent of PAHs from highways are dispersed and 30 percent are transported in runoff. The majority of PAHs could be transported through the atmosphere into water-supply reservoirs. Modeling could help determine the transport and fate of dispersed PAHs and potentially affected waters.

SUMMARY

This review evaluated the quality and geographic distribution of existing data on SVOCs and VOCs, summarized significant findings, compared concentrations in highway runoff and urban stormwater with current (1998) water-quality criteria, and identified areas where additional information is needed. A total of 44 articles and reports were reviewed. Only 17 studies were related to highways, and 5 of these are review papers. Most of the data were collected during the late 1970's to mid-1980's. SVOCs in urban stormwater and sediments was the subjects of most studies.

Only 10 percent of studies described where in the stream cross section water samples were collected. This was the largest deficiency in documenting the sampling protocol. About 80 percent of SVOCs in runoff are in the suspended solids. Because suspended solids can vary significantly in the stream cross section even in narrow channels, the representativeness of discrete point samples and interpretations based on those data, especially load estimates, are questionable

without information regarding sample location, how samplers were used, or how well the streamflow was mixed.

Only 30 percent of studies documented the MRL or MDL of the analytical method and only 15 percent of studies used field quality-control samples. The lack of MRL and MDL documentation hinders the ability to compare stormwater quality from different parts of the country. Evaluating the quality of environmental data, especially low concentrations, is difficult because few studies collected QC data and documented that samplers were cleaned.

PAHs, petroleum hydrocarbons, and oil and grease are the major SVOCs in urban stormwater and highway runoff. Suspended solids concentrations is the most significant factor affecting SVOCs in water. In sediment, the most significant factors affecting SVOC concentrations are organic carbon content and distance from sources, such as highways and power plants. Rainfall intensity, storm volume, and land use also are important factors affecting concentrations and loads of SVOCs. The highest SVOC concentrations in runoff, snow, and bottom sediment were measured from highways and industrial areas. Crankcase oil and vehicle emissions are the primary sources of SVOCs. The few loading factors and regression equations that were developed in the 1970's and 1980's are inadequate to estimate current (1998) loads of SVOCs because they use inconsistent units, some are independent of rainfall and have limited application, and they are based on few data. Also, more cars have catalytic converters and fuels are cleaner than when loading factors and regression equations were developed. PAHs, phenolic compounds, and phthalates in runoff exceeded drinking-water and aquatic-life standards. PAHs exceeded upper threshold concentrations in sediments near highways, indicating adverse effects on receiving streams.

VOCs were detected in precipitation adjacent to a highway in England, and chloromethane, toluene, xylenes, 1,2,4-trimethylbenzene, and 1,2,3-trichloropropane were detected in runoff from a highway in Texas. VOCs were detected in as many as 23 percent of the urban stormwater samples; gasoline-related compounds were the most frequently detected VOCs. Land use could be the most significant factor affecting the occurrence of VOCs. The highest concentrations of VOCs were found in industrial areas, suggesting urban land surfaces are the primary nonpoint source of most VOCs. Temperature is another important factor affecting the occurrence of VOCs. MTBE, benzene, xylenes, and 1,2,4-trimethylbenzene were detected more frequently during winter than summer. The seasonal detection could be due to the increased partitioning of VOCs in air into water at cold temperatures, suggesting that the atmosphere could be a nonpoint source of some VOCs. Tetrachloroethene, dichloromethane, and benzene were the only VOCs in stormwater that exceeded drinking-water standards.

Information deficiencies identified during the review included a need to determine if highways are a source of phenolic compounds and VOCs and if the occurrence and concentrations of SVOCs and VOCs vary regionally. A better understanding of the factors that affect SVOCs and VOCs is needed to estimate contaminant loads and concentrations at unmonitored sites and to identify potentially affected water resources. Deterministic studies and modeling also are needed to understand the physical and chemical processes controlling highway-runoff quality and contaminant transport and fate.

Table 3. Loading factors for semivolatile organic compounds as a function of land use

[kg, kilogram; km^2, square kilometer; km, kilometer; yr, year; cm, centimeter; m^2, square meter; PAHs, polycyclic aromatic hydrocarbons; µg, microgram; m, meter; hwy, highway; E-5, 10 to the exponent -5; --, factors were not estimated]

Compound class	Residential	Commercial	Industrial	Highway	Bridges	Reference
			Stormwater			
Petroleum hydrocarbons	180 $(kg/km^2)/yr$	580 $(kg/km^2)/yr$	14,000 $(kg/km^2)/yr$	7,800 $(kg/km^2)/yr$	--	Hoffman and Quinn, 1987
	--	--	--	2.5E-5 (kg/vehicle)/km	--	Hoffman and others, 1985
	--	--	--	126 (kg/km^2)/cm rain	--	Hoffman and others, 1985
	2,560 $(kg/km^2)/yr$	--	--	--	--	Hunter and others, 1979
Oil and grease	--	--	--	485-76,700 $(kg/km^2)/yr$	4.1 kg/yr	Barrett and others, 1993
	--	--	--	9-16 (kg/km^2)/event	--	Barrett and others, 1993
	--	--	--	27-298 (kg/km^2)/cm rain	--	Wiland and Malina, 1976
	9.8 (kg/km^2)/cm rain	239 (kg/km^2)/cm rain	--	--	--	Stenstrom and others, 1984
PAHs	[1]0.009 $(kg/km^2)/yr$	[1]0.100 $(kg/km^2)/yr$	[1]2.42 $(kg/km^2)/yr$	[1]1.22 $(kg/km^2)/yr$	--	Hoffman and Quinn, 1987
	[2]0.258 $(kg/km^2)/yr$	[2]0.589 $(kg/km^2)/yr$	[2]3.97 $(kg/km^2)/yr$	[2]16.9 $(kg/km^2)/yr$	--	Hoffman and Quinn, 1987
	--	--	--	0.5-1.8 $(kg/km^2)/yr$	--	Stotz, 1987
	--	--	--	5.8E-8 (kg/vehicle)/km	--	Hoffman and others, 1985
	--	--	--	0.151 (kg/km^2)/cm rain	--	Hoffman and others, 1985
			Bulk deposition			
Petroleum hydrocarbons	61.4 (summer) $(\mu g/m^2)$/day	--	1,130 (winter) 4,120 (summer) $(\mu g/m^2)$/day	--	--	Latimer and others, 1990
Oil and grease	--	--	--	--	8.1 kg/yr	Barrett and others, 1993
PAHs	--	--	--	[3]15.6-48 µg/m of hwy/day	--	Hewitt and Rashed, 1990
	--	--	--	29-71 $(\mu g/m^2)/yr$	--	Harrison and Johnston, 1985

[1]Low-molecular-weight PAHs.
[2]High-molecular-weight PAHs.
[3]Within 50 meters of highway.

Table 4. Upper threshold concentrations of selected semivolatile organic compounds in sediment

[CAS, Chemical Abstracts]

Compound name	CAS number	Threshold concentration, in micrograms per kilogram of sediment
Acenaphthene	83-32-9	[1]1,300
Acenaphthylene	208-96-8	640
Anthracene	120-12-7	1100
Benz[a]anthracene	218-00-9	693
Benzo[a]pyrene	50-32-8	782
Bis(2-ethylhexyl)phthalate	117-81-7	2,650
Butylbenzylphthalate	85-68-7	11,000
Chrysene	218-00-9	862
Dibenz[a,h]anthracene	53-70-3	260
1,2-Dichlorobenzene	120-83-2	350
1,4-Dichlorobenzene	95-50-1	340
Diethylphthalate	84-66-2	630
Di-n-butylphthalate	84-74-2	11,000
Fluoranthene	206-44-0	[1]6,200
Naphthalene	91-20-3	470
Phenanthrene	85-01-8	[1]1,800
Pyrene	129-00-0	1,398
1,2,4-Trichlorobenzene	120-82-1	9,200

[1]Assumes 1 percent sediment organic carbon.

Table 5. Comparison of volatile organic compounds detected in the NURP and NPDES studies

[NURP, Nationwide Urban Runoff Program; NPDES, National Pollutant Discharge Elimination System; NA, not analyzed]

Compound	Frequency of detection, in percent, NURP[1]	Frequency of detection, in percent, NPDES[2]
Toluene	2	23
Xylenes	NA	17.5
Chloroform	12	13
Trimethylbenzene	NA	12
Tetrachloroethene	5	8
Naphthalene	11	7
methyl-*tert* butyl ether	NA	7
Dichloromethane	10	6
Bromodichloromethane	1	6
Ethylbenzene	4	5

[1]Cole and others, 1984.
[2]Delzer and others, 1996.

Table 6. Comparison of volatile organic compounds in stormwater to drinking-water standards

[µg/L, micrograms per liter; IUPAC, International Union of Pure and Applied Chemistry; CAS, Chemical Abstracts; NPDES, National Pollutant Discharge Elimination System; MCL, maximum contaminant level; HAL, health advisory level (U.S. Environmental Protection Agency, 1996c)]

IUPAC name	CAS number	Maximum concentration in NPDES samples	Standard, in µg/L	Type of standard
Methylbenzene	108-88-3	6.6	1,000	MCL
Dimethylbenzenes	1330-20-7	15	10,000	MCL
Trichloromethane	67-66-3	7.0	[1]100	MCL
Tetrachloroethene	127-18-4	42	5	MCL
Naphthalene	91-20-3	5.1	20	HAL
Methyl *tert*-butyl ether	1634-04-4	8.7	[2]20	HAL
Dichloromethane	75-09-2	13	5	MCL
Bromodichloromethane	75-27-4	2.8	[1]100	MCL
Ethylbenzene	100-41-4	2.0	700	MCL
Benzene	71-43-2	0.8	5	MCL

[1]Total for all trihalomethanes combined cannot exceed the 100 µg/L.
[2]Standard varies from 20 to 40 µg/L.

Table 7. Concentrations of detected semivolatile and volatile organic compounds in stormwater, suspended sediment, and bottom material/soil

Stormwater Sampling – StormFilter™ Performance Results

Burwell/Straley's Union 76 Station
Bremerton, Washington

Storms Captured - April through October 2000 (3 storms)

Overview: The following is a summary of the stormwater sampling results obtained from the StormFilter unit located at Straley's Union 76 Station, 308 North Montgomery Avenue, Bremerton, Washington. Sampling and reporting provided by EnCo Environmental Corporation, Puyallup, Washington.

Site and System Description: Straley's BP is a typical gasoline station with accompanying convenience store. The site is 2.53 acres with 1.99 acres being impervious surface. The site drains to a Type II 54" upstream manhole followed by an 8' x 16' StormFilter containing 23 filtration cartridges. The cartridges contain CSF® leaf media that is composed of granulated deciduous leaf compost. The systems peak treatment flow is 0.78 cfs (350 gpm) based on the 6 month – 24 hour storm event. (*Note: Each cartridge filters at 15 gpm.*)

Sampling: Samples consisted of first flush and flow weighted composite samples. The first flush samples were collected during the first hour of runoff (3 samples) with flow weighted composite samples taken in 20-minute intervals during the course of the storm. Samples were composited based on flow rates and volumes passing through the system over the 20-minute interval. (*Note: Influent samples were taken as flow entered the StormFilter unit rather than the upstream manhole such that the reported efficiencies reflect the filtration unit and not total system efficiency. Effluent samples were taken as water exited the unit.*)

Storm Sample Results: Three storms were captured between the months of April and October 2000. The tables below present the acquired data with a brief description of the storm following each table.

Table One: Storm Event – April 25th 2000 (Peak Flow = 0.91 cfs)

Sample	pH (IN)	pH (OUT)	Dissolved Zinc (IN) (mg/l)	Dissolved Zinc (OUT) / % Removed (mg/l)	Total Zinc Influent (IN) (mg/l)	Total Zinc Effluent (OUT) / % Removed (mg/l)
First Flush	6.5	6.5	0.27	0.076 / 71.9%	0.30	0.086 / 71.3%
Flow Composite	6.5	6.5	0.24	0.11 / 54.2%	0.27	0.12 / 55.5%

Table One (Cont.): Storm Event – April 25th 2000 (Peak Flow = 0.91 cfs)

Sample	Total Phosphorus (IN) (mg/l)	Total Phosphorus (OUT) (mg/l)	Oil and Grease – HEM* (IN) (mg/l)	Oil and Grease – HEM (OUT) / % Removed (mg/l)	TSS (IN) (mg/l)	TSS (OUT) (mg/l) / % Removed
First Flush	<0.25	<0.25	10	4 / 60%	18	4 / 77.8%
Flow Composite	<0.25	<0.25	2	3 / -50%	24	10 / 58.3%

* HEM = Hexane Extractable Method (EPA 1664)

Table One presents the acquired data from April 25th 2000. The storm was fairly low intensity with a total rainfall accumulation of 0.165" producing a treated volume of 10,853 gallons (1,450 ft^3). Rainfall started at 5:00 am and was spotty through 1:30pm (0.1" accumulation occurred at 1:00pm). Some hail occurred at the onset of the storm with light rain in patches occurring during the remainder of the event. Temperature was recorded to be 59°F.

Table Two: Storm Event – June 6th 2000 (Peak Flow = 0.20 cfs)

Sample	pH (IN)	pH (OUT)	Dissolved Zinc (IN) (mg/l)	Dissolved Zinc (OUT) / % Removed (mg/l)	Total Zinc Influent (IN) (mg/l)	Total Zinc Effluent (OUT) / % Removed (mg/l)
First Flush	5.74	5.82	0.23	0.11 / 52.2%	0.39	0.11 / 71.8%
Flow Composite	5.61	5.81	0.13	0.085 / 34.6%	0.18	0.11 / 38.9%

Table Two (Cont.): Storm Event – June 6th 2000 (Peak Flow = 0.20 cfs)

Sample	Total Phosphorus (IN) (mg/l)	Total Phosphorus (OUT) / % Removed (mg/l)	Oil and Grease – HEM (IN) (mg/l)	Oil and Grease – HEM (OUT) / % Removed (mg/l)	TSS (IN) (mg/l)	TSS (OUT) (mg/l) / % Removed
First Flush	0.50	0.71 / -42%	4	6 / -50%	93	9 / 90.3%
Flow Composite	0.35	0.59 / -68.6%	5	12 / -140%	14	9 / 35.7%

June 6, 2000 storm event lasted 5 ½ hours with a total accumulation of 0.10" producing 5,522 gallons (738 ft^3) of runoff. The intensity was a light drizzle with spotty patches of rain. Temperature recorded at 68°F.

Table Three: Storm Event – October 19th 2000 (Peak Flow = 0.60 cfs)

Sample	pH (IN)	pH (OUT)	Dissolved Zinc (IN) (mg/l)	Dissolved Zinc (OUT) / % Removed (mg/l)	Total Zinc Influent (IN) (mg/l)	Total Zinc Effluent (OUT) / % Removed (mg/l)
First Flush	6.62	6.53	0.078	0.009 / 88.5%	0.18	0.11 / 39%
Flow Composite	6.67	6.62	0.070	<0.006 / 91.4%	0.16	0.091 / 43.1%

Table Three (Cont.): Storm Event – October 19th 2000 (Peak Flow = 0.60 cfs)

Sample	Total Phosphorus (IN) (mg/l)	Total Phosphorus (OUT) (mg/l)	Oil and Grease – HEM (IN) (mg/l)	Oil and Grease – HEM (OUT) (mg/l)	TSS (IN) (mg/l)	TSS (OUT) (mg/l) / % Removed
First Flush	<0.5	<0.5	<2.0	<2.0	6	9 / -50%
Flow Composite	<0.5	<0.5	<2.0	<2.0	14	8 / 42.9%

Total rainfall recorded over 3.5 hours was 0.165" with a peak flow of 0.60 cfs. First flush samples were collected within 15 minutes of initial flow. Moderate rain was still occurring at the end of the sample event. Last rainfall recorded at the site was October 15th 2000. A total volume of 12,073 gallons (1,614 ft^3) passed through the system.

Discussion: As presented above, the StormFilter located in Bremerton is functioning well under its designed treatment conditions. Reductions in both total and dissolved zinc were observed for each event. Removal of the metal is associated with physical straining of suspended particles that carry the non-dissolved metal as well as cation exchange of the dissolved zinc for calcium or magnesium within the filtration media.

Total Suspended Solids (TSS) concentrations were low for most storm (*Note: Influent samples were taken as water entered the StormFilter and not he upstream manhole. A site assessment was performed December 21, 2000. Negligible amounts of sediments were observed in the upstream manhole.*)

As presented above each table is the peak flow rate observed during each storm event. The designed flow rate for the system is 0.78 cfs. Table One – April 25, 2000 shows a peak flow of 0.91 cfs, which is over the designed storm but this flow only occurred briefly. The storm was reported to be fairly low in intensity and showed good treatment.

June 6, 2000 – Table Two produced a peak flow of 0.20 cfs and produced excellent treatment of all parameters except phosphorus. Elevations in effluent phosphorus concentrations may arise from decaying organic matter within the cartridge bay of the StormFilter.

October 19, 2000 – Table Three produced a peak flow of 0.60 cfs that falls under the designed parameters of the StormFilter. Treatment for this storm showed reductions in all parameters except of TSS during the first flush. It must be noted however that the influent TSS concentration observed for this event approached the detection limit of 5 mg-TSS/l. Removal of concentrations this low are difficult due to the particles being extremely fine (clays and silts).

Oil and Grease concentrations were low for each storm event with changes in concentrations from the influent to the effluent being near the detection limit for analytical instrumentation.

LEGISLATIVE ANALYSIS

Committee Hearing: Economic Development, Transportation and Technology
File Number: 97-97-057 - Motor Fuel Prices
Origin: Supervisor Yaki

Summary of Requested Action:

By adding Chapter 80 (Sections 80.1 through 80.9) to the San Francisco Administrative Code, this measure would:

1. Require oil refining companies to incrementally relinquish control of **gasoline** service stations in the City and County of San Francisco and ultimately prohibit refining companies from owning or operating any **gasoline** service station on or after 1/1/2000. This policy is commonly referred to as "divorcement."

2. Require oil refiners to allow dealers of their branded **gasoline** to purchase fuel from any location, or through any vendor, in that refiner's wholesale fuel network.

3. Prohibit oil companies from charging service station operators differing wholesale prices.

Policy Question:

1. Should the City prohibit specified companies from controlling and/or operating certain **retail** businesses?

2. Should the City prohibit specified companies from establishing contractual agreements with the distributors of their product as to how the product will be delivered?

3. Should the City dictate the pricing structure specified companies establish for the sale of their product?

Current Law:

While there are a number of state and federal laws dealing with the marketing of motor fuel and/or the relationship between major oil companies and service station dealers, there do not appear to be any state or federal laws which directly prohibit refinery operation of service stations; nor do there appear to be any state or federal laws which directly regulate the wholesale or **retail** price of motor fuel, or the distribution agreements between refiners and service stations. Additionally, there do not appear to be any statutes which directly prohibit local jurisdictions from imposing regulatory control in these policy areas

R0009343

However, there is considerable debate on the whether existing price discrimination laws preempt provisions of this ordinance prohibiting zone pricing.

An in-depth discussion of these existing laws can be found in "Policy Issue #6" below.

Proposed Legislative Action

This measure would:

1. Make findings that (a) address the importance of motor vehicle transportation in the lives of San Franciscans, (b) declare the relatively high **retail** price of **gasoline** in San Francisco, (c) suggest that the relatively high price of **gasoline** in San Francisco is due to artificially high wholesale prices charged by refiners, and (d) declare that higher gas prices and the practices by refiners resulting in higher **gasoline** prices are injurious to the general health, safety and welfare of San Franciscans.

2. Prohibit any oil company from owning or operating any new or additional **retail** service stations on or after 1/1/98.

3. Incrementally require refiners to relinquish ownership and/or the operation of service stations within the City and County of San Francisco. By 1/1/99, refiners would be required to relinquish control/operation of at lease one-half (1/2) of the service station the refiner owned or operated on 1/1/98. By 1/1/2000, refiners would be required to relinquish control/operation of any and all service stations in the City and County of San Francisco.

4. Provide an exception to the divorcement provisions by allowing refiners to operate service stations after 1/1/2000 for 90 days under specified circumstances.

5. Prohibit oil companies from charging service station operators differing wholesale prices at the same tanker truck loading terminal unless the difference is related to the actual cost of doing business. "Tanker truck loading terminal" refers to the location at which **gasoline** is sold at wholesale and loaded onto tanker trucks that transport the fuel to service stations

6. Require refiners to allow **retail** dealers of the refiner's branded **gasoline** to purchase the branded **gasoline** from any location, or through any vendor, in that refiner's wholesale fuel network.

7. Prohibit refiners from setting, controlling or economically influencing the **retail** prices and profit margins of service stations operators.

8. Specify that this ordinance will not effect the provisions of the San Francisco Planning Code requiring Planning Commission or Zoning Administrator approval of the conversion of a service station to another use.

9. Provide that the ordinance would be enforceable by local, county or state prosecutors.

10. Provide that the maximum penalty for a violation of this ordinance would be a misdemeanor punishable by a fine not to exceed $500 or by imprisonment in the county jail for up to six months or both fine and imprisonment.

11. Provide any private person the right to bring civil action under the provision of this measure.

Background and Discussion:

IS THERE A RELATIVELY HIGHER **RETAIL** PRICE FOR **GASOLINE** IN THE SAN FRANCISCO BAY AREA. Based on price comparisons compiled by independent petroleum consultant, Tim Hamilton, San Francisco has seen higher prices for **retail gasoline** relative to the Los Angeles area throughout the past fifteen month period (see the attached Chart 1). Price comparisons where conducted every two weeks from January 10, 1997 to March 6, 1998. The observed price differential ranged from a low of $.01 per gallon (August 22, 1997 and September 19, 1997) to a high of $0.29 per gallon (March 6, 1998). It should be noted that of the 29 price comparison days, the price differential rarely dropped below $.08 per gallon (on only 7 of the 29 comparison dates). The average differential for the 15 month period was approximately $.10 per gallon. The mode and median price differential was also $.10 per gallon.

When looking at the price differential since the beginning of 1998, we see a much different story. Since the beginning of this year, the higher price differential of gas sold in San Francisco relative to Los Angeles has continually increased from $.16 per gallon on January 9, 1998 to $.29 per gallon on March 6, 1998. The average higher price paid for **gasoline** in San Francisco since the first of the year has been approximately $.22 per gallon.

WHAT ARE THE FORCES DRIVING THESE HIGHER PRICES? Proponents (led by the Automotive Trade Organizations of California) of this measure argue that the higher relative price of **gasoline** in San Francisco is driven by anti-competitive practices conducted by oil companies in San Francisco **gasoline retail** market.

The opponents of this measure (led by the Western States Petroleum Association), instead argue that the relative price differential is the result of lack of competition resulting from the barriers to entry that exist in entering the **gasoline retail** business in San Francisco and the relatively high cost of doing any type of business in the City.

<u>**PROPONENTS:**</u> ANTI-COMPETITIVE FORCES RESULT IN ARTIFICIALLY HIGHER PRICE. The anti-competitive practices that the proponents argue lead to artificially higher prices are closed supply, zone pricing and vertical integration. The following is a brief discussion of each::

> **Closed supply**. Current petroleum industry contracts limit a **gasoline retail** dealer's ability to purchase branded fuel from sources other than the local wholesale distributor. This practice permits oil companies to charge station-specific, neighborhood-specific or City-specific wholesale prices that need not reflect broader wholesale market conditions.
>
> For example, if a San Francisco lessee station dealer of a given branded **gasoline** finds that a Stockton wholesale distributor of the same branded **gasoline** is offering the branded **gasoline** at a price so low that the dealer could pay the added transportation costs and still offer the **gasoline** at a lower **retail** price than if the dealer purchased the **gasoline** from the local wholesaler, under current business operation agreements, the dealer is prohibited from purchasing from the Stockton provider and passing the saving onto the consumer.
>
> This proposed ordinance would apply free market principles to the wholesale distribution of **gasoline** in San Francisco by requiring refiners to allow **retail** dealers of the that refiner's branded **gasoline** to purchase **gasoline** from any location or through any vendor in the refiners wholesale fuel network.
>
> COUNTER-ARGUMENT - CURRENT DISTRIBUTION SYSTEM PROTECTS DEALERS AND IMPROVES DELIVERY EFFICIENCY. Major oil companies argue that the bill will disrupt the present **retail** distribution system for **gasoline** products that allow for greater efficiencies. They state that these greater efficiencies result in lower prices and reliable supply which are due to the major

investments that have been made in transportation and distribution systems.

They argue that this proposed ordinance would undermine these benefits by interfering with existing contractual relationships. They further contend that refiners would no longer be able to enter into agreements that create stable dependable **outlets** in which they have a vested interest in ensuring survive. This would remove the major reason that refiners have to support lessee service stations and other **retail outlets**, possibly causing their elimination.

Wholesale price differentials or zone pricing. Proponents of this proposed ordinance argue that oil companies set wholesale prices through a complex set of pricing zones which exert significant control over **retail** prices. They argue that the companies draw zones between which they charge different prices on a community-by-community, neighborhood-by-neighborhood, or even a station-by-station basis. The oil companies can then set the zone price for each zone at the tanker truck loading terminal. The retailer must purchase the gas at that wholesale price due to the wholesale purchasing obligation explained above which prohibit **retail** dealers from purchasing their supply of **gasoline** from any source other than the local distributor.

The proposed ordinance would ban wholesale price differentials. When delivering **gasoline** to service stations from the same loading terminal, oil companies would be limited to setting only one price for wholesale **gasoline** and then only add to the price the actual additional cost of delivering the fuel.

COMPANIES ARGUE THAT ZONE PRICING ALLOWS DEALERS TO REMAIN COMPETITIVE - ELIMINATION WOULD RESULT IN LOST JOBS AND HIGHER PRICES. Rather than using zone pricing to force station operators to charge higher prices, the oil companies assert that they employ zone pricing to allow retailers to offer lower prices and remain competitive in areas of high competition. If zone pricing is eliminated, it is argued that the companies would not longer be able to offer lower prices in more competitive areas and the prices would raise and stabilize at a higher overall level.

They also assert that by prohibiting the companies from offering lower wholesale prices to stations that are having trouble competing at a higher wholesale price, the station is at risk of going out of business. If the station closes its doors, San Francisco would experience a loss of jobs and possibly an increase in prices due to the tightening of competition.

Vertical integration. Vertical integration is a practice whereby oil companies can control the price of **gasoline** from the ground to the pump by (1) extracting crude oil, (2) refining it into **gasoline**, (3) delivering the **gasoline** to **retail outlets**, and (4) setting the price the **gasoline** is offered at the **retail** level through contractual agreements with the **retail** operator or by actually operating the **retail** outlet.

The proponents argue that in areas where there are a significant number of service stations operated or controlled by a specific company, the **retail** price for a large portion of the service stations in the area is established by one entity, the company. They go on to argue that the oil companies use their wholesale pricing power to charge franchise or lessee dealers prices that force them to meet the **retail** prices the oil companies charge at their company operated stations.

In an October, 1997, hearing of the State Senate Energy, Utilities and Communications Committee, the independent service station associations stated that some major oil companies are engaged in a deliberate campaign to replace franchisee operations with company-owned service stations. One important tool in this effort seems to be lease agreements which limit the amount that franchisees can make from the operations of the station. The associations state that these lease agreements can severely reduce the market value of the franchise and act as an inducement for the franchisee to sell the franchise back to the company.

The associations also charged that company operated stations have, in some cases, been subsidized using station-specific prices to be able to offer **gasoline** at prices that force adjacent franchisees of the same company to operate at a loss. The association believes that a further loss of franchise dealers would enhance the ability of the oil companies to shield pricing in regional **gasoline** markets from normal market forces.

In an effort to reverse this trend, this proposed ordinance would require the "divorcement" of service stations from oil companies and ultimately prohibit oil companies from operating **retail** service stations and controlling **retail** fuel prices through any type of contractual agreement.

OPPONENTS ARGUE THAT THE SAN FRANCISCO MARKET HAS FEW COMPANY-OPERATED STATIONS. The Western State Petroleum Association provided figures showing the only 6 of the 123 service stations in San Francisco are company operated (5%). With such a small portion of the market being comprised by company operated stations, the industry questions their ability to overwhelmingly influence **retail** prices with such a small relative share of the **retail** market. They argue that with such a small share of the market, they must price their company operated stations to be competitive with their own dealers and the retailers of competing oil companies.

OPPONENTS ARGUE THAT DIVORCEMENT REDUCES COMPETITION RESULTING IN INCREASED PRICES. The free market system allows any group or individual to offer goods and services for sale. One of the basic tenets of economics stipulate that the greater the number of competitors in a free market, the lower the prices. In most competitive markets, price competition is a major factor in attracting customers. If there are only a few competitors in a given market, price is not as an important factor in attracting customers. However, as competition grows, price distinction becomes a greater factor.

In a completely free market, the exclusion of any group or individual from entering and operating in a given market in which they would otherwise operate, limits competition. If the basic tenets of competitive markets addressed above hold true, then it follows that this reduction in competition would result in increased prices as there are fewer purchasing options available to the consumer.

The oil industry argues that by prohibiting them from owning and operating **gasoline retail outlets**, divorcement eliminates an entire class of competitors, thereby, reducing purchasing options which leads to higher prices.

ANALYSIS OF THIS ASSERTION: This would hold true if it could be shown that the competitors that were being removed for the market (1) would not be replaced by other competitors or (2) had offered a product distinction that others could not provide. In this case, it would be hard to prove that the stations currently operated by companies would close and no other competitors would assume operation of the vacant stations.

In fact, the proponents of divorcement would argue that the opposite would occur. For example, Chevron currently operates three (3) service stations in San Francisco. If they were forced to cease operation of these stations, there is the possibility that the operation of three stations would be assumed by three different dealers, thereby, increasing competition. However, there is the possibility that the operation of all three stations would be assumed by a single dealer that already operates multiple stations in San Francisco. In such a case, competition would decease.

OPPONENTS: LACK OF COMPETITION, COST OF DOING BUSINESS, OPPORTUNITY COSTS RESULT IN HIGHER PRICES. The opponents argue that the higher price of **gasoline** in San Francisco is due to the following:

Lack of competition. The oil industry argues that one of the major reasons San Francisco gas prices are higher than other California cities is because of the relatively fewer stations that exist in the City. There are 1.5 **retail gasoline** stations per 10,000 residents, compared to 2.7 stations per 10,000 residents in Los Angeles. As discussed above, one of the basic tenets of economic stipulates that the greater the number of competitors in a free market, the lower the prices. With the relatively fewer amount of stations per capita, the oil companies argue that economic theory would predict higher prices within a free market.

While these figures appear to be correct, it is interesting to note the reduction in the number of **retail** stations operating in the Bay Area. According to the Bay Area Air Quality Management District (BAAQMD) there were 3309 **retail** gas stations in the Bay Area in 1978, currently there are 1420. This decrease in service stations has not necessarily resulted in a commensurate reduction the number of gas dispensing nasals.

According to BAAQMD personnel, the common Bay Area gas station in 1978 contained 6 to 8 dispensing nozzles. Today, stations commonly have 24 to 36 nozzles per station, thereby, allowing more drivers to be serviced at fewer stations. The following is data generated by the BAAQMD presenting this information in table form:

YEAR	NUMBER OF SERVICE STATIONS	AVERAGE NUMBER OF NOZZLES	TOTAL NUMBER OF NOZZLES	NUMBER OF CARS	NUMBER OF NOZZLES PER CAR
1978	3309	6-8	23,163	no data	--
1988	2265	11	24,300	4.17 million	.0058/car
1998	1420	20	29,000	4.60 million	.0063/car

High costs of doing business. The Western States Petroleum Association commissioned Kosmont & Associates to provide an economic assessment of the costs of developing **retail gasoline outlets** in various California jurisdictions, including San Francisco.

The study reviewed issues including (i) zoning and land use regulations, (ii) environmental regulations, (iii) entitlement process and time requirements, and (iv) building department and construction issues. Kosmont & Associates found "that there are substantially higher land development costs in San Francisco, than in Southern California."

The study provides a comparative analysis of the cost of service station development in San Francisco relative to Los Angeles and Orange Counties. The study found that in San Francisco "costs associated with land acquisition are almost 100% higher, ...while overall construction costs are 15% higher." Consequently, few new stations are built which limits competition. According to the BAAQMD, new **gasoline** station construction in San Francisco has been relatively low. Records show that the Air District issued 6 new permits in the last 10 years.

The study contends that intense urban development and the scarce supply of readily available land for development, make **gasoline** prices, along with home prices and the overall cost of living higher in San Francisco than in Southern California.

Opportunity costs. In a completely free market, the owner of property is free to use that property for any use the owner chooses. In economic theory, it is assumed that the property owner will use the property in such a fashion that will maximize profit.

Under current City law, it is difficult for property containing service stations to be redeveloped into another use. Consequently, the property owner of a parcel on which a service station currently exists cannot change the use of the property in order to take advantage of a use that could realize greater economic return. Therefore, due to City regulations, there could be an opportunity cost associated with owning property containing a **gasoline** service station. This places pressure on rent prices which are passed on to the consumers through higher gas prices.

The oil industry argues that the opportunity costs associated with service stations is one of the reasons there are so few stations in San Francisco. The inability to change property use out of the service station business places financial burden on property owners where **retail gasoline** services are not the best economic use for the property. Therefore, property owners are reluctant to allow their property to be used for service station operations as they will have difficulty in converting the property to another use in the future.

Policy Issues:

1. APPROPRIATE ROLE OF GOVERNMENT IN THE FREE MARKET. When is it appropriate for government to exert control over the participation, pricing structure and other business practices of a given industry?

   The proposed ordinance exerts substantial control over participation in the **gasoline retail** business. It also limits the ability of oil companies to make wholesale pricing decisions and regulates how oil companies deliver their product to distribution centers.

   There is precedence for government to exert this type of control in the market system. This primarily occurs when a good or service is viewed as a utility or when it is determined that the market is conducive to monopolistic practices.

   Evidence suggests that the wholesale **gasoline** pricing and distribution system in not a purely "free market" in the San Francisco area. It appears that there is no price competition within the wholesale market for branded **gasoline**. Once a retailer enters into a contract to sell a specific branded **gasoline**, that retailer is required to purchase their supply of **gasoline** from only one designated tanker truck terminal.

   Furthermore, these contractual obligations allow oil companies to charge different prices to stations within the same area through "zone pricing" as retailers are denied the opportunity to shop around for a cheaper price that may be offered in another location or by another wholesaler.

   The only entities that are free to shop around for the best price are independent dealers that are not associated with branded companies. Due to the fact that there are so few independent dealers in San Francisco, the independents have a very limited effect on the market

   Does the Board believe that the high price of **gasoline** in San Francisco relative to Los Angeles is due to monopolistic-like practices that result in prices that would not be as high in a free wholesale market?

R0009349

If the answer to this question is yes, then there is precedence for government to regulate an industry with the potential to implement these characteristics -- some examples include cable television, residential natural gas, and solid waste disposal.

2. HOW MANY STATIONS DO THE OIL COMPANIES CONTROL? One of the basic components to support the accusation that a given company or individual controls the price at the **retail** market level, is to prove that that entity controls a substantial number of **retail outlets**. In the case of **retail** stations in San Francisco, the number of company operated **retail** stations is minimal at 5%.

   However, the Automotive Trade Organizations Association suggests that while the oil companies do not actually operate a large number of stations, they do have direct control over the actual **retail** price of the **gasoline** offered at branded stations. It is suggested that the companies enter into contractually agreements with the operators of **retail** stations that require the operator to offer the price set by the oil company.

   The Board may want clarification from oil industry representatives if these type of contractual agreements exist, and if so, the number of stations currently operating under this type of agreement.

3. WILL THIS ORDINANCE ACHIEVE ITS GOAL - LOWER GAS PRICES IN SAN FRANCISCO? The major stated goal of the proponents of this ordinance is low gas prices in San Francisco. There are a number of studies examining the effects of similar measures that have been implemented in other areas, including the jurisdictions described in #4 below. The results of these various studies are conflicting. Some studies show that "divorcement" laws have resulted in lower gas prices, while other show that they have increased overall prices.

   Many of the other "divorcement" measures do not contain all the provisions contained in the proposal before the Board, therefore, it is extremely difficult to rely on past studies to conclusively determine whether or not the ordinance will result in lower **gasoline** prices.

4. OTHER AREAS WITH "DIVORCEMENT" MEASURES ENACTED. Other areas that have enacted measure containing provisions similar to provision contained in the proposed ordinance include:

   - State of Maryland
   - State of Nevada
   - State of Connecticut
   - State of Virginia
   - State of Delaware
   - State of Hawaii
   - Washington DC

5. ENFORCEMENT ISSUES. The fine for violation of this ordinance is $500, six months in the county jail, or both. It is hard to imagine that a $500 fine would serve as a great deterrent to companies the size of the oil companies operating in the San Francisco market.

   The one apparent deterrent contained in the ordinance is the possibility of sending a high ranking company executive to county jail. However, it seems it would be hard to place an executive in jail based on the provisions of this measure.

   How would the pricing discriminations provisions be enforced? Which agency would monitor the price charged to the various service stations and who would calculate the actual transportation costs

R0009350

for delivery from the terminal to station?

6. DO EXISTING LAWS PREEMPT THIS ORDINANCE? There are a number of state and federal laws dealing with the marketing of motor fuel and/or the relationship between major oil companies and service station dealers. These include:

   - Chapter 14 of Division 5 of the California Business and Professions Code which establishes various rules regulating the business operations of service stations (i.e. false advertising, posting of business hours, **gasoline** standards, and price indicators on dispensers). This section of the law does not prohibit or restrict refiner operation of service stations.
   - Chapter 7.5, Division 8 of the California Business and Professions Code deals with the termination and non-renewal of service stations franchises, however, does not prohibit or restrict refiner operation of service stations.
   - The California Franchise Disclosure Law (Corporations Code 31000 *et seq.*) which require a franchiser to make specified disclosures to a franchisee when a franchise is sold.
   - Division 7.8 of Division 8 of the Business and Professions requiring franchise fair practices.
   - Chapter 7.9 of Division 8 of the California Business and Professions Code specifies the circumstances under which a service station may be closed during late night and early morning hours. This section does not prohibit the operation of a service station by an oil company nor does it mention motor fuel pricing or wholesale distribution.
   - Chapter 8 of Division 8 of the California Business and Professions Code prohibits price discrimination in the sale of **gasoline** and oil, when the discrimination injures competition.
   - There are a number of state and federal antitrust laws which deal with vertical price fixing and restraints on trade.

   There do not appear to be any state laws which directly prohibit refiner operation of service stations, directly regulate the wholesale or **retail** price of motor fuel, or directly regulate the distribution agreements between refiners and service stations; however, it is unclear as to whether existing price discrimination laws preempt the zone pricing provisions of this ordinance.

   The Board may wish to seek a City Attorney's opinion on this question.

7. EFFECTIVE DATE. The de facto effective date of this ordinance would be 1/1/98 as that is when the ordinance prohibits any oil company from assuming the operation of any new or additional **retail** service stations in the City. Does the Board wish to make this measure retroactive?

   Also, the measure requires oil companies to relinquish control of 50% of their current **retail** holdings by 1/1/99 and all of their holdings 1/1/2000. The earliest this measure could become effect is mid-June. Does the Board feel this is an adequate amount time. The Board may wish to consider amending the legislation to change the effective dates of these provisions to allow a year for the 50% deadline and two years for the final deadline.

8. REGIONAL EFFECT. There is some debate as to whether this type of ordinance can be effected when implemented within a single jurisdiction. Some economist suggest that for an ordinance such as this to be effective, it must be implemented on a regional basis (see discussion of San Diego County's experience below). With this in mind, the Association of Bay Area Governments and the Bay Area Economic Forum are currently preparing studies on the issue (it is anticipated that Supervisor Yaki will amend this proposal in Committee to stipulate that it will not become effective unless 2/3 of the nine (9) Bay Area counties adopt similar measures).

9. SAN DIEGO COUNTY AND MUNICIPALITIES CONSIDERING REGIONAL

R0009351

IMPLEMENTATION OF SIMILAR LEGISLATION. The County of San Diego recently approved a county ordinance that would ban oil companies from operating **retail** service station **outlets** in unincorporated areas of the county by 2000 if similar legislation is approved by enough of the county's 18 municipalities to constitute at least two-thirds of the county's total population.

The ordinance includes a regional component because of the minimal number of stations within the unincorporated areas relative to those in incorporated areas – stations in unincorporated areas represent 12% of the total stations in San Diego County. It is extremely difficult for such a small percentage of the **retail** market to affect regional practices. The county believes that in order for the ordinance to be effective, a large majority of stations within a region must be included in the provisions of the measure.

According to San Diego Supervisor Ron Roberts' office, the requisite number of cities have approved the ordinance and it would be expected to become effective in 2000. However, the County of San Diego has decided to test the legal validity of the ordinance before it becomes effective by requesting a declaratory judgment from the courts. A decision in this matter is expected this summer.

10. STATE MEASURES. There are currently two measures before the California State Legislature dealing with this issue to varying degrees – Assembly Bill 2228 (Davis) and House Resolution 58 (Sweeney).

    AB 2228 would provide that nothing in state law invalidates or prohibits a local ordinance regulating competition in the refining, wholesale or **retail** distribution, pricing, manufacturing, or transporting of motor vehicle fuel or oil.

    HR 58 requests that the California Attorney General, in cooperation with the United States Attorney General, United States Secretary of Energy, and the Federal Trade Commission, investigate "anti-competitive" practices in the oil industry and in the **retail gasoline** marketplace. It also requests that the California Attorney General report the findings of the investigation to the Legislature and take any necessary legal actions against those engaged in illegal acts.

    Two measures were introduced last year to address the issue of oil company control over the **retail** price of gas. They were SB 52 (Kopp) and SB 404 (Peace), which would have allowed a franchised **gasoline** dealer to purchase branded **gasoline** from a supplier other than its franchiser. Both bills were defeated in the Senate last year.

Options:

1. Approve the ordinance in its current form.
2. Amend the ordinance to change deadlines for divorcement as outlined in "policy issue" #7 above and approve the measure.
3. Delay action on the measure until the Association of Bay Area Government and the Bay Area Economic Forum have completed their analysis of the issue.
4. Delay action on the measure until a decision is handed down on the declaratory judgment requested by the County of San Diego.
5. Reject the ordinance.

California Retail Service Stations, Fleet Fueling Facilities and Private Storage Tank Sites and Other Statistical Data by County

Note: Clicking on each of the counties below will take you to a complete list of ALL the retail gasoline and diesel services stations, fleet fueling facilities and private storage tank sites in each county in 1999. **(Most of the fleet and private sites do not sell fuel to the public.)** Facilites are alphabetically arranged, first by city or town in which they are located, and then by site name.

Some of these files may be very large and may take some time to download depending on the type of connection you have to the Internet. For example, the Los Angeles file is about 1.2 megabytes in size.

For convenience, the number of **retail** gasoline and diesel service stations only (including also marinas and cardlocks) is provided on the table of county statistics below.

The fueling facilities data files are also available to download as Microsoft Excel spreadsheets. Please note that the spreadsheet for the entire state is 6.7 megabytes in size and should only be downloaded if you have a high speed Internet connection. Otherwise your download times may be excessive. Spreadsheets for each county are also available.

1999 California Retail, Fleet and Private Fueling Facilities Spreadsheet
(Excel file, 6.7 megabytes)

Individual Counties' Retail, Fleet and Private Fueling Facilities Spreadsheets
(Excel Spreadsheets)

Please also read our DISCLAIMER about these lists.

Subject: RE: Background Information on Impact of Gas Stations to Storm Water

Dan-

Sorry for the delayed response on your inquiry. I do not have pollutant loading numbers from gas stations myself. I would contact Mr. Stewart Comstock at the Maryland Department of the Environment for information on those numbers at (410) 631-3563. Ernie Shepp at Metropolitan Washington Council of Governments (unknown telephone number, ask Stew Comstock for it) is another person I would ask. I do have some photos of Delaware Sand Filters in practice, one at a gas station (photos 18 and 19) and one at a fast food restaurant(photos 14-17), both land uses are considered "hotspots" in Maryland regulations. Photos attached. I have also attached an Internet Explorer file with links to non-point source pollution websites where you may be able to gain more information on Gas Stations.

Please contact me if I can be of further assistance.

Daniel J. O'Leary, P.E.

Subject: Background Information on Impact of Gas Stations to Storm Water

Hello,

My name is Dan Radulescu and I am a Water Resources Control Engineer at the CAL-EPA Regional Water Quality Control Board in Los Angeles. We are renewing the MS4 Permit for LA County and I need background information on the impacts of gas stations on the quality of storm water runoff.

We've met at the ASCE Workshop on Friday, and you mentioned that you may have some slides and background information on the efficiency of filters as BMPs at gas stations (Delaware filters). You also mentioned that you may have some contact persons who studied this problem and may have some additional information on the impact of gas stations (referred to as hot spots) on the quality of storm water runoff, and how the requirements for gas stations have developed in the East Coast area States.

I appreciate your help and Dr. Xavier Swamikannu also extends his thanks for your support.

Dan Radulescu
dradules@rb4.swrcb.ca.gov

Article 2

Feature article from Watershed Protection Techniques. 1(1): 3-5

Hydrocarbon Hotspots in the Urban Landscape

Two central paradigms emerged from the EPA's Nationwide Urban Runoff Study in the early 1980s. One was that pollutant concentrations in urban runoff were more or less the same regardless of the contributing land use. The second was that urban runoff carried relatively few priority pollutants, most of which were metals.

Subsequent monitoring has generally reinforced both paradigms, particularly for conventional pollutants such as sediments, nutrients, and organic carbon. However, two recent research studies suggest that there may be major exceptions to these paradigms. The studies point to the existence of *hotspots* in the urban landscape that produce significantly greater loadings of hydrocarbons and trace metals than other areas.

Hotspots are often linked to places where vehicles are fueled and serviced, such as gas stations, bus depots, and vehicle maintenance areas. Others occur where many vehicles are parked for brief periods during the day (convenience stores and fast food outlets), or where large numbers of vehicles are parked for a long time (commuter parking lots).

Hotspots are evident in the data of Schueler and Shepp (1992). Their survey of oil and grit separators in suburban Maryland show the differences in the quality of pool water and trapped sediments in separators draining five different paved areas (Table 1). Gas stations and convenience stores had much higher levels of hydrocarbons and metals both in the water column and the sediments. Streets and residential parking lots, on the other hand, had much lower hydrocarbon and metal concentrations.

Gas stations were found to be an extremely significant hotspot for hydrocarbons. Composite priority pollutant scans at the gas station sites revealed the presence of 37 potentially toxic compounds in the sediment and 19 in the water column. Many compounds were polycyclic aromatic hydrocarbons (PAHs) that are thought to be harmful to both humans and aquatic organisms (Table 2). Non-gas station sites, on the other hand, recorded far fewer priority pollutants that had much lower concentrations.

Pitt and Field (1991) monitored metal and PAH levels in runoff from a number of sites in Mobile,

Table 1: Sediment and Pool Water Quality Found in Oil Grit Separators at Various Urban Locations (Schueler and Shepp, 1992)

Parameter	Gas Stations	Convenience Stores	All-Day Parking Lots	Streets	Residential Parking
Comparative Sediment Quality (reported in mg/kg of sediment)					
Total P	1,056	1,020	466	365	267

Zinc	554	201	190	92	ND

ND = Not Detected   * in units of mg/l

Table 2: Some Priority Pollutants Detected in Gas Station Oil Grit Separator Sediments or Pool Water (Schueler and Shepp, 1992)	
Napthalene	Di-n-octyl pthalate
2-Methylnapthalene	Benzo(b) flouranthene
Acenapthene	Indeno (123-cd) pyrene
Flourene	Di-n-butyl pthalate
Phenathrene	Toulene
Flouranthrene	Ethyl benzene
Pyrene	Total xylenes
Butylbenzylpthalate	Methylene chloride
Chrysene	Benzene
	Acetone phenols

Alabama, including vehicle service areas, parking lots, salvage yards, landscaped areas, and loading docks. They employed the rapid Microtox procedure to assess the possible toxicity of several hundred runoff samples.

Although their monitoring data was variable, they reported that many of the maximum PAH and metals concentrations in runoff samples were found at vehicle service areas and parking lots, as opposed to street surfaces. Of greater concern, nearly 60% of the hotspot runoff samples were classified as moderately to most toxic, according to their relative toxicity screening procedure.

Are Hotspots Environmentally Significant?

The mere presence of high pollutant concentrations at hydrocarbon hotspots does not always imply actual toxicity. Indeed, acute toxicity to aquatic organisms exposed to hotspot runoff is probably a rare event. This is due to relatively brief exposures during storm events, large dilution factors in urban creeks, and the fact that many pollutants are strongly bound to sediments and thus are not readily available to aquatic life. Pitt and Field (1992) reviewed a series of studies that provide convincing evidence of longer-term chronic toxicity to aquatic organisms when exposed to urban runoff.

The greatest environmental risk appears to occur when metal and hydrocarbon-laden sediments are deposited in downstream lakes and estuaries. The bottom sediments of many small, highly urbanized estuaries are heavily contaminated with metals and PAHs. Runoff from urban hotspots appears to be a major contributing factor to sediment contamination in these cases, as witnessed in both the Anacostia and Delaware estuaries (Schueler and Shepp, 1992; McKenzie and Hunter, 1979). The consequences of sediment contamination often include greatly reduced benthic diversity and transfer of pollutants into fish tissue. Techniques to remedy bottom sediment contamination are in their infancy, and have yet to be proven effective.

Difficulty in Treating Hotspots

Few stormwater technologies are currently available to effectively control the runoff from hydrocarbon hotspots. Most hotspot source areas are less than an acre in size, exist in already developed areas, and are widely scattered across the urban landscape. Nichols (1993) notes that there are over 1,500 vehicle maintenance operations in the Washington, DC area alone.

The most common method to control hydrocarbon loadings from small sites has been the oil grit separator (OGS). It consists of a concrete structure linked to the storm drain system with two pools used to trap oil and grit (Figure 1). Recent research, however, indicates that oil grit separators are not effective in trapping pollutants (see article 119). For example, in field inspections of over 100 OGS systems, the average depth of trapped sediment was found to be a mere two inches.

Further, the mass of trapped sediments in OGS systems did not increase over a five year time frame. Monthly sampling revealed sharp reductions in the depth of trapped sediments of as much as 25 or 50% from one month to the next. Dye tests indicated that OGS systems had a residence time of less than 30 minutes during even minor storms. In contrast, Pitt *et al.* (1991) conclude that at least 24 hours of settling are needed to achieve any meaningful reduction in potential toxicity from hotspot areas.

The poor performance of oil grit separators can be attributed to three key flaws: (1) an on-line design that promotes frequent resuspension of previously deposited oil and sediments, (2) insufficient treatment volume, and (3) poor internal geometry.

Prospects for Improving On-Site Technology

Can the dismal performance of the current generation of oil grit separators be improved? New off-line designs have been developed in a number of communities to reduce resuspension (Shepp, 1992). Not much performance data are yet available to evaluate the performance of these new designs. However, it is reasonable to expect that they will be more retentive than current designs, but the question remains—by how much?

Ultimately, the effectiveness of any design is dependent on regular and frequent clean-out of trapped sediments. This, unfortunately, has been the "Achilles heel" of existing OGS technology. For example, in a recent Maryland study not a single OGS system out of over 100 inspected had ever been maintained.

Four factors explain this poor track record. First, a market does not yet exist to clean out and dispose of sediments. Few vendors are available to perform the task themselves. Second, many local governments have been slow in enforcing clean-out requirements on small business owners. Third, clean-outs are quite expensive, ranging from as much as $1,000 to $2,000

R0009370

per site each year. Lastly, concerns about the actual or perceived toxicity of the trapped sediments have limited options for safe and economical disposal. Many landfill operators are loath to accept wet sediments with pollutant concentrations on the order of those reported in Table 1.

Sand filters may turn out to be a better alternative for treating runoff from hydrocarbon hotspots than OGS systems. As a filtering medium, sand is very effective in "straining" out hydrocarbons and metals. Also, most sand filters are designed to treat a much greater volume of runoff than OGS systems. Perhaps most importantly, clean-out of sand filters is easier and less frequent. On the downside, sand filters are more expensive to construct, and may still be subject to disposal problems at some hotspot sites.

Source control may hold the greatest promise to reduce the delivery of pollutants from hotspots. This pollution prevention approach stresses the importance of eliminating the spills, leaks, and emissions that create the hotspot in the first place. A series of better handling, recycling, storage and disposal practices can reduce the chance that automotive fluids and cleaning solvents come into contact with rainwater and run off the site. The Santa Clara Valley Nonpoint Source Program has published an excellent summary of pollution prevention practices for gas stations (see article 136).

Summary

Although small in size, pollution hotspots are prevalent in the urban landscape. More monitoring is needed to define the magnitude of the metal and PAH loads they deliver to downstream waters. Currently, few effective techniques are available to treat hydrocarbon hotspots. Further testing of new designs of oil grit separators and sand filters is warranted.

In the end, our capability to reduce hotspots may well depend on solving institutional problems—assuring regular and environmentally safe sediment clean-outs, and preventing pollutants from being exposed to stormwater runoff at hotspot areas. **See also articles 119 and 120.**

Numerous types of pollutants can enter a stream from the street surface.

Slide 36 of 75

Notes:

The sources of pollutants in stormwater are predominately associated with impervious areas. Impervious areas act as a collector and conveyor for pollutants that arrive from many pathways. Pollutants can fall out of the sky during dryfall. They may also arrive in rain or snow as wetfall. Automobiles are also sources of pollutants. Wear of tires (a known source of zinc), deteriorating brake pads, or just leaks, drips and spills of oil and other pollutants from the car can accumulate on impervious surfaces. Pollutants can also be blown in from adjacent pervious areas. Pollutants land on the street where they often stay in curbs, cracks and other areas until the next rain storm where they are washed off the surface and into the storm drain system and ultimately to receiving streams.

Notes:

Stormwater hotspots are areas which produce higher concentrations of pollutants than normally found in urban runoff. Certain areas of the urban landscape are known to be hotspots of stormwater pollution. Examples include gas stations, parking lots, and auto recycling facilities. Generally, stormwater hotspots contribute 5 to 10 times higher concentrations of trace metals and hydrocarbons in stormwater runoff. These hotspots merit special management and pollution prevention activities.

Cars Are Leading Source of Metal Loads in California

Metals can follow many pathways before they become entrained in urban stormwater run off. A recent California study sponsored by the Santa Clara Valley Nonpoint Source Program suggests that cars are the dominant loading source for many metals of concern, such as cadmium, chromium, copper, lead, mercury, and zinc.

Researchers examined the significance of various metal pathways into the Lower San Francisco Bay. Specifically, the comparative loading potential of five urban source areas were studied using a mass balance approach. The sources were atmospheric deposition, automotive leaks and wear, runoff from industrial and residential sites, and water supply.

Cars and other vehicles were found to produce over 50% of the total load of three metals: copper, cadmium and zinc. This number was generated even without accounting for tailpipe emissions that produce further atmospheric deposition of metals. For example, 50% of the total copper load to the Bay was attributed solely to brakepad wear.

Atmospheric deposition accounted for an additional 25% of the total copper load, much of which came from mobile emission sources, such as cars. Copper consistently ranks as a metal of great concern because it can be acutely toxic to aquatic species even at low concentrations.

Another major metal loading pathway was the wear and tear of automobile tires. The authors conclude that tire wear alone could account for at least half of the total cadmium and zinc loads delivered to the Bay each year. Since both brakepads and tires wear directly onto impervious surfaces, it is likely that the delivery of the metals into the storm drain system is almost 100%.

The authors note that the most effective, and perhaps the only, technique to reduce copper, cadmium, and zinc loads would be to get the automotive industry to reduce the metal content of tires and brakepads. This "pollution prevention" approach has historically worked in such cases as unleaded gas and engine coolants.

Atmospheric deposition, however, remains the primary loading pathway for lead. The chief culprit appears to be exhaust from diesel-fueled vehicles. Diesel fuel exhaust also factored as a significant source for chromium, silver, mercury, copper, and zinc. Again, a pollutant prevention strategy that focused on cleaner fuels or reducing vehicle emissions was recommended.

The authors made an attempt to calculate metal loadings from leaks of motor oil, gasoline, and coolant leaks from cars, as well as illegal disposal from oil and coolant changes. The data on leak and illegal disposal rates is extremely sketchy. For example leak rates of 0.3, 0.01, and 1.2% of all cars were cited for gasoline, motor oil and coolant, respectively. The rate of illegal disposal of motor oil was estimated to be 15%.

Based on these rates, leaks and illegal disposal were not believed to be a major pathway for metals into stormwater drains (about eight and 2% of the copper and zinc load, respectively).

The metal load contained in stormwater runoff from industrial sources could not be calculated due to a lack of data. However, the authors ranked the potential importance of different industrial source areas to contributing metal loads. The industrial categories with the highest risk for metal loading included mining activities, metal plating and galvanizing operations, metal scrap processing, boat building/repair, and automotive repair. Automotive repair was by far the most prevalent "industrial" activity in the basin.

Multi-Chamber Treatment Train Developed for Stormwater Hot Spots

Stormwater runoff from paved urban "hot spots," particularly automotive service and repair stations, can contain pollutant concentrations three to 600 times greater than those found in other urban sources. The higher potential for heavy stormwater pollutant loading becomes apparent when one also considers the multitude of potential hot spots located throughout urban areas (Table 1). This being the case, it becomes prudent to treat a relatively small amount of runoff at the source as opposed to allowing contaminated runoff to become part of a much larger volume that may or may not be effectively treated at the end of the pipe.

Effective, on-site treatment of stormwater hot spots has been a problem for several reasons. First, most hot spots tend to be small in size and lack adequate space for the installation of typical stormwater management practices such as ponds and wetlands. Second, the use of gravitational settling as a sole pollutant removal mechanism does not provide sufficient hot spot pollutant removal. Third, infiltration is not an option due to risks of groundwater contamination. Lastly, the traditional underground approaches using oil grit separators have not been reported to be effective (Schueler, 1994).

To help solve the hot spot treatment problem, Robert Pitt and his colleagues at the University of Alabama-Birmingham have developed and tested a prototype known as the multi-chambered treatment train (MCTT). This device employs screening in the first chamber, settling in the next, and filtration in the last (Figure 1). It is designed for underground use. It can be sized to contain runoff from various rain events and typically requires between 0.5 and 1.5% of the paved drainage area. Present information places construction costs of the MCTT ranging from $10,000 to $20,000 per one-quarter acre of drainage area, assuming use and availability of prefabricated units (Pitt, personal com-

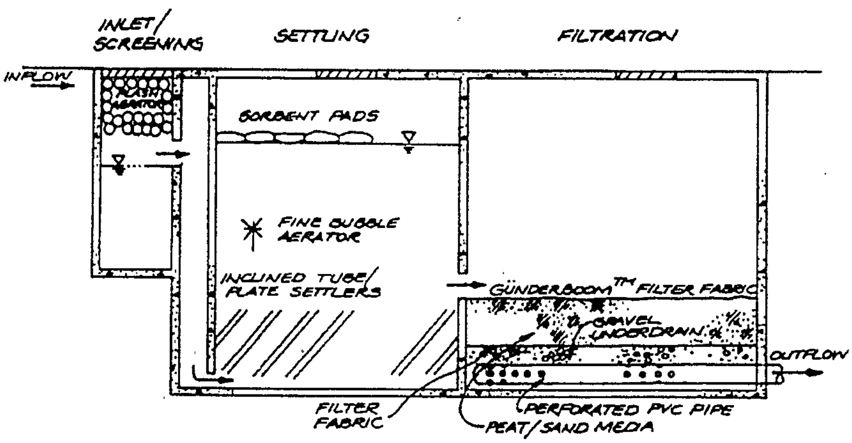
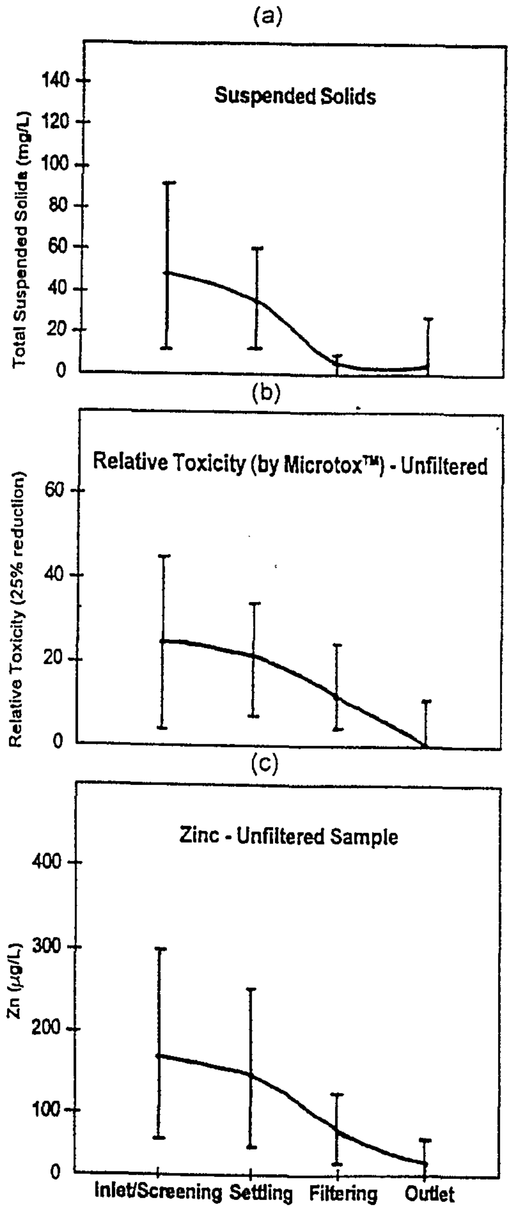
Table 2: Specialized Components of the MCTT

Chamber	Component	Description	Function
Inlet	flash aerator	small column packing balls with counter current air flow	removes volatile pollutants and traps trash
	catch basin sump	conventional catch basin sump	traps grit and sand-size particles
Settling	sorbent pads	floating absorbent pads	traps oil and grease
	fine bubble aerator	generator powered fish farm aeration stone	enhances aeration
	inclined tube or plate settlers	plastic tubes 2" x 2', inclined 30-45 degrees, arranged in rows ofopposing direction	increases surfaces area of settling chamber; enhances sedimentation and prevents scour
Filtration	Gunderboom™ filter fabric	covers top of filter	reduces channelization, slows infiltration, sorbs oils
	peat/sand filter media	50/50 mix, at least 12" depth	removes small and dissolved particles, provides ion exchange
	filter fabric	separates peat/sand layer from gravel and pipe layer	prevents gravel layer from clogging
	gravel packed under drain	perforated PVC pipe and gravel	provides additional filtration/outlet



The multi-chamber treatment train (MCTT) consists of three treatment units in sequence—an inlet screening chamber, a sedimentation chamber and a filtration chamber. Most of the high pollutant removal occurs in the last two chambers.

Figure 2: Detailed Schematic of the MCTT



Depending on the nature of the pollutant, the MCTT provides greatest removal in the settling chamber (panel a) or the filtration chamber (panel b and c).

Figure 3: MCTT Pollutant Removal Profile by Chamber

munication). Additional data on operation and maintenance costs of the MCTT is currently being collected.

The MCTT is divided into three main chambers (Figure 2). Stormwater enters the first chamber where the largest particulates are screened out and the bulk of highly volatile materials are removed when they pass over a flash aerator (additional, innovative components within each chamber are listed in Table 2). The stormwater then either flows under gravity or is pumped into the settling chamber. Here, settling of fine sediment is enhanced through the use of inclined tube or plate settlers while floating hydrocarbons and additional volatile compounds are removed by sorbent pads and bubble diffusers. Next, the stormwater flows, or is pumped slowly into, the filtration chamber containing a sand and peat filter bed for final removal of dissolved toxicants. The filter also functions in the partial treatment of runoff that may have bypassed prior chambers in the event of excess stormwater flow. To ensure that the water volume is distributed evenly over the filter bed, a fabric covers the top of the filter.

The size of this device varies according to the climatic conditions of the geographic region being served. Parameters considered include: rainfall amount, intensity, and elapsed time between storms as well as suspended sediment load and desired maintenance regime. Pitt has developed a computer model to aid in the site-specific design.

A pilot-scale MCTT was constructed by Pitt on the campus of the University of Alabama- Birmingham. This device, designed to catch runoff from a vehicle service area and parking facility, was tested over a six-month monitoring period from May to October of 1994. Two additional full-scale units have since been constructed in Wisconsin for testing how this technology functions in a colder climate. Preliminary pollutant removal data from the Wisconsin site is presented in Table 4.

Preliminary performance results of the pilot-scale MCTT for 13 storm events indicate substantial reductions of total suspended solids, heavy metals, and both dissolved and suspended stormwater toxicity from the unit overall (Table 4). Toxicity values were obtained using a Microtox™ screen that analyzes specific toxins in both dissolved and suspended forms. This test not only detects nonconventional pollutants in stormwater but establishes a standard by which to measure their "treatability."

Of notable significance is the inlet chamber where screening occurs. Screening has little effect on pollutant removal (it has virtually none) but serves an important role in trapping large materials, thereby reducing problematic maintenance concerns throughout the device and enhancing the ability of other chambers to remove pollutants.

Table 3: Prototype (Alabama) MCTT Pollutant Removal Efficiency Rates Based on Concentration Changes from Inflow to Outflow

Pollutant	Screening Chamber	Settling Chamber	Filtration Chamber	Overall Performance
TSS	nsd*	91	-44	83
Turbidity	(some reduction)	50	-150	40
COD	nsd	56	-24	60
Nitrate	nsd	27	-5	14
Ammonia	nsd	-155	-7	-400
Phosphate	nsd	nsd	1c	-
Toxicity (suspended)	nsd	18	70	96
Toxicity (dissolved)	nsd	64	43	98
Lead	nsd	89	38	100
Zinc	nsd	39	62	91
n-Nitro-di-n-propylamine	nsd	82	100	100
Pyrene	nsd	100	NA	100
bis (2-ethylhexy) phthalate	nsd	99	-190	99

*nsd = inflow and outflow concentrations were not significantly different at the 0.05 level

The settling chamber was responsible for most of the pollutant reductions in suspended solids, lead, zinc, polycyclic aromatic hydrocarbons (PAHs), turbidity, COD and to a lesser degree, nitrate and toxicity. The filter chamber provided additional removal of most toxicity and heavy metals. Ammonia nitrogen was increased by several times and nitrate-nitrogen had a very low removal rate. However, this finding is to be expected given the anaerobic nature of the filter system.

Preliminary monitoring data from two full-scale application of the MCTT in Wisconsin appear to confirm that it can achieve consistently high removal for solids, nutrients, metals and two polycyclic aromatic hydrocarbon (see Table 4). The Wisconsin test sites involved a similar design that treated stormwater runoff from a quarter-acre maintenance yard and a newly paved parking lot.

Based on the initial monitoring of the prototype and full-scale system, it appears that the design provides superior performance to conventional sand filter systems (see Table 4), which is reasonable considering that the sand filters employ much less sophisticated measures for screening, settling and filtration.

Pitt's study design was arranged to isolate the relative contribution of each of the three chambers—screening, settling and filtration—to the overall pollutant removal of the system (Figure 3). Pitt found that the importance of each chamber depended on the type of pollutant entering the system. For example, many suspended pollutants were removed quite efficiently using just the settling process, whereas the filtration chamber was responsible for further reduction of those same pollutants as well as the additional removal of dissolved pollutants. Suspended solids were reduced somewhat by screening but were almost totally reduced by settling while filtration was of no consequence (Figure 3, panel a).

Toxicity was basically unaffected by screening, received slight treatment in the settling chamber but was reduced significantly by filtration. This comparison is a clear illustration of the relative importance of settling versus filtration for certain types of pollutants. As shown in panel c of Figure 3, screening accomplished in the inlet chamber only achieved negligible zinc reductions. Pollutant removal was attained through settling followed by more extensive removal from filtration.

Further analysis of MCTT pollutant removal capabilities may be obtained through testing the efficiencies of the innovative components within each chamber and the effects they have on improving and enhancing the three processes of screening, settling and filtration. Given variable climates and pollutant concentrations present at hot spots, a full application of the MCTT may only be needed when a very high level of treatment is desired.

ABSTRACT

This study was initiated with the specific objective to evaluate the impact of AADT on highway pollutants concentration. Analysis of data collected from Caltrans 3-Year (1997-00) highway runoff characterization program revealed that, in general, pollutant concentrations in urban highways were 2 to 10 times higher than those found in non-urban highways. For some pollutants, however, the pollutants in non-urban highways were found to be higher than the pollutant concentration in urban highways. No linear correlation could be found between highway runoff pollutant's event mean concentrations (EMCs) and the AADT. Correlation coefficient in linear regression between pollutant concentration and AADT is a measure of their linear relationship, not a lack of association or influence. In fact, by conducting multiple regression analysis it was shown that AADT was found to have some influence or association with most highway runoff constituent concentration. AADT was not the only factor that could influence the accumulation of pollutants in highways. Other noticeable factors were antecedent dry period, drainage area, maximum rain intensity, and land use.

Keywords: Average annual daily traffic (AADT), highway runoff, linear regression model, multiple regression model, and pollutants.

INTRODUCTION

Caltrans is engaged in a multi-year program of research and monitoring on the environmental effects of stormwater quality from their facilities. Part of the Caltrans storm water quality research and monitoring program relates to the characterization of highway runoff (Kayhanian et al., 2001). These monitoring studies are principally undertaken to comply with the statewide National Pollution Discharge Elimination System (NPDES) storm water permit. The information presented in this paper is based on three-year highway stormwater runoff characterization study that was undertaken during the 1997-00 winter seasons. Data generated from these monitoring studies were compiled into three broad categories of sample description, event description and site description in a database.

These monitoring data are analyzed on a regular basis to assess Caltrans storm water runoff characteristics. One question that is continuously asked is whether annual average daily traffic (AADT) impacts concentration of highway runoff pollutants. This paper is prepared to address this issue. To achieve the stated objective, this paper is organized to present: (1) methods, (2) results and discussions, and (3) conclusions.

METHODS

Highway Runoff Monitoring

Caltrans highway storm water runoff monitoring was accomplished using the specification presented in the Caltrans Guidance Manual: Storm Water Monitoring Protocols (Second Edition, July 2000). The highway runoff characterization was carried out by preparing an extensive Sampling and Analysis Plan (SAP) covering the detail information on: project overview/description, site selection, analytical constituents, data quality objectives, field equipment maintenance, monitoring preparation and logistics, sample collection, sample preservation, sample delivery, quality assurance/quality control, laboratory sample preparation and analytical methods, data management and reporting procedures. Description of each of the above topics is beyond the scope of this paper. However, a brief description of monitoring sites, analytical methods, and steps taken to evaluate the monitoring data are briefly described below.

Monitoring Sites

During the span of 1997 to 2000 monitoring seasons, fifty (50) highway sites were monitored for water quality characteristics. These highway sites were located in 7 of the 12 Caltrans districts (see Figure 1). General physical characteristics of these sites including the AADT are summarized in Table 1.

Analytical Method

Stormwater samples were collected as flow-weighted composite samples. These flow-weighted composite samples were analyzed for constituent event mean concentration (EMC). Different types of constituents that were analyzed during the course of monitoring are summarized in Table 2. These constituents are organized as: (1) conventionals, (2) metals (total and dissolved), (3) nutrients (4) major ions and minerals, (5) microbiological, (6) oil and grease, and (7) pesticides. All laboratory analyses were conducted according to the *Standard Methods* and the USEPA analytical methods specified in the Caltrans Guidance Manual (Second Edition, July 2000). Standard lab QA/QC procedures were followed and analytical results were qualified as necessary based on the results of the QA/QC evaluations.

Highway Runoff Data Evaluation

The following key steps were taken to evaluate the Caltrans highway storm water characterization data.

Data Reporting: To aid in development of a statewide monitoring database and to maintain consistency, Caltrans has established a data reporting protocol (July 2000) that is being used by all monitoring teams collecting and reporting data as Excel spreadsheets to the Caltrans. To ensure uniformity, entries into the data fields have been as standardized as possible.

Database: Once the Excel® spreadsheets are reported to Caltrans per the data reporting protocols, data are imported into an Access® database that holds statewide monitoring data. Data is stored in three main tables:

- Sample Description,
- Sampling Event Description, and
- Site Description

Sample description consists information specific to individual samples including lab results, analysis methods and date information. Event description consists of precipitation event descriptions for each monitoring site such as start and end time, maximum intensity, antecedent dry period, and total flow volume. Site description describes location of the site along with some physical characteristics of the site.

Quality Assurance/Quality Control: All the data reported by the laboratory is reviewed to ensure that the project's data quality acceptability limits and objectives (DQOs) have been met. QA/QC parameters that are reviewed include: reporting limits, holding times, contamination check results, precision and accuracy analysis results. In addition, automatic data checker is used to ensure referential integrity of the database and compliance with data reporting protocols.

Working Data File: The statewide database was queried to extract an Excel file that contained all the highway monitoring sites along with their characteristics like Annual Average Daily Traffic (AADT), land use (LU) and drainage area (DA). For the sampling events antecedent dry period (ADP) and maximum intensity (MI) information was tabulated. Finally for all the highway sites, laboratory analysis results including reported value, units and reporting limit were extracted for the constituents listed in Table 2.

Data Analysis: In most part, the concentrations of highway runoff were reported above the designated reporting limit. Under these conditions, conventional statistical approaches were used to analyze data. For the constituents for which the reported value was below reporting limit the constituent concentration were considered to be non-detect. For the purpose of this report all non-detect value were substituted with one-half of the reporting limit for the conventional statistical analysis.

RESULTS AND DISCUSSIONS

Urban and Non-Urban Highway Runoff Characteristics

The results of AADT values for all fifty highway sites were previously shown in Table 1. As shown, the AADT values ranges from as low as 2200 vehicle per day (VPD) to as high as 307,000 VPD. A report prepared by Driscoll et al (1990) for the Federal Highway Administration (FHWA) attempt to divided highway sites into two general categories of urban and non-urban. According to the report, the highways with AADT values greater than 30,000 are considered as "urban" and those with AADT value less than 30,000 are "non-urban."

Due to large variation in urban AADT values (AADT>30,000 VPD), a single classification for urban highway was found to be impractical in terms of finding a correlation between pollutants and AADT. For this reason the urban highways were further classified into four categories of low, medium, medium high, and high based on the number of vehicles per day (VPD) as shown in Table 3.

Table 3
Classification of Non-Urban and Urban Highways Based on AADT

Classification	AADT Values
Non-Urban Highways	AADT<30,000
Urban Highways	
Low	60,000>AADT>30,000
Medium	100,000>AADT>60,000
Medium High	200,000>AADT>100,000
High	AADT>200,000

A general highway runoff characteristic for both urban and non-urban highways is summarized in Table 4. Results of the average runoff pollutants for both urban and non-urban highways are presented in Table 5. As shown in Table 5, there is a significant difference in the constituents' concentrations at sites with AADT greater than 30,000 (urban highways) and those with AADT less than 30,000 (non-urban highways). On average the concentration of most pollutants in urban highway runoff are 2 to 5 times higher than non-urban highway runoff. Concentrations of more than ten times were noticed for total lead, sodium, and turbidity for urban highway runoff compared to non-urban highways. The higher concentration of pollutants in urban highways will not necessarily address the issue of correlating pollutant with AADT. This aspect of the study is further discussed below.

Correlation Between Highway Runoff Pollutants and AADT

Single Linear Regression Model

A single linear regression analysis was performed to determine the correlation between AADTs and different highway runoff pollutants. The result of this analysis based on R-squared (R^2) value is shown in Table 6. As can be seen, extremely low R^2 values were obtained for all constituents. The low R^2 value suggests weak or no correlation between AADTs and pollutant concentration.

Single linear regression analysis is a useful, but relatively crude form of data analysis. For better understanding of the relationship being examined and to avoid faulty conclusions produced by regression, it is important to examine the data sets by plotting. Two sets of plots were prepared. One is bar graph and the other is scattered plot. The bar and scattered plots for Copper and Lead is shown in Figures 2 and 3, respectively. Bar graphs present the average pollutant concentration against the defined range of urban AADT values and the scattered plots show the pollutant EMC from urban highway sites against their respective AADT values. Nearly all other data plotting examined, no strong correlation between AADT and pollutant concentration could be found.

Several studies attempt to correlate AADT to highway runoff pollutants, most of which could not find a good correlation. For example, Chuiet et al (1982) found only weak correlation. A study conducted by FHWA (Driscoll et al. 1990) suggests that there is no strong and definitive relationship between differences in traffic density and the pollutant level for a site. They conclude that, other than the use of AADT as a surrogate measure to distinguish between "urban" and "non-urban" highways, further use of AADT to refine estimates of pollutant levels in runoff has no supporting basis. Another study conducted by Stotz (1987) on highway runoffs in Germany, also concluded that the amount of pollutants concentration is not dependent on traffic frequency. The results obtained from Caltrans highway storm water runoff monitoring data support those findings that there is no strong relationship between AADT and the highway runoff pollutant.

Other investigators found a weak or somewhat better correlation between AADT and highway runoff pollutants. For example, Dormen et al. (1988) found a direct correlation between pollutants and AADT. In another study McKenzie and Irwin (1983) found that the concentration of lead and zinc are related to AADT and COD concentration is strongly related to AADT. Quantitatively, the positive or negative correlations of pollutants with AADT can be explained if the source of contaminants is taken into consideration. For example, zinc, cadmium, copper, lead, and oil&grease are known to be related to transportation activities and hence is expected to have a positive correlation with AADT (Laxen and Harisson 1977, Gupta et al. 1981, Kim and Fergusson 1994, Moe et al. 1982). On the other hand, nitrogen associated with atmospheric deposition is expected to have little or no correlation with AADT (Young 1996). Pesticides are other pollutants that are commonly found in highway runoff that are considered with atmospheric deposition.

Consider the average concentration of ammonia and TKN against non-urban and urban AADTs (see Figure 4). As expected, no correlation could be found between these pollutants and AADTs. Similarly, the concentration of Diazinon and Chlorpyrifos found in highway runoff are also considered to be associated with atmospheric deposition and has nothing to do with AADT values. But, the results have shown in Figure 4 indicate both Diazinon and Chlorpyrifos concentration increased as the values of AADT increased. This correlation can be problematic since the pesticide source can not be related to the transportation activities. It is, however, possible that there are higher atmospheric deposition of these pollutants in urban compared to non-urban areas.

Results obtained for metals concentrations, which can quantitatively be related to transportation activities, revealed opposite conclusions as presented in the literature. For instance, as shown in Figure 5, the average Cadmium (Cd) concentration decreased as AADT values increased (only dissolved Cd is shown). Similarly, looking at 5 a proportional increase in total and dissolved Cu, Pb, and Zn average concentration (only total concentration is shown) relative to AADT values could not be established. Oil and grease (see Figure 16) is the only pollutant concentration showed a strong correlation with AADT and quantitatively be related to transportation activity.

Previous linear regression analysis performed on most highway runoff pollutants showed that there is a weak or no correlation between constituents' concentration and AADT. It is important to remember that the correlation coefficient between pollutant concentration and AADT is a measure of their linear relationship, and that the value of $R^2 = 0$ implies a lack of linearity and not a lack of association. It is however, possible to argue that these lack of linear correlation is due to unusual data point in specific data set known as *outlier.*

Close examination of plotted data (for example see Figure 3) indicate that for some pollutant there is one or more outlier data, substantially higher than all other values in data set. Even though the data was processed through vigorous QA/QC, the validity of these data for those specific sites is questionable. Clearly these data are not consistent with the remaining data, and at best suggest an unusual or atypical situation. The inclusion of these data points in regression analyses may influence the correlation relationship between pollutant concentration and AADT.

Consider the possible outliers for TSS, Pb, and Ortho-P shown in Figures 7, 8 in which, removing these outliers did not improve the regression coefficient. Similar results were obtained for other conventionals, metals, nutrients, and major ions in which exclusion of the possible outliers did not result in any significant improvement in R-squared value. On the contrary, removal of possible outliers resulted in reduction of R-squared value in some cases. In conclusion, the presence of outliers in data sets was found to have little or no influence on constituent's correlation with AADT.

From the findings of this study and information presented in the literature, the validity of AADT as a predictor in regression type analysis should only be considered on a broad-scale measure of pollutant loads. Possible reason for the lack of regression correlation, are may be due to factors such as wind, vehicular turbulence, volatilization, and oxidation process. These factors will limit the accumulation of pollutants on road surfaces and thereby decreasing the importance of AADT for short time (Irish et al. 1995, Winstrom and Matsumoto, 1999). In the absence of strong correlation between AADT and pollutant, few investigators (Keri et al. 1985, Chui et al. 1982) suggest that AADT during storm event, vehicle during storm (VDS), is a better independent variable for estimating total runoff loads for certain pollutants. Literature reviewed by Winstrom and Matsomoto (1999), however, conclude that AADT is not generally expected to be useful as a control variables for the design, operation, and maintenance of specific runoff control structure as traffic intensity on a particular stretch of highway is expected to fairly constant from day to day.

Multiple Regression Model

Evaluation of the plotted data and linear regression analysis revealed that there is no strong correlation between the highway runoff pollutant concentration and AADTs. Therefore, one can assume that the AADT is not the sole factor of pollutant accumulation in highway sites. It appears that there are other parameters that can influence the pollutant accumulation in highway sites. These parameters may include but are not limited to: drainage area, antecedent dry period, rain intensity, and land use.

In the absence of a strong relationship between AADT and highway runoff pollutants, a search for a better model shifted to a multiple regression where variables other than AADT were considered. The choice of an appropriate method for doing the multiple regression analysis wasn't that straightforward, since the statistical methods give the ability to adjust for variability in one or more confounding factors, but are still have to decide whether we *want* to adjust for the impact of a given variable. For example, the antecedent dry period (how long it's been since it last rained) is one confounder that would have little if anything to do the average daily traffic. Thus it makes sense to adjust for this variable. On the other hand local land use might be associated with AADT, since the more urbanized areas would tend to have certain types of land use, compared to more rural areas. Thus it might *not* be appropriate to adjust for this variable. A third consideration here is that a given analysis can involve only the observations for which all of the relevant variables were measured. Since one of these (the storm's maximum intensity) was not reported for about half of the data, this variable was not adjusted, since by doing so, it would reduce the available data by about half. Three different multiple regression models are used to evaluate the impact of AADT on highway runoff pollutants. These models include: analysis of covariance, stepwise regression, and partial correlation.

Analysis of Covariance: Analysis of covariance (ANOCOVA was selected since the predictors were both continuous and categorical variables. This analysis included all of the predictor variables in the model, along with both linear and quadratic terms in AADT. The results of the ANOCOVA analysis for selected constituents based on *p*-value and R-squared (R^2) is summarized in Table 6.

The effect of AADT on pollutant concentration for all pollutants could not be estimated because there was a lot of confounding in these models. Major confounding factors were largely due to the fact that AADT is a site characteristic and there were enough other site characteristics that can impact AADT. In addition, the rain intensity and antecedent dry period were not reported for all monitoring sites. For these reasons, the ANOCOVA could not be performed for all pollutants. The significance of this analysis was strictly reported in terms of a *p*-value for the effect of AADT in the model, along with an overall R^2 value for the predictive power of the entire model. It is important to note that if p-value is less than 0.05, then the observed relationship is not attributable to chance alone and hence there is nontrivial relationship between the pollutant and the AADT. For those pollutants with p-value greater than 0.05, we can not, however, conclude that AADT is unimportant given the amount of confounding in the model.

Comparing the R^2 of the ANOCOVA model to those predicted by a linear regression model (see Table 5), it can be seen that the correlation relationship has been improved significantly. This improved correlation is assumed to be due to the continuous and categorical predictor variables that were included in the ANOCOVA analysis. The influence of these predictor parameters is evaluated by stepwise regression as discussed below.

Stepwise Regression Analysis: This model was chosen to evaluate the impact of the most important predictors for a given pollutant from the full set of predictors, and then assess the impact of AADT on the outcome after adjusting for that shortened list of predictors. The result of this analysis is presented in Table 7.

The significance of each predictor variable in the stepwise regression analyses were evaluated in terms partial R^2 value and the *p*-value for testing whether a predictor is impacting the dependent variable (pollutant). The partial R^2 value indicates how much of the variation in the dependent variable can be explained in terms of the predictor variable, apart from variation that can be explained in terms of other predictors in the model. In general, low partial R^2 value was obtained for the predictor variables evaluated for common highway runoff pollutants. The low partial R^2 values indicate that no single predictor can uniquely attribute to dependent variable. The results, however, revealed that AADT and ADP, and MI (maximum intensity) are among the common predictor variables for most pollutants.

The *p*-value is interpreted as the probability that the amount of variability attributable to a predictor would have been at least as large as the observed value, if there was in fact no relationship and this was due to chance alone. If the p-value is small (traditionally 0.05 or less), then the observed relationship is not attributable to chance alone, and we conclude that there is in fact a non-trivial relationship between the predictor and the response. Referring to Table 7, impact of predictors on each pollutant are reported as positive, negative, concave, or convex response. Interpretation of these responses is shown as table footnote.

Interspersed with the stepwise regression results, a series of equations were developed to show the non-trivial relationships. These equations indicate both the *direction* of each relationship (i.e., whether the response increases or decreases as a function of the predictor) as well as its strength or elasticity. For example the stepwise correlation relationship predicted for Cadmium is shown in Equation 1.

Equation 1:

Cadmium concentration

$$= 97.647 - 0.00149 \times AADT + 0.0000000038 \times AADT^2 + .0795 \times ADP - 0.00126 \times ADP^2 - 0.214 \times MI + 1.908 \times DA - 0.0499 \times DA^2 + 8.734 \times LU_C + 43.569 \times LU_I + 7.204 \times LU_R + 47.145 \times LU_T + \epsilon$$

Where,

AADT=	Annual average daily traffic, vehicles/day
ADP=	Antecedent dry period, day
MI=	Maximum rain intensity, mm/hr
DA=	Drainage area, hectares
LU_c=	Land use-Commercial (if the monitoring site was commercial, use 1 for LU_c and 0 for others)
LU_I =	Land use-Industrial (if the monitoring site was industrial, use 1 for LU_I and 0 for others)
LU_R =	Land use-Residential (if the monitoring site was residential, use 1 for LU_R and 0 for others)
LU_T =	Land use-Transportation (if the monitoring site was transportation, use 1 for LU_T and 0 for others)

From Equation 1 it can be seen that AADT has negative impact, whereas the quadratic AADT has positive impact on Cadmium concentration. Opposite relationship was found for antecedent dry period (ADP) and drainage area (DA). The maximum rain intensity (MI) has negative impact on Cadmium concentration. The impact of land use on Cadmium concentration is found to be positive.

It is important to note that direct comparison between different predictors can not be done since they represent the expected change in the response. For instance an increase of 1 unit might be a big change for land use, which can only be equal to zero or one, and a small change for AADT or ADP.

Partial Correlation Analysis: The last analysis performed was partial correlation. This model looked at the strength of the relationship between the constituents and AADT, after adjusting for either all of the other predictors, or else just the antecedent dry period. Because the normality of the data is questionable both parametric (Pearson) and nonparametric (Spearman) correlations were performed. These results are summarized in terms of a correlation and an associated *p*-value in Tables 8 and 9.

Significance of this test can be evaluated in terms of adjusted R^2 correlation and associated *p*-value. As with other correlation measures, the adjusted squared correlation can be interpreted as the proportion of the variability in the response, which can be explained in terms of the predictor. This analysis was performed to limit the risk of concluding significance of a pattern and relating that to AADT, when the pattern observed is in fact due to land use, or drainage area, or something else. Referring to Tables 8 and 9, adjusting the dry period and maximum intensity, as predictor variables, did not significantly improve the correlation coefficient.

In summary, while no direct relationship could be found, significant numbers of pollutants were found to be effected by AADT. In general, however, it's safe to say that while the regression relationship may be significant, they still don't account for that large a fraction of the variability in the dependent variables.

CONCLUSIONS

The following conclusions can be drawn from this study:

- In general, the pollutant concentrations in urban highways (AADT>30,000 vehicle per day) are found to be 2 to 10 times higher than those found in non-urban (AADT<30,000 vehicle per day) highways. However, some of the pollutants in non-urban highways were found to be higher than the pollutant concentration in urban highways.
- No linear correlation could be found between highway runoff pollutant's event mean concentrations (EMCs) and the AADT including those pollutants that are known to be related to transportation activities (e.g., Pb, Cu, Zn).
- Correlation coefficient in linear regression between pollutant concentration and AADT is a measure of their linear relationship, not a lack of association or influence. In fact, the AADT was found to have some influence or association with most highway runoff constituent concentration.
- AADT is not the only factor that can influence the accumulation of pollutants in highways. Other noticeable factors include antecedent dry period, drainage area, maximum rain intensity, and land use.

ACKNOWLEDGEMENTS

We greatly acknowledge many individuals of the monitoring teams who worked relentlessly during the past three years to chase every storm event in California. Without their hard work the information presented in this report would not have been possible. We appreciate the assistance of Mr. Neil Willits from UC Davis Statistics Laboratory who performed multiple regression tests. We are also thankful to Mr. Scott Meyer for his assistance in obtaining the correct AADT for highway sites and preparing Tables 7, 8 and 9; and Mrs. Yolanda Ramirez for her help in literature search.

Technical Note #101 from Watershed Protection Techniques. 2(3): 539-542

Performance of Oil-Grit Separators in Removing Pollutants at Small Sites

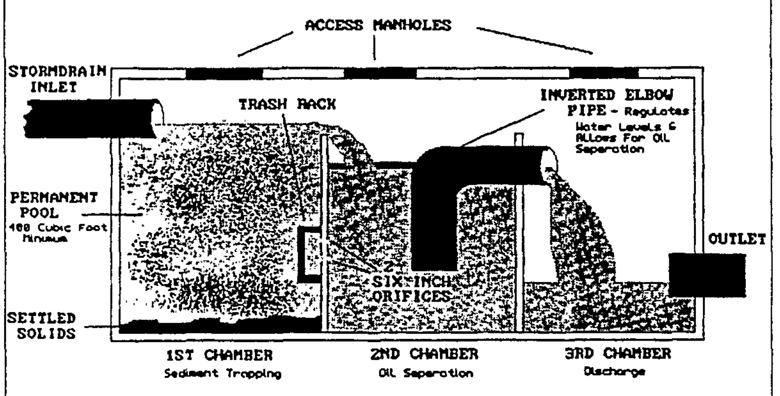
Despite our best hopes, some dogs just won't hunt. The same is true with the performance of some stormwater practices. A case in point is the standard oil-grit separator, or OGS (Figure 1). These underground structures consist of three chambers, two of which are wet. An inverted elbow pipe drains the second chamber, under the theory that oil and grease will initially float on the surface, but then adhere to suspended particles, which eventually settle to the bottom of the chamber. The first chamber is designed to trap grit, coarse sediments, trash and debris. The contents of both chambers are removed on a quarterly basis as part of the normal maintenance regime.

Oil-grit separators are popular because they are relatively cheap and can be easily installed at many small sites without sacrificing land. Unlike other stormwater practices that are sized to handle a half inch or more of runoff, the total design storage volume within an OGS is about a tenth of an inch. While it has always been acknowledged that such a small treatment volume limits overall pollutant removal, it was reasoned that the basic design should at least be capable of trapping oil, grit or trash generated at parking lots. Consequently, OGS systems have enjoyed wide application at gas stations, fast food joints and other small, but highly impervious development sites. Over the last decade, several hundred OGS have been installed across the Washington D.C. metropolitan area, and they are still routinely included in many stormwater practice manuals in other parts of the country.

Our understanding about the pollutant removal capability of the OGS has been fundamentally changed as a result of a five-year research study by Dave Shepp and his colleagues at the Metropolitan Washington Council of Governments. In the first phase of the study, Shepp discovered four indirect lines of evidence that suggest OGS pollutant removal performance is extremely limited. First, dye tests revealed that OGS had very short residence times during small storms (often less than 30 minutes). Second, an average of only two inches of sediment accumulation in the two pool chambers was measured in 109 installed OGSs, and deposition did not increase no matter how long an OGS had been in service. Third, the initial finding that OGS systems did not retain sediments was confirmed by monitoring the accumulation of sediment in 17 OGSs on a monthly basis. Shepp found sediment depths frequently changed within the OGS, but seldom accumulated over time. A characteristic profile is shown in Figure 2. Lastly, none of the 109 OGS surveyed in field were found to have had sediment cleanouts specified in their maintenance agreements.

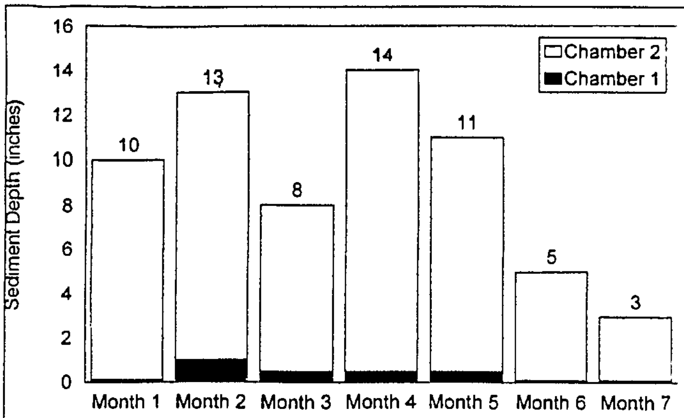
In the second phase of the study, the pollutant removal performance of a typical OGS was directly measured in the field. The OGS served a one-acre parking lot of a fast food joint. Prior small site monitoring revealed that fast food parking lots generated above normal concentrations of many urban pollutants, such as hydrocarbons, nutrients, metals and carbon—giving new meaning to the term "a greasy spoon" (see Table 1). Thirteen storm samples were collected at the OGS site, using innovative sampling techniques within the confined spaces of the practice. Rainfall during the monitored storms ranged from 0.2 to 1.96 inches in depth (median 0.61 inches, mean duration three hours). Inflow and outflow event mean concentrations (EMCs) were then compared to examine pollutant removal performance for 18 different water quality parameters.

By almost any measure of performance, the oil-grit separator did not show any capability to remove pollutants in storm runoff (Table 2). Net negative removal efficiency was computed for suspended sediment, total organic carbon, hydrocarbons, total phosphorus, organic nitrogen, and extractable and soluble copper. Negative removal efficiencies were observed in over half the



An oil grit separator is an underground structure used to treat stormwater runoff at very small sites. Recent research demonstrates that this practice has little or no pollutant removal capability.

Figure 1: Schematic of Standard Design of Oil-Grit Separator



Poor sediment retention in an OGS is evident in the month-by-month fluctuation in the two main chambers.

Figure 2: Change in Sediment Depth in an Oil-Grit Separator over a Seven-Month Period (Shepp, 1995)

Table 1: Mean of Storm Runoff EMCs for Takoma Park McDonald's Site (Shepp, 1995; Rabinal and Grizzard, 1995)

Stormwater Pollutant	Median Concentration (mg/l)	Mean Concentration (mg/l)
Total Suspended Solids	20.8	42.9
Total Hydrocarbons	7.0	12.4
Total Organic Carbon	18.6	41.3
Total Phosphorus	0.27	0.49
Ortho phosphorus	0.06	0.101
Total Nitrogen	2.22	2.85
Total Zinc	0.144	0.452
Total Copper	0.010	0.021

storms sampled for these parameters (with the exception of suspended sediment and soluble copper). Positive removal rates were calculated for a few parameters, most notably ortho-phosphorus, nitrate, lead and zinc, but the improvement in pollutant concentration was often very minor. This is evident when the mean outflow concentrations from the OGS are considered (last column of Table 2). The concentration of nearly every water quality parameter remains well above levels frequently encountered in "untreated" urban stormwater runoff. OGS also appear to have little capability to retain litter and debris, as less than 30% of the OGS surveyed in the project had accumulated moderate to high levels of trash and debris.

Taken together, the four different performance indicators suggest that the OGS tested was a modest exporter of several key storm water pollutants. At first glance, this finding seems physically impossible, as it is hard to imagine an internal source of pollutants within an underground concrete vault. The likely answer to this mystery involves parking lot maintenance. It seemed to be a daily practice for employees to wash down the parking lot to provide a cleaner atmosphere for customers. It is speculated the wash water may have been the source of the missing pollutants.

Based on his research, Shepp recommends that the use of standard OGS design be abandoned at small sites. Performance monitoring has shown sand filters to be a much more effective practice. He contends that no practice is likely to be effective on small sites unless it is designed to capture 0.25 to 0.5 inches of runoff at a bare minimum. Further, such practices should be designed to be off-line from the major storm water conveyance systems. Otherwise, Shepp maintains that the flows from pipes designed to carry the ten-year peak discharge rate will "hydraulically doom" any small site practice.

This contention is supported by recent performance monitoring of a modified oil-grit separator in Austin, Texas. Tom Curran sampled 17 storm events at an OGS that served a parking lot (LCRA, 1996). The modified two chamber tank contained sorbent pillows to adsorb oils, and was regularly maintained. Designed to pretreat runoff for a peat sand filter, the off-line OGS appeared to perform the pretreatment function reasonably well. Curran found that it was able to remove about 10 to 40% of stormwater pollutants that entered it (see Table 3).

Much higher removal rates were recently reported for three full-size, off-line underground structures known as multiple chamber treatment trains or MCTTs (see article 111). The design of these advanced structures stand in sharp contrast to the typical OGS. For example, the MCTT has up to ten times more storage volume than standard OGS design and is equipped with numerous other internal design features to promote greater removal.

In summary, the evidence overwhelmingly suggests that oil-grit separators are a very poor stormwater practice and should probably be dropped as a treatment option, unless these systems are designed off-line and with the same treatment volume of other stormwater practices.

Petroleum Hydrocarbon Concentrations Observed in Runoff From Discrete, Urbanized Automotive-Intensive Land Uses.

David L. Shepp, Senior Environmental Engineer
Metropolitan Washington Council of Governments, Washington, DC

Introduction

This documents a portion of work performed by the Metropolitan Washington Council of Governments (MWCOG) for the State of Maryland Department of the Environment (MDE) and EPA's Chesapeake Bay Program Office (CBPO) pertaining to a comprehensive study of the generation and control of petroleum hydrocarbons in urban runoff. The purpose of this particular study task was to characterize the relative contribution of petroleum hydrocarbons and other typically encountered urban pollutants contained within stormwater runoff from small, single land use catchments. The following four automotive-intensive land uses were evaluated: (1) all-day parking lots, (2) streets, (3) gas stations, and (4) convenience commercial. The study was conducted from October, 1992 through December, 1993. The study area encompassed the District of Columbia and Suburban Prince George's County, Maryland.

Methodology

Due to budgetary constraints, only one site per land use was studied. The following prerequisite conditions were met for each site: (1) the selected site had to be representative of the general land use classification, (2) the selected site had to be uncontrolled from the perspective of stormwater management, (3) the selected site had to be feasible for discrete land use monitoring (e.g. all stormwater flows had to emanate exclusively from the targeted land use).

The study monitoring contractor, the Occoquan Watershed Monitoring Laboratory (OWML) suggested the use of Cashockton Wheel samplers due to their ability to sample a vertical "slice" of the influent stormwater column. Due to the known partitioning of various petroleum hydrocarbon fractions in stormwater runoff, OWML felt the Cashockton Wheel samplers were superior to traditional automated samplers in obtaining a representative characterization of petroleum hydrocarbons from each site's runoff. They consist of a small "H" flume connected to a gravity-driven, rotating flow splitting device. As runoff flows from the impervious surface to the monitoring station, it is collected and funneled to the sampler by the "H" flume. The elevational differential between the flume and the horizontally-oriented platter-like wheel turns the wheel, via energy imparted to turning vanes from the falling inflow. As the wheel spins (similar to a record player), it splits a fraction, or "slice" of the stormwater inflow into a collection vessel through a small slot in its surface. This configuration yields a flow-weighted composite runoff sample and associated event mean concentrations (EMC) for each of the evaluated constituents. The Cashockton Wheels were deployed inside catch basins (3 sites) and within a locked fiberglass monitoring shed in a surface installation (1 site). Notable operation and maintenance constraints were encountered with the use of the Cashockton Wheel samplers in the study context. Urban grit and organics were found to impede the normal rotation of the samplers. For this reason, all samplers were temporarily removed from service and retrofitted with sealed, Teflon-coated central bearings. Even following retrofitting, the problem persisted, requiring close attention and frequent cleaning following storm events and regularly-scheduled weekly maintenance visits.

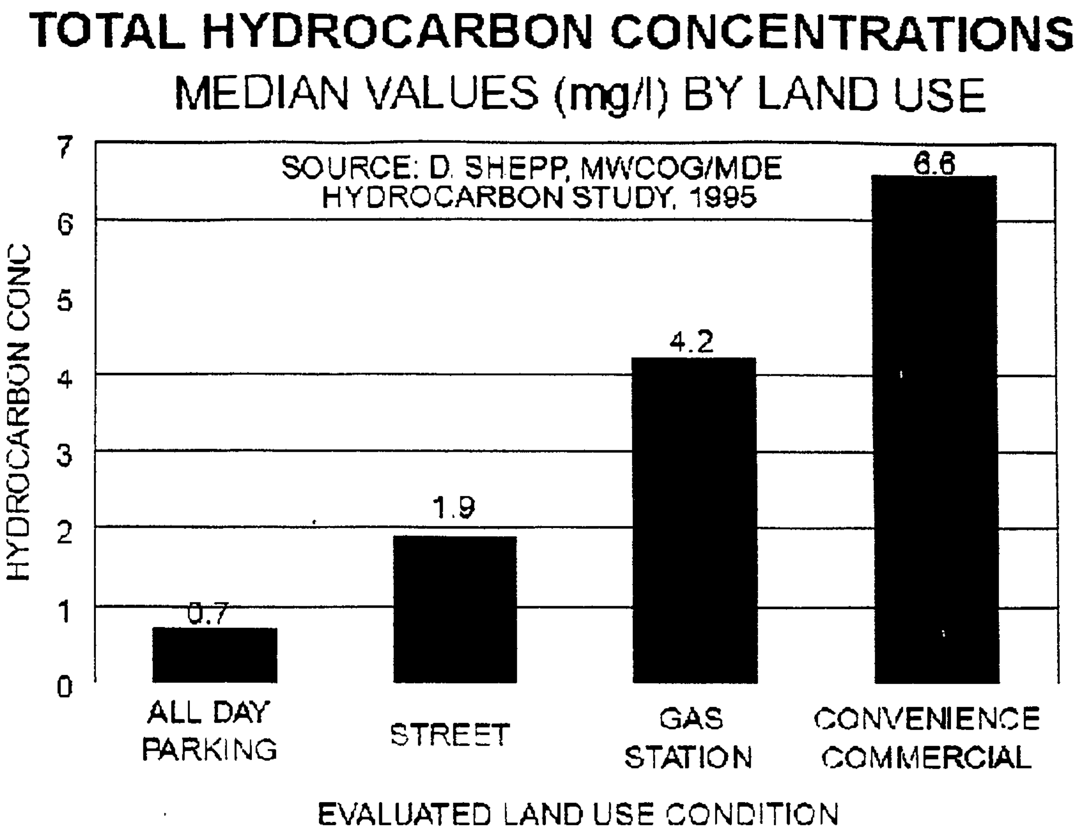
Rainfall measurements (rain depth) for 3 of the 4 sites were collected at the nearby USDA National Arboretum raingage. Due to the distance to the gas station site (located in Laurel, Maryland) an additional gage was installed on the stations' rooftop. Storm samples were retrieved following rainfall events and transported to OWML in Manassas, Virginia for laboratory analysis. A technique, utilizing non-dispersive infrared spectrometry, was developed for the purpose of evaluating the concentration of total hydrocarbons. OWML staff developed a functional relationship between petroleum hydrocarbon concentration and associated light transmittance in the infrared wavelength of 3.5 microns. It represents an improvement over standard gravimetric methods for oil and grease since it requires less lab time, reduced sample volumes and avoids "noise" from non-target solids in the sample volume. Associated limitations for this methodology include its lack of specificity (the results cannot be compared with results from studies which generate a higher degree of fractional resolution) and the potential for a lack of accounting for as much as 50% of the lighter fractions (due to their loss via volatilization during extraction); this can result in a conservative estimate of the total hydrocarbons. In a practical context, the total hydrocarbon concentration represents a changable, dynamic index where, due to field volatilization rates, the lighter fractions escape within a few days from the surface of the water column to the atmosphere.

Results

The following include the most important findings of the study:

1. While the total imperviousness for each site was virtually equivalent (estimated values ranged from 95-100%), the observed median EMC's for each site exhibited substantial differences (see Figure 1). The observed mean EMC's for each site exhibited a similar pattern as evidence... arraying the studied land uses in descending order of total hydrocarbon concentration: (... Convenience Commercial, mean observation: 12.4 milligrams per liter, range: 2.7 to 56.0 milligrams per liter, (2) Gas Station, mean observation 3.7 milligrams per liter, (3) Street, m... 2.2 milligrams per liter, range: 0.8 to 4.7 milligrams per liter, and (4) All day Parking, mean milligrams per liter, range: 0.3 to 4.4 milligrams per liter.

R0009414



2. Analysis of variance (ANOVA) indicated that significant differences exist between the observed means. Two-sample F-Tests of significance revealed that the majority of the means were significantly different from each other. Only the comparison of street and gas station means lacked sufficient significance to accept the null hypothesis. This suggests that imperviousness is not an acceptable singular indicator for predicting total hydrocarbon concentrations associated with automotive-intensive land use.

3. Data scatter plots revealed the following observed relationships:

   - Rainfall Depth vs. Total Hydrocarbons. The All day parking, Street and Convenience commercial sites exhibited a negative relationship, whereas the gas station site exhibited a positive relationship.

   - Rainfall Depth vs Total Suspended Solids. The All day parking, Gas Station and Convenience commercial sites exhibited a negative relationship, whereas the Street site exhibited a positive relationship.

   - Total Hydrocarbons vs Total Suspended Solids. All sites exhibited a positive relationship.

4. Observed data suggests a relationship between automotive exposure and total hydrocarbon concentration. Thermal expansion and contraction of oil-bearing regions of automotive drive trains is thought to be the primary source of petroleum hydrocarbons, via seepage. Duration of automotive exposure (i.e. the time a given impervious surface is exposed to hot vehicles in a thermal expansion mode) as well as volume of automotive exposure (i.e. the number of hot

R0009415

vehicles in a thermal expansion mode exposed to a given impervious surface) are suggested as the principal factors in the generation of petroleum hydrocarbon pollution upon automotive intensive land uses (see Table 1).

Table 1. Automotive Exposure and Observed Hydrocarbon Concentraions by Land Use.

Land Use	Duration of Automotive Exposure	Volume of Automotive Exposure	Observed Median Conc.
ALL DAY PARKING *National Arboretum*	LONG (4 to 8 Hours per Car per Day)	LOW (1 to 2 Cars per Parking Space per Day)	0.7 mg/l
GAS STATION *Laurel Texaco*	MODERATE (5 to 10 Minutes per Car per Day**No Repair/Maint. Service Provided**Pump & Pour Your Own "Micro Spills" Anticipated)	MODERATE (A Steady Stream of Cars Throughout Day)	4.2 mg/l
STREET *20th @ Franklin St.*	BRIEF (10 to 60 Seconds, Depending on the Traffic Light Cycle)	HIGH (1,000 plus Cars Estimated; AM & PM Rush Hr. Peaks, Steady Midday Use as Secondary Roadway)	1.9 mg/l
CONVENIENCE COMM. *N.h. Ave. Mcdonald's*	MODERATE (10 to 30 Minutes per Car per Day Estimated)	MODERATE/HIGH (Breakfast, Lunch & Dinner Peaks, Steady Throughout Day)	6.6 mg/l

5. Many of the highest observed concentrations were associated with rainfall depths less than 0.25 inch, with accompanying durations spanning 2 to 3 days. Concentrations associated with such low volume, low intensity events clearly underscore the relative ease of mobilization of petroleum hydrocarbons from impervious surfaces. Examination of rainfall patterns in the middle Atlantic region show that on average, (approximately every 3 to 4 days) precipitation events, with the potential to mobilize surprisingly high concentrations of petroleum hydrocarbons, occur. Furthermore, given their relative ease of mobilization, the potential for the delivery of substantial concentrations of petroleum hydrocarbons from automotive-intensive land uses to receiving waters exists both regionally and nationally for the majority of measurable annual rainfall events. The observed data suggest the principal source (automotive), its associated accumulation medium (imperviousness) and delivery mechanism (normal rainfall) central to this cycle.

6. Two separate items of information serve to provide a useful context for understanding the importance of the observed median total hydrocarbon concentrations presented in Figure 1 and the previously-mentioned range of observed concentrations for each land use (i.e. 0.3 to 2.4 milligrams per liter for the All day parking site, 0.8 to 4.7 milligrams per liter for the Street site, 1.2 to 5.5 milligrams per liter for the Gas station site, and 2.7 to 56.0 milligrams per liter for the Convenience Commercial site). First, maximum concentrations observed from the Convenience commercial site, 56.0 milligrams per liter, exceeded recently monitored observations for Hickey Run in the District of Columbia (50.0 milligrams per liter). Hickey Run has the dubious distinction as the most polluted subwatershed in the degraded Anacostia Watershed (due pri

R0009416

to a history of chronic and episodic waste oil dumping) and as one of the most polluted urban subwatersheds in the entire Chesapeake Bay drainage. Secondly, recommended maximum concentrations of petroleum hydrocarbons for drinking water supplies and fisheries protection typically range from 0.01 to 0.1 milligrams per liter; crude oil concentrations of 0.3 milligrams per liter can cause toxic effects in freshwater fish (D. Chapman and V. Kimstach, 1992).

7. Evaluation of rank and percentile of observed rainfall and hydrocarbon concentrations occuring over the span of an entire year indicated that 23 of 30 (or 77%) of the top half, or highest, observed total hydrocarbon concentrations could be managed via effective stormwater controls designed to treat the first 0.5 inch of runoff from the studied sites. If a 0.25 inch design treatment volume was utilized, 12 of 30 (or 40%) of the top half of the highest observed concentrations could be managed. These values stand in stark contrast when compared to the currently prevailing design rules for target treatment volumes relative to the control of petroleum hydrocarbons in urban runoff. Typical oil-grit separator design is based upon a 0.10 inch treatment volume of runoff. Utilizing the same overall dataset, this level of control equates to treating 2 of 30 (or 7%) of the highest hydrocarbon generating events of the evaluated annual rainfall.

Implications

Based upon analysis of the study observations, the following conclusions were reached:

1. Evaluation of the observations suggest that runoff concentrations of petroleum hydrocarbons from automotive-intensive land uses typically range from 0.7 to 6.6 milligrams per liter. Given the recommended maximum petroleum hydrocarbon concentrations of petroleum hydrocarbons for drinking water supply and fisheries protection (0.01 to 0.1 milligrams per liter) and the reported toxic effects observed in freshwater fish from crude oil concentrations of 0.3 milligrams per liter (D. Chapman and V. Kimstach, 1992), the observed total hydrocarbon concentrations suggest their substantial national impact as a nonpoint source pollutant. This suggestion is futher reinforced by the knowledge that many of the monitored automotive-intenstive land uses are commonly found throughout all, but the most rural and remote areas, of the United States.

2. Evaluation of the observations and their respective catchment areas suggest that the degree of automotive exposure (a combination of duration of exposure and volume of exposure) is the primary factor in the generation of petroleum hydrocarbons in runoff from automotive-intensive land uses. The pollutant pathway: (1) originates via drive train seepage from automotive vehicles, (2) accumulates upon highly impervious surfaces designed for automotive conveyance or parking, and (3) is readily mobilized via runoff produced by low volume, low intensity storms. The measured and visual observations gathered throughout the course of the study suggested, with the notable exception of expensive, new cars (W. Bell, et.al., 1995), virtually all motorized vehicles seep a measurable volume of petroleum hydrocarbon based lubricating agents. Casual visual observation suggests a wide range in the relative rates of seepage exists from vehicle-to-vehicle. Further visual observation suggests this variability is primarily a function of the age and relative degree of mechanical upkeep associated with a given vehicle.

3. Application of BMP's effective in the control of petroleum hydrocarbons is suggested for the treatment of runoff from automotive-intensive catchments as small as 0.5 acres. Recent performance evaluations of sand filtration BMP's , independently conducted by the District of Columbia (H. Troung, et. al.,1993) and the City of Alexandria, Virginia (W. Bell , et.al., 1995), suggest removal efficiencies for total hydrocarbons in excess of 77 per-cent. In addition to their reported removal efficiencies, the local availability of sand and gravel resources in the Middle

Atlantic's Coastal Plain enhances the attractiveness of filtration-based treatment of runoff from automotive-intensive land uses. Design treatment storage volumes up to the first 0.5 inch of runoff are suggested for the treatment of petroleum hydrocarbons in the Middle Atlantic region.

4. A seepage evaluation is suggested as a new pollution prevention component of regularly-scheduled vehicular safety/emissions inspections. A simple, relatively "low tech" approach could be developed, possibly using kraft paper as an evaluation medium. The diameter and number of seepage stains accumulated over a pre-determined evaluation period could potentially be utilized to develop an evaluation metric for identifying unacceptably high petroleum hydrocarbon seepage rates. A possible hierarchy of corrective actions could include: (1) mechanical tightening of drive train mating surfaces containing petroleum hydrocarbon lubricants, (2) the external application of petroleum hydrocarbon and heat resistant flexible sealants to seeping areas and (3) replacement of deteriorated and/or hardened gaskets and seals (this represents the last choice due to its associated disassembly time and related expense). An accompanying public education/outreach initiative as an additional component of a comprehensive pollution prevention program is suggested. The effort could be specifically targeted for the general public and the automotive repair and service industry. Its focus could revolve around the need to raise the public's awareness of the ubiquitous nature and potential environmental damage associated with uncontrolled/untreated petroleum hydrocarbons in runoff from automotive-intensive land uses.

EXECUTIVE SUMMARY

Urban stormwater runoff is currently one of the largest sources of pollutants discharged to the coastal oceans of southern California. However, the quality and quantity of stormwater runoff are highly variable. In particular, impervious (paved) surfaces directly affect a watershed's water quality. The goal of this study was to: (1) identify and measure constituent concentrations and toxicity found in parking lot surface runoff; (2) measure the effect of antecedent conditions on constituent accumulation between storms; and (3) investigate the effects of rainfall intensities and duration on runoff composition. A secondary objective was to assess the effects of traffic use and maintenance on the chemical composition and toxicity of parking lot runoff.

In order to control natural variability in precipitation, periodic rainfall simulations were used to quantify pollutant accumulation and washoff on two parking lots in the City of Long Beach for three months during the summer of 2000. Samples of surface runoff were analyzed for suspended solids, trace metals (Cd, Cr, Cu, Fe, Ni, Pb and Zn) in dissolved and particulate-bound phases, and 25 polycyclic aromatic hydrocarbons (PAHs). Among the metals studied, the highest mean concentrations in surface runoff samples were for Fe, Zn, Cu and Pb (810, 620, 40 and 40 µg/L, respectively). The Zn, Pb and Cu in the dissolved phase accounted for 65 to 81% of concentrations in surface runoff samples. Mean total PAH concentrations in surface runoff samples ranged from 0.08 to 180 µg/L.

Significant accumulation of mean constituent concentrations were observed for all constituents after 28 antecedent dry days, with the exception of total PAHs. Of the trace metals studied, Zn showed the largest accumulation in parking lot surface runoff, increasing by a factor of 3. Factors such as parking lot usage and maintenance did not affect the accumulation of runoff constituents. Similar concentrations of total suspended solids (TSS), trace metals, and total PAHs were found among high-use and low-use parking lots. Street sweeping as a maintenance activity did not reduce or improve runoff concentrations. However, the use of pressure washing did appear to reduce, but not completely remove, suspended solid and trace metal concentrations.

Washoff of all constituents was strongly inversely correlated with rainfall intensity and duration. Parking lot runoff samples collected during the first 10 min of a rain event contained the highest constituent concentrations indicative of a first-flush event. A "first flush" occurs when initial runoff during a storm has substantially higher concentrations than runoff later in the storm. Longer, simulated storms appeared to dilute parking lot runoff, and significantly lowered the average concentration of most constituents. Increases in rainfall intensity decreased the magnitude of the first flush, but the importance of rainfall intensities decreased with longer duration. Simulated rainfall, regardless of intensity, washed off most loose particles collected on the parking lot surface after approximately 15 min; concentrations of constituents collected after 15 min were generally low and less variable.

One hundred percent of simulated runoff samples were toxic, but not all species responded similarly after exposure to runoff samples. The sea urchin and marine bacteria were the most sensitive organisms; the mysid was the least sensitive organism. Toxicity patterns were consistent with the accumulation and rainfall duration/intensity patterns of constituent concentrations. After 28 d of accumulation, toxicity in runoff samples increased by a factor of 6. When comparing runoff from either high-use or low-use parking lots, the magnitude of toxicity did not change. Similarly, the magnitude of toxicity between parking lots with and without street sweeping showed no difference. However, toxicity was reduced, but not completely eliminated, after pressure washing. A toxicity "first-flush" effect was present in runoff samples collected during the first 10 min of the simulated rain event. Runoff samples collected during this time interval were twice as toxic as runoff samples taken later during the storm event. This finding is in agreement with the results of chemical analyses of the samples, which showed the first portion of the runoff event to contain the highest constituent concentrations.

The toxicant characterization and identification experiments suggested that trace metals were an important contributor to toxicity. These evaluations targeted trace metals, particularly zinc, as constituents responsible for toxicity in the purple sea urchin fertilization test. This conclusion was based upon the following findings: (1) complexation of trace metals completely removed toxicity; (2) concentrations of dissolved zinc were sufficient to induce toxic responses; and (3) variations in zinc concentrations among samples were significantly correlated with toxic responses.

The rapid accumulation, the nearly complete washoff of constituent concentrations, and the level of toxicity observed from parking lot runoff in this study indicate that uncontrolled discharges of parking lot runoff have the potential to impact receiving water quality and may require remediation by appropriate stormwater BMPs. Targeting the first flush appears to be the most effective management scenario based upon the results herein. Additional simulated rainfall events are recommended for other constituents and for various land uses besides parking lots.

ACKNOWLEDGEMENTS

The authors wish to thank Property Prep Inc. and Wastewater Remediation for construction of the rainfall simulators. The authors are also indebted to the following SCCWRP personnel, who assisted in this project: Darrin Greenstein, Jeffrey Brown, Ehren Doris, Kim Johnson, and Julie Kalman assisted with toxicity studies and field sampling; Andrea Steinberger and Dario Diehl assisted with field preparation and sampling; and David Tsukada assisted with field sampling and TSS analysis.

I. INTRODUCTION

Urban stormwater runoff has been recognized as a leading source of contaminants to coastal oceans and inland waterways (U.S. EPA 1995a). Research has found a direct relationship between the amount of impervious surface in a watershed and the watershed's water quality (City of Olympia 1994). This research, which has been conducted in many geographic areas using many different variables and employing widely different methods, has yielded a surprisingly similar conclusion: stream degradation occurs at relatively low levels of imperviousness (~10%) (Booth and Reinelt 1993 and Shaver *et al.* 1995). In southern California, watersheds average 25% imperviousness; hence, the impacts of land development on the quality of surface runoff and on aquatic organisms are likely to be found in southern California.

Streets and parking lots comprise a large proportion of impervious area; runoff from these areas is therefore considered to be a significant source of chemical contamination to receiving waters. These pollutants are derived from wear of automotive parts (e.g., tires and brake pads), spills and leaks of automotive fluids (e.g., motor oil and coolant), and materials deposited on parking lots from the air (e.g., atmospheric deposition and wind transported pollutants) (Hoffman *et al.* 1985, Ellis *et al.* 1987, and Muschack 1990). During rainstorms, a portion of these pollutants are washed off and transported from the street surfaces to the urban storm drain system and discharged to local receiving waters. In a nationwide coring study of aquatic sediment quality by the U.S. Geological Service (Van Metre *et al.* 2000), a clear relationship was reported between increasing traffic volume and increasing PAH concentration. Traffic volume, therefore, seems to be an important factor affecting the type and accumulation of contaminant concentrations and is valuable as a measure for predicting runoff quality.

Contaminant accumulation and washoff are commonly assumed to be effective measures of runoff contamination in our semi-arid environment; however, the effectiveness of these measures has not been well quantified in southern California. The accumulation of contaminants on southern California streets and parking lots has become a focal point since periods of infrequent rainfall (long, dry periods without rain) followed by intense rainfall are common. Other factors have been shown to influence the quality of surface runoff including surface maintenance practices, the time of the year (season), and the intensity and duration of the storm. Storm intensity is strongly correlated to the type and quantity of pollutants found in stormwater runoff (Pitt and Shawley 1981, Spangberg and Niemczynowicz 1992). Measurements of stormwater discharges sampled in 1997-98 from the Santa Ana River in Santa Ana, California (Leecaster *et al.* 2001, Schiff and Tiefenthaler 2001, and Tiefenthaler *et al.* 2001) showed evidence of a seasonal flush of contaminants.

The goal of this report is to evaluate the effects of rainfall characteristics and antecedent conditions on the composition of parking lot surface runoff. The primary objective is to identify and measure contaminant and toxicity concentrations found in runoff from parking lots, assess the length of time required for constituents to re-accumulate once washed off, and investigate how variations in intensity and duration of rainfall affect runoff composition. A secondary objective is to assess the effects of traffic use and parking lot maintenance on the chemical composition and toxicity of runoff.

II. METHODS

Experimental Design

This study was grouped into two major components: (1) The assessment of accumulation rates of selected contaminants over time and during discrete time periods. (2) The investigation of variations in rainfall intensities and durations affecting parking lot surface runoff concentrations to determine whether similar quantities of rainfall cause similar effects on contaminant concentrations over time (i.e., 6 millimeters of rainfall per hour [mm/h] for 40 min vs. 25 mm/h for 10 min). Possible interactions between treatments (i.e., low-use/maintained stations vs. high-use/unmaintained stations) were also examined.

A randomized factorial design was selected to measure the effects of a variety of treatments on contaminant accumulation and washoff on parking lots over time including: (1) low use (1 car/4 h--i.e., faculty parking); (2) high use (5 or more cars/h--i.e., public parking); (3) maintained stations vs. unmaintained stations (defined as the presence or absence of street sweeping); (4) rainfall intensities; and (5) rainfall durations. All rainfall simulations for the accumulation study were run for 20-min durations with a constant storm intensity of 13 mm/h). The rainfall duration/intensity study had simulations that were run for the following time intervals: 0-10, 10-20, 20-40 and 0-20 min, using rainfall intensities of 6 (0.25 inches/hr), 13 (0.5 in/hr), and 25 (1 in/hr) mm/hr. Treatments were assigned randomly among 27 test stations. The "first-flush" effect of storms was also evaluated.

Study Area

All samples were collected within the City of Long Beach, the fifth largest city in California with an estimated population of 440,000 citizens living in a 50-square-mile area. (City of Long Beach, Economic Development Bureau 1999). Long Beach is a port city bounded on its southern border by the Pacific Ocean. It has a semi-arid climate with an annual precipitation of only 30.5 centimeters (cm). An average 0.4 cm of rain falls each month from May to October, with 4.6 cm/month falling from November to April.

Sampling Sites

Two parking lots located within the Long Beach City College Liberal Arts Campus (LBCC LAC) at 4901 E. Carson Street in the City of Long Beach, California, were selected for monitoring runoff from parking lots (Figure II-1). The parking lots differed in daily traffic flow and maintenance practices. The parking lots have a combined capacity of 150 cars with a dimension of approximately 8 meters by 76 meters and a 4% grade. The lots operate seven days per week with five days at full capacity. A total of 9 replicate sampling stations were located on the site off of Lew Davis Street, which received no maintenance. Eighteen sampling stations, representing both low-use and high-use as well as maintained and unmaintained conditions, were located on the lot at Faculty Street. Six maintained stations (3 low use and 3 high use) were located in the southern portion of this lot and comprised approximately 30% of the total parking lot area. The land around the sites is mostly commercial. The sites, which were constructed of 100% asphalt, were used for both visitor and staff parking. Accessibility for runoff sampling was a consideration in site selection. Every effort was made to select sites which were as similar as possible in terms of condition and slope. The prevailing weather conditions were similar at all sites.

Dry conditions were prevalent in Long Beach from May to October of 2000, with less than a trace of rain at any of the two sites for a period of 160 d. Manual observation of traffic counts were recorded 1 d prior to each simulated rainfall event and averaged approximately 100 vehicles per day.

Rainfall Simulator

Rainfall simulation equipment and techniques were used for assessing the effects of rainfall on surface runoff. In this study, sampling was carried out using three identical rainfall simulators (spray rigs) designed to duplicate natural rainfall intensities. Each spray rig was comprised of polyvinylchoride (PVC) pipes with its own pressure gauge, flow meter, control valve, and fixed-rate Rainbird or Hunter PGM rotating polyurethane spray heads. One fixed-rate Rainbird spray head at 45/36 pounds per square inch (psi) and 5.0 liters per minute (L/min) produced a 3.8 m radius semicircle with an intensity of 13 mm/h (Figures II-2 and II-3). This system provided a relatively uniform simulated rainstorm washing off 2 parking stalls measuring 18 m^2. Approximated rainfall intensities were determined for two types of storm events that occur in southern California. Typical (6 mm/h) and worst-case (25 mm/h) rainfall intensities were simulated using 2 Hunter spray heads with 0.75 gallon-per-minute (gpm) emitters while also varying the pressure and flow rate. Simulating rainfall for a period of 20 min at an intensity of 13 mm/h resulted in a total runoff volume of 26.4 liters.

The rainfall simulators were designed to isolate and capture the entire portion of the surface runoff traveling off each sampling site. The surface runoff generated by the rainfall simulators was collected continuously during each run using a vacuum system that transferred the runoff into a 55-gallon plastic barrel. At the end of each simulation run, the runoff collected in each barrel was stirred vigorously to distribute the sediment evenly in the sample. Chemistry and toxicity samples were taken.

The source water for the rainfall simulators was obtained from hose bibs located around the perimeter of the campus' "Q & R" building. All test water passed through a portable filtration system to ensure removal of chlorine and sediments from the source water before it was supplied to the simulated rainfall systems (Figure II-4).

A series of quality assurance and quality control (QA/QC) performance evaluations were conducted on all rainfall simulators including evenness of spread and precision of pressure, flow rate and volume to determine accuracy of reproducibility among spray rigs. Rainfall simulator measurements were designed to be within approximately 20% coefficient of variation and were verified prior to the onset of each simulated rainfall run. At time zero (T0) all parking lots were cleaned using cold, high-pressure washing to establish background values for contaminants. All simulated rainfall equipment was thoroughly cleaned after each simulation. Chemistry and toxicity blank samples were taken from the source water prior to each sampling period.

Parking Lot Maintenance

The effectiveness of street sweeping in improving the quality of parking lot runoff was measured by comparing runoff concentrations between maintained and unmaintained stations. Maintained test stations were cleaned on a weekly basis using the following procedure. One individual operated both the backpack blower and the brooms, and either blew or swept all visible loose debris and surface dirt into the path of a power vacuum truck for collection and removal.

Surface Runoff Sampling

From July 2000 until October 2000, 155 rainfall runoff samples were collected periodically from two parking lots located on a college campus in Long Beach, California. All samples were stored under refrigeration and analyzed for TSS, both total and dissolved metals (cadmium, chromium, copper, iron, lead, nickel, and zinc), 26 selected PAHs, and toxicity to 3 species. The rainfall intensity/duration experiment was conducted during the third month of the study in order to allow contaminants to accumulate.

During this study, three different duration type samples were collected. In order to generate the TSS pollutograph, discrete samples were taken every 2 min for 20 min at 6, 13, and 25 mm/h rainfall intensities. This sampling scheme continued for 40 min at the 6 mm/h intensity. For the accumulation study, rainfall simulations with an intensity of 13 mm/h were run for a fixed time period (20 min) and a composited sample was taken. In the rainfall duration/intensity experiment, composited samples represented discrete time intervals. Samples representing 0-10 min and 10-20 min durations were taken at 6 and 25 mm/h rainfall intensities, respectively. An additional rainfall duration sample representing 20-40 min was taken at the 6 mm/h intensity. To facilitate a comparison with the accumulation study, simulations were also run for 20 min at a rainfall intensity of 13 mm/h.

Analytical Chemistry

Suspended Solids

Total suspended solids were analyzed by filtering a 10 to 100 mL aliquot of stormwater through a tared 1.2 µm (micron) Whatman GF/C filter (EPA Method 160.2). The filters plus solids were dried at 60° C for 24 h, cooled, and weighed.

Polycyclic Aromatic Hydrocarbons

The PAHs were extracted, isolated, and analyzed using the procedures documented by EPA Method 8270C (U.S. EPA 1991). The PAHs were separated, identified, and quantified by capillary gas chromatography (GC) coupled to mass spectrometry (MS). Acenaphthene and

Pyrene were used for quality control check standards. Twenty-five specific PAHs were determined for this study. Total PAHs (∑PAH) was computed as the sum of these values.

Trace Metal Analysis

Samples for total and dissolved trace metal analysis were prepared by digestion. Dissolved metals were defined as passing through a 0.45 µm filter. A well-mixed, 25 mL aliquot of acidified sample was dispensed to a Teflon digestion vessel and 2 mL of ultra-pure HNO3 (Optima, Fisher Scientific) were added, and the vessel was capped and sealed. The acidified samples were digested in a CEM MSP1000 Microwave Oven by ramping to 100 psi over 15 min and then holding at 100 psi for 10 min. After cooling, the digestate was centrifuged to remove any remaining residue from the sample. The supernatant with sample digest was transferred to a 15 mL test tube prior to analysis.

Inductively coupled plasma-mass spectroscopy (ICP-MS) was used to determine total and dissolved concentrations of inorganic constituents (aluminum, antimony, arsenic, beryllium, cadmium, chromium, copper, iron, lead, mercury, nickel, selenium, silver, and zinc) from sample digest solutions using a Hewlett Packard Model 4500 with Hewlett Packard Data Systems software and following protocols established by EPA Method 200.8, EPA Method 236.1 and 236.2, and by EPA Modified Method 245.1. The internal standard solution included rhodium and thulium. Instrument blanks were processed to identify sample carry-over. A spiked sample of known concentration was used as the laboratory control material. . The Certified Reference Material was ERA 9970 and ERA 9977 (Environmental Resource Associates, WasteWatR Lot No. 9970 and 9977, respectively).

Data Analysis

Significant differences among mean concentrations were determined using one-way ANOVA, Kruskall-Wallace and Tukey tests ($p = 0.05$). This study examined potential differences between low-use and high-use stations and maintained and unmaintained stations. General comparisons were made for all treatments. To provide a more accurate assessment of the magnitude and trends of contaminant contributions from parking lot surface runoff, the mean contaminant concentrations from the combined low-use treatments from maintained and unmaintained stations were pooled and compared with those of the high-use treatments from maintained and unmaintained stations from the same time period.

Toxicity Measurement

Since the ultimate destination for most runoff from the City of Long Beach is the ocean, toxicity testing was conducted using three marine species: sea urchin, mysid, and bacteria. The toxicity testing program was designed to accomplish three objectives. The first objective was to determine the magnitude of toxicity in each runoff sample collected from either the accumulation or rainfall intensity and duration experiments. The sea urchin fertilization test was used to accomplish this objective. The second objective was to determine the relative sensitivity of various species to parking lot runoff. Selected samples from the accumulation experiment were tested with all three species (sea urchin, mysid, and bacteria) to accomplish this objective. The final objective was to investigate the nature of the toxic components in parking lot runoff. To address this objective, Phase I toxicity identification evaluations (TIE) were conducted on selected samples using the sea urchin fertilization test.

All samples were adjusted to a constant salinity so only the effect of toxic constituents, not the effect of freshwater, was evaluated. Each sample was tested at a minimum of two concentrations in order to estimate the magnitude of toxicity present. The maximum sample concentration tested was 50% (i.e., 50% runoff sample and 50% seawater or salinity adjustment solution). The concentrations tested in the accumulation experiment varied from test to test in order to maximize the value of the results for estimating the median effect concentration (EC50) and no observed effect concentration (NOEC). In general, runoff samples from the high-use treatment groups of the accumulation experiment were tested at concentrations of 50, 25, 12, 6, and 3%, while the low-use treatment groups were tested at a reduced number of concentrations. All samples from the rainfall intensity and duration experiment were tested at concentrations of 50% and 12%.

Prior to the start of the project and during each sampling period, samples of water from the simulated rainfall delivery and collection system were collected and tested to verify that they were not causing toxicity.

Seas Urchin Fertilization

The purple sea urchin sperm cell test was performed as described by Chapman *et al.* 1995. Gametes were obtained from adult specimens of the purple sea urchin, *StrongylocentroTU purpuraTU*, collected from a relatively uncontaminated area in northern Santa Monica Bay. In the test, sea urchin sperm are exposed to various concentrations of the test sample for 20 min at a temperature of approximately 15° C. Sea urchin eggs were then added to each sample and given 20 min for fertilization to occur. Preservative was then added to the samples and they were later analyzed under a microscope to determine the percentage of fertilized eggs. Comparing the fertilization success of the sample to that of the control determines the degree of toxicity.

Since the toxicity test uses a marine organism, the salinity of the runoff samples was adjusted to a typical seawater value by the addition of brine. Addition of the brine diluted the samples, restricting the highest concentration of sample tested to 50%. Additional test concentrations were prepared by adding laboratory seawater (filtered natural seawater collected from offshore Redondo Beach) to the samples. A brine control was included in the experiment to check for toxicity introduced by the salinity adjustment procedure. The brine control consisted of deionized water plus laboratory seawater and brine at the same concentration found in the most concentrated runoff sample tested.

A reference toxicant test was conducted concurrently with each test in order to document variability in test sensitivity. This test consisted of five concentrations of dissolved copper, ranging from 10 μg/L to 65 μg/L.

Mysid Survival and Growth

The mysid short-term chronic survival and growth bioassay was performed according to methods described in Klemm *et al.* 1994. Juvenile mysids of the species *Americamysis bahia* (formerly *Mysidopsis bahia*) were obtained from Aquatic Biosystems of Ft. Collins, CO. To perform the test, 5 animals are added to 250 mL polypropylene beakers containing 150 m of sample with 8 replicates per concentration. The mysids are fed newly hatched *Artemia* daily. Each day the solution in the beakers is removed and renewed. The exposure period of 7 d is conducted at 26° C with a salinity of 30 g/Kg. At the end of the exposure period, the number of surviving animals is recorded and the survivors are dried and weighed. The endpoints for this test are percentage of survival and average individual dry weight compared to the control values.

The salinity of the runoff samples was adjusted by the addition of Forty Fathoms bioassay grade sea salts. Various test concentrations were prepared by diluting the salinity-adjusted runoff sample with 30 g/kg of laboratory seawater. A salt blank was included in each experiment to check for toxicity introduced by the salinity adjustment procedure. The salt blank consisted of deionized water plus sea salts and laboratory seawater at the same concentration found in the most concentrated runoff sample tested.

A reference toxicant test was conducted concurrently with each of the runoff tests in order to document variability in test sensitivity. This test consisted of five concentrations of dissolved copper, ranging from 100 µg/L to 350 µg/L. Both the survival and growth endpoints were examined for the reference toxicant exposure.

Bacteria Luminescence

Toxicity of the runoff samples to marine bacteria (*Vibrio fischeri*) was measured using the Microtox™ Rapid Toxicity Testing System. Two different tests were conducted on each sample, a 15-min short-term acute test and 24-h long-term chronic test. Samples for both procedures were analyzed using a Microtox M500 analyzer following the Microtox Comparison Test Method (Microbics Corporation 1995).

For the acute test, bacteria were added to triplicate cuvettes containing 1.5 mL of sample and incubated at 15° C. The salinity of the samples was adjusted by adding a saline solution. Microtox diluent was added to the samples to produce various test concentrations. The luminescence of each replicate was measured at 0, 5 and 15 min. Mean percent luminescence was then calculated as the average of the replicates within each concentration as normalized to the time zero value of each sample and corrected for natural light loss between zero and 15 min. Reproducibility of the test organism response was determined by testing a copper reference toxicant solution at a series of concentrations.

The Microtox chronic test procedure was similar to the acute method, except that the samples were tested in quadruplicate and incubated at 27° C for 24 h. Nutrient media were added to the test solution, with dilutions made using DIW and the Microtox control media solution. Luminescence at 24 h was measured and compared to the control value. Reproducibility of the test organism response was determined by testing a copper reference toxicant solution at a series of concentrations.

Data Analysis

The NOEC (highest test concentration not producing a statistically significant reduction in fertilization or survival) and the EC50 or LC50 (concentration of runoff producing a 50% reduction in fertilization or survival, respectively) were calculated for each sample whenever suitable data were obtained. For the NOEC calculation, the data were arcsine transformed and then tested for homogeneity of variance and normal distribution. Data that met these criteria were then tested using the one-way analysis of variance (ANOVA) and Dunnett's multiple comparison test to identify differences between the control and each of the samples. Data that did not pass the test for homogeneity of variance and/or normal distribution were analyzed using the non-parametric Steel's Many-One Rank test. The EC50 or LC50 were calculated using probit analysis.

Toxicity Characterization

Phase I TIEs were conducted on runoff samples from months 2 and 3 of the accumulation experiment in order to determine the characteristics of the toxicants present. Each sample was subjected to treatments designed to remove selectively or neutralize classes of compounds (e.g., metals, nonpolar organics) and any associated toxins. Treated samples were then tested to determine the change in toxicity using the sea urchin fertilization test.

Four treatments were applied to each sample: particle removal, trace metal chelation, nonpolar organic extraction, and chemical reduction. With the exception of the organics extraction, each treatment was applied independently on a salinity-adjusted sample. A control sample (laboratory dilution water) was included with each type of treatment to verify that the manipulation itself was not causing toxicity. A reduced set of concentrations of untreated sample was tested at the time of the TIE to determine the baseline toxicity and control for changes in toxicity due to sample storage.

Ethylenediaminetetraacetic acid (EDTA), a chelator of metals, was added at a concentration of 60 mg/L to the test samples. Sodium thiosulfate (STS), a treatment that reduces oxidants such as chlorine and also decreases the toxicity of some metals, was added at a concentration of 50 mg/L to separate portions of each sample. The EDTA and STS treatments were given at least 1 h to interact with the sample prior to toxicity testing.

Samples were centrifuged for 30 min at 3000 X g to remove particle-borne contaminants and were then tested for toxicity. A portion of the centrifuged sample was also passed through a 12 mL Varian Mega Bond Elute C-18 solid phase extraction column in order to remove nonpolar organic compounds. The C-18 columns have also been found to remove some metals from aqueous solutions.

The used C-18 columns were stored under refrigeration for 1 to 2 months and then eluted in order to recover the retained toxic constituents. Each column was eluted sequentially with methylene chloride ($MeCl_2$) and hydrochloric acid (HCl) to recover the organic and metal fractions. Each column was rinsed with deionized water to remove excess salts. $MeCl_2$ (100%) was then passed through the column and the eluate was collected. The column was then rinsed with methanol to remove any residual $MeCl_2$. Finally, 2 M HCl was passed through the columns and the eluate was collected. The $MeCl_2$ eluates were solvent exchanged into isopropanol. Dilutions of the organic and acid eluates were tested for toxicity using the sea urchin fertilization test.

III. CONTAMINANT ACCUMULATION

Results

Rapid accumulation of all constituents was observed after 28 antecedent dry days (sampling month T1) with the exception of total PAHs (Figure III-1, Table III-1). Mean suspended solids concentrations increased from 29.2 mg/L to a maximum of 51.8 mg/L during this time period. Of the trace metals studied, zinc demonstrated the highest potential for accumulation in parking lot surface runoff (increasing by as much as 182%) at T1. After 28 d, all trace metals were detected in the dissolved phase and accounted for 31 to 81% of the total metals concentrations in parking lot runoff samples. Reported concentrations of dissolved zinc increased significantly from 200 μg/L to 553 μg/L between T0 and T1. In contrast, mean total PAH concentrations were highest (105 μg/L) at T0 and decreased 20% at T1 (Figure III-1, Table III-1).

Mean contaminant concentrations in subsequent sampling months (T2 and T3) tended to decrease relative to T1 (Figure III-1, Table III-1). For example, total zinc concentrations in parking lot surface runoff from T1 were about 1 to 4 times larger than the concentrations in runoff from other time periods. Monthly PAH concentrations gradually decreased to a minimum of 52.9 μg/L at T2 before a small increase to 53.3 μg/L at T3. Both of these time periods had significantly reduced mean concentrations from the initial (T0) pollutant concentration.

Average TSS concentrations measured at T0 were 26% lower than mean TSS precleaned concentrations (Figure III-1, Table III-1). All total and dissolved trace metals also had lower concentrations after the sites were cleaned, with the exception of cadmium and chromium, which increased by 30 and 8%, respectively. Mean total PAH concentrations decreased by 14% after cleaning. However, none of the lowered contaminant concentrations produced a statistically significant change.

Parking Lot Usage

Changes in parking lot use had little influence on surface runoff contaminant concentrations. Only 8 of 18 contaminants displayed higher runoff concentrations from the high-use stations compared to the low-use stations (Table III-2). However, no significantly different concentrations were found for any of the constituents among the treatments measured for parking lot runoff.

Mean contaminant concentrations followed similar temporal trends as observed in the accumulation study. Both low-use and high-use runoff within T1 had higher mean zinc concentrations (643 and 597 ug/L, respectively) than runoff from stations within T0 and T3. For copper, time periods T0 and T1 had much higher concentrations than T3. Suspended solids concentrations found in runoff from the high-use stations consistently increased from T0 to T2 (31.8 mg/L to 60 mg/L) before dipping during T3 (Figure III-2). On the low-use stations, TSS concentrations fluctuated from 29.2 to 51.8 mg/L. However, the monthly mean TSS concentrations did not vary significantly by use or time period. Concentrations of total PAHs exhibited a similar decreasing trend with respect to time.

Maintenance

Street sweeping was shown to have a minimal effect on parking lot runoff water quality because the sweeping practices used in this study removed very few contaminants. On the contrary, 15 of 18 contaminant concentrations were highest in runoff from maintained stations (Figure III-3, Table III-2). All constituent concentrations were not significantly different among maintenance sites.

As stated previously, the treatments within T1 exhibited higher monthly average TSS, total, and dissolved trace metal concentrations than any other month (Figure III-3). During T1, the mean total zinc concentration of 608 ug/L at the unmaintained stations was up to 4 times larger than zinc concentrations measured in runoff from unmaintained stations during all other time periods. Even though average total zinc concentrations from unmaintained parking lots decreased over the study period, concentrations were substantially higher than at T0. Dissolved zinc concentrations exhibited a similar trend. For TSS, no significant differences existed between time periods; however, mean TSS values from maintained stations (82 mg/L) at T2 were much higher than values measured from unmaintained stations (29 mg/L). Mean total PAH concentrations found in surface runoff from maintained stations decreased considerably during each time period from 143 µg/L at T0 to 47 µg/L at T3. Similar decreased mean total PAH concentrations were also observed between unmaintained stations within T1 (96 µg/L) and unmaintained stations within T2 (48 µg/L), as well as between maintenance levels within T0 (maintained = 143 µg/L, unmaintained = 67 µg/L).

Discussion

Accumulation of Contaminant Concentrations

Although short-term accumulation was observed in the present study, long-term accumulation was not found. Contaminants accumulated relatively quickly on the parking lot surface (within 28 d). As the study continued, however, monthly average contaminant concentrations slowly decreased, approaching initial T0 level concentrations. Research on urban stormwater quality has indicated that pollutants accumulate on a street surface between sweeping and storm events. Physical removal processes, however, such as winds and rain or human activity (e.g., from the turbulence of traffic or by street sweeping) can limit the accumulation of solids and other pollutants from road and parking lot surfaces, obscuring the relationship between traffic volume, pollutant loads, and concentrations in runoff (Kerri *et al.* 1985, Pitt and Shawley 1981, Asplund 1980). Pitt and Sutherland (1982) estimated that the total mass concentration of pollutants that can accumulate on street surfaces is limited, requiring approximately two to three weeks to reach maximum levels.

Rainfall has the greatest potential to affect the accumulation of constituents. Unmeasureable amounts of rain fell on the parking lots between the sampling periods, reducing the number of antecedent dry days for events T2 and T3. Although these rainfall events did not appear to be significant, the amount of dry days prior to each of the last two sampling events were both less than two weeks. The effect of these trace quantities of rainfall is assumed to be negligible since rainfall did not pool and no flow was observed. Furthermore, we found that it takes an intensity of 6 mm of rain to fall for 15 min in order to wash off nearly all contaminants from the parking lot surface during the duration/intensity study (See Section IV).

Chemical processes can also limit the accumulation of potential pollutants on parking lot surfaces. Mean total PAH concentrations dropped significantly over the 3-month period of study. Hewitt and Rashad (1992) reported that between 70 and 99% of PAHs were removed from the road environment either by the atmosphere, volatilization, photo-oxidation, or other oxidation processes.

Traffic Usage

Vehicles are one of the major sources of pollutants, both directly and indirectly, in parking lot runoff (Hahn and Pfeifer 1994, Asaeda *et al.* 1996). Therefore, the amount of traffic on a given lot should influence the accumulation of pollutants on the parking lot surface. Our study did not establish a strong relationship between traffic volume and increased contaminant concentrations. Similar results were found when comparing runoff concentrations from highways of different traffic densities in studies by McKenzie and Irwin (1983) and Boucier *et al.* (1980). These studies found a weak correlation between TSS concentrations and average daily traffic (ADT), and no correlation of metal loadings with ADT. In another study, Stotz (1986) concluded that the amount of pollutants discharged has a higher correlation to the physical characteristics of the area than the traffic frequency.

Compared to mean cadmium concentrations, the relatively large arithmetic mean concentrations of total and dissolved zinc in parking lot surface runoff from the different treatments observed in this study support previous findings that automobiles are a large potential source of these constituents. Vehicles contribute contaminants directly into the environment from normal operation and wear to parts caused by friction. Road dust contaminated by tire wear products and zinc-plated metal erosion material contributes the highest levels of zinc to urban runoff (Kobriger and Geinopolos 1984, Smith and Lord 1990 and Lorant 1992). It is likely that these sources may have caused the high zinc concentrations observed in this study. Indirect or acquired contaminants are solids that are acquired by the vehicle for later deposition. Indirectly, vehicles contribute to parking lot contaminants by carrying solids from urban roadways. Indeed, Shaheen (1975) demonstrated that more than 95% of solids on a given road originate from sources other than the vehicles themselves.

Maintenance Effectiveness

The street sweeping practices performed in this study did not prove to be an effective measure for reducing the concentrations of most constituents in parking lot surface runoff. The objective was to remove dry-weather accumulations of contaminants, especially fine particulate matter, before they were washed off by rainwater, and thus reduce the potential for contaminant impacts on receiving waters. Studies by Pitt (1985), Maestri *et al.* (1985) and Gupta *et al.* (1981) reported that intensive street cleaning conducted three times a week using the traditional mechanical street cleaners showed no significant improvement in runoff water quality and was only effective in removing large solids. Most recently, studies conducted in the Pacific Northwest by Sutherland and Jelen (1997) and reported in the Runoff Report (1998), have evaluated the use of vacuum-assisted sweepers and regenerative-air sweepers to determine an optimum sweeping frequency. These improved sweeping mechanisms removed finer street surface materials than the standard mechanical street cleaning equipment, with measureable improvements in pollutant removal efficiency obtained with a sweeping frequency once every week or two.

IV. RAINFALL INTENSITY / DURATION

Results

Contaminant Washoff Patterns

Simulated rainfall washed off nearly all of the suspended solids that collected on the parking lot surface after approximately 15 min regardless of rainfall intensity. Higher concentrations were recorded during approximately the first 10 min for most constituents; however, the concentrations quickly reached a baseline concentration for the duration of the sampling period (Figure IV-1). The suspended solids concentrations varied from about 2 to 140 mg/L, with a decrease in concentrations with increasing rain intensity during these constant rain intensity tests. No concentrations higher than 52 mg/L occurred after approximately 10 min of rain. All TSS concentrations were less than 30 mg/L after approximately 15 min of rain. Suspended solids concentrations for all intensities showed slightly higher concentrations at the beginning (first flush) of the simulated storm events. The magnitude of the first-flush effect varied between intensities, ranging from 112 to 140 mg/L, and was more evident at the 6 mm/h rainfall intensity.

Rainfall duration was the most important factor we observed. Washoff of all measured constituent variables was inversely correlated with duration at single or lumped rainfall intensities (Table IV-1, Figure IV-2). Longer simulated storms diluted parking lot runoff and significantly lowered the concentrations of contaminants. For example, mean suspended solids concentrations measured after 10 minutes significantly decreased from 57 mg/L to 16.2 mg/L measured during the 10-20 minute interval of the simulated storm ($F = 7.95$, $p = 0.00$) (Figure IV-2). At the end of the simulated storm event (20-40 min interval), mean suspended solids concentrations decreased to 11.7 mg/L and were significantly different from concentrations measured after 10 min ($F = 7.95$, $p = 0.00$). Simulated storm events with 20 minute rainfall durations had a mean TSS concentration of 28.7 and were not significantly different relative to the other time intervals.

Washoff of contaminant concentrations exhibited trends similar to TSS over different durations, but the importance of intensity was only detected at the shortest durations (Table IV-1, Figure IV-3). When durations were pooled, mean total zinc concentrations were highest (240 ug/L) at the 6 mm/h rainfall intensity. More intense simulated storms had the same dilution effect on average pollutant concentrations, as did longer simulated storms, however, the concentrations were not significantly lower. Mean zinc concentrations were reduced to a minimum of 143 ug/L with 25 mm/h of rainfall (Figure IV-3). The mean dissolved zinc concentrations ranged from approximately 51 to 338 ug/L, comprising a large percentage of the total zinc loadings. For all rain intensities, dissolved metals comprised up to 90% of the total metals.

DISCUSSION

Urban stormwater runoff is comprised of discharges from many separate source area components (parking lots, streets and highways) that are combined within the watershed drainage area before entering the receiving water. Bannerman *et al.* (1993) characterized parking lots as critical source areas contributing most of the runoff and contaminant loads during small rain events. One study in Toronto, Ontario by Pitt and McLean (1986), evaluated specific source areas to identify any possible trends of concentrations with rain volume. They found that lead and zinc concentrations were highest in runoff from paved parking areas and streets. Several other studies (Barrett *et al.* 1995, Driscoll *et. al.* 1990, and Pitt 1985) measured runoff and contaminant concentrations on roads and highways.

To understand the potential impacts on water quality from surface runoff from parking lots, we compared the average constituent concentrations found in parking lot runoff to both the range of average national pollutant concentrations in highway runoff, and to the range of concentrations observed in the City of Long Beach's wet-weather stormwater monitoring program (Table IV-2). This comparison shows that the average concentrations in surface runoff from parking lots in Long Beach are at the lower end of range of concentrations for transportation land uses nationwide (FHWA 1998, Barrett *et. al.* 1995). However, parking lot runoff concentrations generated during simulated rainfall events were similar to the concentrations measured in wet-weather discharges from the City of Long Beach during the winter of 2001 (Kinnetic Laboratories, Inc and SCCWRP, 2001). For example, the average concentrations of lead in parking lot runoff were lower than the range of mean runoff concentrations in transportation areas nationwide, but were within the range of concentrations measured in City of Long Beach wet-weather runoff. Interestingly, the ranges of mean zinc concentrations were similar among national transportation areas and the City of Long Beach, approximately 50 to 900 µg/L. The zinc concentration measured during simulated rainfall on a parking lot within the City of Long Beach was below the mid-range near 300 µg/L.

In this study, changes in rainfall duration were found to have the greatest effect on constituent concentrations. Parking lot runoff samples collected during the first 10 min of a rain event contained the highest constituent concentrations, indicating that a first-flush effect was present. After peaking during the first flush, constituent concentrations decreased and then remained relatively stable after approximately 15 min when most loose particles were washed off. Longer storms were found to dilute parking lot runoff and lower the variability in measured contaminant concentrations during this study. Rainfall intensity was also an important variable in determining removal of runoff constituents during a storm, but only during shorter durations (i.e., less than 15 min). Higher intensity storms produced higher concentrations during these small duration events. Others (Athayde *et al.* 1983; Irish *et al.* 1996) have documented a similar correlation among rainfall duration and intensity. For example, Dorman *et al.* (1988) found that concentrations of runoff pollutants were higher during shorter, low-volume storms.

The results of the intensity and duration experiments indicate that stormwater treatment systems that capture or treat the initial portion of stormwater discharge from parking lots are likely to provide the greatest benefit in terms of reducing constituent concentrations. This will, in turn, help to reduce mass emissions, particularly for shorter storm events. However, several factors need to be considered when designing BMPs including sizing, trapping and treatment efficiency for specific constituents of concern, and flood protection among others.

V. TOXICITY RESULTS

Comparative Toxicity to Marine Species

Each of the four test methods detected toxicity in the samples from sampling periods T2 and T3 (Table V-1). Toxicity was widespread among the three species used: sea urchins, mysids, and bacteria. Five of the six samples tested were toxic to all three species.

Responses to the month 2 samples (T2) were similar among the three samples tested (Figure V-1). Mysid survival was affected only at the highest concentration tested, 50%. The sea urchin fertilization and chronic Microtox tests always detected toxicity at lower concentrations, with the Microtox test showing the highest magnitude of response relative to the controls.

The relative responses of the three species showed a different pattern of response to the samples tested after 3 months of accumulation (Figure V-2). Mysid survival was less responsive, compared to the month 2 samples that were tested. In addition, the sea urchin test usually showed a greater relative response compared to the chronic Microtox test for the month 3 samples.

The mysid survival/growth and Microtox acute tests were the least sensitive methods overall. The NOECs for these two methods were usually ≥25% and no toxicity was detected in 1 or 2 samples (Table V-1). In many cases, less than a 50% response was measured in the highest sample concentration tested (EC50>50%). Mysid growth was a more sensitive response than survival in three of the five toxic samples (Table V-1). The reduction in mysid weight was relatively small, however, and did not exceed a 50% effect for any of the samples. The greatest growth effect was measured for sample 202B (T2), where the weight of mysids exposed to 25% sample was 57% of the control.

The sea urchin fertilization and chronic Microtox test methods were substantially more sensitive. Every sample tested was toxic to both species and the NOECs for these tests ranged from <3 to 12% (Table V-1). The magnitude of response was similar between these tests; the EC50s ranged from 14->25% and 7-31% for the sea urchin and chronic Microtox tests, respectively.

Accumulation Time Effects

Toxicity to sea urchin sperm was detected in every sample collected during the accumulation study (Table V-2). The magnitude of toxicity was similar among most samples collected within a time period. For example, the toxic units (TU) for the T3 samples were within a factor of 2 of each other and ranged from 4.3 TU to 8.8 TU. Samples collected at T2 showed the greatest variability in toxicity within a time interval. Toxicity for these samples ranged from <4 TU to 10.8 TU. In all other cases, there was no more than a two-fold range of toxicity within a time interval (Table V-2).

R0009460

Substantial differences in the mean level of toxicity were present among time intervals. The lowest level of toxicity and least variability were present in samples collected immediately after pressure washing the study sites (T0). All of the T0 samples had the highest NOEC (25%) and lowest toxic units (<2 TU to 2.7 TU) measured in the study (Table V-2). The mean toxicity in the T0 group (2.0 TU) was significantly lower than the average toxicity of all other groups, which ranged from 5.0 to 12.1 TU (Figure V-3).

The temporal variation of toxicity was similar to the pattern observed for most of the chemical constituents. The highest magnitude of toxicity was present in samples collected following 1 month of accumulation (T1). The average toxicity of these samples was significantly greater than the toxicity at T0 or prior to cleaning (Figure V-3). Toxicity in the T2 and T3 samples declined by approximately 50% relative to T1, but these differences were not statistically significant from the T1 mean.

Variations in traffic use did not have a consistent effect on toxicity. High traffic use sites tended to have greater toxicity in the T1 samples, but the differences were relatively small (Figure V-4). An opposite trend was observed for the T2 and T3 samples. Toxicity within these intervals tended to be approximately 50% lower in samples from high traffic areas (Figure V-4).

Variation in maintenance level produced no discernible effect on toxicity of samples from most of the sampling events. Maintained high use sites were approximately twice as toxic at T2 (Figure V-4). The difference in toxicity between maintained and unmaintained sites was much less for all other sampling events.

Rainfall Intensity and Duration Effects

Sea urchin fertilization tests of the runoff samples collected during the intensity and duration study detected toxicity in every sample. The magnitude of toxicity was quite variable among treatments, ranging from 2.6 to 13.8 TU (Table V-3). However, little variability in toxicity was present among the samples within a treatment group. Less than a two-fold difference in toxicity was found among the three replicate samples within each intensity/duration group (Table V-3).

Differences in both rain intensity and duration had a pronounced and predictable effect on toxicity. Toxicity was inversely related to both of these factors, as illustrated in Figure V-5. For the same duration interval (i.e., 10-20 min), toxicity decreased as rainfall intensity increased from 6 mm/hr to 25 mm/hr. Samples collected later in the rainfall event at the same intensity always contained less toxicity.

The toxicity data also indicated that an interaction between intensity and duration was present. For example, the relative decrease in toxicity between the 0-10 min and 10-20 min intervals at 6 mm/hr was less (31 %) than the change (54 %) measured at an intensity of 25 mm/hr.

The magnitude of toxicity present in the various intensity/duration groups was determined in large part by the portion of the rainfall event captured in the sample. This relationship is evident when toxicity is plotted relative to the volume of simulated rainfall represented by a sample (Figure V-6). For example, the highest toxicity was present in samples that contained runoff from the first 15 L of flow. A similar amount of toxicity was present in samples that contained runoff corresponding to 13.2-26.4 L of runoff. even though the intensity of the simulated rainfall varied four-fold (6-25 mm/hr).

Toxicant Characterization

Phase I TIEs were conducted on one runoff sample from each of the T2 and T3 sampling events. Similar results were obtained for each sample (Figures V-7 and V-8): both the EDTA addition and C-18 extraction treatments eliminated most of the toxicity. Extraction of nonpolar organic compounds from the samples using a C-18 column was the most effective treatment; this procedure eliminated essentially all of the toxicity. Addition of EDTA to complex cationic trace metals (e.g., copper and zinc) eliminated 44 to 76% of the toxicity.

The two other TIE procedures, the removal of particles and addition of sodium thiosulfate (to reduce oxidants), were not effective in reducing toxicity. The TIE results also indicated that toxicity in the samples was stable during short-term storage; no significant change in toxicity was found between the initial measurement and the TIE baseline measurement conducted 2 d later.

Chemical analysis of the TIE samples indicated that detectable concentrations of three potentially toxic constituents (zinc, copper, and total PAH) were present. Of these three constituents, only zinc was present at a sufficiently high concentration to cause substantial toxicity (Figures V-7 and V-8). Limited data are available that describe the toxicity of individual PAHs to sea urchin sperm, but unpublished SCCWRP data for several PAHs indicates that concentrations of ≥100 µg/L are needed to produce toxicity. The PAH concentrations in these samples were below 30 µg/L, which suggested that these organics were unlikely to be responsible for much of the sample toxicity.

Correlation analysis of the chemistry and toxicity data for all test samples supported the hypothesis that the runoff toxicity was likely related to trace metals. Significant correlations were obtained for both the total and dissolved forms of most metals, with no significant correlation between PAH concentration and toxicity (Table V-4). Correlations were highest (>0.6) for total and dissolved chromium, total aluminum, total nickel, and total and dissolved zinc.

Plots of the chemistry and toxicity data corroborate the correlation results. A clear trend of increased toxicity at higher concentrations of total Cr or dissolved Zn is evident (Figure V-9). However, variations in the concentration of TSS or PAH show little relationship with toxicity.

The correlation results indicate that the concentrations of the primary cause of toxicity in these samples covary with the metals concentrations, but they do not prove that metals are the cause. Other (unmeasured) constituents that occur with metals in runoff may be the cause of toxicity.

Elution of the C-18 columns with solvent recovered a portion amount of toxicity (Figure V-10). The eluate was toxic when tested at a concentration that was 1.5-3x greater than the original concentration of the test sample. The inability of solvent elution to recover all of the toxicity removed could be due to several factors, inability of the solvent to remove all of the organics from the column, degradation of the toxicants during storage of the column between extraction and elution, and the binding of inorganic toxicants that are not soluble in the solvent (e.g., metals) to the column.

The binding of copper and zinc to C-18 columns has been observed in a previous study (Schiff *et al.* 2001); thus, an attempt was made to elute metals from the C-18 columns with an acid solution. The acid eluate of both columns was much more toxic than the solvent eluates (Figure V-10). All of the acid eluates, tested at 0.8-3x of the original sample concentration, were highly toxic to sea urchin sperm. Some toxicity was present in the blank for the acid eluate sample, but the unusual dose response pattern for this sample suggests that this toxicity may be an outlier.

The concentration of dissolved zinc in the runoff samples ranged from 140 to 620 ug/L. The toxic units of zinc corresponding to these concentrations (calculated using laboratory-derived EC50s for these metals) is greater than the number of toxic units measured using the sea urchin fertilization test (Figure V-11). This result indicates that a sufficient concentration of zinc was present in each of the runoff samples to account for all of the toxicity measured. Dissolved copper in these samples ranged from 0 to 37 µg/L, corresponding to less than 10% of the toxicity of any sample.

Discussion

The results of this study indicate that runoff from transportation land uses, such as parking lots and roadways, are an important source of toxicity in urban runoff. All of the simulated runoff samples measured in the present study were toxic, and the magnitude of toxicity was usually higher than that measured in other urban stormwater samples. For example, composite stormwater samples collected from the Los Cerritos Channel in Long Beach, California, during 2001 contained fewer than 4 TU (Kinnetic Laboratories, Inc. and SCCWRP 2001), whereas nearly all parking lot runoff samples contained greater than 4 TU. Samples from the Los Cerritos Channel contained the highest magnitude of toxicity among the Long Beach stormwater sampling locations during the 2000/2001 NPDES monitoring program.

The high relative sensitivity of the sea urchin fertilization test found in this study are similar to those obtained in other recent studies. Two previous studies have used multiple marine species to measure the toxicity of urban stormwater. In each case, the sea urchin fertilization test was more sensitive than the 7-d mysid survival and growth test (Kinnetic Laboratories, Inc. and SCCWRP 2001, SCCWRP 1999).

The Microtox chronic test was similar in sensitivity to parking lot runoff as the sea urchin fertilization test. Both test methods detected toxicity in all six samples analyzed as part of the method comparison study (Table V-1). In addition, the magnitude of toxicity, as indicated by the EC50, was similar between these two test methods. These results indicate that the chronic Microtox test procedure may be useful for stormwater toxicity monitoring and research. However, the acute Microtox is of limited value for stormwater assessment in Long Beach. The acute test failed to detect toxicity in several samples that contained approximately 5 TU of chronic Microtox toxicity.

The accumulation study results indicated that typical street/parking lot maintenance activities (i.e., sweeping) were not effective for reducing runoff toxicity. Manual sweeping of the study sites did not significantly affect runoff toxicity levels. However, more rigorous cleaning activities may be effective in reducing stormwater toxicity. For example, pressure washing of the study sites at the beginning of the experiment reduced the toxicity of the runoff by a factor of 3. Toxicity was not eliminated by pressure washing, indicating that more research is needed to identify the most effective methods for eliminating stormwater toxicity.

Toxicity measurements at different time intervals indicated that a toxicity first-flush effect was present. Runoff samples collected during the first 10 min of a rain event were approximately twice as toxic as runoff from later portions of the simulated storm (Figure V-5). This finding was in agreement with the results of chemical analyses of the samples, which showed the first portion of the runoff event to contain the highest constituent concentrations. These results indicate that stormwater treatment systems that capture or treat the initial portion of stormwater discharge from parking lots are likely to provide the greatest benefit in terms of reducing toxic constituents.

The results of the intensity and duration experiment also illustrate the importance of collecting a sample of known and representative composition for stormwater monitoring programs. Failure to capture the initial phase of stormwater runoff may underestimate the magnitude of toxicity present and variations in sample compositing methods may increase the variability in the results.

The toxicant characterization and identification experiments, though limited in number, suggested that parking lot runoff toxicity to sea urchins was due primarily to metals, especially zinc. These results are similar to the results of TIEs from other studies, which have identified zinc as a primary toxicant of concern in stormwater runoff from Ballona Creek in Los Angeles, California, and Chollas Creek in San Diego, California (Bay *et al.* 1999, SCCWRP 1999). The TIE experiments also determined that the toxic constituents of parking lot runoff were confined to the dissolved fraction, which is usually a more biologically available form than particulate metals. This finding has implications for the design of BMPs to reduce stormwater toxicity. The BMPs that are based primarily on particulate removal are not likely to be effective in reducing the toxicity of stormwater runoff from parking lots.

TABLE V-1. Comparison of toxicity test responses for three marine species. Data for the mysid test are based on the most sensitive of either the survival (s) or growth (g) endpoints, as indicated by the letter following the value.

			NOEC (%)				EC50 (%)			
		Use/	Sea		Microtox		Sea		Microtox

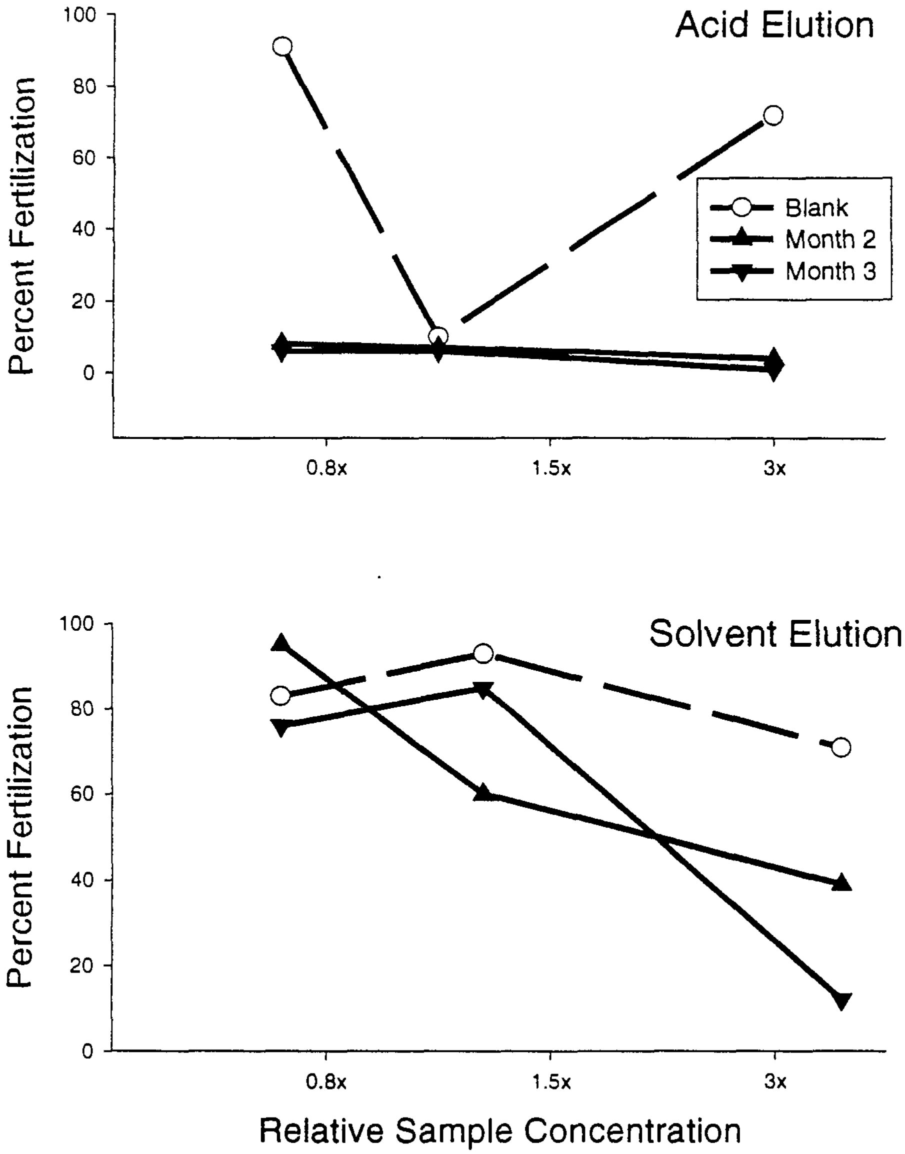

FIGURE V-10. Toxicity of acid or solvent eluates of C-18 column used for TIE. Concentration is expressed relative to the highest concentration tested in the Phase I TIE test.

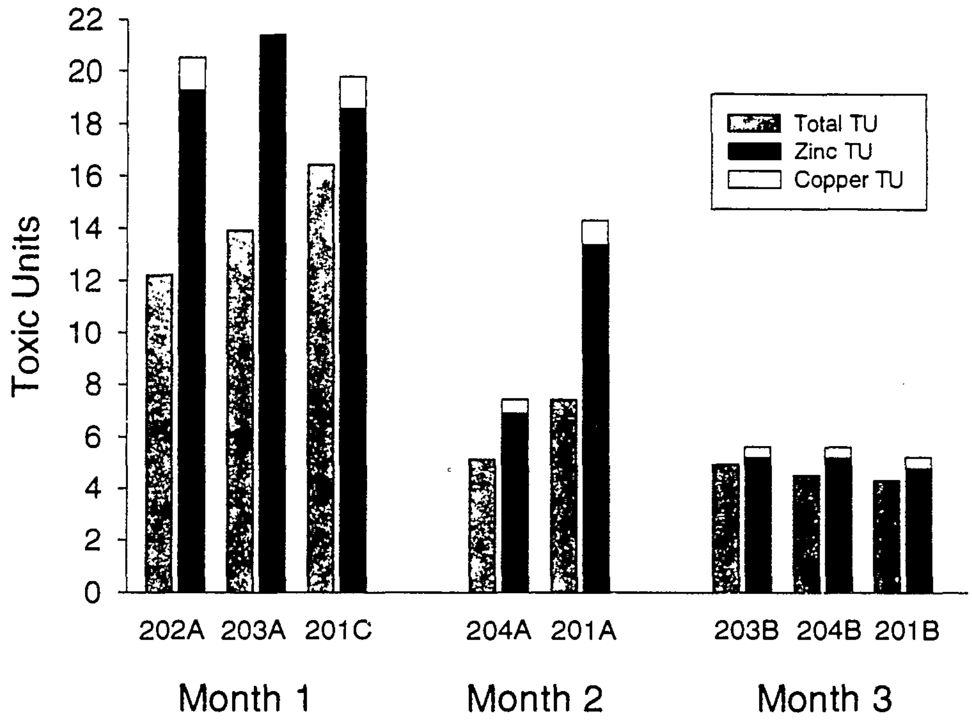

FIGURE V-11. Comparison of measured and calculated toxic units for runoff samples analyzed during the accumulation experiment. Calculated toxic units are based on the concentration of dissolved zinc and copper in the sample.

VI. CONCLUSIONS

- *Accumulation of most constituents occurred within 28 d.*

  Seventeen of 18 constituents had increased concentrations relative to the T0 sampling, ranging from 20-181%, in runoff samples collected after one month of accumulation. Zinc showed the highest accumulation, increasing by nearly a factor of 3 during the antecedent time period. Only total PAH did not increase; concentrations of PAH declined by 20%.

  -- The variability in temporal patterns remains unexplained.

  Constituent concentrations peaked during the first month of accumulation and then decreased in months 2 and 3. Physical factors other than those addressed in this study may play a role in increasing or decreasing the accumulation of constituents on parking lot surfaces including human activities, indirect vehicle deposition, wind, and atmospheric deposition, among others. This study measured time over a period of months; shorter time scales (days to weeks) are needed to explain these types of patterns and interactions.

- *Parking lot usage did not affect the accumulation of runoff constituents.*

  Similar concentrations of TSS, trace metals, and total PAH were observed between parking lots with ≤ 4 cars per hour and parking lots with > 5 cars per hour.

- *Parking lot maintenance did not affect the accumulation of runoff constituents.*

  Parking lots where street sweeping was employed as a maintenance activity had similar runoff concentrations compared to parking lots without street sweeping. Improved street sweeping technology or alternative BMPs will be required to reduce concentrations of contaminants in runoff. Current street sweeping technology may be effective, however, in reducing other types of runoff-transported pollution such as trash or debris.

- *Pressure washing appeared to be partially effective in reducing the accumulation of runoff constituents.*

  Mean constituent concentrations in parking lot runoff were lower after pressure washing compared to mean constituent concentrations in parking lot runoff immediately following pressure washing. Some constituents, in particular zinc, were reduced by as much as 50%.

- *Runoff constituent concentrations were inversely correlated with rainfall duration and intensity. Rainfall duration was more important than intensity during this study.*

  The TSS concentrations varied by one order of magnitude between samples collected at 2 min and samples collected 12 min after the onset of rain, indicating the presence of a first flush. Moreover, more than 75% of the TSS load was washed off in the first 15 min of the simulated storms. The "first-flush" effect was more pronounced during less intense simulated rain events, but the importance of rainfall intensity decreased with longer storm duration.

- *Toxicity was consistently measured in parking lot runoff, but not all species responded similarly to exposure to runoff samples.*

  One hundred percent of simulated runoff samples elicited toxic responses. The sea urchin and marine bacteria were the most sensitive organisms; the mysid was the least sensitive organism. The level of toxicity observed in samples exposed to parking lot runoff was higher than the level observed during the Long Beach wet-weather monitoring program.

- *Toxicity patterns corresponded with constituent accumulation and rainfall intensity/duration patterns.*

  Toxicity in runoff samples increased by a factor of six after one month of accumulation. The magnitude of toxicity between runoff from high-use and low-use parking lots showed no consistent difference. Similarly, the magnitude of toxicity between parking lots with or without street sweeping was similar. A toxicity first-flush effect was also present in runoff samples collected during the first 10 min of a rain event. Runoff samples collected during this time interval were twice as toxic as runoff samples collected from later portions of the simulated storm.

- *Trace metals were an important contributor to toxicity.*

  The TIEs identified trace metals, particularly zinc, as the constituent responsible for toxicity in the purple sea urchin fertilization test. This conclusion was based upon the following findings: (1) complexation of trace metals completely removed toxicity; (2) concentrations of dissolved zinc were sufficient to induce toxic responses; and (3) variations in zinc concentrations among samples were significantly correlated with toxic responses.

VII. RECOMMENDATIONS

- *Parking lot BMPs that focus on initial storm flows will be most effective.*

  A large first-flush effect was observed during this study. Suspended solids concentrations were highest and nearly 75% of the mass emissions occurred in the first 15 min of the simulated rainfall events. Capturing or treating these initial storm flows, particularly at relatively small temporal scales (0-15 min), would likely be most effective at reducing concentrations and loads of runoff constituents.

- *Managers should give priority to reducing dissolved trace metals in runoff treatment programs.*

  Dissolved trace metals, in particular zinc, were identified as the constituents responsible for toxicity to marine organisms such as the purple sea urchin. This finding has been observed in wet-weather discharges from watersheds throughout southern California. Most structural BMPs today do not attempt to ameliorate dissolved constituents in wet-weather runoff.

- *Additional maintenance strategies need to be tested.*

  Parking lot sites that received street sweeping every two weeks showed no difference when compared to parking lot sites that received no street sweeping. However, some moderate decreases in constituent concentrations were observed in runoff samples following pressure washing as a maintenance activity. Additional maintenance strategies, such as, improved street sweepers (i.e. regenerative air sweepers), should be evaluated to assess their effectiveness. Existing maintenance strategies should be retested using additional variable factors (i.e., land uses, constituents, antecedent dry periods, etc.)

- *The accumulation study design needs to be refined.*

  A significant increase in constituent concentrations and toxicity was observed after one month of accumulation. However, most constituent concentrations and some toxicity levels decreased in subsequent months, indicating that secondary factors may influence the accumulation of toxics on parking lot surfaces. Future studies should attempt to account for these factors by measuring wind speed and direction, rainfall, and other variables while decreasing the time interval between sampling events.

Chapter 4: Unified Stormwater Sizing Criteria

4.1 Introduction

This chapter presents a unified approach for sizing SMPs in the State of New York to meet pollutant removal goals, maintain groundwater recharge, reduce channel erosion, prevent overbank flooding, and control extreme floods. For a summary, please consult Table 4.1 below. The remaining sections describe the four sizing criteria in detail and present guidance on how to properly compute and apply the required storage volumes. Justification for the selected sizing criteria can be found in the Technical Support Memorandum submitted to the New York DEC on September 5th, 2000.

Table 4.1. Proposed New York Stormwater Sizing Criteria

Water Quality (WQ_v)	**90% Rule:** $WQ_v = [(P)(R_v)(A)]/12$ $R_v = 0.05+0.009(I)$ I = Impervious Cover (Percent) Minimum Rv = 0.2 P = 90% Rainfall Event Number (See Figure 4.1) A = site area in acres
Channel Protection (Cp_v)	**Default Criterion:** Cp_v = 24 hour extended detention of post-developed 1-year, 24-hour storm event. **Option for Sites Larger than 50 Acres:** Distributed Runoff Control - geomorphic assessment to determine the bankfull channel characteristics and thresholds for channel stability and bedload movement.
Overbank Flood (Q_p)	Control the peak discharge from the 10-year storm to 10-year predevelopment rates.
Extreme Storm (Q_f)	Control the peak discharge from the 100-year storm to 100-year predevelopment rates. Safely pass the 100-year storm event.

Note: The local review authority may waive channel protection, overbank flood, and extreme storm requirements in some instances. Guidance is provided with each of the these stormwater practices

Section 4.2 Water Quality Volume (WQ_v)

The Water Quality Volume (denoted as the WQ_v) is designed to improve water quality sizing to capture and treat 90% of the average annual stormwater runoff volume. The WQ_v is directly related to the amount of impervious cover created at a site. Contour lines of the 90% rainfall event are presented in Figure 4.1.

The following equation can be used to determine the water quality storage volume WQ_v (in acre-feet of storage):

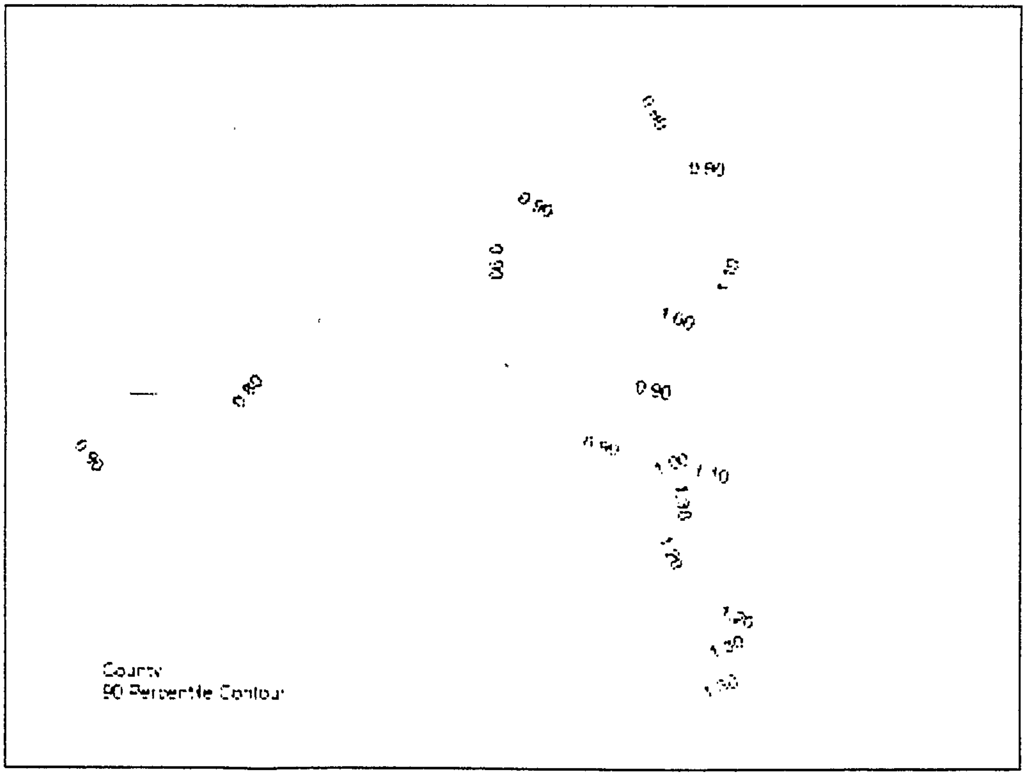
$$WQ_v = \frac{(P)(R_v)(A)}{12}$$

where:

WQ_v	= water quality volume (in acre-feet)
P	= 90% Rainfall Event Number (see Figure 4.1)
R_v	= 0.05 + 0.009(I), where I is percent impervious cover
A	= site area in acres

A minimum WQ_v of 0.2 inches per acre shall be met at residential sites that have less than 17% impervious cover.

Figure 4.1 90% Rainfall in New York State



The water quality criterion presented here assumes that sizing practices using these volumes, and using the practices presented in Table 5.1, using the technical support provided in this manual will by default meet water quality objectives. In some jurisdictions, on-site loading is required to demonstrate removal of specific pollutants. As an aid to these communities, Appendix A of this manual includes a discussion of a method for calculating pollutant export loads from development sites. This method, known as the "Simple Method," provides estimates for stormwater runoff pollutant loads for urban areas using a modest amount of information, including the subwatershed drainage area and impervious cover, stormwater runoff pollutant concentrations, and annual precipitation. Please consult Appendix A for a more detailed discussion of the Simple Method and its applications for water quality.

Basis For Design for Water Quality

As a basis for design, the following assumptions may be made:

- *Measuring Impervious Cover:* the measured area of a site plan that does not have permanent vegetative or permeable cover shall be considered total impervious cover. Impervious cover is defined as all impermeable surfaces and includes: paved and gravel road surfaces, paved and gravel parking lots, paved driveways, building structures, paved sidewalks, and miscellaneous impermeable structures such as patios, pools, and sheds. Porous or modular block pavement may be considered 50% impervious. Where site size makes direct measurement of impervious cover impractical, the land use/impervious cover relationships presented in Table 4.2 can be used to initially estimate impervious cover.

Table 4.2. Land Use and Impervious Cover (Source: Cappiella and Brown, 2001)

Land Use Category	Mean Impervious Cover
Agriculture	2
Open Urban Land*	9
2 Acre Lot Residential	11
1 Acre Lot Residential	14
1/2 Acre Lot Residential	21
1/4Acre Lot Residential	28
1/8 Acre Lot Residential	33
Townhome Residential	41

Table 4.2. Land Use and Impervious Cover (Source: Cappiella and Brown, 2001)	
Land Use Category	**Mean Impervious Cover**
Multifamily Residential	**44**
Institutional**	**31-38%**
Light Industrial	**50-56%**
Commercial	**70-74%**
* Open urban land includes developed park land, recreation areas, golf courses, and cemeteries. ** Institutional is defined as places of worship, schools, hospitals, government offices, and police and fire stations	

- *Aquatic Resources*: More stringent local regulations may be in place or may be required to protect drinking water reservoirs, lakes, or other sensitive aquatic resources. Consult the local authority to determine the full requirements for these resources.

- *SMP Treatment*: The final WQ_v shall be treated by an acceptable practice from the list presented in this manual. Please consult Chapter 5 for a list of acceptable practices.

- *Determining Peak Discharge for WQ_v Storm*: When designing flow splitters for off-line practices, consult the small storm hydrology method provided in Appendix B.

- *Extended Detention for Water Quality Volume*: The water quality requirement can be met by providing 24 hours of the WQ_v (provided a micropool is specified) extended detention. A local jurisdiction may reduce this requirement to as little as 12 hours in trout waters to prevent stream warming. This storm must be routed separately from the channel protection (Cpv) storm.

- *Off site Areas:* Off site areas shall be assumed to be undeveloped for computing the water quality volume (i.e., treatment is required for only on-site impervious areas).

Section 4.3 Stream Channel Protection Volume Requirements (Cp_v)

Stream Channel Protection Volume Requirements (Cp_v) are designed to protect stream channels from erosion. In New York State this goal is accomplished by providing 24-hour extended detention of the one-year, 24-hour storm event. Trout waters may be exempted from the 24-hour ED requirement, with only 12 hours of extended detention required to meet this criterion.

For developments greater than 50 acres, with impervious cover greater than 25%, it is recommended that a detailed geomorphic assessment be performed to determine the appropriate level of control. Appendix J provides guidance on how to conduct this assessment.

The Cp_v requirement may not apply in certain conditions, including:

- This criterion *is not* required on areas that recharge the entire Cp_v volume.
- The site generates less than one (1) acre of impervious cover.
- The site discharges directly to a fourth order stream or greater, or tidal water.
- A downstream analysis reveals that channel protection is not required (see section 4.6).

A detention pond or underground vault are methods to meet the Cp_v requirement (and subsequent Q_{p10} and Q_f criteria). Schematics of the typical designs are shown in Figures 4.2. and 4.3. Note that, although these practices meet water quantity goals, they are unacceptable for water quality, and need to be coupled with a practice listed in Table 5.1. The Cp_v requirement may also be provided above the water quality (WQ_v) storage in a wet pond or wetland.

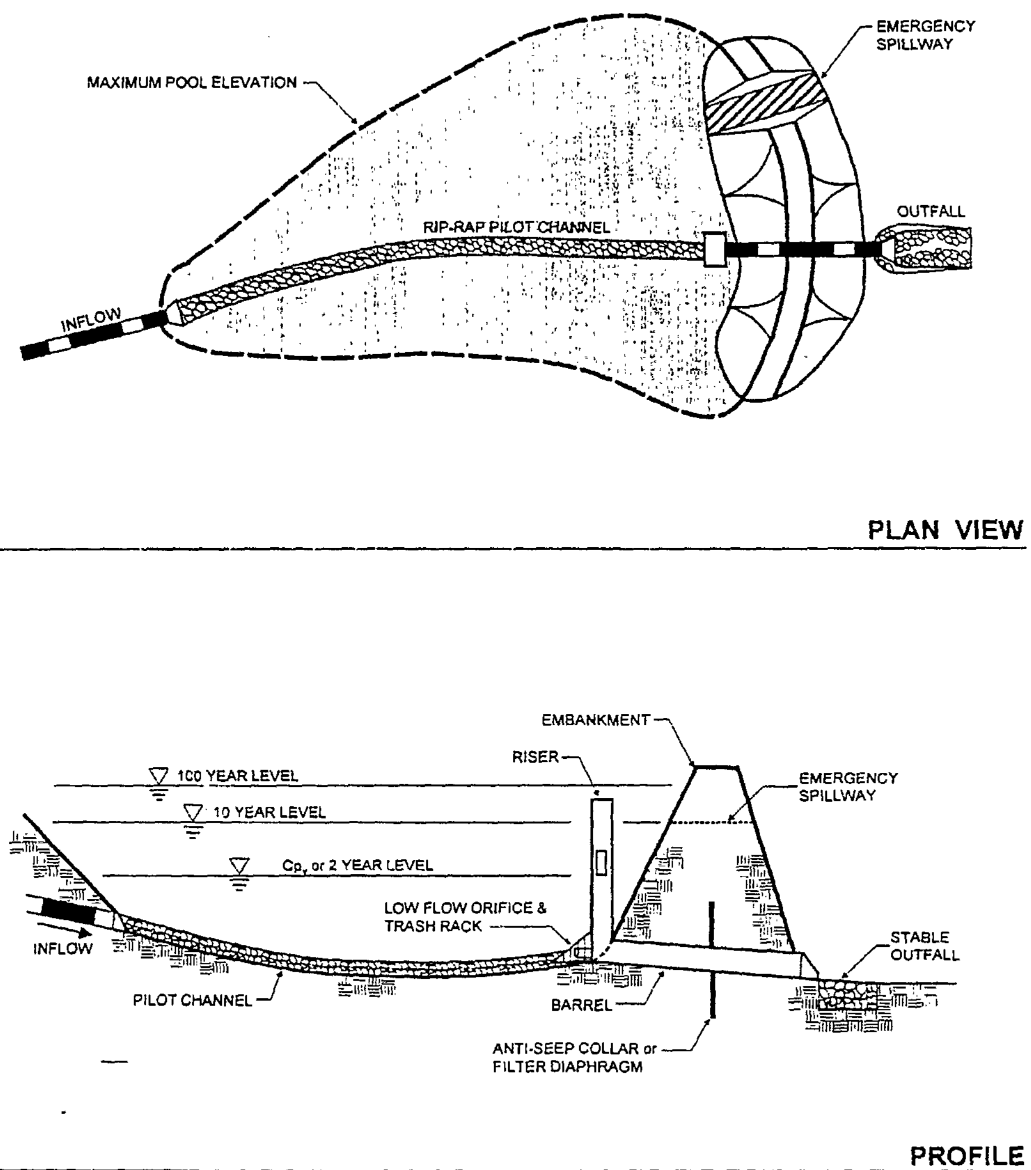
Basis for Determining Channel Protection Storage Volume

The following represent the minimum basis for design:

- The models TR-55 and TR-20 (or approved equivalent) shall be used to determine peak discharge rates.
- Rainfall depths for the one-year, 24 hour storm event are provided in Table 4.3.
- Off-site areas should be modeled as "present condition" for the one year storm event.
- The length of overland flow used in time of concentration (t_c) calculations is limited to no more than 100 feet for post development conditions.

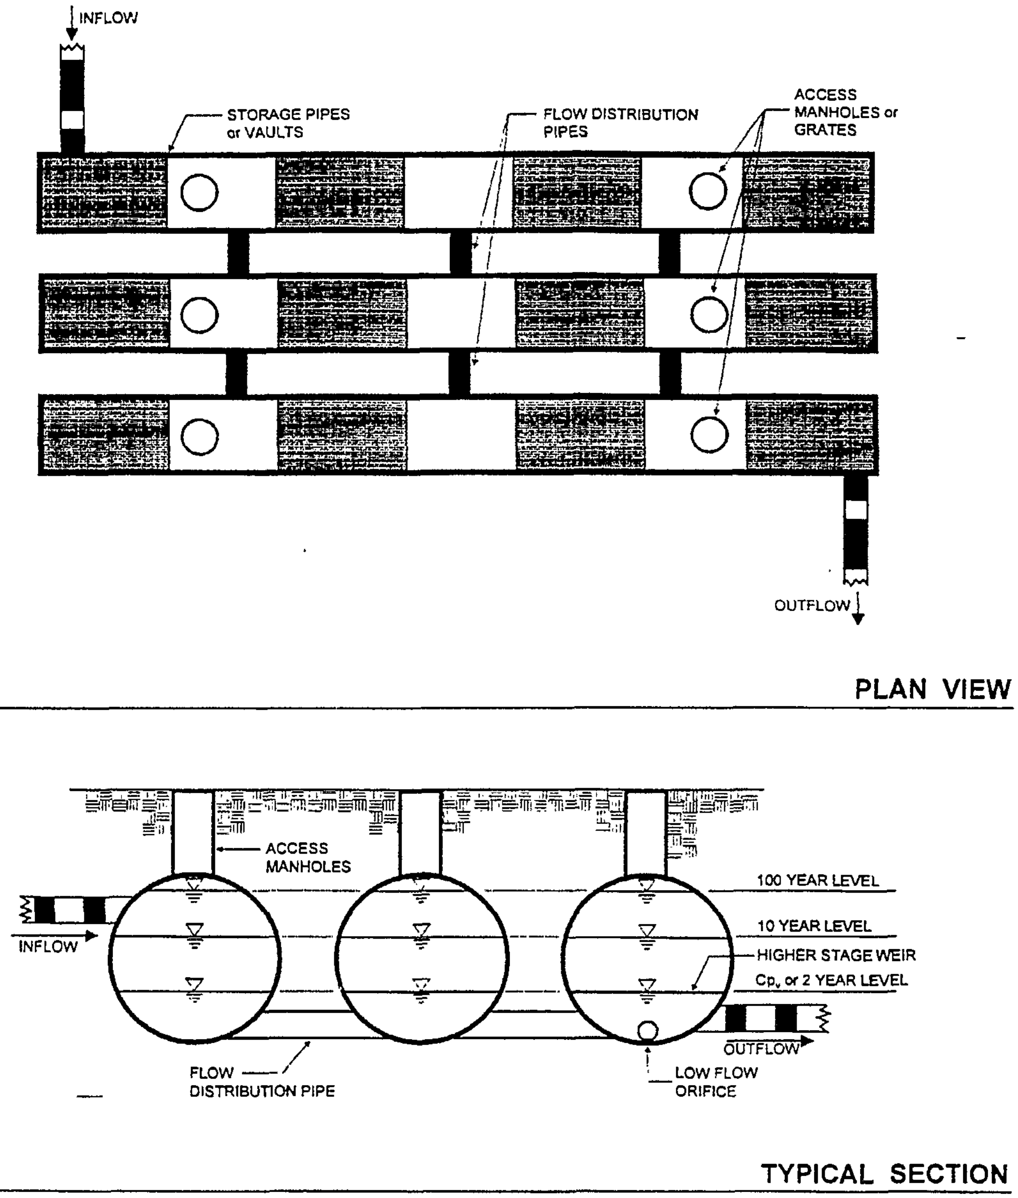
- Cp_v is not required at sites where the resulting diameter of the ED orifice is too small to prevent clogging. (A minimum 3" orifice with a trash rack or 1" if the orifice is protected by an exterior standpipe with slots less than the internal orifice are recommended to prevent clogging. See Figure 3 in Appendix K for design details).
- Extended detention storage provided for the channel protection (Cp_v-ED) does not meet the WQ_v requirement (that is Cp_v-ED and WQ_v-ED should be provided separately).
- The detention time for the one-year storm is defined as the difference in time from the center of mass of the inflow hydrograph and the center of mass of the outflow hydrograph (See Appendix B).

Figure 4.2. Example of a Conventional Stormwater Detention Pond



A typical detention facility provides channel protection control (Cp_v) and overbank control (Q_p) but no water quality control (WQ_v). If this practice is used, WQv must be provided in a separate facility listed on Table 5.1.

Figure 4.3. Example of Stormwater Detention Provided by an Underground Pipe System



An underground pipe system or vaults may be used to provide Cp_v, Q_p and Q_f controls but not WQ_v.

Section 4.4 Overbank Flood Control Criteria (Q_p)

The primary purpose of the overbank flood control sizing criteria is to prevent an increase in the frequency and magnitude of out-of-bank flooding generated by urban development (i.e., flow events that exceed the bankfull capacity of the channel, and therefore must spill over into the floodplain).

Overbank control must reduce 10-year post development runoff levels to 10-year pre-development levels.

The overbank flood control requirement (Q_p) does not apply in certain conditions, including:

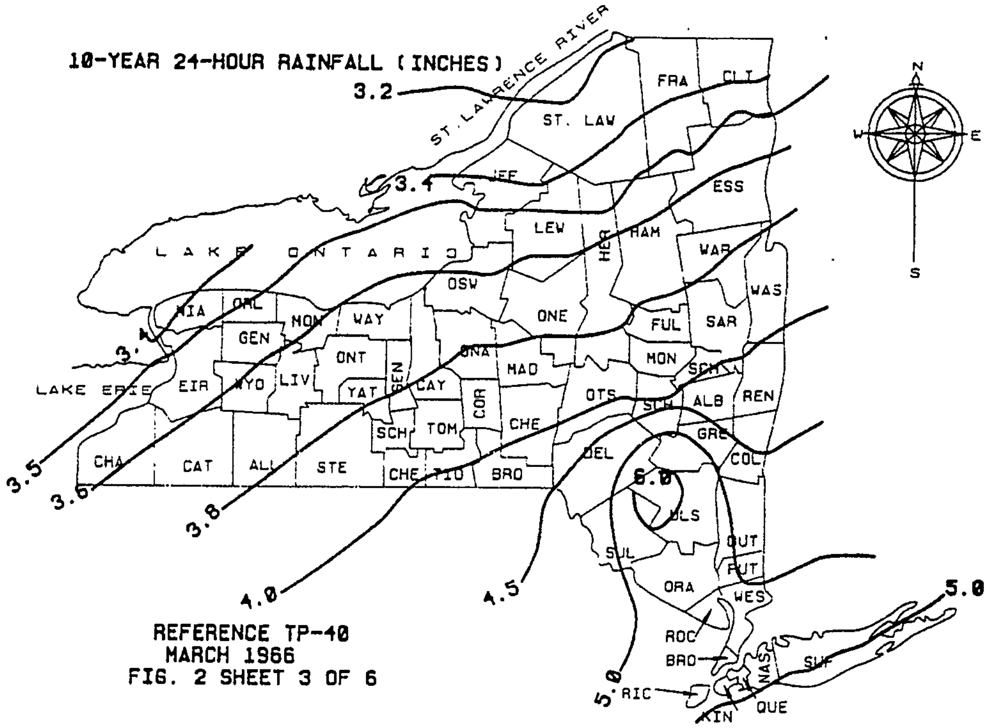
- The site is smaller than five (5) acres
- The site discharges directly tidal waters or fourth order or larger streams
- A downstream analysis reveals that overbank control is not needed (see section 4.7).

Basis for Design of Overbank Flood Control

When addressing the overbank flooding design criteria, the following represent the minimum basis for design:

- The models TR-55 and TR-20 (or approved equivalent) will be used for determining peak discharge rates.
- The standard for characterizing predevelopment land use for non-forested vegetated areas (including agriculture) shall be meadow in good condition.
- Off-site areas should be modeled as "present condition" for the 10-year storm event.
- Table 4.3 indicates the depth of rainfall (24 hour) associated with the 10-year storm event for all counties in the State of New York, and Figure 4.4 provides a graphical representation of this event.
- The length of overland flow used in t_c calculations is limited to no more than 150 feet for predevelopment conditions and 100 feet for post development conditions. On areas of extremely flat terrain, this maximum distance is extended to 250 feet for predevelopment conditions and 150 feet for postdevelopment conditions.

Figure 4.4. 10-Year Design Storm



R0009499

Section 4.5 Extreme Flood Control Criteria (Q_f)

The intent of the extreme flood criteria is to (a) prevent the increased risk of flood damage from large storm events, (b) maintain the boundaries of the predevelopment 100-year floodplain, and (c) protect the physical integrity of stormwater management practices

100 Year Control requires storage to attenuate the post development 100-year, 24-hour peak discharge rate (Q_f) to predevelopment rates.

The 100-year storm control requirement can be waived if:

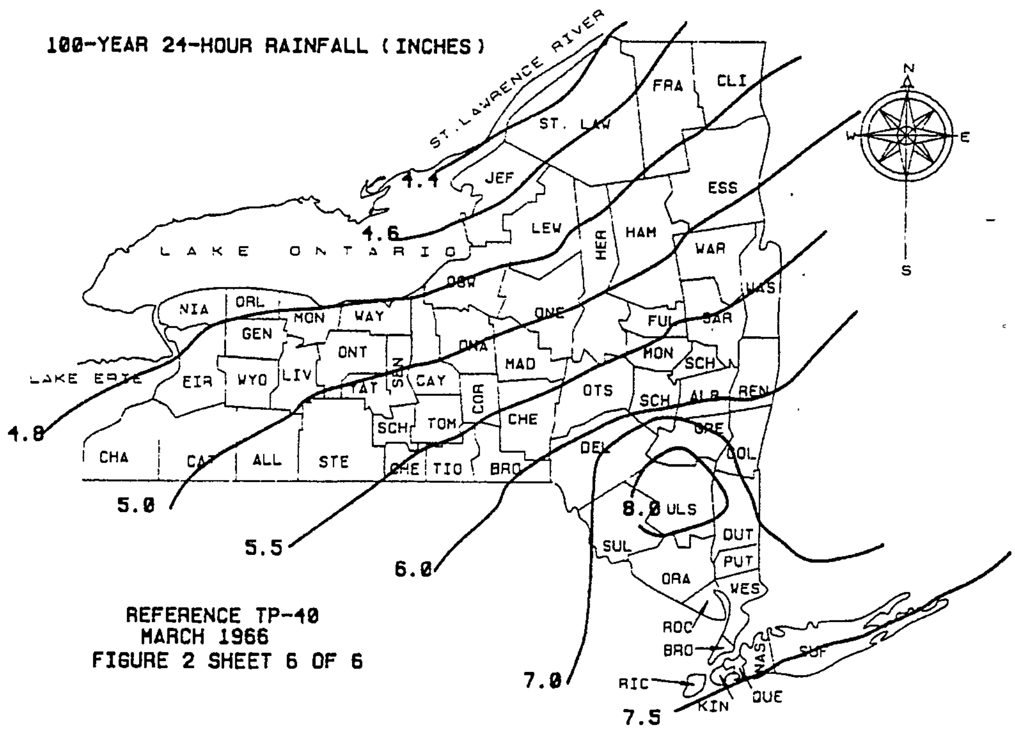
- The outfall discharges directly into tidal waters or fourth order or larger streams
- Development is prohibited within the ultimate 100-year floodplain
- A downstream analysis reveals that 100-year control is not needed (see section 4.7)

Detention structures must provide safe overflow of the 100-year storm event, according to State of New York Dam Construction Specifications and Guidance. For the most recent copy of this document, contact the New York State Department of Environmental Conservation, Dam Safety Division, at (518) 457-0834.

Basis for Design for Extreme Flood Criteria

- Consult with the appropriate review authority to determine the analyses required for the Q_f storm.
- The same hydrologic and hydraulic methods used for overbank flood control shall be used to analyze Q_f.
- Table 4.3 indicates the depth of rainfall (24 hour) associated with the 100-year storm event for all counties in the State of New York, and Figure 4.5 shows a graphical representation.
- For 100-year control, model off-shore areas as "existing," but to safely pass the 100-year flood, use ultimate conditions.

Figure 4.5. 100-Year Design Storm



R0009501

4.6 Conveyance Criteria

In addition to the stormwater treatment volumes described above, the manual also provides guidance on safe and non-erosive conveyance to, from, and through stormwater management practices (SMPs). Typically, the targeted storm frequencies for conveyance are the two-year and ten-year events. The two-year event is used to ensure non-erosive flows through roadside swales, overflow channels, pond pilot channels, and over berms within practices. Table 4.3 provides rainfall depths for the two-year, 24-hour storm event, and Figure 4.6 presents the information graphically. The ten-year storm is typically used as a target sizing for outfalls, and as a safe conveyance criterion for open channels practices and overflow channels.

4.7 Downstream Analysis

A community may waive the channel protection, overbank, and extreme flood requirements based on the results of a downstream analysis. In addition, such an analysis is recommended for larger sites (i.e., greater than 50 acres) to size facilities in the context of a larger watershed. This section provides brief guidance for conducting this analysis, including the area of stream to be evaluated and minimum elements to be included in the analysis.

Downstream analysis can be conducted using the 10% rule. That is, the analysis should extend downstream to the point where the site represents 10% of the total drainage area. For example, a 10-acre site would be analyzed to the point downstream with a drainage area of 100 acres.

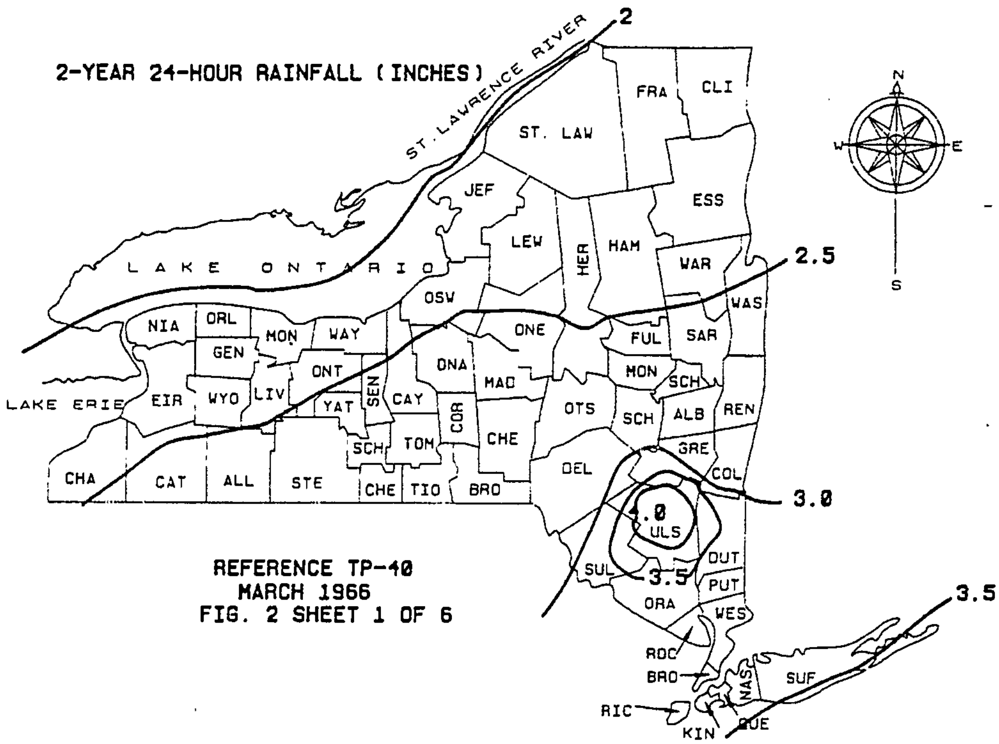
The analysis should include the following:

- Computation of flows and velocities for channel protection, overbank, and flood control storms at the point where the 10% rule is met, as well as all confluences along the downstream channel with first order or higher streams.
- Hydrologic and hydraulic effects of all culverts and/or obstructions within the downstream channel.
- An assessment of water surface elevations to determine if an increase in water surface elevations will impact existing buildings and other structures.

The design, or waiver, at a site level can be approved if the following criteria are met at both:

- Flow rates and velocities increase by less than 5% of the pre-developed condition for all flow conditions analyzed.
- No downstream structures or buildings are impacted.
- The site as designed is not expected to exacerbate downstream channel erosion.

Figure 4.6. 2 - Year Design Storm



R0009503

4.8 Stormwater Hotspots

A stormwater hotspot is defined as a land use or activity that generates higher concentrations of hydrocarbons, trace metals or toxicants than are found in typical stormwater runoff, based on monitoring studies. If a site is designated as a hotspot, it has important implications for how stormwater is managed. First and foremost, stormwater runoff from hotspots cannot be allowed to infiltrate into groundwater, where it may contaminate water supplies. Second, a greater level of stormwater treatment is needed at hotspot sites to prevent pollutant washoff after construction. This typically involves preparing and implementing *a stormwater pollution prevention plan* that involves a series of operational practices at the site that reduce the generation of pollutants from a site or prevent contact of rainfall with the pollutants. Table 4.4 provides a list of designated hotspots for the State of New York

Under EPA's stormwater NPDES program, some industrial sites are required to prepare and implement a stormwater pollution prevention plan. A list of industrial categories that are subject to the pollution prevention requirement can be found in the State of New York SPDES. In addition, New York's requirements for preparing and implementing a stormwater pollution prevention plan are also described in the general discharge permit provided in the SPDES. The stormwater pollution prevention plan requirement applies to both existing and new industrial sites.

Table 4.4 Classification of Stormwater Hotspots
The following land uses and activities are deemed *stormwater hotspots:* • Vehicle salvage yards and recycling facilities # • Vehicle fueling stations • Vehicle service and maintenance facilities • Vehicle and equipment cleaning facilities # • Fleet storage areas (bus, truck, etc.) # • Industrial sites (based on SIC codes outlined in the SPDES) • Marinas (service and maintenance) # • Outdoor liquid container storage • Outdoor loading/unloading facilities • Public works storage areas • Facilities that generate or store hazardous materials # • Commercial container nursery • Other land uses and activities as designated by an appropriate review authority
indicates that the land use or activity is required to prepare a stormwater pollution prevention plan under the EPA NPDES stormwater program.

In addition, if a site falls into a "hotspot" category outlined in Table 4.4, a pollution prevention plan may also be required by the appropriate reviewing authority. Golf courses and commercial nurseries may also be required to implement a plan by the appropriate review authority

The following land uses and activities are not normally considered hotspots:

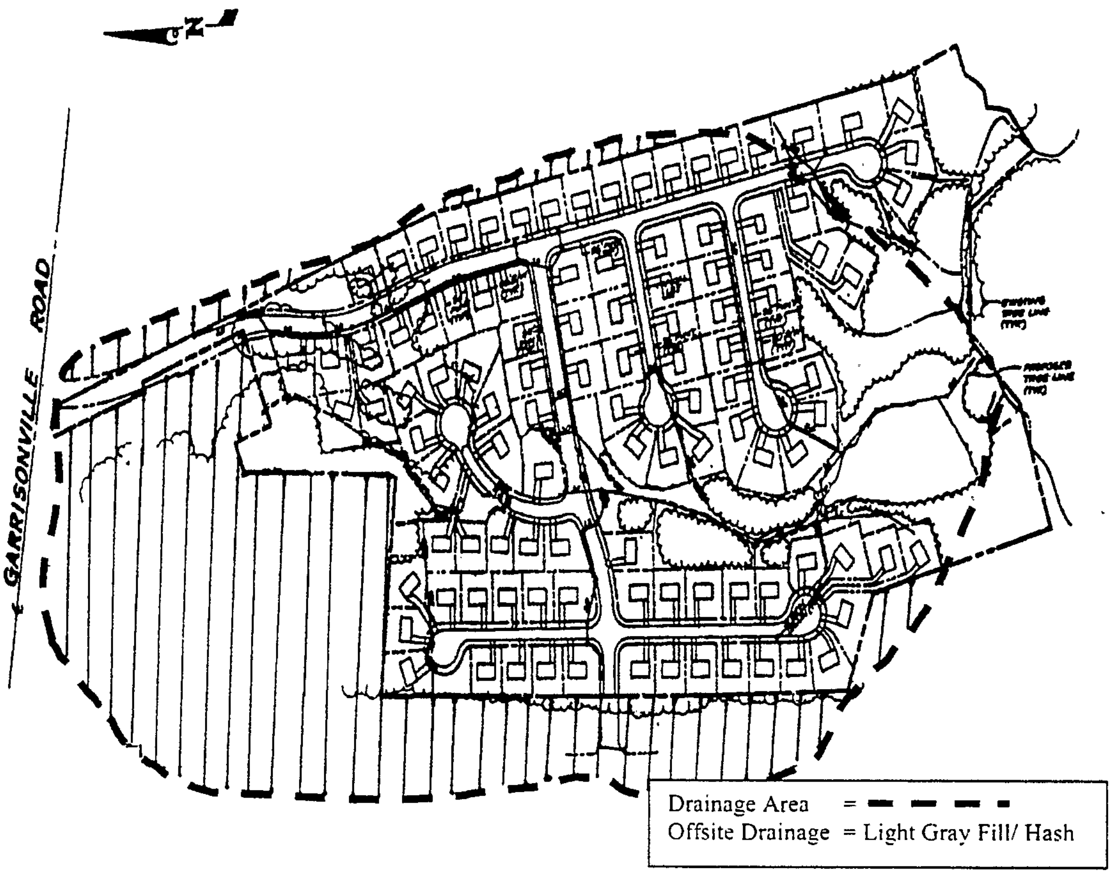
- Residential streets and rural highways
- Residential development
- Institutional development
- Office developments
- Non-industrial rooftops
- Pervious areas, except golf courses and nurseries (which may need an IPM Plan)

While large highways (average daily traffic volume (ADT) greater than 30,000) are not designated as a stormwater hotspot, it is important to ensure that highway stormwater management plans adequately protect groundwater.

4.9 Sizing Example - Stonehill Estates

Following is a sizing example for the hypothetical "Stone Hill Estates," a 45-acre residential develoment in Ithaca, New York (Figure 4.7). The site also drainas approximately 20 acres of off-site drainage, which is currently in a meadow condition. The site is on mostly C soils with some D soils.

Figure 4.7 Stone Hill Site Plan



Base Data
Location: Ithaca, NY
Site Area = 45.1 ac; Offsite Area = 20.0 ac (meadow)
Total Drainage Area (A) = 65.1
Measured Impervious Area=12.0 ac; or I=12.0/45.1=26.6%
Site Soils Types: 78% "C", 22% "D"
Offsite Soil Type: 100% "C"
Zoning: Residential (½ acre lots)

Hydrologic Data

	Pre	Post	Ult.
CN	72	78	82
t_c (hr)	.46	.35	.35

Computation of Preliminary Stormwater Storage Volumes and Peak Discharges

The layout of the Stone Hill subdivision is shown on the previous page.

Step 1. Compute preliminary runoff control volumes from Stormwater Sizing Criteria

Water Quality Volume, WQ_v

- Compute Runoff Coefficient, R_v

$$R_v = 0.05 + (I)(0.009)$$
$$= 0.05 + (26.6)(0.009) = 0.29$$

- Compute WQ_v (Offsite area does not need to be considered when determining the water quality volume)

Use the 90% capture rule with 0.9" of rainfall.

$$WQ_v = (0.9")(R_v)(A)$$
$$= (0.9")(0.29)(45.1\ ac)(1ft/12in)$$
$$= \underline{0.98\ ac\text{-}ft}$$

Figure 4.10. Stone Hill Ultimate Buildout Conditions

Compute Stream Channel Protection Volume, (Cp_v)

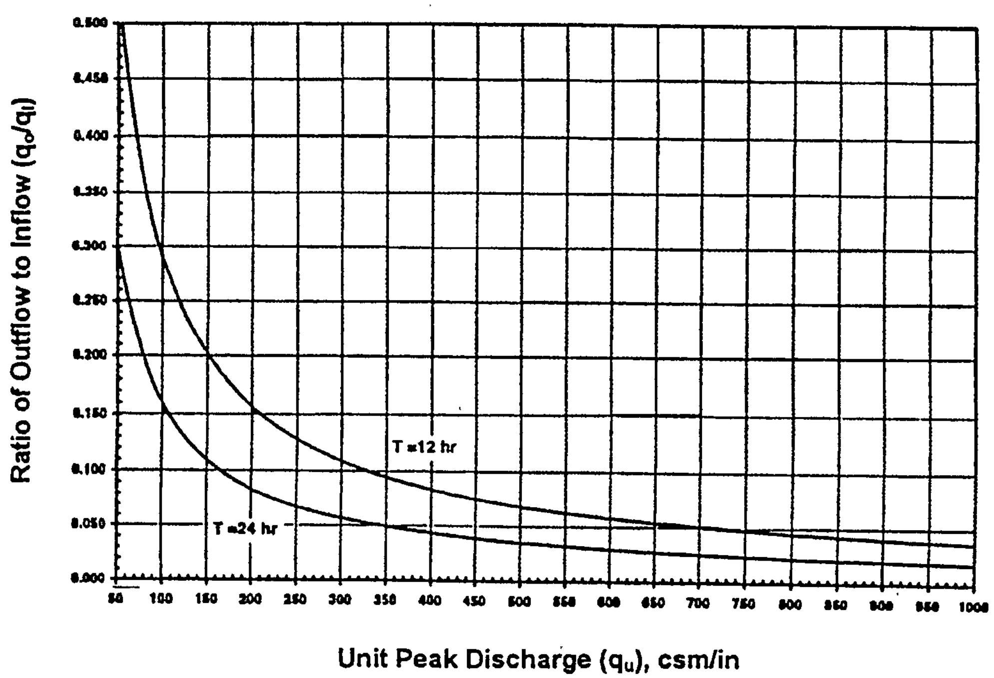
For stream channel protection, provide 24 hours of extended detention (T) for the one-year event.

Utilize SCS approach to Compute Channel Protection Storage Volume

- Initial abstraction (Ia) for CN of 78 is 0.564: [Ia = (200/CN - 2)]
- Ia/P = (0.564)/2.3 inches = 0.245
- T_c = 0.35 hours
- q_u = 570 csm/in (Type II Storm)

Knowing q_u and T (assume 24 hours of extended detention time), find q_o/q_i using Figure 4.11 (MDE, 2000). [Also see methodology in Appendix B]

Figure 4.11. Detention Time vs. Discharge Ratios (Source: MDE, 1998)



- Peak outflow discharge/peak inflow discharge (q_o/q_i) = 0.035
- $Vs/Vr = 0.683 - 1.43(q_o/q_i) + 1.64(q_o/q_i)^2 - 0.804(q_o/q_i)^3$
  - Where Vs equals channel protection storage (Cp_v) and Vr equals the volume of runoff in inches.
  - Vs/Vr = 0.63
  - Therefore, Vs = Cp_v = 0.63(0.7")(1/12)(65.1 ac) = 2.4 ac-ft (104,214 cubic feet)

Define the average ED Release Rate

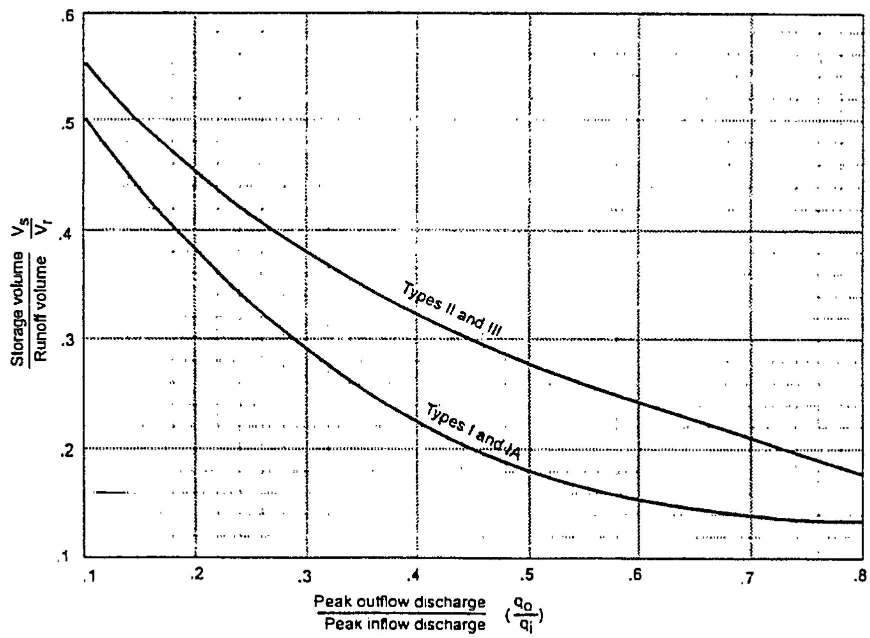
- The above volume, 2.4 ac-ft, is to be released over 24 hours
- (2.4 ac-ft × 43,560 ft^2/ac) / (24 hrs × 3,600 sec/hr) = 1.2 cfs

Compute Overbank Flood Protection Volume, (Qp_{10})

For both the overbank flood protection volume and the extreme flood protection volume, size is determined using the TR-55 "Short-Cut Method," which relates the storage volume to the required reduction in peak flow and storm inflow volume (Figure 4.12).

- For a Q_{in} of of 112 cfs (post-developed), and an allowable Q_{out} of 72 cfs (pre-developed), the value of $(Q_{out})/(Q_{in})$ is 0.64
- Using figure 4.12, and assuming a post-developed curve number of 78, the value of Vs/Vr is 0.23
- Using a runoff volume of 427,155 cubic feet (9.8 acre-feet), the required storage (Vs) is 2.23 acre-feet

Figure 4.12. Approximate Detention Basin Routing for Rainfall Types I, IA, II, and III
Source: TR-55, 1986



While the TR-55 short-cut method reports to incorporate multiple stage structures, experience has shown that an additional 10-15% storage is required when multiple levels of extended detention are provided inclusive with the 10-year storm. So, for preliminary sizing purposes, add 15% to the required volume for the 10-year storm. $Q_{p\text{-}10}$ = 2.23 × 1.15 = 2.56 ac-ft.

Compute Extreme Flood Protection Volume, (Q_f)

Extreme flood protection is calculated using the same methodology as overbank protection.

- For a Q_{in} of, and an allowable Q_{out} of, and a runoff volume of the Vs necessary for 100-year control is, under a developed CN of 78. Note that 5.5 inches of rain fall during this event, with approximately 3.1 inches of runoff.
- While the TR-55 short-cut method reports to incorporate multiple stage structures, experience has shown that an additional 10-15% storage is required when multiple levels of extended detention are provided inclusive with the 100-year storm. So, for preliminary sizing purposes add 15% to the required volume for the 100-year storm. $Q_{f\text{-}100} = 3.53 \times 1.15 = 4.06$ ac-ft.

Analyze Safe Passage of 100 Year Design Storm (Qf)

If peak discharge control of the 100-year storm is not required, it is still necessary to provide safe passage for the 100-year event under ultimate buildout conditions (Q_{ult} = 227 cfs).

Table 4.5. Summary of General Storage Requirements for Stone Hill Estates

Symbol	*Category*	Volume Required (ac- ft)	Notes
WQ_v	Water Quality Volume	0.98	
Cp_v	Stream Protection	2.4	Average ED release rate is 1.2 cfs over 24 hours
Q_p	Peak Control	2.5	10-year, in this case
Q_f	Flood Control	4.1

New York SW Management Manual -

4.1 Introduction

This chapter presents a unified approach for sizing SMPs in the State of New York to meet pollutant removal goals, maintain groundwater recharge, reduce channel erosion, prevent overbank flooding, and control extreme floods. For a summary, please consult Table 4.1 below. The remaining sections describe the four sizing criteria in detail and present guidance on how to properly compute and apply the required storage volumes. Justification for the selected sizing criteria can be found in the Technical Support Memorandum submitted to the New York DEC on September 5th, 2000.

Table 4.1. Proposed New York Stormwater Sizing Criteria

Water Quality (WQ_v)	**90% Rule:** $WQ_v = [(P)(R_v)(A)] / 12$ $R_v = 0.05+0.009(I)$ I = Impervious Cover (Percent) Minimum $R_v = 0.2$ P = 90% Rainfall Event Number (See Figure 4.1) A = site area in acres
Channel Protection (Cp_v)	**Default Criterion:** Cp_v = 24 hour extended detention of post-developed 1-year, 24-hour storm event. **Option for Sites Larger than 50 Acres:** Distributed Runoff Control - geomorphic assessment to determine the bankfull channel characteristics and thresholds for channel stability and bedload movement.
Overbank Flood (Q_p)	Control the peak discharge from the 10-year storm to 10-year predevelopment rates.
Extreme Storm (Q_f)	Control the peak discharge from the 100-year storm to 100-year predevelopment rates. Safely pass the 100-year storm event.

Note: The local review authority may waive channel protection, overbank flood, and extreme storm requirements in some instances. Guidance is provided with each of the these stormwater practices

R0009515

The water quality criterion presented here assumes that sizing practices using these volumes, and using the practices presented in Table 5.1, using the technical support provided in this manual will by default meet water quality objectives. In some jurisdictions, on-site loading is required to demonstrate removal of specific pollutants. As an aid to these communities, Appendix A of this manual includes a discussion of a method for calculating pollutant export loads from development sites. This method, known as the "Simple Method," provides estimates for stormwater runoff pollutant loads for urban areas using a modest amount of information, including the subwatershed drainage area and impervious cover, stormwater runoff pollutant concentrations, and annual precipitation. Please consult Appendix A for a more detailed discussion of the Simple Method and its applications for water quality.

Basis For Design for Water Quality

As a basis for design, the following assumptions may be made:

- *Measuring Impervious Cover*: the measured area of a site plan that does not have permanent vegetative or permeable cover shall be considered total impervious cover. Impervious cover is defined as all impermeable surfaces and includes: paved and gravel road surfaces, paved and gravel parking lots, paved driveways, building structures, paved sidewalks, and miscellaneous impermeable structures such as patios, pools, and sheds. Porous or modular block pavement may be considered 50% impervious. Where site size makes direct measurement of impervious cover impractical, the land use impervious cover relationships presented in Table 4.2 can be used to initially estimate impervious cover.

Table 4.2. Land Use and Impervious Cover (Source: Cappiella and Brown, 2001)

Land Use Category	Mean Impervious Cover
Agriculture	2
Open Urban Land*	9
2 Acre Lot Residential	11
1 Acre Lot Residential	14
1/2 Acre Lot Residential	21
1/4Acre Lot Residential	28
1/8 Acre Lot Residential	33
Townhome Residential	41

Section 4.3 Stream Channel Protection Volume Requirements (Cp_v)

Stream Channel Protection Volume Requirements (Cp_v) are designed to protect stream channels from erosion. In New York State this goal is accomplished by providing 24-hour extended detention of the one-year, 24-hour storm event. Trout waters may be exempted from the 24-hour ED requirement, with only 12 hours of extended detention required to meet this criterion.

For developments greater than 50 acres, with impervious cover greater than 25%, it is recommended that a detailed geomorphic assessment be performed to determine the appropriate level of control. Appendix J provides guidance on how to conduct this assessment.

The Cp_v requirement may not apply in certain conditions, including:

- This criterion *is not* required on areas that recharge the entire Cp_v volume.
- The site generates less than one (1) acre of impervious cover.
- The site discharges directly to a fourth order stream or greater, or tidal water.
- A downstream analysis reveals that channel protection is not required (see section 4.6).

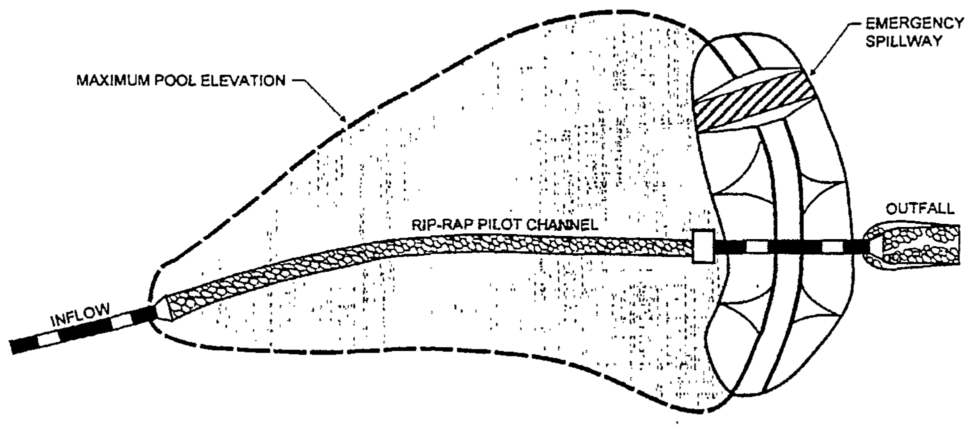
A detention pond or underground vault are methods to meet the Cp_v requirement (and subsequent Q_{p10} and Q_f criteria). Schematics of the typical designs are shown in Figures 4.2. and 4.3. Note that, although these practices meet water quantity goals, they are unacceptable for water quality, and need to be coupled with a practice listed in Table 5.1. The Cp_v requirement may also be provided above the water quality (WQ_v) storage in a wet pond or wetland.

Basis for Determining Channel Protection Storage Volume

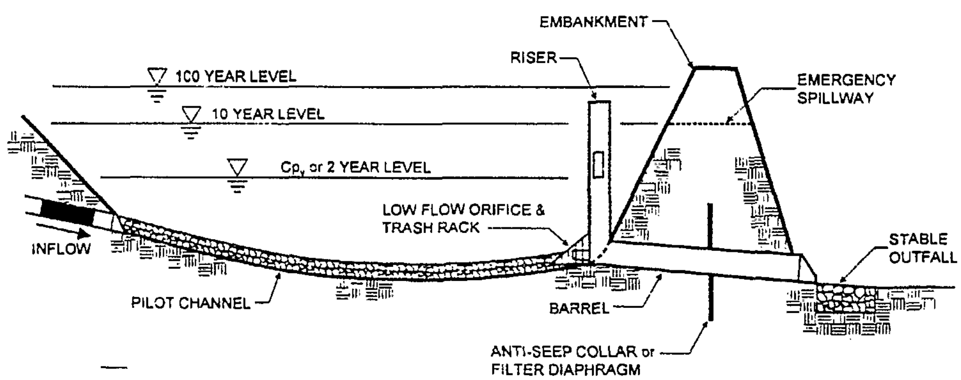
The following represent the minimum basis for design:

- The models TR-55 and TR-20 (or approved equivalent) shall be used to determine peak discharge rates.
- Rainfall depths for the one-year, 24 hour storm event are provided in Table 4.3.
- Off-site areas should be modeled as "present condition" for the one year storm event.
- The length of overland flow used in time of concentration (t_c) calculations is limited to no more than 100 feet for post development conditions.

Figure 4.2. Example of a Conventional Stormwater Detention Pond



PLAN VIEW



PROFILE

A typical detention facility provides channel protection control (Cp_v) and overbank control (Q_p) but no water quality control (WQ_v). If this practice is used, WQv must be provided in a separate facility listed on Table 5.1.

In addition, if a site falls into a "hotspot" category outlined in Table 4.4, a pollution prevention plan may also be required by the appropriate reviewing authority. Golf courses and commercial nurseries may also be required to implement a plan by the appropriate review authority

The following land uses and activities are not normally considered hotspots:

- Residential streets and rural highways
- Residential development
- Institutional development
- Office developments
- Non-industrial rooftops
- Pervious areas, except golf courses and nurseries (which may need an IPM Plan)

While large highways (average daily traffic volume (ADT) greater than 30,000) are not designated as a stormwater hotspot, it is important to ensure that highway stormwater management plans adequately protect groundwater.

4.9 Sizing Example - Stonehill Estates

Following is a sizing example for the hypothetical "Stone Hill Estates," a 45-acre residential develoment in Ithaca, New York (Figure 4.7). The site also drainas approximately 20 acres of off-site drainage, which is currently in a meadow condition. The site is on mostly C soils with some D soils.

Computation of Preliminary Stormwater Storage Volumes and Peak Discharges

The layout of the Stone Hill subdivision is shown on the previous page.

Step 1. Compute preliminary runoff control volumes from Stormwater Sizing Criteria

Water Quality Volume, WQ_v

- Compute Runoff Coefficient, R_v

$$R_v = 0.05 + (I)(0.009)$$
$$= 0.05 + (26.6)(0.009) = 0.29$$

- Compute WQ_v (Offsite area does not need to be considered when determining the water quality volume)

Use the 90% capture rule with 0.9" of rainfall.

$$WQ_v = (0.9")(R_v)(A)$$
$$= (0.9")(0.29)(45.1\ ac)(1ft/12in)$$
$$= \underline{0.98\ ac\text{-}ft}$$

Establish Hydrologic Input Parameters and Develop Site Hydrology (See Figures 4.8, 4.9, and 4.10)

Condition	**Area**	**CN**	**Tc**
	Ac		*hrs*
Pre-developed	65.1	72	0.46
Post-developed	65.1	78	0.35
Ultimate buildout	65.1	82	0.35

Figure 4.9. Stone Hill Post-Development Conditions

R0009526

Compute Stream Channel Protection Volume. (Cp_v)

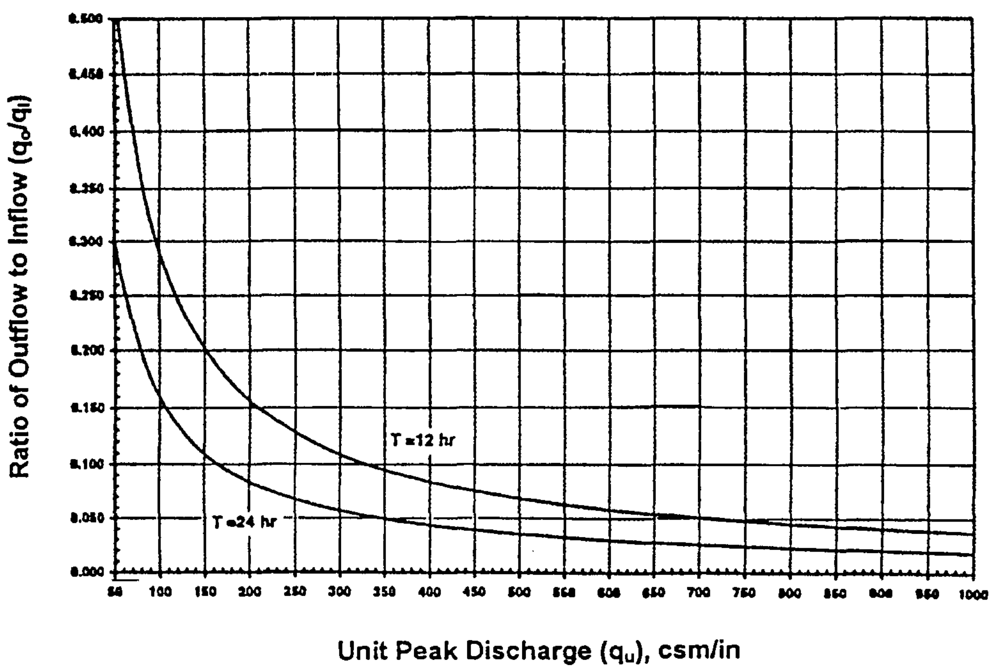
For stream channel protection, provide 24 hours of extended detention (T) for the one-year event.

Utilize SCS approach to Compute Channel Protection Storage Volume

- Initial abstraction (Ia) for CN of 78 is 0.564: [Ia = (200/CN - 2)]
- Ia/P = (0.564)/ 2.3 inches = 0.245
- T_c = 0.35 hours
- q_u = 570 csm/in (Type II Storm)

Knowing q_u and T (assume 24 hours of extended detention time), find q_o/q_i using Figure 4.11 (MDE, 2000). [Also see methodology in Appendix B]

Figure 4.11. Detention Time vs. Discharge Ratios (Source: MDE, 1998)



- Peak outflow discharge/peak inflow discharge (q_o/q_i) = 0.035
- $Vs/Vr = 0.683 - 1.43(q_o/q_i) - 1.64(q_o/q_i)^2 - 0.804(q_o/q_i)^3$
  - Where Vs equals channel protection storage (Cp_v) and Vr equals the volume of runoff in inches.
  - Vs/Vr = 0.63
  - Therefore, Vs = Cp_v = 0.63(0.7")(1/12)(65.1 ac) = 2.4 ac-ft (104,214 cubic feet)

R0009527

Compute Extreme Flood Protection Volume, (Q_f)

Extreme flood protection is calculated using the same methodology as overbank protection.

- For a Q_{in} of, and an allowable Q_{out} of, and a runoff volume of the Vs necessary for 100-year control is, under a developed CN of 78. Note that 5.5 inches of rain fall during this event, with approximately 3.1 inches of runoff.
- While the TR-55 short-cut method reports to incorporate multiple stage structures, experience has shown that an additional 10-15% storage is required when multiple levels of extended detention are provided inclusive with the 100-year storm. So, for preliminary sizing purposes add 15% to the required volume for the 100-year storm. $Q_{f-100} = 3.53 \times 1.15 = 4.06$ ac-ft.

Analyze Safe Passage of 100 Year Design Storm (Qf)

If peak discharge control of the 100-year storm is not required, it is still necessary to provide safe passage for the 100-year event under ultimate buildout conditions ($Q_{ult} = 227$ cfs).

Table 4.5. Summary of General Storage Requirements for Stone Hill Estates

Symbol	*Category*	Volume Required (ac- ft)	Notes
WQ	Water Quality Volume	0.98	
Cp	Stream Protection	2.4	Average ED release rate is 1.2 cfs over 24 hours
Q..	Peak Control	2.5	10-year, in this case
Q.	Flood Control	4.1	

CHAPTER 2

STORMWATER MANAGEMENT and URBAN BMPs

2-1 COMPONENTS OF STORMWATER MANAGEMENT

The goal of storm water management is to mitigate the impact on the hydrologic cycle resulting from changes to the land surface. Urban development has been identified as having a direct impact on the hydrologic cycle by reducing or even eliminating the natural storage capacity of the land. This impact is the result of a decrease in tree cover, loose organic surface soils, and natural depressions, all of which provide natural storage capacity. These natural storage areas are then replaced with impervious and managed pervious surfaces. Impervious cover prevents the percolation of the runoff into the soil, which means that most, if not all of the rainfall is converted to runoff. In addition, managed pervious areas, such as courtyards and lawn areas typically do not provide opportunities for infiltration due to compaction of the surface soil profile and improved drainage conveyances. (The impact of development on the hydrologic cycle is discussed in detail in **Chapter 4; Hydrologic Methods**.) The results of increased stormwater runoff can be classified by its impact on *water quality*, *stream channel erosion*, and *localized flooding*. These components are identified in the Virginia Stormwater Management (SWM) Regulations.

2-1.1 Water Quality

One of the impacts of stormwater runoff is that of the quality of the runoff on the aquatic ecosystem. Various soluble and particulate pollutants are found in stormwater runoff. Studies have shown that the source of these pollutants are atmospheric deposition, urban and agricultural lands, and natural spaces. The focus of this document is on the urban land sources. The impervious surfaces, such as parking lots, roof tops, roads, etc., which are associated with land development serve to accumulate and transport these pollutants to receiving stream channels. It should be noted that pervious areas associated with development, such as golf courses, parks, open space, etc., also contribute pollutants.

The following presents a basic overview of the typical urban pollutants. Additional discussion of urban pollutants associated with certain ultra-urban development environments, referred to as *stormwater hotspots* (Claytor, 1996) is discussed in **Section 2-3: BMP Selection Criteria**.

Nutrients. Concentrations of nutrients, such as nitrogen and phosphorus, found in urban runoff can cause eutrophication of receiving streams, lakes, and rivers, and estuaries. As these nutrients collect in slower moving water bodies, they promote the growth of algae, which in turn blocks sunlight to bottom grasses, and eventually leads to a depletion of available dissolved oxygen (DO). Nutrients in urban runoff have been identified as being a significant contributor to the decline of the Chesapeake Bay. The Virginia Tributary Strategy initiative calls for a 40% reduction in nutrients reaching the Chesapeake Bay by the year 2000.

Suspended solids. All natural drainage channels have a natural sediment bed load which helps maintain a state of equilibrium within the channels of undeveloped watersheds. Increases in the peak rates of flow through the channel or stream system will disrupt the equilibrium by increasing the amount of sediment removed from the channel bed and banks. Suspended solids which result from excessive erosion and scour channel, however, is quite often a very efficient conveyance system and promotes an even faster velocity of flow, which in turn, accelerates the channel erosion process. Once this process has begun, it is very difficult to stop because typical stream channel soils are highly erodible once the protective lining of cobble or vegetation is eroded away.

2-1.3 Flooding

When the rate of stormwater runoff exceeds the capacity of the various manmade or natural conveyance systems, the result is localized flooding. The conveyance system gradually catches up and drains the flood waters as the rainfall subsides. In some cases debris or other materials dislodged by the rising flood waters will clog the drainage system and cause longer periods of flooding. In either case, pockets of standing water which do not drain will remain for periods of time and eventually percolate into the ground or evaporate.

In the pre-developed condition, most stream channels have an adequate floodplain or flood fringe to convey and store the out of bank flows with minimal damage. With urbanization, however, these floodplain areas are often eliminated or developed with improvements. The periodic ponding of water in developed areas often results in damage. Pavement will fail or be undermined, structures will be water damaged, landscaping and other improvements not used to inundation will be damaged.

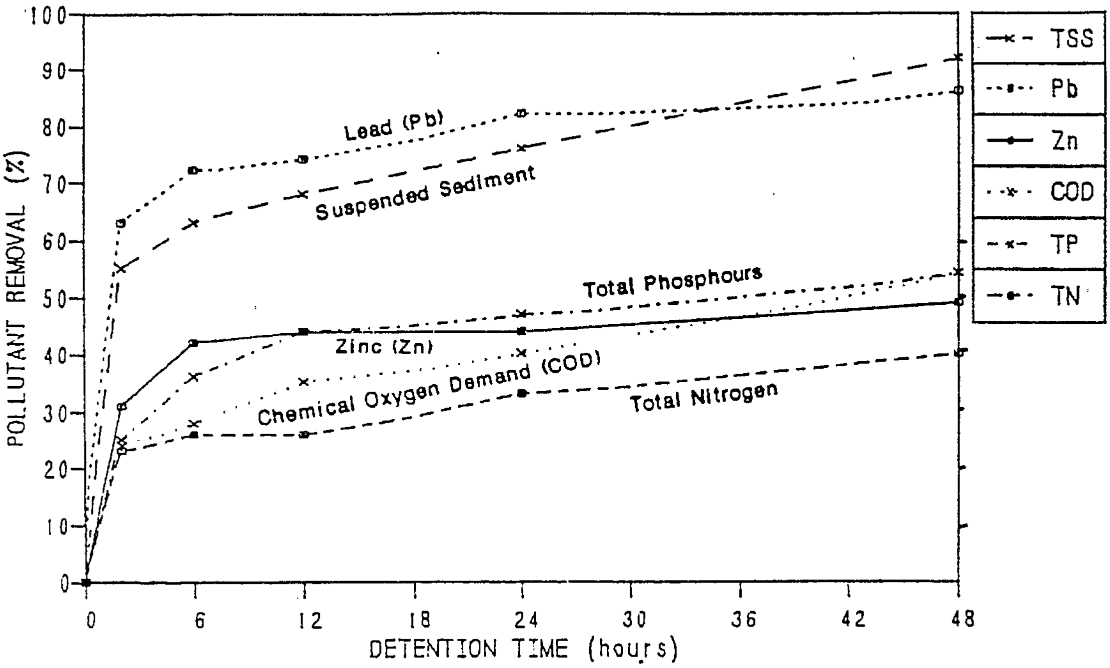
2-1.4 Regional (watershed-wide) Stormwater Plans

The cumulative effect of sedimentation, scouring, increased flooding, lower summer flows, higher water temperature, and pollution contribute to the overall degradation of the stream ecosystem. Many studies have documented the decline of fish diversity in urbanized watersheds. The aquatic insects which are a major food resource for fish are impacted by the increased sediment load, trace metals, nutrients, and flow velocities. Less noticeable impacts to the stream systems are changes in water temperature, oxygen levels, and substrate composition.

A regional or watershed-wide stormwater plan provides the framework needed to evaluate the impacts of changes to the land on water resources. A comprehensive watershed management plan considers all of the impacts of increased stormwater runoff: water quality, channel erosion, and flooding. The plan is the result of studying the environmental features of the watershed to identify those areas that should be protected and preserved. The plan identifies and strategically locates stormwater management measures and design criteria to be utilized to protect the watershed. The plan also aims to utilize and protect ecological processes to lessen the need for structural control methods that require capital costs and maintenance.

FIGURE 2-1

Removal Rate vs. Detention Time for Selected Pollutants



Source: Schueler, Controlling Urban Runoff, 1987

Stormwater filtering or *filtration* is typically limited to BMPs which address water quality. These facilities utilize a filter media, such as sand, peat, grass, compost, or various types of fabrics or other material to strain pollutants out of the stormwater. Since the stormwater must pass through the filter media in order to be treated, these structures are limited to small drainage areas (less than 5 acres) and low flow rates. A drawback to these structures is the overflow or bypass of large flows from high intensity storms. The current sizing criteria for these BMPs is the water quality volume. The Department is currently evaluating the option of designating a flow rate or return frequency intensity for design purposes. In most cases a bypass or diversion structure is needed to allow large flows to bypass the BMP without flushing previously deposited pollutants out of the BMP. Guidance on this issue will be provided in the future.

and filtering of pollutants, as well as decreased export of sediment and attached pollutants via erosion.

Water Quality Volume (WQV)

Ideally, the pollutant removal mechanism should dictate the treatment volume or frequency storm for water quality BMPs. The sizing of BMPs which utilize gravitational settling of pollutants as the removal mechanism can be based on a volume of runoff, while BMPs which utilize filtering should probably be based on a flow rate or frequency. Design criteria provided in **Chapter 3: BMP Minimum Standards**, specifies maximum flow velocities for grass swales and filter strips, as well as the need for a flow splitter or bypass structure for sand filters and other flow through structures.

The Virginia Stormwater Management Regulations require that the *first flush* of runoff be captured and "treated" to remove pollutants. The first flush, or water quality volume (WQV) is generally defined as the first ½" to 1" of runoff from impervious surfaces. Other methods of defining this first flush have been developed. One method in particular, developed by The Center for Watershed Protection, utilizes the Runoff Frequency Spectrum (RFS) for the Washington D.C. area and surrounding Chesapeake Bay watershed. The RFS is based on the fact that 90% of the annual runoff is generated by storms of 1" of rainfall or less. Therefore, the goal of treating at least 90% of the annual runoff results in a treatment volume based on a 1" rainfall. The volume of runoff is determined by multiplying a volumetric runoff coefficient (R_v), based on site imperviousness, by the 1" of rainfall. This method generates a water quality volume of close to 1" for highly impervious sites and gradually decreasing volumes for gradually decreasing levels of imperviousness.

As noted in the Virginia Stormwater Management Regulations, water quality BMPs which are dependent on volume, such as extended detention, constructed stormwater wetlands, and in some cases infiltration, have a required treatment volume of 2.0 x WQV (or 2.0 x 0.5" = 1.0" per impervious acre). This will result in a very similar volume as that based on the RFS method described above. As these methods are studied and BMPs are monitored, the design criteria for determining the WQV may be refined to achieve a greater overall level of treatment.

While the first flush from a storm event is considered to contain the highest concentration of pollutants, there is considerable debate over the intensity of rain needed to wash the pollutants from the urban landscape. Studies have shown that intensity is the critical wash off factor for most storm events, and many people can intuitively comprehend that higher intensity rains leave impervious surfaces cleaner than lower intensity rains. (Adams, 1997). The typical SCS rainfall hyetograph starts with a low rainfall intensity which gradually rises to a peak and then declines. This may indicate that in some cases the designated water quality volume provided in a stormwater basin may fill up with the relatively clean water at the onset of a rain event, consequently allowing the larger flows associated with the high intensity rain and pollutant wash off to pass through the facility.

frequency of every three to six months rather than two years. In addition, for the 2-year storm, the *volume* of runoff has increased to 1.15 watershed inches, more than double the pre-developed volume, which means a significant increase in the *duration* of the peak flow can be expected. Under this scenario, the receiving stream will experience a significant increase in erosive flows.

The solution to designing for stream channel erosion is evolving into a study of stream channel geomorphology. Several studies have indicated that the level of erosion (or bed-material load) is a function of the difference between the flow velocity and the *critical* velocity.(McCuen, 1987). The critical velocity is a function of the type of soil of which the channel bed is composed. The studies indicate that the amount of bed sediment moved is a function of the time duration over which the velocity is greater than the critical velocity. According to McCuen, this explains from a conceptual standpoint why the duration of flow is just as important as the rate of flow. Further, it may explain why detention basins may actually increase the erosion compared to providing no control of the post-developed flows. When no control is provided, the flow tends to exceed the channel capacity and extend out into the floodplain; thus the velocity within the channel banks may not increase significantly even though the peak flow rate does increase significantly.

This should not be interpreted as justification for no control of stormwater runoff. Rather, it highlights the need for a design criteria that replicates the pre-development sediment load transport characteristics of the channel. Several methodologies have been recommended, some of which are very subjective as they are based upon the ability of the designer to analyze and interpret the stream sediment characteristics. This could easily become an expensive and cumbersome methodology, especially in localities that do not experience significant development pressure. The review and approval process could become bogged down in the analysis of field data and trying to verify the channel characteristics, especially when the requirements of the field work may be different for every project.

The Virginia Stormwater Management Regulations address stream channel erosion by requiring compliance with Minimum Standard 19 of the Virginia Erosion and Sediment Control Regulations (4VAC50-30-40.19). This standard requires that **properties downstream from development sites be protected from sediment deposition, erosion, damage due to increases in volume, velocity, and peak flow rate of stormwater runoff.** The specific design criteria specifies that downstream *natural channels* by analyzed for adequacy to convey the developed condition 2-year peak discharge within the channel banks and at a non-erosive velocity. In addition, *man made channels* are analyzed for adequacy to convey the 10-year peak discharge within the channel banks and the 2-year peak discharge at a non-erosive velocity.

When a channel is determined to be not adequate, the use of a stormwater detention BMP sized to discharge the 2-year and 10-year frequency developed-condition peak discharge at the respective pre-developed rates is one of the available options. (Refer to **Chapter 1** for the complete language of Minimum Standard 19.) As we discussed above, this criteria may not be adequate for natural channels due to the increase in the frequency, duration, and volume of the "pre-developed" discharge.

An alternative is to identify a design frequency storm and control the discharge such that it does not exceed

2-3 BMP SELECTION CRITERIA

The following discussion provides a general outline for choosing the appropriate BMPS for a development site. The order of presentation **does not** imply a decision making process that will systematically progress towards an acceptable BMP. On the contrary, any one of the criteria can render a preferred BMP unacceptable. **In some cases**, the designer may be able to accommodate certain limiting feasibility factors by providing an innovative design which addresses or remedies the constraint. **In all cases**, once a BMP is selected, we strongly recommend that the selection, along with the supporting criteria and any compromises or design features, be presented to the various review or permitting agencies to ensure proper evaluation and review. This will help avoid extensive changes to the stormwater management strategy during the review process.

One of the first considerations in selecting a stormwater BMP is the functional goal of the BMP. Previously, we discussed the components of SWM: *stormwater quality, stream channel erosion,* and *flooding*. Any one or combination of these components may be addressed by the local ordinance and will dictate the functional goal of the BMPs. (State agency projects, are required to comply with all three of these regulatory components). In general, stormwater BMPs can be categorized into water *quality* BMPs and water *quantity* (stream channel erosion and flooding) BMPs. **Table 2-2** provides a general categorization of BMPs by functional goal. Note, that some BMPS can be designed to satisfy both quality and quantity goals while others are specifically suited for only one.

The use of some BMPS are limited by site or watershed feasibility factors such as environmental impacts, drainage area or watershed size, and topographic constraints.

Finally, the BMPS designed for water quality control provide varying levels of pollutant removal and are suited for specific development densities. **Table 2-3** presents a generic list of water quality BMPS, their target phosphorus removal efficiency, and appropriate percent impervious cover.

The decision making process of choosing a stormwater BMP must weigh the goals of the proposed facility against the limiting site feasibility factors of the proposed site or BMP location. The limiting *site feasibility* factors include:

1. Topographic and geologic constraints,
2. Contributing drainage area size, and
3. Environmental impacts.
4. Access for maintenance

The possible stormwater management requirements or goals which influence BMP selection include:

1. Multiple Criterion: Stormwater quality, stream channel erosion, flooding, and environmental mitigation,
2. Multiple discharge points,

stormwater to drain out of (or under) the proposed facility.

A thorough geotechnical investigation and report should verify the subsurface conditions for the presence of any of the above features. The scope and requirements of a geotechnical investigation may vary from site to site. Refer to **Minimum Standard 3.10: General Infiltration Practices** for additional information on geotechnical investigations.

d. *Proximity to structures, steep slopes, and water supply wells.* One of the goals of stormwater facilities is to provide recharge of the groundwater. This tends to saturate the adjacent ground during, and for a period of time, after, a storm event. Building foundations, basements, and other structures may be impacted by the wet/dry cycle of the surrounding soils.

Saturating the soils on or adjacent to steep slopes (6 to 10 percent or greater) can cause a failure of the slope and adjacent structures.

The proximity to water supply wells raises concern over the introduction of pollutants into the water supply aquifer. Minimum distances from these features are presented in **Chapter 3: Minimum Standards.**

2. Contributing Drainage Area Size

Some BMPs are restricted based upon the size of the contributing drainage area. The recommended maximum and minimum sizes are considered guidelines and some flexibility should be allowed. The exceptions, however, are the Manufactured BMP Systems (**Minimum Standard 3.15**) The manufacturers design criteria should be adjusted or modified **by the manufacturer only**. The proper operation of these BMPs is dependent on the proper sizing of the structure.

3. Environmental Impacts

It is extremely important for the designer to asses the environmental impacts associated with the site development and the placement of the stormwater BMP. Local, State, and Federal regulations may restrict the disturbance, or encroachment upon any of the following: wetlands, Waters of the United States, stream or wetland buffers, floodplains, conservation easements, and other sensitive resources.

Virginia Water Protection Permit Program: The Virginia Department of Environmental Quality implements the Virginia Water Protection Permit (VWPP) Program. This program regulates all activities in Virginia which result in discharge or dredge or fill material into state waters. This can include wetlands, perennial streams, and other aquatic resources. The VWPP program is in conjunction with the U.S. Corps. of Engineers Federal Permit authorized by the Clear Water Act. Some projects may require one or both permits. The permit typically requires that the developer investigate alternatives to the proposed impacts. If

2. Multiple Discharge Points

The simplest site design includes a stormwater management strategy that consists of one discharge point from the site. Large developments, however, often contain multiple discharge locations as dictated by the topography. Traditionally, this situation has been addressed one of two ways: 1) Provide a Stormwater BMP at each location as required by the size of the contributing drainage area and associated increase in peak discharge, percent imperviousness, etc; or 2) overcompensate at one discharge point in order to allow the other discharge point(s) to go uncontrolled.

Overcompensation of Peak Discharge should be subject to the following conditions:

1. The drainage channels which leave the site must be part of the same stream or tributary network and the confluence should occur at some reasonable distance from the site.

2. The uncontrolled discharge is still subject to the requirements of MS-19, that is the receiving channel is adequate to convey the increased flow.

3. The overall peak rate of discharge leaving the site must not exceed that of the pre-developed condition.

Overcompensation of Water Quality is covered in more detail in the next section which discusses the use of the Performance-based Water Quality Criteria. However, as it applies to multiple discharge points, the following conditions should apply:

1. The drainage channels which leave the site must be part of the same stream or tributary network and the confluence should occur at some reasonable distance from the site.

2. Every effort should be made to provide water quality enhancement through the use of vegetated buffers, open grass/vegetated swales, bioretention, or other low maintenance water quality BMPs.

3. Every effort should be made to minimize the impacts in the uncontrolled drainage area through non-structural means as discussed previously.

4. The overall site water quality compliance must be determined using the performance-based water quality criteria.

Another alternative which may be considered is the control of existing development in lieu of the proposed development. This trade off should be considered only if specific site, watershed, or environmental considerations hinder the successful incorporation of on-site BMPs.

TABLE 2-2

Functional Goal of Stormwater BMPs

Stormwater BMP	Quality	Stream Channel Erosion	Flooding

Manufactured BMPs	• ←+		

Legend:
- • ←+ = Primary functional goal
- • ← = Potential secondary functional goal
- • • = Potential secondary functional goal with design modifications or additional storage

NOTE: *Some BMPs, when properly designed, can provide secondary goals. Table 2-2 indicates several water quality BMPs with potential secondary goals. This is not meant to restrict the designer from incorporating design modifications or additional storage as appropriate for the particular site. Care must be taken to ensure that the the design modifications do not diminish the primary goal capabilities of the BMP.*

TABLE 2-4
Classification of Stormwater Hotspots

The following land uses and activities are deemed *stormwater hotspots*
•• vehicle salvage yards and recycling facilities #
•• vehicle fueling stations
•• vehicle service and maintenance facilities
•• vehicle and equipment cleaning facilities #
•• fleet storage areas (bus, truck, etc.) #
•• industrial sites (for SIC codes contact Virginia Dept. Of Environmental Quality)
•• marinas (service and maintenance) #
•• outdoor liquid container storage
•• outdoor loading/unloading facilities
•• public works storage areas
•• facilities that generate or store hazardous materials #
•• commercial container nursery
# indicates that the land use or activity is required to prepare a stormwater pollution prevention plan in accordance with the Virginia Pollution Discharge Elimination System program permit as required by the Virginia Department of Environmental Quality.

2-3.3 *Technology-Based* and *Performance-Based* Water Quality Criteria

The *Technology-based* and *Performance-based* water quality criterion represent a consolidation of the water quality technical criteria of three state agencies charged with the responsibility of monitoring and improving the water resources of the Commonwealth: The Department of Conservation and Recreation (DCR), the Department of Environmental Quality (DEQ), and the Chesapeake Bay Local Assistance Department (CBLAD). The specific responsibilities of these agencies are presented in **Chapter 1**. The stormwater management water quality regulations require compliance by **either** a *performance-based water quality criteria* **or** a *technology-based water quality criteria.*

The *performance-based* water quality criteria states that for land development, the calculated post-development nonpoint source pollutant runoff load shall be compared to the calculated pre-development load based upon the average land cover condition or the existing site condition. This approach requires the designer to calculate the pollutant load to be removed, implement a BMP strategy, and then calculate the performance of that strategy, based on the effectiveness or pollutant removal efficiency of the selected BMP(s), (**Table 2-3**).

3. *Situation 3* consists of land development where the existing percent impervious cover is greater than the average land cover condition.

> Requirement: The pollutant discharge after development shall not exceed (i) the pollutant discharge based on existing conditions less 10% or (ii) the pollutant discharge based on the average land cover condition, whichever is greater.

("...which ever is greater" refers to the calculated pollutant discharge to which the after development pollutant discharge is compared. Additional explanation is provided in the discussion following this section.)

4. *Situation 4* consists of land development where the existing percent impervious cover is served by an existing stormwater management BMP that addresses water quality.

> Requirement: The pollutant discharge after development shall not exceed the existing pollutant discharge based on the existing percent impervious cover while served by the existing BMP. The existing BMP shall be shown to have been designed and constructed in accordance with proper design standards and specifications, and to be in proper functioning condition.

The definition of the average land cover condition is important to the successful implementation of the performance-based water quality criteria. An analysis of the Chesapeake Bay watershed identified the average land cover condition using the following categories: urban land use, forest cover, pasture land, conservation till acreage, and conventional till acreage. Using the pollutant load values from the N.U.R.P. studies, the average land cover condition was then used to establish a baseline existing land use condition pollutant load value of 0.45 lb/ac/yr of phosphorous. Since the Simple Method is based on impervious cover, an equivalent percent impervious cover is needed. 16% impervious cover has been determined to be an equivalent pollutant load source for all of the urban and non-urban land uses which contribute nonpoint source pollution. These values (16% impervious cover and 0.45 lb/ac/yr of phosphorous) represent the average land cover conditions for the Chesapeake Bay watershed. (Keep in mind that these values may be adjusted based on actual land use conditions within the locality or individual watersheds within the locality at the time of DCR or CBLAD program adoption, whichever occurred first.) This allows the designer to calculate, using the Simple Method, the pre-developed pollutant load using average land cover conditions, and the post-developed pollutant load using the project post-developed impervious cover. The difference between the pre- and post-developed pollutant load represents the increase in pollutant load which must then be controlled by an appropriate BMP.

low while allowing for the preservation of high priority open space such as stream buffers and unmanaged open space. However, the clustered development represents a significant source of increased runoff and pollutant load when directly connected to the drainage system. Guidance on mitigating these impacts within the LID strategy can be found in the references provided at the end of this chapter.

If, on the other hand, the development consists of commercial or industrial development and associated infrastructure (parking lots, roads, and other impervious surfaces), located on a sufficiently large parcel such that the total area of impervious cover is less than 16%, and the improvements include a directly connected drainage network, then water quality controls should be provided. This type of development poses a very difficult development situation to regulate using the performance-based water quality criteria since the overall percent impervious cover is low. Initial efforts to define the impervious cover as connected or disconnected led to very awkward and subjective regulatory language. Another option considered revising the definition of *percent impervious* to read "the impervious area divided by the drainage area within the site multiplied by 100." Again, various development situations were presented which led to subjective interpretations of these definitions. The preferred method of dealing with this issue was determined to be clear guidance on the intent of the 16% impervious cover "average land cover condition," and a case by case evaluation of the application of the performance-based water quality criteria.

When improvements on a site are concentrated such that the impervious area is collected and drained to a single receiving channel (connected impervious cover), it is reasonable to expect that the developed condition runoff will have an impact on the receiving system in terms of water quality impairments, regardless of the overall "site" percent imperviousness, and therefore should be considered in the water quality strategy. In such cases, DCR recommends that the percent impervious cover calculation be based on the drainage area being collected by the improved drainage system.

Development Situation 2 describes new development which results in impervious cover greater than the average land cover condition. The selection and location of a BMP to satisfy the pollutant removal requirement is verified using the Simple Method.

Development Situation 3 describes development of a site with existing development already present. This development situation is provided to help create an incentive for development, or "redevelopment" of existing infrastructure as opposed to developing a raw piece of land. Clearly redevelopment contains more challenges with regard to existing utilities, building locations, entrances, drainage systems, etc. The requirement of 10% reduction in calculated pollutant load from the site allows flexibility in siting a BMP at the most advantageous location with regard to existing site restrictions. If the amount of impervious surface does not change significantly, the designer has the choice of several BMPs to achieve the 10% reduction including the Manufactured BMP Systems (**Minimum Standard 3.15**) which can be easily located on an existing storm system.

an imperviousness range of 67 - 100%).

Likewise the development of a low density subdivision in the range of 16 -21% imperviousness would indicate the selection of a vegetated filter strip or grassed swale (or any of the more efficient BMPs). The designer need only verify using the performance-based calculation procedure that the required removal efficiency would dictate a similar selection, thus indicating the equality of the two methodologies.

The difference in the two methodologies is the ability to incorporate a combination of BMPs using the performance-based criteria. Consider the just mentioned office park. If an extended detention-enhanced basin is selected, yet does not capture the runoff from the entire site to the effect that the calculated pollutant removal of the BMP does not satisfy the site or planning area pollutant removal requirement, then an additional BMP or a more efficient BMP must be designed.

Consider, as part of the office park, a two acre parking area along the edge of the office park which does not drain to the extended detention-enhanced facility. The designer may choose to incorporate a grassed swale with check dams to control the two acre drainage area. Since the two acre drainage area is almost entirely impervious, strict application of the technology-based criteria would preclude the use of anything but the most efficient BMPs (sand filter, infiltration, etc.) The performance-based criteria, on the other hand, allows for a total pollutant removal to be calculated to measure the combined effectiveness of the more efficient extended detention-enhanced facility on the majority of the site along with the lower efficiency grassed swale serving the small portion of the site.

The use of sound judgement in the application of multiple BMPs should dictate. If the designer is using the technology approach to control a majority of the site, and proposes a less efficient BMP to control the small area draining in the other direction, the requirement to calculate the total site pollutant removal using the performance-based calculation procedure is at the discretion of the plan approving authority. On the other hand, if a portion of the development site is being left uncontrolled, the plan approving authority may certainly require the performance-based calculation procedure to verify compliance.

Several examples will be provided by DCR as guidance in these types of review decisions.

Asserted problems with on-site facilities:

1. Not as efficient at pollutant removal as larger facilities.

2. More land is disturbed because of need for a number of smaller facilities; an additional 5 to 10 acres will not be available for development out of every 1, 000 acres served by stormwater management facilities.

3. Not well maintained, reducing pollutant removal efficiency.

4. More complicated for localities to maintain a large number of small facilities.

5. Access may be more difficult.

6. Do not typically have maintenance features such as forebays, access roads, and sediment disposal areas. Difficulty in access and maintenance often results in maintenance responsibility being shifted to homeowner's associations, which experience has shown, are not generally capable of coordinating the public works function required to effectively maintain stormwater management facilities. Uncertainty of maintenance puts long- term reliability of the facility in question.

7. Pose a greater public safety hazard.

8. Have more potential to become "eyesores."

9. Can only be sited to address stormwater discharges from future development since they are implemented for individual development projects only.

10. More expensive.

11. May result in a haphazard siting pattern for stormwater management facilities; with only limited control of down stream erosion and flooding.

Asserted benefits of regional facilities:

1. More efficient and ensure the highest possible efficiencies for the entire watershed, rather than one small site.

2. Offer the ability to control temperature of outflow which is not possible with small facilities.

3. Can be strategically located within a watershed and designed for coincident stormwater releases,

a master plan specifying the sites and design criteria, (2) implement a phased construction program so that facilities are in place when new development occurs, and (3) recover pro-rata charges from new development or establish a stormwater utility with which to offset the costs for the regional facilities.

These three components include the following:

A. **Inventory**

1. **Define the watershed boundary.**
2. **Conduct a watershed inventory of natural resource features** (wetlands, floodplains, stream corridors, greenways, rare and endangered species, steep slopes, erodible soils, karst bedrock areas, sensitive habitats, fish and wildlife resources, recreational areas, sources of water supply).
3. **Conduct a stream inventory** (size, order, water and habitat quality, flow regime).
4. **Identify significant environmental features in neighboring watersheds** (large pollution sources, wildlife refuges, sources of water supply).
5. **Identify and quantify existing sources of point and nonpoint source pollution.**
6. **Model the existing hydrology and hydraulics of the watershed** (understand the impact of land use, conveyances, land cover, stormwater management facilities, stream cross sections, roadway crossings, flooding and drainage problems).

B. **Planning**

1. **Define the goals of the watershed management plan** (what is envisioned for the watershed and who is going to lead the implementation efforts).
2. **Identify and quantify future sources of point and nonpoint source pollution.**
3. **Model the future hydrology and hydraulics of the watershed.**
4. **Develop and evaluate alternatives to meet the goals and manage water quality** (point and nonpoint source pollution) **and quantity** (hydrology and hydraulics).
5. **Identify opportunities to restore natural resources.**
6. **Develop the watershed management plan** (include specific recommendations on development and land use evaluation, selection of structural and non-structural BMPs, public education needs, regulatory requirements, and funding).

C. **Implementation**

1. **Identify the stakeholders responsible for developing, implementing and updating the plan to ensure long-term accountability.**
2. **Define the implementation costs** (capital costs and annual administrative, operations and maintenance costs) **and who will pay for the implementation of the watershed management plan** (provide incentives and secure commitments).
3. **Develop a watershed monitoring program.**
4. **Develop an evaluation and revision process for the watershed management plan.**
5. **Establish and implementation schedule.**

The natural resource features to be inventoried would depend on the characteristics of the watershed being studied and could include:

- Wetlands
- Floodplains
- Stream corridors and greenways
- Steep slopes
- Erodible soils
- Karst bedrock areas
- Rare and endangered species
- Sensitive habitats
- Cultural resources
- Fish and wildlife resources
- Recreational areas
- Sources of water supply

Wetlands

Wetlands provide unique habitats for both plants and wildlife, including many threatened and endangered species. As a consequence, wetlands are valued for aesthetic and recreational reasons. Wetlands also provide valuable flood storage, groundwater recharge, and pollutant-filtering functions.

Wetlands are widely scattered throughout Virginia and commonly are encountered on development sites and throughout watersheds. Protecting the natural functions of wetlands is a critical element of the site development process and watershed management planning. For moderate- to high-quality wetlands, which are very difficult to replace, avoidance is recommended. If the watershed contains scattered, small, low-quality wetlands, which are more readily replaced, mitigating the wetlands at a central location may be more appropriate, thereby enhancing wetland functions and reducing a potential constraint to development. Early coordination with resource agencies is recommended.

Floodplains and Stream Corridors

Floodplains and stream corridors include waterways and adjacent riparian lands that may be subject to flooding. Natural waterways provide habitat for fish, aquatic plants, and benthic (bottom dwelling) organisms. Development in waterways may destroy aquatic organisms and introduce large loads of sediment and pollutants into the waterways. Modifying waterways to accommodate development also may destroy the physical features essential to a good habitat, including: stable stream banks and bottom substrates, pools and riffles, meanders, and spawning areas.

Vegetated riparian land adjacent to streams stabilizes the stream bank, filters pollutants from storms and floods, and provides habitats for a variety of amphibians, aquatic birds, and mammals that depend on the proximity to water for their life functions. Development in floodplains and riparian corridors can impair the functions and subject structures to damage from flooding and the meandering of natural streams.

A filter strip or riparian-forested buffer should be preserved or created along the banks of streams, where possible. Furthermore, consideration should be given to establishing setbacks for intensive development is likely. The United States Geological Survey is a good source of information on karst bedrock in Virginia. If an area is prone to sink hole development, site drainage should be planned to minimize the concentration of runoff. This can be accomplished by reducing the hydraulic connectivity of impervious surfaces and by the use of filter strips. Where they are required, channels or ponds should be lined.

Certain BMPs can be used in karst areas to provide infiltration opportunities over a very large area. Examples are filter strips, large bioretention facilities, and permeable pavement. These practices mimic the natural process by which rainfall enters the subsurface. Point sources of infiltration, such infiltration trenches or dry wells should be avoided (CH2M HILL, 1998).

Threatened and Endangered Species

Existing information can be obtained from surveys conducted by the Division of Natural Heritage (DNH) of the Virginia Department of Conservation and Recreation. For portions of the watershed that have not been previously surveyed, DNH's Element List can be compared to plant community information derived from previous investigations in the watershed, as well as from wetlands identification efforts. The inventory should include a list of potential threatened or endangered species.

Cultural Resources

Existing information can be obtained from the Virginia Department of Historic Resources. For potential regional (watershed) BMP sites, background research to characterize the cultural resource potential of the project area can be conducted. This research will provide a historic context for evaluating any cultural resources that might be located in the project area.

Fish and Wildlife Resources

Existing information can be obtained from the Virginia Department of Game and Inland Fisheries. This information will be useful when defining watershed goals and selecting BMPs to protect sensitive areas. In addition, fish can be a good indicator of stream health and can be used during the evaluation of effectiveness of the watershed management plan, as part of a watershed monitoring program.

Recreational Areas and Sources of Water Supply

An inventory of recreational areas and sources of water supply will also facilitate, and in some cases mandate, the goals of the watershed. This information will also be important in the selection of models that will be needed to identify sources of pollution, understand the hydrologic and hydraulic characteristics of the watershed, and evaluate alternatives to meet the watershed goals and manage water quality.

The objectives of the model application for a watershed management plan may range from simple screening of environmental problems that require minimum data input to detailed analysis of water quantity and quality in the watershed. Detailed analysis requires more input data and usually provides information needed for the design of a specific project or for the analysis and solution of specific environmental problems. Detailed analyses are used to represent the watershed processes that affect pollution generation. However, it is not always true that detailed analyses, based on sophisticated models, provide the most accurate representation of the watershed and its environmental problems; it is best to use the least complicated model that will produce the results for appropriate decision making.

Model selection also depends significantly on the data available in the watershed. The precision of the model predictions is affected by dynamic and transient conditions, high spatial variability (mainly related to rainfall variability and land use), and differences in event conditions (such as antecedent moisture conditions, infiltration potential, local pipe or stream conditions, etc.). The data availability and the simulation complexities affect model selection by tempering the decision towards acceptance of a model that is accurate but not as precise as other more sophisticated models.
In addition to data availability issues, monitoring data and watershed responses can be highly variable. Selecting a simpler model, and accepting results that are not as precise as desired but remain accurate, is an appropriate strategy.

6. Model the Existing Hydrology and Hydraulics of the Watershed

The model selection strategy presented in the previous section also applies to hydrologic and hydraulic models.

Hydrologic models provide information on the amount of runoff that will reach the outlet of the watershed and any receiving waters. Hydraulic models estimate water surface elevations and velocities of surface water. These models are also used to characterize the drainage system in the watershed. Groundwater models represent the movement of groundwater.

The focus of the modeling of the existing characteristics of the watershed is to develop baseline information that will be used to evaluate BMP siting and sizing alternatives for meeting the watershed goals and solving drainage and flooding problems. The hydrologic and hydraulic models will also facilitate the understanding of the impact of land use, conveyances, land cover, stormwater management facilities, stream cross sections, roadway crossings, and flooding and drainage problems.

Accurate land use data will ensure accurate modeling results. Developing an updating land use and impervious cover information will facilitate the implementation of the watershed plan.

4. **Develop and Evaluate Alternatives to Meet the Goals and Manage Water Quality and Quantity**

In order to meet the watershed goals and to solve the watershed's problems effectively, the watershed master plan should consider all feasible alternatives. These alternatives will manage water quantity and quality in the watershed. Therefore, the alternatives will address flooding, drainage, erosion, and stormwater pollution problems.

Generally, alternative solutions mitigate **flooding and drainage damages** by providing additional storage of flows, by increasing the conveyance capacity of the drainage and stream system, or by floodproofing structures at risk of flooding. Alternative solutions mitigate **erosion damages** by stabilizing stream banks using non-erosive materials and/or by redefining the meandering pattern and using the channel and floodplain to dissipate the flow energy. Alternative solutions mitigate **stormwater pollution** problems by providing structural and non-structural BMPs.

Alternatives should be evaluated by using the existing and future condition models and the information from the inventory component described in **Section 2-5.1**. A map of the watershed showing the recommended alternatives should be prepared and distributed to all stakeholders.

Each alternative, or combination of alternatives, also could be evaluated according to screening criteria that address technical, practical, environmental, economic, and political feasibility. Alternatives can be investigated in detail when they appeared to have potential to be cost-effective and satisfy all project criteria.

Selecting sites for regional (watershed-level) BMPs or flood/erosion controls involves balancing pollutant removal, runoff attenuation, environmental permitting constraints, and cost issues. The following is a typical sequence of the iterative process to be completed for each of the potential sites:

A. Identify potential regional BMP sites and sites for flood/erosion controls.

B. Field screen the sites taking into account the following:
   - drainage area
   - topography
   - existing development and projected future development
   - access and construction issues
   - wetlands constraints
   - other regulatory constraints
   - land ownership/value issues

C. Use the previously described watershed models to analyze pollutant reduction (phosphorous and total suspended solids management), flood/erosion control, and resource protection.

D. Use the inventory and models to identify performance standards for the selection, design, and location

2. **Define the implementation costs and who will pay for the implementation of the watershed management plan**

Use uniform and consistent procedures to estimate project costs for the alternatives developed to solve the problems in each watershed. The cost should include capital costs and annual administrative, operations and maintenance costs for all the elements of the plan.

Identify the funding sources for implementation of the watershed management plan. Below is a summary of the possible funding sources: .

- General obligation and revenue bonds
- Stormwater utility fees
- Land development fees
- Pro-rata share contributions
- General fund resources
- Loans and grant programs
- Special service districts and watershed improvement districts

3. **Develop a watershed monitoring program**

Develop a monitoring program that enables the stakeholders to objectively measure and track indicators of the watershed management plan's success. The indicators should focus on water quantity and quality issues, programmatic and socioeconomic needs, and physical and hydrologic measures.

Stormwater chemistry is fairly well understood. Therefore, chemical monitoring of stormwater outfalls will not necessarily provide valuable data. On the other hand, physical and biological monitoring and selected long-term stream monitoring stations will provide valuable information to "measure" the successful implementation of the watershed plan. If success is not achieved, the monitoring program will provide the data to make revisions to the plan. The monitoring program also will provide information to re-evaluate the watershed goals and the implementation schedule.

4. **Develop an evaluation and revision process for the watershed management plan**

During the implementation of the watershed management plan, it is likely that at least one of the following problems will occur:

- Monitoring indicates that the wrong problem is being solved.
- Solving one problem unmasks another problem that is more difficult to control.
- The program reaches some program or activity goals but may not be effective enough to reach the water

Muck deposition influences design and maintenance of stormwater ponds

Pollutant Dynamics of Pond Muck

Historically, most research on stormwater ponds has focused on the movement of pollu
and out of the pond. This is quite understandable, as knowledge about inputs and outputs c
helps to estimate pollutant remov al performance. An impressive amount of input/output n
data has been collected; nearly 65 pond monitoring studies have been conducted in the U.S
Canada.

Most of the monitoring studies have shown that stormwater ponds and wetlands are
effective in trapping pollutants carried in urban stormwater. Much less is known, however
fate of stormwater pollutants once they are trapped in a pond. It is generally assumed that
pollutants eventually settle out to the pond bottom and form a muck layer. [The term muck
used here to distinguish newly-deposited bottom sediments from the older parent so ils tha
original pond bottom.- ed.]

n't get your boots stuck in the muck layer

The muck layer deepens as the pond
Pollutants may remain trapped within the
until the entire layer is excavated during a
clean-out. In most cases the muck is event
dewatered, excavated, and a pplied back tc
surface. Research on bottom sediments in
shallow water systems, however, suggests
muck layer may not be so inert. Figure 1 il
how a given pollutant can follow a numbe
and complex pathways into an d out of the
layer.

Some runoff pollutants are transformed within the muck layer, while others are deco
through chemical and microbial processes involved in sediment diagenesis. Indeed, diagen
a key pathway for decompos ition of organic matter and some nutrients. Alternatively, pol
migrate further below the muck layer and into the original soil profile. In some extreme ca
pollutants can travel into groundwater.

Pollutants
number o

complex
and out of the

Alternatively, pollutants might enter the food chain while in the muck layer, either th uptake by wetland plants or by bottom feeding fish. Under the right conditions, some pollu also be released from t he muck into the water column (where they could exit the pond dur storm).

In this article, we examine the internal dynamics within the muck layer of stormwate based on an extensive review of research studies on the physical, chemical, and biological the muck layer of over 5 0 stormwater ponds and wetlands. While it must be admitted that muck is somewhat lacking in glamour, it can have many important implications for the de operation of stormwater ponds and wetlands. Typical questions include:

- What is the average deposition rate of muck in ponds?
- After how many years of deposition will muck need to be removed?
- Can the deposition rate be used to calculate the size of the sediment forebay for a po
- How tightly are pollutants held in the muck layer?
- Is there any risk that pollutants could be released back into the water column? – or i groundwater supplies? – or enter the aquatic food chain where toxicity might be ma
- If pollutants do remain in the muck layer, should muck be considered hazardous or t
- Can muck be safely applied back on the land surface after it is cleaned out from the are more exotic and expensive methods needed to safely dispose of muck?
- Finally, the depth of accumulated muck generally represents the long term work of a trapping pollutants. Can the characteristics of pond muck allow us to infer anything pollutant removal processes operating in ponds or the land uses that drain to it? Do concentrations "fingerprint" land uses?

To answer these questions, we reviewed bottom sediment chemistry data from 37 we detention basins, and two wetland systems, as reported by 14 different researchers. Althou studies covered a broad geogr aphic range, almost 50% of the sites were located in Florida Mid-Atlantic states. Analysis was restricted to mean dry weight concentrations of the surfa sediments that comprise the muck layer (usually the top 5 centimeters). The stormwater pc in age from 3 to 25 years.

The Nature of Pond Muck

The muck layer can be easily distinguished from the parent soils that comprise the pc original bottom. Distinguishing features include the following:

- **a very "soupy" texture** – 57% moisture, Number of studies reporting (N) = 15;
- **a distinctive grey to black color;**
- **a high organic matter content** – nearly 6% volatile suspended solids on average (N
- **a low density** (about 1.3 gms/cm^3); and
- **poorly-sorted sands and silts dominating the muck layer.**

Figure 1. A field guide to the muck layer

Pond muck represents a long term repository for the pollutants trapped within a stor pond. A pollutant, however, can take many different pathways through the mucklayer as s the diagram above.

(a) Pollutant inflow. Sediment, nutrients, trace metals, and hydrocarbons enter the pond during each storm. The total pollutant load delivered to the pond depends to some degree on land use. Some evidence exists that metal and hydrocarbon loads are significantly greater from watersheds draining roads or industrial areas.

(b) Sediment Deposition. A steady rain of sediment particles, attached pollutants, and algal detritus forms the muck layer over time. Field measurements indicate that the muck layer grows from 0.1 to 1 inch per year, with greater deposition note d near the inlet.

(g) Phosphorus Release. In the s low oxygen levels near the bottor can induce a "burp" of soluble ph ammonia, or methane back into tl column.The potential for this phe greatest in deeper ponds in warm itudes.

(h) Groundwater Migration. Pc tightly bound to the pond muck c downward through sediment pore and ultimately reach the watertab pollutants, such as chloride and n the most mobile and have been r

R0009554

(c) Muck Microlayer. The uppermost layer of muck represents the recently deposited sediments and pollutants. Consequently, it is very high in organic matter and constantly worked over by microbes, worms and other organisms.

(d) Downward Migration. Most pollutants are tightly bound to sediment particles and remain fixed within the muck layer. Other pollutants can migrate downward into the subsoil via pore spaces between sediment particles.

(e) Fish Bio-magnification. Bottom feeding fish that dwell in larger ponds, such as carp and catfish, ingest detritus from the muck layer. Not much is known about pollutants accumulating in their tissues over time.

(f) Sediment Diagenesis. Organic matter and nutrients are gradually reduced and decomposed over time in the muck layer through a process known as sediment diagenesis. Diagenesis is a key pollutant removal pathway that combines physical, chemical , and biological processes within the sediment to slowly breakdown organic matter, in the presence or absence of oxygen.

migrate outward from ponds into groundwater at modest levels. M monitoring studies, however, rev any risk of groundwater contamir stormwater pond muck.

(i) Wetland Plant Uptake. The r wetland plants take up both nutri metals from the muck layer and t them upward to tubers, stems, an the end of the growing season, th above-ground plant matter often Some of the nutrients are release the pond, while others settle back muck layer as detritus.

(j) Pollutant Export from thePc Pollutants remaining in the pond' column will often flush out durin storm event. Consequently, any p that were released from the muck into the water column may exit a thereby reducing the long term pc removal performance of the pond

(k) Sediment Clean-outs. The ul removal of stormwater pollutants accomplished when the muck lay excavated from the pond and app on the land. This operation may r conducted every 25 to 50 years, d on whether the pond has a foreba existing data and sediment qualit pond muck does not usually cons toxicity hazard.

Deposition of Muck

Muck essentially represents the bulk of all sediments and pollutants that have been h trapped within a pond (excepting those that are microbially broken down into gaseous forr pollutants that migra te below the pond). Therefore, the long term deposition rate of the m of great interest.

The annual deposition rate can be easily calculated if the age of the pond and the dep muck layer are known. The depth of the muck layer is relatively easy to estimate in the fie unique physical characteristics. Annual muck deposition rates on the order of 0.1 to 1.0 in have been reported for a series of ponds in Florida.[23] These rates compare favorably with sedimentation rates calculated at 0.5 inches/yr[6] and 0.8 inches/yr[19] utilizing different tech

R0009555

The deposition rate of muck is not always the same throughout a pond. however. Th rates tend to be observed near the inlets of wet ponds. and to some extent. the outlets of de basins.[9] In a ddition. muck deposition rates increase sharply for ponds that are small in rel contributing watershed areas and for ponds that located directly in streams.[6]

Nutrient Content of Pond Muck

As might be expected, the muck layer is highly enriched with nutrients (Table 1). Ph concentration for the 23 studies reviewed averaged 583 mg/kg (range 110 to 1,936 mg/kg, Nearly all the nitrogen found in pond muck is organic in nature, with a mean concentratior mg/kg (range 219 to 11,200, N=20). Nitrate is present in extremely small quantities, whict indicate that some denitrification is occurring in the sediments, or perhaps merely that l es initially trapped in muck.

Muck essential
the bulk of a
and polluta
been histori
w

In the entire pond data set, the nitrogen to phosphorus (N:P) ratio of the muck layer a about 5 to 1, whereas the average N:P ratio for incoming stormwater runoff is typically arc This lower N:P ratio is not unexpected. Ponds are generally more effective in trapping pho than nitrogen and the decay rate for nitrogen in the muck layer is generally thought to be m than for phosphorus.

Researchers have expressed concern that phosphorus trapped in the muck layer migh released back into the water column, particularly when oxygen levels are low in the summ number of investigators have observed hypoxic and even anoxic conditions near the muck ponds as shallow as 5 feet deep.[6, 22]

An intriguing suggestion for possible sediment phosphorus release is evident in a hai Florida ponds (Table 1). These ponds had unusually high N:P ratios of the muck layer, oft of 10 to 1. One explana tion for the apparent depletion of phosphorus in the muck layer wc mobilization and release of phosphorus from recurring anoxia over many years.

Still, most of the more Northern ponds, as well as many Southern ones, appear to ret the phosphorus deposited in the muck layer. For example, phosphorus levels in the muck l to 10 times higher th an the soils underlying the pond bottom. Also, muck layer phosphoru not normally show a decrease as ponds grow older.

Trace Metal Content of the Muck Layer

The muck layer of stormwater ponds is heavily enriched with trace metals. This pher consistent with reported performance data (Table 2). Trace metal levels are typically 5 to 3 higher in the muck layer, compared to parent soils. Trace metal levels in the muck layer al consistent pattern and distribution, (zinc > lead >> chromium = nickel = copper > cadmiur

This pattern is nearly identical to their reported concentrations monitored in urban st runoff. It also suggests that rarely monitored (or detected) trace metals, such as chromium, nickel, and possibly cadmium, are actually trapped by stormwater ponds. The muck layers ponds often contain more lead than zinc, whereas in younger ponds the converse is true. T reflect the gradual introduction of lead-free fuels over the last decade, with the consequent in lead loadings delivered to the younger ponds.

* = Total Nitrogen
# = May have been influenced by fuel spill

The trace metal content of the muck layer happens to be directly influenced by the ty use that drains to it (Table 3). Muck layers in stormwater ponds that drain residential areas lightest metal enrichment. Commercial sites were subject to slightly greater enrichment. p for copper. lead. and zinc. Ponds that primarily served roads and highways were highly en metals. presumably due to the influence of automotive loading sources (e .g., cadmium. co nickel, and chromium)

Although the muck layer is highly enriched with metals, it should not be considered an especially toxic or hazardous material.

Although the sample size was small (N=2), industrial catchments had. by far and aw greatest level of trace metal enrichment in the muck layer of any land use. Clearly, further of heavily industrial ca tchments is warranted to confirm if muck enrichment represents a

Most trace metals are very tightly fixed in the muck layer and do not migrate more th inches into the soil profile. Many researchers have examined soil cores to determine the di trace metal concent ration with depth. A consistent pattern is noted. Trace metal levels are maximum at the top of the surface layer, and then decline exponentially with depth. Event reach normal background levels within 12 to 18 inches below the pond. Rep resentative se metal profiles are shown in Figure 2.

Although the muck layer is highly enriched with metals, it should not be considered especially toxic or hazardous material. For example, none of over 400 muck layer samples the 50 ponds sites examined in this study exceeded current EPA's land application criteria (Table 2). In fact, metal levels in the muck layer are usually less than ten times higher than national mean for agricultural soils in the U.S.12 (Table 4).

Of perhaps greater interest is whether soluble metals can easily leach from the muck they could exert a biological or groundwater impact. The capacity for metals to leach from is measured by EPA's Toxicity Characteristics Leaching Procedure (TCLP). The TCLP tes variant, has been applied by four different investigators to pond muck 2, 11, 22, 23 with m same result usually less than 5% of the bulk metal concentration is suscepti ble to leaching

In general, cadmium and zinc exhibited the greatest potential for leaching (usually le 10%) while copper and lead showed little or no leaching potential. Moreover, leachate con seldom exceeded the mea n metal concentrations reported for urban stormwater runoff.

Hydrocarbon Content in Muck

One aspect of the muck layer that has yet to be well explored is the potential for hyd and PAH contamination. The limited data on hydrocarbon levels in the muck layer (Table cause for some concern, particularly at an Auckland, New Zealand industrial site. Gavens that the concentration of total PAH and aliphatic hydrocarbons in the muck layer of a 120 London basin were 3 and 10 times greater, respectively, than the basal sediments. Only lin biodegradation of the hydrocarbons trapped in the muck appeared to have occurred in the l recent years. Yousef[24] on the other hand, reports that hydrocarbons were rarely detected i of Florida ponds.

Aquatic Community

A soupy substrate, high pollutant load, and perio oxygen level render the muck layer a rather poor habit aquatic life. Macroinvertebrate sampling conducted by and Galli[5] indicate that the muck layer community ha diversity and characteristics of high pollution stress. Cl and tubificid worms comprised over 90% of all organi in a Florida pond muck layer, and dipteran midge larva constituted 95% of all organisms collected in the muck Maryland pond. While the diversity of the community low, the benthic population can become very dense at of the year. This is not surprising, given that extensive population that uses the highly organic muck layer as food source.

Comparison of Pond Muck to Sediments Trapped in Other BMPs

How does pond muck compare to the sediments trapped in other best management p: Table 4 shows that the metal content of the muck layer of wet ponds and stormwater wetla similar to concentrations see n in the soils of "dry" detention basins. The metal content of | and grassed swale soils are also quite similar in most respects, although swale soils tend tc twice as much phosphorus and lead as their pond counterparts. Sediments trapp ed within bed and sedimentation chamber of sand filters also appear to be generally comparable to p although only one sand filter has been sampled to date.[20]

The one best management practice that sharply departs from this pattern is the oil gri (OGS). The metal content of trapped sediment within OGSs is 5 to 20 times higher than ot particularly if the OG S drains a gas station.[17] Hydrocarbon and priority pollutant levels ir sediments are also much higher.

This condition reflects the fact that OGSs often exclusively serve hydrocarbon hotsp designed to trap lighter fractions of oil.[18] It is doubtful that metal and hydrocarbon levels i muck coul d approach the level seen in OGSs, since they typically drain larger watersheds the influence of an individual hydrocarbon hotspot.

Implications for Pond Design and Maintenance

An understanding of the dynamics of the pond muck layer has many implications for and maintenance of stormwater ponds.

Pond Clean-out Frequency

Based on observed muck deposition rates..stormwater ponds should require sedimen on a 15 to 25 year cycle.[19, 23] For example, using a 0.5 inch/year muck deposition rate, an that the muck consolidates over time as it deepens, up to 15 to 25% of pond depth can be l 25 year period. The loss of capacity would be faster if construction occurs in the contributi watershed over this time period.

Most ponds are now designed with a forebay to capture sediments. A common foreb criteria is that it constitutes at least 10% of the total pool volume. Based on a 0.5 inch yr m deposition rate, and the *u ntested* assumption that a forebay traps 50% of all muck deposit pond, the forebay could lose 25 percent of its capacity within 5 to 7 years. At the same tim sediment removal frequency for the main pool might be extended to about 50 yea rs. These calculations assume that turbulence in the forebay does not cause muck to be resuspended exported to the main pool. To meet this critical assumption, the forebay must be reasonabl 6 feet) and have exit velocities no greater than 1 foot/ second at the maximum design inflo

The Proper Disposal of Muck

All of the available evidence strongly argues that pond muck does not constitute a ha toxic material. Thus it can be safely land-applied with appropriate techniques to contain ar as it dewaters. The hi gh organic matter and nutrient content of pond muck might even ma as a soil amendment. Chemical testing of pond muck prior to land application is probably for most residential and commercial sites, given the consistent pattern in the distribution o reviewed in this paper.

Greater care should probably be exercised when disposing of pond muck from indust and perhaps some heavily travelled highways. Although only a few industrial sites have be to date, the data suggests these sites may pose a risk. In addition, there is a much greater cl pollutant spills, leaks, or illegal discharges occurring in a pond over the 20 or 25 year time between clean-outs. It would seem prudent, therefore, to require prior test ing at selected i and roadway ponds to reduce this risk.

Greater care sho
be exercised wh
of pond muck frc
sites and p
heavily travelle

Further Research into the Muck Layer

While our emerging understanding about the muck layer is probably sufficient to ma reasonably good management decisions regarding clean-outs and disposal, further researct layer dynamics is needed in several are as.

- Ponds need to be sampled to verify the deposition rate of muck over a broader range geographic and regional conditions. Based on this data a predictive model of muck c rates could be developed to help practitioners who design and maintain ponds.
- Much more data needs to be collected concerning the accumulation of hydrocarbons in the muck layer, particularly in ponds draining roads and industrial sites. Further te muck layer for these compounds would give managers greater c onfidence about the method for muck disposal, as well as providing inferences about how well stormwat can trap these key pollutants.

R0009562

- The significance of muck layer phosphorus release as a factor in reducing the long t pollutant removal performance of a stormwater pond remain an open question. Perh insitu measurements of phosphorus flux in a stormwater pond, such as th ose used f years in estuarine studies, could help resolve this issue.
- So far, few researches have explored the possible risk of pollutant biomagnification layer, either by wetland plant uptake or by bottom feeding fish. A systematic sampli to define pollutant levels in plant and animal tissue in a large population of stormwa and wetlands would help assess the nature of this risk. Such a survey would also prc guidance to designers on the issue of whether efforts should be made to attract wildl systems.

MANUAL READER AND USER

From: BES Staff

Subject: Corrections and Updates

Through painstaking effort and numerous reviews, we have strived to provide the most accurate, complete and up-to-date manual as possible. However, there is always room for improvement. This is where you, the reader and user of this manual, can help us in this process and with our efforts to improve this manual.

Should you discover an error, you are encouraged to use this form. Please make a copy of this form, fill it out completely, and either fax it to the City or mail it to us at:

Attn: Steve Fancher
Bureau of Environmental Services
1120 SW 5th Ave., Room 1000
Portland, OR 97204-1972

Fax #: (503) 823-7126 Attn: Steve Fancher

This form can also be used for suggestions and recommendations for changes or to include new information in this manual. The field of stormwater is very dynamic. Sometimes the only way to stay on top of it is by receiving information from individuals and businesses like you. Thank you.

9.0 STORMWATER POLLUTION CONTROLS FOR HIGHER-RISK CATEGORIES

R0009572

Chapter 9.0

STORMWATER POLLUTION CONTROLS FOR HIGHER-RISK CATEGORIES

Chapter 9.0
STORMWATER POLLUTION CONTROLS FOR HIGHER-RISK CATEGORIES

Summary of Chapter 9.0

This chapter presents stormwater pollution controls (SPCs) required for higher-risk site uses and characteristics that generate, or have the potential to generate, specific pollutants of concern.

9.1 INTRODUCTION AND APPLICABILITY

Some site characteristics and uses may generate pollutants that are not addressed solely through implementation of the pollution reduction measures identified in Chapters 4.0 and 5.0. This chapter presents stormwater pollution controls (SPCs) for controlling those pollutants at their source.

Stormwater Discharge benchmarks for pollutants exist in NPDES Industrial Stormwater General Permits issued by the State of Oregon for facilities with industrial activities that are exposed to rainfall and stormwater runoff. The state also has water quality standards listed in Oregon Administrative Rules Division 340 for discharges to surface waters. In addition, City Code 17.39 lists prohibited discharges to the City's storm sewer. The City has utilized these standards and benchmarks in the development of the listed Stormwater Pollution Control BMP's so that discharges to the City's storm sewer system achieve these criteria.

Section 9.1.1, below, describes the site uses and characteristics subject to the requirements of this chapter. Sections 9.2 through 9.12 then provide detailed information about the required SPCs.

These SPCs apply to <u>all new development and redevelopment</u> (Management Levels 1, 2, 3) with the defined uses or characteristics. *(See Chapter 1.0, Section 1.5, for definitions of management levels.)* The SPCs are also applicable to <u>tenant improvements</u> that result in any of the defined site uses or characteristics. With tenant improvements, only those areas of a structure that are being disturbed under the permit are required to make the structural changes identified in the SPCs.

The requirements of this chapter are in addition to the applicable pollution reduction requirements of Chapters 4.0 and 5.0.

If any of the SPC requirements apply to the development site, applicants shall submit **Form SPC** (located at the end of this chapter) as part of their submittal package. (*See Chapter 3.0 for complete submittal requirements.*) Development subject to the requirements of Section 9.5 shall also submit **Form HAZ** (located at the end of this chapter) separately to the Bureau of Water Works.

NOTE: Unless there is an existing plan to the contrary, it is assumed that combined sewers will become separated storm sewers that will discharge to the river through the implementation of the City's Combined Sewer Overflow Plan. Therefore, requirements placed on projects with the site characteristics and uses found in this chapter shall meet the water quality requirements appropriate for separated storm sewer areas even though currently, the site is discharging to a combined storm sewer.

Applicants may propose alternatives to the SPCs identified in this chapter if they believe such alternatives would work better on the site (*see Section 9.1.3*). In this case, the applicant shall complete Part B of Form SPC. Proposal of an alternative SPC or alternative design element will require an additional review process and may delay issuance of related building permits.

Note: Developments citing special circumstances (*see Chapter 1.0, Section 1.7*) are not exempt from the SPC requirements of this chapter.

9.1.1 Site Uses and Characteristics

Projects with the following site uses and characteristics are subject to the requirements of this chapter.

- **Fuel Dispensing Facilities (*Section 9.2*):** Places where fuel is transferred from bulk storage tanks to vehicles, equipment, and/or mobile containers (including fuel islands, above-ground fuel tanks, fuel pumps, and the surrounding pad). Applies to large-sized gas stations as well as single-pump fueling operations.

- **Above-Ground Storage of Liquid Materials (*Section 9.3*):** Places where there is any exterior storage (either permanent of temporary) of liquid chemicals, food products, waste oils, solvents, or petroleum products in above-ground containers, in quantities of 50 gallons or more.

- **Solid Waste Storage Areas, Containers, and Trash Compactors (*Section 9.4*):** Places with facilities that store solid waste (both food and non-food waste) outdoors in one or more solid waste storage areas. Single-family residential sites are exempt.

- **Storage, Use, and Transportation of Hazardous/Toxic Materials in Designated Groundwater Resource Protection Areas (*Section 9.5*):** Storage, use, and transportation areas for substances that are toxic, carcinogenic, or halogenated solvents. Materials are also mobile and exceed specified threshold quantities, as defined in Section 9.5.

Note: Section 9.5 applies to sites within the following designated groundwater resource protection areas: Columbia South Shore Plan District, Cascade Station/ Portland International Center Plan Districts, and Powell Valley Groundwater Resource Protection Area. The requirements of Section 9.5 apply to any development or other activity that requires a building permit. Refer to Section 9.5 for more information.

- **Exterior Storage of Bulk Materials (*Section 9.6*):** Places that stockpile erodable materials outside.

- **Material Transfer Areas/Loading Docks (*Section 9.7*):** Areas designed to accommodate a truck/trailer being backed up to or into them, and used specifically to receive or distribute materials to/from trucks/trailers. Includes loading/ unloading facilities with docks, and large bay doors without docks.

- **Vehicle and Equipment Traffic Areas, Parking, and Storage (*Section 9.8*):** Parking lots, retail store parking lots, fleet vehicle lots and yards, equipment sale and rental lots, and access roads with defined high-use or high-risk conditions. Single-family and duplex residential sites are exempt.

- **Covered Vehicle Parking Areas (*Section 9.9*):** Covered vehicle parking areas, as defined in Section 9.9. Single-family and duplex residential sites are exempt.

- **Equipment and/or Vehicle Washing Facilities** (*Section 9.10*): Designated equipment and/or vehicle washing or steam cleaning areas. Single-family and duplex residential sites are exempt.

- **Interior Floor Drains** (*Section 9.11*): Buildings and facilities that have interior floor drains. Single-family residential and duplex residential sites are exempt.

- **Stormwater Disposal from Development on Recycled Land** (*Section 9.12*): Land that currently or previously has had pollutants detected in the soil or groundwater at concentrations that exceed risk-based cleanup levels or state/federal cleanup standards for the pollutant(s) of concern.

Note: Definitions of terms used in Sections 9.2 through 9.12 are provided on page 9-65.

9.1.2 Goals and Objectives for Stormwater Pollution Controls

Development of the specific SPC requirements was based on the following goals and objectives:

1) Prevent stormwater pollution by eliminating pathways that may introduce pollutants into stormwater.

2) Protect soil, groundwater, and surface water by capturing acute releases and reducing chronic contamination of the environment.

3) Segregate stormwater and wastewater flows to minimize additions to the sanitary and combined sewer systems.

4) Drain wastewater discharges and areas with the potential for relatively consistent wastewater discharges (such as vehicle washing facilities) to the sanitary or combined sewer system.

5) Drain areas that have the potential for acute releases or accidental spills, and are not expected to regularly receive flow or require water use (such as covered fuel islands or covered containment areas), to an approved method of containment.

6) Contain spills on-site.

7) Emphasize structural controls over operational procedures. Structural controls are not operator dependent and are considered to provide more permanent and

reliable pollution control. Any proposals for operation-based SPCs need to describe the long-term viability of the maintenance program.

8) Provide permanent structural solutions to address the range of potential impacts resulting from multiple site uses and tenant turnover.

9.1.3 Performance Approach

The design professional may propose alternative designs to achieve the intent of the SPC requirements presented in this chapter. Alternative SPCs designed using the performance-based approach shall satisfy the following:

1) If a stormwater management facility described in Chapter 5.0 is used to control pollutants generated by specific site uses, the designer shall comply with applicable sizing and design requirements in Chapter 5.0.

2) The designer shall fulfill all applicable requirements of Chapters 7.0 and 8.0. The designer shall also address overflow, safety, and access requirements similar to the requirements for facilities described in Chapter 5.0.

Applicants who want to use the performance approach shall fill out Part B of Form SPC (located at the end of this chapter) and include it in their submittal package. This form shall be used to request alternatives or major modifications to the SPCs required under this chapter. It shall also be used when SPCs already exist on the site that differ from the requirements, or when implementation of the required SPC(s) is not the best or preferred solution.

9.1.4 Approval of SPCs

The following process will be used after Form SPC is submitted:

1) The Bureau of Environmental Services (BES) Industrial Source Control Division will review the request and the proposed plan.

2) BES will notify the applicant if there is a denial, including any deficiencies and needed corrections. When additional information is needed or corrections need to be addressed, the notification is referred to as a "check-sheet." Notification of approval is part of the overall plan review process.

R0009579

3) The applicant may resubmit the request and plan after making the requested revisions.

4) Applicants who are not satisfied with a decision can challenge the decision through the appeals process outlined in Chapter 2.0.

9.1.5 Multiple SPC Requirements

Applicants are required to address all of the site characteristics and uses listed in Sections 9.2 through 9.12. For example, if a development includes both a fuel dispensing area and a vehicle washing facility, the SPCs in both Sections 9.2 and 9.10 will apply. A separate Form SPC is required for each applicable use or characteristic.

9.1.6 Operations and Maintenance Requirements

Chapter 8.0 describes operations and maintenance (O&M) requirements, including preparation of an O&M plan, for stormwater management facilities and facility elements. Applicants are required to include all O&M activities related to SPCs in the overall site O&M plan. An O&M template is provided at the end of Chapter 8.0.

Applicants shall review Chapter 8.0 to determine the O&M requirements relevant to the SPCs in this chapter. Chapter 8.0 may not, however, specifically address all of the structural or nonstructural stormwater controls implemented as a result of SPC requirements. It is the applicant's responsibility to determine all appropriate O&M provisions for the proposed SPCs and include them in the O&M plan.

9.1.7 Signage Requirements

Informational signage is required for some site uses and activities that have the potential to contaminate stormwater. Signage addresses good housekeeping rules and provides emergency response measures in case of an accidental spill.

All signage shall conform to the requirements described in the following box. Additional signage requirements for specific activities are noted in 9.2, 9.3, 9.5, and 9.7.

Signs shall be located and plainly visible from all activity areas. More than one sign may be needed to accommodate larger activity areas. Signs shall also be water resistant. They shall include the following information:

- Safety precautions
- Immediate spill response procedures—for example: "Turn the valve located at..." or "Use absorbent materials"
- Emergency contact(s) and telephone number(s)—for example: "Call 911" and "City of Portland (BES) Spill Response Number 503-823-7180"

Signs may need to be in more than one language if required to effectively communicate with employees and delivery personnel.

A complete copy of spill response and any loading/unloading procedures shall be mounted within 20 feet of the loading/unloading area. Any applicable spill response supplies need to be clearly marked and located where the signage is posted. More than one spill response kit may be necessary to accommodate larger activity areas.

9.1.8 Additional Requirements

Conformance with this chapter's requirements does not relieve the applicant of other applicable local, state, or federal regulatory or permit requirements. This chapter is intended to complement any additional requirements, and is not expected to conflict with, exclude, or replace those requirements. In case of a conflict, the most stringent local, state, or federal regulations shall apply. Any conflict shall be resolved by a City review representative in consultation with appropriate agencies. The applicant may appeal the decision through the appeals process outlined in Chapter 2.0.

Some of the more common requirements that may apply are summarized below.

SPILL RESPONSE SUPPLIES

The City requires spill response supplies, such as absorbent material and protective clothing, to be available at the tank storage area. Employees shall be familiar with the site's operations and maintenance plan and/or proper spill cleanup procedures.

STORMWATER AND WASTEWATER DISCHARGE PERMITS

Some facilities may be required to obtain an NPDES stormwater permit before discharging to the City's separated storm sewer system or to waters of the state. Applicants may also be required to obtain an industrial wastewater permit for discharges to the sanitary sewer system. Facilities subject to these requirements are generally commercial or industrial facilities. Typical discharges include process wastewaters, cooling water, or other discharges generated by some of the SPCs in this chapter that drain to a City sewer system (storm, sanitary, or combined). (*See Appendix 9-A: Sanitary Sewer Discharge Limits.*)

An evaluation will be done during the building permit review process to determine if an industrial discharge permit is required. If a permit is required, the application process will be independent of the building permit review/issuance process.

OTHER LOCAL, STATE, AND FEDERAL REGULATIONS

The requirements presented in this chapter do not exclude or replace the requirements of other applicable codes or regulations, such as the hazardous substances storage requirements of articles 79 and 80 of the Oregon State Fire Code; the spill prevention control and containment (SPCC) regulations of 40 CFR 112 (EPA); the Resource Conservation and Recovery Act (RCRA); or any other applicable local, state, or federal regulations or permit requirements.

The Oregon Department of Environmental Quality has identified drywells and/or sumps as "Class V Injection Wells" under the federal Underground Injection Control (UIC) Program. Since the UIC Program states that these types of wells have a direct impact on groundwater, stormwater pollution controls will apply. More information about the UIC program can be found on DEQ's web site at: Http://waterquality.deq.state.or.us/wq/groundwa/uichome.htm

Additional City of Portland and Oregon Department of Environmental Quality (DEQ) permit requirements may apply. Contact BES's Industrial Source Control Division at 503-823-7122 for additional information about stormwater or wastewater discharges to City-owned sanitary, stormwater, or combined sewer systems.

9.2 FUEL DISPENSING FACILITIES

9.2.1 Applicability

The requirements in this section apply to all development where vehicles or equipment are refueled on the premises—whether a large-sized gas station or a single-pump maintenance yard. They do not apply to propane tanks.

A fuel dispensing facility is defined as the area where fuel is transferred from bulk storage tanks to vehicles, equipment, and/or mobile containers (including fuel islands, above-ground fuel tanks, fuel pumps, and the surrounding pad).

Applicants subject to these requirements shall prepare a **Form SPC** located at the end of this chapter) that fulfills the requirements of Section 9.2.3, below, and include it in their submittal package.

> NOTE: Mobile fueling operations require authorization by BES's Industrial Stormwater Permitting Section and may have specific SPC requirements not identified in this chapter. These types of operations are typically used for construction activities or other limited-duration projects.

9.2.2 Issue

Fuel dispensing facilities are a potential source of chronic loading and acute releases of pollutants to the environment. Stormwater runoff from fuel dispensing facilities may contain oil and grease, toxic hydrocarbons, heavy metals, and other pollutants.

9.2.3 Requirements

The following SPCs are required for fuel dispensing operations, unless an equivalent alternative is requested on Form SPC and approved by BES.

1) COVER

The fuel dispensing area shall be covered with a permanent canopy, roof, or awning so precipitation cannot come in contact with the fueling area. Precipitation shall be directed from the cover to a stormwater disposal system that meets all applicable code requirements.

- **Covers 10 feet high or less** shall have a minimum overhang of 3 feet on each side. The overhang shall be measured relative to the perimeter of the hydraulically isolated fueling area it is to cover.

- **Covers higher than 10 feet** shall have a minimum overhang of 5 feet on each side. The overhang shall be measured relative to the perimeter of the hydraulically isolated fueling area it is to cover.

This SPC should be implemented in conjunction with prevention of stormwater run-on into the covered area.

2) PAVEMENT

A paved fueling pad shall be placed under and around the fueling activity. The pad shall be sized to adequately cover the activity area, including placement of the vehicle or piece of equipment to be fueled.

Gasoline and other materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks.

3) DRAINAGE

The paved area beneath the cover shall be hydraulically isolated through grading, berms, or drains. This will prevent uncontaminated stormwater from running onto the area and carrying pollutants away. Drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, an approved on-site industrial wastewater treatment facility, or other approved on-site temporary storage facility or containment device/structure.

> **Note:** An on-site temporary storage facility or containment device/structure shall be used only as a last resort and only for temporary storage of the wastewater or contaminated stormwater (*see Appendix 9-B*).
>
> If a water pollution control facility permit (WPCF) is required by DEQ and results in changes to the facility, Source control must be given copies of these changes.

4) SIGNAGE

Signage shall be provided at the fuel dispensing area and shall be plainly visible from all fueling activity areas (*see section 9.1.7).*

The following language shall be added to the building plan set, as a general note on the site and/or utility plan:

> "Signage will be provided at the fuel dispensing area that is plainly visible and water resistant, and includes the following information:
>
> - Safety precautions
> - Immediate spill response procedures
> - Emergency contacts and telephone numbers"

5) SEDIMENTATION MANHOLE

A sedimentation manhole shall be installed on the discharge line of the fueling pad (before the domestic waste line tie-in). The manhole shall be located on property. For more information about sedimentation manholes, refer to the City's *Standard Construction Specifications Book,* detail 4-11.

The requirement for a sedimentation manhole prior to sanitary discharge is to help achieve local discharge limitations applicable to the City's sanitary sewer. (See *Appendix 9-A* for more information about sanitary sewer discharge limits.)

Design Retrofit of Sedimentation Manhole: The outlet of the manhole will need to be revised to reflect a tee installation, with a removable watertight cap for cleaning. The tee must extend downward approximately 18 inches. This feature is to help capture oils and greases.

6) SHUT-OFF VALVE

A shut-off valve shall be installed downstream of the sedimentation manhole, before the domestic waste line tie-in. The shut-off valve must be located on property. For more information about shut-off valves and associated valve boxes, contact the City's Commercial Plumbing Department at 503-823-7302.

This requirement is to comply with City Code, Chapter 17.34.090, requiring spills that occur within the activity area to be effectively contained for appropriate clean-up and disposal. (The emergency contacts and responders identified on the required signage shall determine the appropriate clean-up and disposal of a spill.)

7) ADDITIONAL REQUIREMENTS

Please carefully review the following additional requirements. These requirements are not applicable to all development projects. If they do apply, however, and are not addressed in the project design, revisions will be required. This could delay issuance of related building permits.

A) **Above-ground fuel tanks** are subject to additional requirements (*see Section 9.3*).

B) **Additional oil controls** may be required for vehicle traffic, parking, and storage areas if the facility is defined as a higher-use or higher-risk site (*see Section 9.8*).

C) **Bulk fuel terminals** require an additional review process to determine regulatory authority and requirements.

8) EXCEPTIONS

A) The requirement to cover the fuel dispensing area can be waived if the fuel dispensing area is generally used to service oversized equipment (e.g., cranes) that cannot maneuver under a roof or canopy.

City Code (Chapter 17.32.080 and 17.32.090) prohibits stormwater from being discharged to a City separated sanitary sewer, with limited exceptions allowed by the Chief Engineer. If approval is granted and a cover is not installed because of oversized equipment, Chapter 17.36 of the City Code allows the City of Portland to bill a facility for the disposal of stormwater into the City separated sanitary sewer. Charges are determined by either calculated volumes (based on the average annual rainfall and the square footage of impervious area drained) or by meter readings from a City-approved discharge meter.

A written **stormwater volume charge request** will be required as part of the approval process for this exception. The written request shall document the property owner's acknowledgement of the City's right to charge the facility sanitary sewer rates for the volume of stormwater discharged to the sanitary sewer system. The application shall be signed by the property owner and notarized.

B) Propane tanks are exempt from requirements #1 through 5 in 7.2.3. Traffic protection crash posts shall be placed at a maximum spacing of 5 feet on all sides of the AST where traffic patterns may exist and a containment wall is not present.

9.3 ABOVE-GROUND STORAGE OF LIQUID MATERIALS

9.3.1 Applicability

The requirements in this section apply to all development where there is any exterior storage of liquid chemicals, food products, waste oils, solvents, or petroleum products in above-ground containers, in quantities of 50 gallons or more. This includes permanent storage and temporary storage areas.

The requirements do not apply to underground storage tanks or to businesses permitted by the Oregon Department of Environmental Quality (DEQ) to treat, store, or dispose of regulated substances or wastes.

Double-walled tanks may be exempt from complying with the requirements of this SPC, depending on the loading and unloading procedures used for the tank.

Note: Storage of reactive, ignitable, or flammable liquids shall comply with the Uniform Fire Code as adopted by the State of Oregon. See #6 under "Additional Requirements," below.

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter) that fulfills the requirements of Section 9.3.3, below, and include it in their submittal package.

9.3.2 Issue

Stationary containers that store liquid materials have the potential to introduce toxic compounds, solvents, oil, grease, heavy metals, abnormal pH, nutrients, and bacteria to stormwater. In addition, spills may occur during liquid transfer operations or tank failure.

9.3.3 Requirements

1) CONTAINMENT

Liquid materials shall be stored and contained in such a manner that if the container(s) is ruptured, the contents will not discharge, flow, or be washed into a receiving system.

Double-walled containers are generally exempt from these spill containment measures. Exposed dispensing hoses or other fixtures may require some form of containment; this will be determined during the SPC application review process.

2) COVER

Storage containers (other than tanks) shall be completely covered so precipitation cannot come in contact with them. Precipitation shall be directed from the cover to a stormwater disposal system that meets all applicable code requirements.

Liquid storage tanks are not required to be covered with a canopy or roof. However, all taps, couplings, pumps, and other potential drip, spill, and leak-prone spots (during liquid transfer operations, and when making and breaking connections) shall be completely covered with rain shields. Drip pans shall be placed under the rain shields. Any materials collected in the drip pans and any soiled absorbent materials shall be reused, recycled, or appropriately disposed of. Disposal locations and dates shall be recorded as part of the facility's operations and maintenance log, as identified under the requirements of Chapter 8.0 of this manual.

3) PAVEMENT

A paved storage area is required unless otherwise approved by BES's Industrial Source Control Division staff. The paved area shall be sized to adequately cover the area intended for storage.

Gasoline and other materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks.

When an exception to the requirement is allowed, the stored material shall still need to be raised off the ground by pallets or similar methods, with provisions for spill control. The applicant shall clearly identify this alternative method in Form SPC, Sections B and C.

4) DRAINAGE

All paved storage areas shall be hydraulically isolated through grading, berms, or drains to prevent uncontaminated stormwater run-on to a storage area.

Covered storage areas with containment: Significant amounts of precipitation are not expected to accumulate in covered storage areas, and drainage facilities are not required for the containment area beneath the cover. If the applicant elects to install drainage facilities, the drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, approved on-site industrial wastewater treatment system, or other approved on-site temporary storage facility or containment device/structure.

Uncovered storage areas with containment: Water will accumulate in uncovered storage areas during and after rain. Any *contaminated* water cannot simply be drained from the area. It must be collected, inspected, and possibly tested before proper disposal can be determined. Frequent draining may be required during the wet season, which may prove costly. Some type of monitoring may also be needed to determine the characteristics and level of contamination of the stormwater.

In uncovered storage areas, a valve shall be installed in the storage area so excess stormwater can be drained out of the activity area and directed either to the storm drainage facilities (*if clean*) or into the City sanitary sewer, an on-site industrial wastwater treatment system, or other approved on-site temporary storage facility or containment device/structure (*if contaminated*). Except when excess stormwater is being discharged, the valve shall always be kept closed so any spills within the activity area can be effectively contained.

Note: An on-site temporary storage facility or containment device/structure shall be used only as a last resort and only for temporary storage of the wastewater or contaminated stormwater (*see Appendix 9-B*).

All discharges to the sanitary sewer shall be considered batch discharges and shall require approval and pretreatment prior to discharge. Pretreatment requirements will be set as part of the discharge approval process, based on the types and quantities of material to be discharged. A discharge evaluation shall be performed before connection to a sanitary sewer. Testing may be required to establish characteristics of the wastewater or contaminated stormwater and to verify that local discharge limits are not exceeded. For batch discharge applications, call BES's Source Control Division at 503-823-5320.

5) SIGNAGE

Signage shall be provided at the fuel dispensing area and shall be plainly visible from all fueling activity areas (*see section 9.1.7).*

The following language shall be added to the building plan set, as a general note on the site and/or utility plan:

> "Signage will be provided at the fuel dispensing area that is plainly visible and water resistant, and include the following information:
>
> - Safety precautions
> - Immediate spill response procedures
> - Emergency contacts and telephone numbers"

Signage shall be provided at the storage area, in accordance with the requirements of Section 9.1.7.

6) ADDITIONAL REQUIREMENTS

Please carefully review the following additional requirements. These requirements are not applicable to all development projects. If they do apply, however, and are not addressed in the project design, revisions will be required. This could delay issuance of related building permits.

A) **A shut-off valve** may be required for the covered storage area if the applicant elects to install drainage facilities to an approved City sanitary sewer. BES will make this determination based on the type of material stored and the proposed system receiving the discharge.

This requirement is to comply with City Code, Chapter 17.34.090, requiring spills that occur within the activity area to be effectively contained for appropriate clean-up and disposal. (The emergency contacts and responders identified on the required signage shall determine the appropriate clean-up and disposal of a spill.)

B) **Storage of hazardous materials** that are toxic, carcinogenic, or halogenated solvents (located in designated groundwater resource protection areas) are subject to additional requirements, as identified in Section 9.5: Storage, Use, and Transportation of Hazardous Materials in Designated Groundwater Resource Protection Areas.

C) **Storage of reactive, ignitable, or flammable liquids** shall comply with the Uniform Fire Code as adopted by the State of Oregon. SPCs presented in this section are intended to complement, not conflict with, current fire code requirements. None of these requirements shall exclude or supersede any other requirements in this manual, other City permit requirements, or state and federal laws pertaining to water quality. Contact the Portland Fire Bureau (503-823-7366) and/or BES's Industrial Source Control Division (503-823-7122) for further information and requirements.

9.4 SOLID WASTE STORAGE AREAS, CONTAINERS, AND TRASH COMPACTORS

9.4.1 Applicability

The requirements in this section apply to all development with facilities that store solid wastes (both food and non-food wastes) outdoors in one or more solid waste storage areas. A solid waste storage area is a place where solid waste containers are collectively stored. Solid waste containers include trash compactors, dumpsters, and garbage cans (including those used to contain recyclable materials).

Single family homes are exempt from these requirements. Multi-family residential sites are not exempt.

Applicants subject to these requirements shall prepare **Form SPC** located at the end of this chapter) that fulfills the requirements of Section 9.4.3, below, and include it in their submittal package.

9.4.2 Issue

Pollutants may be introduced into stormwater if the stormwater mixes with solid waste or with fluids leaking from waste containers. Stormwater run-off from food waste storage areas may be contaminated with oils, greases, nutrients, and suspended solids if waste containers are leaking, not covered, or are too small to contain the amount of waster generated. Improper storage of non-food wastes can allow toxic compounds such as, oil, grease, heavy metals, , nutrients, and suspended solids to contaminate stormwater run-off.

9.4.3 Requirements

1) COVER

Dumpsters and Garbage Cans Used to Store Non-Food Solid Waste

Non-food solid wastes include refuse typically generated by a household or business. These areas are not required to have a structured cover, but shall be covered with a lid. Only leak-proof containers shall be used.

Dumpsters and Garbage Cans Used to Store Food Wastes and Materials other than Solid Waste

Food waste refuse, as discussed here, is typically generated by restaurants and other food industry businesses. Food waste includes foods not consumed by customers and excess or spoiled food.

Dumpsters and garbage cans used to store food wastes and materials other than solid wastes (such as fertilizers, chemicals, oil, and waste oil) shall be covered with a permanent canopy or roof to prevent stormwater contact and minimize the quantity of stormwater entering the waste storage area. The area beneath the cover shall be hydraulically isolated from other portions of the site through grading, berms, or drains.

Trash Compactors without A Hard-Piped Connection to the Sanitary Sewer

Trash compactors without a hard-piped connection to the sanitary sewer shall be covered with a canopy or roof to prevent stormwater contact and minimize the quantity of stormwater entering the waste storage area. The area beneath the cover shall be hydraulically isolated from other portions of the site through grading, berms, or drains. Drainage from the area beneath the cover shall be directed to a sanitary sewer or other approved on-site containment structure.

Trash Compactors with A Hard-Piped Connection to the Sanitary Sewer

Trash compactors with a hard-piped connection to the sanitary sewer shall be kept closed except when loading material and are not required to have a permanent cover or canopy.

2) PAVEMENT

The area beneath the cover shall be paved with asphalt or concrete and meet all applicable City of Portland Building Code requirements. A paved waste storage area is required for waste storage areas with a structural cover or using a trash compactor, as identified above. The area beneath the cover shall be hydraulically isolated through grading, berms, or drains.

3) DRAINAGE

Drainage beneath any covered area shall be hydraulically isolated through berming, grading, or drains to prevent uncontaminated stormwater from running onto the area and carrying pollutants away. Drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, an approved on-site industrial wastewater treatment facility, or other approved on-site temporary storage device and/or containment structure. Stormwater drainage from the cover shall be directed to an approved stormwater system that meets all applicable City of Portland Building Code requirements.

Note: An on-site temporary storage facility or containment device/structure shall be used only as a last resort and only for temporary storage of the wastewater or contaminated stormwater (*see Appendix 9-B*).

OPERATION AND MAINTENANCE REQUIREMENTS

4) WASHING

If the solid waste storage area and/or solid waste containers are washed, the wastewater shall be directed to a sanitary sewer or contained and disposed of by a licensed contractor. This wastewater shall not be allowed to enter a stormwater system.

5) INSPECTION

Solid waste containers shall be inspected by a trained facility employee at least once a month to verify that fluids have not leaked. Inspection records shall be retained as part of the facility's operations and maintenance records.

6) DRY SWEEPING

The solid waste storage area shall be dry-swept and cleaned every two months (or more often as needed) by the property owner, operator, or their contractor or designee.

9.5 STORAGE, USE, AND TRANSPORTATION OF HAZARDOUS/ TOXIC MATERIALS IN DESIGNATED GROUNDWATER RESOURCE PROTECTION AREAS[1]

9.5.1 Applicability

The requirements of this section apply to development that:

- Requires a building permit, AND
- Has either **interior or exterior** hazardous/toxic materials storage, use, or transportation areas, AND
- Is located within any of the following groundwater resource protection areas (see **Exhibit 9-1** and **Exhibit 9-2**):
  - Columbia South Shore (COSS) Plan District
  - Cascade Station/Portland International Center (CS/PIC) Plan Districts
  - Powell Valley Groundwater Resource Protection Area (PVRPA)

The groundwater resources in the COSS, CS/PIC and PVRPA provide the primary and back-up water supply for the City of Portland and much of the metropolitan area. Developments in these areas are subject to stringent management requirements in order to protect groundwater and drinking water resources.[2]

Hazardous materials[3] are considered to be materials that are classified as, or have constituents with, one or more of the following characteristics:

[1] The City of Portland Bureau of Water Works, Groundwater Resource Protection Program, is responsible for implementing the requirements of Section 9.5.

[2] Section 9.5 supersedes the Draft *COSS Hazardous Materials Containment Handbook* that previously provided guidance regarding hazardous materials containment within groundwater resource areas. That is why the requirements of section 9.5 may also apply to all developments requiring building permits within the COSS, CS/PIC and PVRPA, even if no new impervious area is created.

[3] This section does not use the Resource Conservation and Recovery Act (RCRA) definition of "hazardous." For purposes of this section, "hazardous material" is intended to include hazardous, toxic, and other harmful substances. Refer to "Definition of Terms" at the end of this chapter for further clarification.

Powell Valley Road Water District Groundwater Resource Protection Area

POWELL VALLEY ROAD WATER DISTRICT – DRINKING WATER PROTECTION PLAN

93-0279.404

MSA

R0009599

23 G:\9310279.40\dwg\... 5 23 99 9:59:16 am

- Carcinogenic
- Toxic
- Halogenated solvents

If the site use(s) potentially meet the above criteria, the applicant shall complete a hazardous materials inventory, as identified in 9.5.3 (Step 1). Based on the results of the inventory and subsequent guidance in 9.5.3, the applicant may have no further requirements under this section if:

a) The materials are not mobile, as defined in 9.5.3.
b) The quantity stored/transported does not exceed specified threshold quantities defined in 9.5.3.

LIQUID MATERIALS STORED IN ABOVE-GROUND TANKS

Liquid materials stored in above-ground storage tanks may be subject to the requirements in this section. Applicants who use, transport, or store liquid materials in above-ground storage tanks that may be hazardous, toxic, or a halogenated solvent (within the designated groundwater resource protection areas) shall perform the inventory in Section 9.5.3. If results of the inventory indicate the applicant has materials regulated by Section 9.5 in quantities that exceed threshold amounts, the requirements of Section 9.5 shall supersede the requirements of Section 9.3.

9.5.2 Issue

Stormwater runoff may gather many pollutants when it contacts exposed bulk or chemical materials. Stormwater runoff and spills from some materials storage, use, or transportation areas have the potential to contribute chemical, physical, and biological pollutants to receiving systems, including toxic substances, organic compounds, oil and grease, heavy metals, bacteria, nutrients, and suspended solids. These substances can enter the groundwater or surface water through acute releases or chronic loading. Potential pollutants can vary extensively in type and severity, depending on the characteristics of the material being stored.

9.5.3 Requirements

Section 9.5.3 identifies the requirements for the storage, use, and transportation of hazardous/toxic materials. **Exhibit 9-3** summarizes the steps the applicant shall perform.

Exhibit 9-3
SUMMARY OF APPLICANT REQUIREMENTS

STEP 1: Applicant completes a hazardous materials inventory.

STEP 2: Applicant uses the inventory to determine risk classification, based on chemical mobility and threshold quantities. This step involves the following procedures:

A) Determine chemical mobility.
B) Evaluate carcinogens, toxics, and halogenated solvent characteristics.
C) Determine threshold quantities.
D) Determine site risk classification.

If materials are defined as mobile and exceed threshold quantities, the applicant shall proceed to Step 3. **If materials are not mobile and/or do not exceed threshold quantities, the applicant does not need to proceed further.**

> *Note: The applicant may seek technical assistance to evaluate the risk classification. Contact the Portland Bureau of Water Works (503-823-7577) to obtain technical assistance after the materials inventory has been completed.*

STEP 3: Applicant determines required management measures. This step involves the following procedures, as relevant:

A) Identify functional areas: hazardous material containment zones (HMCs), site transportation routes, and loading/unloading facilities.
B) Prepare a hazardous materials containment plan and provide signage.
C) Implement interior containment requirements.
D) Implement exterior containment requirements.
E) Implement transportation route requirements.

Section 9.5.3 identifies the applicant's required submittal forms relevant to these steps.

Following receipt of the applicant's submittal, the City will review the inventory, proposed HMCs, transportation zones, loading/unloading facilities, and containment plan and make a final determination on site risk classification and the proposed management measures.

R0009601

STEP 1: HAZARDOUS MATERIALS INVENTORY

If the proposed site use(s) fall under the applicability criteria defined in section 9.5.1, the applicant shall complete a hazardous materials inventory. **Form HAZ: Hazardous Materials Inventory** and instructions are provided at the end of this chapter.

STEP 2: RISK CLASSIFICATION

The applicant shall use the completed Form HAZ to evaluate the risks associated with using and storing hazardous materials on the site. The risk classification procedure involves four components, as identified under A through D, below.

Note: The applicant may seek technical assistance to evaluate the risk classification. Contact Portland Bureau of Water Works (503-823-7577) to obtain technical assistance after Form HAZ (Step 1) has been completed.

A) Determine Chemical Mobility

Note: Some of this information may be obtained from the product Material Safety Data Sheet (MSDS). Applicants should check with the product manufacturer or supplier if they do not have an MSDS or are unsure if the product is required to have one.

A mobile chemical is defined as a substance that has one or both of the following characteristics:

- Is a solid with measurable solubility in water (see MSDS).
- Is in liquid state at ambient temperature.

➔ If a used, stored, or transported material has one or both of these characteristics, it is considered to be mobile, and the applicant shall continue to B), below. **If the material does not have either of the characteristics listed above**, it is not mobile for purposes of this evaluation. The material is considered to be a low risk, and **no further action is required under Section 9.5.**

R0009602

B) **Evaluate Carcinogens, Toxics, and Halogenated Solvent Characteristics**

Threshold quantities apply to the following materials if they have been classified as mobile:

1) Carcinogens
2) Highly and moderately toxic materials
3) Halogenated solvents

Definitions for these materials are provided below.

1) ***Carcinogens***

The City of Portland uses the National Toxicology Program list of nationally recognized carcinogens (NTP list) to identify chemicals that are confirmed or suspected carcinogens. The lists of suspected and known carcinogens can be found on the NTP website:

http://ntp-server.niehs.nih.gov/Main_pages/NTP_8RoC_pg.html.

If the material in question is included on this list, the City considers the material a confirmed carcinogen for purposes of this evaluation.

Carcinogenic mixtures (products that contain any confirmed carcinogen) shall be considered carcinogenic.

2) ***Toxic Materials***

The City of Portland uses the oral ingestion lethal dose for 50 percent of the experimental population (LD-50) value to classify the level of toxicity associated with a particular substance. The LD-50 can be determined from the following sources (presented in the order in which they should be consulted):

- The product MSDS sheet.
- The product manufacturer.
- The hazardous material list presented in **Appendix 9-C**.
- A City representative. Contact Portland Bureau of Water Works, 503-823-7577, for assistance.

Chemical mixtures (products that contain multiple chemical constituents) shall be evaluated using the most toxic constituent (lowest LD-50 value) present above 10 percent of the total mixture.

Definitions for materials and mixtures are:

Highly toxic:	Any material with a LD-50 under 500 mg/kg
Moderately toxic:	Any material with a LD-50 between 500 mg/kg and 5000 mg/kg

3) ***Halogenated Solvents***

A list of halogenated solvents is provided in **Appendix 9-D.** Any material included on that list shall be evaluated.

➔ If the stored or transported materials have any of the defined characteristics, the applicant shall continue to C), below, to determine threshold quantities. **If the materials do not have any of the defined characteristics, no further action is required under Section 9.5.**

C) Determine Threshold Quantities

The threshold quantities listed in **Exhibit 9-4** apply to carcinogens, toxic materials, halogenated solvents, and combinations of these categories.

Facilities that use, store or transport multiple categories of materials (carcinogenics, toxics, halogenated solvents), each in quantities of 10 gallons, or 50 pounds, or greater, shall add quantities of materials within each category. If the total quantity within each category does not exceed the quantity thresholds for that individual category (carcinogen, highly toxic, moderately toxic, or halogenated solvents), the total quantities in all categories shall be added together to determine the overall total for the site.

> Example: One site has the following materials present: 25 gallons of confirmed carcinogens, 15 gallons of highly toxic materials, and 140 gallons of moderately toxic materials. None of the quantities exceeds the threshold amounts for an individual category, so the site threshold would be determined based on the sum total of all the categories, or 180 gallons.

Sites where two or more categories of material are used, but do not exceed the threshold amounts for individual categories (confirmed carcinogens, highly toxic, moderately toxic, or halogenated solvents), are called multiple-chemical sites.

Exhibit 9-4
APPLICABLE THRESHOLD QUANTITIES

Category	Definition	Threshold Quantity
Carcinogen	Included on NTP list	40 gallons or 300 lbs
Highly toxic	LD-50 under 500 mg/kg	40 gallons or 300 lbs
Moderately toxic	LD-50 between 500 mg/kg and 5000 mg/kg	160 gallons or 1200 lbs
Halogenated solvents	See Appendix 9-D for chemical listing	10 gallons or 100 lbs
Multiple-chemical sites	Sum of all individual categories if none of the categories exceeds thresholds	180 gallons or 1200 lbs

➔ If the quantity of stored, used, or transported materials exceeds any threshold quantity for individual or multiple-chemical sites, the applicant shall continue to D), below, to determine site risk classification. **If the stored or transported materials do not exceed these thresholds, no further action is required under Section 9.5.**

D) Determine Site Risk Classification

Sites are classified as Class 1 or Class 2, based on the total quantity of the most dangerous materials present on the entire site at one time. Class 1 sites pose a higher risk and Class 2 sites pose a lesser risk. A site's classification will determine the degree to which containment facilities are required to keep any material spills or leaks from reaching groundwater or surface water.

Containment facilities may also be classified individually within a site. For example, a site that exceeds the threshold quantities for both highly toxic and moderately toxic materials would be classified as a Class 1 site. Based on site design, function, and chemical compatibility, the materials could be stored together or separately within the site. If the materials are stored together, the more stringent containment requirements (Class 1) would apply. (When compatible materials with different classifications are stored together, the more stringent classification applies.) Individual containment requirements would apply, however, if all the highly toxic materials (Class 1) were stored in one area and all the moderately toxic materials (Class 2) were stored in another.

Sites where two or more categories of material are used, but do not exceed the threshold amounts for specific site categories (confirmed carcinogens, highly toxic, moderately toxic, halogenated solvents), shall be regulated as multiple-chemical sites.

Exhibit 9-5 shows how the site and any individual containments should be classified, based on the category of material and the threshold quantity.

Exhibit 9-5
RISK CLASSIFICATIONS

Category	Threshold Quantity	Classification
Carcinogen	40 gallons or 300 lbs	Class 1
Highly toxic	40 gallons or 300 lbs	Class 1
Halogenated solvents	10 gallons or 100 lbs	Class 1
Moderately toxic	160 gallons or 1200 lbs	Class 2
Multiple chemicals	180 gallons or 1200 lbs	Class 2

STEP 3: REQUIRED MANAGEMENT MEASURES

This step specifies the management measures required for Class 1 and Class 2 storage, use, and transportation areas. The requirements are summarized in **Exhibit 9-6** and described in more detail following the exhibit.

Development projects required to implement management measures shall complete **Form SPC,** located at the end of this chapter, and include it in their submittal package.

Exhibit 9-6
REQUIRED MANAGEMENT MEASURES

Management Measure	Class 1	Class 2
A) Identify functional areas: hazardous material containment zones (HMCs), loading/unloading areas, and transportation routes.	X	X
B) Prepare a hazardous materials containment plan and install signs.	X	X
C) Implement interior containment requirements.	X	X
D) Implement exterior containment requirements.	X	X
E) Implement transportation route requirements.	X	

R0009607

A) Identify Functional Areas: Hazardous Material Containment Zones (HMCs), Loading/Unloading Areas, and Transportation Routes

The applicant shall identify all HMCs, loading/unloading areas, and transportation routes (see following definitions) that will occur on the proposed development site. These different areas can be thought of as "functional areas" that are associated with certain kinds of activities/functions. The intent is to identify the types of activities that occur at a site, and group chemical storage, use, and transportation/transfer areas in a manner that will satisfy functional needs and facilitate site safety, yet minimize containment areas and associated requirements. All functional areas shall be designated on Form SPC (Parts D and E), located at the end of this chapter.

Hazardous materials containment zones (HMCs) are areas where a specific individual activity takes place and where chemical quantities at that location are expected to exceed the thresholds identified in this section. HMCs are typically subject to permanent structural containment requirements and shall be physically or hydraulically separated from the surroundings. HMCs may include (but are not be limited to) storage and/or process areas, transportation routes, work areas, and loading/unloading facilities.

If the total quantity of material stored in a specific location (such as a maintenance area or within a piece of machinery) does not exceed 25 percent of the quantity threshold for the material, containment is not required in that area.

Loading/unloading areas are any areas that: 1) are designed (size, width, etc.) to accommodate a truck/trailer being backed up to or into them, and 2) are expected to be used specifically to receive or distribute materials to/from trucks or trailers.

Transportation routes are any paths used to transport materials regulated in section 9.5 onto, off of, or within a site.

Functional areas collectively identify the HMCs, loading/unloading areas, work areas using hazardous materials, and transportation routes on a site. The applicant shall separately evaluate the risk and classify each functional area.

B) Prepare a Hazardous Materials Containment Plan and Provide Signage

Form SPC, Part E (located at the end of this chapter) provides the form and instructions for preparing a hazardous materials containment plan.

The hazardous materials containment plan shall include the management requirements specified in C), D), and E), below, as appropriate. These shall include secondary containment of hazardous materials, spill prevention/detention measures for loading/unloading areas and transportation corridors.

Signage shall be provided for all designated HMCs, in accordance with the requirements of Section 9.1.7.

C) Implement Interior Requirements

These interior requirements address activities conducted inside a building. All interior HMCs that exceed the appropriate threshold quantities shown in Exhibit 9-4 shall implement the following requirements:

1) Provide secondary containment. Secondary containment can be achieved through flooring, paving, liners, walls, curbs, gutters, berms, drains, piping, valves, self-contained sumps, vaults, double-walled tanks, or other commercially available secondary containment devices.

2) Use impervious materials. All secondary containment devices shall be constructed of impervious materials. Impervious surfaces may consist of concrete, asphalt, pavement, synthetic liners, or any other material having a permeability of less than 1×10^{-6} cm/sec. Testing may be required.

   The applicant may also use the following mix specifications to achieve presumed compliance with impervious requirements:

   - For concrete, a water: cement ratio of less than 0.6 and a maximum size of aggregate of less than 3 inches shall be used.

   - For asphalt, the air voids shall be less than 10 percent.

3) Seal all joints and cracks with a bonded epoxy or similar material.

D) Implement Exterior Containment Requirements

The following requirements apply to all designated HMC zones.

1) Cover the materials.

   All HMCs shall be covered to prevent rainfall from entering the area. Exterior areas may be constructed with or without sidewalls.

a) Structures with sidewalls:

Exterior HMCs constructed with sidewalls may include sheds manufactured specifically for materials storage and spill containment purposes. The structure shall meet the requirements for impervious surfaces and spill containment capacity stated in this section.

b) Structures without sidewalls:

Exterior HMCs may also be covered with a pole building, awning, or other permanent cover. The cover for an exterior materials storage area shall have a minimum overhang of 3 feet on each side for covers 10 feet high or less. The cover shall have a minimum overhang of 5 feet on each side for covers more than 10 feet high. The overhang shall be measured relative to the berm beneath the cover.

2) Store materials on an impervious surface. All designated HMC zones shall be underlain by impervious surfaces over the entire area of the zone. Impervious surfaces are defined above under C) Implement Interior Requirements.

3) Berm the perimeter of all HMC zones without sidewalls. All materials shall be stored within the berm and under a cover, or inside a building.

4) Direct drainage from the paved area beneath the cover to an approved on-site containment structure. The area beneath the canopy or roof shall be reverse-graded or bermed to hydrologically isolate the area from other portions of the facility and minimize the amount of stormwater runoff accumulating beneath the cover. The approved containment structure shall also contain material spills inside the bermed area.

5) Provide spill containment for 110 percent of the largest volume of any single container being stored within the containment, or 10 percent of the total volume of material being stored, whichever is greater. Some interior or completely enclosed materials storage areas shall also provide containment volume for 20 minutes of fire flow. (See the Uniform Fire Code for further definition of this requirement.)

E) Implement Transportation Route Requirements

A transportation route is defined as any route used to transport materials regulated under Section 9.5 onto, off of, or within a site. This includes driveways, parking areas, and all other passageways used to transport regulated materials onto, off of, or within a site.

1) Provide spill containment.[4] All containment facilities shall provide a minimum capacity adequate to capture 150 gallons. This containment volume may be provided by treatment facilities, oversized piping, or a combination. Spill control containment volume shall be incorporated into stormwater quality/quantity systems using either of the following:

   - A spill control separator or multi-chambered oil/water treatment device may be used to satisfy the requirements for both the transportation corridors and paved surfaces/parking areas. Oil/water treatment devices used for spill containment purposes shall be equipped with a shut-off mechanism immediately downstream. The valve shall be well marked and in good working order, and employees shall be trained in spill response procedures.

   - Spill containment that will be integrated into the site stormwater quality/quantity systems shall be constructed with a quick-closing valve and lined forebay that precede the stormwater facility. The forebay and piping system shall be designed to capture 150 gallons. In addition, a valve or other shut-off device shall be placed between the forebay and the treatment facility to isolate any spilled materials. The valve shall be well marked and placed in a location that can be accessed easily and safely in an emergency situation and shall be in good working order. Employees shall be trained in spill response procedures.

2) Use pavement, curb, and gutter materials constructed of impervious materials. Impervious surfaces are defined above under C) Implement Interior Requirements.

3) Seal all joints and cracks with a bonded epoxy or similar material.

---

[4] Stormwater drainage shall also meet the requirements in Section 9.8 for parking area/paved surfaces. Those requirements specify that stormwater drainage shall be treated for oil and grease prior to disposal.

9.6 EXTERIOR STORAGE OF BULK MATERIALS

9.6.1 Applicability

The requirements in this section apply to developments that stockpile erodable materials outside. This includes, but is not limited to, the following general categories:

- Pesticides/fertilizers
- Food items and wastes
- Scrap and recycling materials and/or yards.
- Soil, sand, and other materials that increase total suspended solids (TSS) in stormwater (including contaminated soil)
- Raw by-product materials, waste or final product.

Materials with any of the following characteristics are exempt from the requirements of this section:

- Have no measurable solubility or mobility in water and no hazardous, toxic, or flammable properties, or

- Exist in a gaseous form at ambient temperature, or

- Are containerized in a manner that prevents contact with stormwater (excluding pesticides and fertilizers)

Exhibit 9-7 lists some common bulk materials. The list is separated into materials that typically require SPCs and those that are not expected to affect water quality and therefore do not generally require SPCs.

This section does not regulate construction sites subject to the City's *Erosion Control Manual* and City Code, Title 10.

Applicants subject to the requirements in 9.6 shall prepare **Form SPC** located at the end of this chapter) that fulfills the requirements of Section 9.6.3, below, and include it in their submittal package.

Exhibit 9-7
BULK MATERIAL CATEGORIES

Bulk Materials with SPC Requirements	Bulk Materials without SPC requirements
Recycling materials	Washed gravel/rock
Scrap or salvage goods	Finished lumber
Metal	Rubber and plastic products (hoses, gaskets, pipe, etc.)
Sawdust/barkchips	Clean concrete products (blocks, pipe, etc.)
Storage and processing of food items	Glass products (new, non-recycled)
Chalk/gypsum products	Inert products
Sand/dirt/soil (including contaminated soil piles)	
Feedstock/grain	
Material by-products	
Asphalt	
Fertilizer/compost	
Pesticides	
Unwashed gravel/rock	
Lime/lye/soda ash	
Animal/human wastes	

9.6.2 Issue

Exterior storage of non-containerized bulk materials has the potential to contribute a variety of pollutants to stormwater, depending on the material being stored. Impacts generally associated with bulk materials storage include oil and grease, heavy metals, toxic or organic compounds, biochemical oxygen demand (BOD), suspended solids, bacteria, nutrients, metals, pH, and temperature.

The primary problem with most of these types of pollutants is that they are soluble, which means they cannot easily be filtered out of stormwater runoff or out of contaminated water that seeps into the soil.

9.6.3 Requirements

The following SPCs are required unless an equivalent alternative measure has been requested on Form SPC and approved by BES's Industrial Source Control Division.

1) COVER

Bulk materials shall be covered with a canopy or roof to prevent stormwater contact and minimize the quantity of precipitation entering the storage area. Precipitation shall be directed from the cover to a stormwater disposal system that meets all applicable code requirements.

2) PAVEMENT

A paved storage area is required beneath the structural cover.

Gasoline and other materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks that could contribute to soil contamination.

3) DRAINAGE

The paved area beneath the structural cover shall be hydraulically isolated through grading, berms, or drains to prevent uncontaminated stormwater from running onto the area and carrying pollutants away. Significant amounts of precipitation are not expected to accumulate in covered storage areas, and drainage facilities <u>are not required</u> for the containment area beneath the cover. If the applicant elects to install drainage facilities, the drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, approved on-site industrial stormwater treatment system, or other approved on-site temporary storage facility or containment device/structure.

Note: An on-site temporary storage facility or containment device/structure shall be used only as a last resort and only for temporary storage of the wastewater or contaminated stormwater. (*See Appendix 9-B.*)

4) ADDITIONAL REQUIREMENTS

Please carefully review the following additional requirements. These requirements are not applicable to all development projects. If they do apply, however, and are not addressed in the project design, revisions will be required. This could delay issuance of related building permits.

A) **Storage of pesticides and fertilizers** may need to comply with specific regulations outlined by the Oregon Department of Environmental Quality (DEQ). Applicants should contact DEQ for additional information.

B) **A sampling manhole** or other suitable stormwater monitoring access point may be required to monitor stormwater runoff from the storage area. This may apply to certain types of storage activities and materials or if an alternative SPC is proposed. This requirement is to comply with City Code, Chapter 17.39.080, to ensure appropriate stormwater disposal, BES Source Control staff will review for applicability of this requirement.

C) **Signage** shall be provided at the storage area if hazardous materials or other materials of concern are stored. Signage shall be located so it is plainly visible from all storage activity areas. More than one sign may be needed to accommodate large storage areas.

The following language shall be added to the building plan set, as a general note on the site and/or utility plan:

"Signage will be provided at the storage area that is plainly visible and water resistant, and include the following information:

- Safety precautions
- Immediate spill response procedures
- Emergency contacts and telephone numbers"

D) **A shut-off valve** may be required for the structurally covered storage area if the applicant elects to install drainage facilities to an approved City sanitary sewer. BES will make this determination based on the type of material stored and the proposed system receiving the discharge.

This requirement is to comply with City Code, Chapter 17.34.090, requiring spills that occur within the activity area to be effectively contained for appropriate clean-up and disposal. (The emergency contacts and responders identified on the required signage shall determine the appropriate clean-up and disposal of a spill.)

E) **Storage of hazardous materials** that are toxic, carcinogenic, or halogenated solvents (located in designated groundwater protection areas) are subject to additional requirements, as identified in Section 9.5: Storage, Use, and Transportation of Hazardous/Toxic Materials in Designated Groundwater Resource Protection Areas.

9.7 MATERIAL TRANSFER AREAS/LOADING DOCKS

9.7.1 Applicability

The requirements in this section apply to all development with a material transfer area.

Two construction techniques are generally associated with material transfer areas: 1) loading/unloading facilities with docks, and 2) large bay doors without docks. The requirements apply to all material transfer areas, including loading/unloading docks, bay doors, and any other building access point(s) with the following characteristics:

- The area is designed (size, width, etc.) to accommodate a truck/trailer being backed up to or into it, <u>and</u>

- The area is expected to be used specifically to receive or distribute materials to/from trucks or trailers.

The requirements may not apply to areas that are used only for mid-sized to small-sized passenger vehicles and that are restricted (by lease agreements or other regulatory requirements) to storing, transporting or using materials that are:

- Typically used by a household, or

- Classified as domestic use, such as a primary educational facility (elementary, middle, or high school); a building used for temporary storage (a lease agreement will need to be provided); a church, etc.

For assistance in making this determination, contact BES's Industrial Source Control Division at 503-823-7122.

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter that fulfills the requirements of Section 9.7.3, below. include it in their submittal package

9.7.2 Issue

Stormwater runoff may pick up many pollutants when it comes into contact with transfer areas through acute and chronic releases of materials in these areas. These may include oils and greases, toxic hydrocarbons, chemicals, heavy metals, and a variety of other substances that can degrade water quality. Releases or contact with materials of concern are generally expected to occur during material transfer activities in the area surrounding the truck or trailer end.

9.7.3 Requirements

1) COVER

New Buildings with Loading Docks

Loading docks shall be covered with a canopy, roof, or other permanent overhang that shall extend a minimum of 10 feet over the trailer or truck end. The cover shall minimize the volume of precipitation discharged to the City sanitary sewer, on-site industrial wastewater treatment system, or other approved on-site temporary storage facility or containment device/structure. Precipitation shall be directed from the cover to a stormwater disposal system that meets all applicable code requirements.

Existing Buildings with Loading Dock Improvements

Loading docks shall be covered with a canopy, roof, or other permanent overhang that shall extend a minimum of 4 feet over the trailer or truck end.

(Note: As part of an existing building's improvements, 10-foot overhangs make it difficult to meet Fire Code regulations.)

Bay Doors and Other Interior Transfer Areas

All transfer of materials shall be conducted with the truck or trailer end backed into the building a minimum of 5 feet (see additional requirements below). A cover is not required for these areas.

2) PAVEMENT

A paved area shall be placed underneath and around the loading and unloading activities. This will reduce the potential for soil contamination with potential impacts on groundwater and will help control any acute or chronic release of materials present in these areas.

Some materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks.

3) DRAINAGE

Loading Docks

The paved area beneath the cover shall be hydraulically isolated through grading, berms, or drains to prevent uncontaminated stormwater running onto the area and carrying pollutants away. Drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, approved on-site industrial wastewater treatment facility, or other approved on-site temporary storage facility or containment device/structure.

Note: An on-site temporary storage facility or containment device/structure shall be used only as a last resort and only for temporary storage of the wastewater or contaminated stormwater (*see Appendix 9-B*).

Bay Doors and Other Interior Transfer Areas

Bay doors and other interior transfer areas shall be designed so stormwater run-on does not enter the building. This can be accomplished by grading or drains.

Because interior material transfer areas are not expected to accumulate precipitation, installation of floor drains is not required or recommended. It is preferable to handle these areas with a dry-mop or absorbent material such as cat liter. If interior floor drains are installed, they shall be plumbed to an approved City sanitary sewer or approved on-site industrial wastewater treatment facility.

4) SIGNAGE

The following requirements apply to all material transfer areas/loading docks.

Signage shall be provided and shall be plainly visible from all material transfer activity areas (*see section 9.1.7*). More than one sign may be needed to accommodate large transfer areas.

The following language shall be added to the building plan set, as a general note on the site and/or utility plan:

> "Signage will be provided at the material transfer area that is plainly visible and water resistant, and will include the following information:
> - Safety precautions
> - Immediate spill response procedures
> - Emergency contacts and telephone numbers"

5) ADDITIONAL REQUIREMENTS

Please carefully review the following additional requirements. These requirements are not applicable to all development projects. If they do apply, however, and are not addressed in the project design, revisions will be required. This could delay issuance of related building permits.

A) **Bay doors and other interior transfer areas** shall provide a 10-foot "no obstruction zone" beyond the entrance. This will allow the transfer of materials to occur with the truck or trailer end placed at least 5 feet inside the building, with an additional staging area of 5 feet beyond that.

B) A **shut-off valve** may be required for discharges to an approved City sanitary sewer. BES will make this determination based on the type of material being transferred and the proposed system receiving the discharge.

This requirement is to comply with City Code, Chapter 17.34.090, requiring spills that occur within the activity area to be effectively contained for appropriate clean-up and disposal. (The emergency contacts and responders identified on the required signage shall determine the appropriate clean-up and disposal of a spill.)

C) **Transport and handling of hazardous materials** that are toxic, carcinogenic, or halogenated solvents (located in designated groundwater protection areas) are subject to are subject to additional requirements, as identified in Section 9.5: Storage, Use, and Transportation of Hazardous/Toxic Materials in Designated Groundwater Resource Protection Areas.

D) **Appropriate spill response training** shall be provided to all employees. The operations and maintenance agreement shall include information about the spill response training plan. The City requires spill response supplies, such as absorbent material, to be stored at the transfer area.

6) EXCEPTIONS

A) **Cover:** The requirement to cover the loading dock area will be waived under either of the following conditions:

- A retractable curtain is installed that automatically extends out from the building and over the back end of the truck or trailer during material transfer activities. This curtain then retracts back into the building when not in use. A detail of the curtain shall be submitted with the building plans at the time of building permit application. The detail will be reviewed to ensure that there is no possibility for spills to be discharged to stormwater.

- The loading dock is an improvement to an existing building, and the property owner agrees to pay the City for stormwater discharges to the sanitary sewer system (if drainage from the uncovered loading dock discharges to the City's sanitary sewer).

  City Code (Chapter 17.32.080 and 17.32.090) prohibits stormwater from being discharged to a City separated sanitary sewer, with limited exceptions allowed by the Chief Engineer. If an exception is approved and a cover is not installed, Chapter 17.36 of the City Code allows the City of Portland to bill a facility for the disposal of stormwater into the City separated sanitary sewer. Charges are determined by either calculated volumes (based on the average annual rainfall and the square footage of impervious area drained) or by meter readings from a City-approved discharge meter.

  A written **stormwater volume charge request** shall be submitted as part of the approval process for this exception. The request shall document the property owner's acknowledgement of the City's right to charge the facility sanitary sewer rates for the volume of stormwater discharged to the sanitary sewer system. The application shall be signed by the property owner and notarized.

B) **Drainage:** The requirement for the drainage from the hydraulically isolated area of the loading dock to be directed to an approved City sanitary sewer, approved on-site industrial wastewater treatment facility, or other approved on-site temporary storage facility or containment device/structure will be waived under any of the following conditions:

- A dock leveler is used where the transfer activities occur, and has been retrofitted with a 4" – 6"metal plate across the front to provide spill containment and capture any contaminated stormwater within the leveling well. A detail of the leveler shall be submitted with the building plans at the time of building permit application. Any fluids collected should be batch discharged.

- The loading dock is an improvement to an existing building; the sanitary sewer service is not easily accessible; and the tenant is not handling materials of concern.

If any of these three conditions applies, an operations and maintenance agreement is required, stating the property owner will be responsible for ensuring the tenants do not handle materials of concern and is accountable for discharges from the activity area to the storm sewer system. BES's Industrial Source Control Division (503-823-7122) can provide preferred language that will satisfy this requirement.

9.8 VEHICLE AND EQUIPMENT TRAFFIC AREAS, PARKING, AND STORAGE

9.8.1 Applicability

The requirements of this section apply to all types of parking lots (commercial, public, and private), retail store parking lots, fleet vehicle lots and yards (including rental car lots and car dealerships), equipment sale and rental lots, and access roads with any of the following **higher-use** or **higher-risk** conditions:

- A commercial or industrial site subject to an expected average daily traffic (ADT) count equal to or greater than 100 vehicles per 1,000 square feet of gross building area.
- A commercial or industrial site subject to use, storage, or maintenance of a fleet of 25 or more vehicles or equipment (trucks, buses, heavy equipment, etc.).
- A commercial or industrial area identified for the specific use and traffic from vehicles or equipment that are over 10 tons gross weight (trucks, trains, heavy equipment, etc.).
- A commercial or industrial site subject to the storage of wrecked or impounded vehicles.
- Sites with a high likelihood of oil and grease releases (e.g., vehicle repair, vehicle sales, vehicle parts sales, vehicle fueling services).

<u>The requirements of this section do not apply to single-family and duplex residential sites.</u>

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter. Form SPC shall be included in the submittal package.

Notes:

The traffic threshold focuses on vehicle turnover per square foot of building area (trip generation) rather than ADT alone. This is because oil leakage is greatest when engines are idling or cooling. In general, all-day parking areas are not intended to be captured by these thresholds. The petroleum storage and transfer stipulation is intended to address regular transfer operations such as service stations, not occasional filling of heating oil tanks. Traffic thresholds are researched and compiled by the Institute of Transportation Engineers (ITE).

Parking lots that do not have the above higher-use or higher-risk conditions must use required landscaping within the project area for stormwater (*See Chapter 1.0, Section 1.6.*)

9.8.2 Issue

Stormwater runoff from higher-use or higher-risk sites can contain toxic materials and other organic compounds, oil and grease, heavy metals, nutrients, and suspended solids. Pollutants of concern are primarily generated by vehicle washing and maintenance activities, road oils, and vehicle drips/leaks. These pollutant loads may not be adequately addressed when no water quality facility is required or when volumes exceed the capacity of any required facilities. In such cases, additional pollution reduction facilities or activities may be required. BES will identify additional pollutant prevention or removal needs during SPC application review.

9.8.3 Requirements

1) PAVEMENT

Because of the potential for soil and groundwater contamination, all high-use or high-risk sites shall be paved.

Gasoline and other materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks.

2) DRAINAGE

Drainage from these areas shall be directed to a stormwater disposal system that meets all water quality requirements of this manual and any other applicable codes.

> The Oregon Department of Environmental Quality has identified drywells and/or sumps as "Class V Injection Wells" under the federal Underground Injection Control (UIC) Program. Since the UIC Program states that these types of wells have a direct impact on groundwater, stormwater pollution controls will apply. More information about the UIC program can be found on DEQ's web site at:
> Http://waterquality.deq.state.or.us/wq/groundwa/uichome.htm

3) OIL CONTROL

City code prohibits the discharge of stormwater with a visible sheen to the City's storm sewer system The following oil control options are designed to capture and detain oil and associated pollutants.

Oil/Water Separators

Oil/water separators rely on passive mechanisms that take advantage of oil being lighter than water. Oil rises to the surface and can be periodically removed. The two types of oil/water separators used for stormwater treatment are the baffle type or API (American Petroleum Institute) oil/water separator and the coalescing plate oil/water separator.

- **Baffle oil/water separators** use vaults that have multiple cells separated by baffles extending down from the top of the vault. The baffles block oil flow out of the vault. Baffles are also commonly installed at the bottom of the vault to trap solids and sludge that accumulate over time. In many situations, simple floating or more sophisticated mechanical oil skimmers are installed to remove the oil once it has separated from the water.

- **Coalescing plate separators** are manufactured units consisting of a baffled vault containing several inclined corrugated plates stacked and bundled together. The plates are equally spaced and are made of a variety of materials, most commonly fiberglass and polypropylene. Efficient separation results because the plates reduce the vertical distance oil droplets must rise in order to separate from the stormwater. Once they reach the plate, oil droplets form a film on the plate surface. The film builds up over time until it becomes thick enough to migrate upward under the influence of gravity along the inclined plate. When the film reaches the edge of the plate, oil is released as large droplets that rise rapidly to the surface, where the oil accumulates until the unit is maintained. Because the plate pack significantly increases treatment effectiveness, coalescing plate separators can achieve a specified treatment level with a smaller vault size than a simple baffle separator.

Design Criteria and Requirements for Oil/Water Separators when Not Discharged to a Sanitary Sewer: Research has shown that baffle oil/water separators are not as effective for stormwater management as those with coalescing plate separators and cannot be guaranteed to meet the City's prohibited discharge requirements. For this reason, the sizing of oil/water separators with baffles reflects a factor of safety to ensure that they meet the benchmarks. The following design criteria are established to treat the first flush of a storm event, not the complete storm.

- Characteristics of the runoff shall be assumed to be:
  - Specific gravity (SG) of oil is .9
  - Temperature of stormwater runoff is 50°F to 60°F
  - Oil droplet size is 50 microns.

- Baffled separators shall be able to handle a water quality (WQ) design flow equal to two-thirds of a 2- year storm event, in a 24-hour period.

- Coalescing plate separators shall have a WQ design flow equal to one-third of a 2-year storm event, in a 24-hour period.

- Flow calculation shall be based on the impervious area before mitigation has been credited; however, the roof area shall be excluded from the total.

- Oil/water separators shall be installed off-line, bypassing flows greater than the WQ design flow.

- The separator shall precede other water quality treatment facilities when open surface approaches (e.g. swales, infiltration basins) are used. When other types of treatment facilities are used (e.g., manufactured subsurface facilities), the separator may be downstream of those treatment facilities. The separator may be positioned either upstream or downstream of detention facilities, since there are both advantages and disadvantages with either placement.

- If the oil/water separator is discharging to an open-surface water quality facility, the flows shall not exceed three feet per second, per water quality requirements as identified in Chapter 5.0.

- To maintain efficiencies and reduce size, all roof drainage shall enter the stormwater system downstream of the oil/water separator.

- Any pumping devices shall be installed downstream of the separator to prevent oil emulsification in stormwater.

- Engineered calculations shall be required, using the Santa Barbara Unit Hydrograph (SBUH), to verify appropriate sizing of the oil/water separator.

Note: Additional design considerations are required for a baffled oil/water separator is installed. Design requirements are twice the standard water quality requirement for other water quality facilities in this manual, and flow management will need to be engineered. A possible solution may be a flow splitter upstream of the separator and another flow splitter downstream of the separator (but upstream of the water quality facility design).

Design Criteria and Requirements for Oil/Water Separators Discharged to a Sanitary Sewer: Since the discharge limits for the sanitary sewer are not as restrictive as the storm sewers, the design criteria are not as complicated:

- The characteristics of the runoff shall be assumed to be the same as stated above.

- Baffled separators shall retain maximum flows of a system for 45 minutes.

- Coalescing plate separators shall retain maximum flows of a system for 15 minutes.

- Engineered calculations shall be required to verify appropriate sizing of the oil/water separator.

Note: For high-use or high-risk sites located within a larger commercial center, only the impervious surface associated with the high-use or high-risk portion of the site is subject to treatment requirements. If common parking for multiple businesses is provided, treatment shall be applied to the number of parking stalls required for the high-use or high-risk business only. However, if the treatment collection area also receives runoff from other areas, the treatment facility must be sized to treat all water passing through it.

Linear Sand Filters

Linear sand filters have proven effective in meeting standard water quality requirements (*see Chapter 4.0*). Because design criteria are still being established to ensure these facilities can also effectively control oil and grease, their proposed use will require an additional review process for approval. This may delay issuance of related building permits. For more information on the use of linear sand filters to remove oil and grease, contact BES's Industrial Source Control Division at 503-823-7122.

Other Options

There may be other acceptable oil controls not listed above. In many cases landscaping alternatives may be equally or more effective. Applicants may propose an oil control option that would be as effective as those listed. However, proposal of a new oil control will require an additional review process for approval, which may delay issuance of related building permits.

5) ADDITIONAL REQUIREMENTS

Please carefully review the following additional requirements. These requirements are not applicable to all development projects. If they do apply, however, and are not addressed in the project design, revisions will be required. This could delay issuance of related building permits.

Hazardous materials that are toxic, carcinogenic, or halogenated solvents (located in designated groundwater protection areas) are subject to additional requirements, as identified in Section 9.5: Storage, Use, and Transportation of Hazardous/Toxic Materials in Designated Groundwater Resource Protection Areas.

9.9 COVERED VEHICLE PARKING AREAS

9.9.1 Applicability

The requirements in this section apply to all development with a covered vehicle parking area, except single-family and duplex residential sites. Existing parking structures are not required to retrofit unless the structure is being redeveloped. New parking structures are required to meet these requirements.

Applicants subject to these requirements shall prepare **Form SPC**, located at the end of this chapter, fulfills the requirements of Section 9.9.3. Form SPC shall be included in the submittal package.

9.9.2 Issue

Run-off from covered vehicle parking areas can be contaminated with toxic substances, organic compounds, oil and grease, heavy metals, and suspended solids.

9.9.3 Requirements

1) DRAINAGE

Top Floor Drainage of a Multi-Level Parking Structure

Stormwater runoff from the top floor shall be directed to a stormwater disposal system that meets all water quality requirements of this manual and any other applicable codes.

Lower Floor Drainage of a Multi-Level Parking Structure

Significant amounts of precipitation are not expected to accumulate in covered vehicle parking areas, and drainage facilities are not required for the lower floors. If the applicant elects to install drainage facilities, the drainage from the lower floors shall be directed to an approved City sanitary sewer.

Adjacent, Uncovered Portions of the Site

The surrounding uncovered portions of the site shall be designed so stormwater run-on does not enter the covered parking areas. This can be accomplished through grading or drains.

9.10 EQUIPMENT AND/OR VEHICLE WASHING FACILITIES

9.10.1 Applicability

The requirements in this section apply to all development with a designated equipment and/or vehicle washing or steam cleaning area. The types of vehicles may include, but are not limited to, highway maintenance trucks, taxicabs, buses, rental cars, new and used automobiles on lots, government and company cars, construction equipment, fork lifts, golf carts, riding lawn mowers, and similar large vehicles. Single-family and duplex residential sites are exempt.

Development that is intended for the storage of 10 or more fleet vehicles shall include a designated vehicle washing area. An exception is granted if the applicant can show evidence that vehicles are routinely washed in an approved location.

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter, that fulfills the requirements of Section 9.10.3. Form SPC should be included in the submittal package.

9.10.2 Issue

Wastewater from equipment and/or vehicle washing may contain toxic substances, organic compounds, oil and grease, nutrients, heavy metals, and suspended solids.

9.10.3 Requirements

1) COVER

The washing area shall be covered with a permanent canopy or roof so precipitation cannot come in contact with the washing area. Precipitation shall be directed from the cover to a stormwater disposal system that meets all applicable code requirements.

- **Covers 10 feet high or less** shall have a minimum overhang of 3 feet on each side. The overhang shall be measured relative to the perimeter of the hydraulically isolated washing area it is to cover.

- **Covers higher than 10 feet** shall have a minimum overhang of 5 feet on each side. The overhang shall be measured relative to the perimeter of the hydraulically isolated washing area it is to cover.

2) PAVEMENT

A designated paved wash area shall be placed underneath and around permanent washing areas. This area shall be hydraulically isolated through grading, berms, or drains. Sizing of the paved area shall adequately cover the activity area, including the placement of the vehicle or piece of equipment to be cleaned.

Some materials can react with asphalt pavement, causing the release of toxic oils from the pavement. It is therefore preferable to pave the area with Portland cement concrete. If the area is already paved with asphalt, an asphalt sealant shall be applied to the pavement surface. Whichever paving material is used, the paved surface shall be properly maintained to prevent gaps and cracks.

3) DRAINAGE

The paved area beneath the cover shall be hydraulically isolated through grading, berms, or drains to prevent uncontaminated stormwater from running onto the area and carrying pollutants away. Drainage from the hydraulically isolated area shall be directed to an approved City sanitary sewer, approved on-site industrial wastewater treatment facility, or other approved on-site wash recycling system (process treatment system).

4) OIL CONTROLS

Any vehicle and equipment washing activity that cleans large commercial vehicles (vans, trucks, buses, etc), or more than 10 mid to small sized vehicles, and all equipment washing will be reviewed for needed oil control

EXCEPTIONS

If a washing facility is generally used to service oversized equipment that cannot maneuver under a roof or canopy (cranes, etc.) an exception to the roof or canopy requirement will be granted.

A request for the exception will need to be submitted to BES Source Control Division of BES. This request should document the property owner's acknowledgement of the City's right to charge the facility sanitary sewer rates for the volume of stormwater discharged to the sanitary sewer. Charges will be based on either calculated volumes from the area being drained to the sanitary sewer times the annual average rainfall OR by meter readings from a City approved discharge meter. The document should be titled "**Stormwater Volume Application** "and must be signed and notarized by the property owner(s).

9.11 INTERIOR FLOOR DRAINS

9.11.1 Applicability

The requirements in this section apply to all development with buildings and facilities that have interior floor drains, except single-family and duplex residential sites.

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter, that fulfills the requirements of Section 9.11.3. Form SPC should be included in the submittal package.

9.11.2 Issue

A variety of wastewaters generated by floor washing, accidental spills, and other activities may be present near interior floor drains. Directing the drainage from interior floor drains to a City sanitary treatment facility or other approved on-site temporary storage facility or containment structure provides proper wastewater treatment or spill containment.

9.11.3 Requirements

1) DRAINAGE

Drainage entering interior floor drains is prohibited from discharge into a stormwater system. All drainage from floor drains within buildings shall be directed to a City sanitary treatment facility or other approved on-site temporary storage facility or containment structure.

Prohibited Uses

Interior floor drains are prohibited in all areas designated for manufacture, storage, or processing of materials required to have a permit under the Uniform Fire Code (UFC) or regulated by the Resource Conservation and Recovery Act (RCRA) or Toxic Substances Control Act (TSCA). If chemical use or chemical waste generation may occur at a site, the user should consult these listed regulations or policies for further information.

All wastewater that will/may be discharged to interior floor drains shall be evaluated before discharge. Certain types of discharges may require a permit and/or pretreatment before discharge to a City of Portland sanitary sewer. Contact BES's Industrial Source Control Division (503-823-7122) for a discharge evaluation and additional information.

9.12 STORMWATER DISPOSAL FROM DEVELOPMENT ON RECYCLED LAND

9.12.1 Applicability

The requirements in this section apply to all development on recycled land. Recycled lands, commonly referred to as "brownfields," are lands that currently or previously have had pollutants detected in soil or groundwater at concentrations that exceed risk-based cleanup levels or state/federal cleanup standards for the pollutant(s) of concern.

Applicants subject to the requirements of this section shall prepare **Form SPC,** located at the end of this chapter, that fulfills the requirements of Section 9.12.3,, and include it in the submittal package.

9.12.2 Issue

Contaminated soils or groundwater can cause long-term impacts is in two ways:

- Stormwater runoff that comes into contact with contaminated soils or groundwater can carry some of those contaminants along with suspended solids into receiving waters.
- Contaminants can be transported by discharges from footings or foundation drains.

9.12.3 Requirements

Because the pollutants, media, and site conditions are unique to each parcel of land, stormwater management practices for development on recycled land shall be reviewed on a case-by-case basis. If assistance is needed prior to submittal, call BES's Source Control Division at 503-823-7122 to schedule an evaluation. The City of Portland will coordinate with the owner/developer and the Oregon Department of Environmental Quality (DEQ) to arrive at an acceptable stormwater management plan. General requirements are included here to assist the applicant in planning.

1) COVER

All contaminated soils shall be covered to prevent stormwater from coming into contact with them. Contaminated soils that are stockpiled shall also be covered, and a berm shall be used to prevent stormwater run-on and run-off.

Contaminated groundwater shall be stored in an above-ground containment structure for appropriate pretreatment before disposal.

2) PAVEMENT

Pavement is not required beneath stored contaminated materials. However, an impervious layer shall be placed beneath the materials so they do not contaminate uncontaminated areas if they leach.

3) DRAINAGE

All drainage shall be evaluated for contamination prior to disposal. No infiltration will be allowed without pretreatment to ensure that soils and groundwater are not further transported or spread to other areas.

Note: All proposed discharges are required to go through a batch discharge process, as identified in *Appendix 9-B*: Temporary Storage Facilities and Containment Devices/Structures.

4) LABORATORY ANALYSIS REPORTS

Laboratory analysis reports are required to identify the characteristics and levels of contamination in groundwater and stormwater run-off. An additional review process will be applied to these reports to determine regulatory authority and requirements. This may delay issuance of related building permits.

5) PRETREATMENT OR DISPOSAL

Pretreatment or disposal must follow specific regulations outlined by DEQ and any other local pretreatment requirements identified by City Code.

NOTE: A Letter of Authorization of a No Further Action (NFA) Report from DEQ will be required by the City of Portland and may delay issuance of related building permits if not included with submittal.

DEFINITION OF TERMS

Above-ground storage tank (AST): A stationary container, vessel, or other permanent holding device designated for the storage and/or distribution of a liquid product.

Approved on-site containment structure: A structure that satisfies the definition of a dead-end sump and has been accepted by BES. This could include berms, walls, or other new technological devices or materials that temporarily hold and store spilled liquid.

Approved receiving system: Any system approved by BES to receive stormwater runoff or other discharges. Receiving systems include, but are not limited to, groundwater; on-site, off-site, or public stormwater, sanitary, or combined sewers; and waters of the state.

Approved stormwater system: Any system approved by BES to provide conveyance and quality and/or quantity management of stormwater or other discharges. Stormwater systems include, but are not limited to, on-site, off-site, or public stormwater systems.

Batch discharge: The controlled discharge of a discrete, contained volume of water or wastewater.

Bulk fuel terminal: Any area whose primary function is dedicated to the storage and distribution of fuel to distributors such as gas stations.

Bulk materials: Non-containerized materials.

Containerized: The storage of any product, by-product, or waste that is completely held or included on all sides, within a discrete volume or area.

Containment: The temporary storage of potentially contaminated stormwater or process wastewater when a City sanitary sewer is not available for appropriate disposal.

Driveway: The area that provides vehicular access to a site. A driveway is the same width as a curb cut, excluding any aprons or extensions of the curb cut. A driveway begins at the property line and extends into the site. Driveway does not include parking, maneuvering, or circulation areas in parking areas.

Exterior materials storage area: Any exterior materials storage location that is not completely enclosed by a roof and sidewalls.

Hazardous material: Any material or combination of materials that, because of its quantity, concentration, or physical, chemical, or infectious characteristics, may cause or significantly contribute to an increase in mortality or an increase in serious, irreversible, or incapacitating reversible illness; or that may pose a present or potential hazard to human health, safety, or welfare, or to animal or aquatic life or the environment when improperly used, stored, transported or disposed of, or otherwise managed. For purposes of chemical regulation by this manual, moderate to high toxicity and confirmed human carcinogenicity are the criteria used to identify hazardous substances. (Note: This manual does not use the Resource Conservation and Recovery Act (RCRA) definition of hazardous. For the purpose of this manual, hazardous material is intended to include hazardous, toxic, and other harmful substances.)

Hazardous material containment zone (HMC zone): An area where a specific individual activity involving use of a hazardous material takes place, and where chemical quantities at that location are expected to exceed defined thresholds. HMCs may include (but are not limited to) storage and/or process areas, transportation routes, work areas, and loading/unloading facilities.

High-use or high-risk sites: As used in Section 9.8, high-use or high-risk sites include any one of the following:

- A commercial or industrial site subject to an expected average daily traffic (ADT) count equal to or greater than 100 vehicles per 1,000 square feet of gross building area.
- A commercial or industrial site subject to use, storage, or maintenance of a fleet of 25 or more vehicles or equipment (trucks, buses, heavy equipment, etc.).
- A commercial or industrial area identified for the specific use and traffic from vehicles or equipment that are over 10 tons gross weight (trucks, trains, heavy equipment, etc.).
- A commercial or industrial site subject to the storage of wrecked or impounded vehicles.
- Sites with a high likelihood of oil and grease releases (e.g., vehicle repair, vehicle sales, vehicle parts sales, vehicle fueling services).

LD-50 : The lethal dose of a substance that is expected to kill approximately 50 percent of experimental animals through oral ingestion. (Refer to product Material Safety Data Sheet.)

Local dispensing location: An area within 15 feet of an above-ground storage tank (AST) and used to dispense fuel directly from the AST, typically through a flexible hose.

Multi-level parking structure: Any parking facility with greater than one contiguous level of parking.

Parking area: All the area devoted to the standing, maneuvering, and circulation of motor vehicles. Parking areas do not include driveways or areas devoted exclusively to non-passenger loading.

Receiving System: Any system that receives stormwater runoff. Receiving systems include, but are not limited to groundwater; on-site, off-site, or public surface water facilities; and waters of the state.

Roadway: Any paved surface used to carry traffic (trucks/vehicles, forklifts, farm machinery, and any other large machinery).

Transportation route: Any path routinely used to transport materials regulated in Section 9.5 onto, off of, or within a site. Transportation routes shall be constructed with impervious surfaces and shall provide spill containment.

Form SPC	Stormwater Pollution Control Plan for:
Use this form to describe: • Proposed SPC measures in conformance with the requirements of this manual • Proposed alternatives to the SPC requirements of this manual • SPC requirements specific to Section 9.5 (Hazardous/ Toxic Materials)	______________________________ (Identify section and site use/characteristic—for example, 9.2: Fuel Dispensing Facilities) *Note: A separate form shall be filled out for each type of use/characteristic.*

Please answer each question as briefly as possible, while still conveying relevant information. Use additional pages if necessary.

GENERAL INFORMATION (to be completed for all SPCs)

Date: ________________ Applicant's Name: ______________________________

Facility Name: ______________________ Owner/Operator Name: ____________________

Facility Address: ____

Business Mailing Address: ____

Phone No.: ________________ Type of business/facility: ________________________

Describe the site activity(ies) the SPC(s) apply to:

Describe the SPC(s) required by Chapter 9.0 of the manual:

R0009640

Form SPC (page 2)

PART A **(Complete if proposing approved SPC measures in conformance with the requirements of this manual.)**

Describe how the SPC(s) will be implemented on the site. Include all required and any non-required management practices.

PART B **(Complete if proposing alternatives to the SPC requirements of this manual.)**

Describe why the SPC requirements in the manual will not work on the site or are not desirable:

Describe the proposed alternative SPC(s):

Explain why the alternative(s) will work: (*use additional sheets or manufacturer information as necessary*)

Form SPC (page 3)

PART C **(Complete for both approved SPCs described in Part A and alternative SPCs described in Part B.**

Describe any constraints or limitations of the approved or alternative SPC(s)--e.g., application or seasonal limitations, environmental constraints:

Attach a figure or site plan with the location of the approved or alternative SPC(s). Identify any other attachments (e.g., vendor information).

Date:____________ Signature: ________________ Title: ____________

R0009642

Form SPC (page 4)

Complete Parts D, E, and F only for SPC requirements specific to Section 9.5 (Hazardous/Toxic Materials)

PART D: SITE PLAN

Include the following information on the site plan (see **Form SITE** in Chapter 3.0) that is submitted as part of the development's overall submittal package:

- Property boundaries
- Identification of functional areas on the site (HMCs, loading/ unloading areas, transportation routes). Include the total number of each and their uses.
- Stormwater and other drainage facilities/patterns
- Treatment facilities, if applicable
- Wells
- Surface water features
- Underground and above-ground storage tanks

Form SPC (page 5)

Complete Parts D, E, and F only for SPC requirements specific to Section 9.5 (Hazardous/Toxic Materials)

PART E: CONTAINMENT PLAN

Describe/illustrate the containment system(s) proposed for the site and how they would function to prevent spills from entering groundwater, surface water and/or the City's storm sewer system. List all structures or measures that will be implemented to contain hazardous materials and prevent contamination. Attach sketches and/or cross-sections/schematics of materials/equipment as necessary to adequately describe the containment concept. The containment plan shall contain the following information. A separate plan or sheet shall be prepared for each functional area.

- Area the containment plan applies to (e.g., functional area, such as HMC, loading/unloading area, transportation route)
- Location on site
- Activities/use
- Hazardous materials inventory of the chemicals, products, or wastes that will be used, stored, generated, transported, or otherwise present on the site/functional area *(can be obtained from Form HAZ)*
- Maximum amount of materials present
- Maximum containment volume
- Containment measures (per manual requirements in Section 9.5)
- Receiving system for stormwater runoff

Operation and maintenance measures (non-structural measures to be used in conjunction with structural containment facilities to minimize the potential of spills and contaminated runoff entering groundwater, surface water, and/or the City's storm sewer system). *Note: These O&M measures shall be incorporated into the site-wide O&M plan, as required by Chpt. 9.0.*

Form SPC (page 6)

Complete Parts D, E, and F only for SPC requirements specific to Section 9.5 (Hazardous/Toxic Materials)

PART F: AUTHORIZED SIGNATURE & EMERGENCY CONTACTS

HAZARDOUS MATERIALS INVENTORY

SURVEY OF HAZARDOUS MATERIALS FOR ON-SITE CONTAINMENT PLAN REVIEW

If the development proposal is located within the Columbia South Shore Plan District or Cascade Station/Portland International Center Plan Districts (see Exhibit 9-1) or the Powell Valley Groundwater Resource Protection Area (see Exhibit 9-2), the Water Bureau needs to know what hazardous materials currently exist or are proposed for the **entire site, both exterior and interior.** Please complete this survey form and return it to the Bureau of Water Works, 1001 SW Fifth Avenue, Suite 450, Portland, OR 97204. For questions, call the Water Bureau at 503-823-7577, or fax to 503-823-7269.

1) **Project or Business Name:** 2) **OPDR Permit No.:**

3) **Street Address or Legal Description of Property:**

4) **Description of Business::**

5) **Business SIC Code(s):**

6) **Is any use of cleaners, paints, solvents, fuels or petroleum products currently on the site or planned in the future?**

YES __ NO __ If YES, please complete the inventory listing sheet on page 3.

7) **Will any chemicals, products or wastes containing hazardous ingredients or constituents be used, stored, generated, or otherwise be present on the site for which Material Safety Data Sheets are required?**

YES __ NO __ If YES, please complete the inventory listing sheet on page 3.

Form HAZ (page 2)

8) **Are any wells present on this site?**

YES __ NO __ UNKNOWN __ If YES, please complete the following:

Well No.	*Status*	*Use*	*Casing Diam.*	*Depth*	*Screened Interval*

9) **Are any underground or above-ground liquid storage tanks currently on the site or planned in the future?**

YES __ NO __ UNKNOWN __ If YES, please fill in the following:

Type of Tank	Number	Size	Contents	Current or planned?

10) **Please describe any future use of this site that is different from the above.**

I certify that the statements made above are complete and true to the best of my knowledge. I understand that a separate containment plan review is required for new uses, remodeling and expansions, changes in the types and quantities of hazardous materials, and changes in the location or method of transport, handling or storage of these materials.

Applicant Name	Applicant Signature	Date	Phone No.
Responsible Company Official Title	Responsible Company Official Signature	Date	Phone No.

Form HAZ (page 3)

INVENTORY LISTING SHEET

Please list all liquids, chemicals, products, wastes containing hazardous ingredients or constituents for which Material Safety Data Sheets are required by 29 CFR 1910.1200 or OAR 437 Division 155 that will be used, stored, generated or otherwise present on this site. Attach copies of Material Safety Data Sheets for all listed chemicals/products or make them available to City staff upon request.

Chemical/ Product Name/ Waste Stream Description	Use/Origin (1)	CASRN (2)	Max. Qty. (3, 4)	Avg. Usage (5)	Container Type and Size	Frequency & Amount of Delivery/ Disposal

(1) Indicate what the substance is used for and/or how the waste stream is generated.
(2) CASRN = Chemical Abstracts Service Registry Number (if applicable; look for the CASRN on the MSDS)
(3) Quantities for solids shall be expressed in pounds and quantities for liquids expressed in gallons.
(4) Maximum quantity is defined as the largest amount potentially present on-site at any one time.
(5) Indicate whether average usage is on a monthly or yearly basis.

R0009650

Form HAZ (page 4)

MATERIALS CONTAINMENT / MITIGATION MEASURES SHEET

Please describe any hazardous materials containment and/or mitigation measures proposed for this site.

INSTRUCTIONS FOR FORM HAZ

The following instructions describe how to complete Form HAZ. Form HAZ is required in addition to other state or local requirements pertaining to hazardous substances, such as the requirements for an Oregon State Fire Marshal Hazardous Substance survey or an Industrial Wastewater and/or Stormwater Discharge Permit. **In cases where an applicant has completed other forms that ask for the same information, a copy of the other application may be attached to Form HAZ and a note should be made on Form HAZ.**

General Information (Questions 1 - 5): Provide the name, address and a brief description of the business/project. List the business's primary and secondary (if applicable) Standard Industrial Classification (SIC) code(s), if known. Also provide the permit number from the Office of Planning and Design Review (OPDR).

Hazardous Substances Inventory (Questions 6, 7, and Inventory Listing Sheet): Check yes if any of the listed items will be used. For Question 7, check yes if there will be any substances used, stored, or handled on the site for which a Material Safety Data Sheet (MSDS) is required. (Use of the MSDS criterion is meant to simplify inventory completion. Every employer is required by OSHA to have a complete set of MSDSs on file).

If use of any of these substances is planned, complete the inventory listing sheet. Provide the requested information for each substance to be used during either the construction or operation of the facility (except those listed later in these instructions as exempt).

Consider the following types of materials when preparing the inventory:

- Process Materials - All chemicals used in the plant processes, including feedstock materials, solvents, fuels, liquids in process equipment, cleaners, and lubricants.
- Waste Materials - All liquid, potentially liquid, or water soluble by-products and waste generated on, transported through, stored, on, or handled within the site.
- Products/By-Products - Any products of the facility that may be toxic or hazardous if released into the soil or water.

INSTRUCTIONS FOR FORM HAZ (page 2)

- Stored Materials - All hazardous substances that might be stored or transferred within the site.

- Energy Source Materials - These are distinguished from process materials in that they are often handled, stored, and used outside.

- Construction Materials - Any hazardous substance used during construction, e.g., soil sterilants, herbicides, wood preservatives, paints, thinners, or solvents.

Exemptions

Certain materials are exempt from the inventory reporting. (The amounts given are maximum amounts present on the site at any time.) However, you will need to provide an estimate of the aggregate amount of these supplies.

- Janitorial Supplies - Janitorial and cleaning supplies less than 100 pounds net weight (or 15 gallons net volume), in aggregate. These supplies shall be packaged for consumer use in containers of five gallons or less or having a net weight less than 30 pounds per container. This does not include cleaners or solvents used for cleaning machinery or motor vehicle and machine parts.

- Office Supplies - Office and stationary supplies less than 100 pounds net weight, in aggregate. These supplies shall be packaged for consumer use in containers sized less than five (5) gallons in size or thirty (30) pounds net weight.

- Fluids within Motor Vehicles - Any quantity of fuels, lubricants, fluids and any other hazardous substances contained within on-site vehicles (whether employee, visitor or fleet) or construction equipment for the purposes of vehicle operation. This exemption does not apply to hazardous substances considered to be freight or cargo.

If you are uncertain about whether to include a substance in the inventory, you should list it. If a substance could be present, it should be listed. Keep in mind that listing hazardous substances does not automatically mean that hazardous substance containment will be required. However, if developing a list of hazardous substances is not feasible, the site may be assigned a Class 1 designation by default, and containment facilities appropriate for a high-risk facility may be required.

INSTRUCTIONS FOR FORM HAZ (page 3)

If a hazardous substance is not included in the initial inventory and the site is not constructed for its use, it cannot be used on the site if it triggers a higher containment requirement(s) that is not satisfied by existing containment structures on the site. Because the listing of hazardous substances potentially present on-site may limit future industrial use of the site, the inventory should be comprehensive in order to maintain site marketing options.

Copies of the MSDS sheets for the listed products or materials shall accompany the completed inventory form or be available for review by City staff upon request. Be sure the MSDSs are current, particularly since chemical manufacturers are continually reformulating and producing safer, less hazardous alternatives for many chemicals.

Wells (Question 8): List any existing wells on the site, including water supply wells, monitoring wells, piezometers, cathodic protection wells, oil and gas wells, and geothermal wells. Old, inactive, or improperly constructed wells can potentially provide access for contaminated spills or runoff to enter groundwater.

Provide the well number (if known), well status (i.e. active or inactive), type of use (domestic supply, irrigation, etc.), and construction details. Include casing diameter, depth and screened interval(s). Attach a copy of the well log (if available) to the completed inventory.

Underground or Above-ground Storage Tanks (Questions 13 and 14): Indicate whether there are any existing or proposed underground or above-ground liquid storage tanks, including septic tanks and heating oil tanks. If there are, list the tank type (steel, fiberglass, concrete, etc.), number of tanks, tank size, and tank contents (if empty, what it used to hold), and show the approximate tank locations on the site plan.

Appendix 9-A
SANITARY SEWER DISCHARGE LIMITS

All commercial and industrial users of the City sewer system are to be aware that it is unlawful to discharge industrial waste into the City sewer system in excess of the limitations established in City Code, Section 17.34.030 and 17.34.040, and the Industrial Source Control Division Administrative Rules (below).

CITY CODE, CHAPTER 17.34.010 – DECLARATION OF POLICY

It is the policy of the City of Portland to provide and manage sewer facilities that are adequate for the transportation, treatment, and disposal of wastewater from within the City and to operate the sewer system in such a manner which protects public health and the environment. In carrying out this policy, the objectives of City Code, Chapter 17.34, are:

- To prevent pollutants from entering the sewer system which will interfere with its normal operation or contaminate the resulting sludge
- To prevent the introduction of pollutants into the sewer system which will not be adequately treated and will pass through into the environment
- To improve the opportunity for recycling and reclamation of wastewater and sludge
- To insure protection of worker safety and health
- To insure that all industrial users comply with applicable federal, state and local laws and regulations governing wastewater discharges and that sanctions for failure to comply are imposed

It is the intent of the City to provide needed sewer service to all users while meeting the outlined objectives. Chapter 17.34 provides the structure under which the service will be provided for industrial wastewater so the system is protected and can continue to provide efficiently for the wastewater treatment needs of the City.

Appendix 9-B
FACILITIES AND CONTAINMENT DEVICES/STRUCTURES FOR TEMPORARY STORAGE

An on-site storage facility or containment device/structure shall only be used as a last resort and only for temporary storage of the wastewater or contaminated stormwater.

TEMPORARY STORAGE FACILITIES

If it is not possible to discharge to a City sanitary sewer or approved on-site industrial wastewater or stormwater treatment facility, an alternative temporary storage facility may be allowed for storing the collection of wastewater or contaminated stormwater on a temporary basis.

If the site activity produces large amounts of stormwater runoff, temporary storage will not be very effective because the stray contaminants will overflow the storage facility or pond in the activity area before collection and disposal are possible.

Temporary storage facilities are not intended for hazardous materials containment. Refer to "Containment Devices/Structures," below, for guidance in dealing with hazardous materials containment.

> **Note:** For the purpose of disposal classification, contaminated stormwater from a commercial or industrial site is considered "industrial (non-domestic) wastewater."

- Oversized catch basins, holding tanks, and underground vaults may be used. Alternative storage facilities may be proposed. Additional code requirements may apply; applicants should check with local fire and building code requirements and authorities.

- The storage facility shall be installed underneath or near the collection drains installed for the regulated area(s).

- Sizing of a storage facility is difficult and will be reviewed on a case-by-case basis. This will require an additional review process for approval, which may delay issuance of related building permits.

- The contents of the storage facility shall be pumped out or drained before the facility is full. This requirement can make this type of facility costly, especially during the wet season.

CONTAINMENT DEVICES/STRUCTURES

Containment devices/structures are an effective means for preventing stormwater run-on to a contaminated activity area and for containing spills within the activity area. Spill containment shall be designed so the spilled material/product will not discharge, flow, or be washed into the storm drainage system, surface waters, or groundwater.

- Containment may be achieved with concrete curbing, a berm, a tub such as a plastic wading pool, or some other dike material, depending on the activity, its size, and resources available. Additional code requirements may apply; applicants should check with local fire and building code requirements and authorities.

- If a curb, berm, or dike is used to prevent stormwater run-on to a covered activity area and the activity area is paved or otherwise impermeable, the device shall be placed under the covering so precipitation will not pond inside it. (In some cases, run-on can be prevented by placing containment materials on up-slope sides of the activity areas.)

- A containment device/structure for accidental spills shall have enough capacity to capture a minimum of 110 percent of the product's largest container or 10 percent of the total volume of product stored, whichever is larger.

- If a containment area does not have a cover, water will accumulate in the area during and after a rain event. Depending on the circumstances, an outflow pipe may be allowed, with a valve to allow collected stormwater to be drained out of the activity area and directed to either:

  - the storm drainage system (*if clean*).
  - the sanitary sewer, industrial wastewater or stormwater treatment facility, or hauled off by a licensed provider (*if contaminated*).

  Unless authorized draining activities are occurring, this valve shall always be kept closed to contain any spills that occur within the activity area.

- If containment, rather than covering, is used for stockpiles of material, a dike, berm, or filter shall be placed on at least three sides of every stockpile to act as a barrier or filter to runoff. In some cases, the dike or filter can be made of hay bales, silt fencing, filter fabric, concrete curbing, ecology blocks, or similarly effective materials. Timbers treated with creosote or other preservatives shall not be used because they can leach contaminants into run-off.

- For small items, the simplest containment device is a tub or wading pool. A rubber or plastic children's wading pool may be sufficient for some activities that do not require a lot of space, such as storing remodeling and painting materials. These small containment areas shall also be covered with a tarp or other cover.

- Commercial products are available that are a combination containment box/elevated pedestal. These devices prevent stormwater run-on by elevating containers of liquids (such as drums) off the ground and collecting spills and drips inside the pedestal box.

- In areas where accidental spills may occur, the City requires spill response supplies (such as absorbent material and protective clothing) to be available at the storage area. Employees shall be familiar with the site's proper spill clean-up procedures.

- Spill containment of hazardous materials is more complex then standard containment methods, and depends on the hazardous materials being contained. Sizing requirements are the same as stated above, but the type of containment used will require an additional review process for approval, which may delay issuance of related building permits.

CAUTION: Neglect and poor maintenance can render containment devices/structures useless. Maintenance of containment devices/structures is essential for them to work as intended.

DISPOSAL

Proper disposal of collected wastewater or contaminated stormwater is required. One of two methods can be used.

Licensed Disposal Contractor

Several commercial services are available for pumping out storage facilities or containment devices/structures. These service providers can be found in the telephone directory's yellow pages under the headings "Sewer Contractors" and "Tank Cleaning."

Note: Septic system pump-out and hauling contractors shall not be used for disposing wastewater other than domestic sewage. They are not allowed to haul industrial wastewaters.

Disposal costs vary considerably, depending on the types of materials, quantities, methods of collection and transport, and whether the wastes are mixed. The contractor's rate will generally reflect the costs of testing and/or treating waste materials (if necessary) and subsequent disposal.

It is important to keep different types of wastes separated, so the disposal contractor can take them to the appropriate place(s) without causing inadvertent contamination problems elsewhere. If the wastewater generator is using appropriate SPCs and collecting contaminated wastewater for proper disposal, these efforts will compromised if the disposal contractor subsequently disposes the contaminated wastewater as domestic sewage. It is essential to be familiar with disposal alternatives and the different types of contractors for each disposal option.

Wastewater disposal is the generator's responsibility. The generator should check a company's references before allowing it to handle waste. All wastewater collected by the company should be delivered to an authorized site. Copies of all transactions should be maintained, since this information is required as part of the facility's operations and maintenance log, as identified in Chapter 8.0: Operations and Maintenance Requirements.

Batch Discharge to a City Sewer

The City's batch discharge process can be used if a City sanitary or storm sewer is available on the property. All batch discharge applications will go through an evaluation process and will approval before a discharge to the City sewer system is allowed.

Requests for batch discharges to the sanitary sewer system and to the storm sewer system have separate processes and requirements. Testing may be required to establish characteristics of the wastewater or contaminated stormwater and to verify that local discharge limits are not exceeded. For batch discharge applications, call BES's Industrial Source Control Division at 503-823-7122.

INNOVATIVE URBAN WET-WEATHER FLOW MANAGEMENT SYSTEMS

Chapter 4

Source Characterization

Robert Pitt

The Source Concept

Urban runoff is comprised of many separate source area flow components that are combined within the drainage area and at the outfall before entering the receiving water. Considering the combined outfall conditions alone may be adequate when evaluating the long term, area-wide effects of many separate outfall discharges to a receiving water. However, if better predictions of outfall characteristics (or the effects of source area controls) are needed, then the separate source area components must be characterized. The discharge at the outfall is made up of a mixture of contributions from different source areas. The "mix" depends on the characteristics of the drainage area and the specific rain event. The effectiveness of source area controls is, therefore, highly site and storm specific.

Various urban source areas all contribute different quantities of runoff and pollutants, depending on their characteristics. Impervious source areas may contribute most of the runoff during small rain events. Examples of these source areas include paved parking lots, streets, driveways, roofs, and sidewalks. Pervious source areas become important contributors for larger rain events. These pervious source areas include gardens, lawns, bare ground, unpaved parking areas and driveways, and undeveloped areas. The relative importance of the individual sources is a function of their areas, their pollutant washoff potentials, and the rain characteristics.

The washoff of debris and soil during a rain is dependent on the energy of the rain and the properties of the material. Pollutants are also removed from source areas by winds, litter pickup, or other cleanup activities. The runoff and pollutants from the source areas flow directly into the drainage system, onto impervious areas that are directly connected to the drainage system, or onto pervious areas that will attenuate some of the flows and pollutants, before they discharge to the drainage system.

Sources of pollutants on paved areas include on-site particulate storage that cannot be removed by usual processes such as rain, wind, and street cleaning. Atmospheric deposition, deposition from activities on these paved surfaces (e.g., auto traffic, material storage) and the erosion of material from upland areas that directly discharge flows onto these areas, are the major sources of pollutants to the paved areas. Pervious areas contribute pollutants mainly through erosion processes where the rain energy dislodges soil from between vegetation. The runoff from these source areas enters the storm drainage system where sedimentation in catchbasins or in the sewerage may affect their ultimate discharge to the outfall. In-stream physical, biological, and chemical processes affect the pollutants after they are discharged to the ultimate receiving water.

Knowing when the different source areas become "active" (when runoff initiates from the area, carrying pollutants to the drainage system) is critical. If pervious source areas are not contributing runoff or pollutants, then the prediction of urban runoff quality is greatly simplified. The mechanisms of washoff and delivery yields of runoff and pollutants from paved areas are much better known than from pervious urban areas (Novotny and Chesters 1981). In many cases, pervious areas are not active except during rain events greater than at least five or ten mm. For smaller rain depths, almost all of the runoff and pollutants originate from impervious surfaces (Pitt 1987). However, in many urban areas, pervious areas may contribute the majority of the runoff, and some pollutants, when rain depths are greater than about 20 mm. The actual importance of the different source areas is highly dependent on the specific land use and rainfall patterns. Obviously, in areas having relatively low-density development, especially where moderate and large sized rains occur frequently (such as in the Southeast), pervious areas typically dominate outfall discharges. In contrast, in areas having significant paved areas, especially where most rains are relatively small (such as in the arid west), the impervious areas dominate outfall discharges. The effectiveness of different source controls is, therefore, quite different for different land uses and climatic patterns.

If the number of events exceeding a water quality objective are important, then the small rain events are of most concern. Stormwater runoff typically exceeds some water quality standards for practically every rain event (especially for bacteria and some heavy metals). In the upper midwest, the median rain depth is about six mm, while in the southeast, the median rain depth is about twice this depth. For these small rain depths and for most urban land uses, directly connected paved areas usually contribute most of the runoff and pollutants. However, if annual mass discharges are more important (e.g. for long-term effects), then the moderate rains are more important. Rains from about 10 to 50 mm produce most of the annual runoff volume in many areas of the U.S. Runoff from both impervious and pervious areas can be very important for these rains. The largest rains (greater than 100 mm) are relatively rare and do not contribute significant amounts of runoff pollutants during normal years, but are very important for drainage design. The specific source areas that are most important (and controllable) for these different conditions vary widely.

This chapter describes sources of urban runoff flows and pollutants based on many studies as found in the literature. This chapter also reports on the specific source area sampling activities conducted as part of this research funded by the USEPA for use in this report.

Sources and Characteristics of Urban Runoff Pollutants

Years of study reveal that the vast majority of stormwater toxicants and much of the conventional pollutants are associated with automobile use and maintenance activities and that these pollutants are strongly associated with the particulates suspended in the stormwater (the non-filterable components or suspended solids). Reducing or modifying automobile use to reduce the use of these compounds, has been difficult with the notable exception of the phasing out of leaded gasoline. Current activities, concentrated in the San Francisco, CA area, focus on encouraging brake pad manufacturers to reduce the use of copper.

The effectiveness of most stormwater control practices is, therefore, dependent on their ability to remove these particles from the water, or possibly from intermediate accumulating locations (such as streets or other surfaces) and not through source reduction. The removal of these particles from stormwater is dependent on various characteristics of these particles, especially their size and settling rates. Some source area controls (most notably street cleaning) affect the particles before they are washed-off and transported by the runoff, while others remove the particles from the flowing water. This discussion, therefore summarizes the accumulation and washoff of these particulates and the particle size distribution of the suspended solids in stormwater runoff to better understand the effectiveness of source area control practices.

Table 4-1 shows that most of the organic compounds found in stormwater are associated with various human-related activities, especially automobile and pesticide use, or are associated with plastics (Verschueren 1983). Heavy metals found in stormwater also mostly originate from automobile use activities, including gasoline combustion, brake lining, fluids (e.g., brake fluid, transmission oil, anti-freeze, grease), undercoatings, and tire wear (Durum 1974, Koeppe 1977, Rubin 1976, Shaheen 1975, Solomon and Natusch 1977, and Wilbur and Hunter 1980). Auto repair, pavement wear, and deicing compound use also contribute heavy metals to stormwater (Field et al. 1973 and Shaheen 1975). Shaheen (1975) found that eroding area soils are the major source of the particulates in stormwater. The eroding area soil particles, and the particles associated with road surface wear, become contaminated with exhaust emissions and runoff containing the polluting compounds. Most of these compounds become tightly bound to these particles and are then transported through the urban area and drainage system, or removed from the stormwater, with the particulates. Stormwater concentrations of zinc, fluoranthene, 1,3-dichlorobenzene, and pyrene are unique in that substantial fractions of these compounds remain in the water and are less associated with the particulates.

All areas are affected by atmospheric deposition, while other sources of pollutants are specific to the activities conducted on the areas. As examples, the ground surfaces of unpaved equipment or material storage areas can become contaminated by spills and debris, while undeveloped land remaining relatively unspoiled by activities can still contribute runoff solids, organics, and nutrients, if eroded. Atmospheric deposition, deposition from activities on paved surfaces, and the erosion of material from upland unconnected areas are the major sources of pollutants in urban areas.

Table 4-1. Uses and sources for organic compounds found in stormwater (Verschueren 1983).

COMPOUND	EXAMPLE USE SOURCE
Phenol	gasoline, exhaust
N-Nitroso-di-n-propylamine	contaminant of herbicide Treflan
Hexachloroethane	plasticizer in cellulose esters, minor use in rubber and insecticide
Nitrobenzene	solvent, rubber, lubricants
2,4-Dimethylphenol	asphalt, fuel, plastics, pesticides
Hexachlorobutadiene	rubber and polymer solvent, transformer and hydraulic oil
4-Chloro-3-methylphenol	germicide, preservative for glues, gums, inks, textile, and leather
Pentachlorophenol	insecticide, algaecide, herbicide, and fungicide mfg., wood preservative
Fluoranthene	gasoline, motor and lubricating oil, wood preservative
Pyrene	gasoline, asphalt, wood preservative, motor oil
Di-n-octylphthalate	general use of plastics

Many studies have examined different sources of urban runoff pollutants. These references were reviewed as part of this study and the results are summarized in this section. These significant pollutants have been shown to have a potential for creating various receiving water impact problems, as described in Appendix D (???) of this report. Most of these potential problem pollutants typically have significant concentration increases in the urban feeder creeks and sediments, as compared to areas not affected by urban runoff.

The important sources of these pollutants are related to various uses and processes. Automobile related potential sources usually affect road dust and dirt quality more than other particulate components of the runoff system. The road dust and dirt quality is affected by vehicle fluid drips and spills (e.g., gasoline, oils) and vehicle exhaust, along with various vehicle wear, local soil erosion, and pavement wear products. Urban landscaping practices potentially affecting urban runoff include vegetation litter, fertilizer and pesticides. Miscellaneous sources of urban runoff pollutants include firework debris, wildlife and domestic pet wastes and possibly industrial and sanitary wastewaters. Wet and dry atmospheric contributions both affect runoff quality. Pesticide use in an urban area can contribute significant quantities of various toxic materials to urban runoff. Many manufacturing and industrial activities, including the combustion of fuels, also affect urban runoff quality.

Natural weathering and erosion products of rocks contribute the majority of the hardness and iron in urban runoff pollutants. Road dust and associated automobile use activities (gasoline exhaust products) historically contributed most of the lead in urban runoff. However, the decrease of lead in gasoline has resulted in current stormwater lead concentrations being about one tenth of the levels found in stormwater in the early 1970s (Bannerman et al. 1993). In certain situations, paint chipping can also be a major source of lead in urban areas. Road dust, contaminated by tire wear products and zinc plated metal erosion material, contributes most of the zinc to urban runoff. Urban landscaping activities can be a major source of cadmium (Phillips and Russo 1978). Electroplating and ore processing activities can also contribute chromium and cadmium.

Many pollutant sources are specific to a particular area and on-going activities. For example, iron oxides are associated with welding operations and strontium, used in the production of flares and fireworks, would probably be found on the streets in greater quantities around holidays, or at the scenes of traffic accidents. The relative contribution of each of these potential urban runoff sources, is, therefore, highly variable, depending upon specific site conditions and seasons.

Specific information is presented in the following subsections concerning the qualities of various rocks and soils, urban and rural dustfall, and precipitation. This information is presented to assist in the interpretation of the source area runoff samples collected as part of this project.

Chemical Quality of Rocks and Soils

The abundance of common elements in the lithosphere (the earth's crust) is shown in Table 4-2 (Lindsay l979). Almost half of the lithosphere is oxygen and about 25% are silica. Approximately eight percent is aluminum and five percent is iron. Elements comprising between two percent and four percent of the lithosphere include calcium, sodium, potassium and magnesium. Because of the great abundance of these materials in the lithosphere, urban runoff transports only a relatively small portion of these elements to receiving waters, compared to natural processes. Iron and aluminum can both cause detrimental effects in receiving waters if in their dissolved forms. A reduction of the pH substantially increases the abundance of dissolved metals.

Table 4-2. Common elements in the Lithosphere (Lindsay 1979).

Abundance Rank	Element	Concentration in Lithosphere (mg/kg)
1	O	465,000
2	Si	276,000
3	Al	81,000
4	Fe	51,000
5	Ca	36,000
6	Na	28,000
7	K	26,000
8	Mg	21,000
9	P	1,200
10	C	950
11	Mn	900
12	F	625
13	S	600
14	Cl	500
15	Ba	430
16	Rb	280
17	Zr	220
18	Cr	200
19	Sr	150
20	V	150
21	Ni	100

Table 4-3, also from Lindsay (1979), shows the rankings for common elements in soils. These rankings are quite similar to the values shown previously for the lithosphere. Natural soils can contribute pollutants to urban runoff through local erosion. Again, iron and aluminum are very high on this list and receiving water concentrations of these metals are not expected to be significantly affected by urban activities alone.

Table 4-3. Common elements in soils (Lindsay 1979).

Abundance Rank	Element	Typical Minimum (mg/kg)	Typical Maximum (mg/kg)	Typical Average (mg/kg)
1	O	- -	- -	490,000
2	Si	230,000	350,000	320,000
3	Al	10,000	300,000	71,000
4	Fe	7,000	550,000	38,000
5	C	- -	- -	20,000
6	Ca	7,000	500,000	13,700
7	K	400	30,000	8,300
8	Na	750	7,500	6,300
9	Mg	600	6,000	5,000
10	Ti	1,000	10,000	4,000
11	N	200	4,000	1,400
12	S	30	10,000	700
13	Mn	20	3,000	600
14	P	200	5,000	600
15	Ba	100	3,000	430
16	Zr	60	2,000	300
17	F	10	4,000	200
18	Sr	50	1,000	200
19	Cl	20	900	100
20	Cr	1	1,000	100
21	V	20	500	100

The values shown on these tables are expected to vary substantially, depending upon the specific mineral types. Arsenic is mainly concentrated in iron and manganese oxides, shales, clays, sedimentary rocks and phosphorites. Mercury is concentrated mostly in sulfide ores, shales and clays. Lead is fairly uniformly distributed, but can be concentrated in clayey sediments and sulfide deposits. Cadmium can also be concentrated in shales, clays and phosphorites (Durum 1974).

Street Dust and Dirt Pollutant Sources

Characteristics

Most of the street surface dust and dirt materials (by weight) are local soil erosion products, while some materials are contributed by motor vehicle emissions and wear (Shaheen 1975). Minor contributions are made by erosion of street surfaces in good condition. The specific makeup of street surface contaminants is a function of many conditions and varies widely (Pitt 1979).

Automobile tire wear is a major source of zinc in urban runoff and is mostly deposited on street surfaces and nearby adjacent areas. About half of the airborne particulates lost due to tire wear settle out on the street and the majority of the remaining particulates settle within about six meters of the roadway. Exhaust particulates, fluid losses, drips, spills and mechanical wear products can all contribute lead to street dirt. Many heavy metals are important pollutants associated with automobile activity. Most of these automobile pollutants affect parking lots and street surfaces. However, some of the automobile related materials also affect areas adjacent to the streets. This occurs through the wind transport mechanism after being resuspended from the road surface by traffic-induced turbulence.

Automobile exhaust particulates contribute many important heavy metals to street surface particulates and to urban runoff and receiving waters. The most notable of these heavy metals has been lead. However, since the late 1980s, the concentrations of lead in stormwater has decreased substantially (by about ten times) compared to early 1970 observations. This decrease, of course, is associated with significantly decreased consumption of leaded gasoline.

Solomon and Natusch (1977) studied automobile exhaust particulates in conjunction with a comprehensive study of lead in the Champaign-Urbana, IL area. They found that the exhaust particulates existed in two distinct morphological forms. The smallest particulates were almost perfectly spherical, having diameters in the range of 0.1 to 0.5 μm. These small particles consisted almost entirely of PbBrCl (lead, bromine, chlorine) at the time of emission. Because the particles are small, they are expected to remain airborne for considerable distances and can be captured in the lungs when inhaled. The researchers concluded that the small particles are formed by condensation of PbBrCl vapor onto small nucleating centers, which are probably introduced into the engine with the filtered engine air.

Solomon and Natusch (1977) found that the second major form of automobile exhaust particulates were rather large, being roughly 10 to 20 μm in diameter. These particles typically had irregular shapes and somewhat smooth surfaces. The elemental compositions of these irregular particles were found to be quite variable, being predominantly iron, calcium, lead, chlorine and bromine. They found that individual particles did contain aluminum, zinc, sulfur, phosphorus and some carbon, chromium, potassium, sodium, nickel and thallium. Many of these elements (bromine, carbon, chlorine, chromium, potassium, sodium, nickel, phosphorus, lead, sulfur, and thallium) are most likely condensed, or adsorbed, onto the surfaces of these larger particles during passage through the exhaust system. They believed that these large particles originate in the engine or exhaust system because of their very high iron content. They found that 50 to 70 percent of the emitted lead was associated with these large particles, which would be deposited within a few meters of the emission point onto the roadway, because of their aerodynamic properties.

Solomon and Natusch (1977) also examined urban particulates near roadways and homes in urban areas. They found that lead concentrations in soils were higher near roads and houses. This indicated the capability of road dust and peeling house paint to contaminate nearby soils. The lead content of the soils ranged from 130 to about 1,200 mg/kg. Koeppe (1977), during another element of the Champaign-Urbana lead study, found that lead was tightly bound to various soil components. However, the lead did not remain in one location, but it was transported both downward in the soil profile and to adjacent areas through both natural and man-assisted processes.

Street Dirt Accumulation

The washoff of street dirt and the effectiveness of street cleaning as a stormwater control practice are highly dependent on the available street dirt loading. Street dirt loadings are the result of deposition and removal rates, plus "permanent storage." The permanent storage component is a function of street texture and condition and is the quantity of street dust and dirt that cannot be removed naturally or by street cleaning equipment. It is literally trapped in the texture, or cracks, of the street. The street dirt loading at any time is this initial permanent loading plus the accumulation amount corresponding to the exposure period, minus the re-suspended material removal by wind and traffic-induced turbulence. Removal of street dirt can occur naturally by winds and rain, or by human activity (e.g., by the turbulence of traffic or by street cleaning equipment). Very little removal occurs by any process when the street dirt loadings are small, but wind removal may be very large with larger loadings, especially for smooth streets (Pitt 1979).

Figure 4-1 shows very different street dirt loadings for two San Jose, CA residential study areas (Pitt 1979). The accumulation and deposition rates (and therefore the amounts lost to air) are quite similar, but the initial loading values (the permanent storage values) are very different. The loading differences were almost solely caused by the different street textures.

Table 4-4 summarizes many accumulation rate measurements obtained from throughout North America. In the earliest studies (APWA 1969; Sartor and Boyd 1972; and Shaheen 1975), the initial street dirt loading values after a major rain or street cleaning were assumed to be zero. Calculated accumulation rates for rough streets were, therefore, very large. Later tests measured the initial loading values close to the end of major rains and street cleaning and found that they could be very high, depending on the street texture. When these starting loadings were considered, the calculated accumulation rates were, therefore, much lower. The early, uncorrected, Sartor and Boyd accumulation rates that ignored the initial loading values were almost ten times the correct values shown on this table. Unfortunately, most urban stormwater models used these very high early accumulation rates as default values.

The most important factors affecting the initial loading and maximum loading values shown on Table 4-4 were found to be street texture and street condition. When data from many locations are studied, it is apparent that smooth streets have substantially less loadings at any accumulation period compared to rough streets for the same land use. Very long accumulation periods relative to the rain frequency resultant in high street dirt loadings. During these conditions, the wind losses of street dirt (as fugitive dust) may approximate the deposition rate, resulting in relatively constant street dirt loadings. At Bellevue, WA, typical interevent rain periods average about three days. Relatively constant street dirt loadings were observed in Bellevue because the frequent rains kept the loadings low and very close to the initial storage value, with little observed increase in dirt accumulation over time (Pitt 1985). In Castro Valley, CA, the rain interevent periods were much longer (ranging from about 20 to 100 days) and steady loadings were only observed after about 30 days when the loadings became very high and fugitive dust losses caused by the winds and traffic turbulence moderated the loadings (Pitt and Shawley 1982).

An example of the type of research conducted to obtain the values shown in Table 4-4 was conducted by Pitt and McLean (1986) in Toronto. They measured street dirt accumulation rates and the effects of street cleaning as part of a comprehensive stormwater research project. An industrial street with heavy traffic and a residential street with light traffic were monitored about twice a week for three months. At the beginning of this period, intensive street cleaning (one pass per day for each of three consecutive days) was conducted to obtain reasonably clean streets. Street dirt loadings were then monitored every few days to measure the accumulation rates of street dirt. Street dirt sampling procedures developed by Pitt (1979) were applied. Powerful industrial vacuums (two units, each having two HP, combined with a "Y" connector, and using a six inch wide solid aluminum head) were used to clean many separate subsample strips across the roads which were then combined for physical and chemical analyses.

In Toronto, the street dirt particulate loadings were quite high before the initial intensive street cleaning period and were reduced to their lowest observed levels immediately after the last street cleaning. After street cleaning, the loadings on the industrial street increased much faster than for the residential street. Right after intensive cleaning, the street dirt particle sizes were also similar for the two land uses. However, the loadings of larger particles on the industrial street increased at a much faster rate than on the residential street, indicating more erosion or tracking materials being deposited onto the industrial street. The residential street dirt measurements did not indicate that any material was lost to the atmosphere as fugitive dust, probably because of the low street dirt accumulation rate and the short periods of time between rains. The street dirt loadings never had the opportunity to reach the high loading values needed before they could be blown from the streets by winds or by traffic-induced turbulence. The industrial street, in contrast, had a much greater street dirt accumulation rate and reached the critical loading values needed for fugitive losses in the relatively short periods between the rains.

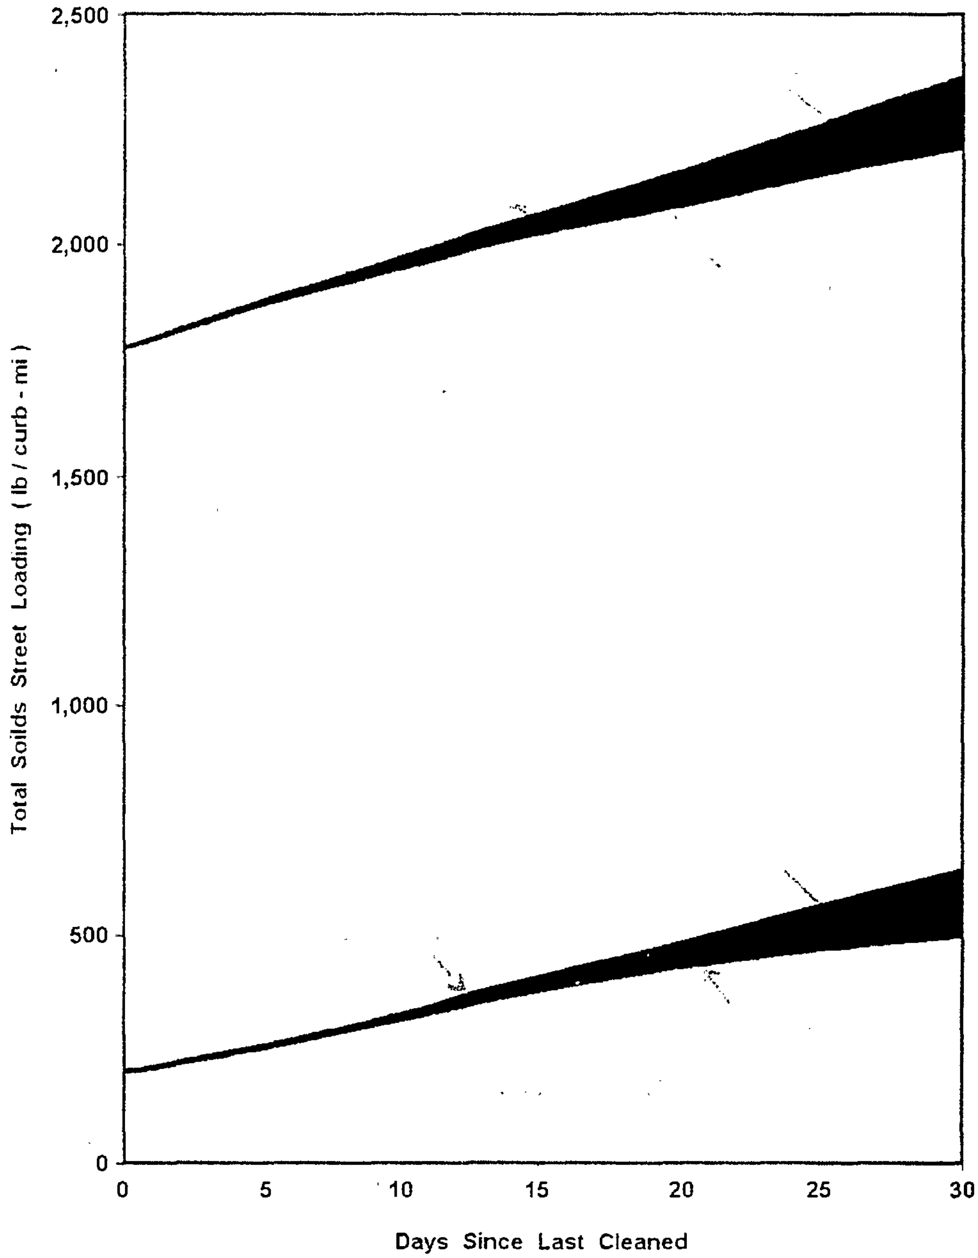

Figure 4-1. Deposition and accumulation of street dirt (Pitt 1979).

Table 4-4. Street dirt loadings and deposition rates.

	Initial Loading Value (grams/curb-meter)	Daily Deposition Rate (grams/curb-meter-day)	Maximum Observed Loading (grams/curb-meter)	Days to Observed Maximum Loading	Reference
Smooth and Intermediate Textured Streets

Washoff of Street Dirt

The Yalin equation relates the sediment carrying capacity to runoff flow rate (Yalin 1963). Yalin stated that sediment motion begins when the lift force of flow exceeds a critical lift force. Once a particle is lifted, the drag force of the flow moves it downstream until the weight of the particle forces it back down. The Yalin equation is used to predict particle transport, for specific particle sizes, on a weight per unit flow width basis. It is used for fully turbulent channel flow conditions, typical of shallow overland flow in urban areas. The receding limb (tail) of a hydrograph may have laminar flow conditions, and the suspended sediment carried in the previously turbulent flows would settle out. The predicted constant Yalin sediment load would therefore only occur during periods of rain, and, the sediment load would decrease, due to sedimentation, after the rain stops.

The critical particle bedload tractive force, the tractive force at which the particle begins to move, can be obtained from the Shields' diagram. However, Shen (1981) warned that the Shields' diagram alone cannot be used to predict "self-cleaning" velocities, because it gives only a lower limit below which deposition will occur. It defines the boundary between bed movement and stationary bed conditions. The Shields' diagram does not consider the particulate supply rate in relationship to the particulate transport rate. Reduced particulate transport occurs if the sediment supply rate is less than the transport rate. The Yalin equation by itself is, therefore, not sensitive to particulate supply; it only predicts the carrying capacity of flowing waters.

Besides the particulate supply rate, the Yalin equation is also very sensitive to local flow parameters (specifically gutter flow depth). Therefore, a hydraulic model that can accurately predict sheetflow across impervious surfaces and gutter flow is needed. Sutherland and McCuen (1978) statistically analyzed a modified form of the Yalin equation, in conjunction with a hydraulic model for different gutter flow conditions. Except for the largest particle sizes, the effect of rain intensity on particle washoff was found to be negligible.

The Yalin equation is based on classical sediment transport equations and requires some assumptions concerning the micro-scale aspects of gutter flows and street dirt distributions. The Yalin equation, as typically used in urban stormwater evaluations, assumes that all particles lie within the gutter and no significant washoff occurs by sheetflows traveling across the street towards the gutter. The early measurements of across-the-street dirt distributions made by Sartor and Boyd (1972) indicated that about 90 percent of the street dirt was within about 30 cm of the curb face (typically within the gutter area). These measurements, however, were made in areas of no parking (near fire hydrants because of the need for water for the sampling procedures that were used) and the traffic turbulence was capable of blowing most of the street dirt against the curb barrier (or over the curb onto adjacent sidewalks or landscaped areas) (Shaheen 1975).

In later tests, Pitt (1979) and Pitt and Sutherland (1982) examined street dirt distributions across the street in many additional situations. They found distributions similar to Sartor and Boyd's observations only on smooth streets, with moderate to heavy traffic, and with no on-street parking. In many cases, most of the street dirt was actually in the driving lanes, trapped by the texture of rough streets. If extensive on-street parking was common, much of the street dirt was found on the outside edge of the parking lanes, where much of the resuspended (in air) street dirt blew against the parked cars and settled to the pavement.

Another process that may result in washoff less than predicted by Yalin is bed armoring (Sutherland et al. 1982). As the smaller particulates are removed, the surface is covered by predominantly larger particulates which are not effectively washed-off by rain. Eventually, these larger particulates hinder the washoff of the trapped, underlying, smaller particulates. Debris on the street, especially leaves, can also effectively armor the particulates, reducing the washoff of particulates to very low levels (Singer and Blackard 1978).

Observations of particulate washoff during controlled tests using actual streets and natural street dirt and debris are affected by street dirt distributions and armoring. The earliest controlled street dirt washoff experiments were conducted by Sartor and Boyd (1972) during the summer of 1970 in Bakersfield, CA. Their data were used in many stormwater models (including SWMM, Huber and Heaney 1981; STORM, COE 1975; and HSPF, Donigian and Crawford 1976) to estimate the percentage of the available particulates on the streets that would wash off during rains of different magnitudes. Sartor and Boyd used a rain simulator having many nozzles and a drop height of 1.5 to two meters in street test areas of about five by ten meters. Tests were conducted on concrete, new asphalt, and old asphalt, using simulated rain intensities of about five and 20 mm/hr. They collected and analyzed runoff samples every 15 minutes for about two hours for each test. Sartor and Boyd fitted their data to an exponential curve, assuming that the rate of particle removal of a given size is proportional to the street dirt loading and the constant rain intensity:

$$dN/dt = krN$$

where: dN/dt = the change in street dirt loading per unit time
k = proportionality constant (1/hr)
r = rain intensity (in/hr)
N = street dirt loading (lb/curb-mile)

This equation, upon integration, becomes:

$$N = N_0 e^{-krt}$$

where: N = residual street dirt load (after the rain)
N_o = initial street dirt load
t = rain duration (hr)

Street dirt washoff is, therefore, equal to N_o minus N. The variable combination rt, or rain intensity (in/hr) times rain duration (t), is equal to total rain depth (R), in inches. This equation then further reduces to:

$$N = N_o e^{-kR}$$

Therefore, this equation is only sensitive to the total depth of the rain that has fallen since the beginning of the rain, and not rain intensity. Because of decreasing particulate supplies, the exponential washoff curve also predicts decreasing concentrations of particulates with time since the start of a constant rain (Alley 1980 and 1981).

The proportionality constant, k, was found by Sartor and Boyd to be slightly dependent on street texture and condition, but was independent of rain intensity and particle size. The value of this constant is usually taken as 0.18/mm, assuming that 90 percent of the particulates will be washed from a paved surface in one hour during a 13 mm/hr rain. However, Alley (1981) fitted this model to watershed outfall runoff data and found that the constant varied for different storms and pollutants for a single study area. Novotny (as part of Bannerman et al. 1983) also examined "before" and "after" rain event street particulate loading data from the Milwaukee Nationwide Urban Runoff Program (NURP) project and found almost a three-fold difference between the constant value of k for fine (<45 μm) and medium sized particles (100 to 250 μm). The calculated values were 0.026/mm for the fine particles and 0.01/mm for the medium sized particles, both much less than the "accepted" value of 0.18/mm. Jewell et al. (1980) also found large variations in outfall "fitted" constant values for different rains compared to the typical default value. Either the assumption of the high removal of particulates during the 13 mm/hr storm was incorrect or/and the equation cannot be fitted to outfall data (most likely, as this would require that all the particulates are originating from homogeneous paved surfaces during all storm conditions).

This washoff equation has been used in many stormwater models, along with an expression for an availability factor. An availability factor is needed, because N_o is only the portion of the total street load available for washoff. This availability factor (the fraction of the total street dirt loading available for washoff) is generally used as 1.0 for all rain intensities greater than about 18 mm/hr and reduces to about 0.10 for rains of one mm/hr.

The Bellevue, WA urban runoff project (Pitt 1985) included about 50 pairs of street dirt loading observations close to the beginnings and ends of rains. These "before" and "after" loading values were compared to determine significant differences in loadings that may have been caused by the rains. The observations were affected by rains falling directly on the streets, along with flows and particulates originating from non-street areas. The net loading differences were, therefore, affected by street dirt washoff (by direct rains on the street surfaces and by gutter flows augmented by "upstream" area runoff) and by erosion products that originated from non-street areas that may have settled out in the gutters. When all the data were considered together, the net loading difference was about 10 to 13 g/curb-m removed. This amounted to a street dirt load reduction of about 15 percent, which was much less than predicted using either of the two previously described washoff models. Very large reductions in street dirt loadings during rains were observed in Bellevue for the smallest particles, but the largest particles actually increased in loadings (due to deposited erosion materials originating from off-street areas). The particles were not source limited, but armor shielding may have been important. Most of the particulates in the runoff were in the fine particle sizes (<63 µm). Very few particles greater than 1000 µm were found in the washoff water. Care must be taken to not confuse street dirt particle size distributions with stormwater runoff particle size distributions. The stormwater particle size distributions are much more biased towards the smaller sizes, as described later.

Suspended solids washoff predictions for Bellevue conditions were made using the Sutherland and McCuen modification of the Yalin equation and the Sartor and Boyd equation. Three particle size groups (<63, 250-500, and 2000-6350 µm), and three rains, having depths of 5, 10, and 20 mm and 3-hr durations, were considered. The gutter lengths for the Bellevue test areas averaged about 80 m, with gutter slopes of about 4.5%. Typical total initial street dirt loadings for the three particle sizes were: 9 g/curb-m for <63 µm, 18 g/curb-m for 250-500 µm, and 9 g/curb-m for 2000-6350 µm. The actual Bellevue net loading removals during the storms were about 45% for the smallest particle size group, 17% for the middle particle size group, and minus six percent (six percent loading increase) for the largest particle size group. The predicted removals were 90 to 100% using the Sutherland and McCuen method, 61 to 98% using the Sartor and Boyd equation, and 8 to 37% using the availability factor with the Sartor and Boyd equation. The ranges given reflect the different rain volumes and intensities only. There were no large predicted differences in removal percentages as a function of particle size. The availability factor with the Sartor and Boyd equation resulted in the closest predicted values, but the great differences in washoff as a function of particle size was not predicted.

The Bellevue street dirt washoff observations included effects of additional runoff water and particulates originating from non-street areas. The additional flows should have produced more gutter particulate washoff, but upland erosion materials may also have settled in the gutters (as noted for the large particles). However, across-the-street particulate loading measurements indicated that much of the street dirt was in the street lanes, not in the gutters, before and after rains. This particulate distribution reduces the importance of these extra flows and particulates from upland areas. The increased loadings of the largest particles after rains were obviously caused by upland erosion, but the magnitude of the settled amounts was quite small compared to the total street dirt loadings.

In order to clarify street dirt washoff, Pitt (1987) conducted numerous controlled washoff tests on city streets in Toronto. These tests were arranged as an overlapping series of 2^3 factorial tests, and were analyzed using standard factorial test procedures described by Box et al. (1978). The experimental factors examined included: rain intensity, street texture, and street dirt loading. The differences between available and total street dirt loads were also related to the experimental factors. The samples were analyzed for total solids (total residue), dissolved solids (filterable residue: <0.45 μm), and SS (particulate residue: >0.45 μm). Runoff samples were also filtered through 0.45 μm filters and the filters were microscopically analyzed (using low power polarized light microscopes to differentiate between inorganic and organic debris) to determine particulate size distributions from about 1 to 500 μm. The runoff flow quantities were also carefully monitored to determine the magnitude of initial and total rain water losses on impervious surfaces.

The total solids concentrations varied from about 25 to 3000 mg/l, with an obvious decrease in concentrations with increasing rain depths during these constant rain intensity tests. No concentrations greater than 500 mg/l occurred after about two mm of rain. All concentrations after about 10 mm of rain were less than 100 mg/l. Total solids concentrations were independent of the test conditions. A wide range in runoff concentrations was also observed for SS, with concentrations ranging from about 1 to 3000 mg/l. Again, a decreasing trend of concentrations was seen with increasing rain depths, but the data scatter was larger because of the experimental factors. The dissolved solids (<0.45 μm) concentrations ranged from about 20 to 900 mg/l, comprising a surprisingly large percentage of the total solids loadings. For small rain depths, dissolved solids comprised up to 90 percent of the total solids. After 10 mm of rain depth, the filterable residue concentrations were all less than about 50 mg/l.

Manual particle size analyses were also conducted on the suspended solids washoff samples, using a microscope with a calibrated recticle. Figures 4-2 and 4-3 are examples of particle size distributions for two tests. These plots show the percentage of the particles that were less than various sizes, by measured particle volume (assumed to be similar to weight). The plots also indicate median particle sizes of about 10 to 50 μm, depending on when the sample was obtained during the washoff tests. All of the distributions showed surprisingly similar trends of particle sizes with elapsed rain depth. The median size for the sample obtained at about one mm of rain was much greater than for the samples taken after more rain. The median particle sizes of material remaining on the streets after the washoff tests were also much larger than for most of the runoff samples, but were quite close to the initial samples' median particle sizes. The washoff water at the very beginning of the test rains, therefore, contained many more larger particles than during later portions of the rains. Also, a substantial amount of larger particles remained on the streets after the test rains. Most street runoff waters during test rains in the 5 to 15 mm depth category had median suspended solids particle sizes of about 10 to 50 μm. However, dissolved solids (less than 0.45 μm) made up most of the total solids washoff for elapsed rain depths greater than about five mm.

These particle size distributions indicate that the smaller particles were much more important than indicated during previous tests. As an example, the Sartor and Boyd (1972) washoff tests (rain intensities of 50 mm/h for two hour durations) found median particle sizes of about 150 μm which were typically three to five times larger than were found during these tests. They also did not find any significant particle size distribution differences for different rain depths (or rain duration), in contrast to the Toronto tests, which were conducted at more likely rain intensities (3 to 12 mm/hr for two hours).

The particulate washoff values obtained during these Toronto tests were expressed in units of grams per square meter and grams per curb-meter, concentrations (mg/l), and the percent of the total initial loading washed off during the test. Plots of accumulative washoff are shown on Figures 4-4 through 4-11. These plots show the asymptotic washoff values observed in the tests, along with the measured total street dirt loadings. The maximum asymptotic values are the "available" street dirt loadings (N_o). The measured total loadings are seen to be several times larger than these "available" loading values. As an example, the asymptotic available total solids value for the HDS (high intensity rain, dirty street, smooth street) test (Figure 4-10) was about 3 g/m^2 while the total load on the street for this test was about 14 g/m^2, or about five times the available load. The differences between available and total loadings for the other tests were even greater, with the total loads typically about ten times greater than the available loads. The total loading and available loading values for dissolved solids were quite close, indicating almost complete washoff of the very small particles. However, the differences between the two loading values for SS were much greater. Shielding, therefore, may not have been very important during these tests, as almost all of the smallest particles were removed, even in the presence of heavy loadings of large particles.

The actual data are shown on these figures, along with the fitted Sartor and Boyd exponential washoff equations. In many cases, the fitted washoff equations greatly over-predicted suspended solids washoff during the very small rains (usually less than one to three mm in depth). In all cases, the fitted washoff equations described suspended solids washoff very well for rains greater than about 10 mm in depth.

Table 4-5 presents the equation parameters for each of the eight washoff tests for suspended solids. Pitt (1987) concluded that particulate washoff should be divided into two main categories, one for high intensity rains with dirty streets, possibly divided into categories by street texture, and the other for all other conditions. Factorial tests also found that the availability factor (the ratio of the available loading, N_o, to the total loading) varied depending on the rain intensity and the street roughness, as indicated below:

- Low rain intensity and rough streets: 0.045
- High rain intensity and rough streets, or low rain intensity and smooth streets: 0.075
- High rain intensity and smooth streets: 0.20

Obviously, washoff was more efficient for the higher rain energy and smoother pavement tests. The worst case was for a low rain intensity and rough street, where only about 4.5% of the street dirt would be washed from the pavement. In contrast, the high rain intensities on the smooth streets were more than four times more efficient in removing the street dirt.

Observed Particle Size Distributions in Stormwater

The particle size distributions of stormwater greatly affect the ability of most controls to reduce pollutant discharges. This research included particle size analyses of 121 stormwater samples from three states that were not affected by stormwater controls (southern New Jersey as part of the inlet tests; Birmingham, AL as part of the MCTT pilot-scale tests; and in Milwaukee and Minocqua, WI, as part of the MCTT full-scale tests). These samples represented stormwater entering the stormwater controls being tested. Particle sizes were measured using a Coulter Multi-Sizer IIe and verified with microscopic, sieve, and settling column tests.

Figures 4-12 through 4-14 are grouped box and whisker plots showing the particle sizes (in µm) corresponding to the 10^{th}, 50^{th} (median) and 90^{th} percentiles of the cumulative distributions. If 90% control of SS was desired, for example, then the particles larger than the 90^{th} percentile would have to be removed. The median particle sizes ranged from 0.6 to 38 µm and averaged 14 µm. The 90^{th} percentile sizes ranged from 0.5 to 11 µm and averaged 3 µm. These particle sizes are all substantially smaller than have been typically assumed for stormwater. In all cases, the New Jersey samples had the smallest particle sizes, followed by Wisconsin, and then Birmingham, AL, which had the largest particles. The New Jersey samples were obtained from gutter flows in a residential semi-xeroscaped neighborhood, the Wisconsin samples were obtained from several source areas, including parking areas and gutter flows mostly from residential, but from some commercial areas, and the Birmingham samples were collected from a long-term parking area.

Atmospheric Sources of Urban Runoff Pollutants

Atmospheric processes affecting urban runoff pollutants include dry dustfall and precipitation quality. These have been monitored in many urban and rural areas. In many instances, however, the samples were combined as a bulk precipitation sample before processing. Automatic precipitation sampling equipment can distinguish between dry periods of fallout and precipitation. These devices cover and uncover appropriate collection jars exposed to the atmosphere. Much of this information has been collected as part of the Nationwide Urban Runoff Program (NURP) and the Atmospheric Deposition Program, both sponsored by the USEPA (EPA 1983a).

This information must be interpreted carefully, because of the ability of many polluted dust and dirt particles to be resuspended and then redeposited within the urban area. In many cases, the measured atmospheric deposition measurements include material that was previously residing and measured in other urban runoff pollutant source areas. Also, only small amounts of the atmospheric deposition material would directly contribute to runoff. Rain is subjected to infiltration and the dry fall particulates are likely mostly incorporated with surface soils and only small fractions are then eroded during rains. Therefore, mass balances and determinations of urban runoff deposition and accumulation from different source areas can be highly misleading, unless transfer of material between source areas and the effective yield of this material to the receiving water is considered. Depending on the land use, relatively little of the dustfall in urban areas likely contributes to stormwater discharges.

Dustfall and precipitation affect all of the major urban runoff source areas in an urban area. Dustfall, however, is typically not a major pollutant source but fugitive dust is mostly a mechanism for pollutant transport, as previously mentioned. Most of the dustfall monitored in an urban area is resuspended particulate matter from street surfaces or wind erosion products from vacant areas (Pitt 1979). Point source pollutant emissions can also significantly contribute to dustfall pollution, especially in industrial areas. Transported dust from regional agricultural activities can also significantly affect urban stormwater.

Wind transported materials are commonly called "dustfall." Dustfall includes sedimentation, coagulation with subsequent sedimentation and impaction. Dustfall is normally measured by collecting dry samples, excluding rainfall and snowfall. If rainout and washout are included, one has a measure of total atmospheric fallout. This total atmospheric fallout is sometimes called "bulk precipitation." Rainout removes

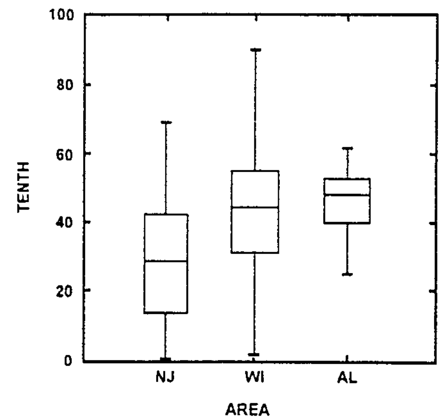

Figure 4-12. Tenth percentile particle sizes for stormwater inlet flows.

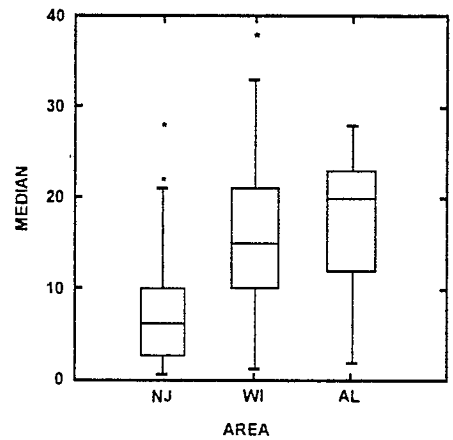

Figure 4-13. Fiftieth percentile particle sizes for stormwater inlet flows.

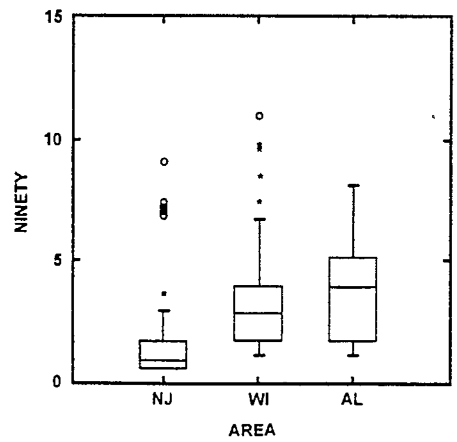

Figure 4-14. Ninetieth percentile particle sizes for stormwater inlet flows.

contaminants from the atmosphere by condensation processes in clouds, while washout is the removal of contaminants by the falling rain. Therefore, precipitation can include natural contamination associated with condensation nuclei in addition to collecting atmospheric pollutants as the rain or snow falls. In some areas, the contaminant contribution by dry deposition is small, compared to the contribution by precipitation (Malmquist 1978). However, in heavily urbanized areas, dustfall can contribute more of an annual load than the wet precipitation, especially when dustfall includes resuspended materials.

Table 4-6 summarizes rain quality reported by several researchers. As expected, the non-urban area rain quality can be substantially better than urban rain quality. Many of the important heavy metals, however, have not been detected in rain in many areas of the country. The most important heavy metals found in rain have been lead and zinc, both being present in rain in concentrations from about 20 µg/l up to several hundred µg/l. It is expected that more recent lead rainfall concentrations would be substantially less, reflecting the decreased use of leaded gasoline since these measurements were taken. Iron is also present in relatively high concentrations in rain (about 30 to 40 µg/l).

The concentrations of various urban runoff pollutants associated with dry dustfall are summarized in Table 4-7. Urban, rural and oceanic dry dustfall samples contained more than 5,000 mg iron/kg total solids. Zinc and lead were present in high concentrations. These constituents can have concentrations of up to several thousand mg of pollutant per kg of dry dustfall. Spring et al. (1978) monitored dry dustfall near a major freeway in Los Angeles, CA. Based on a series of samples collected over several months, they found that lead concentrations on and near the freeway can be about 3,000 mg/kg, but as low as about 500 mg/kg 150 m (500 feet) away. In contrast, the chromium concentrations of the dustfall did not vary substantially between the two locations and approached oceanic dustfall chromium concentrations.

Table 4-7. Atmosphere dustfall quality.

Constituent, (mg constituent/kg total solids)	Urban[1]	Rural/ suburban[1]	Oceanic	Near freeway (LA)[2]	500' from freeway (LA)[2]

1) Summarized by Rubin 1976
2) Spring 1978

Much of the monitored atmospheric dustfall and precipitation would not reach the urban runoff receiving waters. The percentage of dry atmospheric deposition retained in a rural watershed was extensively monitored and modeled in Oakridge, TN (Barkdoll et al. 1977). They found that about 98% of the lead in dry atmospheric deposits was retained in the watershed, along with about 95% of the cadmium, 85% of the copper, 60% of the chromium and magnesium and 75% of the zinc and mercury. Therefore, if the dry deposition rates were added directly to the yields from other urban runoff pollutant sources, the resultant urban runoff loads would be very much overestimated.

Tables 4-8 and 4-9 report bulk precipitation (dry dustfall plus rainfall) quality and deposition rates as reported by several researchers. For the Knoxville, KY, area (Betson 1978), chemical oxygen demand (COD) was found to be the largest component in the bulk precipitation monitored, followed by filterable residue and nonfilterable residue. Table 4-9 also presents the total watershed bulk precipitation, as the percentage of the total stream flow output, for the three Knoxville watersheds studies. This shows that almost all of the pollutants presented in the urban runoff streamflow outputs could easily be accounted for by bulk precipitation deposition alone. Betson concluded that bulk precipitation is an important component for some of the constituents in urban runoff, but the transport and resuspension of particulates from other areas in the watershed are overriding factors.

Rubin (1976) stated that resuspended urban particulates are returned to the earth's surface and waters in four main ways: gravitational settling, impaction, precipitation and washout. Gravitational settling, as dry deposition, returns most of the particles. This not only involves the settling of relatively large fly ash and soil particles, but also the settling of smaller particles that collide and coagulate. Rubin stated that particles that are less than 0.1 μm in diameter move randomly in the air and collide often with other particles. These small particles can grow rapidly by this coagulation process. These small particles would soon be totally depleted in the air if they were not constantly replenished. Particles in the 0.1 to 1.0 μm range are also removed primarily by coagulation. These larger particles grow more slowly than the smaller particles because they move less rapidly in the air, are somewhat less numerous and, therefore, collide less often with other particles. Particles with diameters larger than 1 μm have appreciable settling velocities. Those particles about 10 μm in diameter can settle rapidly, although they can be kept airborne for extended periods of time and for long distances by atmospheric turbulence.

The second important particulate removal process from the atmosphere is impaction. Impaction of particles near the earth's surface can occur on vegetation, rocks and building surfaces. The third form of particulate removal from the atmosphere is precipitation, in the form of rain and snow. This is caused by the rainout process where the particulates are removed in the cloud-forming process. The fourth important removal process is washout of the particulates below the clouds during the precipitation event. Therefore, it is easy to see that re-entrained particles (especially from street surfaces, other paved surfaces, rooftops and from soil erosion) in urban areas can be readily redeposited through these various processes, either close to the points of origin or at some distance away.

Pitt (1979) monitored airborne concentrations of particulates near typical urban roads. He found that on a number basis, the downwind roadside particulate concentrations were about 10% greater than upwind conditions. About 80% of the concentration increases, by number, were associated with particles in the 0.5 to 1.0 µm size range. However, about 90% of the particle concentration increases by weight were associated with particles greater than 10 µm. Pitt found that the rate of particulate resuspension from street surfaces increases when the streets are dirty (cleaned infrequently) and varied widely for different street and traffic conditions. The resuspension rates were calculated based upon observed long-term accumulation conditions on street surfaces for many different study area conditions, and varied from about 0.30 to 3.6 kg per curb-km (one to 12 lb per curb-mile) of street per day.

1) Average for three Knoxville, KY, watersheds.

Murphy (1975) described a Chicago study where airborne particulate material within the city was microscopically examined, along with street surface particulates. The particulates from both of these areas were found to be similar (mostly limestone and quartz) indicating that the airborne particulates were most likely resuspended street surface particulates, or were from the same source.

PEDCo (1977) found that the re-entrained portion of the traffic-related particulate emissions (by weight) is an order of magnitude greater than the direct emissions accounted for by vehicle exhaust and tire wear. They also found that particulate resuspensions from a street are directly proportional to the traffic volume and that the suspended particulate concentrations near the streets are associated with relatively large particle sizes. The medium particle size found, by weight, was about 15 μm, with about 22% of the particulates occurring at sizes greater than 30 μm. These relatively large particle sizes resulted in substantial particulate fallout near the road. They found that about 15% of the resuspended particulates fall out at 10 m, 25% at 20 m, and 35% at 30 m from the street (by weight).

In a similar study Cowherd et al. (1977) reported a wind erosion threshold value of about 5.8 m/s (13 mph). At this wind speed, or greater, significant dust and dirt losses from the road surface could result, even in the absence of traffic-induced turbulence. Rolfe and Reinbold (1977) also found that most of the particulate lead from automobile emissions settled out within 100 m of roads. However, the automobile lead does widely disperse over a large area. They found, through multi-elemental analyses, that the settled outdoor dust collected at or near the curb was contaminated by automobile activity and originated from the streets.

Source Area Sheetflow and Particulate Quality

This section summarizes the source area sheetflow and particulate quality data obtained from several studies conducted in California, Washington, Nevada, Wisconsin, Illinois, Ontario, Colorado, New Hampshire, and New York since 1979. Most of the data obtained were for street dirt chemical quality, but a relatively large amount of parking and roof runoff quality data have also been obtained. Only a few of these studies evaluated a broad range of source areas or land uses.

Source Area Particulate Quality

Particulate potency factors (usually expressed as mg pollutant/kg dry particulate residue) for many samples are summarized on Tables 4-10 and 4-11. These data can help recognize critical source areas, but care must be taken if they are used for predicting runoff quality because of likely differential effects due to washoff and erosion from the different source areas. These data show the variations in chemical quality between particles from different land uses and source areas. Typically, the potency factors increase as the use of an area becomes more intensive, but the variations are slight for different locations throughout the country. Increasing concentrations of heavy metals with decreasing particle sizes was also evident, for those studies that included particle size information. Only the quality of the smallest particle sizes are shown on these tables because they best represent the particles that are removed during rains.

Warm Weather Sheetflow Quality

Sheetflow data, collected during actual rain, are probably more representative of runoff conditions than the previously presented dry particulate quality data because they are not further modified by washoff mechanisms. These data, in conjunction with source area flow quantity information, can be used to predict outfall conditions and the magnitude of the relative sources of critical pollutants. Tables 4-12 through 4-15 summarize warm weather sheetflow observations, separated by source area type and land use, from many locations. The major source area categories are listed below:

1. Roofs
2. Paved parking areas
3. Paved storage areas
4. Unpaved parking and storage areas
5. Paved driveways
6. Unpaved driveways
7. Dirt walks
8. Paved sidewalks
9. Streets
10. Landscaped areas
11. Undeveloped areas
12. Freeway paved lanes and shoulders

Toronto warm weather sheetflow water quality data were plotted against the rain volume that had occurred before the samples were collected to identify any possible trends of concentrations with rain volume (Pitt and McLean 1986). The street runoff data obtained during the special washoff tests reported earlier were also compared with the street sheetflow data obtained during the actual rain events (Pitt 1987). These data observations showed definite trends of solids concentrations verses rain volume for most of the source area categories. Sheetflows from all pervious areas combined had the highest total solids concentrations from any source category, for all rain events. Other paved areas (besides streets) had total solids concentrations similar to runoff from smooth industrial streets. The concentrations of total solids in roof runoff were almost constant for all rain events, being slightly lower for small rains than for large rains. No other pollutant, besides SS, had observed trends of concentrations with rain depths for the samples collected in Toronto. Lead and zinc concentrations were highest in sheetflows from paved parking areas and streets, with some high zinc concentrations also found in roof drainage samples. High bacteria populations were found in sidewalk, road, and some bare ground sheetflow samples (collected from locations where dogs would most likely be "walked").

Some of the Toronto sheetflow contributions were not sufficient to explain the concentrations of some constituents observed in runoff at the outfall. High concentrations of dissolved chromium, dissolved copper, and dissolved zinc in a Toronto industrial outfall during both wet and dry weather could not be explained by wet weather sheetflow observations (Pitt and McLean 1986). As an example, very few detectable chromium observations were obtained in any of the more than 100 surface sheetflow samples analyzed. Similarly, most of the fecal coliform populations observed in sheetflows were significantly lower than those observed at the outfall, especially during snowmelt. It is expected that some industrial wastes, possibly originating from metal plating operations, were the cause of these high concentrations of dissolved metals at the outfall and that some sanitary sewage was entering the storm drainage system.

Table 4-15 summarizes the very little filterable pollutant concentration data available, before this EPA project, for different source areas. Most of the available data are for residential roofs and commercial parking lots.

Other Pollutant Contributions to the Storm Drainage System

The detection of pentachlophenols in the relatively few samples previously analyzed indicated important leaching from treated wood. Frequent detections of polycyclic aromatic hydrocarbons (PAHs) during the U.S. Environmental Protection Agency's Nationwide Urban Runoff Program (EPA 1983a) may possibly indicate leaching from creosote treated wood, in addition to fossil fuel combustion sources. High concentrations of copper, and some chromium and arsenic observations also indicate the potential of leaching from "CCA" (copper, chromium, and arsenic) treated wood.

The significance of these leachate products in the receiving waters is currently unknown, but alternatives to these preservatives should be considered. Many cities use aluminum and concrete utility poles instead of treated wood poles. This is especially important considering that utility poles are usually located very close to the drainage system ensuring an efficient delivery of leachate products. Many homes currently use wood stains containing pentachlorophenol and other wood preservatives. Similarly, the construction of retaining walls, wood decks and playground equipment with treated wood is common. Some preservatives (especially creosote) cause direct skin irritation, besides contributing to potential problems in receiving waters. Many of these wood products are at least located some distance from the storm drainage system, allowing some improvement to surface water quality by infiltration through pervious surfaces.

Sources of Stormwater Toxicants

This project included the collection and analysis of 87 urban stormwater runoff samples from a variety of source areas under different rain conditions as summarized in Table 4-16. All of the samples were analyzed in filtered (0.45 μm filter) and non-filtered forms to enable partitioning of the toxicants into "particulate" (non-filterable) and "dissolved" (filterable) forms.

Table 4-16. Numbers of samples collected from each source area type.

Local Source Areas [1]	Residential	Commercial/ Institutional	Industrial	Mixed
Roofs	5	3	4	
Parking Areas	2	11	3	
Storage Areas	na	2	6	
Streets	1	1	4

Vehicle Service Area	na	5	na	
Landscaped Areas	2	2	2	
Urban Creeks				19
Detention Ponds				12

1) All collected in Birmingham, AL.

Analyses and Sampling

The samples listed in Table 4-16 were all obtained from the Birmingham, AL, area. Samples were taken from shallow flows originating from homogeneous source areas by using several manual grab sampling procedures. For deep flows, samples were collected directly into the sample bottles. For shallow flows, a peristaltic hand operated vacuum pump created a small vacuum in the sample bottle, which then gently drew the sample directly into the container through a Teflon™ tube. About one liter of sample was needed, split into two containers: one 500 ml glass bottle with Teflon™ lined lid was used for the organic and toxicity analyses and another 500 ml polyethylene bottle was used for the metal and other analyses.

An important aspect of the research was to evaluate the effects of different land uses and source areas, plus the effects of rain characteristics, on sample toxicant concentrations. Therefore, careful records were obtained of the amount of rain and the rain intensity that occurred before the samples were obtained. Antecedent dry period data were also obtained to compare with the chemical data in a series of statistical tests.

All samples were handled, preserved, and analyzed according to accepted protocols (EPA 1982 and 1983b). The organic pollutants were analyzed using two gas chromatographs, one with a mass selective detector (GC/MSD) and another with an electron capture detector (GC/ECD). The pesticides were analyzed according to EPA method 505, while the base neutral compounds were analyzed according to EPA method 625 (but only using 100 ml samples). The pesticides were analyzed on a Perkin Elmer Sigma 300 GC/ECD using a J&W DB-1 capillary column (30m by 0.32 mm ID with a 1 µm film thickness). The base neutrals were analyzed on a Hewlett Packard 5890 GC with a 5970 MSD using a Supelco DB-5 capillary column (30m by 0.25 mm ID with a 0.2 µm film thickness). Table 4-17 lists the organic toxicants that were analyzed.

Metallic toxicants, also listed in Table 4-17, were analyzed using a graphite furnace equipped atomic absorption spectrophotometer (GFAA). EPA methods 202.2 (Al), 213.2 (Cd), 218.2 (Cr), 220.2 (Cu), 239.2 (Pb), 249.2 (Ni), and 289.2 (Zn) were followed in these analyses. A Perkin Elmer 3030B atomic absorption spectrophotometer was used after nitric acid digestion of the samples. Previous research (Pitt and McLean 1986; EPA 1983a) indicated that low detection limits were necessary in order to measure the filtered sample concentrations of the metals, which would not be achieved by use of a standard flame atomic absorption spectrophotometer. Low detection limits would enable partitioning of the metals between the solid and liquid phases to be investigated, an important factor in assessing the fates of the metals in receiving waters and in treatment processes.

Table 4-17. Toxic pollutants analyzed in samples.

Pesticides Detention Limit = 0.3 μg/l	Phthalate Esters Detention Limit = 0.5 μg/l	Polycyclic Aromatic Hydrocarbons Detention Limit = 0.5 μg/l		Metals Detention Limit = 1 μg/l
BHC (Benzene hexachloride)	Bis(2-ethylhexyl) Phthalate	Acenaphthene	Fluoranthene	Aluminum
Heptachlor	Butyl benzyl phthalate	Acenapthylene	Fluorene	Cadmium
Aldrin	Di-n-butyl phthalate	Anthracene	Indeno (1,2,3-cd) pyrene	Chromium
Endosulfan	Diethyl phthalate	Benzo (a) anthracene	Naphthalene	Copper
Heptachlor epoxide	Dimethyl phthalate	Benzo (a) pyrene	Phenanthrene	Lead
DDE (Dichlorodiphenyl dichloroethylene)	Di-n-octyl phthalate	Benzo (b) fluoranthene	Pyrene	Nickel
DDD (Dichlorodiphenyl dichloroethane)		Benzo (ghi) perylene		Zinc
DDT (Dichlorodiphenyl trichloroethane)		Benzo (k) fluoranthene		
Endrin		Chrysene		
Chlordane		Dibenzo (a,h) anthracene		

The Microtox™ 100% sample toxicity screening test, from Azur Environmental (previously Microbics, Inc.), was selected for this research after comparisons with other laboratory bioassay tests. During the first research, 20 source area stormwater samples and combined sewer samples (obtained during a cooperative study being conducted in New York City) were split and sent to four laboratories for analyses using 14 different bioassay tests. Conventional bioassay tests were conducted using freshwater organisms at the EPA's Duluth, MN, laboratory and using marine organisms at the EPA's Narragansett Bay, RI, laboratory. In addition, other bioassay tests, using bacteria, were also conducted at the Environmental Health Sciences Laboratory at Wright State University, Dayton, OH. The tests represented a range of organisms that included fish, invertebrates, plants, and microorganisms.

The conventional bioassay tests conducted simultaneously with the Microtox™ screening test for the 20 stormwater sheetflow and combined sewer overflow (CSO) samples were all short-term tests. However, some of the tests were indicative of chronic toxicity (e.g., life cycle tests and the marine organism sexual reproduction tests), whereas the others would be classically considered as indicative of acute toxicity (e.g., Microtox™ and the fathead minnow tests). The following list shows the major tests that were conducted by each participating laboratory:

1. University of Alabama at Birmingham, Environmental Engineering Laboratory
   Microtox™ bacterial luminescence tests (10-, 20-, and 35-minute exposures) using the marine *Photobacterium phosphoreum.*

2. Wright State University, Biological Sciences Department
   Macrofaunal toxicity tests:
      Daphnia magna (water flea) survival; *Lemma minor* (duckweed) growth; and *Selenastrum capricornutum* (green alga) growth.
   Microbial activity tests (bacterial respiration):
      Indigenous microbial electron transport activity;
      Indigenous microbial inhibition of β-galactosidase activity;
      Alkaline phosphatase for indigenous microbial activity;
      Inhibition of β-galactosidase for indigenous microbial activity; and
      Bacterial surrogate assay using O-nitrophenol-β-D-galactopyranside activity and *Escherichia coli.*

3. EPA Environmental Research Laboratory, Duluth, MN
   Ceriodaphnia dubia (water flea) 48-h survival; and
   Pimephales promelas (fathead minnow) 96-h survival.

4. EPA Environmental Research Laboratory, Narragansett Bay, RI
   Champia parvula (marine red alga) sexual reproduction (formation of cystocarps after 5 to 7 d exposure); and
   Arbacua punctulata (sea urchin) fertilization by sperm cells.

Table 4-18 summarizes the results of the toxicity tests. The *C. dubia. P. promelas,* and C. *Parvula* tests experienced problems with the control samples and, therefore, these results are therefore uncertain. The *A. pustulata* tests on the stormwater samples also had a potential problem with the control samples. The CSO test results (excluding the fathead minnow tests) indicated that from 50% to 100% of the samples were toxic, with most tests identifying the same few samples as the most toxic. The toxicity tests for the stormwater samples indicated that 0% to 40% of the samples were toxic. The Microtox™ screening procedure gave similar rankings for the samples as the other toxicity tests.

Laboratory toxicity tests can result in important information on the effects of stormwater in receiving waters, but actual in-stream taxonomic studies should also be conducted. A recently published proceedings of a conference on stormwater impacts on receiving streams (Herricks 1995) contains many examples of actual receiving water impacts and toxicity test protocols for stormwater.

Table 4-18. Fraction of samples rated as toxic.

Sample series	Combined sewer overflows (%)	Stormwater (%)
Microtox™ marine bacteria	100	20
C. Dubia	60	0[1]
P. promelas	0[1]	0[1]
C. parvula	100	0[1]
A. punctulata	100	0[1]
D. magna	63	40
L. minor	50[1]	0

1) Results uncertain, see text

All of the Birmingham samples represented separate stormwater. However, as part of the Microtox™ evaluation, several CSO samples from New York City were also tested to compare the different toxicity tests. These samples were collected from six CSO discharge locations having the following land uses:

1. 290 acres, 90% residential and 10% institutional.
2. 50 acres, 100% commercial.
3. 620 acres, 20% institutional, 6% commercial, 5% warehousing, 5% heavy industrial, and 64% residential.
4. 225 acres, 13% institutional, 4% commercial, 2% heavy industrial. and 81% residential.
5. 400 acres, 1% institutional and 99% residential.
6. 250 acres, 88% commercial. 6% warehousing, and 6% residential.

Therefore, there was a chance that some of the CSO samples may have had some industrial process waters. However, none of the Birmingham sheetflow samples could have contained any process waters because of how and where they were collected.

The Microtox™ screening procedure gave similar toxicity rankings for the 20 samples as the conventional bioassay tests. It is also a rapid procedure (requiring about one hour) and only requires small (<1 ml) sample volumes. The Microtox™ toxicity test uses marine bioluminescence bacteria and monitors the light output for different sample concentrations. About one million bacteria organisms are used per sample, resulting in highly repeatable results. The more toxic samples produce greater stress on the bacteria test organisms that results in a greater light attenuation compared to the control sample. Note that the Microtox™ procedure was not used during this research to determine the absolute toxicities of the samples or to predict the toxic effects of stormwater runoff on receiving waters. It was used to compare the relative toxicities of different samples that may indicate efficient source area treatment locations, and to examine changes in toxicity during different treatment procedures.

Potential Sources

A drainage system captures runoff and pollutants from many source areas, all with individual characteristics influencing the quantity of runoff and pollutant load. Impervious source areas may contribute most of the runoff during small storm events (e.g., paved parking lots, streets, driveways, roofs, and sidewalks). Pervious source areas can have higher material washoff potentials and become important contributors for larger storm events when their infiltration rate capacity is exceeded (e.g., gardens, bare ground, unpaved parking areas, construction sites, undeveloped areas). Many other factors also affect the pollutant contributions from source areas, including: surface roughness, vegetative cover, gradient and hydraulic connections to a drainage system; rainfall intensity, duration, and antecedent dry period; and pollutant availability due to direct contamination from local activities, cleaning frequency/efficiency, and natural and regional sources of pollutants. The relative importance of the different source areas is therefore a function of the area characteristics, pollutant washoff potential, and the rainfall characteristics (Pitt 1987).

Important sources of toxicants are often related to the land use (e.g., high traffic capacity roads, industrial processes, and storage area) that are unique to specific land uses activities. Automobile related sources affect the quality and quantity of road dust particles through gasoline and oil drips/spills, deposition of exhaust products, and wear of tire, brake, and pavement materials (Shaheen 1975). Urban landscaping practices potentially produce vegetation cuttings and fertilizer and pesticide washoff. Miscellaneous sources include holiday firework debris, wildlife and domestic pet wastes, and possible sanitary wastewater infiltration. In addition, resuspension and deposition of pollutants/particles via the atmosphere can increase or decrease the contribution potential of a source area (Pitt and Bozeman 1982, Bannerman et al. 1993).

Results

Table 4-19 summarizes the source area sample data for the most frequently detected organic toxicants and for all of the metallic toxicants analyzed. The organic toxicants analyzed, but not reported, were generally detected in five, or less, of the non-filtered samples and in none of the filtered samples. Table 4-19 shows the mean, maximum, and minimum concentrations for the detected toxicants. Note that these values are based only on the observed concentrations. They do not consider the non-detectable conditions. Mean values based on total sample numbers for each source area category would therefore result in much lower concentrations. The frequency of detection is therefore an important consideration when evaluating organic toxicants. High detection frequencies for the organics may indicate greater potential problems than infrequent high concentrations.

Table 4-19 also summarizes the measured pH and SS concentrations. Most pH values were in the range of 7.0 to 8.5 with a low of 4.4 and a high of 11.6 for roof and concrete plant storage area runoff samples, respectively. This range of pH can have dramatic effects on the speciation of the metals analyzed. The SS concentrations were generally less than 100 mg/l, with impervious area runoff (e.g., roofs and parking areas) having much lower SS concentrations and turbidities compared to samples obtained from pervious areas (e.g., landscaped areas).

Out of more than 35 targeted compounds analyzed, 13 were detected in more than 10% of all samples, as shown in Table 4-19. The greatest detection frequencies were for 1,3-dichlorobenzene and fluoranthene, which were each detected in 23% of the samples. The organics most frequently found in these source area samples (i.e., polycyclic aromatic hydrocarbons (PAH), especially fluoranthene and pyrene) were similar to the organics most frequently detected at outfalls in prior studies (EPA 1983a).

Roof runoff, parking area and vehicle service area samples had the greatest detection frequencies for the organic toxicants. Vehicle service areas and urban creeks had several of the observed maximum organic compound concentrations. Most of the organics were associated with the non-filtered sample portions, indicating an association with the particulate sample fractions. The compound 1,3-dichlorobenzene was an exception, having a significant dissolved fraction.

In contrast to the organics, the heavy metals analyzed were detected in almost all samples, including the filtered sample portions. The non-filtered samples generally had much higher concentrations, with the exception of zinc, which was mostly associated with the dissolved sample portion (i.e., not associated with the SS). Roof runoff generally had the highest concentrations of zinc, probably from galvanized roof drainage components, as previously reported by Bannerman et al. (1983). Parking and storage areas had the highest nickel concentrations, while vehicle service areas and street runoff had the highest concentrations of cadmium and lead. Urban creek samples had the highest copper concentrations, which were probably due to illicit industrial connections or other non-stormwater discharges.

Table 4-20 shows the relative toxicities of the collected stormwaters. A wide range of toxicities was found. About 9% of the non-filtered samples were considered highly toxic using the Microtox™ toxicity screening procedure. About 32% of the samples were moderately toxic and about 59% were considered non-toxic. The greatest percentage of samples considered the most toxic were from industrial storage and parking areas. Landscaped areas also had a high incidence of highly toxic samples (presumably due to landscaping chemicals) and roof runoff had some highly toxic samples (presumably due to high zinc concentrations). Treatability study activities indicated that filtering the samples through a range of fine sieves and finally a 0.45μm filter consistently reduced sample toxicities. The chemical analyses also generally found much higher toxicant concentrations in the non-filtered sample portions, compared to the filtered sample portions.

Table 4-19. Stormwater toxicants detected in at least 10% of the source area sheetflow samples (µg/l, unless otherwise noted).

1) N.F.: concentration associated with a nonfiltered sample.
2) F.: concentration after the sample was filtered through a 0.45 µm membrane filter.
3) Number detected refers to the number of samples in which the toxicant was detected.
4) Mean values based only on the number of samples with a definite concentration of toxicant reported (not on the total number of samples analyzed).
5) The minimum values shown are the lowest concentration detected, they are not necessarily the detection limit.

Replicate samples were collected from several source areas at three land uses during four different storm events to statistically examine toxicity and pollutant concentration differences due to storm and site conditions. These data indicated that variations in Microtox™ toxicities and organic toxicant concentrations may be partially explained by rain characteristics. As an example, high concentrations of many of the PAHs were associated with long antecedent dry periods and large rains (Barron 1990).

Table 4-20. Relative toxicity of samples using Microtox™ (non-filtered).

Local Source Areas	Highly Toxic (%)	Moderately Toxic (%)	Not Toxic (%)	Number of Samples
Roofs	8	58	33	12
Parking Areas	19	31	50	16
Storage Areas	25	50	25	8
Streets	0	67	33	6
Loading Docks	0	67	33	3
Vehicle Service Areas	0	40	60	5
Landscaped Areas	17	17	66	6
Urban Creeks	0	11	89	19
Detention Ponds	8	8	84	12
All Areas	9	32	59	87

Microbics suggested toxicity definitions for 35 minute exposures:
Highly toxic - light decrease >60%
Moderately toxic - light decrease <60% & >20%
Not toxic - light decrease <20%

Urban Runoff Pollution Prevention and Control Planning

STORM WATER MANAGEMENT

50 percent of the total solids and heavy metals could be removed from urban runoff when city streets were cleaned once or twice a day. When the streets were cleaned only once or twice a month, the removal rate dropped to less than 5 percent (U.S. EPA, 1979). Increased frequency also could result in increased fugitive air emissions. Regular street sweeping and catch basin cleaning can, in any case, remove some of the large floatable litter that is unsightly in urban surface waters. Street sweeping twice a week and catch basin cleaning once or twice a year have been found effective in removing these large floatable pollutants (U.S. EPA, 1983). Determining the effectiveness of street sweeping programs, however, is difficult because of variations in pollutant buildup and storm events. In addition, studies have shown that the choice of sweeping equipment can significantly affect the effectiveness of cleaning programs (Pitt, 1989).

Commercial/Industrial Runoff Control. Certain commercial and industrial sites can be responsible for disproportionate contributions of some pollutants (e.g., grit, oils, grease, and toxic materials) to the drainage system. Typical sources of potential concern include gasoline stations, railroad yards, freight loading areas, and parking lots. In specific cases where significant pollutant loadings to the system are contributed by well-defined locations of limited area, pretreatment of the runoff from these areas could be a practical and effective control measure. Pretreatment measures can be required as part of a community's regulations. Examples of pretreatment measures include oil/water separators for gasoline stations, or the use of modified catch basin designs to enhance the retention of oil and grease or solids. Procedures for the detection and location of illicit connections to separate storm drains by testing for specific chemical tracers could be applied to identify commercial or industrial sources contributing substantial levels of problem pollutants.

Solid Waste Management. Most communities have programs to collect and dispose of solid waste in an effort to maintain clean streets and provide a service for local residents and businesses. Some communities provide added services during times of particularly high waste generation. For example, some municipalities in the northern United States provide extra collection services during the fall to collect leaves—an added service that helps keep leaves from blowing into surface waters. A study of storm water runoff into Minneapolis lakes found that phosphorus levels were reduced by 30 to 40 percent when street gutters were kept free of leaves and lawn clippings (MPCA, 1989). Actual reductions of pollutant loads, however, are difficult to predict. In general, any solid waste that is picked up and disposed of in a controlled manner will be less likely to enter a drainage system.

Animal Waste Removal. Domesticated and wild animal wastes represent a source of bacteria and other pollutants that can be washed into surface waters by urban runoff. These pollutants can be reduced by reducing the animal waste on paved surfaces. Municipalities often enact and enforce leash laws and pet waste cleanup ordinances. The effectiveness of these programs in reducing pollutant loads is unknown, however, and usually depends on voluntary actions by private citizens.

Toxic and Hazardous Waste Management. Improper dumping of household and automotive toxic and hazardous wastes into municipal storm inlets, catch basins, and other storm drainage system entry points can result in significant discharges of pollutants to surface waters during rainstorms. This dumping can be a particular problem in urban areas where individuals change the oil or antifreeze in their cars and dispose of the wastes in nearby catch basins. In addition, homeowners and small businesses sometimes dispose of products such as waste paints and solvents in storm water inlets and catch basins. To address the problem, municipalities can educate residents on the consequences of dumping these wastes into storm drainage system entry points. In addition, communities can develop hazardous- and toxic-waste collection days to dispose of or recycle these wastes properly. Also, storm drain systems can be labeled with warnings about the pollution problems associated with dumping wastes. The effectiveness of such programs, however, cannot be determined in advance because of the voluntary nature of compliance. For business and industry, an inspection, testing, and enforcement program (similar to an industrial pretreatment program) can be developed.

Reduced Fertilizer, Pesticide, and Herbicide Use. Fertilizers, pesticides, and herbicides washed off the ground during storms can contribute to water pollution. Agricultural, park land, and other land uses can be sources of these pollutants. Many communities use these chemicals on park lands, and homeowners utilize them on their lawns. Controlling the use of these chemicals on municipal lands and educating the public can help reduce nutrient and toxic pollutant concentrations in urban runoff.

Reduced Roadway Sanding and Salting. In areas of the United States with freezing road conditions, sand and salt are used in the winter to improve driving conditions. Salt and sand can be washed off roadways, however, and pollute receiving waters. The problem is exacerbated during spring snowmelt and early spring rainstorms when most of these pollutants are available for transport. These problems can be reduced by minimizing the use of chemicals for snow and ice control to the minimum necessary for public safety and

LIST OF TABLES

1. INTRODUCTION

Nonpoint pollution resulting from storm water runoff has recently been recognized as one of the leading causes of the degradation of the quality of receiving waters in the United States. The area southwest of Austin is part of the recharge zone of the Barton Springs portion of the Edwards aquifer. This is a karst aquifer, which is characterized by numerous caves, sinkholes, and other solution features. Recharge enters the aquifer directly through fractures and other openings a the surface, so very little filtration of the runoff occurs before entering the aquifer. The aquifer provides the sole source of drinking water for approximately 35,000 residents of Hays and Travis counties. Construction of new highways in the recharge area of the aquifer led to the concern that nonpoint source pollution from highway runoff could pose a serious threat to the quality of the groundwater and the health of area residents.

Accurate knowledge of the quantity and quality of runoff is required to assess the impacts of runoff on the environment and to develop appropriate mitigation technologies. A comprehensive study of the effects of runoff from highway construction and operation was undertaken by the Center for Research in Water Resources to help develop this information. The primary objective of this portion of the research study was the development and execution of a program to characterize the quantity and quality of runoff from existing highways in the Austin, Texas area.

This portion of the research study focused on the characterization of the quantity and quality of runoff from existing sections of the MoPac expressway and estimation of the pollutant loads resulting from runoff from existing and newly completed sections of highway under different vehicle use patterns. The effects of drainage system type, traffic volume, and surrounding land use on highway storm water runoff characteristics were investigated. In addition to the average quality of runoff, the temporal variation in quality was also studied. A "first flush" effect (i.e., higher concentrations of pollutants at the beginning of runoff events) has been reported in several studies and is often used as the justification for the design standards which require capture and treatment of the first 1/2 inch (or other arbitrary volume) of storm water runoff. The information developed in this study should result in improvement in the design of drainage and treatment systems for highway storm water runoff. Better designs will act to reduce the impact of highway derived nonpoint source pollution on the environment.

2. MATERIALS AND METHODS

2.1 Site Descriptions

Three sites along the MoPac Expressway in the Austin, Texas area were selected for monitoring runoff from highways. The locations were identified as MoPac at West 35th Street, MoPac at Convict Hill Road and MoPac at Walnut Creek. The sites differed in daily traffic flow, surrounding land use, and drainage area. Accessibility for runoff sampling also was a consideration in site selection. Runoff samples were collected during the time period of September 1993 though May 1995. The physical characteristics of the sites are discussed below.

2.1.1 MoPac at West 35th Street

MoPac at West 35th Street is a high traffic site located in central Austin (Figure 2.1). The land use of the area is mixed residential and commercial. Samples were collected from a storm drain inlet located along the gutter of a curbed section of the three southbound lanes. The catchment covers an area of 5,341 m^2 which is 100% asphalt. The average daily volume of traffic at this site was approximately 60,000 vehicles per day, ranging from a maximum of 6,000 vehicles per hour to a minimum of about 100 vehicles per hour. Induction coils installed in each lane of traffic recorded traffic counts during each rainfall event.

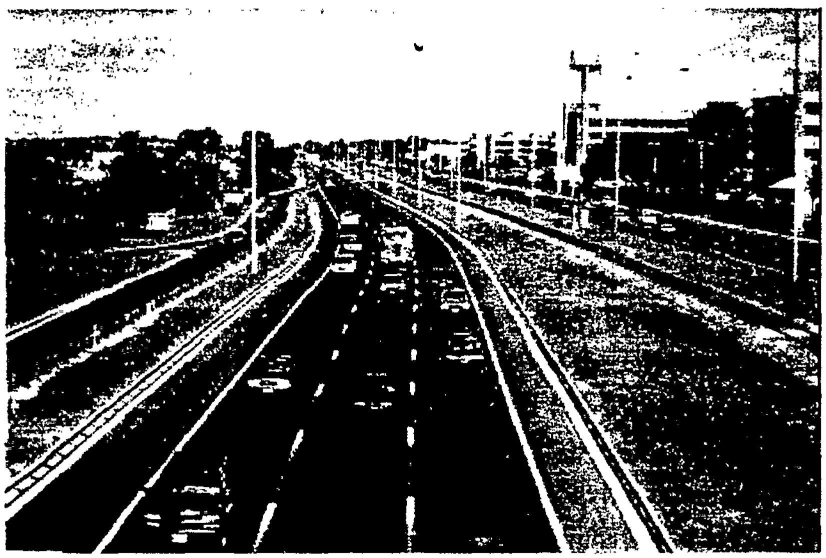

Figure 2.1 Photograph of MoPac at West 35th Street

2.1.2 MoPac at Convict Hill Road

MoPac at Convict Hill Road is a low traffic site located on the southwestern edge of Austin (Figure 2.2). The land around Convict Hill Road is mostly residential and rural property. Runoff was collected from the down spout of the northbound lanes of the MoPac overpass over Convict Hill Road. This outfall drains 526 m^2 of bridge deck, which is 100% asphalt paved and has two lanes of traffic and wide shoulders. One meter high concrete barriers are located along each side of the roadway. The average traffic count in April 1995 was approximately 8780 vehicles per day, ranging from less than 10 vehicles per hour to nearly 1400 vehicles per hour.

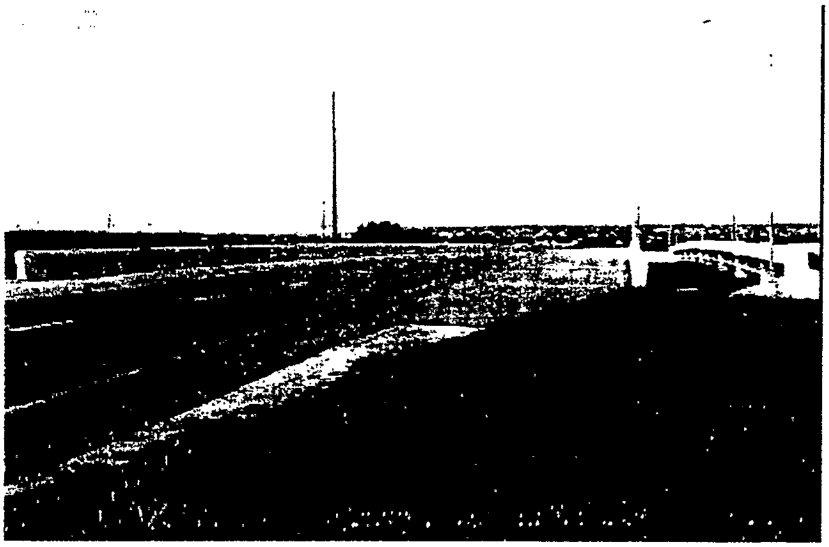

Figure 2.2 Photograph of MoPac at Convict Hill Road

2.1.3 MoPac at Walnut Creek

The Walnut Creek site is located in north Austin and consists of a combination of paved highway and grassy shoulder and median (Figure 2.3). The land use classification of the area is mostly commercial and high density residential. Water was collected from a 10.46 ha (104,600 m^2) area. Approximately 37.6% of the drainage area is paved with asphalt and consists exclusively of the six north- and south-bound lanes of MoPac. No curb or gutter was installed and the highway runoff drains into a large grassy median. Runoff from the median enters a 1.22 m diameter storm sewer system through drop inlets. In April 1995, approximately 47,000 vehicles per day were recorded for this section of MoPac. The hourly traffic counts ranged from about 100 to 3600 vehicles.

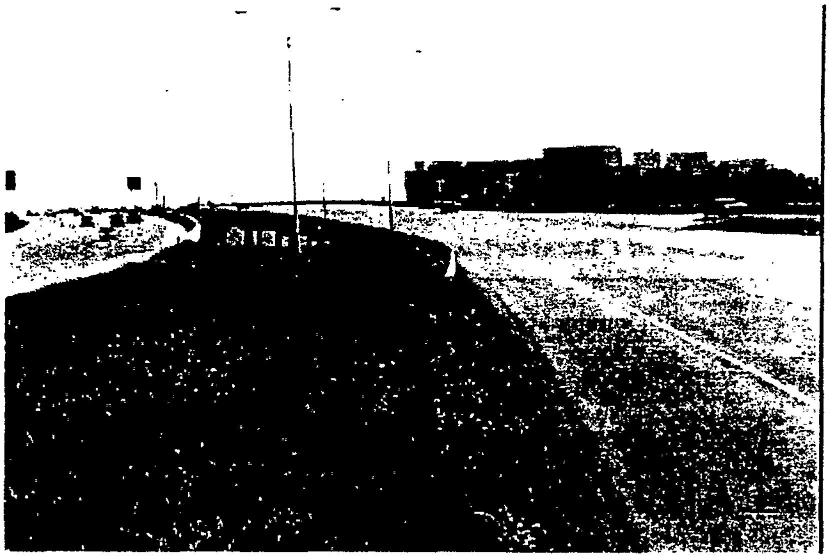

Figure 2.3 Photograph of MoPac at Walnut Creek

A summary of the physical characteristics of the three sites is presented in Table 2.1. Drainage area and average daily traffic also are included in this table. The traffic count at the low traffic volume site (Convict Hill Road) was only 20 percent of the traffic count at the site which had the highest traffic volume (35th Street). The size of the catchment at Convict Hill Road was only 10 percent of the highway surface drained at 35th Street. The traffic mix, and prevailing weather conditions were similar at all sites.

2.2 Climatic Conditions

The National Weather Service data indicate that annual rainfall in Austin, Texas is 82.6 cm; however, during the 12 month period July 1993 - July 1994, the total rainfall was only 44.4 cm. The National Weather Service data indicate that average storm event is 1.4 cm at storm intensities of about 0.18 cm/hr and storm duration of 11.8 hrs. However, storm characteristics vary greatly. Coefficients of variations associated with the data reported for average rainfalls were 1.63 for total volume of rainfall, 1.47 for rainfall intensity, and 1.9 for storm duration.

The National Weather Service data indicate that the wettest seasons occurred during the Spring and Fall. Dry conditions prevailed in the summer months. The rainfall intensity of events that occurred during the late fall and winter months was usually light and occurred over long duration (several hours to over a day). Rainfall events that occurred during the early fall and spring months ranged from drizzle to heavy down pours. Midsummer rainfall events are rare in Austin and tend to be heavy downpours resulting from electrical storms. Dry conditions were prevalent in Austin from June to August of 1994 with less than 0.25 mm of rain at any of the three sites for a period of 40 days.

Table 2.1 Summary of Characteristics of Three Highway Runoff Sampling Sites

	Convict Hill Road	Walnut Creek	West 35th Street
Drainage area	526 m^2	104,600 m^2	5,341 m^2
Pavement	100% asphalt	37% asphalt	100 % asphalt
Lanes of Traffic	2 (3.66 m)	6 (3.66 m each)	3 (3.66 m)
Shoulders	2.44 m and 6.71 m	2.4 m	2.4 m and 3.3 m
Curb/Guardrail	1 m retainer	none	15 cm curb
Average Daily Traffic	8,780	47,240	58,150
Speed Limit	88 km/hr	88 km/hr	88 km/hr
Land Use	rural/residential	commercial/ high density residential	commercial/ residential

2.3 Water Quantity Measurements

Automatic flow measuring and sampling systems were installed and operated at three (3) sites: MoPac at West 35th Street, MoPac at Convict Hill Road, and MoPac at Walnut Creek. The monitoring system installed at MoPac at 35th Street was in operation from October 1993 through July 1995, and the units at the other two sites were in operation April 1994 through July 1995. Water levels at each site were measured using bubble flow meters (ISCO 3230). The water levels were converted into a flow rate based on rating curves developed for each site. The information recorded at the automatic sampling station included rainfall volume, runoff flow rate, and the sampling times. These data were downloaded from the flow meters to a laptop computer, and were converted to text format and exported to Microsoft Excel.

Each sampling station included a 12 volt battery to power the flow meter, sampler, and recorder. A solar panel (Solarex Megamodule MSX60) recharged the battery. The flow meter, sampler, and battery were housed in a large steel enclosure. A rain gauge (ISCO 674) also was placed at each site to measure rainfall. Because of the relatively small size of each of the contributing watersheds, a single gauge at each site was determined to be sufficient for accurately measuring rainfall volume and intensity.

2.3.1 Flow Measurement at West 35th Street

Water level was read from a bubbler tube located at the bottom of the curbing system before the water entered the catchment inlet. A rating curve was developed for this location by discharging water from a fire hydrant approximately 100 meters upstream of the level measuring location. The water was discharged at metered flow rates to construct the rating curve. The water elevation recorded at different flow rates by the flow meter allowed the development of an accurate relationship between water level and flow rate. The flow meter was active at this site for more than one year. Monitoring flow rates of numerous storms produced an average runoff coefficient of about 0.90 which is consistent with values commonly reported in the literature for 100% impervious surfaces. The runoff coefficient calculations are shown in Figure 2.4.

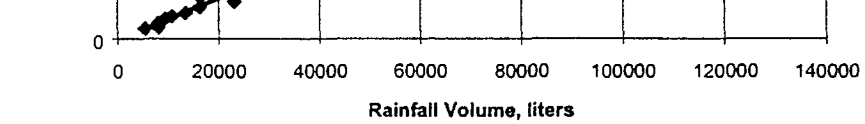

Figure 2.4 Runoff Coefficient for MoPac and West 35th Street

2.3.2 Flow Measurement at Convict Hill Road

Runoff discharge at the Convict Hill Road site was measured using a weir installed on a collection box at the base of a 6-inch diameter down spout. The weir was a compound weir, consisting of three sections: a bottom section which was 20.32 cm high with 30 degree throat, a middle portion which was 4.83 cm high with a 90 degree cross section and a top section which was a rectangular weir which had 5.33 cm sides. Depth of water in the collection box was measured and the discharge was calculated from a rating curve for each section.

$$Q = 137.7H^{2.5} \text{ (30 degree)}$$
$$Q = 372.9H^{2.5} \text{ (90 degree)}$$

where: Q = flow rate (L/s), and
H = head (m).

An identical weir was calibrated at the Center for Research in Water Resources (CRWR) laboratory. The observed discharge of the 30 degree section was almost identical to that predicted by the formulas. The recommended length and weir elevation of the collection box were limited by the height of the down spout at the base of the bridge support and the concrete pad that was located below it. However, the consistency of the results and the resulting runoff coefficient indicated that the system employed was reliable and yielded accurate flow data. The runoff coefficient calculated in this manner was about 0.94. The runoff-rainfall relationship is shown in Figure 2.5.

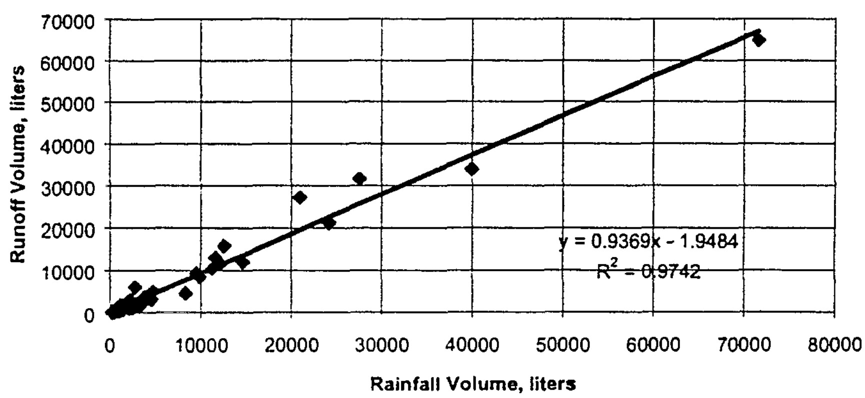

Figure 2.5 Runoff Coefficient for MoPac at Convict Hill Road

2.3.3 Flow Measurement at Walnut Creek

Samples were collected by an automatic sampler from the 1.22 m diameter outfall of the system prior to the discharge entering Walnut Creek. Flow in the storm sewer system at Walnut Creek was calculated using the Manning formula for pipe flow. The slope of the pipe (S), the roughness coefficient (n), the diameter of the pipe (D), and the depth of water in the pipe (d), were used to calculate the flow rate using:

$$Q = \frac{1000}{n} A R^{2/3} S^{1/2}$$

where:
- Q = flow rate (L/s),
- A = cross-sectional area of flow (m^2),
- R = hydraulic radius (m),
- S = pipe slope, and
- n = the roughness coefficient of the pipe (n = 0.013).

The rainfall runoff relationship is shown in Figure 2.6. The larger scatter of the points is the result of the large percentage of the area which is grass covered and where the initial moisture content of the soil strongly influences the volume of runoff. The average runoff coefficient for this site was approximately 0.10, which is in the expected range of values for a site of these characteristics.

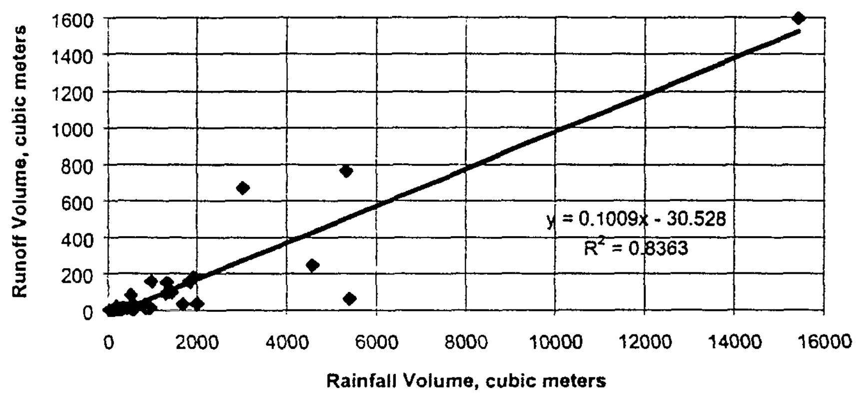

Figure 2.6 Runoff Coefficient for MoPac and Walnut Creek

R0009767

The calculated runoff for the three sites are presented in Table 2.2. These runoff coefficients were determined from an analysis of volume of runoff collected and the volume of rainfall occurring in natural rainfall events.

Table 2.2 Runoff Coefficients

Sampling Site	Calculated Runoff Coefficient
MoPac at Convict Hill Road	0.94
MoPac at Walnut Creek	0.10
MoPac at West 35th Street	0.85

A second sampler installed at the Walnut Creek site collected runoff directly from the northbound lanes of MoPac. Water falling from a down spout located in the Walnut Creek overpass was collected in a 190L barrel. Flow out of an orifice at the base of the barrel was calculated using Bernoulli's formula. The formula used to measure flow was:

$$Q = C_D \cdot A_O \sqrt{2 \cdot g \cdot H}$$

where: Q = flow rate (L/s),
C_D = a coefficient of discharge (0.6),
A_o = the area of the orifice (m^2),
g = gravity (9.81 m/s^2),
H = the depth of water above the orifice (m).

The area drained is approximately 1,060 m^2. Only about 50% of the runoff was collected during heavier storms, because of the large distance the runoff fell before collection in the barrel. The sample collection interval was determined based on experience at the 100% paved sites at Convict Hill Road and West 35th Street.

2.4 Water Quality Sampling

Water quality samples were collected during runoff events at each site with an automatic sampler (ISCO 3700). The automatic samplers were programmed to sample based on the volume of runoff flowing past the sampling point or based on time after runoff initiated the sampling program. At Walnut Creek and Convict Hill Road the sampler was programmed to draw samples at set volumes of flow. At the 35th Street site, the sampler was initially programmed to collect samples on a timed basis, but was later converted to collect flow weighted composite samples. The sampler was initiated by the flow meter when the water level at the collection site exceeded a predetermined value. Samples were collected and analyzed according to the methodology specified by the U.S. Environmental Protection Agency (EPA).

Initially, the samplers were configured to collect samples in twenty-four 350 mL bottles. Therefore either six samples in four bottles each, or four samples in six bottles each were composited on a flow weighted basis. Later, four 3.8 L glass bottles were installed in the automatic samplers to facilitate the collection of larger volumes of samples for analysis. The samplers were programmed to collect four flow weighted composite samples representing different portions of the runoff so that pollutant concentrations as a function of runoff volume could be investigated. Flow intervals were changed to reflect weather patterns at different times of the year.

2.5 Chemical Analyses

During rainfall events the runoff flow rates were measured and samples were collected automatically. Water quality parameters analyzed in the laboratory for all runoff samples included: turbidity, total and volatile suspended solids (TSS and VSS), 5-Day Biochemical Oxygen Demand (BOD_5), Chemical Oxygen Demand (COD), Total Organic Carbon (TOC), oil and grease (O&G), nutrients (nitrate and total phosphorus), heavy metals (iron, lead, cadmium, nickel, zinc, and copper), and bacteria (total coliform, fecal coliform, and fecal streptococcus). Analyses were performed at The Center for Research in Water Resources in Austin, Texas. Results of all analyses performed as part of this study are reported in the Appendix.

The detection limits for the analytical procedures (analyses and instrumentation) used to determine constituents in the rainfall and runoff samples are summarized in Table 2.3. The detection limit was used in calculating EMCs for concentrations of constituents which were present in the runoff samples at concentrations below the detection limit. Therefore, the EMC of a constituent which is present below the detection limit will be reported as being greater than the actual concentration in the sample.

Table 2.3 Detection Limits at CRWR Laboratory

Analytical Procedure	Detection Limit (mg/L)
TSS	4
VSS	4
BOD	2
COD	5
Total Carbon	10.0
Dissolved Total Carbon	10.0
Nitrate	0.10
Total Phosphorus	0.005-0.05
Oil and Grease	1.0
Copper	0.002-0.006
Chromium	0.0023-0.007
Cadmium	0.0013-0.004
Nickel	0.005-0.015
Iron	
Lead	0.0014-0.042
Zinc	0.0007-0.005

3. RESULTS

3.1 Water Quality of Highway Runoff

Summary water quality characteristics for runoff samples are presented as median event mean concentrations (EMC) in Table 3.1. The concentrations measured in flow weighted composite samples at were used to calculate the EMC. The EMC's for each constituent were derived from the average value of the constituent for each of the runoff events monitored and for which a sufficient volume of runoff was generated to complete the chemical analyses. Median EMCs for the rainfall which could be sampled (i.e. sufficient accumulation to yield the volume required for analyses) also are included in Table 3.1. The volume of rainfall collected usually was insufficient to allow complete chemical characterization.

Table 3.1 Constituents in Highway Runoff

Parameter	35th Street		Convict Hill Rd.		Walnut Creek		Rainfall
	Median	Mean	Median	Mean	Median	Mean	Median
Total Coliform (CFU/100ml)	13000	48000	4200	7900	189000	145000	0
Fecal Coliform (CFU/100ml)	5800	13000	1000	22000	102000	116000	0
Fecal Streptococcus (CFU/100ml)	12000	16000	3800	17000	78000	89000	0
pH	7.15	6.94	5.61	6.14	6.51	7.16	
TSS (mg/L)	131	202	118	142	19	27	0
VSS (mg/L)	36	41	20	22	7	7	0
BOD_5 (mg/L)	12.2	16.5	5.0	6.3	3.5	4.1	ND[a]
COD (mg/L)	126	149	40	48	35	33	6
Total Carbon (mg/L)	47	58	21	24	16	18	ND
Dissolved Tot. Carbon (mg/L)	25	31	11	14	13	15	ND
NO_3-N (mg/L)	1.03	1.25	0.73	0.96	0.28	0.36	0.52
Total Phosphorus (mg/L)	0.33	0.42	0.11	0.13	0.10	0.10	0.05
Oil & Grease(mg/L)	4.1	6.5	1.7	2.2	0.5	0.5	ND
Cu (mg/L)	0.034	0.038	0.007	0.010	0.008	0.007	0.003
Fe (mg/L)	2.606	3.537	1.401	2.437	0.361	0.442	0.079
Pb (mg/L)	0.050	0.099	0.016	0.041	0.007	0.009	ND
Zn (mg/L)	0.208	0.237	0.050	0.077	0.022	0.019	0.019

a) ND = not detected

Nickel and cadmium were rarely present at concentrations above detection limits; therefore they are not shown in Table 3.1. Many of the constituents found in runoff are present in measurable quantities in the rainfall itself. The impact of constituents in rainfall on the quality of highway runoff is limited to nutrients and some metals.

Median EMCs for the runoff at the high traffic sites compare well with the data summarized by Driscoll (1990a, b, and c) for various locations throughout the United States with the exception of lead and zinc. Table 3.2 shows the comparison between the median concentrations measured at 35th Street with the median value reported by Driscoll et al. (1990a) for all sites with average daily traffic greater than 30,000 vehicles per day. The concentrations are extremely similar except for lead which is much lower at 35th Street. The elimination of lead in gasoline is probably responsible for this difference.

Table 3.2 Comparison of High Traffic Site Concentrations

Parameter	MoPac at 35th Street (mg/L)	Driscoll et al. (1990a) - (mg/L)
TSS	131	142
VSS	36	39
COD	126	114
NO_2+NO_3	1.03[a]	0.76
Copper	0.034	0.054
Lead	0.050	0.400
Zinc	0.208	0.329

a) NO_3 only

Table 3.3 contains a comparison with the median EMC at Convict Hill Road with the median value reported by Driscoll et al. (1990a) for all sites with an average daily traffic of less than 30,000 vehicles per day. Concentrations at Convict Hill Road were lower for metals and COD, but were much higher for suspended solids. Three factors may have contributed to the higher solids concentrations. Urban development was occurring near this site during the monitoring period. The increased construction traffic may have contributed more solids than a normal vehicle mix might. In addition, the concrete barrier lining the roadway may retain more solids on the road surface, which would then be mobilized during storms. In contrast to most low traffic, rural highways, the catchment sampled had an impervious cover of 100% so that the runoff did not flow across any grassy areas which might have reduced solids concentrations.

Table 3.3 **Comparison of Low Traffic Site Concentrations**

Parameter	MoPac at Convict Hill Rd. (mg/L)	Driscoll et al. (1990a) (mg/L)
TSS	118	41
VSS	20	12
COD	40	49
NO_2+NO_3	0.73[a]	0.46
Copper	0.007	0.022
Lead	0.016	0.080
Zinc	0.050	0.080

a) NO_3 only

The event mean concentrations reported for the site having the high traffic density are higher for all water quality parameters than the observed EMC's for the other sites. However, the event mean concentrations observed at the site with medium traffic density are lower than those observed for the other two sites, including the low traffic site. This phenomenon may be explained by the fact that the runoff from the highway at the high traffic and low traffic sites is directly from the pavement into a catch basin where the samples are collected. However, the highway runoff at the medium traffic density site passes over approximately 60 m of grassy area (swale) before entering the storm drain pipe from which samples are collected. The lower concentrations of the various water quality parameters at this site may reflect removal by the grassy swale. The effects of the grassy swale on the water quality at this site is reported in Section 3.3.

3.2 Estimate of Annual Pollutant Loads

The product of the volume of runoff from a section of highway, over a given period of time, and the concentration of a specific constituent yields the pollutant load contributed by the highway. For many types of water bodies, the pollutant load is a more important indicator of potential water quality impacts than is EMC. Annual constituent loads for the three highway sites were calculated based on the "simple method" described by Schueler (1987).

$$L = \left[\frac{(P)(CF)(R_v)}{20.4} \right] (C_i)$$

where: L = Annual pollutant load (kg/ha)

P = Annual precipitation (825 mm/yr)

CF = Correction factor that adjusts for storms where no runoff occurs (0.9)

R_v = Average runoff coefficient

C_i = Event mean concentration (mg/L)

Estimated annual loadings (grams per square meter of pavement) are presented in Table 3.4. The loads for each site were normalized by watershed area to facilitate a comparison between the three sites.

Table 3.4 Estimated Annual Pollutant Loadings

Pollutant	35th Street (kg/ha)	Convict Hill Rd. (kg/ha)	Walnut Creek (kg/ha)
TSS	229	145	3.3
VSS	46	23	0.8
BOD_5	18.7	6.5	0.5
COD	169	49	4.0
Total Carbon	66	25	2.2
Dissolved Tot. Carbon	35	14	1.8
NO_3-N	1.42	0.98	0.04
Total Phosphorus	0.48	0.13	0.01
Oil & Grease	7.36	2.25	0.06
Cu	0.043	0.010	0.001
Fe	4.008	2.497	0.053
Pb	0.112	0.042	0.001
Zn	0.269	0.079	0.002

All estimated loadings at Walnut Creek are far less than those at the other two sites. This is the result of the initial low concentrations of constituents in the runoff at Walnut Creek combined with the low runoff coefficient caused by the grassy swale. Differences between expected loads at 35th Street and Convict Hill Road are primarily the result of differences in the EMC's for the constituents.

3.3 Effect of Drainage System Type

Grassy swales are vegetated ditches which have gentle slopes and cover large areas of land. Swales have been shown in studies to effectively remove many constituents from highway runoff. The swales promote settling of suspended solids and infiltration of the runoff into the soil. A curb and gutter system, which tends to concentrate and transport constituents in highway runoff, also is eliminated by a grassy swale (Schueler, 1991). Factors reported to affect the removal efficiency include type of grass, grass density, blade size, blade shape, flexibility and texture (Umeda, 1988). Channel dimensions and swale area affect removal efficiencies and the amount of infiltration that occurs.

A second sampler was installed to collect runoff directly from the road surface for comparison with the runoff from the swale to investigate the effect of the grassy swale on the runoff quality at the Walnut Creek site. A limited number of samples were collected from the overpass and concentrations of constituents were similar to those at Convict Hill Road. The data observed for the runoff samples collected from the two surfaces (the overpass before the runoff reached the grassy swale and from the outfall into which the runoff flowed after passage through the grassy median strip) at MoPac at Walnut Creek are presented in Table 3.5.

Table 3.5 Removal Efficiency of a Grassy Swale

Parameter	Roadway	Grassy Swale	Removal (%)
Total Coliform (CFU/100mL)	3,678	188,197	-
Fecal Coliform (CFU/100mL)	1,934	101,545	-
Fecal Streptococcus (CFU/100mL)	6,909	89,482	-
TSS (mg/L)	104	27	74
VSS (mg/L)	23	7	72
BOD_5 (mg/L)	7.5	4.1	46
COD (mg/L)	51	33	35
Total Carbon (mg/L)	34	18	48
Dissolved Tot. Carbon (mg/L)	17	15	9
NO_3-N (mg/L)	0.88	0.36	59
Total Phosphorus (mg/L)	0.15	0.10	31
Oil & Grease (mg/L)	3.9	0.5	88
Cu (mg/L)	0.014	0.007	49
Fe (mg/L)	2.066	0.442	79
Pb (mg/L)	0.014	0.009	35
Zn (mg/L)	0.074	0.019	74

Significant pollutant removal occurs for all constituents except bacteria and dissolved total carbon. These reductions in concentration are similar to that reported by other studies. Schueler et al. (1991) reported that well-designed, well-maintained grassed swales may remove up to 70% of TSS, 30% of total phosphorus, 25% of total nitrogen, and 50-90% of various trace metals. Little et al. (1982) found removal efficiencies of 67-93% of oil and grease, and TSS and VSS reductions of at least 65%.

The use of a grassy swale as a runoff control device raises some concerns. The bacterial counts found in samples of runoff from the swale were much higher than at the other sites. The concentrations also show that more bacteria are in the samples from the outfall than in the runoff of the roadway. Apparently, the soil of the swale or the storm sewer act as a source of bacteria. It is unlikely, given the setting, that the high levels of fecal coliform and fecal streptococcus are of human origin or that they are indicative of significant human health risk.

3.4 Pollutant Washoff Patterns

Concentrations of pollutants in runoff are often higher at the beginning of a runoff event, a phenomenon commonly referred to as the "first flush." Many storm water treatment systems are designed to capture the initial runoff from storm events to remove and treat the runoff with the highest concentrations of pollutants. It is thought by many that the majority of pollutants are contained in the first flush. Suspended solids often display the first flush effect as shown in Figure 3.1. If the rate that material is washed from the road is proportional to the amount on the road then a simple exponential function will describe the instantaneous concentrations. The magnitude of the first flush phenomenon varied between events and monitored sites in this study.

The first flush effect was more evident at West 35th Street than at Convict Hill Road or Walnut Creek because the concentrations of the constituents were higher at West 35th Street and changes were more evident. A first flush was most pronounced during short storms with fairly constant rainfall intensities. For longer events, changes in traffic volume, rainfall intensity and other variables reduced the magnitude of the first flush. Vehicles acted as a continuing source of pollutants during storm events, so complete washoff never occurred. For all storms monitored at this site the percentage of total mass

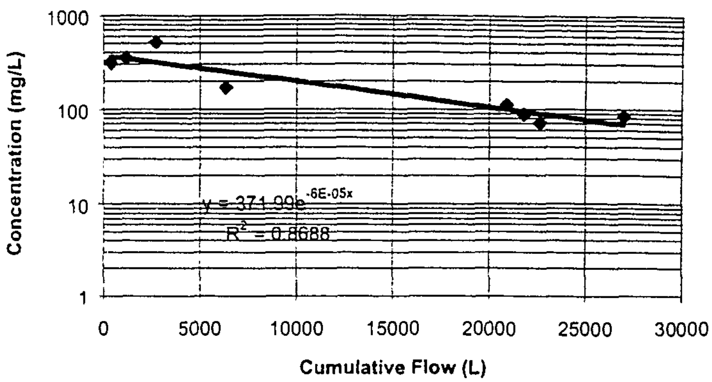

Figure 3.1 Washoff of TSS at 35th Street, 10/29/93

discharged at any point in the storm was only slightly higher than the percentage of the total runoff volume at that point. A more detailed description of the first flush effect at 35th Street is contained in CRWR Technical Report #264 (Irish et al, 1995).

At Convict Hill Road most sample collection was limited to the first 12.1 mm of runoff, because of the requirements of the NPDES permit and the rainfall characteristics in the Austin area. This limited the evaluation of the first flush characteristics at this site. Higher concentrations were recorded during approximately the first 3 mm of runoff for most constituents; however, the concentrations quickly became approximately constant for the duration of the sampling period. The typical pattern is shown in Figure 3.2 for TSS. Since the concentration of TSS stabilizes at approximately 100 mg/L, significant loading continues for the duration of the sampling period.

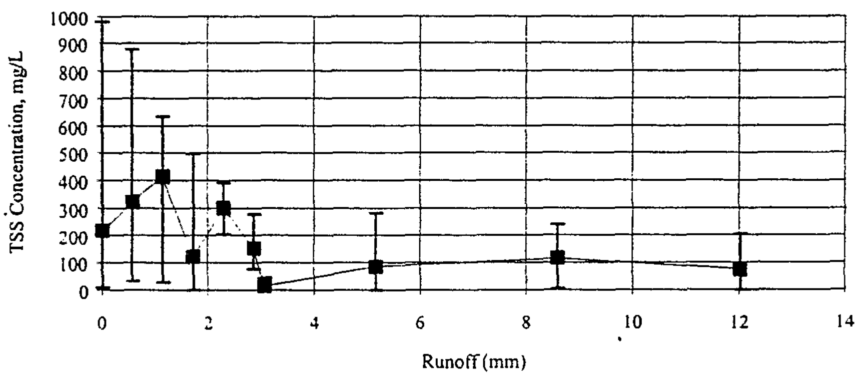

Figure 3.2 TSS Washoff Pattern at Convict Hill Road Site

First flush effects were less evident at Walnut Creek than at the other two sites because of the lack of variability and low concentrations of constituents in runoff. Low concentrations of most pollutants minimized the differences in concentrations between the start and end of the storm. The range of concentrations tend to narrow with more rainfall and average concentrations near the end of the storm are smaller than those observed at the start of the storm. Only a few constituents showed somewhat higher concentrations at the beginning of an event. The higher concentrations were limited to approximately the first 5 mm of runoff. The concentrations stabilized at this point resulting in continued input of each constituent for the duration of the event.

Although concentrations were somewhat higher at the beginning of runoff events at the sites monitored in this study, the effect was not pronounced. Concentrations stabilized at elevated levels resulting in a continuous input of pollutant load for the duration of the event. Decisions about the size of proposed runoff controls should be based on the assumption that storm water runoff has a constant concentration for each storm event.

4. SUMMARY AND CONCLUSIONS

Water quality of highway runoff in the Austin, Texas area was determined by monitoring runoff at three locations on MoPac, which represented different daily traffic volumes, surrounding land uses, and highway drainage system types. MoPac at West 35th Street is a high traffic site (60,000 vehicles per day) located in central Austin. The land use of the area is mixed residential and commercial. MoPac at Convict Hill Road is a low traffic site (8700 vehicles per day) located on the southern edge of Austin. The land use around Convict Hill Road is mostly residential and rural undeveloped. The Walnut Creek site is located in north Austin and consists of a combination of paved highway and grassy shoulder and median. The land use classification of the area is mostly commercial and high density residential, and approximately 47,000 vehicles per day pass this location. At Walnut Creek, the highway runoff crosses a large grassy median before entering the storm sewer system where the samples were collected. The watersheds of the other two sites were 100 % impervious.

Runoff flow rates were measured and samples were collected automatically during rainfall events. Water quality parameters analyzed in the laboratory for all runoff samples included: turbidity, total and volatile suspended solids (TSS and VSS), 5-Day Biochemical Oxygen Demand (BOD_5), Chemical Oxygen Demand (COD), Total Organic Carbon (TOC), oil and grease (O&G), nutrients (nitrate and total phosphorus), heavy metals (iron, lead, cadmium, nickel, zinc, and copper), and bacteria (total coliform, fecal coliform, and fecal streptococcus).

The highest concentrations of all constituents were measured at the high traffic site at 35th Street. The lowest concentrations were found at the Walnut Creek monitoring site. The concentrations at all sites were similar to median values compiled in a nationwide study of highway runoff quality.

The total load of pollutant discharged is more important for estimating water quality impacts for many receiving waters than is concentration. Pollutant load is a function of concentration and volume of runoff. Normalized for surface area, the greatest loads were generated at 35th Street, while the lowest amounts were found at the Walnut Creek monitoring site. The monitored watershed at Walnut Creek had a runoff coefficient of only about 10 % while the other two sites had runoff coefficients of approximately 90 %. The lower concentrations at Walnut Creek combined with the much lower flows at this site were responsible for the low loads at this site.

Little adverse impact would be expected for all but the most sensitive receiving waters based on the quantity and quality of highway runoff generated during storms. The water quality of highway runoff is generally similar to that reported for urban runoff, and does not contain appreciably higher concentrations of toxic metals or oil and grease. The impacts of highway runoff alone, like many other nonpoint sources of pollution generally are not significant when considered singly, but may result in degradation of water quality when combined with other sources such as urban runoff.

The effectiveness of grassy swales for treating highway runoff was evaluated by comparing the runoff at Walnut Creek, before and after passing across a swale. The grassy swale proved effective for reducing the concentrations of most constituents in runoff. The low runoff coefficient due to infiltration of runoff into the swale produced a large reduction (90%) in pollutant load discharged. This reduction of runoff volume effectively reduces the impact of constituents whose concentrations are not reduced by the swale. Large increases in bacteria counts occurred in either the swale or the storm sewer system; however, they probably do not indicate the presence of a significant human health threat. The use of a grassy swale precludes the installation of hazardous material traps designed to catch spills of gasoline or other chemicals during traffic accidents.

A first flush effect (i.e., higher pollutant concentrations at the beginning of an event) was very evident during selected events, but was generally limited to a small volume. When all monitored events were considered, the overall effect was small or negligible. The concentrations appeared to be affected by changes in traffic volume, rainfall intensity, and other factors. In addition, vehicles provided a continuous input of pollutants to the road surface and runoff for the duration of runoff events. In considering the potential effectiveness of storm water treatment systems, constant concentrations for individual storm events should be assumed.

The Virginia Department of Conservation and Recreation has developed the Virginia Stormwater Management Handbook, First Edition, in order to provide guidance for compliance with the Virginia Stormwater Regulations. (4VAC3-20 et seq.) The technical material provided in the Handbook includes hydrologic and hydraulic analysis procedures. This information was derived in part from SCS sources such as the SCS National Engineering Handbook (NEH), and the SCS Engineering Field Manual (EFM), and others.

A brief Summary of the Handbook is provided here.

Chapter 1: Virginia Stormwater Management Program, provides an overview of the various State regulations which address water quality and nonpoint source pollution.

Chapter 2: Stormwater Management and Urban BMPs, presents the basic components of stormwater management, as found in the Virginia SWM Regulations, and follows them through the BMP sizing and selection criteria. Most importantly, this Chapter presents the basics of Regional Stormwater Management and Comprehensive Watershed Management.

Chapter 3: Minimum Standards, provides the technical design requirements and specifications, and maintenance requirements for stormwater BMPs defined in the Regulations. These minimum standards represent current, and in some cases innovative, design information pulled together under one cover in order to promote consistency in the design and construction, and therefore the effectiveness, of stormwater BMPs. These BMPs include: **3.01** Earthen Embankments; **3.02** Principal Spillways; **3.03** Vegetated Emergency Spillway; **3.04** Sediment Forebay; **3.05** Landscaping; **3.06** Retention Basins; **3.07** Extended Detention Basin; **3.08** Detention Basin; **3.09** Constructed Stormwater Wetlands; **3.10** Infiltration Practices; **3.11** Bio-Retention; **3.12** Sand Filters; **3.13** Grassed Swale; **3.14** Vegetated Filter Strip; and **3.15** Manufactured BMP Systems.

Chapter 3 Appendix: Design & Plan Review, Inspection and As-Built, and Maintenance Checklist.

Chapter 4:Hydrologic Methods, presents four methods for conducting a hydrologic analysis and determining the peak discharge from a watershed or drainage area. These methods include the Rational Method, Modified Rational Method, SCS TR-55 Graphical Peak Discharge Method, and Tabular Hydrograph Method. Also included is a basic overview of various types of design hydrographs used in stormwater modeling.

Chapter 4 Appendix: Various hydrological data including soil classifications, rainfall tables, etc.

Chapter 5: Engineering Calculations, provides very detailed calculation procedures for designing BMPs using standard hydraulic equations. These procedures include storage volume requirements, water quality and channel erosion control volume calculations, extended detention calculations, principal spillway and emergency spillway design, anti-seep collar design, outlet protection, riser floatation calculations, and water quality calculation procedures.

Chapter 5 Appendix: Hydraulic calculation worksheets, water quality criteria worksheets, etc.

Chapter 6: Example Problems, provides some design examples including hydrologic and hydraulic analyses.

Technical Bulletins: Purchasers of the Handbook will automatically receive three Technical Bulletins which will provide additional and updated information and guidance. These Technical Bulletins will provide information on local program development, local program funding ideas and experiences, innovative BMP design, BMP pollutant removal efficiencies, BMP maintenance, etc.

MINIMUM STANDARD 3.12

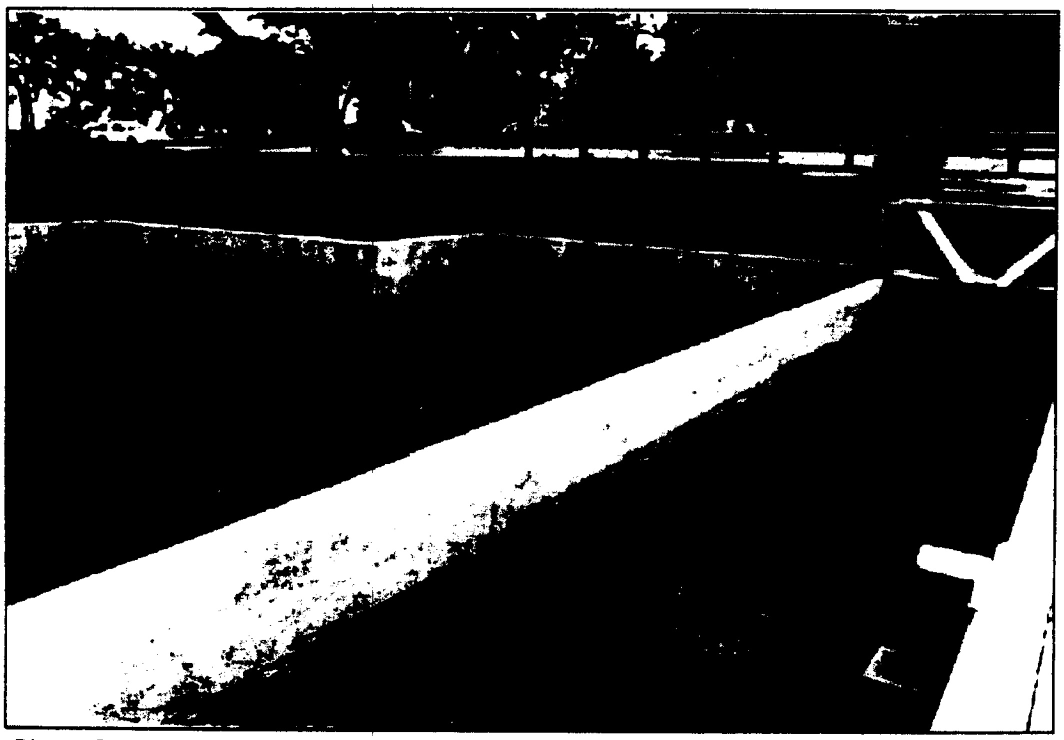
GENERAL INTERMITTENT SAND FILTER PRACTICES

Definition

Intermittent sand filter facilities capture, pretreat to remove sediments, store while awaiting treatment, and treat to remove pollutants (by percolation through sand media) the most polluted stormwater (the water quality volume) from a site. Intermittent sand filter BMPs may be constructed in underground vaults, in paved trenches within or at the perimeter of impervious surfaces, or in either earthen or concrete open basins. They have been successfully used in Austin Texas, the District of Columbia, The State of Delaware, and in Alexandria, Virginia over the last two decades. **Figure 3.12-1** is a photograph of a sand filter BMP in Austin.

FIGURE 3.12 - 1
Austin Partial Sedimentation Surface Sand Filter



(Photo Courtesy of City of Austin, Texas)

Purpose

Intermittent sand filter facilities are primarily used for water quality control. However, they do provide detention and slow release of the water quality volume from the site being treated. Whether this amount will be sufficient to provide the necessary peak flow rate reductions required for channel erosion control is dependent upon site conditions (hydrology) and required discharge reductions. The 10-year and 100-year flows will usually exceed the detention capacity of a sand media filter. When this occurs, separate quantity facilities must be provided. Table 3.12-1 contains the target removal efficiencies of sand and other soil media filter BMPs. Table 3.12-2 contains the results of an extensive sand filter monitoring study in Alexandria conducted for the Chesapeake Bay Local Assistance Department (Bell, Stokes, Gavan, and Nguyen, 1995).

Pollutant Removal Mechanisms at Work in Intermittent Sand Filter BMPs

Pollutant removal processes at work in intermittent sand filters are complex and involve physical, chemical, and biological transformations (Tchobanoglous and Burton, 1991; Anderson, Siegrist, and Otis, Undated). The most obvious mechanism is physical straining of suspended solids and particulate nutrients.

Suspended Solids

Mechanical straining, straining due to chance contact, and sedimentation are the principal mechanisms by which suspended solids are removed, although the growth of bacterial colonies within the sand grains may also cause autofiltration (Tchobanoglous and Burton, 1991).

Table 3.12-2

Pollutant Removal Efficiencies for a Delaware Sand Filter in Alexandria

Constituent	Mass Balance Removal Efficiency (%)

Phosphorous

Phosphorous removal is performed by physiochemical processes such as mechanical and chance contact straining, precipitation, and adsorption (Piluk and Hao, 1989; Laak, 1986).

There are three general types of adsorption (the condensation and concentration of ions or molecules of one material [the adsorbate] on the surface of another [the adsorbent]): physical, chemical, and exchange. Physical adsorption results from the weak forces of attraction between molecules and is generally quite reversible. Chemical adsorption results from much stronger forces comparable to those leading to the formation of chemical compounds, with the adsorbed material forming a one molecule thick layer over the surface of the absorbent until the capacity of the absorbent is exhausted. Chemical adsorption is seldom reversible. Exchange adsorption, on the other hand, results from electrical attraction between the adsorbate and the surface, such as occurs with ion exchange. Ions of the adsorbate concentrate on the surface of the adsorbent as a result of electrical attraction to opposite charges on the surface. It is sometimes difficult to assign a given adsorption to a specific type (Sawyer, Mcarty, and Parkin, 1994).

Although exchange adsorption may also be involved, most adsorption in intermittent sand filters appears to be chemical adsorption (Piluk and Hao, 1989; Otis, Undated; Anderson, Siegrist, and Otis, Undated).

In addition to the **filter mass available**, the adsorption of phosphorous in sand filters is also affected by the pH of the material being filtered (with higher removal rates occurring with the reduction of pH), temperature, contact time, and the character of the filter media (Laak, 1986). Sands containing iron, aluminum, or calcium have a higher phosphorous removal potential because phosphorous will combine with these elements through chemical precipitation and become relatively insoluble (Laak, 1986, Tchobanoglous and Burton, 1991). If the filter becomes anaerobic, the bonding with iron may break down, releasing orthophosphates (Harper and Herr, 1993). However, aerobic filters enriched with iron may attain almost complete phosphorous removal until the filter capacity is exhausted, and properly sized filters may have a life of up to 20 years (Laak, 1986). Sand particles with sufficient iron content may become positively charged, leading to more favorable medium-particle interactions and increased removal rates (Stenkamp and Benjamin, 1994). Entrapment in the filter of a high percentage of the iron in the runoff being treated may provide a source to replenish used up phosphorous adsorption capacity.

Nitrogen and Biochemical Oxygen Demand

Mineralization of organic nitrogen into ammonium (NH^-_4) may occur under either aerobic or anaerobic conditions if the required naturally occurring chemoautotrophic bacteria (organisms which obtain energy by oxidizing simple chemical compounds) are present (*Nitrosomonas, Nitrosococcus, Nitrospira, Nitrosolobus, Nitrososovibrio*)((Laak, 1986; The Cadmus Group, 1991).

Organic N • • Bacterial enzymes • • NH_4^- + other products

Positively charged ammonium ions are then adsorbed to negatively charged sand filter particles through exchange adsorption (The Cadmus Group, 1991).

The transformation of ammonia (NH_3) and ammonium into nitrite and nitrate (NO_2^- and NO_3^-) and the removal of BOD_5 occur under aerobic conditions by microorganisms (such as *Nitrosomonas* and *Nitrobacter*) present in the sand bed (Tchobanoglous and Burton, 1991;, Laak, 1991; The Cadmus Group, 1991).

R0009798

$NH_4^+ + 1.5O_2$ • •*Nitrosomonas*, etc • • $NO_2^- + 2H + H_2O$ + Energy

$NO_2^- + 0.5O_2$ • •*Nitrobacter* • • NO_3^- + Energy

Since nitrite and nitrate are soluble anions, they are not affected by the cation exchange complex of the filter, but rather tend to leach readily to the filter effluent (Gold, Lamb, Loomis, and McKiel, Undated). However, anaerobic microenvironments (sometimes called "microsites") routinely coexist in principally aerobic intermittent sand filters (Tchobanoglous and Burton,1991; Gold, Lamb, Loomis, and McKiel, Undated). Naturally occurring anaerobic bacteria (*Pseudomonas, Micrococcus, Achromobacter, Bacilluss*) in these pockets may convert much of the nitrite into nitrate and the nitrate to nitrogen gas, resulting in total nitrogen removal in intermittent sand filters ranging up to 45-50 percent (Tchobanoglous and Burton, 1991; Laak, 1986; Ronayne, Paeth, and Osborne, Undated).

NO_3^- + Organic Carbon • •Denitrifying bacteria • • $N_2 + H_2O + CO_2$ + Cells

Organic carbon must be present for denitrification to occur, but low organic carbon/nitrogen rations will suffice (1:2 or less) (Laak, 1986, p.62). Some studies indicate that optimal denitrification occurs at ratios of 1:1-3:1 (Gold, et al, p.298). The maximum rate of denitrification occurs at temperatures above 10 degrees C and at a pH above 5.5, with the optimum pH range falling between 7.0 and 8.0. (The Cadmus Group, 1991, p.11). However, home wastewater systems have demonstrated excellent denitrification performance when the wastewater temperature was as low as 4 degrees C (Piluk and Hoa, 1989).

Heavy Metals

More than 70 percent of heavy metals in stormwater runoff is in particulate form (Harper and Herr, 1993). Over 70 percent of particulate heavy metals are of greater than 104 microns in size (Shaver and Baldwin, 1990). Particle settling in presettling basins and mechanical straining appear to be the principal mechanism for removing heavy metals in stormwater intermittent sand filter systems. Some iron may be removed by reacting with phosphorous in the runoff being treated.

Hydrocarbons

Mechanical straining and physical adsorption appear to be the mechanisms removing hydrocarbons which reach the sand filter.

Conditions Where Practice Applies

Intermittent sand filters are suitable for use in ultra-urban settings with a high degree of imperviousness where the land cost or loss of economic return on real estate required to construct retention basins may be prohibitive. They are generally suited for high pollutant removal on medium to high density development (65 to 100% impervious cover). Specific conditions such as drainage area size and development conditions are discussed with each type of intermittent sand filter. Because they are subject to failure by clogging, intermittent sand filters are not recommended for use on watersheds where sediment loadings can be significant. Wherever possible, their use should be limited to treating runoff from impervious surfaces. Most of the practices discussed below are designed to treat runoff from watersheds with at least 65% impervious cover. Where other runoff must be treated, sediment protection must be increased to severely curtail the sediment load reaching the filter media.

Planning Considerations

Site Conditions

1. *Size and Topography of the Site*

Some types of intermittent sand filter BMPs are especially suited to larger drainage sheds, while others have upper size limits on their effective use. **Table 3.12-3** outlines drainage shed size applications of various types of intermittent sand filter facilities. On larger sites with multiple drainage sheds, a variety of BMPs might prove to be most cost effective.

TABLE 3.12 - 3
Appropriate Intermittent Sand Filter Applications to Various Site Areas

Type of Intermittent Sand Filter	Appropriate Drainage Shed to filter
District of Columbia Underground Vault Sand Filters	Medium (0.25-1.25 impervious acres)
Delaware Sand Filters	Small-Medium (≤ 1.25 impervious acres)
Austin Full Sedimentation Sand Filters (Surface or Vault)	Large (≥ 1.25 impervious acres)
Austin Partial Sedimentation Sand Filters (Surface)	Medium-Large
Austin Partial Sedimentation Sand Filters (Underground)	Medium

2. *Stormwater Infrastructure Serving Site*

Both the size and the elevations of stormwater infrastructure serving the site as a whole are important considerations. A critically important design parameter is the potential difference in elevation of the receiving manhole in the stormwater infrastructure and the elevation of the closest manhole in the new storm sewer system draining the site to be served. This will determine the depth of water than can be pooled above the filter media with the system operating on gravity flow. Almost all intermittent sand filter BMPs are designed to flow by gravity. However, in commercial and industrial applications where dedicated maintenance crews with familiarity with mechanical equipment will be available, pumped flow should be considered a viable alternative.

3. *Depth to Seasonally High Groundwater Table*

The liner or concrete shell of intermittent sand filter BMPs is usually placed at least 2 to 4 feet above the seasonally high water table or bedrock in order to assure dry conditions for construction and to minimize infiltration of groundwater into the filter structure. However, in some cases, it may be economical and practical to place filter shells below the seasonally high water table. In such cases, floatation effects must be countered by providing extra weight or hold down components in the filter shell.

4. *Value of the Real Estate and Expected Income from Development*

The value of real estate in highly urbanized areas may drive the overall cost of traditional structural BMPs too high for serious consideration. In Alexandria, for example, the cost of real estate alone to construct retention ponds averages $60,000 per impervious acre treated, while the cost of real estate for extended detention basins averages $40,000 per impervious acre treated. The overall costs of underground vault sand filters, which may be placed under parking lots and private streets or even within building structures and therefore have no real estate cost, can become quite competitive under such circumstances. The income stream from increased development allowed by underground BMPs should also be considered in such analyses.

5. *Aesthetic and Land Use Considerations*

Most traditional stormwater BMPs may be severely lacking in visual attractiveness. This may be especially true with some extended detention basins and retention basins lacking a base flow to prevent eutrophication during hot, dry weather. Questions also often arise about the use of valuable open space on projects for BMPs instead of alternative uses such as recreation. Most sand filter BMPs are visually unobtrusive and may be used in situations where aesthetic considerations or open space use are important.

Sediment Control

Intermittent sand filter BMPs which have been subjected to heavy sediment loadings have historically failed very quickly (LaRock, 1988; Harper and Herr, 1993). In a study in Denver, Colorado, Urbonis, Doerfer, and Tucket found that the hydraulic conductivity of a sand filter serving an equipment parking lot dropped rapidly as sediment accumulated on the surface of the filter (Urbonis, Doerfer, and Tucker, 1996) . A layer of sediment approximately 1/16 inch (1.6 millimeters) thick was found to limit hydraulic conductivity to 0.05 feet per hour (1.6 ft/day), considerably less than the design coefficient of permeability used by Northern Virginia jurisdictions in the design of sand filters (*ibid.*; Bell, Stokes, Gavan, and Nguyen, 1995). The filter media of intermittent sand filter BMPs must therefore be protected from excessive sediment loads. This requires isolation during construction of the development, site design to restrict the amount of runoff from pervious areas reaching the filter after construction, and proper sizing of sediment removing features of the BMP to match final site conditions.

1. ***Construction Runoff***

> *Sand filter BMPS must **never** be placed in service until all site work has been completed and stabilization measures have been installed and are functioning properly.*

When this precaution has not been taken in the past, the sand filter BMPs have become clogged with sediment from upland construction operations almost immediately, requiring complete reconstruction of the sand filter and sometimes the collector pipe system. This can prove very expensive. However, since most sand filter BMPs are constructed off-line with a flow splitting device employed to divert only the Water Quality Volume to the filter, the BMP may usually be completely constructed but isolated from runoff by blocking the inflow pipe until the site is fully stabilized.

2. ***Urban Runoff***

While experience indicates that intermittent sand filters fail very quickly when directly exposed to runoff from watersheds with low imperviousness and poor vegetated cover (LaRock, 1988; Harper and Herr, 1993), filters which treat runoff from almost exclusively impervious areas, such as highway surfaces, may perform satisfactorily for several years with very little maintenance (Shaver and Baldwin, 1991).

An 18-month, comprehensive study of runoff from street surfaces in 12 cities throughout the U.S. determined that, while most particulate matter is in the fractions equating to sand and gravel, the approximately 6 percent of particles in the silt and clay soil size contain over half the phosphorous and some 25 percent of other pollutants (Sartor, Boyd, and Agardy, 1974). **Table 3.12-4** illustrates this finding.

In planning the layout for a site on which sand filter BMPs are to be employed, care should be taken to direct only runoff from impervious surfaces to the filter insofar as possible. The drainage sheds feeding sand filter BMPs with only partial sediment protection (as delineated in the individual BMP discussions which follow) should ***never*** contain less than 65% impervious cover. Even when full sediment protection is provided in the form of a carefully sized presettlement basin, the amount of runoff from pervious areas directed to the filter must be minimized. The Denver study also indicates that full sediment protection may be required in areas subject to heavy atmospheric deposition of suspended solids even when only runoff from impervious surfaces is being treated.

The presettling basin or sedimentation chamber of an intermittent sand filter BMP is expected to remove all but the very fine particles of sediment, while most of the other pollutant removal is expected to occur in the sand filter, where the very fine particles will be trapped.

TABLE 3.12-4
Percent of Street Pollutants in Various Particle Size Ranges

	Particle Size (Microns)					
Pollutant	**>2000**	**840-2000**	**246-840**	**104-246**	**43-104**	**<43**

(Source: Shaver and Baldwin, 1990; adapted from Sartor, Boyd, and Agardy, 1974)

Trash Exclusion

Underground vault BMPs are confined space under Occupational Safety and Health Regulations and are therefore more expensive to enter and maintain than open facilities. Future operations and maintenance costs can substantially reduced by assuring that trash is, insofar as possible, excluded from entering the vault. Grated storm inlets and trash racks in flow splitters are two ready solutions to this problem.

Projected Hydrocarbon Loadings

Sand filters will quickly clog when subjected to direct heavy hydrocarbon loadings. Where such loadings are expected, a design which removes unemulsified hydrocarbons in a separate chamber or structure in the treatment train ahead of the filter should be selected.

Maintenance

The maintenance requirements for intermittent sand filters must be considered during the planning and design of the facility. All chambers of underground sand filters must have personnel access manholes and built-in access ladders . Access roads or streets must be of sufficient width and bearing capacity to support dump trucks loaded with accumulated sediments or heavy vacuum (e.g."VACTOR") trucks for removing accumulated sediments and hydrocarbons from sediment chambers and traps on a regular basis. Approximately every 3-5 years, the filter can be expected to clog to the point that replacement of the top few inches of sand or, where employed, the layer of washed gravel and the top layer of filter cloth will be required. **A minimum maintenance headspace of 60 inches above the filter is required in underground vault filters BMPs.** A 36-38-inch diameter maintenance manhole with a small, concentric personnel access lid or a rectangular load bearing access door (minimum 4 ft. x 4 ft.) should be positioned directly over the center of the filter. Large sedimentation basins and open filters must be equipped with access ramps to allow small earthmoving equipment such as "Bobcats" and light trash raking equipment to go into the basins. Finally, before finalizing the BMP design, follow the advice of Joseph J. Skupien, Principal Hydraulic Engineer of Somerset County, New Jersey, and "close your eyes, kick back, and think your BMP through a full year of operations, visualizing how it will perform under the conditions of all four seasons."

General Design Criteria

The purpose of this section is to provide recommendations and minimum criteria for the design of intermittent sand filter practices intended to comply with the Virginia Stormwater Management program's runoff quality requirements.

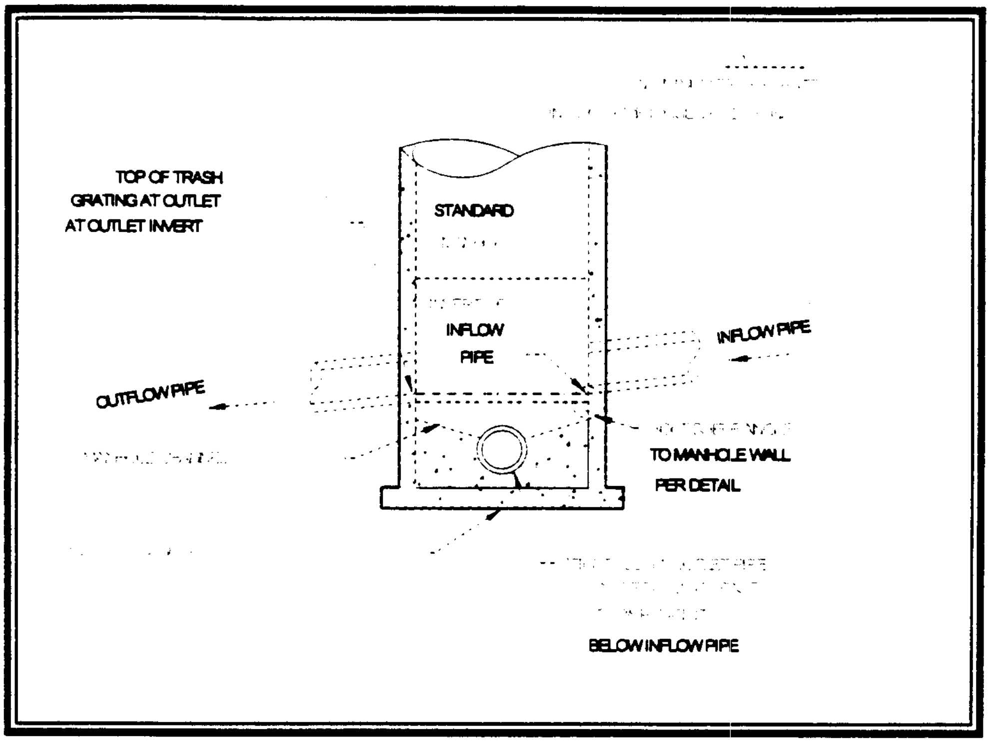
Several types of intermittent sand filter facilities are recognized for stormwater quality management purposes, including ***District of Columbia Underground Vault Filters***, ***Delaware Sand Filters***, ***Austin Full Sedimentation Sand Filters***, and ***Austin Partial Sedimentation Sand Filters***.

The general design criteria presented below apply to the design of intermittent sand filter facilities for ***water quality control***. This implies that the volume of runoff to be treated is determined by the **water quality volume** (the first 0.5 inches of runoff from the impervious surfaces on the site or drainage shed) and the desired pollutant removal efficiency.

Isolating the Water Quality Volume

The usual method for isolating the WQV is to construct an isolation/diversion weir in the stormwater channel or pipe, with the elevation of the weir set to allow overflow when the BMP is completely full. Additional runoff greater than the WQV spills over the weir to enter a peak flow rate reducer or exit directly to the storm sewer, minimizing mixing with the water in the BMP. Another approach is to provide a lower pipe to feed the filter until it fills, after which water rises in the slitter manhole and continues down a higher pipe. **Figure 3.12 - 2** illustrates this approach (source: Montgomery County, Maryland).

FIGURE 3.12 - 2
Flow Splitting Manhole Structure



Sizing Procedure

The majority of jurisdictions which are employing sand filter BMPs use hydraulic calculations based on Darcy's Law to establish the filter area that will allow flow-through of the treatment volume within the desired time frame, typically 40-48 hours (Austin, 1988, Shaver and Baldwin, 1991, Truong, 1989). Florida uses more complex falling-head computations and allows a drawdown time of up to 72 hours (Livingston, McCarron, Cox, and Sanzone, 1988). However, creating storage for the full WQV in shallow configuration systems may result in a larger filter than the hydraulic calculations would indicate (Alexandria, 1992).

Virginia uses the Austin Sand Filter Formula derived from Darcy's Law by the Austin Environmental and Conservation Services Department to size sand filters (Austin, 1988):

$A_f = I_a H d_f / k(h+d_f)t_f$ where,

A_f = surface area of sand bed (acres or sq. ft.)
I_a = impervious drainage area contributing runoff to the basin (acres or sq. ft.)
H = runoff depth to be treated (ft.)
d_f = sand bed depth (ft.)
k = coefficient of permeability for sand filter (ft/hr)

R0009805

h = average depth (ft.) of water above surface of sand media between full and empty basin conditions (½ max. depth)
t_f = time required for runoff volume to pass through filter media (hrs.)

1. Coefficient of Permeability

When first installed, the coefficient of permeability of sand filters may be as high as 3.0 ft/hour, but these will typically decrease dramatically after the first few storms. Actual observations of filters in Austin, Texas, established that "ripe" filters stabilized in the range of 0.5-2.7 ft/day for filters with partial sedimentation control (Austin, 1988). This is probably caused by a combination of clogging of some filter pores from sediment loads and initial consolidation of the filter sand. **Figure 3.12 - 3** illustrates the similar rapid decrease in coefficient of permeability as sediment loads accumulated on a sand filter in Denver, Colorado (Urbonas, Doerfer, and Tucker, 1996). Falling head tests on a one year old Delaware Sand Filter in Alexandria, Virginia, resulted in an average coefficient of permeability of 8.5 ft/day (Bell, Stokes, Gavan, and Nguyen, 1995). The Alexandria filter was treating only runoff from pavement surfaces, and the mean input concentration of total suspended solids was only in the range of 75 milligrams/liter (75ppm)(*ibid)*. The Denver runoff, by contrast, had a mean concentration of 400 ppm (Urbonas, Doerfer, and Tucker, 1996), while the filters observed by Austin lacked full sedimentation protection. Use of conservative values for the coefficient of permeability is clearly indicated.

Based on long term observation of existing sand filter basins, Austin uses k values of 3.5 feet per day for systems with full sedimentation pretreatment and 2.0 feet per day for systems with only partial sedimentation pretreatment (full sedimentation pretreatment is defined as complete removal of particles with a diameter equal to or greater than 20 microns). Virginia jurisdictions utilizing intermittent sand filter BMPs have also adopted these values. Full sedimentation may usually be accomplished by capturing the WQV and releasing it to the filter over 24 hours. **Figure 3.12-4** illistrates a full sedimentation basin in Austin. Partial sedmientation basins, such as the one shown on **Figure 3.12-1**, should hold at least 20 percent of the WQV.

2. Drawdown time

Both Austin and the Virginia jurisdictions employ a BMP drawdown time (t_f) of 40 hours. This allows the filter to fully drain down and dry out to maintain an aerobic environment between storms (filters which remain continually wet may develop anaerobic conditions, under which previously captured iron phosphates may break down and wash out).

3. Simplified Filter Formula for Filters with Full Sedimentation Protection

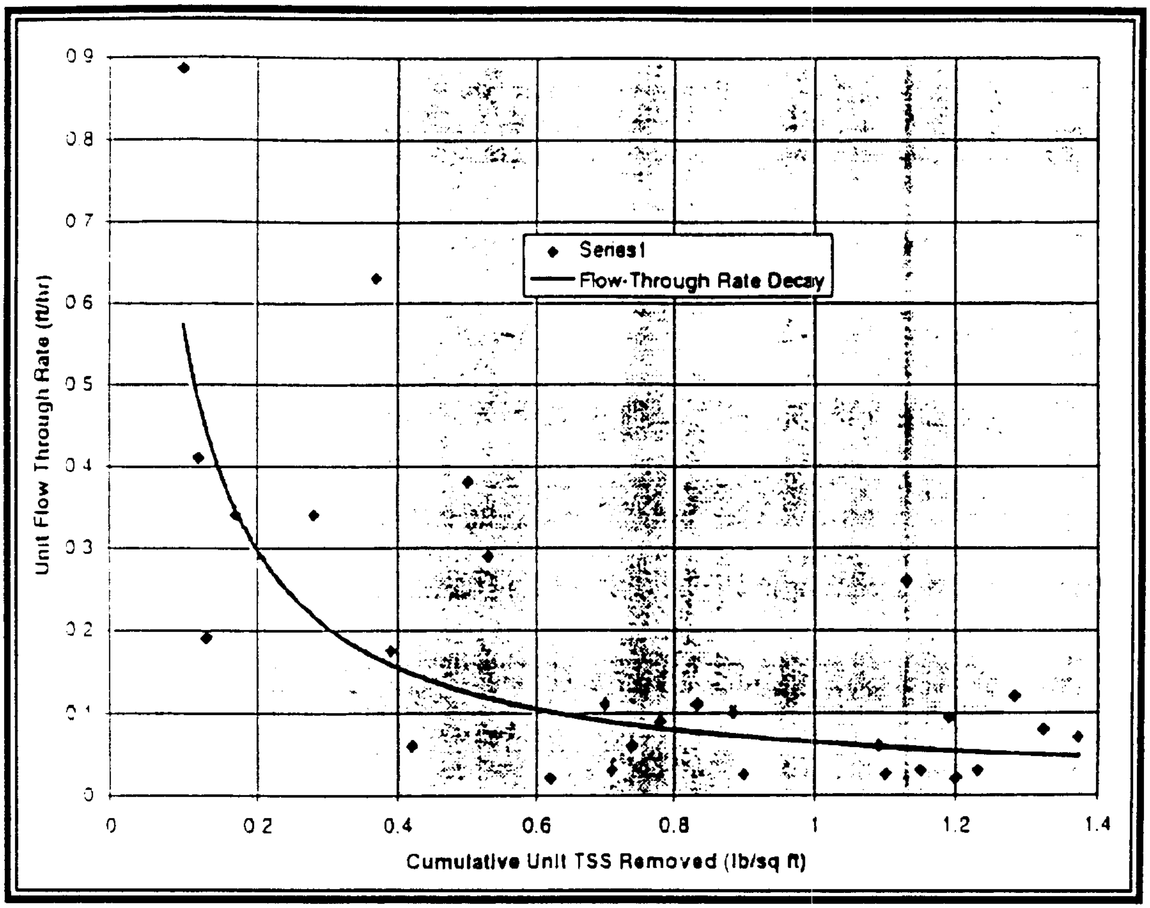
(Sedimentation Basin containing full WQV with 24-hour drawdown to filter)

With k = 3.5 ft/day (0.146 ft/hour) and t_f = 40 hours, the sand filter formula reduces to:

$$A_{f(FS)} = 310 I_a d_f / (h + d_f)$$

where A_f is in ft^2 and I_a is in acres.

FIGURE 3.12-3
Degradation of Hydraulic Conductivity of Denver Sand Filter



(Source: Urbonas, Doeffler, and Tucker, 1996)

4. **Simplified Filter Formula for Filters with Partial Sedimentation Protection**
(Sediment Chamber containing 20% of WQV with free hydraulic flow to filter)

With k = 2.0 ft/day (.0833 ft/hour) and t_f = 40 hours, the formula reduces to:

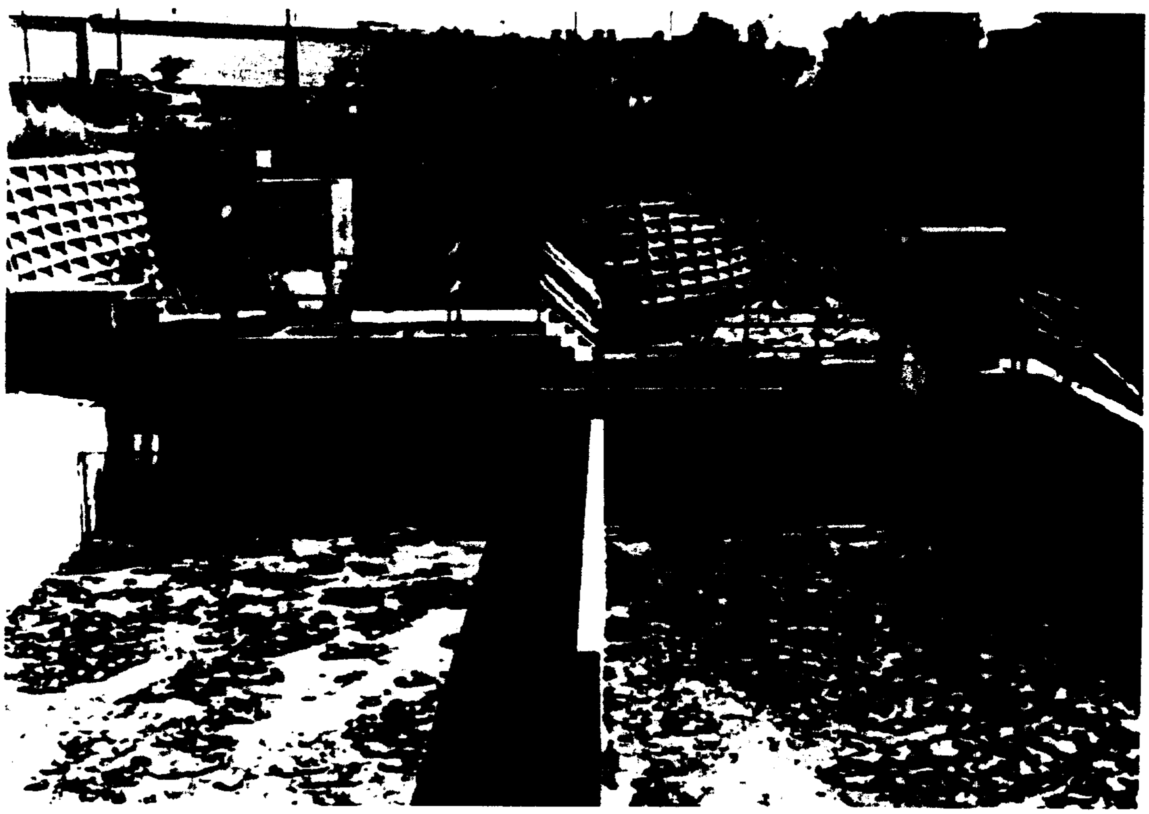
$$A_{f(PS)} = 545 I_a d_f / (h + d_f)$$

where A_f is in ft^2 and I_a is in acres.

FIGURE 3.12-4

R0009807

Full Sedimentation Basin on Austin Sand Filter



Exclusion of Continuous Flows and Chloronated Flows

Intermittent sand filter BMPs will **NOT** function properly if subjected to continuous or frequent flows. The basic principles upon which they operate assume that the sand filter will dry out and reaerate between storms. If the sand is kept continually wet by such flows as basement sump pumps, anaerobic conditions will develop, creating a situation under which previously captured iron phosphates degrade, leading to **export** of phosphates rather than the intended high phosphorous removal (Bell, Stokes, Gavan, and Nguyen, 1995). It is also essential to **exclude flows containing chlorine and other swimming pool and sauna chemicals** since these will kill the bacteria upon which the principle nitrogen removal mechanisms depend.

> ***Continuous or frequent flows (such as basement sump pump discharges, cooling water,condensate water, ariesian wells, etc.) and flows containing swimming pool and sauna chemiclals*** *must be* ***EXCLUDED*** *from routing through intermittent sand filter BMPs since such flows will cause the BMP to* ***MALFUNCTION!***

R0009808

Checklists

The **Construction Inspection and As-Built Survey Checklist** found in **Appendix 3D** is for use in inspecting intermittent sand filter facilities during construction and, where required by the local jurisdiction, engineering certification of the filter construction. The **Operation and Maintenance Checklist**, also found in **Appendix 3D**, is for use in conducting maintenance inspections of intermittent sand filter facilities.

MINIMUM STANDARD 3.12A

WASHINGTON D.C. UNDERGROUND VAULT SAND FILTER
(WET SEDIMENTATION CHAMBER)

Definition

A Washington D.C. vault sand filter is an underground stormwater sand filter contained in a structural shell with three chambers. The shell may be either precast or cast-in-place concrete, corrugated metal pipe, or fiberglass tanks. This BMP was developed by Mr. Hung V. Truong of the D.C. Environmental Regulation Administration. **Figure 3.12A-1** depicts Mr. Truong's system.

The three feet deep plunge pool in the first chamber and the throat of the second chamber, which are hydraulically connected by an underwater rectangular opening, absorbs energy and provides pretreatment, trapping grit and floating organic material such as oil, grease, and tree leaves.

The second chamber also contains a typical intermittent sand filter. The filter material consists of gravel, sand, and filter fabric. At the bottom is a subsurface drainage system of pierced PVC pipe in a gravel bed. The primary filter media is 18-24 inches of sand. A layer of plastic reinforced geotextile filter cloth secured by gravel ballast is placed on top of the sand. The top filter cloth is a pre-planned failure plane which can readily be replaced when the filter surface becomes clogged. A dewatering drain controlled by a gate valve must be installed to facilitate maintenance.

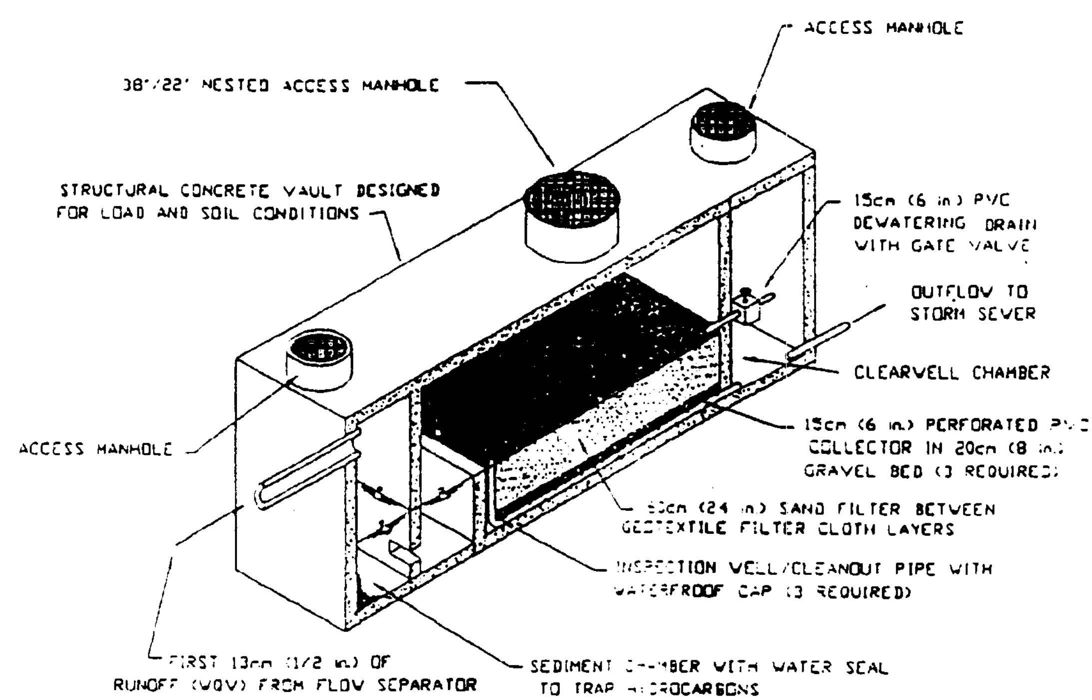
The third chamber, or clearwell, collects the flow from the underdrain pipes and directs it to the storm sewer.

In Virginia, D.C. Sand Filters will normally be placed off-line and be sized to treat the WQV.

Purpose

D.C. Sand Filters are primarily used for water quality control. However, they do provide detention and slow release of the water quality volume from the site being treated. Whether this amount will be sufficient to provide the necessary peak flow rate reductions required for channel erosion control is dependent upon site conditions (hydrology) and required discharge reductions. The 10-year and 100-year flows will usually exceed the detention capacity of a sand media filter. When this occurs, separate quantity must be provided.

FIGURE 3.12A - 1
Washington D.C. Underground Vault Sand Filter



Conditions Where Practice Applies

D.C. Sand Filters are ultra-urban BMPs best suited for use in situations where space is too constrained and/or real estate values are too high to allow the use of conventional retention ponds. Where possible, runoff treated should come only from impervious surfaces.

Drainage Area

Drainage areas served by one vault filter should be limited to 1.25 acres. For larger drainage sheds, either multiple vault filters or Austin Full Sedimentation Filters (surface or vault) should be utilized.

R0009811

Development Conditions

D.C. Sand Filters are generally suitable BMPs for medium to high density commercial or industrial development. Because of confined space entry restrictions and maintenance requirements, they are not generally suitable for residential applications except for apartment complexes or large condominiums where a dedicated maintenance force will be present.

Planning Considerations

Refer to the **Planning Considerations** for **General Intermittent Sand Filter Practices, Minimum Standard 3.12,** previously discussed in this section. Of special concern are the stormwater infrastructure serving the site and the requirement to isolate the sand filter from receiving flows until the drainage shed is fully stabilized.

Potential and existing elevations of stormwater infrastructure serving the site will determine one of the most critical design parameters: the maximum depth to which runoff may be pooled over the filter and preserve a gravity flow configuration (whatever the pooling depth, there must be a minimum of five feet of clearance between the top of the filter and the top slab of the filter shell to allow filter maintenance).

Sand filter BMPS must ***never*** *be placed in service until all site work has been completed and stabilization measures have been installed and are functioning properly.*

Design Criteria

The purpose of this section is to provide recommendations and minimum criteria for the design of D.C. Sand Filter BMPs intended to comply with the Virginia Stormwater Management program's runoff quality requirements.

Refer to the **General Design Criteria** previously discussed under **General Intermittent Sand Filter Practices, Minimum Standard 3.12**

Filter Sizing Criteria

The D.C. Sand Filter is a partial sedimentation protection intermittent sand filter BMP. To compute the minimum area of filter required, utilize the Austin Filter Formula for partial sedimentation treatment:

$$A_{fm(PS)} = \frac{545 I_a d_f}{(h + d_f)}$$

where,

A_{fm} = minimum surface area of sand bed (square feet)
I_a = impervious cover on the watershed in acres
d_f = sand bed depth (normally 1.5 to 2ft)
h = average depth of water above surface of sand media between full and empty basin conditions (ft.)

Structural Requirements

The load-carrying capacity of the filter structure must be considered when it is located under parking lots, driveways, roadways, and, certain sidewalks (such as those adjacent to State highways). Traffic intensity may also be a factor. The structure must be designed by a licensed structural engineer and the structural plans require approval by the plan approving jurisdiction.

Design Storm

The inlet design or integral large storm bypass must be adequate for isolating the WQV from the design storm for the receiving storm sewer system (usually the 10 year storm) and for conveying the peak flow of that storm past the filter system. Since D.C. Sand Filters will be used only as off-line facilities in Virginia, the interior hydraulics of the filter are not as critical as when used as an on-line facility. The system should draw down in approximately 40 hours.

Infrastructure Elevations

For cost considerations, it is preferable that D.C. Sand Filters work by gravity flow. This requires sufficient vertical clearance between the invert of the prospective inflow storm piping and the invert of the storm sewer which will receive the outflow. In cases where gravity flow is not possible, a clearwell sump and pump are required to discharge the effluent into storm sewer. Such an application would be appropriate in commercial or industrial situations where a dedicated maintenance force will be available (shopping malls, apartment houses, factories of other industrial complexes, etc.).

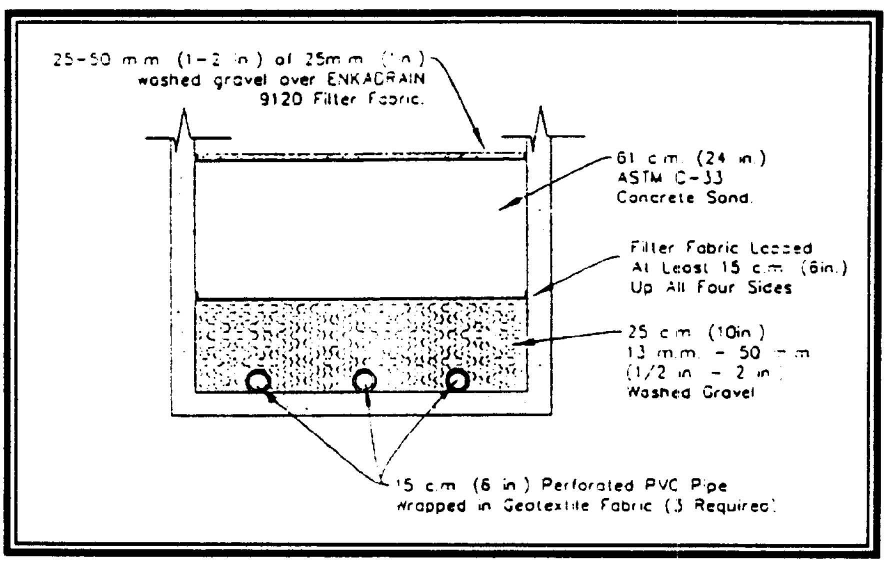
Accessibility and Headroom for Maintenance

Both the sedimentation basin and the filter must be accessible to approriate equipment and vacuum trucks for removing accumulated sediments and trash. The sedimentation basin must be cleaned approximately once per year, and the filter will likely need raking on that frequency to remove trash and restore permeability. When filters are placed in underground vaults, all three chambers must have personnel access manholes and built-in access ladders. **A minimum headspace of 60 inches above the filter is required to allow such maintenance and repair.** A 38-inch diameter maintenance manhole with eccentric nested covers (a 22-inch personnel access lid inside the 38-inch diameter lid) or a rectangular load bearing access door (minimum 4 ft. x 4 ft.) should be positioned directly over the center of the filter.

Construction Specifications

Figure 3.12A-2 is a cross-section of the filter chamber.

FIGURE 3.12A - 2
D.C. Sand Filter Cross-Section



R0009814

Depth of Sedimantation Pool

The sedimentation "plunge pool" must be at least 36 inches deep to properly remove sediment and absorb energy from the incoming flow.

Depth of the Underwater Opening Between Chambers

To preserve an effective hydrocarbon trap, the top of the underwater opening between chambers must be at least 18 inches below the depth of the weir which divides the filter from the pool. To retain sediment in the first chamber, the bottom of the opening should be at least six inches above the floor. The area of the opening should be at least 1.5 times the cross-sectional area of the inflow pipe(s) to assure that the water level remains equal between the first and second chambers.

Total Depth of Filter Cross-Section

The total depth of the filter cross-section must match the height of the weir dividing the sedimentation pool from the filter. Otherwise, a "waterfall" effect will develop which will gouge out the front of the filter media. If a sand filter less than 24 inches is used, the gravel layer must be increased accordingly to preserve the overall filter depth.

Upper Aggregate Layer

The washed aggregate or gravel layer at the top of the filter shall be at least one inch thick and meet ASTM standard specifications (1-inch maximum diameter).

Geotextile Fabrics

The filter cloth layer beneath the upper aggregate layer shall be reinforced by an HDPE or PVC geomatrix (such as ENKADRAIN 9120) and meet the specifications shown in **Table 3.12C-1**. The filter fabric between the sand layer and the collector gravel shall conform to the specifications in **Table 3.12A-2**. The fabric rolls must be cut with sufficient dimensions to cover the entire wetted perimeter of the filtering area and lap up the filter walls at least six-inches.

Sand Filter Layer

For applications in Virginia, use **ASTM C33 Concrete Sand** or sand meeting the Grade A fine aggregate gradation standards of Section 202 of the VDOT ***Road and Bridge Specifications.*** The top of the sand filter must be completely level.

TABLE 3.12A - 1

Specifications for Nonwoven Geotextile Fabric Beneath Sand in D.C. Filter

Property	Test Method	Unit	Specification
Unit Weight	--	Oz./sq.yd.	8.0 (min.)
Filtration Rate	--	In/sec	0.08 (min.)
Puncture Strength	ASTM D-751 (Modified)	Lb.	125 (min.)
Mullen Burst Strength	ASTM D-751	Psi	400 (min.)
Equiv. Opening Size	U.S. Standard Sieve	No.	80 (min.)
Tensile Strength	ASTM D-1682	Lb.	300 (min.)

Gravel Bed Around Collector Pipes

The gravel layer surrounding the collector pipes shall be ½ to two (2) inch diameter gravel and provide at least two (2) inches of cover over the tops of the drainage pipes.

Underdrain Piping

The underdrain piping consists of three 6-inch schedule 40 or better polyvinyl perforated pipes reinforced to withstand the weight of the overburden. Perforations should be 3/8 inch, and each row of perforations shall contain at least six (6) holes. Maximum spacing between rows of perforations shall be six (6) inches.

The minimum grade of piping shall be 1/8 inch per foot (one [1] percent slope). Access for cleaning all underdrain piping is needed. Clean-outs for each pipe shall extend at least six (6) inches above the top of the upper filter surface, e.g. the top layer of gravel.

Each pipe shall be thoroughly wrapped with 8 oz./sq.yd. geotextile fabric meeting the specification in **Table 3.12A-2** above.

Dewatering Drain

When the filter is placed in an underground vault, A 6-inch dewatering drain controlled by a gate valve shall be installed between the filter chamber and the clearwell chamber with its invert at the elevation of the top of the filter. The dewatering drain penetration in the chamber dividing wall shall be sealed with a flexible strip joint sealant which swells in contact with water to form a tight pressure seal.

Access Manholes

When the filter is installed in an underground vault, access to the headbox (sediment chamber) and the clearwell shall be provided through at least 22-inch manholes. Access to the filter chamber shall be provided by a rectangular dood (minimum size: 4 feet by four feet) of sufficient strength to carry prospective imposed loads or by a manhole of at least 3- inch diameter with an offset concentric 22-inch lid (Neenah R-1741-D or equivalent).

Protection from Construction Sediments

The site erosion and sediment control plan must be configured to permit construction of the filter system while maintaining erosion and sediment control.

No runoff is to enter the sand filtration system prior to completion of all construction and site revegitation. Construction runoff shall be treated in separate sedimentation basins and routed to by-pass the filter system. Should construction runoff enter the filter system prior to site revegitation, all contaminated materials must be removed and replaced with new clean materials.

Watertight Integrity Test

After completion of the filter shell but before placement of the filter layers, entrances to the structure shall be plugged and the shell completely filled with water to demonstrate water tightness. Maximum allowable leakage is 5 percent of the filter shell volume in 24 hours. Should the structure fail this test, it shall be made watertight and successfully retested prior to placement of the filter layers.

Hydraulic Compaction of Filter Components

After placement of the collector pipes, gravel, and lower geotextile layer, fill the shell with filter sand to the level of the top of the sediment pool weir. Direct clean water into the sediment chamber until both the sediment chamber and filter chamber are completely full. Allow the water to draw down until flow from the collector pipes ceases, hydraulically compacting the filter sand. After allowing the sand to dry out for a minimum of 48 hours, refill the shell with sand to a level one inch beneath the top of the weir and place the upper geotextile layer and gravel ballast.

Portland Cement Concrete

Concrete liners may be used for sedimentation chambers and for sedimentation and filtration basins. Concrete shall be at least five (5) inch thick Class A3 defined in the Virginia Department of Transportation *Road and Bridge Specifications*.

Maintenance/Inspection Guidelines

The following maintenance and inspection guidelines are not intended to be all inclusive. Specific facilities may require other measures not discussed here.

Inspection Schedule

The water level in the filter chamber shall be monitored by the owner on a quarterly basis and after every large storm for the first year after completion of construction and a log shall be maintained of the results indicating the rate of dewatering after each storm and the water depth for each observation. Once the governing jurisdiction staff indicates that satisfactory performance of the structure has been demonstrated, the monitoring schedule can be reduced to an semiannual basis.

The BMP shall be inspected annually by representatives of the owner and the governing jurisdiction to assure continued proper functioning.

Sediment Chamber Pumpout

The sediment chamber must be pumped out halfway through the inspection cycle (e.g. after six months) and after each joint owner-governing jurisdiction annual inspection. If the chamber contains an oil skim, it should be removed by a firm specializing in oil recovery and recycling. The remaining material may then be removed by vacuum pump and disposed of in an appropriate landfill. **After each cleaning, refill the first chamber to a depth of three feet with clean water to reestablish the water seals.**

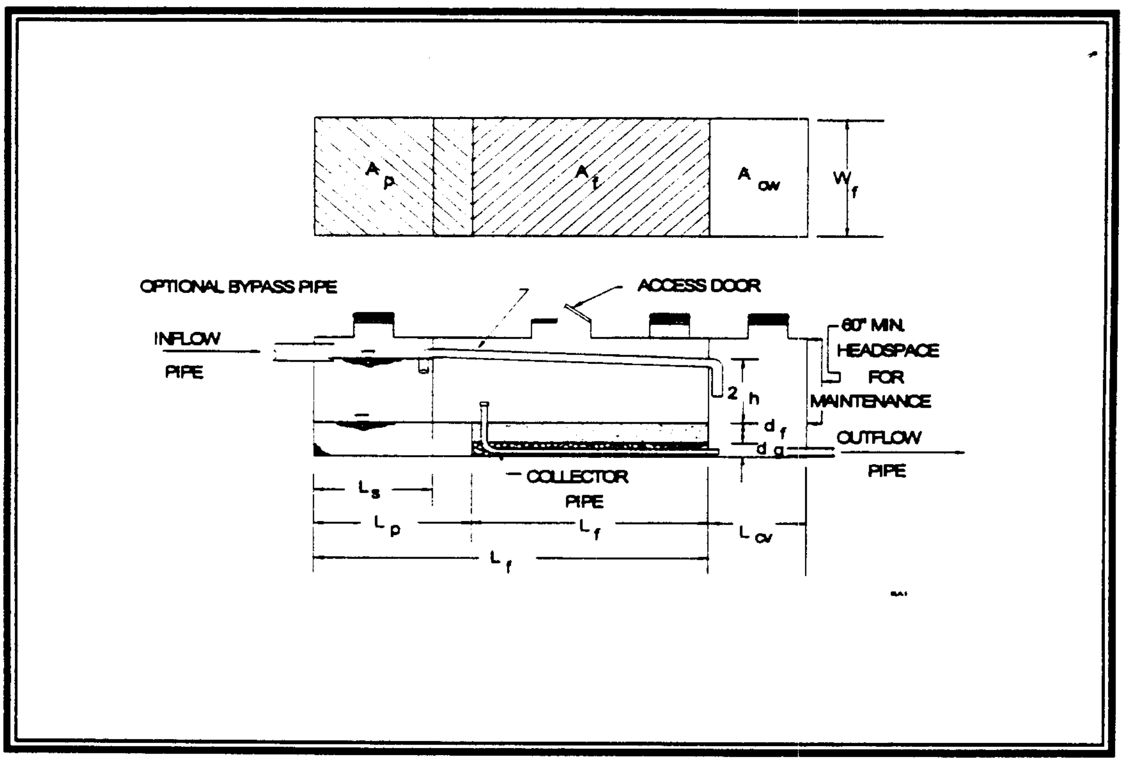
When the filter will no longer draw down within the required 40-hour period, the top layer of filter cloth and ballast gravel must be removed and replaced with new materials conforming to the original specifications. Any discolored or sediment contaminated sand shall also be removed and replaced.

Design Procedures

The following design procedure is structured to assure that the desired water quality volume is captured and treated by the D.C.Sand Filter. The procedure assumes that a filter shell with a rectangular cross-section is to be used.

Figure 3.12A-3 shows the dimensional relationships for a D.C. Sand Filter.

FIGURE 3.12A - 3
Dimensional Relationships for a D.C. Sand Filter



R0009819

Standard Design Logic

Employ the following design logic to design D.C. Sand Filters for use in Virginia:

1. Determine Governing Site Parameters

Determine the Impervious area on the site (I_a in acres), the water quality volume to be treated (WQV in $ft.^3 = 1816\, I_a$), and the site parameters necessary to establish 2h, the maximum ponding depth over the filter (storm sewer invert at proposed connection point, elevation to inflow invert to BMP, etc).

2. Select Filter Depth and Determine Maximum Ponding Depth

Considering the data from Step 1) above, select the Filter Depth ((d_f) and determine the maximum achievable ponding depth over the filter (2h).

3. Compute the Minimum Area of the Sand Filter (A_{fm})

To compute the area of the filter, use the formula:

$$A_{fmPS} = \frac{545 I_a d_f}{(h + d_f)}$$

A_{fm} = minimum surface area of sand bed (square feet)
I_a = impervious cover on the watershed in acres
d_f = sand bed depth (normally 1.5 to 2ft)
h = average depth of water above surface of sand media between full and empty basin conditions (ft.)

4. Select Filter Width and Compute Filter Length and Adjusted Filter Area

Considering site constraints, select the Filter Width (W_f). Then compute the Filter Length (L_f) and the Adjusted Filter Area (A_f)

$$L_f = A_{fm}/W_f$$

$$A_f = W_f \times L_f$$

Note: From this point forward, computations assume a rectangular filter.

5. Compute the Storage Volume on Top of the Filter (V_{Tf})

$$V_{Tf} = A_f \times 2h$$

6. Compute the Storage in the Filter Voids (V_v)
   (Assume 40% voids in filter media)

$$V_v = 0.4 \times A_f \times (d_f + d_g)$$

7. Compute Flow Through Filter During Filling (V_Q)
   (Assume 1-hour to fill per D.C. practice)

$$V_Q = \frac{kA_f(d_f + h)}{d_f} \text{ ; use } k = 2 \text{ ft./day} = 0.0833/\text{hr.}$$

8. Compute Net Volume to be Stored Awaiting Filtration (V_{st})

$$V_{st} = WQV - V_{Tf} - V_v - V_Q$$

9. Compute Length of the Permanent Pool (Lpm)

$$Lpm \quad \frac{V_{st}}{(2h \times W_f)}$$

10. Compute Minimum Length of the Sediment Chamber (Lsc)
    (to contain 20% of WQV per Austin practice)

$$L_{sm} = \frac{0.2WQV}{(2h \times W_f)}$$

11. Set Final Length of the Permanent Pool (L_p)

$$\text{If } L_{pm} \geq L_{sm} + 2 \text{ ft., make } L_p = L_{pm}$$

$$\text{If } L_{pm} < L_{sm} + 2 \text{ ft., make } L_p = L_{sm - 2 \text{ ft.}}$$

It may be economical to adjust final dimensions to correspond with standard precast structures or to round off to simplify measurements during construction.

Set the length of the clearwell (L_{cw}) for adequate maintenance and/or access for monitoring flow rate and chemical composition of the effluent (minimum = 3 ft.)

Minimizing Filter Shell Costs

Underground vault sand filter costs have been widely varying because many developers have simply had their foundation contractors cast the vault in place. Each installation therefore became a prototype with associated costs and overhead. Precast manufacturers currently offer precasting services for D.C. and other types of sand filter vaults, which should stabilize underground vault costs. **Figure 3.12A-4** is a photograph of a segmented precast filter shell installation in Alexandria.

Checklists

Worksheet 3.12A is for use in sizing calculations for D.C. Sand Filters. The **Construction Inspection and As-Built Survey Checklist** found in **Appendix 3D** is for use in inspecting intermittent sand filter facilities during construction and, where required by the local jurisdiction, engineering certification of the filter construction. The **Operation and Maintenance Checklist**, also found in **Appendix 3D**, is for use in conducting maintenance inspections of intermittent sand filter facilities.

= ________ + ________ + ________ + ________

= [ ] ft

Part 12: Design Effluent Pump if Required

Since pump must be capable of handling flow when filter is new, use k = 12 feet/day = 0.5 ft/hr

$$Q = \frac{kA_f(d_f + h)}{d_f}$$

= [0.5 x ________ x (________ + ________)] / ________

= [ ] ft^3/hr ; /3600 = [ ] cfs;

x 448 = [ ] gpm

Part 13: Design Structural Shell to Accommodate Soil and Load conditions at Site:

It may be economical to adjust final dimensions upward to correspond with standard precast structures or to round dimensions upward to simplify layout during construction.

MINIMUM STANDARD 3.12B

DELAWARE SAND FILTER (DSF) SYSTEMS

Definition

Mr. Earl Shaver of the Delaware Department of Natural Resources and Environmental Control has developed a surface sand filter system for use in Delaware ([illegible]

As originally conceived, the Delaware Sand Filter is an **on-line** facility processing all stormwater exiting the treated site up to the point that its overflow limit is reached (Delaware provides for treating the first one inch of runoff). However, when employed in Virginia, it will usually be provided with an integral flow-splitter to isolate and treat the Water Quality Volume.

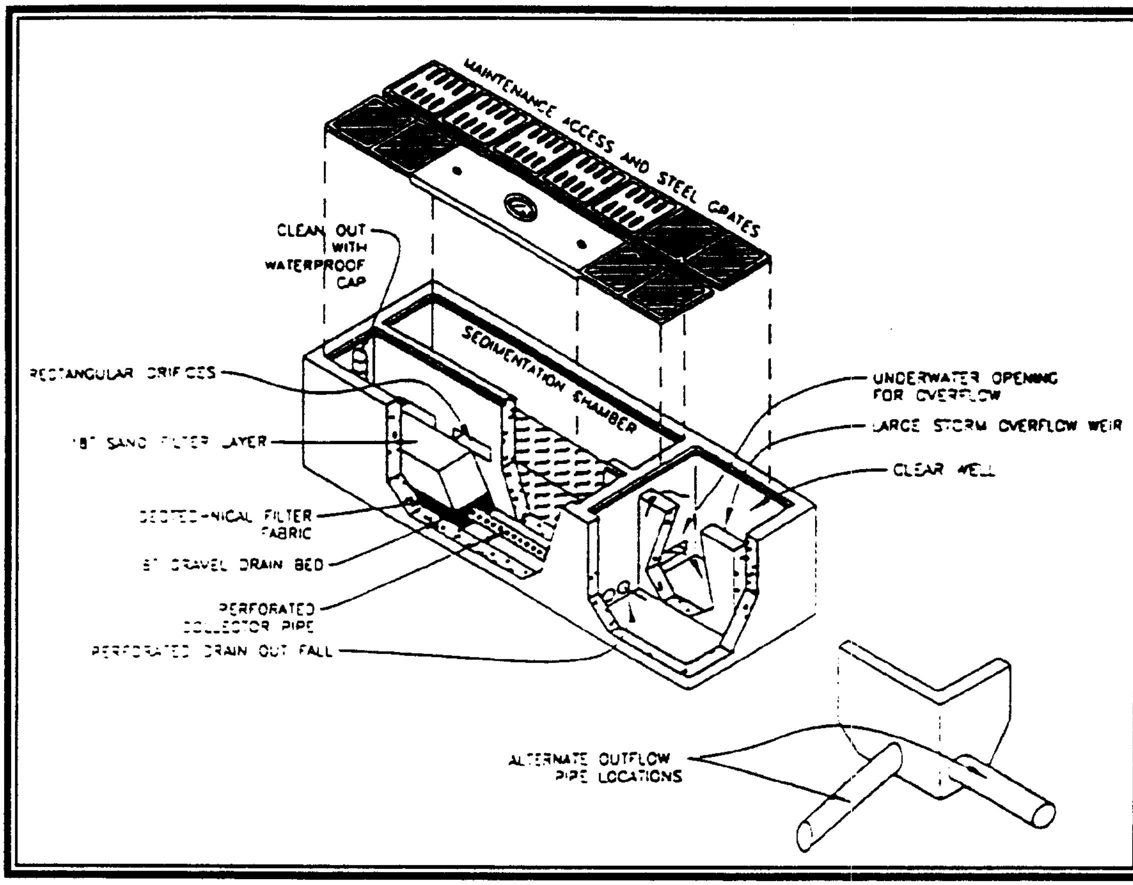
Figure 3.12B-1 shows a schematic drawing of the Delaware Sand Filter as used in Virginia. The system consists of two parallel concrete trenches connected by close-spaced wide notches in the wall dividing the trenches. The trench adjacent to the site being served is the sedimentation chamber. When accepting sheet flow, it is fitted with a grated cover. Concentrated stormwater may also be conveyed to the chamber in enclosed storm drain pipes. The second chamber, which contains the sand filter, is always fitted with a solid cover.

Storm flows enter the sedimentation chamber through the grates, causing the sedimentation pool to rise and overflow into the filter chamber through the weir notches in the dividing wall, assuring that the water to be treated **arrives at the filter as sheet flow**. This is essential to prevent scouring out the sand. The permanent pool in the sedimentation chamber is dead storage, which inhibits resuspension of particles that were deposited in earlier storms and prevents the heavier sediments from being washed into the filter chamber. Floatable materials and hydrocarbon films, however, may reach the filter media through the surface outflow.

The second trench contains at least 18 inches of ASTM C-33 Concrete Sand . When used in Virginia, an underdrain capability must be provided. Runoff percolates through the sand to the underdrain (s) and exits into the flow splitter/clearwell.

A transverse flow-splitter/clearwell at the lower end of the structure collects treated effluent and overflow and conveys the water to the storm sewer. When the filter shell fills with the Water Quality Volume, excess flow is forced through the underwater opening from the sedimentation chamber to the "wet" section of the clearwell to overflow the weir to the outflow pipe chamber. Floating trash and hydrocarbons are retained in the sedimentation chamber by this "trap."

FIGURE 3.12B - 1
Precast Delaware Sand Filter as Used in Virginia



Purpose

Delaware Sand Filters primarily used for water quality control. However, they do provide detention and slow release of the water quality volume from the site being treated. Whether this amount will be sufficient to provide the necessary peak flow rate reductions required for channel erosion control is dependent upon site conditions (hydrology) and required discharge reductions. The 10-year and 100-year flows will usually exceed the detention capacity of a sand media filter. When this occurs, separate quantity must be provided.

Conditions Where Practice Applies

Delaware Sand Filters are ultra-urban BMPs best suited for use in situations where space is too constrained and/or real estate values are too high to allow the use of conventional retention ponds. A major advantage of the Delaware Sand Filter is that it can be installed in shallow configurations, which is especially critical in flatter regions where high water tables or shallow storm sewers exist. The simplicity of the system and the ready accessibility of the chambers for periodic maintenance allow it to be used where a filter built in confined space is unacceptable. Where possible, only runoff from impervious surfaces should be treated.

Drainage Area

Drainage areas served by one filter should be limited to approximately one acre. For larger drainage sheds, multiple DSFs may be used.

Development Conditions

Delaware Sand Filters are generally suitable BMPs for medium to high density commercial or industrial development. Because of confined space entry restrictions and maintenance requirements, they are not generally suitable for residential applications except for apartment complexes or large condominiums where a dedicated maintenance force will be present.

Planning Considerations

Refer to the **Planning Considerations** for **General Intermittent Sand Filter Practices, Minimum Standard 3.12,** previously discussed in this section. Of special concern are the stormwater infrastructure serving the site and the requirement to isolate the sand filter from receiving flows until the drainage shed is fully stabilized.

Potential and existing elevations of stormwater infrastructure serving the site will determine one of the most critical design parameters: the maximum depth to which runoff may be pooled over the filter and preserve a gravity flow configuration.

> *Sand filter BMPS must **never** be placed in service until all site work has been completed and stabilization measures have been installed and are functioning properly.*

Design Criteria

The purpose of this section is to provide recommendations and minimum criteria for the design of Delaware Sand Filter BMPs intended to comply with the Virginia Stormwater Management program's runoff quality requirements.

Refer to the **General Design Criteria** previously discussed under **General Intermittent Sand Filter Practices, Minimum Standard 3.12**

Filter Sizing Criteria

Because of the shallow configuration of this BMP, resulting in low levels of hydraulic head above the filter, application of the usual partial sedimentation filter formula may not create enough storage volume to contain the WQV. With the dimensional relationships shown in **Figure 3.12B-2** and k = 2.0 ft/day, the required DSF filter area to contain the WQV may be written as follows:

$$A_f = \frac{1816 I_a}{(4.1h + 0.9)} = \frac{WQV}{(4.1h + 0.9)}$$

where:

A_f = the **area of the filter** in sq.ft.
I_a = the impervious area on the watershed in acres
h = 1/2 the maximum ponding depth over the filter (ft.)

If the maximum ponding depth above the filter (2h) is less than 2.67 feet (2'-8"), the WQV storage requirement governs and the above foumula must be used to size the filter (Alexandria, 1992). If the the maximum ponding depth above the filter (2h) is 2.67 feet or greater, use the partial sedimentation filter formula:

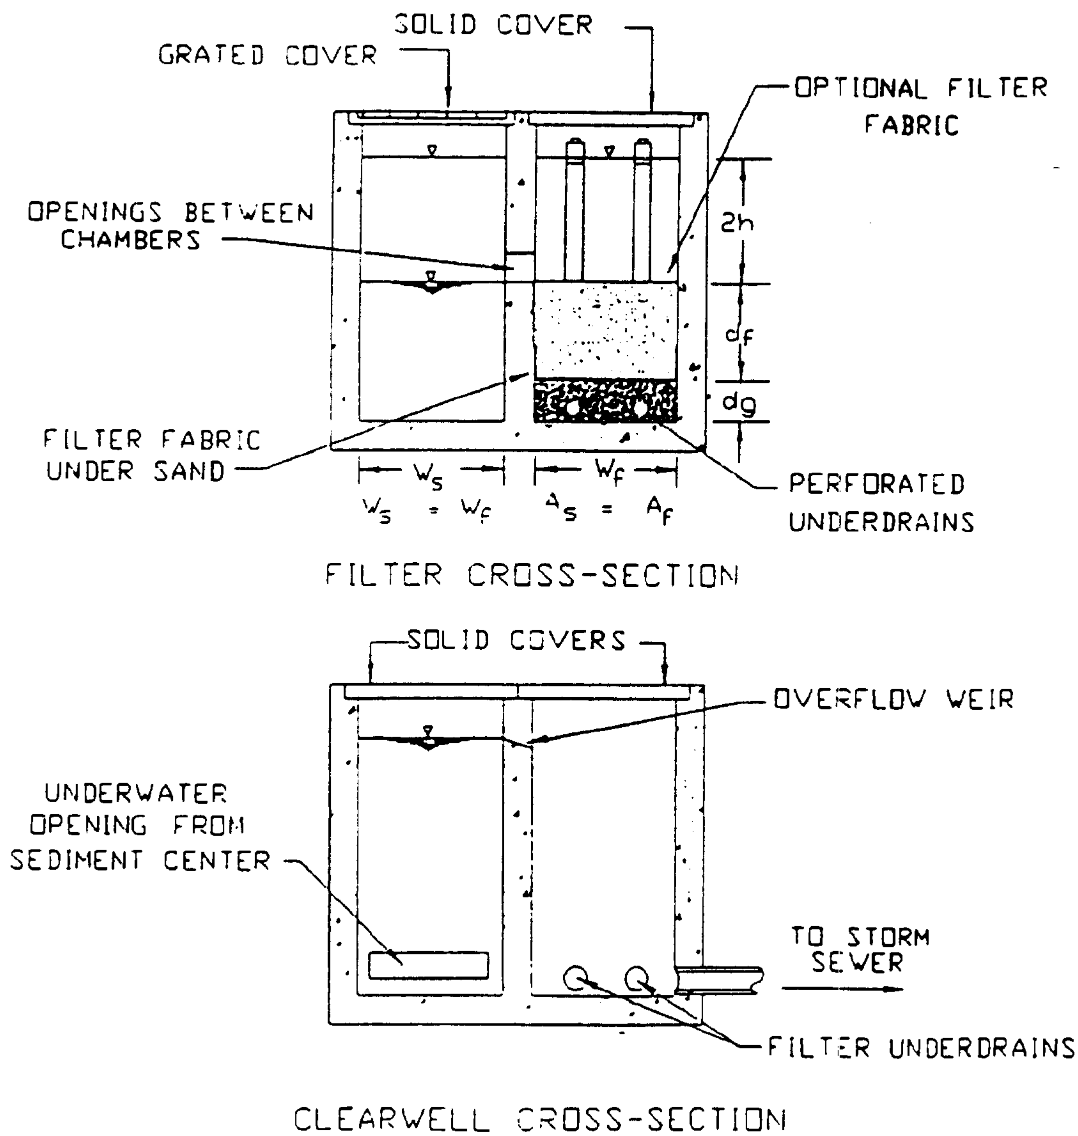
$$A_f = \frac{545 I_a d_f}{(h + d_f)}$$

Where d_f = depth of the filter media in ft. (1.5-2.0)

Delaware and Virginia make the area of the sediment chamber(A_s) equal the area of the filter:

$$A_f = A_s$$

FIGURE 3.12B- 2
Dimensional Relationships for Delaware Sand Filter



Structural Requirements

When the system is placed in a street or parking lot, it must be designed to support traffic wheel loads. When placed completely off the pavement, lower structural loads will be involved. The structure must be designed by a licensed professional engineer, and the design must be approved by the governing jurisdiction.

Design Storm

The inlet integral large storm bypass must be adequate for isolating the WQV from the design storm for the receiving storm sewer system (usually the 10 year storm) and for conveying the peak flow of that storm past the filter system. The system should draw down in approximately 40 hours.

Infrastructure Elevations

For cost considerations, it is preferable that Delaware Sand Filters work by gravity flow. This requires sufficient vertical clearance between the invert of the prospective inflow storm piping and the invert of the storm sewer which will receive the outflow. In cases where gravity flow is not possible, a clearwell sump and pump are required to discharge the effluent into storm sewer. Such an application would be appropriate in commercial or industrial situations where a dedicated maintenance force will be available (shopping malls, apartment houses, factories of other industrial complexes, etc.).

Construction Specifications

Upper Aggregate Layer

Some jurisdictions require a layer of filter cloth and gravel on top of the filter. When used, the washed aggregate or gravel layer at the top of the filter shall be one inch thick and meet ASTM standard specifications (1 inch maximum diameter.)

Geotextile Fabrics

When used, the filter fabric beneath the one-inch layer of gravel on top of the filter shall be Enkadrain 9120 filter fabric or equivalent with the specifications shown in **Table 3.12B - 1**.

Table 3.12B - 1
Specifications for Nonwoven Geotextile Fabric on Top of Delaware Sand Filter

Property	Test Method	Unit	Specification
Unit Weight	ASTM D-1777	Oz./sq.yd.	4.3 (min.)
Flow Rate	Falling Head Test	Gpm/sq.ft.	120 (min.)
Puncture Strength	ASTM D-751 (Modified)	Lb.	60 (min.)
Thickness	--	In.	0.8 (min.)

In instances where heavy hydrocarbon loadings are expected, a layer of activated carbon impregnated filter fabric such as Enkadrain PF-3 may be advantageous. When used, a plan to dispose of the hydrocarbon laden used filter fabric must be approved by the applicable jurisdiction prior to placing the sand filter in service.

The filter cloth layer beneath the sand shall conform to the specifications shown in **Table 3.12B-2**.

Table 3.12B - 2
Specifications for Nonwoven Geotextile Fabric Beneath Sand in Delaware Sand Filter

Property	Test Method	Unit	Specification
Unit Weight	--	Oz./sq.yd.	8.0 (min.)
Filtration Rate	--	In/sec	0.08 (min.)
Puncture Strength	ASTM D-751 (Modified)	Lb.	125 (min.)
Mullen Burst Strength	ASTM D-751	Psi	400 (min.)
Equiv. Opening Size	U.S. Standard Sieve	No.	80 (min.)
Tensile Strength	ASTM D-1682	Lb.	300 (min.)

The fabric rolls must be cut with sufficient dimensions to cover the entire wetted perimeter of the filtering area and lap up the filter walls at least six-inches.

Sand Filter Layer

For applications in Virginia, use **ASTM C33 Concrete Sand.** The top of the sand filter must be completely level. No grade is allowable.

Gravel Bed Around Collector Pipes

The gravel layer surrounding the collector pipes shall be ½ to two (2) inch diameter gravel and provide at least two (2) inches of cover over the tops of the drainage pipes. The gravel and the sand layer above must be separated by a layer of geotextile fabric meeting the specification listed above.

Underdrain Piping

When round perforated pipes are used, the underdrain piping shall consist of a minimum of two (2) schedule 40 or better four (4) inch polyvinyl perforated pipes reinforced to withstand the weight of the overburden. Perforations shall be 3/8 inch, and each row of perforations shall contain at least four (4) holes. Maximum spacing between rows of perforations shall be six (6) inches.

The minimum grade of piping shall be 1/8 inch per foot (one [1] percent slope). Access for cleaning all underdrain piping is needed. Clean-outs for each pipe shall extend at least six (6) inches above the top of the upper filter surface.

Each pipe shall be thoroughly wrapped with 8 oz./sq.yd. geotextile fabric meeting the specification in **Table 3.12B - 2** above.

Alternative Underdrains

Shallow rectangular drain tiles may be fabricated from such materials as fiberglass structural channels, saving several inches of filter depth. Drain tiles shall normally be in two-foot lengths and spaced to provide gaps 1/8-inch less than the smallest gravel sizes on all four sides. Sections of tile may be cast in the dividing wall between the filter and the clearwell to provide shallow outflow oricices. Flat perforated drainage piping such as AdvantEdge® may also be used to reduce the depth of filter. Another approach is to raise a grate on small masonary units above the floor of the shell, lay a layer of PVC or polyethelene geomatrix on the grate to spread the load, and install the filter cloth and sand above this matting; molded HDPE infiltration chambers may also be used as shown in **Figure 3.12A-5.** The entire bottom of the filter shell thus becomes a collector channel. When the shell bottom is so used, it shall have a minimum slope of 1/8 inch per foot (1%).

Weepholes

In addition to the underdrain pipes, weepholes may be installed between the filter chamber and the clearwell to provide relief in case of pipe clogging. The weepholes shall be three (3) inches in diameter. Minimum spacing shall be nine (9) inches center to center. The openings on the filter side of the dividing wall shall be covered to the width of the trench with 12 inch high plastic hardware cloth of 1/4 inch mesh or galvanized steel wire, minimum wire diameter 0.03-inch, number 4 mesh hardware cloth anchored firmly to the dividing wall structure and folded a minimum of 6 inches back under the bottom stone.

Protection from Construction Sediments

The site erosion and sediment control plan must be configured to permit construction of the filter system while maintaining erosion and sediment control.

No runoff is to enter the sand filtration system prior to completion of all construction and site revegitation. Construction runoff shall be treated in separate sedimentation basins and routed to by-pass the filter system. Should construction runoff enter the filter system prior to site revegitation, all contaminated materials must be removed and replaced with new clean materials.

Watertight Integrity Test

After completion of the filter shell but before placement of the filter layers, entrances to the structure shall be plugged and the shell completely filled with water to demonstrate water tightness. Maximum allowable leakage is 5 percent of the filter shell volume in 24 hours. Should the structure fail this test, it shall be made watertight and successfully retested prior to placement of the filter layers.

Hydraulic Compaction of Filter Components
