Environmental Protection Agency

40 CFR Part 131

Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants for the State of California; Rule

R0019104

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 131

[FRL–6587–9]

RIN 2040–AC44

Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants for the State of California

AGENCY: Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: This final rule promulgates: numeric aquatic life criteria for 23 priority toxic pollutants; numeric human health criteria for 57 priority toxic pollutants; and a compliance schedule provision which authorizes the State to issue schedules of compliance for new or revised National Pollutant Discharge Elimination System permit limits based on the federal criteria when certain conditions are met.

EPA is promulgating this rule based on the Administrator's determination that numeric criteria are necessary in the State of California to protect human health and the environment. The Clean Water Act requires States to adopt numeric water quality criteria for priority toxic pollutants for which EPA has issued criteria guidance, the presence or discharge of which could reasonably be expected to interfere with maintaining designated uses.

EPA is promulgating this rule to fill a gap in California water quality standards that was created in 1994 when a State court overturned the State's water quality control plans which contained water quality criteria for priority toxic pollutants. Thus, the State of California has been without numeric water quality criteria for many priority toxic pollutants as required by the Clean Water Act, necessitating this action by EPA. These Federal criteria are legally applicable in the State of California for inland surface waters, enclosed bays and estuaries for all purposes and programs under the Clean Water Act.

EFFECTIVE DATE: This rule shall be effective May 18, 2000.

ADDRESSES: The administrative record for today's final rule is available for public inspection at the U.S. Environmental Protection Agency, Region 9, Water Division, 75 Hawthorne Street, San Francisco, California 94105, between the hours of 8:00 a.m. and 4:30 p.m. For access to the administrative record, call Diane E. Fleck, P.E., Esq. at 415 744–1984 for an appointment. A reasonable fee will be charged for photocopies.

FOR FURTHER INFORMATION CONTACT: Diane E. Fleck, P.E., Esq. or Philip Woods, U.S. Environmental Protection Agency, Region 9, Water Division, 75 Hawthorne Street, San Francisco, California 94105, 415–744–1984 or 415–744–1997, respectively.

SUPPLEMENTARY INFORMATION: This preamble is organized according to the following outline:

A. Potentially Affected Entities

Citizens concerned with water quality in California may be interested in this rulemaking. Entities discharging pollutants to waters of the United States in California could be affected by this rulemaking since water quality criteria are used by the State in developing National Pollutant Discharge Elimination System (NPDES) permit limits. Categories and entities that ultimately may be affected include:

Category	Examples of potentially affected entities
Industry	Industries discharging pollutants to surface waters in California or to publicly-owned treatment works.
Municipalities	Publicly-owned treatment works discharging pollutants to surface waters in California

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be affected by this action. This table lists the types of entities that EPA is now aware could potentially be affected by this action. Other types of entities not listed in the table could also be affected. To determine whether your facility might be affected by this action, you should carefully examine the applicability criteria in § 131.38(c). If you have questions regarding the applicability of this action to a particular entity, consult the persons listed in the preceding **FOR FURTHER INFORMATION CONTACT** section.

R0019105

B. Introduction and Overview

1. Introduction

This section introduces the topics which are addressed in the preamble and provides a brief overview of EPA's basis and rationale for promulgating Federal criteria for the State of California. Section C briefly describes the evolution of the efforts to control toxic pollutants; these efforts include the changes enacted in the 1987 CWA Amendments, which are the basis for this rule. Section D summarizes California's efforts since 1987 to implement the requirements of CWA section 303(c)(2)(B) and describes EPA's procedure and actions for determining whether California has fully implemented CWA section 303(c)(2)(B). Section E provides the rationale and approach for developing this final rule, including a discussion of EPA's legal basis for this final rule. Section F describes the development of the criteria included in this rule. Section G summarizes the provisions of the final rule and discusses implementation issues. Sections H, I, J, K , L, M, N, O, P, and Q briefly address the requirements of Executive Order 12866, the Unfunded Mandates Reform Act of 1995, the Regulatory Flexibility Act, the Paperwork Reduction Act, the Endangered Species Act, the Congressional Review Act, Executive Order 13084, Consultation and Coordination with Indian Tribal Governments, the National Technology Transfer and Advancement Act, and Executive Order 13132, Federalism, respectively.

The proposal for this rulemaking was published in the **Federal Register** on August 5, 1997. Changes from the proposal are generally addressed in the body of this preamble and specifically addressed in the response to comments document included in the administrative record for this rulemaking. EPA responded to all comments on the proposed rule, including comments received after the September 26, 1997, deadline. Although EPA is under no legal obligation to respond to late comments, EPA made a policy decision to respond to all comments.

Since detailed information concerning many of the topics in this preamble was published previously in the **Federal Register** in preambles for this and other rulemakings, references are frequently made to those preambles. Those rulemakings include: Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants for the State of California; Proposed Rule, 62 FR 42159, August 5, 1997 (referred to as the "proposed CTR"); Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants, 57 FR 60848, December 22, 1992 (referred to as the "National Toxics Rule" or "NTR"); and the NTR as amended by Administrative Stay of Federal Water Quality Criteria for Metals and Interim Final Rule, Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants; States' Compliance—Revision of Metals Criteria, 60 FR 22228, May 4, 1995 (referred to as the "National Toxics Rule [NTR], as amended"). The NTR, as amended, is codified at 40 CFR 131.36. A copy of the proposed CTR and its preamble, and the NTR, as amended, and its preambles are contained in the administrative record for this rulemaking.

EPA is making this final rule effective upon publication. Under the Administrative Procedure Act, 5 U.S.C. 553(d)(3), agencies must generally publish a rule no more than 30 days prior to the effective date of the rule except as otherwise provided for by the Agency for good cause. The purpose of the 30-day waiting period is to give affected parties a reasonable time to adjust their behavior before the final rule takes effect. See *Omnipoint Corp.* v. *F.C.C.*, 78 F.3d 620, 630–631 (D.C. Cir. 1996); *Riverbend Farms, Inc.* v. *Madigan*, 958 F.2d 1479, 1485 (9th Cir. 1992).

In this instance, EPA finds good cause to make the final rule effective upon publication. In order to find good cause, an Agency needs to find that the 30-day period would be: (1) Impracticable, (2) unnecessary, or (3) contrary to the public interest. Here EPA is relying on the second reason to support its finding of good cause. EPA also notes that the State has requested EPA to make the rule immediately effective.

EPA finds that in this instance, waiting 30 days to make the rule effective is unnecessary. As explained in further detail elsewhere in this preamble, this rule is not self implementing; rather it establishes ambient conditions that the State of California will implement in future permit proceedings. These permit proceedings will, by regulation, take longer than 30 days to complete. This means that although the rule is immediately effective, no discharger's conduct would be altered under the rule in less than 30 days, and therefore the 30-day period is unnecessary.

2. Overview

This final rule establishes ambient water quality criteria for priority toxic pollutants in the State of California. The criteria in this final rule will supplement the water quality criteria promulgated for California in the NTR, as amended. In 1991, EPA approved a number of water quality criteria (discussed in section D), for the State of California. Since EPA had approved these criteria, it was not necessary to include them in the 1992 NTR for these criteria. However, the EPA-approved criteria were subsequently invalidated in State litigation. Thus, this final rule contains criteria to fill the gap created by the State litigation.

This final rule does not change or supersede any criteria previously promulgated for the State of California in the NTR, as amended. Criteria which EPA promulgated for California in the NTR, as amended, are footnoted in the final table at 131.38(b)(1), so that readers may see the criteria promulgated in the NTR, as amended, for California and the criteria promulgated through this rulemaking for California in the same table. This final rule is not intended to apply to waters within Indian Country. EPA recognizes that there are possibly waters located wholly or partly in Indian Country that are included in the State's basin plans. EPA will work with the State and Tribes to identify any such waters and determine whether further action to protect water quality in Indian Country is necessary.

This rule is important for several environmental, programmatic and legal reasons. Control of toxic pollutants in surface waters is necessary to achieve the CWA's goals and objectives. Many of California's monitored river miles, lake acres, and estuarine waters have elevated levels of toxic pollutants. Recent studies on California water bodies indicate that elevated levels of toxic pollutants exist in fish tissue which result in fishing advisories or bans. These toxic pollutants can be attributed to, among other sources, industrial and municipal discharges.

Water quality standards for toxic pollutants are important to State and EPA efforts to address water quality problems. Clearly established water quality goals enhance the effectiveness of many of the State's and EPA's water programs including permitting, coastal water quality improvement, fish tissue quality protection, nonpoint source controls, drinking water quality protection, and ecological protection. Numeric criteria for toxic pollutants allow the State and EPA to evaluate the adequacy of existing and potential control measures to protect aquatic ecosystems and human health. Numeric criteria also provide a more precise basis for deriving water quality-based effluent limitations (WQBELs) in

R0019106

National Pollutant Discharge Elimination System (NPDES) permits and wasteload allocations for total maximum daily loads (TMDLs) to control toxic pollutant discharges. Congress recognized these issues when it enacted section 303(c)(2)(B) to the CWA.

While California recognizes the need for applicable water quality standards for toxic pollutants, its adoption efforts have been stymied by a variety of factors. The Administrator has decided to exercise her CWA authorities to move forward the toxic control program, consistent with the CWA and with the State of California's water quality standards program.

Today's action will also help restore equity among the States. The CWA is designed to ensure all waters are sufficiently clean to protect public health and/or the environment. The CWA allows some flexibility and differences among States in their adopted and approved water quality standards, but it should be implemented in a manner that ensures a level playing field among States. Although California has made important progress toward satisfying CWA requirements, it has not satisfied CWA section 303(c)(2)(B) by adopting numeric water quality criteria for toxic pollutants. This section was added to the CWA by Congress in 1987. Prior to today, the State of California had been the only State in the Nation for which CWA section 303(c)(2)(B) had remained substantially unimplemented after EPA's promulgation of the NTR in December of 1992. Section 303(c)(4) of the CWA authorizes the EPA Administrator to promulgate standards where necessary to meet the requirements of the Act. The Administrator determined that this rule was a necessary and important component for the implementation of CWA section 303(c)(2)(B) in California.

EPA acknowledges that the State of California is working to satisfy CWA section 303(c)(2)(B). When the State formally adopts, and EPA approves, criteria consistent with statutory requirements, as envisioned by Congress in the CWA, EPA intends to stay this rule. If within the applicable time frame for judicial review, the States' standards are challenged, EPA will withdraw this rule after such judicial review is complete and the State standards are sustained.

C. Statutory and Regulatory Background

The preamble to the August 5, 1997, proposed rule provided a general discussion of EPA's statutory and regulatory authority to promulgate water quality criteria for the State of California. See 62 FR 42160–42163. EPA is including that discussion in the record for the final rule. Commenters questioned EPA's authority to promulgate certain aspects of the proposal. EPA is responding to those comments in the appropriate sections of this preamble, and in the response to comments document included in the administrative record for this rulemaking. Where appropriate, EPA's responses expand upon the discussion of statutory and regulatory authority found in the proposal.

D. California Water Quality Standards Actions

1. California Regional Water Quality Control Board Basin Plans, and the Inland Surface Waters Plan (ISWP) and the Enclosed Bays and Estuaries Plan (EBEP) of April 1991

The State of California regulates water quality through its State Water Resources Control Board (SWRCB) and through nine Regional Water Quality Control Boards (RWQCBs). Each of the nine RWQCBs represents a different geographic area; area boundaries are generally along watershed boundaries. Each RWQCB maintains a Basin Plan which contains the designated uses of the water bodies within its respective geographic area within California. These designated uses (or "beneficial uses" under State law) together with legally-adopted criteria (or "objectives" under State law), comprise water quality standards for the water bodies within each of the Basin areas. Each of the nine RWQCBs undergoes a triennial basin planning review process, in compliance with CWA section 303. The SWRCB provides assistance to the RWQCBs.

Most of the Basin Plans contain conventional pollutant objectives such as dissolved oxygen. None of the Basin Plans contains a comprehensive list of priority toxic pollutant criteria to satisfy CWA section 303(c)(2)(B). The nine RWQCBs and the SWRCB had intended that the priority toxic pollutant criteria contained in the three SWRCB statewide plans, the Inland Surface Waters Plan (ISWP), the Enclosed Bays and Estuaries Plan (EBEP), and the Ocean Plan, apply to all basins and satisfy CWA section 303(c)(2)(B).

On April 11, 1991, the SWRCB adopted two statewide water quality control plans, the ISWP and the EBEP. These statewide plans contained narrative and numeric water quality criteria for toxic pollutants, in part to satisfy CWA section 303(c)(2)(B). The water quality criteria contained in the SWRCB statewide plans, together with the designated uses in each of the Basin Plans, created a set of water quality standards for waters within the State of California.

Specifically, the two plans established water quality criteria or objectives for all fresh waters, bays and estuaries in the State. The plans contained water quality criteria for some priority toxic pollutants, provisions relating to whole effluent toxicity, implementation procedures for point and nonpoint sources, and authorizing compliance schedule provisions. The plans also included special provisions affecting waters dominated by reclaimed water (labeled as Category (a) waters), and waters dominated by agricultural drainage and constructed agricultural drains (labeled as Category (b) and (c) waters, respectively).

2. EPA's Review of California Water Quality Standards for Priority Toxic Pollutants in the ISWP and EBEP, and the National Toxics Rule

The EPA Administrator has delegated the responsibility and authority for review and approval or disapproval of all new or revised State water quality standards to the EPA Regional Administrators (see 40 CFR 131.21). Thus, State actions under CWA section 303(c)(2)(B) are submitted to the appropriate EPA Regional Administrator for review and approval.

In mid-April 1991, the SWRCB submitted to EPA for review and approval the two statewide water quality control plans, the ISWP and the EBEP. On November 6, 1991, EPA Region 9 formally concluded its review of the SWRCB's plans. EPA approved the narrative water quality criterion and the toxicity criterion in each of the plans. EPA also approved the numeric water quality criteria contained in both plans, finding them to be consistent with the requirements of section 303(c)(2)(B) of the CWA and with EPA's national criteria guidance published pursuant to section 304(a) of the CWA.

EPA noted the lack of criteria for some pollutants, and found that, because of the omissions, the plans did not fully satisfy CWA section 303(c)(2)(B). The plans did not contain criteria for all listed pollutants for which EPA had published national criteria guidance. The ISWP contained human health criteria for only 65 pollutants, and the EBEP contained human health criteria for only 61 pollutants for which EPA had issued section 304(a) guidance criteria. Both the ISWP and EBEP contained aquatic life criteria for all pollutants except cyanide and chromium III (freshwater only) for which EPA has CWA section

304(a) criteria guidance. The SWRCB's administrative record stated that all priority pollutants with EPA criteria guidance were likely to be present in California waters. However, the SWRCB's record contained insufficient information to support a finding that the excluded pollutants were not reasonably expected to interfere with designated uses of the waters of the State.

Although EPA approved the statewide selenium objective in the ISWP and EBEP, EPA disapproved the objective for the San Francisco Bay and Delta, because there was clear evidence that the objective would not protect the designated fish and wildlife uses (the California Department of Health Services had issued waterfowl consumption advisories due to selenium concentrations, and scientific studies had documented selenium toxicity to fish and wildlife). EPA restated its commitment to object to National Pollutant Discharge Elimination System (NPDES) permits issued for San Francisco Bay that contained effluent limits based on an objective greater than 5 parts per billion (ppb) (four day average) and 20 ppb (1 hour average), the freshwater criteria. EPA reaffirmed its disapproval of Californias' site-specific selenium objective for portions of the San Joaquin River, Salt Slough, and Mud Slough. EPA also disapproved of the categorical deferrals and exemptions. These disapprovals included the disapproval of the State's deferral of water quality objectives to effluent dominated streams (Category a) and to streams dominated by agricultural drainage (Category b), and the disapproval of the exemption of water quality objectives to constructed agricultural drains (Category c). EPA found the definitions of the categories imprecise and overly broad which could have led to an incorrect interpretation.

Since EPA had disapproved portions of each of the California statewide plans which were necessary to satisfy CWA section 303(c)(2)(B), certain disapproved aspects of California's water quality standards were included in EPA's promulgation of the National Toxics Rule (NTR) (40 CFR 131.36, 57 FR 60848). EPA promulgated specific criteria for certain water bodies in California.

The NTR was amended, effective April 14, 1995, to stay certain metals criteria which had been promulgated as total recoverable. Effective April 15, 1995, EPA promulgated interim final metals criteria as dissolved concentrations for those metals which had been stayed (Administrative Stay of Federal Water Quality Criteria for Metals and Interim Final Rule, Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants; States' Compliance—Revision of Metals Criteria; 60 FR 22228, 22229, May 4, 1995 (the NTR, as amended)). The stay was in response to a lawsuit against EPA challenging, among other issues, metals criteria expressed as total recoverable concentrations. A partial Settlement Agreement required EPA to stay specific metals criteria in the NTR. EPA then promulgated certain metals criteria in the dissolved form through the use of conversion factors. These factors are listed in the NTR, as amended. A scientific discussion of these criteria is found in a subsequent section of this preamble.

Since certain criteria have already been promulgated for specific water bodies in the State of California in the NTR, as amended, they are not within the scope of today's final rule. However, for clarity in reading a comprehensive rule for the State of California, these criteria are incorporated into 40 CFR 131.38(d)(2). Footnotes to the Table in 40 CFR 131.38(b)(1) and 40 CFR 131.38(d)(3) clarify which criteria (and for which specific water bodies) were promulgated by the NTR, as amended, and are therefore excluded from this final rule. The appropriate (freshwater or saltwater) aquatic life criteria which were promulgated in the NTR, as amended, for all inland surface waters and enclosed bays and estuaries include: chromium III and cyanide. The appropriate (water and organism or organism only) human health criteria which were promulgated in the NTR, as amended, for all inland surface waters and enclosed bays and estuaries include:

antimony
thallium
asbestos
acrolein
acrylonitrile
carbon tetrachloride
chlorobenzene
1,2-dichloroethane
1,1-dichloroethylene
1,3-dichloropropylene
ethylbenzene
1,1,2,2-tetrachloroethane
tetrachloroethylene
1,1,2-trichloroethane
trichloroethylene
vinyl chloride
2,4-dichlorophenol
2-methyl-4,6-dinitrophenol
2,4-dinitrophenol
benzidine
bis(2-chloroethyl)ether
bis(2-ethylhexyl)phthalate
3,3-dichlorobenzidine
diethyl phthalate
dimethyl phthalate
di-n-butyl phthalate
2,4-dinitrotoluene
1,2-diphenylhydrazine
hexachlorobutadiene
hexachlorocyclopentadiene
hexachloroethane
isophorone
nitrobenzene
n-nitrosodimethylamine
n-nitrosodiphenylamine

Other pollutant criteria were promulgated in the NTR, as amended, for specific water bodies, but not all inland surface waters and enclosed bays and estuaries.

3. Status of Implementation of CWA Section 303(c)(2)(B)

Shortly after the SWRCB adopted the ISWP and EBEP, several dischargers filed suit against the State alleging that it had not adopted the two plans in compliance with State law. The plaintiffs in a consolidated case included: the County of Sacramento, Sacramento County Water Agency; Sacramento Regional County Sanitation District; the City of Sacramento; the City of Sunnyvale; the City of San Jose; the City of Stockton; and Simpson Paper Company.

The dischargers alleged that the State had not adopted the ISWP and EBEP in compliance with the California Administrative Procedures Act (Gov Code. Section 11340, *et seq.*), the California Environmental Quality Act (Pub. Re Code, Section 21000, *et seq.*), and the Porter-Cologne Act (Wat. Code, Section 13200, *et seq.*). The allegation that the State did not sufficiently consider economics when adopting water quality objectives, as allegedly required by Section 13241 of the Porter Cologne Act, was an important issue in the litigation.

In October of 1993, the Superior Court of California, County of Sacramento, issued a tentative decision in favor of the dischargers. In March of 1994, the Court issued a substantively similar final decision in favor of the dischargers. Final judgments from the Court in July of 1994 ordered the SWRCB to rescind the ISWP and EBEP. On September 22, 1994, the SWRCB formally rescinded the two statewide water quality control plans. The State is currently in the process of readopting water quality control plans for inland surface waters, enclosed bays and estuaries.

CWA section 303(c)(2)(B) was fully implemented in the State of California from December of 1992, when the NTR was promulgated, until September of 1994, when the SWRCB was required to rescind the ISWP and EBEP. The provisions for California in EPA's NTR together with the approved portions of

California's ISWP and EBEP implemented the requirements of CWA section 303(c)(2)(B). However, since September of 1994, when the SWRCB rescinded the ISWP and EBEP, the requirements of section 303(c)(2)(B) have not been fully implemented in California.

The scope of today's rule is to re-establish criteria for the remaining priority toxic pollutants to meet the requirements of section 303(c)(2)(B) of the CWA. Pursuant to section 303(c)(4), the Administrator has determined that it is necessary to include in today's action criteria for priority toxic pollutants, which are not covered by the NTR, as amended, or by the State through EPA-approved site-specific criteria, for waters of the United States in the State of California.

4. State-Adopted, Site-Specific Criteria for Priority Toxic Pollutants

The State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over-or under-protective of designated uses. Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete, the criteria become State law.

These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted under the State's process and has become State law.

a. State-Adopted Site-Specific Criteria Under EPA Review

The State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of the Basin Plans have completed the State review and adoption process and have been submitted to EPA for review and approval. Some of the Basin Plans contain site-specific criteria. In these cases, the State-adopted site-specific criteria are used for water quality programs.

EPA has not yet concluded consultation under the Endangered Species Act with the U.S. Department of Interior, Fish and Wildlife Service, and the U.S. Department of Commerce, National Marine Fisheries Service, on EPA's tentative approval/disapproval actions on the RWQCB Basin Plans. In this situation, the more stringent of the two criteria (the State-adopted site-specific criteria in the RWQCB Basin Plans, or the Federal criteria in this final rule), would be used for water quality programs including the calculation of water quality-based effluent criteria in National Pollutant Discharge Elimination System (NPDES) permits.

b. State-Adopted Site-Specific Criteria With EPA Approval

In several cases, the EPA Regional Administrator has already reviewed and approved State-adopted site-specific criteria within the State of California. Several of these cases are discussed in this section. All of the EPA approval letters referenced in today's preamble are contained in the administrative record for today's rule.

Sacramento River: EPA has approved site-specific acute criteria for copper, cadmium and zinc in the Sacramento River, upstream of Hamilton City, in the Central Valley Region (RWQCB for the Central Valley Region) of the State of California. EPA approved these site-specific criteria by letter dated August 7, 1985. Specifically, EPA approved for the Sacramento River (and tributaries) above Hamilton City, a copper criterion of 5.6 μg/l (maximum), a zinc criterion of 16 μg/l (maximum) and a cadmium criterion of 0.22 μg/l (maximum), all in the dissolved form using a hardness of 40 mg/l as $CaCO_3$. (These criteria were actually adopted by the State and approved by EPA as equations which vary with hardness.) These "maximum" criteria correspond to acute criteria in today's final rule. Therefore, Federal acute criteria for copper, cadmium, and zinc for the Sacramento River (and tributaries) above Hamilton City are not necessary to protect the designated uses and are not included in the final rule. However, the EPA Administrator is making a finding that it is necessary to include chronic criteria for copper, cadmium and zinc for the Sacramento River (and tributaries) above Hamilton City, as part of the statewide criteria promulgated in today's final rule.

San Joaquin River: The selenium criteria in this rule are not applicable to portions of the San Joaquin River, in the Central Valley Region, because selenium criteria have been either previously approved by EPA or previously promulgated by EPA as part of the NTR. EPA approved and disapproved State-adopted site-specific selenium criteria in portions of the San Joaquin River, in the Central Valley Region of the State of California (RWQCB for the Central Valley Region). EPA's determination on these site-specific criteria is contained in a letter dated April 13, 1990.

Specifically, EPA approved for the San Joaquin River, mouth of Merced River to Vernalis, an aquatic life selenium criterion of 12 μg/l (maximum with the understanding that the instantaneous maximum concentration may not exceed the objective more than once every three years). Today's final rule does not affect this Federally-approved, State-adopted site-specific acute criterion, and it remains in effect for the San Joaquin River, mouth of Merced River to Vernalis. Therefore, an acute criterion for selenium in the San Joaquin River, mouth of Merced River to Vernalis is not necessary to protect the designated use and thus is not included in this final rule.

By letter dated April 13, 1990, EPA also approved for the San Joaquin River, mouth of Merced River to Vernalis, a State-adopted site-specific aquatic life selenium criterion of 5 μg/l (monthly mean); however, EPA disapproved a State-adopted site-specific selenium criterion of 8 μg/l (monthly mean—critical year only) for these waters. Subsequently, EPA promulgated a chronic selenium criterion of 5 μg/l (4 day average) for waters of the San Joaquin River from the mouth of the Merced River to Vernalis in the NTR. This chronic criterion applies to all water quality programs concerning the San Joaquin River, mouth of Merced River to Vernalis. Today's final rule does not affect the Federally-promulgated chronic selenium criterion of 5 μg/l (4 day average) set forth in the NTR. This previously Federally-promulgated criterion remains in effect for the San Joaquin River, mouth of Merced River to Vernalis.

Grassland Water District, San Luis National Wildlife Refuge, and Los Banos State Wildlife Refuge: EPA approved for the Grassland Water District, San Luis National Wildlife Refuge, and Los Banos State Wildlife Refuge, a State-adopted site-specific aquatic life selenium criterion of 2 μg/l (monthly mean) by letter dated April 13, 1990. This Federally-approved, State-adopted site-specific chronic criterion remains in effect for the Grassland Water District, San Luis National Wildlife Refuge and Los Banos State Wildlife Refuge. Therefore it is not necessary to include in today's final rule, a chronic criterion for selenium for the Grassland Water District, San Luis National Wildlife Refuge and Los Banos State Wildlife Refuge, and thus, it is not included in this final rule.

R0019109

San Francisco Regional Board Basin Plan of 1986: EPA approved several priority toxic pollutant objectives (CWA criteria) that were contained in the1986 San Francisco Regional Board Basin Plan, as amended by SWRCB Resolution Numbers 87–49, 87–82 and 87–92, by letters dated September 2, 1987 and December 24, 1987. This Basin Plan, the SWRCB Resolutions, and the EPA approval letters are contained in the administrative record for this rulemaking. It is not necessary to include these criteria for priority toxic pollutants that are contained in the San Francisco Regional Board's 1986 Basin Plan as amended, and approved by EPA. Priority pollutants in this situation are footnoted in the matrix at 131.38(b)(1) with footnote "b." Where gaps exist in the State adoption and EPA approval of priority toxic pollutant objectives, the criteria in today's rule apply.

EPA is assigning "human health, water and organism consumption" criteria to waters with the States' municipal or "MUN" beneficial use designation in the Basin Plan. Also, some pollutants regulated through the Basin Plan have different averaging periods, *e.g.*, one hour as compared with the rule's "short-term." However, where classes of chemicals, such as polynuclear aromatic hydrocarbons, or PAHs, and phenols, are regulated through the Basin Plan, but not specific chemicals within the category, specific chemicals within the category are regulated by today's rule.

E. Rationale and Approach for Developing the Final Rule

This section explains EPA's legal basis for today's final rule, and discusses EPA's general approach for developing the specific requirements for the State of California.

1. Legal Basis

CWA section 303(c) specifies that adoption of water quality standards is primarily the responsibility of the States. However, CWA section 303(c) also describes a role for the Federal government to oversee State actions to ensure compliance with CWA requirements. If EPA's review of the States' standards finds flaws or omissions, then the CWA authorizes EPA to correct the deficiencies (see CWA section 303(c)(4)). This water quality standards promulgation authority has been used by EPA to issue final rules on several separate occasions, including the NTR, as amended, which promulgated criteria similar to those included here for a number of States. These actions have addressed both insufficiently protective State criteria and/or designated uses and failure to adopt needed criteria. Thus, today's action is not unique.

The CWA in section 303(c)(4) provides two bases for promulgation of Federal water quality standards. The first basis, in paragraph (A), applies when a State submits new or revised standards that EPA determines are not consistent with the applicable requirements of the CWA. If, after EPA's disapproval, the State does not amend its rules so as to be consistent with the CWA, EPA is to promptly propose appropriate Federal water quality standards for that State. The second basis for an EPA action is in paragraph (B), which provides that EPA shall promptly initiate promulgation "* * * in any case where the Administrator determines that a revised or new standard is necessary to meet the requirements of this Act." EPA is using section 303(c)(4)(B) as the legal basis for today's final rule.

As discussed in the preamble to the NTR, the Administrator's determination under CWA section 303(c)(4) that criteria are necessary to meet the requirements of the Act could be supported in several ways. Consistent with EPA's approach in the NTR, EPA interprets section 303(c)(2)(B) of the CWA to allow EPA to act where the State has not succeeded in establishing numeric water quality standards for toxic pollutants. This inaction can be the basis for the Administrator's determination under section 303(c)(4) that new or revised criteria are necessary to ensure designated uses are protected.

EPA does not believe that it is necessary to support the criteria in today's rule on a pollutant-specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA section 304(a) criteria guidance there is a "discharge or presence" of that pollutant which could reasonably "be expected to interfere with" the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) to the CWA. Moreover, because these criteria are ambient criteria that define attainment of the designated uses, their application to all water bodies will result in additional controls on dischargers only where necessary to protect the designated uses.

EPA's interpretation of section 303(c)(2)(B) is supported by the language of the provision, the statutory framework and purpose of section 303, and the legislative history. In adding section 303(c)(2)(B) to the CWA, Congress understood the existing requirements in section 303(c)(1) for States to conduct triennial reviews of their water quality standards and submit the results of those reviews to EPA and in section 303(c)(4)(B) for promulgation. CWA section 303(c) includes numerous deadlines and section 303(c)(4) directs the Administrator to act "promptly" where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. Congress, by linking section 303(c)(2)(B) to the section 303(c)(1) three-year review period, gave States a last chance to correct this deficiency on their own. The legislative history of the provision demonstrates that chief Senate sponsors, including Senators Stafford, Chaffee and others wanted the provision to eliminate State and EPA delays and force quick action. Thus, to interpret CWA section 303(c)(2)(B) and (c)(4) to require such a cumbersome pollutant specific effort on each stream segment would essentially render section 303(c)(2)(B) meaningless. The provision and its legislative background indicate that the Administrator's determination to invoke section 303(c)(4)(B) authority can be met by the Administrator making a generic finding of inaction by the State without the need to develop pollutant specific data for individual stream segments. Finally, the reference in section 303(c)(2)(B) to section 304(a) criteria suggests that section 304(a) criteria serve as default criteria; that once EPA has issued them, States were to adopt numeric criteria for those pollutants based on the 304(a) criteria, unless they had other scientifically defensible criteria. EPA also notes that this rule follows the approach EPA took nationally in promulgating the NTR for States that failed to comply with CWA section 303(c)(2)(B). 57 FR 60848, December 22, 1992. EPA incorporates the discussion in the NTR preamble as part of this rulemaking record.

This determination is supported by information in the rulemaking record showing the discharge or presence of priority toxic pollutants throughout the State. While this data is not necessarily complete, it constitutes a strong record supporting the need for numeric criteria for priority toxic pollutants with section 304(a) criteria guidance where the State does not have numeric criteria.

Today's final rule would not impose any undue or inappropriate burden on the State of California or its dischargers. It merely puts in place numeric criteria for toxic pollutants that are already used in other States in implementing CWA programs. Under this rulemaking, the State of California retains the ability to adopt alternative water quality criteria simply by completing its criteria adoption process. Upon EPA approval of those criteria, EPA will initiate action to stay the Federally-promulgated criteria and subsequently withdraw them.

2. Approach for Developing This Rule

In summary, EPA developed the criteria promulgated in today's final rule as follows. Where EPA promulgated criteria for California in the NTR, EPA has not acted to amend the criteria in the NTR. Where criteria for California were not included in the NTR, EPA used section 304(a) National criteria guidance documents as a starting point for the criteria promulgated in this rule. EPA then determined whether new information since the development of the national criteria guidance documents warranted any changes. New information came primarily from two sources. For human health criteria, new or revised risk reference doses and cancer potency factors on EPA's Integrated Risk Information System (IRIS) as of October 1996 form the basis for criteria values (see also 63 FR 68354). For aquatic life criteria, updated data sets resulting in revised criteria maximum concentrations (CMCs) and criteria continuous concentrations (CCCs) formed the basis for differences from the national criteria guidance documents. Both of these types of changes are discussed in more detail in the following sections. This revised information was used to develop the water quality criteria promulgated here for the State of California.

F. Derivation of Criteria

1. Section 304(a) Criteria Guidance Process

Under CWA section 304(a), EPA has developed methodologies and specific criteria guidance to protect aquatic life and human health. These methodologies are intended to provide protection for all surface waters on a national basis. The methodologies have been subject to public review, as have the individual criteria guidance documents. Additionally, the methodologies have been reviewed by EPA's Science Advisory Board (SAB) of external experts.

EPA has included in the record of this rule the aquatic life methodology as described in "Appendix B—Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and Its Uses" to the "Water Quality Criteria Documents; Availability" (45 FR 79341, November 28, 1980) as amended by the "Summary of Revisions to Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses" (50 FR 30792, July 29, 1985). (Note: Throughout the remainder of this preamble, this reference is described as the 1985 Guidelines. Any page number references are to the actual guidance document, not the notice of availability in the **Federal Register**. A copy of the 1985 Guidelines is available through the National Technical Information Service (PB85–227049), is in the administrative record for this rule, and is abstracted in Appendix A of *Quality Criteria for Water*, 1986.) EPA has also included in the administrative record of this rule the human health methodology as described in "Appendix C—Guidelines and Methodology Used in the Preparation of Health Effects Assessment Chapters of the Consent Decree Water Criteria Documents" (45 FR 79347, November 28, 1980). (Note: Throughout the remainder of this preamble, this reference is described as the Human Health Guidelines or the 1980 Guidelines.) EPA also recommends that the following be reviewed: "Appendix D—Response to Comments on Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and Its Uses," (45 FR 79357, November 28, 1980); "Appendix E—Responses to Public Comments on the Human Health Effects Methodology for Deriving Ambient Water Quality Criteria" (45 FR 79368, November 28, 1980); and "Appendix B—Response to Comments on Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses" (50 FR 30793, July 29, 1985). EPA placed into the administrative record for this rulemaking the most current individual criteria guidance for the priority toxic pollutants included in today's rule. (Note: All references to appendices are to the associated **Federal Register** publication.)

EPA received many comments related to the issue of what criteria should apply in the CTR if the CWA section 304(a) criteria guidance is undergoing re-evaluation, or if new data are developed that may affect a recommended criterion. As science is always evolving, EPA is faced with the challenge of promulgating criteria that reflect the best science and sound science. EPA addressed this challenge in some detail in its **Federal Register** notice that contained the Agency's current section 304(a) criteria guidance (63 FR 68335, December 10, 1998). There, EPA articulated its policy, reiterated here, that the existing criteria guidance represent the Agency's best assessment until such time as EPA's re-evaluation of a criteria guidance value for a particular chemical is complete. The reason for this is that both EPA's human health criteria guidance and aquatic life criteria guidance are developed taking into account numerous variables. For example, for human health criteria guidance, EPA evaluates many diverse toxicity studies, whose results feed into a reference dose or cancer potency estimate that, along with a number of exposure factors and determination of risk level, results in a guidance criterion. For aquatic life, EPA evaluates many diverse aquatic toxicity studies to determine chronic and acute toxicity taking into account how other factors (such as pH, temperature or hardness) affect toxicity. EPA also, to the extent possible, addresses bioaccumulation or bioconcentration. EPA then uses this toxicity information along with exposure information to determine the guidance criterion. Importantly, EPA subjects such evaluation to peer review and/or public comment.

For these reasons, EPA generally does not make a change to the 304(a) criteria guidance based on a partial picture of the evolving science. This makes sense, because to address one piece of new data without looking at all relevant data is less efficient and results in regulatory impacts that may go back and forth, when in the end, the criteria guidance value does not change that much. Certain new changes, however, do warrant change in criteria guidance, such as a change in a value in EPA's Integrated Risk Information System (IRIS) because it represents the Agency consensus about human health impacts. These changes are sufficiently examined across the Agency such that EPA believes they can be incorporated into EPA's water quality criteria guidance. EPA has followed this approach in the CTR. Included in the administrative record for today's rule is a document entitled "Status of Clean Water Act Section 304(a) Criteria" which further explains EPA's policy on managing change to criteria guidance.

2. Aquatic Life Criteria

Aquatic life criteria may be expressed in numeric or narrative form. EPA's 1985 Guidelines describe an objective, internally consistent and appropriate way of deriving chemical-specific, numeric water quality criteria for the protection of the presence of, as well as the uses of, both fresh and salt water aquatic organisms.

An aquatic life criterion derived using EPA's CWA section 304(a) method "might be thought of as an estimate of the highest concentration of a substance in water which does not present a significant risk to the aquatic organisms in the water and their uses." (45 FR 79341.) EPA's guidelines are designed to derive criteria that protect aquatic communities. EPA's 1985 Guidelines attempt to provide a reasonable and adequate amount of protection with only a small possibility of substantial overprotection or underprotection. As discussed in detail below, there are several individual factors which may make the criteria somewhat overprotective or underprotective. The approach EPA is using is believed to be as well balanced as possible, given the state of the science.

Numerical aquatic life criteria derived using EPA's 1985 Guidelines are expressed as short-term and long-term averages, rather than one number, in order that the criterion more accurately reflect toxicological and practical realities. The combination of a criterion maximum concentration (CMC), a short-term concentration limit, and a criterion continuous concentration (CCC), a four-day average concentration limit, are designed to provide protection of aquatic life and its uses from acute and chronic toxicity to animals and plants, without being as restrictive as a one-number criterion would have to be (1985 Guidelines, pages 4 & 5). The terms CMC and CCC are the formal names for the two (acute and chronic) values of a criterion for a pollutant; however, this document will also use the informal synonyms acute criterion and chronic criterion.

The two-number criteria are intended to identify average pollutant concentrations which will produce water quality generally suited to maintenance of aquatic life and designated uses while restricting the duration of excursions over the average so that total exposures will not cause unacceptable adverse effects. Merely specifying an average value over a time period may be insufficient unless the time period is short, because excursions higher than the average may kill or cause substantial damage in short periods.

A minimum data set of eight specified families is recommended for criteria development (details are given in the 1985 Guidelines, page 22). The eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. EPA's application of its guidelines to develop the criteria matrix in this rule is judged by the Agency to be appropriate for all waters of the United States (U.S.), and to all ecosystems (1985 Guidelines, page 4) including those waters of the U.S. and ecosystems in the State of California.

Fresh water and salt water (including both estuarine and marine waters) have different chemical compositions, and freshwater and saltwater species often do not inhabit the same water. To provide additional accuracy, criteria are developed for fresh water and for salt water.

For this rule, EPA updated freshwater aquatic life criteria contained in CWA section 304(a) criteria guidance first published in the early 1980's and later modified in the NTR, as amended, for the following ten pollutants: arsenic, cadmium, chromium (VI), copper, dieldrin, endrin, lindane (gamma BHC), nickel, pentachlorophenol, and zinc. The updates used as the basis for this rule are explained in a technical support document entitled, *1995 Updates: Water Quality Criteria Documents for the Protection of Aquatic Life in Ambient Water* (U.S. EPA–820–B–96–001, September 1996), available in the administrative record to this rulemaking; this document presents the derivation of each of the final CMCs and CCCs and the toxicity studies from which the updated freshwater criteria for the ten pollutants were derived.

The polychlorinated biphenyls (PCB) criteria in the criteria matrix for this rule differs from that in the NTR, as amended; for this rule, the criteria are expressed as the sum of seven aroclors, while for the NTR, as amended, the criteria are expressed for each of seven aroclors. The aquatic life criteria for PCBs in the CTR are based on the criteria contained in the 1980 criteria guidance document for PCBs which is included in the administrative record for this rule. This criteria document explains the derivation of aquatic life criteria based on total PCBs. For more information see the Response to Comments document for this rule. Today's chronic aquatic life criteria for PCBs are based on a final residue value (FRV). In EPA's guidelines for deriving aquatic life criteria, an FRV-based criterion is intended to prevent concentrations of pollutants in commercially or recreationally important aquatic species from affecting the marketability of those species or affecting the wildlife that consume aquatic life.

The proposed CTR included an updated freshwater and saltwater aquatic life criteria for mercury. In today's final rule, EPA has reserved the mercury criteria for freshwater and saltwater aquatic life, but is promulgating human health criteria for mercury for all surface waters in California. In some instances, the human health mercury criteria included in today's final rule may not protect some aquatic species or threatened or endangered species. In such instances, more stringent mercury limits may be determined and implemented through use of the State's narrative criterion. The reasons for reserving the mercury aquatic life numbers are explained in further detail in Section L, Endangered Species Act.

a. Freshwater Acute Selenium Criterion

EPA proposed a different freshwater acute aquatic life criterion for selenium for this rule than was promulgated in the NTR, as amended. EPA's proposed action was consistent with EPA's proposed selenium criterion maximum concentration for the Water Quality Guidance for the Great Lakes System (61 FR 58444, November 14, 1996). This proposal took into account data showing that selenium's two most prevalent oxidation states, selenite and selenate, present differing potentials for aquatic toxicity, as well as new data which indicated that various forms of selenium are additive. Additivity increases the toxicity of mixtures of different forms of the pollutant. The proposed approach produces a different selenium acute criterion concentration, or CMC, depending upon the relative proportions of selenite, selenate, and other forms of selenium that are present.

The preamble to the August 5, 1997, proposed rule provided a lengthy discussion of this proposed criterion for the State of California. See 62 FR 42160–42208. EPA incorporates that discussion here as part of this rulemaking record. In 1996, a similar discussion was included in the proposed rule for the Great Lakes System. Commenters questioned several aspects of the Great Lakes proposal. EPA is continuing to respond to those comments, and to follow up with additional literature review and toxicity testing. In addition, the U.S. FWS and U.S. NMFS (collectively, the Services) are concerned that EPA's proposed criterion may not be sufficiently protective of certain threatened and endangered species in California. Because the Services believe there is a lack of data to show for certain that the proposed criterion would not affect threatened and endangered species, the Services prefer that EPA further investigate the protectiveness of the

R0019112

criterion before finalizing the proposed criterion. Therefore, EPA is not promulgating a final acute freshwater selenium criterion at this time.

b. Dissolved Metals Criteria

In December of 1992, in the NTR, EPA promulgated water quality criteria for several States that had failed to meet the requirements of CWA section 303(c)(2)(B). Included among the water quality criteria promulgated were numeric criteria for the protection of aquatic life for 11 metals: arsenic, cadmium, chromium (III), chromium (VI), copper, lead, mercury, nickel, selenium, silver and zinc. Criteria for two metals applied to the State of California: chromium III and selenium.

The Agency received extensive public comment during the development of the NTR regarding the most appropriate approach for expressing the aquatic life metals criteria. The principal issue was the correlation between metals that are measured and metals that are bioavailable and toxic to aquatic life. It is now the Agency's policy that the use of dissolved metal to set and measure compliance with aquatic life water quality standards is the recommended approach, because dissolved metal more closely approximates the bioavailable fraction of the metal in the water column than does total recoverable metal.

Since EPA's previous aquatic life criteria guidance had been expressed as total recoverable metal, to express the criteria as dissolved, conversion factors were developed to account for the possible presence of particulate metal in the laboratory toxicity tests used to develop the total recoverable criteria. EPA included a set of recommended freshwater conversion factors with its Metals Policy (see Office of Water Policy and Technical Guidance on Interpretation and Implementation of Aquatic Life Metals Criteria, Martha G. Prothro, Acting Assistant Administrator for Water, October 1, 1993). Based on additional laboratory evaluations that simulated the original toxicity tests, EPA refined the procedures used to develop freshwater conversion factors for aquatic life criteria. These new conversion factors were made available for public review and comment in the amendments to the NTR on May 4, 1995, at 60 FR 22229. They are also contained in today's rule at 40 CFR 131.38(b)(2).

The preamble to the August 5, 1997, proposed rule provided a more detailed discussion of EPA's metals policy concerning the aquatic life water quality criteria for the State of California. See 62 FR 42160–42208. EPA incorporates that discussion here as part of this rulemaking record. Many commenters strongly supported the Agency's policy on dissolved metals aquatic life criteria. A few commenters expressed an opinion that the metals policy may not provide criteria that are adequately protective of aquatic or other species. Responses to those comments are contained in a memo to the CTR record entitled "Discussion of the Use of Dissolved Metals in the CTR" (February 1, 2000, Jeanette Wiltse) and EPA's response to comments document which are both contained in the administrative record for the final rule.

Calculation of Aquatic Life Dissolved Metals Criteria: Metals criteria values for aquatic life in today's rule in the matrix at 131.38(b)(1) are shown as dissolved metal. These criteria have been calculated in one of two ways. For freshwater metals criteria that are hardness-dependent, the metals criteria value is calculated separately for each hardness using the table at 40 CFR 131.38(b)(2). (The hardness-dependent freshwater values presented in the matrix at 40 CFR 131.38(b)(1) have been calculated using a hardness of 100 mg/l as CaCO3 for illustrative purposes only.) The hardness-dependent criteria are then multiplied by the appropriate conversion factors in the table at 40 CFR 131.38(b)(2). Saltwater and freshwater metals criteria that are not hardness-dependent are calculated by taking the total recoverable criteria values (from EPA's national section 304(a) criteria guidance, as updated and described in section F.2.a.) before rounding, and multiplying them by the appropriate conversion factors. The final dissolved metals criteria values, as they appear in the matrix at 40 CFR 131.38(b)(1), are rounded to two significant figures.

Translators for Dissolved to Total Recoverable Metals Limits: EPA's National Pollutant Discharge Elimination System (NPDES) regulations require that limits for metals in permits be stated as total recoverable in most cases (see 40 CFR 122.45(c)) except when an effluent guideline specifies the limitation in another form of the metal, the approved analytical methods measure only dissolved metal, or the permit writer expresses a metal's limit in another form (*e.g.*, dissolved, specific valence, or total) when required to carry out provisions of the CWA. This is because the chemical conditions in ambient waters frequently differ substantially from those in the effluent and these differences result in changes in the partitioning between dissolved and absorbed forms of the metal. This means that if effluent limits were expressed in the dissolved form, additional particulate metal could dissolve in the receiving water causing the criteria to be exceeded. Expressing criteria as dissolved metal requires translation between different metal forms in the calculation of the permit limit so that a total recoverable permit limit can be established that will achieve water quality standards. Thus, it is important that permitting authorities and other authorities have the ability to translate between dissolved metal in ambient waters and total recoverable metal in effluent.

EPA has completed guidance on the use of translators to convert from dissolved metals criteria to total recoverable permit limits. The document, *The Metals Translator: Guidance for Calculating a Total Recoverable Permit Limit From a Dissolved Criterion* (EPA 823–B–96–007, June 1996), is included in the administrative record for today's rule. This technical guidance examines how to develop a metals translator which is defined as the fraction of total recoverable metal in the downstream water that is dissolved, *i.e.*, the dissolved metal concentration divided by the total recoverable metal concentration. A translator may take one of three forms: (1) It may be assumed to be equivalent to the criteria guidance conversion factors; (2) it may be developed directly as the ratio of dissolved to total recoverable metal; and (3) it may be developed through the use of a partition coefficient that is functionally related to the number of metal binding sites on the adsorbent in the water column (*e.g.*, concentrations of total suspended solids or TSS). This guidance document discusses these three forms of translators, as well as field study designs, data generation and analysis, and site-specific study plans to generate site-specific translators.

California Regional Water Quality Control Boards may use any of these methods in developing water quality-based permit limits to meet water quality standards based on dissolved metals criteria. EPA encourages the State to adopt a statewide policy on the use of translators so that the most appropriate method or methods are used consistently within California.

c. Application of Metals Criteria

In selecting an approach for implementing the metals criteria, the principal issue is the correlation between metals that are measured and metals that are biologically available and toxic. In order to assure that the metals criteria are appropriate for the chemical conditions under which they are applied, EPA is providing for the

R0019113

adjustment of the criteria through application of the "water-effect ratio" procedure. EPA notes that performing the testing to use a site-specific water-effect ratio is optional on the part of the State.

In the NTR, as amended, EPA identified the water-effect ratio (WER) procedure as a method for optional site-specific criteria development for certain metals. The WER approach compares bioavailability and toxicity of a specific pollutant in receiving waters and in laboratory waters. A WER is an appropriate measure of the toxicity of a material obtained in a site water divided by the same measure of the toxicity of the same material obtained simultaneously in a laboratory dilution water.

On February 22, 1994, EPA issued *Interim Guidance on the Determination and Use of the Water-Effect Ratios for Metals* (EPA 823-B-94-001) now incorporated into the updated Second Edition of the Water Quality Standards Handbook, Appendix L. A copy of the Handbook is contained in the administrative record for today's rule. In accordance with the WER guidance and where application of the WER is deemed appropriate, EPA strongly encourages the application of the WER on a watershed or water body basis as part of a water quality criteria in California as opposed to the application on a discharger-by-discharger basis through individual NPDES permits. This approach is technically sound and an efficient use of resources. However, discharger specific WERs for individual NPDES permit limits are possible and potentially efficient where the NPDES discharger is the only point source discharger to a specific water body.

The rule requires a default WER value of 1.0 which will be assumed, if no site-specific WER is determined. To use a WER other than the default of 1.0, the rule requires that the WER must be determined as set forth in EPA's WER guidance or by another scientifically defensible method that has been adopted by the State as part of its water quality standards program and approved by EPA.

The WER is a more comprehensive mechanism for addressing bioavailability issues than simply expressing the criteria in terms of dissolved metal. Consequently, expressing the criteria in terms of dissolved metal, as done in today's rule for California, does not completely eliminate the utility of the WER. This is particularly true for copper, a metal that forms reduced-toxicity complexes with dissolved organic matter.

The *Interim Guidance on Determination and Use of Water-Effect Ratios for Metals* explains the relationship between WERs for dissolved criteria and WERs for total recoverable criteria. Dissolved measurements are to be used in the site-specific toxicity testing underlying the WERs for dissolved criteria. Because WERs for dissolved criteria generally are little affected by elevated particulate concentrations, EPA expects those WERs to be somewhat less than WERs for total recoverable criteria in such situations. Nevertheless, after the site-specific ratio of dissolved to total metal has been taken into account, EPA expects a permit limit derived using a WER for a dissolved criterion to be similar to the permit limit that would be derived from the WER for the corresponding total recoverable criterion.

d. Saltwater Copper Criteria

The saltwater copper criteria for aquatic life in today's rule are 4.8 µg/l (CMC) and 3.1 µg/l (CCC) in the dissolved form. These criteria reflect new data including data collected from studies for the New York/New Jersey Harbor and the San Francisco Bay indicating a need to revise the former copper 304(a) criteria guidance document to reflect a change in the saltwater CMC and CCC aquatic life values. These data also reflect a comprehensive literature search resulting in added toxicity test data for seven new species to the database for the saltwater copper criteria. EPA believes these new data have national implications and the national criteria guidance now contains a CMC of 4.8 µg/l dissolved and a CCC of 3.1 µg/l dissolved. In the amendments to the NTR, EPA noticed the availability of data to support these changes to the NTR, and solicited comments. The data can be found in the draft document entitled, *Ambient Water Quality Criteria—Copper, Addendum 1995*. This document is available from the Office of Water Resource Center and is available for review in the administrative record for today's rule.

e. Chronic Averaging Period

In establishing water quality criteria, EPA generally recommends an "averaging period" which reflects the duration of exposure required to elicit effects in individual organisms (TSD, Appendix D-2). The criteria continuous concentration, or CCC, is intended to be the highest concentration that could be maintained indefinitely in a water body without causing an unacceptable effect on the aquatic community or its uses (TSD, Appendix D-1). As aquatic organisms do not generally experience steady exposure, but rather fluctuating exposures to pollutants, and because aquatic organisms can generally tolerate higher concentrations of pollutants over a shorter periods of time, EPA expects that the concentration of a pollutant can exceed the CCC without causing an unacceptable effect if (a) the magnitude and duration of exceedences are appropriately limited and (b) there are compensating periods of time during which the concentration is below the CCC. This is done by specifying a duration of an "averaging period" over which the average concentration should not exceed the CCC more often than specified by the frequency (TSD, Appendix D-1).

EPA is promulgating a 4-day averaging period for chronic criteria, which means that measured or predicted ambient pollutant concentrations should be averaged over a 4-day period to determine attainment of chronic criteria. The State may apply to EPA for approval of an alternative averaging period. To do so, the State must submit to EPA the basis for such alternative averaging period.

The most important consideration for setting an appropriate averaging period is the length of time that sensitive organisms can tolerate exposure to a pollutant at levels exceeding a criterion without showing adverse effects on survival, growth, or reproduction. EPA believes that the chronic averaging period must be shorter than the duration of the chronic tests on which the CCC is based, since, in some cases, effects are elicited before exposure of the entire duration. Most of the toxicity tests used to establish the chronic criteria are conducted using steady exposure to toxicants for a least 28 days (TSD, page 35). Some chronic tests, however, are much shorter than this (TSD, Appendix D-2). EPA selected the 4-day averaging period based on the shortest duration in which chronic test effects are sometimes observed for certain species and toxicants. In addition, EPA believes that the results of some chronic tests are due to an acute effect on a sensitive life stage that occurs some time during the test, rather than being caused by long-term stress or long-term accumulation of the test material in the organisms.

Additional discussion of the rationale for the 4-day averaging period is contained in Appendix D of the TSD. Balancing all of the above factors and data, EPA believes that the 4-day averaging period falls within the scientifically reasonable range of values for choice of the averaging period, and is an appropriate length of time of

R0019114

pollutant exposure to ensure protection of sensitive organisms.

EPA established a 4-day averaging period in the NTR. In settlement of litigation on the NTR, EPA stated that it was "in the midst of conducting, sponsoring, or planning research related to the basis for and application of" water quality criteria and mentioned the issue of averaging period. See Partial Settlement Agreement in *American Forest and Paper Ass'n, Inc. et al.* v. *U.S. EPA* (Consolidated Case No. 93–0694 (RMU), D.D.C.). EPA is re-evaluating issues raised about averaging periods and will, if appropriate, revise the 1985 Guidelines.

EPA received public comment relevant to the averaging period during the comment period for the 1995 Amendments to the NTR (60 FR 22228, May 4, 1995), although these public comments did not address the chronic averaging period separately from the allowable excursion frequency and the design flow. Comments recommended that EPA use the 30Q5 design flow for chronic criteria.

While EPA is undertaking analysis of the chronic design conditions as part of the revisions to the 1985 Guidelines, EPA has not yet completed this work. Until this work is complete, for the reasons set forth in the TSD, EPA continues to believe that the 4-day chronic averaging period represents a reasonable, defensible value for this parameter.

EPA added language to the final rule which will enable the State to adopt alternative averaging periods and frequencies and associated design flows where appropriate. The State may apply to EPA for approval of alternative averaging periods and frequencies and related design flows; the State must submit the bases for any changes. Before approving any change, EPA will publish for public comment, a notice proposing the changes.

f. Hardness

Freshwater aquatic life criteria for certain metals are expressed as a function of hardness because hardness and/or water quality characteristics that are usually correlated with hardness can reduce or increase the toxicities of some metals. Hardness is used as a surrogate for a number of water quality characteristics which affect the toxicity of metals in a variety of ways. Increasing hardness has the effect of decreasing the toxicity of metals. Water quality criteria to protect aquatic life may be calculated at different concentrations of hardnesses measured in milligrams per liter (mg/l) as calcium carbonate ($CaCO_3$).

Section 131.38(b)(2) of the final rule presents the hardness-dependent equations for freshwater metals criteria. For example, using the equation for zinc, the total recoverable CMCs at a hardness of 10, 50, 100 or 200 mg/l as $CaCO_3$ are 17, 67, 120 and 220 micrograms per liter (μg/l), respectively. Thus, the specific value in the table in the regulatory text is for illustrative purposes only. Most of the data used to develop these hardness equations for deriving aquatic life criteria for metals were in the range of 25 mg/l to 400 mg/l as $CaCO_3$, and the formulas are therefore most accurate in this range. The majority of surface waters nationwide and in California have a hardness of less than 400 mg/l as $CaCO_3$.

In the past, EPA generally recommended that 25 mg/l as $CaCO_3$ be used as a default hardness value in deriving freshwater aquatic life criteria for metals when the ambient (or actual) hardness value is below 25 mg/l as $CaCO_3$. However, use of the approach results in criteria that may not be fully protective. Therefore, for waters with a hardness of less than 25 mg/l as $CaCO_3$, criteria should be calculated using the actual ambient hardness of the surface water.

In the past, EPA generally recommended that if the hardness was over 400 mg/l, two options were available: (1) Calculate the criterion using a default WER of 1.0 and using a hardness of 400 mg/l in the hardness equation; or (2) calculate the criterion using a WER and the actual ambient hardness of the surface water in the equation. Use of the second option is expected to result in the level of protection intended in the 1985 Guidelines whereas use of the first option is thought to result in an even more protective aquatic life criterion. At high hardness there is an indication that hardness and related inorganic water quality characteristics do not have as much of an effect on toxicity of metals as they do at lower hardnesses. Related water quality characteristics do not correlate as well at higher hardnesses as they do at lower hardnesses. Therefore, if hardness is over 400 mg/l as $CaCO_3$, a hardness of 400 mg/l as $CaCO_3$ should be used with a default WER of 1.0; alternatively, the WER and actual hardness of the surface water may be used.

EPA requested comments in the NTR amendments on the use of actual ambient hardness for calculating criteria when the hardness is below 25 mg/l as $CaCO_3$, and when hardness is greater than 400 mg/l as $CaCO_3$. Most of the comments received were in favor of using the actual hardness with the use of the water-effect ratio (1.0 unless otherwise specified by the permitting authority) when the hardness is greater than 400 mg/l as $CaCO_3$. A few commenters did not want the water-effect ratio to be mandatory in calculating hardness, and other commenters had concerns about being responsible for deriving an appropriate water-effect ratio. Overall, the commenters were in favor of using the actual hardness when calculating hardness-dependent freshwater metals criteria for hardness between 0–400 mg/l as $CaCO_3$. EPA took those comments into account in promulgating today's rule.

A hardness equation is most accurate when the relationships between hardness and the other important inorganic constituents, notably alkalinity and pH, are nearly identical in all of the dilution waters used in the toxicity tests and in the surface waters to which the equation is to be applied. If an effluent raises hardness but not alkalinity and/or pH, using the hardness of the downstream water might provide a lower level of protection than intended by the 1985 guidelines. If it appears that an effluent causes hardness to be inconsistent with alkalinity and/or pH, the intended level of protection will usually be maintained or exceeded if either (1) data are available to demonstrate that alkalinity and/or pH do not affect the toxicity of the metal, or (2) the hardness used in the hardness equation is the hardness of upstream water that does not contain the effluent. The level of protection intended by the 1985 guidelines can also be provided by using the WER procedure.

In some cases, capping hardness at 400 mg/l might result in a level of protection that is higher than that intended by the 1985 guidelines, but any such increase in the level of protection can be overcome by use of the WER procedure. For metals whose criteria are expressed as hardness equations, use of the WER procedure will generally be intended to account for effects of such water quality characteristics as total organic carbon on the toxicities of metals. The WER procedure is equally useful for accounting for any deviation from a hardness equation in a site water.

3. Human Health Criteria

EPA's CWA section 304(a) human health criteria guidance provides criteria recommendations to minimize adverse human effects due to substances in ambient water. EPA's CWA section 304(a) criteria guidance for human health are based on two types of toxicological endpoints: (1) carcinogenicity and (2) systemic toxicity (i.e., all other adverse effects other than cancer). Thus, there are two procedures for assessing these health effects: one for carcinogens and one for non-carcinogens.

If there are no data on how a chemical agent causes cancer, EPA's existing human health guidelines assume that carcinogenicity is a "non-threshold phenomenon," that is, there are no "safe" or "no-effect levels" because even extremely small doses are assumed to cause a finite increase in the incidence of the effect (i.e., cancer). Therefore, EPA's water quality criteria guidance for carcinogens are presented as pollutant concentrations corresponding to increases in the risk of developing cancer. See Human Health Guidelines at 45 FR 79347.

With existing criteria, pollutants that do not manifest any apparent carcinogenic effect in animal studies (i.e., systemic toxicants), EPA assumes that the pollutant has a threshold below which no effect will be observed. This assumption is based on the premise that a physiological mechanism exists within living organisms to avoid or overcome the adverse effect of the pollutant below the threshold concentration.

Note: Recent changes in the Agency's cancer guidelines addressing these assumptions are described in the Draft Water Quality Criteria Methodology: Human Health, 63 FR 43756, August 14, 1998.

The human health risks of a substance cannot be determined with any degree of confidence unless dose-response relationships are quantified. Therefore, a dose-response assessment is required before a criterion can be calculated. The dose-response assessment determines the quantitative relationships between the amount of exposure to a substance and the onset of toxic injury or disease. Data for determining dose-response relationships are typically derived from animal studies, or less frequently, from epidemiological studies in exposed populations.

The dose-response information needed for carcinogens is an estimate of the carcinogenic potency of the compound. Carcinogenic potency is defined here as a general term for a chemical's human cancer-causing potential. This term is often used loosely to refer to the more specific carcinogenic or cancer slope factor which is defined as an estimate of carcinogenic potency derived from animal studies or epidemiological data of human exposure. It is based on extrapolation from test exposures of high doses over relatively short periods of time to more realistic low doses over a lifetime exposure period by use of linear extrapolation models. The cancer slope factor, q1*, is EPA's estimate of carcinogenic potency and is intended to be a conservative upper bound estimate (e.g. 95% upper bound confidence limit).

For non-carcinogens, EPA uses the reference dose (RfD) as the dose-response parameter in calculating the criteria. For non-carcinogens, oral RfD assessments (hereinafter simply "RfDs") are developed based on pollutant concentrations that cause threshold effects. The RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime. See Human Health Guidelines. The RfD was formerly referred to as an "Acceptable Daily Intake" or ADI. The RfD is useful as a reference point for gauging the potential effect of other doses. Doses that are less than the RfD are not likely to be associated with any health risks, and are therefore less likely to be of regulatory concern. As the frequency of exposures exceeding the RfD increases and as the size of the excess increases, the probability increases that adverse effect may be observed in a human population. Nonetheless, a clear conclusion cannot be categorically drawn that all doses below the RfD are "acceptable" and that all doses in excess of the RfD are "unacceptable." In extrapolating non-carcinogen animal test data to humans to derive an RfD, EPA divides either a No Observed-Adverse Effect Level (NOAEL), Lowest Observed Adverse Effect Level (LOAEL), or other benchmark dose observed in animal studies by an "uncertainty factor" which is based on professional judgment of toxicologists and typically ranges from 10 to 10,000.

For CWA section 304(a) human health criteria development, EPA typically considers only exposures to a pollutant that occur through the ingestion of water and contaminated fish and shellfish. Thus, the criteria are based on an assessment of risks related to the surface water exposure route only where designated uses are drinking water and fish and shellfish consumption.

The assumed exposure pathways in calculating the criteria are the consumption of 2 liters per day of water at the criteria concentration and the consumption of 6.5 grams per day of fish and shellfish contaminated at a level equal to the criteria concentration but multiplied by a "bioconcentration factor." The use of fish and shellfish consumption as an exposure factor requires the quantification of pollutant residues in the edible portions of the ingested species.

Bioconcentration factors (BCFs) are used to relate pollutant residues in aquatic organisms to the pollutant concentration in ambient waters. BCFs are quantified by various procedures depending on the lipid solubility of the pollutant. For lipid soluble pollutants, the average BCF is calculated from the weighted average percent lipids in the edible portions of fish and shellfish, which is about 3%; or it is calculated from theoretical considerations using the octanol/water partition coefficient. For non-lipid soluble compounds, the BCF is determined empirically. The assumed water consumption is taken from the National Academy of Sciences publication *Drinking Water and Health* (1977). (Referenced in the Human Health Guidelines.) This value is appropriate as it includes a margin of safety so that the general population is protected. See also EPA's discussion of the 2.0 liters/day assumption at 61 FR 65183 (Dec. 11, 1996). The 6.5 grams per day contaminated fish and shellfish consumption value was equivalent to the average per-capita consumption rate of all (contaminated and non-contaminated) freshwater and estuarine fish and shellfish for the U.S. population. See Human Health Guidelines.

EPA assumes in calculating water quality criteria that the exposed individual is an average adult with body weight of 70 kilograms. EPA assumes 6.5 grams per day of contaminated fish and shellfish consumption and 2.0 liters per day of contaminated drinking water consumption for a 70 kilogram person in calculating the criteria. Regarding issues concerning criteria development and differences in dose per kilogram of body weight, RfDs are always derived based on the most sensitive health effect endpoint. Therefore, when that basis is due to a chronic or lifetime health effect, the exposure parameters assume the exposed individual to be the average adult, as indicated above.

In the absence of this final rule, there may be particular risks to children. EPA believes that children are protected by the human health criteria contained in this final rule. Children are protected against other less sensitive adverse health endpoints due to the conservative way that the RfDs are derived. An RfD is a public health protective endpoint. It is an amount of a chemical that can be consumed on a daily basis for a lifetime without expecting an adverse effect. RfDs are based on sensitive health endpoints and are calculated to be protective for sensitive human sub-populations including children. If the basis of the RfD was due to an acute or shorter-term developmental effect, EPA uses exposure parameters other than those indicated above. Specifically, EPA uses parameters most representative of the population of concern (*e.g.*, the health criteria for nitrates based on infant exposure parameters). For carcinogens, the risk assessments are upper bound one in a million (10^{-6}) lifetime risk numbers. The risk to children is not likely to exceed these upper bounds estimates and may be zero at low doses. The exposure assumptions for drinking water and fish protect children because they are conservative for infants and children. EPA assumes 2 liters of untreated surface water and 6.5 grams of freshwater and estuarine fish are consumed each day. EPA believes the adult fish consumption assumption is conservative for children because children generally consume marine fish not freshwater and estuarine.

EPA has a process to develop a scientific consensus on oral reference dose assessments and carcinogenicity assessments (hereinafter simply cancer slope factors or slope factors or q1*s). Through this process, EPA develops a consensus of Agency opinion which is then used throughout EPA in risk management decision-making. EPA maintains an electronic data base which contains the official Agency consensus for oral RfD assessments and carcinogenicity assessments which is known as the Integrated Risk Information System (IRIS). It is available for use by the public on the National Institutes of Health's National Library of Medicine's TOXNET system, and through diskettes from the National Technical Information Service (NTIS). (NTIS access number is PB 90–591330.)

Section 304(a)(1) of the CWA requires EPA to periodically revise its criteria guidance to reflect the latest scientific knowledge: "(A) On the kind and extent of all identifiable effects on health and welfare * * *; (B) on the concentration and dispersal of pollutants, or their byproducts, through biological, physical, and chemical processes; and (C) on the effects of pollutants on the biological community diversity, productivity, and stability, including information on the factors affecting eutrophication rates of organic and inorganic sedimentation for varying types of receiving waters." In developing up-to-date water quality criteria for the protection of human health, EPA uses the most recent IRIS values (RfDs and q1*s) as the toxicological basis in the criterion calculation. IRIS reflects EPA's most current consensus on the toxicological assessment for a chemical. In developing the criteria in today's rule, the IRIS values as of October 1996 were used together with currently accepted exposure parameters for bioconcentration, fish and shellfish and water consumption, and body weight. The IRIS cover sheet for each pollutant criteria included in today's rule is contained in the administrative record.

For the human health criteria included in today's rule, EPA used the Human Health Guidelines on which criteria recommendations from the appropriate CWA section 304(a) criteria guidance document were based. (These documents are also placed in the administrative record for today's rule.) Where EPA has changed any parameters in IRIS used in criteria derivation since issuance of the criteria guidance document, EPA recalculated the criteria recommendation with the latest IRIS information. Thus, there are differences between the original 1980 criteria guidance document recommendations, and those in this rule, but this rule presents EPA's most current CWA section 304(a) criteria recommendation. The basis (q1* or RfD) and BCF for each pollutant criterion in today's rule is contained in the rule's Administrative Record Matrix which is included in the administrative record for the rule. In addition, all recalculated human health numbers are denoted by an "a" in the criteria matrix in 40 CFR 131.38(b)(1) of the rule. The pollutants for which a revised human health criterion has been calculated since the December 1992 NTR include:

mercury
dichlorobromomethane
1,2-dichloropropane
1,2-trans-dichloroethylene
2,4-dimethylphenol
acenaphthene
benzo(a)anthracene
benzo(a)pyrene
benzo(b)flouranthene
benzo(k)flouranthene
2-chloronaphthalene
chrysene
dibenzo(a,h)anthracene
indeno(1,2,3-cd)pyrene
N-nitrosodi-n-propylamine
alpha-endosulfan
beta-endosulfan
endosulfan sulfate
2-chlorophenol
butylbenzyl phthalate
polychlorinated biphenyls.

In November of 1991, the proposed NTR presented criteria for several pollutants in parentheses. These were pollutants for which, in 1980, insufficient information existed to develop human health water quality criteria, but for which, in 1991, sufficient information existed. Since these criteria did not undergo the public review and comment in a manner similar to the other water quality criteria presented in the NTR (for which sufficient information was available in 1980 to develop a criterion, as presented in the 1980 criteria guidance documents), they were not proposed for adoption into the water quality criteria, but were presented to serve as notice for inclusion in future State triennial reviews. Today's rule promulgates criteria for these nine pollutants:

copper
1, 2-dichloropropane
1,2-trans-dichloroethylene
2,4-dimethylphenol
acenaphthene
2-chloronaphthalene
N-nitrosodi-n-propylamine
2-chlorophenol
butylbenzene phthalate

All the criteria are based on IRIS values—either an RfD or q1*—which were listed on IRIS as of November 1991, the date of the proposed NTR. These values have not changed since the final NTR was published in December of 1992. The rule's Administrative Record Matrix in the administrative record of today's rule contains the specific RfDs, q1*s, and BCFs used in calculating these criteria.

Proposed Changes to the Human Health Criteria Methodology: EPA recently proposed revisions to the 1980 ambient water quality criteria derivation guidelines (the Human Health Guidelines). See *Draft Water Quality Criteria Methodology: Human Health*, 63 FR 43756, August 14, 1998; see also *Draft Water Quality Criteria Methodology: Human Health*, U.S. EPA Office of Water, EPA 822–Z–98–001. The EPA revisions consist of five documents: *Draft Water Quality Criteria Methodology: Human Health*, EPA 822–Z–98–001; *Ambient Water Quality Criteria Derivation Methodology Human Health, Technical Support Document, Final Draft*, EPA–822–B–98–005; and three Ambient Water Quality Criteria for the Protection of Human Health, Drafts—one each for Acrylonitrile, 1,3-Dichloropropene (1,3-DCP), and Hexachlorobutadiene (HCBD), respectively, EPA–822–R–98–006, –005, and –004. All five documents are contained in the administrative record for today's rule.

The proposed methodology revisions reflect significant scientific advances that have occurred during the past nineteen years in such key areas as cancer and noncancer risk assessments, exposure assessments and bioaccumulation. For specific details on these proposed changes and others, please refer to the **Federal Register** notice or the EPA document.

It should be noted that some of the proposed changes may result in significant numeric changes in the ambient water quality criteria. However, EPA will continue to rely on existing criteria as the basis for regulatory and non-regulatory decisions, until EPA revises and reissues a 304(a) criteria guidance using the revised final human health criteria methodology. The existing criteria are still viewed as scientifically acceptable by EPA. The intention of the proposed methodology revisions is to present the latest scientific advancements in the areas of risk and exposure assessment in order to incrementally improve the already sound toxicological and exposure bases for these criteria. As EPA's current human health criteria are the product of many years worth of development and peer review, it is reasonable to assume that revisiting all existing criteria, and incorporating peer review into such review, could require comparable amounts of time and resources. Given these circumstances, EPA proposed a process for revisiting these criteria as part of the overall revisions to the methodology for deriving human health criteria. This process is discussed in the Implementation Section of the Notice of *Draft Revisions to the Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (see 63 FR 43771–43776, August 14, 1998).

The State of California in its Ocean Plan, adopted in 1990 and approved by EPA in 1991, established numeric water quality criteria using an average fish and shellfish consumption rate of 23 grams per day. This value is based on an earlier California Department of Health Services estimate. The State is currently in the process of readopting its water quality control plans for inland surface waters, enclosed bays, and estuaries. The State intends to consider information on fish and shellfish consumption rates evaluated and summarized in a report prepared by the State's Pesticide and Environmental Toxicology Section of the Office of Environmental Health Hazard Assessment of the California Environmental Protection Agency. The report, entitled, *Chemicals in Fish Report No. 1: Consumption of Fish and Shellfish in California and the United States*, was published in final draft form in July of 1997, and released to the public on September 16, 1997. The report is currently undergoing final evaluation, and is expected to published in final form in the near future. This final draft report is contained in the administrative record for today's rule. Although EPA has not used this fish consumption value here because this information has not yet been finalized, the State may use any appropriate higher state-specific fish and shellfish consumption rates in its readoption of criteria in its statewide plans.

a. 2,3,7,8-TCDD (Dioxin) Criteria

In today's action, EPA is promulgating human health water quality criteria for 2,3,7,8-tetrachlorodibenzo-p-dioxin ("dioxin") at the same levels as promulgated in the NTR, as amended. These criteria are derived from EPA's 1984 CWA section 304(a) criteria guidance document for dioxin.

For National Pollutant Discharge Elimination System (NPDES) purposes, EPA supports the regulation of other dioxin and dioxin-like compounds through the use of toxicity equivalencies or TEQs in NPDES permits (see discussion below). For California waters, if the discharge of dioxin or dioxin-like compounds has reasonable potential to cause or contribute to a violation of a narrative criterion, numeric water quality-based effluent limits for dioxin or dioxin-like compounds should be included in NPDES permits and should be expressed using a TEQ scheme.

EPA has been evaluating the health threat posed by dioxin nearly continuously for over two decades. Following issuance of the 1984 criteria guidance document, evaluating the health effects of dioxin and recommending human health criteria for dioxin, EPA prepared draft reassessments reviewing new scientific information relating to dioxin in 1985 and 1988. EPA's Science Advisory Board (SAB), reviewing the 1988 draft reassessment, concluded that while the risk assessment approach used in 1984 criteria guidance document had inadequacies, a better alternative was unavailable (see SAB's *Dioxin Panel Review of Documents from the Office or Research and Development relating to the Risk and Exposure Assessment of 2,3,7,8-TCDD* (EPA–SAB–EC–90–003, November 28, 1989) included in the administrative record for today's rule). Between 1988 and 1990, EPA issued numerous reports and guidances relating to the control of dioxin discharges from pulp and paper mills. See e.g., EPA Memorandum, "Strategy for the Regulation of Discharges of PHDDs & PHDFs from Pulp and Paper Mills to the Waters of the United States," from Assistant Administrator for Water to Regional Water Management Division Directors and NPDES State Directors, dated May 21, 1990 (AR NL–16); EPA Memorandum, "State Policies, Water Quality Standards, and Permit Limitations Related to 2,3,7,8-TCDD in Surface Water," from the Assistant Administrator for Water to Regional Water Management Division Directors, dated January 5, 1990 (AR VA–66). These documents are available in the administrative record for today's rule.

In 1991, EPA's Administrator announced another scientific reassessment of the risks of exposure to dioxin (see Memorandum from Administrator William K. Reilly to Erich W. Bretthauer, Assistant Administrator for Research and Development and E. Donald Elliott, General Counsel, entitled *Dioxin: Follow-Up to Briefing on Scientific Developments*, April 8, 1991, included in the administrative record for today's rule). At that time, the Administrator made clear that while the reassessment was underway, EPA would continue to regulate dioxin in accordance with existing Agency policy. Thereafter, the Agency proceeded to regulate dioxin in a number of environmental programs, including standards under the Safe Drinking Water Act and the CWA.

The Administrator's promulgation of the dioxin human health criteria in the 1992 NTR affirmed the Agency's decision that the ongoing reassessment should not defer or delay regulating this potent contaminant, and further, that the risk assessment in the 1984 criteria guidance document for dioxin continued to be scientifically defensible. Until the reassessment process was completed, the Agency could not "say with any certainty what the degree or directions of any changes in the risk estimates might be" (57 FR 60863–64).

The basis for the dioxin criteria as well as the decision to include the dioxin criteria in the 1992 NTR pending the results of the reassessment were challenged. See *American Forest and Paper Ass'n, Inc. et al. v. U.S. EPA* (Consolidated Case No. 93–0694 (RMU) D.D.C.). By order dated September 4, 1996, the Court upheld EPA's decision. EPA's brief and the Court's decision are included in the administrative record for today's rule.

EPA has undertaken significant effort toward completion of the dioxin reassessment. On September 13, 1994, EPA released for public review and comment a draft reassessment of toxicity and exposure to dioxin. See *Health Assessment Document for 2,3,7,8-Tetrachlorobenzo-p-Dioxin (TCDD) and Related Compounds*, U.S. EPA, 1994. EPA is currently addressing comments made by the public and the SAB and anticipates that the final

R0019118

revised reassessment will go to the SAB in the near future. With today's rule, the Agency reaffirms that, notwithstanding the on-going risk reassessment, EPA intends to continue to regulate dioxin to avoid further harm to public health, and the basis for the dioxin criteria, both in terms of the cancer potency and the exposure estimates, remains scientifically defensible. The fact that EPA is reassessing the risk of dioxin, virtually a continuous process to evaluate new scientific information, does not mean that the current risk assessment is "wrong". It continues to be EPA's position that until the risk assessment for dioxin is revised, EPA supports and will continue to use the existing risk assessment for the regulation of dioxin in the environment. Accordingly, EPA today promulgates dioxin criteria based on the 1984 criteria guidance document for dioxin and promulgated in the NTR in 1992.

Toxicity Equivalency: The State of California, in its 1991 water quality control plans, adopted human health criteria for dioxin and dioxin-like compounds based on the concept of toxicity equivalency (TEQ) using toxicity equivalency factors (TEFs). EPA Region 9 reviewed and approved the State's use of the TEQ concept and TEFs in setting the State's human health water quality criteria for dioxin and dioxin-like compounds.

In 1987, EPA formally embraced the TEQ concept as an interim procedure to estimate the risks associated with exposures to 210 chlorinated dibenzo-p-dioxin and chlorinated dibenzofuran (CDD/CDF) congeners, including 2,3,7,8-TCDD. This procedure uses a set of derived TEFs to convert the concentration of any CDD/CDF congener into an equivalent concentration of 2,3,7,8-TCDD. In 1989, EPA updated its TEFs based on an examination of relevant scientific evidence and a recognition of the value of international consistency. This updated information can be found in EPA's 1989 *Update to the Interim Procedures for Estimating Risks Associated with Exposures to Mixtures of Chlorinated Dibenzo-p-dioxins and -dibenzofurans (CDDs and CDFs)* (EPA/625/3–89/016, March 1989). EPA had been active in an international effort aimed at adopting a common set of TEFs (International TEFs/89 or I–TEFs/89), to facilitate information exchange on environmental contamination of CDD/CDF. This document reflects EPA's support of an internationally consistent set of TEFs, the I–TEFs/89. EPA uses I–TEFs/89 in many of its regulatory programs.

In 1994, the World Health Organization (WHO) revised the TEF scheme for dioxins and furans to include toxicity from dioxin-like compounds (Ahlborg et al., 1994). However, no changes were made to the TEFs for dioxins and furans. In 1998, the WHO re-evaluated and revised the previously established TEFs for dioxins (Ds), furans (Fs) and dioxin-like compounds (Vanden Bers, 1998). The nomenclature for this TEF scheme is TEQDFP–WHO98, where TEQ represents the 2,3,7,8-TCDD Toxic Equivalence of the mixture, and the subscript DFP indicates that dioxins (Ds) furans (Fs) and dioxin-like compounds (P) are included in the TEF scheme. The subscript 98 following WHO displays the year changes were made to the TEF scheme.

EPA intends to use the 1998 WHO TEF scheme in the near future. At this point however, EPA will support the use of either the 1989 interim procedures or the 1998 WHO TEF scheme but encourages the use of the 1998 WHO TEF scheme in State programs. EPA expects California to use a TEF scheme in implementing the 2,3,7,8-TCDD water quality criteria contained in today's rule. The TEQ and TEF approach provide a methodology for setting NPDES water quality-based permit limits that are protective of human health for dioxin and dioxin-like compounds.

Several commenters requested EPA to promulgate criteria for other forms of dioxin, in addition to 2,3,7,8-TCDD. EPA's draft reassessment for dioxin examines toxicity based on the TEQ concept and I–TEFs/89. When EPA completes the dioxin reassessment, the Agency intends to adopt revised 304(a) water quality criteria guidance based on the reassessment for dioxin. If necessary, EPA will then act to amend the NTR and CTR to reflect the revised 304(a) water quality criteria guidance.

b. Arsenic Criteria

EPA is not promulgating human health criteria for arsenic in today's rule. EPA recognizes that it promulgated human health water quality criteria for arsenic for a number of States in 1992, in the NTR, based on EPA's 1980 section 304(a) criteria guidance for arsenic established, in part, from IRIS values current at that time. However, a number of issues and uncertainties existed at the time of the CTR proposal concerning the health effects of arsenic. These issues and uncertainties were summarized in "Issues Related to Health Risk of Arsenic" which is contained in the administrative record for today's rule. During the period of this rulemaking action, EPA commissioned a study of arsenic health effects by the National Research Council (NRC) arm of the National Academy of Sciences. EPA received the NRC report in March of 1999. EPA scientists reviewed the report, which recommended that EPA lower the Safe Drinking Water Act arsenic maximum contaminant level (MCL) as soon as possible (The arsenic MCL is currently 50 µg/l.) The bladder cancer analysis in the NRC report will provide part of the basis for the risk assessment of a proposed revised arsenic MCL in the near future. After promulgating a revised MCL for drinking water, the Agency plans to revise the CWA 304(a) human health criteria for arsenic in order to harmonize the two standards. Today's rule defers promulgating arsenic criteria based on the Agency's previous risk assessment of skin cancer. In the meantime, permitting authorities in California should rely on existing narrative water quality criteria to establish effluent limitations as necessary for arsenic. California has previously expressed its science and policy position by establishing a criterion level of 5 µg/l for arsenic. Permitting authorities may, among other considerations, consider that value when evaluating and interpreting narrative water quality criteria.

c. Mercury Criteria

The human health criteria promulgated here use the latest RfD in EPA's Integrated Risk Information System (IRIS) and the weighted average practical bioconcentration factor (PBCF) from the 1980 section 304(a) criteria guidance document for mercury. EPA considered the approach used in the Great Lakes Water Quality Guidance ("Guidance") incorporating Bioaccumulation Factors (BAFs), but rejected this approach for reasons outlined below. The equation used here to derive an ambient water quality criterion for mercury from exposure to organisms and water is:

$$\mathrm{HHC} = \frac{\mathrm{RfD} \times \mathrm{BW}}{\mathrm{WC} + (\mathrm{FC} \times \mathrm{PBCF})}$$

Where:

RfD = Reference Dose
BW = Body Weight
WC = Water Consumption
FC = Total Fish and Shellfish Consumption per Day
PBCF = Practical Bioconcentration Factor (weighted average)

For mercury, the most current RfD from IRIS is 1×10^{-4} mg/kg/day. The RfD used a benchmark dose as an estimate of a No Observed Adverse Effect Level (NOAEL). The benchmark dose was calculated by applying a Weibel model for extra risk to all neurological effects observed in 81 Iraqi children exposed in utero as reported in Marsh, et. al. (1987). Maternal hair mercury was the measure of exposure. Extra risk refers to an adjustment for background incidence of a given health effect. Specifically, the extra risk is the added incidence of observing an effect above the background rate relative to the proportion of the population of interest that is not expected to exhibit such as effect. The resulting estimate was the lower 95% statistical bound on the 10% extra risk; this was 11 ppm mercury in maternal hair. This dose in hair was converted to an equivalent ingested amount by applying a model based on data from human studies; the resulting benchmark dose was 1×10^{-3} mg/kg body weight /day. The RfD was calculated by dividing the benchmark dose by a composite uncertainty factor of 10. The uncertainty factor was used to account for variability in the human population, in particular the wide variation in biological half-life of methylmercury and the variation that is observed in the ration of hair mercury to mercury in the blood. In addition the uncertainty factor accounts for lack of a two-generation reproductive study and the lack of data on long term effects of childhood mercury exposures. The RfD thus calculated is 1×10^{-4} mg/kg body weight/day or 0.1 µg/kg/day. The body weight used in the equation for the mercury criteria, as discussed in the Human Health Guidelines, is a mean adult human body weight of 70 kg. The drinking water consumption rate, as discussed in the Human Health Guidelines, is 2.0 liters per day.

The bioconcentration factor or BCF is defined as the ratio of chemical concentration in the organism to that in surrounding water. Bioconcentration occurs through uptake and retention of a substance from water only, through gill membranes or other external body surfaces. In the context of setting exposure criteria it is generally understood that the terms "BCF" and "steady-state BCF" are synonymous. A steady-state condition occurs when the organism is exposed for a sufficient length of time that the ratio does not change substantially.

The BCFs that were used herein are the "Practical Bioconcentration Factors (PBCFs)" that were derived in 1980: 5500 for fresh water, 3765 for estuarine coastal waters, and 9000 for open oceans. See pages C–100–1 of Ambient Water Quality Criteria for Mercury (EPA 440/5–80–058) for a complete discussion on the PBCF. Because of the way they were derived, these PBCFs take into account uptake from food as well as uptake from water. A weighted average PBCF was calculated to take into account the average consumption from the three waters using the following equation:

$$\text{Weighted Average Practical BCF} = \frac{\sum(\text{FC} \times \text{PBCF})}{\sum(\text{FC})} = \frac{(0.00172)(5500) + (0.00478)(3765) + (0.0122)(9000)}{0.00172 + 0.00478 + 0.0122} = \frac{137.3}{0.0187} = 7342.6$$

Given the large value for the weighted average PBCF, the contribution of drinking water to total daily intake is negligible so that assumptions concerning the chemical form of mercury in drinking water become less important. The human health mercury criteria promulgated for this rule are based on the latest RfD as listed in IRIS and a weighted PBCF from the 1980 § 304(a) criteria guidance document for mercury.

On March 23, 1995 (60 FR 15366), EPA promulgated the Great Lakes Water Quality Guidance ("Guidance"). The Guidance incorporated bioaccumulation factors (BAFs) in the derivation of criteria to protect human health because it is believed that BAFs are a better predictor than BCFs of the concentration of a chemical within fish tissue since BAFs include consideration of the uptake of contaminants from all routes of exposure. A bioaccumulation factor is defined as the ratio (in L/kg) of a substance's concentration in tissue to the concentration in the ambient water, in situations where both the organism and its food are exposed and the ratio does not change substantially over time. The final Great Lakes Guidance establishes a hierarchy of four methods for deriving BAFs for non-polar organic chemicals: (1) Field-measured BAFs; (2) predicted BAFs derived using a field-measured biota-sediment accumulation factor; (3) predicted BAFs derived by multiplying a laboratory-measured BCF by a food chain multiplier; and (4) predicted BAFs derived by multiplying a BCF calculated from the log Kow by a food-chain multiplier. The final Great Lakes Guidance developed BAFs for trophic levels three and four fish of the Great Lakes Basin. Respectively, the BAFs for mercury for trophic level 3 and 4 fish were: 27,900 and 140,000.

The BAF promulgated in the GLI was developed specifically for the Great Lakes System. It is uncertain whether the BAFs of 27,900 and 140,000 are appropriate for use in California at this time; therefore, today's final rule does not use the GLI BAF in establishing human health criteria for mercury in California. The magnitude of the BAF for mercury in a given system depends on how much of the total mercury is present in the methylated form. Methylation rates vary widely from one water body to another for reasons that are not fully understood. Lacking the data, it is difficult to determine if the BAF used in the GLI represents the true potential for mercury to bioaccumulate in California surface waters. The true, average BAF for California could be higher or lower. For more information see EPA's Response to Comments document in the administrative record for this rule (specifically comments CTR–002–007(b) and CTR–016–007).

EPA is developing a national BAF for mercury as part of revisions to its 304(a) criteria for human health; however, the BAF methodology that will be used is currently under evaluation as part of EPA's revisions to its National Human Health Methodology (see section F.3 above). EPA applied a similar methodology in its Mercury Study Report to Congress (MSRC) to derive a BAF for methylmercury. The MSRC is available through NTIS (EPA–452/R–97–003). Although a BAF was derived in the MSRC, EPA does not intend to use this BAF for National application. EPA is engaged in a separate effort to incorporate additional mercury bioaccumulation data that was not considered in the MSRC, and to assess uncertainties with using a National BAF approach for mercury. Once the proposed revised human health methodology, including the BAF component, is finalized, EPA will revise its 304(a) criteria for mercury to reflect changes in the underlying methodology, recommendations contained in the MSRC, and recommendations in a National Academy of Science report on human health assessment of methylmercury. When EPA changes its 304(a) criteria recommendation for mercury, States and Tribes will be expected to review their water quality standards for mercury and make any revisions necessary to ensure their standards are scientifically defensible.

New information may become available regarding the bioaccumulation of mercury in certain water bodies in California. EPA supports the use of this information to develop site-specific criteria for mercury. Further, if a California water body is impaired due to mercury fish tissue or sediment contamination, loadings of mercury could contribute to or exacerbate the impairment. Therefore, one option regulatory authorities should consider is to include water quality-based effluent limits (WQBELs) in permits based on mass for discharges to the impaired water body. Such WQBELs must be derived from and comply with applicable State water quality standards (including both numeric and narrative criteria) and assure that the discharge does not cause or contribute to a violation of water quality standards.

d. Polychlorinated Biphenyls (PCBs) Criteria

The NTR, as amended, calculated human health criteria for PCBs using a cancer potency factor of 7.7 per mg/kg-day from the Agency's IRIS. This cancer potency factor was derived from the Norback and Weltman (1985) study which looked at rats that were fed Aroclor 1260. The study used the linearized multistage model with a default cross-species scaling factor (body weight ratio to the ⅔ power). Although it is known that PCB mixtures vary greatly as to their potency in producing biological effects, for purposes of its carcinogenicity assessment, EPA considered Aroclor 1260 to be representative of all PCB mixtures. The Agency did not pool data from all available congener studies or generate a geometric mean from these studies, since the Norback and Weltman study was judged by EPA as acceptable, and not of marginal quality, in design or conduct as compared with other studies. Thereafter, the Institute for Evaluating Health Risks (IEHR, 1991) reviewed the pathological slides from the Norback and Weltman study, and concluded that some of the malignant liver tumors should have been interpreted as nonmalignant lesions, and that the cancer potency factor should be 5.1 per mg/kg-day as compared with EPA's 7.7 per mg/kg-day.

The Agency's peer-reviewed reassessment of the cancer potency of PCBs published in a final report, *PCBs: Cancer Dose-Response Assessment and Applications to Environmental Mixtures* (EPA/600/P-96/001F), adopts a different approach that distinguishes among PCB mixtures by using information on environmental processes. (The report is included in the administrative record of today's rule.) The report considers all cancer studies (which used commercial mixtures only) to develop a range of cancer potency factors, then uses information on environmental processes to provide guidance on choosing an appropriate potency factor for representative classes of environmental mixtures and different pathways. The reassessment provides that, depending on the specific application, either central estimates or upper bounds can be appropriate. Central estimates describe a typical individual's risk, while upper bounds provide assurance (*i.e.*, 95% confidence) that this risk is not likely to be underestimated if the underlying model is correct. Central estimates are used for comparing or ranking environmental hazards, while upper bounds provide information about the precision of the comparison or ranking. In the reassessment, the use of the upper bound values were found to increase cancer potency estimates by two or three-fold over those using central tendency. Upper bounds are useful for estimating risks or setting exposure-related standards to protect public health, and are used by EPA in quantitative cancer risk assessment. Thus, the cancer potency of PCB mixtures is determined using a tiered approach based on environmental exposure routes with upper-bound potency factors (using a body weight ratio to the ¾ power) ranging from 0.07 (lowest risk and persistence) to 2 (high risk and persistence) per mg/kg-day for average lifetime exposures to PCBs. It is noteworthy that bioaccumulated PCBs appear to be more toxic than commercial PCBs and appear to be more persistent in the body. For exposure through the food chain, risks can be higher than other exposures.

EPA issued the final reassessment report on September 27, 1996, and updated IRIS to include the reassessment on October 1, 1996. EPA updated the human health criteria for PCBs in the National Toxics Rule on September 27, 1999. For today's rule, EPA derived the human health criteria for PCBs using a cancer potency factor of 2 per mg/kg-day, an upper bound potency factor reflecting high risk and persistence. This decision is based on recent multimedia studies indicating that the major pathway of exposure to persistent toxic substances such as PCBs is via dietary exposure (*i.e.*, contaminated fish and shellfish consumption).

Following is the calculation of the human health criterion (HHC) for organism and water consumption:

$$HHC = \frac{RF \times BW \times (1{,}000\ \mu g/mg)}{q1^* \times [WC + (FC \times BCF)]}$$

Where:

RF = Risk Factor = 1×10^{-6}
BW = Body Weight = 70 kg
$q1^*$ = Cancer slope factor = 2 per mg/kg-day
WC = Water Consumption = 2 l/day
FC = Fish and Shellfish Consumption = 0.0065 kg/day
BCF = Bioconcentration Factor = 31,200

the HHC (μg/l) = 0.00017 μg/l (rounded to two significant digits).

Following is the calculation of the human health criterion for organism only consumption:

$$HHC = \frac{RF \times BW \times (1{,}000\ \mu g/mg)}{q1^* \times FC \times BCF}$$

Where:

RF = Risk Factor = 1×10^{-6}
BW = Body Weight = 70 kg
$q1^*$ = Cancer slope factor = 2 per mg/kg-day
FC = Total Fish and Shellfish Consumption per Day = 0.0065 kg/day
BCF = Bioconcentration Factor = 31,200

the HHC (μg/l) = 0.00017 μg/l (rounded to two significant digits).

The criteria are both equal to 0.00017 μg/l and apply to total PCBs. *See PCBs: Cancer Dose Response Assessment and Application to Environmental Mixtures* (EPA/600/9–96–001F). For a discussion of the body weight, water consumption, and fish and shellfish consumption factors, see the Human Health Guidelines. For a discussion of the BCF, see the 304(a) criteria guidance document for PCBs (included in the administrative record for today's rule).

e. Excluded Section 304(a) Human Health Criteria

As is the case in the NTR, as amended, today's rule does not promulgate criteria for certain priority pollutants for which CWA section 304(a) criteria guidance exists because those criteria were not based on toxicity to humans or aquatic organisms. The basis for those particular criteria is organoleptic effects (*e.g.*, taste and odor) which would make water and edible aquatic life unpalatable but not toxic. Because the basis for this rule is to protect the public health and aquatic life from toxicity consistent with the language and intent in CWA section 303(c)(2)(B), EPA is promulgating criteria only for those priority toxic pollutants whose criteria recommendations are based on toxicity. The CWA section 304(a) human health criteria based on organoleptic effects for zinc and 3-methyl-4-chlorophenol are excluded for this reason. See the 1992 NTR discussion at 57 FR 60864.

R0019121

f. Cancer Risk Level

EPA's CWA section 304(a) criteria guidance documents for priority toxic pollutants that are based on carcinogenicity present concentrations for upper bound risk levels of 1 excess cancer case per 100,000 people (10^{-5}), per 1,000,000 people (10^{-6}), and per 10,000,000 people (10^{-7}). However, the criteria documents do not recommend a particular risk level as EPA policy.

As part of the proposed rule, EPA requested and received comment on the adoption of a 10^{-5} risk level for carcinogenic pollutants. The effect of a 10^{-5} risk level would have been to increase (*i.e.*, make less stringent) carcinogenic pollutant criteria values (noted in the matrix by footnote c) that are not already promulgated in the NTR, by one order of magnitude. For example, the organism-only criterion for gamma BHC (pollutant number 105 in the matrix) is 0.013 µg/l; the criterion based on a 10^{-5} risk level would have been 0.13 µg/l. EPA received several comments that indicated a preference for a higher (10^{-4} and 10^{-5}) risk level for effluent dependent waters or other types of special circumstances.

In today's rule, EPA is promulgating criteria that protect the general population at an incremental cancer risk level of one in a million (10^{-6}) for all priority toxic pollutants regulated as carcinogens, consistent with the criteria promulgated in the NTR for the State of California. Standards adopted by the State contained in the Enclosed Bays and Estuaries Plan (EBEP), and the Inland Surface Waters Plan (ISWP), partially approved by EPA on November 6, 1991, and the Ocean Plan approved by EPA on June 28, 1990, contained a risk level of 10^{-6} for most carcinogens. The State has historically protected at a 10^{-6} risk level for carcinogenic pollutants.

EPA, in its recent human health methodology revisions, proposed acceptable lifetime cancer risk for the general population in the range of 10^{-5} to 10^{-6}. EPA also proposed that States and Tribes ensure the most highly exposed populations do not exceed a 10^{-4} risk level. However, EPA's draft methodology revisions also stated that it will derive 304(a) criteria at a 10^{-6} risk level, which the Agency believes reflects the appropriate risk for the general population and which applies a risk management policy which ensures protection for all exposed population groups. (Draft Water Quality Criteria Methodology: Human Health, EPA 822–Z–98–001, August 1998, Appendix II, page 72).

Subpopulations within a State may exist, such as recreational and subsistence anglers, who as a result of greater exposure to a contaminant are at greater risk than the standard 70 kilogram person eating 6.5 grams per day of fish and shellfish and drinking 2.0 liters per day of drinking water with pollutant levels meeting the water quality criteria. EPA acknowledges that at any given risk level for the general population, those segments of the population that are more highly exposed face a higher relative risk. For example, if fish are contaminated at a level permitted by criteria derived on the basis of a risk level of 10^{-6}, individuals consuming up to 10 times the assumed fish consumption rate would still be protected at a 10^{-5} risk level. Similarly, individuals consuming 100 times the general population rate would be protected at a 10^{-4} risk level. EPA, therefore, believes that derivation of criteria at the 10^{-6} risk level is a reasonable risk management decision protective of designated uses under the CWA. While outside the scope of this rule, EPA notes that States and Tribes, however, have the discretion to adopt water quality criteria that result in a higher risk level (*e.g.*, 10^{-5}). EPA expects to approve such criteria if the State or Tribe has identified the most highly exposed subpopulation within the State or Tribe, demonstrates the chosen risk level is adequately protective of the most highly exposed subpopulation, and has completed all necessary public participation.

This demonstration has not happened in California. Further, the information that is available on highly exposed subpopulations in California supports the need to protect the general population at the 10^{-6} level. California has cited the Santa Monica Bay Seafood Consumption Study as providing the best available data set for estimating consumption of sport fish and shellfish in California for both marine or freshwater sources (Chemicals in Fish Report No. 1: Consumption of Fish and Shellfish in California and the United States, Final Draft Report, July 1997). Consumption rates of sport fish and shellfish of 21g/day, 50 g/day, 107 g/day, and 161 g/day for the median, mean, 90th, and 95th percentile rates, respectively, were determined from this study. Additional consumption of commercial species in the range of approximately 8 to 42 g/day would further increase these values. Clearly the consumption rates for the most highly exposed subpopulation within the State exceeds 10 times the 6.5 g/day rates used in the CTR. Therefore, use of a risk level of 10^{-5} for the general population would not be sufficient to protect the most highly exposed population in California at a 10^{-4} risk level. On the other hand, even the most highly exposed subpopulations cited in the California study do not have consumption rates approaching 100 times the 6.5 g/day rates used in the CTR. The use of the 10^{-6} risk level to protect average level consumers does not subject these subpopulations to risk levels as high as 10^{-4}.

EPA believes its decision to establish a 10^{-6} risk level for the CTR is also consistent with EPA's policy in the NTR to select the risk level that reflect the policies or preferences of CWA programs in the affected States. California adopted standards for priority toxic pollutants for its ocean waters in 1990 using a 10^{-6} risk level to protect human health (California Ocean Plan, 1990). In April 1991, and again in November 1992, California adopted standards for its inland surface waters and enclosed bays and estuaries in its Inland Surface Waters Plan (ISWP) and its Enclosed Bays and Estuaries Plan (EBEP) using a 10^{-6} risk level. To be consistent with the State's water quality standards, EPA used a 10^{-6} risk level for California in the NTR at 57 FR 60867. The State has continued using a 10^{-6} risk level to protect human health for its standards that were not withdrawn with the ISWP and EBEP. The most recent expression of risk level preference is contained in the Draft Functional Equivalent Document, Amendment of the Water Quality Control Plan for Ocean Waters of California, October 1998, where the State recommended maintaining a consistent risk level of 10^{-6} for the human health standards that it was proposing to revise.

EPA received several comments requesting a 10^{-5} risk level based on the risk level chosen for the Great Lakes Water Quality Guidance (the Guidance). There are several differences between the guidelines for the derivation of human health criteria contained in the Guidance and the California Toxics Rule (CTR) that make a 10^{-5} risk factor appropriate for the Guidance, but not for the CTR. These differences result in criteria developed using the 10^{-5} risk factor in the Guidance being at least as stringent as criteria derived under the CTR using a 10^{-6} risk factor. The relevant aspects of the Guidance include:

• Use of fish consumption rates that are considerably higher than fish consumption rates for the CTR.

• Use of bioaccumulation factors rather than bioconcentration factors in

R0019122

estimating exposure, considerably increasing the dose of carcinogens to sensitive subgroups.

• Consideration of additivity of effects of mixtures for both carcinogenic and noncarcinogenic pollutants.

This combination of factors increase the calculated carcinogenic risk substantially under the Guidance (the combination would generally be more than one order of magnitude), making a lower overall risk factor acceptable. The Guidance risk factor provides, in fact, criteria with at least the same level of protection against carcinogens as criteria derived with a higher risk factor using the CTR. A lower risk factor for the CTR would not be appropriate absent concomitant changes in the derivation procedures that provide equivalent risk protection.

G. Description of Final Rule

1. Scope

Paragraph (a) in 40 CFR 131.38, entitled "Scope," states that this rule is a promulgation of criteria for priority toxic pollutants in the State of California for inland surface waters, enclosed bays, and estuaries. Paragraph (a) in 40 CFR 131.38 also states that this rule contains an authorizing compliance schedule provision.

2. EPA Criteria for Priority Toxic Pollutants

EPA's criteria for California are presented in tabular form at 40 CFR 131.38. For ease of presentation, the table that appears combines water quality criteria promulgated in the NTR, as amended, that are outside the scope of this rulemaking, with the criteria that are within the scope of today's rule. This is intended to help readers determine applicable water quality criteria for the State of California. The table contains footnotes for clarification.

Paragraph (b) in 40 CFR 131.38 presents a matrix of the applicable EPA aquatic life and/or human health criteria for priority toxic pollutants in California. Section 303(c)(2)(B) of the CWA addresses only pollutants listed as "toxic" pursuant to section 307(a) of the CWA for which EPA has developed section 304(a) criteria guidance. As discussed earlier in this preamble, the section 307(a) list of toxics contains 65 compounds and families of compounds, which potentially include thousands of specific compounds. Of these, the Agency identified a list of 126 "priority toxic pollutants" to implement the CWA (see 40 CFR 131.36(b)). Reference in this rule to priority toxic pollutants, toxic pollutants, or toxics refers to the 126 priority toxic pollutants.

EPA has not developed both aquatic life and human health CWA section 304(a) criterion guidance for all of the priority toxic pollutants. The matrix in 40 CFR 131.38(b) contains human health criteria in Column D for 92 priority toxic pollutants which are divided into Column 1: criteria for water consumption (i.e., 2.0 liters per day) and aquatic organism consumption (i.e., 6.5 grams per day of aquatic organisms); and Column 2: criteria for aquatic organism consumption only. The term aquatic organism includes fish and shellfish such as shrimp, clams, oysters and mussels. One reason the total number of priority toxic pollutants with criteria today differs from the total number of priority toxic pollutants contained in earlier published CWA section 304(a) criteria guidance is because EPA has developed and is promulgating chromium criteria for two valence states with respect to aquatic life criteria. Thus, although chromium is a single priority toxic pollutant, there are two criteria for chromium for aquatic life protection. See pollutant 5 in today's rule at 40 CFR 131.38(b). Another reason is that EPA is promulgating human health criteria for nine priority pollutants for which health-based national criteria have been calculated based on information obtained from EPA's IRIS database (EPA provided notice of these nine criteria in the NTR for inclusion in future State triennial reviews. See 57 FR 60848, 60890).

The matrix contains aquatic life criteria for 23 priority pollutants. These are divided into freshwater criteria (Column B) and saltwater criteria (Column C). These columns are further divided into acute and chronic criteria. The aquatic life criteria are considered by EPA to be protective when applied under the conditions described in the section 304(a) criteria documents and in the TSD. For example, water body uses should be protected if the criteria are not exceeded, on average, once every three year period. It should be noted that the criteria maximum concentrations (the acute criteria) are short-term concentrations and that the criteria continuous concentrations (the chronic criteria) are four-day averages. It should also be noted that for certain metals, the actual criteria are equations which are included as footnotes to the matrix. The toxicity of these metals is water hardness dependent and may be adjusted. The values shown in the table are illustrative only, based on a hardness expressed as calcium carbonate of 100 mg/l. Finally, the criterion for pentachlorophenol is pH dependent. The equation is the actual criterion and is included as a footnote. The value shown in the matrix is for a pH of 7.8. Several of the freshwater aquatic life criteria are incorporated into the matrix in the format used in the 1980 criteria methodology which uses a final acute value instead of a continuous maximum concentration. This distinction is noted in footnote g of the table.

The final rule at 40 CFR 131.38(c) establishes the applicability of the criteria to the State of California. 40 CFR 131.38(d) is described later in Section F, of this preamble. EPA has included in this rule provisions necessary to implement numeric criteria in a way that maintains the level of protection intended. These provisions are included in 40 CFR 131.38(c) of today's rule. For example, in order to do steady state waste load allocation analyses, most States have low flow values for streams and rivers which establish flow rates for various purposes. These low flow values become design flows for sizing treatment plants and developing water quality-based effluent limits and/or TMDLs. Historically, these design flows were selected for the purposes of waste load allocation analyses which focused on instream dissolved oxygen concentrations and protection of aquatic life. With the publication of the 1985 TSD, EPA introduced hydrologically and biologically based analyses for the protection of aquatic life and human health. (These concepts have been expanded subsequently in EPA's *Technical Guidance Manual for Performing Wasteload Allocations, Book 6, Design Conditions*, U.S. EPA, 1986. These analyses are included in Appendix D of the revised TSD. The discussion here is greatly simplified and is provided to support EPA's decision to promulgate design flows for instream flows and thereby maintain the adequacy of the criteria for priority toxic pollutants.) EPA recommended either of two methods for calculating acceptable low flows, the traditional hydrologic method developed by the U.S. Geological Survey or a biological based method developed by EPA. Other methods for evaluating the instream flow record may be available; use of these methods may result in TMDLs and/or water quality-based effluent limitations which adequately protect human health and/or aquatic life. The results of either of these two methods, or an equally protective alternative method, may be used.

The State of California may adopt specific design flows for streams and rivers to protect designated uses against the effects of toxics. EPA believes it is important to specify design flows in today's rule so that, in the absence of state design flows, the criteria promulgated today would be implemented appropriately. The TSD also recommends the use of three dynamic models to perform wasteload allocations. Dynamic wasteload models do not generally use specific steady state design flows but accomplish the same effect by factoring in the probability of occurrence of stream flows based on the historical flow record.

The low flows specified in the rule explicitly contain duration and frequency of occurrence which represent certain probabilities of occurrence. Likewise, the criteria for priority toxic pollutants are defined with duration and frequency components. Dynamic modeling techniques explicitly predict the effects of variability in receiving water, effluent flow, and pollution variation. Dynamic modeling techniques, as described in the TSD, allow for calculating wasteload allocations that meet the criteria for priority toxic pollutants without using a single, worst-case concentration based on a critical condition. Either dynamic modeling or steady state modeling can be used to implement the criteria promulgated today. For simplicity, only steady state conditions are discussed here. Clearly, if the criteria were implemented using design flows that are too high, the resulting toxic controls would not be adequate, because the resulting ambient concentrations would exceed EPA's criteria.

In the case of aquatic life, assuming exceedences occur more frequently than once in three years on the average, exceedences would result in diminished vitality of stream ecosystems characterized by the loss of desired species. Numeric water quality criteria should apply at all flows that are equal to or greater than flows specified below. The low flow values are:

Type of criteria	Design flow
Acute Aquatic Life (CMC).	1 Q 10 or 1 B 3
Chronic Aquatic Life (CCC).	7 Q 10 or 4 B 3
Human Health	harmonic mean flow

Where:

1 Q 10 is the lowest one day flow with an average recurrence frequency of once in 10 years determined hydrologically;

1 B 3 is biologically based and indicates an allowable exceedence of once every 3 years. It is determined by EPA's computerized method (DFLOW model);

7 Q 10 is the lowest average 7 consecutive day low flow with an average recurrence frequency of once in 10 years determined hydrologically;

4 B 3 is biologically based and indicates an allowable exceedences for 4 consecutive days once every 3 years. It is determined by EPA's computerized method (DFLOW model);

EPA is requiring that the harmonic mean flow be applied with human health criteria. The harmonic mean is a standard calculated statistical value. EPA's model for human health effects assumes that such effects occur because of a long-term exposure to low concentration of a toxic pollutant, for example, two liters of water per day for seventy years. To estimate the concentrations of the toxic pollutant in those two liters per day by withdrawal from streams with a high daily variation in flow, EPA believes the harmonic mean flow is the correct statistic to use in computing such design flows rather than other averaging techniques. (For a description of harmonic means see "Design Stream Flows Based on Harmonic Means," Lewis A. Rossman, Jr. of Hydraulics Engineering, Vol. 116, No. 7, July, 1990.)

All waters (including lakes, estuaries, and marine waters), whether or not suitable for such hydrologic calculations, are subject to the criteria promulgated today. Such criteria will need to be attained at the end of the discharge pipe, unless the State authorizes a mixing zone. Where the State plans to authorize a mixing zone, the criteria would apply at the locations allowed by the mixing zone. For example, the chronic criteria (CCC) would apply at the defined boundary of the chronic mixing zone. Discussion of and guidance on these factors are included in the revised TSD in Chapter 4.

EPA is aware that the criteria promulgated today for some of the priority toxic pollutants are at concentrations less than EPA's current analytical detection limits. Analytical detection limits have never been an acceptable basis for setting water quality criteria since they are not related to actual environmental impacts. The environmental impact of a pollutant is based on a scientific determination, not a measuring technique which is subject to change. Setting the criteria at levels that reflect adequate protection tends to be a forcing mechanism to improve analytical detection methods. See 1985 Guidelines, page 21. As the methods improve, limits based on the actual criteria necessary to protect aquatic life and human health become measurable. The Agency does not believe it is appropriate to promulgate criteria that are not sufficiently protective. EPA discusses this issue further in its Response to Comment Document for today's final rule.

EPA does believe, however, that the use of analytical detection limits are appropriate for assessing *compliance* with National Pollutant Discharge Elimination System (NPDES) permit limits. This view of the role of detection limits was first articulated in guidance for translating dioxin criteria into NPDES permit limits. See "Strategy for the Regulation of Discharges of PHDDs and PHDFs from Pulp and Paper Mills to Waters of the U.S." Memorandum from the Assistant Administrator for Water to the Regional Water Management Division Directors, May 21, 1990. This guidance presented a model for addressing toxic pollutants which have criteria less than current detection limits. EPA, in more recent guidance, recommends the use of the "minimum level" or ML for reporting sample results to assess compliance with WQBELs (TSD page 111). The ML, also called the "quantification level," is the level at which the entire analytical system gives recognizable mass spectra and acceptable calibration points, i.e., the point at which the method can reliably quantify the amount of pollutant in the sample. States can use their own procedures to average and otherwise account for monitoring data, *e.g.*, quantifying results below the ML. These results can then be used to assess compliance with WQBELs. (See 40 CFR part 132, Appendix F, Procedure 8.B.) This approach is applicable to priority toxic pollutants with criteria less than current detection limits. EPA's guidance explains that standard analytical methods may be used for purposes of assessing compliance with permit limits, but not for purposes of establishing water quality criteria or permit limits. Under the CWA, analytical methods are appropriately used in connection with NPDES permit limit compliance assessments. Because of the function of water quality criteria, EPA has not considered the sensitivity of analytical methods in deriving the criteria promulgated today.

EPA has promulgated 40 CFR 131.38(c)(3) to determine when freshwater or saltwater aquatic life criteria apply. This provision incorporates a time parameter to better define the critical condition. The structure of the paragraph is to establish applicable rules and to allow for site-specific exceptions where the rules are not consistent with actual field conditions. Because a distinct separation generally does not exist between freshwater and saltwater aquatic communities, EPA is establishing the following: (1) The freshwater criteria apply at salinities of 1 part per thousand and below at locations where this occurs 95% or more of the time; (2) saltwater criteria apply at salinities of 10 parts per thousand and above at locations where this occurs 95% more of the time; and (3) at salinities between 1 and 10 parts per thousand the more stringent of the two apply unless EPA approves the application of the freshwater or saltwater criteria based on an appropriate biological assessment. The percentiles included here were selected to minimize the chance of overlap, that is, one site meeting both criteria. Determination of these percentiles can be done by any reasonable means such as interpolation between points with measured data or by the application of calibrated and verified mathematical models (or hydraulic models). It is not EPA's intent to require actual data collection at particular locations.

In the brackish water transition zones of estuaries with varying salinities, there generally will be a mix of freshwater and saltwater species. Generally, therefore, it is reasonable for the more stringent of the freshwater or saltwater criteria to apply. In evaluating appropriate data supporting the alternative set of criteria, EPA will focus on the species composition as its preferred method. This assignment of criteria for fresh, brackish and salt waters was developed in consultation with EPA's research laboratories at Duluth, Minnesota and Narragansett, Rhode Island. The Agency believes such an approach is consistent with field experience.

Paragraph (d) in 40 CFR 131.38 lists the designated water and use classifications for which the criteria apply. The criteria are applied to the beneficial use designations adopted by the State of California; EPA has not promulgated any new use classifications in this rule.

Exceedences Frequency: In a water quality criterion for aquatic life, EPA recommends an allowable frequency for excursions of the criteria. See 1985 Guidelines, pages 11–13. This allowable frequency provides an appropriate period of time during which the aquatic community can recover from the effect of an excursion and then function normally for a period of time before the next excursion. An excursion is defined as an occurrence of when the average concentration over the duration of the averaging period is above the CCC or the CMC. As ecological communities are naturally subjected to a series of stresses, the allowable frequency of pollutant stress may be set at a value that does not significantly increase the frequency or severity of all stresses combined. See also TSD, Appendix D. In addition, providing an allowable frequency for exceeding the criterion recognizes that it is not generally possible to assure that criteria are never exceeded. (TSD, page 36.)

Based on the available data, today's rule requires that the acute criterion for a pollutant be exceeded no more than once in three years on the average. EPA is also requiring that the chronic criterion for a pollutant be exceeded no more than once in three years on the average. EPA acknowledges that States may develop allowable frequencies that differ from these allowable frequencies, so long as they are scientifically supportable, but believes that these allowable frequencies are protective of the designated uses where EPA is promulgating criteria.

The use of aquatic life criteria for developing water quality-based effluent limits in permits requires the permitting official to use an appropriate wasteload allocation model. (TSD, Appendix D–6.) As discussed above, there are generally two methods for determining design flows, the hydrologically-based method and the biologically-based method.

The biologically-based method directly uses the averaging periods and frequencies specified in the aquatic life criteria for determining design flows. (TSD, Appendix. D–8.) Because the biologically-based method calculates the design flow directly from the duration and allowable frequency, it most accurately provides the allowed number of excursions. The hydrologically based method applies the CMC at a design flow equal to or equivalent to the 1Q10 design flow (i.e., the lowest one-day flow with an average recurrence frequency of once in ten years), and applies the CCC at the 7Q10 design flow (i.e., the lowest average seven consecutive day flow with a recurrence frequency of once in ten years).

EPA established a three year allowable frequency in the NTR. In settlement of the litigation on the NTR, EPA stated that it was in the midst of conducting, sponsoring, or planning research aimed at addressing scientific issues related to the basis for and application of water quality criteria and mentioned the issue of allowable frequency. See Partial Settlement Agreement in *American Forest and Paper Ass'n, Inc. et al.* v. *U.S. EPA* (Consolidated Case No. 93–0694 (RMU) D.D.C. To that end, EPA is reevaluating issues raised about allowable frequency as part of its work in revising the 1985 Guidelines.

EPA recognizes that additional data concerning (a) the probable frequency of lethal events for an assemblage of taxa covering a range of sensitivities to pollutants, (b) the probable frequency of sublethal effects for such taxa, (c) the differing effects of lethal and sublethal events in reducing populations of such taxa, and (d) the time needed to replace organisms lost as a result of toxicity, may lead to further refinement of the allowable frequency value. EPA has not yet completed this work. Until this work is complete, EPA believes that where EPA promulgates criteria, the three year allowable frequency represents a value in the reasonable range for this parameter.

3. Implementation

Once the applicable designated uses and water quality criteria for a water body are determined, under the National Pollutant Discharge Elimination System (NPDES) program discharges to the water body must be characterized and the permitting authority must determine the need for permit limits. If a discharge causes, has the reasonable potential to cause, or contributes to an excursion of a numeric or narrative water quality criteria, the permitting authority must develop permit limits as necessary to meet water quality standards. These permit limits are water quality-based effluent limitations or WQBELs. The terms "cause," "reasonable potential to cause," and "contribute to" are the terms in the NPDES regulations for conditions under which water quality-based permit limits are required. See 40 CFR 122.44(d)(1).

Since the publication of the proposed CTR, the State of California adopted procedures which detail how water quality criteria will be implemented through NPDES permits, waste discharge requirements, and other regulatory approaches. These procedures entitled, *Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California* were adopted on March 2, 2000. Once these procedures are submitted for review under CWA section 303(c), EPA will review them as they relate to water quality standards, and approve or disapprove them.

Several commenters understood the language in the preamble to the proposed rule regarding implementation to mean that site-specific criteria, variances, and other actions would be prohibited or severely limited by the CTR. Site-specific criteria, variances and other actions modifying criteria are neither prohibited nor limited by the CTR. The State, if it so chooses, still can make these changes to its water quality standards, subject to EPA approval. However, with this Federal rule in effect, the State cannot implement any modifications that are less stringent than the CTR without an amendment to the CTR to reflect these modifications. EPA will make every effort to expeditiously accommodate Federal rulemaking of appropriate modifications to California's water quality standards. In the preamble to the proposed CTR, and here today, EPA is emphasizing that these efforts to amend the CTR on a case-by-case basis will generally increase the time before a modification can be implemented.

4. Wet Weather Flows

EPA has for a longtime maintained that CWA section 301(b)(1)(C) applies to NPDES permits for discharges from municipal separate storm sewer systems. Recently, the U.S. Court of Appeals for the Ninth Circuit upheld NPDES permits issued by EPA for five Arizona municipal separate storm sewer systems and addressed this issue specifically. *Defenders of Wildlife, et al.* v. *Browner*, No. 98–71080 (9th Cir., October 1999). The Court held that the CWA does not require "strict compliance" with State water quality standards for municipal storm sewer permits under section 301(b)(1)(C), but that at the same time, the CWA does give EPA discretion to incorporate appropriate water quality-based effluent limitations under another provision, CWA section 402(p)(3)(B)(iii).

The Court based its decision on the structure of section 402(p)(3), which contains distinct language for discharges of industrial storm water and municipal storm water. In section 402(p)(3)(A), Congress requires that "dischargers associated with industrial activity shall meet all applicable provisions of [section 402] and section [301]." 33 U.S.C. section 1342(p)(3)(A). The Court noted, therefore, that by incorporation, industrial storm water discharges need to achieve "any more stringent limitation, including those necessary to meet water quality standards * * *" The Court explained that industrial storm water discharges "must comply strictly with State water quality standards" but that Congress chose not to include a similar provision for municipal storm sewer discharges, including instead a requirement for controls to reduce pollutants to the maximum extent practicable or MEP standard in section 402(p)(3)(B). Reading the two related sections together, the Court concluded that section 402(p)(3)(B)(iii) does not require "strict compliance" by municipal storm sewer discharges according to section 301(b)(1)(C). At the same time, however, the Court found that the language in CWA section 402(p)(3)(B)(iii) which states that permits for discharges from municipal storm sewers shall require "such other provisions as the Administrator of the state determines appropriate for the control of such pollutants" provides EPA with discretion to incorporate provisions lending to ultimate compliance with water quality standards.

EPA believes that compliance with water quality standards through the use of Best Management Practices (BMPs) is appropriate. EPA articulated its position on the use of BMPs in storm water permits in the policy memorandum entitled, "Interim Permitting Approach for Water Quality-Based Effluent Limitations In Storm Water Permits" which was signed by the Assistant Administrator for Water, Robert Perciasepe on August 1, 1996 (61 FR 43761, August 9, 1996). A copy of this memorandum is contained in the administrative record for today's rule. The policy affirms the use of BMPs as a means to attain water quality standards in municipal storm water permits, and embraces BMPs as an interim permitting approach.

The interim permitting approach uses BMPs in first-round storm water permits, and expanded or better-tailored BMPs in subsequent permits, where necessary, to provide for the attainment of water quality standards. In cases where adequate information exists to develop more specific conditions or limitations to meet water quality standards, these conditions or limitations are to be incorporated into storm water permits, as necessary and appropriate.

This interim permitting approach, however, only applies to EPA. EPA encourages the State to adopt a similar policy for municipal storm water permits. This interim permitting approach provides time, where necessary, to more fully assess the range of issues and possible options for the control of storm water discharges for the protection of water quality. More information on this issue is included in the response to comment document in response to specific storm water issues raised by commenters.

5. Schedules of Compliance

A compliance schedule refers to an enforceable sequence of interim requirements in a permit leading to ultimate compliance with water quality-based effluent limitations or WQBELs in accordance with the CWA. The authorizing compliance schedule provision authorizes, but does not require, the permit issuing authority in the State of California to include such compliance schedules in permits under appropriate circumstances. The State of California is authorized to administer the National Pollutant Discharge Elimination System (NPDES) program and may exercise its discretion when deciding if a compliance schedule is justified because of the technical or financial (or other) infeasibility of immediate compliance. An authorizing compliance schedule provision is included in today's rule because of the potential for existing dischargers to have new or more stringent effluent limitations for which immediate compliance would not be possible or practicable.

New and Existing Dischargers: The provision allows compliance schedules only for an "existing discharger" which is defined as any discharger which is not a "new California discharger." A "new California discharger" includes "any building, structure, facility, or installation from which there is, or may be, a 'discharge of pollutants', the construction of which commences after the effective date of this regulation." These definitions are modeled after the existing 40 CFR 122.2 definitions for parallel terms, but with a cut-off date modified to reflect this rule. Only "new California dischargers" are required to comply immediately upon commencement of discharge with effluent limitations derived from the criteria in this rule. For "existing dischargers" whose permits are reissued or modified to contain new or more stringent limitations based upon certain water quality requirements, the permit could allow up to five years, or up to the length of a permit, to comply with such limitations. The provision applies to new or more stringent effluent limitations based on the criteria in this EPA rule.

EPA has included "increasing dischargers" within the category of "existing dischargers" since "increasing dischargers" are existing facilities with a change—an increase—in their discharge. Such facilities may include those with seasonal variations. "Increasing dischargers" will already have treatment systems in place for their current discharge, thus, they have less opportunity than a new discharger does to design and build a new treatment system which will meet new water quality-based requirements for their changed discharge. Allowing existing facilities with an increasing discharge a compliance schedule will avoid placing the discharger at a competitive disadvantage vis-a-vis other existing dischargers who are eligible for compliance schedules.

Today's rule does not prohibit the use of a short-term "shake down period" for new California dischargers as is provided for new sources or new dischargers in 40 CFR 122.29(d)(4). These regulations require that the owner or operator of (1) a new source; (2) a new discharger (as defined in 40 CFR 122.2) which commenced discharge after August 13, 1979; or (3) a recommencing discharger shall install and implement all pollution control equipment to meet the conditions of the permit before discharging. The facility must also meet all permit conditions in the shortest feasible time (not to exceed 90 days). This shake-down period is not a compliance schedule. This approach may be used to address violations which may occur during a new facility's start-up, especially where permit limits are water quality-based and biological treatment is involved.

The burden of proof to show the necessity of a compliance schedule is on the discharger, and the discharger must request approval from the permit issuing authority for a schedule of compliance. The discharger should submit a description of the minimum required actions or evaluations that must be undertaken in order to comply with the new or more restrictive discharge limits. Dates of completion for the required actions or evaluations should be included, and the proposed schedule should reflect the shortest practicable time to complete all minimum required actions.

Duration of Compliance Schedules: Today's rule provides that compliance schedules may provide for up to five years to meet new or more stringent effluent limitations in those limited circumstances where the permittee can demonstrate to the permit authority that an extended schedule is warranted. EPA's regulations at 122.47 require compliance with standards as soon as possible. This means that permit authorities should not allow compliance schedules where the permittee fails to demonstrate their necessity. This provision should not be considered a default compliance schedule duration for existing facilities.

In instances where dischargers wish to conduct toxicological studies, analyze results, and adopt and implement new or revised water quality-based effluent limitations, EPA believes that five years is sufficient time within which to complete this process. See the preamble to the proposed rule.

Under this rule, where a schedule of compliance exceeds one year, interim requirements are to be specified and interim progress reports are to be submitted at least annually to the permit issuing authority, in at least one-year time intervals.

The rule allows all compliance schedules to extend up to a maximum duration of five years, which is the maximum term of any NPDES permit. See 40 CFR 122.46. The discharger's opportunity to obtain a compliance schedule occurs when the existing permit for that discharge is issued, reissued or modified to contain more stringent limits based on the water quality criteria in today's rule. Such compliance schedules, however, cannot be extended to any indefinite point of time in the future because the compliance schedule provision in this rule will sunset on May 18, 2005. The sunset applies to the authorizing provision in today's rule (40 CFR 131.38(e)), not to individual schedules of compliance included in specific NPDES permits. Delays in reissuing expired permits (including those which continue in effect under applicable NPDES regulations) cannot indefinitely extend the period of time during which a compliance schedule is in effect. This would occur where the permit authority includes the single maximum five-year compliance schedule in a permit that is reissued just before the compliance schedule provision sunsets (having been previously issued without WQBELS using the rule's criteria on the eve of the effective date of this rule). Instead, the effect of the sunset provision is to limit the longest time period for compliance to ten years after the effective date of this rule.

EPA recognizes that where a permit is modified during the permit term, and the permittee needs the full five years to comply, the five-year schedule may extend beyond the term of the modified permit. In such cases, the rule allows for the modified permit to contain a compliance schedule with an interim limit by the end of the permit term. When the permit is reissued, the permit authority may extend the compliance schedule in the next permit, provided that, taking into account the amount of time allowed under the previous permit, the entire compliance schedule contained in the permit shall not exceed five years. Final permit limits and compliance dates will be included in the record for the permit. Final compliance dates must occur within five years from the date of permit issuance, reissuance, or modification, unless additional or less time is provided for by law.

EPA would prefer that the State adopt an authorizing compliance schedule provision but recognizes that the State may not be able to complete this action for some time after promulgation of the CTR. Thus, EPA has chosen to promulgate the rule with a sunset provision which states that the authorizing compliance schedule provision will cease or sunset on May 18, 2005. However, if the State Board adopts, and EPA approves, a statewide authorizing compliance schedule provision significantly prior to May 18, 2005, EPA will act to stay the authorizing compliance schedule provision in today's rule. Additionally, if a Regional Board adopts, and the State Board adopts and EPA approves, a Regional Board authorizing compliance schedule provision, EPA will act to stay today's provision for the appropriate or corresponding geographic region in California. At that time, the State Board's or Regional Board's authorizing compliance schedule provision will govern the ability of the State regulatory entity to allow a discharger to include a compliance schedule in a discharger's NPDES permit.

Antibacksliding: EPA wishes to address the potential concern over antibacksliding where revised permit limits based on new information are the result of the completion of additional studies. The Agency's interpretation of the CWA is that the antibacksliding requirements of section 402(o) of the CWA do not apply to revisions to effluent limitations made before the scheduled date of compliance for those limitations.

State Compliance Schedule Provisions: EPA supports the State in adopting a statewide provision independent of or as part of the effort to readopt statewide water quality control plans, or in adopting individual basin-wide compliance schedule provisions through its nine Regional Water Quality Control Boards (RWQCBs). The State and RWQCBs have broad discretion to adopt a provision, including discretion on reasonable lengths of time for final compliance with WQBELs. EPA recognizes that practical time frames within which to set interim goals may be necessary to achieve meaningful, long-term improvements in water quality in California.

At this time, two RWQCBs have adopted an authorizing compliance schedule provision as an amendment to

R0019127

their respective Basin Plans during the Boards' last triennial review process. The Basin Plans have been adopted by the State and have come to EPA for approval. Thus, the Basin Plans' provisions are effective for the respective Basins. If and when EPA approves of either Regional Basin Plan, EPA will expeditiously act to amend the CTR, staying its compliance schedule provision, for the appropriate geographic region.

6. Changes From Proposed Rule

A few changes were made in the final rule from the proposal both as a result of the Agency's consideration of issues raised in public comments and Endangered Species Act consultation with the U.S. Fish and Wildlife Service (FWS) and U.S. National Marine Fisheries Service (NMFS). The important changes include: reserving the mercury aquatic life criteria; reserving the selenium freshwater acute aquatic life criterion; reserving the chloroform human health criteria; and adding a sunset provision to the authorizing compliance schedule provision. EPA also clarified that the CTR will not replace priority toxic pollutant criteria which were adopted by the San Francisco Regional Water Quality Control Board in its 1986 Basin Plan, adopted by the State Board, and approved by EPA; specifying the harmonic mean for human health criteria for non-carcinogens and adding a provision which explicitly allows the State to adopt and implement an alternative averaging period, frequency, and design flow for a criterion after opportunity for public comment.

The first two changes, the reservation of mercury criteria and selenium criterion, are discussed in more detail below in Section L., The Endangered Species Act (ESA). The selenium criterion is also discussed in more detail above in Section E., Derivation of Criteria, in subsection 2.b., Freshwater Acute Selenium Criterion. EPA has also decided to reserve a decision on numeric criteria for chloroform and therefore not promulgate chloroform criteria in the final rule. As part of a large-scale regulation promulgated in December 1998 under the Safe Drinking Water Act, EPA published a health-based goal for chloroform (the maximum contaminant level goal or MCLG) of zero, see 63 FR 69390, Dec. 16, 1998. EPA provided new data and analyses concerning chloroform for public review and comment, including a different, mode of action approach for estimating the cancer risk, 63 FR 15674, March 31, 1998, but did not reach a conclusion on how to use that new information in establishing the final MCLG, pending further review by the Science Advisory Board. EPA has now concluded that any further actions on water quality criteria should take into account the new data and analysis as reviewed by the SAB. This decision is consistent with a recent federal court decision vacating the MCLG for chloroform (*Chlorine Chemistry Council* v. *EPA*, No. 98–1627 (DC Cir., Mar. 31,2000)). EPA intends to reassess the human health 304(a) criteria recommendation for chloroform. For these reasons, EPA has decided to reserve a decision on numeric criteria for chloroform in the CTR and not promulgate water quality criteria as proposed. Permitting authorities in California should continue to rely on existing narrative criteria to establish effluent limitations as necessary for chloroform.

The sunset provision for the authorizing compliance schedule provision has been added to ease the transition from a Federal provision to the State's provision that was adopted in March 2000 as part of its' new statewide implementation plan. The sunset provision is discussed in more detail in Section G.5 of today's preamble. The CTR matrix at 40 CFR 131.38(b)(1) makes it explicit that the rule does not supplant priority toxic pollutant criteria which were adopted by the San Francisco Regional Water Quality Control Board in its 1986 Basin Plan, adopted by the State Board, and approved by EPA. This change is discussed more fully in Section D.4. of today's preamble. EPA modified the design flow for implementing human health criteria for non-carcinogens from a 30Q5 to a harmonic mean. Human health criteria for non-carcinogens are based on an RfD, which is an acceptable daily exposure over a lifetime. EPA matched the criteria for protection over a human lifetime with the longest stream flow averaging period, i.e., the harmonic mean. Lastly, the CTR now contains language which is intended to make it easier for the State to adopt and implement an alternative averaging period, frequency and related design flow, for situations where the default parameters are inappropriate. This language is found at 40 CFR 131.38(c)(2)(iv).

H. Economic Analysis

This final rule establishes ambient water quality criteria which, by themselves, do not directly impose economic impacts (see section K). These criteria combined with the State-adopted designated uses for inland surface waters, enclosed bays and estuaries, and implementation policies, will establish water quality standards. Until the State implements these water quality standards, there will be no effect of this rule on any entity. The State will implement these criteria by ensuring that NPDES permits result in discharges that will meet these criteria. In so doing, the State will have considerable discretion.

EPA has analyzed the indirect potential costs and benefits of this rule. In order to estimate the indirect costs and benefits of the rule, an appropriate baseline must be established. The baseline is the starting point for measuring incremental costs and benefits of a regulation. The baseline is established by assessing what would occur in the absence of the regulation. At present, State Basin Plans contain a narrative water quality criterion stating that all waters shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal, or aquatic life. EPA's regulation at 40 CFR 122.44(d)(1)(vi) requires that where a discharge causes or has the reasonable potential to cause an excursion above a narrative criterion within a State water quality standard, the permitting authority must establish effluent limits but may determine limits using a number of options. These options include establishing "effluent limits on a case-by-case basis, using EPA's water quality criteria published under section 304(a) of the CWA, supplemented where necessary by other relevant information" (40 CFR 122.44(d)(1)(vi)(B)). Thus, to the extent that the State is implementing its narrative criteria by applying the CWA section 304(a) criteria, this rule does not impose any incremental costs because the criteria in this rule are identical to the CWA section 304(a) criteria. Alternatively, to the extent that the State is implementing its narrative criteria on a "case-by-case basis" using "other relevant information" in its permits this rule may impose incremental indirect costs because the criteria in these permits may not be based on CWA 304(a) criteria. Both of these approaches to establishing effluent limits are in full compliance with the CWA.

Because a specific basis for effluent limits in all existing permits in California is not known, it is not possible to determine a precise estimate of the indirect costs of this rule. The incremental costs of the rule may be as low as zero, or as high as $61 million. The high estimate of costs is based on the possibility that most of the effluent limits now in effect are not based on 304(a) criteria. EPA evaluated these indirect costs using two different approaches. The first approach uses existing discharge data and makes assumptions about future State NPDES permit limits. Actual discharge levels are usually lower than the level set by current NPDES permit limits. This approach, representing the low-end scenario, also assumes that some of the discretionary mechanisms that would enhance flexibility (*e.g.*, site specific criteria, mixing zones) would be granted by the State. The second approach uses a sample of existing permit limits and assumes that dischargers are actually discharging at the levels contained in their permits and makes assumptions about limits statewide that would be required under the rule. This approach, representing the high-end scenario, also assumes that none of the discretionary mechanisms that would enhance flexibility (*e.g.*, site specific criteria, mixing zones) would be granted by the State. These two approaches recognize that the State has significant flexibility and discretion in how it chooses to implement standards within the NPDES permit program, the EA by necessity includes many assumptions about how the State will implement the water quality standards. These assumptions are based on a combination of EPA guidance and current permit conditions for the facilities examined in this analysis. To account for the uncertainty of EPA's implementation assumptions, this analysis estimates a wide range of costs and benefits. By completing the EA, EPA intends to inform the public about how entities might be potentially affected by State implementation of water quality standards in the NPDES permit program. The costs and benefits sections that follow summarize the methodology and results of the analysis.

1. Costs

EPA assessed the potential compliance costs that facilities may incur to meet permit limits based on the criteria in today's rule. The analysis focused on direct compliance costs such as capital costs and operation and maintenance costs (O&M) for end-of-pipe pollution control, indirect source controls, pollution prevention, monitoring, and costs of pursuing alternative methods of compliance.

The population of facilities with NPDES permits that discharge into California's enclosed bays, estuaries and inland surface waters includes 184 major dischargers and 1,057 minor dischargers. Of the 184 major facilities, 128 are publicly owned treatment works (POTWs) and 56 are industrial facilities. Approximately 2,144 indirect dischargers designated as significant industrial users discharge wastewater to those POTWs. In the EA for the proposed CTR, EPA used a three-phased process to select a sample of facilities to represent California dischargers potentially affected by the State's implementation of permit limits based on the criteria contained in this rule.

The first phase consisted of choosing three case study areas for which data was thought to exist. The three case studies with a total of 5 facilities included: the South San Francisco Bay (the San Jose/Santa Clara Water Pollution Control Plant and Sunnyvale Water Pollution Control Plant); the Sacramento River (the Sacramento Regional Wastewater Treatment Plant); and the Santa Ana River (the City of Riverside Water Quality Control Plant and the City of Colton Municipal Wastewater Treatment Facility). The second phase consisted of selecting five additional major industrial dischargers to complement the case-study POTWs.

The third phase involved selecting 10 additional facilities to improve the basis for extrapolating the costs of the selected sample facilities to the entire population of potentially affected dischargers. The additional 10 facilities were selected such that the group examined: (1) Was divided between major POTWs and major industrial discharger categories in proportion to the numbers of facilities in the State; (2) gave greater proportionate representation to major facilities than minor facilities based on a presumption that the majority of compliance costs would be incurred by major facilities; (3) gave a proportionate representation to each of four principal conventional treatment processes typically used by facilities in specified industries in California; and (4) was representative of the proportionate facilities located within the different California Regional Water Quality Control Boards. Within these constraints, facilities were selected at random to complete the sample.

In the EA for today's final rule, EPA primarily used the same sample as the EA for the proposed rule with some modifications. EPA increased the number of minor POTWs and minor industrial facilities in the sample. EPA randomly selected four new minor POTW facilities and five new minor industrial facilities to add to the sample. The number of sample facilities selected in each area under the jurisdiction of a Regional Water Quality Control Board was roughly proportional to the universe of facilities in each area.

For those facilities that were projected to exceed permit limits based on the criteria, EPA estimated the incremental costs of compliance. Using a decision matrix or flow chart, costs were developed for two different scenarios—a "low-end" cost scenario and a "high-end" cost scenario—to account for a range of regulatory flexibility available to the State when implementing permit limits based on the water quality criteria. The assumptions for baseline loadings also vary over the two scenarios. The low-end scenario generally assumed that facilities were discharging at the maximum effluent concentrations taken from actual monitoring data, while the high-end scenario generally assumed that facilities were discharging at their current effluent limits. The decision matrix specified assumptions used for selection of control options, such as optimization of existing treatment processes and operations, in-plant pollutant minimization and prevention, and end-of-pipe treatment.

The annualized potential costs that direct and indirect dischargers may incur as a result of State implementation of permit limits based on water quality standards using today's criteria are estimated to be between $33.5 million and $61 million. EPA believes that the costs incurred as a result of State implementation of these permit limits will approach the low-end of the cost range. Costs are unlikely to reach the high-end of the range because State authorities are likely to choose implementation options that provide some degree of flexibility or relief to point source dischargers. Furthermore, cost estimates for both scenarios, but especially for the high-end scenario, may be overstated because the analysis tended to use conservative assumptions in calculating these permit limits and in establishing baseline loadings. The baseline loadings for the high-end were based on current effluent limits rather than actual pollutant discharge data. Most facilities discharge pollutants in concentrations well below current effluent limits. In addition, both the high-end and low-end cost estimates in the EA may be slightly overstated since potential costs incurred to reduce chloroform discharges were included in these estimates. EPA made a decision to reserve the chloroform human health criteria after the EA was completed.

Under the low-end cost scenario, major industrial facilities and POTWs would incur about 27 percent of the potential costs, indirect dischargers would incur about 70 percent of the potential costs, while minor dischargers would incur about 3 percent. Of the major direct dischargers, POTWs would incur the largest share of projected costs (87 percent). However, distributed among 128 major POTWs in the State, the average cost per plant would be $61,000 per year. Chemical and petroleum industries would incur the highest cost of the industrial categories (5.6 percent of the annual costs, with an annual average of $25,200 per plant). About 57 percent of the low-end costs would be associated with pollution prevention activities, while nearly 38 percent would be associated with pursuing alternativa methods of compliance under the regulations.

Under the high-end cost scenario, major industrial facilities and POTWs would incur about 94 percent of the potential costs, indirect dischargers would incur about 17 percent of the potential costs, while minor dischargers would incur about 5 percent. Among the major, direct dischargers, two categories would incur the majority of potential costs—major POTWs (82 percent), Chemical/Petroleum Products (9 percent). The average annual per plant cost for different industry categories would ranges from zero to $324,000. The two highest average cost categories would be major POTWs ($324,000 per year) and Chemical/Petroleum Products ($221,264 per year). The shift in proportion of potential costs between direct and indirect dischargers is due to the assumption that more direct dischargers would use end-of-pipe treatment under the high-end scenario. Thus, a smaller proportion of indirect dischargers would be impacted under the high-end scenario, since some municipalities are projected to add end-of-pipe treatment which would reduce the need for controls from indirect discharges. Over 91 percent of the annual costs are for waste minimization and treatment optimization costs. Waste minimization would represent nearly 84% of the total annual costs. Capital and operation and maintenance costs would make up less than 9 percent of annual costs.

Cost-Effectiveness: Cost-effectiveness is estimated in terms of the cost of reducing the loadings of toxic pollutants from point sources. The cost-effectiveness is derived by dividing the projected annual costs of implementing permit limits based on water quality standards using today's criteria by the toxicity-weighted pounds (pound-equivalents) of pollutants removed. Pound-equivalents are calculated by multiplying pounds of each pollutant removed by the toxic weight (based on the toxicity of copper) for that pollutant.

Based on this analysis, State implementation of permit limits based on today's criteria would be responsible for the reduction of about 1.1 million to 2.7 million toxic pound-equivalents per year, or 15 to 50 percent of the toxic-weighted baseline loadings for the high- and low-end scenarios, respectively. The cost-effectiveness of the scenarios would range from $22 (high-end scenario) to $31 (low-end scenario) per pound-equivalent.

2. Benefits

The benefits analysis is intended to provide insight into both the types and potential magnitude of the economic benefits expected as a result of implementation of water quality standards based on today's criteria. To the extent feasible, empirical estimates of the potential magnitude of the benefits were developed and then compared to the estimated costs of implementing water quality standards based on today's criteria.

To perform a benefits analysis, the types or categories of benefits that apply need to be defined. EPA relied on a set of benefits categories that typically apply to changes in the water resource environment. Benefits were categorized as either use benefits or passive (nonuse) benefits depending on whether or not they involve direct use of, or contact with, the resource. The most prominent use benefit categories are those related to recreational fishing, boating, and swimming. Another use benefit category of significance is human health risk reduction. Human health risk reductions can be realized through actions that reduce human exposure to contaminants such as exposure through the consumption of fish containing elevated levels of pollutants. Passive use benefits are those improvements in environmental quality that are valued by individuals apart from any use of the resource in question.

Benefits estimates were derived in this study using an approach in which benefits of discrete large-scale changes in water quality beyond present day conditions were estimated wherever feasible. A share of those benefits was then apportioned to implementation of water quality standards based on today's criteria. The apportionment estimate was based on a three-stage process:

First, EPA assessed current total loadings from all sources that are contributing to the toxics-related water quality problems observed in the State. This defines the overall magnitude of loadings. Second, the share of total loadings that are attributable to sources that would be controlled through implementation of water quality standards based on today's criteria was estimated. Since this analysis was designed to focus only on those controls imposed on point sources, this stage of the process entailed estimating the portion of total loadings originating from point sources. Third, the percentage reduction in loadings expected due to implementation of today's criteria was estimated and then multiplied by the share of point source loadings to calculate the portion of benefits that could be attributed to implementation of water quality standards based on today's criteria.

Total monetized annual benefits were estimated in the range of $6.9 to $74.7 million. By category, annual benefits would be $1.3 to $4.6 million for avoided cancer risk, $2.2 to $15.2 million for recreational angling, and $3.4 to $54.9 million for passive use benefits.

There are numerous categories of potential or likely benefits that have been omitted from the quantified and monetized benefit estimates. In terms of potential magnitudes of benefit, the following are likely to be significant contributors to the underestimation of the monetized values presented above:

• Improvements in water-related (in-stream and near stream) recreation apart from fishing. The omission of potential motorized and nonmotorized boating, swimming, picnicking, and related in-stream and stream-side recreational activities from the benefits estimates could contribute to an appreciable underestimation of total benefits. Such recreational activities have been shown in empirical research to be highly valued, and even modest changes in participation and or user values could lead to sizable benefits statewide. Some of these activities can be closely associated with water quality attributes (notably, swimming). Other recreational activities may be less directly related to the water quality improvements, but might nonetheless increase due to their association with fishing, swimming, or other activities in which the participants might engage.

• Improvements in consumptive and nonconsumptive land-based recreation, such as hunting and wildlife observation. Improvements in aquatic habitats may lead (via food chain and related ecologic benefit mechanisms) to healthier, larger, and more diverse populations of avian and terrestrial species, such as waterfowl, eagles, and otters. Improvements in the populations for these species could manifest as improved hunting and wildlife viewing opportunities, which might in turn increase participation and user day values for such activities. Although the scope of the benefits analysis has not allowed a quantitative assessment of these values at either pre- or post-rule conditions, it is conceivable that these benefits could be appreciable.

• Improvements in human health resulting from reduction of non-cancer risk. EPA estimated that implementation of water quality standards based on the criteria would result in a reduction of mercury concentrations in fish tissue and, thus, a reduction in the hazard from consumption of mercury contaminated fish. However, EPA was unable to monetize benefits due to reduced non-cancer health effects.

• Human health benefits for saltwater anglers outside of San Francisco Bay were not estimated. The number of saltwater anglers outside of San Francisco Bay is estimated to be 673,000 (based on Huppert, 1989, and U.S. FWS, 1993). The omission of other saltwater anglers may cause human health benefits to be underestimated. In addition, benefit estimates in the EA may be slightly overstated since potential benefits from reductions in chloroform discharges were included in these estimates. EPA made a decision to reserve the chloroform human health criteria after the EA was completed.

EPA received a number of comments which requested the Agency use the cost-benefit analysis in the EA as a factor in setting water quality criteria. EPA does not use the EA as a basis in determining protective water quality criteria. EPA's current regulations at 40 CFR 131.11 state that the criteria must be based on sound scientific rationale and must protect the designated use. From the outset of the water quality standards program, EPA has explained that while economic factors may be considered in designating uses, they may not be used to justify criteria that are not protective of those uses. 44 FR 25223–226, April 30, 1979. See e.g. *Mississippi Commission on Natural Resources* v. *Costle*, 625 F. 2d 1269, 1277 (5th Cir. 1980). EPA reiterated this interpretation of the CWA and its implementing regulations in discussing section 304(a) recommended criteria guidance stating that "they are based solely on data and scientific judgments on the relationship between pollutant concentrations and environmental and human health effects and do not reflect consideration of economic impacts or the technological feasibility of meeting the chemical concentrations in ambient water." 63 FR 36742 and 36762, July 7, 1998.

I. Executive Order 12866, Regulatory Planning and Review

Under Executive Order 12866 (58 FR 51735, October 4, 1993), the Agency must determine whether the regulatory action is "significant" and therefore subject to Office of Management and Budget (OMB) review and the requirements of the Executive Order. The Order defines "significant regulatory action" as one that is likely to result in a rule that may:

(1) Have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or tribal governments or communities;

(2) Create a serious inconsistency or otherwise interfere with an action taken or planned by another Agency;

(3) Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or

(4) Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

It has been determined that this rule is not a "significant regulatory action" under the terms of Executive Order 12866 and is therefore not subject to OMB review.

J. Unfunded Mandates Reform Act of 1995

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, establishes requirements for Federal agencies to assess the effects of their regulatory actions on State, local, and tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with "Federal mandates" that may result in expenditures to State, local, and tribal governments, in the aggregate, or to the private sector, of $100 million or more in any one year. Before promulgating any regulation for which a written statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows an Agency to adopt an alternative other than the least costly, most cost-effective or least burdensome alternative if the Administrator publishes with the final rule an explanation why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including tribal governments, it must have developed under section 203 of the UMRA a small government Agency plan. The plan must provide for notifying potentially affected small governments, enabling officials of the affected small governments to have meaningful and timely input in the development of regulatory proposals with significant Federal intergovernmental mandates, and EPA informing, educating, and advising small governments on compliance with the regulatory requirements.

Today's rule contains no Federal mandates (under the regulatory provisions of Title II of the Unfunded Mandates Reform Act (UMRA)) for State, local, or tribal governments or the private sector. Today's rule imposes no enforceable duty on any State, local or Tribal governments or the private sector; rather, the CTR promulgates ambient water quality criteria which, when combined with State-adopted uses, will create water quality standards for those water bodies with adopted uses. The State will then use these resulting water quality standards in implementing its existing water quality control programs. Thus, today's rule is not subject to the requirements of sections 202 and 205 of the UMRA.

EPA has determined that this rule contains no regulatory requirements that might significantly or uniquely affect small governments. This rule establishes ambient water quality criteria which, by themselves do not directly impact any entity. The State will implement these criteria by ensuring that NPDES permits result in discharges that will meet these criteria. In so doing, the State will have considerable discretion. Until the State implements these water quality standards, there will be no effect of this rule on any entity. Thus, today's rule is not subject to the requirements of section 203 of UMRA.

K. Regulatory Flexibility Act

The Regulatory Flexibility Act generally requires Federal agencies to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the Agency certifies that the rule will not have a significant economic impact of a substantial number of small entities. Small entities include small businesses, small organizations, and small governmental jurisdictions. For purposes of assessing the impacts of today's rule on small entities, small entity is defined as: (1) A small business according to RFA default definitions for small businesses (based on SBA size standards); (2) a small governmental jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise which is independently owned and operated and is not dominant in its field.

After considering the economic impacts of today's final rule on small entities, I certify that this action will not have a significant economic impact on a substantial number of small entities. This final rule will not impose any requirements on small entities.

Under the CWA water quality standards program, States must adopt water quality standards for their waters that must be submitted to EPA for approval. If the Agency disapproves a State standard and the State does not adopt appropriate revisions to address EPA's disapproval, EPA must promulgate standards consistent with the statutory requirements. EPA has authority to promulgate criteria or standards in any case where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. These State standards (or EPA-promulgated standards) are implemented through various water quality control programs including the National Pollutant Discharge Elimination System (NPDES) program that limits discharges to navigable waters except in compliance with an EPA permit or permit issued under an approved State NPDES program. The CWA requires that all NPDES permits must include any limits on discharges that are necessary to meet State water quality standards.

Thus, under the CWA, EPA's promulgation of water quality criteria or standards establishes standards that the State, in turn, implements through the NPDES permit process. The State has considerable discretion in deciding how to meet the water quality standards and in developing discharge limits as needed to meet the standards. In circumstances where there is more than one discharger to a water body that is subject to water quality standards or criteria, a State also has discretion in deciding on the appropriate limits for the different dischargers. While the State's implementation of federally-promulgated water quality criteria or standards may result indirectly in new or revised discharge limits for small entities, the criteria or standards themselves do not apply to any discharger, including small entities.

Today's rule, as explained above, does not itself establish any requirements that are applicable to small entities. As a result of EPA's action here, the State of California will need to ensure that permits it issues include limits as necessary to meet the water quality standards established by the criteria in today's rule. In so doing, the State will have a number of discretionary choices associated with permit writing. While California's implementation of today's rule may ultimately result in some new or revised permit conditions for some dischargers, including small entities, EPA's action today does not impose any of these as yet unknown requirements on small entities.

The RFA requires analysis of the economic impact of a rule only on the small entities subject to the rule's requirements. Courts have consistently held that the RFA imposes no obligation on an Agency to prepare a small entity analysis of the effect of a rule on entities not regulated by the rule. *Motor & Equip. Mrfrs. Ass'n* v. *Nichols*, 142 F.3d 449, 467 & n.18 (D.C. Cir. 1998)(quoting *United States Distribution Companies* v. *FERC*, 88 F.3d 1105, 1170 (D.C. Cir. 1996); see also *American Trucking Association, Inc.* v. *EPA*, 175 F.3d 1027 (D.C. Cir. 1999). This final rule will have a direct effect only on the State of California which is not a small entity under the RFA. Thus, individual dischargers, including small entities, are not directly subject to the requirements of the rule. Moreover, because of California's discretion in implementing these standards, EPA cannot assess the extent to which the promulgation of this rule may subsequently affect any dischargers, including small entities. Consequently, certification under section 605(b) is appropriate. *State of Michigan, et al.* v. *U.S. Environmental Protection Agency*, No. 98–1497 (D.C. Cir. Mar. 3, 2000), slip op. at 41–42.

L. Paperwork Reduction Act

This action requires no new or additional information collection, reporting, or record keeping subject to the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.*

M. Endangered Species Act

Pursuant to section 7(a) of the Endangered Species Act (ESA), EPA has consulted with the U.S. Fish and Wildlife Service and the U.S. National Marine Fisheries Service (collectively, the Services) concerning EPA's rulemaking action for the State of California. EPA initiated informal consultation in early 1994, and completed formal consultation in April 2000. As a result of the consultation, EPA modified some of the provisions in the final rule.

As part of the consultation process, EPA submitted to the Services a Biological Evaluation for their review in October of 1997. This evaluation found that the proposed CTR was not likely to jeopardize the continued existence of any Federally listed species or result in the destruction or adverse modification of designated critical habitat. In April of 1998, the Services sent EPA a draft Biological Opinion which tentatively found that EPA's proposed rule would jeopardize the continued existence of several Federally listed species and result in the destruction or have adverse effect on designated critical habitat. After lengthy discussions with the Services, EPA agreed to several changes in the final rule and the Services in turn issued a final Biological Opinion finding that EPA's action would not likely jeopardize the continued existence of any Federally listed species or result in the destruction or adverse modification of designated critical habitat. EPA's Biological Evaluation and the Services' final Biological Opinion are contained in the administrative record for today's rule.

In order to ensure the continued protection of Federally listed threatened and endangered species and to protect their critical habitat, EPA agreed to reserve the aquatic life criteria for mercury and the acute freshwater aquatic life criterion for selenium. The Services believe that EPA's proposed criteria are not sufficiently protective of Federally listed species and should not be promulgated. EPA agreed that it would reevaluate these criteria in light of the Services concerns before promulgating them for the State of California. Other commitments made by EPA are described in a letter to the Services dated December 16, 1999; this letter is contained in the administrative record for today's rule.

N. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the Agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This rule is not a major rule as defined by 5 U.S.C. 804(2). This rule will be effective May 18, 2000.

O. Executive Order 13084, Consultation and Coordination With Indian Tribal Governments

Under Executive Order 13084, EPA may not issue a regulation that is not required by statute, that significantly or uniquely affects the communities of Indian tribal governments, and that imposes substantial direct compliance costs on those communities, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by the tribal governments, or EPA consults with those governments. If EPA complies by consulting, Executive Order 13084 requires EPA to provide to the Office of Management and Budget, in a separately identified section of the preamble to the rule, a description of the extent of EPA's prior consultation with representatives of affected tribal governments, a summary of the nature of their concerns, and a statement supporting the need to issue the regulation. In addition, Executive Order 13084 requires EPA to develop an effective process permitting elected officials and other representatives of Indian tribal governments "to provide meaningful and timely input in the development of regulatory policies on matters that significantly or uniquely affect their communities."

Today's rule does not significantly or uniquely affect the communities of Indian tribal governments nor does it impose substantial direct compliance cots on them. Today's rule will only address priority toxic pollutant water quality criteria for the State of California and does not apply to waters in Indian country. Accordingly, the requirements of section 3(b) of Executive Order 13084 do not apply to this rule.

P. National Technology Transfer and Advancement Act

Section 12(d) of the National Technology Transfer and Advancement Act of 1995 ("NTTAA"), Public Law No. 104–113, section 12(d) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impractical. Voluntary consensus standards are technical standards (e.g., materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by voluntary consensus standards bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the Agency decides not to use available and applicable voluntary consensus standards.

This final rule does not involve technical standards. Therefore, EPA did not consider the use of any voluntary consensus standards.

Q. Executive Order 13132 on Federalism

Executive Order 13132, entitled "Federalism" (64 FR 43255, August 10, 1999), requires EPA to develop an accountable process to ensure "meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications." "Policies that have federalism implications" is defined in the Executive Order to include regulations that have "substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government."

Under section 6 of Executive Order 13132, EPA may not issue a regulation that has federalism implications, that imposes substantial direct compliance costs, and that is not required by statute, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by State and local governments, or EPA consults with State and local officials early in the process of developing the proposed regulation. EPA also may not issue a regulation that has federalism implications and that preempts State law, unless the Agency consults with State and local officials early in the process of developing the proposed regulation.

This final rule does not have federalism implications. It will not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. The rule does not affect the nature of the relationship between EPA and States generally, for the rule only applies to water bodies in California. Further, the rule will not substantially affect the relationship of EPA and the State of California, or the distribution of power or responsibilities between EPA and the State. The rule does not alter the State's authority to issue NPDES permits or the State's considerable discretion in implementing these criteria. The rule simply implements Clean Water Act section 303(c)(2)(B) requiring numeric ambient water quality criteria for which EPA has issued section 304(a) recommended criteria in a manner that is consistent with previous regulatory guidance that the Agency has issued to implement CWA section 303(c)(2)(B). Further, this rule does not preclude the State from adopting water quality standards that meet the requirements of the CWA. Thus, the requirements of section 6 of the Executive Order do not apply to this rule.

Although section 6 of Executive Order 13132 does not apply to this rule, EPA did consult with State and local government representatives in developing this rule. EPA and the State reached an agreement that to best utilize its respective resources, EPA would promulgate water quality criteria and the State would concurrently work on a plan to implement the criteria. Since the proposal of this rule, EPA has kept State officials fully informed of changes to the proposal. EPA has continued to invite comment from the State on these changes. EPA believes that the final CTR incorporates comments from State officials and staff.

R. Executive Order 13045 on Protection of Children From Environmental Health Risks and Safety Risks

Executive Order 13045: "Protection of Children from Environmental Health Risks and Safety Risks" (62 FR 19885, April 23, 1997) applies to any rule that: (1) Is determined to be "economically significant" as defined under Executive Order 12866, and (2) concerns an environmental health or safety risk that EPA has reason to believe may have a disproportionate effect on children. If the regulatory action meets both criteria, the Agency must evaluate the environmental health or safety effects of the planned rule on children, and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the Agency.

While this final rule is not subject to the Executive Order because it is not economically significant as defined in Executive Order 12866, we nonetheless have reason to believe that the environmental health or safety risk addressed by this action may have a disproportionate effect on children. As a matter of EPA policy, we therefore have assessed the environmental health or safety effects of ambient water quality criteria on children. The results of this assessment are contained in section F.3., Human Health Criteria.

List of Subjects in 40 CFR Part 131

Environmental protection, Indians—lands, Intergovernmental relations, Reporting and recordkeeping requirements, Water pollution control.

R0019133

Dated: April 27, 2000.

Carol Browner,

Administrator.

For the reasons set out in the preamble, part 131 of chapter I of title 40 of the Code of Federal Regulations is amended as follows:

PART 131—WATER QUALITY STANDARDS

1. The authority citation for part 131 continues to read as follows:

Authority: 33 U.S.C. 1251 *et seq.*

Subpart D—[Amended]

2. Section 131.38 is added to subpart D to read as follows:

§ 131.38 Establishment of Numeric Criteria for Priority Toxic Pollutants for the State of California.

(a) *Scope.* This section promulgates criteria for priority toxic pollutants in the State of California for inland surface waters and enclosed bays and estuaries. This section also contains a compliance schedule provision.

(b)(1) Criteria for Priority Toxic Pollutants in the State of California as described in the following table:

BILLING CODE 6560-50-P

BILLING CODE 6560-50-C

R0019139

Footnotes to Table in Parargraph (b)(1):

a. Criteria revised to reflect the Agency q1* or RfD, as contained in the Integrated Risk Information System (IRIS) as of October 1, 1996. The fish tissue bioconcentration factor (BCF) from the 1980 documents was retained in each case.

b. Criteria apply to California waters except for those waters subject to objectives in Tables III–2A and III–2B of the San Francisco Regional Water Quality Control Board's (SFRWQCB) 1986 Basin Plan, that were adopted by the SFRWQCB and the State Water Resources Control Board, approved by EPA, and which continue to apply.

c. Criteria are based on carcinogenicity of 10 (-6) risk.

d. Criteria Maximum Concentration (CMC) equals the highest concentration of a pollutant to which aquatic life can be exposed for a short period of time without deleterious effects. Criteria Continuous Concentration (CCC) equals the highest concentration of a pollutant to which aquatic life can be exposed for an extended period of time (4 days) without deleterious effects. ug/L equals micrograms per liter.

e. Freshwater aquatic life criteria for metals are expressed as a function of total hardness (mg/L) in the water body. The equations are provided in matrix at paragraph (b)(2) of this section. Values displayed above in the matrix correspond to a total hardness of 100 mg/l.

f. Freshwater aquatic life criteria for pentachlorophenol are expressed as a function of pH, and are calculated as follows: Values displayed above in the matrix correspond to a pH of 7.8. CMC = exp(1.005(pH) – 4.869). CCC = exp(1.005(pH) – 5.134).

g. This criterion is based on 304(a) aquatic life criterion issued in 1980, and was issued in one of the following documents: Aldrin/Dieldrin (EPA 440/5–80–019), Chlordane (EPA 440/5–80–027), DDT (EPA 440/5–80–038), Endosulfan (EPA 440/5–80–046), Endrin (EPA 440/5–80–047), Heptachlor (440/5–80–052), Hexachlorocyclohexane (EPA 440/5–80–054), Silver (EPA 440/5–80–071). The Minimum Data Requirements and derivation procedures were different in the 1980 Guidelines than in the 1985 Guidelines. For example, a "CMC" derived using the 1980 Guidelines was derived to be used as an instantaneous maximum. If assessment is to be done using an averaging period, the values given should be divided by 2 to obtain a value that is more comparable to a CMC derived using the 1985 Guidelines.

h. These totals simply sum the criteria in each column. For aquatic life, there are 23 priority toxic pollutants with some type of freshwater or saltwater, acute or chronic criteria. For human health, there are 92 priority toxic pollutants with either "water + organism" or "organism only" criteria. Note that these totals count chromium as one pollutant even though EPA has developed criteria based on two valence states. In the matrix, EPA has assigned numbers 5a and 5b to the criteria for chromium to reflect the fact that the list of 126 priority pollutants includes only a single listing for chromium.

i. Criteria for these metals are expressed as a function of the water-effect ratio, WER, as defined in paragraph (c) of this section. CMC = column B1 or C1 value x WER; CCC = column B2 or C2 value x WER.

j. No criterion for protection of human health from consumption of aquatic organisms (excluding water) was presented in the 1980 criteria document or in the 1986 Quality Criteria for Water. Nevertheless, sufficient information was presented in the 1980 document to allow a calculation of a criterion, even though the results of such a calculation were not shown in the document.

k. The CWA 304(a) criterion for asbestos is the MCL.

l. [Reserved]

m. These freshwater and saltwater criteria for metals are expressed in terms of the dissolved fraction of the metal in the water column. Criterion values were calculated by using EPA's Clean Water Act 304(a) guidance values (described in the total recoverable fraction) and then applying the conversion factors in § 131.36(b)(1) and (2).

n. EPA is not promulgating human health criteria for these contaminants. However, permit authorities should address these contaminants in NPDES permit actions using the State's existing narrative criteria for toxics.

o. These criteria were promulgated for specific waters in California in the National Toxics Rule ("NTR"), at § 131.36. The specific waters to which the NTR criteria apply include: Waters of the State defined as bays or estuaries and waters of the State defined as inland, i.e., all surface waters of the State not ocean waters. These waters specifically include the San Francisco Bay upstream to and including Suisun Bay and the Sacramento-San Joaquin Delta. This section does not apply instead of the NTR for this criterion.

p. A criterion of 20 ug/l was promulgated for specific waters in California in the NTR and was promulgated in the total recoverable form. The specific waters to which the NTR criterion applies include: Waters of the San Francisco Bay upstream to and including Suisun Bay and the Sacramento-San Joaquin Delta; and waters of Salt Slough, Mud Slough (north) and the San Joaquin River, Sack Dam to the mouth of the Merced River. This section does not apply instead of the NTR for this criterion. The State of California adopted and EPA approved a site specific criterion for the San Joaquin River, mouth of Merced to Vernalis; therefore, this section does not apply to these waters.

q. This criterion is expressed in the total recoverable form. This criterion was promulgated for specific waters in California in the NTR and was promulgated in the total recoverable form. The specific waters to which the NTR criterion applies include: Waters of the San Francisco Bay upstream to and including Suisun Bay and the Sacramento-San Joaquin Delta; and waters of Salt Slough, Mud Slough (north) and the San Joaquin River, Sack Dam to Vernalis. This criterion does not apply instead of the NTR for these waters. This criterion applies to additional waters of the United States in the State of California pursuant to 40 CFR 131.38(c). The State of California adopted and EPA approved a site-specific criterion for the Grassland Water District, San Luis National Wildlife Refuge, and the Los Banos State Wildlife Refuge; therefore, this criterion does not apply to these waters.

r. These criteria were promulgated for specific waters in California in the NTR. The specific waters to which the NTR criteria apply include: Waters of the State defined as bays or estuaries including the San Francisco Bay upstream to and including Suisun Bay and the Sacramento-San Joaquin Delta. This section does not apply instead of the NTR for these criteria.

s. These criteria were promulgated for specific waters in California in the NTR. The specific waters to which the NTR criteria apply include: Waters of the Sacramento-San Joaquin Delta and waters of the State defined as inland (*i.e.*, all surface waters of the State not bays or estuaries or ocean) that include a MUN use designation. This section does not apply instead of the NTR for these criteria.

t. These criteria were promulgated for specific waters in California in the NTR. The specific waters to which the NTR criteria apply include: Waters of the State defined as bays and estuaries including San Francisco Bay upstream to and including Suisun Bay and the Sacramento-San Joaquin Delta; and waters of the State defined as inland (i.e., all surface waters of the State not bays or estuaries or ocean) without a MUN use designation. This section does not apply instead of the NTR for these criteria.

u. PCBs are a class of chemicals which include aroclors 1242, 1254, 1221, 1232, 1248, 1260, and 1016, CAS numbers 53469219, 11097691, 11104282, 11141165, 12672296, 11096825, and 12674112, respectively. The aquatic life criteria apply to the sum of this set of seven aroclors.

v. This criterion applies to total PCBs, e.g., the sum of all congener or isomer or homolog or aroclor analyses.

w. This criterion has been recalculated pursuant to the 1995 Updates: Water Quality Criteria Documents for the Protection of Aquatic Life in Ambient Water, Office of Water, EPA–820–B–96–001, September 1996. See also Great Lakes Water Quality Initiative Criteria Documents for the Protection of Aquatic Life in Ambient Water, Office of Water, EPA–80–B–95–004, March 1995.

x. The State of California has adopted and EPA has approved site specific criteria for the Sacramento River (and tributaries) above Hamilton City; therefore, these criteria do not apply to these waters.

General Notes to Table in Paragraph (b)(1)

1. The table in this paragraph (b)(1) lists all of EPA's priority toxic pollutants whether or not criteria guidance are available. Blank spaces indicate the absence of national section 304(a) criteria guidance. Because of variations in chemical nomenclature systems, this listing of toxic pollutants does not duplicate the listing in Appendix A to 40 CFR Part 423–126 Priority Pollutants. EPA has added the Chemical Abstracts Service (CAS) registry numbers, which provide a unique identification for each chemical.

2. The following chemicals have organoleptic-based criteria recommendations that are not included on this chart: zinc, 3-methyl-4-chlorophenol.

3. Freshwater and saltwater aquatic life criteria apply as specified in paragraph (c)(3) of this section.

(2) Factors for Calculating Metals Criteria. Final CMC and CCC values should be rounded to two significant figures.

(i) $CMC = WER \times (\text{Acute Conversion Factor}) \times (\exp\{m_A[\ln(\text{hardness})]+b_A\})$

(ii) $CCC = WER \times (\text{Acute Conversion Factor}) \times (\exp\{m_C[\ln(\text{hardness})]+b_C\})$

(iii) Table 1 to paragraph (b)(2) of this section:

Metal	m_A	b_A	m_C	b_C
Cadmium	1.128	−3.6867	0.7852	−2.715
Copper	0.9422	−1.700	0.8545	−1.702
Chromium (III)	0.8190	3.688	0.8190	1.561
Lead	1.273	−1.460	1.273	−4.705
Nickel	0.8460	2.255	0.8460	0.0584
Silver	1.72	−6.52		
Zinc	0.8473	0.884	0.8473	0.884

Note to Table 1: The term "exp" represents the base e exponential function.

(iv) Table 2 to paragraph (b)(2) of this section:

Metal	Conversion factor (CF) for freshwater acute criteria	CF for freshwater chronic criteria	CF for saltwater acute criteria	CF [a] for saltwater chronic criteria
Antimony	[d]	[d]	[d]	[d]
Arsenic	1.000	1.000	1.000	1.000
Beryllium	[d]	[d]	[d]	[d]
Cadmium	[b] 0.944	[b] 0.909	0.994	0.994
Chromium (III)	0.316	0.860	[d]	[d]
Chromium (VI)	0.982	0.962	0.993	0.993
Copper	0.960	0.960	0.83	0.83
Lead	[b] 0.791	[b] 0.791	0.951	0.951
Mercury	....	....	....	....
Nickel	0.998	0.997	0.990	0.990
Selenium	....	[c]	0.998	0.998
Silver	0.85	[d]	0.85	[d]
Thallium	[d]	[d]	[d]	[d]
Zinc	0.978	0.986	0.946	0.946

Footnotes to Table 2 of Paragraph (b)(2):

[a] Conversion Factors for chronic marine criteria are not currently available. Conversion Factors for acute marine criteria have been used for both acute and chronic marine criteria.

[b] Conversion Factors for these pollutants in freshwater are hardness dependent. CFs are based on a hardness of 100 mg/l as calcium carbonate ($CaCO_3$). Other hardness can be used; CFs should be recalculated using the equations in table 3 to paragraph (b)(2) of this section.

[c] Bioaccumulative compound and inappropriate to adjust to percent dissolved.

[d] EPA has not published an aquatic life criterion value.

Note to Table 2 of Paragraph (b)(2): The term "Conversion Factor" represents the recommended conversion factor for converting a metal criterion expressed as the total recoverable fraction in the water column to a criterion expressed as the dissolved fraction in the water column. See "Office of Water Policy and Technical Guidance on Interpretation and Implementation of Aquatic Life Metals Criteria", October 1, 1993, by Martha G. Prothro, Acting Assistant Administrator for Water available from Water Resource Center, USEPA, Mailcode RC4100, M Street SW, Washington, DC, 20460 and the note to § 131.36(b)(1).

(v) Table 3 to paragraph (b)(2) of this section:

	Acute	Chronic
Cadmium	CF=1.136672—[(ln {hardness}) (0.041838)]	CF = 1.101672—[(ln {hardness})(0.041838)]
Lead	CF=1.46203—[(ln {hardness})(0.145712)]	CF = 1.46203—[(ln {hardness})(0.145712)]

(c) *Applicability*. (1) The criteria in paragraph (b) of this section apply to the State's designated uses cited in paragraph (d) of this section and apply concurrently with any criteria adopted by the State, except when State regulations contain criteria which are more stringent for a particular parameter and use, or except as provided in footnotes p, q, and x to the table in paragraph (b)(1) of this section.

(2) The criteria established in this section are subject to the State's general rules of applicability in the same way and to the same extent as are other Federally-adopted and State-adopted numeric toxics criteria when applied to the same use classifications including mixing zones, and low flow values below which numeric standards can be exceeded in flowing fresh waters.

(i) For all waters with mixing zone regulations or implementation procedures, the criteria apply at the appropriate locations within or at the boundary of the mixing zones; otherwise the criteria apply throughout the water body including at the point of discharge into the water body.

(ii) The State shall not use a low flow value below which numeric standards can be exceeded that is less stringent than the flows in Table 4 to paragraph (c)(2) of this section for streams and rivers.

(iii) Table 4 to paragraph (c)(2) of this section:

Criteria	Design flow
Aquatic Life Acute Criteria (CMC).	1 Q 10 or 1 B 3
Aquatic Life Chronic Criteria (CCC).	7 Q 10 or 4 B 3
Human Health Criteria.	Harmonic Mean Flow

Note to Table 4 of Paragraph (c)(2): 1. CMC (Criteria Maximum Concentration) is the water quality criteria to protect against acute effects in aquatic life and is the highest instream concentration of a priority toxic pollutant consisting of a short-term average not to be exceeded more than once every three years on the average.

2. CCC (Continuous Criteria Concentration) is the water quality criteria to protect against chronic effects in aquatic life and is the highest in stream concentration of a priority toxic pollutant consisting of a 4-day average not to be exceeded more than once every three years on the average.

3. 1 Q 10 is the lowest one day flow with an average recurrence frequency of once in 10 years determined hydrologically.

4. 1 B 3 is biologically based and indicates an allowable exceedence of once every 3 years. It is determined by EPA's computerized method (DFLOW model).

5. 7 Q 10 is the lowest average 7 consecutive day low flow with an average recurrence frequency of once in 10 years determined hydrologically.

6. 4 B 3 is biologically based and indicates an allowable exceedence for 4 consecutive days once every 3 years. It is determined by EPA's computerized method (DFLOW model).

(iv) If the State does not have such a low flow value below which numeric standards do not apply, then the criteria included in paragraph (d) of this section apply at all flows.

(v) If the CMC short-term averaging period, the CCC four-day averaging period, or once in three-year frequency is inappropriate for a criterion or the site to which a criterion applies, the State may apply to EPA for approval of an alternative averaging period, frequency, and related design flow. The State must submit to EPA the bases for any alternative averaging period, frequency, and related design flow. Before approving any change, EPA will publish for public comment, a document proposing the change.

(3) The freshwater and saltwater aquatic life criteria in the matrix in paragraph (b)(1) of this section apply as follows:

(i) For waters in which the salinity is equal to or less than 1 part per thousand 95% or more of the time, the applicable criteria are the freshwater criteria in Column B;

(ii) For waters in which the salinity is equal to or greater than 10 parts per thousand 95% or more of the time, the applicable criteria are the saltwater criteria in Column C except for selenium in the San Francisco Bay estuary where the applicable criteria are the freshwater criteria in Column B (refer to footnotes p and q to the table in paragraph (b)(1) of this section); and

(iii) For waters in which the salinity is between 1 and 10 parts per thousand as defined in paragraphs (c)(3)(i) and (ii) of this section, the applicable criteria are the more stringent of the freshwater or saltwater criteria. However, the Regional Administrator may approve the use of the alternative freshwater or saltwater criteria if scientifically defensible information and data demonstrate that on a site-specific basis the biology of the water body is dominated by freshwater aquatic life and that freshwater criteria are more appropriate; or conversely, the biology of the water body is dominated by saltwater aquatic life and that saltwater criteria are more appropriate. Before approving any change, EPA will publish for public comment a document proposing the change.

(4) *Application of metals criteria.* (i) For purposes of calculating freshwater aquatic life criteria for metals from the equations in paragraph (b)(2) of this section, for waters with a hardness of 400 mg/l or less as calcium carbonate, the actual ambient hardness of the surface water shall be used in those equations. For waters with a hardness of over 400 mg/l as calcium carbonate, a hardness of 400 mg/l as calcium carbonate shall be used with a default Water-Effect Ratio (WER) of 1, or the actual hardness of the ambient surface water shall be used with a WER. The same provisions apply for calculating the metals criteria for the comparisons provided for in paragraph (c)(3)(iii) of this section.

(ii) The hardness values used shall be consistent with the design discharge conditions established in paragraph (c)(2) of this section for design flows and mixing zones.

(iii) The criteria for metals (compounds #1—#13 in the table in paragraph (b)(1) of this section) are expressed as dissolved except where otherwise noted. For purposes of calculating aquatic life criteria for metals from the equations in footnote i to the table in paragraph (b)(1) of this section and the equations in paragraph (b)(2) of this section, the water effect ratio is generally computed as a specific pollutant's acute or chronic toxicity value measured in water from the site covered by the standard, divided by the respective acute or chronic toxicity value in laboratory dilution water. To use a water effect ratio other than the default of 1, the WER must be determined as set forth in Interim Guidance on Determination and Use of Water Effect Ratios, U.S. EPA Office of Water, EPA–823–B–94–001, February 1994, or alternatively, other scientifically defensible methods adopted by the State as part of its water quality standards program and approved by EPA. For calculation of criteria using site-specific values for both the hardness and the water effect ratio, the hardness used in the equations in paragraph (b)(2) of this section must be determined as required in paragraph (c)(4)(ii) of this section. Water hardness must be calculated from the measured calcium and magnesium ions present, and the ratio of calcium to magnesium should be approximately the same in standard laboratory toxicity testing water as in the site water.

(d)(1) Except as specified in paragraph (d)(3) of this section, all waters assigned any aquatic life or human health use classifications in the Water Quality Control Plans for the various Basins of the State ("Basin Plans") adopted by the California State Water Resources Control Board ("SWRCB"), except for ocean waters covered by the Water Quality Control Plan for Ocean Waters of California ("Ocean Plan") adopted by the SWRCB with resolution Number 90–27 on March 22, 1990, are subject to the criteria in paragraph (d)(2) of this section, without exception. These criteria apply to waters identified in the Basin Plans. More particularly, these criteria apply to waters identified in the Basin Plan chapters designating beneficial uses for waters within the region. Although the State has adopted several use designations for each of these waters, for purposes of this action, the specific standards to be applied in paragraph (d)(2) of this section are based on the presence in all waters of some aquatic life designation and the presence or absence of the MUN use designation (municipal and domestic supply). (See Basin Plans for more detailed use definitions.)

(2) The criteria from the table in paragraph (b)(1) of this section apply to the water and use classifications defined in paragraph (d)(1) of this section as follows:

R0019142

Water and use classification	Applicable criteria
(i) All inland waters of the United States or enclosed bays and estuaries that are waters of the United States that include a MUN use designation.	(A) Columns B1 and B2—all pollutants (B) Columns C1 and C2—all pollutants (C) Column D1—all pollutants
(ii) All inland waters of the United States or enclosed bays and estuaries that are waters of the United States that do not include a MUN use designation.	(A) Columns B1 and B2—all pollutants (B) Columns C1 and C2—all pollutants (C) Column D2—all pollutants

(3) Nothing in this section is intended to apply instead of specific criteria, including specific criteria for the San Francisco Bay estuary, promulgated for California in the National Toxics Rule at § 131.36.

(4) The human health criteria shall be applied at the State-adopted 10 (−6) risk level.

(5) Nothing in this section applies to waters located in Indian Country.

(e) *Schedules of compliance.* (1) It is presumed that new and existing point source dischargers will promptly comply with any new or more restrictive water quality-based effluent limitations ("WQBELs") based on the water quality criteria set forth in this section.

(2) When a permit issued on or after May 18, 2000 to a new discharger contains a WQBEL based on water quality criteria set forth in paragraph (b) of this section, the permittee shall comply with such WQBEL upon the commencement of the discharge. A new discharger is defined as any building, structure, facility, or installation from which there is or may be a "discharge of pollutants" (as defined in 40 CFR 122.2) to the State of California's inland surface waters or enclosed bays and estuaries, the construction of which commences after May 18, 2000.

(3) Where an existing discharger reasonably believes that it will be infeasible to promptly comply with a new or more restrictive WQBEL based on the water quality criteria set forth in this section, the discharger may request approval from the permit issuing authority for a schedule of compliance.

(4) A compliance schedule shall require compliance with WQBELs based on water quality criteria set forth in paragraph (b) of this section as soon as possible, taking into account the dischargers' technical ability to achieve compliance with such WQBEL.

(5) If the schedule of compliance exceeds one year from the date of permit issuance, reissuance or modification, the schedule shall set forth interim requirements and dates for their achievement. The dates of completion between each requirement may not exceed one year. If the time necessary for completion of any requirement is more than one year and is not readily divisible into stages for completion, the permit shall require, at a minimum, specified dates for annual submission of progress reports on the status of interim requirements.

(6) In no event shall the permit issuing authority approve a schedule of compliance for a point source discharge which exceeds five years from the date of permit issuance, reissuance, or modification, whichever is sooner. Where shorter schedules of compliance are prescribed or schedules of compliance are prohibited by law, those provisions shall govern.

(7) If a schedule of compliance exceeds the term of a permit, interim permit limits effective during the permit shall be included in the permit and addressed in the permit's fact sheet or statement of basis. The administrative record for the permit shall reflect final permit limits and final compliance dates. Final compliance dates for final permit limits, which do not occur during the term of the permit, must occur within five years from the date of issuance, reissuance or modification of the permit which initiates the compliance schedule. Where shorter schedules of compliance are prescribed or schedules of compliance are prohibited by law, those provisions shall govern.

(8) The provisions in this paragraph (e), Schedules of compliance, shall expire on May 18, 2005.

POLLUTION PREVENTION PLAN FOR WATER SYSTEM DISCHARGES

Prepared By: Wastewater Quality Compliance Group

Approved by: [illegible]
Assistant General Manager - Water

Date: 5/31/2000

Pollution Prevention Plan for Water System Discharges

Table of Contents

PART I - BACKGROUND

PART II - BEST MANAGEMENT PRACTICES (BMPs)

PART I -- BACKGROUND

I. Historical

Congress enacted the Clean Water Act (CWA) to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters" through reduction and eventual elimination of the discharge of pollutants into those waters. The CWA prohibits the discharge of pollutants from a point source, except in compliance with a National Pollutant Discharge Elimination System (NPDES) permit.

Water suppliers may have numerous releases of potable water from their storage and distribution systems to surface waters and surface water drainage courses. These releases include but are not limited to: pressure relief valves; system maintenance activities (e.g., cement lining); well development and maintenance activities; fire hydrant flow testing; and flushing and dewatering of pipelines, reservoirs, tanks, vaults, sumps and wells.

The Los Angeles Department of Water and Power (DWP) is required to either prohibit, or control by NPDES permit, the contribution of pollutants to surface waters or the storm drain system. The Federal regulations allow authorized states to issue either "general" NPDES permits (which lump numerous similar discharges under a single permit) or "individual" NPDES permits (permits issued on a site-by-site, activity-by activity basis) to regulate discharges of pollutants to Waters of the United States. Failure to comply with these requirements may result in a fine of up to $25,000 per day of violation and possible imprisonment.

II. Introduction

In 1990, the Environmental Protection Agency (EPA) adopted regulations for permitting stormwater and non-stormwater discharges to surface water and storm drain conveyances. The State Water Resources Control Board (SWRCB) and the respective regional boards, as well as local cities and counties, have been aggressively managing these discharges.

Over the past several years, significant changes have occurred in the regulations governing the direct, short term and intermittent discharges of drinking water supplies to Waters of the State. Based on the nature of water supplier discharges, a general permit was initially sought to legalize these discharges.

In 1994, the State of California began drafting a general permit that would allow utilities and water suppliers to discharge water system discharges and power system substructure discharges legally under the State Porter-Cologne Act. In February 1996, the SWRCB decided it was unable to adopt the draft general permit because of a conflict of interest on the part of some State Board members who were also water suppliers. When this permitting avenue closed, and in order to legally discharge water from water system activities to the storm drain, the Wastewater Quality Compliance Group (WQG) sought coverage of these activities under the Los Angeles Regional Water Quality Control Board's (RWQCB) Municipal Countywide Stormwater Permit (Muni Permit).

The Muni Permit (effective July 1996) provides for the legal discharge of water system releases to the storm drain, provided the American Water Works Association (AWWA) Pollution Prevention Plan (PPP) document is used. For all intents and purposes, such a document does not exist. However, the regulatory intent is none the less very clear, and it requires the application of Best Management Practices (BMPs) for preventing stormwater pollution. Thus, in accordance with the Muni Permit provisions, this document is the PPP for DWP and contains the BMPs which will be implemented when discharging potable water from water supply activities to surface waters of the State

This PPP is intended to cover all new or existing discharges from water system facilities to the storm drain. This PPP is also intended to cover short-term, intermittent discharges to surface waters or conveyances that in turn discharge to surface waters. Regulation of these discharges under the Muni Permit reduces the administrative burdens otherwise associated with processing and overseeing thousands of individual permit applications. The specific discharges addressed in this document are described in Table I.

Table 1
Water Supply Discharges

	Discharge Process	Activities	Probable Pollutants of Concern
1.	Cement Lining	Flushing, Disinfection	Sediment, Chlorine, Algae
2.	Main Flushing	Flushing	Sediment, Rust Particles, Chlorine, Algae
3.	Main/Service Pipeline Installation/Replacement	Leak Testing, Disinfecting, Flushing	Sediment, Chlorine, Algae
4.	Reservoir Dewatering/ Tank Dewatering	Tank Draining/Cleaning, Maintenance, Cyclic Blowoff Testing, Emergency Drawdown	Sediment, Chlorine, Algae, Metals
5.	Pump Station /Chlorination Station / Regulator Station Discharges	Relief Valves, Pump Packing/Sealing Water, Emergency Pump Cooling Water	Sediment, Chlorine, Algae
6.	Groundwater Well Development/ Maintenance/WQ Sampling	Sampling, Developing, Testing, Flushing, Drilling	Sediment, Chlorine, Algae, PCE,TCE, Nitrate
7.	System Pressure Protection	Relief Valves	Sediment, Chlorine, Algae
8.	Main and Service Leaks, Leak Repair and Hydrant Knockoffs	System Failures, Hydrant Knock-Offs	Sediment, Chlorine, Algae
9.	Service/Lateral Replacements	Flushing	Sediment, Chlorine, Algae
10.	Substructure/Vault Dewatering	Pumping	Sediment, Chlorine, Algae

R0019148

III. Pollution Prevention Plan

Pollution Prevention Plans (PPP) are prepared by the regulated community and are required to contain the procedures or practices which each company will institute to reduce or eliminate, to the maximum extent practicable, the discharge of pollutants to the Waters of the State. This PPP, when properly implemented, is intended to reduce or prevent the discharge of pollutants through the development and implementation of BMPs which constitute compliance with Best Available Technology (BAT) and Best Conventional Control Technology (BCT) and, in most cases, will achieve compliance with water quality standards

The objective of this PPP is twofold: (1) to help identify the sources of pollution that affect the quality of the discharges; and (2) to identify BMPs which will reduce or eliminate pollutants in the discharges. This approach provides the flexibility necessary to establish multiple BMPs for different types of water system activities and pollutant sources in lieu of "end of pipe" controls or treatment. As this PPP covers vastly different types of facilities/activities, the SWRCB recognizes that there is no single best way of developing or organizing a PPP. This PPP attempts to adequately identify and assess all potential sources of pollutants and describe and assess the appropriate BMPs necessary to reduce or eliminate pollutants. In implementing these BMPs, DWP will strive to achieve environmental results in the most cost-effective manner.

The following BMPs constitute the DWP's PPP for handling water supply discharges in order to ensure that a minimum of regulated contaminants are discharged to the storm drain system, and that DWP's discharges comply with the criteria in the Muni Permit.

Administrative, contracting and inspection procedures will be implemented to achieve the BMPs contained in this document. The procedures will target those activities with the potential to generate significant pollutant loads and focus on source minimization, education, good housekeeping, good waste management and good site planning.

IV. PPP Applicability - Conditions, Limitations, or Restrictions

The Muni Permit stipulates that allowed discharges shall not cause or contribute to a violation of an applicable water quality standard. Therefore, as a condition of coverage under the Muni Permit, the discharges in Table I shall not cause or contribute to a violation of a water quality standard. Facilities or activities covered by individual NPDES permits and facilities which do not discharge into Waters of the United States are not covered by this PPP. Discharges associated with auto washing, auto maintenance, groundwater cleanup activities or construction activities are also not covered by this PPP.

The applicable sections of the PPP shall be applied whenever there is discharge unless BMP implementation is technically infeasible, in which case the WQG (213) 367-0279 should be contacted in advance of commencing the job. To the extent possible, these BMPs will be employed during emergency operations, including taking all reasonable steps to minimize or prevent any discharge that has a reasonable likelihood of adversely affecting human health or the environment.

It is also recognized that some discharges may have unusual conditions which require additional treatment or control, and that these situations are best handled on a case-by-case basis in concert with the Regional Board. Discharges that are suspected of having the potential to impact the quality of the State's water after the implementation of the identified BMPs shall be held in impervious containers and handled in an appropriate legal manner. Discharges with acute or chronic toxicity, chemicals or organic constituents, bacteria, herbicides, pesticides, oil and grease, radioactivity, salinity or elevated temperature that may adversely affect the quality and beneficial uses of the State's receiving waters are not allowed to be discharged under the Muni Permit and therefore are not covered by this PPP.

Discharges under the Muni Permit are subject to periodic review and revision by the RWQCB. The regulating agency may conduct infrequent unannounced inspections to verify that the PPP is being followed and that it is effective at preventing contaminants from entering the storm drain system. Specifically, the regulating agency is allowed to:

1. enter the premises or job site where a regulated activity is located or conducted, or where records pertaining to this activity are kept;

2. gain access and copy any records pertaining to this activity;
3. inspect any facility, equipment, or practices pertaining to a regulated activity;
4. halt any discharge if the RWQCB Executive Officer so orders; and
5. photograph, sample, or monitor for the purpose of assuring compliance with existing regulations.

In addition, relevant sections of the PPP shall:

1. be made available to the RWQCB upon request;
2. be amended whenever there is a change in construction, operation or maintenance, when such amendment is necessary to ensure compliance with BAT/BCT and receiving water limits; and
3. be available at the activity site by the time the activity begins.

PART II - BEST MANAGEMENT PRACTICES (BMPs)

I General Guidelines

This section is designed to describe those Best Management Practices (BMPs) that can be applied to all activities described in Table I. Specific BMPs for each activity are discussed in the sections that follow. However, there are some practices which are generic and applicable to all types of discharges. These generic activities are discussed below.

Before discharging potable water from a water supply activity, the expected flow path should be quickly surveyed for the presence of such contaminants as motor fluid leaks or spills, fecal matter, dirt, or debris. If items such as these are found, they should be removed from the path by sweeping, or if necessary, the flows can be redirected around the contaminants. If the impact area (where the water first contacts the ground) or the surrounding area is unpaved or easily eroded, the flow path should be either redirected to a paved or non-erodible area or mechanisms to dissipate the water's energy should be considered.

Control practices that, to the extent feasible, will prevent an increase in sediment load in the discharge should be used. One or more sediment controls should be implemented for all significant discharges. Whenever possible, direct the discharge flow such that the water has the opportunity to pond or otherwise percolate into the soil rather than flow via gutters, storm drains, flood control channels, rivers, creeks, or streams. Whenever possible, projects shall be scheduled during the dry season or when not expecting rain, in order to minimize the exposure of maintenance activities to storm water.

Another source of discharge pollutants could come from the leaking vehicles and equipment used at the job site. All vehicles should be inspected prior to leaving DWP's equipment yard, and leaking vehicles or equipment should not be dispatched to the job site. Vehicles and equipment found to be leaking during the job should be reported and the vehicle/equipment repaired as soon as possible upon returning to the yard. For jobs which occur over several days and the equipment is to remain at the job site, fueling, maintenance, or vehicle/equipment washing at the job site should be avoided whenever feasible. Vehicles and equipment stored at job sites should either be stored on impermeable surfaces or drip pans and absorbent material should be placed under the stored equipment that is prone to leaks and drips.

There shall be no intentional release of petroleum products into streams or onto the soil. The site foreman is to ensure containment, prompt cleanup, and proper transportation of all petroleum waste to approved offsite areas for subsequent disposal in accordance with applicable regulations. If a significant spill occurs, the site foreman shall contact the Environmental Hotline at (213) 792-4989. In order to minimize risk, the use of hazardous materials will be minimized and employees will be trained in proper material use.

In project areas exposed to storm water, all fuels, chemicals, fuel and chemical wastes, animal waste, garbage, batteries, and other materials which have potentially adverse impacts on water quality are to be removed and lawfully disposed of from the project site. Hazardous material spills and leaks should be cleaned up with materials appropriate for the types of chemicals used on the job site such as brooms, gloves, shovels, dustpans, adsorbent for liquid spills, etc.

These BMPs are generic in nature and they may need to be tailored to the unique specifics of each job, location, topography, etc. in order to be effective. Some specific considerations may include: proximity of the job to the nearest storm drain or watercourse; and the presence of a busy intersection vs. undeveloped property; the slope the water travels down. Many of the BMPs are applicable to all types of activities, while some of them require preplanning and are applicable only to scheduled activities. Our approach is to conduct a pre-job evaluation of on-site conditions whenever practicable. This type of evaluation may also minimize the amount of area disturbed and the duration of the disturbance. Part of the evaluation process is to conduct a job site review to determine the anticipated flow path of the discharge and the relevant and appropriate BMPs for the job based on the site characteristics.

Prior to implementing any <u>scheduled</u> discharge activity, survey the project site and identify:

1. the entire affected area;
2. the location of buildings and paved areas;
3. the location of major activity areas;
4. drainage areas and the direction of runoff flows;
5. the discharge points from the job; and
6. points of entrance into the storm drain.

A key aspect to the implementation of this PPP is to ensure that all appropriate employees have knowledge and access to the BMPs described herein. An initial step towards this goal is to identify all appropriate employees who should receive training. Environmental awareness training for maintenance crews and subcontractors should be based on the following four objectives:

- promote a clear understanding of the problem, including activities with the potential to pollute storm water;
- identify the BMPs applicable or appropriate to the job;
- promote employee/subcontractor ownership of the problems and solutions;
- integrate employee/subcontractor feedback into training and BMP implementation.

Integrating employee/subcontractor training into existing programs will make the training process more streamlined.

Contractors who perform work for DWP will be responsible for implementing the BMPs outlined in this document.

Since the BMPs might be different depending on conditions (e.g., rainy days vs. dry days, summer vs. winter, etc.), employees should be trained with step-by-step guidance in the selection of appropriate BMPs. After the training sessions, provide employees with handouts, manuals or other documentation that can be used later as reference information.

Safety concerns should also be incorporated into the training programs. BMPs should be established for unexpected accidents and a safety program should be initiated which includes first aid, accident prevention and emergency response. The safety program should emphasize that public health and safety must be the highest priority when conducting emergency response activities.

II BMPs for Cement Mortar Lining

Background

Unlined cast iron and steel water mains are subject to tuberculation. Cleaning and lining such mains with cement mortar improves their performance, extends their life, and delays their replacement (which is a more disruptive activity).

Procedure:

A 6-foot by 8-foot section of the street is cut out (Hole A), and a hole is dug down to about 1 foot below the main line. The rubble and dirt is transported by truck to the contractor's yard. A 6-foot section of the pipe is removed. Any residual water is pumped out from the hole into the street. About 300 feet away another 6-foot by 8-foot hole is dug (Hole B) and the process is repeated.

A cable is pulled within the main line from Hole A to Hole B. A scraping device is then attached to a cable and moved from Hole A to Hole B. Successively thicker scrapers are added until they can be heard scraping against the metal pipe (that is, when all of the deposits, namely iron oxides, have been scraped off the pipe). A cement mortar application device is then inserted in Hole B and pulled through the pipe while cement mortar is pumped to it from Hole A. A smoothing device is then inserted in Hole B and pulled through to Hole A to smooth out the cement that was applied to the pipe. The cut sections of the pipe are replaced with new pipe.

The debris scraped from the pipe is removed from Hole A and Hole B with a backhoe and sent to an appropriate disposal facility. The holes are backfilled with slurry and are paved over. The line is then superchlorinated before it is returned to service.

All the service meters running along side of the newly lined main are replaced and new curb valves installed. If the service line from the main to the meter is galvanized, a new copper line is installed.

Potential Pollutants

The potential pollutants generated during this activity are tuberculation debris, soil, cement, chlorine, algae and oil and grease. The cement is generated when the mortar is handled and used to line the pipes, while rubble and sediment is generated when water comes into contact with the material in the excavation. The oil and grease may be generated by the construction equipment or vehicles. Chlorine is potentially generated when the line is initially opened up and the potable water drains out and also during the superchlorination process.

BMPs

Residue from the saw-cutting process should be contained and removed from the pavement. In some instances, a wet "shop-vac" can be used to vacuum up the water associated with the saw cutting. Drip pans or absorbent materials should be placed under saw-cutting equipment when not in use. Trenching and backfilling procedures shall be followed which minimize the contamination of storm water by sediment and debris.

Prior to excavation, berms will be deployed downstream of the excavation as a precautionary measure in the event that buried water-containing substructures are inadvertently hit causing an unexpected release of water to the street. During the excavation of the holes, the least possible amount of material shall be excavated from the hole. In order to minimize the amount of sediment escaping to the storm drain, the pavement surrounding the hole shall be swept up after excavation at the end of each day. The excavated material shall be hauled off site and disposed of appropriately. If rainfall is expected, all unfilled trenches shall be covered overnight to minimize the amount of rainfall that might potentially enter the trench. Whenever possible, work shall be performed during the dry season or when heavy rain is not anticipated.

While pumping the residual water out of the trench to the street, the hose inlet shall be underlain with coarse rock and have a screen on the inlet to reduce the amount of small pebbles and sediment being pumped out. Burlap sacks will be placed over the hose outlet to reduce the discharge of sediment. Where feasible, the pump discharge rate will be moderated to minimize the potential to stir up sediment in the excavation. Drainage controls, such as sediment traps, will be used where necessary. These drainage controls would be temporary set- ups intended to impede the water sufficiently for the sediment to settle out. Sediment retained behind the traps shall be removed promptly. Lastly, geotextile fabric will be secured over the storm drain inlet to minimize the discharge of sediment and debris to the storm drain system.

If sediment/debris removal from the hole is required <u>during</u> the course of the job, minimize the release of material to the street. Furthermore, the material which does land on the street should be minimized from entering the storm drain by sweeping the job site at the end of each day.

No cement washwater shall be discharged to the stormdrain. The washing of trucks, equipment or tools in contact with the cement is prohibited unless the washwater is discharged into the excavation hole and remains there.

In general, the reduction of residual chlorine by organic debris and other reducing agents in the gutter and storm drain, as well as the volatilization and dissipation of chlorine which will occur before the discharge reaches the receiving waters should lead to chlorine levels being acceptably low. The superchlorinated water shall be dechlorinated to a residual chlorine level of approximately 0.3 ppm prior to the discharge reaching the storm drain.

The backfill should be composed of cement slurry. This process will allow future work done at this site to be performed in the dried slurry, which will not produce a muddy water discharge to the storm drain, and which will reduce the overall discharge of sediment into the storm drain.

III BMPs for Main Flushing

Background

Existing water mains are periodically flushed to remove sediment and biofilm that can harbor microbiological organisms. The presence of these organisms can cause a violation of state and federal drinking water regulations, while other organisms produce chemicals that can cause drinking water violations. Periodic flushing of water mains also improves the aesthetic properties of the water (e.g., appearance, taste, and odor). Newly installed or repaired mains are flushed prior to and after being disinfected.

Procedure

Water Quality Inspectors manage two water main flushing programs, the Dead-end Flushing Program and the System-wide Flushing Program. The Dead-end Flushing Program is conducted by a Water Distribution flushing crew who open blow-off valves and flush across system divides at all dead-end water mains in the City. The System-wide Flushing Program is conducted by two Water Distribution flushing crews who systematically close gate valves and discharge water from fire hydrants in order to flush every water main in the City. For both programs, the mains are flushed anywhere from 10 minutes to approximately 2 hours depending on the amount of sediment in the line. The crews observe the discharge path to identify and correct any problems such as flooding. Discharging of water ceases when the water being discharged is visually clear of color, turbidity, and sediment.

Potential Pollutants

The potential pollutants generated during this activity are sediment (sand, dirt, pebbles) rust, algae, and chlorine. The sediment, rust and algae are generated when the hydrant valve is opened and the water discharged. The chlorine originates from the residual chlorine levels in the drinking water within the distribution system as required for public health by the Department of Health Services.

BMPs

Prior to initiating the flush, the discharge path shall be inspected and, if practicable, any potential pollutants (e.g., litter) in the path shall be removed. Wherever possible, hydrants shall be chosen that discharge to a storm drain without crossing major thoroughfares. This will minimize the contribution of pollutants due to automobile traffic.

All valves and hydrants to be used in the cleaning operation shall be inspected to ensure that a tight shutdown is possible in case any potential pollutants are discovered during discharge.

The potable water discharged from water system activities has residual chlorine levels ranging from 0.2 to 4 parts per million (ppm). However, the reduction of chlorine by organic debris and other reducing agents found in the gutter and storm drain, as well as the volatilizing of chlorine due to turbulence encountered by the discharge before it reaches the receiving waters, should lead to the levels of chlorine being acceptably low prior to the discharge reaching the receiving waters of the state.

To optimize the settling of suspended material flushed from the water distribution lines, temporary sediment traps (e.g., sand bag barriers) will be strategically placed upstream of all affected nearby storm drain inlets. Geotextile fabric will be secured over the entrance to all affected nearby storm drain inlet structures. Clear water shall continue to be discharged until it appears that the majority of the debris has been removed from the drainage path and is trapped behind the sediment dams. Alternatively, the drainage path shall be cleaned at the conclusion of the flushing job until the majority of sediment along the drainage path has been removed. The debris retained behind the sediment traps will be removed and properly handled so as to minimize the introduction of pollutants to the storm drain.

IV BMPs for Main/Service Pipeline Installation/Replacement

Background

The pipes used to distribute water age over time and occasionally need to be replaced to reduce the risk of leakage or breakage and to improve water quality. New installations of pipelines are done by both DWP and contractors, with contractors typically installing water mains and services for new developments (e.g., contractors typically install the 6" and 8" mains for new housing tracts).

DWP replaces mains that are leaky or have become too small to supply the necessary water for a given area. Most mains have diameters that range from 6 to 30 inches. DWP replaces any existing galvanized steel or lead services with 1 inch copper.

Trunklines are mains that are used to transport water over large distances without any branching off to serve distribution. Trunklines tend to be larger than other mains, ranging from 24 to 100 inches. Because of specialized equipment and mobilization required, contractors usually install trunklines with diameters of 60 or greater inches.

Procedure

Design engineers determine the size of the pipe to be installed and its location. The engineers then compile a construction work package (CWP). The district superintendent receives the CWP and assigns it to a crew supervisor. The supervisor reviews the CWP, goes to the site, lays out the job and orders marking for the underground utilities. He then orders the saw cutting for the trenches.

A main line crew is mobilized to the site with a backhoe and digs out the street where the saw cutting took place. The excavated soil is dumped into a dump truck which hauls off the material to be disposed of properly. In the case of replacement pipe, the new pipe is placed adjacent to the old pipe which is left undisturbed. The old pipe's valves are closed and the crew cuts through the pipe in order to connect the new pipe with the existing line. Water between the closed valve and the cut will run into the trench. If necessary, water is pumped out from trench to the gutter. Mud, which interferes with the replacement work, is lifted out by backhoe into a dump truck.

Before connecting the new pipe, it is disinfected with superchlorinated water, which is dechlorinated while being released to the street. The trench is backfilled with sand slurry and the street paved.

Potential Pollutants

The potential pollutants generated during this activity are sediment, chlorine, and debris. The sediment is generated when water comes into contact with the material in the hole. Sediment is also generated from saw cutting, trench excavation and backhoe mud removal. The chlorine is generated during the superchlorination process. The debris is generated with the removal of the pavement from the street.

BMPs

Residue from the saw cutting process should be contained and removed from the pavement. In some instances, a wet "shop-vac" can be used to vacuum up the water associated with the saw cutting. Drip pans or absorbent materials should be placed under saw cutting equipment when not in use. Trenching and backfilling procedures which minimize the contamination of storm water by sediment and debris shall be followed.

Prior to excavation, berms will be deployed downstream of the excavation as a precautionary measure in the event that buried water-containing substructures are inadvertently hit causing an unexpected release of water to the street. Whenever possible, the minimum amount of excavation necessary to perform the work should be done. In order to reduce the amount of sediment which can be potentially deposited onto the street and thus ultimately reach the storm drain, the pavement surrounding the hole shall be swept up after excavation at the end of each day. The excavated material shall be hauled off site and disposed of appropriately. If the material is transported to a yard prior to its disposal at a landfill, it shall be covered at the yard for protection against erosion from potential rainfall. If rainfall is expected, all unfilled trenches shall be covered overnight to minimize the amount of rainfall that might potentially enter the trench. Whenever possible, the work shall be performed during the dry season or when heavy rain is not anticipated.

The inlet of hoses used to pump residual water out of the trench shall be underlain with coarse rock and shall be fitted with screens to reduce the amount of sediment and debris being pumped out. Burlap sacks will be placed over the hose outlet to reduce the discharge of sediment. Where feasible, the pump discharge rate will be moderated to minimize the potential to stir up sediment in the excavation. Temporary sediment traps which promote sedimentation behind the trap, can be constructed of sandbag barriers. Sediment traps will be used on all discharges that have the potential to introduce substantial amounts of sediments into the storm drain. In all cases where the soil is expected to contain hazardous materials (e.g., the soil emits petroleum or solvent odors), sediment traps shall be used. Sediment shall be promptly removed from the sediment traps. Lastly, geotextile fabric will be secured over the storm drain inlet to minimize the discharge of sediment and debris to the storm drain system.

In general, the reduction of residual chlorine by organic debris and other reducing agents in the gutter and storm drain, and the volatilization and dissipation of chlorine which will occur before the discharge reaches the receiving waters should lead to chlorine levels being acceptably low. The superchlorinated water shall be dechlorinated to a residual chlorine level of 0.3 ppm prior to the discharge reaching the storm drain.

Any galvanized steel or lead service pipelines encountered during main pipeline installations will be replaced with 1 inch copper line, since copper pipelines are less likely to retain sediment, thereby making a pipeline leak or rupture less likely.

V BMPs for Reservoir/Tank Dewatering

Background

Tanks accumulate sediment that is contained in the water. To remove sediment, the tanks are occasionally drained. Tanks are drained more frequently than reservoirs, so the BMPs in this section will apply primarily to tank discharges. Approximately 20 tanks per year are drained.

DWP has reservoirs ranging from 3.3 acre-feet to 33,767 acre-feet. Dewatering for reservoirs over 1,000 acre-feet occurs very infrequently. Reservoirs are typically dewatered for improvement or construction reasons; some examples include lining the bottom/sides of the reservoir, improving the piping on the inlet/outlet of the reservoir, or dam improvements. Typically about two reservoirs per year are emptied for maintenance.

Procedure for Tank and Small Reservoir (<1000AF) Dewatering

Prior to dewatering a tank, the water in the tank is "drunk down." That is, the majority of tank's water is emptied into the distribution system and the tank is not refilled. This minimizes the amount of water being discharged.

The water is then discharged from the tank or small reservoir. Once the water is removed from the tank or small reservoir, the majority of the sediment is manually removed. The tank/small reservoir interior is then hosed down and discharged.

Procedure for Reservoir (>1000AF) Dewatering

Prior to dewatering a reservoir, the water in the reservoir is "drunk down" to a minimal operating level. That is, as much of the reservoir's water as possible is emptied into the distribution system and the reservoir is not refilled. This minimizes the amount of water that is being discharged to the storm drain.

The water is then discharged from the reservoir. Once the water is removed from the reservoir, the majority of the sediment is removed from the reservoir bottom. For larger reservoirs, heavy equipment is used for sediment removal. The sediment is transported to an approved landfill.

Once the sediment is removed, reservoir maintenance activities, such as dam improvements, piping improvements and reservoir lining, can be performed.

Potential Pollutants

The potential pollutants generated during this activity are sediment, debris, and chlorine. These pollutants originate from the drinking water that is brought into the tank or reservoir. Sediment is also generated from the reservoir maintenance activities performed. Oil and grease may be generated by the construction equipment or vehicles.

BMPs

The frequency of tank cleaning will be increased to once every 4 years so as to minimize the amount of accumulated sediment, if any, per cleaning event. Drinking the tank/reservoir down will minimize the amount of water being discharged. The residual water will be discharged at a rate that will minimize the potential for erosion to the surrounding environment. Draining the tanks/reservoirs in a slow, controlled manner will minimize the sediment leaving the tank/reservoir and will also allow more sedimentation to occur in the discharge stream, thus minimizing the amount of sediment reaching the storm drain.

Manually removing the majority of sediment from the tank/reservoir bottom minimizes the amount of sediment being discharged to the storm drain.

When tanks/reservoirs are in rural settings, water will be discharged via natural water courses to hillsides or other soil surfaces (i.e., not pavement or concrete) when possible. This will allow the water not to be "wasted" and to percolate into the ground without being discharged into the storm drain system. The residual water will be discharged at a rate that will allow the water to percolate into the ground with only minimal erosion to the environment.

Temporary sediment traps, which promote sedimentation behind the trap, will be constructed of sandbag barriers. Sediment traps will be used on all discharges that have the potential to introduce substantial amounts of sediments into the storm drain. The storm drainage structures shall be protected from entering sediment by promoting sedimentation upstream of the inlet and securing geotextile fabric over the inlet. Sediment traps shall be designed and used to minimize the amount sediment that reaches the storm drain. The sediment shall be promptly removed from the drainage path or from behind the sediment traps.

In general, the reduction of residual chlorine by organic debris and other reducing agents in the gutter and storm drain, and the volatilization and dissipation of chlorine which will occur before the discharge reaches the receiving waters should lead to chlorine levels being acceptably low.

VI BMPs for Pump Station/Regulator Station Discharges

Background

DWP has over 110 different pressure zones in the City. Pump stations and regulator stations are the primary means of modifying pressure from zone to zone. Some pump station or regulator station equipment may leak water, and some of this potable water may potentially enter the storm drain.

The primary purpose of the pumping station is to pump water from one pressure zone (alternatively, hydraulic grade) to a higher pressure zone. Water is taken from a trunk line, water tank, or a distribution main.

The purpose of a regulator station is to supply water from a higher hydraulic grade zone to a lower hydraulic grade zone.

Procedures

Small amounts of water from the pump and valve leaks at pumping stations are discharged from time to time into the storm drain. Water from relief valves at regulator stations unexpectedly discharge into the storm drain in order to protect the lower hydraulic grade zone.

Potential Pollutants

The potential pollutant generated during this activity is chlorine. Since the water is of potable quality, the amount of chlorine present is minimal. This chlorine is dissipated via volatilization during its exposure to the atmosphere.

BMPs

The valves isolating the high-pressure area shall be closed so that the discharge will release the minimum amount of water necessary to test or maintain the relief valve. This practice, which is controlled automatically, keeps the pipes from having a failure or rupture; should that happen, water, mud, rocks and all sorts of sediment would flow uncontrollably into the storm drain.

The stations shall be frequently maintained to minimize the need for relief valves to operate and to also minimize the amount of drips from leaky equipment.

VII BMPs for Groundwater Well Development/Well Maintenance

Background

Wells are important sources of water supply to the City. About 15 percent of the City's water is obtained from over 100 active and standby wells. This percentage can vary from year to year and during different seasons depending on quantity of source surface water and economics. During emergencies, such as severe drought or natural disasters (i.e. earthquake), groundwater makes up a large percent of the City's water supply. In addition, having wells on standby status gives greater flexibility in groundwater operations and adds to the available water supply.

The Department redevelops/rehabilitates groundwater wells because the well's production decreases. Specifically, the well perforations where the groundwater comes in through the soil matrix tend to clog up over time, decreasing the amount of water available to pump out of the well. The rehabilitation of the wells, which are usually 20 inches in diameter, decreases the draw down and maintains the groundwater production close to original design.

Procedure

Initially, the pump and motor are pulled up from the well where they usually reside about 300 to 400 feet down. This equipment is sent offsite for inspection and overhaul. A camera is lowered into the well to videolog the status of the well.

If necessary, mechanical measures are then employed to improve efficiency of the well. The well casing is cleaned to remove scaling from the inside of the well. A bailer with a one-way valve is then lowered into the well to bring out any sediment from the bottom and any debris floating on top of the well. As needed, a test pump is lowered into the well and surging is performed to backwash the perforations. The well is then test-pumped at a rate of between 2500 and 4000 gallons per minute for 8 to 40 hours, depending on the state of the well, to redevelop and test the capacity of the well. Usually the first 15 to 30 minutes of the discharge, and the first few minutes after surging, contain the majority of the turbidity.

If necessary, a camera is again lowered into the well to re-videolog the status of the well. The rebuilt or new pumps and motors are then reinstalled in the well.

R0019167

Potential Pollutants

The potential pollutants generated during this activity are groundwater contaminants (if any), suspended solids and an oil sheen from pump motors. Potential groundwater contaminants include PCE, TCE and nitrates. These pollutants are generated as a result of a property owner's improper handling of industrial products which result in subsurface contamination impacting the groundwater. Private sewage disposal facilities that are now mostly abandoned, as well as the historic use of crop fertilizers, have contributed elevated levels of nitrate to the basin groundwater.

Some of the pumps, which may be lubricated with food grade oil, may potentially contribute an oil sheen to the surface of the water within the well.

BMPs

A bailer is used to remove sediment and debris from the well. If the well produces more than one cubic yard of sediment or debris, the material is contained, hauled away, and either recycled or disposed of properly.

Water from the long-term well testing (testpumping) is directed from the well head to the gutter via extended piping to minimize any surface erosion which might otherwise occur over the ground surface.

The submersible motors will be cooled with food grade oil. Any leakage from the motor will float to the top and will not be discharged, since the motors are usually submerged about 100' from the surface of the well.

If oil-filled motors that are removed from the well have a potential to leak, they will have drip pans placed under them to prevent drips of oil from contaminating the area.

Temporary sediment traps which promote sedimentation behind the trap, will be constructed of sand bag barriers. Sediment traps will be used on all discharges that have the potential to introduce substantial amounts of sediments into the storm drain. Sediment traps may be placed along the discharge path or in front of the storm drain inlet. The sediment shall be promptly removed from the drainage path or from behind the sediment traps. Lastly, geotextile fabric will be secured over the storm drain inlet to minimize the discharge of sediment and debris to the storm drain system.

VIII BMPs for Main/Service Leaks, Leak Repair and Fire Hydrant Knock-offs

Background

All leaks and fire hydrant knock-offs are unanticipated occurrences, and are therefore very difficult to mitigate. Additionally, only large or catastrophic leaks, which occur infrequently, have the potential to produce significant pollutant discharges.

Most leaks occur in service pipelines and flow out onto the street and into a storm drain. Blowouts are pipeline failures that are so large that they cause at least $10,000 worth of damage to the street.

With respect to fire hydrants, in order to prevent unnecessary injury to motorists, DWP uses hollow bolts in its hydrants so as to break away during impact. At the request of the Fire Department, DWP uses wet barrel hydrants which are always charged with pressure from a main. As a result, when a knock-off occurs, a water gusher will occur. These usually range from 5- to 20-feet high, but they could gush as high as 100 feet. The testing of hydrants is performed by the Fire Department and therefore the development and implementation of any applicable BMPs associated with hydrant testing will be under their jurisdiction. Accordingly, this document does not address hydrant testing.

Procedure for Leaks and Leak Repair

Once the source of the leak is isolated, the crew supervisor orders saw cutting into the asphalt surrounding the leak. The field crew comes out with a backhoe and digs out the street where the saw cutting took place. The asphalt, concrete or asphalt/concrete combination comprising the topmost covering of the pipe is removed using a backhoe and loaded into a dump truck. The soil covering the pipe is also removed and put into a dump truck. These dump trucks either dispose of the material immediately at a landfill or stockpile it covered at a facility yard for a few days until enough soil and debris are accumulated for larger deliveries to the landfill.

The crew may repair the leak by either plugging the leak, placing a sleeve around the failed pipeline portion, or replacing the failed line with new pipe. Mud which forms in the trench and which needs to be removed in order to complete the job, is lifted via backhoe into a dump truck and is disposed of properly.

The trenches are then backfilled with a sand slurry and the street is paved.

Procedure for Hydrant Knock-offs

Once DWP is notified of a knock-off, a field crew is dispatched to turn off the valves to the hydrant as soon as possible.

Potential Pollutants

The potential pollutants generated during this activity are sediment, chlorine and debris. Sediment and debris are generated from catastrophic ruptures and from excavations during leak repair. Fire hydrant knock-offs may cause debris which is already present in the street to enter the storm drain. Chlorine may be present in the discharge from the residual levels in the drinking water as mandated by law.

BMPs for Leaks or Leak Repair

Reported leaks shall be responded to as quickly as possible in order to minimize the amount of water lost and the effects of that water on the surrounding areas.

Residue from the saw-cutting process should be contained and removed from the pavement. In some instances, a wet "shop-vac" can be used to vacuum up the water associated with the saw cutting. Drip pans or absorbent materials should be placed under saw-cutting equipment when not in use. Trenching and backfilling procedures shall be followed which minimizes the contamination of storm water by sediment and debris.

Prior to excavation, berms will be deployed downstream of the excavation as a precautionary measure in the event that buried water-containing substructures are inadvertently hit causing an unexpected release of water to the street. Whenever possible, the minimum amount of excavation necessary to perform the work should be done. This reduces the amount of sediment, rocks, etc. which can be potentially deposited onto the street and thus enter the storm drain. In order to further reduce the amount of sediment which can reach the storm drain, the pavement surrounding the hole shall be swept up after excavation at the end of each day. The excavated material shall be hauled off site and disposed of appropriately. If the material is transported to a yard prior to its disposal at a landfill, it shall be covered at the yard as protection against erosion from potential rainfall. If rainfall is expected, all unfilled trenches shall be covered overnight to minimize the amount of rainfall that might potentially enter the trench.

The inlet of hoses used to pump residual water out of the trench, if necessary, shall be underlain with coarse rock and shall be fitted with screens to reduce the amount of sediment and debris being pumped out.

Burlap sacks will be placed over the hose outlet to reduce the discharge of sediment. Where feasible, the pump discharge rate will be moderated to minimize the potential to stir up sediment in the excavation. Temporary sediment traps which promote sedimentation behind the trap, will be constructed of sandbag barriers or other equally effective devices. Sediment traps will be used on all discharges that have the potential to introduce substantial amounts of sediments into the storm drain. In all cases where the soil is expected to contain hazardous materials (e.g., the soil emits petroleum or solvent odors), sediment traps shall be used. Sediment shall be promptly removed from behind the sediment traps. Lastly, geotextile fabric will be secured over the storm drain inlet to minimize the discharge of sediment and debris to the storm drain system.

In general, the reduction of residual chlorine by organic debris and other reducing agents in the gutter and storm drain, the volatilization and dissipation of chlorine which will occur before the discharge reaches the receiving waters should lead to chlorine levels being acceptably low.

BMPs for Hydrant Knock-Offs

The most effective BMP DWP employs is to turn off the valves supplying water to the hydrant as soon as it is notified of the knock-off. DWP also ensures that Fire Department personnel have been trained in turning off the valves to the hydrant so that they may do so if they are notified.

Hydrants are usually situated on a street corner, near the curb. Storm drains are also usually located near a street corner, so hydrant knock-offs frequently flow directly into the storm drain, without collecting a large amount of debris and pollutants from the street.

General

BMPs will be instituted as warranted and as conditions permit for hydrant knock-offs, blow outs, and catastrophic ruptures. However, DWP's first responsibility is to respond to restoring essential public services, ensuring public health and safety and minimizing damage to public and private property.

IX BMPs for Underground Substructure Dewatering (Using Sensory-Screening Techniques)

Background

DWP addresses two categories of underground structures in this chapter: service boxes and vaults. Service boxes have dimensions of 4-feet by 5-feet or less, are prefabricated of a fiberglass compound and have no bottom. The great majority of underground structures are domestic service meter boxes with dimensions of 12 inches by 18 inches.

These underground structures can fill with water due to groundwater intrusion, storm water runoff, a leak from pipes within the structure, or runoff from some domestic activity (e.g., irrigation).

DWP conducted a four-month study of water infiltrated power system structures in an attempt to develop a reliable yet easy-to-use field administered "sensory screening technique". This study led to the development of the Sensory Checklist Method (SCM). While the pilot study focused on Energy System applications, it has also been applied to the Water Service Organization's (WSO) contaminated commercial water meter vaults and can be applied to the larger WSO vaults and substructures.

The pilot study involved the inspecting of over one hundred underground water-filled substructures using the SCM. Water which passed the SCM, and presumed dischargable, was subject to parallel laboratory water quality analysis. Vaults passing the SCM were then compared with the lab test results to check for consistency and reliability. The results of the study validated the use of the SCM as a dependable, reliable, and easy to use means of detecting the presence of gross pollutants.

The SCM was found to be so effective for the presence of gross pollutants that, in fact, the only class of contaminants regularly present in <u>trace</u> amounts in the sample water which could not be detected by the sensory method were pesticides and herbicides. The presence of pesticides and herbicides cannot be attributed to DWP operations (i.e., DWP did not add the pollutant), but rather is the result of "run on" into DWP substructures from stormwater infiltration.

Procedure

An SCM Checklist is completed for any partial or full discharge of vault/substructure water to the street/storm drain system. A copy of the SCM and an overview of the checklist follows.

CHECK 1 – Is the water cloudy, discolored and/or have an unusual odor?

This first check identifies substructure conditions that would require it to be contained and formally tested by a chemistry laboratory to determine the proper handling procedures. These conditions include but are not limited to cloudiness, discoloration and odors (sewage, chemicals, solvents, gasoline, etc.).

CHECK 2 – While monitoring the discharge being pumped, is there an occurrence of oil, tar, soil, cloudy discharge and/or unusual odors?

Monitor the discharge while pumping and enter the required information when appropriate (date pumped, amount pumped, and where it was pumped to [alley, street, etc.]). If any contaminants are detected during discharge, immediately stop pumping. Return to CHECK 1 to reassess the situation. If it is subsequently determined that containment is necessary, an SCM Checklist must still be completed and the line labeled "Storm Drain Discharge Stopped" must be marked. Give a detailed description of the condition that prompted the stopping of the discharge.

Completed SCM Checklists should be kept on file by the discharging facility for one year. After one year, they must be forwarded to the Wastewater Quality Compliance Group in Room 1213 for permanent record keeping.

BMPs

The primary BMP we employ is the SCM. DWP's four-month study, referenced above, revealed that hazardous chemicals, solvents, oil, grease, tar, sewage, etc. found in the vault/substructure waters could be easily detected in a sensory manner by inspecting the substructure and the water for the following signs:

- Strong chemical odor for - solvents, gasoline, diesel, etc.;
- Rainbow sheens or layers for - oil;
- Floating, suspended, and/or sinking materials for - debris, tar, etc.;
- Sulfurous (rotten egg) odor for - decaying matter, sewage, etc.;
- Color or discoloration for - sediment, minerals, heavy metals, etc.

SCM Checklist

Must be Completed for Every Discharge to the Street/Stormdrain System

DATE : ____________________ VAULT LOCATION : ____________________

TIME : ____________________ VAULT SIZE : ____________________

RECENT RAIN : Yes ___ No ___ ESTIMATED WATER DEPTH : ____________________

CHECK 1. Conditions Requiring Containment of Vault Water

1. Is the vault water cloudy, discolored, and/or has an unusual odor ? No ___ Yes ___

NO. Go on to CHECK 2.

YES. The vault water must be pumped to containment for formal chemistry laboratory testing to determine proper handling.

CHECK 2. Oil, Tar, and/or Soil

2. Is there any oil, tar or soil particles ? No ___ Yes ___

NO. Go on to CHECK 3.

YES. Can the water be pumped without disturbing the pollutants such that they are not discharged to the street ?

NO. The vault water must be pumped to containment for formal chemistry laboratory testing to determine proper handling.

YES. Go on to CHECK 3. If needed, the remaining contaminants must be pumped to containment for formal laboratory testing to determine proper handling.

CHECK 3. Pumping Clean Water / Monitoring the Discharge (Form must be completed)

3. While monitoring the discharge begin pumping the vault water to the street/stormdrain system. Fill in only the information directly below (date, amount, and destination). If any of the following conditions appear during discharge, immediately stop pumping. Return to CHECK 1 to reassess the situation. If it is determined that containment is necessary, mark "Storm Drain Discharge Stopped" and describe the condition that prompted the stopping of the discharge and the new condition of the vault water itself.

Date pumped ____________ Amount (gal) ____________ Discharge destination (alley, etc.) ____________

STOP IF : Oil, Tar, Soil, Cloudy Discharge, and/or Unusual Odors Occur

______ Storm Drain Discharge Stopped

Describe conditions : ____________________

The information provided is true and correct to the best of my knowledge.

Introduction

Pollution of our nation's waters is a continuing problem despite nearly thirty years of regulatory attention and funding. The largest remaining obstacle is "nonpoint source" water pollution. The federal Clean Water Act's National Pollutant Discharge Elimination System (NPDES) permit program regulates discharges of pollutants from "point sources," which include wastewater discharges from pipes, outlets, and other discrete conveyances, and stormwater discharges from industrial facilities, municipal sewer systems, and construction sites of five acres or more (one acre or more under recent regulations). But the NPDES program does not address nonpoint source water pollution from farms, forests, and other lands. Runoff from these lands carries sediment, nutrients, bacteria, metals, pesticides, organic compounds and other forms of pollution into the nation's rivers, lakes, estuaries, and wetlands.

The primary federal and state responses have been to provide financial and technical assistance and to encourage voluntary actions. Traditional nonpoint control methods include planning, technical assistance, promotion of voluntary best management practices (BMPs), funding of cost-share mechanisms, and public funding of stream buffers. But these assistance-oriented approaches have not succeeded in preventing pollution of the nation's rivers and streams.

Paying landowners not to pollute, providing free technical advice, and relying on voluntary adherence to BMPs has proven to be an incomplete strategy in many cases. Gradually, states are turning to enforceable mechanisms – including discharge prohibitions, direct enforcement of water quality standards, pollution abatement orders, required operating practices, nuisance and misdemeanor prosecutions, and civil and administrative penalties – to supplement other approaches. While enforceable mechanisms are not the primary instrument used to address nonpoint source pollution in any state, they are increasingly used to complement the other mechanisms.

This study examines representative experiences in eight states. It is intended to assess how enforceable mechanisms are used in practice. The study builds on several prior studies by the Environmental Law Institute (ELI) and available at www.eli.org. In 1997, ELI published a detailed analysis of enforceable state laws that were being used, or could be used, to address nonpoint source pollution. That report, *Enforceable State Mechanisms for the Control of Nonpoint Source Water Pollution*, identified the types of enforceable mechanisms available to the states and described their legal advantages and limitations. In late 1998, ELI published a companion state-by-state compendium of the enforceable laws – *Almanac of Enforceable State Laws to Control Nonpoint Source Water Pollution.* In 1999, ELI also published a related look at state programs affecting livestock operations, including those that can assist in making water pollution controls more effective – *Locating Livestock: How Water Pollution Control Efforts Can Use Information from State Regulatory Programs.*

The need for states to take further action to control nonpoint sources has been prompted by highly visible fish kills, endangered species listing of salmon runs in the Northwest, unacceptable fecal coliform levels in drinking water supplies, manure spills, nutrient pollution of major estuaries and lakes, and pollution effects on beaches and waterfronts. Concerns from point source dischargers that other polluters share some pollution prevention obligations are beginning to have some effect. Federal laws are also helping to drive the trend. Under section 6217 of the 1990 Coastal Zone Act Reauthorization Amendments (CZARA), over half the states are developing and beginning to implement enforceable mechanisms in their coastal zones in order to remain eligible for continued grant funding. And all states will need to develop Total Maximum Daily Loads (TMDLs) to clean up their impaired waters identified under section 303(d) of the Clean Water Act. As they do so, many will need to use enforceable mechanisms to achieve more effective control over the nonpoint source discharges that comprise a significant source of the impairments.

The current challenges are deciding how to integrate enforceable mechanisms into the broad menu of assistance-oriented approaches, determining when enforcement is appropriate, and structuring a system that can act effectively when enforcement is invoked.

Methodology

This study uses a case study method to look at application of the tools identified in the *Almanac of Enforceable State Laws*. ELI examined the operation of nonpoint source control programs in the context of specific watersheds – including programs operated by state, local, and federal environmental, agriculture, forestry, natural resources, soil and water conservation, and land use agencies. The study:

- examines how these programs work, and what tools they use to achieve results;
- identifies how and where the enforceable mechanisms interact with the cost-share, voluntary, and technical assistance methods that comprise the primary approaches in these watersheds; and
- describes tools that can be adopted or adapted for use in other states.

The case studies include all of the pieces of the puzzle that now constitute nonpoint source controls in each watershed -- ranging from federal agricultural funding, to EPA funding, to state environmental programs, forestry programs, and agriculture programs, to local government programs, and soil and water conservation district programs.

We selected eight states for study: Georgia, Maine, Maryland, Ohio, Oregon, Texas, Virginia, and Wisconsin. Neither a cross section nor a collection of leading programs, the states were selected primarily to study particular enforceable mechanisms identified in the prior studies. A watershed approach was used to assess the operation of state nonpoint source programs. In several states we included more than one watershed in the study in order to examine different tools or different pollution problems. Although states were selected in order to study particular mechanisms, the research examined all of the enforceable and assistance-oriented policy tools relevant to the watersheds studied.

Georgia was selected because of its apparent authority to regulate nonpoint pollution sources under the state's water pollution law, and because of its river corridor protection law imposing enforceable obligations on local jurisdictions. Maine was selected to examine its array of land use laws relevant to nonpoint source pollution. Maryland was selected because of its new mandatory nutrient management planning law and its enforcement programs addressing discharges from agriculture, development, and forest harvest sites. Ohio was selected because of its authority to issue state-level nonpoint source abatement orders to farming and forest operations. Oregon offered the opportunity to examine integration of land use and watershed planning, an agricultural abatement order linked to watershed planning, and a comprehensive forest practices act. Texas was selected in order to examine its programs authorizing local regulatory controls, and specifically special controls in the Edwards Aquifer area. Virginia's forest and agriculture nonpoint source abatement orders were the basis for its selection. Wisconsin was selected because of its integration of enforceable, technical assistance, and cost share mechanisms through the state's long-standing priority watershed program.

This study focuses on program delivery and implementation rather than on water quality outcomes. One of the incidental findings – worthy of its own future analysis – is how little monitoring data exist to assess the effect of any nonpoint source programs on water quality. Indeed, even where water quality data exist for a particular place and time – demonstrating nutrient impairment, for example – there is rarely comparable data from an earlier and later time that can show trends. Thus, program effectiveness is expressed in this study in terms of compliance with standards, norms, or BMPs, that are believed to protect water quality.

ELI conducted the research by collecting and examining laws, regulations, manuals, policies, and reports, and by conducting numerous interviews. Draft chapters were prepared and circulated for comment, then revised.

Each state chapter begins with a brief summary. This is followed by descriptions of the watershed(s) studied, the enforceable mechanisms available, and the assistance-oriented nonpoint source programs available in the watershed. Each chapter then discusses how these various tools and resources have been applied – or not applied – in the study watersheds. A brief conclusion to each chapter highlights issues, impediments, and opportunities resulting from each state's approach.

Putting the Pieces Together: Nonpoint Source Enforceable Mechanisms in Context

The eight case studies offer lessons for state and federal officials, policy makers, and others interested in improving nonpoint source pollution programs. Among these are the following:

1. ***Enforcement is already a small part of the strategic mix to control nonpoint sources.***

Each state, even though leading with other strategies, has recourse to enforcement tools for some nonpoint source problems. Some results simply cannot be accomplished by other means. For example, enforceable standards are widely used in addressing land clearing and grading activities not subject to NPDES stormwater permitting. States have found that waiting until after pollution occurs to take action, or relying wholly on voluntary standards, is an ineffective strategy. Similarly, for timber harvesting – where the land disturbance is temporary and the logger often is not readily available for post-harvest correction of problems – standards and enforceable mechanisms can be used to prevent pollution problems. Enforcement plays a critical role in agricultural pollution control as well. For agricultural animal operations falling below the numerical thresholds for NPDES permitting as concentrated animal feeding operations (CAFOs), many states have found that regulation and enforcement is needed to promote construction of necessary facilities and adherence to management plans. This is the case both because control costs may be fairly high for such operations (thus inhibiting voluntary compliance even where cost shares are available), and because the impacts that occur are significant as most livestock operations are sited near water. Finally, for all forms of nonpoint source pollution, there is always some set of actors that will not respond to other means (not even 100 percent funding). For these actors, enforcement is an essential back-stop to other strategies.

2. *Enforcement authority can be 1) linked to operating requirements or standards, and 2) integrated with a watershed plan.*

Enforceable nonpoint source mechanisms fall generally into two categories. One category provides an after-the-fact remedy. This category includes sanctions associated with violating a general prohibition on the discharge of pollution to the waters of the state, enforceable water quality standards, and authority to order the abatement of a nonpoint activity. The other category prescribes enforceable operating standards intended to prevent nonpoint pollution. Such mechanisms include construction requirements for the containment of manures, requirements for the filing of forest harvest plans, prohibitions on certain activities within 50 feet of streams, site erosion control requirements, and many other measures.

The study states have both of these types. State mechanisms that provide only an after-the-fact remedy without significant influence on operating approaches or inspection and monitoring appear to be less effective. For example, Ohio is able to invoke its nonpoint source abatement order authority only after pollution occurs. Virginia recently amended its formerly complaint-driven silvicultural nonpoint abatement order law in order to gain greater information and accountability from operations prior to any discharge occuring. In contrast, Maryland's agricultural enforcement programs are linked to on-farm water quality management planning and to nutrient management planning. Oregon links enforcement of agricultural practices to water quality management planning.

Some states link all of their nonpoint source efforts to watershed assessment and planning. This improves accountability for outcomes, while it enhances delivery of cost share and technical assistance. It also ties enforcement more closely to water quality objectives. Of the eight study states, Wisconsin and Oregon have the most detailed and comprehensive watershed planning associated with their nonpoint source controls. Maine is increasing its reliance on this kind of approach. While EPA's § 319 nonpoint source grant program has recently required watershed assessments in order for states to share in the additional funding available under that program, a number of states have used this approach for some time – applying it to other cost-shares, technical assistance, and enforceable mechanisms.

3. *Cost-share mechanisms continue to play a substantial role, particularly for agricultural sources.*

All of the states use cost-share and technical assistance as a primary approach to nonpoint source water pollution controls on agricultural lands. Federal funds often provide the bulk of cost-shares, but several of the study states – including Wisconsin, Maryland, and Virginia – have made significant state-funded cost-shares available. Several states have also enacted property and income tax breaks to encourage agricultural planning and installation of pollution control practices. Cost shares can play an important role in assuring compliance with regulatory programs. For example, Maryland has supported its new mandatory nutrient planning law's implementation with additional loan and cost-share funding. Wisconsin integrates costs shares with enforcement by linking eligibility for some cost shares to an operator's prompt response to an enforceable mechanism – such as the notice of discharge for animal operations. Ohio takes the opposite approach by prohibiting the issuance of an enforcement order that requires installation of a cost sharable practice unless cost share funding is actually provided.

Integration of technical assistance and cost share with enforcement has been difficult in some respects. Many agriculturally-oriented agencies do not want to be associated with enforcement. The case studies show that even states with the most fully developed enforceable mechanisms generally seek to assure that in addressing agriculture and forestry, the enforcement function is assigned to a separate entity from the cost-share and technical assistance function.

4. *Geographically-targeted enforceable protections are significant features of state nonpoint programs.*

Although many state programs emphasize BMPs and rely on "no discharge of pollution" or abatement order provisions to address violations wherever they may occur, there is a clear trend toward geographically focused protections. For example, Georgia's unique river corridor protection program is intended to focus particular regulatory attention on these areas. Maine's Natural Resources Protection Act and Mandatory Shoreland Zoning Act provide special protections for areas vulnerable to nonpoint source pollution. So do the Chesapeake Bay protection acts of Maryland and Virginia, and the Edwards Aquifer protection program in Texas. Wisconsin's use of a priority watershed program – and designation of critical sites within these watersheds – reflects another way to focus both cost share and regulatory efforts.

5. *Enforcement procedures are more effective when simple to use and prompt in their effect.*

Because in the nonpoint source universe enforcement generally comes only after all other approaches have failed, it is important that the enforceable mechanisms be straightforward and effective as early as possible. The track record of the states in this area is mixed. Ohio's abatement orders often restart the negotiations that led to the request for enforcement by the soil and water conservation district. Wisconsin's state-level agricultural pollution abatement orders also can result in a long waiting period. Prompt approaches include measures that can be locally taken. This can include enforcement by county and local officials and enforcement by other state officials using local magistrates (as with Ohio's wildlife officers). Local governments play a significant role in nonpoint source regulation in a number of states – primarily in the field of erosion and sediment control from nonagricultural activities, but also including agriculture and silviculture in several states.

Local programs seem to require a great deal of state support, funding, and technical assistance, but when fully staffed seem to offer some advantages in effectiveness and visibility. Maryland, Wisconsin, and Maine have integrated nonpoint concerns into a vast array of laws, many of which involve local government. Georgia has some interesting locally-enforceable mechanisms, including the river corridor protection law, but its implementation experience is too recent to assess the effectiveness of this program generally. Texas's Edwards Aquifer program provides another example of a targeted regulatory regime with local enforcement that seems to operate well.

Enforceable Mechanisms Are Here To Stay

States are adopting enforceable mechanisms to supplement more traditional approaches. The case studies show that states often take some time to adopt and then use these mechanisms, but that once in use the enforceable mechanisms are supplemented or strengthened.

Maryland and Wisconsin appear to have the most fully integrated systems of nonpoint source controls. Both combine substantial cost-share funding with the realistic option to use enforceable mechanisms. Of the two, Wisconsin seems to have devoted greater effort to planning and targeting, Maryland to the development of an array of enforceable programs.

Nonpoint source enforcement is not a great unknown. Nor is it a mere spectre of the much debated TMDL process. The experiences of the states examined in this study offer substantial guidance about ways to structure enforcement, to develop programs, and to integrate traditional approaches with enforcement.

Nonpoint source pollution is perhaps our biggest water quality problem, and it remains one of our greatest problems of environmental governance. It will continue to be a problem until we address nonpoint source pollution with the same seriousness with which we addressed industrial and sewage discharges beginning in 1972. The solution will require a shared state and national commitment to solve the problem – demonstrated by:

! accountability for results in improving water quality,
! adequate state and federal funding, and
! enforcement.

Many of the pieces of this puzzle are already on the table. Some states have even assembled parts of the picture. It is time to finish the job.

Georgia Case Study

Summary

This study examines the mechanisms used to manage and control nonpoint source pollution in the Coosa River watershed in northwestern Georgia.[1] The study specifically examines the relationship between enforcement approaches and voluntary, technical assistance, and cost share approaches as used in the watershed. Georgia primarily uses voluntary and technical assistance programs that emphasize best management practices for nonpoint source pollution management – especially in agriculture and forestry. Although the need to maintain certain water quality standards can be used to enforce against agricultural and forestry nonpoint source runoff, in practice this enforcement mechanism seldom is used. Georgia does have an innovative mechanism for requiring localities to include environmental criteria in their comprehensive plans and local ordinances, including river corridor protection criteria. Georgia also requires localities to implement erosion and sedimentation control requirements on land development activities, and especially localities in high growth areas are developing innovative enforcement programs to manage this type of nonpoint source pollution. The state is strengthening its permitting programs for stormwater, concentrated animal feeding operations, and land application systems.

The Coosa River Watershed

The Coosa watershed in the northwest corner of Georgia is a mixture of rural and rapidly suburbanizing lands. Its streams are impacted by runoff from farms, forestry operations, and small surface mining sites. However, the southern counties of the region and the areas around municipalities are seeing an increase in subdivision development. Such development is leading to increased erosion and sedimentation runoff from construction, as well as urban runoff and sewer overflow problems. In general, the Coosa watershed is still fairly pristine, however threats exist from a variety of nonpoint sources and certain stream segments are impaired. Impaired streams in the Coosa watershed are primarily impacted by nonpoint source and urban runoff, fecal coliform being the most common contaminant.[2]

Named among the ten most endangered rivers in the United States in 1999, by the conservation group American Rivers, the Coosa River Basin in Georgia and Alabama flows through many wild and natural areas and supports a wide range of biodiversity.[3] The Coosa watershed, encompassing approximately 4,700 square miles, includes most of the counties in the Northwest corner of Georgia.[4] Several major rivers run through the watershed, including the Conasauga River, the Coosawattee River, the Oostanaula River, the Etowah River, and the Coosa River.[5]

The Coosa region is a priority watershed for agricultural nonpoint source management. Approximately 6 of its rivers and streams exhibit water quality impairments due to agricultural nonpoint source pollution, while 16 have a high potential of water quality problems.[6] Most of the farms in the region are still small family farms, but there is a recent increase in concentrated animal feeding operations. The watershed includes 2.4 million acres of forested land of which 11% is owned by the forestry industry while the rest are held by landowners. Nonpoint source pollution from forestry accounts for a relatively small percentage of the overall water quality impairment. Major pollution risks involve sediment from roads and skid trails, soil disturbance during site preparation, and streamside cutting.

Georgia Environmental Protection Division (EPD) studies have concluded that, statewide, sediment is the most severe pollutant from nonpoint sources.[7] The proximity to suburban Atlanta affects both water quality and water quantity in the Coosa watershed. Increased construction from new housing developments contributes to sedimentation in the southeastern localities of the watershed.

Finally, surface mining is a $1.7 billion industry in Georgia. Mining in Georgia is concentrated primarily in stone, clays, and other construction and industrial materials. The Coosa watershed has a mixture of surface mining operations, some of which require NPDES permits, such as quarries, and some of which require surface mining permits, such as pit operations and borrow pits for clay, fill dirt, gravel, etc. Almost every county in the watershed has some type of surface mining.[8] There are approximately 24 quarries, 18 borrow pits, 12 dredgers, and 10 pits (primarily for clay) permitted in the region.

Enforceable Mechanisms

Of the Georgia nonpoint source enforceable mechanisms, the following were reviewed because of their relevance to the Coosa watershed.

! *Water quality standards.* The Georgia Water Quality Control Act requires that the water quality standards for Georgia not be violated and provides civil and criminal enforcement sanctions for water quality violations.[9] As implemented, it does not establish a permitting process for nonpoint discharges, although the Act apparently would allow EPD to do so.[10] The Act is used primarily in forestry and agricultural nonpoint source discharge cases where there is a serious violation of water quality standards and the agency responsible for best management practices (BMP) implementation and technical assistance cannot secure compliance or implementation of BMPs. In these cases, the responsible agency may turn the case over to Georgia Department of Natural Resources' Environmental Protection Division (EPD) for enforcement.

! *Land disturbance permitting.* The state Erosion and Sedimentation Act establishes a permitting process for land-disturbing activities such as clearing, grading, excavating, or filling of land.[11] To receive a permit, an applicant must submit an erosion and sediment control plan that outlines specific BMPs for implementation. This Act also directs local governments to enact erosion and sedimentation ordinances for review by the EPD. Once an ordinance has been found consistent with state law, EPD grants the local government authority to issue and enforce permits for land-disturbing activities. In areas where a local government has not been certified, the EPD is responsible for permitting, inspection, and enforcement under the Act. However, in much of the state, local governments have adopted erosion and sedimentation ordinances and have been given the authority to issue and enforce permits for land-disturbing activities.[12]

! *Surface mining permitting*. The Georgia Surface Mining Act requires a permit from EPD for surface mining operations.[13] The Act applies to surface mining activities statewide. Surface mining is defined as any activity or process for the removal of minerals, ores, or other solid matter.[14] Tunnels, shafts, and dimension stone quarries are not considered to be surface mining. Minerals include sand, clay, stone, gravel, phosphate, and other rocks and ore of commercial value found in natural deposits on or in the earth. The Act covers dredging of sand as well as other surface mining activities. EPD has the authority to enforce violations of the permit, including water quality and discharge violations.[15]

! *Land application systems permitting*. Under the Water Quality Control Act, Georgia requires a general permit for all land application systems (LAS), including agricultural systems for spreading animal waste, municipal systems for spreading treated wastewater, and industrial systems for spreading treated wastewater.[16] A general permit can be issued for all facilities within a specific geographic area or to a specific category of LAS facilities. EPD may also require specific facilities to obtain an individual LAS permit. LAS permits are no-discharge permits and refer back to the accepted best management practices for land application of animal waste, human waste, or industrial waste, including a requirement for a treatment, storage, operation, and management plan that is incorporated by reference into the permit.

! *River corridor protection*. Under state law, protection of river corridors and other critical natural resources is to be accomplished through comprehensive planning at the local level. Localities in Georgia are required to develop comprehensive plans if they wish to receive and maintain the status of "qualified local government" in order to participate in certain state financial assistance programs.[17] These plans must contain the minimum environmental criteria set out by EPD to protect large rivers from the impacts of human activities on land immediately adjacent to the river.[18] Each local government with a protected river in its jurisdiction is directed to adopt a river corridor protection plan which meets minimum planning standards established by the Department of Natural Resources.[19] Further, the river corridor protection standards must be incorporated into a local ordinance.

! *Total Maximum Daily Loads*. Under section 303(d) of the Clean Water Act states must list impaired waters and provide that information to USEPA. Further, states must develop total maximum daily loads for certain pollutants for the impaired waters identified in the section 303(d) report. The state must then ensure that the TMDLs are met by point and nonpoint sources alike. In Georgia, a 1997 consent decree after litigation initiated in part in the Coosa watershed by the Coosa River Basin Initiative, started the TMDL identification and implementation process in the state. The draft Georgia 2000 list of waters under section 303(d) was submitted March 2, 2000 to USEPA.[20]

Assistance-Oriented Nonpoint Source Programs

This section describes a number of the technical assistance, cost-share and voluntary programs that address nonpoint source water pollution in the Coosa watershed. It is not an exhaustive list, but provides a brief description of programs that have influenced activities and water quality in the watershed.

! *Agricultural Incentives to Protect Sensitive Lands.* Incentive programs offer a combination of rent payments and cost-share assistance covering 50-100 percent of the expense of the specific conservation practices or restoration activities. Incentives to shift agricultural production from sensitive lands and to restore them to more natural conditions mainly are provided through four federal programs, the Conservation Reserve Enhancement Program, the Wetlands Reserve Program, the Environmental Quality Incentives Program (EQIP), and Section 319 financing under the federal Clean Water Act. In the Coosa watershed, EQIP and Section 319 funding are the two most common programs used to manage nonpoint source pollution. The Wetlands Reserve Program and the Conservation Reserve Program are less commonly used, partly because eligible land is not as abundant as in other parts of Georgia and partly due to rising land values making landowners reluctant to enter into long term conservation agreements.

! *Forestry Best Management Practices.* Forestry is subject to the Georgia Water Quality Control Act, but exempt from erosion and sedimentation control permit programs, provided that best management practices are used. Education and training focus on proper installation and maintenance of BMPs to minimize or eliminate nonpoint source pollution from forestry activities.

! *Watershed Assessments.* Georgia has a relatively recent policy that any locality asking for an environmental permit from the state that facilitates growth and development, such as a wastewater permit or a water withdrawal permit must conduct a watershed assessment before receiving the permit.[21] There are 30 assessments currently taking place around Georgia.

! *Adopt-A-Stream and Citizen Monitoring.* Georgia Adopt-A-Stream is a volunteer network of citizens and local governments that monitor water quality and conduct water body enhancement activities. Volunteers in the Georgia Adopt-A-Stream program and in other citizen programs monitor and record water quality providing valuable information to help citizens, the state, and localities understand both point and nonpoint pollution discharge sources, types, and quantities.

Discussion and Analysis

River Corridor Protection and Local Comprehensive Planning

Georgia establishes corridors along selected rivers as critical natural resource areas. The Conasauga, Oostanaula, Etowah and Coosa Rivers of the Coosa watershed are all state-designated protected river corridors. State law requires the Department of Natural Resources to develop minimum standards for the "protection of the natural resources, environment, and vital areas of the state, including, but not limited to, the protection of mountains, the protection of river corridors, the protection of watersheds of streams and reservoirs which are to be used for public water supply, for the protection of the purity of ground water, and for the protection of wetlands, which minimum standards and procedures shall be used by local governments in developing" comprehensive plans.[22]

The minimum standards for watershed protection include buffer areas along streams and reservoirs, land development densities, and land use activities.[23] Standards for protection of river corridors include natural vegetative buffer areas for a distance of 100 feet on both sides as measured from river banks.[24] Septic tanks and septic tank drainfields for non-single family residential developments are expressly prohibited within the 100-foot buffer. In addition, areas for receiving, storing, or disposing hazardous waste or hazardous materials, as well as solid waste landfills are prohibited within the buffer. Construction of single family dwellings with a two acre minimum lot size which comply with local zoning is exempt from the river corridor protection requirements.[25] The statute gives local government the authority to exempt agriculture and silviculture consistent with BMPs from river corridor protection plans, but it does not require that agriculture and forestry be exempt.[26] The regulations, in contrast, treat agriculture and forestry as acceptable uses provided they do not impair the long term functions of the protected river or the river corridor.[27] It is not clear how EPD, DCA, and localities have dealt with this inconsistency.

In addition, at the discretion of local governments, mining and quarrying activities may also be exempted from river corridor protection requirements, according to both the statute and the regulations.[28] Finally, local governments may exempt wildlife and fisheries management activities and wastewater treatment.

In 1990, when comprehensive plans were first required, the Georgia Department of Community Affairs (DCA) asked local governments to address how they would handle river protection both in the comprehensive plan and in a 5-year short-term work-plan. DCA required that local governments also develop ordinances, but did not yet enforce this requirement.

As most governments complete their first 5-year short term review, DCA is requiring ordinances for all of the environmental criteria under the Comprehensive Planning Act. Localities that do not pass ordinances according to the time schedule set out by DCA will loose their qualified local government status until the ordinances and other planning requirements are in place. A loss of the qualified local government status means that a locality is no longer eligible for state environmental permits, state grants, and state loans.

All but four of the localities in the Coosa River Watershed contain river corridors for which ordinances must be developed.[29] Cherokee, Floyd, Gordon, and Forsyth Counties and the City of Rome recently have adopted river corridor protection ordinances. The other localities that require the ordinances have due dates in the year 2000 or beyond. All local governments in the Coosa River Watershed have had qualified local government status. Recently the qualified local government status for a few localities in the Coosa watershed was put on hold pending review of river corridor and wetlands protection ordinances that were submitted after their deadline had passed.

The river corridor ordinances typically follow the model ordinance developed by EPD, with a few exceptions. For example, the City of Rome widened the required buffer for tributaries specifically identified in the ordinance to 40 feet.[30] Localities tend to combine enforcement of the river corridor protection ordinances with erosion and sediment control inspections for new construction. For example, in the City of Rome when a developer asks for a zoning verification prior to receiving a building permit, he or she also receives verification of the buffer requirements. The Building Inspector must enforce the buffer during the inspection process. To date, no enforcement actions have taken place in this area under this ordinance in Rome.

Construction Activities: Erosion and Sedimentation Control

Certain activities under the Erosion and Sedimentation Act are unconditionally exempt from permitting requirements; these include: surface mining, granite quarrying, home gardening and landscaping, *agricultural and forestry operations*, and any other project carried out under the technical supervision of the Natural Resources Conservation Service. Other activities are partially exempt, meaning they do not need to obtain a permit prior to land disturbance, but BMPs must be followed. Such activities include: construction of single-family residences, construction or maintenance of roads by state or local governments, and land-disturbing activities conducted by public utilities.

Under state law, activities on sites of one and one-tenth acres or less are exempt from both permitting and BMP requirements unless such activities occur within 200 feet of lakes or perennial streams, in which case landowners must prevent sediment from moving beyond the property boundaries. Local governments with delegated authority for erosion and sediment control can, however, elect not to exempt activities on small sites from permitting or BMP requirements.

Local governments, with oversight by the EPD and the area Soil and Water Conservation District (SWCD) are primarily responsible for implementing the Erosion and Sedimentation Act. The Erosion and Sedimentation Control Act directs local governments to enact erosion and sedimentation ordinances. These ordinances are reviewed by EPD and, if consistent with state law, the local government is granted the authority to issue permits for land-disturbing activities. In much of the state, local governments have adopted erosion and sedimentation ordinances and have been given the authority to issue and enforce permits for land-disturbing activities.[31]

The state Soil and Water Conservation Commission (SWCC) has instituted program oversight to help municipalities to implement the erosion and sediment control requirements. In cases where a locality consistently does not implement the program, the SWCC can ask EPD to take back the issuing authority. This has happened or been threatened in several cases in the Coosa River Basin Watershed – as is described in the description of the revised Cherokee County program below.

Reports of suspected violations of the Erosion and Sedimentation Control Act are made to the body that issued the permit. Except in localities with strong inspection programs, the complaints typically come from citizens. In cases with a local issuing authority, if the violation continues, the complaint is then referred to the SWCC. The SWCC typically will write a letter to the issuing authority asking it to solve the violation. In the Coosa watershed region (Region 1), the SWCC received over 1000 complaints in 1999. Approximately half were successfully handled with a phone call or a letter to put the locality on notice. Of the remaining complaints, approximately 1 in 4 needed a site visit from the SWCD before they were remedied. Approximately 10% are ongoing problems that need stricter enforcement measures. If the situation remains unresolved after the appropriate SWCD has exhausted site visits, letters, and action by the locality, the complaint is then referred to EPD for enforcement.

Enforcement, by EPD or the issuing authorities, consists of administrative orders, injunctions, and civil penalties. Civil penalties for non-certified counties and municipalities are authorized up to $2,500 per day. Permit revocation, suspension, modification, and bond forfeiture constitute additional enforcement sanctions.

In addition to erosion and sediment control, Georgia also has a NPDES permit program regulating discharge of stormwater from construction activities. As of 1997, the program was undergoing judicial review and implementation had been halted pending the results of that review. According to a February 2000 settlement of cases challenging the stormwater NPDES permit system, EPD will issue new stormwater permits for construction sites of 5 acres or more sometime in summer 2000.[32]

Erosion and Sediment Control in Cherokee County -- As a metro-Atlanta locality, Cherokee County is one of the fastest growing areas in the nation. The constant development and construction poses an enormous erosion and sediment control challenge to the county. In 1997, Cherokee County was put on warning by the EPD that if it did not do a better job as an issuing authority under the Erosion and Sediment Control Act, the program would be taken away and assumed by EPD. At the time, Cherokee County had an erosion and sediment control ordinance based on the model ordinance prepared for localities by the SWCC. However, there was very little implementation of the ordinance. Cherokee County hired new inspectors and developed a teamwork approach to enforcement of the erosion and sediment control provisions, that included housing all erosion and sediment control permitting in a single department. With the backing of elected officials, they restarted their program with a zero tolerance policy for non-compliance.

Currently, in Cherokee County, developers submit a plan in order to be granted a permit to clear, allowing trees to be cut and erosion control devices to be put in place.[33] The area is then inspected, after which the developer can receive a land disturbance permit. Once the projects start, inspectors drop by regularly, as much as several times a week, depending on the nature of the project. To build a house, the builder must apply for an erosion control permit in order to cut trees and install the erosion control devices. Once the site is inspected, the builder can receive the erosion control permit. Only with the erosion control permit can the builder receive a building permit from the Building Inspections Department.

Cherokee County counts on cooperation with its County Marshall and Magistrate to implement the zero tolerance enforcement policy. Inspectors can and regularly do issue stop work orders in the field as soon as they spot a violation. These stop work orders last until the violation is fixed, sometimes a day, sometimes a week or longer. One recent stop work order lasted a year. If inspectors find a problem that is actively impacting a waterway, they ask the County Marshall to issue a field citation. The developer must then go in front of the County Magistrate. Under this zero tolerance policy, compliance rates in the county are rising.

Agricultural Pollution

Education, technical assistance, and financial incentives are the primary mechanisms used to prevent agricultural nonpoint source pollution. Agricultural programs emphasize the use of best management practices (BMPs) to minimize or eliminate erosion, sedimentation, and runoff of other pollutants. Georgia has developed recommended BMPs for a wide range of agricultural activities. The Georgia Soil and Water Conservation Commission (SWCC), in conjunction with the 40 Soil and Water Conservation Districts (SWCD) and with other cooperating agencies, such as the U.S. Natural Resources Conservation Service (NRCS), conducts a statewide education and technical assistance program to promote the adoption of BMPs.

Agricultural operations fall under the Georgia Water Quality Control Act which sets water quality standards that may not be violated by agricultural runoff. Enforcement actions are rarely if ever brought for nonpoint source pollution from activities that do not need any type of permit. Only land application systems and concentrated feeding operations need permits in Georgia under the Water Quality Control Act regulations.

All agricultural operations are exempt from the Erosion and Sedimentation Control Act, and may be exempt from the River Corridor Protection Act provided the activities are consistent with BMPs.

In general, the SWCC and the NRCS believe that enforcement techniques do not work well with farmers, finding that family farms respond best to assistance, voluntary programs and training. However, the growing number of concentrated animal feeding operations (CAFOs) and other large scale hog and chicken farms is causing the state agencies to think about permitting and enforcement techniques for these types of farming operations.

Concentrated Animal Feeding Operations (CAFOs) – The DNR Board recently promulgated rules on permits for swine feeding operations with over 300 animal units.[34] New rules covering dairy and poultry are expected in late 2000. The rules allow no discharge from the swine feeding operations into surface waters of the state. By October 31, 2001, the owner or operator of an existing swine operation is required to submit a comprehensive nutrient management plan to EPD. The owner or operator of a new operation must have the plan in place before receiving the permit. Any failure to comply with any condition of the regulations will be deemed a violation of the Water Quality Control Act and may be punishable in accordance with the penalties provided for in the Act.

Prior to these rules, EPD had a memorandum of understanding (MOU) with the NRCS and the SWCC about best management practices for land application systems (LAS) on concentrated animal feeding operations. The MOU was first developed in 1981 and revised in 1991. Under the MOU, EPD issued new large CAFOs (over 1000 animal units for swine, dairy, and poultry) with land application system permits. There were only 13 permitted CAFOs statewide. The MOU is still in place for those facilities not covered by the new regulations (dairy and poultry), although its implementation is currently on hold pending new regulations that are expected later in 2000 concerning dairy and poultry. The SWCC has seen an increased interest among CAFOs in improving their pollution prevention systems: the SWCC reports an increase in calls from CAFOs requesting assistance with best management practices since the new regulations were proposed.

Agricultural land application systems require permits. Violations by farmers are handled by SWCC in the first instance to try to bring the system into compliance. If there is a fish kill or public health hazard associated with the violation then EPD will consider enforcement actions. EPD issues approximately 2 - 3 consent orders a year concerning agricultural land application system violations. A review of the EPD published enforcement orders found that no EPD enforcement orders had been proposed or finalized between 1998 and early 2000 in any of the localities of the Coosa watershed for violations of agricultural LAS permits.

Resource Conservation and Development Program (RC&D) – Most of the Coosa watershed is covered by the Resource Conservation and Development Program of USDA. Jurisdictions have banded together to form "Council Areas" that then identify the most important resource issues, set priorities, develop projects, and look for funding. Funding under Section 319 of the federal Clean Water Act is commonly used in the RC&D program and the projects carried out are often water quality demonstration projects. Water quality demonstration projects are a common component of the education and technical assistance program. Assistance with implementation of total resource management systems or of specific BMPs is provided in identified priority project areas. Assistance can include, for example, funding to agricultural producers for water related BMPs. These demonstration projects are implemented through cost-sharing programs with a combination of federal funds and state, local, and producer matching funds. The Coosa watershed is divided into three Council areas that would impact the basin. The Chestatee - Chattahoochee RC&D program covers the area around Lake Lanier and the Upper Coosa watershed. The Limestone Valley RC&D progra covers most of the Northwest to the Alabama line. The Rolling Hills RC&D program picks up west of the metro-Atlanta area.

Environmental Quality Incentives Program (EQIP) Priority Areas – The federal EQIP program focuses on priority areas where agricultural improvements will help meet water quality objectives and where financial assistance is available from state or local governments. EQIP will offer five to 10-year contracts providing incentive payments and cost-sharing for selected conservation practices, including grassed waterways, filter strips, buffer strips, and others. The SWCC encourages fencing out of streams to keep animals from watering directly in streams by providing financial assistance to build alternative watering locations. The Coosa watershed includes two EQIP priority areas: Armuchee Creek in Floyd, Walker and Chatooga Counties and the Conasauga River. Under EQIP a local workgroup sets conservation priorities for the area that are funded in part through EQIP and in part through other programs such as Section 319 funding. The types of practices that are typically priorities in the Coosa watershed concern livestock waste, alternative water supplies, and grazing practices.

Forestry Water Quality Programs

In 1978, EPD designated the Georgia Forestry Commission (GFC) as the lead agency in coordinating the forest water quality portion of the overall state program.[35] The Forestry Nonpoint Source Pollution Technical Task Force developed recommendations that forestry activities be carried out in accordance with voluntary best management practices.[36]

Because soil characteristics and slope vary greatly across the state, BMPs have been tailored to each of Georgia's four regions. The Coosa watershed falls in both the Piedmont and the Mountains regions. Individual BMPs have been developed for eight groups of forestry activities: streamside management zones, stream crossings, access roads and their construction, timber harvesting, site preparation, reforestation, forest protection (prescribed burning, fire lines, and chemical fire retardants), and chemical treatments. BMPs include recommended activities as well as practices to be avoided. The Georgia Forestry Commission issued revised BMPs for commercial forestry, specifying new widths for streamside management zones, a refined list of streamside scheduled recommended activities within those zones, and other BMPs in January 1999.[37]

Since 1991, the GFC has carried out BMP compliance surveys in each river basin. The surveys identify any problems with implementation of best management practices. The compliance surveys function as a compliance audit. The GFC acts on findings of non-compliance by notifying the landowner and working with them to bring the forestry operation into compliance. In the Coosa River Basin, the 1992 compliance survey found that most of the forestry operations were in compliance. For example, in the Coosawattee River Basin where 3 sites involving 260 acres of forestry operations were evaluated, 72% of road miles, 96% of harvested acres, and 98% of prepared sites were in compliance. In the Etowah River Basin where 10 sites involving 1161 acres of forestry operations were evaluated, 89% of road miles, 95% of harvested acres, 69% of prepared sites, and 100% of regenerated areas were in compliance. GFC carries out the compliance surveys every two years.

In addition to helping the GFC identify problems, the compliance survey is used to target educational needs in the forestry community. GFC has carried out 3 or 4 workshops since 1995 in the Coosa River Basin. In general they have found that sites on U.S. Forest Service land are almost always in compliance, industrial forestry operations are generally in compliance, while private landowners are less often in compliance. For example, in the Etowah River Basin, as discussed above, on private lands compliance for roads was 72% while on forest industry lands, compliance for roads was 93%.

Complaints about actual or potential water quality impacts from commercial forestry activities first are referred to the GFC. Complaints from citizens are common, particularly in the counties with growing populations where landowners are living closer to forestry operations than in prior years. After notifying the forest owner, the GFC district coordinator makes a field inspection to determine if BMPs were followed, if there is a potential for water quality problems and who was responsible for the activity (e.g., site preparation or timber harvesting). If problems exist, the GFC will work with the responsible parties until the problem is corrected or until it determines that the issue cannot be resolved. GFC estimates that it has a 90% success rate in obtaining compliance through working with the responsible parties.

In situations where the GFC cannot gain satisfactory compliance, the case is turned over to EPD for action under the Georgia Water Quality Control Act.[38] For example, in Lumpkin County, a case was turned over to EPD for enforcement where the developer was trying to use the forestry exemption from the Erosion and Sedimentation Control Act to cut timber without a permit in order to sell the land for development. Under the Georgia Water Quality Control Act, if during logging the water quality standards in streams are exceeded and best management practices are not in place, EPD may bring enforcement actions. EPD actions include issuing a warning to the responsible party or landowner, undertaking water quality investigations to document nonpoint source impacts, referring the complaint to USEPA or initiating enforcement action as provided by the Georgia Water Quality Control Act. Typically, enforcement action will be taken by EPD where there is a demonstrable violation of water quality standards and the responsible party has a history of causing chronic water quality problems. There have been a few cases, including in the Coosa River Basin, where EPD assessed civil penalties.

Surface Mining Runoff Control

There is some surface mining in the Coosa River Basin Watershed, primarily stone or granite quarries and extraction of fill materials. An application for a surface mining permit must be accompanied by a mining land use plan consistent with the land use in the area of the mine. The plan also must specify activities for control of erosion and sedimentation and disposal of refuse, as well as provisions for reclamation of the affected land. The mine operator is responsible for completion of the plan. In addition to the land use plan, surface mining operators must file a surety bond with EPD for land reclamation activities. EPD surface mining permits incorporate best management practices for protecting water quality. Site operation, objectives of the land use plan, and estimated cost factors for completion of the mining land use plan are subject to review and evaluation by EPD at least every five years. Following the review, bonding amounts will be adjusted as needed to ensure adequate funding for site reclamation.

In practice, EPD Land Protection Branch will take actions under both the Surface Mining Act and the Water Quality Control Act to enforce permits and to remedy violations of water quality standards. The Branch typically uses the Surface Mining Act with its lesser fines of $1,000 per violation and $500 for each day of violation thereafter for minor or one-time violations,[39] and uses the Water Quality Control Act with its higher penalties for major or continuing violations. EPD enforcement typically starts with one to two notices of violation, a consent order if the problem is not fixed, and an administrative order if the violation is severe or if the consent order does not achieve compliance. EPD can also request penalty hearings connected to the administrative order.[40]

New Water Quality Enforcement Policy

As of 1998, EPD has become more vigilant about bringing enforcement actions in the case of violations of the Water Quality Control Act for certain areas, including the Coosa River watershed.[41] These enforcement actions are primarily brought in urban areas against violations of NPDES permits and sanitary sewer overflows. In practice, the Georgia Water Quality Control Act is rarely used to enforce against nonpoint source pollution. According to the published EPD enforcement orders, as of 1998, only two enforcement orders were brought in the Coosa watershed for nonpoint source violations of the Water Quality Control Act. These were both in Forsyth County and included an unauthorized discharge from a hog farm in September 1998 and an unpermitted land disturbing activity violation by a developer in January 1999.[42] The bulk of the enforcement orders in the Coosa watershed were for violations of NPDES permits and for sewer system overflows. There was one enforcement order concerning violation of a LAS permit.

In late 1997, the Georgia Department of Natural Resources (DNR) Board in reaction to several high profile water quality problems in high growth areas, asked EPD to identify areas of the state where the water systems were under stress. At the time there were a significant number of sanitary sewer overflows due to high growth in the metro-Atlanta region straining the existing sewer systems. EPD identified the Coosa River Basin, the Chattahochee River Basin, the Tallapoosa River Basin, and the 14 county metro-Atlanta region. The DNR Board asked EPD to come up with a strategy for addressing and resolving the water quality problems in these areas. Based on EPD's report, the DNR Board issued a resolution that any violation of the Georgia Water Quality Control Act, especially in the metro-Atlanta region, would be addressed by immediate enforcement action.[43] Although this theoretically covers both point and nonpoint source violations, it is primarily intended to address permit violations (NPDES, LAS, pretreatment, and CSOs) and sanitary sewer overflows. The resolution is silent about enforcement of violations of water quality standards. In addition, inspection and surveillance is required to be increased in the designated areas. This "zero tolerance" policy is also seen as an added incentives for localities and others to invest in compliance.

Total Maximum Daily Loads (TMDLs)

As the process for determining TMDLs continues in Georgia, ensuring compliance with pollutant load allocations on the part of nonpoint sources on impaired waters will most likely require that some type of enforceable mechanism be implemented. However, the TMDL process in Georgia has not yet reached a stage where TMDLs are being enforced. Under the current implementation schedule, the EPD will provide public notice of TMDLs for the Coosa watershed by June 30, 2003.[44]

Watershed Assessments

Under a new Georgia policy, any locality asking for an environmental permit from the state that facilitates growth and development, such as a wastewater permit or a water withdrawal permit must conduct a watershed assessment before receiving the permit.[45] There are 30 assessments currently taking place around Georgia, creating an additional pool of information about nonpoint sources of water pollution.

Under the watershed assessment guidelines, the permit applicant must identify the point and nonpoint sources of water pollution, carry out predictive modeling and land use scenarios based on future growth, and propose solutions to address current and future water quality problems.[46] The watershed assessment must be carried out for the entire service area covered by the local authority. The assessment includes the gathering of existing information about a watershed and its point and nonpoint pollution sources. This information is then used to evaluate current and predicted future water quality problems and to recommend short and long term solutions, including a list of corrective actions. The local government can use this information to develop a watershed protection plan, parts of which will be incorporated into an NPDES discharge permit or other enforceable program.

In the Coosa watershed, the Regional Development Councils, the City of Rome, various other localities, and EPD have undertaken a regional watershed assessment. The City of Rome initiated this approach when they were considering applying for a wastewater treatment facility expansion permit. Although they will only apply for the permit in another 2 or 3 years, the City decided to initiate a watershed assessment that would meet the watershed assessment policy and go beyond it by undertaking an assessment of a much larger area than required in the policy. The hope is that a regional assessment will avoid each wastewater and drinking water service area conducting small assessments in an uncoordinated fashion and that the assessment will provide the localities with new information concerning sources, types, and quantities of point and nonpoint source pollution.

Georgia Adopt-A-Stream and Citizen Water Monitoring

At the state-level, the Georgia Adopt-A-Stream program is coordinated through the Environmental Protection Division's Non-Point Source Program, which provides technical advice and information. In addition, there are five Regional Training Centers located at colleges and universities throughout the state. Currently, there are 225 Adopt-A-Stream groups in Georgia, with two in the Coosa Basin (City of Rome and Conasauga). In addition, through the Coosa River Basin Initiative and Alabama Waterwatch, citizens get test kits and monitor water quality on a monthly basis. This data is sent to Alabama Waterwatch which compiles the information for the whole Basin. Currently USEPA accepts Alabama Waterwatch data and Georgia EPD accepts Adopt-A-Stream data, but the two programs are coordinating their protocols and training practices in the hope that all the monitoring data will be accepted by both EPA and EPD.

Conclusions

Georgia has a variety of nonpoint source control programs operating in the Coosa watershed, including cost-share, technical assistance, voluntary, and enforceable programs. The

Coosa watershed reflects many of the trends and nonpoint source pollution programs found throughout Georgia.

The Coosa watershed shows that local erosion and sedimentation control programs such as the Cherokee County program can make a difference in water quality through a zero tolerance enforcement policy, adequate staff and funding, consolidation of the program in one office, and cooperation with local law enforcement agencies. The Coosa watershed also shows that the state requirement that local governments incorporate environmental criteria, such as river corridor protection criteria into their comprehensive plans and local ordinances strengthens local protection of these resources.

At the same time, the review of the Coosa watershed shows that while Georgia has worked to have best management practices in place for management of nonpoint source pollution from agricultural and forestry operations, it is very difficult to bring enforcement actions in these areas. The only enforcement "hook" is the Water Quality Control Act. Although fish kills and overt violations of water quality standards could be used in theory to enforce against nonpoint source pollution from agriculture and forestry operations, in practice, EPD has recorded only one enforcement order between 1998 and early 2000 for the Coosa watershed for agriculture and none for forestry operations. In addition, with very different agencies responsible for technical assistance and enforcement, coordination of these efforts can be very difficult.

The use of enforceable mechanisms has increased slightly over the past, although the primary nonpoint source control mechanisms are still technical assistance, cost-share and voluntary programs. In most cases, regulatory programs seemed understaffed with few financial resources at their disposal. Technical assistance programs are well-established for farmers and foresters, although those programs also seemed understaffed. Cost-share programs rely almost exclusively on federal funds, with few apparent state financial assistance programs.

Georgia seems to divide the traditional areas of nonpoint source pollution management, such as family farms and forestry operations, from newer sources, such as land development and concentrated animal feeding operations. In the traditional areas of nonpoint source pollution management, the state and the localities depend almost exclusively on traditional nonpoint source management mechanisms, such as best management practices and one-on-one resolution of compliance problems for family farms and forestry operations. When dealing with newer sources, such as erosion and runoff from sprawling development, sanitary sewer overflows, and concentrated animal feeding operations, permitting and the use of enforceable mechanisms are becoming more common. The state government also is pushing localities to protect their local water resources, using the carrot of maintaining "qualified local government" status to encourage the development of environmental ordinances, such as river corridor protection ordinances or threatening to assume authority for local programs such as erosion and sedimentation control.

The Georgia programs maintain a sharp distinction between entities providing assistance in coming into compliance (the soil and water conservation districts and the forestry commision), and enforcers (the EPD and the localities). This leads to complexity in coordination. It is understandable that the organizations with technical assistance as their primary function have a harder time referring their constituents to EPD or the localities for enforcement actions. Enforcement has been more likely where the entity providing technical assistance is also the enforcer, such as erosion and sedimentation control from land development, although even here state oversight has been important.

10. Georgia has a provision at O.C.G.A. 12-5-30(b) that requires a permit for anyone seeking to "erect or modify facilities or commence or alter an operation of any type which will result in the discharge of pollutants from a *nonpoint source* into the waters of the state, which will render or is likely to render such waters harmful to the public health, safe, or welfare, or harmful or substantially less useful for domestic, municipal, industrial, agricultural, recreational, or other lawful uses, or for animals, birds, or aquatic life." But the regulations limit this provision. They require only "written approval" and use of BMPs under the circumstances described in the statute, but do not require a permit unless the Director of the Environmental Protection Division (EPD) "has issued one to the

same person for a point source discharge." Ga. Comp. R. & Regs. 391-3-6-.06(3). This provision is not used to regulate nonpoint source dischargers.

Maine Case Study

Summary

In controlling nonpoint source pollution Maine relies on a combination of enforceable mechanisms and technical and financial assistance programs.[1] The Maine Department of Environmental Protection (DEP) is the lead agency for both enforceable and voluntary nonpoint source pollution control mechanisms. Although Maine gives priority to educational and technical assistance efforts in promoting compliance, it does have authority under several statutes to institute formal enforcement proceedings. Under the Natural Resources Protection Act, the Mandatory Shoreland Zoning Act, the Site Location of Development Law, the Stormwater Management Law, the Erosion and Sedimentation Control Law and a general discharge prohibition under the Protection and Improvement of Waters Act, DEP has enforceable authority to address a wide range of nonpoint source problems, including those resulting from development, forestry, and agricultural activities. In enforcing these laws, DEP officials follow a policy of progressive compliance, attempting first to educate, then obtain voluntary compliance, then pursuing administrative consent orders, filing a civil case in district court and ultimately referring the case to the Attorney General's Office. Most cases are resolved early in the progressive compliance process without advancing to more formal enforcement measures.

One of the unique aspects of Maine's nonpoint source efforts is the important role played by municipalities in setting, promoting compliance with, and enforcing nonpoint source laws. Under the Mandatory Shoreland Zoning Act, municipalities are required to adopt a local ordinance consistent with and no less stringent than the state standards. The Growth Management Law allows municipalities to adopt growth management programs, which may include drafting local ordinances to implement the program. Several communities have, for example, drafted their own phosphorous control ordinances. The Subdivision Law also requires that communities consider nonpoint source pollution prevention in reviewing subdivisions for approval and when adopting any subdivision regulations. Local code enforcement officers (CEOs) certified by the state and appointed by the local planning board implement and enforce these ordinances, with the state retaining oversight authority.

Maine has created a number of innovative institutional mechanisms that support the development and implementation of enforceable authorities as well as traditional forms of technical and financial assistance. For instance, municipalities may form watershed districts to protect and restore water quality. Watershed districts are authorized to undertake research, develop and implement plans, and implement municipal ordinances that protect water quality.[2] To date, only one watershed district has been formed under these provisions. Another mechanism the state has recently created to strengthen its enforcement presence is the position of lakes enforcement and compliance officer. This official is responsible for pro-actively seeking out potential nonpoint source violations in targeted watersheds. The targeted watersheds include priority lakes and other local water bodies. If a violation is found, the officer follows the same progressive compliance strategy as other DEP officials. Another unique institutional mechanism that supports enforcement in Maine is the Rule 80k certification program that trains and authorizes local code enforcement officers and

DEP staff who are not lawyers to bring cases in district court. By reducing the backlog of cases to be processed by the Attorney General that must be heard in district court, this mechanism has increased the likelihood of enforcement in the eyes of the regulated community.

Maine also has several sectoral laws that provide additional enforceable mechanisms to address nonpoint source pollution. The recently amended Forestry Practices Act now requires separation areas for clearcuts, and harvest plans must describe actions that will be taken to protect riparian zones and minimize erosion into water bodies. Statewide timber harvesting standards for riparian areas are currently being proposed which would transfer authority to Maine Forest Service (MFS) from DEP and the Land Use Regulation Commission.[3] The Department of Agriculture, Food, and Rural Resources (DAFRR) also has a number of enforceable tools under the Right to Farm Law, the Cull Potato Law and the Action Against Improper Manure Handling. DAFRR consider its authority to revoke protection against enforcement of local nuisance laws under the Right to Farm Law one of its most effective enforcement tools. The Right-to-Farm law protects farmers from enforcement of these laws if they are in compliance with best management practices; when this protection is revoked the farmer may be subject to enforcement under nuisance provisions.

In addition to the wide array of enforceable mechanisms, Maine has a number of non-enforceable mechanisms to address nonpoint source pollution, including cost sharing, technical assistance, and land conservation programs. DEP administers the state's Nonpoint Source Program, which coordinates the nonpoint source activities of all state agencies, designates priority rivers and lakes, and funds grants for nonpoint source and watershed mangement projects. The funding for grants under the program comes from the federal 319 program and a state bond initiative. Grants for nonpoint source projects are also available through other federal programs, primarily EQIP.

Local lake and river associations play a role in nonpoint source programs in Maine. These associations address the concerns of a specific waterbody. In the Sebago Lake watershed, the Lakes Environmental Association (LEA) is one of few regional lake associations in the state that is working on more than one lake. Generally the associations conduct outreach on BMPs and will refer landowners to technical assistance and cost share programs such as the Soil and Water Conservation Districts (SWCD). Representatives of the groups may on occassion also accompany DEP and local CEOs on enforcement activities.

Sebago Lake Watershed

In order to obtain a better understanding of the role of the enforceable mechanisms in Maine's overall strategy to address nonpoint source pollution, and particularly the coordination and interplay between enforcement and voluntary efforts, this report examined these issues in the context of the Sebago Lake watershed. This watershed was selected because a diversity of governmental and non-governmental actors are involved in nonpoint source control in the area using a wide range of tools.

The Sebago Lake watershed is the largest of five subwatersheds that make up the Casco Bay Watershed, occupying 640 square miles of the 985 square miles of the Casco Bay watershed. It is also the primary source of water used by the Portland Water District. The Portland Water District is a quasi-municipality that provides water and wastewater services to Portland and surrounding communities.[4] Sebago Lake covers approximately 100 square miles and supplies one-third of the state's water. The water from Sebago Lake is piped to 180,000 consumers in the greater Portland area. The watershed is considered pristine; water quality is high enough that the district received a waiver from drinking water filtration requirements. The lake is one of the state's priority lakes for nonpoint source efforts due to the potential for high population growth in the area, use for water supply, outstanding clarity of the lake, high use of the lake, and outstanding fishery resources.[5]

Approximately 10 percent of the state's population lives in the watershed. The lakes are used for recreation and are the site of many seasonal cottages. Land in the watershed is 90 percent forested. Until spring 1999, a pulp and paper mill operated in the area and most of the pulp that was harvested in the watershed was used at the mill. It is unclear whether this harvesting will continue now that the pulp mill closed, but there continues to be lumber harvesting for board. Agricultural operations are scattered throughout the watershed.

The Sebago Lake watershed falls within the organized portion of the state. In the unorganized portion of the state the Land Use Regulation Commission (LURC) regulates many of the sources of nonpoint source pollution.

Enforceable Mechanisms

The following section provides an introduction to the enforceable mechanisms studied in detail in this report. The mechanisms were selected from the universe of mechanisms described in the *Almanac*[6] because of their relevance to the Sebago Lake watershed, their importance to the Maine program, or their innovative nature.

! *Protection and Improvement of Waters Act.* Maine's Protection and Improvement of Waters Act prohibits any person from directly or indirectly discharging or causing to be discharged any pollutant without first obtaining a license.[7] This prohibition (§413) includes nonpoint source discharges. The term "discharge" encompasses "any spilling, leaking, pumping, pouring, emptying, dumping, disposing or other addition of any pollutant to water of the State." The term "pollutant" is broadly defined and includes "rock, sand, dirt and industrial, municipal, domestic, commercial or agricultural wastes of any kind." Erosion from agricultural activities may be exempt if an erosion and sedimentation control plan or conservation plan has been certified for the land and the agricultural activities are in compliance with the plan or federal and state funds are not available for implementation.

Whenever there is a soil discharge, DEP usually cites this authority in addition to the other statutory violations cited. Although there have been some instances of this provision being relied upon to negotiate consent agreements or to take a violator to court, this prohibition normally serves as a threat to bring a violator into compliance.

! *Mandatory Shoreland Zoning Act.* The Mandatory Shoreland Zoning Act[8] protects areas within 250 feet of the normal highwater line of any great pond, river or saltwater body, within 250 feet of a coastal wetland or the upland edge of a freshwater wetland, and within 75 feet of the highwater line of a stream if the stream is the outward stream of a great pond or below the confluence of two perennial streams shown on a USGS topographic map. The law requires setbacks, limits on timber harvesting, and vegetation buffers between buildings and shorelands.[9] Municipalities are required to adopt a local ordinance consistent with and no less stringent than the state standards. Alternatively, the state may impose these requirements. A local CEO and the local planning board are responsible for implementing and enforcing the ordinance. If the town fails to act, the state may enforce against the town and/or the violator.[10] To encourage municipal enforcement, which can be expensive, there is a state fund to reimburse towns for their enforcement costs, which is currently unfunded.

! *Natural Resources Protection Act.* The Natural Resources Protection Act (NRPA) prohibits certain development activities without a permit if the activity will take place in, on, or over any protected natural resource or will result in material or soil being washed into coastal and freshwater bodies and wetlands.[11] Examples of activities that may be regulated by NRPA include construction and renovation projects, culvert construction, and wetland fill. Permit standards address erosion and sedimentation control, protection of wildlife habitat, and water quality. Routine projects may qualify for a "permit by rule" with standard setback and erosion control requirements. Eighty-five percent of all NRPA development permits are issued under permit-by-rule provisions. Permit-by-rule standards have been developed for 13 activities. Activities affecting wetlands or intended to alter wetlands require more detailed individual permits. Various activities, including farming activities and forest management, are exempt from permitting requirements provided other regulatory requirements are met. NRPA is normally enforced by DEP, but DEP may delegate enforcement authority to qualified municipal CEOs as well.

NRPA is administered by the DEP Bureau of Land and Water Quality, Division of Land Resource Regulation. The Division has staff in all four regional offices. In most of the offices, all of the staff do compliance inspections; only the enforcement staff, however, resolve violations.

! *Site Location of Development Law.* The Site Location of Development Law regulates large scale development by requiring a permit from DEP prior to construction, operation, sale or lease.[12] There are two permit triggers: 1) development creating more than three acres of impervious cover (buildings or building parts dating prior to 1975 are exempt from the permitting requirement); and 2) development of a residential subdivision involving more than 30 acres or 15 lots.[13] Development in the unorganized areas of the state subject to the jurisdiction of the Maine Land Use Regulation Commission is exempt from regulation under this law as are developments protected under certain other regulatory programs.

! *Stormwater Management Law.* The 1996 Stormwater Management Law requires a permit in two situations. In watersheds designated as "most at risk," a permit is required if there will be 20,000 square feet of new impervious area or five acres of open, disturbed area. In watersheds "not at risk," a permit is required if there is one acre of new impervious area or five acres of disturbed area.[14] Stormwater standards address both water quality and water quantity. Water quality standards include standards for phosphorous and suspended solids, and apply only in watersheds considered at risk. The law does not apply within the unorganized areas of the state. Certain forest management and farming activities, as well as single family home construction and federally-permitted industrial facilities are exempt from the law. Department of Transportation (DOT) construction projects are exempt if they are constructed pursuant to the stormwater quality and quantity standards set forth in the Memorandum of Agreement between DOT and DEP.

! *Erosion and Sedimentation Control Law.* Pursuant to this law unreasonable erosion of soil and sedimentation from construction activities beyond the project site or into a protected natural resource must be prevented.[15] Activities in the unorganized portion of the state as well as certain forestry management and agricultural activities are exempt from this requirement.

This law was enacted in 1996 and became effective July 1, 1997. No civil or criminal enforcement of these provision was allowed prior to July 1, 1998 if a good faith effort to comply was demonstrated. In a 1998 report to the state legislature, DEP recommended that the Erosion and Sedimentation Control Law be made retroactive so it would apply to chronic, historical erosion control problems. The legislature acted on DEP's recommendation to require any person who owns property that is subject to erosion as a result of filling, displacing, or exposing soil prior to July 1, 1997 to take measures to prevent unreasonable erosion of soil or sediment into a protected natural resource. This requirement applies as of July 1, 2005 to property in watersheds most at risk and as of July 1, 2010 to other property.[16]

! *Comprehensive Planning and Land Use Regulation Act, and Subdivision Law.* The Comprehensive Planning and Land Use Regulation Act (also known as the Growth Management Law) allows municipalities to adopt local growth management programs. These include comprehensive plans and implementation programs.[17] The towns also have home rule authority to take these actions.[18] Although towns are not required to develop a plan or implement a program, there are financial incentives (discussed below) to do so. The majority of the nearly 500 cities and towns in Maine have a comprehensive plan, although not all of the plans have been implemented.

The Subdivision Law provides another legal framework for towns to implement growth management plans. Towns must consider several criteria relating to nonpoint source pollution control when reviewing a subdivision for approval and when adopting any subdivision regulations. The proposed subdivision must not result in undue water or air pollution.[19] If the proposed subdivision is within the watershed of any pond or lake or within 250 feet of any wetland, great pond or river, it must not adversely affect the quality of that body of water or unreasonably affect the shoreline of that body of water.[20] Also, the long-term cumulative effects of the proposed subdivision must not unreasonably increase a great pond's phosphorous concentration during the construction phase and life of the proposed subdivision.[21] The State Planning Office (SPO) provides model ordinances and guidelines for subdivision ordinances and grants for developing them. Most towns currently have subdivision ordinances on the books.

The local CEO conducts all enforcement of the Growth Management Law and Subdivision Law. SPO trains and certifies code officers on administering and enforcing the Mandatory Shoreland Zoning Act, the Growth Management Law and the Subdivision Law. They also provide training on the Stormwater Management Law.

! *Forest Practices Act.* During 1999 changes were made to the Forest Practices Act and rules that provide for enforcement activities related to non-point source pollution. Under the old version of the law, the Commissioner of Forestry was authorized to promulgate rules establishing forest practices for clearcuts and forest harvests to ensure adequate regeneration, and set performance standards for clearcuts including standards to minimize soil erosion and protect water quality.[22] Management plans conforming to these standards were required for clear-cuts of 50 acres more. Landowners were required to give notice of harvesting operations. None of these requirements or the initial regulations implementing them provided a significant opportunity for formal enforcement. The requirement that the landowner provide notice prior to commencing operations was simply a notice requirement, not a permitting requirement which could be reviewed. The initial regulations for the management plans did not have substantive performance standards linked to nonpoint source pollution or water quality. The clearcut standards were not developed to address nonpoint source pollution. Under the old law, harvest plans were not reviewed in advance or kept on file.

Under the new harvest plan[23] requirements for clearcuts greater than 20 acres, there are 13 minimum elements required, including an assessment of the soil erosion potential of the harvest area and a description of the actions that will be taken to protect riparian zones and minimize erosion into water bodies.[24] For clearcuts of 20 - 75 acres, the plans must be developed and made available for inspection. For clearcuts over 75 acres, the plans must be reviewed and approved. The Forest Policy and Management Division Field Team Leaders or their field staff will review the plans for sufficiency.

Although not specifically aimed at addressing nonpoint source pollution, Maine's Forest Practices Act also requires that there be a separation zone between clearcut areas if the harvesting activities result in a clearcut larger than five acres. In this case, regeneration standards must be met as well.[25]

! *Agricultural Requirements (Right to Farm Law, Cull Potato Law, Manure Law).* The Right to Farm Law provides protection against nuisance suits if a farmer complies with BMPs. However, the Commissioner of the Department of Agriculture, Food, and Rural Resources (DAFRR) is required to investigate all complaints involving farms. If the source of the problem is found to be a nuisance caused by failure to use BMPs, the Commissioner shall determine the changes needed in the farm to comply with BMPs and prescribe site-specific BMPs for the operation.[26]

The Cull Potato Law prohibits cull potato piles between June 10 and October 1 each year and requires immediate and proper disposal of any cull potatoes generated during that time period.[27] The rules establish standards for disposal during the prohibited periods by various methods. Violations of this law may be identified during inspections or through complaints made from farmers or DEP to DAFRR.

In 1998 the legislature enacted a Action Against Improper Manure Handling Law (or the Manure Law) which requires farms with more than 50 animal units or that receive 100 or more tons of manure a year to implement a certified nutrient management plan.[28] New farms with more than 300 animal units must hold a livestock operations permit issued by DAFFR. Beginning December 1, 1999, manure spreading is prohibited between December 1 and March 15. Failure to develop or implement a nutrient management plan or to comply with a permit are offenses punishable by civil forfeiture of up to $1,000 plus $250 per day; winter spreading of manure is punishable by civil forfeiture of up to $1,000 for every day that spreading occurs.

Assistance-Oriented Nonpoint Source Programs

Nonpoint Source Program

In 1991 Maine created its Nonpoint Source Program.[29] The Maine Department of Environmental Protection (DEP) is the lead agency for the program. DEP is charged with cooperating with DAFFR, Department of Conservation (Maine Forest Service), Department of Transportation, Department of Human Services (Division of Health Engineering), Department of Marine Resources, and the State Planning Office to ensure a coordinated approach to nonpoint source pollution control for agriculture, forestry, transportation, and development. DEP also coordinates with other state, federal and local governmental agencies, non-governmental organizations, and citizens.

The program promotes the use of "best management practice guidelines" (BMPs) to address nonpoint source pollution. Four state agencies (DAFFR, Maine Forest Service, Transportation and DEP) are charged with developing and implementing best management practice guidelines to prevent water pollution from nine types of activities: agriculture, forestry, development, resource extraction, transportation facilities and support, chemical use and storage, solid waste disposal, marine industries, and hydrologic modification.

In 1997 the comprehensive watershed protection program was established.[30] The Maine Land & Water Resources Council (L&WRC) works with other state agencies to develop and implement nonpoint source strategies, conduct scientific research and water quality surveys, implement regulatory and nonregulatory approaches, coordinate with other governmental and non-governmental organizations, and establish priorities for directing resources. DEP and the State Planning Office (SPO) co-chair the Maine Watershed Management Committee which implements this program. The committee developed the "Nonpoint Source Priority Watershed List" to be used by federal, state and local authorities in directing resources. Under Maine's nonpoint source grant program, projects that aim to protect or restore waters on the priority watershed list are given priority. Other state and federal agencies also direct discretionary resources towards activities to improve waters on the list.

The Division of Watershed Management administers the nonpoint source program and relies on voluntary cooperation. They help prepare nonpoint source watershed surveys, identify specific nonpoint problems of concern and develop voluntary projects to address these problems.

Nonpoint Source Grants Program/319 Funding

Maine's Nonpoint Source Grants Program, administered by DEP, provides financial assistance to help public entities, including state agencies, Soil and Water Conservation Districts (SWCDs), regional planning councils, watershed districts, municipalities and nonprofit organizations, conduct projects to reduce or prevent nonpoint source pollution.[31] Maine solicits proposals for projects annually. Four types of projects may be submitted for consideration: a watershed survey project; a nonpoint source implementation project; development of a watershed management plan; or implementation of a watershed management plan. Priority is given to projects that benefit nonpoint source priority watersheds. DEP program staff serve as technical advisors to the projects. In 1999, 30 project were funded. There are currently over 100 active projects, including several in the Sebago Lake watershed.

The Nonpoint Source Grants Program is financially supported by the state bond funds for planning or implementing a "watershed management plan" and U.S. Environmental Protection Agency 319 funds.[32] In 1999, $500,000 of state bond funds went to the Nonpoint Source Grants Program. Approximately 50 percent of the 319 funds received by the State since 1992 have been used for Nonpoint Source Program Grants.

Nonpoint Source Training and Resource Center

The Nonpoint Source Training and Resource Center managed by DEP provides publications, videos and training on stormwater management and erosion control, and coordinates the Voluntary Contractor Certification Program, which provides education and certification to contractors engaged in earth moving activities.[33] Certification entitles the contractor to reduce the mandatory waiting period for permit-by-rule projects. Certification may be revoked in the event of a formal enforcement action against the contractor. The Center also serves as a clearinghouse for nonpoint source and BMP information.

Volunteer Lake Monitoring Program

Maine supports one of the nation's oldest and largest citizen-based environmental monitoring program, known as the Volunteer Lake Monitoring Program (VLMP). VLMP is an independent non-profit corporation with close links to DEP. Volunteer efforts provide a substantial amount of data on lake water quality. In 1999, volunteers made 4,450 visits to 400 lake basins in Maine to monitor for clarity through Secchi disk readings and in some cases to measure for dissolved oxygen. To ensure that volunteer data is of high quality, DEP has developed quality assurance standards for volunteers, and all volunteers must be certified at least every two years (every year for those monitoring dissolved oxygen). The data gathered by volunteers is used by Main state agencies, including DEP, Department of Conservation, and SPO, as well as lake associations and educational institutions. The data is used by DEP specifically for its phosphorous review programs, to determine the lakes at risk for the stormwater protection program, and identifying priority watersheds. The program is supported by 319 funding.

USDA/NRCS/SWCD Programs

Soil and Water Conservation Districts are the primary providers of nonpoint source related technical training programs sponsored by USDA, DEP, DAFRR, and MFS. Resource specialists conduct watershed and BMP demonstration projects which include technical assistance, education and outreach, BMP installation and demonstration, and workshops for targeted audiences. NRCS and the SWCDs provide cost share assistance for BMPs through the EQIP program. The Nonpoint Source Priority Watershed List is part of the criteria for EQIP cost-share funds for landowners adopting conservation measures to benefit water resources. Maine receives approximately $1 to $2 million in EQIP funding annually to provide cost-shares to landowners, and funding is primarily used for animal waste management and erosion control purposes.

Land for Maine's Future

The Land for Maine's Future (LMF) program seeks to acquire lands of state significance which "make a substantial and lasting contribution towards assuring all of Maine citizens, present and future, the traditional Maine heritage of public access to Maine's land and water resources or continued quality and availability of natural resources important to the interests and continued heritage of Maine people."[34] The program is primarily funded through a $35 million state bond authorized by voter referendum in 1987.[35] A LMF affinity credit card which features two local natural scenes has provided approximated $40,000 in revenue for the program from royalties to date. In addition to these sources, the program receives some Farm Bill funding for acquiring farm development rights and money from the Land and Water Conservation Fund and Forest Legacy Program when it is available. The Land and Water Conservation Fund provides funding to federal, state, and local governments for acquisition of private lands for conservation and recreation purposes. The Forest Legacy Program supports acquisition of conservation easements on forest lands by state and federal governments.

To select land for acquisition, the program uses a scoring system to ensure that the purchase will provide protection of undeveloped land and preservation of ecological integrity of riparian, wetland, coastal, and other systems. The program will only purchase natural, unbuilt lands. The LMF Board receives proposals for acquisitions which are ranked by a subcommittee of the board according to scoring criteria. The criteria address the prevention of deterioration of natural resource systems. The top ten percent are then considered by the full Board, which considers criteria like geographic distribution and other more intangible qualities. The top choices are appraised, and the designated negotiator deals with the seller. Once the seller has agreed to the appraisal value, the acquisition is subject to a public vote by the Board.

The program requires that agricultural land be managed under a conservation plan that meets

NRCS standards for erosion control and nutrient management. Management plans are also required for non-agricultural lands that receive access-improvement funds for trail development, parking lot construction, and boat launch facilities (or other public access features). The managing agency can receive up to five percent of the appraisal value in access improvement funds. The program is not regulatory so must rely on the managing agencies to ensure that the properties are maintained in a way that will not cause damage to ecosystems.

One site enrolled in the LMF program is located in the case study watershed. On Sebago Lake, the Department of Conservation holds an easement on a 35 acre tract of lakefront land.[36] The land has 980 feet of high quality sand beach and 35 acres of white pine and hardwood forests. It was identified as one of the eight outstanding beaches in Maine's organized towns in an inventory prepared for the Maine Critical Areas Program. The town of Raymond manages the property as a park with a day-use area for swimming and picnicking.

State Revolving Loan Fund

Maine also offers nutrient management loans which can be used for building storage and handling facilities for manure and milk room wastes, including equipment that is used solely for this purpose. The loans are available through the Finance Authority of Maine (FAME) and have an effective interest rate of 2% for up to 20 years.[37] The program offers low interest loans of up to $350,000 for installation of manure storage facilities to assist facilities in complying with the Nutrient Management Law and other DAFRR rules. CAFOs may not be eligible for loans under this program.

Forestry Programs

For forestry stewardship and best management practices, funding is available from the Stewardship Incentive Program (SIP) and Forestry Incentive Program (FIP). SIP funding comes from the US Forest Service, and is provided to landowners with forest management needs through the Maine Forest Service. The funding can be used to develop recreational trails or improve wildlife habitat. FIP funding through USDA Natural Resources Conservation Service has not been as significant. However, a large ice storm in 1998 devastated area forests and special "Ice Tree money" was available to repair and improve forests. Some EQIP money is used for erosion controls on forest harvests.

The state of Maine also has a tree growth program which provides a tax break for forest land under a management plan. The elements of the management plan vary based on the goals for the land (*i.e*, preservation v. timber harvest) but usually address erosion concerns and identify state sensitive areas, including shoreland zones.[38]

Watershed Districts

Municipalities are authorized to form watershed districts "to protect, restore and maintain the natural functions and values," of wetlands, rivers, great ponds, bays, and estuaries.[39] A watershed district is authorized to conduct research on water quality in the district; implement natural resource protection, management, and restoration plans; work with municipal officials and state agencies to encourage enforcement or enactment of ordinances or laws that will improve or protect water quality in the district; and enter into agreements with municipalities to administer municipal land use ordinances.[40] The Cobbossee Watershed District is the only district in the state formed under these provisions.

Discussion and Analysis

This section discusses the implementation and enforcement of the mechanisms described above and describes the relationship between these mechanisms and traditional cost-share and technical assistance programs. Examples drawn from the Sebago Lake watershed are provided when appropriate; however, innovative statewide enforcement practices are also described. Maine's land use and development provisions are discussed first, with a focus on DEP and local CEO roles in enforcement and technical assistance. Regulation and technical assistance for forestry and agriculture are discussed more briefly.

Land Use and Development

Many of Maine's mechanisms to control nonpoint source pollution are directed at land use activities, both during and subsequent to development. Many laws specifically target development activities, for instance the Site Location of Development Law and NRPA, the Erosion and Sedimentation Control Law, the Stormwater Management Law, the Mandatory Shoreland Zoning Act, and local subdivision and growth control regulations. These laws employ permit mechanisms, BMPs, performance standards, and critical area protection provisions. Additionally, the Protection and Improvement of Waters Act does not specifically address development but serves more generally as a backup to protect water quality through general discharge prohibitions. These laws apply not only to construction activities, but also to activities conducted by landowners on their properties. For instance, in some areas of Maine landowners commonly violate shoreland zoning provisions by removing trees within 75 feet of the shoreline to create a view of the lake. Another common landowner violation of land use laws occurs when landowners add sand to their lake front beaches. In addition to ensuring compliance with the array of related laws, both DEP and the local CEOs, the principal enforcement entities, provide technical assistance to landowners in complying with these laws. In the Sebago Lake watershed, laws regulating land development and use are the most commonly invoked of the laws regulating nonpoint source pollution due to the limited extent of agricultural and forestry operations in the area.

DEP Role Generally

As the lead agency in Maine for nonpoint source pollution concerns, DEP plays a major role in enforcement of related laws, primarily in the area of land use and development. The Water Resource Regulation Division and Land Resource Regulation Division of DEP have primary enforcement responsibility for the Protection and Improvement of Waters Act, Site Location of Development Law, Stormwater Management Act, Erosion and Sedimentation Control Law, and NRPA.

The Water Resource Regulation Division of DEP is primarily responsible for enforcement of point source pollution violations, but a small part of the enforcement efforts relate to nonpoint source pollution. Nonpoint source enforcement is generally triggered by complaints from citizens or lake associations. The four regional DEP offices handle the complaints. When a complaint is received in the regional office the department first determines if the complaint has merit. Next DEP will conduct a site investigation, although the timing of the inspection is based on the severity of the problem. For example, DEP will respond immediately to a severe violation. If there is not a potentially severe impact, DEP may schedule the inspection with other trips to the area or after priority complaints are addressed.

If a problem is documented DEP discusses the necessary corrective action with the property owner. DEP sometimes accompanies representatives of voluntary programs to visit a site. DEP's presence provides a glimpse of the threat of enforcement if violators do not voluntarily comply. DEP staff report that they usually have only to write a letter to the violator to obtain compliance. For severe violations or uncooperative violators, DEP will propose an administrative settlement. DEP must clear the proposed settlement with the Attorney General's office before presenting it to the violator. The Board of Environmental Protection gives final approval to all settlements.

DEP staff also have the authority to go to District Court. Most people will settle after these cases are filed. The last option is to refer the case to the Attorney General's office who will file an enforcement action in Superior Court. Cases referred usually involve developers and medium sized commercial operations, not homeowners. Follow-up inspections are done as needed.

Another example of DEP's enforcement approach is that of the Land Resources Regulation Division's enforcement activities under NRPA. DEP's first priority when a *permit* violation is discovered is to request the violator to correct the problem. If the problem is not corrected, DEP will send the permit holder a notice of violation. For significant violations (even in some cases where the party is being cooperative), there are three enforcement mechanisms that DEP can use. DEP can file a civil case in District Court (only a few have been filed); it can refer the case to the Attorney General's office (only a few have been referred); or it can enter into an administrative consent agreement, the most common mechanism used. Most violations are resolved voluntarily, and if there have been no prior problems, usually no penalty is imposed. Voluntarily resolved cases are recorded to track repeat violations. In addition to enforcing this law, DEP will refer people to other programs for technical assistance if there are complicated requirements.

DEP will coordinate its efforts with the Department of Marine Resources (DMR). DMR monitors shellfish for pollution and can close shellfish beds. It conducts shoreland surveys and gives DEP information on pollution sources. However, DMR generally calls the local plumbing inspector before calling DEP in response to a problem believed to originate from overboard discharge systems. The departments conduct joint sanitary surveys to identify malfunctioning septic systems. In one situation in Vinalhaven, an island where there is no sewage treatment plant, DEP and DMR discovered numerous illegal discharges. DEP and DMR looked at the entire watershed for each cove including houses on and behind the shore. In bringing these illegal discharges under control they were able to open a substantial acreage for shellfish harvesting.

In response to a recommendation of the Great Ponds Task Force, the Maine legislature recently created a new full-time position for enforcement and compliance on lakes. The initial goal for the enforcement position was to boost compliance with state and local laws by improving CEO capacity. This position is currently held by an individual based in the Southern Maine Regional Office. He focuses his attention exclusively on a few ponds and watersheds that are identified in coordination with the Division of Watershed Management. The selection process first involves identifying several priority watersheds to be covered. Several "non-priority list" great ponds within the geographical area of the identified priority watersheds are also selected for attention. DEP hopes to be proactive at these lakes to prevent them from becoming a priority watershed. As described above, there are other field and enforcement officials in the office that have primary responsibility for responding to citizen complaints and answering compliance questions.

The lakes enforcement and compliance official goes out on his own initiative, not only in response to complaints, to patrol by boat, car and foot looking for violations of land use laws including NRPA, the Site Location of Development law, the Erosion and Sedimentation Control Law, and the Stormwater Management Law. The focus on a few lakes allows local people to see an increase in DEP presence. This situation is in contrast to traditional enforcement work which has almost exclusively responded to complaints. The large geographical scope of problems and limited resources have prevented DEP from using the proactive inspection and enforcement strategy of the lakes official statewide. The official also devotes considerable time to education and outreach, advising government officials and the public on how to use BMPs He works very closely with CEOs, serving as a liaison between towns and DEP shoreland zoning staff. He focuses on small towns where limited resources may prevent the CEO from being aware of the latest information from DEP. In these towns, the CEO may work only part time or may lack expertise on specific issues.

Sometimes requirements under NRPA, the Site Location of Development Law, and the Mandatory Shoreland Zoning Act prohibitions overlap. The officer will address problems jointly with the CEO in this case since the CEO has responsibility for enforcing some of these laws. Both will agree on the action a violator should take and the deadline for compliance, and will jointly notify violator of the violation.

DEP provides financial support to local projects through its Nonpoint Source Program. DEP has funded these types of projects in the Sebago Lake watershed through the Nonpoint Source Program and 319 funds. In 1999, the Portland Water District received approximately $100,000 in 319 and state matching funds to encourage the use of BMPs with demonstration projects in subwatersheds around Sebago Lake. Certain DEP units also provide technical and engineering assistance in dealing with nonpoint source pollution concerns from land development and land use activities. DEP also provides funding to small communities to build individual septic or small cluster septics where there is no municipal treatment.[41]

The Portland Water District falls within the jurisdiction of the Southern Region of DEP. In this area, DEP actively enforces NRPA, the Site Location of Development Law, and the Protection and Improvement of Waters Act. The Erosion and Sedimentation Control Law may be used if water is directly affected. NRPA and the Protection and Improvement of Waters Act address erosion and sediment control concerns as well. DEP also inspects for compliance with the stormwater program.

In the entire Southern Region last year, 234 complaints were received and 224 complaints resolved. Not all of these complaints were related to nonpoint source problems. Fifteen were resolved through formal penalties, one through a judicial proceeding, and 106 cases were resolved voluntarily. In 98 cases no violation was identified. Four cases were referred to other agencies. One case involving a minor discharge from a gravel pit was referred to the Attorney General's office, mostly because of ownership issues of the site and not because of the nature of the violation.

DEP regional offices inspect facilities permitted under NRPA. Of the facilities permitted under "permit by rule" in the Southern Region in 1998, 40 percent were inspected in 1999. "Permit by rule" facilities are only inspected for two years after permit issuance, usually after construction to ensure that the site is stabilized. Sites issued individual permits under NRPA and under the Site Location of Development are also inspected by the licensing staff. One hundred percent were inspected in 1999. The licensing staff will refer violations to enforcement staff.

The Southern Region works with other agencies, including the SWCDs, local CEOs, the LEA, and the Portland Water District.[42] DEP receives complaints from LEA and makes site visits with them. Generally, other agencies do not refer complaints to DEP.

Local Code Enforcement

Local code enforcement officers are employed by municipalities to enforce the Mandatory Shoreland Zoning Act; the Growth Management Act; and plumbing, subsurface waste water and building standard codes.[43] Municipalities may also employ plumbing inspectors to inspect plumbing and other construction projects.[44] Plumbing inspectors approve permits for interior plumbing and subsurface waste disposal; some towns may task a CEO with these duties.[45] All CEOs and plumbing inspectors must be certified by the State Planning Office in their areas of responsibility.[46] Separate certifications are required for areas such as planning, plumbing, electrical, shoreland and 80k enforcement functions. In some cases, certification is required for subspecialities (e.g, indoor and outdoor plumbing). Recertification is required every five years.

Septic tank problems are a nonpoint source concern that DEP has regulated since the 1970s. Today, DEP serves as a backstop to local enforcement efforts and in response to a problem, DEP will generally call the town plumbing inspector or code enforcement officer. The municipally-appointed plumbing inspectors have the authority to act more immediately than DEP in response to plumbing or septic problems if there is a direct discharge that can be observed. If the plumbing inspector doesn't have the political support or isn't aggressive enough, DEP may act directly.

Local CEOs may be trained and certified to bring enforcement actions in district court. The District Court sets aside one day a month for hearing these cases. Maine officials describe this provision as a "velvet hammer" in promoting compliance. In the past people thought they could stall cases in the court system because cases might take years to be scheduled. Because the district court sets aside a day to hear these cases, it is more likely that a case against a violator will be heard quickly. Since violators are aware that their cases may be heard quickly under these provisions, they are more likely to cooperate at an earlier point in the compliance process.

In the Sebago Lake watershed, the local code enforcement officers conduct enforcement activities although most nonpoint source-related violations are resolved without resorting to formal enforcement. In one town, the local CEO has not had to go beyond informing a violator of a problem in order to achieve compliance. Property owners around the lakes generally want to protect their investments by keeping the lake clean. The local code enforcement officers from five towns (Casco, Raymond, Bridgton, Naples and Harrison) coordinate with LEA and the Portland Water District to coordinate strategies and exchange information. Information concerning violations is commonly received from neighbors who are acutely aware of the restrictions on development and other activities. This reduces the need to conduct inspections to monitor for compliance. When a complaint is received, the local CEO will check to see if there is a permit on file for the activity and will investigate the complaint initially by phone. If needed, a site investigation will also be conducted.

The local CEOs also rely heavily on education as an important tool for promoting compliance. The target audience for their outreach is broad; for instance, the CEOs conduct road shows for real estate brokers so brokers can educate new owners about nonpoint source regulations. CEOs often advise the public on restrictions and prohibited activities under the Mandatory Shoreland Zoning Act and NRPA.

The local CEOs will on occasion work jointly or turn a case over to the state to handle enforcement and work cooperatively with them. One major case in the late 1980s involved a subdivision with a 72 unit complex which ultimately was shut down. The subdivision was built on a wet, low property back from the shore. The engineering calculations and construction techniques for stormwater retention during floods and storms did not work correctly, and while the project was under construction the dams broke and a large sediment plume went into the water. LEA joined the CEO and state against the developer. The local CEO issued a stop work order which gave the state and LEA time to bring other orders and actions. The developer eventually ended the project.

Growth Management Law Implementation

Local CEOs are responsible for enforcing municipal ordinances adopted pursuant to the Comprehensive Planning and Land Use Act (or the Growth Management Law). For 13 years, SPO through the Growth Management Program has provided grants to towns to develop and implement comprehensive local growth management plans as well as technical assistance. When a town requests a grant, it agrees to develop the plan in accordance with the state goals and guidelines outlined in the Growth Management Law. SPO has seven staff who work with towns on developing comprehensive plans. Several guidelines for the comprehensive plans address nonpoint source pollution. One guideline directs that plans should "Protect, maintain and, when warranted, improve the water quality of each water body. . . and ensure that the water quality will be protected from long-term and cumulative increases in phosphorous from development in great pond watersheds."[47] SPO grants for implementing the plan include funding for drafting a phosphorus control ordinance. SPO and the eleven regional planning councils provide technical assistance to draft the ordinances. DEP also provides technical assistance in developing ordinances. For example, DEP developed a phosphorus control manual in the early years of the program that serves as a specific guide for drafting phosphorus control ordinances as well as local implementation of the Site Location of Development Law and Stormwater Management Law.

The financial incentive for implementing the plan is that "certified programs" get preference for certain state funding programs including Land for Maine's Future, community development block grants and other community development programs. SPO reviews plans to determine if they are consistent with the Growth Management Law. Other state agencies review the plans in the certification process. SPO also certifies town growth management programs based on a review of the plans and the implementation strategies. Implementation strategies include ordinance drafting and plans for capital improvements like sewer and fire protection. "Certified programs" become eligible for preferential funding, but SPO also encourages funding preference for aspects of certified plans.

Shoreland Zoning Implementation

DEP provides an oversight role in local enforcement of shoreland zoning laws. Three DEP staff members provide technical assistance to municipalities and help them enforce the Shoreland Zoning Program (one in Bangor and two in Augusta). DEP staff review local ordinances and make recommendations to the Commissioner of DEP who is responsible for approving all ordinances and amendments. The staff conduct general oversight of enforcement by municipalities. If towns continually fail to enforce their shoreland zoning ordinance, the state can take action against the town. In the last 13 years, however, only three towns have been taken to court. DEP attempts to resolve problems with towns before resorting to prosecution.

Some towns have gone beyond the minimum state standards in their local ordinances. For example, some have developed legislation on control of phosphorus in their local shoreland zoning ordinance or in separate legislation (*i.e.*, China, Manchester). Some towns have greater setbacks than required by the state (greater than 100 ft. v. 75 ft.). However, misunderstandings in measurement of the high water line have caused a problem in the application of the more stringent standards in at least one case. Another modification to the state standards implemented by towns in the Sebago Lake watershed is setting minimum lake frontage standards for high density development to prevent funnel lots and clustered housing on the shore. Most towns adopt the state minimum standards in their ordinances.

The federal Coastal Zone Management Program provides substantial funding for the staff and day-to-day operation of DEP's Shoreland Zoning Program. There has been no funding to date from agricultural programs or 319 grants.

There are some concerns about the ability of local municipalities to administer the program, particularly in the area of enforcement. Specific concerns include: the capacity of local administration, the influence of local politics and limited resources. Also, some municipalities do not have a local CEO or only have one that works part-time or is uncertified. Towns are concerned, on the other hand, about the lack of state funding to cover a CEO's time spent in state training programs as well as the possibility of having to pay for training courses in the future.

Portland Water District

The Portland Water District also plays a significant role in controlling nonpoint source pollution both through enforcement and voluntary programs. The PWD has authority to inspect all septic systems within 200 feet of the high water mark of Sebago Lake pursuant to the private and special law adopted in 1912. This law requires that notice in writing be provided to PWD prior to any construction in this lakeside zone.[48] The notification must include the method for disposing of waste and drainage, which may then be inspected by the trustees of PWD. The law also provides for the state board of health to make orders or regulations to protect Sebago Lake or any of its tributaries. Today PWD inspectors patrol only Sebago Lake. PWD may require the implementation of erosion control measures. The town CEOs who enforce this requirement under NRPA depend on PWD to identify problems around Sebago Lake. If people do not comply with their recommendations, the PWD refers the matter to the local CEO for formal enforcement, and then to DEP.

There is a 3,000 foot no trespassing zone around the two water intakes in Lake Sebago. No body contact with the water is allowed within two miles of the intakes. One PWD inspector stays at the boat launch area to enforce the no body contact rule by ensuring that boats are launched by people wearing boots. There is another inspector who patrols the area by boat to ensure there is no swimming, sailboarding, or jet skiing. Only boats with more than seven inches of freeboard are allowed in this zone.

In wintertime, the District has on staff a source protection coordinator, an inspector, an educator and two Americorps volunteers. In summertime, they add five positions, including two inspectors who provide information to property owners and look for failing septic systems.

As the water supplier, the Portland Water District also conducts outreach to homeowners and others on ways they can maintain good water quality in the watershed. In addition to inspection and enforcment activities, PWD conducts outreach activities at schools and camps, helping to identify problems and the BMPs to solve them. They will make small grants to schools and camps for low cost BMP projects such as building paths to the lake and planting vegetation. The District has received a Section 319 grant to work at Kettle Cove, a residential area with nonpoint source erosion problems. Work under this grant is directed at nonpoint source problems from camp roads. The District conducted a watershed survey to identify problems, and installed BMPs. They monitored the condition of the cove before the project began and will monitor after implementation of the BMPs.

Lakes Environmental Association

The Lakes Environmental Association (LEA) assists with compliance and technical assistance activities in the area of the Portland Water District. The Lakes Environmental Association is a nongovernmental regional lake association. LEA works on 37 lakes. Its direct service area includes the towns of Bridgton, Naples, Harrison, Denmark, and Sweden, as well as the rim of Sebago Lake. Indirectly, LEA works throughout the Portland region. The organization is 60 percent member-supported, and members include local residents and businesses. Additional funding comes from federal grants, endowment, the Portland Water District, and miscellaneous grants. LEA conducts educational programs in schools and the community and conducts water quality monitoring in all 37 lakes.

Six years ago LEA developed the Clean Lake Check Up program, which has since been adopted by the Portland Water District. The program involves visiting properties to provide an analysis of what the landowner can do to reduce pollutants entering the lake. Sometimes the visit will be at the request of the local CEO or through a referral from DEP; most visits are at the request of the landowner. Sometimes the visit will identify serious concerns and the code officer will also work with the landowner. LEA conducts 30 to 40 of these check ups annually. LEA also assists with full NRPA permitting or permitting-by-rule.

LEA formerly appeared before town planning boards and provided comments on applications for subdivision. For the past five or ten years, developers have been consulting with LEA during the planning stage so that LEA has input while the application is developed and no longer needs to provide comments in front of the boards. LEA has also drafted some local ordinances, either on request or on its own initiative. LEA drafted a phosphorous control amendment to the townwide zoning ordinance for the town of Sweden. Using DEP's phosphorous control manual, LEA developed a matrix which requires a buffer with a variable width based on the land area disturbed during development. LEA is considering developing a phosphorous standard for the Highland Lake watershed based on triggers dependent on water quality.

LEA has received two 319 grants. One grant three years ago provided funding for 19 demonstration sites in the Highland Lake watershed in conjunction with the SWCD and DEP. LEA also conducted a survey of the watershed during a heavy rain and identified the "Big Nine" spots with the worst stormwater problems. The office uses a GIS Hotspots model to predict where problems may be found. PWD has adopted the Hotspots model as well as the Clean Lake Check Up program for its own use. The two organizations work together and try to leverage their resources. For instance, LEA works with the Portland Water District on the Crooked River Initiative. The Crooked River is a major tributary to Sebago Lake. Long Lake and the Crooked

River come together at the locks to provide 80 percent of the flow to Sebago Lake. The initiative develops conservation easements on land near the river.

Forestry

Under forest harvest regulations, landowners are required to give notice to the Maine Forest Service (MFS) before beginning activities. Statewide, 5,000 - 7,000 notifications of harvest are received annually. MFS conducts regular inspections of forest harvest sites. Each ranger is assigned a unit. When a notice of intent to harvest is sent to the state, the information is sent to the unit officer. Inspections are based on priorities, such as operations in a salmon area, or an area where there is a sensitive feature (e.g. an eagle's nest) or where there have been past violations. MFS responds immediately to any complaints. MFS randomly selects sites for in-depth BMP monitoring to ensure that BMPs are properly applied. There are approximately 75 unit managers statewide. There is no state financial assistance for the preparation of harvest plans. Large landowners usually have foresters on staff and small landowners (under 100 acres) are exempt from the requirements. There are only nine field staff at MFS who have training to help in the preparation of harvest plans. Full forest management plans are still voluntary.

MFS has developed voluntary Best Management Practices for reducing erosion and sedimentation.[49] Since discharges are generally prohibited, the BMPs focus on eliminating "discharge" through site appropriate measures. There are two vehicles to disseminate information and provide training on BMPs. The nine field foresters conduct training with the certified logging professional program (a private course). Another mechanism is the Sustainable Forestry Initiative, an industry program in which MFS personnel serve as trainers. MFS disseminates information on BMPs by speaking at NRCS and SWCD workshops. MFS also conducts some landowner and logging site visits.

MFS has a Memorandum of Agreement (MOA) with DEP to coordinate enforcement. The MOA allows MFS field staff to identify and investigate water quality violations and to work out a solution; if no solution is achieved, they are required to turn the case over to DEP or the local code enforcement officer. In most cases, if a water quality violation is found, an enforcement action would be brought under the water quality laws rather than the clearcut laws and regulations. There has been some initial enforcement activity under forest harvest plan provisions. In one case the operator did not leave an adequate separation zone between the clear cuts and the plan did not reflect on-the-ground practice. This represented a violation of the Forest Practices Act. The violator received a letter of warning and then corrected the problem. Since a letter of warning was sent, a further violation would be treated as a second violation for penalty purposes. Violation of these provisions results in a civil penalty.[50]

DEP and LURC also have regulations addressing nonpoint source pollution from forestry activities and are currently considered the primary agencies for dealing with these problems. In order to harmonize the regulations in the organized and unorganized areas of Maine, statewide timber harvesting standards for riparian areas have been proposed.[51] They are based on current LURC and DEP shoreland zoning rules. These standards would be administered and enforced by MFS. Forestry activities in riparian zones would be exempt from regulation under LURC, the NRPA and Shoreland Zoning statutes if conducted in accordance with the new statewide standards.

R0019230

There is little forest harvest activity in the Sebago Lake watershed. Forestry activities are monitored by PWD by air twice a year to make sure buffers and BMPs are maintained.

Agriculture

Agricultural Compliance Officer

There is one Agricultural Compliance Officer for the entire state of Maine who works on compliance and enforcement activities for the Right to Farm Law, the Cull Potato Law, and the Manure Law. Enforcement activity under the "Right to Farm Law" is completely complaint driven; the state does not conduct regular inspections to identify compliance problems. About 75 percent of the complaints are made to DAFRR and 25 percent to DEP; all complaints are then forwarded to the Agricultural Compliance Officer. Once received, the officer investigates the site. If there is a problem, the officer recommends changes or BMPs to address the problem. Normally, the farmer has 30 days to begin making the changes. Other agencies may be brought in to identify and design appropriate BMPs. The Agricultural Compliance Officer will also visit the complaining party to explain the problem, and what changes have been recommended, although in some cases there are no changes recommended because the activity does not violate the law.

Regular follow-up inspections are conducted by the Agricultural Compliance Officer after the recommendations are given. If the requested changes have not been made, the complaint will be referred to DEP if it involves a water quality violation or to the Attorney General's office if it involves a nuisance. For example, in the case of a manure pile too close to a stream, the case would be referred to DEP to test the stream for a water quality violation. If a violation were found, the Agricultural Compliance Officer would work with DEP to develop the case. To date, no court cases have resulted from nuisance complaints referred to the Attorney General's office; most cases have been resolved with a letter from the Attorney General's office to the violator.

Another enforcement option is to revoke protection of the Right to Farm Law. Ordinarily if a farmer complies with BMPs, the farmer cannot be sued for creating a nuisance. Potential revocation of this protection has proven to be the most effective enforcement tool.

Violations of the Cull Potato Law are identified during inspections by the Agricultural Compliance Officer as well as through complaints from the public. When a violations is identified, the Agricultural Compliance Officer first tries to solve the problem voluntarily. If immediate action is not taken in a reasonable period (12 hours to 10 days depending on problem), the case is turned over to the Attorney General's office. Only the Attorney General can obtain fines. The Agricultural Compliance Officer also has the authority to have the state hire a contractor to remove the problem and then recuperate costs through the Attorney General's office. Under this law, there has been only one case where fines have been sought by the

Attorney General. Only a few cases have gone to the Attorney General's office and most are resolved early in the process.

The Agricultural Compliance Officer usually handles between 100 - 150 complaints a year. During calendar year 1998, 99 complaints were received (three related to noise problems, 21 for water quality problems, and 75 related to insect, odor, carcass and potato cull pile problems). Of these cases, the majority (92) were resolved by voluntary compliance. Three were resolved by MOUs between the department heads and the violator. One case was referred to the Attorney General's Office. In another case involving a farmer who refused to move a manure pile in a ditch, the Agricultural Compliance Officer pulled the protection of the Right to Farm Law, allowing the town to proceed with enforcement. Two cases are still active, with the officer working on developing BMPs.

The Agricultural Compliance Officer relies on NRCS and the SWCD to provide assistance in identifying and designing appropriate BMPs. He also uses the Extension Service at the University of Maine and occasionally a hydrogeologist from DEP and the state soil scientist. A farmer may apply for EQIP money to fund the implementation of BMPs. Section 319 funding is available for projects that will protect salmon habitat.

The Agricultural Compliance Officer also enforces the new Manure Law. Legal mechanisms in existence prior to the adoption of this law were ineffective in dealing with nonpoint source pollution from manure handling because it was difficult to identify a water quality violation during the spring melt. Enforcement of this law begins in the winter of 2000. It is not expected to play a major role in the Sebago Lake watershed, but in other areas of the state this law may generate some enforcement actions. Generally, the local CEO will refer people to other government agencies for help.

In the Sebago Lake watershed, there are scattered agricultural operations and these laws are infrequently invoked. The statewide Agricultural Compliance officer has not handled many problems in the Sebago Lake watershed. DEP is involved with some agricultural problems in the area. In most cases, DEP will only become involved if the Agricultural Compliance Officer determines that there is a water quality problem and that the farmer is not willing to implement BMPs. In one example near Waterford a pig farmer was expanding his herd and had runoff problems. The pigs were in the wetland near a stream. Because the farmer cooperated with DEP and SWCD the state did not resort to formal enforcement. If the violator had not cooperated, DEP reports that it would have initiated a formal enforcement action even if the violation was not severe.

Soil and Water Conservation Districts/NRCS

Although Soil and Water Conservation Districts and NRCS are primarily agricultural agencies, in areas of Maine the staff will provide technical assistance to anyone with erosion problems, regardless of the source. Lake associations often refer people to NRCS and the local SWCD for assistance with non-agriculturally related problems, such as camp roads. DEP and DAFRR will also refer people to NRCS. Most often, DEP refers farmers to the SWCD if they are eligible for cost-share or technical assistance. The SWCD may suggest that a farmer contact DEP for technical assistance, but will not inform DEP if they suspect a farmer is violating a law. The local SWCD and NRCS staff distance themselves from enforcement efforts generally. NRCS notifies landowners if they observe a situation where the landowner may need to obtain a permit, and ensures that any plans they develop abide by the regulations. In the course of planning, if any activity is proposed that might cause a violation of state law, NRCS will suggest that the landowner check with the town to ensure the activity is in compliance with the law. In cases where it is clear that a permit is needed, NRCS will tell the landowner to get a permit. NRCS will not normally notify the town that an activity that might violate local ordinances is ongoing.

No state funding is currently provided for cost share assistance. The state does provide low-interest loans for manure storage equipment through the state's financing entity.

There have been significant nonpoint efforts by NRCS and the SWCDs in the Sebago Lake watershed since the early 1990s. In 1991 the Casco Bay Regional Water Quality project was funded by NRCS to support management practices for nonpoint source treatment in the watershed. This program was related to the Casco Bay Estuary Project, a ten year program involving a five year planning period and five year implementation period. The current focus is on-the-ground implementation of nonpoint management practices. As part of the project several area SWCDs developed a comprehensive land use inventory for the Casco Bay watershed. The watershed received an EQIP grant in 1996. EQIP is the primary program used for land treatment activities in the watershed. There are currently eight EQIP contracts in the Portland Water District. The most requested practice is waste management systems, but EQIP can also fund erosion controls, agricultural chemical handling facilities, and riparian and stream bank protection. Early in the 1990's the Portland Water District organization worked with NRCS on a 319 project to protect drinking water quality through reduction in nonpoint source pollution. NRCS was involved in bringing together various organizations to combat erosion problems at the intake pipes for the water supply system, and coordinated the installation of 1000 feet of erosion controls.

Conclusions

A variety of enforceable mechanisms to control nonpoint source pollution are available to state and local officials in Maine. Because of limited forestry and agricultural operations in the Sebago Lake watershed, enforceable mechanisms are more often used to control pollution from land development or land use activities than from agricultural sources. Statewide, the preponderance of enforceable mechanisms also address nonpoint source pollution from development, although the use of enforceable mechanisms is growing in the agricultural and forestry areas. In the watershed and throughout the state, Maine uses a variety of tools to address nonpoint source pollution from land use and development activities, including planning and zoning provisions, permit-based schemes requiring control of sedimentation, critical area protection, and prohibitions on discharges of sediment to water during construction activities.

Most often, formal enforcement provisions serve as threats or deterrents. DEP, as well as local CEOs enforcing municipal ordinances, follows a progressive compliance policy that seeks voluntary cooperation prior to the use of penalties or more formal enforcement approaches. Voluntary program staff tend to draw a distinction between their roles and the role of enforcement staff. DEP enforcement staff report that they rarely have to develop a consent agreement to bring landowners into compliance; a letter informing the landowner of the violation is generally a sufficient incentive to elicit compliance. Local CEOs may also bring a case in District Court under special procedures or enforce laws using standard enforcement procedures. However, they report that they generally do not need to resort to these procedures to obtain compliance. Even though the District Court enforcement procedure provides CEOs with the opportunity and basic skills to bring a case in court, some hesitate to go up against a formally trained lawyer. Nevertheless, by increasing the likelihood of enforcement, the procedure serves as a "velvet hammer" for obtaining compliance.

Some attribute the ease with which compliance may be obtained to the ethics of state residents. SPO conducted a survey of Maine home buyers which showed a strong ethic for resource protection. In the Sebago Lake watershed, lakeside residents are very aware of the restrictions on activity near the lakes and report violations to municipal and state enforcers.

However, some associated with enforcement activity in Maine report that the limited number of cases referred to formal enforcement proceedings reflects DEP's preference for voluntary measures to respond to problems. Others state that limited formal enforcement is the result of insufficient enforcement staff and reduced attention to violations. Some report witnessing substantial violations with minimal or no DEP enforcement. Where laws are enforced by municipalities with DEP oversight (eg shoreland zoning), limited DEP enforcement activity of other laws sends a mixed message to the towns regarding the need to rigorously prosecute violations of the laws. In particular, people note that the compliance situation is worse in rural areas of the state in terms of both DEP and CEO enforcement. It was noted that a visit from DEP enforcement staff makes a difference in these areas by demonstrating that DEP cares about compliance with the law.

Towns in Maine may enact more stringent ordinances than state laws require. In the Portland Water District, towns have worked with the Lakes Environmental Association to develop phosphorous control ordinances that are not required by state law. The ability of towns to enact a variety of more stringent laws provides for the possibility of enhanced water quality protection.

However, the effectiveness of the municipal law often depends more on the quality of town administration and enforcement than the quality of the rules. The local code enforcement officer, often a part-time employee, bears heavy responsibility in the decentralized scheme. Limited town support for CEO enforcement or poor enforcement by the CEO may create a weak link in nonpoint source pollution control process. Training and certification programs for CEOs are considered by some to be crucial to the success of local efforts, and there is some concern that the state may decrease its support for these activities. For instance, the state does not always provide full funding for CEO training; the state pays for the course but not for the time the instructor spends at the course. There has recently been some discussion that the state will start charging for classes.

Many of Maine's sectoral laws addressing significant sources of nonpoint source pollution, such as the revised Forest Practices Act, Erosion and Sedimentation Control Law, and the Manure Law, have been recently enacted. Some enforcement activity has been initiated by the Maine Forest Service for violations of forest harvest laws. MFS may be increasing its enforcement role if statewide standards for forest harvesting are adopted. The state manure spreading law became effective this winter so it is difficult to assess the results of any enforcement. Some observers report that there has been significant earth moving activity without erosion and sedimentation controls as required by the recently enacted erosion and sedimentation control laws.

Maine state agencies leverage their limited resources by working together and adopting MOUs to eliminate duplication of efforts. For instance, MFS and DEP have an MOU to coordinate training and education, inspection and technical assistance, investigation of complaints, and both formal and informal enforcement. Inspections and corrective actions are the responsibility of MFS; DEP staff are responsible for issuing notices of violation or other less formal notification, as well as carrying out the formal enforcement process, if necessary. Through this collaboration DEP enlists the support of MFS rangers, who are present in the forests, in enforcement of DEP laws such as NRPA or Shoreland Zoning.

Maine nonpoint programs reflect a significant level of attention to nonpoint problems by a variety of actors. The effectiveness of these programs, particularly in regulation of lakeside activities, appears to be enhanced to varying degrees by the participation of local residents and lake associations. For example, in the Sebago Lake watershed, LEA serves as a link between the providers of technical assistance services and the enforcement entities. Although technical assistance staff rarely turn the attention of enforcement personnel to violators, enforcement personnel will refer violators to technical assistance programs. The high concentration of nonpoint source programs, both enforcement and voluntary, in DEP serves to coordinate at least some aspects of the enforcement and technical assistance processes.

Maryland Case Study

Summary

This study examines the relationship between enforceable mechanisms for the control of nonpoint source water pollution, and the voluntary, technical assistance, and cost share approaches used in a Maryland watershed, the Monocacy River watershed. Maryland uses a great many programs and planning mechanisms to address nonpoint source water pollution, and it provides substantial cost share funding from state sources as well as from federal programs. The state also has a full suite of enforceable mechanisms. In the agricultural sector these are used primarily to move producers into planning, cost share, and technical assistance programs and to provide a backup approach where these assistance-based mechanisms are not implemented by the discharger. Among the key enforceable mechanisms for agriculture are a back-up "no discharge" provision to deal with significant problems, a soil and sediment discharge provision with exemptions for agricultural operations operating under approved plans, and a mandatory enforceable nutrient planning program. For non-agricultural sources, including land development activities and forest harvests, Maryland relies on county enforcement of a state sediment control law. Maryland also has a forest conservation law, administered by the counties, which requires retention of forests and buffers in connection with development activities.

Monocacy River Watershed

The Monocacy River watershed is a subbasin of the Potomac River[1]. The 899 square mile watershed is mostly in Maryland, although part of the headwaters lies within Pennsylvania.[2] In Maryland, the watershed lies mostly within Frederick County and Carroll County, north of Washington, DC and northwest of Baltimore. The Monocacy was designated a state Scenic River in 1974.[3] It is part of the Upper Potomac watershed for purposes of Maryland's tributary strategy under the Chesapeake Bay Agreement, which is aimed at reducing nutrients entering the Bay. The watershed includes substantial agriculture, comprising about 3,500 farms within these two counties. Dairy and other livestock operations are significant. Both counties are also undergoing rapid suburban development.

The Monocacy watershed and its subwatersheds have been the focus of a number of targeted projects to address nonpoint source water pollution from agriculture, including sediment, nitrogen, and phosphorous, among other pollutants. The state's required assessment under § 303(d) of the federal Clean Water Act lists nutrients and suspended sediment as impairments from non-point and natural sources.[4] Maryland's Unified Watershed Assessment for 1998 classifies the Monocacy as both Category 1 (waters needing restoration) and Category 3 (waters needing protection).

Enforceable Mechanisms Studied

Of the Maryland nonpoint source enforceable mechanisms described in the *Almanac*,[5] the following were reviewed in detail because of their relevance in the Monocacy watershed.

! *No discharge.* Maryland's water pollution control law contains a broad prohibition against discharges of any pollutant to the waters of the state. "Except as provided in this subtitle [regarding permits][6] and Subtitle 4 of Title 4 of this article [relating to soil and sediment discharges] and the rules and regulations adopted under those subtitles, a person may not discharge any pollutant into the waters of this State."[7] The term "discharge" is defined as "(1) The addition, introduction, leaking, spilling, or emitting of a pollutant into the waters of this State; or (2) The placing of a pollutant in a location where the pollutant is likely to pollute."[8] This broad prohibition is enforced by the Maryland Department of the Environment (MDE), which may use administrative orders, injunctions, and civil penalties of up to $10,000 per day (judicially) or $1,000 per day (administratively), or criminal prosecution.[9] The discharge prohibition is referred to by MDE generally as its Title 9 authority.

! *Soil or sediment discharges.* Maryland also has a law prohibiting the discharge of soil or sediment into the waters of the state *except* as authorized under a discharge permit or when discharged from land managed under an agricultural soil conservation and water quality plan approved by the local soil conservation district. This provision, referred to as 4-413, provides that apart from these exceptions, "it is unlawful for any person to add, introduce, leak, spill, or otherwise emit soil or sediment into waters of the State or to place soil or sediment in a condition or location where it is likely to be washed into waters of the State by runoff of precipitation or by any other flowing waters."[10] MDE enforces the soil or sediment provisions by corrective action order[11] or injunction.[12] Civil penalties are authorized up to $25,000 per day (judicially) or $10,000 per day (administratively), and criminal sanctions up to $50,000 and/or one year imprisonment.[13] A person engaged in agricultural land management practices *without* an approved soil conservation and water quality plan is covered by the law, but is not liable for penalties if the person complies with MDE's corrective action order.[14] Conversely, if a person has an approved soil conservation and water quality plan, and violates that plan and a discharge of soil or sediment results, the MDE may enforce under its Title 9 authority described above.

! *Maryland's Water Quality Improvement Act.* This law, passed in 1998, requires farmers that use commercial fertilizers to prepare nitrogen and phosphorous nutrient management plans by December 31, 2001 and to implement them by December 31, 2002.[15] Farmers that use manure or sewage sludges must similarly prepare a nitrogen management plan and implement it by the same dates. Farmers using manure or sludges must prepare phosphorous management plans by July 1, 2004, and implement them by July 1, 2005. The plans must be prepared by state-certified nutrient management consultants. The requirements apply to all agricultural operations with an annual income of at least $2,500, and livestock operations with 8 or more animal units.

Enforcement will be the responsibility of the Maryland Department of Agriculture (MDA). Farmers who fail to develop a plan may be fined up to $250; those who fail to implement a plan by the required dates will receive a warning for a first offense and an administrative penalty of up to $100 for each subsequent violation, not to exceed $2,000 per year.[16] Persons applying commercial fertilizer for hire to nonagricultural property of three or more acres or to state property inconsistently with University of Maryland Cooperative Extension recommendations will be subject to a penalty of up to $1,000 for a first violation, and up to $2,000 for subsequent violations, but not to exceed a total of $10,000.[17]

! *Grading and land clearing permits.* This enforceable permitting program for the control of non-agricultural sediment and erosion is administered by MDE or by county and municipal governments to which the program has been delegated. It applies to forestry activities as well as land clearing and development exceeding 5,000 square feet, but not to "agricultural land management practices, construction of agricultural structures, or, except in Calvert County, to construction of single-family residences or their accessory buildings that disturb an area of less than one-half acre and occur on lots of two acres or more."[18] "A grading or building permit may not be issued until the developer (1) submits a grading and sediment control plan approved by the appropriate soil conservation district, and (2) certifies that all land clearing, construction, and development will be done under the plan."[19] "A person may not begin or perform any construction unless the person: (i) Obtains an approved sediment control plan; (ii) Implements the measures contained in the approved sediment control plan; (iii) Conducts the construction as specified in the sequence of construction contained in the approved sediment control plan; (iv) Maintains the provisions of the approved sediment control plan; and (v) Implements any sediment control measures reasonably necessary to control sediment runoff."[20] Enforcement includes stop work orders, corrective action orders, and injunctions; administrative penalties of up to $1,000 per violation (not exceeding $20,000 for any action), judicial civil penalties of double the cost of installation and maintenance of erosion and sediment controls and permanent restoration of the land; and misdemeanor fines of up to $5,000 and/or one year imprisonment.[21]

! *Forest conservation requirements.* The state also has an enforceable forest conservation program related to land development. "A unit of local government having planning and zoning authority shall develop a local forest conservation program, consistent with the intent, requirements and standards of this subtitle."[22] "Before the approval of the final subdivision plan, or the issuance of the grading or sediment control permit by the State or local authority, the applicant shall have an approved forest conservation plan."[23] The forest conservation subtitle applies "to any public or private subdivision plan or application for a grading or sediment control permit on areas 40,000 square feet or greater." It does not apply to construction of highways, to forest cutting in areas governed by the Chesapeake Bay Critical Area Protection Law (which have their own protective provisions), or to agricultural activity that does not result in a change in land use.[24] Enforcement includes a penalty of 30 cents per square foot of the area found to be in noncompliance,[25] plan revocation,[26] a stop work order by the state or local authority, injunctive relief, and civil penalty of up to $1,000 per day.[27]

These enforceable mechanisms are relevant to nonpoint sources in the Monocacy watershed. Their interaction with Maryland's various nonpoint source voluntary and technical assistance and cost share programs is discussed following the brief description of the latter programs in the watershed.

Maryland's *Chesapeake Bay Critical Areas Law* is not analyzed in this case study, despite its importance statewide to nonpoint source pollution control. It applies to activities within 1000 feet of the Chesapeake Bay and its tributaries influenced by the tide, a definition that does not include the Monocacy watershed. In general, the law limits the creation of impervious surface within the critical area, requires forest buffer retention, and requires that agricultural activities employ best management practices.[28]

Assistance-Oriented Nonpoint Source Programs

This section describes a number of the major programs that address nonpoint source water pollution in the Monocacy watershed. It is not an exhaustive list, but provides a brief description of programs that have influenced activities and water quality in the watershed.

Rural Clean Water Project - Double Pipe Creek Watershed

This project, in a subwatershed of the Monocacy in Carroll County, was funded under a U.S. Department of Agriculture nationwide pilot program in the 1980s to address agricultural water pollution concerns in small watersheds. The project ran from 1980 to 1990, and provided over $3.5 million in cost share assistance to farmers in the 120,000 acre Double Pipe Creek watershed. Dairy farmers were the main participants, although some beef operations and wheat farmers also participated. Each of the over 100 participating farms signed a contract, developed a conservation plan, and implemented best management practices (BMPs) The program provided up to $50,000 in cost share assistance per farmer, paying three-quarters of the cost for installation of BMPs. The contracts required farmers to return the cost share funds if BMPs were not maintained.

The Monocacy River Watershed Water Quality Demonstration Project

The Monocacy Project was funded by USDA from 1989-1998 as a project to "accelerate the widespread, voluntary adoption of land treatment and management practices that provide a cost effective means of reducing agrichemical and nutrient loadings to surface and ground water resources."[29] Primary staffing for the project was provided by Maryland Cooperative Extension, although funds were also allocated to the participating soil conservation districts. For much of the project, the emphasis was on encouraging adoption and implementation of voluntary nutrient management plans and integrated pest management in three subwatersheds of the Monocacy - the Piney/Alloway (in Carroll County), and the Linganore Creek and Israel Creek (in Frederick County).

Voluntary Nutrient Management Planning

The nutrient management program in Maryland has been a voluntary program until the recent enactment of the Water Quality Improvement Act, which makes it mandatory in future years. Carried out by Maryland Cooperative Extension, voluntary nutrient management plans achieved widespread adoption by farmers in the Monocacy watershed. Such nutrient planning has also been required in order to participate in federal or state cost share programs. Extension staff perform tests on the fields and develop a customized plan for the farm which specifies what levels and amounts of fertilizers and manures can be applied consistent with good agronomic practice.

In addition to nutrient plan services provided by Extension free of charge, farmers may also develop a nutrient management plan by consulting a state-certified nutrient management consultant, often an employee or consultant to a fertilizer company. Maryland developed the private nutrient consultant certification program in 1993, and has certified well over 450 consultants, of whom about 70-110 are actively preparing plans. Planners must take a state examination to achieve certification, and the Maryland Department of Agriculture (MDA) reviews a sample of plans from time to time to verify that certified private planners are correctly carrying out their function. Statewide, Extension staff have written 8700 nutrient management plans since 1989, and private consultants over 2600 plans since 1993. Over 1.1 million acres of Maryland farmland have been covered by nutrient management plans, including updates.[30]

Soil Conservation and Water Quality Plans

Soil conservation districts work with farmers to develop soil conservation and water quality plans. Soil conservation district staff develop plans for installation of BMPs, assist with design and cost estimates and applications for cost-share assistance, and provide assistance with installation of practices as well as advice on maintenance. Over half the farmers in the watershed have soil conservation and water quality plans in place. These plans are voluntary, but are required for participation in various cost share programs under federal and state laws. They also provide some protection against enforcement by MDE under section 4-413 of the state's water pollution control law. Provisions in the 1996 federal Farm Bill require farmers on highly erodible lands to adopt and implement soil and water conservation plans in order to receive federal benefits. These Farm Bill provisions have increased the planning workload in the Monocacy watershed.

Property Tax Credit for Conservation Plan and Nutrient Management Plan

Maryland has enacted legislation authorizing counties to offer up to a 50 percent tax credit against property taxes due on agricultural land that is subject to and compliant with a current soil conservation and water quality plan approved by the county soil conservation district, and a nutrient management plan (where eligible).[31] Neither Frederick nor Carroll County has adopted this credit.

Maryland Agricultural Water Quality Cost Share Program (MACS)

The MACS program was created by the Maryland General Assembly in 1984 as part of the Chesapeake Bay Agricultural Initiative. It provides funding for most of Maryland's agricultural water quality programs, including funding for BMPs under various programs. MACS now provides cost-share assistance for the installation of 29 different agricultural BMPs. The amount of assistance available varies for each management practice, but funding is available up to 87.5% of the total cost.[32] MAC cost-share has a lifetime limit per farm while under the same ownership of $75,000, scheduled to increase to $100,000. USDA Farm Services Agency funds may be combined with MACS funds to maximize cost share assistance.

Soil conservation districts provide the farmer with assistance in selecting the appropriate management practices and developing cost estimates used in applying for cost share money. MACS funding is substantial. Statewide, MACS has funded about 12,000 projects with over $48 million in assistance over its 15 year history. Annual funding in recent years has been over $4 million. However, fiscal year 1999 appropriations for MACS are in excess of $8.9 million (not including federal funds). In fiscal year 1998, MACS provided cost share assistance for 121 projects in Carroll County and 86 in Frederick County.[33] MACS usually only funds construction of practices, but not maintenance activities. However, at times funding is available for special practices, such as the cover crop program, which was made available in the Monocacy watershed for the first time in 1998. The cover crop program, which prevents erosion and retains nutrients that would otherwise be washed into the waterways, funds the planting of cover crops in the fall, and then kill-off of the crop in March.

Environmental Quality Incentives Program (EQIP)

EQIP is another of the federal Farm Bill programs. In Maryland, EQIP serves primarily as an additional source of funding beyond MACS cost shares. It provides up to $10,000 in cost share funding per farmer. Until 1998 EQIP money in Maryland was allocated in such a way that the western counties of Maryland all had to compete for funding in the same pool, but this has changed. Carroll and Frederick Soil Conservation Districts each received just under $100,000 in EQIP funds in 1998. Carroll's funds were targeted for use in the Little Pipe Creek watershed.

Conservation Reserve Enhancement Program (CREP)

This addition to the federal Conservation Reserve Program, available in Maryland, is targeted at areas that will provide water quality benefits. It pays farmers to take riparian lands, highly erodible lands, or wetlands out of production for up to 15 years, and provides incentive bonuses to install conservation practices such as forested or vegetative buffers, to retire highly erodible land within 1000 feet of a waterway, or restore wetlands.[34] Eligible lands include cropland that has been planted to an agricultural commodity for two of the last five years, or marginal pastureland suitable for use as a riparian forest buffer. In April 1999 the program, which operates throughout the state, had enrolled 563 acres in Carroll County and 890 acres in Frederick County, mostly in the Monocacy watershed.

CREP has been popular in the watershed. CREP is more attractive to landowners than to many of the active farmers in the watershed, many of whom rent much of the land on which they farm. CREP has also raised some concerns among farmers about making land unavailable for agriculture as well as concerns with having land out of production adjacent to productive land such that deer or Johnson grass might become a problem for the remaining land in production.

319 Program

The federal grant funds provided under Section 319 of the Clean Water Act for control of nonpoint source water pollution have been used for a variety of projects in the watershed, including a number of projects under the Monocacy Project. Statewide, Maryland usually has $1.4 million in 319 money each year, but will have $2.6 million in 1999 and 2000. These funds are in addition to the Chesapeake Bay implementation grant. In the Monocacy, § 319 funds have supported technical assistance for animal waste management practices and erosion controls, monitoring projects to determine the effectiveness of agricultural and forestry best management practices, development of water quality modeling programs, and homeowner education on residential best management practices.

Agricultural Land Preservation Program and Maryland Rural Legacy Program

Maryland's Agricultural Land Preservation Program is aimed at acquiring permanent easements on agricultural land to keep it in agriculture. Since 1985, a condition of the easements has been that the owner must develop a soil conservation and water quality plan, outlining best management practices to be installed and maintained on the property. The plan includes a schedule of implementation and is included as a condition in the easement. In 1998, Carroll County had preserved the most acreage in the state under this program, over 25,000 acres.

The Rural Legacy Program provides funding for 12 areas around the state. Carroll County recently received $2.5 million as part of this program, which will be used in the watershed to create an agricultural buffer around the town of New Windsor. The program will promote CREP, the Maryland Agricultural Land Preservation Program, and also provide for easements on non-agricultural lands such as environmentally sensitive lands and wooded property.

Discussion and Analysis

Agricultural Pollution Generally

The Maryland approach to agricultural sources of nonpoint source pollution is primarily through technical assistance, cost-share, and voluntary programs administered through the soil conservation districts. This is backed by enforcement by MDE for unlawful discharges that are not remedied by farmers when they are put on notice and offered assistance by the soil conservation districts.

MDE's field office acts on agricultural nonpoint source pollution largely in response to citizen complaints, or staff may act on personal observation of a pollution problem. Complaints may be made directly to MDE at its field office or at headquarters. Citizens who complain to a soil conservation district may be referred to the MDE. Under MDE policy, citizen complaints are acted upon within three days. MDE's normal approach upon receipt of a complaint is to contact the local soil conservation district to determine whether the operation has a soil conservation and water quality plan or is working on one with the district. MDE also invites the soil conservation district to conduct a joint inspection of the operation. If there is an existing plan, the district staff will often go with MDE to visit the site. If not – as is more typical in complaint cases – the district usually declines the invitation. Both MDE and soil conservation district staff noted that the districts do not want to be associated by farmers in the first instance with enforcement-oriented activity, believing that this may make their provision of technical assistance and farmer acceptance of voluntary programs more difficult.

An MDE staff member visits the site and determines whether a discharge or potential discharge situation is occurring. The MDE staffer then produces a Field Investigative Report on a computer-generated form and leaves a copy with the farm operator. If there is a violation, the MDE staff member will advise the operator to contact the soil conservation district for assistance. Typically, the MDE will wait a few weeks and then contact the district to determine whether the farmer has sought assistance. If the farmer has not, the MDE visits the farm again. More serious situations may result in issuance of a Site Complaint, whose issuance requires approval from MDE management. (There are 4 regional compliance divisions in the state). The Site Complaint, while more serious in form, has no additional legal significance, however, unless it is accompanied by an order. An order can only be issued if pre-authorized by an assistant state attorney general advising the MDE.

If an observed violation is for soil and sediment under 4-413, the violator is directed to get a soil and water conservation plan from the soil conservation district. If the violator obtains a plan and thereafter does not violate it, then there is no sanction for the original violation. MDE did not identify any instances in the Monocacy watershed of an enforcement action arising after preparation of a plan under these circumstances. However, one Frederick County farmer outside the Monocacy watershed was advised to contact the soil conservation district to develop a plan and to implement it, after he mass-graded his fields and disturbed a stream. The district prepared the plan, but the farmer then failed to maintain the practices specified in the plan. Subsequent MDE enforcement activity resulted in a settlement in which the farmer took corrective action and paid a fine of $750.

The assistant attorney general responsible for advising MDE did not recall any sediment pollution cases prosecuted in court by the attorney general's office against agricultural operations. The approach of directing such violators into the planning process with soil conservation districts has apparently resolved all of the known violations short of formal enforcement.

Most agricultural water pollution in the state, as well as in the Monocacy watershed, involves manure discharges and/or animals in the stream. The MDE can take enforcement for these violations directly under the Title 9 "no discharge" prohibition, and is not required to offer the discharger an initial opportunity to correct the problem without penalty as under 4-413. Ordinarily, however, the MDE official uses a similar approach – advising the farmer to get in touch with the soil conservation district to develop and implement a plan to correct the problem. Carroll County Soil Conservation District officials note that one farm in the county is currently under a site complaint related to discharges of barnyard and dairy wash water to a wetland and stream. While this is a violation, the MDE has not pressed the enforcement action to a formal order (with administrative review, penalties, and other consequences) because the soil conservation district still needs to do the design work to support the remedy and the cost shares necessary to solve the problem. Thus, although provision of cost share money is not a legal prerequisite to enforcement action in Maryland, nevertheless, the MDE exercises its enforcement discretion in cases where the problem is expected to be solved. Frederick County Soil Conservation District officials note a similar case in which a tenant dairy farmer received a field inspection report from MDE advising him to contact the district to resolve a nonpoint source pollution problem and a related problem with a pipe discharging milking parlor waste water. The district perceives some difficulty in solving the problem in the near term as the operator is near retirement, the remedy will require substantial capital investment (including cost share) and the landowner may not want to invest in expensive engineered solutions; the current hope is to develop some sort of management plan. Each of these cases shows that enforcement is intended to serve what remains a largely technical assistance and cost-share oriented approach.

The Frederick County Soil Conservation District currently is working with ongoing projects involving 200-400 farmers; fewer than a dozen of these are relationships initiated by MDE referrals/complaints. Projects can take from 2-6 years to develop and implement. In Carroll County, the Soil Conservation District works with about 1000 farmers annually but fewer than ten of the projects are related to MDE involvement. The office tries to resolve problems within six months, but practices may take between 1 to 3 years to install. Cost share funds play a role in the adoption of practices. Federal funding is currently limited, but state MACS funding is by far the largest source of cost share money.

The soil conservation districts also noted that they do not use the specter of potential MDE enforcement as a "selling point" when seeking to promote the voluntary adoption of practices or participation in agricultural cost share programs – even for animal waste situations (where costs are much higher and enforcement consequences more likely). Their experience shows that a farmer has to have a strong desire to participate and to integrate the recommended practices and constructed facilities into the farm operation if they are to have any chance of long term maintenance or operation. Imposed solutions, in their view, often lack this level of commitment and fail after a few years. This also explains, in part, the districts' desire to be the provider of solutions in an enforcement context, rather than to appear as a co-enforcer (e.g., declining joint site visits with MDE in most instances).

Nutrient Planning and Water Quality Improvement Act Implementation

Maryland has received national attention for its Water Quality Improvement Act adopted in 1998 in response to the *Pfiesteria* problem in certain tributaries of the Chesapeake Bay. The Act imposed mandatory nutrient management planning requirements statewide. This mandatory program follows years of promotion of voluntary nutrient management planning.

However, the new law's approach does not simply make mandatory what was previously voluntary. The law makes substantive changes in the required content of plans, thus requiring new plans and plans that address animal operations more holistically. The law also raises issues of administration. In practice, the law divides responsibility for nutrient management planning and regulation among at least four entities – the Maryland Department of Agriculture, Maryland Cooperative Extension, the local soil conservation districts, and the Maryland Department of the Environment.

Historically, nutrient management planning was the responsibility of Maryland Cooperative Extension, while soil conservation and water quality planning was the responsibility of the soil conservation districts. As described previously, soil conservation districts provide broad planning services for farmers and serve as the gateway for cost-shares and other programs. Within the soil conservation and water quality plans, the districts schedule specific "practices" to meet the needs identified. Nutrient management is one of the component "practices" of the soil conservation and water quality plan, but the nutrient management plan was prepared by Extension (or a private certified consultant) rather than by the district staff.

Soil conservation and water quality plans also contained a "waste management system" practice. The district prepares a waste management plan, which addresses management of animal waste and runoff in the area of the barn and barnyard, but does not address the application of such materials to fields (which is the subject of nutrient management planning). A farmer with a waste management plan must also have a nutrient management plan because it is a component practice of the overall soil conservation and water quality plan.

Alternatively, a farmer could have Extension or a certified private consultant prepare a stand-alone nutrient management plan, without engaging with the soil conservation district in preparation of a soil conservation and water quality plan.

The new Water Quality Improvement Act requires *mandatory* preparation of nutrient management plans. But these plans take in elements that were previously not part of nutrient management planning in Maryland. The plans required by the new law require consideration of rates of runoff and pollution from the land, and measures for management and containment of manures. But the previous nutrient management plans prepared by Extension only determined agronomically appropriate rates of application of manures and fertilizers on the land; they did not address runoff rates or manure storage and management issues. Moreover, the handling and storage of "excess" manure not applied to the fields must also be addressed under the mandatory program, a change from the prior system where this was an issue handled only in the waste management plan prepared by the soil conservation district. Thus, the new mandatory plans involve features not part of the voluntary plans. Some soil conservation district staff are concerned that Extension nutrient planners will not be equipped to handle the new demands of the mandatory program – either because of lack of experience with waste management practices, or unfamiliarity with farm conservation and water quality issues on a holistic basis. Others are confident that the gap can be closed and needs addressed cooperatively. The Maryland Department of Agriculture expects Extension nutrient planners to become familiar with these requirements, and/or to refer the farmer to soil conservation district staff for detailed planning and construction of waste management structural practices. Under any scenario, soil conservation districts will need to work more closely with Extension by providing soil loss and runoff data to aid in the development of the new nutrient management plans and by assuring that the waste management element has been prepared.

The new program is likely to mean that a substantial number of animal operations in the Monocacy watershed will need to upgrade their existing waste management system plans in order to come into full compliance. Soil conservation district staff estimate that up to eighty percent of existing dairy farms in Frederick County are likely to need new or revised waste management plans in conjunction with the new nutrient management plans. In anticipation of these costs, the state recently announced a new loan program to help cover the portion of farmers' expenses not covered by the 87.5 % cost shares available under MACS. This Maryland Agricultural/Nonpoint Source Loan Program uses Water Quality State Revolving Fund (SRF) monies administered by the MDE to make low interest loans. The farmer works with the soil conservation district to develop the necessary practices; the district certifies the need to prevent nonpoint source pollution, and the farmer then seeks a loan from a commercial bank. If the application is approved by the bank, the bank applies to the MDE for a "linked deposit" of SRF monies. The bank disburses the loan.[35]

Cost shares are also available to assist with the planning. The MACS program is providing up to a 50 percent cost share (limited to $3 per acre) for the preparation of nutrient management plans by certified private nutrient consultants.[36] Extension nutrient planners will continue to provide their planning services free of charge.

Enforcement of the new law will be the responsibility of the Maryland Department of Agriculture (MDA), rather than MDE. The soil conservation districts, Cooperative Extension staff, and private nutrient planners will also not have enforcement responsibilities under the Water Quality Improvement Act. The MDA has hired six inspectors statewide in anticipation of implementing the enforcement program. In addition, in anticipation of increased planning and cost share workloads in the soil conservation districts, the state has funded 15 new positions last year and will add 33 this year statewide. Four of these will be in Frederick, five in Carroll. (The net increase in district staffs will be somewhat smaller, owing to downsizing in recent years. For example, the Carroll County Soil Conservation District's five new staff will represent a net gain of two because of three previous unfilled positions).

Although MDA will be responsible for enforcement of the Water Quality Improvement Act, MDE will retain the ability to use its Title 9 authority where there is an unlawful discharge of pollutants. Because MDE has a history as an enforcement agency, and because the penalties are so much higher under its Title 9 authority than under the Water Quality Improvement Act administered by MDA, there is great concern among the agricultural community about sharing of information among the agencies. Under existing practice, a nutrient management plan is kept by the farmer and the preparer. The soil conservation and water quality plan (with its waste management component) is kept by the farmer and the district. Under the new program, MDA will receive only a summary of the new nutrient management plan, not a copy of the plan itself. In 1999, the Maryland legislature amended existing law to provide that information from soil conservation and water quality plans could be shared with MDE "for enforcement under 4-413" (soil or sediment) and further providing that the MDA can share information with MDE "to support the development of a compliance or enforcement case for purposes of addressing *an existing water quality problem*" (viz. Title 9) but only pursuant to procedures to be established between the two departments and the state soil conservation committee.[37] These authorizations and limitations were the subject of substantial negotiations in the legislature. MDE and MDA are currently "negotiating" over how their respective enforcement duties will be carried out under the Water Quality Improvement Act.

Soil conservation districts and Extension staff also have concern with being associated with an "enforceable" program. They suggest that MDA will need to take the heat of doing inspection and enforcement if the two assistance-oriented organizations are to be effective in gaining cooperation of farmers in developing and implementing the plans.

The new enforceable program clearly represents a step forward in water quality protection. It will undoubtedly improve both nutrient and waste management planning for those Monocacy watershed farms that already have plans, and will bring in those farms that do not. However, the program is highly dependent on the provision of sufficient staff and the investment of substantial cost share funds, and its division of functions may complicate implementation.

Land Development Regulation

Nonpoint source pollution from land development activities is addressed by a number of regulatory laws. Here, the approach is not voluntary, but mandatory.

State law requires a sediment control plan for land disturbances over 5,000 square feet other than agriculture. The plan must be reviewed and approved by the soil conservation district before the county may issue grading permits. Frederick and Carroll Counties have taken delegation of the sediment control program. The City of Frederick has not, so MDE enforces the district-approved sediment control plans within the city limits.

Land disturbances over 20,000 square feet in Carroll County (or 15,000 square feet in Frederick county) require a full sediment control and grading permit. The county receives a copy of the plan at the same time as the soil conservation district, but will not issue a permit until the plan has been approved by the district. In Frederick City, the MDE receives a copy of the approved plan. Land disturbances between 5,000 and 20,000/15,000 square feet are subject to minor permits with standard conditions for sediment control. Sediment control plans for minor permits are not individually reviewed by the soil conservation district.

Bonds are required to assure compliance with the plan for disturbances greater than 20,000 square feet. Carroll County requires dedication of a 100 foot water resource protection easement along streams. Frederick County does not, but under its zoning ordinance simply prohibits or limits developments within variously defined "floodplain" widths, and within 50 feet of unmapped intermittent streams. Frederick County also has an inconsistently enforced provision in its zoning laws requiring that intermittent streams be protected with native vegetation/grasses.

County inspectors (or MDE in the city of Frederick) enforce the sediment control law. County inspectors ordinarily visit sites biweekly and also after precipitation events. If the county inspector identifies a violation, the inspector issues a field report identifying the violation and specifying the number of days to correct it. If the violation is not corrected in this time period, the inspector may issue a notice of violation or site complaint, again specifying a time for compliance. Failure to comply may lead to a stop work order. If a violation is significant, such as actual discharge of sediment offsite, a stop work order may be issued on the first inspection. In Carroll County in 1998, 3,204 inspections were performed, resulting in 19 stop work orders and 7 notices of violation. In each case these were resolved without assessment of a fine or commencement of a court case.[38] In Frederick County there were 13 stop work orders and 49 notices of violation issued between July 1998 and July 1999. There were also 3 citations issued with fines totaling $750 in the same period. MDE inspectors do not observe the identical inspection frequency, but prioritize the workload based on anticipated potential for pollution; MDE enforcement is typically by administrative civil penalty.

The Maryland Forest Conservation Law also has requirements that apply to development that affects 40,000 square feet or more of land. The state law sets forth standards which are implemented through county ordinances, which must be at least as stringent as the state law. These ordinances provide that the developer must conduct a forest stand delineation which is reviewed by the county, and then must submit a forest conservation plan. The plan must provide for forest retention and reforestation, and in certain cases for afforestation of previously non-forested areas. Developments in agricultural and resource areas or zoned for medium residential density that have less than 20% of the net tract area in forest cover must be afforested up to 20%; and commercial or industrial properties and high density residential areas with less than 15% must afforest up to 15%. In order to assure that forested areas remain in forest to some extent, areas that are deforested by the development activity must be reforested. Reforestation is required at a ratio of 1:1 (one acre reforested for each acre deforested) in Carroll County; and on a sliding scale (from 1/4:1 to 2:1) in Frederick County. The sliding scale in Frederick County, which follows the state law model, depends on a number of factors. If the forest cover removed by the development activity results in a residual forest area above a specified numerical threshold, reforestation is required only at the 1/4:1 ratio (with a 1 for 1 credit for each acre retained above the threshold). If the amount of forest cover removed results in a residual forest cover below the threshold, reforestation at the ratio of 1/4:1 is required for acres deforested down to the threshold and at 2:1 for acres deforested below the threshold.

In both counties, the developer must post a bond to assure performance of the forest conservation plan. In Carroll County the bond is $5,000 per acre to be forested; in Frederick it is either $0.10 per square foot or, for larger sites, an amount equal to the market rate for the required forest plantings plus a 15% contingency.

Forested or reforested land covered by the forest conservation plan must be placed under easement conveyed to the county. The easement requires that the land remain permanently in forest. In Carroll County developers may use offsite forest mitigation banking; the county does not allow "fee in lieu" mitigation. Frederick County allows offsite banking as well; the county ordinance makes agricultural streams the number one priority for off-site reforestation or forest banking. Such "banks" are subject to the same review, bonding, and easement requirements as for approval of onsite forest conservation activities.

The Carroll County Forest Conservation Ordinance requires creation and retention of a 50 ft. forest stream buffer. (County subdivision ordinances require 100 feet, and the Forest Conservation Ordinance may soon be changed to require 100 feet. The county normally seeks a 100 foot forest buffer despite the current 50 foot provision in the ordinance). Frederick County forest stream buffers under the ordinance are 50 feet or floodplains.

Forest conservation enforcement in Carroll County includes conducting an initial inspection to ensure that the planting has taken place as specified in the plan, then following up after 12 months. At that time, if 75% of the trees planted have survived, the developer receives 50% of the bond back. The final inspection is after 26 months. If 75% of the originally planted trees still survive, the developer receives the remaining 50% of the bond. A similar approach is used in Frederick County.

Frederick County depends on citizen complaints to identify individual landowners who may be conducting activities that are subject to the Forest Conservation Act without filing the appropriate plans. This generally only happens with private landholders since the review process for development ensures that commercial developers follow the requirements. There have been 2 or 3 violations in the county that the landowner rectified.

Forest Harvest Operations

Forest harvesting operations disturbing more than 5,000 square feet are also subject to enforceable mechanisms under the grading and clearing law. Like land development operations, these harvest operations prepare a sediment control plan for soil conservation district review and approval, and must obtain a permit from the county. As noted, operations disturbing between 5,000 and 15,000/20,000 square feet will obtain the standard (or minor) grading permit; larger operations need major permits. While bonds are required for major grading permits involving development, they are not required in either Frederick or Carroll County for forest harvests.

The MDE and the Department of Natural Resources (DNR) have established a "compliance agreement for the standard erosion and sediment control plan for forest harvest operations." This provides the requirements including Best Management Practices (BMPs) and stream buffers needed for sedimentation control.[39] For harvests affecting streams, the approved sediment control plan is required to include a forest stream buffer management plan for the "streamside management zone." The buffers are a minimum of 50 feet at zero percent grade, with an additional 4 feet of width for every percent above zero. The plan must provide for the post-harvest basal area within the buffer being at least 60 percent of the pre-harvest basal area. No landings are allowed in the buffer, and haul roads in the buffer are allowed only if preexisting and stable, or if they merely cross the buffer laterally. Research in the Monocacy watershed funded by 319 money has shown that use of best management practices for forest harvests avoids significant impacts to water quality.

Enforcement is by the county sediment control inspectors. Stop work orders and related enforcement on logging operations occurs in both counties. The last civil citation for a grading violation in Carroll County that resulted in a fine was about 7-8 years ago, involving a timber harvest that occurred without the required plan and approval. It was cited because the harvest involved stream crossings and wetlands.

Maryland has a separate state law authorizing regulation of some forest harvest practices on private lands.[40] The law requires notice to the local district forestry board (in each Maryland County) for commercial harvests affecting more than three acres of forest land, and is implemented mostly in the Chesapeake Bay critical area.[41] However, in Frederick County, the county government has adopted zoning ordinance provisions that require the board to review timber harvests occurring in the county's "conservation areas." This provides an additional level of scrutiny to assure the retention of stream buffers.

Conclusions

Maryland has many programs operating in the Monocacy watershed, including cost-share, technical assistance, voluntary, and enforceable programs. The substantial impression left by review of these efforts is their sheer magnitude - in dollars, staffing, and duration. With respect to agricultural sources of nonpoint pollution, Maryland's approach centers on the delivery of services by the soil conservation districts, but enforcement is the responsibility of the MDE. With respect to the new mandatory nutrient management program, responsibilities will be divided further, with MDA having initial enforcement responsibility, backed by MDE enforcement if water pollution occurs. Thus, the enforcement tools are plainly intended to be used to support traditional planning, cost share, and technical assistance approaches.

Many of the technical assistance and voluntary programs in the watershed have come and gone, often with substantial participation rates and results, but with little formal coordination at the state level. Although Maryland does have all of its waters divided into basins under its tributary strategy, the multi-stakeholder tributary teams seem to be chiefly engaged in public outreach and promotion of water pollution control and prevention techniques rather than in watershed goal-setting or development of projects. Similarly, unified watershed assessment has provided a means for the state to target its 319 money, but the 319 funding (while substantial) is small in comparison with the MACs and USDA funding that has come to the state and into the watershed.

For land development and nonpoint source pollution from forest harvests, enforceable mechanisms adopted by the counties under state legislation are the central approaches in Maryland. These seem to be working in coordinated fashion. Indeed, the centering of approval and enforcement in county governments appears to assure better understanding of requirements and controls over activities. The involvement of the soil conservation districts in review and approval of plans also helps to assure coordination of agriculture and non-agriculture expertise in the watershed.

The Maryland programs maintain a sharp distinction between entities providing assistance in coming into compliance (the soil conservation districts and the cost-share programs they serve as gateways), and enforcers (the MDE, county governments, and now the MDA). While this can lead to complexity in coordination, it also apparently alleviates concerns of land holders who can then seek compliance assistance from familiar entities without concerns over a potential conflicting role as enforcers.

Ohio Case Study

Summary

In addressing nonpoint source water pollution from agriculture and silviculture, Ohio relies primarily on its 88 county soil and water conservation districts.[1] While these districts chiefly use voluntary measures and technical assistance, they have the power to require filing of operations and management plans to *abate* agricultural or silvicultural pollution. If plans are not prepared or carried out to abate ongoing pollution, enforcement can be requested from the chief of the Department of Natural Resources' Soil and Water Conservation Division to ensure that the necessary measures are put in place. These administrative "chief's orders" are enforceable, and can also lead to judicial enforcement. Ohio's law requires the state to provide cost share funds as a condition for the validity of chief's orders that require the installation of any practices eligible for cost-shares. Enforcement-driven cost shares rise to the top of the list for state eligibility. Fairly limited funding, capped at $15,000, is available for such enforcement-based cost shares, however. Very few chief's orders are requested by the districts or issued by the DNR, and use of this mechanism takes significant time. Ohio's state wildlife officers can also address nonpoint source pollution, seeking misdemeanor fines, court orders, and restitution for nonpoint source pollution that results in fish kills. They also may seek enforcement when litter and other materials are found in streams.

Ohio EPA plays a limited role in enforcement in the nonpoint context. The state's general water pollution law administered by OEPA does not cover agricultural, silvicultural, or non-agricultural nonpoint pollution otherwise subject to DNR or county authority. OEPA's involvement occurs primarily when a discharge can be defined as a point source or when a water pollution situation is not covered by these other laws.

Watersheds

Two rural watersheds (in eastern and western Ohio) were examined in order to assess the use of enforceable mechanisms, and their relationship to cost-share and technical assistance approaches to nonpoint source discharges.

Stillwater River Watershed

The Stillwater River Watershed in western Ohio drains an area of 673 square miles. Comprising most of the land area of Darke County and flowing southeastward through western Miami County and northwestern Montgomery County, the Stillwater watershed is a part of the Great Miami River drainage basin. The Stillwater River flows into the Great Miami River at Dayton. The Stillwater River and Greenville Creek (its tributary) were designated State Scenic Rivers by the Ohio legislature in 1975. The watershed is predominantly agricultural; and the largest town in the watershed is Greenville, with a population of 12,850.[2]

The headwaters of the watershed, and 70 percent of its total area, lie in Darke County, on the Indiana border. Of the 400,000 acres in Darke County, approximately 325,000 acres are agricultural. The county is one of the most agriculturally productive in the state, regularly ranking among the top three counties for production of corn, soybeans, and wheat. In addition to crop production, almost two-thirds of agricultural revenue in 1997 was derived from livestock farms. The county has over 200,000 animal units and approximately 10 million animals, more than any other county in the Miami Valley region. While the number of livestock operations has decreased steadily since the 1940s, the number of animals has increased. Poultry and hog numbers have increased, while beef and dairy cattle have declined in number. Chickens now comprise almost half of the total number of animal units, and more than 90 percent of the animals.[3] Most of the stream miles in the watershed are classified as warmwater habitat or exceptional warmwater habitat for water quality purposes. However, almost 60 percent of the stream miles assessed in 1996 were not attaining or were only partially attaining water quality use standards. Causes of impairment included livestock pastures/feedlots, row-crop agriculture, and on-lot wastewater systems, as well as some industrial and municipal point sources.[4]

Belmont County

Belmont County lies in eastern Ohio, and is bordered on the east by the Ohio River. Its terrain is rugged and steep. The major stream systems, running from west to east into the Ohio River, are associated with McMahon Creek and Captina Creek. Most of the streams are designated warmwater habitat.[5] Primary land uses in Belmont County include forestry, agriculture, and mining. The county is the second highest in the state for annual soil losses, and contains the fourth largest amount of highly erodible soil and the third highest number of total stream miles. Forty percent of the county is forested. Forest harvests are increasing in the county as the demand for high quality hardwood increases. Most forest land is privately owned, and logging operations are generally arranged through contracts between logging companies and landowners. Approximately 45 percent of the county is agricultural land, with slightly more land devoted to pastures than cropland. More than half of the cropland is enrolled in cost-shares for conservation practices. Water quality impairments are primarily nonpoint in origin.

Enforceable Mechanisms Studied

"Chief's Orders" for Agriculture and Silviculture

Ohio law directs Ohio DNR's Division of Soil and Water Conservation, with the approval of the Soil and Water Conservation Commission, to adopt rules establishing "technically feasible and economically reasonable standards to achieve a level of management and conservation practices in farming or silvicultural operations that will *abate* wind or water erosion of the soil or *abate* the degradation of the waters of the state by animal waste or by soil sediment including substances attached thereto."[6] The key concept is that these standards come into play where abatement of pollution is needed; absent pollution, operators are not subject to any of these standards except on a voluntary basis.

This law does not "restrict the excrement of domestic or farm animals defecated on land outside a concentrated animal feeding operation or runoff therefrom into the waters of the state."[7] The definitions are important. "Concentrated animal feeding operation" is not defined by numerical animal unit thresholds as under the federal Clean Water Act. Instead, the term is defined as including "animal feedlot and animal waste management facilities and land application areas for managing and disposal of animal waste."[8] An "animal feedlot" is defined as a feeding or holding area "where grass or other suitable vegetative cover is not maintained," while an "animal waste management facility" means "any area or facilities used for the collection, storage, handling or treatment of animal waste."[9] Thus, the law provides authority for the DNR to set standards to address manure spreading, handling, collection, and application practices, and other forms of animal waste such as wash waters; but it does not address animal waste excreted in pastures.

DNR regulations provide that to abate pollution from animal waste collection, storage, or treatment facilities, the operator shall "design, construct, operate, and maintain" such facilities to prevent discharge, and must follow the standards in the "Field Office Technical Guide."[10] The operator must prevent seepage from animal waste management facilities, and "if pollution of waters of the state occurs from an existing facility, corrective measures shall be taken."[11] Pollution from land application of animal waste, flooding, waste waters, and related activities must be prevented.[12]

DNR sediment regulations under this law also require control of sheet and rill erosion, wind erosion, and concentrated channel erosion.[13] Farmers "responsible for agricultural pollution" must apply and maintain "Field Office Technical Guide" measures and install practices in accordance with an approved operation and management plan.[14] Soil and water conservation districts are required to review and approve "operations and management plans."[15] Such plans must "contain implementation schedules and operational procedures for a level of management and pollution abatement practices which will abate the degradation of the waters of the state by animal waste and by soil sediment including attached pollutants."[16] The sediment regulations further provide that there shall be no earth disturbing practices (including tillage) immediately adjacent to waters of the state "except for those practices constructed or implemented in accordance with generally accepted agricultural, silvicultural and engineering practices."[17] The sediment regulations also require silviculture operators to apply Best Management Practices, and provide that such operators "may" file operations and management plans with soil and water conservation districts.[18]

The Division of Soil and Water Conservation is required to "establish procedures for...enforcement of rules for agricultural pollution abatement."[19] The procedures rely on the abatement measures administered by Ohio's 88 soil and water conservation districts (one in each county),[20] but are backed by authority for the chief of the Division at the state level to issue enforcement orders.

Typically, citizen complaints about agricultural or silvicultural pollution are investigated by the conservation district. After the district invites the violator to comply, provides any assistance, and gives a voluntary period to correct the problem,[21] the district may refer the matter to the Division of Soil and Water Conservation for a "chief's order."[22] State law created the chief's order for animal waste pollution in 1978. In 1991, "chief's order" authority was extended to include pollution from discharges of sediment.

After conducting an adjudicatory hearing, the Division chief may order an agricultural or silvicultural operation to comply with the standards, and operate in accordance with an operation and maintenance plan.[23] However, the chief *may not* issue an order that requires the recipient to implement an agricultural pollution abatement practice eligible for cost sharing unless public funds are actually made available to cover not less than 75 percent of the required cost (not exceeding $15,000/person/yr).[24] Cost shares are available only to owners and operators that develop and have approved by the soil and water conservation district a current operation and management plan for their *entire* operation.[25]

Chief's orders are appealable to the court of common pleas.[26] The orders are also judicially enforceable.[27] Violation of an order is a misdemeanor punishable by imprisonment up to 6 months, fine of up to $1,000 per day, and restitution.[28] Also the state may recover any expenditures it made from the "agricultural pollution abatement fund" to protect public health.[29] In addition, the Division may seek a court order against a discharger at any time if the violation "causes pollution of the waters of the state and constitutes a danger to public health."[30] For discharges of animal waste that cause pollution of the waters of the state and require immediate action to protect the public health, the chief may issue an emergency order effective immediately, and the Division may enter on the lands to abate the problem if the person responsible does not comply.[31]

Land Clearing and Development Erosion and Sediment Programs

State law also empowers the Division of Soil and Water Conservation, subject to approval of the Ohio Soil and Water Conservation Commission, to adopt rules for "technically feasible and economically reasonable standards to achieve a level of management and conservation practices that will *abate* wind or water erosion of the soil or *abate* the degradation of the waters of the state by soil sediment in conjunction with land grading, excavating, filling, or other soil disturbing activities on land used or being developed for *nonfarm* commercial, industrial, residential, or other nonfarm purposes."[32] Municipalities and counties may develop their own programs. The Division "may recommend" criteria and procedures for "approval of urban sediment pollution abatement plans and issuance of permits" prior to the disturbance of five or more acres. Although areas less than five acres do not need plans or permits, they are not exempt from the "other [substantive] provisions of this chapter and rules adopted under them."[33] Areas of any size require use of conservation practices including sediment trapping, stabilization of denuded areas, and stream crossing work; and no dumping of material is authorized into waters or in such proximity that material may slough, slip, or erode into the waters unless specifically authorized.[34] Developments of five or more acres must develop an "erosion and sediment control plan" which must be approved by the state or local approving agency, and must institute stormwater controls.[35]

The soil and water conservation districts and the Division do not have enforcement responsibilities under this program, and "chief's orders" are not available. Instead, local municipal or county ordinances provide the enforcement.

Concurrent with these responsibilities, the Ohio EPA has permitting and enforcement responsibility for the federal Clean Water Act industrial and urban Phase I stormwater program, which applies to land development activities including land clearing for development in excess of five acres. Enforcement is by the municipalities or counties, or the Ohio EPA. The Ohio EPA has also entered into agreements with 17 soil and water conservation districts (not including the counties comprising the watersheds examined in this case study). These mostly urban counties do local education on erosion control at construction sites, review notices of intent to construct, and some conduct inspections.

Other Nonpoint Source Authority

Apart from the above provisions, enforceable mechanisms for nonpoint sources are limited in Ohio.

Enforcement by Ohio EPA under the state's *water pollution law* does not apply to most nonpoint sources.[36] The state water pollution law states that "No person shall cause pollution or place or cause to be placed any sewage, industrial waste, or other wastes in a location where they cause pollution of any waters of the state, and any such action is hereby declared to be a public nuisance"[37] But the law expressly exempts from this prohibition "[a]pplication of materials to land for agricultural purposes or runoff of such materials from such application or pollution by animal waste or soil sediment including attached substances, resulting from farming, silvicultural, or earthmoving activities regulated by Chapter 307 or 1515 of the Revised Code."[38] The referenced laws are those discussed above under which Ohio counties regulate earthmoving associated with development, and under which Ohio's soil and water conservation districts and DNR address agricultural discharges of sediment and animal waste. The general prohibition also exempts excrement of domestic and farm animals and runoff therefrom.[39]

Only when an animal operation has a controlled, direct discharge of wastewater or has 1,000 animal units or more, is it required to have a discharge permit or "permit to install" issued by the Ohio EPA.[40] Similarly, only where earthmoving falls under the federal stormwater permitting program or is unregulated by county ordinances does it fall within the Ohio EPA's enforcement purview. Where the prohibition does apply, enforcement includes administrative orders, injunctions, and civil penalties of up to $10,000 per day.[41]

Ohio also has several *nuisance-type misdemeanor* provisions that can be used to address some kinds of water pollution that may include nonpoint sources. For example, "No person shall....corrupt or render unwholesome or impure, a watercourse, stream, or water."[42] This is a third degree misdemeanor, with a penalty of no more than 60 days and/or $500; the court may also impose restitution for any property damage.[43] Similarly, "No person, regardless of intent, shall deposit litter or cause litter to be deposited...in or on waters of the state."[44] "Litter" means "garbage, trash, waste, rubbish, ashes, cans, bottles, wire, paper, cartons, boxes, automobile parts, furniture, glass, or anything else of an unsightly or unsanitary nature."[45] This is also a third degree misdemeanor. And

R0019260

the court may, in lieu of or in addition to any penalty, require such person to "remove litter from any public or private property, or in or on waters of the state.[46] These misdemeanor provisions are enforceable by any sheriff, police officer, constable, wildlife officer, conservancy district officer or any other law enforcement officer.[47]

Ohio's *wildlife law* contains a similar provision: "No person shall place or dispose of in any manner, any garbage, waste, peelings of vegetables or fruits, rubbish, ashes, cans, bottles, wire, paper, cartons, boxes, parts of automobiles, wagons, furniture, glass, oil, or anything else of an unsightly or unsanitary nature...in any ditch stream, river, lake, pond, or other water course...or upon the bank thereof where the same is liable to be washed into the water either by ordinary flow or floods."[48] However, this provision does not apply to substances placed in accordance with a permit under the water pollution control provision referenced above "or exempted by such section." Thus it exempts runoff of waste or sediment from agriculture, silviculture, and earthmoving where otherwise regulated, and exempts animal manure generally. The wildlife law prohibition is enforced in local courts as a misdemeanor by wildlife officers or local law enforcement officials.[49] The first offense is punishable by no more than 60 days and/or $500 fine; subsequent offenses by no more than 6 months and/or $1,000 fine.[50] The court may also impose restitution for all or part of any property damage.

Assistance-Oriented Nonpoint Source Programs

This section describes the primary assistance-oriented state, federal, and local programs used in Darke and Belmont Counties to address nonpoint source pollution.

The Stillwater River Watershed Protection Project

The Stillwater River Watershed Project is a locally initiated watershed project. Working with numerous local partners, the project is administered through the Darke and Miami County Soil and Water Conservation Districts. The project's mission is "to protect and enhance the ground and surface water resource base through voluntary land use practices that are both practical and economical."[51] The project began in the late 1980's but received its first formal funding in the form of a Section 319 grant in 1993. Additional funding from the project has originated in many of the programs described in this section. The project has received over $1.5 million from U.S. EPA 319 funding, from state cost share (HB 88) funding, and from the USDA water quality incentive program (WQIP). In addition, reduced interest loans totaling about $1 million have been issued in the watershed under the Linked Deposit Program.[52] Each of these programs is described in more detail below. The $2.5 million in funding expended or loaned for cost share and incentive practices funded work by 216 landowners, many of whom received funding from multiple sources.[53]

The project continues to use a series of inventories to assess the potential for addressing nonpoint source pollution from a variety of sources. Each of 28 subwatersheds in the Stillwater was evaluated on the number of stream miles, the size of the subwatershed, the percent of the subwatershed that is Highly Erodible Land, the number of animal units, the tons of manure produced per acre per year, and the number of on-site septic systems. On the basis of these evaluations, each subwatershed was ranked to identify the areas with the most likely pollution potential. The project then targets funding to the highest ranked areas.[54] One-third of the project's funding (including loans through the Linked Deposit program) has been targeted at the number-one ranked subwatershed, Swamp Creek.[55] Practices funded include no-till, manure holding structures, erosion control, filter strips, and demonstrations of innovative best management practices. Participation in most programs requires that farmers develop an operation and management plan for livestock facilities, and a conservation plan for all cropland. The Darke and Miami County SWCDs develop these plans with funding from their general allocations.

The project is overseen by a 15 member Joint Board of Supervisors, who hire staff to work on the project out of the Darke County SWCD office. The Board is assisted by a full-time project coordinator hired with 319 funding.

Ohio Cost Share Program ("HB 88")

Ohio's cost share program, commonly referred to as "HB 88," provides funding to individual landowners to implement practices to abate nonpoint source pollution from agricultural and silvicultural activities. The program is administered by DNR's Division of Soil and Water Conservation and provides cost-sharing up to 75 percent of the cost of a practice, with a limit of $15,000 per year. The general assembly allocated $1.3 million in 1999 for this program. Locally, the program is administered by the soil and water conservation districts. Funds are allocated first to resolving complaints, in accordance with Ohio's agricultural pollution abatement laws that require cost share assistance to be provided for the installation of management practices to resolve complaints. An individual requesting cost share assistance must have a soil and water conservation plan in order to receive funding, as well as an operation and management plan if the funding is to be used for an animal waste management facility. DNR also provides small grants to soil and water conservation districts through this program for watershed projects; this source of funding is reserved to provide the required local match for EPA's 319 funding.[56]

In the Stillwater River watershed, HB 88 funding of $50,000 was provided in 1994-96 to help 20 farmers with no-till practices, manure holding structures, soil testing, and manure testing. A second grant of $15,000 was recently issued under the nonpoint source grant program for nonpoint source pollution prevention practices in the watershed.[57]

In Belmont County, HB 88 funding has been used primarily for animal waste management. The county has provided between $30,000 and $40,000 to farmers for animal waste management systems. The program does not generally provide cost-share assistance for the installation of silviculture BMPs, regarding these practices as a cost of doing business.

Water Pollution Control Fund Linked Deposit Program

Ohio's Linked Deposit program, administered by Ohio EPA, is a mechanism for the state to provide loans for water pollution abatement activities through commercial lending institutions at below market interest rates. The program was created in 1993, and has since provided $3.5 million in loans to farmers in six participating Ohio watersheds, including the Stillwater, but not including any in Belmont County. Each participating watershed is required to develop (or amend) a watershed management plan, identifying the pollution sources in the watershed, the proposed solutions to pollution problems, the areas which will be prioritized for assistance, the sources of funding, and a schedule for implementing the plan. The plans are generally developed collaboratively by local water quality and agricultural agencies, and must be approved by Ohio EPA.

Individual landowners work with the soil and water conservation district to develop their applications for loans through this program. Each landowner must develop a soil and water conservation plan, and the landowner must present a Certificate of Qualification issued by the district to the local participating bank in order to receive a loan. The bank evaluates the candidate using its own lending criteria. If the bank chooses to issue a loan, Ohio EPA and the Ohio Water Development Authority then deposit funds equal to the face value of the loan through a certificate of deposit with a term equal to the term of the loan. The bank issues the certificate of deposit at a reduced interest rate, and is required to pass along the interest savings to the landowner in the form of a reduced loan interest rate. The bank services the loan according to its normal procedures.[58]

The Stillwater River Watershed has participated in the program since 1995, and has generated about $1 million in approved loans. A total of $5.4 million in loan authority has been approved for this watershed to finance a variety of pollution control practices, including livestock waste handling systems, manure handling equipment, no-till planters and drills, conservation tillage equipment, and erosion and runoff control practices.[59]

Streambanking

Ohio's Streambanking program is funded by bonds issued under the state's Natureworks bond program. It is intended to establish and conserve forested stream buffers. DNR provides grants to soil and water conservation districts working in cooperation with local park districts or nonprofit land trusts for the purchase of easements or fee-title interests in land. In order to participate, the district and its partners must develop a Riparian Area Protection Plan that includes an inventory of areas in need of improvement or protection, identification of tools to protect areas, and short and long term goals for the watershed. The district must hold the easements or fee ownerships acquired under this program for at least 15 years, and monitor easements annually.[60]

The Miami County soil and water conservation district spearheaded the Streambanking effort in the Stillwater River Watershed, in partnership with the Miami County Park District. The program has purchased seven easements since 1995, protecting 104 acres. Of the acreage enrolled, 84 acres were forested and 20 were cropland. Two of the acquisitions were fee-simple purchases of potential development sites, near or adjoining parcels owned by DNR. These parcels totaled almost 7 acres. The remaining 97 acres are easements on privately owned lands. The total cost of all easements has been close to $150,000.

Belmont County does not participate in the Streambanking program because of the county's topography. The narrow stream gullies make stream buffers a lower priority for most landowners, and cropping rarely extends near streams.

Natureworks Watershed Management Program

A state program funded by the same bond issue as the Streambanking program, the Watershed Management program provides up to $250,000 to watershed projects for cost sharing management practices. By supplementing on-going federal cost share programs, the program provides anywhere from 50 to 100 percent of the cost for materials and installation of water quality improvement practices. Funded practices include stream fencing for livestock exclusion, riparian buffers, streambank stabilization, stream habitat restoration, and animal waste practices. All practices funded under this program must be maintained a minimum of 15 years.[61] The Stillwater Watershed Project has received $250,000 from this program. Funding has been used to install erosion control measures, construct animal waste storage facilities, and improve wetlands and wildlife habitat.[62]

Ohio's 319 Program

Ohio EPA administers the state's 319 program, federal nonpoint source funding available from U.S. EPA under the Clean Water Act. Ohio has received around $3 million annually in 319 money, but received $6 million with the incremental federal funding available in 1999. The federal program requires a 40 percent state match for all funds granted.

The Stillwater River Watershed Project has received three grants through the 319 program totaling approximately $550,000 since 1993. The initial grant, received in 1993, constituted the first funding for the project, and provided funds to test innovative management practices, help purchase manure handling equipment, construct streambank stabilize measures, and hire a project coordinator. Further grants have similarly provided funding for BMP installation and a project coordinator.[63]

Belmont County and 3 adjacent counties receive 319 funding for a project on their Stillwater Creek watershed (unrelated to the Miami-Darke County Stillwater River watershed) which crosses four counties. The grant of $209,000 provides funding for tree planting on reclaimed strip mines, pasture management practices, and livestock watering systems.

USDA Environmental Quality Incentive Program

The Water Quality Incentive Program (WQIP) was replaced by the Environmental Quality Incentive Program (EQIP) in the 1996 Farm Bill. These cost share programs are designed to reduce agricultural nonpoint source pollution problems in small watersheds. The Stillwater Watershed Project received over $500,000 in two grants over a six year period from this program. The funding was directed to projects in two subwatersheds for no-till practices, well-testing, and ICM plans.

Belmont County has also received some funding from EQIP. In 1999, Belmont County also received $300,000 in emergency funding from USDA and state sources due to drought conditions. The funding was provided for livestock watering systems and the purchase of hay.

USDA Conservation Reserve Program

The Conservation Reserve Program (CRP) is administered by the USDA Farm Services Agency. Under CRP, agricultural landowners can apply to enroll their highly erodible and environmentally sensitive lands. In return, landowners must enter into 10-15-year contracts with USDA, under which they agree to convert highly erodible cropland or other environmentally sensitive acreage to vegetative cover, native grasses, wildlife plantings, trees, filterstrips, or riparian buffers.[64] Landowners participating in CRP can receive up to 50 percent of the costs of establishing the approved practices. Landowners may also be reimbursed for up to 25 percent of the cost of restoring wetlands.[65] There are 4100 acres in Darke County enrolled in CRP.

Forestry Practices Information

Ohio does not have a specific cost-share program for forest harvest operations. Belmont County addresses forestry issues through information and outreach to loggers and landowners. The soil and water conservation district has held two outreach programs for landowners on forestry requirements and BMPs. One hundred and twenty two landowners attended these workshops. The soil and water conservation district created a timber packet for landowners with information on best management practices (BMPs), a sample contract, a list of certified loggers, and a sample O&M plan that it will send upon request. There is a full time forester on staff in the district, but requests for assistance exceed availability. Generally, the requests for assistance are from private landowners who are interested in improving or created forested areas on their land. Ohio recognizes a voluntary program for certification of loggers. To become certified, loggers must attend a one day training course on BMPs and pass an exam. However, there is no requirement that loggers become certified or that landowners use certified loggers. The soil and water conservation district has held a logger certification training course.

Discussion and Analysis

Agriculture and Silviculture

Chief's orders play a minor role in Ohio's agriculture and silviculture nonpoint source controls. Traditional cost-share, education, and technical assistance mechanisms are the heart of the program.

DNR's Soil and Water Conservation Division surveys the state's 88 soil and water conservation districts every 3 years to determine how they are responding to complaints. Statewide statistics compiled by the Division in 1997 show that urban stormwater was the leading source of formal and informal complaints, followed by construction runoff, animal waste, rural flooding, and silviculture impacts. The districts receive only about 200 complaints per year statewide from the public about agriculture and silviculture pollution. Of the *formal* pollution complaints received by the districts concerning agriculture and forestry statewide in 1996, 121 concerned animal waste, 23 cropland erosion, and 44 silviculture erosion. Of the formal complaints fielded by the districts concerning agriculture or silviculture, only about 2-5 each year lead to district requests for chief's orders, and even fewer of these result in the issuance of chief's orders.

The Belmont County soil and water conservation district has requested issuance of chief's orders with respect to sediment pollution from logging operations. In 1998, the district requested 3 chief's orders, 2 of which were for logging-related pollution. In both of the logging cases, operators had damaged the areas logged and left the sites. The district contacted the operators numerous times regarding the violations, and sent certified letters as required by law. When the operators did not respond to the district, it forwarded the complaints to the chief. Although orders were drafted, they were not yet issued when the operators agreed (at the encouragement of the local forestry association) to install required practices, including mulch, seeding, and waterbars. The administrative and chief's order request process took between twelve to fifteen months, and the on-site remedy occurred long after the completion of the logging operations.

Because of concern with the timeliness and effectiveness of chief's orders in encouraging operators to avoid pollution (since it is an after-the-fact abatement mechanism rather than a provision for sound logging practices), the Belmont County soil and water conservation district's board of supervisors passed a motion seeking to have the county require a permit for logging in order to gain closer control over logging practices. Such a permit would have required logger adherence to BMPs and following an operations and maintenance plan as a condition of being allowed to operate in the county. (Ohio's agricultural pollution abatement law provides that forestry operators "may" file an operations and maintenance plan with the soil and water conservation district.[66] The districts therefore accept these plans only if volunteered; they cannot require them). The county permit system proposed by the district board was opposed by DNR and by the logging industry, and is no longer under active discussion. DNR increased its education and informational outreach for loggers; and formal complaints related to pollution caused by silvicutural activities decreased in Belmont County. The district reports that it received no complaints related to silviculture in 1999.

The Darke County soil and water conservation district has had among the highest number of citizen complaints about animal operations. Most of these have related to odors rather than to water pollution. This district has never requested a chief's order. Pollution related complaints have all been resolved informally, frequently including the provision of cost-share money as part of the remedy. The existence of the Stillwater River Watershed Protection Project has, in effect, provided a well-funded infrastructure for technical assistance and cost shares that has forestalled the use of enforcement tools.

Financial assistance for producers needing to address livestock pollution problems statewide in Ohio has come from a variety of sources: 38 percent received state funds, 38 percent received USDA program funds, 14 percent required no assistance, 6 percent received § 319 funds, 3 percent received NatureWorks funds, and 1 percent received other funding assistance.[67] Soil and water conservation districts identified the primary practices needed to correct livestock pollution as storage facilities, facility management, runoff control, and nutrient utilization practices. Statewide statistics show that about 2/3 of the agricultural cost share funds administered by the Division of Soil and Water Conservation in recent years have been allocated to addressing complaints (about $647,000 in fiscal year 1998, for example).[68] Requiring cost-shares as a condition for enforcement has been criticized as "paying the polluter."

Ohio has had only 3 chief's orders that couldn't be resolved at the Division level in the last 10 years and that had to be forwarded to the Attorney General for enforcement in court. Referrals to the Attorney General are a last resort for the Division, both because the process is perceived to be time-consuming and because the Attorney General bills the Division for time spent on Division matters. Two of the three cases referred for judicial enforcement subsequently settled, while the third did not but is still expected to settle (culminating a 4-5 year process since the original complaint).

The Ohio system is geared to voluntary compliance at every step, so it is not a speedy process. Both state and local officials noted that the process is unwieldy and slow, and enforcement comes into effect only in the most prolonged of cases. The soil and water conservation districts wish the enforcement process were quicker after they request a chief's order, largely because they seldom refer any cases for chief's orders until they have themselves exhausted every opportunity for informal resolution.

The DNR's Division of Wildlife plays a role in nonpoint source enforcement when there is a fish kill directly attributable to activities on the land. There is a wildlife officer in each county. For a first offense, Wildlife generally refers the situation to the soil and water conservation district if less than $50 in fish are involved in the kill. If a claim of more than $50 is involved, then the Division of Wildlife seeks restitution from the discharger itself – sending a bill for fish and for investigative costs, and offering settlement. If there is no settlement, then the Division seeks a criminal fine and payment of restitution. For repeated offenses, the Division of Wildlife proceeds criminally. Under the stream litter and nuisance provisions, the potential sanctions are up to $500 and/or 60 days in jail (fine up to $3,000 if a corporate violator). Soil and water conservation district staff report that wildlife officers are hesitant to enforce against agricultural or silvicultural pollution because there is some uncertainty as to whether natural substances such as sediment (or tree tops) would be considered stream litter by local judges.

Urban Stormwater/Nonfarm Program

The Division of Soil and Water Conservation developed standards for urban runoff, but has no enforcement authority in this area. Ohio EPA has authority to issue enforcement orders. Ohio EPA has Memoranda of Understanding (MOUs) with 17 soil and water conservation districts on stormwater. These mostly urban counties do local education on erosion control at construction sites, and review notices of intent to construct. Some also conduct inspections. Local governments also have regulatory and enforcement authority.

Conclusions

Ohio DNR's chief's orders present a unique state-based mechanism to address agricultural or silvicultural nonpoint source pollution when soil and water conservation districts cannot resolve matters voluntarily. However, the process depends heavily on voluntary and cost-share programs, requires provision of cost-shares where cost-sharable practices are needed, and takes a great deal of time. The wildlife officer enforcement option is useful in the case of fish kills traceable to particular activities and has been used. Ohio EPA has little enforcement authority with respect to nonpoint source water pollution.

Oregon Case Study

Summary

This study surveys enforceable legal mechanisms for nonpoint source pollution control in Oregon, together with a variety of voluntary and assistance-oriented approaches, as illustrated by practice in two watersheds, the Tualatin River Basin and the Grande Ronde River Basin.[1] The three mechanisms studied include: (1) watershed-level management planning under SB 1010, Oregon's Agricultural Water Quality Act; (2) enforceable best management practices under the Oregon Forest Practices Act and its accompanying rules; and (3) implementation of water-related planning goals through Oregon's statewide comprehensive land-use planning law, which is unique in the nation.

Each of these mechanisms has become a key element of Oregon's attempts to meet not only state water-quality goals and federal TMDL requirements, but also the habitat concerns raised by recent Endangered Species Act listings of several salmonid species. In this context, there has been much discussion in each of the affected sectors as to whether the existing state-law mechanisms can be made adequate to implement federal mandates, or whether more stringent regulation will be needed in the future. In agriculture, debate centers on current policy approaches that favor stakeholder participation and voluntary compliance versus expanded use of SB 1010's relatively untested enforcement and penalty sections; in forestry, where water quality provisions have been enforced for some time, on the adequacy of existing management practices for ensuring continued protection of salmon habitat; and in the urban sector, on the application of generally-worded statewide planning goals to local water quality issues, and their translation into enforceable local ordinances.

Coupled with both new and ongoing programs to encourage voluntary control of nonpoint sources, these enforceable legal mechanisms also are at the core of overarching initiatives by the Governor's Office and the Oregon Department of Environmental Quality to integrate water-related issues statewide. A common aspect of both the voluntary and enforceable mechanisms is their emphasis on planning and management at the watershed level. The two watersheds studied served as models for the approaches now being undertaken, and highlight the path that is being followed in other watersheds throughout the state.

Tualatin and Grande Ronde Watersheds

! The *Tualatin River Basin*, just southwest of the Portland metropolitan area, is about 80 miles long and a tributary of the Willamette River. Its drainage basin is approximately 43 miles long and 29 miles wide, and covers an area of 712 square miles.[2] Over half of the watershed is forested, one-third is agricultural, and fifteen percent (70,000 acres) is urban,[3] including the Portland metropolitan area communities of Tigard, Beaverton, and Hillsboro as well as the cities of Tualatin, Sherwood, and Forest Grove.[4] It is one of the fastest-growing areas in the state, with forecasts of 400,000 additional people living in the Metro region (which includes the Tualatin Basin) over the next twenty years.[5] The river is the major source of drinking and irrigation water in its valley, but the

Oregon DEQ has designated it and its tributaries as "Water Quality Limited."[6] "Tualatin" derives from an Indian word meaning "slow and lazy" – an accurate description of the river's meandering course. For this reason, shading and temperature issues are prominent in the basin, alongside more traditional concerns about discharges and runoff.

The Tualatin basin was chosen for study because it combines agricultural, forest, and urban issues, and thus is affected by each of the enforceable mechanisms examined. In addition, due to a long history of litigation over water quality issues, the basin was among the first to fully develop and adopt various federal and state programs for water quality management and nonpoint source pollution control. It has the oldest TMDL in the state, and also was the first to adopt an agricultural water quality management plan under Oregon law. The basin's early adoption of these mechanisms means that they have recently become eligible for active enforcement action, including enforcement against nonpoint sources.

! The study also briefly examined the *Grande Ronde River Basin* in Northeastern Oregon. This basin, which is centered on the city of La Grande, encompasses the Blue Mountain region, covers more than 5,000 square miles, and includes 280 streams and rivers that contain 2,900 miles of fisheries.[7] Land ownership in the basin is approximately 65% public land and 35% private land.[8] In Eastern Oregon, nonpoint source issues are concentrated in the agricultural sector, and center on ranching, grazing, and irrigation practices and their effect on water quality and stream temperature. A chief concern is the declining population of Snake River spring chinook salmon, which is listed under the Endangered Species Act.[9] The basin was chosen for study because it is frequently cited as an example of a strong voluntary effort -- the Grande Ronde Model Watershed Program, described in detail below -- that predated and provided a solid foundation for more recent planning and regulatory mechanisms in the agricultural sector.

Enforceable Mechanisms Studied

Of the Oregon nonpoint source enforceable mechanisms described in the *Almanac*,[10] the following were reviewed in detail because of their particular relevance to ongoing statewide efforts to control nonpoint source pollution, as illustrated by the Tualatin and Grande Ronde watersheds.

! *Agricultural Water Quality Act (SB 1010).* This 1993 law, still commonly referred to by its bill number, authorized the Oregon Department of Agriculture (ODA) to designate areas to be governed by a water quality management plan and to adopt rules that require landowners in the affected area to perform those actions necessary to carry out the plan.[11] In general, once a plan is implemented, all activities, including pesticide use, irrigation, and grazing, within the affected area of the plan must be conducted "in full compliance with the plan and rules implementing the plan and with all rules and standards of the [Environmental Quality Commission] relating to water pollution control... ."[12]

In 1995, SB 1010 was supplemented and strengthened by SB 502, which required ODA to develop and implement programs and rules "that directly regulate farming practices that are for the purpose of protecting water quality" and that are applicable both to exclusive farm use zones under the state planning law and to other lands where agricultural practices are taking place.[13] ODA has interpreted this mandate as giving it exclusive authority to regulate agricultural activities that affect water quality.[14] The water quality management plans themselves are developed through a public process in individual watersheds, with priority given to impaired watersheds listed under § 303(d) of the Clean Water Act. ODA has enacted administrative rules to ensure consistency and uniformity in the planning process throughout the state.[15]

ODA is authorized to determine compliance with the management plans through entry and inspection, but must give a notice of violation and an opportunity for compliance prior to assessing a civil penalty. Penalties can be up to $2,500 for the first violation and up to $10,000 for a second violation.[16] In addition, violations of the plans and/or administrative rules are subject to all remedies and sanctions available to the Oregon Department of Environmental Quality (DEQ) or Environmental Quality Commission.[17]

! *Oregon Forest Practices Act.* Under the Oregon Forest Practices Act, the Oregon Board of Forestry must establish best management practices (BMPs) "to insure that to the maximum extent practicable nonpoint source discharges of pollutants resulting from forest operations on forestlands do not impair the achievement and maintenance of water quality standards."[18] Forest operators are required to comply with these BMPs, unless they can demonstrate that alternative practices will yield better results.[19] If forest operators are in good-faith compliance with the BMPs, then their operations are given a safe harbor from enforcement, and considered not to be in violation of any water quality standards.[20] BMPs can be subjected to review pursuant to a petition alleging that existing forestry operations conducted in accordance with them are nonetheless contributing to violations of water quality standards. Upon receiving such a petition, the Forestry Board must either revise the BMPs within two years or dismiss the petition;[21] if it fails to issue revisions or dismiss the petition within the specified time, then water quality standards may be enforced directly against forest operators.[22]

Aside from requiring BMPs, the Act also contains specific requirements governing forestry operations. Forest operators must give written notice of all operations to the State Forester, and interested parties may subscribe to receive notification of all proposed operations. Similarly, when operators give notice of chemical applications, the State Forester must notify persons within 10 miles of the application, if those persons have requested such notice and hold downstream surface water rights.[23] The Board of Forestry also has authority to require a written plan for operations conducted within 100 feet of a stream used by fish or for domestic use, or within 300 feet of an area that contains threatened or endangered species, sensitive bird nesting or roosting sites, or significant wetlands.[24]

The State Forester enforces all of these requirements through inspection, citations, and issuance and service of administrative orders, such as cease and desist or reparation orders.[25] No penalties may be imposed unless a citation is issued.[26] The Act provides for general criminal and civil penalties,[27] including potential civil sanctions of up to $5,000 per violation.[28]

! *Statewide comprehensive land-use planning.* Oregon has a comprehensive statewide land-use planning law that in part provides for the protection in local comprehensive plans of a variety of environmentally sensitive areas, including flood plains, estuarine areas, wetlands, lakes, coastal areas, and wilderness and scenic areas.[29] The Department of Land Conservation and Development (DLCD) also has authority to designate "areas of critical state concern" as part of the planning process.[30]

The law is implemented through a series of statewide planning goals, including goals that can be applied to cover nonpoint sources. These goals must be complied with in the development of city and county land use plans and implementing regulations, which govern community growth and development. Of particular relevance are Goal 5, which relates to natural resource protection; Goal 6, which covers the quality of air, water, and land resources; Goal 7, which protects floodplains and other areas subject to natural disasters and hazards; and Goals 3 and 4, which govern agricultural lands and forest lands, respectively. The plans were submitted to DLCD for initial review and "acknowledgment"; once acknowledged by the Department, the plan, rather than the goals, is the controlling legal authority. However, the plans also are subject to periodic review, especially as the planning goals change and evolve.

Local governments then enforce these requirements through their police power. In the "areas of critical state concern," the Commission, as well as the county governing bodies, has investigative and hearing authority for alleged violations, and injunctive relief also is available;[31] however, the Commission has not yet exercised its authority to designate these areas. Remedies for noncompliance of a local plan with the statewide goals include withholding state grant money to local governments, as well as legal and equitable remedies.[32]

These three enforceable mechanisms were chosen for their relevance to nonpoint sources in the Tualatin, Grande Ronde, and other key watersheds not examined in this study. The interaction among these state-level enforceable mechanisms, between these mechanisms and federal pollution control law, and between these mechanisms and Oregon's voluntary, technical assistance, and cost-share nonpoint source pollution programs is complex. Statewide coordination of many of these programs is occurring under the "Oregon Plan," a recent initiative sponsored by the Governor's Office. The Oregon Plan and several of the new and traditional assistance-oriented mechanisms for nonpoint source control are discussed in the next section.

Voluntary and Assistance-Oriented Nonpoint Source Programs

The Oregon Plan for Salmon and Watersheds/Watershed Councils

The Oregon Plan for Salmon and Watersheds is the umbrella for a number of related activities aimed at improving water quality, including nonpoint source control. Developed and administered by the Governor's Office in 1997 in response to declining fish populations and proposed listings of salmonids under the Endangered Species Act (ESA), and affirmed by executive order in 1999, the Oregon Plan establishes three main priorities: (1) achievement of water quality standards through federal and state law and technical assistance through the "Healthy Streams Partnership"; (2) restoration of native fish populations; and (3) watershed assessment and restoration, largely through encouraging and funding the creation of local watershed councils in each basin. The

Oregon Plan's emphasis on basin-level improvements is meant to represent a "place-based" approach to meeting water quality goals.

Central to the Oregon Plan is the distinction between watershed restoration activities, which seek to undo past harm, and planning and regulatory mechanisms that address ongoing pollution. Restoration activities are the primary focus of the watershed councils, and are coordinated at the state level through the Oregon Watershed Enhancement Board (OWEB, formerly the Governor's Watershed Enhancement Board or GWEB). Since July 1997, OWEB has awarded almost 568 grants totalling $39 million to assist with implementation of watershed restoration projects. OWEB's work has included not only grants and other support to the watershed councils, but also projects such as the development of a watershed assessment manual for the councils' use. The Board also has played a role in facilitating coordination among state agencies on water policy.

The watershed council concept emerged from the "Watershed Health Program," a two-year trial program that appropriated ten million dollars between 1993 and 1995 to help create watershed councils in each of two trial basins -- the South Coast and the Grande Ronde -- and worked to integrate state-funded programs and Section 319 efforts in those basins. When this program ended, the remaining activities were incorporated into GWEB. With new funding through the Oregon Plan, 90 watershed councils have now been established statewide. DEQ works with and participates on the watershed councils, largely through training on data collection and sampling, and the other state natural resource agencies also play a major role.

The Oregon Plan also incorporates the Healthy Streams Partnership, a 1997 initiative to forestall additional regulation by developing a series of agreed-upon principles for integrating Clean Water Act and TMDL requirements with aquatic systems preservation and fish habitat needs. The Partnership consists of a stakeholder process supported by the state's commitment to carry out certain regulatory objectives, such as SB 1010 implementation and TMDL development, and to increase agency staffing. The goals of the Partnership include investing in state water resources under existing legal authorities; developing TMDLs for all 92 sub-basins; and developing a stakeholder focus that emphasizes collaborative processes.

In 1997, a total of $30 million was appropriated for implementation of the various aspects of the Oregon Plan, $20 million of which was earmarked for cost-share grants through OWEB. Sources of these funds included timber tax revenue ($13 million), a surcharge on salmon fishing licenses ($1 million), contributions from the concrete industry ($1 million), and monies from the state's general fund ($5 million). In 1998, a ballot initiative passed a constitutional amendment that dedicates 15% of state lottery funds to ongoing support of these initiatives. The amendment is in place for fifteen years, and is expected to yield $30-40 million every two years. These allocations allowed the creation at both the Oregon Department of Environmental Quality and the Oregon Department of Agriculture of 19 new staff positions specifically devoted to water quality issues and to working with the watershed councils.

While the political, financial, and human resources invested in the Oregon Plan have been substantial, some NGO representatives charged that the Governor's Office "significantly oversells the role and efficacy of watershed councils" as a primary solution, favoring them over regulatory approaches. According to these critics, the council process is slow, taking years to draft a restoration workplan for the Tualatin Basin, much less to address regulatory issues. Further, they claimed, the emphasis on involvement of all stakeholders circumvents development of regulatory approaches where they are needed. However, even these NGO sources acknowledged that watershed councils are critical for promoting communication and coordination within a basin, and have served that purpose very well.

The Tualatin River Watershed Council was formed in 1993. The Unified Sewerage Agency, which serves the urban areas of Washington County, was a major force behind initiating the watershed council, even before the Oregon Plan was in place. The Council's stated purposes are to: "increase local input in management of watershed resources; initiate resolution of problems and issues within the watershed; identify problems and issues of importance to local citizens, groups, and users of the watershed; diminish and eliminate further degradation of the watershed and its resources through better management practices; increase the viability, diversity, and health of the watershed; undertake a proactive approach in management of the watershed; [and to] create and implement a watershed action plan encompassing, but not limited to, current and potential problems and issues, potential solutions, restoration/enhancement measures, and monitoring programs within the Tualatin River Watershed."[33]

Like other watershed councils throughout the state, the Tualatin River Watershed Council is not itself an enforcement agency, instead making recommendations to policymakers.[34] It consists of twenty members who represent key interests in the watershed (citizens, agriculture, business and industry, environmental groups, forestry, education, local governments, chambers of commerce, and water and sewer providers), and attempts to reach its decisions by consensus.[35] In 1996, the Council was officially recognized by the Washington County Board of Commissioners, applied for and received an operating grant from the GWEB, and hired a full-time coordinator.[36] In January 1999, the Council adopted the Tualatin River Watershed Action Plan -- "a long-term vision on how to improve water quality, improve fish and wildlife habitat, minimize soil erosion, minimize flooding, and increase recreational opportunities within the Tualatin River Watershed" that strives to integrate existing plans and efforts within the watershed.[37]

The Council views the Action Plan as a technical review that helps set its priorities and define in concrete terms the necessary conditions for ensuring the health of the Tualatin watershed. In addition to this core work, the Council responds to immediate challenges, such as watershed health emergencies and new issues, as they arise. The members interviewed felt that the effort is working well so far, although some noted that the possibility of stricter ESA mandates could present a challenge for the cooperative process. Council representatives have been effective in dealing with their constituencies on smaller problems -- for example, a 1996 flood that caused mudslides on forest land -- but the Council hasn't yet tackled anything as controversial or as comprehensive as the ESA.

Model Watershed Program

The Grande Ronde Model Watershed Program was established in 1992, one of three such programs created in Oregon, Idaho and Washington by the Northwest Power Planning Council. In the Grande Ronde, the Union County and Wallowa County Commissions had foreseen the imminent ESA listing of spring chinook salmon and "determined that a grass-roots, locally-based effort working to coordinate existing local, state and federal programs could effectively maintain, enhance, and restore [the] watershed."[38] The Grande Ronde Program was one of the original models for watershed councils statewide, and continues to act as the watershed council for the Grande Ronde basin. It works closely with the local (Union County and Wallowa County) Soil and Water Conservation Districts, which help implement some of the Program's initiatives.

The Program received initial funding from the Bonneville Power Administration (BPA) and the Bureau of Reclamation, followed by five million dollars from the Watershed Health Program. The BPA has continued to provide funding for administration of the Program, as much as 65-70% of its annual budget. The Program also receives funds or in-kind support from the Bureau of Reclamation, Oregon Watershed Enhancement Board, Natural Resource Conservation Service, and the Union County and Wallowa County SWCDs.

The restoration projects have included small modifications with immediate results, such as upgrading irrigation diversions to allow fish passage; channel restoration, which already has led to significant temperature reduction; and projects, such as fencing and livestock exclusion, vegetation and shading, that are expected to have longer-term results. About 100 projects were undertaken in 1994-95. Since then, between thirty and forty additional projects have been proposed each year, approximately thirty of which get funded -- a total of 260 to date. Funding decisions are made by the Program's Board with the assistance of a technical committee, composed of ten representatives from relevant agencies, that reviews all project proposals and recommends funding priorities to the Board. In addition, OWEB has its own process for reviewing and funding restoration projects, and last year at least fifteen or twenty of these were in the Grande Ronde basin.

The Program maintains a database that keeps track of all restoration projects dating back ten years, and serves as a clearinghouse for that data. Each funded project over a certain size has a monitoring component that requires monitoring for five years, and this data also is made available. In addition, there is a basin-wide water quality monitoring program that is administered through the Union County SWCD, and established to coordinate the activities of the many agencies that were conducting monitoring. The monitoring program's goal is to gather baseline data on temperature, nutrients, sedimentation, and so forth, and to track long-term changes in water quality.

Federal Farm Bill Programs

The various U.S. Department of Agriculture programs for nonpoint source pollution control are administered through the Oregon offices of the Natural Resource Conservation Service, which is headquartered in Portland. The Service's mandate is to provide landowners and local Soil and Water Conservation Districts with technical assistance for carrying out USDA programs. In addition to its regular activities, as part of the Oregon Plan the Service has signed an MOU with the Governor's Office, the EPA Region X office, and NMFS to assist with consultation on ESA issues affecting private lands. NRCS has around 30 field offices in Oregon and 135 staff positions, of which at least two-thirds are in the field.

The Oregon Department of Agriculture coordinates with NRCS to leverage the available funding. The two agencies have formed the "Conservation Partnership," a consortium of agency representatives from ODA, NRCS, the local SWCDs, and the Oregon Association of SWCDs, which meets monthly or bi-monthly to work through issues of common interest. In practice, most implementation activity occurs through the local Soil and Water Conservation Districts, where the real integration happens -- the SWCDs are the direct recipients of both USDA/NRCS and ODA funds.

In 1999, USDA programs active in Oregon included: the Environmental Quality Incentives Program (EQIP), which was described as "the heart and soul" of the Farm Bill programs, with $3.9 million allocated for cost-share assistance in FY 99; the Wetland Reserve Program (WRP), with $1.5 million allocated; the Wildlife Habitat Incentives Program (WHIP), largely focused on threatened and endangered species issues, which had $0.5 million allocated for FY 99 but is unfunded for FY 2000; and the P.L. 556 small watershed program, which has provided "a few million dollars" in targeted planning assistance to address local-level concerns such as watershed plan development and implementation.

Program funding is targeted primarily at identified priority areas within the state. Since Oregon organizes its efforts on a watershed basis, the NRCS has followed suit, creating basin workgroups and local workgoups within the basins that are composed of representatives from NRCS, the local SWCDs and other relevant parties. These workgroups identify resource issues needing attention, set priorities, and make funding recommendations to the State Technical Committee. This approach has been fairly successful; thus far, the greatest limiting factor has not been funding per se, but rather the low availability of technical assistance to implement activities once they are funded.

Recent (FY 98) priority areas for EQIP funding have included the John Day/Umatilla Basin ($742,000), Snake River Basin ($492,000), North Coast Basin ($442,500), Deschutes/Hood Basin ($709,500), Southwest Basin ($481,000), Lower Willamette Basin ($537,000), Central Coast/Upper Willamette Basin ($328,000), and the High Desert Basin ($384,000). However, the Service attempts to fund at least the top priority project in every basin, in order to maintain its presence across the state. In these and other projects statewide, there is a current focus on three issues: salmon habitat, promotion of healthy watersheds, and the Mid-Columbia Plateau.

The NRCS also has a history of providing technical assistance and funding to the Tualatin Basin, dating back to the 1980s. The Tualatin was designated as a "hydrologic unit area," an experimental ground for watershed modeling and testing theories. In addition, the Service has worked on the social aspects of agricultural issues in the basin, including sponsoring focus groups to get the local communities involved and to help them recognize water quality problems.

In addition to the programs described above, Oregon has developed a program under the USDA's Conservation Reserve Program (CRP) and Conservation Reserve Enhancement Program (CREP). Approved in late 1998, the Oregon CREP will be funded at approximately $250 million dollars over 15 years, with 80% coming from the federal government. The program, which is designed to assist in restoration of habitat for salmon and trout listed under the ESA, will restore freshwater riparian habitat along 4,000 miles of streams throughout the state. Agricultural landowners are eligible to enter into 10- to 15-year contracts to plant long-term vegetative cover and exclude livestock in exchange for cost-share and technical assistance. Program goals include: reducing temperature to natural ambient conditions; reducing sediment and nutrient pollution from agricultural lands adjacent to streams by more than 50 percent; stabilizing stream banks along critical salmon and trout streams; and restoring stream hydraulic and geomorphic conditions. The state will conduct monitoring throughout the project to evaluate and record progress in achieving these goals.

Section 319 Program

According to the Oregon DEQ, "grant funds available through Section 319 of the Water Quality Act of 1987 are a critical element in turning Oregon's NPS control program into water quality protection realities in watersheds throughout the state."[39] Section 319 funding totalled $8.7 million dollars between 1991 and 1998, with a budget of $1.35 million in both 1997 and 1998.[40] According to DEQ, funding originally tended toward a large number of smaller projects, peaking in 1994 when EPA approved 32 projects averaging $44,400 each. Starting in 1995, this trend was reversed, "emphasizing fewer, bigger, and longer projects in order to address needs for whole watershed enhancement, to sustain this effort over enough time to effect significant improvements, and to avoid the growing administrative burden on DEQ resulting from having 50 to 60 projects active simultaneously."[41]

The Department has worked to prioritize and apply its Section 319 funding in the basins where TMDLs are needed, because there is more knowledge about water quality concerns in those basins and therefore a greater degree of certainty that money spent will be used directly to meet or achieve water quality standards. In channelling Section 319 funding, DEQ works closely with the local watershed councils. Similarly, Section 319 funds also have provided some support for the local advisory councils and development of water quality management plans under SB 1010, and have been applied to water-quality-related revisions of the Oregon Forest Practices Act.

In the Tualatin Basin, the Section 319 program has funded projects designed to "increase local involvement and stewardship in nonpoint source pollution control projects and contribute to environmental education and water quality monitoring."[42] These include the Dairy-McKay Hydrologic Unit Area Project, which studies the link between agricultural BMPs and water quality; and the Student Watershed Research Project, which encourages middle- and high-school students to monitor water quality data throughout the Tualatin and add it to a regional watershed database.[43]

Discussion and Analysis

Agricultural Water Quality Management Plans (WQMPs)

In 1993, the Oregon Legislature passed Senate Bill 1010 (SB 1010), which directs the Oregon Department of Agriculture to work with the state's agricultural community on non-point source water pollution control. Under the legislation, ODA is authorized to develop and implement watershed-based water quality management plans (WQMPs) that identify measures landowners can use to prevent and control water pollution. ODA must initiate the planning process once water quality concerns have been identified in a watershed and a management plan becomes required by any state or federal law. In practice, EPA's Section 303(d) list of water-quality-impaired watersheds is the strongest driver for watershed planning.

Combined with Senate Bill 502, which further called upon ODA to develop and implement programs and rules that regulate farming practices for the purpose of water-quality protection, this legislation gives ODA exclusive responsibility for regulating agricultural practices that affect water quality. The Department's authority extends to any land being used for agricultural purposes, regardless of its designation under the state land-use planning law or local zoning laws. Although the Department prefers to emphasize technical assistance and other non-regulatory approaches for nonpoint source control, SB 1010 provides enforcement authority when voluntary measures prove insufficient for ensuring compliance with the WQMPs and rules.

ODA has established a four-year time frame for WQMP development in impaired basins. In parallel, the Oregon DEQ has established a ten-year time frame for its issuance of Clean Water Act TMDLs that will cover many of the same basins and apply to many of the same non-point sources. As a result, the WQMPs already in place have in part served as "early action plans," which contain enforceable conditions intended to minimize nonpoint pollution, even before specific TMDL numbers have been calculated and allocated among the various point and nonpoint sources within the basin. ODA acknowledges that its four-year timetable is ambitious, but notes that it has roughly been able to adhere to this schedule, allowing for some initial delays in starting up the process. While only a few final plans are in place at the time of this study, many more are in draft form, and a number of final plans will be issued over the next six months to one year.

To ensure consistency and uniformity in plans throughout the state, ODA has adopted rules governing the process for plan development and enforcement.[44] Although ODA retains the ultimate decision-making authority, these rules call for public consultation with ad hoc local advisory committees (LACs) composed of various stakeholder representatives from the basin. Local advisory committees are distinct from the watershed councils promoted under the Oregon Plan, but there is considerable overlap between the two, and it is generally felt that inclusion of watershed council members on the local advisory committees helps to promote coherence and collaboration.

As developed through this stakeholder process, the WQMPs establish both general goals for the basin (for example, reduction of sediment loading) and performance standards designed to encourage or discourage certain activities consistent with these goals. In crafting the plans and their accompanying rules, ODA's goal is to leave flexibility for landowners to achieve performance standards through the practices they deem most appropriate for their operations. These can include adoption of specific BMPs. After being developed by the LAC and reviewed by ODA, the rules are issued through a formal rulemaking process, and thus go through an additional round of notice and comment before becoming final. They then are given to the appropriate local management agency -- usually the county soil and water conservation district or districts -- for implementation. In many cases, a year or more may elapse from the time a local advisory council is appointed until the rulemaking process is finalized.

The Tualatin River Basin is noteworthy for having adopted Oregon's first agricutural water quality management plan, in April 1996; it also has the state's first TMDLs, for phosphorus and ammonia, which were issued in 1988 and approved by EPA in the early 1990s. Significantly, there is a history of controversy and litigation that played a role in attaining these milestones, including citizen suits that established the TMDL process and subsequent lawsuits to enforce TMDLs. In effect, the existing nonpoint source control measures in the basin stemmed from point source concerns during the 1980's, when local environmental groups went to court over pollution from thirty municipal wastewater treatment facilities. In 1986, the Northwest Environmental Defense Center filed a lawsuit against Oregon DEQ and U.S. EPA for failing to set effluent discharge limits within 180 days, as required by the federal Clean Water Act -- the first successful suit in the nation to require enforcement of the total maximum daily load provision of the Act.[45]

This case was resolved in part by a consent decree that divided the area into forest, agriculture, and urban districts, assigning load allocations for each, and assigning responsibility for meeting the allocations to different local management agencies. For forestry, the designated agency is the Oregon Department of Forestry; for agriculture, the Oregon Department of Agriculture, which can delegate its authority to the local Soil and Water Conservation Districts; for urban, the Unified Sewerage Agency (a regional agency that covers twelve cities), Clackamas, Multnomah, and Washington Counties, and the cities of Portland, Lake Oswego, and West Linn. In short, the consent decree mandated a cooperative, cross-sectoral planning process well before the enactment of SB 1010.

Indeed, the substance of what became SB 1010 was pioneered by the Washington County Soil and Water Conservation District, which helped implement the judge's decision for the agricultural sector. The SWCD developed an approach through a public procedure that involved all stakeholders and attempted to foster agreement on the importance of water quality protection. This approach was directly incorporated into the legislation, and paved the way for further development of the Tualatin WQMP after the legislation was enacted in 1993.

Once SB 1010 was passed, a local advisory committee was formed to develop a draft plan and rules for the Tualatin basin and submit them to ODA. Participants included a number of local farmers, representatives of environmental groups, and various local government agencies. The committee also employed a 15-person technical committee composed of volunteer experts from the NRCS, university extension services, and several state government agencies. Operating through discussion, negotiation, and consensus, the advisory committee spent nearly a year working with ODA to draft the water quality management plan and the proposed implementing rules. Once the plan was drafted, ODA drafted administrative rules, which were subject to notice and comment before being finalized in April 1996.

Opinions were mixed on the level and efficacy of stakeholder involvement in the Tualatin planning process. In general, regulators argue that the composition of the local advisory council is critical to its efficacy; for the rules to carry weight with the landowners, they need to be put forth by credible representatives of the different user groups. Similarly, most participants from the agricultural community appear to feel that the combination of stakeholder representation on the local advisory committee and expert assistance from the technical advisory committee were instrumental in making the process work in the Tualatin. More recently, however, the process has provoked resistance from farmers in other basins.[46]

Further, some representatives of local conservation groups view the heavy emphasis on stakeholder input and consensus as an obstacle to the development of effective, enforceable plans. These sources cited the extensive outreach effort required to raise awareness of the importance of wetland and riparian areas in the first place, and to convince farmers that their practices can have negative impacts on these resources. They further argued that even after the agricultural community had been brought to the table, it exhibited an exclusive preference for voluntary, education-based approaches over regulatory mechanisms, and a "total opposition" to considering any new taxes or fees to cover the cost of implementing even these measures.

The resulting Tualatin WQMP essentially constitutes a basin-wide resource assessment, which identifies performance standards required of all landowners, other resource concerns, endangered species issues, current farming practices and fertilizer use. Its primary objective is to address water quality violations, issues raised by other laws such as the Endangered Species Act, and fish and wildlife concerns as they affect water quality. The Washington County SWCD implements the plan by prescribing best management practices that address erosion control, temperature, and so forth. There was a grace period of two years for public notice and education about the rules and the consequences of violating them, in accordance with SB 1020, a companion bill that requires that the public be adequately informed about the new rules before they become the object of proactive enforcement.

In the Grande Ronde River Basin, the SB 1010 WQMP recently was completed. There, the local advisory committee included a number of local ranchers and farmers, the county extension services, Union County government, the Department of Public Works, and Union County and Wallowa County SWCDs, and produced a plan that has now been enacted into regulations.

On a roughly parallel track, the TMDL process for the Grande Ronde basin is nearing completion for parameters of temperature, nutrients, dissolved oxygen, pH, and sediment -- most of these resulting from nonpoint source discharges. For this reason, the Grande Ronde TMDLs drew upon and incorporated much of the information generated during the SB 1010 process, even though the TMDL process includes sectors besides agriculture. Stakeholders represented on the TMDL planning committee included the SWCDs, Union County, the La Grande city government, transit and public works agencies, the forestry sector, and private companies such as

R0019283

Boise Cascade. The committee was divided into subcommittees that dealt with specific sources such as agriculture, forestry, urban runoff, etc.

Relationship Between WQMPs and the TMDL Process

The situation in the Grande Ronde basin illustrates the complex interrelationship between the SB 1010 WQMP process and the ongoing development of TMDLs under the federal Clean Water Act. Oregon DEQ is currently more than two years into its ten-year schedule to complete all TMDLs statewide. A lot of the work to date has been driven by Clean Water Act citizen suits, decisions, and settlements, as well as ongoing concerns about ESA salmon species listings that have brought habitat issues such as sedimentation and temperature to the forefront. (Indeed, as this study was being drafted, the Sierra Club announced that it was filing suit to compel DEQ to finish TMDLs for all Oregon waters within 180 days.)

The Department has adopted a sub-basin approach, noting that there is incomplete information on water quality in many areas and that it therefore makes most sense to focus more widely rather than on isolated stream segments. By covering an entire sub-basin, both point and nonpoint source concerns can be identified, and point source control and nonpoint source control can be more tightly integrated.

For these reasons, and because of the broader coordination goals under the Oregon Plan, DEQ has decided to include implementation plans as part of its TMDL load allocations. These plans are the point at which the various enforceable elements of state law (SB 1010, the Forest Practices Act, and the statewide planning law) intersect with one another and with the federal TMDL process. DEQ has entered into separate memoranda of agreement with ODA and the Oregon Department of Forestry (ODF), specifying each agency's role in the TMDL process, and has issued guidance on the elements necessary in an SB 1010 plan if it also is to serve as a TMDL for nonpoint sources.[47] In addition, the Governor's Office has been working through the Healthy Streams Partnership to better integrate WQMPs and other state efforts into the TMDL process.

Statewide, there has been some debate over the appropriate timing for development of an SB 1010 plan vis-á-vis TMDL development for the same basin. As noted, ODA is currently on a four-year timetable for completion of all WQMPs, and although the agency is uncertain whether it will meet this goal, it is likely that most plans will be in place before all the TMDLs are completed. As one regulator explained, this discrepancy results in a "chicken-and-egg" problem: it is difficult to craft a definitive SB 1010 plan without knowing load allocations for the agricultural sector, but it is also difficult to calculate and implement realistic load allocations without mechanisms such as the SB 1010 rules and performance standards in place. As a result, some sources thought ODA should postpone WQMP development until TMDLs have been developed, in order to generate plans that are directly driven by numerical standards; others believe it is appropriate for 1010 plan development to get underway before TMDLs are issued.

Most regulators found merit in the early stakeholder involvement afforded by the SB 1010 planning process, arguing that it provides a valuable opportunity to get the agricultural community into the mindset of revising its practices. ODA in particular contends that the lead time is important for introducing new ideas and for facilitating a climate of good stewardship in advance of federal mandates. By issuing plans on a shorter timetable, ODA seeks to set initial performance standards for landowners, and to add elements to these plans as needed to meet the TMDL allocations. The Department claims that it is attempting to reach a middle ground of "goal-oriented" measures rather than purely prescriptive practices. It acknowledges that it has yet to fully convince EPA that its approach will work, but argues that it resonates better with its constituents than prescriptive measures would. In short, ODA doesn't want debate about numerical endpoints to stall the possibility of immediate progress, and it hopes to avoid resistance to a second round of potentially more stringent planning and regulation by anticipating and educating parties about it through the current planning process.

Nevertheless, there remains some concern within the agricultural community about the interaction of the SB 1010 process, the TMDL process, and the perennial specter of Endangered Species Act requirements. According to one source, some farmers wonder why they're doing so much work now if the federal government is simply going to come along and add another layer of regulation. Landowners feel that they can live with what they know now, even if it requires some additional work, but "they're scared to death about what's coming down the pike." One reaction is that DEQ and EPA will need to interact better with people in the field to consider the efficacy of the requirements and the process used, rather than just assign load allocations: "The people writing the [TMDL] rules need to sit down with real live people."

In the Tualatin Basin, TMDL concerns are already being incorporated into the second round of the SB 1010 process, which has reconvened the local advisory committee to review and amend the existing WQMP. Interviewees felt that this was an appropriate juncture for using the local advisory committee process to integrate the two programs, though they expressed some concern about the time required to get new members of the advisory committee up to speed. In the Grande Ronde Basin, the TMDL process used a lot of information generated during the just-completed SB 1010 process, and the TMDL implementation plan specifically identifies the WQMP as a mechanism for meeting load allocations. Interviewees there felt that early development of the WQMP had offered localities a stronger voice in TMDL development and let farmers "get a jumpstart" on updating their practices.

Enforceability of WQMPs

By design, WQMPs tend to embody a "graduated suite" of enforceable mechanisms that grow progressively more severe if violations are not corrected. To begin with, the plans typically allow for a phase-in period of at least two years, during which time notice of the requirements is given, but they are not proactively enforced. During this period and subsequently, the local SWCD is at the front line of compliance efforts. The SWCDs work with landowners to correct any problems, and will give the landowner a certain amount of time to come into compliance. If this approach does not work, the SWCD can correspond with landowners and notify them of the availability of technical assistance, and will continue to work with the landowner to reach agreement on a resolution of the problem. If this effort fails, the District then may turn the case over to ODA for enforcement. In the Tualatin, SWCD officials have resolved more than 300 cases through voluntary compliance since the rules became final in 1996.[48]

Similarly, ODA's policy is that enforcement action "is pursued only when reasonable

R0019285

attempts at voluntary solutions have failed."[49] The Department may initiate an investigation when it receives a written complaint of a violation of WQMP implementing rules, or its staff is referred to or directly observes conditions that violate the rules.[50] If noncompliance is verified, the agency can employ its own spectrum of enforcement actions, including issuance of a warning, issuance of a citation with an order to correct the violation, and generation of a compliance plan with prescribed measures and dates for implementing them and correcting the violation. If a landowner does not comply with these mechanisms, the Department may assess civil penalties of $50 to $2,500 for a first violation and $100 to $10,000 for repeat violations, based on the history of violations and the gravity of the violation's impacts on human health and the environment. Abatement actions also are available.

Given its long history, the Tualatin WQMP was the first plan in the state to become ripe for enforcement action starting in early 1998. Since the plan became enforceable, the Washington County SWCD has received at least sixty complaints requiring investigation, only three of which it referred to ODA. The referrals resulted in the Department issuing one notice of noncompliance and several "water quality advisory letters" warning of potential problems. Ultimately, however, each of these situations was remedied without resorting to penalties.

The Washington County SWCD expressed some initial frustration with the ODA's handling of the enforcement referrals, noting that in each case, the SWCD had established a long history of attempting to work with the landowner prior to the referral, and was more than ready for enforcement to begin. Instead, in the SWCD's view, ODA occasionally had a tendency to retrace the SWCD's steps in attempting to persuade the landowner to make improvements, rather than bringing regulatory mechanisms immediately to bear.

The Washington County SWCD also noted the complementary nature of enforceable and voluntary mechanisms, and the significant amount of voluntary action that is taken in the shadow of a credible enforcement threat. Once a few notices had been issued, the SWCD experienced an influx of other people interested in adopting voluntary measures and taking advantage of technical assistance programs. In one month alone, 35 people came forward wanting to write a voluntary management plan for their land, which created a backlog because the SWCD lacked sufficient staff to accommodate everyone at once. While this situation is atypical, the SWCD believes that interest in voluntary actions will continue to ebb and flow with enforcement, and that the next high-profile enforcement action will cause a similar influx of volunteers.

In sum, the Washington County SWCD believes that enforcement is needed to deal with the small percentage ("three to five percent") of people who are genuine bad actors. In the District's experience, problem cases tend to stem from absentee landowners or new residents who have just moved to the area. In contrast, they view long-time landowners and small commercial farmers as generally more sympathetic to the concept of good stewardship, and able to be convinced to work within the emerging planning and regulatory processes.

Similar attitudes toward enforcement were noted in the Grande Ronde Basin, though the grace period means that there has not yet been a test of enforceability of the new WQMP. There, voluntary actions by the agricultural sector have been spurred by enforcement action taken by the DEQ on water quality, the Oregon Water Resources Department on water quantity -- water rights being a major issue in arid Eastern Oregon -- and the Division of State Lands on fill and removal permits. The threat of what might happen in the future, particularly with respect to water rights, has been a big motivator for restoration and other voluntary activities: "people would rather take the initiative now."

In general, it was felt that attitudes in the Grande Ronde area have improved substantially over recent years, with more people talking about water quality. The large proportion (65-70%) of federal land holdings in the area have simplified the process, as the U.S. Forest Service and Bureau of Land Management have been cooperative. For private landowners, the SWCDs are the focal point, as the majority of their work is on private agricultural or ranch land. Perhaps the most important factor is the local land ethic -- most private landowners are individuals and families, not companies, so they care about aesthetics as well as property values. As in the Tualatin, the locals believe that the only genuine bad actors tend to be recent arrivals or absentee landowners.

Forest Operations

Enacted in 1971 and significantly revised in 1986 and 1991, the Oregon Forest Practices Act[51] is administered by the Oregon Department of Forestry. The Act applies on any non-federal land where a commercial forest operation is being carried out, regardless of how the land is zoned and even inside urban growth boundaries. However, the Act is primarily targeted at ongoing harvest operations, and is not ideally suited for addressing one-time operations such as clearing an urban lot and selling off the timber. For this reason, local governments also have the ability to develop forest ordinances within urban growth boundaries, in which case ODF usually defers to their authority.

Under the Act, the Oregon Board of Foresty has adopted forest practice rules containing best management practices for forestry.[52] The BMPs serve as a safe harbor from the state water quality law and other pollution control statutes; if operators comply with the BMPs, they are also deemed to be in compliance with pollution control laws.[53] In recent years, the Act, rules, and BMPs have increasingly focused on water quality issues. In September 1994, the rules were specifically amended to increase streamside protection -- according to the Department, "the most comprehensive riparian protection rules ever enacted on non-federal land in Oregon."[54] The new rules focused on maintaining trees and vegetation along streams, developing woody debris to create stream structure for fish habitat, and maintaining adequate fish passage along the length of a stream.[55] Among other requirements, they mandate that all fish-bearing streams have a riparian management area of between 50 and 100 feet, including a twenty-foot no-harvest buffer zone on either side.[56]

The Act requires forest operators to notify ODF of pending operations, and the Department receives 18,000-20,000 such notifications annually. There are 54 Forest Practices Foresters who review notifications and written plans, prioritize oversight based on potential risks to natural resources, and issue approvals. A number of operations are then chosen for inspection. ODF is currently in the process of doing a statistical analysis of compliance rates.

Based on the notifications and inspections, ODF issues 200-400 citations per year, some for procedural violations (e.g., failure to notify or to obtain an approval), and others for actual damage to forest resources. For the past 10 years, ODF has focused its efforts on civil penalty mechanisms; while criminal penalties are available, it has proven difficult to get criminal courts to pay attention to water violations as opposed to violent crimes. In assessing civil penalties, ODF uses a formula to ensure consistency. The formula is spelled out in the administrative rules, and takes into account such factors as the level of damage to natural resources and the operator's previous history of violations. The Department has found this procedure to be an effective deterrent, but slow -- any citation can be appealed and receive a full administrative hearing, and 20-30% of violators elect to go this route. As a result, there is a backlog in assessing and collecting penalties, and the agency is constantly lacking adequate staff and budget resources.

ODF maintains a civil penalties database that is capable of generating statistics on penalties issued and breaking out substantive violations from purely procedural violations. According to that database, in 1997 there were 41 cases of penalties assessed for violations of water-quality-related rules, including one instance of criminal penalties for illegal instream operation of machinery. Civil penalties assessed totalled nearly $41,000, for an average of approximately $1,000 per violation, and the highest penalty assessed for a single violation was $3,400. Assessed penalties frequently were reduced, suspended, or mitigated due to new facts or subsequent cooperation by the violator.

The Department cited one significant case in Clatsop County in Northwestern Oregon as crucial to its enforcement efforts. There, an operator with a history of violations was cited $30,000 in civil penalties for multiple violations. As a result of this case, ODF received new legal authority to bar forest operators with outstanding penalties or non-compliant conditions from conducting forest operations altogether, a useful gain: "We have stretched out the continuum of enforcement tools we have available to us."

Given the well-established enforcement structure, most current attention has centered not on enforceability of the existing forest practice rules, but on their adequacy for protecting water quality. In addition to the Forest Practice Act's own provisions for periodic review of the BMPs, the Oregon Plan has been a major driver for various other review mechanisms. In 1997, as part of a memorandum of agreement between the State and the National Marine Fisheries Service that was intended to forestall ESA listing of coho salmon, the Governor agreed to set up a forestry advisory committee to assess current practices. The committee was established, but its work came to a halt in mid-1998, when a federal court ruled that NMFS was required to make the listing.

In January 1999, the Governor's Executive Order 99-01 reaffirming the Oregon Plan spelled out additional requirements for salmon habitat protection. It required the Board of Forestry to reappoint a Forest Practices Advisory Committee to finish the task of considering the adequacy of regulatory and non-regulatory forestry practices, and to provide the Board with policy recommendations, including possible changes in regulations. There has been some carry-over in membership from the original forestry advisory committee, though the current Committee is not as narrowly focused on ESA issues. The Committee's recommendations are expected in 2000.

In parallel, the state legislature has established an "Independent Multidisciplinary Science Team" (IMST) that is charged with looking at all aspects of the salmon issue in Oregon and making recommendations through a series of reports. In September 1999, the IMST issued its assessment of the forest practice rules, concluding that "the current rules for riparian protection, large wood management, sedimentation, and fish passage are not adequate to [p]reserve depressed stocks of wild salmonids."[57] While the IMST report makes several recommendations for improvements within the existing policy framework, it also argues for more sweeping changes, such as incorporation of the Oregon Plan and Executive Order 99-01 into the Oregon Forest Practices Act and/or the Board of

Forstry's policies and adoption of a "landscape-scale approach" that goes beyond site-specific measures to consider cumulative watershed impacts.[58] These recommendations were presented to the Forestry Practices Advisory Committee; ODF believes that the IMST's findings largely parallel recommendations that are already on the table in the Advisory Committee's deliberations.

Relationship Between Oregon Forest Practices Act and the TMDL Process

Beyond the safe harbor provision of the Act, any potential overlap between ODF and DEQ jurisdiction (especially in developing TMDLs) is handled by a memorandum of understanding between the two agencies, which determines what kind of action will be taken in certain kinds of situations. In basins where the two agencies agree that water quality impairment is not attributable to forestry, the existing forest practice rules are deemed to be the compliance mechanism for forest lands, and ODF generally does not participate in the TMDL or WQMP process. In basins where a legacy of forest practices has contributed to water quality impairment but the agencies agree that the current BMPs are adequate for ongoing protection, the forest practice rules are deemed to be the compliance mechanism, and ODF will participate in the planning process "as necessary." In basins where the agencies disagree about whether the current BMPs are adequate, the forest practice rules serve as the interim compliance mechanism, but ODF must design a specific monitoring program as part of the basin plan; if the monitoring indicates that changes are needed, the agencies then will work together to develop further watershed-specific rules. Likewise, if both agencies agree that current BMPs are inadequate for a basin, they also must collaborate on watershed-specific rules.[59]

Similarly, coordination between ODF and other agencies such as ODA varies depending on the basin in question. For the most part, ODF and ODA operate independently from one another, each agency having its own MOU with DEQ. To the extent that the TMDL process is shaped by specific landscapes, DEQ tends to work with each agency independently. The Governor's Office has been encouraging ODA, ODF, and DEQ to coordinate their efforts, and the agencies have met at the policy level several times in the past year. The agencies acknowledge the need to cultivate closer relations in the future, particularly in basins characterized by mixed forest and agricultural practices, such as construction of dual-use roads or grazing on forest land.

More generally, where nonpoint source pollution is concerned, there is a certain amount of finger-pointing between the forestry and agricultural sectors, on the part of both the agencies and the regulated community. The forestry industry cites its history of scrutiny and regulation under the Forest Practices Act, and argues that, whatever reforms may still be needed, it should not bear the brunt of the blame for the salmon crisis. Some regulators agree, noting that forestry has presented an easy target for regulation because it has a smaller constituency of readily identifiable operators, as opposed to agriculture, which has multiple constituencies that are more reluctant to acknowledge their role in nonpoint source pollution. Even environmental NGOs, long-time critics of Oregon's forest industry, conceded that some progress has been made through the Forest Practices Act, and lamented that comparable headway has not yet been made with agriculture.

Responses from agriculture sources sometimes appear to confirm this assessment: in the Grande Ronde, a heavily agricultural basin, a survey conducted by the Union County SWCD showed that "most residents consider watershed health as an issue concerning logging and forestry....and many did not link their own actions to watershed health problems."[60] However, regulators argued that in fairness, the agriculture sector has had ten to fifteen fewer years than the forestry sector to think about nonpoint issues, and pointed to the progress currently being made under SB 1010. They believe it is important for the agricultural community to adopt responsibility for controlling its own pollution, and lauded the steady, if "incrementalist," approach being taken by ODA to bring its own constituency on board. Further, they pointed out that some of the same oversight mechanisms used in the forestry sector, such as a statewide advisory committee, may soon be applied to agriculture; the IMST is planning to do a comparable analysis of the relationship between agricultural practices and the goals of the Oregon Plan.

Statewide Comprehensive Land-Use Planning

Oregon's statewide comprehensive land-use planning program supports nonpoint source pollution control by providing a framework in which local jurisdictions can implement enforceable mechanisms related to development and specifically targeted at nonpoint sources. Passed in 1973, the law requires municipal, county, and regional governments to develop local land-use plans and to comply with 19 statewide planning goals. Plans are updated on an ongoing basis through a process known as "periodic review."

According to DLCD officials, the statewide planning process provides authority to enact local ordinances governing land uses that affect watershed functions and aquatic habitat under several of the existing statewide goals. These include Goal 5 (natural resource protection, including riparian and wetlands resources), Goal 6 (protection of air, water, and land resources), and Goal 7 (natural hazards and floodplain protection). Some also argued that similar results could be achieved through the creative application of Goal 11 (public facilities, including stormwater control), Goal 14 (urbanization and "smart growth"), Goal 15 (the Willamette River Greenway), Goal 16 (estuarine resources), and Goal 17 (coastal shorelands). Only some of the planning goals have been implemented through administrative rules.

Goal 5 covers "natural resources" in their broadest sense; provisions under this goal that are relevant to nonpoint source pollution include protection of riparian areas and wetlands. Goal 5 has been codified in rules that require local jurisdictions to adopt programs that comply with the goal when they revise their comprehensive plans.[61] Goal 5 requires localities to inventory certain specified natural resources to determine their "significance" and to protect significant resources. Importantly, the riparian rule provides a safe harbor whereby communities can opt out of the inventory requirement simply by designating a 50-foot protective buffer zone along all streams as "significant."

The purpose of *Goal 6* is "[t]o maintain and improve the quality of the air, water, and land resources of the state." This goal does not have administrative rules, and in practice typically results in the inclusion in local plans of a statement that all land-use decisions will comply with federal and state environmental laws. However, DLCD officials point out that little attention has been paid to the goal since it was adopted in 1974-75, when point sources were perceived as the major cause of water pollution. For this reason, they believe that the potential for Goal 6 to be applied to nonpoint sources has not been fully analyzed. For example, the goal states that discharges may not exceed the carrying capacity of receiving water bodies, and a recent decision of the Land Use Board of Appeals applied this provision to prevent a local government from amending its plan to allow future development near an impaired water body.[62] Since that decision was not limited to point sources, it could easily extend to planning decisions that affect nonpoint sources.

However, the planning law's interaction with major categories of nonpoint source pollution is unclear. While *Goal 3* and *Goal 4* aim at the conservation of agricultural lands and forest lands, respectively, they do not expressly allow for land-use regulation for the purpose of protecting water quality within areas designated for those uses. Indeed, there is a statutory provision that gives the forest practice rules precedence over land-use rules, and SB 1010 similarly appears to preempt jurisdiction over agricultural practices. DLCD feels the TMDL process ultimately will become the superstructure for integrating these concerns, including the land-use planning goals, but notes that this coordination hasn't yet happened.

Similarly, Department sources believe that there is room for more thorough integration of local land-use planning into the basin-level initiatives taking place under the Oregon Plan and the watershed councils. They expressed admiration for the work of the watershed councils, but note that they are focused on restoration and are careful to avoid regulatory responsibility. The intersection between watershed planning and local comprehensive planning is ill-defined, and there could be more interaction between the two. In part, this is for political reasons -- local officials are not yet paying sufficient attention to the Oregon Plan, except for a forward-looking few who already have some sense of what the ESA mandates may soon require. Until local planners get authority and resources from local administrations and city councils, they will be unable to address these issues in a comprehensive fashion.

In an attempt to raise awareness and to provide regulatory tools at the local level, DLCD presently is drafting a model water quality code for small cities (population 10,000 or less). Essentially a technical assistance document rather than an enforceable mechanism, the model code contains detailed provisions that cities could voluntarily adopt, enact and enforce locally. The Department hopes that growing concern over TMDL load allocations and ESA liability will be the drivers for the code's adoption, and it includes model load allocations on a sliding scale. The draft is expected to be completed in early 2000.

The Tualatin Basin is an excellent example of land-use planning being employed to address water quality issues. There, the combination of a history of water pollution issues, some uniquely powerful regional government agencies, and the political sensibilities of the Portland metropolitan area has resulted in a number of ongoing planning and regulatory efforts. Both state and local government officials, as well as NGOs within the basin, cited these as relevant to nonpoint source control and an essential component of addressing ESA and TMDL concerns.

The metropolitan Portland area has a regional planning organization known as "Metro" that handles comprehensive land-use planning for the entire region, which covers three counties and 24 cities and includes part of the Tualatin Basin.[63] More than a simple council of governments, Metro is the only directly-elected regional government in the country; it was created by referendum and governs directly in its region. By law, once Metro adopts a policy at the regional level, its constituent local governments must amend their comprehensive land-use plans to comply. While Metro has the legal authority to compel localities' compliance, enforcement more typically is through fiscal measures, such as withholding regional transportation funding from the non-complying jurisdiction.

In 1993-94, Metro began work on "Region 2040," a growth concept for the Portland metropolitan region, predicated on holding the urban growth boundary steady and protecting the natural resources within it. In short, Metro projected growth trends and needs, removed 16,000 acres from the "buildable lands" category within the growth boundary, and concluded that there was no need to move the boundary (though it recently has been extended by 5,000 acres, amid much controversy). The original 16,000 acres removed included all floodplains, wetlands, stream corridors, and slopes above 25% grade. In addition to this regulatory move, Metro inaugurated an "Urban Green Spaces Program" to acquire streamside habitat land, a non-regulatory, acquisition-based approach.

More recently, Metro adopted Title 3, a set of regulations on floodplain and water quality management in urban riparian areas that is designed to implement statewide planning Goals 6 and 7. Title 3 has three main focuses: it mandates region-wide erosion controls for all new developments, regardless of size; requires every local government to adopt vegetative corridors for stream segments within their jurisdiction; and improves management of the 100-year floodplain. The regulations include a model local ordinance that has already been adopted and become enforceable in many of Metro's constituent communities; the formal deadline for compliance was December 1999.

Both regulators and NGOs agreed that the next large challenge for the urban portion of the Tualatin Basin will be control of stormwater discharges and the reduction of impervious surfaces. In dealing with stormwater issues, Metro can draw upon the Unified Sewerage Agency (USA), a regional service district that covers the urban areas of Washington County, as well as portions of Multnomah and Clackamas Counties and the City of Portland. USA was formed about 30 years ago to deal with the sanitary waste problem in the watershed, and its initial mandate was limited to sanitary waste.

In the late 1980s, following the TMDL suit filed by the Northwest Environmental Defense Center, USA was given authority to deal with stormwater, and it now holds the Municipal Separate Storm Sewer System (MS4) permit for twelve cities. Stormwater is handled primarily via intergovernmental agreements among these cities, which have agreed to have USA set minimum standards (for example, erosion control and buffer widths) for surface water quality control, and to take responsibility for implementing the standards. USA retains a degree of oversight capability because the cities are required to obtain USA's consent before issuing any new site permit for connection to sewage and stormwater systems.

In addition, through its Surface Water Management Program, USA also has its own regulatory authority. For example, the Agency handles erosion control permits for construction sites up to five acres, and also has an erosion control program that goes down to the single family home. Under the latter program, there is a two-tier enforcement structure. The first step is to notify violators of any problem and to request correction within 24 hours; the next step is to stop work until the situation is corrected. The hook for compliance is the requirement that USA sign off on building permits, although problems arise with developers who modify plans after USA signs off. The Agency is currently trying to identify enforceable mechanisms to control this type of situation.

Metro has asked USA to assist with implementation of Goal 6 water quality standards through Title 3; cities also have asked USA to help them meet the requirements, since Title 3 is modeled in part on USA's model municipal ordinance package that requires certain buffer widths. According to the Agency, it is willing to help, but concerned about trying to simultaneously manage water quality and land use. Its primary responsibility under the MS4 permit is water quality control. In protecting water quality through land use, however, the agency risks falling subject to takings claims, and has therefore been reluctant to make any final decisions on land use.

Some local NGOs were critical of the USA's role in managing stormwater discharges, claiming that the MS4 permit fails to incorporate specific load allocations, instead referencing only BMPs, and that the effect of USA's role has been to shield the individual municipalities from Clean Water Act liability. At the time of this study, Tualatin Riverkeepers and Northwest Environmental Defense Center had filed a notice of intent to sue EPA and Oregon DEQ to correct this situation.

Conclusions

Oregon has a broad array of both assistance-oriented and enforceable mechanisms aimed at improving watershed health and reducing nonpoint source pollution. The steadily growing concern over TMDL requirements and ESA listings of salmonid species has led to increased attention being paid to these issues. It also has led to the need to integrate the State's numerous water quality programs. The main initiative for habitat restoration, the Oregon Plan, relies primarily on cost-share and technical assistance and voluntary activities through local watershed councils. The main regulatory effort, development of TMDLs with enforceable implementation plans at the watershed level, builds upon and attempts to coordinate existing state-law processes for the agricultural, forestry, and urban sectors, among others. In turn, these state mechanisms may need to be ratcheted up to meet potentially stringent federal standards, given the current preference for encouraging voluntary compliance with SB 1010, the criticisms of the adequacy of the current forest practice rules, and the difficulty of ensuring local compliance with statewide planning goals.

There is ample evidence of the efficacy of deploying voluntary and cost-share programs alongside enforceable mechanisms. However, there may also be some tension between the two, or at least the danger of sending mixed signals, particularly if both are administered by the same agency. In this regard, the example set by ODA will be crucial, as it continues to evolve from its historical role of provider of technical assistance to that of implementer and ultimate enforcer of the SB 1010 plans.

The SWCDs appear well-situated to continue to provide technical assistance and cooperative oversight of voluntary activities, in addition to serving as ODA's early warning system for enforcement issues. However, they also indicated a need for more decisive action once an enforcement referral to the Department is made. Oregon's brief experience thus far suggests that while stakeholder participation and voluntary compliance are worthy goals, they must be backed by a credible threat of enforcement against genuine bad actors. It remains an open question whether ODA will be able to overcome the political resistance from its own constituency and be successful, first, in meeting its ambitious timetable for development of the WQMPs; and second, in enforcing their provisions once they are established.

Other questions relate to the integration of the WQMPs, forest practice rules, and land-use planning into the TMDL process. As discussed, Oregon DEQ has devised agreements with both ODA and ODF that govern its relationship with each of those agencies. But equally important is the relationship between ODA and ODF, especially in watersheds that have both farming and forest uses, and the two agencies expressed a desire to cooperate more closely with one another in such watersheds. But each department inevitably reflects its constituency, and finger-pointing between the agriculture and forest sectors could come to hinder their cooperation on planning and regulatory goals. Ultimately, the task of coordination could fall to the Governor's Office, which is attempting to encourage dialogue among all state agencies.

Less well-defined is the actual or potential connection between WQMPs and TMDL implementation on the one hand, and state and local land-use planning on the other. There is significant overlap between the objectives of the water-quality statutes and the planning law, though they are administered in very different ways. Since both WQMPs and TMDLs are being developed through separate planning-oriented processes at the basin level, it may make sense to explore more direct integration of local land-use planning into watershed planning.

Indeed, a key advantage of Oregon's statutory framework and current policy decisions is that all the major legal mechanisms -- the TMDL process, agricultural water quality management plans, forest practice rules, and land-use planning -- are not only being authorized and coordinated at the state level, but also are targeted at, and delegated down to, the watershed or local levels. This thorough adoption of a basin-by-basin approach, which is also reflected in the voluntary activities under the Oregon Plan, provides a sound hydrological basis for water quality improvements, and facilitates coordination among the relevant agencies and regulated communities. Equally important, it allows for meaningful stakeholder participation and decision-making at the local level.

Texas Case Study

Summary

In addressing nonpoint source water pollution from agriculture, Texas relies primarily on the Texas Soil and Water Conservation Board (TSSWCB) which administers the water quality management plan certification program cooperatively with the Soil and Water Conservation Districts.[1] Any facility that is not required to obtain a permit from the Texas Natural Resources Conservation Commission (TNRCC) may develop a certified water quality management plan. The plans are voluntary, although if water pollution is occurring, the TSSWCB may request that the discharger obtain a plan. In most cases, operators will obtain a plan rather than risk regulation or enforcement by TNRCC. Facilities that have a plan may be eligible for cost-share assistance, capped at $10,000 over the lifetime of the operation. These funds are available to a limited degree across the state, but most are specifically targeted at priority watersheds identified by TSSWCB. Failure to comply with the plan may result in repayment of any cost-share assistance and animal feeding operations may be required to obtain a permit from TNRCC. The TSSWCB investigates violations of the plan and any law or rule relating to agricultural pollution in cooperation with the local Soil and Water Conservation District and, if necessary, develops a corrective action plan. If the violator fails to take corrective action the complaint is referred to TNRCC for enforcement. Although authorized by law Texas has yet to develop a certified water quality management program for silvicultural activities.

Development and earth-moving activities are regulated in the Edwards Aquifer region of the state primarily through the Edwards Aquifer Protection Program (EAPP). Any construction-related or post-construction activity that has the potential for polluting the Edwards Aquifer *and hydrologically connected surface streams* may not proceed until the required plans, including a water pollution abatement plan (PAP) have been approved by TNRCC. The PAP must describe temporary and permanent best management practices for preventing pollution of surface water, groundwater, and stormwater. TNRCC reviews and approves the EAPP permits and conducts enforcement.

Development activities may also be regulated on the local level through programs authorized by various state laws that allow a municipality to protect for watersheds, to develop a water pollution control and abatement program, and to enter into cooperative agreements with TNRCC to inspect public waters to determine whether water quality meets state water quality standards and to check compliance with permitting requirements. Austin, for example, has enacted several ordinances over the years regulating development through permit mechanisms, starting with an ordinance regulating development activity near creeks in the Lake Austin and Lake Travis areas and then moving to a comprehensive watershed ordinance for the entire city. A particular stringent ordinance was passed for the Barton Springs watershed. Austin also has a stormwater program and an Emergency Spills and Pollution Complaint Response Project. The City carries out inspections and formal enforcement and also provides technical assistance and outreach activities to implement these programs.

Watersheds

One urban (Edwards Aquifer) and one rural (North Bosque River) watershed in Texas were examined in order to assess the use of enforceable mechanisms and their relationship to cost share and technical assistance approaches.

Edwards Aquifer

The Edwards Aquifer is one of the most valuable water resources in the central Texas area. This aquifer provides water for municipal, industrial, and agricultural uses, and serves as the principal source of water for a number of cities, including San Antonio and Austin. In 1975, the San Antonio portion of the Edwards Aquifer was the first in the country to be designated a Sole Source Aquifer by EPA under the Safe Drinking Water Act, and the Austin portion received the same designation in 1988. The designation is reserved for aquifers that provide 50 percent or more of the drinking water for an area where there are no reasonable alternative drinking water sources.[2]

The aquifer lies in an underground layer of porous limestone that is 400 to 600 feet thick. The aquifer runs in an arch from an area west of San Antonio to north of Austin. The aquifer can be divided into three parts: the contributing zone, or drainage area; the recharge zone; and the artesian area. The contributing zone is found in Texas Hill Country and is about 4400 square miles. The area receives about 30 inches of rainfall per year which drains through streams and the water table into the Edward Aquifer in the recharge zone. The recharge zone is an area where highly faulted and fractured Edwards limestones outcrop at the land surface, allowing large quantities of water to flow into the aquifer. About 85 percent of recharge occurs when rivers and creeks cross the recharge zone. The artesian zone, unlike the recharge zone, is confined between two impermeable rock formations. Artesian wells and natural springs exist where water can be pushed through wells or faults to the surface.[3] The aquifer is unusual due to its rapid acceptance of recharging waters, large yields in springs and wells, and relatively rapid groundwater movement.[4]

The area over the Edwards Aquifer has been subject to increasing development in recent years. Since 1970 the population of the greater Austin area has approximately tripled. The increased urban development has resulted in increased water quality problems due to urban runoff from streets, industries, and lawns.[5]

Barton Springs is the main discharge point for the Barton Springs segment of the Edwards Aquifer. Ninety percent of all water that discharges from this segment of the aquifer emerges at Barton Springs. Water discharged at Barton Springs has been channeled and dammed since the early twentieth century to form a naturally fed pool known as Barton Springs Pool. Recently the spring, pool, and ancillary springs were identified as the only surface habitat of the Barton Springs salamander, which was listed under the Endangered Species Act in 1977. The majority of pollutants that enter the Barton Springs segment of the Edwards Aquifer must exit the aquifer through salamander habitat. The primary threats to the Barton Springs salamander are degradation of the quality and quantity of water that feeds Barton Springs due to urban expansion over the Barton Springs watershed.[6]

North Bosque River

The North Bosque river flows 97 miles through north-central Texas. The river runs through Erath County, Hamilton County, Bosque County and McLennan County where it joins the Middle and South Bosque Rivers and flows into Lake Waco on the edge of the city of Waco. The terrain is generally flat with a clay and sandy loam soil. The watershed is in one of the primary dairy producing areas in Texas. Erath County alone contains over 200 dairies, and the Upper North Bosque watershed has over 38,000 cows[7]. The watershed has been targeted by the state for TMDL development before April 2000, and the Texas Institute for Applied Environmental Research at Tarleton State University has conducted modeling activities and convened stakeholder committees as part of the TMDL development process. Representatives of local governments, the Soil and Water Conservation Districts, and local dairy farmers are among the members of the stakeholder committee that will determine the TMDL. The primary sources of impairment in the watershed are nonpoint sources which have lead to high fecal coliform and nutrient levels in the watershed[8]. Manure spreading from the growing number of dairies may be one of the major causes of the water quality problems in this watershed.

Enforceable Mechanisms

Of the Texas nonpoint source enforceable mechanisms described in the *Almanac*,[9] the following were reviewed in detail because of their relevance in the Edwards Aquifer or North Bosque River Watershed.

! *General discharge prohibition.* The state Water Code provides that, except as authorized, no person may "discharge sewage, municipal waste, recreational waste, agricultural waste, or industrial waste into or adjacent to any water in the state," discharge other waste which in itself or in conjunction with any other discharge or activity causes pollution of any water of the state, or commit any other act which causes pollution of any water of the state[10]. Exempted from this prohibition are: discharges authorized by permit, discharges in compliance with a certified water quality management plan as provided under the state agriculture code (discussed in greater detail below), and activities under the jurisdiction of the Parks and Wildlife Department, the General Land Office (coastal management) or the Railroad Commission of Texas. The Texas Natural Resources Conservation Commission (TNRCC) enforces these provisions.

Enforcement of the water code, or any other rule, permit, or order issued pursuant to it, is through administrative penalties up to $10,000 per day, civil penalties of between $50 and $10,000, and injunctions.[11] TNRCC uses these provisions to enforce against violations of both agricultural and development related permits.

! *Water quality management plan certification program.* The state Soil and Water Conservation Board is the lead agency for the abatement of agricultural and silvicultural nonpoint source pollution.[12] The Board is required to plan, implement and manage programs and practices for abating such pollution, and other state agencies with responsibilities in this area must coordinate their actions with the Board. In areas identified as having agricultural nonpoint source water quality problems (or in coastal zone areas), the Board is required to establish a water quality management plan certification program. The program is administered through the soil and water conservation districts. Participating farmers develop individual water quality management plans for agricultural lands, including animal feeding operations not otherwise permitted under the NPDES program. The state board adopts rules for these plans in compliance with state water quality standards.[13]

All complaints concerning a violation of a water quality management plan or a violation of a law or rule relating to agricultural or silvicultural nonpoint source pollution are referred to the state Board. The Board investigates the complaint in cooperation with the local Soil and Water Conservation District and, if necessary, develops a corrective action plan. If the violator refuses to take corrective action, the Board refers the complaint to TNRCC.

! *Animal feeding operations.* Texas was delegated authority to issue federal NPDES permits to CAFOs in September 1998. All facilities confining more than 1000 animal units (700 mature dairy cattle) for at least a 45 day period annually must obtain a TPDES permit.[14] However, smaller facilities in the Dairy Outreach Program Area, which includes Erath, Bosque, Hamilton, Comanche, Johnson, Hopkins, Wood and Rains counties, must also obtain a TPDES permit if they confine more than 300 animal units (or 200 mature dairy cattle) for the same time period[15]. A facility which qualifies for and obtains a certified water quality management plan as described above is not considered a CAFO and is not subject to permit requirements unless it is referred to TNRCC for enforcement purposes.[16] The TPDES permit requires the operator to develop a pollution prevention plan that addresses water and air pollution as well as the land application of wastes and wastewater.[17]

! *Edwards Aquifer Protection Rules.* Development activities over the Edwards Aquifer, one of the largest sources of drinking water for Austin and San Antonio, are regulated under the Edwards Aquifer protection program. The authority for this program is found in the Water Code, which states that "discharges of pollutants, disposal of wastes, or other activities subject to regulation by state agencies be conducted in a manner that will maintain present uses and not impair potential uses of groundwater."[18] The Edwards Aquifer protection rules govern activities in the recharge and contributing zones of the aquifer. The rules require that developers obtain a letter of approval before beginning construction activity and require that developers implement both temporary and permanent BMPs during and after construction.

! *Protection of Streams and Watershed by Home-Rule Municipality.* Texas's local government code includes provisions allowing a home-rule municipality to prohibit the pollution of streams, drains, and tributaries that "may constitute the source of the water supply of any municipality," including the power to police the water bodies.[19] The law more broadly states that a home-rule municipality may provide protection for and police any watersheds. A municipality may exercise both provisions inside or outside the municipality's boundaries.[20] The city water pollution control program embodied in the city of Austin's Land Development Code, described in detail in the Discussion and Analysis section, is based on the authority granted to home-rule municipalities in the local government code.

! *City Water Pollution Control and Abatement Program.* A city may establish a water pollution control and abatement program. If the watershed water quality assessment reports or other assessments identify water pollution attributable to non-permitted sources in a city that has a population of 10,000 or more, TNRCC, after providing the city an opportunity to correct the problem and after a public hearing, may require the city to establish a water pollution control and abatement program.[21] A city's water pollution control and abatement program includes the entire city and may include areas within its extraterritorial jurisdiction. The law lists a number of program components, including "the development and execution of reasonable and realistic plans for controlling and abating pollution or potential pollution resulting from generalized discharges of waste which are not traceable to a specific source, such as storm sewer discharges and urban runoff from rainwater."[22] The water pollution control and abatement program must be submitted to TNRCC for review and approval.[23] The City of Austin also uses the authority provided under this law to establish its city water pollution control program, described in detail below, and submitted the programs developed under these provisions to TNRCC for review following approval by the City Board.

! *Local government authority.* State law provides local governments with the authority to inspect public water to determine whether water quality meets state water quality standards, unpermitted discharges to water are occurring, and permitted discharges are in compliance with permit requirements.[24] TNRCC may, by cooperative agreement, assign any powers or functions normally held by TNRCC to a local government if necessary for the local government to perform water quality management, inspection, and enforcement functions.[25] Local governments have the same power as TNRCC to enter public and private property within their territorial jurisdiction to inspect and investigate water quality concerns. The results of any inspection made by local government must given to TNRCC if requested.[26] The City of Austin administers municipal storm sewer discharge pollution prevention programs and emergency spills and pollution complaint response programs under the authority of these provisions.

! *City of Austin Water Pollution Control Program.* The City of Austin established its water pollution control program under the authority of Local Government Code 401.002 and Water Code 26.177. The law states that municipalities with a population over 10,000 "may" develop a water pollution control and abatement program through municipal ordinance. Development activities are regulated throughout the city and its extraterritorial jurisdiction (ETJ) area as described in the Land Development Code, volume two of the city's ordinances. Generally, developers must implement erosion and water quality controls and protect critical environmental features on property during and following development.[27] The Comprehensive Watershed Ordinance, passed in 1986, was the first ordinance to regulate development throughout Austin and the ETJ. This ordinances established critical water quality zones, mandatory setbacks, and impervious cover restrictions. In 1992 the city adopted one of the more stringent provisions in the Land Development Code, the citizen-initiated Save Our Springs Initiative, which also limits impervious cover in developments, increases the distance permitted between development and water bodies, and eliminates increased loading of suspended solids, phosphorous, nitrogen, and other contaminants.[28] These regulations apply to the Barton Creek, Barton Springs, and Barton Springs aquifer area. Unlike other ordinances, there are no variances or exemptions permitted from these standards.

A provision of state law requires that permits for development be evaluated only on the basis of the regulations in effect at the time that the original permit was first approved[29]. Under this law, preliminary plans including subdivision plats, site plans, and other development permits on land covered by a preliminary subdivision permit are considered to be a single permit. This may allow certain development activities in the City of Austin to be "grandfathered" under older provisions of the land development code.

Assistance-Oriented Nonpoint Source Programs

Senate Bill 503 Cost Share and Technical Assistance

The Texas State Soil and Water Conservation Board (TSSWCB or Board) administers the 503 program, the state's cost share incentive program established as part of Senate Bill 503. Funds from the incentive program are available to a limited degree across the state, but most are specifically targeted at priority watersheds identified by the Board. Priority watersheds are based on lists developed by the state under Clean Water Act Section 319(a), and include primarily watersheds impacted by agricultural activities. The North Bosque is included among the priority areas. Each priority watershed is allocated funding annually by TSSWCB. Funding for cost share assistance is provided through the Soil and Water Conservation District (SWCD) offices in the priority watersheds. In addition to funding provided to the priority watersheds, funds are set aside for the purpose of addressing animal feedlot operations in any watershed in the state.

To be eligible for cost share assistance, an individual must develop a certified water quality management plan with the assistance of the local SWCD and TSSWCB's regional staff. For animal feedlot operations, any facility not required to obtain a TNRCC permit is eligible to develop a water quality management plan. All other agricultural operations may also develop a plan on a voluntary basis. Plans are approved by NRCS field office staff and agreed to by the SWCD. To receive cost share assistance for a specific practice, the practice must be included in the certified plan. The TSSWCB regional office responsible for the North Bosque has approved approximately 500 plans since the 503 program went into effect in 1994.

Local SWCD's have some latitude in administering the cost share program. State law sets the maximum portion of a project's cost that can be funded by cost share at 75 percent,[30] but the SWCD may set a lower rate. The SWCD also determines which practices it will fund through the 503 program.[31] The lifetime limit for cost share is $10,000 per operation throughout the state, although this does not fund 75 percent of the cost of most waste management systems for animal feedlot operations. In priority watersheds, requests for cost share assistance can be approved by SWCDs without referral to TSSWCB. In other areas of the state, operators of animal feeding operations must submit requests to the Board who will award funding on a first come, first served basis.

R0019303

EQIP

EQIP is the most active of the Farm Bill programs in both the North Bosque river watershed and the Edwards Aquifer. The state has received over $10 million a year in funding for the past three years. The NRCS State Technical Committee selects priority areas around the state from proposals from regional NRCS staff and other agencies. In 1999, 25 priority areas received funding while 25 percent of the state's total allocation was reserved for applicants outside of the priority areas. The North Bosque and Edwards Aquifer are the state's top two priority regions for EQIP. The Edwards Aquifer region has been a priority area for four years. Most contracts are in Medina and Uvalde counties, and focus on water quantity issues such as improving the efficiency of irrigation. The Bosque River region has been a priority area for three years, and contracts are primarily focused on water quality concerns. Funding has been used for waste management systems and nutrient management planning for cropland. In all areas of the state, funding is limited by law to 75 percent of the cost of the practice with a maximum of $50,000 for a five year contract. Grants are evaluated in each priority area for cost-effectiveness, and about 20 percent of applications are funded each year. Applications originating outside priority areas are evaluated against other non-priority area applications statewide, but are grouped into four resource concerns so that problems that may be more costly to address, such as animal waste management, are evaluated against similar proposals.

319 in Texas

TSSWCB's 319 program for agricultural and silvicultural nonpoint source pollution targets its funding to priority areas identified on the state 303(d) list of impaired waters. Efforts under this program are intended to complement the state's TMDL development process. The program receives approximately $2.3 million in funding annually. By Memorandum of Understanding,[32] TNRCC and TSSWCB have divided responsibility for implementing the provisions of the EPA Clean Water Act 319 programs. TNRCC is responsible for programs relating to non-agricultural nonpoint source pollution, while TSSWCB is responsible for managing programs addressing agricultural and silvicultural nonpoint source pollution.

Discussion and Analysis

Agricultural Pollution Generally

The TSSWCB and the TNRCC have entered into a memorandum of understanding that governs the procedure for coordinating jurisdictional authority, program responsibility and procedural mechanisms for nonpoint source pollution programs.

The 503 program allows any facility that is not required to obtain a permit from TNRCC to participate in the program and develop a certified water quality management plan. (See discussion below on when a facility is required to have a permit). The certified plans contain all of the elements that would be required under a TNRCC TPDES permit. They encompass the whole operating unit and all natural resources. For example, even if the landowner comes in only for assistance on animal waste management practices, the plan will also address other problems, such as erosion, that are present on the property. There are approximately 3,000 plans for nonpoint source sites around the state, including small animal feeding lots.

The North Bosque River watershed is under jurisdiction of the regional office of the Board in Dublin. This office covers a number of major dairy areas in Central Texas, including Erath, Commanche, Bosque, Hamilton and Johnson counties. Since 1995, this office has prepared certified water quality management plans. In Erath County the majority of dairies are permitted because of their large size. Although the number of dairies in the area has dropped by 50 percent in the last 4 years (from 212 to 151), the dairy production of the region has remained the same.

The TSSWCB is responsible for investigating complaints and monitoring compliance of all animal feeding operations with a certified water quality management plan or other Board rules. The Board is also responsible for maintaining an electronic database to track and document the proceedings of the plans and corrective actions. If the Board receives a complaint and determines that TNRCC has jurisdiction over the facility (see discussion below), it must refer the case to TNRCC within five working days of the investigation. The Board also automatically refers to TNRCC any complaint involving "an immediate impact to aquatic life"[33] or any complaint involving a documented violation of a plan that requires immediate action because it is affecting human health and safety or will cause serious impact on the environment.

The first step taken by the Board in the case of a complaint is to check whether a facility has a plan and if so, whether the facility is complying with the plan. If a compliance problem exists, a "violation letter" will be sent, citing the facility as in violation of Section 26.121 of the Texas Water Code. The letter will direct the violator either to obtain a plan or to implement a corrective action plan. Corrective actions could include steps necessary to implement the plan or other steps necessary to come into compliance. A facility without a plan may not necessarily be required to obtain a plan; the corrective action may be limited to those steps necessary to come into compliance. Although compliance with the plan technically exempts a party from enforcement of the "no discharge" prohibition, it is unlikely that an agricultural operation would be in compliance with the plan in the event of a discharge causing a public health or wildlife hazard.

In the event that the facility is not under a plan, the operator is given 45 days to apply for one and have the plan approved at a monthly meeting of the Board. The Board follows up after 45 days to see if the operator has applied for the plan. Once the plan is approved, the operator must present evidence of an effort to begin implementation of the plan within 90 days. This allows time for the agencies providing technical assistance, the SWCD and NRCS, to work with the individual. If the violator does not obtain a plan or come into compliance with the existing plan within the time frame established by the Board and the SWCD, the plan will be nullified and the case will be referred to TNRCC for enforcement.

In one example of a complaint handled by the Board, a small hog feeding operation (150 hogs) allowed waste to go into a ditch and then flow into a water source. A letter was sent by the Board requiring the violator to apply for a plan in 45 days and implement the plan. Since the Board meets every 30 days, the violator was basically being given two opportunities to get a plan. The violator did not prepare a plan and the case was referred to TNRCC for enforcement. Usually the TSSWCB does not hear back from TNRCC about cases unless TNRCC determines that the violator is now fully willing to remedy the problem and that a certified water quality management plan would be the appropriate next course of action.

There is one TSSWCB staff person statewide in charge of investigating complaints. The regional TSSWCB offices do not investigate complaints. However, the regional offices conduct status reviews of plan implementation (described below). From the start of FY94 to date, the Board has received 127 complaints, mostly involving animal feeding operations. There have been no complaints received concerning silviculture operations. Fifty-one of those complaints involved dairy operations. The majority (92) of these complaints have been referred by other agencies, while the remainder (35) came from the general public. Most of the complaints under Board jurisdiction relate to problems in suburban areas. Thirty-eight cases were resolved by requiring a water quality management plan, twenty required other corrective action and ten were referred to TNRCC for action. Of these ten referrals, two cases involved operations of permitted facilities or facilities that should have been permitted so TNRCC jurisdiction was automatic. The other eight were referred because they had failed to comply with the water quality management plan program.

Each year ten percent of the certified water quality management plans get a status review. These are conducted by the regional TSSWCB offices. When a status review of a certified plan reveals that the implementation of the plan is not on schedule, TSSWCB works with the operator to correct the problem. The inspector will generally notify the operator of any problems identified. If the problem threatens public health, it will be treated as a priority and the inspector will return to the site to ensure that it is addressed quickly. More often, the problems are less severe such as the operator being unable to meet the implementation schedule. In this case, the regional TSSWCB staff and the SWCD will amend the schedule in the plan and follow up to ensure that the plan is implemented according to the new schedule.

If the operator continually fails to implement the plan on schedule, TSSWCB will eventually void the contract, requiring repayment of cost shares or the return of any equipment purchased, and the plan will be canceled. In the DOPA, TNRCC is aware of all the dairies and the status of any plans. As soon as a plan is cancelled TNRCC can regulate the facility, which may include putting the facility on its inspection list and requiring the facility to obtain a permit. However, given the cost share limit of $10,000, there are very few actions by the Attorney General to retrieve the contract funds. The funds are usually retrieved on the local level without court action.

In the North Bosque River watershed TSSWCB has conducted three 319 program projects, working closely with TNRCC. The projects have studied innovative best management practices to control phosphorous and assessed the contributions of various sources of nonpoint source pollution to the watershed.

Although authorized by law, TSSWCB has yet to develop a water quality management certification program for silvicultural operations. Nonpoint source pollution problems in this area are addressed through voluntary best management practices.

TNRCC Role

TNRCC takes the lead in regulating and enforcing management of livestock and poultry waste from concentrated animal feeding operations. CAFOs over a certain size are required to obtain a permit from TNRCC. For example, dairy operations with 700 or more mature dairy cattle are required to obtain a permit. In the dairy outreach program areas (Erath, Bosque, Hamilton, Comanche, Johnson, Hopkins, Woods and Rains), permits are required for for facilities with at least 200 hundred mature dairy cattle. TNRCC also has general discretion to require an animal feeding operation of any size to acquire a permit in certain cases where water quality is threatened.

Enforcement actions against animal feeding operations are primarily handled by the 16 regional TNRCC offices. Each office has one staff person to handle enforcement. The regional offices may refer cases to the main office by a Regionally Initiated Order (RIO). Examples of cases that may be referred include those with recalcitrant, repeat or egregious violators.

When a TNRCC regional office receives a complaint, an inspector will be sent to investigate. The Stephenville TNRCC office (which handles the North Bosque River watershed) receives most complaints directly and usually responds within a few hours. TNRCC also conducts regular inspections of animal feeding operations under its jurisdiction. All facilities with more than 200 dairy cattle in the dairy outreach program are inspected annually. Facilities that have had their water quality management plan cancelled will also be put on TNRCC's inspection list. During the period September 1, 1998 to August 31, 1999, the TNRCC Stephenville office conducted 265 scheduled compliance inspections and 66 complaint inspections, issued 123 notices of violation and referred 23 cases for enforcement.

If a minor violation is found, the inspector can issue a written notice of violation (NOV). The notice will include a deadline for correcting the problem. If the violator corrects the problem within the specified time, the enforcement proceeding ends. A verbal NOV may be issued if (i) no emissions or discharges occurred, (ii) no documented oral notice or NOV was issued to the operator in the last year, and (iii) the violation can be and is corrected within 14 days.

More serious violations are subject to formal enforcement proceedings. Two types of orders are used depending on the severity of the violation: "1660 orders" and "findings orders." The former are issued for less serious violations. "1660 orders" are no-contest orders that allow for a deferral or reduction of the penalty if the violator complies with the order. "Findings orders" including findings of fact and conclusions of law. Each time a findings order is issued, the penalty increases.

In one recent case involving a permitted animal feeding operation in the North Bosque watershed, TNRCC received a complaint that the facility was discharging onto a neighbor's property. Only a month earlier, TNRCC had issued an order to the same facility for an unauthorized discharge. The facility had five prior NOVs on record. TNRCC is now developing an order for the facility. TNRCC is also considering referral of the case to the Attorney General's office. This office has the authority to institute a civil action or seek a temporary injunction against the violator. Enforcement through the AG's office also opens the possibility for imposing jail time for future violations.

In another case a small dairy operation was given a "1660" order for a first-time discharge violation. The order required the facility to get a Subchapter B permit and to pay a fine of $3,125. When the facility committed a second discharge violation, a findings order with a stiffer penalty of $4,875 was issued.

Land Development Requirements

Nonpoint source pollution from development activities in the Edwards Aquifer region is primarily addressed through a number of regulations at the state and local level that use permitting requirements to impose development restrictions and require the use of best management practices. These regulatory programs are then backed by enforcement mechanisms and technical assistance.

Development activities in various portions of the Edwards Aquifer have been regulated since 1970 when the Texas Water Quality Board issued a board order designed to protect the quality of water entering the Edwards Aquifer recharge zone.[34] Recently the rules were extended to cover the contributing zone to the recharge area. Collectively, the regulations and associated approvals and programs are referred to as the Edwards Aquifer Protection Program (EAPP).

The Edwards Aquifer regulations prohibit any person from commencing any construction-related or post-construction activity that has the potential for polluting the Edwards Aquifer *and hydrologically connected surface streams* until the required plans, including a water pollution abatement plan, have been approved by TNRCC.[35] Specific plans are also required for the rehabilitation or construction of sewage collection systems, underground storage tank systems, and aboveground storage tank systems. Activities exempt from this approval process include agricultural activities (other than feedlots/concentrated animal feeding operations regulated under Chapter 321), oil and gas operations, routine maintenance, and construction of a single family residence on a lot no larger than five acres. The Edwards Aquifer Protection Rules also prohibit new feedlot/concentrated animal feeding operations regulated under Chapter 321 on the recharge zone.[36]

The program requirements and their implementation in the contributing zone are similar to those of the recharge zone. The primary difference is in the activities that are regulated; only activities disturbing more than five acres are included. The plans required are very similar to the Phase I storm water plans required by EPA for construction sites and in some cases TNRCC has allowed the submission of the storm water pollution plan in lieu of the water pollution abatement plan. The BMPs required for post-construction activity are the same as those required in the recharge zone, and inspections are handled in the same way.

The information that must be submitted in the water pollution abatement plan includes the site location, a geologic assessment, a description of the proposed activities, the expected volume and characteristics of wastewater to be produced, any activities or processes which may be a potential source of contamination, and temporary and permanent best management practices for preventing pollution of surface water, groundwater and stormwater.[37]

The plan is submitted to the appropriate TNRCC regional office (in either Austin or San Antonio) where the staff review the plan for administrative completeness. Staff conduct a site inspection to verify that the information submitted in the plan is accurate and perform a technical review of the proposed permanent and temporary BMPs. Most of the time the plan requires little modification before the approval is issued.

TNRCC's Austin and San Antonio Regional Offices provide both formal and informal technical assistance to promote compliance with the requirements of the Edwards Aquifer Protection Program. Informal assistance is the predominant mechanism for providing technical assistance to the engineering, consulting, and development community that is subject to the land development requirements. The Austin regional office receives over 3000 telephone inquiries each year seeking assistance with the requirements of the program. Inspectors rotate through telephone duty where they respond to these calls. The San Antonio regional office reports similarly that it relies on telephone contacts to provide the majority of the technical assistance. The San Antonio office will also contact site owners to let them know about the requirements of the program. The Austin regional office will more formally hold workshops for various associations to discuss the requirements of the program; a recent workshop involved the Highway Contractors Association. TNRCC provides two guidance documents on the requirements of the program, and TNRCC's small business assistance program is assessing ways to assist small businesses in complying with the program.

Once the application meets the requirements, TNRCC issues an approval letter. The approval letter may contain special conditions for approval. Some examples of special conditions are plugging of abandoned wells or installing mitigation practices such as buffers around a sensitive feature (a zone of easy infiltration to the aquifer). The applicant must also provide written notice of the intent to commence construction to the appropriate regional office no later than 48 hours in advance.[38] At this time, it will be determined if the applicant is eligible for an extension of an approved plan. If any sensitive feature is discovered during construction, all regulated activities must cease until the methods proposed to protect the sensitive feature and the Edwards Aquifer from potentially adverse impacts to water quality have been reviewed and approved. When the approval letter has been issued and construction has begun, TNRCC does a follow up inspection during and after construction to ensure that BMPs are being implemented and maintained. The staff reviews from 20 to 30 percent of existing projects.

Over the lifetime of the program there have been 2,500 plans created for development projects. The Austin and San Antonio offices receive about 500 to 600 plans each year.

The letter of approval and a notation that the property is located over the aquifer are recorded in the deed for the parcel.[39] The requirement to maintain the BMPs on the site runs with land. The plans are good as approved for two years in the recharge zone and five years in the contributing zone. Projects in the recharge zone must be 10% completed within the first two years and 50% completed within the first 10 years.

Developers who are not in compliance with their plans are identified randomly by TNRCC staff through the inspection process. Most enforcement of EAPP is carried out by TNRCC regional staff in Austin and San Antonio. When an inspector identifies a site that is not maintaining BMPs as required by their approval letter, or not employing the proper controls, the inspector issues a notice of violation (NOV). The NOV has a due date for compliance. If the developer misses the due date, the inspector can initiate formal enforcement.

Sites that are identified as not having a letter of approval are immediately subject to formal enforcement. TNRCC issues an administrative order. The maximum penalty they can issue under Texas water quality laws is $10,000 per violation per day, but this penalty is reduced by a number of specific factors. The average penalty assessed against a site that is operating without a letter of approval is $2,000. The penalty provisions also call for a 20 percent deferral if this is a first time violation.

Through the third quarter of this year, the Austin regional office (Williamson, Travis, and Hays Counties) monitored 76 sites for compliance by conducting a follow-up inspection. Of those, 20 were issued an NOV, and four were referred to formal enforcement. The four sites referred to formal enforcement may have been operating without an approval letter or violating their plan in other ways.

The most common violations are the failure to submit a water pollution abatement plan or to get approval in advance of construction. One recent case brought by the Austin regional office involved a violator who had failed to identify and notify the regional office of a sensitive feature, in this case, a cave. The original complaint was made to the City of Austin who referred the case to TNRCC which sent out its inspectors. The penalty imposed was $2,000 in accordance with the penalty policy. The violator received a 20 percent deferral and was allowed to conduct a supplemental environmental project (providing kits to test water to the school system for use in fifth grade science classes). There are usually no hearings in connection with EAPP cases because the proposed agreements are usually based on standard policies, but a hearing can be held if the violator is unhappy with the proposed agreement.

The general discharge prohibition under the state water code is rarely used as the basis for enforcement actions involving land development activities in the recharge and contributing zones if the Edwards Aquifer, although it may be used for other types of problems such as a spill. From an enforcement perspective it is difficult to prove a violation of the general discharge prohibition because TNRCC must provide evidence that a discharge actually occurred. This involves having an inspector on the site at the time of the discharge in order to document the event by taking upstream and downstream photographs and samples. Enforcement of violations under the EAPP, such as the failure to implement or maintain BMPs during construction or failure to obtain prior approval before construction, are much easier to prove.

Although the law allows a local authority to be certified to review, approve and enforce Edwards Aquifer Protection plans,[40] no counties or other local entities have been delegated authority to implement their own program and TNRCC administers the EAPP. Even if a local entity were to assume program responsibilities, the EAPP fees would continue to be paid to the Commission to assure continued proper oversight and enforcement. Plans are distributed to appropriate municipalities and groundwater districts for comments. The City of Austin often provides comments.

The TNRCC's Austin regional office receives 319 funding for basic programmatic funding as well as funding to pass through to other local groups conducting research on the Edwards Aquifer. The regional office has received its own 319 grant since 1992. The most recent grant was a three year grant for $100,000 per year. The grant funds two positions for review and enforcement of the Edwards Aquifer Protection Program. One of the other organizations funded through 319 is the Barton Springs Edwards Aquifer Conservation District which conducts studies monitoring the effects of BMPs.

Local Initiatives

Development activities in the Edwards Aquifer may also be restricted by city or municipal laws. State law authorizes cities to establish a water pollution control and abatement program.[41] This program may include areas within a city's extraterritorial jurisdiction if necessary to achieve the objectives for the area within its territorial jurisdiction. In addition, if certain reports, assessments or studies identify a water pollution problem from non-permitted sources, the Commission may require a city that has a population of 10,000 or more to establish this type of program. However, the city in question must first be given an opportunity to correct the problem and a public hearing must be held.

The City of Austin, for example, has enacted several ordinances over the years regulating of nonpoint source pollution created by development activities. The first city ordinance, the Lakes and Creeks Ordinance, was passed in the 1970's. This ordinance regulated development activity near creeks in the Lake Austin and Lake Travis areas in the western part of Austin. Since then, a number of ordinances have been passed regulating development activities in various watersheds. In 1986 the Comprehensive Watershed Ordinance encompassing the entire City of Austin was passed. For the first time, the eastern part of the city was regulated. The ordinance also covered a five mile extraterritorial area. In September 1992 the City adopted the Save our Springs Ordinance for the Barton Creek and Barton Springs Watershed.

The resulting program requires erosion control for site development, restricts impervious surfaces, and requires water quality control measures to be implemented following construction. The program applies to development throughout the city and into a five mile extraterritorial jurisdiction (ETJ) are outside city limits. However, in the ETJ the city's ordinances require only water quality protection measures, not zoning or other land use controls. The requirements applicable to a given area depend on its location; activities in certain watersheds are more stringently regulated. Overall, the city's requirements are as stringent or more stringent than the requirements of the Edwards Aquifer Protection Program.

The Save our Springs ordinance sets out special requirements for development of lands in watersheds which contribute to Barton Springs.[42] Impervious cover for all such development is limited to a maximum of 15 percent in the entire recharge zone, 20 percent in the contributing zone within the Barton Creek watershed and 25 percent in the remainder of the contributing zone. Runoff is to be managed so that no increases occur in the average annual loadings of total suspended solids, total phosphorus, total nitrogen, chemical oxygen demand, biochemical oxygen demand, total lead, cadmium, fecal coliform, fecal streptococci, volatile organic compounds, total organic carbon, pesticides, and herbicides from the site. Impervious cover is to be reduced if needed to assure compliance with these pollutant load restrictions. These requirements are not subject to the regular exemptions, special exceptions, waiver or variances allowed generally under the Land Development Code.

Austin requires a site development permit for all non-single family home construction activity. The Development Review and Inspection Office issues the permit after compliance with the water quality control requirements is verified. In the case of single family home construction, a permit is required for infrastructure development. A building permit, but not a site development permit, is required when the actual home is constructed, and this application is reviewed to ensure compliance with impervious cover limitations and other environmental requirements. Financial assurance is required for each permitted site to cover the costs of maintaining erosion controls or revegetation is the site is abandoned.

Austin has eleven full-time inspectors in the Watershed Protection Department. The frequency of inspections varies. A very large and active site may be visited by inspectors two or three times a month. Inspectors are assigned to a specific area of the city which enables them to identify more easily unpermitted development.

The most common violation is failure to maintain erosion controls.[43] When a violation is identified, it is classified as either a routine or priority violation. Routine violations include failure to maintain or repair erosion controls, or tracking of soils in minor roads. In the case of a routine violation, a verbal warning is given and the violator is allowed 24 hours to remedy the violation. If the violation is not addressed within 24 hours, the inspector will issue a written notice. If the violation is not addressed in the time frame specified in the written notice, the inspector will issue a stop work order, known as a red tag. This requires construction to stop, and also stops all other city inspections that are required for approval.

A red tag is the first step in a priority violation. Priority violations include any activity without a permit or activity that has begun without a pre-construction meeting with Watershed Protection Department staff. Other priority violations are construction that has gone outside the specified limits of construction, any offsite discharge in the Barton Springs zone (even if the construction has been grandfathered under an earlier ordinance) or any violation in a critical water quality zone or involving a critical environmental feature. After the issuance of a stop work order (red tag), the city may file a Class C Misdemeanor in municipal court. The maximum fine is $2,000 per day, with each day counted as a separate violation. The city may offer a deferred disposition when violations are identified. In this scenario, a judge will lay out a schedule for compliance and will require the developer to post bond with this court. A deferred disposition is only considered when construction is on-going.

During the period from October 1, 1998 to September 30, 1999, the Environmental Review and Inspection Division of the Watershed Protection Department issued a total of 111 red tags for violations of the Land Development Code. During the same period, 71 Class C misdemeanor complaints were filed in Municipal Court against 14 developers/owners. The number of complaints filed against each person ranged from two to twelve, depending on several factors, including the severity of the violation, failure to respond to the stop work order, and willingness of the defendant to come into compliance.

Certain development activities may not be subject to these requirements because of grandfathering provisions passed by the state and later by the City of Austin itself. The state legislature passed the grandfathering provisions in direct response to Austin's water quality protection initiatives. The first state law was passed in 1987, one year after the City passed its Comprehensive Watershed Ordinance. The legislature was responding to what it perceived as aggressive regulation by the City that took away land use rights, particularly in regard to impervious surfaces and water quality controls. The first legislative bill simply stated that the regulations in effect on the filing date of a project would apply to *all* subsequent applications.[44] This provision was somewhat general and difficult for the city to implement. Because it was general, the city read the provision as stringently as possible and looked for ways to reject projects from being grandfathered. Much litigation occurred over this provision between 1987 and 1995, with cases decided both in favor of the state and the city.

In 1995, the legislature continued to be alarmed by changes in the Land Development Code and passed SB 1704, which more clearly stated the legislature's intent.[45] Austin enacted guidelines on the grandfathering process in an effort to limit the impact of the new law. These guidelines were much disputed, but considered workable by both the city and the legislature. In September 1997, SB 1704 was inadvertently repealed. The legislature wanted to call a special session to reenact the provisions, but the city suggested instead that they develop a municipal law to address these concerns. The legislature agreed to this suggestion and Austin passed the Interim Development Order. The provisions were very complicated albeit attempting to be fair, but the order upset many people, including the legislature which passed HB 1704 in May 1999, reenacting the provisions of the 1995 statute (SB 1704). Instead of developing formal guidelines, the city has responded by handling each case individually and relying on litigation to enforce its stricter interpretation of this statute. A committee addresses each case and will not decide whether it can be grandfathered unless a member of the law department is present and agrees. Usually several attorneys participate in the decision. Generally, the lawyers will assess how likely they would be to prevail in a suit, and that determines whether the project will be grandfathered or rejected.

Some of the more specific elements that are considered in reviewing the applications are changes in land use and active permits. The city will divide the land use of applications into five categories: single family/duplex; multi-family; office; commercial; industrial; and civic. If the land use of the project has changed since the first permit was approved, the project is considered new and is not grandfathered. Each project must receive a series of permits. The first generally is the subdivision permit, which is based on zoning and may cover a very large area. After this permit is issued, the applicant must have an application for a final plat for a least a portion of the subdivision reviewed and approved within 2 years. If this is done, the subdivision permit remains active; if not, the permit expires. If the first permit has expired, the project is not grandfathered. If the first permit has not expired, the project may be grandfathered; however it is often the case that the proposed land use has changed over time and this too makes the project ineligible for grandfathering.

Local Voluntary Programs

Austin has its own storm sewer discharge pollution prevention program which is an inspection and permitting program that is different from the federal stormwater program. The federal storm water program inspectors are in Dallas and rarely inspect Austin facilities. The City's program is carried out by going to businesses likely to pollute such as auto dealers, detailing businesses, dry cleaners, fuel storage operations, and others that have historical problems with pollution. These facilities are inspected, permitted and required to implement BMPs that have been developed for various sectors. Stormwater Discharge Permits are issued annually for the period January 1 to December 31 and renewal notifications are sent in December of each year.[46] The program tries to obtain compliance without formal believes it is successful with this approach. When contamination is found, staff often provide guidance to owners of small businesses on remediation and assist in the cleanup. If necessary, the City will take people to court to get the actual clean up done.

The City of Austin also has a voluntary program called Clean Water Partners which is primarily an educational program. The City sought partners to implement a checklist of more stringent standards than those in the permit checklist. Those who came into compliance with the standards were given banners, stickers, and public recognition. The City targeted specific geographic areas and types of businesses with a history of problems. The worst offenders chose not to participate. The City also created a "how to" notebook for businesses.

Austin also has an Emergency Spills and Pollution Complaint Response Project which responds to complaints and is on call 24 hours, 7 days a week[47]. The program also provides technical assistance and outreach to the public and other City departments. They try to respond to priority calls in 15 to 30 minutes. Their job is to coordinate cleanup among agencies and to keep the spill out of waterways and identify the responsible party. The responsible party will have to pay for the cleanup. The city is allowed to go after the responsible party under state law; Ch. 26 of the State Water Code gives municipalities authority to enforce state law.

Conclusion

In the North Bosque River watershed efforts to address non-point source pollution from agricultural operations rely heavily on the voluntary water quality management certification program. The primary incentives for participation in this program are limited cost share assistance as well as exemption from regulation under the TPDES in certain cases. In the event of a serious discharge to surface water, TSSWCB might revoke cost share funds, and TNRCC enforcement authority, including enforcement and penalties, might be exercised as well. The thrust of efforts to resolve complaints encourages participation in the voluntary program. The lower threshold of animals required for the TPDES program in the Dairy Outreach Program Area brings a substantial number of operations under the more structured enforcement policies of TNRCC.

Texas's efforts to regulate land development activity over the Edwards Aquifer have resulted in significant TNRCC enforcement activities. The EAPP, unlike the general discharge prohibititions of the Texas Water Code, does not require inspectors to prove that a discharge occurred, but instead requires the use of best management practices which are intended to prevent nonpoint source pollution. TNRCC inspectors are unable to inspect every site regulated under this program to identify an illegal discharge, but have the legal tools to ensure that erosion and other pollution controls are implemented and maintained.

Some believe that the EAPP is a good first step at regulating land development, but would prefer a more stringent approach. The City of Austin, under state authority but of its own initiative, has implemented a series of regulations that are often more stringent that the EAPP in regulating land development. Some provisions, like the Save Our Springs ordinance in the Barton Springs zone, were passed as a result of citizen initiatives. In spite of the popular support behind the land development regulations and the legislative authority to establish a water pollution control program, Austin has been challenged by the state legislature as the stringency and scope of its regulations increase. The legislature has passed a series of laws that limit the power of Austin's regulations by requiring the city to regulate development under the regulations in effect at the time the initial permit for development was issued, often turning the regulatory clock back many years to much weaker provisions. The city has turned to the courts in an attempt to validate its interpretations of grandfathering provisions, but the state laws continue to provide developers an opportunity to evade the more stringent laws, and require the city to expend resources battling the state. The City of Austin appears to determined to protect water quality, not only through its Land Development Code, but also through its stormwater and emergency spill programs which make use of non-enforcement measures such as outreach to reduce pollution.

Virginia Case Study

Summary

This study examines the mechanisms used to manage and control nonpoint source pollution in the James River watershed. The James River starts in the Blue Ridge Mountains and continues through Virginia to the Chesapeake Bay.[1] The study specifically examines the relationship between enforcement approaches and voluntary, technical assistance, tax incentives, and cost share approaches as used in the watershed.

Virginia primarily uses incentive-based programs that emphasize best management practices for nonpoint source pollution management – especially in agriculture and forestry. The state has completed the development of a tributary nutrient and sediment reduction strategy and draft goals for the James River. The goals will, to a large extent, determine the future priorities for technical assistance, funding, and enforcement actions in the James River watershed. Virginia's enforcement of nonpoint source pollution violations largely is triggered by citizen complaints, although forestry recently has included an inspection and monitoring program. Identification of nonpoint source pollution typically first goes through a process of working with the landowner to correct the problems, with enforcement actions taken only where attempts to achieve compliance do not work. Virginia depends heavily on its localities for implementation and enforcement of urban runoff controls, such as erosion and sediment control during construction and other land-disturbing activities, as well as stormwater management of runoff from existing developments and urban areas. Combined with the fact that many areas in Virginia and in the James River watershed are undergoing heavy growth and development pressures, this means that erosion and sediment control and stormwater runoff continue to need attention under nonpoint source pollution management programs.

James River Watershed

Virginia has nine major river basins with an estimated 49,350 miles of rivers and streams and approximately 2,500 square miles of estuaries.[2] In general, fecal coliform bacteria exceedances are the leading cause of non or partial support of designated uses in rivers and streams. Agricultural practices appear to be one of the primary sources causing the loss of designated use support. Indications are present that agricultural and pasture land use results in much of the fecal coliform bacteria and nutrient contamination in Virginia's waters. However, urban runoff, as well as municipal and industrial discharges, are also significant contributing sources.

Forested land covers approximately 55.6% of Virginia's landscape.[3] More than 400,000 private forest landowners own 77% of the commercial timberland, while the forest industry owns 10% and the remaining 13% is owned by federal, state, and local government. The second most prevalent land use in Virginia is agriculture, covering 25.9% of the state's total land area. Cropland accounts for 2,903 square miles, about 7.1% of the state's total area, pasture and hay production accounts for 6,845.3 square miles or about 16.8% of the state's land.

The James River Basin occupies the central portion of Virginia and drains 10,102 square miles or approximately 25% of the Commonwealth's total land area.[4] It is Virginia's largest river basin and is made up of the Upper, Middle, and Lower James River Subbasins and the Appomattox River Subbasin.[5] The James originates along the Virginia/West Virginia border in the Allegheny Mountains, flows in a southeasterly direction to Hampton Roads where it enters the Chesapeake Bay, a total of 450 miles. The James constitutes 10% of the waters flowing to the Chesapeake Bay. Most of the James is forested, with about 25% in cropland and 9% urban.[6] The population along the James River is primarily concentrated in two metropolitan areas: Tidewater and the Richmond Metropolitan area with approximately one million people each. Most of the extensive urban development and industrial activity is concentrated in this lower portion of the James watershed in Richmond, Petersburg, Hopewell, and Hampton Roads. Two smaller, but growing, population centers are the Lynchburg and Charlottesville areas, each with over 100,000 inhabitants. In total, nearly one-third of Virginia's population live in the James watershed and use its waters. The James is stressed by a combination of pollutants, including sediments, nutrients, toxics, and bacteria. The James River watershed is primarily impacted by agricultural and urban nonpoint source pollution.[7]

Enforceable Mechanisms

Of the Virginia nonpoint source enforceable mechanisms, the following were reviewed because of their relevance to the James River watershed.

! *Water quality standards.* Under the Virginia Water Pollution Control Law, it is unlawful to discharge wastes or other deleterious substances into or adjacent to the waters or to alter their state without a permit. Enforcement is by special order and can include injunctive relief and civil penalties of up to $25,000 per day.[8] In practice, enforcement actions in response to water quality standard violations are not common. Silviculture and agriculture have developed their own enforcement mechanisms.

! *Agricultural Stewardship Plans.* Virginia's Agricultural Stewardship Act establishes a complaint-driven enforcement mechanism applicable to agricultural nonpoint source pollution. If, after receiving a complaint, the Commissioner of Agriculture finds pollution or a threat of pollution, he can require that the landowner submit an agricultural stewardship plan to the local soil and water conservation district.[9] Failure to implement an agricultural stewardship plan subjects the landowner or operator to corrective action that sets out a timetable for implementation. The corrective action order can be enforced by injunction, by entry and abatement (with cost recovery), and by assessment of a civil penalty of up to $5,000 per day.[10] The Commissioner also can issue an emergency corrective action if runoff from an agricultural activity is causing or is likely to cause imminent or substantial danger to public health, animals, fish and aquatic life, public water supply, or agricultural, recreational or industrial uses. An emergency order may direct cessation of all or part of the agricultural activity and require specific stewardship measures.

! *Confined animal feeding operations.* Since 1994, animal waste from confined animal operations in excess of 300 animal units (hogs and cattle) has been managed primarily through a Virginia general pollution abatement permit.[11] These operations are required to meet a number of conditions that will assist in reducing nutrients from liquid animal waste and preventing runoff and ground water contamination. These conditions include requirements for an approved nutrient management plan and standards for waste unit operations. In 1999, the Virginia General Assembly passed legislation which requires DEQ to develop regulations for the management of poultry waste.[12] The statute requires that growers with more than 200 animal units of poultry (about 20,000 chickens) implement nutrient management plans which limit land application of manure to crop nutrient needs and crop nutrient uptake.

! *Virginia Chesapeake Bay Preservation Act.* The Virginia General Assembly enacted the Chesapeake Bay Preservation Act in 1988, establishing a cooperative program between state and local governments to reduce nonpoint source pollution.[13] Under the Chesapeake Bay Preservation Act, localities designate and map Chesapeake Bay Preservation Areas, implement specific performance criteria, adopt or amend a comprehensive plan to enhance water quality, and adopt development standards, as necessary to preserve water quality. The localities of Tidewater Virginia must incorporate general water quality protection measures into their comprehensive plans, zoning ordinances, and subdivision ordinances.[14] Localities in the region must establish Chesapeake Bay Preservation Areas, identifying lands that if improperly developed may result in water quality damage. The regulations on land use standards are intended to prevent a net increase in nonpoint source pollution from new development, achieve a 10% reduction in nonpoint source pollution from redevelopment, and achieve a 40% reduction in nonpoint source pollution from agricultural and silvicultural uses.[15] State regulations set out general performance criteria to minimize erosion, reduce land application of nutrients and pesticides, and maximize rainwater infiltration for Chesapeak Bay areas. The criteria become mandatory on the local program adoption date and are enforceable by localities. The local program stormwater management water quality criteria required of local developers is consistent with the state Stormwater Management Program implemented by DCR.

! *Forestry BMPs and water quality enforcement.* The Virginia Department of Forestry has a system of inspection and enforcement for all timber harvesting. When actual or threatened water quality violations occur, the Department has authority to recommend corrective action, issue orders, stop harvesting, or initiate civil penalties.[16] As long as best management practices are not in place, the Virginia State Forester may issue a special order to an operator conducting business in a way that is likely to cause or is causing water pollution.[17] The order can include a stop-work order and corrective actions that must be implemented within a specific timetable. The State Forester can also issue emergency orders if there is an imminent and substantial endangerment of public health or the health of animals or fish, or if commercial or recreational activities are endangered.

! ***Land disturbance permitting.*** Virginia's Erosion and Sediment Control Law sets forth the regulation of land disturbing activities including clearing, grading, excavating, transporting, and filling of land.[18] The Law also sets forth the establishment of a state erosion and sediment control program (state program) and local erosion and sediment control programs (local programs). The state program is administered by the Department of Conservation and Recreation (DCR) under the authority of the Virginia Soil and Water Conservation Board. Counties, cities, and towns currently administer local programs. Local programs (totaling 166 separate programs throughout the Commonwealth) exercise program authority over private and municipal projects. The DCR exercises program authority over all state agency projects. The Virginia Soil and Water Conservation Board is responsible for periodically evaluating the effectiveness of local program implementation to ensure consistency with the state program. Persons undertaking land disturbing activities cannot receive a building or any other permit unless they have an approved erosion and sediment control plan and certification that the plan will be implemented. Plan approval is granted by local program authorities or the Department of Conservation and Recreation as appropriate. The appropriate program or plan approving authority is required to conduct periodic inspections of projects in accordance with the regulations. When violations are found, the inspector notifies the owner about needed corrections and when they must be made. If violations are not corrected on time, the locality (or DCR if applicable) is responsible for enforcement. The program authority can serve notice on the violator specifying a timetable for meeting the requirements of the plan. Localities can establish civil penalty schedules for violations, issue stop-work orders, apply corrective actions, or revoke the permit. The Erosion and Sediment Control Law does not apply to specifically identified agricultural or silvicultural operations. It also does not apply to activities under 10,000 square feet, unless the locality chooses to lower this threshold. For example, Chesapeake Bay Preservation Act areas have a threshold of under 2,500 square feet. Program authorities have authority to grant a variance for specific activities from the requirements of the law.

! *Stormwater Management.* The Virginia Department of Environmental Quality (DEQ), Department of Conservation and Recreation (DCR), and the Chesapeake Bay Local Assistance Department (CBLAD) are coordinating related yet separate state programs that regulate the management of pollution carried by stormwater runoff, including an urban and industrial stormwater permit program under the federal Clean Water Act. The Virginia Stormwater Management Act and regulations enable local governments to establish management plans and adopt ordinances that require control and treatment of stormwater runoff to prevent flooding and contamination of local waterways.[19] Local programs must meet or exceed the minimum standards contained in regulations. Under the act, state agencies must employ management practices whether or not the locality in which a state facility is to be located has a program.

Assistance-Oriented Nonpoint Source Programs

This section describes a number of the technical assistance, cost-share, and voluntary programs that address nonpoint source water pollution in the James River watershed. It is not an exhaustive list, but provides a brief description of programs that have influenced activities and water quality in the watershed.

! *Virginia Agricultural BMP Cost-Share Program.* The cost-share program is administered by DCR to improve water quality in the Commonwealth's streams, rivers, and the Chesapeake Bay. The program is funded with state and federal monies through local Soil and Water Conservation Districts. SWCDs encourage farmers and landowners to use BMPs to better control sediment, nutrient loss, and runoff of pollutants into Virginia's waters from excessive surface flow, erosion, leaching, and inadequate animal waste management. The objective of the program is to solve water quality problems by fixing the worst problems first. Thus, program participants are recruited by the District based upon those factors which most influence their land use impact upon water quality. The individual cost-share limit for all BMPs is $50,000.

! *Virginia Agricultural Best Management Practices Tax Credit Program.* For years, the Virginia SWCB has promoted BMPs. The legislature two years ago added a statewide income tax credit program. This program provides an incentive to install agricultural BMPs in accordance with an approved conservation plan. Its goal is to reduce the amount of nonpoint source pollution entering the state's streams, rivers, and estuaries. For all taxable years beginning on and after January 2, 1998, any individual or corporation engaged in agricultural production for market who has in place a soil conservation plan approved by the local SWCD shall be allowed a credit against the tax imposed by Virginia Code section 58.1-320 of an amount equaling twenty-five percent of the first $70,000 expended for agricultural BMPs by the individual. Agricultural BMP means a practice approved by the SWCB which will provide a significant improvement to water quality in the state's streams and rivers and the Chesapeake Bay, and is consistent with other state and federal programs that address agricultural nonpoint source pollution management. Any practice approved by the local SWCD Board shall be completed within the taxable year in which the credit is claimed. The credit shall be allowed only for expenditures made by the taxpayer from funds of his own. The amount of the credit shall not exceed $17,500 or the total amount of the tax imposed, whichever is less, in the year the project was completed, as certified by the Board. If the amount of the credit exceeds the taxpayer's liability for the taxable year, the excess may be carried over for credit against income taxes in the next five taxable years until the total amount of the tax credit has been taken.

! *Virginia Nutrient and Pesticide Application Equipment Tax Credit* This tax credit program encourages the purchase of improved and more precise nutrient and pesticide application equipment. It is managed by DCR and the SWCDs and is applicable statewide. The Virginia Nutrient and Pesticide Application Equipment Tax may be claimed for the year of purchase for equipment meeting state approved specifications. A 25% Virginia income tax credit may be applied to qualifying purchases of up to $15,000 resulting in a maximum credit of $3,750. The credit balance may be carried forward up to five years into the future if the credit amount exceeds the farmer's tax liability for the year of the purchase. Persons or corporations must be engaged in agricultural production for market to be eligible for the credit. In addition, a nutrient management plan must be developed for the farm and approved by the SWCD by the required filing date of the tax return. A letter from the SWCD indicating plan approval must be sent in with the tax return. The nutrient management plan should incorporate the use of the new equipment and meet DCR criteria for nutrient management plans.

! *Conservation Reserve Enhancement Program (CREP).* CREP is Virginia's largest cost-share program. Beginning in 2000, its five year total will exceed $91 million with 30,500 acres of riparian buffers, 4,500 acres of wetlands restoration, and 8,000 acres of riparian easements anticipated statewide. The federally-funded CREP program supports annual rental payments, cost-share for BMPs, and the ability to add on riparian easements if desired. The program also offers a sign-up incentive payment and a practice incentive payment. The cost-share ranges from 75% to 100% for eligible BMPs and approximately 25% comes from local SWCD funds.

! *Conservation Reserve Program (CRP).* The CRP is primarily for environmentally sensitive lands and for highly erodible lands. Under the CRP, the USDA's Farm Service Agency tries to sign up highly valuable environmental acreage, establish long-term resource conserving covers on eligible land, and to reduce erosion, runoff, and leaching. It is applicable in all counties in Virginia. Offers from landowners to enroll lands, placing them under conservation easements for a period of years, are accepted provided the acreage and producer meet certain eligibility requirements, including suitability of the land for riparian buffers, filter strips, grassed waterways, shelterbelts, salt tolerant vegetation, or shallow water areas for wildlife.

! *Environmental Quality Incentive Program (EQIP).* EQIP is managed by the Natural Resources Conservation Service (NRCS) and is applicable statewide to address priority concerns and in special targeted priority areas. The program was established under the 1996 Farm Bill to provide a single voluntary conservation program for farmers and landowners to address significant natural resource needs. Approximately 65% of the EQIP funding in Virginia is directed towards "priority areas." These areas are selected by the State Technical Committee based on proposals submitted by the locally led conservation work group. The remaining 35% of the funds are directed toward statewide priority concerns of environmental needs. EQIP offers 5-10 year contracts to landowners and farmers to provide cost-share assistance or incentive payments to implement conservation practices. Eligibility is limited to persons who are engaged in livestock or agricultural production. Eligible land includes cropland, pasture, and other agricultural land in priority areas or if the land has a need that matches one of the statewide concerns.

! *Conservation Farm Option (CFO).* The Conservation Farm Option provides landowners and farmers the option of consolidating the different types of payments available under the Conservation Reserve Program, the Wetlands Reserve Program, and the Environmental Quality Incentives Program into a single annual payment. CFO provides an incentive for coordinated, long-term natural resource planning and gives farmers additional flexibility. CFO is managed by the Farm Service Agency and only owners and producers that have a farm with contract acres enrolled in production flexibility contracts established under the Agricultural Market Transition Act (AMTA) are eligible to participate.

! *Forestry Incentive Program (FIP).* FIP is a reforestation program managed by the Natural Resources Conservation Service and the Virginia Department of Forestry. It is applicable statewide. FIP is a voluntary cooperative program with landowners to encourage the development, management, and protection of non-industrial, private forest lands in the state. The program provides cost-sharing assistance to landowners for site preparation and tree planting.

Discussion and Analysis

Tributary Strategies

In Virginia, various state agencies, such as DEQ, DCR, and the Chesapeake Bay Local Assistance Department (CBLAD), work together to develop tributary strategies for river basins, such as the James, to ensure that reductions of nutrients, toxics, and sediments, are sufficient to improve water quality and restore the living resources of the Chesapeake Bay and its tributaries.[20] The *Initial James River Basin Tributary Nutrient and Sediment Reduction Strategy* was completed in July 1998 through a cooperative process among state and local government, agriculture, business, industry, citizens and others. The *Tributary Strategy: Goals for Nutrient and Sediment Reduction in the James River* was sent out for public comment in January 2000.

In 2000, over $20 million was appropriated for the biennium to the Virginia Water Quality Improvement Fund, which by law receives a portion of any budget surplus.[21] The Water Quality Improvement Fund supports point and nonpoint source nutrient and sediment reduction through grants to local governments, farmers and others and is the cornerstone of Virginia's Chesapeake Bay Tributary Strategy Program. The fund also provides grants to areas outside of the Chesapeake Bay watershed. Nonpoint source grants are administered by DCR. Since 1997, approximately 113 million has been appropriated to the Water Quality Improvement Fund. Most of this funding has gone to point sources. In theory, cost-share funding is available for nonpoint source control projects that have been identified in the Initial James River Basin Tributary Strategy, and for other, innovative or cost-effective practices that will help achieve the goals of the Strategy. In practice, access to this funding has been limited, but may increase in the James River Basin when the tributary strategy goals are finalized, although the sufficiency of the amount of available funds to meet the pollution reduction needs is in question.[22] Virginia also applies other funds from Clean Water Act Section 319, Virginia's Chesapeake Bay Implementation Grant Program, and Coastal Zone Management Act Section 6217.

Agricultural Pollution

The Virginia Department of Agriculture and Consumer Services (VDACS) works with farmers and local Soil and Water Conservation Districts to resolve water quality problems reported to VDACS concerning nutrients, sediment and toxins from agricultural activities. Incentives and cost-share programs are the main avenue for nonpoint source pollution management. Enforcement against agricultural nonpoint source pollution is bifurcated. The first prong is regulatory, such as permits for CAFOs. The second prong of Virginia's system addresses agricultural runoff and ground water pollution from CAFOs that are too small for the DEQ permit system, as well as runoff and ground water pollution from crop land and all other forms of agriculture. This second prong is complaint-driven and strives to achieve compliance before resorting to enforcement actions.

Incentive Programs – The primary vehicle for cost-share funding of point source and nonpoint source nutrient controls is the Virginia Water Quality Improvement Fund administered by DEQ and DCR. The Fund is managed as a grant fund for individual projects, identified through the River Basin Strategy. It is also managed as a fund for Soil and Water Conservation Districts to disburse through their normal process of agricultural best management practices and cost share programs.

Animal Feeding Operations – Currently, confined animal feeding operations (CAFOs) (except poultry operations) must obtain a permit. All permitted CAFOs are required to be designed and operated according to specific standards contained in the permit and are subject to inspection by DEQ. Violation of the permit requirements or failure to obtain a permit opens the owner or operator to enforcement by DEQ in the form of civil penalties, criminal charges, and/or injunctive or other equitable relief. Most of Virginia's regulated animal feeding operations are found outside of the James River watershed. However, DEQ has taken some enforcement actions based on violations of permits, primarily on dairy and hog farms. For example, in 1999, statewide, three enforcement actions were completed – one for a small dairy in Tidewater, one for a small dairy in West Central, and one for a larger hog farm. There have not yet been any enforcement actions again chicken farmers as the changes to the law are still too new.

Complaint-Driven Enforcement – Virginia's agricultural stewardship program gives the farmer an opportunity to correct a water quality problem voluntarily before any enforcement action is taken.[23] Under the program, VDACS receives complaints and contacts the local Soil and Water Conservation District for an initial investigation. After the complaint is investigated, VDACS reviews the findings and determines if the complaint is founded and requires further action under the Agricultural Stewardship Act. If so, the farmer is required to develop a plan to correct the problem

R0019324

and then complete plan implementation within 18 months. The Agricultural Stewardship Act does not cover agricultural activities subject to water quality permits from the Department of Environmental Quality, forestry activities, or problems that do not involve agricultural products. Typical activities covered under the Act include nutrients from manure in feedlot runoff, sediment from erosion on crop fields, and toxins from pesticide runoff.

In practice, DEQ, in the course of its water quality monitoring or permit compliance inspections will identify potential water pollution problems under the Agricultural Stewardship Act and notify VDACS as a complainant. Since the complaint-driven process was established in April 1997, VDACS has received approximately 300 inquiries, 100 of which underwent the first step of the process to develop a corrective plan. Of those 100, in only one case was the plan not implemented within the 18 month time limit, causing VDACS to undertake an enforcement action which was still underway in May 2000. This enforcement case is in the James River Basin. In general, the enforcement process is triggered when there is a pollution problem and the landowner (1) does not develop a corrective plan; (2) plan is not being implemented 6 months later upon VDACS inspection; or (3) implementation of the plan is not completed within 18 months of plan approval.[24]

Forestry Water Quality Programs

Virginia has developed best management practices for water quality, such as streamside management zones, design guidance for roads, skid trails, and stream crossings, revegetation of bare soil areas, and wetlands protection.[25] Virginia complements its complaint-driven enforcement mechanism in forestry, with a system of Department of Forestry monitoring, inspection, and specific triggers for enforcement actions.

In order to ensure the monitoring and inspection, Virginia has developed a series of forms to facilitate enforcement of the Silvicultural Water Quality Law.[26] The harvest inspection form is for all private land harvesting operations and is usually filled out by the DOF inspector and then submitted to the Regional Office.[27] Department field personnel can inspect at any time, and in any case will inspect operations of landowners not meeting DOF requirements. If the harvesting inspection form shows that a violation of the Silvicultural Water Quality Law has taken place, the inspector must complete and issue a water quality law enforcement form.[28] In some cases, the inspection form may indicate a BMP deficiency problem that is not a water quality law violation. In these cases, the inspector will re-inspect the tract for BMP corrective action if requested by the owner/operator. Landowners who receive a law enforcement form are given specified periods of time for implementation of corrective measures in a "notice of required action." These deadlines are mandatory. Ninety percent of problems are solved at the notice of required action stage. If the corrective action is not properly taken, the inspector prepares a law enforcement case summary and sets up an informal conference. DOF also can issue emergency special orders or stop-work orders if the silvicultural activity is causing an "imminent and substantial danger to the waters of the Commonwealth by introducing sediment deposition." Landowners can request formal administrative hearings. After either the informal conference or the hearing, DOF issues a final order that can include civil penalties or civil charges. In determination of the civil penalty or charge amount, DOF considers the seriousness of the violation, the degree of negligence, the owner's good faith, and any previous history of violation.

In practice, a weak link in the new enforcement procedures can be identifying logging jobs that do not self-report. The citizen organization Virginia Forest Watch has begun a new program in early 2000 to assist the Virginia Department of Forestry in identifying the location of logging jobs. Between February and April 2000, the watchdog program reported 30 jobs in 15 different counties across the state. According to Virginia Forest Watch, the first two jobs looked at by DOF resulted in the discovery of water quality violations and "notice of required action" was served on the loggers and the owners.

Land Development and Urban Runoff

Erosion and Sediment Control - DCR Soil and Water Division coordinates the erosion and sediment control program for the state. The Soil and Water Conservation Board has the authority to revoke a local program. However, in the case of revocation, the local Soil and Water Conservation District would be able to take over the program, and if they refuse to do so, the program then would fall under the jurisdiction of DCR. In practice, all localities in Virginia have retained control over their erosion and sediment control programs, knowing that lack of resources in the local Soil and Water Conservation Districts and in the DCR offices might cause their building permit fees to rise in order to provide the resources for running the program. However, program consistency with state law generally and in the James specifically is at approximately twenty-five percent. Erosion and sediment control has become a big problem for localities facing increased growth, although sedimentation remains a relatively small contribution to the James River overall.

Stormwater - Eight urban localities (Chesapeake, Norfolk, Newport News, Virginia Beach, Portsmouth, Chesterfield, and Henrico) in the James River basin and its adjacent Bay waters have been required to develop stormwater management programs under provisions of the federal Clean Water Act, administered by Virginia DEQ. Permits obtained by localities require them to implement and monitor programs that reduce the discharge of pollutants from municipal storm sewers to the maximum extent possible and to prohibit illicit discharges into stormwater systems. Other localities regulate stormwater runoff on a case-by-case basis through subdivision laws and other zoning regulations. Most stormwater enforcement actions are taken by localities administering the programs. DEQ has investigations underway, but no enforcement actions.

The Chesapeake Bay Preservation Act establishes requirements for stormwater management within Chesapeake Bay preservation areas in all Tidewater localities. Under this legislation, each local government enforces its own program, which has been patterned on a model developed by the Chesapeake Bay Local Assistance Board and Department. State resources for the implementation and enforcement of stormwater regulations are low, with only five stormwater engineers statewide who oversee state agency stormwater management practices as well as local stormwater management programs.

Conclusions

Virginia has a variety of nonpoint source control programs operating in the James River watershed, including cost-share, technical assistance, voluntary, and enforceable programs. The James River watershed reflects many of the trends and nonpoint source pollution programs found throughout Virginia. The process of developing a tributary strategy for the James River has helped state and local government, as well as citizens and others identify priorities and set goals for reduction of nutrients and sediment from nonpoint source pollution. This process is helping the state government and local governments to determine priorities for technical assistance, cost-share funding, and enforcement actions.

The review shows that Virginia emphasizes best management practices for management of nonpoint source pollution from agricultural and forestry operations. The various regulatory agencies focus on bringing land owners into compliance, using enforcement actions as a final resort in cases of continued noncompliance. Coordination among agencies, such as VDACs and DEQ or DOF and DEQ, can facilitate identification of real and threatened harm to water quality in order to support compliance and enforcement actions. Compliance and enforcement for forestry operations is supplemented by a recently adopted monitoring and inspection process by DOF. The James River watershed experience shows both that local erosion and sedimentation control programs are very important to maintaining healthy rivers, and that a more resource-intensive mixture of technical assistance, training, priority-setting, and enforcement is needed to make the local and state programs in these areas more effective.

In general, the impression left by review of existing efforts is that the use of enforceable mechanisms has increased slightly over the past, although the primary nonpoint source control mechanisms are still technical assistance, cost-share, and voluntary programs. In most cases, regulatory programs seemed understaffed with few financial resources at their disposal. Nonpoint source controls have never been relatively well funded, although there was a significant level of funds this year for the first time. Historically nonpoint controls have been left to be accomplished voluntarily, with cost-share largely carrying out "demonstration" of practices, rather than broader-scale implementation.

Still, a significant level of agency interaction and cooperation in Virginia has enabled the Commonwealth to achieve certain improvements with the limited resources available. Voluntary conservation and stewardship have also played a role. The rapid pace of development, alongside continued agricultural and silvicultural activity, poses a challenge to state and local government agencies. These will require additional resources for strengthening implementation, compliance assurance, and enforcement in the future.

Wisconsin Case Study

Summary

Unlike many other states, Wisconsin has for many years had a fully articulated program for nonpoint source water pollution control.[1] Thus, its enforceable mechanisms have long been linked with its cost share and technical assistance provisions. Wisconsin's nonpoint source pollution abatement program originated in 1978. Initially, the program administered grants to individual landowners and communities in both urban and rural watersheds to cover the cost of voluntary best management practices. To assist in targeting projects, as well as to meet federal and state requirements to identify waters in need of attention, the state developed a system known as the "priority watershed program." The Department of Natural Resources (DNR), with cooperation from the Department of Agriculture, Trade, and Consumer Protection (DATCP), ranked the watersheds. For each priority watershed, DNR, DATCP, and the local government developed a priority watershed plan to guide cost-share assistance and related activities. In 1993, the priority watershed program was amended to include a requirement that "critical sites" be identified in the planning process. A critical site is one that, due to the amount of pollution it generates and/or its location in the watershed, *must* be addressed in order for the plan to achieve its water quality objectives.

After nearly ten years of experience with the nonpoint source program, it became clear that enforceable mechanisms would be needed to assure the state's ability to assure the effectiveness of nonpoint source pollution controls. In 1987, DNR received authority to issue Nonpoint Source Abatement Orders. DNR can issue such orders whether or not the site is in a priority watershed, although more complex procedures apply when the site is agricultural.[2] Orders may be issued for all sources of nonpoint source pollution except animal waste, which has been regulated under a separate program since 1984. The "Notice of Discharge" system for animal waste nonpoint sources provides a way to obtain corrective action for these sites.[3]

In 1997, the Wisconsin legislature significantly changed the direction of the state's nonpoint source programs. Act 27 (the common name for the 1997 amendments) placed the priority watershed program, which is chiefly administered by DNR, into a long multi-year phase-out period. It also strengthened the role of DATCP in addressing agricultural nonpoint source pollution. The changes required the agencies to develop explicit performance standards for nonpoint sources. Further, Act 27 created new competitive funding programs available across the state rather than just in priority watersheds. In 1999, the legislature reinforced these changes by shifting more funding to DATCP to support agricultural nonpoint source control staff and cost share activities in all 72 of Wisconsin's counties.

Wisconsin's counties, and to some extent towns and cities, play a substantial role in the state's nonpoint programs. Funding and cost share assistance are provided by the state through the county Land Conservation Commissions (LCCs). Counties also adopt and administer land

and water resource management plans and enforceable ordinances which may address erosion, shoreline protection, animal waste and manure management, land use, and pollutant management practices.

Wisconsin's comprehensive nonpoint efforts reflect objectives of setting state standards and state priorities, while providing for local control and flexibility. The programs reflect as well the continued legislative experimentation with the role of DNR (which largely administers Chapter 281 of the Wisconsin Statutes) and DATCP (which administers Chapter 92). The legislature adjusts their relationship *each biennium* through budget legislation, which often includes substantive amendments. The recent changes reflect the legislature's judgment that more funding and attention should go to nonpriority counties and watersheds.

Watersheds

This study examines the use of state and local nonpoint source programs and authorities in watersheds in two parts of Wisconsin: La Crosse County (along the Mississippi River in western Wisconsin) and Brown County (in the Green Bay area in northeastern Wisconsin).

Both counties have developed local ordinances for the control of nonpoint source pollution, and both have been funded for priority watershed projects in the past. The watersheds - which have substantial agriculture and development activity - are described in greater detail in the "Discussion and Analysis" section.

Enforceable Mechanisms Studied

This study examines the following enforceable mechanisms:

! *DNR Nonpoint Source Abatement Order.* These orders apply to all types of nonpoint source pollution except animal waste pollution, and may be issued by DNR if pollution is determined to be "significant." Significant nonpoint source pollution is defined as causing violation of a water quality standard, significantly impairing aquatic habitat or organisms, restricting navigation, deleterious to human health, or otherwise significantly impairing water quality.[4]

! *Animal Waste Notice of Discharge.* A complaint-driven process can result in a DNR determination that an animal waste pollution discharge is significant. If so, DNR issues a Notice of Discharge (NOD) which requires correction of the problem. If the NOD does not result in compliance, the DNR requires the operator to obtain a state NPDES permit which specifies all of the requirements to abate the discharge and come into compliance.[5]

! *Local Ordinances.* Wisconsin law provides for many kinds of enforceable local ordinances that may be directed at nonpoint source water pollution. These include soil and water conservation and nonpoint source pollution abatement ordinances; shoreland ordinances; livestock operation and manure management ordinances; and zoning ordinances that address contruction erosion and stormwater runoff.[6]

Nonpoint Source Programs, Cost-Shares, Standards, and Enforcement

Responsible Agencies

Operating under Title 281, DNR's Bureau of Watershed Management has primary responsibility for administering Wisconsin's nonpoint source program, for standard setting, and for grant funding, particularly in priority watersheds.[7] DNR also has abatement order authority. DNR must consult with DATCP on elements of the nonpoint program that relate to agricultural standards and agricultural watersheds.

For its part, operating under Title 92, DATCP sets soil and water conservation policies and administers agricultural grant and planning programs.[8] The legislature recently gave DATCP greater responsibility for standard setting, and for local staffing and cost shares in addressing nonpoint source problems. DATCP interacts with county land conservation committees (LCCs), which are created by Wisconsin's county boards.[9]

The appointed Land and Water Conservation Board (Board) oversees both DNR's nonpoint source program and DATCP's soil and water conservation program, reviewing administrative rules and plans. The Board also approves the list of priority watersheds, which until recently served as the core of the Wisconsin nonpoint program.

Local government units, including cities, counties, villages, towns, metropolitan sewerage districts, town sanitary districts, public inland lake protection and rehabilitation districts, regional planning commissions, or drainage districts, also play a role in nonpoint source controls.[10] County and municipal governments are authorized to enact ordinances to address nonpoint source pollution, including the prohibition of land uses or management practices that cause erosion, sedimentation, nonpoint source water pollution, or storm water runoff.[11]

Priority Watershed Program

The priority watershed program has for two decades been the state's primary vehicle for targeting its cost sharing grants. The process of identifying priority watersheds was linked to Wisconsin's original areawide water quality management planning process.[12] DNR set water quality objectives for each priority watershed and established a committee (including farmers, public inland lake protection and rehabilitation districts, riparian landowners) for each watershed to advise DNR and DATCP.[13] DNR, in consultation with DATCP and the appropriate local governmental unit, prepared the proposed priority watershed plan.[14] During the planning process, DNR:

- Conducted a water resource assessment
- Set water quality goals
- Analyzed alternative management practices
- Incorporated best management practices (BMPs) into the plan
- Determined whether a city, town, village or county must develop construction site erosion control ordinances or manure storage ordinances[15]

The implementation plan[16] prepared by the local government must contain:

- A list of BMPs that are most critical to achieving water quality objectives
- Designations of critical sites
- Priorities for implementation
- Requirement to review plan periodically
- Provisions for public notice and education[17]

Following two public meetings to receive comments, the county could approve, conditionally approve, or reject the priority watershed plan. Once the plan received county approval, its subsequent approval by the Board and by DNR would render the project eligible for funding.[18] DNR was required to provide cost share grants to governmental units and landowners for cost-effective best management practices.[19] The local government unit specified in its application for funding the percentage of the implementation costs that the grant would cover, but the grant could not exceed 70 percent of the cost of implementing the BMPs.[20]

Cost sharing grants could also be issued to governmental units or individual landowners in non-priority watersheds if projects were in conformance with areawide water quality management plans, but at least 70 percent of cost-sharing grants annually were required to be used in priority watersheds.[21]

The priority watershed program was amended in 1993 to include a requirement that "critical sites" be identified in the watershed planning process. A critical site is one that, due to the amount of pollution it generates and/or its location in the watershed, *must* participate and be addressed in order for the plan to achieve its water quality objectives. DNR was required to notify the owner or operator of a designation.[22] The owner or operator could request a review of the designation by the county land conservation committee and further appeal to the Board.[23] The owner or operator of a critical site must apply best management practices.[24] However, once the owner or operator has installed BMPs as provided in the plan, the site is no longer considered a critical site.[25]

The priority watershed program underwent significant changes beginning in 1997. There had been 60 priority watersheds designated – mostly in the southern and eastern part of the state. Legislative concern arose over the treatment of the northern counties. Accordingly, Act 27 required the Land and Water Resource Board to determine by mid-1998 whether or not to continue *existing* priority watershed projects, assuming no increases in the funding available to the program. Act 27 further provided that there would be *no new priority watersheds* designated after that time. DNR was required to submit to the Board a list of watersheds ranked on the basis of impairment (based on the state's § 303(d) list prepared under the federal Clean Water Act).[26] The Board was then to decide on whether to approve continuation of the existing priority watersheds based on the list and DNR and DATCP recommendations.[27] In 1998, the Board voted to approve continuation of *all* of the existing priority watersheds. The continued priority watershed projects will remain a substantial part of the state's program for many years, as the phase-out is expected to run through 2008.

Base-Level County Planning and Funding

Chapter 92 was amended in 1997 and in 1999 to redirect a significant portion of the state's nonpoint efforts. The new focus is on providing a base level of staff and funding for *all* counties, rather than only priority watersheds.

Under an older provision of Chapter 92, DATCP was required to identify priority soil erosion control counties.[28] Under that program, which was never large, a county LCC was to prepare a county land and water resource management plan which specified maximum acceptable rates of soil erosion, identified specific land parcels exceeding acceptable erosion rates and management practices that would bring these lands into compliance, and identified other nonpoint source pollution.[29] This plan was then to be reviewed by the DATCP and Board, and cost share money was to be provided to deal with problems.

Under the 1997 legislation, the priority soil erosion county designation was abolished. Now *every county* is to prepare a land and water resources management plan. The plan must be a multi-year action plan of three to five years, not focused only on soil erosion, but also on meeting water quality objectives through control of nonpoint sources. Counties are encouraged to incorporate the use of local ordinances to achieve their water quality objectives. Under 1999 legislation, each county will be provided with funding to plan for and begin implementing the nonpoint source performance standards discussed below.[30]

DATCP has been given a goal to provide each of the state's 72 counties with an average of $100,000 for cost shares ($7.2 million). It will also provide funding for 3 staff persons for each county (cost shared at 100 percent, 70 percent, and 50 percent), another $7.1 million.[31] About $6 million in base budget funding was transferred from DNR to DATCP for the program.

Competitive Grant Programs

Act 27 also established a new $2 million competitive grant program under which any county or local government or local lake association could apply to DNR for nonpoint source grants. This was intended to help overcome a perceived imbalance that urban watersheds were only receiving 25 percent of priority watershed monies. DNR was required to develop a scoring system for the new money, including 1) the extent to which BMPs will be used in the project; 2) the level of impairment of the water (§303d list); 3) the extent to which the project will result in the attainment of water quality objectives; 4) local interest in the project; 5) the inclusion of a means to measure the results of the project; and 6) the extent to which the project proposes to use federal funding. DNR, with DATCP consultation, scores each project and the Board selects projects for funding by November 1.[32]

R0019336

In 1999, the legislature authorized a further targeted competitive program. It allows anyone, including non-profit groups, to apply to DNR for funding for nonpoint source projects for up to four years. This funding may address anything from watershed scale to subwatersheds to site-specific actions. The program is starting with $1 million. DNR anticipates a substantial increase to this program in the future.

In 1999 the legislature also established a new urban competitive nonpoint source program administered by DNR. The program will have $19 million available in grants. Additional bond funding has been made available for nonpoint source controls, including urban and stormwater controls.

Other Funding

Wisconsin's priority watershed program has been used to target US EPA § 319 funds. Rather than projects applying separately for 319 grants as in most other states, Wisconsin has used 319 funding to augment the state's own funding for priority watersheds. Wisconsin received $2.583 million in 1999 and has been allocated $5.166 million for 2000.

USDA's Environmental Quality Improvement Program (EQIP) has been active in Wisconsin since 1997. The Natural Resources Conservation Service (NRCS) office in Wisconsin establishes EQIP priority watersheds. These are not limited to state priority watersheds. However, incorporating the availability of other sources of funding in the NRCS ranking system gave DNR priority watersheds an advantage in obtaining EQIP funds. The program received $3.2 million in funding in 1998 and again in 1999, of which $2.8 million was reserved for EQIP priority watersheds. Wisconsin's EQIP program also focuses on educational programs. NRCS has received $800,000 during the past three years to implement educational programs. Any local organization can apply for this funding as long as the educational efforts will be directed towards producers.

Standard Setting

Act 27 introduced formal standard setting requirements to the state's nonpoint source programs.

Act 27 requires DNR to prescribe, by rule, performance standards for *non-agricultural nonpoint sources*. The performance standards must be designed to achieve water quality standards.[33] DNR must also, by rule, specify a process for developing and disseminating technical specifications to implement these performance standards.[34]

For *agricultural nonpoint sources*, DNR, in consultation with DATCP, must promulgate rules prescribing performance standards and prohibitions to achieve water quality standards. For its part, DATCP must, in consultation with DNR, promulgate rules prescribing conservation practices to implement the performance standards and prohibitions. DATCP must also identify, by rule, the *process* by which agricultural technical standards are to be developed and disseminated,[35] and develop and disseminate technical standards to implement the performance standards.[36] The agricultural performance standards must at a minimum require livestock operations to 1) have no overflow of

R0019337

manure storage structures; 2) have no unconfined manure pile in a water quality management area; 3) allow no direct runoff from a feedlot or stored manure into water; and 4) prevent unlimited access by livestock to water in a location where high concentrations of animal cause stream bank erosion.[37] The conservation practices and technical standards must at a minimum address animal waste management, nutrients applied to soil, and cropland sediment delivery.[38]

The performance standards and technical specifications rulemakings are scheduled to be completed in 2000.[39] The standard-setting processes relate not only to cost-share requirements, but also to the enforceable mechanisms used in Wisconsin. County-based land and water resources management plans will be required, at a minimum, to address the statewide performance standards and prohibitions. The DNR and DATCP are pursuing an approach that would set statewide performance standards and prohibitions, but that would also provide for targeted performance standards that may be established by DNR or local governments in particular watersheds where statewide performance standards are not adequate to meet water quality goals. Statewide standards would apply to cropland soil erosion, soil loss from riparian fields, manure storage and management, nutrient management, standards for new development and redevelopment during construction activities, and for management of stormwater after construction, and for management of pollution from previously developed urban areas.

Forestry standards are not currently under development as existing forestry BMPs are fairly recent in Wisconsin and hence will be given an opportunity for experience to be gained using them.

DNR Abatement Orders

DNR has authority to issue abatement orders for both agricultural and non-agricultural nonpoint sources of pollution determined to be "significant." Significance includes "pollution which causes the violation of a water quality standard, pollution which significantly impairs aquatic habitat or organisms, pollution which restricts navigation due to sedimentation, pollution which is deleterious to human health or pollution which otherwise significantly impairs water quality."[40] While the abatement order authority operates in both priority and non-priority watersheds, DNR can issue orders for abatement of *agricultural* nonpoint source pollution in priority watersheds *only* if the site has been designated a critical site.[41]

The process begins when DNR sends a written a notice of intent to issue the order to the person responsible for the source of pollution. The notice of intent describes DNR's findings and provides the individual at least one year to abate the pollution or implement the required BMPs, unless the pollution is causing severe water quality degradation, in which case a temporary emergency order (described below) may be issued.[42] If an order is issued and compliance still does not occur, civil forfeitures of up to $5,000 per day are authorized; the state may recover its cosets of investigation and attorney's fees. In addition the DNR may take the action itself and recover the costs incurred.[43]

Agricultural sources are subject to additional procedures. DNR must send the notice of intent to the LCC and DATCP.[44] DATCP must provide the person responsible for the pollution a list of management practices that would reduce pollution to a level acceptable to DNR, as well as a list of sources of financial and technical assistance available from DATCP and other sources.[45]

DATCP must issue a report to DNR within one year after the date of the notice describing the actions taken by the person and providing a recommendation as to whether DNR should issue an order. DNR may not issue an order until it receives DATCP's report.[46]

If the notice of intent involves agricultural pollution in a priority watershed, the LCC may within 60 days of the notice disapprove issuance of an order. DNR can request the Board to review an LCC disapproval decision.[47] If the LCC approves the proposed order, the owner may obtain a review of the proposed order by filing a written request with the Board.[48]

DNR is prohibited from requiring any agricultural facility or practice that was in existence prior to October 14, 1997, to comply with newly prescribed performance standards, prohibitions, conservation practices or technical standards unless cost-share funding is made available.[49]

Despite the one year minimum abatement period, and the special review requirements applicable to agricultural sources, DNR may issue a temporary emergency order before issuing a notice of intent if the pollution is causing or will cause severe water quality degradation and the required abatement action does not involve a capital expense. If the source is agricultural, DNR must provide a copy of the order to DATCP and the appropriate LCCs. As soon as practicable after a temporary order has been issued, DNR must either issue a written notice of intent to issue a regular abatement order or rescind the temporary order.[50]

DNR's abatement order authority has seldom been invoked. Rather it has served chiefly as a back stop to cost share and technical assistance approaches. DNR has used its abatement order authority at least 10 to15 times.

Animal Waste Notices of Discharge

DNR does not have authority to issue nonpoint source abatement orders for pollution caused by animal waste. But it has a complaint-driven process available under its animal waste management regulations (NR 243) to address complaints.[51] If investigation of a complaint reveals that an animal waste pollution discharge is significant, the DNR issues a Notice of Discharge (NOD), which requires correction of pollution. The NOD identifies the problem and potential solutions and identifies cost share and technical assistance sources; it allows a minimum of 60 days and a maximum of two years to remedy the problem. The designated county agency (land conservation commissions) may seek to review the proposed corrective action plan. Issuance of the NOD expressly makes the operator eligible for DATCP cost-share funding during the time that the NOD is in force. If the operator does not remedy the problem, then DNR requires the operator to obtain a state NPDES permit which specifies all of the requirements to abate the discharge and bring the facility into compliance.[52] Accepted animal waste management practices must be used in implementing corrective measures needed for runoff control, storage, or disposal of animal wastes.[53] However, the DNR may not require an animal feeding operation in existence prior to October 14, 1997 to comply with newly prescribed performance standards, prohibitions, conservation practices or technical standards unless cost-sharing is available.[54] If the operator ignores the NOD and also fails to obtain an NPDES permit, the whole range of judicial enforcement tools comes into effect (including civil forfeitures of up to $10,000 per day).[55] Statewide, DNR has issued NODs to about 550 AFOs during the course of the program. Recently, the NOD program at the state level has changed from a reactive program to a targeted program, focusing on complaints arising in outstanding resource waters, exceptional value resource waters, 303 (d) waters, or source water protection. DATCP currently plays a role in administering cost shares for AFOs; it maintains a database of NOD recipients, updated quarterly. In the future, it appears that DNR will be responsible for handling these cost shares (or arranging them with federal agricultural agencies).

Local Ordinances

Wisconsin law authorizes numerous kinds of enforceable local ordinances that may be directed at nonpoint source water pollution.

Under Chapter 92, a county, city, village or town has explicit authority to enact ordinances for soil and water conservation or nonpoint source pollution abatement. Such ordinances may regulate "land use, land management, and pollutant management practices."[56] The ordinance may be made applicable throughout a county or to any part of it, including both incorporated and unincorporated areas. However, the ordinance must be adopted by the county board and by *referendum* of the voters in the area covered by the ordinance. Enforcement of an ordinance adopted under Chapter 92 requires an LCC to make a reasonable effort to contact a landowner and to provide a plan and identify any cost-shares that are available, at least one year before taking any enforcement action. Enforcement includes civil forfeitures (penalties) and injunctions.

Counties, cities, villages, and towns also have authority to adopt certain other ordinances *without* referendum. These include enforceable shoreland ordinances,[57] livestock operation and manure management ordinances,[58] and zoning ordinances that address construction erosion and stormwater runoff.[59] Each of these is enforceable by the local jurisdiction through civil forfeitures (penalties) and injunctions. For example, local governments may enact ordinances requiring manure storage facilities constructed after July 2, 1983 to meet local standards.[60] Likewise, livestock operations that do not meet the new nonpoint performance standards established under Act 27 may be regulated by local ordinance if necessary to achieve water quality standards, provided that cost sharing is made available if the operation was initiated prior to October 14, 1997.[61] Shoreland management ordinances adopted under these provisions may be enforced only if cost share funding is made available.[62]

Local zoning ordinances may also help protect lands under, abutting or lying close to navigable waters. The purposes of such ordinances are to "further the maintenance of safe and healthful conditions; prevent and control water pollution; protect spawning grounds, fish and aquatic life; control building sites, placement of structure and land uses...."[63] The DNR is responsible for providing general recommended standards and criteria for navigable water protection regulations and their administration, and for authorizing such regulations.

Wisconsin counties are *required* to adopt zoning and subdivision regulations for the protection of shorelands in unincorporated areas.[64] State regulations require that these county shoreland ordinances include, at a minimum, zoning regulations for shoreland-wetland zoning districts.[65] The ordinances must "provide sufficient control of the use of shorelands to afford the protection of water quality...."[66] The regulations further specify minimum components, including building setbacks that "conform to health, safety and welfare requirements, preserve natural beauty, reduce flood hazards and avoid water pollution."[67] The regulations also require limits on alterations to existing nonconforming structures.[68] Exemptions from local shoreland zoning ordinances are provided for state highway and bridge work and for farm drainage ditches in certain circumstances.[69] Where a county has not adopted an ordinance that meets the "reasonable minimum standards," the DNR is to adopt an ordinance to be administered by the county.[70]

State law also requires municipalities (cities and villages) to adopt shoreland zoning ordinances to protect wetlands.[71] State regulations establish minimum standards for the municipal ordinances. If a municipality fails to establish an ordinance that meets "reasonable minimum standards," the DNR is to adopt an ordinance for the municipality.[72] Enforcement mechanisms are specified in the local ordinance. In addition, the DNR may initiate enforcement through fines (not more than $50 per day) and injunctions if it determines that the city or village fails to keep its ordinance "current, effective and enforceable." [73]

State law provides that county ordinances in general "shall be enforced by appropriate fines and penalties," and may be enforced by injunction in a suit by the local government or local affected property owners.[74] State law also provides that violations of city zoning ordinances are punishable by fine and by imprisonment for failure to pay such fine, and that violators are subject to suit by local government or affected property owners to prevent or correct the unlawful practice.[75]

Wisconsin law authorizes municipal and county construction site erosion control ordinances "for the efficient use, conservation, development and protection of this state's groundwater [and] surface water," for the prevention and control of water pollution, and for the control of building sites and placement of structures and land uses.[76] Indeed, under the priority watershed program, DNR was authorized to determine that a county, city, village or town was required, as a condition of a grant, to develop a construction site erosion control ordinance in order to meet the water quality objectives.[77]

DNR must establish the minimum standards for local ordinances covering erosion from site activities other than construction of a building.[78] The minimum standards must require regulation of site erosion where the activity involves grading or other land disturbance of 4,000 square feet or more; moving 400 cubic yards or more of material by excavation or filling; constructing a street, highway, or bridge; pipeline construction exceeding 300 feet; or an activity requiring a subdivision plat approval or certified survey.[79] DNR's minimum standards for storm water management must also regulate any residential development larger than five acres (or larger than 3 acres with 1.5 acres of impervious surfaces) or any non-residential development larger than 3 acres.[80] The DNR must consult with the Department of Transportation in developing minimum erosion control and stormwater management standards for street, highway, road or bridge construction.[81] Site erosion control ordinances must require consistency with the Wisconsin Construction Site Best Management Practice Handbook.[82] The Wisconsin Department of Industry, Labor, and Human Relations (DILHR) has developed standards for erosion control related to building construction - for one and two family dwellings and commercial construction projects.[83] Certified local building inspectors or county inspectors enforce these building construction erosion control requirements.

Discussion and Analysis

Wisconsin's many nonpoint source program mechanisms can be observed in operation by examining watershed experiences in western (La Crosse County) and eastern (Brown County) parts of the state.

La Crosse County Nonpoint Source Controls

La Crosse County, with a population of about 90,000, contains portions of three river basins: the Black in the northern part of the county, the La Crosse in the center, and the Bad Axe in the south, all flowing westward to the Mississippi. There are two lakes in the county: Lake Onalaska (5,400 acres of flowage) created by Corps of Engineers dams on the Black and Mississippi Rivers, and Lake Neshonoc (600 acres) created by a dam on the La Crosse River. The county has 274 miles of streams and 730 surface acres of lakes excluding Onalaska. Water sampling in 1998 showed that 84 percent of the county's streams do not meet standards for whole body contact recreation.[84] The county is urbanizing although it still has significant crop and livestock operations. Nonpoint source water quality impairments are attributed to cropland soil erosion, sedimentation from urban development, pesticide and fertilizer runoff, and animal waste runoff. The county's topography has caused runoff problems, as it is a flat plain dissected by streams and gullies, which often have steep slopes. Residential construction is occurring on some of these steeper lands. La Crosse County has a five member LCC, and the county's department of land conservation (DLC) has a six member staff.

Priority Watershed Program

The Lower Black River watershed (one of the three primary watersheds in the county) was selected as a priority watershed project in the early 1980s, and received funding for roughly ten years. At the time that this watershed was chosen for the program, much of the planning responsibility was centralized in DNR. The county's Department of Land Conservation (DLC) provided information on the watershed and DNR developed a fairly generic plan for the county using boilerplate formatting. DNR has greatly increased the county role in recent years of the project, although developing the plan now takes more time. The priority watershed program built staff capacity in the DLC, and the staff hired during the project continue to work in the department.

In its priority watershed effort, La Crosse County focused on implementing streambank corridor practices to prevent soil erosion, on feedlot improvement, and on contour strip cropping. The county had no baseline data, so no numerical phosphorous reduction goal was established and evaluation of the project's success was done on a site-by-site basis. The project also had very little water quality testing or monitoring, although DNR used some bio-monitoring data to conclude that the project had positive results. Lack of baseline water quality data and monitoring results proved problematic for the DLC, which now has instituted an aggressive monitoring program to assess the success of its own recent water quality programs and local ordinances.

Other Watershed Planning

La Crosse County's original cropland erosion control plan was adopted in 1988 in accordance with chapter 92. Approximately 94 percent of the county's identified cropland is under some kind of plan. The county plan established soil loss goals and identified needs for conservation practices as well as for cost-shares and technical assistance. The county attributes not attaining these goals to lack of adequate state funding (particularly base level funding). County officials hope that the additional base level funding provided under the state's revised nonpoint program will make achievement possible.

La Crosse County's new Land and Water Resource Management Plan (required per Act 27) was adopted by the county and approved by DATCP in 1999.[85] It includes identification of data needs, the status of water pollution and erosion issues in the county, a work plan for achieving performance standards, and revenue sources. The plan gives detailed descriptions of how the county ordinances described below (and other programs) are designed to operate; and it identifies watershed objectives. In the state review process the DNR called it "one of the best...plans we have had an opportunity to review," while DATCP in its approval memorandum called it an "excellent plan."[86]

Erosion Control Ordinance

La Crosse County adopted a land disturbance erosion control ordinance in 1992. The county used authority provided by the state's general zoning law in order to avoid the referendum that would have been required had it adopted such an ordinance under chapter 92.[87] The erosion control ordinance applies only in unincorporated areas of the county. It regulates land disturbances of 4,000 sq. feet or greater on slopes less than 20 percent, and disturbances of 2,000 sq. feet or greater on 20-30 percent slopes. The ordinance prohibits development on slopes greater than 30 percent. The ordinance also covers logging road installation, and tracks timber cutting notices filed by landowners. In addition to these sites, the ordinance has a catch-all provision that allows the county to regulate other sites that are causing severe erosion (even if a structure has already been completed).[88]

The ordinance requires submission of a detailed erosion and sedimentation control plan and schedules to the LCC for approval. The county Department of Land Conservation (DLC) issues the erosion control permit. There are three categories of permit. These depend on the slope of the site and the location of the site in relation to the shoreline. The amount of information required and the permit fee increases for each category. It usually takes the county three days to process the information and issue the permit. Data from 1992 to 1998 show that each year between 123-197 permits were granted for activities on 0-12 percent slopes, 17-34 permits on 13-20 percent slopes, and 7-20 permits on 21-30 percent slopes. Logging road permits ranged from 16-32 per year.[89] Enforcement is with stop work orders, permit revocations, forfeitures of $50-500 per offense/day plus costs of prosecution, or injunction.

The county has experienced some difficulty with its ordinance because in 1994 the state adopted a provision in the Uniform Dwelling Code (UDC) prescribing erosion controls for construction of 1 and 2 family homes.[90] The state standards are arguably less stringent than those in the county erosion ordinance. The UDC provisions have been interpreted to allow enforcement only where sediment is actually leaving the site. In contrast, the county erosion control ordinance requires that the erosion control plan be implemented as specified regardless of any offsite impacts.

Eventually the county agreed to apply the state standards for residential construction, and became the enforcer of the state UDC through memoranda of understanding with 10 of the 12 townships. But the grading of sites and roads, and development-wide activities are regulated under the stricter county standards. Once construction of the residence is to begin, the state standards apply. Under the UDC, the county issues a notice of non-compliance. The operator has 72 hours to respond to the notice and fix the problem. If the problem is not repaired the county will issue a stop work order. Although the county can use the courts, it prefers not to because of concern about possible delays, and concern that sediment or erosion violations may not result in a substantial sanction. The county process for enforcement of the county ordinance is similar.

Animal Waste Management Ordinance

La Crosse County's animal waste management ordinance was adopted in December 1998 to implement the animal waste performance standards under Act 27.[91] It requires permits for new manure management impoundments and feedlots. Preexisting feedlots are exempt from enforcement and permit requirements unless a site evaluation has been completed and cost-share funding is provided.

Manure management plans are required for unconfined manure stacks within 1,000 feet of a lake or 300 feet of a stream ("water quality management areas"). Also the ordinance prohibits direct runoff from feedlots (defined as discharging 5 lbs. or greater total phosphorous) and from "mismanaged pastures" within the water quality management area. Mismanaged pastures are defined as areas where confinement of livestock for feeding, browsing, or loafing prevents the adequate maintenance of sod cover, causing bank erosion.

Manure management plans are required for any farmer who receives cost shares, and for any operation constructing a new manure storage pit. The county allows certified private planners to develop manure management plans, but prefers to have farmers develop their own plans in group sessions that DLC conducts. In order to construct a new manure storage pit, a farmer must provide the county with a construction plan developed by a professional engineer and pay a $50 fee. The county does not inspect these sites to ensure that they are constructed as planned; the ordinance gives the professional engineer this responsibility.

Direct runoff from feedlots is prohibited by both the county ordinance and by Chapter 281. The county ordinance defines direct runoff as runoff containing more than 5 lbs of phosphorous per year. The phosphorous load is determined using NRCS's BARNY model, which accounts for the amount and type of livestock, slope of the site, the water at the site, and vegetation. The county has been in conflict with some state officials over the definition of direct runoff. While the state has generally preferred a definition based on the number of animal units, the county believes that such a cutoff point would not be effective in addressing problems caused by small but concentrated dairy operations in the county (many of which, even though including fewer than 100 cattle, cause problems because of the steep topography near the waterways).

The county is working to achieve voluntary compliance, and is offering 100 percent cost share for measures that achieve the county's standards. Cost share funding may be obtained from DATCP, from DNR, or from the county's own "environmental fund." The environmental fund, established in 1998, provides county funding for low-cost practices that have high water quality benefits, such as grass filter areas.[92] Feedlot owners voluntarily seeking assistance will receive first priority for cost shares; the next priority will be volunteers responding to county action in county-targeted watersheds. The county will not seek to provide cost shares for manure storage pits, nor for practices associated with the expansion or the establishment of a new feedlot. The DLC believes that expansion of a business inherently includes costs for protection of the environment, and that the public should not bear those costs.

The county intends to focus its cost shares on existing facilities, as it cannot enforce the new standards against an existing facility (constructed before 1997) unless it can provide cost share assistance. Enforcement has not yet occurred under the ordinance, but when the county begins to enforce the law, it intends to proceed by watersheds on a priority basis. Enforcement will begin with notices of noncompliance setting a timetable for compliance. Stop work orders are authorized if a notice of noncompliance has expired and the severity of the runoff is such that a stop work order is deemed to be warranted. Violations of orders are subject to injunction, and to a civil forfeiture of $50 to $500 per day of offense plus costs of prosecution.

State Enforcement

In La Crosse County, the relevant enforcement authority is ordinarily the county DLC. In part this is because DNR enforcement staff are spread thinly. For instance, one DNR enforcement staff person is assigned to deal with animal waste complaints in more than ten counties in the area. The DLC also has concern with the speed of state response to complaints referred by the DLC. Officials note that the response is slowed by the process and the number of agencies involved. For instance, one case investigated by DNR as a result of a complaint referred by the DLC has taken several years to resolve, in part because of the division of functions – DNR information gathering and enforcement, DATCP technical remedy design, and county distribution of cost share funding.

DNR has apparently not used its nonpoint source abatement order authority in La Crosse County. DLC reports one instance in which the county requested that DNR issue an abatement order. In this case, a large quantity of sediment ran from a quarry into a trout stream, covering the streambed with clay. DNR declined to issue an order, expressing concern that an abatement order would not be upheld in court because DNR might have to demonstrate that the discharge was intentional. The county anticipates using its erosion and sediment control ordinance in the future in such cases where necessary.

Brown County Nonpoint Source Controls

Brown County lies within the Fox-Wolf Basin, which drains 6400 square miles, discharging into Lake Michigan at Green Bay. This is the second largest tributary contributor of sediment to lake Michigan, as well as the largest contributor of phosphorous. Nonpoint discharges from agricultural land are the primary sources of the sediment and nutrients throughout the basin and in Brown County. The region is experiencing a rapid growth in the size of dairy operations, with a total of 200,000 milk cows in Brown County and its 5 bordering counties (33,000 in Brown County alone, which is first in the state in density of cows).[93] About a third of the cows in Brown County are concentrated on ten very large farms. Most of the crop agriculture in the area is corn and alfalfa. The county is also facing significant urban sprawl and growth. The township of Bellevue is the fastest growing in the state, and the village of Alloway is the fastest growing village in the state. The city of Green Bay has over 100,000 residents and is increasing in population. The county has over 200,000 residents. The county's Land Conservation Department has 17 staff, including 3 agronomists to do nutrient management planning.

Priority Watershed Projects

Brown County has five on-going priority watershed projects. These are the East River (started in 1989), Red River (1995), Branch River (1996), Duck Creek (1997), and Apple/Ashwabenon Creek (1997).[94] The East River is the largest area, and the watershed most centrally located in the county, bisecting it from north to south. The county has 150 contracts with landowners in this watershed. Some of the newer priority watershed projects have critical sites.

The large number of staff in the county is due to the high number of priority watershed projects. Of its $1.1 million annual budget, the department receives $750,000 from the state and $350,000 from the county. Most of the staff time is devoted to working in priority watershed areas. The program has built the capability of the staff.

Projects in Brown County have generally focused on reduction of sediment or phosphorous pollution. Each plan included a detailed inventory of problems and potential sources in the watershed. The LCD set goals for the reduction of each pollutant and used models to determine the contribution of each source to the water body. Using the inventory of sources, the county could determine the number of practices that must be installed or initiated to achieve the goal. The implementation plan stated the desired water quality improvement and the type and number of practices required to achieve the goal. Critical sites were designated in the newer priority watershed by use of similar inventory and modeling techniques. When the county submitted the project for public review, proposed critical sites were not identified by name but by number. Once the project was submitted to DNR, the landowners were contacted and informed that their land is a critical site and that they must participate or face potential enforcement by DNR. DNR will enforce against critical sites, although in Brown County most landowners cooperated with the program. Although landowners of critical sites often installed a number of conservation practices, they were not required to develop a full conservation plan but to install only those practices which would bring their properties below the required pollutant discharge level contemplated by the implementation plan.

For each practice, the state has established a cost share. The funding a project receives is directly related to the number of proposed practices, to ensure that the county will be able to provide sufficient cost shares. This process is subject to some negotiation, and with the approval of DNR, counties can reduce the cost share provided to cooperators. Brown County has also increased the cost share it has provided as an incentive when it found that DNR's incentives were not sufficient to encourage participation. For instance, DNR's incentive rates for conservation tillage were $15/acre for 3 years, and Brown County raised the rate to $18.50/acre for up to 6 years, if necessary. Raising the rate allowed farmers to more easily purchase the required equipment. The types of practices stressed in the priority watershed cost-share program have changed since it began in 1978. Originally, the program focused on the construction of "brick and mortar" practices, such as manure storage facilities. In 1978, the state cost share for a manure storage facility was $6000; it has now increased to $35,000. The program has switched to focus on lower-cost measures such as conservation tillage, buffer strips, and manure management.

Funding for priority watershed projects depends on the size of the watershed as well as on the practices funded; urban projects will receive more funding than rural projects because the practices are much more expensive. Generally, the grants reflect funding for a 75% participation rate. The various priority watershed projects in Brown County have received from $0.5 million to $2.5 million in funding.

Other sources of funding often reach the county through the priority watershed program. For instance, EPA § 319 money goes to DNR, which uses the funds to supplement funding available for priority watershed projects. Brown County received a $600,000 EQIP grant to supplement state funding in a priority watershed when state funding was particularly low. The priority watershed funds available to the county helped it leverage the EQIP funds effectively, however, and improved the chances that this watershed would be funded through EQIP. The Duck-Ashwabenon portion of the Duck-Apple-Ashwabenon watershed in Brown County received funding in 1997 and 1998 from EQIP.

Assessment of the result of the priority watershed program is conducted primarily by the use of water quality modeling. Based on the number of practices implemented and the water quality improvement predicted for each practice, the county will determine the water quality improvements achieved throughout the watershed. Continuous water quality monitoring would be more costly, and the county plans to assess its progress in achieving its land and water quality management planning goals with the same model-based mechanisms.

Animal Waste Management

The county's animal waste management ordinance was passed by the county board in 1985. It was significantly amended on January 20, 1999. The ordinance applies only in unincorporated areas, which comprise most of the county.

The original 1985 ordinance regulated the construction of animal waste storage facilities and feedlots. The ordinance required a permit to construct or alter an animal waste management facility and compliance with NRCS Technical Guide standards in the design of the facility. The county began to encounter opposition from town governments to proposed siting of new facilities. The protests generally concerned locating animal waste storage facilities near proposed developments or existing residences. These conflicts, along with Act 27's provisions for performance standards and prohibitions, led to some of the changes in the 1999 amendments to the ordinance. The 1999 amendments added setback requirements and nutrient management requirements. Variances in setback from property lines may be allowed with the approval of the neighboring landowners; four variances have been granted.

The ordinance currently requires animal feedlots and animal waste storage facilities to meet county standards and specifications.[95] The standards and specifications were developed by a group of 14 farmers representing the farm bureau, town chairmen, county Farm Services Agency committee, and large dairy operations. The ordinance also incorporates the four prohibitions included in the state's 1997 Act 27, prohibiting 1) overflow of manure storage structures; 2) unconfined manure stacking; 3) direct runoff from feedlots or stored manure to waters of the state; 4) unlimited access of livestock to water of the state where such a practice prevents sod cover maintenance. Under the county ordinance, new and existing animal feedlots must not discharge more than 20 lbs of phosphorous annually, and new animal feedlots must meet setback requirements from adjacent properties, lakes and streams, and groundwater. New, expanded or modified animal waste storage facilities must meet NRCS technical standards and similar setback requirements. Every animal waste storage facility must develop a nutrient management plan. The plan must be submitted annually to the Land Conservation Department while the facility is in use. An abandonment plan must be submitted for any animal waste storage facility, whether existing or new. The ordinance requires operators to obtain permits from the LCD for any existing animal feedlots with more than 500 animal units, for any new animal feedlots with more than 40 animal units, and for any sites that violate the four prohibitions described above or that have received a notice of discharge (NOD) from the DNR.

Violations of the ordinance are punishable by civil forfeiture of not less than $50 plus costs of prosecution, with each day constituting a separate offense. Injunctions or restraining orders may also be sought by the county.[96]

Since 1985, the county has approved 190 permits for animal feedlots and animal waste storage facilities. One of the county's new efforts under the 1999 ordinance will be to develop nutrient management plans for the 190 existing permitted facilities. Also, in an inventory for the county's Land and Water Conservation Plan, the county identified 20 sites which are discharging more than 20 lbs of phosphorous annually. It plans to address five of these sites each year.

Over 150 animal waste storage facilities have been installed in Brown County since the original ordinance, using state and federal cost share programs. The county cannot require any modification to *existing* barnyards without a cost share. The county will not provide cost share for nutrient management practices or animal waste storage, citing these costs as a cost of doing business. The state has provided the cost share funding to address modifications of barnyards, including animal waste storage facilities.

Shoreland Ordinances

Brown County has adopted two separate ordinances regulating agricultural activities on shorelands - one in 1991 and one in 1998. Both are used in controlling nonpoint source pollution in the county.

The *Shoreland and Floodplain Management Zoning Ordinance* was passed in October 1991.[97] This ordinance is intended to address sediment problems. Green Bay harbor requires significant dredging at great cost. Two watersheds near the mouth of the Fox River contribute 65 percent of the sediment and 55 percent of the phosphorous to Green Bay while comprising only 7 percent of the land area. The county determined that a program of stream buffers on the 1200 miles of streams in Brown County would greatly reduce sediment runoff to Green Bay. The 1991 ordinance requires a minimum of 35 feet of land free of row crops, and seeded to grass, alfalfa, or a close-growing crop to be maintained along the edge of all navigable streams. The exact width of the required buffer is determined by use of a rating worksheet that accounts for slope, land use, and drainage area.

The1991 shoreland management ordinance also provides that in cases where a pollution problem results from grazing or pasturing of livestock, fencing must be installed no closer than 16 ½ feet from the edge of the stream unless another solution is approved by the county Land Conservation Department. The stream fencing provision is enforceable only where cost share funds are available for any required practices. Subject to these provisions, however, the ordinance explicitly permits landowners to water their livestock in streams in some manner.[98]

The county provides landowners with incentive payments of $500 per acre taken out of production under the ordinance. The county uses both state and county funding to provide incentive payments. The county has contributed $10,000 per year, but may double its funding this year. The county will allow payment of incentives to farmers who include additional acres by squaring off their fields instead of contouring along the stream. Due to the incentives offered, demand for participation has been very high, and some farmers want to enroll as much land as possible. The county will only pay incentives as far as the buffer is justifiable by use of the ratings sheet. Buffers can be mowed by landowners, but not plowed. All buffers are perpetual, and a restrictive covenant is attached to the deed stating requiring a future landowner to contact the LCD before removing the buffer. State cost share funds have also been available up to 70 percent for seeding and shaping of the buffer.

Of the 1200 stream miles in Brown County, 500 were determined to be adequately buffered at the time the 1991 ordinance was passed. The county program has established buffers on 200 additional miles of stream. The county goal is to install 50 miles of buffers each year for the next ten years. The LCD staff often identifies landowners who are subject to the buffer requirements while working with them on contracts for other conservation practices. If a staff member identifies an unbuffered stream, he or she will inform the landowner of the requirement to have a stream buffer, and will require the landowner to install a buffer in order to continue working on other cost shared practices.

The Wisconsin farmland preservation program, a state program that provides tax incentives to farmers to keep their land in agriculture, requires that farmers operate to stay below the T value for erosion. There are 800 to 900 farms in this program in the county, and their plans are reviewed by the Land Conservation Department. When the LCD is reviewing the plans, staff also address stream buffers.

There have been more takers than available cost share funds, and while the county has not required anyone to install a buffer without providing cost share, in order to meet its 50 mile goal next year it will do so. The county plans to leverage other cost share funding (e.g. for animal waste or conservation practices) to encourage landowners to install buffers without cost shares. The county will also use the animal waste management ordinance to identify people who are required to have buffers, and will use GIS to determine which landowners have the largest stretches of stream that require buffers. The office will target such landowners and send staff to discuss the ordinance with them.

The county has had some problems with landowners who do not maintain their buffers. This has been particularly a problem with large dairy operations, where contractors or lessees might plow the buffer. The landowner is generally unaware of these violations. When the county identifies violations, it first requires that the buffer be reseeded at the landowner's expense. If a second violation occurs, the county will install posts marking the buffer. Repeat offenders can be turned over to the county attorney for civil enforcement, but this has never been done.

The county passed its *Agricultural Shoreland Management Ordinance* in January 1998.[99] While the ordinance addresses similar concerns as the shoreland ordinance of 1991, it is both broader in scope (in the land areas it regulates) and more limited (in that *all* practices under this ordinance require cost shares, in accordance with recent amendments to Wis. Stat. 92.17). This ordinance regulates activities in the "agricultural shoreland corridor" which is defined as land extending 20 feet from each bank of a perennial stream or from the centerline of an intermittent stream, or the high water mark of a lake; and activities in the "agricultural shoreland management area" which is land within 300 feet of perennial stream banks or the centerline of an intermittent stream, or the high water mark for a lake.

The 1998 ordinance generally requires all agricultural activities within the agricultural shoreland management area to prevent erosion and to minimize movement of sediment to surface water. It prohibits cropland with annually tilled soils from exceeding T, and requires pastures to comply with NRCS Technical Guidance for pasture and hayland management and with University of Wisconsin-Extension guides for rotational grazing. The ordinance also requires all land in the management area on which manure or other nutrients are applied to develop a nutrient management plan.

Within the agricultural shoreland corridor, the ordinance requires that a vegetative buffer be maintained, and prohibits row cropping and tillage. Barnyards (defined as a feedlot, dry lot or area other than a pasture where animals have been fed, confined, maintained, or stabled for 45 or more days in any 12 month period) are prohibited in the agricultural shoreland corridor unless an approved management system is installed. The requirement to maintain a vegetative buffer is similar to the requirement in the county's 1991 ordinance. The county (after battling with the state) included in the 1998 ordinance language providing that "Any conflict or inconsistency between this ordinance and Brown County's Shoreland Zoning Ordinance will be governed by the more restrictive provision." This enables the county to continue to require a 35 foot vegetative buffer as specified in the earlier ordinance, even though the newer ordinance (following DATCP models) only requires a 20 foot buffer in the agricultural shoreland corridor. The county further takes the position that cost shares are not required for the installation of buffers because they are not required by the more restrictive earlier ordinance.

The Land Conservation Department administers and enforces this ordinance. The LCD is required to notify landowners in violation by mailing a notice of problem, including a list of BMPs to address the problem and a statement allowing the landowner to appeal the decision. The 1998 ordinance includes a provision allowing for variances if cost share funds are not provided. Variances are also permitted due to excessive county staff workload or if conservation practices will still not bring the landowner into compliance with the ordinance. The LCD will work with the landowner to develop a conservation plan and a schedule of implementation, and must notify the landowner when funds are available to install or implement the required practices. Penalties include civil forfeitures of up to $50 per day of violation, and the ordinance may be enforced by injunction.

State law allows townships, as well as counties, to develop agricultural shoreland management ordinances, and three towns in Brown County have done so. Towns and counties that have developed an ordinance receive state funding for cost shares to implement the required practices. The LCD administers the ordinance for towns that have passed one, and receives separate cost share money from the state to use in the towns.

State Enforcement

DNR issues 5 to 10 NODs under the NR 243 provisions in Brown County for animal waste each year. The program is complaint driven and most often it is neighbors who report the violations or problems. DNR staff must be able to prove that there has been a discharge to surface or groundwater. Evidence of the discharge is generally persistent enough that it is not difficult to demonstrate that a discharge occurred. If the animal waste site is in a priority watershed, DNR cost sharing is available. If not, the county does not normally provide cost sharing for construction of animal waste storage facilities but does have some funding from DATCP associated with the land and water planning process. This funding can only be used for construction of practices with a twenty year life span. DNR staff cannot recall needing to issue an NPDES permit as a result of noncompliance with an NOD in the county.

DNR does not frequently issue abatement orders for sediment related pollution. Problems with land development generally get referred to the county zoning office for action.

Conclusions

The Wisconsin nonpoint efforts reflect substantial funding, attention to standards, and some use of enforceable mechanisms. The priority watershed approach served as the main paradigm for planning, funding, and regulatory attention. Now, Wisconsin seems to be devoting more base funding and assistance to areas that have not received priority attention in the past, while adding competitive grant programs to take advantage of local initiative.

The enforceable provisions of Wisconsin's nonpoint programs are administered by DNR and by the counties. These are significant, but greatly subordinate to the substantial technical assistance efforts and cost shares available through counties, DATCP, and DNR (including federal 319 and EQIP funds). The state generally relies on counties to handle violations through enforcement of local ordinances. State level enforcement can be time consuming and complex. At the local level, too, enforcement generally follows assistance; stop work orders are more common than civil forfeitures or judicial actions.

Wisconsin has statewide standards and practices and is developing even more detailed performance standards and technical specifications. However, state and county conflicts over standards may hinder a county's ability to handle its nonpoint source pollution problems. La Crosse County has some concerns over enforcement of its animal waste management ordinances because its standards are not entirely in line with state requirements. Brown County has also negotiated with the state to ensure that enforcement of its ordinances is less dependent on the availability of cost shares. While the state's goal of ensuring equity among its counties has increased the focus on counties – both through funding redistribution and the development of statewide performance standards and specifications – the program has also constrained some efforts.

The biennial legislative struggles over how much authority and budget control DATCP and DNR should have respectively, have also increased the complexity and variability of the Wisconsin nonpoint effort. Substantial state agency rulemakings are in progress (largely in response to the 1997 Act 27), but it is not clear whether major modifications will continue to occur each legislative biennium. It may be important to allow the state and county programs the breathing space to establish an ongoing and predictable mode of operation.

Notice

Preface

A wide array of effective water quality management and protection tools has been developed for urban environments, but implementation is hindered by a shortage of technology transfer opportunities. Held in Chicago, Illinois on February 8-10, 2000, the ***National Conference on Tools for Urban Water Resource Management and Protection*** was designed to facilitate the educational process and transfer state-of-the-art information to state, regional, and local urban water quality practitioners.

The Chicago Botanic Garden, which is owned by the Forest Preserve District of Cook County and managed by the Chicago Horticultural Society, was pleased to coordinate the Office of Wastewater Management and its Region 5 office, as well as the Northeastern Illinois Planning Commission. The conference was conducted in cooperation with the Water Environment Federation. Over 450 attendees participated, including representatives from Australia, Brazil, Canada, Chile, New Zealand, and Turkey.

The timing for this conference coincided well with the U.S. Environmental Protection Agency's release of the NPDES Storm Water Phase II Final Rule in October 1999. The conference provided participants with practical, applied information on the most effective tools and technologies for meeting these new NPDES permit requirements. Program topics were carefully chosen to reflect the Phase II Program's six priorities: public education, public involvement, detection and elimination of illicit discharges, construction site runoff control, post-construction storm water management, and pollution prevention for municipal operations.

Two special pre-conference workshops were held on February 7. ***Better Site Design and Storm Water Management Techniques for Phase II Communities*** explored the benefits of alternative urban site design approaches, as well as new advances in storm water management to protect water resources. The workshop was led by staff from the Center for Watershed Protection. The second pre-conference workshop, ***Introduction to Urban TMDLs***, examined current and pending requirements for total maximum daily load (TMDL) programs. Instructors for this workshop were staff from Tetra Tech, Inc. Each of the workshops attracted over 135 participants.

This Conference Proceedings includes many of the papers presented during the conference. All papers included were peer reviewed. Additional copies, in either paper or CD-ROM format, are available free of charge from the U.S. Environmental Protection Agency, telephone 800/490-9198, or visit the web site <http://www.epa.gov/ttbnrmrl/>.

Foreword

The U.S. Environmental Protection Agency is charged by Congress with protecting the Nation's land, air, and water resources. Under a mandate of national environmental laws, the Agency strives to formulate and implement actions leading to a compatible balance between human activities and the ability of natural systems to support and nurture life. To meet this mandate, EPA's research program is providing data and technical support for solving environmental problems today and building a science knowledge base necessary to manage our ecological resources wisely, understand how pollutants affect our health, and prevent or reduce environmental risks in the future.

The National Risk Management Research Laboratory is the Agency's center for investigation of technological and management approaches for reducing risks from threats to human health and the environment. The focus of the Laboratory's research program is on methods for the prevention and control of pollution to air, land, water and subsurface resources; protection of water quality in public water systems; remediation of contaminated sites and ground water; and prevention and control of indoor air pollution. The goal of this research effort is to catalyze development and implementation of innovative, cost-effective environmental technologies; develop scientific and engineering information needed by EPA to support regulatory and policy decisions; and provide technical support and information transfer to ensure effective implementation of environmental regulations and strategies.

This publication has been produced as part of the Laboratory's strategic long-term research plan. It is published and made available by EPA's Office of Research and Development to assist the user community and to link researchers with their clients.

E. Timothy Oppelt, Director
National Risk Management Research Laboratory

Introduction

Stormwater runoff from urban and urbanizing areas is widely recognized as a major cause of water pollution in the United States. The impacts of stormwater runoff are threefold: (1) chemically, contaminants deposited on the land are carried by runoff and infiltration to surface and groundwater; (2) physically, increases in impervious surfaces raise runoff rates which, in turn, increase mass pollutant loadings and contribute to erosion and sedimentation; and (3) biologically, the combined chemical and physical alterations of watershed systems degrade aquatic habitat. Research over the past 20 years consistently shows a strong correlation between the imperviousness of a drainage basin and the health of its receiving waters, with stream health decreasing with increasing impervious coverage of the watershed.[1] The U.S. Environmental Protection Agency cites urban runoff as the second leading cause of impairment to estuaries and the fourth leading cause of impairment to lakes.[2] Increased runoff rates, and the erosion and sedimentation associated with new development and construction, also are significant sources of pollution. In the United States, there are an estimated 522,000 construction "starts" each year, with construction activities disturbing an estimated 5 million acres of land annually.[3]

Connecticut communities, like those in many urbanized states, are confronted with meeting nonpoint source management needs that often conflict with traditional subdivision regulations and construction standards. The challenge of meeting public safety and maintenance requirements in an environmentally sensitive manner is not currently being met, as evidenced by continued water quality impairments associated with new development. Can impervious surfaces be reduced, and curbing and storm drains be eliminated in a way that will not raise objections from municipal boards and commissions? Will homeowners accept cluster housing, natural landscaping, and "greener" home and yard maintenance practices? Most important, will those modifications make a difference in the quality and quantity of nonpoint source runoff under widespread application? Answering these and related questions is the objective of the Jordan Cove Urban Watershed National Monitoring Project.

Project Overview

The primary purpose of the Jordan Cove project is to compare differences in runoff quantity and quality emanating from traditional and "environmentally sensitive" development sites. The 18-acre "Glen Brook Green" subdivision, located in the southeastern Connecticut town of Waterford, is being constructed and monitored to make this comparison. The subdivision is split into two distinct "neighborhoods": one with building lots arranged in a traditional R-20 (half-acre)

R0019371

zoning pattern (Figure 1); the other, cluster housing with a variety of best management practices (BMPs) incorporated into the design (Figure 2).

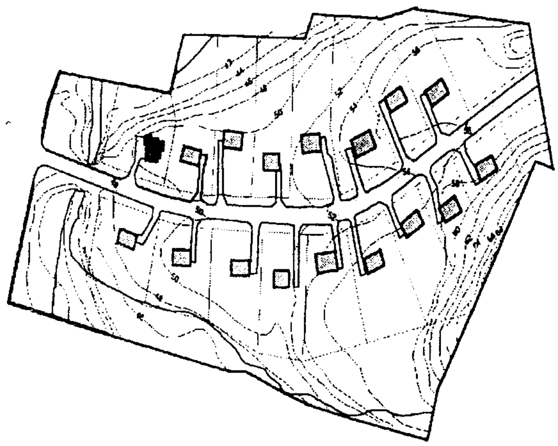

Figure 1. Glen Brook Green "Traditional" Neighborhood.

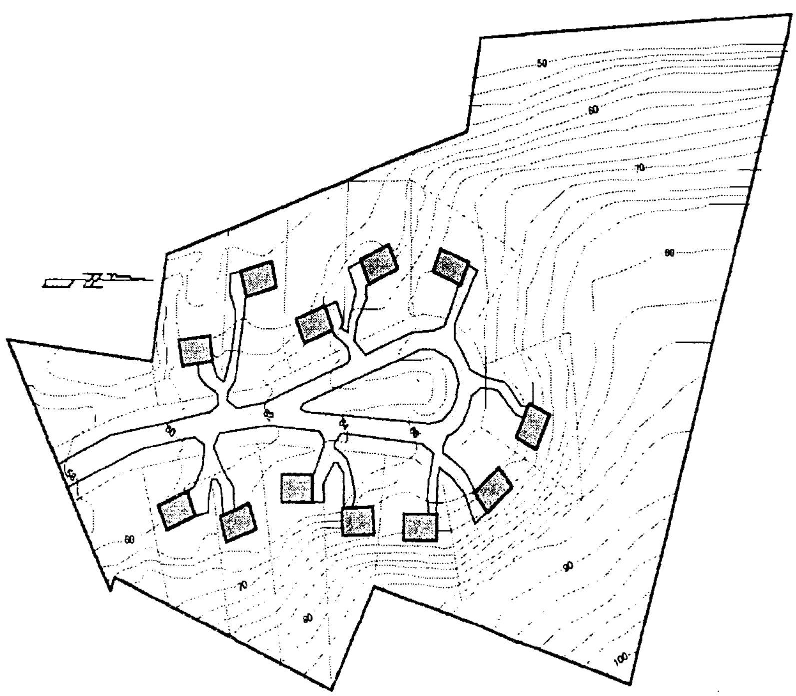

Figure 2. Glen Brook Green "BMP" Neighborhood.

R0019372

Stormwater runoff from the traditional section is collected by curbs and catch basins, then piped through a stormwater treatment system before entering Nevins Brook, a tributary of Jordan Brook and, ultimately, Jordan Cove and Long Island Sound. Homeowners will not be subjected to any enhanced environmental education, or restrictions on how they manage their properties.

The BMP neighborhood will feature grass swales; roof leader "rain gardens;" shared, permeable driveways; small building "foot-prints;" deed restrictions on increasing impervious surfaces; "low-mow," "no-mow," and conservation zones; a narrower, permeable road surface (interlocking concrete pavement); and a vegetated infiltration basin, or bioretention area, located inside a "tear-drop" cul de sac. Several different driveway surfaces will be utilized, including interlocking concrete pavement, gravel, concrete tire strips, and permeable asphalt, and monitored for their relative runoff rates. Homeowners and town road maintenance crews will be encouraged to adopt pollution prevention techniques, including controlled fertilizer and pesticide application, pet waste management, street sweeping/vacuuming, and reduced use of deicing agents.

The BMP neighborhood is expected to generate less stormwater runoff and pollution. Monitoring conducted before, during and after construction will document actual results. The Jordan Cove project team comprises a true public/private partnership, with researchers and educators from the University of Connecticut; federal, state, and local government officials; private consulting firms; and the developer.

National Monitoring Program

The Jordan Cove Urban Watershed National Monitoring Project is funded, in part, through the Connecticut Department of Environmental Protection (CT DEP) by the U.S. Environmental Protection Agency's (EPA) Section 319 National Monitoring Program (NMP). It is one of 22 such projects nationwide. The Jordan Cove project is the only NMP project studying the effects of residential subdivision development on runoff quality and quantity, and of BMPs designed to mitigate those impacts.

The Section 319 NMP was established pursuant to section 319(l) of the federal Clean Water Act (Nonpoint Source Management Programs - Collection of Information). Section 319(l) states that EPA shall collect information and make available:

(1) Information concerning the costs and relative efficiencies of best management practices for reducing nonpoint source pollution.

(2) Data concerning the relationship between water quality and implementation of various management practices to control nonpoint sources of pollution.

The objectives of the Section 319 NMP are twofold:

(1) To scientifically evaluate the effectiveness of watershed technologies designed to control nonpoint source pollution.

(2) To improve our understanding of nonpoint source pollution.

To achieve these objectives, the NMP has selected watersheds across the country to be monitored over a 6- to 10-year period to evaluate how improved land management and the application of BMPs reduce water pollution. The results from these projects will be used to assist land use and natural resource managers by providing information on the relative effectiveness of BMPs to control nonpoint source pollution.

Site Selection

In 1993, nonpoint source program staff from EPA and CT DEP, and a University of Connecticut researcher began efforts to identify a site at which to conduct a nonpoint source monitoring project under the auspices of the NMP. Initial site selection involved three criteria: (1) an appropriate hydrologic setting, with distinct drainage patterns amenable to monitoring; (2) a willing land owner or developer who would allow 1-1½ years of advance monitoring before beginning construction; and (3) a municipality willing to adopt innovative site planning and development strategies. Proximity to the coast was also considered as an important factor because of the need to reduce nonpoint source pollution loads to Long Island Sound and coastal waters in general.

CT DEP mailed letters soliciting interest to a number of municipalities recognized for either their progressive approach to land use planning and management, or for experiencing high development rates. After positive responses from several municipalities, and numerous field visits, the "Glen Brook Green" site in Waterford was selected in May 1995. The 18-acre parcel was an active chicken farm, but its owner, who had grown up on the farm, was planning to develop it into a residential subdivision. The property owner wanted to develop the parcel in an environmentally-sound manner, was interested in the NMP solicitation, and was willing to be flexible with his construction schedule to facilitate monitoring.

The hydrology of the parcel featured two distinct drainage areas, an ideal setting for the proposed monitoring design. Poultry houses and several other buildings occupied the area that would become the traditional neighborhood and an old, partially mined gravel pit dominated the future BMP neighborhood. Soil tests determined that the chicken manure had not elevated nutrient levels significantly enough to bias the monitoring. The town of Waterford, and its planning officials, had a reputation as being progressive on land use issues and had served as one of the pilot communities for the University of Connecticut Cooperative Extension System's Nonpoint Education for Municipal Officials (NEMO) project. Because waivers from Waterford's subdivision regulations would be needed to build the BMP neighborhood, the town's cooperation was critical to the project's implementation.

Planning

Proceeding from a conceptual design to actual construction required a concentrated effort by the project team working together toward a common goal. Once an acceptable plan was agreed upon by the project team and committed to paper, the next step was gaining approval from Waterford's conservation, and planning and zoning commissions. As is typical of New England town governments, both commissions paid close attention to planning decisions at a series of public meetings at which many development alternatives were reviewed. Volunteer commissioners and professional staff raised numerous concerns regarding the health, safety and general welfare of the town residents, and the social economic, environmental, and political viability of the proposed plan. Among their concerns were road widths for emergency access, road surface integrity for plowing and de-icing, traffic, drainage, sidewalks, parking, maintenance of common areas, and responsibility should BMPs fail. The rigorous review was enlightening to the project team and commissioners alike. As the ongoing dialogue between the various parties led to further planning details and innovative solutions to problems, enthusiasm and support for the project grew.

After a series of public meetings in late 1996 and early 1997, the project was approved by both commissions. Technical modifications of existing standards were handled in four ways: as waivers, special design/operation controls, mitigation, or discretionary actions. Table 1 lists each of these categories with associated comments and concerns expressed by Waterford's professional staff and commissions. In the end, it was the willingness of all parties involved to work in concert, reaching compromises, that allowed this innovative project to advance to the construction phase.

It is a generally accepted axiom that resource-based site planning can help minimize increases in runoff and reduce the potential for erosion and sedimentation problems typically associated with new development. In this project, goals identified at the outset are helping to direct the choice of practices and strategies for site development toward those that will reduce adverse impacts on hydrology and water quality. These goals include: (1) reproducing pre-development hydrological conditions; (2) confining development and construction activities to the least critical areas; (3) fitting the development to the terrain; (4) preserving and utilizing the natural drainage system; and (5) creating a desirable living environment.

Table 1. Technical Modifications of Existing Development Standards.

Considerations	Traditional Design	BMP/Cluster Design	Comments
waivers needed	specified road surface materials	segmental concrete pavers (permeable)	must be approved by public works; costs more
	typical road width = 28 feet, reduced to 24 feet	reduced road width to 20 feet for travel lane	must be approved by public works, fire, and police
	curbs and storm drains required	no curbs; grassed swales and sheet flow off road	turf stone installed to maintain road edge integrity; costs less
	90 ft paved cul-de-sac radius	one way cul de sac design to reduce road width and turning radius	further reduction in width and less need for snow plowing
special design/ operational control	planning and zoning standards	bioretention "rain gardens"	retains roof runoff on-site
	home owner discretion	vegetative maintenance	reduces fertilizer use; costs less
	home owner discretion	pesticide management	reduces pesticide use; costs less
	home owner discretion	domestic animal management	reduces pathogen runoff
mitigation required	road runoff piped to storm sewer		need to manage storm water entering the site from adjacent public road
	creation of 13,400 sq ft wetland at subdivision entrance		required to mitigate filling of 5000 sq ft of wetlands within subdivision
discretionary actions	R-20 single-family zoning	cluster and zero setback from lot lines	allows more open space and natural landscaping
	open space not contiguous with all lots	open space layout	compact housing; natural landscaping
	a driveway for each home	combined driveways	reduces curb cuts and impervious surface; cost less

Monitoring Design

This study is utilizing the "paired-watershed" monitoring design, which requires a minimum of two watersheds (control and treatment) and two periods of study (calibration and treatment). This approach assumes that there is a quantifiable relationship between paired water quality data for the two watersheds, and that this relationship is valid until a major change is made in one of the watersheds. It does not require that the quality and quantity of runoff be statistically the same for the two watersheds, but that the relationship between the paired observations of water quality and quantity remains the same over time -- except for the influence of the land use changes in the treatment watershed.[4]

The control watershed accounts for annual and/or seasonal climate variations. During the calibration period, no changes in land use occur in the watersheds and paired water quality and quantity data are collected to develop a baseline. The paired data are used to develop regressions for the control and treatment watersheds. The treatment period begins when changes in land use occur in the treatment watershed. A new regression is developed following the treatment period. Analysis of variance (ANOVA) is used to test the significance of the regressions in each period. Analysis of covariance (ANCOVA) is used to test the differences between the two regression slopes and intercepts. The changes between periods are calculated based on a comparison of predicted values, using the calibration regression equation, and observed values during the treatment period.[5]

For the Jordan Cove project, the treatment period will occur in two phases: (1) during construction of the traditional and BMP neighborhoods; and (2) after construction when the BMPs are in effect. The paired-watershed approach is being used to measure the differences in water quality and quantity between the treatment areas (traditional and BMP neighborhoods) and the control area (a nearby 10-year old subdivision) caused by construction in the two treatment areas and the application of BMPs in the BMP neighborhood. Stormwater quality and quantity are measured at the outlets of each of the two treatment neighborhoods, and the control watershed (Figure 3). Water quality is measured by analyzing weekly flow-weighted composite samples for total suspended solids (TSS), total phosphorus (TP), total Kjeldahl nitrogen (TKN), ammonia nitrogen (NH_3-N), and nitrate+nitrite nitrogen (NO_3-N). Grab samples are analyzed for fecal coliform and BOD_5. Monthly analyses are conducted for copper, lead, and zinc.

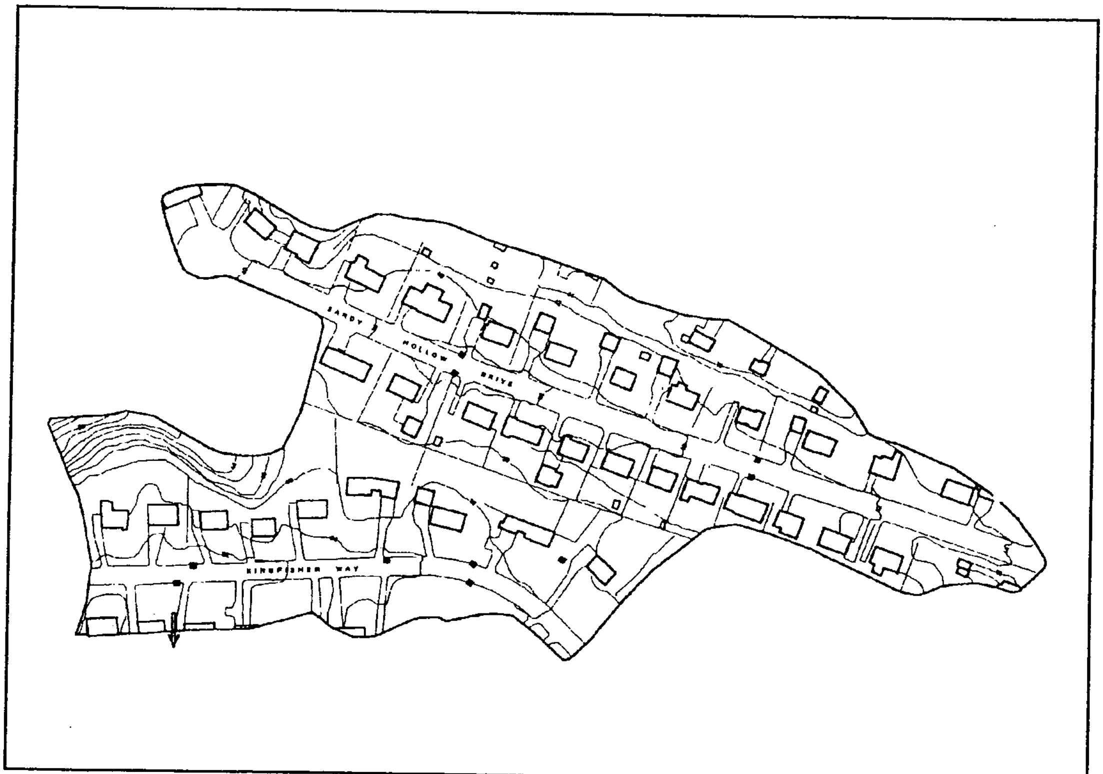

Figure 3. Existing residential (control) watershed.

The calibration period began in January 1996, to establish a baseline for future comparisons. Since the treatment period began in May 1998, runoff monitoring has focused on the effects of construction, and on the relative effectiveness of standard erosion and sediment control practices in the traditional neighborhood. When construction commences in the BMP neighborhood, the focus will be on the effects of construction and the relative effectiveness of enhanced erosion and sediment control practices (e.g., phased grading, stockpile seeding, open space vegetation, cross grading, and detention swales). Post-construction monitoring is scheduled to begin in 2001 and will continue for 3-5 years.

Supplemental monitoring will be conducted on selected BMPs, including different driveway surfaces and enhanced turf management in the BMP neighborhood, and a "state-of-the-art" stormwater treatment device in the traditional neighborhood. This information will be used to evaluate the effectiveness of these specific practices.

Monitoring Results

During the calibration period, 75 runoff events were sampled for the control watershed and 12 runoff events for the two treatment watersheds. In the treatment period to date, 21 and 20 events were sampled for each treatment watershed, respectively. Peak discharge values were obtained for nine paired events in the calibration period and 20 pairs for the treatment period. The total number of samples analyzed was less than the total number of flow observations because not all the samples contained a sufficient volume for analysis[6].

Sampling results to date, as presented in Table 2, indicate that construction of the traditional neighborhood is causing significant impacts on runoff quality and quantity, including observed increases in mean weekly flow volume (99%), runoff frequency (from 16% to 95%), and mean weekly peak discharge (79%).[7] The conversion of the watershed's topography from a "knoll" to a "bowl," combined with an increase in impervious surface, appears to have caused a significant change in hydrologic responses. Concentrations of NO_3-N and Pb in runoff also increased. However, increases in the concentrations of sediment and sediment-associated nutrients, typical of construction sites, did not occur. In fact, TKN concentrations have declined during construction. It is believed that erosion and sediment controls are responsible for TSS concentrations remaining constant before and during construction[8].

Table 2. Summary of means and percent increases of flow, Q_p, nutrient and metal concentrations for the control and traditional watershed in the calibration and treatment periods.

Calibration Period			Treatment Period			
				Traditional

Zn	58	65	79	126	98	22

* P value < 0.05
** P value < 0.01
*** P value < 0.001

Coinciding with the increases in pollutant concentration and flow, the mass export of NO_3-N and Pb increased as well, as did the mass exports of TP, TSS, Cu, and Zn. These increases appear to be attributable to increased stormwater runoff volumes. The preliminary results from this study suggest that increased runoff, rather than erosion, is the cause of increased pollutant export from this construction site. Traditionally, erosion and sediment controls and stormwater management plans focus on the prevention of sediment and, occasionally, peak flow impacts on downstream areas. The preservation of pre-development hydrologic conditions within the watershed where construction is occurring is typically ignored.

Excess runoff, which is the driving force behind nonpoint source pollution, will transport pollutants into waterways and contribute to their degradation. Preliminary monitoring results demonstrate that erosion and sediment controls can reduce sediment and sediment-associated pollutants in construction site runoff. However, current erosion and sediment control practices do not address the increase in runoff from development sites. Consequently, these practices fail at reducing pollutant loads.[9]

Next Steps

By the end of 2000, this combination of traditional and "green" designs for residential subdivisions should be fully constructed. Monitoring of stormwater quality and quantity will be conducted for several years after build-out to determine the overall efficiency of the design. It should demonstrate that careful planning, landscaping, and use of vegetative BMPs can help protect and enhance the environment, while addressing other concerns that local planning and zoning commissions face. Lessons learned from this project have already been, and will continue to be, passed along to other communities through ongoing technical assistance and training programs administered by the CT DEP, the University of Connecticut Cooperative Extension System, and other agencies and organizations.

Abstract

Eutrophication is a common problem for lakes in agricultural and urban areas, such as Lakes Wingra and Mendota in Madison, Wisconsin. This report describes a study to estimate the sources of phosphorus, a major contributor to eutrophication, to Lakes Wingra and Mendota from two small urban residential drainage basins. The Monroe Basin empties into Lake Wingra, and the Harper Basin into Lake Mendota. Phosphorus data were collected from streets, lawns, roofs, driveways, and parking lots (source areas) within these two basins and were used to estimate loads from each area. In addition to the samples collected from these source areas, flow-composite samples were collected at monitoring stations located at the watershed outfalls (storm sewers); discharge and rainfall also were measured. Resulting data were then used to calibrate the Source Loading and Management Model (SLAMM, version 6.3, copyright 1993, Pitt & Vorhees) for conditions in the city of Madison and determine within these basins which of the source areas are contributing the most phosphorus.

Water volumes in the calibrated model were calculated to within 23% and 24% of those measured at the outfalls of each of the basins. These water volumes were applied to the suspended-solids and phosphorus concentrations that were used to calibrate SLAMM for suspended-solids and phosphorus loads. Suspended-solids loads were calculated to be within 4% and 17%, total-phosphorus loads within 24% and 28%, and dissolved- phosphorus loads within 9% and 10% of those measured at the storm-sewer outfall at the Monroe and Harper basins, respectively.

Lawns and streets are the largest sources of total and dissolved phosphorus in the basins. Their combined contribution was approximately 80%, with lawns contributing more than the streets. Streets were the largest source of suspended solids.

Street-dirt samples were collected using industrial vacuum equipment. Leaves in these samples were separated out and the remaining sediment was sieved into >250 µm, 250-63 µm, 63-25 µm, <25 µm size fractions and were analyzed for total phosphorus. Approximately 75% of the sediment mass resides in the >250 µm size fractions. Less than 5% of the mass can be found in the particle sizes less than 63 µm. The >250 µm size fraction also contributed nearly 50% of the total-phosphorus mass. The leaf fraction contributed an additional 30%. In each particle size, approximately 25% of the total-phosphorus mass is derived from leaves or other vegetation.

Introduction

Eutrophication is a common problem for lakes in agricultural and urban areas, such as Lakes Wingra and Mendota in Madison, WI. Primary productivity in northern temperate lakes is most often limited by phosphorus (Schindler 1974; 1977). Urban runoff has been noted to contain high phosphorus concentrations (U.S. Environmental Protection Agency, 1983) that may be increasing the eutrophication. The focus of the study described in this report was to estimate the sources of phosphorus to Lakes Wingra and Mendota from two small urban residential watersheds in Madison, WI (Figure 1). This study was done in cooperation with the city of Madison and the Wisconsin Department of Natural Resources.

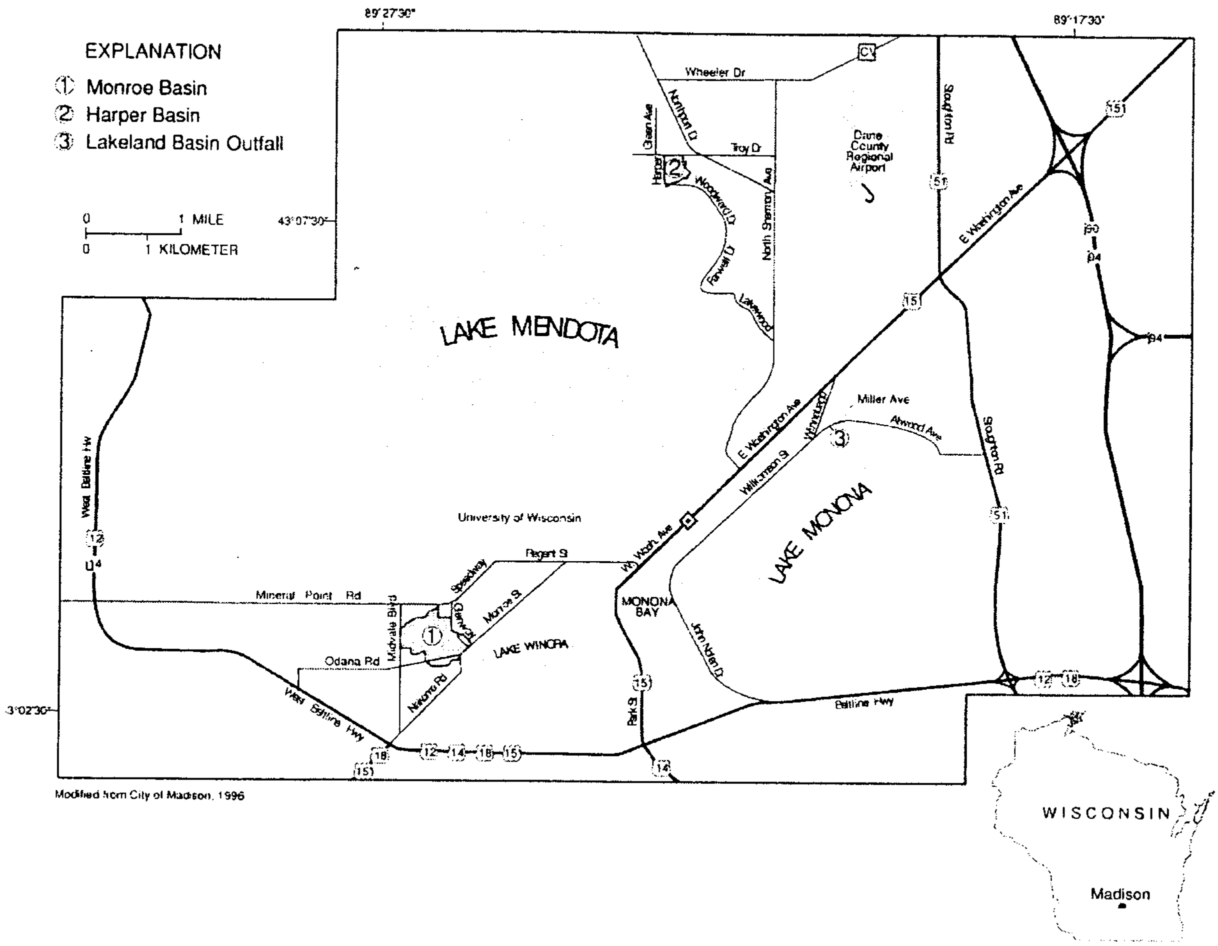

Figure 1. Lakes Wingra and Mendota in Madison, WI.

Lake Mendota and Lake Wingra are both part of the Wisconsin Department of Natural Resources (WDNR) Priority Watershed Program (Betz and others, 1997). State funding is available to help pay for management aimed at reducing the amounts of phosphorus and other pollutants discharged to the lakes. The goal of the Lake Mendota Priority Watershed Project is to reduce the frequency of nuisance algae blooms in the lake from one out of every two days to one out of every five days. To accomplish this goal, it is estimated that a 50% reduction is needed in the amount of phosphorus entering the lake. To help reach this target, the Nonpoint Source Control Plan for the Lake Mendota Priority Watershed Project (Betz and others, 1997) set an objective of reducing phosphorus loading to the lake by 20% from urban areas. The remaining 30% reduction is intended to come from rural phosphorus management.

For this study, phosphorus data were collected from five source areas—streets, lawns, roofs, driveways, and parking lots—within the two drainage basins from urban residential and commercial areas to estimate loads from each source area (Table 1). Resulting data were used to calibrate the Source Loading and Management Model (SLAMM, version 6.3, copyright 1993, Pitt & Vorhees) for conditions in the city of Madison and determine which source areas are contributing the most phosphorus within these basins. The city is planning to use SLAMM to target specific source areas for management efforts to meet the 20% phosphorus-reduction objective of the priority watershed project and to meet requirements of its Wisconsin Pollutant Discharge Elimination System stormwater permit.

Total	224.9	96.8	7.3	3.2	41.1	100

Stormwater runoff samples from source areas and the basin outfall were collected from a medium-density residential watershed draining to Lake Wingra from May to November, 1994 and from a medium-density residential watershed draining to Lake Mendota from June to November 1995. These runoff samples were used to estimate the phosphorus and suspended-solids load that each of these source areas and basins contributes. In addition, a third basin, the Lakeland Basin that drains into Lake Monona, was monitored for lawn runoff in 1995. This basin, which encompasses an older section of Madison, was sampled in an attempt to determine whether any difference exists between this section of the city (which has older, smaller lawns) and other areas of the city.

Study-Area Description

The Monroe Basin, monitored during 1994, drains into Lake Wingra. The basin is 232.2 acres, of which 224.9 acres are residential and 7.3 acres are commercial (Figure 2). Lake Wingra has a surface area of 338.9 acres (1.37 km^2) and a drainage area of 3,889 acres (15.74 km^2). About 75% of the Lake Wingra drainage basin is urbanized and about 25% is composed of forest, prairie, and marsh within the University of Wisconsin Arboretum (Oakes and others 1975).

The Harper Basin, monitored during 1995, drains into Lake Mendota. The Harper Basin is 41.1 acres, all of which is residential land use (Figure 2). Lake Mendota has a surface area of 9,859 acres (39.9 km^2) and has a drainage area of 138,823 acres (561.8 km^2) (Lathrop and others, 1992). Approximately 20% of the Lake Mendota drainage area is urban, 57% is agricultural, and the remaining 23% is grassland/woodland/marsh/open-water area (Betz and others, 1997). The Lakeland Basin is approximately 3 miles southeast of the Harper Basin.

In addition to the samples collected from source areas, a monitoring station was located at each basin storm-sewer outfall to collect flow-composite samples and to monitor discharge and rainfall. The total rainfall amounts for the months of June through October 1994 at Monroe and July through October 1995 at Harper were 9.24 and 10.67 in., respectively. These amounts are 64% and 71% of the average from 1961 to 1990 (Brian Hahn, National Weather Service, oral communication, 1997).

Acknowledgments

We thank all of the volunteers that allowed us to install our sampling equipment in their yards, the City of Madison Engineering Division and Department of Public Health for their efforts in making this study possible, Jeff Beck of the USGS for his exceptional field efforts, and Holly Ray and Dr. Bob Pitt at the University of Alabama at Birmingham for their work analyzing the street-dirt samples. Also, we thank Mary Anne Lowndes of the WDNR and

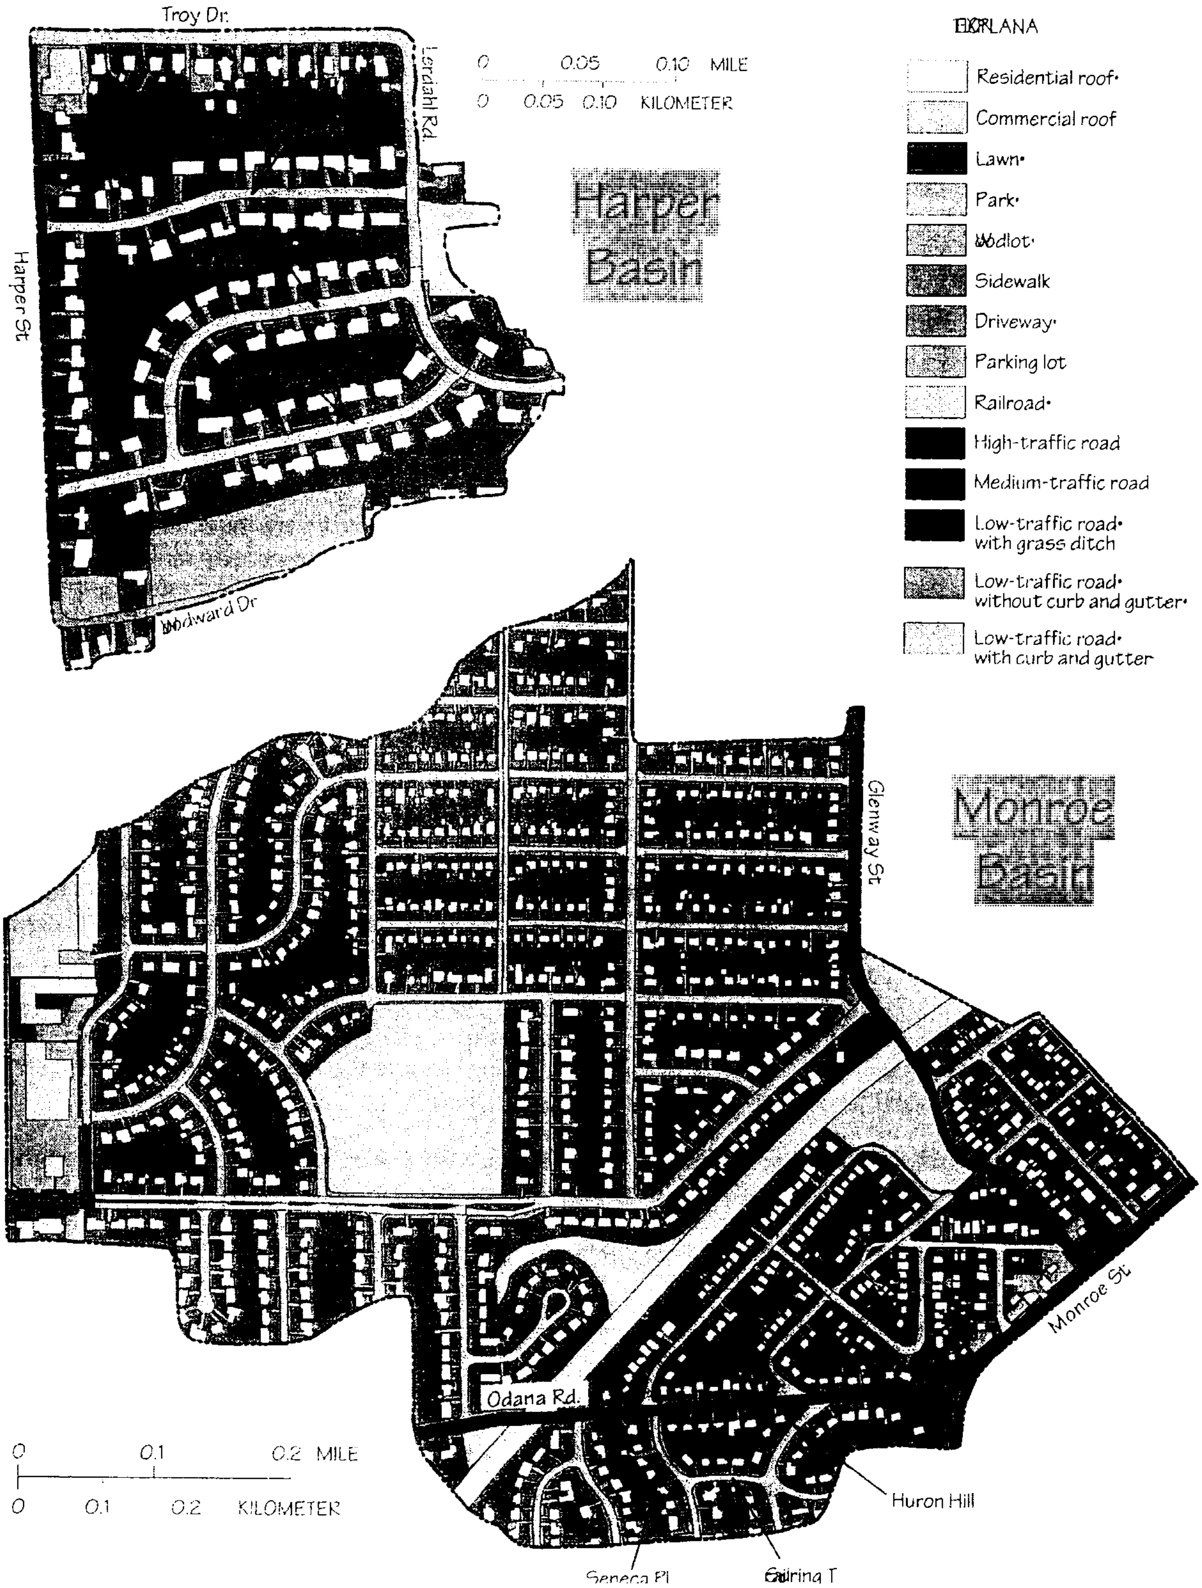

Figure 2. Harper and Monroe Basins.

R0019382

Steve Corsi of the USGS for insightful comments that have greatly improved the report. Lastly, we thank Gail Moede and Aaron Konkol at the USGS for their help with the report editing and preparation of illustrations.

Data-Collection Equipment and Methods

Runoff samples were collected from each source area by use of sampling equipment slightly modified from that described by Bannerman and others (1993). Brief descriptions of the sampling equipment follow.

Street samplers. The street samplers were grouted into the street approximately 5 ft from the curb (Figure 3). The sample bottle was covered with a 6-in. concave polycarbonate cap, set flush with the street surface, with a center drain hole. The bottle and cap were placed into a 6-in. diameter polyvinyl chloride (PVC) sleeve. Water flowed over the top of the cap and drained through the center hole into a collection bottle. The drain hole could be constricted by a set screw that controlled the flow rate into the sample bottle.

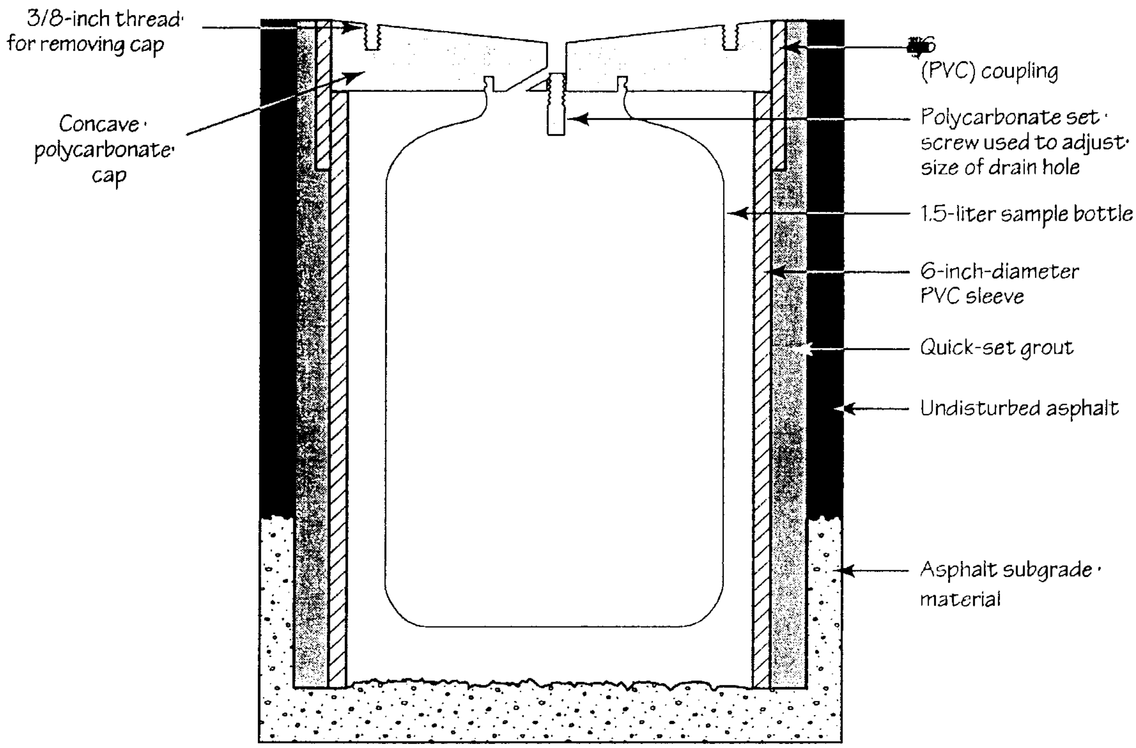

Figure 3. Schematic of street samplers.

Driveway samplers. Runoff water from driveways was diverted into a sampler by means of a flat piece of clear plastic, 1/4 in. high by 1 in. wide by 3 ft long, glued to the surface of the driveway. The sampler consisted of a 1.5-L glass bottle placed in a 10-in.-diameter protective PVC sleeve set into the ground next to the driveway. A 1/2-in.-diameter silicon tube carried the runoff through a plastic cap covering the PVC sleeve and into the sampler. During the 1994 field season, the tubing emptied directly into the sample bottle, causing several sample bottles to overfill. To alleviate this problem, in 1995, the tube emptied onto a polycarbonate cap like those used with the street samplers, so that the volume of water entering the sample bottle could be controlled.

Lawn samplers. Lawn sample bottles received runoff through two 5-ft pieces of 1/2-in.-diameter PVC pipe placed flush with the surface of the ground, on a sloping surface, with an angle of about 150 degrees between the two pipes (Figure 4). Runoff entered the pipes through two slits cut the entire length of pipe. Each pipe was wrapped with fiberglass

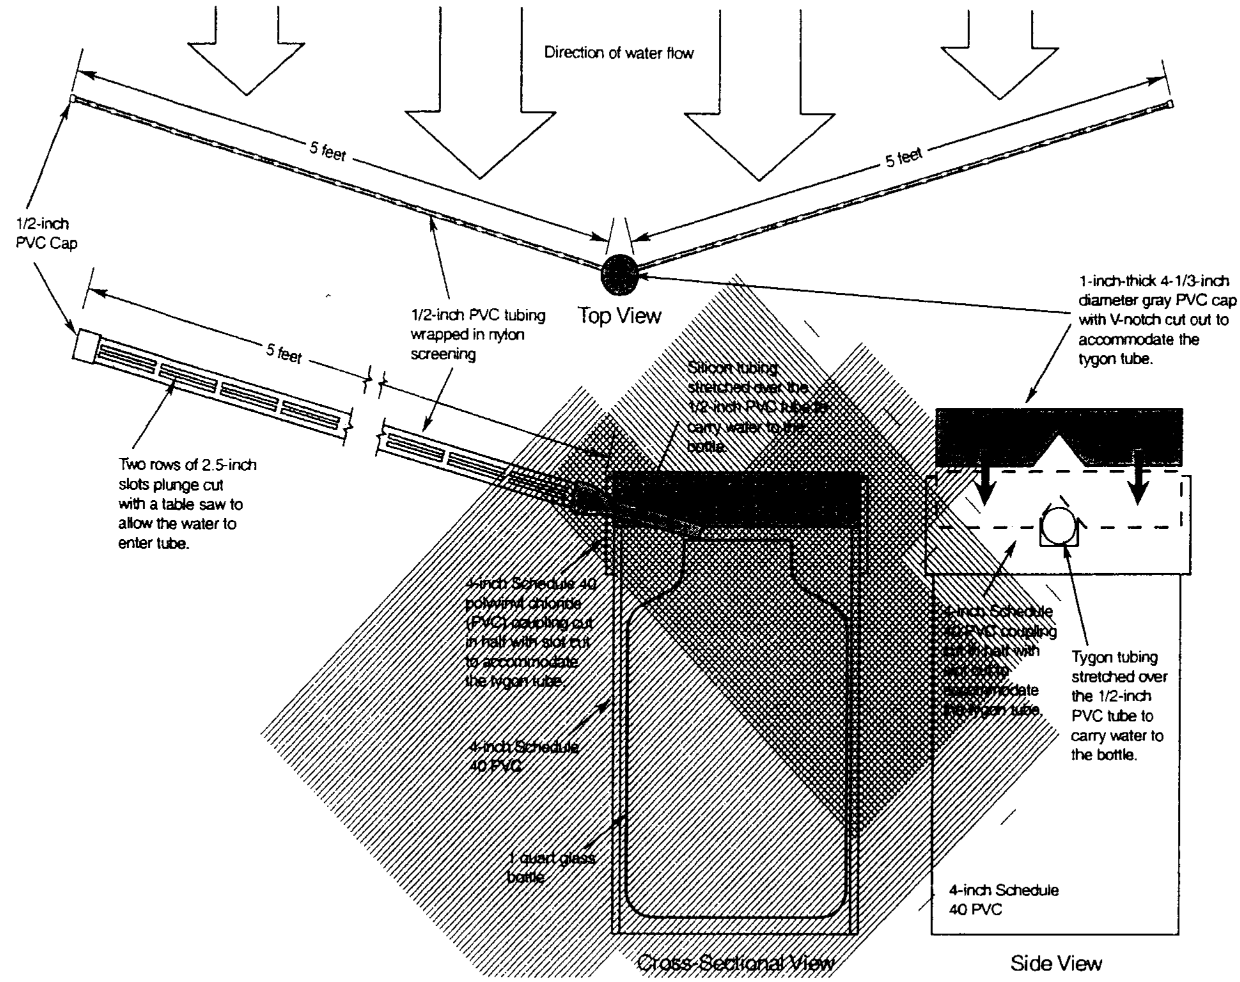

Figure 4. Schematic of lawn samplers.

screen to prevent insects and large debris from entering. Wooden clothespins with small pieces of nylon rope held the pipes in place. Water from the pipes flowed into a sampler through a notched cap. The sampler was a 1- qt glass bottle placed in a 4-in.-diameter protective PVC sleeve. The cap had a notch to accommodate silicon tubing, which ran from the end of the PVC collector pipes to the sample bottle.

Roof samplers. Roof samplers were designed to divert a small portion of the water in the gutter downspout to a sample bottle. A 1/4-in.-diameter vinyl tube was attached to the inside of the downspout by means of plastic wire ties. Each tube went into a 1.5-L glass sample bottle that was placed in a covered 10-in.-diameter protective PVC sleeve. Because of problems with overfilled sample bottles, the design was changed in the same manner as the driveway samplers so that the volume of water entering the sample bottle could be controlled.

Parking Lot sampler. The parking lot sampler collected runoff entering a storm-sewer inlet grate. A small portion of the inlet flow was diverted to a sample bottle by means of a 6-in. trough made of 1/2-in.-diameter PVC pipe cut lengthwise and held in place with stainless steel hose clamps attached to the inlet grating. Water drained from the trough through a tube to a 2.5-gal glass sample bottle hanging from the inlet grate. No samples were collected from parking lots during 1995.

Basin storm-sewer outfall samplers. An automated sampling station was placed at the storm-sewer outfall of both the Monroe and Harper Basins. In 1994, water level in the basin storm- sewer outfall pipe was measured with a pressure transducer as water drained into a detention pond. Velocity was measured with an electromagnetic velocity meter. In 1995, stormwater-runoff volumes were computed using a modified Palmer-Bowlus flume design (Kilpatrick and others, 1985). The water level was measured one pipe diameter (36 in.) upstream from the entrance to the flume using a pressure transducer connected to a nitrogen bubble system. This water level was used in the following equation to calculate the total discharge through the flume:

$$Q = a[H_a/D]^b D^{2.5},$$

where

Q is discharge, in cubic feet per second,
a is a constant, 3.685,
b is a constant, 1.868,
H_a is the water level above the upstream lip of the flume, at a distance of one pipe diameter upstream from the flume entrance, in feet, and
D is pipe diameter, in feet.

Flow-composite water quality samples were collected using programmable, refrigerated automatic samplers with 3/8-in.-diameter Teflon-lined sample tubing. Rainfall was measured using a tipping-bucket rain gage and was recorded by a digital data logger.

Stormwater Sample Collection and Processing Protocols

Sample bottles were placed in the source-area samplers as close to the start of each rain event as possible. As the bottles were being deployed, the sampling equipment was rinsed with deionized water to remove any accumulated surface dirt. Before the lawn sampler pipes were rinsed, they were cleaned with a small test tube brush. As soon as possible after runoff had stopped, the sample bottles were collected and the approximate volume of water in each bottle was recorded.

All the bottles from a given source area were composited by pouring water from each bottle into a 5-gal or 1-gal stainless steel, Teflon-coated churn splitter modified from the type described in Ward and Harr (1990). The City of Madison Department of Public Health Laboratory analyzed a small subsample taken from the churn for suspended solids and phosphorus.

Street Dirt Collection and Analysis

In addition to stormwater-runoff samples, samples of street dirt were collected with a 9-gal wet-dry shop-vacuum using a 6-in.-wide wand. A section of the street was vacuumed from curb to curb, 10 times across each of 3 streets in the basin, similar to the technique described by Pitt (1979) and Bannerman (1983). Monroe Street, Glenway Street, and Seneca Place/Spring Trail/Huron Hill (the latter three are considered one residential street) were sampled during 1994 (Figure 2). Woodward Drive, Nova Way, and Luster Avenue were sampled during 1995. Woodward Drive did not have curbs, so the sample was collected by vacuuming between wooden 4-by 4-in. blocks placed at the edge of the asphalt on each side of the street. During the fall, leaves on the street would often plug the vacuum hose. To alleviate this problem, a 6-in. by 2-ft wooden frame was placed with the 6-in. side abutting the curb. Before vacuuming the inside of the frame, the leaves inside it were collected by hand and placed in the vacuum collection bag. Then the street was vacuumed in the normal manner.

The dirt samples were dried at 105°C, sieved into size fractions of >250 μm, 250-63 μm, 63- 25 μm, and <25 μm and weighed. The sieved samples were sent to the University of Alabama at Birmingham (UAB) for phosphorus analysis. In addition to total phosphorus, samples collected from the Monroe Basin were analyzed for percentage of vegetative material. Two independent methods were used to determine the percentage of vegetative material: thermal chromatography and microscopic examination. In thermal chromatography, dirt samples were placed in ovens at increasing temperatures and the mass that was lost to incineration was determined after each increase in temperature. The mass loss was compared to the standard temperatures where various substances like leaves, rubber, and paper burned off. The sample mass lost at the temperature range corresponding to the leaf standards was assumed to be vegetation. In microscopic examination, samples of the dirt were compared to microscopic pictures of vegetation. More details of these methods can be found in Ray (1997).

Sources of Phosphorus

Measured Concentrations in Runoff from Source Areas

A total of 25 runoff events were monitored at each basin. Runoff samples were collected from May to November of 1994 at Monroe and from June to November of 1995 at Harper and Lakeland. Driveway samples collected from the Monroe Basin were excluded because of problems with the sample bottle overfilling (discussed in the methods section). Summary statistics are listed in Table 2.

Table 2. Concentrations for Suspended Solids, Total Phosphorus, and Dissolved Phosphorus at the Monroe Basin and Harper Basin, 1994–95
[--, concentrations were not used because of problems with the samplers; -, source area not present in basin; mg/L, milligrams per liter]

Median	.81	.08	-	-	.07		.07	-

The concentration data from the Monroe and Harper Basins seem to exhibit log-normal distributions that are consistent with urban-runoff concentration data collected during the Nationwide Urban Runoff Project (U.S. Environmental Protection Agency, 1983). In such cases, the geometric mean is a better estimate of the central tendency than the arithmetic mean because the geometric mean gives less weight to extremes (Helsel, 1992). Several of the coefficients of variation in Table 2 have a value greater than 1, indicating substantial variability in concentrations within a source area.

The large variation seen in the source-area concentration data could cast doubt on the predictability of the data. For lawn runoff, the difference between geometric mean phosphorus concentrations from 1994 to 1995 was greater than a factor of 2; however, the lawn-runoff data collected from the Lakeland Basin are remarkably similar to data collected at Harper (Table 3), indicating that the variation in lawn-runoff phosphorus concentrations is not random. Primary sources of phosphorus, such as tree canopy, also could have a large effect on the source-area concentrations measured between basins. Figure 5 illustrates a trend between the concentration of phosphorus and the percentage of overhead tree canopy on streets for the Monroe and Harper Basins. Canopy in the Monroe Basin tends to be less than 35%, whereas the percentage of canopy in the Harper Basin ranges from 5 to 78%. Variation also could be caused by meteorological factors like rain depth, intensity, or inter-event period or by seasonal variables.

Roof runoff had the lowest geometric mean concentrations of suspended solids, and lawn runoff had the highest total and dissolved phosphorus concentrations in both the Monroe and Harper Basins (Figures 6 and 7). In addition, patterns in geometric mean concentrations between source areas within each basin were similar; however, their magnitudes were very different. The geometric mean concentration of phosphorus for low-traffic streets in the Monroe Basin were about twice those at the Harper Basin. Conversely, geometric mean phosphorus concentrations for lawn and roof runoff in the Harper Basin were more than twice as high as those in the Monroe Basin. The beginning of the sampling periods differed by one month between basins (Monroe Basin in May and Harper Basin in June), and this difference may have caused some of the variability.

Concentration results for suspended solids and phosphorus from earlier source-area studies in Madison, WI, Marquette, MI, and Birmingham, AL (Bannerman and others, 1993; Steuer and others, 1997; Pitt and others, 1995), were compared to the concentration results from this study. Suspended-solids concentrations in street-runoff samples collected during the other studies were considerably higher than those in samples collected for this study. Sandier soils are present in Marquette that could partially account for this difference. Furthermore, some of the same lawns in the Monroe Basin were monitored for phosphorus concentrations in the previous Madison study (Bannerman and others, 1993), and both the dissolved and total phosphorus geometric means calculated for that study were more than three times higher than those in 1994. Because phosphorus concentrations varied highly from Monroe and Harper Basins, did not closely agree with each other, and did not agree well with previous studies, the geometric mean of the combined data collected at Monroe and Harper Basins was used for the modeling phase of this study.

Calibration of the Source Loading and Management Model (SLAMM)

A concentration data base to simulate stormwater quality and theoretical runoff coefficients to simulate runoff volumes is used in the Source Loading and Management Model (SLAMM). Because large amounts of concentration data and runoff information were collected during this study, it was an opportunity to calibrate the model's concentration data base and improve the runoff coefficients with data collected from the Monroe and Harper Basins.

Calibrating SLAMM with concentration and water-volume data was a three-step process. First, the runoff volume generated by each source area was calibrated (a critical step because an accurate water volume is essential for estimating all pollutant loads). Second, sediment was calibrated because sediment concentrations and loads are used in SLAMM to estimate phosphorus loads. The final step was to calibrate the model for phosphorus concentrations.

A systematic procedure was used to calibrate suspended-solids and phosphorus concentrations in SLAMM. First, a mass-balance approach compared total measured loads from source areas summed over 25 events to the loads measured at the outfall. Monitored loads from source areas were calculated using SLAMM-generated water volumes. Individual source areas were not equipped to measure runoff volumes during an event. Therefore, the accuracy of source-area volumes, as assigned by SLAMM, was subject to agreement with the actual volumes measured at the outfall. If the sum of all source-area volumes closely matched what was measured at the outfall, the individual source-area volumes assigned by SLAMM were assumed to be correct. Second, source-area concentrations were adjusted to optimize the mass balance. SLAMM was adjusted after agreement between measured source-area and outfall loads was achieved.

Water-Volume Calibration

Water-runoff volume from each source area for each rain event is calculated with the model. These calculations are based on the amount of rainfall and a runoff coefficient developed for various rainfall depths for each source area. Source-area characteristics such as imperviousness, connectedness (amount of impervious area directly connected to the storm sewer), and infiltration rates on pervious areas were used to develop runoff coefficients (Pitt, 1987). The volumetric discharges for each source area are then summed for each event. The total runoff volume can be decreased in the model by using control measures, such as infiltration devices.

SLAMM was used to estimate runoff volume for the 25 storm events from all source areas in each basin. The sum of the volumes from all of these source areas was compared to the volume measured at the basin storm-sewer outfalls for these 25 events. Initially, the model overpredicted the water volumes measured at Monroe by a total of 55% (over the entire study period), whereas it underpredicted those measured at Harper by only 2%. To obtain a balance of overprediction and underprediction between the basins, the runoff coefficients were adjusted. Historically, more measurements have been made for runoff from impervious surfaces (Pitt, 1987) and more than 50% of the area within each basin is pervious, mostly because of residential lawns. Therefore, it was decided that the runoff coefficients for pervious areas were more uncertain and model calibration could benefit from minor adjustments.

Two sets of runoff coefficients are available for pervious areas; one is designed to represent clayey soils, and the other represents sandy soils. The predicted water volumes mentioned above were determined using the runoff coefficients for clayey soils (based on soil maps). Changing the pervious classification from clayey to sandy resulted in SLAMM underprediction of water volumes; approximately a 4% and a 42% underprediction at the Monroe and Harper Basin storm-sewer outfalls, respectively. A much better agreement was achieved at Monroe by assuming that the original soil classification was incorrect. Sandy and clayey runoff coefficients, available to the model, probably represented two extremes, and more realistic runoff coefficients fell somewhere between these two coefficients.

Lawn-runoff data collected from Monroe and Harper Basins were used to create runoff coefficients that more accurately represent the pervious conditions found in Madison. First, the rainfall depth sufficient to initiate runoff in SLAMM was changed using data on the amount of stormwater in the lawn-sample bottles after each event. For rainfall amounts less than approximately 0.3 in., the bottles were less than 10% filled. From this observation, 0.3 in. was established as the minimum precipitation required to initiate runoff. However, the runoff coefficient table for clayey soils

R0019391

used in SLAMM resulted in 10% runoff for a rainfall depth of 0.2 in. Hence, SLAMM was changed to initiate runoff at 0.3 in. rather than 0.2 in. of precipitation.

In addition to the change described above, a trial-and-error approach was used to change the coefficients until optimum agreement was reached between water volumes predicted in SLAMM and those measured at the Monroe and Harper storm-sewer outfalls. The resulting coefficients were between those for sandy and clayey soils and were approximately two-thirds the value for clayey soils. Figure 8 shows how the new "Madison" runoff coefficients compare to the sandy and clayey coefficients.

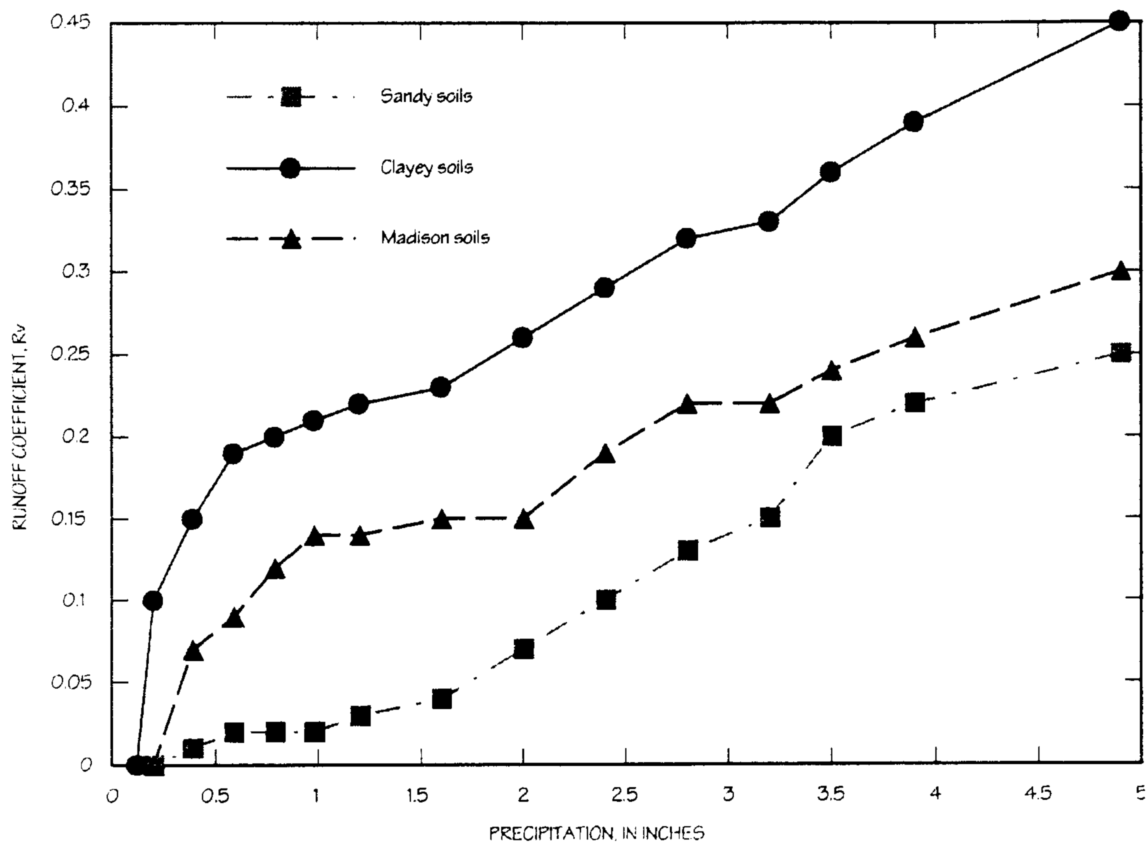

Figure 8. Madison runoff coefficients compared to sandy and clayey coefficients.

Based on the revised Madison runoff coefficients, SLAMM overpredicted storm-sewer outfall volumes at Monroe by 23% and underpredicted Harper storm-sewer outfall volumes by 24% (Table 4). The Madison coefficients also produced consistent lawn-runoff contributions in both basins, approximately 20% of the total volume. It is expected that the percentage of lawn contribution would be similar for both basins because they have nearly the same percentage of lawn area.

Table 4. Percentage Difference in Cumulative Modeled Water Volumes Compared with Measured Outfall Water Volumes Using Three Soil Types, Madison, Wi.

Basin	Sandy soils (%)	Clayey soils (%)	Madison soils (%)
Monroe	-4	55	23
Harper	-42	-2	-24

Sediment Calibration

Once the runoff volumes were calibrated, SLAMM was used to estimate sediment loads for the 25 events in each basin. With the exception of streets, a data base of sediment concentrations for each source area is used in SLAMM and these concentrations are applied to the water volumes to derive a load. Sediment concentrations from streets are computed by a wash-off function that is related to a street-dirt accumulation rate.

A mass-balance approach was used to test the source-area concentrations within each basin with those measured at the storm-sewer outfall. Source-area loads were computed by multiplying the water volumes produced from SLAMM by the concentrations measured at the source areas for each event and then summing these event loads. Sidewalks and woodlots were two of the larger unmonitored source areas in each basin, accounting for 12% and 1% of the water volume produced at Monroe and 7% and 2% at Harper, respectively. To add sidewalks to the load estimates, concentrations measured at driveways were applied to estimates at sidewalks to create a sidewalk load. Woodlot concentrations were estimated by use of data collected in an undeveloped urban site near Superior, WI (Steuer and others, 1997). The source-area loads were 39% lower and 60% lower than the measured load at the storm- sewer outfall in the Monroe and Harper Basins, respectively. This difference between source-area and storm-sewer outfall loads indicates that one or more source areas within each basin were not effectively monitored.

Streets were the most likely source area to be ineffectively monitored. Street samplers were placed approximately 5 ft away from the curb to prevent gutter flow into the sampler because gutter flow usually contains a mixture of water from several source areas. Other street studies (Pitt, 1979) have estimated that 90% of the dirt on residential streets in good condition with little to no parking accumulates within 3 ft of the curb. A larger amount of dirt can sometimes collect along the curb itself rather than in the driving lane. Some of this dirt could have been deposited on the driving lane, and turbulence from passing vehicles and wind may have moved it to the curb. Most street dirt falls within 1 to 2 ft of the curb if the driving lane is next to the curb (Pitt, 1979). This information suggests that the street samplers in the Monroe and Harper Basins were too far from the curb (5 ft) to representatively collect the particulate dirt from the streets.

For the reasons previously described, a trial-and-error approach was used to select a street- sediment concentration that more accurately reflected the street sediment entering the storm sewer. The final suspended-solids concentrations for streets were increased by a factor of 5. Applying this factor to the simulated street suspended-solids concentration during each storm event allowed the sum of source-area loads to be within 7% and 9% of the storm- sewer outfall loads at Monroe and Harper, respectively (Table 5). The geometric means for the revised street suspended-solids concentrations were 340 and 325 mg/L for low- and high-traffic streets, respectively. These values were within 5% of those measured at both Marquette, MI (Steuer and others, 1997), and Madison, WI (Bannerman and others, 1993).

The geometric means of the observed suspended-solids concentrations, excluding streets, for the 25 storm events at Monroe and Harper Basins were placed into the SLAMM data base (Table 6). The suspended-solids concentrations for streets were not as easily altered because they are determined by dirt accumulation and wash-off functions in the model. Entering the geometric means enabled the model to more accurately predict the loads measured at the storm-sewer outfall. After summing the 25 events, sediment loads predicted by SLAMM were 17% lower at Monroe and 32% lower at Harper compared to the measured storm-sewer outfall loads.

To improve the match between measured and simulated storm-sewer outfall loads, the delivery coefficients were removed from SLAMM calculations, essentially assuming 100% delivery from source area to storm-sewer outfall. The delivery coefficients had been added in a previous calibration study to force a match to the storm-sewer outfall numbers. This adjustment resulted in a 4% and 17% undersimulation between storm-sewer outfall loads of suspended solids calculated by SLAMM and those measured at the storm-sewer outfall for Monroe and Harper, respectively (Table 5).

Phosphorus Calibration

One objective in calibrating phosphorus concentrations in SLAMM was to ensure that the Monroe and Harper Basins were accurately represented by the monitored source areas. The sum of source-area loads for total phosphorus for the 25

storm events was nearly identical to the storm-sewer outfall load (Table 7). The difference was larger for dissolved phosphorus, but no information was available to determine what adjustments should have been made to reduce the difference. For this reason, the unadjusted concentrations were entered into the SLAMM data base.

Table 7. Percentage Difference Between Cumulative Source Area Versus Outfall Loads and Modeled Results Versus Outfall Loads, after Calibration of the Source Loading and Management Model for Basins in Madison, Wi. [%, percent]

	Phosphorus load			
	Dissolved (%)	Total (%)	Dissolved (%)	Total (%)
Monroe	39	-1	-9	-24
Harper	35	4	-10	-28

The model simulates total phosphorus loads by adding the dissolved phosphorus and particulate phosphorus loads. For all source areas except streets, particulate-phosphorus concentrations were calculated using total- and dissolved-phosphorus and sediment concentrations measured at the Monroe and Harper Basins. To be consistent with calibration procedures, particulate-phosphorus concentration for street runoff was calculated using the adjusted value for sediment (an increase by a factor of 5). Changing the phosphorus concentrations resulted in SLAMM undersimulation of dissolved and total phosphorus by 9% and 24% at the Monroe storm-sewer outfall and 10% and 28% at the Harper storm-sewer outfall, respectively.

The dissolved- and particulate-phosphorus concentrations entered into the SLAMM data base are listed in Tables 8 and 9. Significant changes in dissolved-phos-phorus concentrations (Table 8) were observed for lawns (from 0.22 to 0.53 mg/L), streets (from 0.39 to 0.12 mg/L), woodlots (from 0.25 to 0.01 mg/L), and sidewalks (from 0.60 to 0.07 mg/L). With the exception of streets, where the particulate-phosphorus concentrations in runoff decreased, particulate-phosphorus concentrations increased significantly (Table 9).

Distribution of Source-Area Loads

The distribution of suspended-solids and total- and dissolved-phosphorus loads for source areas in the Monroe and Harper Basins using measured source-area concentrations multiplied by SLAMM-generated water volumes is shown in Table 10. The distribution of water volumes is nearly identical at Monroe and Harper Basins. The percentage of the total basin represented by each source area is similar for both basins (Table 1); thus, one should expect to see similar relative volumes of water calculated from both basins. Streets contributed most of the suspended-solids loads at both Monroe and Harper Basins, generating 81% and 73%, respectively. Lawns contributed more than 10% of the solids loads at both basins. The phosphorus loading, however, was quite different. Lawns in the Harper Basin generate more than two-thirds of the phosphorus loads, whereas phosphorus in the Monroe Basin is more evenly distributed between lawns and streets. These differences in load distribution are the result of the measured phosphorus concentrations, especially for lawns, which are much higher for the Harper Basin (Table 2).

Table 10. Distribution of Loads Based on Measured Values at Monroe and Harper Basins, Madison, Wi, and Incorporating the Suspended-solids Adjustment [N/A, source area not present; %, percent abundance; --, value less than 0.5 percent]

[1]Water volume totals expressed in cubic feet; all other totals expressed in pounds.
[2]Street-runoff concentrations multiplied by 5.

The suspended-solids load distribution at the Monroe Basin in 1994 is similar to the distribution observed in a 1991 study (Bannerman and others, 1993). Streets contributed 80% of the total basin suspended-solids load in 1991 and 81% in 1994. Lawns also were comparable, contributing 7% and 10% of the total basin suspended-solids load in 1991 and 1994, respectively. Total and dissolved phosphorus, however, were very different. During the 1991 study, the proportion of the total-phosphorus load from streets (58%) outweighed that for lawns (14%). The same was true in 1991 for dissolved phosphorus, where streets produced 46% and lawns 22% of the basin load. However, most total- and dissolved-phosphorus loading in 1994 was attributed to lawns rather than streets. Streets and lawns, in 1994, generated 37% and 44% of the total-phosphorus load and 39% and 45% of the dissolved- phosphorus load in the Monroe Basin. The difference in distributions between the two studies is possibly due to differences in sampling methodology. The street-sampler design was modified for the 1994 study to eliminate a first-flush effect, where the sample bottle would quickly fill with stormwater and act as a sediment trap for the remaining duration of the storm event. Also, during the 1994 study, 25 events were monitored, whereas only 10 events were monitored in 1991. This larger sample size in 1994 improves confidence in the loading-distribution estimates.

Distribution of suspended-solids, total-phosphorus, and dissolved-phosphorus loads estimated by SLAMM are given in Table 11. The distribution of loads is consistent with the distribution of measured loads shown in Table 10. For each constituent, slightly less total load was simulated with SLAMM than calculated using the measured concentrations (other than suspended solids from streets), yet the distributions of each constituent were similar. Streets and lawns contribute nearly all of the suspended-solids load for the entire basin. Streets alone contribute more than 75% of the suspended solids at both Monroe and Harper Basins. Additionally, the significance of lawns as generators of phosphorus is again noted in SLAMM simulations. Lawns in the Harper Basin contribute 52% and 61% of total and dissolved phosphorus loads, and lawns in the Monroe Basin contribute 49% and 57%. Streets contribute the second largest phosphorus loads (about 25%), whereas driveways and sidewalks combined contribute approximately 10%.

The distribution of suspended solids and total and dissolved phosphorus for source areas in the Monroe and Harper Basins using measured source-area concentrations multiplied by SLAMM-generated water volumes is shown in Table 12. Only loads for the source areas measured are shown in Table 12; concentrations of suspended solids in street runoff have not been adjusted. These source areas accounted for 82% and 90% of the total water volume from the Monroe and Harper Basins, respectively.

Roofs	12	3	3	4	9	3	2	1

The suspended-solids distributions shown in Table 12 differ from Tables 10 and 11, in that the significance of lawns as a source increases and the significance of streets as a source decreases. Streets are still the largest source of suspended solids in both basins. The phosphorus distributions also change, but not as much as the suspended solids because the measured phosphorus concentrations were used in all three tables (Tables 10, 11, and 12). The significance of lawns as a source increases slightly, and streets are a slightly larger source in some cases, and in others, are slightly smaller sources. Results shown in Table 12 indicate that the adjustments made to suspended-solids concentrations in street runoff do not greatly affect the phosphorus distributions in the basins.

Sediment and Phosphorus Mass in Street-Dirt Samples

Approximately 75% of the total sediment mass in the street-dirt samples originated in the >250 μm size fraction, whereas the smaller fractions (<63 μm) made up less than 5%. Material composed of leaves, twigs, and other organic debris also were measured, contributing, on average, less than 10% of the total sediment mass of the sample (Figure 9).

Like sediment mass, the largest amount of total phosphorus was found in the >250 μm size fraction (nearly 50%) (Figure 9). Combining this size fraction with the leaf fraction, about 80% of the total phosphorus is accounted for. The contribution of total phosphorus mass decreased as the size fraction decreased. Other studies have shown that large phosphorus concentrations correspond with small particle sizes because of the high surface area to mass ratio for small particles (Sartor and Boyd, 1972).

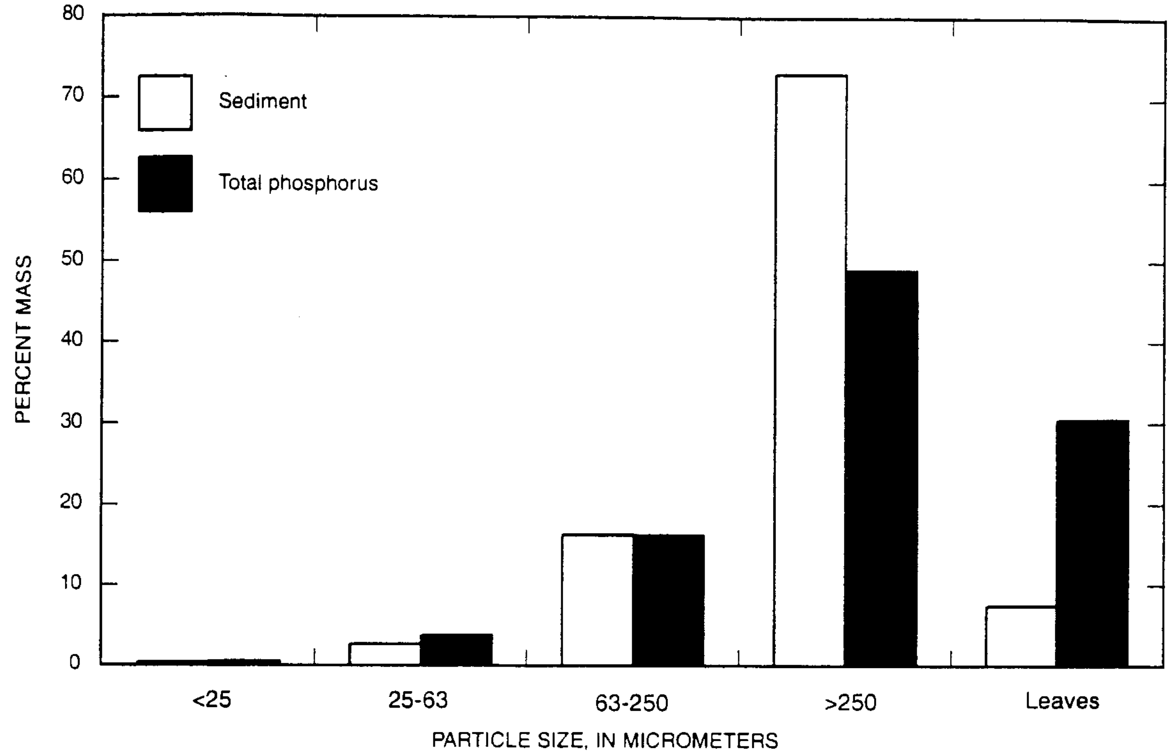

Figure 9. Relations between sediment and total-phosphorus mass from street-dirt samples for five particle-size fractions for basins in Madison, WI.

However, the bulk of the phosphorus phosphorus load results from the greater particle-size fractions (Ray, 1997). Approximately 25% of the total phosphorus mass in each size fraction can be attributed to leaves (Ray, 1997).

A recent study of particle-size distribution in stormwater at the Monroe storm-sewer outfall demonstrated that most of the solids are in the particle sizes <63 ?m (Greb and Bannerman, 1997). This distribution is the opposite of the particle-size distribution observed for the street dirt collected in this study. These results indicate either a loss of the larger particles somewhere between the street and the outfall or a problem in collecting larger particles in the runoff samples. Most of the larger particles (>63 ?m) might settle out before reaching the storm-sewer outfall. Street sweeping, resuspension onto street terraces, and catch basins can remove these particles from the streets before they reach the storm sewer. Also, the transport of large particles in a storm sewer is not as efficient as the transport of smaller, more mobile particles. Large sediment particles may become trapped or part of the bedload before reaching the sampler. Bedload is not sampled efficiently by the automatic samplers described earlier in this report.

Summary and Conclusions

Concentrations of suspended solids, total phosphorus, and dissolved phosphorus were collected from various source areas at two urban residential basins in Madison, WI. To represent a range of source-area concentrations for urban residential basins in Madison, the geometric means of the combined concentration data from the Monroe and Harper Basins were incorporated into the urban-runoff model, SLAMM.

Source-area suspended solids and phosphorus loads from the Monroe and Harper Basins were determined based on measured concentrations that were multiplied by water volume estimated by use of SLAMM. Collected data were used to calibrate and increase confidence in water volumes, suspended solids, and phosphorus source-area loads estimated by SLAMM. The calibrated model calculated water volumes to within 23% and 24% of those measured at the outfalls of the Monroe and Harper Basins. These calibrated water volumes were then applied to the calibrated suspended-solids and phosphorus concentrations entered into the SLAMM data bases. Suspended-solids loads were estimated by the calibrated SLAMM to be within 4% and 17%, total-phosphorus loads within 24% and 28%, and dissolved-phosphorus loads within 9% and 10% of those measured at the storm-sewer outfall to the Monroe and Harper Basins, respectively.

Streets and lawns are the largest contributors of suspended-solids, total-phosphorus, and dissolved-phosphorus loads in a residential urban basin. Lawns are the largest contributors of total and dissolved phosphorus; however, streets contributed nearly 40% of the basin load, as seen in the Monroe Basin. Streets were found to be the largest source of suspended solids.

There was a large difference between geometric mean concentrations of phosphorus in lawn runoff from 1994 to 1995. Phosphorus data collected from lawns in the Harper and Lakeland Basins during 1995 are remarkably similar, which suggests that the phosphorus concentration in lawn runoff is affected by some variable or variables that are not yet understood.

Street-dirt samples indicate that approximately 75% of the sediment mass resides in the >250 μm particle-size fraction. Less than 5% of the mass can be found in the particle sizes less than 63 μm. The >250 μm particle-size fraction also contributed nearly 50% of the total- phosphorus mass, and the leaf fraction contributed an additional 30%. In each particle-size fraction, approximately 25% of the total-phosphorus mass is derived from leaves or other vegetation.

A possible limitation of this study may be that in order for the sum of the source-area loads to match the basin-outfall loads, it was assumed that the concentrations of suspended solids in street runoff were about 5-times higher than the concentrations measured. However, the analysis of load distributions based only on unadjusted monitored concentration data shows little change in the distributions. In addition, samples from more rain events were collected in this study than previous source-area studies. Also, improved data-collection equipment were used during this study. Both of these factors lead to greater confidence in the study results.

Most of the measured suspended-solids concentrations were lower than those measured from previous studies. However, when comparing concentration results in this study to results from earlier studies, it is important to note that with the exception of the Marquette study, previous studies used earlier generation source-area sampling equipment. In Marquette, MI, the soils are considerably more sandy than those in Madison, which may explain why the suspended-solids concentrations determined for the Marquette study are higher than those from Madison even though both studies used the same sample-collection equipment.

The recalibration of the SLAMM model results in an improved model that should more accurately simulate phosphorus and sediment runoff loads in Wisconsin than the earlier version of the model. The newly created lawn-runoff coefficients for Madison represent a compromise between the two previous soil-type options available for model input, which probably represented runoff extremes. The runoff coefficients calculated for Madison should probably be applied to most urban lawns in Wisconsin unless soils are known to be either sandy or clayey. The phosphorus- and sediment-concentration data bases created for this study are the largest to date using the most advanced source-area sample collection technology available.

Abstract

This study consisted of a quantitative analysis of the relationship between the Index of Biotic Integrity (IBI), an indicator of urban land use, and a qualitative analysis of overlying stressors in six of the major metropolitan areas of Ohio. A database consisting of 267 sampling locations was extracted from the Ohio EPA statewide biological and habitat database. Most of these sites were sampled between 1990 and 1998 and contained watershed areas less than 50 $mi.^2$, with most draining less than 20 $mi.^2$. A negative relationship between IBI and urban land use was observed in four of the six areas, whereas little or no relationship was seen in two areas. For each area, the highest percentage of urban land use that corresponded to minimum attainment of the applicable warmwater habitat IBI biocriterion ranged from 1% (Cleveland/Akron) to 12% (Dayton) for the regression line, and 15% (Cleveland/Akron) to 58% (Columbus) as the highest %urban land use where the IBI biocriterion was attained at any given site. No significant linear relationship was found in either the Toledo or Youngstown areas, and only a weak relationship was visually apparent for the Toledo streams. The lack of association was due to the strong presence of overlying stressors (e.g., legacy pollutants, sewage discharges, combined sewer overflows) that resulted in very low IBI values at sites with lower levels of urbanization. The percentage of urban land use explained approximately 35% of the variation in IBI scores in the regression model when these impact types were excluded (compared to 11% when included). The maximum %urban land use that commonly corresponded to attainment of the warmwater habitat IBI biocriterion based on inspection of the scatter plot was approximately 26%. Only a very few sites exhibited attainment at urban land uses between 40-60% and none occurred above 60%. These former sites had either an intact, wooded riparian zone, a continuous influx of groundwater, and/or the relatively recent onset of urbanization. These results indicate that it might be possible to mitigate the negative effects of urbanization by preserving or enhancing near and instream habitats, particularly the quality of the riparian buffer zone. The results also suggest that there is a threshold of watershed urbanization (e.g., >60%) beyond which attainment of warmwater habitat is unlikely. This threshold is not the same in all watersheds and it can occupy a rather wide range. It is affected by co-factors such as pollutant loadings, watershed development history, chemical stressors, and watershed scale influences such as the quality of the riparian buffer and the mosaic of different types of land use. Thus, single-dimension urban land use indicators, such as watershed imperviousness, are not sufficiently precise or robust as a single indicator of use attainability. The further development and refinement of multiple indicators of watershed urbanization has merit from a management and decision-making standpoint. We suggest that co-factors, in addition to more refined urban land use indicators, be better developed. More precise definitions of different urban land uses are also needed to better understand and respond to the water quality management challenges posed in existing and developing urban areas.

Introduction

The health and well-being of the aquatic biota in surface waters is an important barometer of how effectively we are achieving the goals of the Clean Water Act (CWA); namely the maintenance and restoration of biological integrity, and the basic intent of water quality standards. States designate water bodies for beneficial uses (termed designated uses) that, along with chemical, physical, and biological criteria, assure the protection and restoration of aquatic life, recreational, and water supply functions and attributes. Biological criteria are the principal tool for determining impairment of designated aquatic life uses as defined by the Ohio WQS (Ohio Administrative Code 3745-1). As such, bioassessments play a central role in the Ohio Nonpoint Source Assessment (Ohio EPA 1990; 1991), the biennial Ohio Water Resource Inventory (305b Report; Ohio EPA 1998), and watershed-specific assessments, of which Ohio EPA completes between 6 and 12 each year. Biological criteria represent a measurable and tangible goal, against which the effectiveness of pollution control and other water quality management efforts can be judged. However, biological assessments must be accompanied by appropriate chemical/physical measures, land use characterization, and pollution source information necessary to establish linkages between stressors and the biological responses (Yoder and Rankin 1998). Biological criteria in the Ohio WQS also supports the determination of appropriate aquatic life use designations for individual water bodies, provides for a "reality check" on the application of surrogate indicators, assesses cumulative impacts, extends anti-degradation concerns to nonpoint sources and habitat influences, defines high quality waters, and serves as a meaningful indicator in the management of regulatory programs for environmental results. This provides a means to incorporate the broader concept of water resource integrity (Karr et al. 1986) in policy and planning while preserving the appropriate roles of the traditional chemical/physical and toxicological approaches developed over the past three decades.

We, and others at Ohio EPA, have previously described the status of Ohio's streams and rivers as affected by watershed urbanization (Yoder et al. 1999; Yoder and Rankin 1997; Yoder 1995). Small watersheds are especially impacted, as illustrated by Yoder and Rankin (1997), where no headwater streams in established urban settings throughout Ohio attained the minimum CWA benchmark use designation of warmwater habitat. This finding has led to the perception that the impairment of beneficial aquatic life uses in these small watersheds is intractable, at least within the constraints of current land use policies, restoration technologies, and funding levels. Together, these factors present potentially significant barriers to the objective of fully restoring degraded watersheds or upgrading urban streams that are presently designated for less than fishable and swimmable uses.

Headwater streams are critical to watershed functioning in that they serve as the principal interface between runoff from land use and receiving streams. The ability of a headwater stream to physically filter and biologically assimilate the primary and secondary effects of pollutants is a function of habitat quality and the structure of the biological system. A healthy headwater stream ecosystem is characterized by good habitat and a well balanced assemblage of aquatic organisms and plants, one which processes external inputs in a manner which promotes high quality downstream exports. These exports include good quality water and high value biomass, both of which positively impact the ability of downstream waters to deliver quality goods and services (e.g., water supply, recreation, waste assimilation, water retention, ecological values). A degraded headwater stream ecosystem is characterized by poor habitat and an assemblage of aquatic organisms and plants that processes external inputs in a manner which promotes low quality downstream exports. Thus in this latter scenario, the effects from urban runoff can accumulate in a downstream direction and adversely affect water quality and ecosystem goods and services in larger water bodies. In Ohio, more than 78% of stream miles drain less than 20 $mi.^2$ and are classified as headwater streams. While these may individually seem less significant than larger water bodies, they are collectively the most numerous and perhaps important stream type. In many ways, and in a collective sense, headwater streams are analogous to the capillaries of the human circulatory system where essential product transport and waste assimilation functions are accomplished. Certainly the finding that a high proportion of headwater streams fail to meet CWA goals in Ohio urban areas translates to the potential for undesirable impacts in downstream waters and obvious consequences for the overall health of the "patient".

There is concern that the attainment of CWA goal uses (e.g., warmwater habitat in Ohio) within small urban watersheds may be precluded by the legacy of urbanization. If this is true, how is this determined and what are the protection endpoints to guide water quality management? Federal water quality standards regulations (40CFR, Part 131) allow for the establishment of a use that is less than the CWA fishable and swimmable goals when it is precluded by the following:

1) the degraded conditions are naturally occurring;

2) restoring the degraded conditions would result in widespread adverse socioeconomic impacts;

3) the degraded conditions are irretrievable and human induced.

Such uses are established on a waterbody-specific basis and are supported by a use attainability analysis. In Ohio, such analyses are routinely conducted as a result of the five-year basin approach to monitoring, assessment, and water quality management. One purpose of this paper is to advance the development of the tools and indicators needed to make use attainability decisions in urban watersheds.

Ohio EPA routinely conducts biological and water quality surveys, or "biosurveys", on a systematic basis statewide. A biosurvey is an interdisciplinary monitoring effort coordinated on a waterbody-specific or watershed scale. Such efforts may be relatively simple, focusing on one or two small streams, one or two principal stressors, and a handful of sampling sites; or much more complex, including entire drainage basins, multiple and overlapping stressors, and tens of sites. Each year, Ohio EPA conducts biosurveys in 10-15 different study areas with an aggregate total of 350-450 sampling sites. Biological, chemical, and physical monitoring and assessment techniques are employed in biosurveys in order to meet three major objectives: 1) determine the extent to which use designations assigned in the Ohio Water Quality Standards (WQS) are either attained or not attained; 2) determine if use designations assigned to a given water body are appropriate and attainable; and 3) determine if any changes in key ambient biological, chemical, or physical indicators have taken place over time, particularly before and after the implementation of point source pollution controls or best management practices. The data gathered by a biosurvey is processed, evaluated, and synthesized in a biological and water quality report. The findings and conclusions of each biological and water quality study may factor into regulatory actions taken by Ohio EPA and are incorporated into Water Quality Permit Support Documents (WQPSDs), State Water Quality Management Plans, the Ohio Nonpoint Source Assessment, and the Ohio Water Resource Inventory (305[b] Report).

In 1990, the Ohio EPA initiated an organized, sequential approach to monitoring and assessment, termed the Five-Year Basin Approach. One of the principal objectives of this new approach was to better coordinate the collection of ambient monitoring data so that information and reports would be available in time to support water quality management activities such as the reissuance of NPDES permits and periodic revision of the Ohio Water Quality Standards (WQS). Ohio EPA's approach to surface water monitoring and water quality management via the Five-Year Basin Approach essentially serves as an environmental feedback process taking "cues" from environmental indicators to effect needed changes or adjustments within water quality management. The environmental indicators used in this process are categorized as stressor, exposure, and response indicators (Yoder and Rankin 1998). *Stressor* indicators generally include activities that impact, but which may or may not degrade the environment. This includes point and nonpoint source loadings, land use changes, and other broad-scale influences that generally result from anthropogenic activities. *Exposure* indicators include chemical-specific, whole effluent toxicity, tissue residues, and biomarkers, each of which suggests or provides evidence of biological exposure to stressor agents. *Response* indicators include the direct measures of the status of use designations. For aquatic life uses, the community and population response parameters that are represented by the biological indices that comprise Ohio EPA's biological criteria are the principal response indicators.

Previously, our analyses examined the water quality and biological assessment database from watersheds in and near existing and developing urban and suburban areas of Ohio. Yoder and Rankin (1997) compiled their analyses based on sampling conducted at more than 100 stream sampling locations. Yoder et al. (1999) examined more detailed land use and stressor relationships with the Index of Biotic Integrity (IBI), based on fish assemblage data, and the Invertebrate Community Index (ICI), based on macroinvertebrate assemblage data, within two major Ohio urban areas (Akron/Cleveland and Columbus). This study consisted of a quantitative analysis of the relationship between the IBI, an indicator of urban land use, and a qualitative analysis of other stressors influencing this relationship using available data from all six of the major metropolitan areas within Ohio. The importance of understanding these relationships is heightened by contemporary water quality management issues such as combined sewers and stormwater permitting. One challenge we faced was in attempting to separate the influences of these multiple stressors on aquatic life attainment status. Could we sufficiently understand the baseline influence of urbanization apart from these other and better understood stressors?

The principal analysis conducted in this study examined the relationship between urban land cover and the IBI, both visually and by statistical analysis. Some goals were to determine the extent to which biological performance (as expressed by the IBI) was correlated with urban land use, thresholds at which this occurred, and the overlying effects of other stressors.

Methods

A database consisting of 267 sampling locations from the six major metropolitan areas of Ohio was extracted from the Ohio EPA statewide biological and habitat database. Most of these sites were sampled between 1990 and 1998 and contained watershed areas less than 50 mi.^{2}, with most draining less than 20 mi.^{2}. As such, the database represents a collection of discrete watershed units where land uses may have a significant effect on the composition and quality of the instream habitat and biological communities. Urban land use effects have been much more apparent in these smaller watersheds as evidenced by the higher proportion of impaired stream miles compared to larger streams and rivers in Ohio (Yoder 1995; Yoder and Rankin 1997).

Fish communities were sampled using generator-powered, pulsed D.C. electrofishing units and a standardized methodology (Ohio EPA 1987a,b, 1989a,b; Yoder and Smith 1999). Fish community attributes were collectively expressed by the Index of Biotic Integrity (IBI; Karr 1981; Karr et al. 1986), as modified for Ohio streams and rivers (Yoder and Rankin 1995; Ohio EPA 1987b, 1989b). Habitat was assessed at all fish sampling locations using the Qualitative Habitat Evaluation Index (QHEI; Rankin 1989, 1995). The QHEI is a qualitative, visual assessment of the functional aspects of stream macrohabitats (*e.g.*, amount and type of cover, substrate quality and condition, riparian quality and width, siltation, channel morphology, etc.). Ohio EPA also collected macroinvertebrate assemblage data at some of these sites, but it was not included in this study because of the partial coverage and the extensive use of the qualitative method was not always compatible with regression analysis. Some of the analyses in our earlier studies (Yoder et al. 1999) included macroinvertebrate data.

The urban land use indicator was derived from Landsat Thematic Mapper satellite imagery of land cover classification (September 1994) provided by the Ohio Department of Natural Resources. The percentage of land use in the urban classification was calculated for the subwatershed upstream from each fish sampling location to the boundary of the watershed. Because many of the sites included in the statewide data set are subjected to a variety of stressors, each site was qualitatively classified by predominant impact type. Impact types included least impacted sites, estate sites (i.e., subwatersheds with large lot sizes or green space provided by parks), sites reflecting gross instream habitat alterations (i.e., channel modifications or impoundment), sites impacted directly by discharges from combined sewer overflows (CSOs), sites impacted by wastewater treatment plant discharges, sites impacted by instream sewer line placement and construction (Cincinnati area only), sites with evidence of impacts by legacy pollutants, or sites affected by general urbanization only. This latter category included urban land uses not containing any of the other impact types and usually consisted of residential development.

Results

The relationship between the IBI and urban land use was initially characterized by regressing IBI scores against percent urban land use (log_{10} transformed) and QHEI scores using a database of 267 sites for all of the six major metropolitan areas of Ohio (Figure 1). Diagnostic plots (e.g., residuals, normal probability) indicated nonconstancy of error variance. To provide insights into whether the results varied substantially between each metropolitan area, scatter plots of the relationship between urban land use and IBI in each of the six metro areas were also made (Figure 2). A negative relationship between IBI and urban land use was observed in four of the six areas, whereas little or no relationship was seen in two areas. For each area, the highest percentage of urban land use that corresponded to minimum attainment of the WWH IBI biocriterion was determined by inspection of the scatter plot and the intersection of the regression line and the WWH IBI biocriterion were determined (Figure 2). This ranged from 1% (Cleveland/Akron) to 12% (Dayton) for the regression line, and 15% (Cleveland/Akron) to 58% (Columbus) as the highest %urban land use where WWH was attained in each area at a given sampling location. No significant linear relationship was found in either the Toledo or

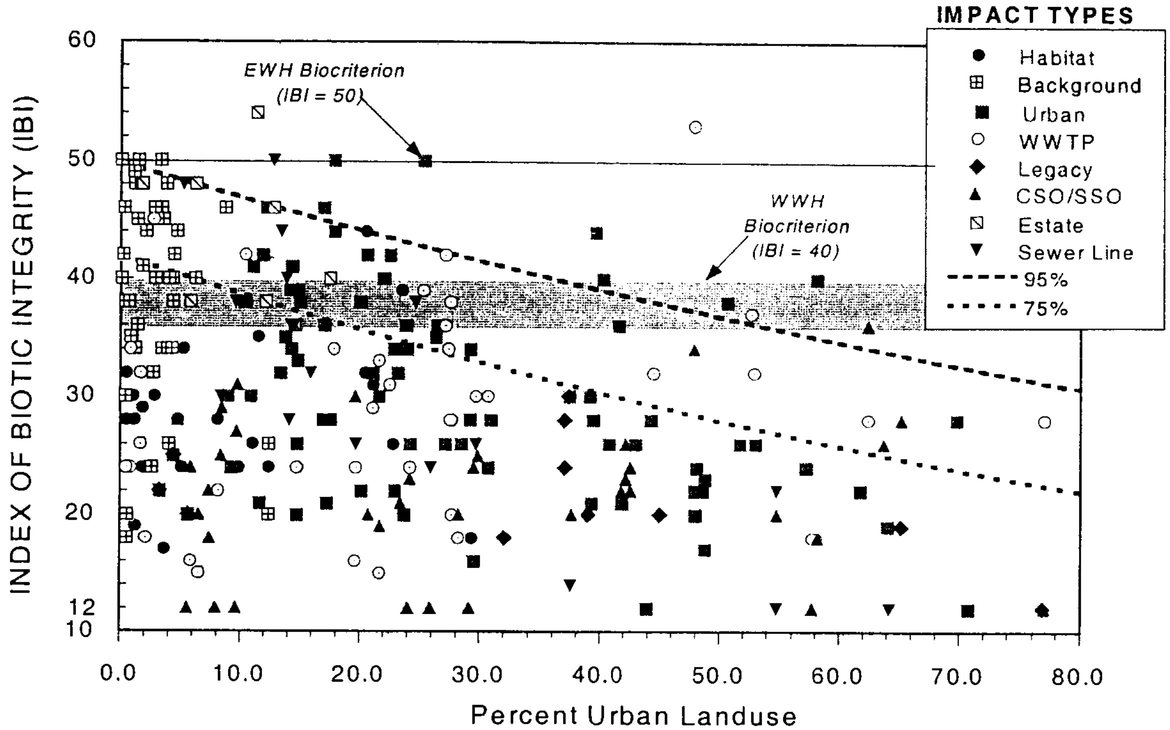

Figure 1. Scatter plot of Index of Biotic Integrity (IBI) scores against percentage of watershed upstream from the site in urban land use at 267 small (<50 mi.^{2}) sampling sites.

Youngstown areas, and only a weak relationship was visually apparent for the Toledo streams. All of the sites in the Youngstown area were impaired, and so severely that no land use relationship was evident (Figure 2). In the Toledo area, the highest urban land use corresponding to WWH attainment was 28%. However, the WWH IBI biocriterion in the Huron/Erie Lake Plain ecoregion is the lowest in the state and almost all of the small streams in the Toledo area have been channel modified to some degree. It was apparent that the lack of a stronger association between IBI and urban land use was due to overlying stressors (e.g., legacy pollutants, WWTPs, CSOs/SSOs), particularly those that resulted in very low IBI values at sites with low levels of urbanization. While some threshold relationships were evident in these results, the resulting variability in IBI scores led to only weak or non-existent linear relationships.

Some of the impact types had a strong effect on the IBI regardless of the effect of urban land use. The IBI results were examined by impact type across all six metro areas (Figure 3). The legacy, CSO/SSO, habitat, and WWTP impact types had the strongest negative effects on the IBI, respectively, and this was independent of the urban land use indicator. While these impact types are common to urban areas, they were removed from the remaining statistical analyses (elimination of these impact types reduced the sample size to 123 sites) to better develop the IBI/urban land use relationship. The entire Toledo and Youngstown datasets were also removed since they are comprised entirely of these impact types. This resulted in a better regression model fit, and diagnostics consistent with regression model assumptions (Neter et al. 1990). This also allowed us to discern the threshold of urbanization at which WWH attainment is lost with greater precision and in the absence of potentially confounding impacts, which was a major objective of our study. The relationship between different levels of urbanization and biotic integrity was further quantified with an analysis of variance model where quartiles of percent urban land use determined factor level (e.g., all sites within the 1st quartile of percent urban land use were coded as factor level 1). Similarly, an analysis of covariance model using QHEI as the covariate was employed to test for further refinements. Multiple comparisons of factor level mean differences were made using Tukey's method (Neter et al., 1990).

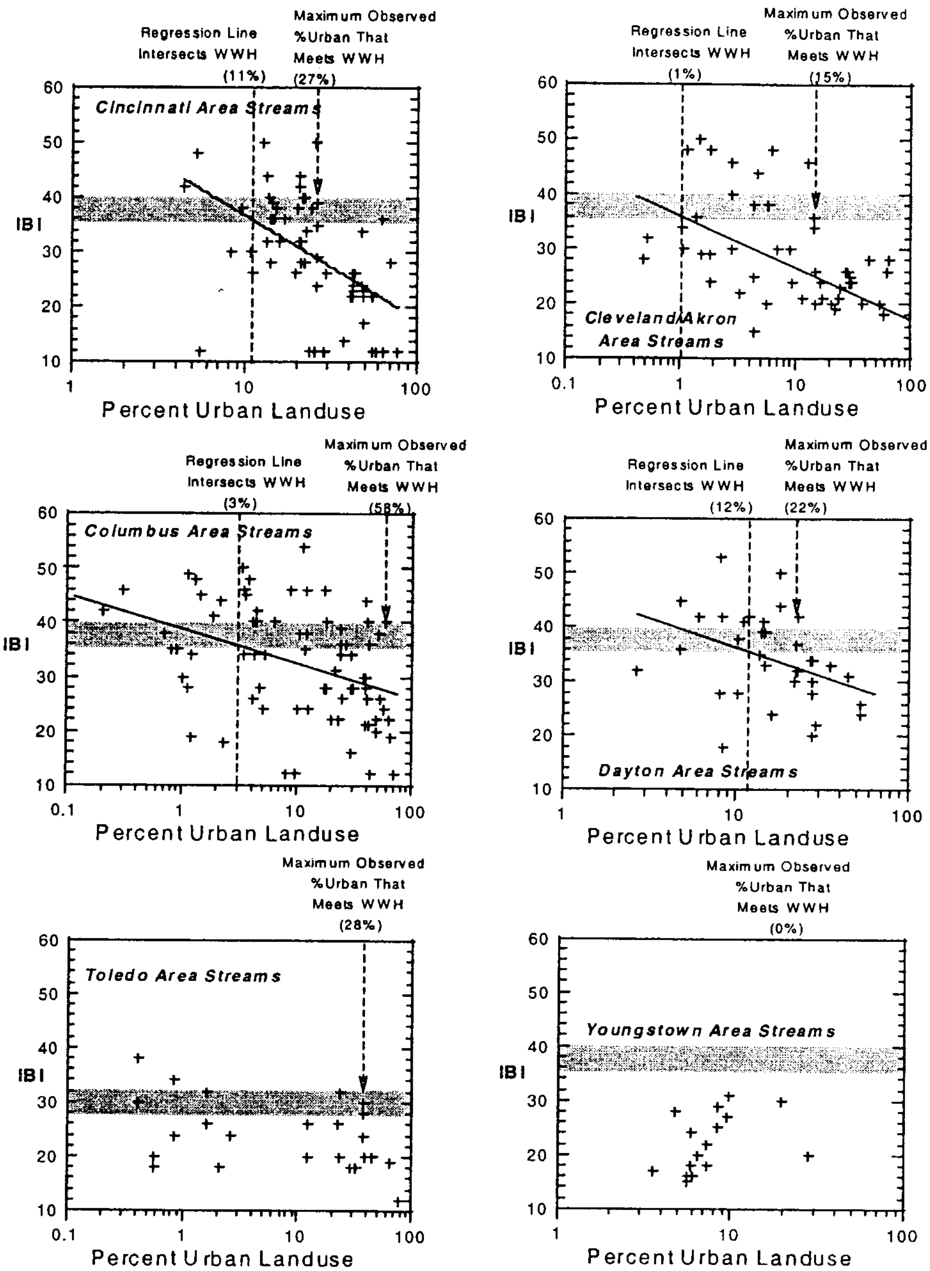

Figure 2. Scatter plots of Index of Biotic Integrity (IBI) scores against percentage of watershed upstream from the site in urban land use at small stream (<50 mi.^{2}) sampling sites in six of the major metropolitan areas of Ohio. Predominant impact types are indicated for each site (see Figure 1) along with the regression line. The warmwater habitat and exceptional warmwater habitat biological criteria for the IBI are also indicated.

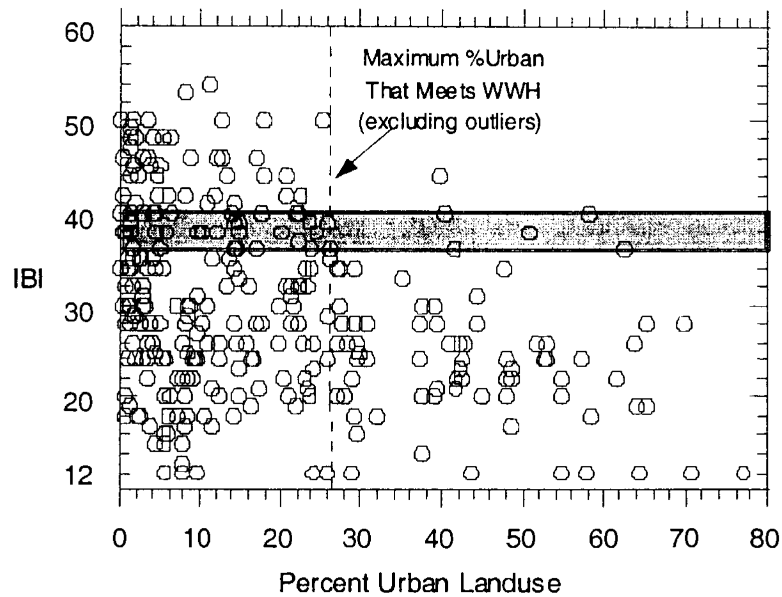

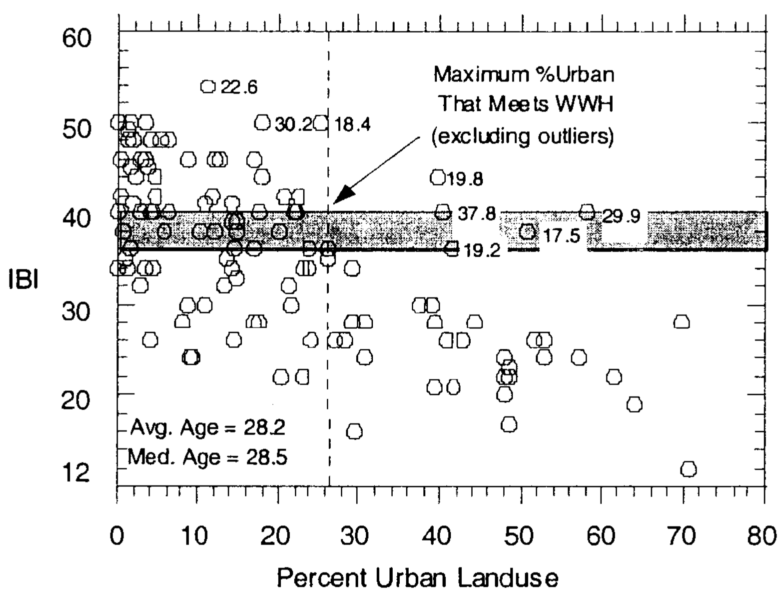

Figure 3. Box-and-whisker plots of Index of Biotic Integrity (IBI) scores by each of the major impact types used in Figures 1 and 2. The warmwater habitat and exceptional warmwater habitat biological criteria for the IBI are indicated.

R0019408

The percentage of urban land use explained approximately 35% of the variation in IBI scores in the regression model when the other impact types were excluded. Local habitat quality (as measured by the QHEI) explained an additional 7% of the variation (Table 1). The ANOVA model showed that there were significant differences in mean IBI scores between quartile level of percent urbanization, with sites exceeding 29 % urban land cover having lower IBI scores on average than sites with less urban land cover (Figure 4). Sites characterized by less than 4% urban land cover had higher IBI scores than sites with urban land use exceeding 15% The ANCOVA model provided a slightly better fit, but the additional variation explained was marginal (Table 2), and the results of pairwise comparisons were similar between models (Figure 4).

Table 1. Regression Results for the Model IbI = Log_{10}(Percent Urban Land Use+1)+qhei for All Sites and the Removal of Selected Impact Types.

Effect	Coefficient	SE	t	P(2 Tail)	Adj. R-Squared

QHEI	0.2390	0.0605	3.9493	0.0001	0.4199

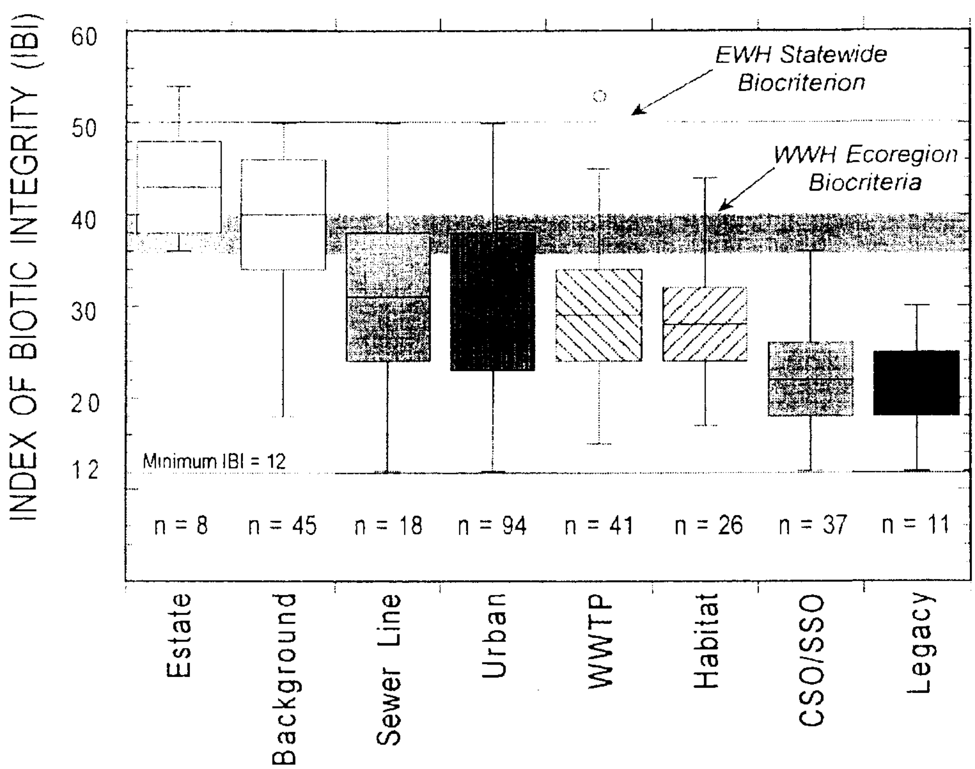

Figure 4. Distributions of Index of Biotic Integrity (IBI) from small streams (<50 mi.^{2}) in the six major metropolitan areas of Ohio plotted by quartiles of percent of urbanization upstream from sampling locations. Horizontal lines spanning adjacent box plots indicate similar means. Levels of percent of urbanization corresponding to the 25th, 50th and 75th percentile are indicated. The shaded areas indicate the applicable warmwater habitat biological criterion and the range of insignificant departure for the IBI.

Table 2. Analysis of Variance Results for the Anova Model, and the Ancova Model Using Qhei as a Covariate.

ANOVA Source	Sum-of-Squares	df	Mean-Square	F-ratio	P	R-Squared
Urban	4248.53	3	1416.18	27.50	0.0000	0.4094
Error	6129.10	119	51.51			
ANCOVA Source	Sum-of-Squares	df	Mean-Square	F-ratio	P	
Urban	4020.66	3	1340.22	28.81	0.0000	
QHEI	640.71	1	640.71	13.78	0.0003	0.4711
Error	5488.39	118	46.51			

In an attempt to better visualize where attainment of warmwater habitat occurs along the urban land use gradient, the IBI results were plotted against percent of urban land use for all sites used in this study and with the other impact types excluded (Figure 5). The elimination of the other impact types provided for a more precise statistical relationship between urban land use and the IBI (i.e., lower error of regression estimates). For example, the R^2 was higher with the removal of the other impact types and the slope of the regression was steeper, both of which suggest a more meaningful relationship between the IBI and urban land use (Table 1). However, the percent of urban land use that corresponded to attainment of the warmwater habitat IBI biocriterion based on inspection of the scatter plot was the same (approximately 26%) in both plots.

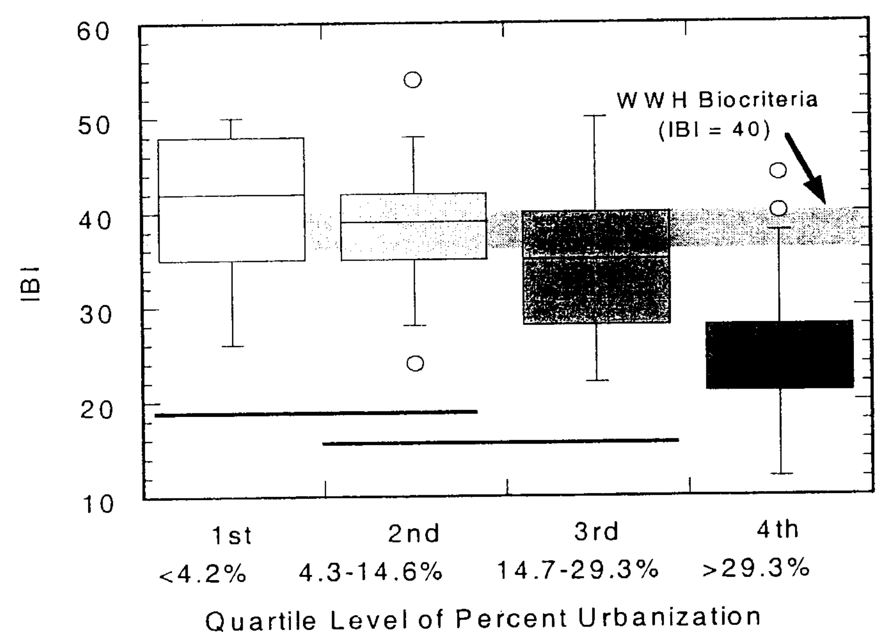

Figure 5. Scatter plots of Index of Biotic Integrity (IBI) scores against percentage of watershed upstream from the site in urban land use at small stream (<50 mi.^{2}) sampling sites in six of the major metropolitan areas of Ohio for all sites (upper) and a subset with non-urban impact types removed (lower). The age of the urbanized area is indicated for selected sites and the mean and median age for entire dataset. The warmwater habitat biological criterion and the range of insignificant departure for the IBI are indicated.

Also apparent in both plots was the occurrence of "outliers" where IBI scores above the warmwater habitat biocriterion occurred at sites with 40% to 60% urban land use. These sites had either an intact, wooded riparian zone, a continuous influx of groundwater, and/or the relatively recent onset of urbanization. Intact riparian buffers can mitigate the effects of urban land use up to a point (Steedman 1988; Horner et al. 1997) and local hydrology can strongly influence the quality of the fish assemblage (Poff and Allen 1995). The three sites with the relatively recent onset of urbanization (all <20 years) may not yet have accrued the types of negative effects that are readily apparent in some of the older urbanized areas of Ohio.

Discussion

Threshold levels of urbanization beyond which biological communities are likely to be impaired have previously been identified in the range of 8% to 20% impervious cover within a watershed (Schuler 1994). Our previous analyses (Yoder et al. 1999) produced results of approximately 8% and 33% urban land use cover for the Cuyahoga River basin and Columbus area streams, as identified by analysis of variance. We also concluded that the threshold level identified by regression for the Cuyahoga River basin was lowered by the presence of other stressors (e.g., CSOs, point sources, legacy pollutants). The elimination of those sites impacted by these other stressors from the regression analysis resulted in a higher threshold of urbanization. Our expanded study seemed to confirm this phenomenon, as the elimination of the other impact types helped clarify the urban land use/IBI relationship in a broader array of urban influenced streams throughout Ohio (Figure 5). The upper threshold of urbanization which corresponded to a loss of warmwater habitat attainment was in the 25-30% range. However, our results show that non-attainment also occurs at lower thresholds of urbanization (Figure 5) due primarily to the co-occurrence of other stressors. This makes both the linear and visual derivation of sufficiently precise indicator thresholds such as percentage of impervious surfaces more difficult.

In terms of understanding the potential effect of urbanization on aquatic life use attainment, the most meaningful results of our analyses are the upper thresholds at which attainment of CWA goal uses are mostly lost (e.g., 25%) and that beyond which it never occurs (>60%). Only a very few sites exhibited full attainment of the warmwater habitat biocriteria at urban land uses between 40-60% (Figure 5). A closer examination of these sites and the watersheds showed the presence of high quality riparian zones, an influx of flow augmenting groundwater, and/or development of the urban land use occurring within the past 20 years. For the latter, we hypothesized that the full effect of negative impacts in an urban setting may take time to accumulate and may not be immediately manifest in the form of instream impairments. This could account for the higher-than-expected urban land use (i.e., 40-60%) correlating with full attainment of the biocriteria. If this is true, then we might expect these sites to exhibit declines in IBI scores over the next one or two decades. It also suggests that newly urbanizing watersheds should be developed with an emphasis on determining which attributes (e.g., riparian zones, wetlands, flow regime) need to be maintained and preserved in order to protect and maintain instream habitat and biological quality.

The results of this study indicate that it might be possible to partially mitigate the negative effects of urbanization by preserving or enhancing near and instream habitats, particularly the quality of the riparian buffer zone. The "outlier" sites that exhibited full attainment of the warmwater habitat biocriteria had more extensive and higher quality riparian zones and good to excellent instream habitat quality. Some streams were nestled in small valleys which were not amenable to development and the accompanying encroachment of urban land uses. This generally agrees with the findings of Steedman (1988) who demonstrated a co-relationship between riparian zone quality and land use in terms of how each affected the fish communities and IBI values of Toronto area streams. Horner et al. (1997) also found that the negative effects of urban land use were mitigated by riparian protection and other management interventions. However, in both studies the quality and extent of the riparian zone ceased to be effective above 45-60% impervious land cover, which generally corresponds to the thresholds identified by our study. Until we better understand the effect of the "age" of the urban effect, it seems prudent to advocate policies that preserve existing riparian zones rather than responding with post-urbanization retrofits.

Yoder et al. (1999) discussed the implications of their findings on the designation of aquatic life uses in state water quality standards, particularly to the use attainability analysis process. Uses designated for specific water bodies are done so with the expectation that the criteria associated with the use are reasonably attainable. If CWA goal uses (*e.g.*, warmwater habitat in Ohio) are found to be unattainable, then lower quality uses may be established and assigned on a case-by-case basis (40CFR, Part 131.10[g]). Recently, the imperviousness of the watershed has been suggested as an indicator that is correlated with use attainability. If the frequently cited threshold of 25% impermeability is used, streams in watersheds with greater than this value could be considered unlikely to ever attain a beneficial use regardless of site- and reach-specific factors. This assumes that the negative effects of urbanization cannot be remediated, which has yet to be extensively tested. However, the results of our study suggest that there is a threshold of watershed urbanization (e.g., >60%) beyond which attainment of the WWH use becomes increasingly unlikely, at least as affected by contemporary practices. This threshold is not the same in all watersheds, as evidenced by the results from the six Ohio metropolitan areas, and it can occupy a rather wide range. In addition, co-factors such as pollutant loadings, watershed development history, chemical stressors, and watershed scale influences such as the quality of the riparian buffer and the mosaic of different types of land use, also act singly and in combination to determine to the resultant biological quality in the receiving streams. Thus, single dimensional urban land use indicators, such as watershed imperviousness, is not sufficiently precise or reliable as a single indicator of use attainability.

The further development and refinement of multiple indicators of watershed urbanization has merit from a management and decision-making standpoint. Because of the many co-factors involved (e.g., water quality, habitat quality, hydrologic regime, etc.), some of which are controllable and amenable to reasonable remediation, this will be a complex undertaking. We suggest that these co-factors, in addition to more refined urban land use indicators, be developed and tested using datasets from broad geographic areas spanning the extremes of the urbanization gradient. Urban land use and its analogs (e.g., % imperviousness) are coarse approximations of the cumulative effect of all negative influences within a watershed. Thus co-factors and more precise definitions of different urban land uses need to be defined in order to better understand and respond to the water quality management challenges posed in existing and developing urban areas.

A management outgrowth of such an effort could be the development of an urban stream habitat use designation. Yoder et al. (1999) previously indicated where the biological criteria for this potential new use designation might occur compared to the already existing hierarchy of aquatic life uses in the Ohio WQS (Figure 6). This designated use would

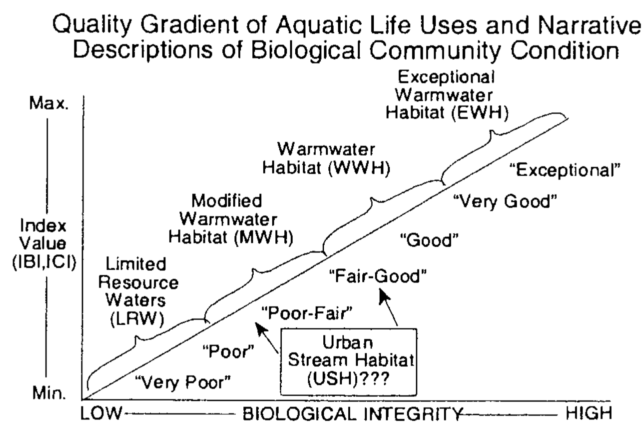

Figure 6. Relationship between the tiered aquatic life uses in the Ohio WQS and narrative evaluations of biological community performance and how this corresponds to a qualitative scale of biological integrity and of the biological indices that comprise the Ohio biological criteria. The position of a potential new Urban Stream Habitat (USH) use designation is indicated (after Yoder et al. 1999).

R0019412

satisfy the desire to afford urban streams the maximum protection practicable, while recognizing the inherent limitations that the irretrievable effects of urbanization may impose on stream quality. In the meantime, simplistic regulatory and management approaches should be avoided, particularly in those watersheds where uncertainty about the attainability of CWA goal uses (i.e., WWH and higher) exists. For example, a single indicator of urban development (e.g., proportion of impermeable surfaces) is alone insufficient to drive this process. We envision that more refined, multiple indicators of urban development will provide the necessary sophistication to more appropriately define when this less than CWA goal use should be applied. In the meantime, management strategies such as the nine minimum controls for CSOs seem reasonable analogies for the management of urban watersheds and stormwater runoff. However, proceeding beyond such minimum requirements with long-term remediation plans should be done with deference to the use attainability issues and with the aid of sufficiently robust before-and-after biological and water quality assessments.

Getting Past the Obvious

Robbin B. Sotir, President

Abstract

Long Leaf Creek is located within an urbanized watershed along coastal North Carolina. The specific stream reach addressed is located in a residential subdivision. Conditions had dramatically changed there due to the continued development of the watershed. The stream had deepened and widened as result of increased runoff and high concentration events, including hurricanes. This increased the loss of aesthetic value, riparian corridor vegetation, and aquatic and terrestrial habitats. Water quality was also degraded.

Before they could decide how best to control flooding and stabilize and restore Long Leaf Creek to a naturally functioning channel within its changed watershed conditions, citizens had to be educated about natural stabilization and restoration technologies and specific methods that would work, including conventional options. Soil bioengineering was agreed upon, with numerous modifications to meet specific needs.

This paper is presented from both the client's and consultant's perspectives. It identifies what worked, what did not work, and what was necessary to improve the process for successful, long-term results. We present the lessons learned from criteria issue development and understanding, educational process alternatives preparation, design, construction, and project results since construction.

Paper

Long Leaf Creek is located within an urbanized watershed along coastal North Carolina. The specific stream reach addressed is approximately 2000 feet in length and is located in a residential subdivision. It is a highly sensitive project with a variety of multi-objective goals specific to its location and function and typical to urbanizing areas. The watershed includes residential, office, institutional, and commercial properties, including 25 homes that line the creek in this area. Residents living along the creek described the former Long Leaf, as a small, picturesque stream that pleasantly flowed through their neighborhood--a stream that could be jumped across. It was enjoyed by many people. The conditions had dramatically changed, however, due to the continued development of the watershed, especially a new road and large shopping center immediately upstream. Residents have seen their stream deepen by almost ten feet and widen by 40 feet in areas, a result of increased runoff and high concentration events, including hurricanes. In many areas, the banks were vertical. Large, woody debris filled much of the channel, and many people were now using the "ditch" as a yard and construction waste dump (see Figure 1). This has resulted in increased the loss of aesthetic value, riparian corridor vegetation, and aquatic and terrestrial habitats. Water quality has also been degraded.

Many people had already lost property due to stream widening and were unwilling to lose more. Flooding was a major problem in the downstream end, while erosion was occurring throughout the project reach. The City of Wilmington was interested in exploring a natural approach to solving the problem. After assessing the site and conditions, and listening to the residents= concerns and desired solutions, it was clear that a strong, continual working relationship had to be formed with the neighborhood to ensure project success.

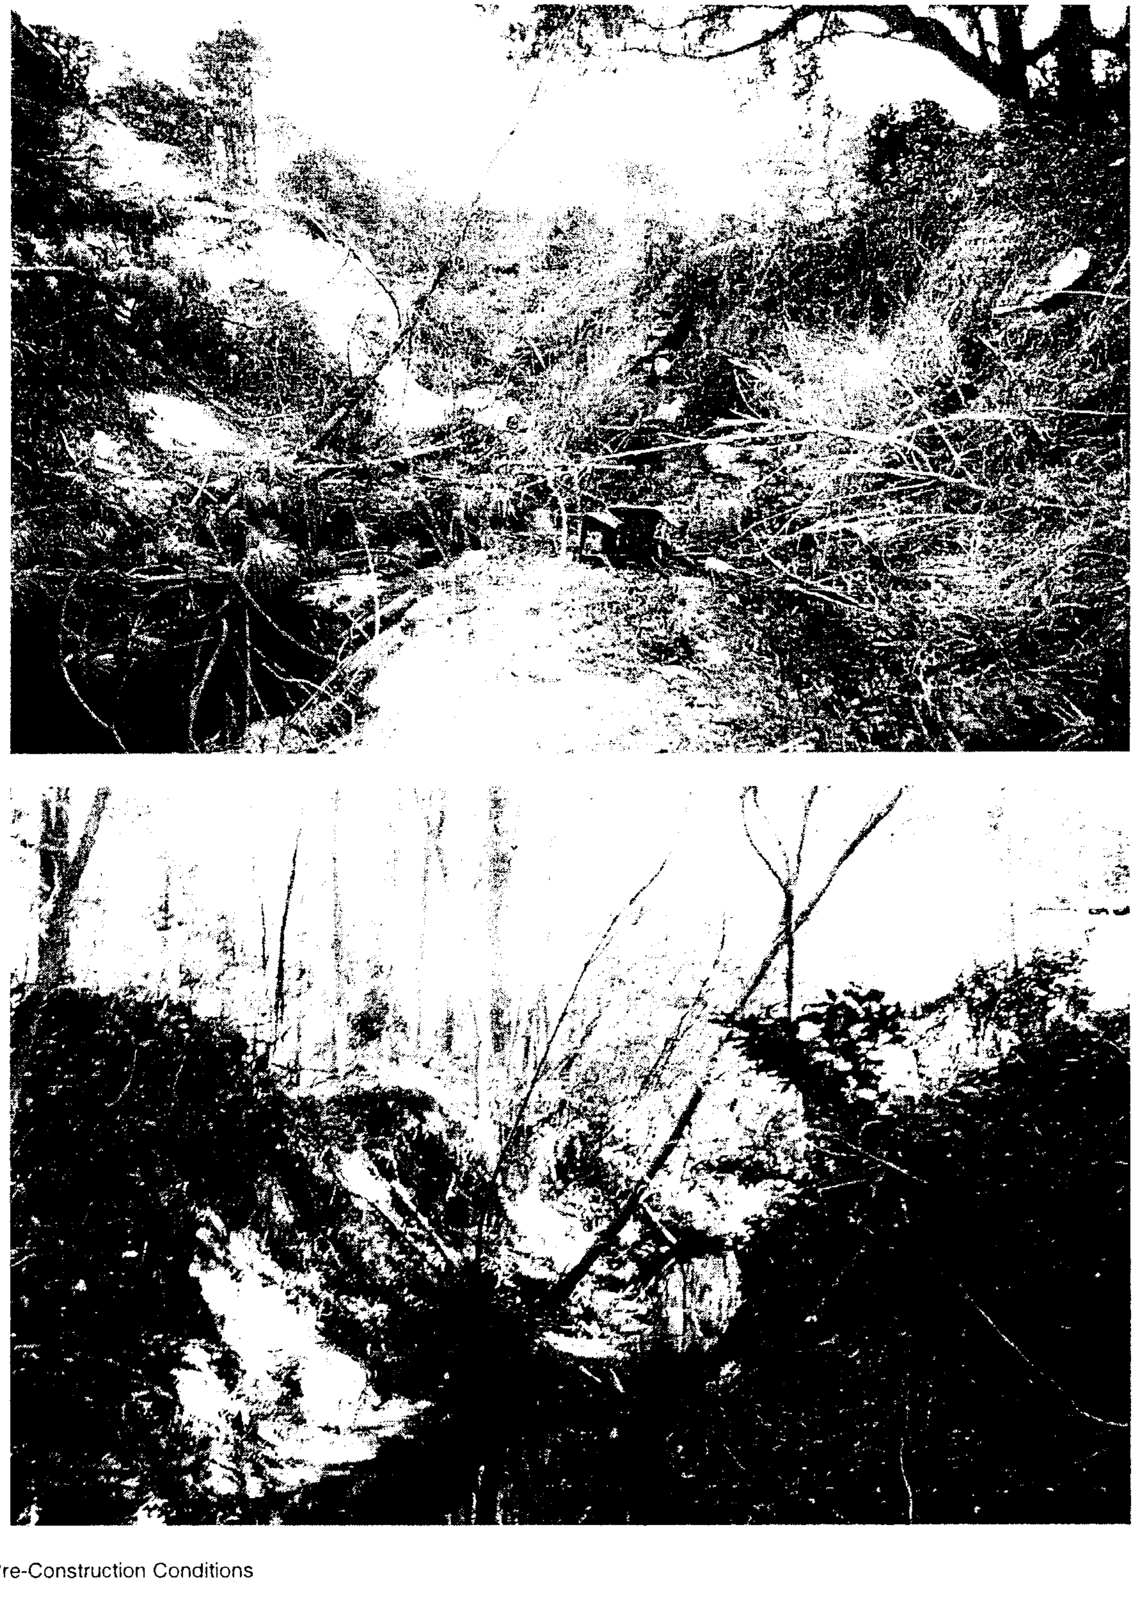

Figure 1. Pre-Construction Conditions

Before they could decide how best to control flooding and stabilize and restore Long Leaf Creek to a naturally functioning channel within its changed watershed conditions, citizens had to be educated about natural stabilization and restoration technologies and the specific methods that would work, including comparative conventional options. To "get past the obvious," it was clear that almost everyone would have to give up some land and existing trees to solve their continued land loss and flooding problems and to improve the environmental and aesthetic values of Long Leaf Creek. How much land and how many trees they would lose would ultimately depend on their selected restoration alternative. A matrix was developed using critical issues and matching these to possible alternatives (Table 1). Soil bioengineering was agreed upon, with numerous modifications to meet specific needs.

Robbin B. Sotir & Associates, Inc., (RBSA), served as the soil bioengineering consultant to the prime, the Kimley-Horn's interdisciplinary team, developed the geotechnical design and hydraulic efficiencies of a soil bioengineering solution to address the desired goals and critical engineering, environmental, and aesthetic issues.

Alternatives were compared with such critical issues as erosion control, streambank stabilization, safer and healthier environment, flood control, timely project completion, environmental and aesthetic improvement, property loss minimization, hydraulic efficiency, and cost feasibility.

After an initial investigation, an alternative analysis was produced in the summer of 1997. This alternative analysis explored numerous approaches to solving each of the project goals, with cost and risk factors assigned to each alternative. Several alternatives were considered, such as box culverts, 3:1 (horizontal : vertical) grassed slopes, 2:1 riprap rock, 2:1 concrete lining, and soil bioengineered slope systems. With input from the residents and permit authorities, the City selected the soil bioengineering approach and commissioned a design team to produce plan and specification documents, including construction cost estimates.

The selected systems employed the use of live fascines, brushlayer/live fascines, joint planting and vegetated geogrids (see Figures 2 through 5).

The majority of the improvement was done using vegetated geogrid, due to its soil reinforcing capabilities and ability to reduce land losses (see Figure 6).

Pre-bid, pre-construction, and permit application services were provided to support the project. Construction was completed by the spring of 1999.

The project has performed well from a biological perspective. Willow, baccharis, and myrtle installed as cuttings in the lower layer had a survival rate of approximately 80%. The rooted stock installed in the upper two layers comprised of spirea bush, carolina allspice, serviceberry, and viburnum, were less successful, with a survival rate of approximately 60% due to an insect infestation (see Figure 7). Hydraulically, we have had some bed scour, accompanied by toe erosion.

The survival rate of the rooted stock would have been higher had the watering maintenance program been followed. It is also possible that the insect infestation would not have occurred if the plants had been kept healthier by better maintenance practices. The rooted plants will be replaced by the contractor under the maintenance agreement. The contractor is also responsible for taking care of the insect infestation. The bed scour in the upper level caused by Hurricane Floyd is being handled with check dams to stop the bank from lowering and to control the toe scour.

[1] Does not address geotechnical issues of sandy bank material stability and major land loss requirements.

[2] Does not address increase safety concerns or reduction in property values.

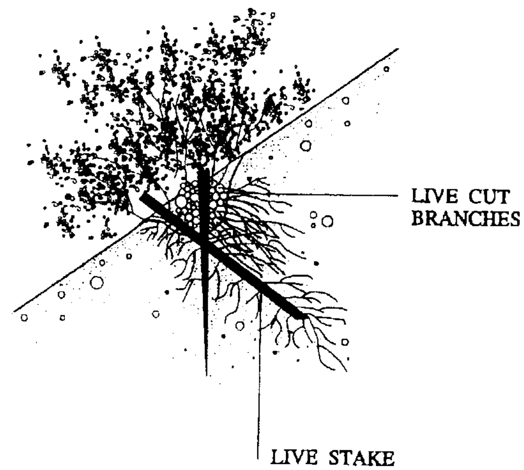

Figure 2. Live Fascine.

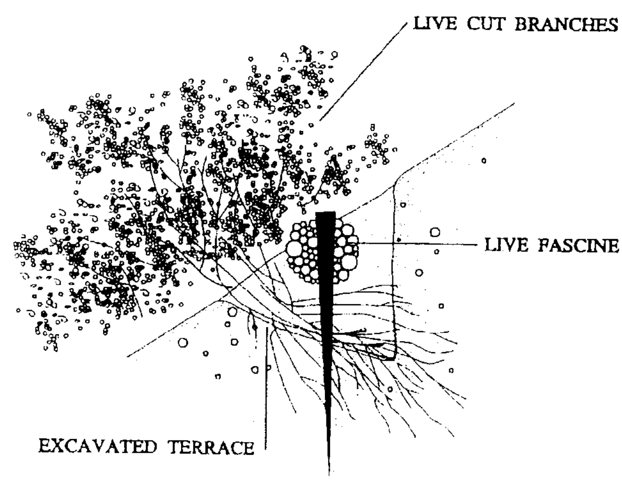

Figure 3. Brushlayer/Live Fascine.

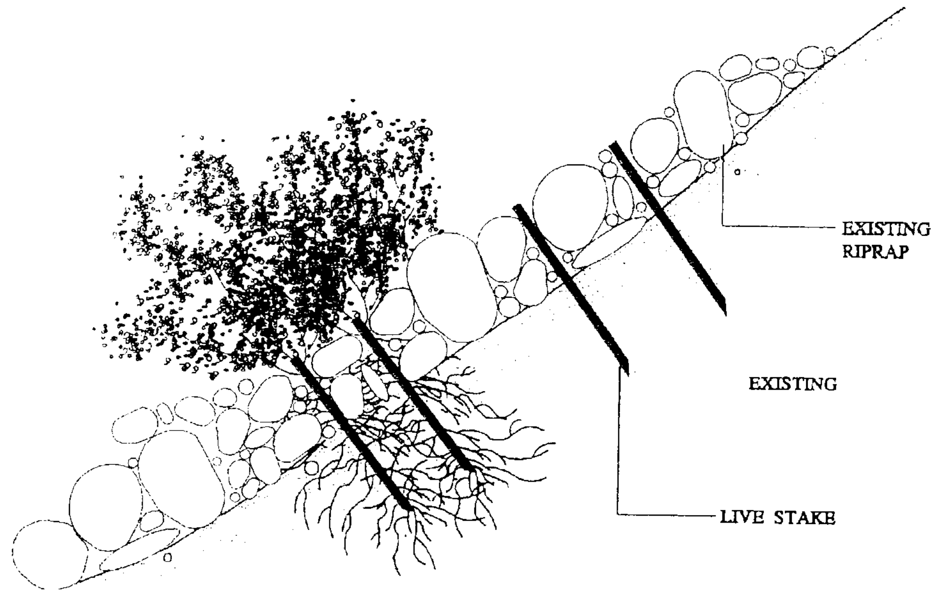

Figure 4. Joint Planting.

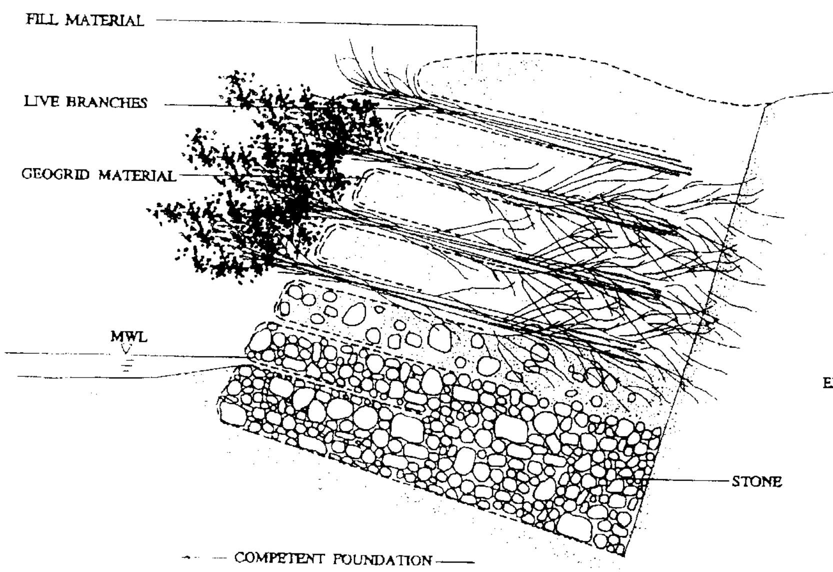

Figure 5. Vegetated Geogri

Figure 6. During Construction.

Figure 7. Three Months After Construction.

The project is functioning well from the bank stability and flood control aspects and the stream is operating within the parameters of the new watershed conditions. It is aesthetically attractive and, over time, should develop some ecological diversity. In summary, it is clear that the soil bioengineering approach is succeeding. The most important lessons learned were as follows:

- Learn more about the bed conditions in areas that have had high deposits of mobile materials
- Employ sophisticated grade control structures
- Ensure installation procedures are followed correctly and that materials are not changed
- Keep tabs on the contractor's maintenance schedule
- There is no substitute for communication and cooperation

Protecting and Enhancing Urban Waters: Using All the Tools Successfully

Eric H. Livingston
Stormwater/NPS Management Section
Florida Department of Environmental Protection
Tallahassee, Florida 32399-2400

Abstract

Reducing the hydrologic effects and pollutant loadings from urban drainage systems and restoring aquatic habitats to improve the health of our aquatic ecosystems presents many unique challenges. These challenges can be categorized as technical, institutional, financial, and cultural. This paper will examine each of the challenges and the tools that have and are being developed to overcome them. A case study on how the tools are being used in Florida to enhance the health of the Tampa Bay aquatic ecosystem will be presented.

Introduction

Research conducted in Florida during the late 1970s characterized stormwater pollutants, provided cost and benefit information on many types of stormwater treatment practices, and determined the importance of stormwater discharges as a major source of pollution. As a result, in 1979, the Florida Environmental Regulation Commission adopted the state's first stormwater treatment requirements. In 1982, the state's stormwater rule was fully adopted, requiring all new development and redevelopment projects to include site appropriate BMPs to treat stormwater. This technology-based program establishes a performance standard of removing at least 80% of the average annual post-development loading of total suspended solids for stormwater discharged to most waters. Stormwater discharges to the state's most pristine waters, known as Outstanding Florida Waters, are required to reduce pollutant loading by 95%.

Florida's stormwater treatment program, in combination with the state's wetlands protection, land acquisition, and growth management programs, has greatly minimized the effects of Florida's rapid growth on its water bodies. However, land uses and hydrologic alterations that occurred before the mid-1980s has continued to adversely affect the state's vulnerable and valuable aquatic ecosystems. Accordingly, the focus of Florida's watershed management program shifted to cleaning up "older sources" such as existing land uses, whether urban or agricultural, and to integrating program components to eliminate duplication and improve efficiency and effectiveness. This has led to greater emphasis on more holistic approaches to address cumulative effects of land use activities within a watershed and to a greater emphasis on regional structural controls and the purchase or restoration of environmentally sensitive lands. The key institutional components of this watershed approach have been described in detail (WMI, 1997; Livingston et al., 1995).

Development of Florida's Watershed Assessment Tools

Florida's Water Implementation Rule, Chapter 62-40, F.A.C., establishes a performance standard for reducing, on a watershed basis, the pollutant loading from older stormwater systems. The goal is to protect, maintain or restore the beneficial uses of the receiving water body. The amount of needed pollutant load reduction is known as a "Pollutant Load Reduction Goal or PLRG". The rule further specifies that PLRGs be established as part of the states's priority watershed program, Surface Water Improvement and Management (SWIM), which is implemented by the state's five water management districts. Consequently, stormwater PLRGs have been established for several water bodies leading to the development and implementation of watershed plans to reduce pollutants from urban and agricultural stormwater discharges. For example, farms within the Everglades Agricultural Area have implemented BMPs to reduce phosphorus loadings by 40%. Additionally, the federal and state government, SFWMD, and landowners within the EAA are sharing the cost of constructing tens of thousands of acres of wetlands (Stormwater Treatment Areas) to provide for additional reduction of phosphorus.

Having a sound institutional framework, however, is only one of the tools needed to successfully reduce stormwater pollutant loadings from existing land uses. Equally important are funding and public education to promote the cultural change necessary to reduce "Pointless Personal Pollution". A final cornerstone is good science - to establish ecologically meaningful watershed management goals, evaluate the effectiveness of BMPs and management programs, and assess the cumulative effects of wet weather discharges.

Unlike traditional point sources of pollution, the effluent quality and environmental effects of stormwater and other nonpoint sources of pollution are highly variable because of their intermittent, diffuse, land use-specific nature. Of particular environmental concern is the cumulative impact on a water body from the numerous stormwater/nonpoint sources within a watershed. Consequently, traditional water quality monitoring and management efforts used for point discharges generally suffer from several deficiencies when trying to understand and manage stormwater/NPS pollution. These deficiencies include difficulty in:

1. Assessing intermittent, shock loadings of pollutants.
2. Assessing cumulative impacts of multiple sources.
3. Comparing water bodies and establishing priorities for management actions.
4. Assessing hydrologic, geomorphological, and habitat alterations within a watershed.
5. Distinguishing actual or potential problems from perceived problems.
6. Discriminating anthropogenic loadings from natural watershed loadings of metals and nutrients.
7. Establishing cost-effective ways to assess pollution sources and trends on a watershed basis.

To overcome these problems, the Florida Department of Environmental Protection (DEP) has developed cost-effective sediment and biological monitoring tools that are much better suited for assessing cumulative effects than traditional water chemistry monitoring (Livingston et. al, 1995; McCarron et al., 1997). Most stormwater pollutants accumulate over time in sediments, not the water column. Therefore, the sediments and the organisms that reside in them offer an in-situ monitoring opportunity to determine the cumulative effects of watershed stormwater/NPS pollution sources on aquatic systems or to evaluate the effectiveness of management programs.

Sediment quality is a sensitive indicator of overall environmental quality. Sediments influence the environmental fate of many toxic and bioaccumulative substances in aquatic ecosystems (Long and Morgan, 1990). Sediments tend to integrate contaminant concentrations over time and may represent long-term sources of contamination. Specifically, sediment quality is important because many toxic contaminants found in only trace amounts in water can accumulate to elevated levels in sediments. Sediment-associated contaminants can also directly affect benthic and other sediment-associated organisms since sediments provide benthic and pelagic communities suitable habitats for essential biological processes (e.g. spawning, incubation, rearing, etc.).

Sediments provide an essential link between chemical and biological processes. By understanding this link, environmental scientists can develop assessment tools and conduct monitoring programs to more rapidly and accurately evaluate the health of aquatic systems (Pardue et al., 1992). Therefore, sediment quality data provide essential information for evaluating ambient environmental quality conditions in water bodies. Additionally, information about the amount and quality of sediments within stormwater systems, stormsewers and other stormwater conveyances can help trace pollution sources, prioritize areas for implementing control measures, and help to assure proper disposal of accumulated sediments.

Inclusion of biological community monitoring allows a more holistic, systems approach that greatly enhances surface water quality assessment and management (Yoder, 1989; Yoder and Rankin, 1997). In particular, it allows assessment of the degradation of habitat (e.g., channel and bank erosion) and siltation within water bodies, neither of which are detected by water chemistry sampling, and both of which are typically associated with wet weather discharges. While chemical data reflect short-term conditions that exist when a particular sample is collected, biological communities accurately indicate overall environmental health because they continuously inhabit receiving waters where they integrate a variety of environmental influences - chemical, physical and biological.

Biological assessment involves an integrated analysis of functional and structural components of aquatic communities (Karr and Dudley, 1981; Karr, 1991). Bioassessments are best used to detect aquatic life impairments and assess their relative severity. Once an impairment is detected, additional chemical and biological toxicity testing can identify the causative agent and its source. Both biological and chemical methods play critical roles in successful pollution control and environmental management programs. They are complementary, not mutually exclusive, approaches that enhance overall program effectiveness.

A fundamental part of bioassessments is "metrics" (Karr and Chu, 1998). Just as a doctor uses metrics such as blood pressure and heart rate to assess human health, biological metrics allow the ecologist to use meaningful indicator attributes to assess the status of communities in response to perturbation. The definition of a metric is a characteristic of the biota that changes in some predictable way with increased human influence (Barbour et al., in review). By using multiple metrics to assess biological condition, the information available about the elements and processes of aquatic communities is maximized. The validity of an integrated assessment using multiple metrics is supported by the use of measurements of biological attributes firmly rooted in sound ecological principles (Fausch et al. 1990; Lyons 1992).

In 1983, the DEP began developing assessment tools that could be used to assess stormwater and NPS effects and the effectiveness of management programs, practices, and activities. The first efforts focused on estuarine sediment assessment tools (FDER, 1988; Schropp et al., 1989, 1990; MacDonald, 1994). In 1989, efforts began to modify national bioassessment protocols (EPA, 1989) to develop quantitative bioassessment protocols for Florida (Griffith et al., 1994; Barbour et al., 1996, FDEP, 1996). The tools that have been developed and that are under development (noted by a *) include:

A. Sediment assessment tools

   1. Standardized sediment collection and analysis protocols.

   2. Estuarine normalization of metal concentrations to aluminum concentrations ratio.

   3. Estuarine sediment quality assessment guidelines

   4. Freshwater normalization of metal concentrations to aluminum concentrations ratio(*).

5. Freshwater sediment quality assessment guidelines(*).

B. Bioassessment tools:

   1. Stream Condition Index

   2. Lake Condition Index (* - nearly completed)

   3. Wetland bioassessment methods (* - in early stages of development)

   4. Canal bioassessment methods (* - in middle stages of development)

   5. Estuarine bioassessment methods (* - in early stages of development)

Using the Tools for Watershed Management

Sediment assessment, together with watershed characterization, future land use plans, stormwater master plans, and mapping of pollution sources, can be used to screen watersheds and sub-basins to determine potential "hot spots".

Bioassessment and water chemistry sampling can then be done to assess the actual health of the aquatic system in these locations. An important component of the bioassessment is habitat quality, especially since urbanization often leads to dramatic changes in stream hydrology, geomorphology, riparian zones, habitats, and ultimately biological communities. Possible outcomes of the bioassessment are: (1) no biological effects; (2) effects due to habitat degradation; (3) effects due to sediment or water quality; or (4) effects due to a combination of sediment, water quality and habitat degradation. Bioasssessments also allow the establishment of an ecologically-based aquatic resource goal, rather than one based solely on traditional water chemistry standards to which the applicability to wet weather discharges is questionable. Once an aquatic resource goal is established, then relationships between the needs of the biological community and the chemical, sediment, and habitat influences on the community can be established. The next step is to then use all of this information to develop a watershed management plan that includes specific projects, schedules, and funding sources that will ultimately result in the acheïvement of the desired aquatic ecological goal. Much of this effort can be coordinated and implemented using the rotating basin approach that many states are now using in combination with the NPDES stormwater permitting program.

Putting the Puzzle Pieces Together: Tampa Bay Case Study

Puzzle Piece 1: The Assessment - As part of the development of the Tampa Bay SWIM Plan (SWFWMD, 1992) and the Tampa Bay NEP Comprehensive Conservation and Management Plan (TBNEP, 1996), existing environmental information was assessed to determine the ecological health of the bay system. Major findings of these assessments are summarized below.

Habitats

1. Since 1950, about half of the bay's natural shoreline and 40% of its seagrasses have been destroyed.

2. In 1950, the bay's shallow shelf supported about 40,000 acres of seagrasses. By 1982, only 21,600 acres remained and virtually all of Hillsborough Bay's 2,700 acres were gone. Seagrass decline is due to dredging and filling for residential development, turbidity caused by dredging of the main shipping channel, and reduced light penetration caused by shading by algae fueled by excess nutrient discharges.

3. Since the early 1900s approximately 13,200 acres of bay bottom (3.6% of the bay's surface area) were filled, with over 90% of the activity occurring along the bay's shallow shelf where seagrasses once thrived. The surface area of Hillsborough Bay has been reduced by 14%.

4. Upgrading sewage plants in the 1980s to provide advanced wastewater treatment reduced nitrogen loadings, leading to a decline in phytoplankton, an increase in water clarity, and greater light penetration. Consequently, between 1982 and 1992 seagrass coverage increased by about 4,000 acres (18.5%) raising the bay's total acreage to over 25,600 acres.

5. About 43% (9,700 acres) of Tampa Bay's original saltwater wetlands were lost between 1950 and 1990, primarily because of dredging and filling for waterfront development. However, as many as 5,900 acres of new wetlands formed along causeways and other emergent land created by dredged spoil material during this period. Recent estimates of wetland habitat in Tampa Bay indicate that about 18,000 acres of mangroves and saltmarsh remain but many thousands of acres are damaged by invasion by exotic plants such as Brazilian pepper.

Fish and Wildlife

1. Between 1966 and 1990, the harvest of 11 commercial species of fish declined by 24%, primarily because of smaller catches of mullet and sea trout. Each of these species is dependent on seagrass habitats.

2. Harvest of spotted sea trout declined by 86% between 1950 and 1990, from 487,000 pounds to 67,000 pounds. Similarly, red drum harvests plummeted from 80,000 pounds in 1950 to 15,000 pounds in 1986.

3. Tampa Bay's once-thriving shellfish industry has virtually collapsed, except for bait shrimping. Harvests of clams or oysters are restricted or prohibited throughout the bay because of high bacterial levels associated with stormwater discharges and septic tanks. The bay scallop, a highly pollution sensitive organism, all but disappeared from the bay in the 1960s.

Water and Sediment Quality

1. While water quality has improved over the past ten years, primarily as a result of better wastewater treatment, water clarity, nutrients, and toxics continue to be a problem.

2. Because of natural circulation and flushing from the Gulf of Mexico water clarity is greatest in the lower part of Tampa Bay (2.5 m), and naturally decreases moving up the bay, dropping to an average of 2 meters (6.6 feet) in Middle Tampa Bay and Old Tampa Bay. The lowest average water clarity is in Hillsborough Bay (1.5 m) which has poor circulation and receives a larger share of nutrients and sediments from major rivers.

3. Excessive amounts of nitrogen continue to accelerate algal growth which subsequently reduces light penetration to seagrasses and contributes to oxygen depletion. The bay's total annual nitrogen load was estimated to be 2.5 times greater in 1976 than the load computed for 1985 to 1991 (Figure 1).

4. Recent studies by NOAA, in cooperation with FDEP, provide an excellent overview of the levels and distribution of toxics in bay sediments (Long, et. al. 1991, 1994; FDEP, 1994). Compared to other urban estuaries, Tampa Bay has low-to-moderate levels of most toxic parameters. Contamination is centered around large urban centers, ports and marinas, and concentrations generally decrease from the top of the bay toward the Gulf of Mexico.

5. Generally, the highest levels of sediment toxic contamination occur in Hillsborough Bay, the bay's most industrialized area and home to the state's busiest port. Upper Hillsborough Bay has the highest levels of cadmium, copper, mercury, zinc, and lead, as well as the pesticide DDT. Concentrations in sediments at a site in northern Hillsborough Bay were the highest of any toxic pollutant measured in Tampa Bay. Two other bays with heavily urbanized watersheds, Boca Ciega Bay and Bayboro Harbor, also can be considered as hot spots of toxic contamination.

6. Figure 2 shows sites in Tampa Bay where concentrations of toxic contaminants in sediments exceeded Florida's Probable Effects Level (PEL) and No Observable Effects Level (NOEL). Sites above the PEL indicate a high probability for biological impact to marine organisms while those above the NOEL are considered "at risk" to biological impact (MacDonald, 1994).

Puzzle Piece 2: The Goal: A critical component of watershed management is using biological living resources as a measure of a water body's health, with far less emphasis on traditional laboratory-based water quality standards. This approach addresses critical ecological effects that are not seen by water chemistry standards, allows greater flexibility to achieve the desired ecological goals, and provides taxpayers with a better benchmark to judge the return on their expenditures. Through the SWIM Plan and the Tampa Bay NEP CCMP, the primary overall goals have been established for the restoration and protection of Tampa Bay:

1. To reverse the environmental degradation of the Tampa Bay estuarine system.

2. To optimize water quality and other habitat values, thereby promoting the sustained existence or re-establishment of thriving, integrated, biological communities.

3. To ensure the maintenance of a productive, balanced ecosystem complimentary with human needs and uses of the resources.

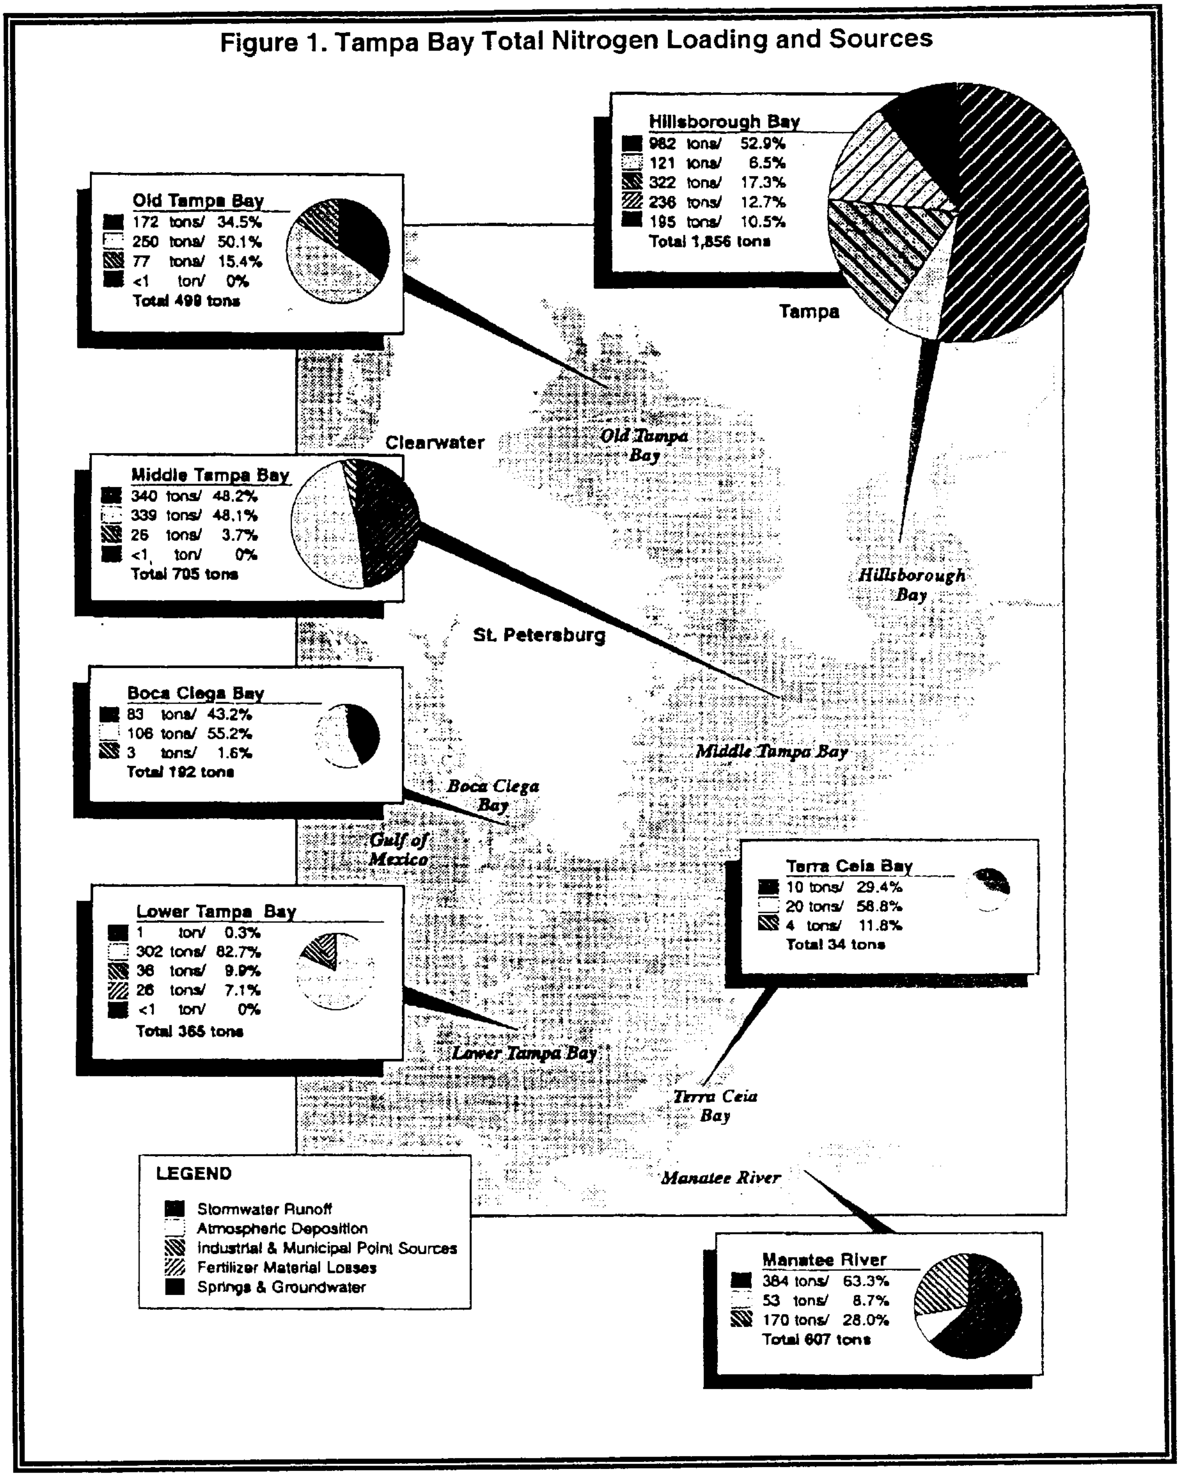

Figure 1. Tampa Bay Total Nitrogen Loading and Sources.

Figure 2. Sediment Toxic Hot Spots in Tampa Bay

Figure 2 shows sites in Tampa Bay where concentrations of toxic contaminants in sediments have exceeded Florida's Probable Effects Level (PEL) and No Observable Effects Level (NOEL) for biological impact. Sites registering above the PEL indicate that some biological impact to marine organisms is likely. Sites registering above the NOEL are "at risk" to biological impact.

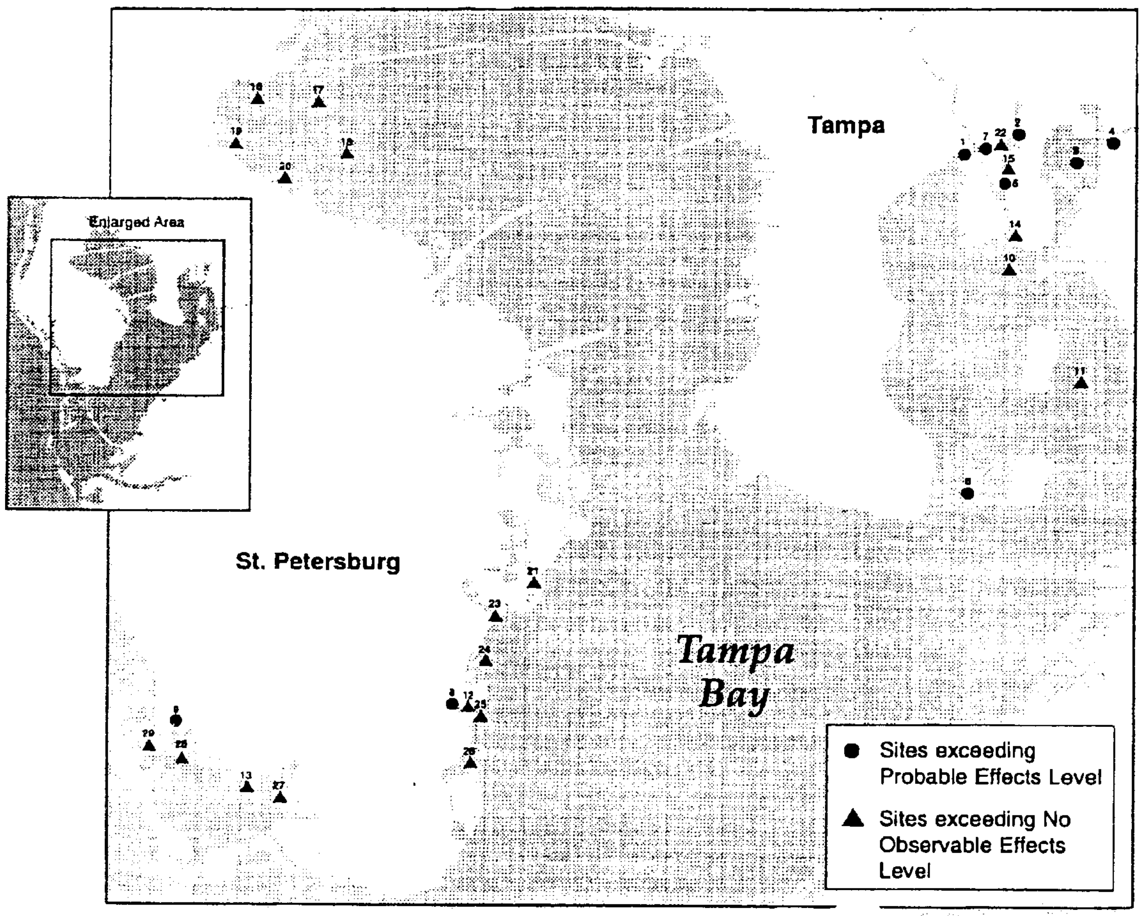

Figure 2. Sediment Toxic Hot Spots in Tampa Bay.

To achieve these overall goals the following specific goals have been established:

1. The overall goal is to restore seagrasses to 1950s levels. This will lead to restoration of commercially important species such as the bay scallop, mullet, sea trout, and red drum.

2. To restore seagrasses to 14,000 acres of the bay. The ability of seagrasses to recolonize the bay depends on the amount of sunlight the grass species require, as well as shading factors such as the amount of drift macro-algae and attached algal growth on grass blades. For most seagrasses in the bay, an estimated 20% to 25% of the light striking the bay's surface must penetrate to target depths to allow seagrass regrowth. Reducing nitrogen loadings will reduce chlorophyll a concentrations thereby increasing the depth of sunlight penetration.

3. As many as 12,000 acres of seagrass can be recovered by maintaining recent water quality conditions. This will require local communities to reduce their nitrogen loadings to the bay by about 10% by the year 2010 to compensate for increases in nitrogen loadings associated with the watershed's population growth.

4. A coastal habitat master plan has been developed for the watershed that will help to coordinate and prioritize existing state, regional, and local restoration programs. The long term goal is to recover 1,800 acres of low-salinity tidal marshes while maintaining and enhancing salt marshes and mangroves at existing levels. A minimum goal is to restore 100 acres of tidal marsh habitat every five years.

5. Reduce sediment toxicity to minimize risks to marine life and humans. Using three tests - evaluation of sediment chemistry, sediment toxicity, and benthic community health - bay sediments will be characterized and prioritized for management.

6. Reduce bacterial contamination to levels safe for swimming and shellfish harvesting.

Puzzle Piece 3: The PLRG: To achieve the ecological goal, nitrogen loadings would need to be held to those occurring in 1992-94 meaning that the 17 tons of nitrogen loading that would accompany projected growth within the watershed would have to be compensated. Reduction of nitrogen would reduce chlorophyll a levels which would increase how deep the minimum levels of light needed for seagrass growth would penetrate the water column.

Puzzle Piece 4: Quantifying Pollution Sources: Before load reductions can be achieved, it is essential that the sources and relative contribution of the sources be quantified.

Figure 3 summarizes sources of nonpoint nitrogen loadings to Tampa Bay.

1. Stormwater runoff from the Tampa Bay watershed contributes about 47% of the bay's total annual nitrogen load with urban runoff accounting for about 16%, or 680 tons. Residential areas, the watershed's largest land use, is responsible for over half of the nitrogen loading while commercial/industrial sites account for about 20%.

2. About 28% of the bay's total nitrogen loadings, or 1,200 tons, are from atmospheric pollutants falling directly on the water. An additional 7,500 tons fall in the watershed, although no one can determine how much enters the bay via stormwater. EPA estimates that as much as 67% of the bay's total nitrogen load may be from the atmosphere.

3. Stationary sources, primarily power plants, contribute an estimated 50% of the anthropogenic NO_x emissions as compared to 35% from motor vehicles.

4. Domestic wastewater discharges still discharge about 8% (340 tons) of the bay's total annual nitrogen loadings, even though all plants provide AWT. Hillsborough Bay receives about two-thirds of the cumulative nitrogen load from the 36 billion gallons of effluent discharged to Tampa Bay each day.

5. Industrial wastewater discharges, primarily fertilizer manufacturing and shipping facilities, are responsible for about 6% of the bay's total annual nitrogen loadings.

Figure 3. Total Nitrogen Loadings

Per-Acre Nitrogen Loadings from Non-Point Sources

	% Loading	% Watershed	Yield lbs/ac/yr
Residential	11	15.5	4.52
Commercial Industrial/Institutional	5	6.4	5.26
Mining	4	3.2	4.97
Range and Pasture	13	28.4	2.81
Intensive Agriculture	6	6.5	5.63
Undeveloped Land	8	39.93	1.15

Total Nitrogen Loadings to Tampa Bay (1992-1994 average)

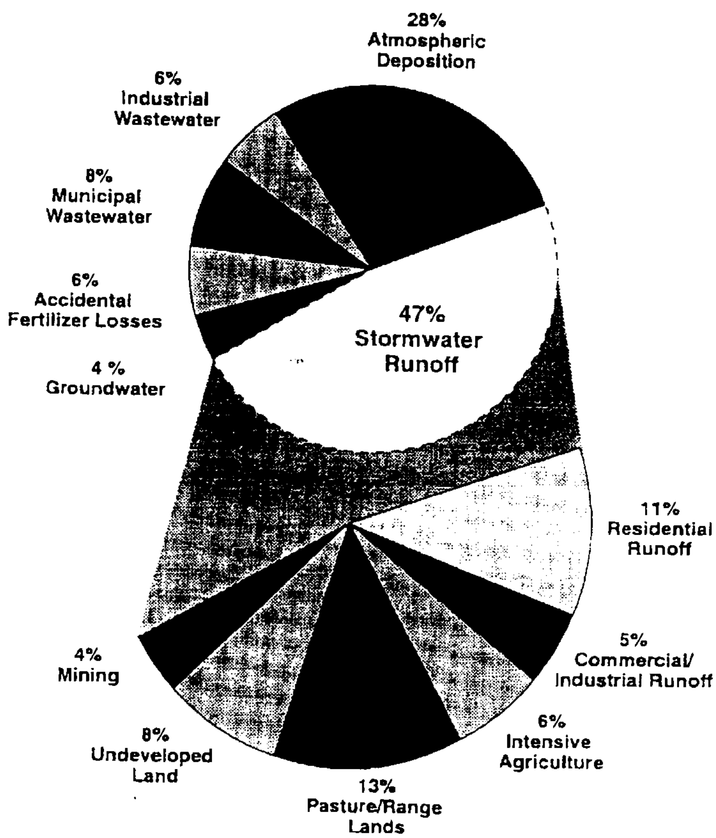

Figure 3. Total Nitrogen Loadings.

6. Septic tanks, which serve about 20% of the watershed's population, are another important source of nitrogen and pathogen loadings, especially in some areas such as Allen's Creek and tributaries to McKay Bay.

7. Another 7% of the bay's total nitrogen loadings had been attributed to losses of fertilizer during ship loading and en route to port. However, this figure has declined substantially since 1991 as source control BMPs were implemented at the port.

8. More than 60% of the bay's annual loadings of chromium, zinc, mercury and lead, as well as significant amounts of petroleum hydrocarbons and pesticides are conveyed by stormwater.

9. Atmospheric deposition also is a major source of toxic substances accounting for 44% of the bay's total cadmium loading and about 17% of the copper and lead loadings. PAHs also enter the bay from the atmosphere.

10. Industrial and domestic point sources also contribute about 30% of the bay's total loadings of aresenic, cadmium, chromium, and copper.

Puzzle Piece 5: The Watershed Management Plan: The state's Surface Water Improvement and Management (SWIM) program was established by the legislature in 1987. Tampa Bay was named in the SWIM Act as a priority waterbody within the Southwest Florida Water Management District and a SWIM Plan was adopted in 1992. In 1990, Tampa Bay was adopted into the National Estuary Program by EPA leading to the development of *Charting the Course,* a Comprehensive Conservation and Management Plan (CCMP) for the bay. Community participation was an essential component of the development of both watershed plans. In particular, many of the agencies, citizen groups, and others long active in the restoration and management of Tampa Bay participated in the development of the CCMP. The CCMP built on many of the region's ongoing environmental programs, from land acquisition to urban stormwater retrofitting to habitat restoration. It also identified where unneccesary duplication existed in current environmental programs and provided recommendations to ensure that limited public funds are spent in the most environmentally effective manner.

Puzzle Piece 6: Setting Priorities: To assure that limited financial resources were used judiciously, restoration projects and programs were prioritized and targeted to specific subbasins. This was done by combining GIS analysis with watershed modeling and characterization with the results of the sediment, biological, habitat, and chemical assessments. For example, an essential early activity of the SWIM program was a watershed-wide assessment of pollution sources, especially stormwater, to identify "hot spots" - subbasins with high stormwater loadings - and to prioritize urban stormwater retrofitting projects (SWFWMD, 1990). Similarly, priority habitat restoration sites were also selected as were projects to reduce overall nitrogen loadings to the bay, including those from atmospheric deposition.

Puzzle Piece 7: Action Plans: A successful watershed management plan must include a specific set of actions that will be taken within a specified time. *Charting the Course* includes 41 specific actions that are needed to achieve the plan's goals. These include the construction of numerous urban stormwater treatment and habitat restoration projects that have been built, are underway, or are planned in priority subbasins (Figure 4). Since vacant land in the highly urbanized area is scarce or extremely expensive, many of these projects are being conducted on existing public lands providing multiple benefits including regional stormwater management, open space, and recreation. Public education is a frequent component of these projects with the placement of signs depicting the effects of urbanization, the importance of wetlands and riparian vegetation, and the need for stormwater treatment and habitat restoration.

Programs and actions that rely upon nonstructural BMPs are also being used to reduce "Pointless Personal Pollution" at its source and increase the effectiveness of existing programs. For example, since surveys showed that up to 70% of the stormwater BMPs serving new development are not being properly maintained, assuring their long-term operation and maintenance can greatly reduce stormwater pollution. Maintenance and operation of BMPs typically is the legal responsibility of private land owners and property owner associations. Unfortunately, DEP, SWFWMD, and local governments do not have enough staff to conduct regular inspections. To improve this deficiency, DEP is implementing, in cooperation with local governments and the WMDs, a training and certification program for public and private sector individuals involved in erosion, sediment, and stormwater inspections. Local governments also are encouraged to implement Stormwater Operating Permit systems which require an annual inspection and certification that the stormwater system has been maintained and is properly operating. As an economic incentive, some local stormwater utilities provide credits for individuals served by a properly maintained and operating system. Additionally, Hillsborough County has implemented the "Adopt a Pond" program to help educate stormwater system owners on how to maintain their systems.

Other nonstructural efforts include assisting businesses in developing and implementing pollution prevention plans and the continued implementation of the Florida Yards and Neighborhoods Program. This program is being expanded to help develop model landscaping guidelines for commercial landscapes, and promote the incorporation of FYN

Figure 4. Active SWIM Habitat Restoration and Stormwater Retrofitting Projects

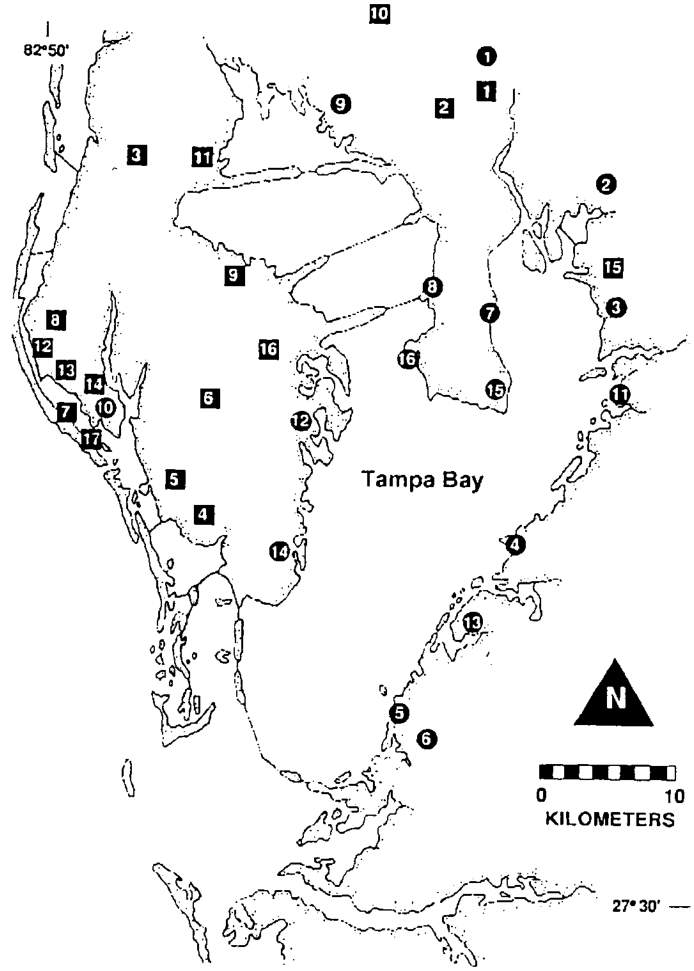

Figure 4. Active SWIM Habitat Restoration and Stormwater Retrofitting Projects.

landscaping guidelines into local government site review processes for new development. The region's continuing rapid growth provides opportunities through local government comprehensive plans and land development regulations to promote compact development and to reduce impervious surfaces, especially parking lots at commercial developments.

Puzzle Piece 8: Assuring Implementation: An important aspect of any watershed management program is an institutional framework that assures that all of the partners will implement their responsibilities. In 1998, an Interlocal Agreement was signed by the Tampa Bay NEP's local government and regulatory implementation partners. The agreement requires the partners to submit detailed plans describing how they will fulfill their responsibitlities for bay restoration and protection. Additionally, all of the local governments within the watershed have been issued, either as individual permittees or co-permittees, NDPES muncipal stormwater permits. These permits include specific requirements that are identified in the CCMP's action plans.

12. 102nd Avenue
13. 94th Avenue
14. Lake Carroll
15. Delaney Creek
16. Haynsworth
17. 141st Avenue

Puzzle Piece 9: Funding Implementation: Partners in the implementation of the CCMP include EPA, Florida DEP, SWFWMD, local cities and counties, and the private sector. Each of the partners has made a substantial commitment of financial resources since 1995 to accomplish the desired aquatic ecological goals. Primary funding sources have included the P2000 (state and local land acquisition funds), the SWIM Program (state and SWFWMD funds), SWFWMD Basin Boards, the private sector, and local stormwater utility fees. In many cases, funding for projects is from a combination of sources that often allow the leveraging of other funds needing nonfederal matching funds such as those from the Section 319 nonpoint source implementation grant program.

Costs associated with the individual actions presented in the Tampa Bay SWIM Plan and the NEP CCMP are considerable. However, these should not automatically be construed as requirements for new sources of revenues, since some of these initiatives can and are being accomplished with existing resources or by redirecting current funding allocations to better address the bay's needs. A number of actions seek to improve coordination, cooperation, and planning among state and local governments, and the private sector. These may actually result in cost savings for currently funded activities.

A 1994 survey by the Tampa Bay NEP attempted to quantify how much money is spent to manage and monitor bay quality and administer environmental programs. Based on FY94-95 budgets, the study indicates that over $260 million is spent annually by federal, state, and local agencies on the restoration and management of Tampa Bay. As seen in Figure 5, the largest part of the funds (65% or $170 million) are spent on wastewater collection, treatment, and reuse.

Figure 5. Funds Spent

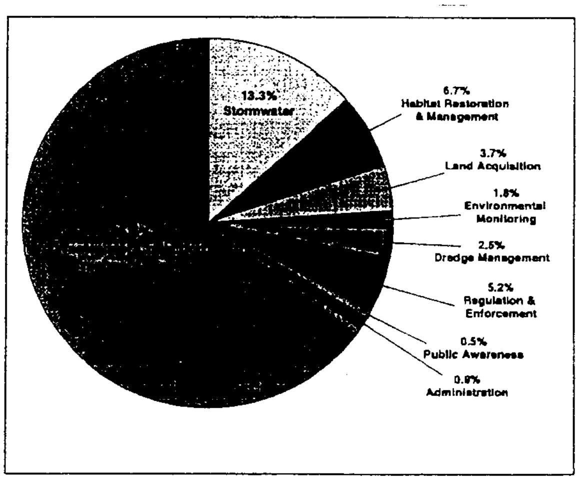

Figure 5. Funds Spent.

Approximately $35 million (13%) is spent by local governments and the SWFWMD on stormwater management. Habitat restoration and land acquisition, two long favored and implemented environmental programs in the Tampa Bay region, account for over $27 million in expenditures.

Puzzle Piece 10: Monitoring Implementation: Since the adoption of *Charting the Course* in 1996, numerous projects and programs have been implemented. The Tampa Bay NEP recently issued the first official progress report on implementation (TBNEP, 1999). It shows that the program's partners are on or ahead of schedule in achieving most of the priority goals for bay improvement. Highlights of implementation activities that occurred between 1995-99 include:

- Goal: Recover an additional 12,350 acres of seagrass over 1992 levels, while preserving the bay's existing 25,600 acres.

  Status: Since 1988, seagrass acreage is increasing at about 500 acres per year meaning the goal will be reached in 25 years.

- Goal: Restoring and protecting bay habitats

  Status: A total of 250 acres of low-salinity habitat will be restored in all bay segments, exceeding the five year target by 150 acres. Additionally, a total of 1,340 acres of mangrove and saltmarsh habitat have been restored. All 28 priority sites identified in the habitat master plan have been given the highest priority for acquisition under the state's land-buying programs.

- Goal: "Hold the line" at nitrogen loadings estimated from 1992-94.

  Status: When fully implemented, the 105 projects constructed, underway, or planned will reduce the amount of nitrogen entering the bay by an average of 134 tons per year, exceeding the target by 60%.

In addition to progress on the above goals, very good progress has been made on other goals. These include:

- The goal of protecting the endangered manatee population in Tampa Bay. The Manatee Awareness Coalition has implemented "Manatee Watch" where trained volunteers help educate and encourage boaters to go slow in waters frequented by manatees.

- The goal of returning bay scallop to Tampa Bay. Stocking programs are adding bay scallops and citizen volunteers are measuring the effectiveness of these efforts through the Great Bay Scallop Search.

- The goal of reducing atmospheric deposition into and onto Tampa Bay. To better understand the linkage between air pollution and water quality, eight research and monitoring programs addressing atmospheric deposition are underway.

- The goal of making Tampa Bay safe for shellfish harvesting and swimming. As part of the "Healthy Beaches Project", research is underway to identify and test better indicators of microbial contamination, the prevalence of the indicators at bay and gulf beaches, and probable sources of the contamination.

- The goal of providing flows necessary to support plant and animal communities below the dam on the Hillsborough River. In February 1999, the SWFWMD approved a draft minimum flow rule for the Hillsborough River that hopefully will provide a basis for resolving conflicts over competing uses of the river.

- The goal of developing a long term dredge material management plan for Tampa Bay. A Dredged Material Advisory Committee is being organized in partnership with the U. S. Army Corps of Engineers.

Discussion and Recommendations

Florida has established a wide variety of laws, regulations and programs at the state, regional and local level to protect, manage and restore the state's incredibly valuable yet vulnerable natural resources, especially its water resources. There is no doubt that these programs have been effective in helping to reduce adverse impacts on natural resources resulting from the state's rapid and continuing growth over the past twenty years. However, even with the implementation of these programs, many of Florida's natural resources have been severely strained or degraded. Some of these adverse effects can be attributed to activities that occurred before the implementation of modern watershed management programs such as the channelization of the Kissimmee River and the creation of the vast drainage canal network south of Lake Okeechobee both of which are contributing to the decline of Lake Okeechobee, the Everglades and Florida Bay. Other adverse impacts, though, are directly related to the state's rapid growth and development during the last twenty years. These include water supply problems, water quality problems, declining habitat and impacts on endangered species such as the manatee and the Florida panther.

Why are these adverse impacts still occurring given the wide range of watershed management programs that have been implemented in Florida? What could be done to reduce these effects and possibly restore already degraded areas? The continuing evolution of Florida's land and water management programs into a more holistic approach which seek to manage cumulative effects can help to overcome many of the current program deficiencies. Cooperative efforts and partnerships, together with citizen education and involvement to improve the stewardship ethic of all Floridians is essential. With increased support and participation by all Floridians, the effectiveness of the state's programs can be improved helping to assure that our natural resources will be able to be enjoyed by future generations.

Urban Stream Structure And Selection Of Structures To Build Habitat To Support Wild Fish Populations

Douglas T. Sovern
URS Greiner Woodward-Clyde
Seattle, Washington

Abstract

This paper gives a brief overview of the physical impacts of urbanization on streams and examines the selection of in-stream methods, tools, and devices for stabilizing streams and creating habitat to support native fish species. Although the paper discusses salmonid species in the Pacific Northwest in particular, the methodologies and tools employed to evaluate and support fish habitat can be generally applied to streams and watersheds in other regions.

The effects of urbanization, such as decreased pervious area and vegetative cover and increased stormwater runoff and erosion, destabilize watersheds and streambeds and destroy aquatic habitats. Stable stream environments are necessary if biological systems including fish and their supporting food web are to flourish. Changes to urban streams and watersheds may be so significant, however, that decades may pass before they reach stability. Even then, the resulting Astable environment@ might not provide the type of habitat needed to support species from the natural environments.

The evaluation of channel erosion and sedimentation in urban streams provides one measure to assess the relative stability of streams and, thus, their ability to support fish and amphibian species. For most streams, an evaluation of relative streambed stability can be completed through a visual examination of streambed morphology and minimal supporting calculations. Tools for performing these analyses will be presented in this paper.

Rehabilitation of streams in urban and heavily logged watersheds requires establishing a stream structure that will maintain streambed stability and create the different types of habitats needed to support desired fish species. One size or type of in-stream device cannot meet all stabilization and habitat requirements. The selection of devices should correspond to the relative stability of the individual stream reach. Devices for maintaining streambed stability and creating habitat, as well as the procedures for selecting them, will be discussed in this paper.

Introduction

Salmon populations in the Pacific Northwest are dwindling. One significant cause of this reduction in population is the destruction of small stream (1st to 4th order) habitats.

In order to respond to the destruction of fish habitat in small streams, we must have an understanding of watershed processes and natural stream morphology. Although this paper concerns western Washington streams, which are surrounded by heavy forests and fed by rain and groundwater, the general principles for stabilizing streams discussed here can be applied to most natural small stream systems.

Natural Stream Morphology

Streambed gradients gradually decrease from the upper reaches of a watershed to the outlet of a stream because flow rates increase in the lower parts of the watershed (Leopold, Wolman, and Miller, 1964).

The streambed gradients create different types of fish habitat features (Rosgen, 1994). Figure 1 shows the relationship of habitat type to streambed slope in western Washington streams. Pool/drop habitat is dominant in reaches with smaller flows and steeper valley gradients. The pools are formed by large organic debris or rock formations. As the stream flow rates increase, valley gradients tend to decrease and the streams are dominated by pool/riffle habitats.

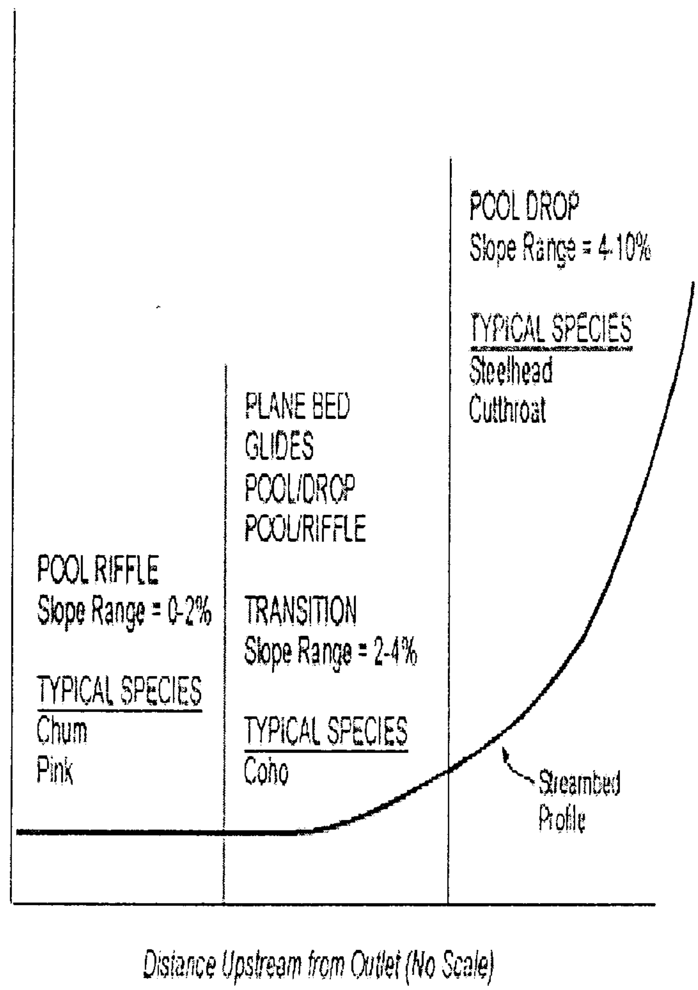

Figure 1. Relationship of Stream Habitat to Streambed Slope in Western Washington Streams.

Pools and riffles form alternately on the outside of stream bends. These alternating pools and riffles are present in practically all perennial channels. In straight or meandering streams, pools and riffles generally form every 5 to 7 channel widths. As the stream widths increase, however, the number of pools decrease (Leopold, Wolman, Miller, 1964).

In each non-rigid, natural stream, a dominant channel is formed by the stream=s dominant discharge. This dominant discharge channel is a component of most fish habitats. The dominant discharge has a recurrence period of approximately once each 1.5 years in natural systems (Simons, Senturk, 1991). In urban systems, the bank-full discharge has a recurrence period of about one year (MacCrae, 1996).

Western Washington Natural Stream Characteristics The small streams of western Washington are fed by rain and groundwater and are found in steep-sided canyons with fairly straight valley bottoms. In their natural (forested) state, small streams have a slightly meandering, low-flow channel in a narrow valley bottom. The vegetation along the stream banks is often dense and provides shade, channel stability, and cover. Debris jams are common and act to slow stream flows during storm events. Western Washington soils are products of glacial activity and consist of smooth cobbles and stones, as well as fine materials. Clayey bank materials, heavy root structures along the banks, and steady base flows create channels with nearly vertical sides and small widths (3 to 6 feet wide, and sometimes as small as 1 foot wide) relative to the width of the valley bottom. Typical old-growth forest streams have low nutrient levels and low annual sediment yields.

Most natural Pacific Northwest streams can be described as sediment starved. Natural watersheds are heavily forested and act as a sponge for rainfall. In natural watersheds, the storm runoff response is slow and the flow rates are low. Because the ratio of the 1.5-year storm to the base flow is quite low (often less than 5), these streams have small width to depth ratios, with most of the dominant discharge channel acting as an aquatic habitat channel. The width of the dominant discharge channel is coincident with the width of the aquatic habitat channel. The aquatic habitat channel is the normally wetted, low-flow part of the streambed (Seattle, 1997). Most small, natural Western Washington streams are dominated by pools and drops formed by large organic debris (Gustav, Sovern, Washington, 1993)

The aquatic biological community in western Washington may include as many as 250 plant and animal species. The aquatic biological community depends on a stable aquatic habitat associated with old growth, coniferous watersheds. Much of this aquatic community functions as a food web, with fish populations representing the mega fauna. Some salmon and trout species are the top aquatic predators (Sovern, Washington, 1996).

Salmon and trout in western Washington evolved to take advantage of these regional stream conditions. Figure 1 lists different species found in the various regions of the watershed. More athletic fish species like coho, steelhead, and cutthroat trout occupy the upper reaches (steeper gradient) of the watershed. The young coho and steelhead reside in the stream for a year before migrating to saltwater. Cutthroat may reside in fresh water for two years before migrating to saltwater. Less athletic species, such as chum and pink salmon, can not migrate through the steeper gradients of the upper watershed to spawn. The fry of these species occur in the lower regions of the watershed and migrate to saltwater shortly after emergence. Young salmon, as well as young and adult trout, will utilize any part of the watershed that meets their habitat requirements. For example, if fish habitat in the upper reaches of a watershed is unsuitable, young coho may seek winter refuge in the lower regions of a watershed (Sovern, Washington, 1996).

Five general categories of habitat occur in natural western Washington streams (Sovern, Washington, 1996):

- Estuaries/Deltas
- Passage
- Refuge
- Rearing
- Spawning and Incubation

Pacific Northwest fish derive most of their food from organisms (benthos) that live in, or on, the substrate of the stream. Most food production occurs in the same stream areas that provide spawning and incubation habitat for fish. An annual surplus of approximately 10 pounds of biomass is required to support one pound of fish in the stream (Washington, 1999).

Assessing Stream Deterioration

Visual inspection of stream morphology can provide rapid and relatively accurate assessments of a stream=s ability to support fish populations. Practical experience working in western Washington streams has shown that visual streambed assessments correlate well with benthic sampling (Seattle, 1999). Although benthic sampling is necessary, visual inspections can reduce the amount of benthic sampling required when quick assessments are needed or extensive benthic testing is cost-prohibitive.

Natural streams are generally non-rigid. Their cross-sections vary with changes in flow rates and yearly rainfall volumes. Stream systems will generally aggrade during low flow periods, and degrade during high flow periods. To assess the deterioration of non-rigid streams, it is necessary to understand the following three concepts:

- Sediment transport

•Effects of urbanization on stream stability

•Effects of urbanization on fish habitat

Sediment Transport Concepts Understanding the dynamics of sediment transport is useful for predicting hydraulic equilibrium conditions in a stream. Any stream will respond to imposed changes. Six basic relationships exist between discharge levels and channel form, regardless of stream size (Simons and Sentürk, 1991):

Depth of flow in the dominant discharge channel is directly proportional to discharge.

- Width of the dominant discharge channel is directly proportional to water discharge and sediment discharge.
- Dominant discharge channel shape is directly related to sediment discharge.
- Channel gradient is inversely proportional to water discharge and directly proportional to sediment discharge and grain size.
- Sinuosity is directly proportional to valley gradient and inversely proportional to sediment discharge (larger valley gradient causes greater meander, larger sediment discharge causes less meander).
- Transport of bed materials is directly related to flow velocity and concentration of fine material, and inversely proportional to the fall diameter of the bed material (greater depths and higher velocities cause larger bed load volume in transport, sediments shaped like kites fall slower than round-shaped sediments).

A stable channel exists when a stream has the bed slope and cross-section which allow its channel to transport water and sediment from upstream without aggradation, deposition, or streambank erosion (Simons and Senturk, 1991).

When natural flow rates are exceeded, sedimentation and erosion can be a dominant limiting factor for fish populations. The exaggerated volumes and rates of stormwater runoff in urban areas increase both the rate of erosion and volume of sediments generated from upland and riparian areas in the watershed. Soil erosion can lead to excess streambed erosion and sedimentation and destroy redds, fish rearing habitats, and food production areas.

Effects of Urbanization on Stream Stability Urbanization permanently alters the hydrologic balance within stream in the following ways:

- Total water passing through urban streams increases.
- Stormwater runoff rates and volumes increase.
- Increased impervious surface areas prevent groundwater recharge; as a result, base flow rates during summer and fall are often less than natural flow rates were.
- Increased stormwater runoff causes erosion and transports significant amounts of sediments and pollutants, including oil, grease, and polluted fine sediments from streets and parking lots, into urban streams.

In urban areas, the ratio of the 1-year storm to the stream=s base flow (dominant discharge) is large, sometimes greater than 100. In many watersheds, terrestrial sediment volumes are dramatically increased by urbanization. Excess sediment increases the width of the dominant discharge channel.

Stable urban streambeds have 1B2% gradients, compared to the 2B10% gradients that support anadromous species in natural watersheds. To reach a stable gradient, the streambed can lower several feet, causing significant bed load sediments from shallow landslides. Measurements taken from several western Washington streams show that streambeds will flatten from a 4% gradient to a 1% gradient as a result of urbanization. A change in streambed gradient from 4% to 1% over the distance of 1,000 feet can result in streambed erosion and an elevation difference of 30 feet at the upper end of the reach. During the transition from steep to flat gradients, fish habitat is in a perpetual state of change (Sovern, Washington, 1996). Unfortunately, it can take decades before stability is again reached.

In unstable streams, braiding occurs at crossover points between bends where stream gradients are steep. At normal stage, a braided section has a divided flow with small, mid-channel bars and a single large channel composed of subordinate channels. The base flow channel often changes location within the bottom of the dominant discharge channel (Sovern, Washington, 1996).

The erosion of the channel bottom along the basin (often called head-cutting) indicates a readjustment of the basin's gradient, the stream discharge, and the sediment load. (Simons and Sentürk, 1991).

Effects of Urbanization on Habitat Stable habitat conditions within the channel have stringent requirements in urban streams, including a sediment-starved condition and minimal movement of spawning-sized gravel (3-inch and smaller) during most storm runoff events.

In urban streams, the benthic system can be limited both by erosion (which provides conditions of constant change) and by sedimentation (which smothers redds and food production areas, and fills rearing habitats with silt). In addition, streams in urban or deforested watersheds experience significant habitat loss and are unable to support the biological diversity that fish species depend upon. In contrast to natural watersheds, where 250 plant and animal species may comprise the aquatic habitat, urban watersheds may have fewer than 50 plant and animal species.

Living systems do not adapt to constantly changing environmental conditions. The changes in aquatic habitats caused by urbanization decrease food production and destroy spawning and incubation areas (Bell, 1990). As flow rates and volumes increase, streambeds become unstable. When streambeds become unstable, the aquatic habitat channel may retain a small width to depth ratio, but it will be substantially less than the width of the dominant discharge channel. In addition, streambed instability causes a constant shifting of the aquatic habitat channel and this limits development of the benthic community and destroys redds.

As an urban stream approaches stability, the resulting aquatic habitat channel will be too wide, shallow, and homogeneous to support fish populations. Streams naturally deposit bed load on the inside of bends and form point bars. Because natural sinuosity is low in western Washington streams, point bars form infrequently or incompletely leaving a wide, shallow, cross section during base flows. Under these conditions, the flow depths of most urban streams are insufficient to submerge returning adult fish. Because small-grained sediments settle as flow rates decrease, redds and food production areas are smothered with silt and pool habitats are filled with sediment.

Perhaps the greatest general impact is the permanent loss of habitat types that sustain coho and steelhead populations. These species prefer pool/drop habitat. Coho, in particular, require quiet pools (Seattle, 1997). Examination of Figure 1 shows that as the streambed gradient lessons, the habitat type shifts from pool/drop to pool/riffle. Pool/riffle habitat does not provide sufficient pool depth for normal fish rearing or urban storm refuge. Because large storms frequently occur after the fry emerge from the streambed gravels, the need for urban storm refuge habitat is critical. Juvenile fish cannot maintain their position in high velocity reaches. In fact, normal urban storm flows often wash juvenile fish into larger bodies of water (salt water or streams) where they cannot survive.

Tools and Methodologies

The methodologies available to assess existing stream conditions and predict future conditions include the use of visual streambed assessments and analytical tools such as simple hydraulic mathematics.

Streambed Assessment

General indicators of habitat degradation in urban streams are visually apparent and include the following elements:

- Dominant discharge channel wider than in natural conditions
- Reduced pool frequency and less diverse habitat
- Increased sediment from terrestrial sources

- Reduced large woody debris

- Drastically reduced aquatic community diversity

Both natural and urban streams fluctuate between stability, degrading, or aggrading. Compared to natural streams, however, streams in urban watersheds exhibit extreme traits of aggradation, degradation, or instability. Urban stream deterioration indicators differ according to the condition of the specific reach (stable, degrading, or aggrading). In a degrading streambed, there is a progressive lowering of the channel due to scour. In an aggrading streambed, there is a progressive buildup or raising of the channel due to sediment deposition. Both degradation and aggradation are indicators that a change in the stream=s discharge and sediment load is taking place (Simons and Senturk, 1991).

Urban stream deterioration indicators differ according to the condition of the specific reach. Table 1 (the following bulleted paragraphs) describes the deterioration indicators in a stable, degrading, or aggrading stream.

Table 1. Urban Stream Deterioration Assessment Indicators

Stable B If an urban stream reach is stable and terrestrial sediment loads are low, the reach may be able to support species that reside temporarily in the stream before moving to salt water. The wide, shallow channel of a stable stream provides little protection from predation, however, and also lacks resting pools. The following are indicators of stable urban streams:

- Apparent changes in channel shape and configuration after large storms are small.
- Width of aquatic habitat channel coincident with width of dominant discharge channel B shallow flow depth, prevents fish passage.
- Head-cutting and nick points are absent or nearly absent.
- Substrate stability:
  - Periphyton stays on streambed after significant storms B streambed is stable.
  - Streambed gravel lack periphyton B gravel is being moved during significant runoff and replaced when the storm flow recedes.
- Small-grained sediments settle when storm flows recede, smothering redds and food production areas.
- Pools (on-stream or off-stream) that can retain newly hatched fry are generally not present.

Degrading B In a degrading urban stream the dominant discharge channel is as wide as in a stable stream, but base flow rarely covers the bottom of the channel except at crossover points between bends. When streams begin to unravel due to degradation, the effects do not appear instantly. Head-cuts move through a stream until it reaches a vertical drop. When enough head-cuts accumulate, the vertical drop will be undercut, releasing large amounts of bed load type sediments. Occasional pools will develop that may support anadromous fish, however, they are often inaccessible.

- Streambed gravel sizes are larger than stable sections of the stream, but are mostly bare of periphyton or other aquatic growth.
- Channel braiding occurs at crossovers between bends.
- The substrate of the base flow channel is not coated with periphyton.
- The base flow channel and dominant discharge channel lack large woody debris.
- Large woody debris that spans the banks of the dominant discharge channel may indicate a recent streambed elevation and may illustrate the amount of degradation that has occurred.
- Stream banks are bare and often nearly vertical.

Aggrading B Aggrading stream reaches may be visually similar to stable reaches. Generally, aggrading streams will have a flatter streambed gradient and accumulate more fine sediment. Disturbing the bed of an aggrading reach usually results in long periods of murky water flow. Aggradation will occur locally in pools, which reduces habitat value, but has less impact on habitat than an entire aggrading stream reach would.

- Head-cuts and nick points do not exist.
- Deltas may be visible at the top of the reach.
- Periphyton covers the substrate.
- Large woody debris in streambed is partially buried.
- Pool/riffle and pool/drop habitat can occur as isolated conditions.
- Substrate surface gravel sizes are small.

The visual indicators described in Table 1 (combined with assessments of fish passage problems and periodic benthic population checks) can be used to describe the potential habitat capacity for a stream reach or, collectively, for an entire stream. Needless to say, habitats for fish species that reside in the stream for one year or longer must be able to support the full life cycle of the species. In addition, fish need to have full access to these habitats.

A methodology based on visual streambed assessment was developed for rapid stream assessments in Longfellow Creek and Pipers Creek in Seattle, Washington (it was also used within six watersheds in Snohomish County, Washington). The streambed assessments provided an accurate measurement of the ability of the watershed or stream in question to support fish. An example of the summary rating for Longfellow Creek is shown in Table 2.

Table 2. Summary Rating for Longfellow Creek

Creek Segment	Description	Map Sheet	Habitat*	Bank Erosion*	Sediments Sources*	Other Pollutants*	Total
1	Pipe from outfall to Andover Street	1,2,3	5	3	3	2	13
2	Open channel from Andover Street to Genessee Street	4,5	10	1	1	2	14
3	Open channel from Genessee Street to confluence of unnamed tributary in West Seattle Golf Course	5,6,7	10	2	2	2	16
4	Unnamed tributary in West Seattle Golf Course	6,7	6	2	2	2	12
5	Open channel from confluence with West Seattle Golf Course tributary to Brandon Street	7,8,9	9	1	1	2	13
6	Open channel from Brandon Street to Findlay Street. Contains confluence of Juneau Street bypass via "biochannel."	9	9	2	2	2	15
7	Open channel from Findlay Street to Juneau Street. Also contains piped high flow bypass starting at Juneau Street and rejoining Creek in Segment 6.	9,10	8	2	2	2	14
8	Open channel from Juneau Street to Graham Street	10,11	11	2	3	2	18
9	Open channel from Graham Street to Willow Street	11,12	8	2	1	2	13
10	Open channel from Willow Street to Myrtle Street	12,13	8	2	2	2	14
11	Piped channel Webster Basin; open channel to Holden Street. Contains "K-Mart bypass."	13,14	7	2	2	2	13
12	Open channel from Holden Street to Thistle Street	14,15,16	8	2	1	2	13
13	Pipe from Thistle Street to head of basin at Roxbury Street	16	6	3	1	2	12

Notes:

Ranking Codes:

1 = Poor condition
2 = Moderate
3 = Relatively good
* = The value in the "habitat" column is the result of another ranking process. The total "habitat" volume for each Creek segment is transferred into this table to complete the ranking process. The habitat rank has a range of 0-18 which is developed from evaluating bed erosion, fine sediment accumulation, gravels (clean/stable), benthic (quantity, quality), habitat structure, and riparian vegetation. All other columns in this table are ranked from 1 (poor condition) to 3 (relatively good condition).

Analytical Tools Simple hydraulic mathematical tools can be applied to analyze existing conditions and are needed to check passage conditions for channel rehabilitation projects. In addition to depth and velocity, the amount of turbulence in a stream has significant impact on the amount of sediment that can be moved. Greater turbulence increases the amount and size of sediments that can be moved. Maximum turbulence occurs when the Froude number is equal to 1.0. The Froude number is defined by Equation 1:

$$F_N = V/(gY)^{1/2} \qquad \text{(Equation 1)}$$

Where

F_N = Froude number

V = average velocity in the cross-section

g = acceleration force due to gravity

Y = the hydraulic depth, which is the cross-sectional area divided by the top width

The Froude number should not exceed 0.8 for large storms (like the 25 or 100-year event) except at channel drops. This criterion is the same for rigid, grass, and dirt lined channels in most stormwater manuals. For frequently occurring storm flows (1 to 2 year events), the Froude number has to be much less in order to meet the criteria for larger flows. Spawning-size gravel will generally be stable if this Froude number criterion is met.

In the author's experience, backwater analysis (HEC-2 or HEC-RAS) may not be strictly applicable to analyze natural streams, but is a useful tool to analyze deteriorated channels and to model proposed improvements for stream rehabilitation. For stream rehabilitation backwater analysis is done for large and small events (base flow, 1-year flow, and one point in between) to ensure passage of juveniles throughout their life-cycle habitat within the stream. To provide accurate results, more cross-sections are needed to conduct backwater analysis on non-rigid, urban streams compared to conventional backwater analysis.

Selecting Rehabilitation Devices

Unless excess stormwater from both frequent and rare storm runoff events can be eliminated, it is the author=s opinion that some form of structural intervention is needed to create fish habitat in urban streams. In western Washington, streams become unstable and significant fish habitat is lost when the impervious area reaches 10 to 15 percent (Booth, 1996). The dominant discharge channel will respond to hydrologic changes (Simons and Senturk, 1991). As a result, modifying how land is urbanized can reduce the effects of urbanization, but it will not obviate the hydraulic impact on the dominant discharge channel. Stream rehabilitation measures will still work best where there are fewer disturbances to the watershed and where wide riparian corridors are maintained.

The goal of urban stream rehabilitation is to stabilize the streambed with devices that also create a habitat for fish populations. The stream must develop sufficient food mass and diversity to support desired fish species. Quality salmon and trout habitat can exist in urban streams when hydraulic/habitat criteria are met, the streambed is stable, and the base flow channel is confined (Sovern and Washington, 1996).

Establishing stable streams in urban watersheds is often a moving target. As more urbanization occurs, hydrologic and biological changes accumulate. The extent that the dominant discharge channel spreads is a direct function of the amount of pavement in a watershed.

The New Urban Stream. Restoring an urban stream to pre-development conditions is not possible (National Research Council, 1992). It is the author's opinion that too many stream rehabilitation projects emphasize stream bank rehabilitation rather than focusing on the root causes of stream habitat destruction. Often, that root cause is streambed instability, which is a natural response to increased flow rates and volumes in the stream.

To maintain pre-development species in urban and deforested streams, a "new urban stream" is needed that can provide a variety of fish habitats including pools. Without intervention, the urban streams will convert pool/drop habitat into pool/riffle habitat, eliminating the diversity of habitat required to support a variety of fish species (Sovern and Washington, 1996).

The goal is to stabilize the stream and return it to its original sediment-starved condition. While bed load and suspended sediment are readily available, the object is to sculpt sediment deposition to form bars and banks and confine the aquatic habitat channel within a single location. Concentrating flows in the aquatic habitat channel helps keep the substrate size optimal and clears the stream of fines.

Urban stream rehabilitation must focus on historic conditions that can be re-created, rather than on the conditions that cannot be meaningfully restored. Except for the following three exceptions, historic environmental conditions can be re-created in urban streams:

- The width of the dominant discharge channel will always be greater in urban streams.
- The banks of the aquatic habitat channel cannot be coincident with the dominant discharge channel (in pool/riffle habitat).
- High flood flows, deep flow depths, and large velocities are more frequent.

In form, the resulting channels resemble snowmelt type streams, where flow rates significantly exceed base flows for several weeks each year. Most urban streams lack large woody debris that can be incorporated into the stream's structure when a reach attains stability. Most reaches will take decades to reach stability. Just because the channel will not look "natural", doesn't mean that we will have failed or that anadromous species cannot be supported. Many eastern Washington snowmelt type streams support anadromous species.

A rehabilitated stream has five primary needs:

- A dominant discharge channel sized to carry the 1-year to 1.5-year storm (depending on the degree of urbanization) at full bank. It is important to recognize this need because the stream will reshape the dominant discharge channel and may undo much of the rehabilitation effort.

- Within the dominant discharge channel, hydraulic conditions must provide biologic and stream stability (keep most of the spawning sized gravel and rock from moving during frequent storms).

- Within the dominant discharge channel, habitat must be provided for the entire life cycle of the desired species.

- Because fine-grained sediment falls out last and needs to be kept in transport, the base flow channel has to be narrow, deep, and stable.

- Stream banks need to be stable to support riparian vegetation. Bio-stabilization techniques can help reduce the width of the dominant discharge channel.

Ideally, long reaches of unstable streams will be stabilized. Near the spanning structures, aggradation will replace degradation (as long as a sediment supply is available). If only short reaches are stabilized, large storms will deposit substantial sediments within the stabilized reach, particularly at the upstream end of the reach. The sediment sizes most likely to accumulate during the stabilization of a reach are the larger sizes that are moved as bed load. Once stable streambed gradients are attained, the amount of sediment that can move and cause aggradation is finite. After a few larger storms, bed load movement will be minimal.

Rehabilitation Devices A variety of devices may be used to confine the base flow channel and provide streambed stability. The author has experience with several types of bed control structures, glides, lunkers, and confining devices. In small streams, these devices may be a well-placed piece of timber, a boulder, or randomly placed stones and rootwads (to increase roughness). In larger streams, stabilization and confining devices are much more complex.

Selection and siting of devices is dependent on the stream condition in a specific area and the type of habitat that is to be provided. It is important to realize that one type of structure is not suitable for all applications. Selection of a stream rehabilitation device depends on the type of habitat needed and the device's perceived hydraulic attributes. Both non-rigid channel design and biologic skills are required to be successful.

This section will address issues related to the selection of three types of structures: timber stepdown structures, boulder bed control structures, and deflectors.

Timber Stepdown stepdown. Sometimes referred to as a "K-structure". A form of timber is shown in Figure 2. The logs, which are set at 45 degrees to the channel, are called weir logs and create pools during high storm flows. The weir logs need to have a steep pitch (the bank end higher than the center of the stream). In dense, urban western Washington watersheds, storms with high yearly return frequencies produce flows 20 to 50 times the base flow. Timber stepdown structures form large, quiet pools during storms, allowing newly emerged fish juveniles to find refuge. In

Figure 2. Timber Stepdown K-Structure (shown with weir logs).

addition, the K-type stepdown creates rollers. Rollers assist fish passage upstream for less athletic adults and juveniles during higher flow rates (Kerr Wood Leidal Associates, LTD, 1980).

Common variations of the K-structure include a straight timber stepdown (no weir logs) and a vortex structure (with weir logs). In creating a diverse habitat environment, both types can be used.

While the straight timber stepdown does not form an upstream pool, the substrate above the stepdown is turned-over, even for frequently occurring storm flows. The Washington Department of Fisheries and Wildlife has successfully installed many straight timber stepdowns in logged watersheds and those with minimum to moderate urbanization. For lower flow rates, the substrate above the stepdown remains stable and provides excellent spawning habitat.

The vortex type timber stepdown does not form storm refuge pools as well as the k-structure and the log configuration stymies formation of a roller. The structure can help develop confined low flows, however, and creates good fish-rearing habitat for many northwest species (not Coho).

Boulder Bed Control Structure. Figure 3 shows a boulder bed control structure. Like the K-structure, the boulders that form the structure are on the upstream side, but these boulders could also be on the downstream side to form a vortex-type structure. In the author's experience, changing the configuration and the angles of the boulders provides slightly different habitat characters, all of which are acceptable. While wood is usually preferred in small streams, boulder bed control structures are flexible and can adjust to channel degradation in unstable streams. Boulder bed control structures are most beneficial at the downstream end of a reach where no streambed control is established in the reach below.

Deflectors. Deflectors can be made of either wood or boulders. Figure 4 shows a timber deflector with a bank log on the opposite bank. Point bars form on the insides of bends. Deflectors should be installed on the insides of bends to help build larger point bars and to confine the base flow channel. The reach in Figure 4 is nearly straight (sinuosity about 1.0). To develop point bars in straight reaches, several deflectors may be needed and could be on one side of the channel, or on alternating sides. The reach shown in Figure 4 has a large bed load, and point bar formation would have occurred if the deflector installations were correctly located and implemented. Without modification, however, the deflector shown in Figure 4 will not form a point bar.

Conclusions

Streambed assessment based on sediment transport principles can be a useful tool to rapidly determine a stream's capability to support fish populations. Standard engineering analytical tools can be used with streambed assessment to support hydraulic design for stream rehabilitation projects. Although the stream will not have the same appearance as a natural stream, stream rehabilitation can be successful and urban streams can support anadromous fish populations in western Washington. Hydraulic design is needed to develop the dominant discharge channel and properly place structures to attain the desired habitat conditions. Selection of the rehabilitation devices must consider design needs of non-rigid channels, as well as habitat requirements. Finally, one size or type of habitat rehabilitation device cannot serve

Another benefit of infiltration practices is their ability to serve multiple uses since they are temporary storage basins. Recreational areas (e.g., ballfields, tennis courts, volleyball courts), greenbelt areas, neighborhood parks, and even parking facilities provide excellent settings for the temporary storage of stormwater. Such areas are not usually in use during periods of precipitation and the ponding of stormwater for short durations does not seriously impede their primary functions.

Longevity of Infiltration Systems

One of the problems with infiltration BMPs that has been consistently identified, either quantitatively or qualitatively, is their high rate of failure. Maryland's Stormwater Program produced one of the most comprehensive quantitative reviews of the longevity of infiltration systems (Pensyl and Clement, 1987; Lindsey et al, 1992). This information is summarized in Table 1, where it can be seen that the overall condition and functioning of infiltration systems declined over time. In 1986, about two-thirds of all surveyed facilities were functioning as designed, while in 1990, only about half were. Only 42% of the facilities were functioning as designed in both 1986 and 1990, while about 27% were not functioning as designed in both years. About 24% of the systems were functioning in 1986, but not in 1990; while only 7% of those not working in 1986 were working in 1990. Maintenance was needed at more facilities in 1990 (66%) than in 1986 (45%). Additionally, 38% of facilities that needed maintenance in 1986, still needed maintenance in 1990, while 32% of the facilities that did not need maintenance in 1986, did need it in 1990. Only 10% of the systems that needed maintenance in 1986 did not need maintenance in 1990. These data suggest that little effort is expended on maintaining the operational capabilities of stormwater management systems.

Additional quantitative information on the success and failure of infiltration systems was collected in the Puget Sound, Washington, area (Klochak, 1992; Gaus, 1993; Hilding, 1993; Jacobson and Horner, 1993). Of 23 infiltration basins evaluated, 12 did not comply with the region's guidelines for either infiltration rate or time for the basin to recover its storage volume. Interestingly, the authors found no relationship between lack of basin maintenance and failure, with examples of basins with and without maintenance that did not function properly. Some basins were functioning properly even though they had never been maintained, while 43% of the 23 basins had been scarified to enhance performance.

The above data, when combined with qualitative information from Florida and Delaware (Baldwin, 1999, personal communication), seem to indicate that infiltration basin failures are associated with:

1. Inaccurate estimation of infiltration rates
2. Inaccurate estimation of the seasonal high water table
3. Excessive compaction during the construction process
4. Excessive sediment loadings either from improper erosion and sediment control during the construction process or a lack of pretreatment BMPs
5. Lack of maintenance

Factors Influencing Successful Use of Infiltration Systems

Factors that influence the successful use of any stormwater BMP can be categorized as institutional, technical, and implementational. This section of the paper will examine the components of each of these categories that must be included in a stormwater program if the causes of infiltration system failure are to be minimized.

Institutional Components

The "BMP Golden Rule" states that stormwater BMPs should never be required unless the stormwater program includes components that will assure that the BMPs are correctly designed, approved, constructed, inspected, maintained,

and operated (Livingston, 1997). Specifically, the program must have stormwater treatment and management goals, performance standards, education, and an institutional framework that includes plan approval, inspections during and after construction, legal operation and maintenance entity requirements, effective compliance mechanisms, and dedicated funding mechanisms.

Program goals: Experience has shown that stormwater programs need to have multiple objectives that are important to the general public in order to gain the support of the community. Typically, these will include flood protection, erosion and sediment control during construction, water quality and habitat protection, and open space and recreation. Infiltration systems can help achieve all of these goals.

Performance standards: Nearly all stormwater treatment programs in the United States are technology-based, relying upon a performance standard (minimum level of treatment) and design criteria for various BMPs that assure that they achieve the desired treatment goal. A review of 32 stormwater programs around the country showed that the most common performance standard is removing at least 80% of the average annual loading of total suspended solids (WMI, 1997a). Some programs require higher levels of treatment for stormwater discharges to sensitive waters, such as Florida's requirement that discharges to Outstanding Florida Waters remove at least 95% of the average annual pollutant load. Technology-based performance standards such as these provide water quality goals for nonpoint sources that create equity with the minimum treatment requirements for domestic wastewater point sources (Livingston, 1988).

Institutional framework: The stormwater program must have a strong institutional framework that assures that all BMPs are (1) properly designed, (2) reviewed and approved, (3) inspected during and after construction, and (4) operated and maintained. The components of this institutional framework are set forth in Figure 1. One of the most important components especially for infiltration practices, is a feedback mechanism among system inspectors, plan reviewers, and designers about what is working and what is not. This information can then be used to revise the design criteria for infiltration BMPs and improve their potential for long-term success.

Technical Components:

Successful implementation of any BMP depends on a thorough understanding of the factors that determine the BMP's treatment effectiveness, a strong scientific basis for the BMP's design criteria, and an understanding of the site conditions that are required or that limit the utility of a specific BMP. Infiltration practices are also commonly called retention practices because they retain the runoff on-site and are designed to infiltrate a design volume (treatment volume) of stormwater. Factors that influence the treatment effectiveness and feasibility of infiltration practices include (1) precipitation patterns, (2) whether the system is designed as an on-line or off-line system, (3) whether pretreatment via the BMP treatment train is provided, and (4) site characterisitcs such as land use, soil type, geology, water table elevation, topography, and vegetation.

Infiltration areas, especially off-line ones, can be incorporated easily into landscaping or open space areas of a site. These can include natural or excavated grassed or landscaped depressions and recreational areas. Parking lots, with their landscape islands, offer an excellent opportunity for the use of this concept since even the infiltration of a quarter inch of runoff will greatly reduce sediments, metals, oils and greases. Placing storm sewer inlets within recessed parking lot landscape areas, raising the inlet a few inches above the bottom, and using curb cuts to allow runoff to enter this area represents a highly effective treatment train. If site conditions prevent the exclusive use of infiltration, then off-line retention areas should be used as pretreatment practices in a stormwater treatment train. This is especially true if detention lakes are the primary component of the stormwater system and the lakes are intended to serve as a focal point of the development.

Pollutant removal efficiency factors: Average annual pollutant removal efficiency is calculated considering the annual mass of pollutants available for discharge and the annual mass removed. The primary removal mechanism for infiltration practices is the volume of stormwater that is infiltrated, since this eliminates the discharge of stormwater and its associated pollutants. In addition, the system's vegetation and the surficial soils play an important role in binding and transforming pollutants as the water infiltrates. As with any type of stormwater management practice, actual field efficiency will depend on a large number of factors. For infiltration practices, such factors include:

1. Long-term precipitation characteristics; such as mean number of storms per year, their intensity and volume, and average inter-event time.

Legal	**Funding**	**Staffing**	**Public**	**Govt. Roles Responsibilities**

2. The occurrence of first flush, which is related to the amount of directly connected impervious area; type of stormwater conveyance system; and the pollutant of interest

3. Whether the system is an "on-line" or an "off-line" design

4. Cumulatively, the above three factors determine the minimum treatment volume and maximum storage recovery time

The U. S. Weather Bureau has measured weather statistics at many locations around the country. Long-term precipitation records, including such information as day and duration of event, intensity, volume, etc., are available from either the Federal government or private vendors. Statistical analysis of these records can develop probability frequencies for storm characteristics such as the mean storm volume and the mean inter-event period between storms.

"First flush" describes the washing action that stormwater has on accumulated pollutants in the watershed. In the early stages of runoff, the land surfaces, especially impervious ones like streets and parking areas, are flushed clean by the stormwater. This flushing creates a shock loading of pollutants. However, the occurrence and prevalence of first flush depends largely on precipitation patterns, the degree of imperviousness of the contributing drainage area, the size of the drainage area, and the type of stormwater conveyance system. Florida studies have determined that for highly impervious urban land uses with drainage areas under 100 acres, there is a first flush for many pollutants, especially particulates (Yousef et al., 1985; Miller, 1985). In areas such as Oregon and Washington, however, where rainfall consists of low intensity, long-duration "events," first flush is not very prevalent.

On-line stormwater practices store runoff temporarily before most of the volume is discharged to surface waters. These systems capture all of the runoff from a design storm. This mixes all stormwater within the system, thereby masking first flush and reducing pollutant removal. They primarily provide flood control benefits, with water quality benefits usually secondary--although on-line wet detention systems provide both.

Off-line practices are designed to divert the more polluted first flush stormwater for water quality treatment, isolating it from the remaining stormwater that is managed for flood control. In infiltration systems, the diverted first flush is not discharged to surface waters, but is stored until it is gradually removed by infiltration, evaporation, and evapotranspiration. Vegetation, such as grass in the bottom and sides of infiltration areas, helps to trap stormwater pollutants and reduce the potential for transfer of these pollutants to groundwater. Off-line retention practices are the most effective for water quality enhancement of stormwater.

Since an off-line retention area primarily provides for stormwater treatment, it must be combined with other BMPs for flood protection to form a comprehensive stormwater management system. Figure 2 is a schematic of an off-line system, commonly referred to as a "dual pond system." In these systems, a smart weir directs the first flush stormwater into the infiltration area until it is filled, with the remaining runoff being routed to the detention facility for flood control.

A more recent investigation of the influence of long-term rainfall characteristics on the efficiency of retention practices included inter-event dry periods, leading to the development of diversion volume curves for inter-event dry periods of varying length (Wanielista et al., 1991a). Figure 3 shows an example diversion volume curve for the Orlando area. It is important to note that first flush is not considered in these curves. If a first flush effect does exist, the design curves would be conservative in that the percent treatment efficiency of the infiltration system would increase. Furthermore, these curves are based on precipitation-interevent-frequency (PIF) curves that also include consideration of the probability that a storm greater than the design storm will occur. The PIF analysis looked at exceedance probabilities storms with a return period of 2, 3, 4, or 6 months, representing a chance that the storm will exceed the design volume 6, 4, 3, or 2 times per year. Other useful products from this project are Rate-Efficiency-Volume charts and curves that can be used to design wet detention ponds that reuse runoff and thereby help to balance pre- and post-development volume (Livingston et al., 1999).

Site Characteristics: The suitability of a site for using infiltration practices will depend on a careful evaluation of the site's natural attributes. Proposed infiltration areas should be evaluated for feasibility on any particular site or project by examining the following:

SOILS - Must be suitable for infiltration. Nationally, most states recommend that soil textures should not have more than 30% clay content or 40% silt content. Most importantly, they need to be able to percolate the diverted volume to infiltrate within 72 hours, or within 24-36 hours for infiltration areas that are planted with grasses. Therefore, soils that have been classified by the NRCS as HSG A are recommended for infiltration practices, although they can be successfully used with HSG B soil types.

INFILTRATION RATES - In recent years, the minimum permeability rate recommended for infiltration practices has been raised by implementing agencies. Shaver (1986) recommended a minimum rate of 0.25 inches per hour, but Maryland's regulations now recommend 0.52 inches per hour. One of the most difficult aspects of designing infiltration practices is obtaining reliable information about the actual infiltration rate of the soil where the practice will be constructed. Unfortunately, such information is not easily obtainable. Avellaneda (1985) conducted 20 hydrologic studies of vegetated swales constructed on sandy soils with a water table at least one foot below the bottom during dry conditions. Infiltration rates were measured using laboratory permeability tests, double ring infiltrometers, and field mass balance experiments. The field mass balance method measured a minimum infiltration rate of 2-3 inches/hour. This measured rate was much less than lab permeabilities, rates measured by double ring infiltrometer tests (5-20 in/hr), or rates published in the Detailed Soil Survey.

The following should be considered for determining the infiltration rate for retention practices:

1. Since the infiltration rate is the key to designing any retention practices, conservative estimates should be used, and safety factors incorporated into the design to ensure that the design volume will actually be percolated into the soil and not discharged downstream.

2. It is important that on-site infiltration measurements be taken at the locations where retention practices will be located. More importantly, since soil characteristics and infiltration rate change with depth, it is crucial that the measurements be made at the depth of the design elevation of the bottom of the retention practice.

3. Infiltration rates should be determined by mass balance field tests if possible. They provide the most realistic, accurate estimate of the percolation rate. If field tests are not possible, infiltrometer tests should be used, with lab permeability tests a third option. In either of these latter two tests, the design infiltration rate should be half of the lowest measured rate. As a last resort, information from Detailed Soil Surveys can be used to estimated the infiltration rate. However, the lowest rate should be used--as should a safety factor of two.

A recent assessment of infiltration practices in Carroll County, Maryland, quantified the infiltration rates for six basins and six trenches of differing ages (Nelson et al., 1999). They found that 64% of the systems had an average infiltration rate below the state's minimum recommended rate. However, 70% of the practices were still recovering their storage volume within the required 72 hours. Interestingly, for some facilities (mainly trenches), the infiltration rate met or exceeded the minimum state rate for a large percentage of the volume of water infiltrated, while the remaining water persisted for much longer periods of time before infiltrating. This may indicate that (1) the infiltration rate is related to the hydraulic head, where the higher depth of the stormwater in the BMP creates a higher pressure pushing water into the ground, or (2) the bottoms of the systems accumulate fines that impede percolation, while the sides of the systems are still infiltrating runoff rapidly.

WATER TABLE - The seasonal high water table should be at least three feet beneath the bottom of the infiltration area to assure that stormwater pollutants are removed by the vegetation, soil, and microbes before contacting the groundwater. Jacobson and Horner (1993) recommend a minimum of five feet if the seasonal high water table cannot be estimated accurately. When considering the groundwater elevation, it is important to remember that the retention area can cause a mounding effect on the water table, thereby raising it above the predevelopment level. The Southwest Florida Water Management District (SWFWMD) has developed a model that can be used to more accurately determine the seasonal high water table and the effects of mounding (SWFWMD, 1998).

GEOLOGY - Bedrock should be at least three feet beneath the bottom of the infiltration area. In those parts of the country where limestone is at or near the land surface, special precautions must be taken when using infiltration practices. The potential for groundwater contamination in such areas is quite high, especially in "Karst Sensitive Areas" (KSA) where sinkhole formation is common. In KSAs, solution pipe sinkholes may form in the bottom of infiltration areas creating a direct conduit for stormwater pollutants to enter the groundwater. Solution pipes often open in the bottom of retention areas because the natural soil plug capping the solution pipe is thinned by partial excavation to create the retention area and because the stormwater creates a hydraulic pressure which can wash out the plug.

In KSAs, a site-specific hydrogeologic investigation should be undertaken that includes geologic borings wherever infiltration areas are proposed and mapping limerock outcroppings and sinkholes on site. Infiltration systems in KSAs should (1) include several small off-site areas, (2) use swale conveyances for pretreatment, (3) be as shallow as possible, (4) be vegetated with a permanent cover such as sodded grasses, and (5) have flat bottoms to keep the stormwater spread out across the entire area.

TOPOGRAPHY - Infiltration practices should not be located on areas with slopes over 20% to minimize the chance of downstream water seepage from the subgrade. Sloping sites often require extensive cut and fill operations. Infiltration practices should not be sited on fill material, since fill areas are very susceptible to slope failure, especially when the interface of the fill/natural soil becomes saturated.

VEGETATION - To reduce the potential for stormwater pollutants to enter groundwater, and to help maintain the soil's capacity to absorb water, infiltration practices should be vegetated with appropriate native vegetation, especially grasses. However, this type of vegetation cannot tolerate long-term inundation, so the retention area must be capable of infiltrating all of its runoff within a relatively short time period (i.e., 24 to 36 hours). The design of "bioretention" systems incorporates soils and vegetation that are proficient in trapping stormwater pollutants within them and takes advantage of microbial processes that help transform and trap pollutants in the terrestrial environment.

SET BACKS - Infiltration areas should be located at least 100 feet from any water supply well and at least 12 feet down-gradient from any building foundations. Additionally, they should be set back at least 50 feet from on-site wastewater systems, especially drain fields.

LAND USE RESTRICTIONS - Certain infiltration practices can only be applied to particular land uses. For example, some sites are so small or intensively developed that space is insufficient for surficial practices (e.g., retention basin), but they may allow for infiltration or exfiltration trenches if pretreatment can be provided. A concern with any infiltration practice is the potential for hazardous or toxic wastes to enter the system and migrate into the groundwater. Land uses where such substances are used should implement comprehensive pollution prevention, spill containment, and emergency response plans that will prevent dangerous materials from getting into the infiltration system.

POTENTIAL FOR GROUNDWATER POLLUTION - A possible concern about infiltration practices is whether they simply are transferring the stormwater pollution problem from surface waters to groundwaters. Stormwater pollutants, especially heavy metals, quickly bind to soil particles and vegetation is effective in filtering pollutants, thereby minimizing the risk of groundwater contamination (Harper, 1985; Yousef et al, 1985b). However, groundwater beneath swales, and retention areas located in highly sandy soils with low organic content, did show elevated levels of heavy metals down to depths of 20 feet (Harper, 1988).

Design Criteria

Once all of the above factors have been quantified using state, regional, or local data as appropriate, specific design criteria can be established. Table 2 summarizes the design criteria for infiltration systems set forth in Florida's stormwater regulations. St. John's River Water Management District (SJRWMD, 1992).

Table 2. Florida's Design Criteria for Infiltration Practices

BMP	80% Treatment Effectiveness Diversion Volume
Swales	Infiltrate 80% of the runoff from a 3-yr, 1-hr storm (2.5 inches)
Retention - Off-line	Infiltrate the larger of 0.5 inches of runoff or 1.25" X % impervious
Retention - On-line	Infiltrate an additional 0.5 inches of runoff
DESIGN FACTOR	CRITERIA
Soil type	HSG A or B with < 30% clay or < 40% silt/clay
Treatment volume recovery time	72 hours, 24 to 36 hours if grassed
Water table or bedrock	At least 3 feet beneath bottom after mounding
Topography	On slopes < 20%, not on fill soils
Vegetation	Recommended to reduce potential for groundwater pollution and to maintain soil permeability
Land use	May not be appropriate at sites where hazardous materials spills may occur

Swales: Traditionally, swales are used primarily for stormwater conveyance and, as such, are considered an on-line practice. The removal of stormwater pollutants by swales can occur by infiltration or vegetative filtration. Investigations in Florida (Yousef et al., 1985a; Harper, 1985) have concluded that swale treatment efficiency largely depends on the volume of stormwater that can be infiltrated through the filtering vegetation and into the soil.

Avellaneda (1985) developed the following equation for a triangular-shaped swale to estimate the length of swale necessary to infiltrate the design stormwater treatment volume:

$$L=\frac{KQ^{5/8}S^{3/16}}{n^{3/8}i}$$

where:

L = swale length (m)
Q = average runoff flow rate (m3/S)
S = longitudinal slope (m/m)
K = constant which is a function of side slope that varies from 4,722 to 10,516
n = Mannings roughness coefficient
i = infiltration rate (cm/hr)

For most residential, commercial, and highway projects, the length of swales necessary to percolate the stormwater needed to achieve the 80% performance standard was found to be excessive, or at least twice the distance available. Thus, some type of swale block (berm) or on-line detention/retention may be more helpful. Swales make excellent pretreatment practices by providing for the infiltration of some stormwater and for some vegetative filtration. By using a raised storm sewer inlet, swales can provide water quality enhancement via retention and still serve as effective conveyances for flood protection. Swales can incorporate retention by using swale blocks, small check dams, or elevated driveway culverts to create storage; thereby reducing runoff velocity, reducing erosion, and promoting infiltration. In highway designs for high speed situations, safety must be considered; thus, a maximum depth of water equal to 1.5 feet and flow line slopes on the berms of 1 vertical/20 horizontal are recommended. Along lower speed highways or in some residential/commercial urban settings, steeper flow line berm slopes (1 on 6) are acceptable (Wanielista et.al., 1986).

Unlike Florida, investigations in Washington State (Horner, 1988; WPCD, 1992) indicate that swales can also act as a biofilter, with removal of particulate pollutants without infiltration of stormwater. The following recommendations were made to improve their water quality benefits:

1. Maximum design velocity should not exceed 27 cm per second.

2. A hydraulic residence time of at least 9 minutes is recommended for removal of about 80% of the total suspended solids. Longer residence times will provide higher removal effectiveness.

3. Swale width should be limited to 6 to 8 feet, unless special measures are provided to assure a level swale bottom, uniform flow spreading, and management of flows to prevent formation of low-flow channels.

4. Swale slopes should be between 2 and 4%.

5. Water depth should be limited to no greater than one half the height of the grass, up to a maximum of 3 inches of water depth.

6. Swale length will be a function of the hydraulic residence time, swale width, and stormwater volume and velocity.

Implementation Components

Even if effective design criteria have been established for an infiltration system, the design has been reviewed and approved, and the institutional framework to assure performance has been established, an infiltration system may still not work correctly. In fact, assessments of the success or failure of infiltration systems have determined that poor construction is a major factor in system failure (Pensyl and Clement, 1987; Lindsey et al., 1991). We will discuss five considerations that are essential to proper implementation of infiltration practices including (1) education, (2) erosion and sediment control, (3) construction, (4) inspections, and (5) maintenance.

Education: The stormwater program needs to include an extensive education program that targets BMP designers, plan reviewers, inspectors, contractors, and maintenance personnel. Each of these practitioners is an important part of the stormwater team. They must each understand their role in BMP design and implementation, as well as the technical factors discussed above. Additionally, a communication mechanism needs to be established among all of these practitioners so that in-the-field knowledge of what works, and what does not work, is transferred back to all other team members. With respect to BMP installation, the plan reviewers and inspectors should meet with the project engineers and contractors on-site to review the site plan, construction sequencing, erosion and sediment control plan and details, and the infiltration system's detailed standards and specifications.

Erosion and sediment control: Infiltration practices must be protected from sediment loadings, especially during the project's construction phases. Infiltration practices should never be used as part of the erosion and sediment control system, nor should they be put into operation until all contributing drainage areas are fully stabilized. Although sediment loads drop sharply after construction is completed, gradual clogging of infiltration practices can still occur. Pre-treatment practices such as swale conveyances or vegetated buffer strips can help to filter out sediments and extend the life of retention practices. Do not forget the treatment train concept.

Construction considerations: To prevent clogging of infiltration areas, special precautions must be taken during the entire construction phase of a project to prevent reduction of the system's infiltration capacity. In particular, two areas need to be stressed, including preventing sedimentation during construction and preventing compaction of the soil. Areas that are selected for infiltration use should be well marked during site surveying and protected during construction. Specifical construction recommendations are as follows (WMI, 1997b):

1. If possible, schedule construction so it does not occur during the rainy season but does occur during the vegetation growing season. For example, in Auckland, New Zealand, construction sites are shut down during the winter when long, prolonged rains make erosion and sediment controls ineffective and when vegetation does not grow well. Unfortunately, in the United States, these seasons often overlap and the economics of development dictate the time frame for starting construction.

2. Before the development site is graded, areas planned for use as infiltration systems should be well marked during site surveying, and all traffic and heavy equipment kept away from the area to prevent compacting the underlying soils.

3. Construction should be overseen by someone who is trained and experienced in the installation of infiltration practices, and who is knowledgeable about their purpose and operation.

4. The design team should inspect the exposed soil after excavation to confirm that soil conditions are as expected and are suitable for the approved design. If they are not, work should not proceed and the situation should be analyzed to determine whether or not design or construction changes should be made to the approved design.

5. Construction of the infiltration system should not begin until after the site has been completely stabilized. If this is not possible, then:

   a. Diversion berms should be placed around the perimeter of the infiltration area during all phases of construction to divert runoff and sediment away from it.

   b. Sediment and erosion control plans for the site should be oriented to keep sediment and runoff completely away from the area.

   c. The facility should not be excavated to final grade until after the contributing drainage area is stablilized. Leave at least two feet of native soil during the initial excavation.

6. Infiltration areas should never be used as a temporary sediment basins during the construction phase. Unfortunately, it is common for infiltration areas, especially basins, to be used as a sediment trap, with initial excavation to within two feet of the final design elevation of the basin floor. If the facility is to be used during construction, this soil can be removed in layers as it clogs. Once construction is completed, sediment that accumulated during the construction phase can then be removed when the basin undergoes final excavation to its design elevation. However, recent experience indicates that even with this type of construction practice, infiltration areas used as sediment traps have a higher rate of failure.

7. Infiltration areas/basins should be excavated using light earth-moving equipment with tracks or over-sized tires. Normal rubber tires should be avoided since they compact the subsoil and reduce its infiltration capabilities. For the same reason, the use of bulldozers or front end loaders should be avoided.

8. During construction, place excavated material at least 10-15 feet away from the infiltration area.

9. Since some compaction of the underlying soils is still likely to occur during excavation, the floor of the basin should be deeply tilled with a rotary tiller or disc harrow at the end of the excavation process.

10. Rock used in infiltration or exfiltration trenches should be washed clean of sediments. Rock should be placed in lifts and compacted after each lift.

11. Trenches should be clear of any protruding objects and carefully inspected before installing geotextile fabrics. The fabrics should have the proper permeability and be installed with at least a 12-inch overlap, in a shingle-like manner

12. Trenches should be covered and not put into operation until the contributing drainage area is completely stabilized and all pretreatment BMPs installed.

13. Pervious asphalt and concrete should be installed only by certified personnel who are specifically trained in their batching, pouring, and finishing.

14. The basin should be stabilized with vegetation within a week after construction. Use of low maintenance, rapidly germinating native grasses are recommended. The condition of the newly established vegetation should be checked several times over the first two months, and any necessary remedial actions taken (e.g., reseeding, fertilization, and irrigation).

Inspections: Like all stormwater treatment practices, infiltration systems need to be inspected during construction and on a regular basis after construction. Inspections during construction are needed to assure that the infiltration system is built in accordance with the approved design and standards and specifications. Five inspections are recommended: (1) pre-construction, (2) during excavation, (3) during construction of the embankment (if applicable), (4) after final excavation, and (5) after construction is completed. During this final inspection, the inspector should have a copy of the "As-built or record drawings." In addition, infiltration systems should be inspected semi-annually after construction (before and after wet seasons) to ensure that they continue to function. Two site trips are recommended: one during or immediately after a rainfall, so that conditions during operation can be observed, and a second from 24 to 72 hours after the rainfall, to determine whether the system is recovering its storage volume as designed. Inspection forms are highly recommended. Examples of inspection forms (WMI, 1997b) can be downloaded from the EPA web site located at http://www.epa.gov/owow/NPS/orderform.html.

Maintenance: All infiltration practices will require regular and non-routine maintenance to maintain their ability to infiltrate stormwater. The frequency and need for maintenance will depend primarily on the loading of particulates and whether pre-treatment practices have been employed. Routine maintenance includes revegetating eroding areas, removing materials that accumulate in pretreatment BMPs, and removing materials from inlets and outlets. Non-routine, restorative maintenance activities should be conducted whenever inspections reveal that stormwater remains in the system beyond the designed time. These may include structural repairs to the inlets or outlets and restoration of the infiltration capability of the system.

Additional Concerns and Recommendations

Concerns with Pervious Pavement: Local land development codes typically specify the type of material for a parking lot (i.e., paved, grass, gravel) and determine the number and size of parking spaces within a parking lot. These requirements should be reviewed carefully to ensure that they are necessary (is paving really required in every case) and that the number of spaces is related to actual traffic demands. After these requirements have been reviewed and verified, the use of pervious pavement within a parking lot should be examined. Pervious pavement materials include pervious asphalt, pervious concrete, turf blocks, and even Geoweb covered with sod.

Overall, experiences with pervious pavements have not been very good. Pervious pavements have been prone to clogging. Causes include poor erosion and sediment control during construction, unstabilized drainage areas after construction, improper mixing and finishing of the pavement, and poor maintenance. However, field investigations of pervious concrete that has been in use for up to 15 years in Florida indicate that these parking lots can continue to infiltrate rainfall and runoff if they were installed and maintained properly (FCMA, undated). Pervious concrete not only helps reduce site imperviousness, but also reduces hydroplaning and road noise.

Recommendations: Specific recommendations and other important information about infiltration systems that will help increase their successful implementation are summarized in Table 3. This table includes essential information about the advantages, disadvantages, maintenance, and other aspects of successfully using infiltration practice. To improve evaluation of site conditions for the suitability of infiltration practices, Jacobson and Horner (1993) recommended a quan titative rating system. The factors used in the system included: (1) soil till layer (presence and location), (2) location of seasonal high water table, (3) removal efficiency of the pretreatment BMPs, (4) degree of siltation protection, (5) soil type, and (6) infiltration rate. Different degrees of acceptability are possible: (1) disqualifying (characteristics that eliminate design or location from further consideration), (2) passable (characteristics that allow consideration but not ideal), and (3) ideal (optimum characteristics for design or siting of facility). Table 4 illustrates the proposed rating system factors.

Table 3. Additional Information About Infiltration Systems to Enhance Successful Implementation

Infiltration Bmp Type	Advantages	Disadvantages	Maintenance	Comments
Surface Basin (Typically recessed areas or, in Mid-Atlantic States, rock filled)	•Integrate into land-scaping, open space, parking lot islands •Use for recreation •Easier inspection and maintenance	•Land area required •Potential mosquito problem if not designed or maintained properly	•Vegetated basins should be mowed and clippings removed •Remove sediments when dry and cracked •Non-vegetated basins require annual disking	•Can serve larger drainage 3:1 or flatter side slopes, flat bottom •Bottom and side slope vegetation recommended
Infiltration Trench (Typically a rock filled trench)	•Can be used where land or space is limited	•Easily clogged •Difficult to unclog •Difficult to monitor performance	•Removing sediments that accumulate in rocks	•Pretreatment essential •Use observation well •Keep covered until drainage area stabilized
Exfiltration Trench (Typically a perforated pipe with a gravel envelope)	•Can be used where land or space is limited	•Easily clogged •Difficult to unclog •Difficult to monitor performance	•Remove materials that enter pipe •High pressure wash perforated pipe •Removing sediments that Accumulate in rocks, replace rocks	•Pretreatment essential •Source controls useful •Geotextile is limiting infiltration factor •Inf. rate 0.5"/hr if use sides and bottom •Inf. rate 1"/hr if use bottom
Pervious Pavement	•Reduces impervious-ness •Reduces hydroplaning and highway noise •Higher recharge rates	•Easily clogged •Lack of trained practitioners •Anaerobic conditions may develop in soils	•Regular vacuum street sweeping •High pressure cleaning •Drilling holes to restore infiltration •Replacement	•Proper batching and placement is crucial •Education programs needed for practitioners •Post signs to inform users and keep dir and mud out
Swale (Typically a shallow, grassed conveyance system)	•Can be incorporated into site 's landscaping/ open areas •Great car in BMP Train •Aesthetically pleasing	•Not for flood control •May "disappear" from residential back yards •May become depository for trash, yard wastes	•Mow and remove grass clippings •Hydroscope accumulated sediments and resod •Repair erosion areas	•Wet swales (wetland plants) work great too •Use swale blocks, raised driveway culverts to retain runoff

Table 4. Possible Rating System to Evaluate the Suitability of Infiltration BMPs

Factor	Disqualifying Characteristic	Passable Characteristic	Ideal Characteristic
Soil till layer	Impenetrable, thick layer near surface	Layer present but at >5' depth, or easily penetrable	No till layer present
Seasonal High Water Table	Close to surface, within 5'	At intermediate depth, at least 5' below BMP bottom	Very deep, well below BMP bottom
Pretreatment	None provided	Some,minimum 50% TSS removal	Pretreatment provides >80% TSS removal
Siltation Protection	None provided	Any silt or construction sediment removed before final BMP construction	Fully protected from silt during construction
Soils	Saturated or with >30% clay or >40% silt/clay content	Coarse, highly infiltrative soil that can be modified to produce proper inf. rate	Loam or loamy sand
Infiltration Rate	<0.5"/hr	>2.5"/hr but with very deep water table or modified to slower rate	0.5 to 2.5"/hr

Abstract

This paper is a description of previously developed methods used to identify sources of contaminants in storm drainage systems, plus a review of emerging techniques that may also be useful. The original methods, along with selected new procedures, were tested using almost 700 stormwater samples collected from telecommunication manholes from throughout the U.S. About 10% of the samples were estimated to be contaminated with sanitary sewage, using these methods, similar to what is expected for most stormwater systems. The original methods are still recommended as the most useful procedure for identifying contamination of storm drainage systems, with the possible addition of specific tests for *E. coli* and enterococci and UV absorbance at 228 nm. Most newly emerging methods require exotic equipment and unusual expertise and are therefore not very available, especially at low cost and with fast turn-around times for the analyses. These emerging methods may therefore be more useful for special research projects than for routine screening of storm drainage systems.

Introduction

Urban stormwater runoff includes waters from many other sources which find their way into storm drainage systems, besides from precipitation. There are cases where pollutant levels in storm drainage are much higher than they would otherwise be because of excessive amounts of contaminants that are introduced into the storm drainage system by various non-stormwater discharges. Additionally, baseflows (during dry weather) are also common in storm drainage systems. Dry-weather flows and wet-weather flows have been monitored during numerous urban runoff studies. These studies have found that discharges observed at outfalls during dry weather were significantly different from wet-weather discharges and may account for the majority of the annual discharges for some pollutants of concern from the storm drainage system.

There have been numerous methods used to investigate inappropriate discharges to storm drainage systems. Pitt, *et al.* (1993) and Lalor (1994) reviewed many of these procedures and developed a system that municipalities could use for screening outfalls in residential and commercial areas. They are currently updating these earlier methods under funding from the U.S. EPA and the University of New Orleans. In these areas, sewage contamination, along with low-rate discharges from small businesses (especially laundries, vehicle repair shops, plating shops, etc.) are of primary concern. One of the earliest methods used to identify sewage contamination utilized the ratio of fecal coliform to fecal strep. bacteria. This method is still in use, but unfortunately has proven inaccurate in most urban stormwater applications. The following discussion reviews the methodology developed by Pitt, *et al.* (1993) and Lalor (1994), and some new approaches that were investigated.

Use of Tracers to Identify Sources of Contamination in Urban Drainage Systems

This research investigated inappropriate discharges into storm drainage systems. It was of most concern to identify toxic or pathogenic sources of water, typically raw sewage or industrial wastewaters, that were being discharged accidentally into the storm drainage system.

Investigations designed to determine the contribution of urban stormwater runoff to receiving water quality problems have led to a continuing interest in inappropriate connections to storm drainage systems. Urban stormwater runoff is traditionally defined as that portion of precipitation which drains from city surfaces and flows via natural or man-made drainage systems into receiving waters. In fact, urban stormwater runoff also includes waters from many other sources which find their way into storm drainage systems. Sources of some of this water can be identified and accounted for by examining current National Pollutant Discharge Elimination System (NPDES) permit records for permitted industrial wastewaters that can be legally discharged to the storm drainage system. However, most of the water comes from other sources, including illicit and/or inappropriate entries to the storm drainage system. These entries can account for a significant amount of the pollutants discharged from storm sewerage systems (Pitt and McLean 1986).

Permits for municipal separate storm sewers include a requirement to effectively prohibit problematic non-stormwater discharges, thereby placing emphasis on the elimination of inappropriate connections to urban storm drains. Section 122.26 (d)(1)(iv)(D) of the rule specifically requires an initial screening program to provide means for detecting high levels of pollutants in dry weather flows, which should serve as an indicator of illicit connections to the storm sewers. To facilitate the application of this rule, the EPA's Office of Research and Development's Storm and Combined Sewer Pollution Control Program and the Environmental Engineering & Technology Demonstration Branch, along with the Office of Water's Nonpoint Source Branch, supported research for the investigation of inappropriate entries to storm drainage systems (Pitt, *et al.* 1993). The approach presented in this research was based on the identification and quantification of clean baseflow and the contaminated components during dry weather. If the relative amounts of these components are known, the importance of the dry weather discharge can be determined.

The ideal tracer to identify major flow sources should have the following characteristics:

- Significant difference in concentrations between possible pollutant sources;
- Small variations in concentrations within each likely pollutant source category;
- A conservative behavior (i.e., no significant concentration change due to physical, chemical or biological processes); and,
- Ease of measurement with adequate detection limits, good sensitivity and repeatability.

In order to identify tracers meeting the above criteria, literature characterizing potential inappropriate entries into storm drainage systems was examined. Several case studies that identified procedures used by individual municipalities or regional agencies were also examined.

Parameters Suitable for Indicators of Contamination by Sanitary Sewage

Tracer Characteristics of Local Source Flows. Table 1 is a summary of tracer parameter measurements for Birmingham, Alabama. This table is a summary of the "library" that describes the tracer conditions for each potential source category. The important information shown on this table includes the median and coefficient of variation (COV) values for each tracer parameter for each source category. Appropriate tracers are characterized by having significantly different concentrations in flow categories that need to be distinguished. In addition, effective tracers also need low COV values within each flow category. The study indicated that the COV values were quite low for each category, with the exception of chlorine, which had much greater COV values. Chlorine is therefore not recommended as a quantitative tracer to estimate the flow components. Similar data must be collected in each community where these procedures are to be used. Recommended field observations include color, odor, clarity, presence of floatables and deposits, and rate of flow, in addition to the selected chemical measurements.

Simple Data Evaluation Methods to Indicate Sources of Contamination

Indicators Implying Contamination. Indicators of contamination (negative indicators) are clearly apparent visual or physical parameters indicating obvious problems and are readily observable at the outfall during the field screening

activities. These observations are very important during the field survey because they are the simplest method of identifying grossly contaminated dry-weather outfall flows. The direct examination of outfall characteristics for unusual conditions of flow, odor, color, turbidity, floatables, deposits/stains, vegetation conditions, and damage to drainage structures is therefore an important part of these investigations. Table 2 presents a summary of these indicators, along with narratives of the descriptors to be selected in the field.

Table 2. Interpretations of Physical Observation Parameters and Likely Associated Flow Sources

Odor - Most strong odors, especially gasoline, oils, and solvents, are likely associated with high responses on the toxicity screening test. Typical obvious odors include: gasoline, oil, sanitary wastewater, industrial chemicals, decomposing organic wastes, etc.
sewage: smell associated with stale sanitary wastewater, especially in pools near outfall.
sulfur ("rotten eggs"): industries that discharge sulfide compounds or organics (meat packers, canneries, dairies, etc.).
oil and gas: petroleum refineries or many facilities associated with vehicle maintenance or petroleum product storage.
rancid-sour: food preparation facilities (restaurants, hotels, etc.).

Color - Important indicator of inappropriate industrial sources. Industrial dry-weather discharges may be of any color, but dark colors, such as brown, gray, or black, are usually of most common.
yellow: chemical plants, textile and tanning plants.
brown: meat packers, printing plants, metal works, stone and concrete, fertilizers, and petroleum refining facilities.
green: chemical plants, textile facilities.
red: meat packers.
gray: dairies.

Turbidity - Often affected by the degree of gross contamination. Dry-weather industrial flows with moderate turbidity can be cloudy, while highly turbid flows can be opaque. High turbidity is often a characteristic of undiluted dry-weather industrial discharges.
cloudy: sanitary wastewater, concrete or stone operations, fertilizer facilities, automotive dealers.
opaque: food processors, lumber mills, metal operations, pigment plants.

Floatable Matter - A contaminated flow may contain floating solids or liquids directly related to industrial or sanitary wastewater pollution. Floatables of industrial origin may include animal fats, spoiled food, oils, solvents, sawdust, foams, packing materials, or fuel.
oil sheen: petroleum refineries or storage facilities and vehicle service facilities.
sewage: sanitary wastewater.

Deposits and Stains - Refer to any type of coating near the outfall and are usually of a dark color. Deposits and stains often will contain fragments of floatable substances. These situations are illustrated by the grayish-black deposits that contain fragments of animal flesh and hair which often are produced by leather tanneries, or the white crystalline powder which commonly coats outfalls due to nitrogenous fertilizer wastes.
sediment: construction site erosion.
oily: petroleum refineries or storage facilities and vehicle service facilities.

Vegetation - Vegetation surrounding an outfall may show the effects of industrial pollutants. Decaying organic materials coming from various food product wastes would cause an increase in plant life, while the discharge of chemical dyes and inorganic pigments from textile mills could noticeably decrease vegetation. It is important not to confuse the adverse effects of high stormwater flows on vegetation with highly toxic dry-weather intermittent flows.
excessive growth: food product facilities.
inhibited growth: high stormwater flows, beverage facilities, printing plants, metal product facilities, drug manufacturing, petroleum facilities, vehicle service facilities and automobile dealers.

Damage to Outfall Structures - Another readily visible indication of industrial contamination. Cracking, deterioration, and spalling of concrete or peeling of surface paint, occurring at an outfall are usually caused by severely contaminated discharges, usually of industrial origin. These contaminants are usually very acidic or basic in nature. Primary metal industries have a strong potential for causing outfall structural damage because their batch dumps are highly acidic. Poor construction, hydraulic scour, and old age may also adversely affect the condition of the outfall structure.
concrete cracking: industrial flows
concrete spalling: industrial flows
peeling paint: industrial flows
metal corrosion: industrial flows

Correlation tests were conducted to identify relationships between outfalls that were known to have severe contamination problems and the negative indicators (Lalor 1994). Pearson correlation tests indicated that high turbidity and obvious odors appeared to be the most useful physical indicators of contamination when contamination was defined by toxicity and the presence of detergents. High turbidity was noted in 74% of the contaminated source flow samples. This represented a 26% false negative rate (indication of no contamination when contamination actually exists), if one relied on turbidity alone as an indicator of contamination. High turbidity was noted in only 5% of the uncontaminated source flow samples. This represents the rate of false positives (indication of contamination when none actually exists) when relying on turbidity alone. Noticeable odor was indicated in 67% of flow samples from contaminated sources, but in none of the flow samples from uncontaminated sources. This translates to 37% false negatives, but no false positives. Obvious odors identified included gasoline, oil, sewage, industrial chemicals or detergents, decomposing organic wastes, etc.

False negatives are more of a concern than a reasonable number of false positives when working with a screening methodology. Screening methodologies are used to direct further, more detailed investigations. False positives would be discarded after further investigation. However, a false negative during a screening investigation results in the dismissal of a problem outfall for at least the near future. Missed contributors to stream contamination may result in unsatisfactory in-stream results following the application of costly corrective measures elsewhere.

The method of using physical characteristics to indicate contamination in outfall flows does not allow quantifiable estimates of the flow components and, if used alone, will likely result in many incorrect determinations, especially false negatives. These simple characteristics are most useful for identifying gross contamination: only the most significantly contaminated outfalls and drainage areas would therefore be recognized using this method.

Detergents as Indicators of Contamination. Results from the Mann-Whitney U tests (Lalor 1994) indicated that samples from any of the dry-weather flow sources could be correctly classified as clean or contaminated based only on the measured value of any one of the following parameters: detergents, color, or conductivity. Color and high conductivity were present in samples from clean sources as well as contaminated sources, but their levels of occurrence were significantly different between the two groups. If samples from only one source were expected to make up outfall flows, the level of color or conductivity could be used to distinguish contaminated outfalls from clean outfalls. However, since multi-source flows occur, measured levels of color or conductivity could fall within acceptable levels because of dilution, even though a contaminating source was contributing to the flow. Detergents, on the other hand, can be used to distinguish between clean and contaminated outfalls simply by their presence or absence, using a detection limit of 0.06 mg/L. All samples analyzed from contaminated sources contained detergents in excess of this amount (with the exception of three septage samples collected from homes discharging only toilet flushing water). No clean source samples were found to contain detergents. Contaminated sources would be detected in mixtures with uncontaminated waters if they made up at least 10% of the mixture.

Flow Chart for Most Significant Flow Component Identification. A further refinement is the flow chart shown on Figure 1. This flow chart describes an analysis strategy which may be used to identify the major component of dry-weather flow samples in residential and commercial areas. This method does not attempt to distinguish among all potential sources of dry-weather flows identified earlier, but rather the following four major groups of flow are identified: (1) tap waters (including domestic tap water, irrigation water and rinse water), (2) natural waters (spring water and shallow ground water), (3) sanitary wastewaters (sanitary sewage and septic tank discharge), and (4) wash waters (commercial laundry waters, commercial car wash waters, radiator flushing wastes, and plating bath wastewaters). The use of this method would not only allow outfall flows to be categorized as contaminated or uncontaminated, but would allow outfalls carrying sanitary wastewaters to be identified. These outfalls could then receive highest priority for further investigation leading to source control. This flow chart was designed for use in residential and/or commercial areas only.

In residential and/or commercial areas, all outfalls should be located and examined. The first indicator is the presence or absence of dry-weather flow. If no dry-weather flow exists at an outfall, then indications of intermittent flows must be investigated. Specifically, stains, deposits, odors, unusual stream-side vegetation conditions, and damage to outfall structures can all indicate intermittent non-stormwater flows. However, frequent visits to outfalls over long time periods, or the use of other monitoring techniques, may be needed to confirm that only stormwater flows occur. If intermittent flow is not indicated, then the outfall probably does not have a contaminated non-stormwater source. The other points on the flow chart serve to indicate if a major contaminating source is present, or if the water is uncontaminated. Component contributions cannot be quantified using this method, and only the "most contaminated" type of source present will be identified.

If dry-weather flow exists at an outfall, the flow should be sampled and tested for detergents. If detergents are not present, the flow is probably from a non-contaminated non-stormwater source. The lower limit of detection for detergent should be about 0.06 mg/L.

R0019469

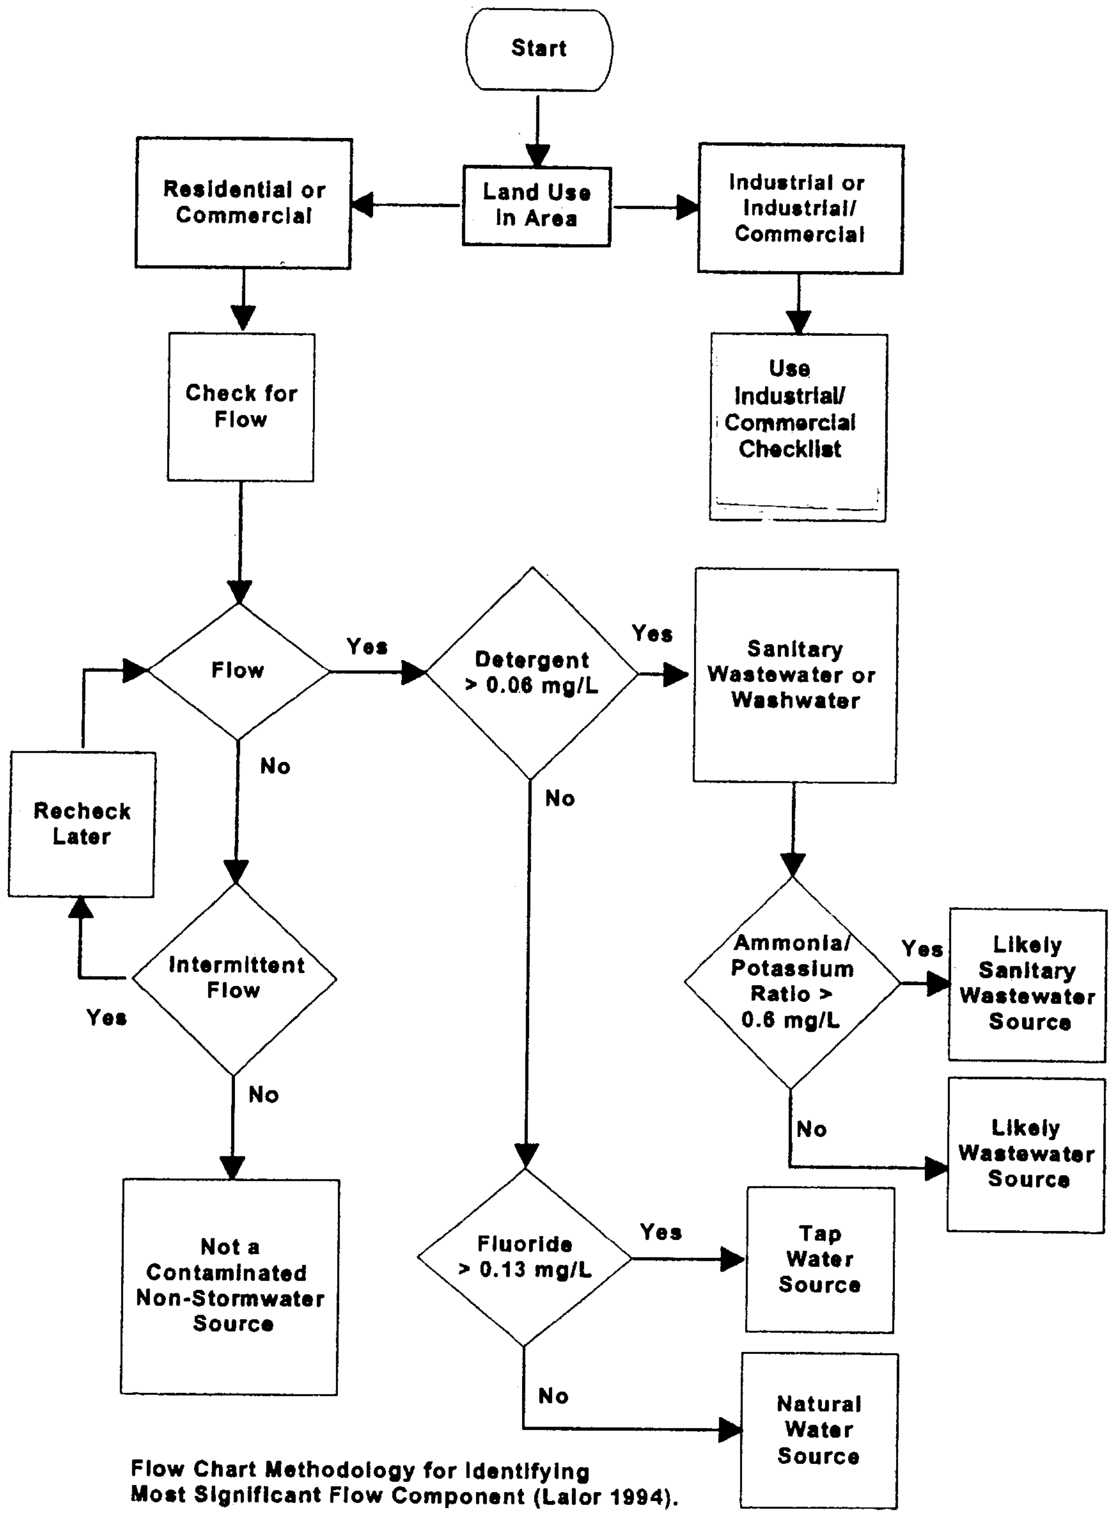

Figure 1. Simple Flow Chart Method to Identify Significant Contaminating Sources

If detergents are not present, fluoride levels can be used to distinguish between flows with treated water sources and flows with natural sources in communities where water supplies are fluoridated and natural fluoride levels are low. In the absence of detergents, high fluoride levels would indicate a potable water line leak, irrigation water, or wash/rinse water. Low fluoride levels would indicate waters originating from springs or shallow groundwater. Based on the flow source samples tested in this research (Table 1), fluoride levels above 0.13 mg/L would most likely indicate that a tap water source was contributing to the dry-weather flow in the Birmingham, Alabama, study area.

If detergents are present, the flow is probably from a contaminated non-stormwater source, as indicated on Table 1. The ratio of ammonia to potassium can be used to indicate whether or not the source is sanitary wastewater. Ammonia/potassium ratios greater than 0.60 would indicate likely sanitary wastewater contamination. Ammonia/potassium ratios were above 0.9 for all septage and sewage samples collected in Birmingham (values ranged from 0.97 to 15.37, averaging 2.55). Ammonia/potassium ratios for all other samples containing detergents were below 0.7, ranging from 0.00 to 0.65, averaging 0.11. One radiator waste sample had an ammonia/potassium ratio of 0.65.

Non-contaminated samples collected in Birmingham had ammonia/potassium ratios ranging from 0.00 to 0.41, with a mean value of 0.06 and a median value of 0.03. Using the mean values for non-contaminated samples (0.06) and sanitary wastewaters (2.55), flows comprised of mixtures containing at least 25% sanitary wastes with the remainder of the flow from uncontaminated sources would likely be identified as sanitary wastewaters using this method. Flows containing smaller percent contributions from sanitary wastewaters might be identified as having a wash water source, but would not be identified as uncontaminated.

Emerging Tools for Identifying Sources of Discharges

Coprostanol and Other Fecal Sterol Compounds Utilized as Tracers of Contamination by Sanitary Sewage. A more likely indicator of human wastes than fecal coliforms and other "indicator" bacteria may be the use of certain molecular markers, specifically the fecal sterols, such as coprostanol and epicoprostanol (Eaganhouse, *et al.* 1988). However, these compounds are also discharged by other carnivores in a drainage (especially dogs). A number of research projects have used these compounds to investigate the presence of sanitary sewage contamination. The most successful application may be associated with sediment analyses instead of water analyses. As an example, water analyses of coprostanol are difficult due to the typically very low concentrations found, although the concentrations in many sediments are quite high and much easier to quantify. Unfortunately, the long persistence of these compounds in the environment easily confuses recent contamination with historical or intermittent contamination.

Particulates and sediments collected from coastal areas in Spain and Cuba receiving municipal sewage loads were analyzed by Grimalt, *et al.* (1990) to determine the utility of coprostanol as a chemical marker of sewage contamination. Coprostanol can not by itself be attributed to fecal matter inputs. However, relative contributions of steroid components can be a useful indicator. When the relative concentrations of coprostanol and coprostanone are higher than their 5? epimers, or more realistically, other sterol components of background or natural occurrence, it can provide useful information.

Sediment cores from Santa Monica Basin, CA, and effluent from two local municipal wastewater discharges were analyzed by Venkatesan and Kaplan (1990) for coprostanol to determine the degree of sewage addition to sediment. Coprostanols were distributed throughout the basin sediments in association with fine particles. Some stations contained elevated levels, either due to their proximity to outfalls or because of preferential advection of fine-grained sediments. A noted decline of coprostanols relative to total sterols from outfalls seaward indicated dilution of sewage by biogenic sterols.

Other chemical compounds have been utilized for sewage tracer work. Saturated hydrocarbons with 16-18 carbons, and saturated hydrocarbons with 16-21 carbons, in addition to coprostanol, were chosen as markers for sewage in water, particulate, and sediment samples near the Cocoa, FL, domestic wastewater treatment plant (Holm and Windsor, 1990). The concentration of the markers was highest at points close to the outfall pipe and diminished with distance. However the concentration of C16-C21 compounds was high at a site 800 m from the outfall indicating that these compounds were unsuitable markers for locating areas exposed to the sewage plume. The concentrations for the other markers were very low at this station.

The range of concentrations of coprostanol found in sediments and mussels of Venice; Italy, were reported by Sherwin, *et al.* (1993). Raw sewage is still discharged directly into the Venice lagoon. Coprostanol concentrations were determined in sediment and mussel samples from the lagoon using gas chromatography/mass spectroscopy. Samples were collected in interior canals and compared to open-bay concentrations. Sediment concentrations ranged from 0.2-41 .0 µg/g (dry weight). Interior canal sediment samples averaged 16 µg/g compared to 2 µg/g found in open bay sediment samples. Total coprostanol concêntrations in mussels ranged from 80 to 620 ng/g (wet weight). No mussels were found in the four most polluted interior canal sites.

Nichols, *et al.* (1996) also examined coprostanol in stormwater and the sea-surface microlayer to distinguish human versus nonhuman sources of contamination. Other steroid compounds in sewage effluent were investigated by Routledge, *et al.* (1998) and Desbrow, *et al.* (1998) who both examined estrogenic chemicals. The most common found were 17β-Estradiol and estrone which were detected at concentrations in the tens of nanograms per liter range. These were identified as estrogenic through a toxicity identification and evaluation approach, where sequential separations and analyses identified the sample fractions causing estrogenic activity using a yeast-based estrogen screen. GC/MS was then used to identify the specific compounds.

Estimating Potential Sanitary Sewage Discharges into Storm Drainage and Receiving Waters using Detergent Tracer Compounds. As described above, detergent measurements (using methylene blue active substance, MBAS, test methods) were the most successful individual tracer to indicate contaminated water in storm sewerage dry-weather flows. Unfortunately, the MBAS method uses hazardous chloroform for an extraction step. Different detergent components, especially linearalkylbenzene sulphonates (LAS) and linear alkylbenzenes (LAB), have also been tried to indicatesewage dispersal pattems in receiving waters. Boron, a major historical ingredient of laundry chemicals, can also potentially be used. Boron has the great advantage of being relatively easy to analyze using portable field test kits, while LAS requires chromatographic equipment. LAS can be measured using HPLC with fluorescent detection, after solid phase extraction, to very low levels. Fujita, *et al.* (1998) developed an efficient enzyme-linked immunosorbent assay (ELISA) for detecting LAS at levels from 20 to 500 µg/L.

LAS from synthetic surfactants (Terzic and Ahel 1993) which degrade rapidly, as well as nonionic detergents (Zoller, *et al.* 1991) which do not degrade rapidly, have been utilized as sanitary sewage markers. LAS was quickly dispersed from wastewater outfalls except in areas where wind was calm. In these areas LAS concentrations increased in freshwater but were unaffected in saline water. After time, the lower alkyl groups were mostly found, possibly as a result of degradation or settling of longer alkyl chain compounds with sediments. Chung, *et al.* (1995) also describe the distribution and fate of LAS in an urban stream in Korea. They examined different LAS compounds having carbon ratios of Cl 2 and Cl 3 compared to Cl 0 and Cl 1, plus ratios of phosphates to MBAS and the intemal to external isomer ratio (I/E) as part of their research. Gonález-Mazo, *et al.* (1998) examined LAS in the Bay of Cádiz off the southwest of Spain. They found that LAS degrades rapidly (Fujita, *et al.*, 1998, found that complete biodegradation of LAS requires several days), and is also strongly sorbed to particulates. In areas close to shore and near the untreated wastewater discharges, there is significant vertical stratification of LAS: the top 3 to 5 mm of water had LAS concentrations about 100 times greater than found at 0.5 m.

Zeng and Vista (1997) and Zeng, *et al.* (1997) describe a study off of San Diego where LAB was measured, along with polycyclic aromatic hydrocarbons (PAHs) and aliphatic hydrocarbons (AHs) to indicate the relative pollutant contributions of wastewater from sanitary sewage, nonpoint sources, and hydrocarbon combustion sources. They developed and tested several indicator ratios (alkyl homologue distributions and parent compound distributions) and examined the ratio of various PAHs (such as phenanthrene to anthracene, methylphenanthrene to phenanthrene, fluoranthene to pyrene, and benzo(a)anthracene to chrysene) as tools for distinguishing these sources. They concluded that LABs are useful tracers of domestic waste inputs to the environment due to their limited sources. They also describe the use of the internal to extemal isomer ratio (I/E) to indicate the amount of biodegradation that may have occurred to the LABs. They observed concentrations of total LABs in sewage effluent of about 3 µg/L, although previous researchers have seen concentrations of about 150 µg/L in sewage effluent from the same area.

The fluorescent properties of detergents have also been used as a tracer by investigating the fluorescent whitening agents (FWAs), as described by Poiger, *et al.* (1996) and Kramer, *et al.* (1996). HPLC with fluorescence detection was used in these studies to quantify very low concentrations of FWAs. The two most frequently used FWAs in household detergents (DSBP and DAS 1) were found at 7 to 21 µg/L in primary sewage effluent and at 3 to 9 µg/L in secondary effluent. Raw sewage contains about 10 to 20 µg/L FWAs. The removal mechanisms in sewage treatment processes is by adsorption to activated sludge. The type of FWAs varies from laundry applications to textile finishing and paper production, making it possible to identify sewage sources. The FWAs were found in river water at 0.04 to 0.6 µg/L. The FWAs are not easily biodegradable but they are readily photodegraded. Photodegradation rates have been reported to be about 7% for DSBP and 71% for DAS 1 in river water exposed to natural sunlight, after one hour exposure. Subsequent photodegradation is quite slow.

Other Compounds Found in Sanitary Sewage that may be used for Identifying Contamination by Sewage. Halling-Sørensen, *et al.* (1998) detected numerous pharmaceutical substances in sewage effluents and in receiving waters. Their work addressed human health concerns of these low level compounds that can enter downstream drinking water supplies. However, the information can also be possibly used to help identify sewage contamination. Most of the research has focused on clofibric acid, a chemical used in cholesterol lowering drugs. It has been found in concentrations ranging from 10 to 165 ng/L in Berlin drinking water samples. Other drugs commonly found include aspirin, caffeine, and ibuprofen. Current FDA guidance mandates that the maximum concentration of a substance or its active metabolites at the point of entry into the aquatic environment be less than 1 µg/L (Hun 1998).

Caffeine has been used as an indicator of sewage contamination by several investigators (Shuman and Strand 1996). The King County, WA, Water Quality Assessment Project is examining the impacts of CSOs on the Duwamish River and Elliott Bay. They are using both caffeine (representing dissolved CSO constituents) and coprostanol (representing particulate bound CSO constituents), in conjunction with heavy metals and conventional analyses, to help determine the contribution of CSOs to the river. The caffeine is unique to sewage, while coprostanol is from both humans and carnivorous animals and is therefore also in stormwater. They sampled upstream of all CSOs, but with some stormwater influences, 100 m upstream of the primary CSO discharge (but downstream of other CSOs), within the primary CSO discharge line, and 100 m downriver of the CSO discharge location. The relationship between caffeine and coprostanol was fairly consistent for the four sites (coprostanol was about 0.5 to 1.5 µg/L higher than caffeine). Similar patterns were found among metals; chromium was always the lowest and zinc was the highest. King Co. is also using clean transported mussels placed in the Duwamish River to measure the bioconcentration potential of metal and organic toxicants and the effects of the CSOs on mussel growth rates (after 6 week exposure periods). Paired reference locations are available near the areas of deployment, but outside the areas of immediate CSO influence. *US Water News* (1998) also described a study in Boston Harbor that found caffeine at levels of about 7 µg/L in the harbor water. The caffeine content of regular coffee is about 700 mg/L, in contrast.

Kratch (1997) summarized several investigations on cataloging the DNA of *E. coli* to identify their source in water. This rapidly emerging technique seems to have great promise in addressing a number of nonpoint source water pollution issues. The procedure, developed at the Virginia Polytechnic Institute and State University, has been used in Chesapeake Bay. In one example, it was possible to identify a large wild animal population as the source of fecal coliform contamination of a shellfish bed, instead of suspected failing septic tanks. DNA patterns in fecal coliforms vary among animals and birds, and it is relatively easy to distinguish between human and non-human sources of the bacteria. However, some wild animals have DNA patterns that are not easily distinguishable. Some researchers question the value of *E. coli* DNA fingerprinting believing that there is little direct relationship between *E. coli* and human pathogens. However, this method should be useful to identify the presence of sewage contamination in stormwater or in a receiving water.

One application of the technique, as described by Krane, *et al.* (1999) of Wright State University, used randomly amplified polymorphic DNA polymerase chain reaction (RAPD-PCR) generated profiles of naturally occurring crayfish. They found that changes in the underlying genetic diversity of these populations were significantly correlated with the extent to which they have been exposed to anthropogenic stressors. They concluded that this rapid and relatively simple technique can be used to develop a sensitive means of directly assessing the impact of stressors upon ecosystems. These Wright State University researchers have also used the RAPD-PCR techniques on populations of snails, pill bug violets, spiders, earthworms, herring, and some benthic macroinvertebrates, finding relatively few obstacles in its use for different organisms. As noted above, other researchers have used DNA profiling techniques to identify sources of *E. coli* bacteria found in coastal waterways. It is possible that these techniques can be expanded to enable rapid detection of many different types of pathogens in receiving waters, and the most likely sources of these pathogens.

Other Tracer Methods for Identifying Sources of Water. Stable isotopes had been recommended as an efficient indicator of illicit connections to storm sewerage. A demonstration was conducted in Detroit as part of the Rouge River project to identify sources of dry weather flows in storm sewerage (Sangal, *et al.* 1996). Naturally occurring stable isotopes of oxygen and hydrogen can be used to identify waters originating from different geographical sources (especially along a north-south gradient). Ma and Spalding (1996) discuss this approach by using stable isotopes to investigate recharge of groundwaters by surface waters. During water vapor transport from equatorial source regions to higher latitudes, depletion of heavy isotopes occurs with rain. Deviation from a standard relationship between deuterium and 18O for a specific area indicates that the water has undergone additional evaporation. The ratio is also affected by seasonal changes. As discussed by Ma and Spalding (1996), the Platte River water is normally derived in part from snowmelt from the Rocky Mountains, while the groundwater in parts of Nebraska is mainly contributed from the Gulf air stream. The origins of these waters are sufficiently different and allow good measurements of the recharge rate of the surface water to the groundwater. In Detroit, Sangal, *et al.* (1996) used differences in origin between the domestic water supply, local surface waters, and the local groundwater to identify potential sanitary sewage contributions to the separate storm sewerage. Rieley, *et al.* (1997) used stable isotopes of carbon in marine organisms to distinguish the primary source of carbon being consumed (sewage sludge vs. natural carbon sources) in two deep sea sewage sludge disposal areas.

Stable isotope analyses would not be able to distinguish between sanitary sewage, industrial discharges, washwaters, and domestic water, as they all have the same origin, nor would it be possible to distinguish sewage from local groundwaters if the domestic water supply was from the same local aquifer. This method works best for situations where the water supply is from a distant source and where separation of waters into separate flow components is not needed. It may be an excellent tool to study the effects of deep well injection of stormwater on deep aquifers having distant recharge sources (such as in the Phoenix area). Few laboratories can analyze for these stable isotopes, requiring shipping and a long wait for the analytical results. Sangal, *et al.* (1995) used Geochron Laboratories, in Cambridge, Massachusetts.

Dating of sediments using 137Cs was described by Davis, *et al.* (1997). Arsenic contaminated sediments in the Hylebos Waterway in Tacoma, WA, could have originated from numerous sources, including a pesticide manufacturing facility, a rock-wool plant, steel slags, powdered metal plant, shipbuilding facilities, marinas and arsenic boat paints, and the Tacoma Smelter. Dating the sediments, combined with knowing the history of potential discharges and conducting optical and electron microscopic studies of the sediments, was found to be a powerful tool to differentiate between the different metal sources to the sediments.

Conclusions

Recent tests examined several potential tracer parameters during a project characterizing stormwater that had collected in telecommunication manholes, funded by Tecordia (previously Bellcore), AT&T, and eight regional telephone companies throughout the country (Pitt and Clark 1999). Numerous conventional constituents, plus major ions, and toxicants were measured, along with candidate tracers to indicate sewage contamination of this water. Boron, caffeine, coprostanol, *E. coli*, enterococci, fluorescence (using specific wavelengths for detergents), and a simpler test for detergents were evaluated, along with the use of fluoride, ammonia, potassium, and obvious odors and color. About 700 water samples were evaluated for all of these parameters, with the exception of bacteria and boron (about 250 samples), and only infrequent samples were analyzed for fluorescence. Coprostanol was found in about 25% of the water samples (and in about 75% of the 350 sediment samples analyzed). Caffeine was found in very few samples, while elevated *E. coli* and enterococci (using IDEXX tests) were observed in about 10% of the samples. Strong sewage odors in water and sediment samples were also detected in about 10% of the samples. Detergents and fluoride (at >0.3 mg/L) were found in about 40% of the samples and are expected to have been contaminated with industrial activities (lubricants and cleansers) and not sewerage. Overall, about 10% of the samples were therefore expected to have been contaminated with sanitary sewage, about the same rate previously estimated for stormwater systems.

Additional laboratory tests, funded by the University of New Orleans and the EPA, were conducted using many sewage and laundry detergent samples and found that the boron test was a poor indicator of sewage, possibly due to changes in formulations in modern laundry detergents. Other laboratory tests found that fluorescence was an excellent indicator of sewage, especially when using specialized "detergent whitener" filter sets, but was not very repeatable. We also examined several UV absorbance wavelengths as sewage indicators and found excellent correlations with 228 nm, a wavelength having very little background absorbance in local spring waters, but with a strong response factor with increasing strengths of sewage. We recommend that our originally developed and tested protocol still be used as the most efficient routine indicator of sewage contamination of stormwater drainage systems, with the possible addition of specific *E. coli* and enterococci measurements and UV absorbance at 228 nm. The numerous exotic tests requiring specialized instrumentation and expertise reviewed in this paper do not appear to warrant their expense and long analytical turn-around times, except in specialized research situations.

Elimination of Illicit Connections in Coastal New Hampshire Spurs Cooperation and Controversy

Natalie Landry and Robert Livingston
New Hampshire Department of Environmental Services
Concord, New Hampshire

Introduction

Discharging stormwater runoff into our waterways has long been an accepted practice. In theory, storm drainage pipes should only discharge during and after storm events unless the source is groundwater or surface water piped underground. Therefore, the dry weather discharge should be relatively free of contaminants. However, many communities across the country are finding out this is not always true. Some cities and towns are discovering illegal connections of residential and commercial sewer lines to storm water collection systems. Illicit connections have been identified by the New Hampshire Department of Environmental Services (DES) as the point source of high fecal coliform levels in the New Hampshire coastal basin (Jones, 1995). These illegal connections pose a health risk to those recreating in the coastal waters and have forced the closure of shellfish growing waters to harvesting.

Goals of the Coastal Investigations Programs

Determining the extent of dry weather contamination in storm drainage systems is the first step an investigator should take when researching stormwater pollution. Dry weather flows in storm drainage systems are often the result of groundwater infiltration, but can also result from inappropriate connections from commercial, industrial, or residential buildings. In 1996, the New Hampshire DES published the Coastal Basin Nonpoint Source Pollution Assessment and Abatement Plan (NHDES, 1996) that directed coastal investigations of each community's storm drainage system during dry weather. This decision to conduct dry weather investigations in the coast was made after 300 illicit connections were identified in the northern New Hampshire city of Berlin. State environmental officials were convinced that illicit connections were always present in storm drainage systems that were once considered a pollution threat only during wet weather.

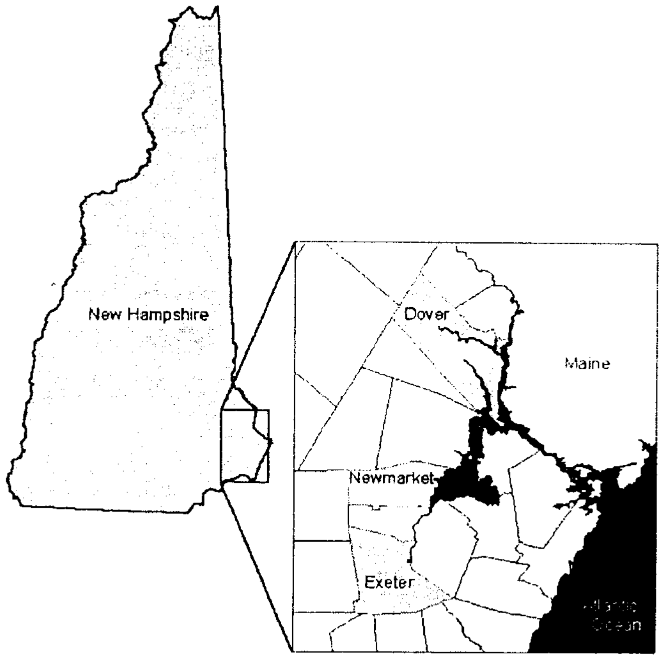
DES initiated a multi-year effort that focused on identifying and abating the sources of the bacterial violations found in the state's coastal waters with the goal of opening shellfish growing waters during dry weather (Landry, 1997). About the same time, the New Hampshire Estuaries Project (NHEP) began a three-year process of developing a comprehensive management plan aimed at restoring, protecting and enhancing the water quality and living resources of the state's estuaries. The major goal of the NHEP was to address the sources of pollution currently impacting the estuaries and prevent future problems through effective land use planning and shoreline protection of the coastal resources (NHEP, 1996). To accomplish this goal, part of the NHEP strategy was to locate and remediate the sources of the water quality violations, primarily bacterial violations, found in the estuaries and coastal waters (Landry, 1997). DES and NHEP combined resources and developed an investigation strategy with the overall goal of improving and protecting estuarine water quality.

Specific Program Objectives

The main objectives of the investigation strategy were to identify inappropriate connections in the storm drainage systems of urban, coastal communities and to eliminate the illicit connections through the available means, which include voluntary compliance and enforcement.

A Brief Look at Coastal New Hampshire

The eighteen miles of New Hampshire coastline do not begin to tell the story of the state's abundant marine resources. The relatively modest coastline is only a small part of the coastal basin. The estuarine resources include the Great Bay Estuary and seven associated tidal rivers, Hampton Harbor, and Rye Harbor. These waters are used by residents and many visitors for swimming, boat touring, shellfish harvesting, surfing, and angling. Forty-two communities



comprise the coastal basin watershed, with a population density just under 300 residents/mile^2 (Jones, In Review). The upper watershed is generally undeveloped and forested while the more urban centers are situated in the lower watershed as the rivers approach the coast.

Ten wastewater treatment facilities are situated on the tributaries of Great Bay and Hampton Harbor and two facilities discharge directly into the Atlantic Ocean. Coastal communities are working diligently to upgrade the wastewater treatment facilities and sewage collection systems. Inflow/infiltration problems and undersized pump stations plague the treatment facilities and have resulted in financial hardships for affected municipalities. Shellfish growing waters have been temporarily closed after heavy rainstorms when bacteria levels rise due to sewage by-passes. Sewage is a well-recognized threat to the marine environment because it often contains harmful chemicals, disease-causing bacteria and viruses, dissolved material and solid matter. Pathogens can cause a variety of illnesses and humans are exposed to these organisms through contaminated water, shellfish, and fish (Sea Grant, 1999).

Investigating Illicit Connections

Recently, more and more watershed studies are investigating inappropriate discharges in storm drainage systems. This pollution source originates from an identifiable point and flows through the storm drainage system to the outfall pipe. For example, instead of connecting to the sewer system, a direct connection of sewer service discharges into the storm drainage system. Other inappropriate sources include floor drains and laundry pipes. These inappropriate connections are also referred to as illicit or illegal cross connections. The health threat and the potential to interfere with stormwater contamination assessments elevate illicit connections to priority status for watershed managers to investigate.

Pitt et al. (1993), in cooperation with the Center of Environmental Research Information, U.S. Environmental Protection Agency, published a user's guide for conducting investigations of illicit connections. Several of the methods suggested in this guide were implemented during the New Hampshire coastal investigations. Detailed surveys to determine the extent of contamination through specific water quality monitoring and careful observation of storm drainage outfalls are recommended for each type of land use in the watershed. Pitt recommends an initial phase of investigative protocol that includes the initial mapping and field surveys. The initial activities are followed by more detailed watershed surveys to locate and correct the sources of the contamination in the identified problem areas. After corrective action has been taken, repeated outfall field surveys are required to ensure that the outfalls remain uncontaminated.

Surveys of Storm Drainage Systems

Over the course of the investigations, several methods were used, ranging from the initial screening process of surveying storm drainage discharges to dye testing the indoor plumbing of suspected sources. Steps between the initial survey and the final determination of the source, included analyzing the discharge for water quality; visual and odor observations at outfalls, manholes, and catchbasins; smoke testing; and video inspection of the storm drainage and sewer systems.

Tidal rivers and coastal waters were divided into study sections by community. The urban, downtown centers of these communities were targeted based on the existence of the storm drainage infrastructure. The investigators compiled maps and as-built drawings of the storm drainage and sewer infrastructure. If the maps were inaccurate, insufficient, or unavailable, information on the storm drainage system was developed based on field investigations by the staff, typically with the assistance of public works employees.

Communities with maps based in a geographic information system (GIS) saved staff time and were generally more accurate than record drawings that are not updated regularly (Landry, 1997). Tuomari (1996) applied the Rouge Watershed Geographic Information System to the Wayne County Illicit Connections Detection Program and concluded that the new GIS strategy eliminated the need to use maps and graphics from disparate reports and sources, significantly reducing the time and effort once spent on research, field data acquisition, and interpretation.

Beginning in the summer of 1996, the coastal shorelines were surveyed at low tide, on foot or by canoe, depending on access, for potential pollution sources. All pipes, seeps, streams, and swales with flow were sampled for bacteria. In addition, temperature was measured and observations relating to the condition of the pipe (stained or structurally damaged), odor, evidence of untreated wastewater (toilet paper, etc.), turbidity, color, debris, estimated flow, and any other observations were noted. Dry pipes were rechecked on several occasions for intermittent flow. Evidence indicating the presence of wastewater and/or elevated bacteria levels prompted further investigation of these locations.

Upstream catchbasins and manholes associated with the outfall pipes that were identified in the screening process previously described, were surveyed for evidence of wastewater and sampled for bacteria. Smoke testing (using non-toxic smoke blown into catch basins) was then used to identify buildings connected to the storm drainage system by canvassing the neighborhood for vents emitting smoke. Final confirmation of an illicit connection from the buildings that emitted smoke was accomplished with dye testing of indoor plumbing and observing the storm drainage and sewer systems for the presence/absence of the dye.

Feeder streams were surveyed for outfall pipes with dry weather flow. Other potential bacteriological sources (e.g., pigeon roosting sites on bridges) were bracketed with water quality sampling stations. Where contaminated seeps and swales were suspected, the drainage area was surveyed for potential sources such as broken sewer mains.

Water Quality Results

Bacteria data (1997/98) from outfall pipes with confirmed cross connections ranged from 1,700 - >1,000,000 *E. coli* counts/100 ml during dry weather in Dover, New Hampshire. Many outfall pipes with cross connections had a gray biomat comprised of filamentous bacteria coating the inside of the pipe and, often, the rocks or sediment below. These biomats were used as a wastewater indicator based on the presence of these mats at more than 50% of the outfalls with confirmed cross connections.

Dr. Stephen Jones of the University of New Hampshire Jackson Estuarine Laboratory conducted a twelve-month study that examined the significance of all flow coming from urban storm drainage systems in the downtown Dover watershed of the Cocheco River (Jones, 1998). Jones found that storm drains were consistent sources of relatively high concentrations of bacterial indicators and pathogens at concentrations that exceeded state standards for recreational and shellfish-growing waters during both dry and wet weather.

Flow from a damaged stormwater outfall pipe was determined to have a geometric mean *E. coli* concentration of 1,047,199 cfu/100 ml and a dissolved inorganic nitrogen (DIN) concentration of 22.4 mg/l. The data were brought to the attention of DES and an investigation revealed a cross connection from a commercial building. Dr. Jones continued to monitor the quality of flow after the cross connection was eliminated and the results show a significant decline in both bacteria and DIN geometric means. The post-repair results were 93 *E. coli* cfu/100 ml and 7.2 DIN mg/l.

Although no public health problems were known to have occurred as a result of exposure to bacterial pathogens in the Cocheco River, the contamination may be a significant contribution to the fecal-borne bacteria that are presently the reason for closing the area's shellfish growing waters in New Hampshire and restricting harvests in Maine (Jones, 1998).

Remedial Actions

Once confirmed, illicit connections in coastal New Hampshire have been eliminated in different ways. The most desired course of action from the regulatory perspective is voluntary compliance and many fixes have been accomplished through this process. Economics and prioritization of the many demands on public works departments sometimes compel the state and federal environmental agencies to initiate regulatory action to eliminate raw wastewater discharges into surface waters. Lawsuits, although not common, have been filed against municipalities after cross connections were discovered.

Voluntary Compliance: Town of Exeter Case Study

In 1994, researchers at the UNH Jackson Estuarine Laboratory (Jones and Langan, 1995) reported elevated dry-weather bacterial levels collected in Norris Brook, a tributary to the Squamscott River in Exeter, New Hampshire. In 1996, DES collected bacteria samples at various locations on Norris Brook (NHDES, 1997) and found relatively low *E. coli* concentrations of <150 counts/100 ml. In 1998, an Exeter official urged DES to investigate the watershed for contamination based on the 1994 data that showed a fecal coliform concentration of 600 counts/100 ml. In April of 1998, DES and a town official conducted a survey of the lower watershed and discovered a storm drainage outfall discharging a large volume of flow even though the weather had been dry. Upon closer inspection, toilet paper was observed in the outfall pipe and the immediate area.

The town public works department was notified of the survey results and, following reminders by DES, began investigations to determine the sources of untreated wastewater. Progress was slowed because several of the residences were rental properties which involved contacting the owner, who was in some cases from out-of-state, and gaining permission to access the building for dye testing. By November, the town reported that a few of the cross connections still remained. DES considered enforcement action and an administrative fine but did not take that action to maintain the spirit of cooperation. In January of 1999, the town reported that the owner of the last remaining property to be dye tested was not responding to requests for access. More prodding by DES followed and in February 1999, DES received notification that the cross connections were eliminated. A follow up inspection confirmed the absence of untreated wastewater in the storm drainage outfall.

A lesson learned from this experience is that a persistent, local advocate is often the key to maintaining attention on a local water quality problem. In addition, local advocates, whether a conservation commissioner, selectmen, or citizen, often have detailed knowledge of the complaint and the locale, which provides valuable and time-saving information to the state investigators.

Time and resource demands on local officials as well as state investigators can cause this process to be distressingly slow. Budgeting for 2-3 cross connection investigations and fixes per year is recommended at approximately $6,000 per fix, to help alleviate the unexpected financial burdens on urban communities when illicit connections are found.

Bacteria alone should not be the determining factor of the presence or absence of an illicit connection for a variety of reasons. Chlorine or other toxins in untreated wastewater may depress bacteria levels and bacteria lack conservative behavior, which deem it a poor indicator (Pitt, 1993). Investigators have found that a careful and thorough outfall survey is usually more informative than just collecting water samples.

Enforcement Action: City of Newmarket Case Study

Enforcement is another tool available to DES to achieve compliance. For example, setting timetables for compliance milestones in a legal document is a method that, while typically thought of as a burden to a community, may actually provide the impetus for action in a positive way. Public works departments of New Hampshire coastal communities are not equipped with large, discretionary budgets to address unplanned remediation of illicit connections. When faced with this dilemma, an enforcement action against the community provides public works departments with the validation to support a request for additional funding from the officials who approve the allocation of funds.

As the mill Town of Newmarket, New Hampshire, developed over the years, a small watercourse named Moonlight Brook was built over and culverted in the center of downtown. In 1996, DES investigated Moonlight Brook based on historic elevated bacteria levels. The DES investigation revealed dry weather *E. coli* concentrations as high as 41,600 counts/100ml in the brook. DES encouraged the town to initiate dye testing of the structures in the vicinity of Moonlight Brook but, at that time, the town was reluctant to allocate staff and funding for clean up efforts (NHDES, 1997).

An administrative order was issued by the US Environmental Protection Agency for various violations of permitted effluent limitations in October, 1997 and included a requirement that the town eliminate the raw sewage discharges from the storm sewer system (USEPA Docket No. 97-78). The order required a plan and schedule for eliminating any pollutants discharging during dry weather. The order also specified sampling of each active dry weather discharge that remained following elimination of the illicit connections to the system identified by the town's fieldwork.

In response to the order, the town hired an environmental consultant to address the problems at the wastewater treatment facility and the illicit connections. During the summer of 1997, the consultant and the town performed a dye study of the subdrainage area that the town suspected was the likely source of bacterial contamination identified at the discharge. The dye study resulted in the identification of a total of four untreated discharges to the storm drainage system from three properties. A subsequent video inspection of the sewer lines adjacent to these properties revealed that the sewer service connections from these properties might have been installed at the time the original sewer was constructed. The consultant then concluded that this would indicate the sources of sewage discharging to the storm drainage are broken sewer service connections rather than direct connections. The town stated that the remedial work would be completed by June 1998 (Plante, 1998).

Another storm discharge pipe servicing this area was separated in 1985 and 1986, at which time dye testing was performed to identify sanitary services that were connected to the sewer. The consultant determined that it would be unlikely that direct sanitary service connections to the storm drain were present in this area, however, broken service connections could result in sewage entering the storm drain culvert along Main Street. A dye study was planned for May 1998.

A total of 59 properties were included in the dye-testing program. Four of the properties were confirmed to be cross-connected to the storm drainage system. Two of the four were the result of direct connections of sewer laterals to the drainage system. The remaining two were a result of exfiltration from the sewer lateral through the ground to the drain line (Town of Newmarket, 1999). The town reports a 90% reduction in the *E. coli* counts following the elimination of the illicit discharges.

Legal Action: City of Dover Case Study

In the 1970's, the City of Dover, New Hampshire, constructed a new sewage collection system and treatment facility. In 1997, DES investigators began surveying the storm drainage outfalls for contamination. Around this same time, University of New Hampshire researcher Dr. Stephen Jones initiated a study in Dover to determine the significance of flow (both dry and wet weather) coming from urban storm drainage systems (Jones, 1998). Jones identified a source of bacterial contamination to be a cross connection later confirmed by DES and the City of Dover Public Works Department. The city fixed the illicit connection by connecting the sanitary service into the sewer main, at no charge to the building owner, while noting substantial flow from this service due to a hair salon in the building.

After learning about the existence of the cross connection, the building owners made an unsuccessful request to the city for an abatement of the sewer fees they had paid since 1981 and initiated legal proceedings. The city alleged that the case law mandated a decision in its favor and filed a motion for summary judgement (Strafford Superior Court, Order #98-C-207). In a responding order from the judge, the case law was said to illustrate that the Court had considered a variety of factors in related cases including (1) whether the new and old system were integral to one another, (2) whether the benefit provided to the plaintiff under the new and old systems was comparable, and (3) whether the property owner had access to the new system. The motion for summary judgment was denied because the Court found that these were issues for a jury and that summary judgment at that stage would be premature.

A trial date was set. One week before the trial was to occur, the two parties settled out of court. The terms of the settlement were confidential. If the property owners were successful in seeking a tax abatement and damages for unjust enrichment, implied contract, and negligent misrepresentation, as sought, the pollution investigations could have been in jeopardy of becoming ineffective. Such a precedent could have led to other similar suits and would effectively remove the incentive for municipalities to be proactive in fixing cross connections.

Conclusions

The Department of Environmental Services, in conjunction with the New Hampshire Estuaries Project, has systematically identified illicit connections in the urban communities of coastal New Hampshire. Applying both voluntary compliance and enforcement has resulted in the removal of cross connections to the storm drainage systems and a decrease in the contamination reaching the coastal surface waters. DES is currently monitoring the shellfish growing waters to determine the extent of water quality improvement resulting from the removal of illicit connections.

Introduction

In North Carolina coastal estuarine systems, land use change has been implicated as a significant cause of water quality impairment (NC Department of Environment and Natural Resources, 1997; White, et al., 1998). Such development processes change surface hydrology, pollutant delivery, and, as a consequence, adjacent water quality. Decisions regarding placement, density, and type of development are controlled by policy implementation at the local level. Furthermore, while the degree of impact may vary with each location, it is the cumulative effects throughout a watershed that can be most damaging to water quality. Hence, there is a need to develop and enact policy locally, but on a multi-jurisdictional, watershed basis.

Increasingly, local communities and governments are showing interest in playing a role in developing and implementing solutions to water quality problems (NC Department of Environment and Natural Resources, 1997). However, logistical complications arise upon implementation of this concept. First, a mechanism for effectively involving local citizen stakeholders in the policymaking process may not exist and/or is difficult to establish (Danielson, 1998). Second, technical data needed to address local issues and concerns are often not readily available, or are in a form not easily understood. Third, programs for addressing water quality problems on a watershed-basis may not exist, suggesting a need to develop, coordinate, and deliver multi-jurisdictional education on water quality issues and policy alternatives. Through a project entitled *Watershed Education for Communities and Local Officials (WECO)*, the North Carolina Cooperative Extension Service has worked with a number of state and federal agencies, along with citizens and local governments within a coastal watershed to address these needs.

The goal of this project is to improve water quality in all of the White Oak River Watershed through involvement and education of citizens and government officials who live and work in the watershed. The project's main thrusts are : 1) the delivery of technical information and educational material on water quality, management strategies, and policy options that support watershed-based planning; 2) the empowerment of local citizens by facilitating collaborative partnerships between communities, local officials, and state agencies within the watershed; and 3) the facilitation of the development

of local stakeholder - driven policy recommendations for the entire watershed. This paper discusses the application of these concepts to an issue of critical importance to local citizens.

Background

The White Oak River watershed is one of four rivers in the White Oak River Basin (Figure 1). It is 48 miles long and encompasses 320 mi^2. The watershed begins in freshwater creeks and swamps of Jones County, NC, and contains portions of three other counties--Craven, Onslow, and Carteret. Along its route to Bogue Sound and the Atlantic Ocean, the river traverses between 30 ft. banks, which are relics of ancient dune ridges. This river is home to five threatened or endangered organisms, including alligators; loggerhead, green, and leatherback turtles, and the Croatan crayfish. The river and its estuarine waters have extensive primary nursery waters and provide habitat for several anadromous species--herring, shad, striped bass, and sturgeon. The majority of the river is classified as SA, or saltwater suitable for commercial shellfish harvesting.

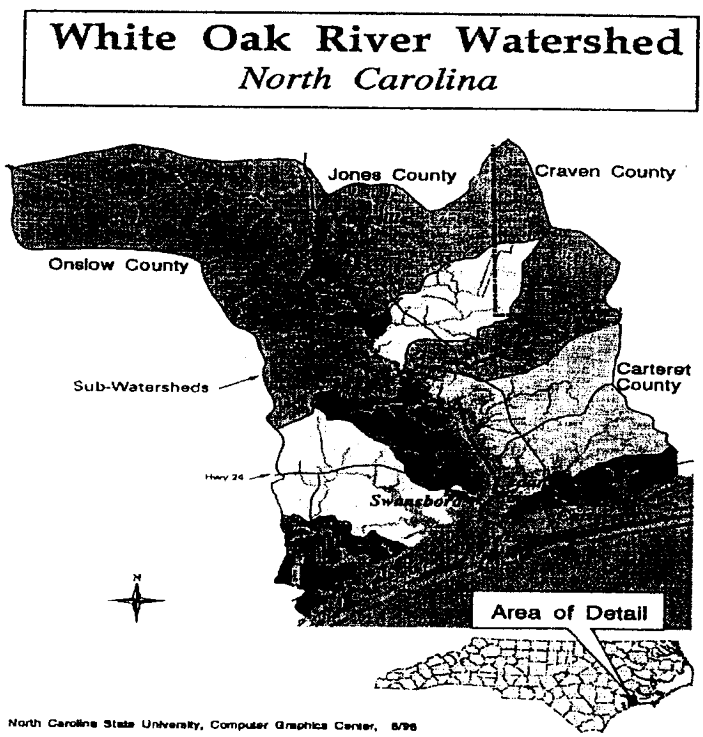

Figure 1. General map of White Oak River Watershed in North Carolina.

The White Oak River watershed has six major land cover/land use classes with wetlands encompassing the largest single type at 52% of the total. Forests are the second largest land cover type constituting the majority of the headwaters in the Croatan National and Hoffman State Forests (22%). A very small portion of the watershed is urban (2%) and agricultural (11%) (NC Department of Environment and Natural Resources, 1997).

Despite the low level of urbanization, the North Carolina Division of Water Quality's basinwide management plan notes an increase in shellfish closures in the river (North Carolina Division of Environmental and Natural Resources, 1997). At state-sponsored public meetings, over 100 citizens expressed concern and called for more public education on water quality.

Recognizing the interest of their constituencies in water quality education, local NC Cooperative Extension Service leaders assembled a project team involving members from the North Carolina Division of Water Quality, North Carolina Division of Coastal Management, North Carolina Division of Environmental Health - Shellfish Sanitation Branch, North Carolina Cooperative Extension, and 25 citizens who comprise the stakeholder-based Advisory Board for the White Oak River Watershed. This group includes crop farmers, livestock farmers, fisherpersons, developers, foresters, tourism directors, teachers, scientists, and local government officials from the watershed (see Table 1). The citizen advisory board is the decision-making entity. The government agency representatives and Cooperative Extension personnel function as support staff to the Board. Support staff provide resources, perform research and reviews, make reports, serve as technical advisors, and provide formal facilitation and consensus-building services.

The White Oak Advisory Board's Primary Issue of Concern

The Board began meeting in August of 1996. Their first task was to prioritize water quality issues upon which to focus their efforts. Board members expressed concern that past bridge and road construction across the mouth of the river had contributed to a decline in water quality. Furthermore, this road, Highway 24, was slated for expansion, and they were concerned that this would exacerbate the problems. The Board acknowledged the need for expansion of the road, but recognized a unique opportunity to mitigate its impact if they could move quickly to work with the North Carolina Department of Transportation (NC-DOT)

At the time that the Board was convened and identified the highway and its expansion as an issue, NC-DOT was in the process of conducting an Environmental Assessment of the project and were anticipating a Finding of No Significant Impact. During a meeting between the Extension Project Team and NC-DOT, DOT representatives were made aware of the Board's concerns and expressed an interest in working with the Board to address those concerns. However, timing was an issue because in several months, NC-DOT was planning right of way acquisition to begin the expansion project. Because of the urgency of the matter, the Board resolved to meet twice monthly and work to develop their comments and recommendations.

Technical Information Gathered by the Board

In response to the Board's inquiry, the Project Team reviewed, summarized, and presented scientific studies that had been conducted on the river that related to sedimentation and flow patterns in the river and the possible effects of highway construction over the mouth of the river. Results from the following four studies were especially useful in understanding the science behind this policy issue.

One study (Martens and Goldhaber, 1978) determined that the metabolic pathways by which bacteria degrades organic matter in the sediments differ depending on whether the overlying aquatic environment is salty or fresh. Chemistry analyses done on soil cores taken at various locations in the river found framboidal pyrite at upstream samples, which indicated that saltwater wedges had previously penetrated further upstream than current patterns in soil chemistry showed. These results provided evidence to the Board that saltwater flows in the river had changed over time.

Adams, Benniger, Hosier, Overton, and Reed (1982) studied water circulation and sedimentation patterns in the White Oak Estuary and found that sedimentation in the estuary varies from 0.3 cm/yr to 5 cm/yr. approximating the annual rate of submergence along the Atlantic coast. Their study confirmed for the Board that the system is a flood tide dominated system with sediment transport primarily occurring during storms with strong on-shore winds. The study also noted that the construction of the Intracoastal Waterway (ICWW) in 1930-32 in conjunction with the construction of Highway 24 in 1933 altered channel flow from one channel (adjacent to Huggins Island) to another (adjacent to the mainland near Highway 24). Spoil deposition from dredging operations may also be responsible for decreased channel flow in the west channel of the Inlet. The authors noted no evidence of a declining fishery based on the fact that it was comparable to other fisheries in the area and in line with historical production rates for the estuary. This study also quantified the extent of fill and alteration to the estuary caused by the original construction of the ICWW and the road in 1932 and 1933, respectively. Historical maps, when compared to current data, showed that two inlets were closed and that more than 80% of the river was obstructed by these projects.

Benniger and Martens (1983) investigated the age and the sources of organic matter in the estuary. This study characterized the organic matter degradation rates, which is important in understanding the estuary's capability to process organic inputs. The researchers determined that the upstream organic matter inputs were primarily terrestrial and the downstream organic inputs were primarily marine. However, they found that microbial processes acted preferentially to remove recently produced organic matter. This implies that recently produced or partially treated organic matter could substantially increase sediment oxygen demand and the rate of nutrient regeneration. This would increase the vulnerability of the estuaries to anoxia and algal blooms.

Kelley, Martens, and Chanton (1990), by collecting and analyzing sediment cores, characterized the relative remineralization rates of sedimentary carbon for the fresh and saltwater environments in the river. They found that the upstream environment, which is dominated by terrestrial inputs and the process of methane reduction, remineralized at a rate three times faster than the downstream site, which is dominated by marine inputs and uses sulfate reduction as the energy pathway for organic matter remineralization. As indicated in the previously described paper by Martens and Goldhaber (1978), saltwater circulation patterns, as well as freshwater inputs, appear to have changed such that the estuarine ecology has shifted towards a more freshwater system. Since freshwater facilitates rapid remineralization of organic carbons, this, over time, can reduce the river's buffering capacity and result in nutrient enrichment.

Initial Conclusions of Board

Based on these and other related studies, the Board concluded the following:

- Salt wedges that used to extend upstream have not occurred in recent history.
- Organic inputs upstream are from terrestrial sources and downstream are from marine sources.
- Salinity regimes in the river are highly variable seasonally and spatially.
- Salinity helps buffer the river from nutrient inputs.
- Sedimentation at the mouth of the estuary was considered normal for coastal estuary systems.
- There was no evidence to support a perceived decline in the fishery.
- Increased fresh water inputs from the expanded impervious surface area related to the highway expansion may have a negative impact.

- Higher salinity reduces concentrations of fecal coliform bacteria.

- Ditching and other means of moving water faster off the land causes problems with increased freshwater to the river as well as increased bacterial contamination in shellfish beds.

- There is a significant shellfish resource at the mouth of the river that has historically remained open.

Next, the Advisory Board convened a panel of specialists to discuss this information and potential mitigation strategies. The panel participants included:

- Dr. Larry K. Benninger, Geologist, University of North Carolina at Chapel Hill (UNC-CH);

- Archie Hankins, Biologist, NC-DOT;

- Tom Jarrett, Hydraulic Modeling, United States Army Corps of Engineers (USCOE);

- Dr. Chris Martens, Marine Sciences, UNC-CH;

- Dr. Paul Hosier, Biologist, UNC-CH;

- Dr. Rick Leuttich, Sedimentary Geologist, UNC-CH; and

- Howard Varnam, Hydrologist, USCOE.

The panel reviewed the scientific information presented to the Board, and they agreed that there has been an impact on the circulation and flushing of the White Oak River since the construction of the causeway and the ICWW, but quantification of those effects would require intensive modeling that would take a minimum of 1.5 to 2 years. The panel felt that any action to increase circulation and salt water inputs to the river would have an overall positive effect on water quality. However, the best manner in which to accomplish those goals and the particular effects on fisheries, sedimentation, or other water resource values would be difficult without modeling studies. The panel concluded that due to changes in land use, hydrology in the watershed had been altered. As a result, runoff volume during storm flows has increased. This increases pollutant loading and increases erosion processes during storms. The panel noted that a reduction in freshwater runoff would not have any significant effect on the diversity and density of species, but on their distribution. This would have little effect on flora and fauna in the river, but might improve water quality. The panel also noted that the most effective strategy for protecting water quality is to involve all of the communities impacting the system and to implement overall land use planning in the watershed. It was suggested that the group needed to define their water quality goals and how they want to manage the river and watershed to achieve those goals. Individual actions for localized effects would require some additional modeling and research to determine the best options.

The panel concluded with a list of mitigation recommendations listed below:

- Pursue a study of the river to determine what, if any, actions should be taken to improve circulation up and downstream of the highway.

- Examine options to manage stormwater in new and existing developments.

- Pursue the maintenance of buffers along creeks and streams.

- Pursue stricter enforcement of sediment and erosion control at construction sites.

- Endorse, encourage, and facilitate the use of BMPs in forests and farms.

- Work to develop a mechanism for watershed - based or coordinated land-use planning to address all of the suggestions.

- Explore alternative waste management strategies for both single users and municipalities to reduce nutrients.

The Board's Recommendations

Over the next several meetings, and as a consequence of these findings, the Board recommended the following actions;

1. To reduce freshwater inputs to the estuary and possible negative impacts of highway runoff on water quality, the Advisory Board recommended storm water runoff from bridge and highway expansion not be discharged into the river and that the Department of Transportation (DOT) explore options to eliminate discharge into the waterways. At a minimum, discharge from Highway 24 should be directed south (downstream) of the causeway to prevent impacts to shellfish. In addition, it was recommended that amelioration of the velocity, volume, and quality of that runoff be implemented; if feasible.

2. Historic maps showed that, prior to the 1930's, the mouth of the White Oak River was open and unrestricted, allowing free tidal flow. In 1932 and 1933, Department of Transportation and US Army Corps of Engineers (ACOE) projects closed approximately 80% of the mouth of the river and altered physical processes. The Advisory Board recommended that to restore salinity regimes, increase tidal circulation, and reduce sedimentation, DOT take actions to reopen the mouth of the river to the maximum extent possible. One option would be the creation of a north-south channel connecting the estuary with the sound near the current location of the Flying Bridge Restaurant on the Carteret County side of the river spanned by a bridge or connected by a culvert. Additionally, the Board recommended that DOT and ACOE access ACOE ecological restoration funds and collaborate with each other to mitigate the impacts of this expansion and past actions.

3. Since efforts to open the channel would not remain effective unless the State of North Carolina initiates an ongoing maintenance program, the Advisory Board recommended that a long-term maintenance program supporting improved circulation, reduced sedimentation, and restored salinity regimes be developed and implemented by responsible agencies.

These recommendations were presented to and adopted by commissioners for Carteret and Jones Counties in May and June of 1997. In addition, the White Oak River Watershed Advisory Commission of Onslow County (a group appointed by the Onslow County Board of Commissioners to address water quality issues in Onslow County) endorsed the recommendations of the Board at their May of 1997, meeting. This collaborative, consistent, watershed-based policy statement became part of the public record for the NC-DOT hearings in May of 1997, and a preliminary draft was included in the NC Division of Water Quality's Basinwide Water Quality Management Plan for the White Oak River Basin (North Carolina Division of Environmental and Natural Resources, 1997).

Response to the Recommendations of the Board

At a joint meeting that included representatives of the NC-DOT, the White Oak River Advisory Board, the Extension Project Team, and USCOE, the DOT agreed to support the Board's recommendations and revise their stormwater plans to direct runoff away from the shellfish resource in the river.

Blueprints for construction were redrawn reflecting the following features. In the vicinity of the bridges carrying Highway 24 over the White Oak River at Swansboro, NC-DOT agreed, to the extent possible, to direct the stormwater runoff from the roadway to the Bogue Sound side of Highway 24 and away from the river. In Swansboro (west of the island causeway), the existing stormwater collection system (which has outfalls on both the river and sound side of Highway 24) will continue to be used for the runoff following roadway expansion, thus preventing the need for additional outfalls in the river.

From the island causeway eastward for approximately 2.5 miles, the stormwater runoff from the highway will be collected and piped to outfalls on the sound side of Highway 24. Also, NC-DOT has designed special channelization islands for commercial driveways to accommodate some of the stormwater runoff from the highway and bridges. These water quality islands are depressed inside the curb to allow the first inch of highway runoff to pond within these islands and filter through the grassed areas located there. The filtered runoff from these islands is then collected and piped to outfalls on the sound side of Highway 24.

In addition to the stormwater design changes, it was agreed that DOT would cooperate with other state and federal agencies in any efforts to improve circulation and tidal flushing. Currently, the Board is continuing to work on adding a section to the Congressional *Water Resources Development Act* that would authorize the USCOE to conduct the study necessary to determine what, if any, actions could be taken to improve flushing in the river.

Conclusions

Local stakeholder-based citizen groups can impact policies that affect their environment. Support for gathering, summarizing, and delivering technical information to local citizens and governments is an important aspect of the success of these processes. Knowing who to approach for answers to specific questions, and where to look for scientific information is an important function of the group's technical support. In addition, translating the information gathered into digestible and usable material is also critical.

Stormwater runoff threatens the nation's waterways and public health, and costs Americans hundreds of millions of dollars each year. Concerns about urban runoff and interest in proposed new federal stormwater regulations prompted the Natural Resources Defense Council (NRDC) to document existing, effective stormwater strategies. Our report aims to encourage municipal action and empower communities to address this critical issue. More than 150 case studies from across the nation were compiled and evaluated to highlight effective pollution prevention, administrative, and financing strategies for addressing stormwater runoff. The case studies show, on a practical level, that stormwater management can be environmentally effective, economically advantageous, and politically feasible. The report also forms the foundation of a comprehensive outreach effort. Together, they help guide communities as they implement or improve stormwater management programs by providing detailed examples of proven tools and approaches used to prevent stormwater pollution. Collectively, the case studies offer an outline for further successful stormwater management strategies. Elements critical to the effectiveness of these programs include: a pollution prevention emphasis with structural treatment measures when needed; a focus on preserving natural features and processes; programs that inform and involve the public; a framework that creates and maintains accountability; a dedicated and equitable funding source to ensure long-term viability; strong leadership; and effective administration. These broad themes translate into a set of nine local actions for addressing the technical, social, and political issues associated with stormwater runoff. The case studies show that following these actions will help communities form a sound stormwater policy.

Key Terms: urban stormwater runoff, impervious surfaces, pollution prevention, best management practices, diffuse pollution, accountability.

[3] *formerly Policy Analyst, Natural Resources Defense Council*

Introduction

Currently, there is substantial concern about the impacts of urban and suburban runoff. Pollution from diffuse sources, including urban stormwater, is the leading source of contamination in the nation's waters (U.S. Environmental Protection Agency, 1997a). Stormwater runoff pollution is a particularly important issue since most of the population of the United States lives in urban and coastal areas. Water resources in urban and coastal areas are highly vulnerable to and are often severely degraded by stormwater runoff. Specifically, urban and suburban runoff is the second most prevalent source of water quality impairment in the nation's estuaries after industrial discharges (U.S. Environmental Protection Agency, 1998b).

Economic impacts are an important aspect of this concern. Even a partial accounting shows that hundreds of millions of dollars are lost each year through added government expenditures, illness, or loss in economic output due to urban runoff pollution and damages (U.S. Environmental Protection Agency, 1998a). The ecological damage is also severe and is at least as significant. In particular, uncontrolled urban runoff contributes to hydrologic and habitat modification, two important sources of river impairment identified by the U.S. Environmental Protection Agency (EPA).

The polluted stormwater runoff problem has two main components: the increased volume and rate of runoff from impervious surfaces and the concentration of pollutants in the runoff. Both components are closely related to development in urban and urbanizing areas (Booth and Reinelt, 1993; Schueler, 1994; U.S. Environmental Protection Agency, 1997b). When impervious cover (roads, highways, parking lots, and roof tops) reaches between 10 and 20 percent of the area of a watershed, ecological stress becomes clearly apparent (Klein, 1979; Booth and Reinelt, 1993; Schueler, 1994). Everyday activities can deposit on these surfaces a coating of various harmful materials. When it rains or when snows melts, many of these pollutants are washed into receiving waters, often without any treatment.

The deposition of pollutants and the increased velocity and volume of runoff together cause dramatic changes in hydrology and water quality (Klein, 1979; Jones and Clark, 1987; Booth, 1990; Galli, 1990; U.S. Environmental Protection Agency, 1997b). These changes affect ecosystem functions, biological diversity, public health, recreation, economic activity, and general community well-being (Bannerman *et al.*, 1993; Novotny and Olem, 1994; Haile *et al.*, 1996; Carpenter *et al.*, 1998). Urban stormwater is not alone in polluting the nation's waters. Industrial and agricultural runoff are often equal or greater contributors. But the environmental, aesthetic, and public health impacts of diffuse pollution will not be eliminated until urban stormwater pollution is controlled.

While urban and suburban runoff continues to be a critical issue, there is substantial evidence that the problems are not intractable. Increasingly, communities are recognizing the causes and consequences of uncontrolled urban runoff and taking action to control and prevent runoff pollution, often without any mandate. These innovative communities are realizing the environmental, economic, and social benefits of preventing stormwater pollution. However, neither the extent of these efforts nor the specific actions being taken have been well documented.

There is also a growing interest in proposed new federal stormwater regulations. Comprehensive stormwater regulation is required under Section 402(p) of the Clean Water Act. Since 1992, cities with populations over 100,000, certain industries, and construction sites over 5 acres have been required to develop and implement stormwater plans under Phase I of the National Pollutant Discharge Elimination System (NPDES) stormwater regulations (U.S. Environmental Protection Agency, 1990). In October 1999, EPA is expected to promulgate a new rule requiring municipalities with populations fewer than 100,000 people located in "urbanized areas" (where population density is greater than 1,000 persons per square mile) to develop stormwater plans. Under what is known as the "Phase II" rule, the EPA and states will develop "tool boxes" from which the smaller local governments can choose particular stormwater strategies to develop their stormwater plans (U.S. Environmental Protection Agency, 1998a).

To address all of these issues and concerns, the authors developed a study to examine, document, and disseminate information on environmentally effective and economically advantageous stormwater pollution prevention strategies. The study resulted in a report, *Stormwater Strategies: Community Responses to Runoff Pollution*, that highlights some of the most effective existing stormwater strategies from around the country (Lehner *et al.*, 1999). The report provides substantial evidence that such programs exist and highlights a variety of innovative strategies actually being used. The report also aims to provide guidance to communities addressing stormwater issues, encourage municipal action, and help empower communities to be involved in this critical issue. This paper summarizes the study and presents its primary findings and recommendations.

Study Design and Approach

The study was exploratory in nature, with the intent of presenting information on existing effective stormwater management programs. To achieve this goal, we collected examples of environmentally beneficial and cost-effective stormwater programs from across the country. We compiled this information into the case-study-based report described above. This information and report have become the basis for a comprehensive outreach effort.

The first step was to gather information on programs and projects by examining existing programs (several begun under Phase I as well as many that started earlier), reviewing literature, contacting regional and local stormwater management experts and researchers, and interviewing representatives from stormwater management or other local government agencies. We gathered information on over 250 programs. The information was then examined in detail and narrowed down to a set of case studies that demonstrated elements of success. Three fundamental criteria for selection were used: environmental gains, economic advantages, and community benefits. Environmental gains included biological, hydrological, or chemical improvements resulting from stormwater management. Economic advantages included cost savings to the municipality or developers, or increases in property values related to the pollution prevention measure. Community benefits included aesthetic or recreational enhancement, administrative or institutional successes, or community relations improvements.

Seventy-seven programs and projects were selected as case studies for the final report. Another 88 programs were annotated to provide additional programs/locations not fully evaluated for the report. The case studies represent communities of all sizes, types, and regions throughout the United States. To help ensure accuracy, local experts or people familiar with the program, called "groundtruthers," were contacted to review the case studies and add information from their own knowledge and experience.

The case studies were first organized geographically by dividing the United States into six regions based in part on general rainfall patterns. Within each of the regions, case studies were then further subdivided into five categories of stormwater management measures including, (1) addressing stormwater in new development and redevelopment, (2) promoting public education and participation, (3) controlling construction site runoff, (4) detecting and eliminating improper or illegal connections and discharges, (5) and implementing pollution prevention for municipal operations. These categories roughly parallel those measures that large municipalities address under existing Federal regulations (40 CFR parts 122.26 and 123.25) and small municipalities will address under pending Federal regulations (U.S. Environmental Protection Agency, 1998a).

Case Study Findings

Through reporting over 150 examples of actual programs, the full report provides substantial evidence that stormwater pollution can be reduced or prevented with proper planning and implementation in growing or re-developing areas. The examples presented in the report also demonstrate that if some communities can measurably and cost-effectively reduce stormwater pollution, so can other communities and states (Lehner, et al., 1999).

The Five Categories of Stormwater Management Measures

Individually, the case studies provide detailed examples of substantial water quality improvement, effective or innovative stormwater control strategies to protect the natural environment, significant cost-savings, and important ancillary benefits to the community. The programs and strategies highlighted come from communities of all sizes, types, and regions. They include efforts by municipal agencies, developers, and community groups. In many cases, several of these groups worked together to create win-win outcomes. The case studies highlight a variety of strategies for addressing the five categories of stormwater management measures previously enumerated, and are described in more detail as follows.

Addressing Stormwater in New Development and Redevelopment. By far the most important category of stormwater strategies focuses on land use and development. It encompasses a wide range of measures including regional or watershed planning, buffers and open space preservation, infill development, conservation design, and the use of site-specific structural and nonstructural treatment measures. One of the best strategies a municipality or developer can employ is to minimize the aggregate amount of new impervious surfaces. For example, developers of the Prairie Crossing project in Grayslake, Illinois, prevented runoff pollution and saved money by using conservation design strategies. The developers first reduced impervious cover by clustering 317 residences on only 132 acres of the site, which left 80 percent as open space. They then designed the developed area around a natural drainage system consisting of vegetated swales, restored prairie, and wetlands. Modeling indicates that this stormwater treatment drain system will remove approximately 85% of nutrients, metals, and suspended sediments and reduce peak flows by 68%. Eliminating curbs and gutters resulted in savings of $1.6 to $2.7 million. The development is also very appealing to homebuyers, with sales comparable to or better than conventional developments in the area (see Lehner *et al.*, 1999, p. 224).

Promoting Public Education and Participation. Individuals play a key role in reducing stormwater impacts both in their own day-to-day activities and in showing support for municipal programs and ordinances. The most successful highlighted programs accomplished three goals: they educated the public about the nature of the problem, they informed the people about what they can do to solve the problem, and they involved citizens in hands-on activities to achieve pollutant reduction or restoration targets. One example of this success is in Minneapolis, Minnesota, where a decline in water quality motivated the Lake Harriet Watershed Awareness Project. Monitoring revealed that lawn-care chemicals were a significant contributor to the problem, which suggested focused education efforts. In turn, the project developed two approaches: a volunteer master gardener program and the distribution of educational materials. Evaluation showed that 67% of watershed residents reported using the information presented and 30% reported a change in behavior. As a result, concentrations of lawn-care pesticides have dropped by 50% or more since the program began (see Lehner *et al.*, 1999, p. 231).

Controlling Construction Site Runoff. The case studies demonstrate that effective construction site pollution prevention is politically and economically feasible and can dramatically reduce pollution. The most effective programs rest on four cornerstones laid in pairs: enforcement and education; erosion prevention and sediment control. However, the first and over-arching necessity is a clear set of requirements. For example, Herzog *et al.* (1998) found that in Geauga County, Ohio, and St. Joseph County, Indiana, aggressive, widespread seeding and mulching reduced construction site erosion by up to 86% and reduced phosphorus loadings by 80%. These measures can also benefit developers financially. They found that homebuyers perceive these "green" lots to be worth $750 more than comparable "brown" lots (see Lehner *et al.*, 1999, p. 236). While existing programs employ a wide variety of erosion and sediment control practices, virtually all successful strategies require proper planning and phasing of construction activities to minimize land disturbance.

Detecting and Eliminating Improper or Illegal Connections and Discharges. Local governments have found that identifying and eliminating illicit connections and discharges is a remarkably simple and cost-effective way to address some of the worst stormwater pollution. The case studies show that two factors are critical to success of this element of stormwater programs: finding illicit connections and discharges, and enforcement. In Washtenaw County, Michigan, the Huron River Pollution Abatement project resulted in a 75% reduction in the river's fecal coliform levels in just 4 years. The project focused on eliminating existing illicit connections and preventing future incidents through chemical storage surveys, industrial inspections, water-quality monitoring, public education, and complaint and spill response. Over a six-year period, the program dye-tested more than 3,800 facilities, after which 328 of the 450 illicit connections found were removed (see Lehner *et al.*, 1999, p. 239).

Implementing Pollution Prevention for Municipal Operations. A wide range of municipal operations can affect stormwater quantity and quality. The case studies reveal that some local governments have been able to manage their municipal operations to reduce stormwater pollution. The municipalities highlighted have done so in a variety of ways including reducing the use of harmful chemicals in the maintenance of municipal properties and vehicles, improving the maintenance and cleaning of roads and stormwater infrastructure, and training staff in pollution prevention practices. Several municipalities have taken these steps at their golf courses. For example, the Village Links Golf Course in Glen Ellyn, Illinois, is preventing runoff pollution by incorporating integrated pest management, water conservation, stormwater detention, native planting, recycling, and public outreach into its day-to-day management. The golf course relies on both mechanical and biological pest controls and has significantly increased natural areas. The course collects runoff from nearby streets and neighborhoods in its system of ponds and spillways. These ponds provide approximately 60% of the course's irrigation water, and the course itself passively treats and filters all excess runoff from irrigation (see Lehner *et al.*, 1999, p. 243).

Themes Common to Success Stories

Collectively, over 150 case studies present a clear model for success. Evaluation of the case studies revealed several common elements among the highlighted programs. We distilled those elements into the seven broad themes listed below to help guide communities as they develop or improve stormwater programs. Since they are based on actual programs, these themes form a solid foundation for successful programs.

Preventing pollution is highly effective and saves money. Pollution prevention measures dramatically and cost-effectively reduce the quantity and concentration of pollutants "winding up" in stormwater. Common pollution prevention measures include reducing or eliminating the use of harmful products, preventing erosion, reducing the amount of pavement in new developments, and changing maintenance practices. In highly urbanized areas, however, such measures may be difficult. In such cases, several communities have found treatment of runoff with structural measures or retrofitting existing structures to be effective alternatives.

Preserving and utilizing natural features and processes have many benefits. Many communities and developers have found strategies that rely on natural processes to be highly effective and economically advantageous. Undeveloped landscapes absorb large quantities of rainfall and snowmelt and vegetation helps to filter out pollutants from stormwater. Buffer zones, conservation-designed development, sensitive area protection, or encouragement of infill development all enhance natural processes.

Educating and informing the general public and municipal staff improves program effectiveness. Providing information and training to the general public and local businesses is a key component to many of the highlighted programs. Since many sources of stormwater pollution are derived from individual activities such as driving and maintaining homes, educating the public goes a long way to reducing stormwater pollution. Several communities involve the public in civic activities, such as monitoring water quality or stenciling storm drains, which not only provide educational opportunities but also save the municipality money.

Strong incentives, routine monitoring, and consistent enforcement establish accountability. Enforcement, or more broadly accountability, is a key element to improving water quality. All actors need a clear statement of performance goals, and they need to be held accountable by others for accomplishing these goals. We found that programs with high accountability were the most effective, often achieving pollutant reductions of 50% or greater.

Financial stability helps ensure effective programs. Effective stormwater programs are financially viable and affordable. Dedicated funding sources, such as stormwater utilities or environmental fees are equitable ways to build stability into stormwater programs. Stability and equity are also important in gaining public support. Nearly 200 communities across the nation are already realizing the benefits of implementing stormwater utilities as dedicated and equitable funding sources.

Strong leadership is often a catalyst for success. Success, at least initially, often requires an individual to champion the project and make it happen.

Effective administration is critical. Regardless of which strategies a community chooses, those programs with clear goals and objectives are the most successful. Such clarity enhances accountability, responsibility, and trust. Furthermore, an established and understood institutional framework often improves administration by fostering collaboration among different parts and levels of government, neighboring communities, and local citizens. Effective administration allows implementation of broad-based, multi-faceted programs, which are often the most effective at controlling the diffuse problem of stormwater pollution.

Authors' Recommendations for Local Action

To further guide communities addressing stormwater runoff issues, we translated the broad themes presented above into an action plan based on nine key recommendations. These actions roughly parallel the broad themes presented above. The case studies demonstrated that following the nine local actions outlined below will help build a strong framework for effective, efficient, and successful stormwater management over the long term.

1) *Plan in advance and set clear goals.* Carefully plan programs, as opposed to simply reacting to provided opportunities, crises, or transient pressures. Planning allows development of more effective and cost-effective actions. An essential outcome of planning is addressing the issues and concerns of all stakeholders involved.

2) *Encourage and facilitate broad participation.* Program planning, development, and implementation should involve multiple levels of government, key members of the community, and professionals from a variety of related disciplines. A key to success is the public's understanding of the issue, how it relates to them, and what they can do about it.

3) *Promote public education opportunities.* Implement broad-based programs that reach a range of audiences and solicit different levels of public involvement. Remain committed to the education program and take advantage of existing community organizations to enhance participation.

4) *Work to prevent pollution first; rely on structural treatment only when necessary.* Focus on prevention-based approaches, through regional and watershed planning, local zoning ordinances, preservation of natural areas, stormwater-sensitive site design, and erosion prevention as these are significantly more effective than treatment of polluted runoff.

5) *Establish and maintain accountability.* Essential components of this process are setting clear standards, creating strong incentives and disincentives, conducting routine monitoring and inspections, keeping the public informed, promoting public availability of stormwater plans and permits, and consistently enforcing laws and regulations. Strong enforcement is often key to significant water quality improvements.

6) *Secure financial resources.* Consider establishing a dedicated funding source such as a stormwater utility. Combine with it budget-saving measures such as creative staffing, public-public and public-private collaboration, and building off existing programs.

7) *Tailor strategies to the region and setting.* Recognizing that every case will be different, consider strategies that are particularly tailored to the region, the specific audience, and the problem.

8) *Evaluate and allow for evolution of programs.* Set clear goals and priorities, and allow programs to develop over time. Establish clear ways to check and see that goals and objectives are being met. This opens opportunities for improvements and helps ensure long-term success.

9) *Recognize the importance of associated community benefits.* Stormwater pollution prevention measures usually offer ancillary quality-of-life benefits in addition to targeted improvements. For example, preserved areas offer parks, ponds offer beauty and habitat, clean streets are more attractive, education helps empower people, and sediment control improves fisheries and prevents flooding.

Conclusion

Many fine handbooks provide theoretical and technical guidance concerning the design and implementation of effective stormwater pollution prevention and control measures. This study took a different approach and focused on existing effective programs in a variety of settings. In doing so, it accomplished two key goals. First, the study demonstrates that stormwater management is quite possible. The case studies show on a practical level that stormwater management can be environmentally effective, economically advantageous, and politically feasible. Second, the case studies enable communities developing or improving stormwater programs to learn from their peers. In doing so, the case studies offer an outline for future successful stormwater management strategies.

Acknowledgments

The authors extend their appreciation to all the communities, organizations, agencies, and individuals who provided information for this study; the technical consultants, peer reviewers, and groundtruthers for their helpful comments; and the volunteers and Natural Resources Defense Council staff who assisted with this study. The study was supported by a grant from the EPA under Section 104(b)(3) of the Clean Water Act.

Abstract

Urban stormwater management agencies are increasingly being called upon to address water quality and natural resources issues in addition to their traditional focus on flood conveyance. In response to this, stormwater drainage master plans have been increasingly addressing stormwater quality and, in limited cases, natural resources and habitat. This paper will describe some of the problems with traditional stormwater master planning approaches, including those where water quality and natural resources have been included as "add-ons," and the urban stormwater problems we are now trying to address which have resulted from these approaches. A framework for how communities can develop integrated stormwater master plans that address multiple objectives, as increasingly mandated by public concern as well as by regulations, will be presented. Given that the tools available for master planning are not equivalent in their numerical evaluations, new procedures and project approaches are required. Especially important is how the hydrology/hydraulic methods are performed, including both flood evaluations and evaluation of the smaller channel-forming storms.

Communities are often not institutionally organized to address multiple objectives. Master planning has traditionally been led and performed by engineers trained in hydrology and hydraulics, and they are usually in different departments from those who are responsible for other environmental aspects of the drainage system. This paper will focus on the technical, institutional, and process-oriented aspects of how master planning can be improved. Several case studies from the Pacific Northwest of the United States will be discussed.

Introduction

The purpose of this paper is to discuss some of the attributes of urban stormwater master planning and how those master plans can be improved to more fully address issues besides conveyance capacity and flood control. Stormwater master plans go by a number of names, including storm drain master plans, stormwater infrastructure plans, and urban catchment management plans. These plans are usually very focused on flood control and, until just recently, address water quality minimally. This paper will discuss some of the attributes of traditional urban stormwater master planning and its results, regulatory programs (which in the US and New Zealand are requiring a different approach), how integrated master planning can be accomplished, and institutional barriers which often prevent integrated master planning from being accomplished. In this paper, an Integrated Stormwater Master Plan is an infrastructure and management plan that not only addresses flood control and property protection issues, but also considers stream stability and habitat, along with water quality and aesthetics.

Urban Stormwater Drainage Problems

It has long been recognized that in urban areas, unplanned stormwater management systems result in damage to property and sometimes people. As it will be well demonstrated by other papers in these proceedings, urbanization of watersheds and the resulting impervious areas also cause changes to the hydrology and water quality of receiving waters which ultimately result in other impacts to aquatic life and humans. Even some of our measures to control impacts can have unplanned detrimental effects. Especially sensitive to these changes are stream systems and coastal embayments that are not well flushed. Almost always there are also direct impacts to stream riparian areas which also increase these changes through canopy removal and channel modifications.

Urbanization usually includes impervious areas directly connected to efficient stormwater conveyance systems (including roof drains and driveways connected to streets and curbs to inlets to pipes) which then are discharged to streams directly or through engineered channels. This has resulted in stormwater being conveyed as fast as possible to receiving waters (and away from properties). Increasingly, it is being recognized that because stormwater is drained to streams in this manner, small storm hydrological changes that result in increased runoff flows can significantly increase the frequency and duration of elevated flows. This energy change within the normal wetted channel often results in channel cutting, widening, and/or sedimentation, which in turn can cause severe habitat and water quality degradation (MacRae 1996; Sovern and Washington, 1996). Often to "fix" these channel problems, streams are enclosed, hardened, and/or straightened. Even without considering the water quality of stormwater, our stormwater systems are severely impacted from a physical habitat standpoint, including habitat loss, higher velocities, and temperature changes. Figure 1 shows an example of how stream runoff can change with urbanization, including much higher and peaky flows as well as increased volumes of runoff.

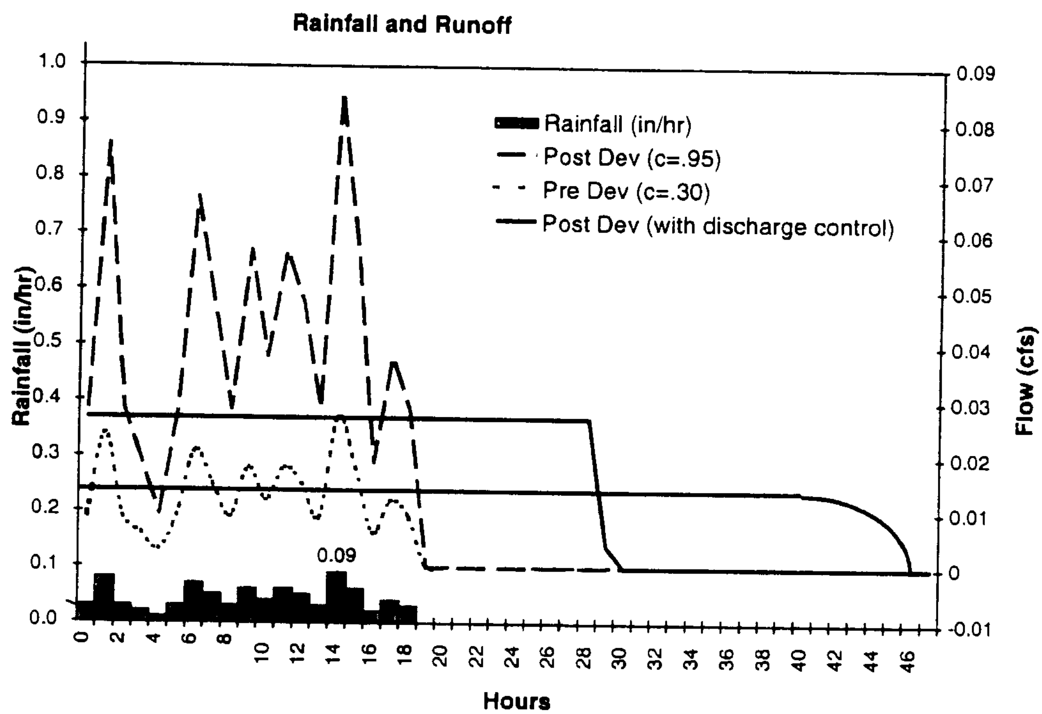

Figure 1. Example Schematic of Changing Rainfall/Runoff Relationships with Development.

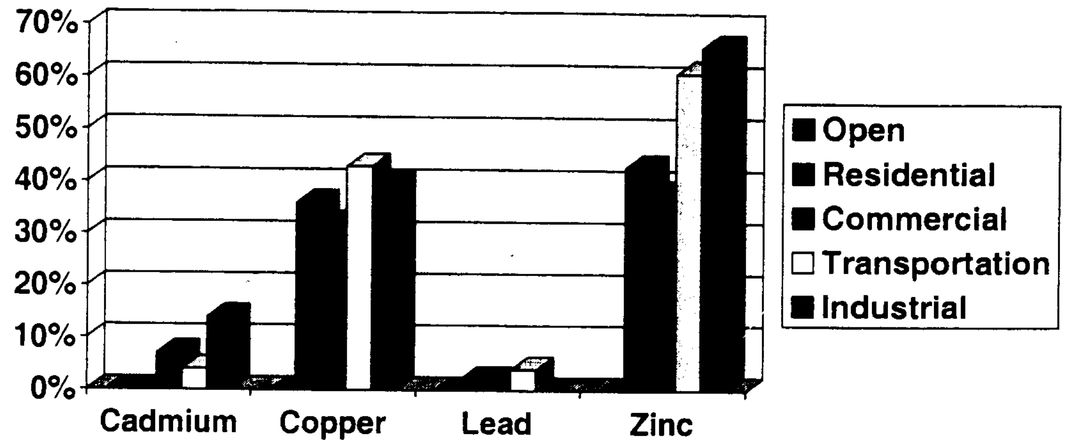
With urbanization also comes a dramatic change in water quality. Urban stormwater systems are the efficient conveyance system of urban pollutants, both those discharged during storm events and those occurring during dry-weather discharges. There are numerous ways that pollutants enter stormwater from those in the rainfall itself to commonly thought of sources such as street dirt and car drippings. Stormwater often exceeds US EPA water quality criteria. Figure 2 is a graph of the frequency that stormwater runoff from identified land uses in Oregon exceed US EPA acute dissolved metals water quality criteria in runoff from identified land uses (Strecker et al., 1997). It should be noted that most of this runoff was measured in pipes, while the criteria are meant to apply to receiving waters. A data set of flow-weighted composite samples (representing average storm concentrations) from over 40 land use stations from various areas of the Willamette Valley was utilized to develop the information displayed in the figure. The stations included an open land use station in an urban area (Forest Park in Portland) for comparison. Note that dissolved copper and zinc in developed land uses exceeded criteria for 30 to 65% of the storm events. Similar findings have been found in other programs, including the San Francisco Bay area programs (Cooke and Lee, 1993).



Based upon Oregon NPDES Stormwater Monitoring Data Compiled by ACWA. Developed areas: 27 to 67 storm events; Open space: 9 storm events

Figure 2. Frequency that Flow-weighted Composite Urban Stormwater Runoff Samples Metals Concentrations Exceeded US EPAs Acute Criteria for Aquatic Life.

The water quality impacts together with the physical hydrology changes described above have caused our urban stream systems to become severely degraded. Our traditional systems have not protected the resources nearly as well as they have protected property. As many have now recognized, at about 10 to 25% imperviousness, the health of the aquatic system is severely degraded (May et al., 1997; Schueler, 1994). In many cases because of the longer-term channel stresses, property has been damaged as well, including under cutting of headwalls, etc. The plans typically only identified solutions that solved large flooding problems, sometimes just temporally until what has been considered "maintenance" problems such as head wall failures, occur.

Environmental Concerns and Regulatory Requirements

In the US, Congress has recognized that urban stormwater plays a major role in affecting receiving waters when it mandated in the revised Clean Water Act that urban stormwater water quality be addressed through a permitting (consent) program. New Zealand has similar requirements through its Resources Management Act of 1991. Both these programs are still evolving. The stormwater permit program in the US specifically requires that larger cities (over 100,000) and soon smaller cities address stormwater quality issues as they conduct flood control projects. New Zealand's program also requires that municipalities obtain consents for stormwater discharges.

Under the overall program, one area that has been slow to change is how urban stormwater master plans are developed and implemented. Although there are requirements to consider water quality in conducting flood control efforts, for a number of reasons (including institutional inertia) agencies have been somewhat slow in actually giving water quality and habitat protection equal weight with flood control in master planning. Some of this is due to the fact that stormwater master plans are typically the responsibility of engineers who are experienced in hydraulics, but that often lack experience and knowledge in other aspects of environmental stormwater management. To be fair, engineers have been told to plan for managing stormwater based upon land-use zoning that was selected without considering stormwater issues. Another major issue is the resources allocated to conduct integrated planning efforts which are more expensive; often agencies do not recognize the value of better up-front planning compared to capital and maintenance costs.

Increasingly though, the public has started to demand that more environmentally sound and/or aesthetically pleasing stormwater management approaches be utilized. For example, with the endangered species act (ESA) listings and proposed listings of salmon and trout species in the US Pacific Northwest, many neighborhood organizations are pressuring municipal agencies to change their stormwater management approaches. Some of these efforts are having more success than the regulatory programs.

Stormwater Management Agency Functions

Understanding a stormwater management agency's function and history is important to understanding its approach to stormwater management. Stormwater management agencies typically fulfill the following roles:

1. Stormwater System Maintenance
2. Development Standard
3. Stormwater Master Planning
4. CIP Design and Construction
5. Funding-Utilities/System Development Charges
6. Stormwater System Permitting and Environmental Impact Minimization
7. Education

The last two elements are the most recent. Many agencies began by responding to emergencies and problems, and were then tasked to develop onsite design conveyance standards. Stormwater master plans for the most part were developed in response to problems that arose after watersheds were developing with little or no stormwater planning. They also were typically focused on just flood control and property protection. Most often they focused on the piped systems and road culverts. Often creeks away from culverts were not evaluated unless there had been a particular problem identified. In the US, the Federal Emergency Management Agency (FEMA) had separately developed flood plain maps for larger systems, which communities relied upon for protecting structures from larger river and stream flooding. This was done to meet requirements for participation in FEMA's flood insurance program. Therefore, flood plains and the creeks themselves have not been a focus of master plan (e.g., creek sections were typically not evaluated to a great extent).

Stormwater Drainage Master Plan Goals and Results

The traditional purposes of the Stormwater Drainage Master Plan were to:

- Guide a city's stormwater drainage system capital improvement project (CIP) program. (e.g., identify, select, cost, and prioritize stormwater system construction projects.)
- Establish a maintenance program for the stormwater system (recommended stormwater system maintenance practices and frequencies)
- Establish onsite conveyance requirements (design standards for level of peak flow conveyance by an engineered stormwater system and, sometimes, requirements for street conveyance of stormwater beyond the onsite requirements)

Master plans seldom included requirements for development with regard to stormwater system impacts (e.g., downstream flow and/or water quality impacts). Master plans were sometimes utilized to assess potential future problems as well as to fix existing problems. Often systems were evaluated under current conditions and future planned zoning to be able to assess costs to current rate/tax payers or new developments. Because master plans were not usually completed prior to some significant level of development, attributing these costs was important to the development community as well as to the residents.

The traditional approach to stormwater master planning has been to focus on hydrology and hydraulics of the existing stormwater systems, and proposed larger trunk systems to determine whether there is enough capacity. This is usually is accomplished by the following steps:

- Route a designated large storm through system, assume worst case conditions (saturated, etc.) and determine capacity deficiencies

- Develop an enlarged (or more efficient) system to handle larger flows or, when necessary, reduce peak flows by detention (if the cost of detention is less than a conveyance upgrade)

- Sometimes consider water quality as a "add-on" (e.g., if detention is required, claim a water quality benefit)

This approach has certainly significantly reduced property damage (sometimes only for short-term), but has led to more damage in streams. The damage has been a result of a significant increase and duration in small storm runoff flows. The result of not planning for this increased energy, which is primarily contained within the stream channel, has often been an increase in maintenance and property damage. For example, channel cutting that occurs upstream of culverts often causes headwall and culvert failures. In other areas where channel cut sediments settle out (often in over-designed or poorly designed culverts), areas are filled in with sediments. When this occurs (especially in a culvert), it can lead to flooding. These problems (headwall failures, culverts filled in, etc.) are often called maintenance issues, when they are in fact really failures of the master plan to adequately address stream impacts of development.

Typically smaller urban stormwater systems (e.g., 10 to 50 acre catchments) are dominated from a flooding standpoint by shorter-duration, more-intense storms (thunderstorms), whereas, the larger urban watersheds are often impacted by larger, but less-intense storms of longer duration. Master plans typically utilize a single large design storm event based upon a rainfall depth (mm of rain over a watershed) for a specified duration and return period. This depth is then assigned a conservative shape such as the SCS type IA shape shown in Figure 3). The storm shown is the 25-year, 24-hour storm depth for Eugene, Oregon, with the SCS distribution applied to it. As an example of how overly conservative the peak of

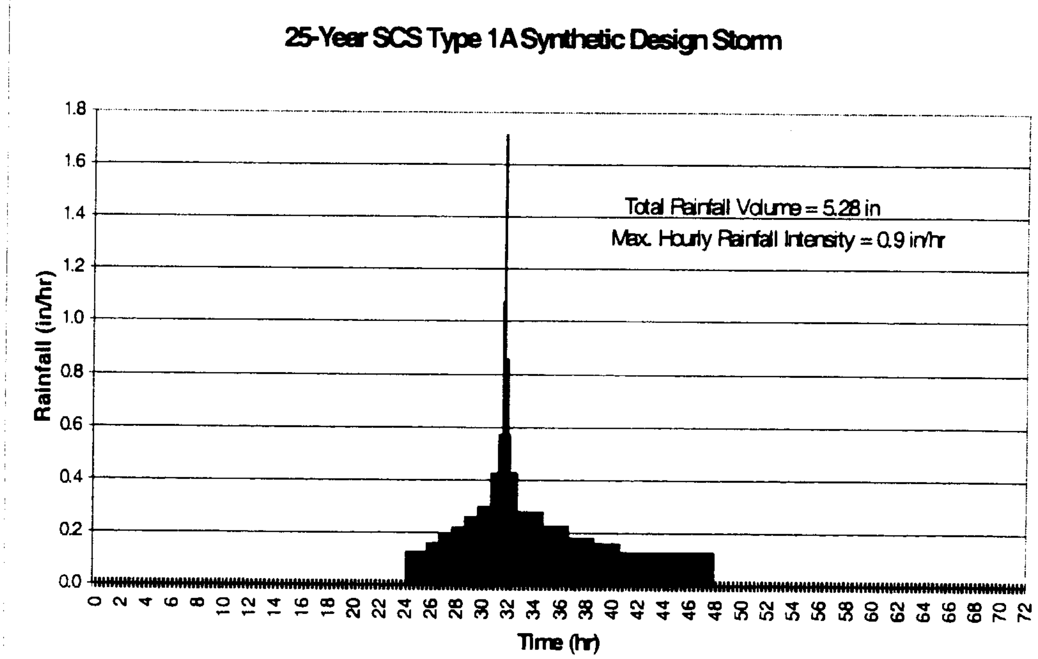


Figure 3. 25-Year, 24-Hour SCS Type 1A Synthetic Design Storm for Eugene, Oregon.

the "design" hydrograph is, Figure 4 shows an actual 25-year storm hydrograph (based upon analysis of the Eugene Airport rain gage). This storm was confirmed by long-term simulation modeling to have caused approximately the 25-year return-period flows in the larger stormwater systems in the city. In reality, the 25-year return-period storm depth seldom if ever arrives with the peaky "shape" given it in master plans.

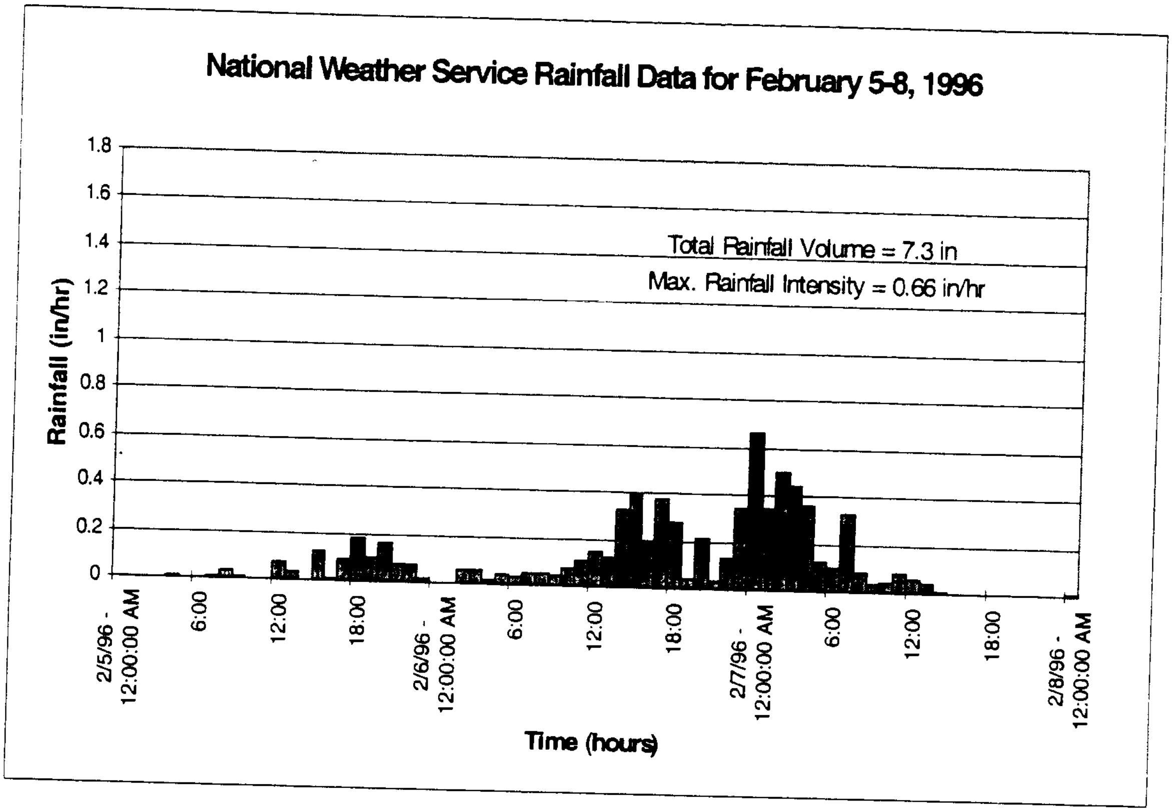

Figure 4. Rainfall Event that was Considered to Cause the Approximately 25-Year Return Period Peak Runoff Flows in Eugene, Oregon.

Many have justified this shape as being one that will also allow flood control effects of smaller thunderstorms on the smaller stormwater systems to be adequately evaluated. When the peak is modeled in this fashion on a larger watershed during an already large rainfall, the peak may greatly affect the larger system design. This conservative design approach we believe has led many communities to determine that streams are undersized and must be widened, channeled, and/or piped.

Of course in communities where there is the potential for combined phenomenon to cause severe flooding (e.g., snowmelt and frozen ground combined with a hard rain), there may be good reason to over size facilities. However, in most cases, it may be more appropriate to utilize methods that account for this and to strive to preserve open channels in more natural ways (e.g., larger stream buffers) to the extent possible.

Another assumption that is often made is that the watershed is saturated before the design storm arrives. This assumption is made to be "conservative." However, it results in an uneven level of conservatism. This assumption would tend to lead to the most over-designed conveyance systems in the least paved areas. That is, the saturation assumption would tend to make systems most over-designed in low-density, single-family areas vs. less over-designed in the downtown core area. The point here is that the levels of over-design are not consistent, nor targeted to the areas where the greatest level of protection is desired (highest property value).

Finally, water quality, and sometimes habitat, is only now being considered in master planning. This is most often accomplished by adding water quality to a detention feature or specifically selecting and locating several demonstration water quality projects. Some communities have chosen to not emphasize habitat by engineering their streams with the purpose of providing flood conveyance as recreational amenities. The Denver area is a good example of this type of design. In arid areas, where streams are seasonal or even just storm driven, this may be a good choice for communities. However, some communities are considering the value of seasonal streams play for downstream resources from a biological and water quality perspective. For example in Eugene, Oregon, the city has determined that seasonal streams contain a rich fauna of aquatic invertebrates (WCC, 1995) which likely would benefit the health of downstream systems.

There are a number of reasons why the above approaches have continued to be employed. First, planning that considers multiple objectives is much more difficult to accomplish, from the technical approaches, due to the need to involve more parties in decision making. The traditional technical approach described above is straightforward, while design of more natural systems is not (e.g., pipe flow equations are much easier to utilize then open channel flow in natural streams). In addition, there are many more people to involve in making decisions than dealing only with engineered physical structures within the stormwater system. Second, most municipalities are not organized well for the purpose of urban watershed planning. The City of Portland, Oregon (which has been very progressive in many ways) still has four separate departments (all in one bureau) that do: 1) facilities planning (stormwater system master planning), 2) site stormwater standards, 3) stormwater quality (permit compliance), and 4) watershed management. Each of these groups has developed its own plans and programs that have understandably not been very well-coordinated or integrated. Finally, and probably most important, is that integrated planning studies cost significantly more (on the order of 2 to 4 times as much).

Integrated Storm Drainage Master Plans - Approach

The new approach to stormwater master plans is the integration of flood control, water quality, natural resources, and aesthetics of stormwater systems. This approach requires significantly more effort and should be thought of as one that will entail adaptive management. That is, the master plan must include components that allow for changing conditions as development occurs and the downstream systems react.

In completing a stormwater master plan, it is difficult to achieve "maximums" of flood control, water quality, natural aquatic habitat, and aesthetics. It is somewhat analogous to the rule that it is hard to get a cheap price, good service, and high quality. It is our belief that one of the problems with master plans has been a lack of recognition that streams will change and that the plans should be developed to manage change in a positive fashion.

One of the keys to successful integrated master planning is that the planning approach places the proper emphasis on the technical and decision-making processes employed. As mentioned above, master plans typically have been driven by the hydrologic/hydraulic modeling of large storm(s) and usually begin with model data collection and analysis. Figure 5 presents a suggested flow diagram for an alternative way of sequencing the development of a master plan. It begins by conducting an inventory of all aspects of the stormwater system, including all attributes related to the multiple objectives mentioned above. The approach suggests utilizing multi-disciplinary teams to review conditions in the field to look for opportunities for meeting objectives, as well as reviewing existing and suspected future problems. Next, before any modeling is done, the project team and decision-makers should utilize the collected information to develop goals and objectives for the plan. Then additional technical analyses, including where and what type of detailed hydrologic/hydraulic modeling is appropriate, can be decided upon based upon these objectives. We have found this approach sharpens the focus of modeling so that the model is not "driving" the master plan into solutions that focus primarily on conveyance upgrades.

In developing an integrated master plan, it is generally understood that the right mix of multi-disciplinary technical specialists should be involved. In addition, it is important to involve the "right" decision-makers and stakeholders early in the process. It is also important to agree up-front upon the decision-making process that will be utilized. We have found that utilizing an agreed upon set of factors to evaluate, select, and rank projects is very useful not only for guiding the process more objectively, but also to serve as a history of why certain projects were recommended and why others were not. This is very useful for future decision-makers for two reasons. First, when questioned by others, there will be

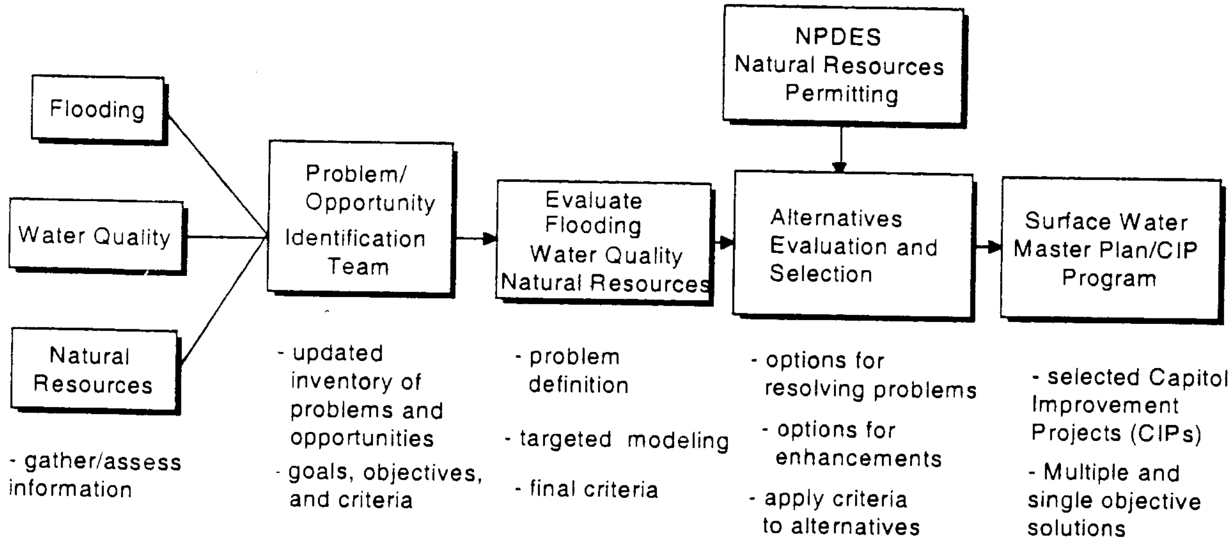

Figure 5. Suggested Integrated Stormwater Master Plan Project Approach.

some backing for why certain decisions were made. Second, as conditions that affect the factors change, selection of projects can also change in a logical fashion.

The approach we recommend is to evaluate solutions that are primarily single objective rather than those that are multiple objective. That is, a two-stage decision process is employed to make sure that good single-objective solutions are not ignored because of the multi-objective nature of the factors. The factors employed include:

- Addresses flooding problems
- Addresses water quality pollutants of concern
- Meets community amenity objectives
- Habitat value
- Life-cycle costs
- Meets regulatory requirements
- Implementability
- Reliability/sustainability
- Other environmental impacts
- Equability

Integrated Storm Drainage Master Plans - Hydrology

Integrated stormwater master planning includes evaluating and considering smaller storm hydrological impacts. Figure 6 presents a storm-depth frequency curve for Portland, Oregon. The figure demonstrates that storms of a depth of 1.5 inches and less dominate both the number of storms (more than 95%) and the volume of runoff (over 90%). It is the smaller storms of about 0.3 to 0.8 inches in depth that change the most in their characteristics. In natural areas of the Northwest, these often did not result in appreciable runoff or resulted only in slightly elevated flows for a long duration. However, after urbanization, these storms are causing severe and rapid changes in flow levels with each storm. This kind of analysis can be used to assist decision makers in deciding what level of water quantity and water quality control is going to be the most cost-effective in reducing the impacts of urbanization.

The best hydrologic and hydraulic modeling approach for assessing and designing stormwater systems is likely the use of continuous simulation models using long-term rainfall records to evaluate a system under a wide range of varying hydrologic conditions. However, this is quite expensive. One of the approaches that we have been taking is to utilize long-term simulations of stormwater systems to select design storms. We believe that this improves the consistency in providing design storms that are closer to the level of protection that is being "advertised," without having to run long-term simulations. This approach involves using real rainfall data with continuous simulation models (e.g., SWMM) to define the resulting return frequency of runoff peaks in various parts of the stormwater system. Then, real storms are selected

R0019507

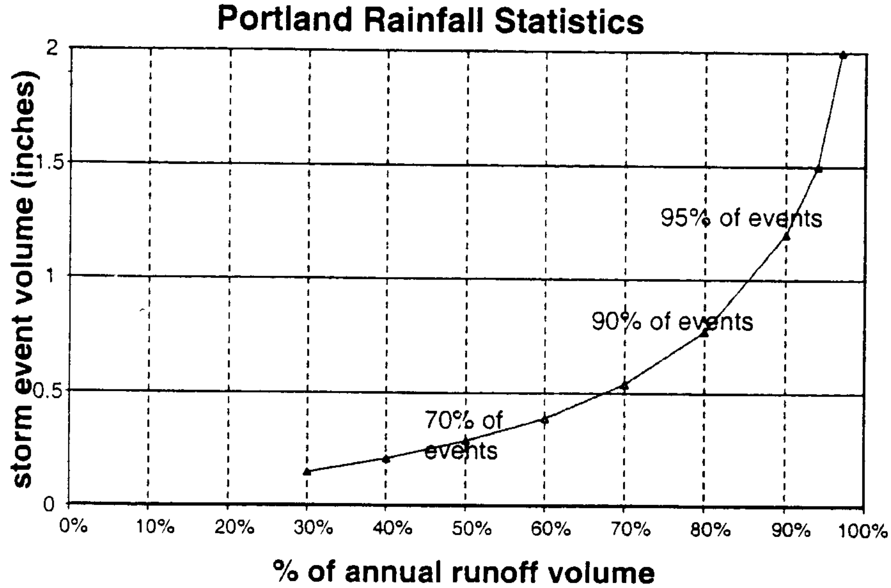

Figure 6. Cumulative Storm Event Rainfall Depth Analysis for Portland, OR Airport.

that resulted in the return period of interest (using a partial duration frequency analysis). These "real" storms are then utilized to design the system. Figure 7 presents an example of partial-duration frequency evaluation of peak flows in one of the basins in the Eugene, Oregon area. From this frequency distribution, the storm that was closest to the intended design level (25-year) was selected for design analysis of the system. Figure 8 shows a similar analysis for another basin in Eugene, along with the design flows from an earlier master plan (which utilized the traditional SCS storm method with saturated conditions).

What Figure 8 demonstrates is that in this basin, the more traditional approach would have resulted in what is likely a significant over-design of the system. In most basins, this was found to be the case. However, there were several basins that were close and a few where the real storm approach resulted in larger designs. Figure 9 and 10 compare the resulting designs in the Flat Creek basin in Eugene. Note that the real storm approach resulted in fewer and smaller projects in this basin. This means that the city can utilize more of its scarce resources to complete other types of multi-objective projects. One of the advantages of the use of real storms is that the concept is very easy to communicate to citizens. In addition, the city has found that some of its channels are over-designed compared to the stated level of protection, and that they may be able to relax vegetation maintenance requirements to allow for more natural channels. Overall, the city is finding that allocating sufficient resources to conduct an integrated plan will likely lead to a more cost-effective program overall, in terms of multiple benefits.

Integrated Storm Drainage Master Plans – Water Quality

There are a number of stormwater quality models and approaches (Donigian and Huber, 1991). Some are quite simple and straightforward, while others are much more complex. In general, water quality models currently cannot accurately predict how pollutants get into stormwater. Although some researchers have made great strides in establishing sources of pollutants in the urban environment (Pitt, 1993), there still are numerous pollutant sources that are not fully understood. Most models rely on either some land-use-based concentrations to drive water quality predictions or they use a build-up/wash-off function to describe pollutant concentrations (Donigian and Huber, 1991).

③	30" RCCP replaced by 2-3'x3' RCBC	$31,800
④	existing channel expansion	$9,100
⑤	existing channel expansion	$3,900
⑥	existing channel expansion	$21,000
⑦	3-43"x27" CMP replaced by 2-6'x3' RCBC	$87,100
⑧	2-36" RCCP replaced by 2-4'x3' RCBC	$81,100
⑨	58"x36" and 24" CMP replaced by 2-5'x3' RCBC	$117,100
	Total	$553,800

Figure 7

Figure 9. Proposed Conveyance System Improvements Utilizing the SCS Type 1A Synthetic Design Storm and Assuming Saturated Conditions.

The build-up/wash-off of suspended solids (TSS) is modeled and then TSS concentrations are utilized to predict other concentrations for such parameters as phosphorus and heavy metals. The first problem with this approach is that it assumes that the build-up/wash-off of TSS is much greater than any other source pathway. This has not been found to be the case (Pitt, 1993). When build-up based/wash-off models are calibrated to real data, the build-up/wash-off function must be set to be much larger than it really is in order to match actual data. When a source control such as street sweeping is applied, the model will then significantly overestimate its effectiveness no matter what the assumed street sweepingefficiency is. This may explain why street sweeping has seldom if ever been found to be as effective as predicted. The second problem with these models is the assumption that other constituent concentrations can be related

to TSS concentrations. Strecker (1997) presented data on TSS vs. metals relationships for Portland, Oregon stormwater data. Although the correlations were significant (r^2 of .3 to .4), we do not believe that they are high enough to be utilized without some stochastic functions employed. We believe that many master plans have utilized over-complicated stormwater pollutant load models that have not represented the actual processes well and have not resulted in better plans compared to their cost.

Based upon the above, we believe that the proper approach to assessing water quality in master planning is to utilize land-use based, simpler spreadsheet-based statistical models for water quality assessments and planning. If hydrologic/hydraulic based solutions are being contemplated then more complex models (such as SWMM) can evaluate detention times might be called for.

There have been a number of attempts to develop a better understanding of how stormwater quality BMPs work and why (Strecker, 1992; Brown and Schueler, 1997). However, what we know about the effectiveness of stormwater best management practices in improving water quality and ultimately aquatic health has been questioned with good reason (Strecker 1994; Urbonas 1995; Maxted and Shaver, 1996). Some of the questions arise from the actual studies and how they have not been completed as to be very useful in assessing effectiveness. In addition, there have been suggestions that pollutant removal efficiencies may not be the best way to assess effectiveness (irreducible concentrations, etc.).

Finally, there have been some studies that have shown that downstream of some BMPs (e.g., detention systems), aquatic invertebrate populations are no different from systems that do not have such in-stream ponds (Maxted and Shaver, 1996).

What we know is the application of BMPs is an evolving science and that the exact cause and effect relationships are not well known. However, we do know that BMPs have been effective at reducing concentrations. In cases where there has been no downstream improvement in aquatic invertebrate health from BMPs, we should ascertain what the limiting factors are and whether the BMP was able to mitigate some if not all of them before we dismiss a BMP. In addition, we need to understand whether other attributes of the BMP may be contributing to downstream problems such as demonstrated downstream temperature impacts (Galli, 1991) of on-line ponds, as well as the interruption of drift of aquatic invertebrates downstream. It is becoming increasingly clear that within-stream detention systems need to be very carefully evaluated before they are selected as BMPs. What we will need to do in master planning is to make good subjective decisions regarding the appropriate application of BMPs for water quality. We do not have the data and models to do otherwise.

Integrated Storm Drainage Master Plans – Stream Stability/Habitat

Unless a watershed has a great ability to infiltrate stormwater or evaporation is a viable technique, stream hydrology will change (increased runoff) with development. While there are some great techniques to reduce the changes (e.g., Prince Georges Department of Environmental Resources. 1997), in many cases these techniques will not be able to reduce the increased energy within a stream enough to stop channel cutting and downstream sedimentation from occurring. A technique that has been employed in an attempt to prevent downstream damage is the requirement that new development controls runoff from a one- or two-year event such that pre- and post- development peak flows for that event are equaled. MacRae (1996) has demonstrated that this approach may actually cause more problems then it solves. It usually leads to shifting over-bank flow energy to the wetted channel, further exacerbating channel down cutting. Figure 1 demonstrates this. Suppose that the peak in hour 14 was the one-year pre-development flow for this creek. Maintaining post-development flows to this level would significantly lengthen the time the creek is subject to this channel-forming flow condition, while reducing over-bank flows. Even setting post-development peak runoff rates to one-half pre-development, results in significant extended energy in the channel. One would likely have to set a requirement that the flow rate be one-fourth or one-fifth to have a positive effect. This would require very large detention areas.

In many, if not most cases, we believe that the master plan must include within-stream structures to assist it in changing with development (Sovern, 1996). That is, the plan must move beyond just getting runoff to a stream and making sure any culverts in the stream are "right-sized." Master plans should include a component to design in-stream structures (habitat friendly ones, of course) and have an adaptive management program for them. This approach has been successfully applied to the Pipers Creek and Thorton Creek watersheds in Seattle, both heavily urbanized watersheds. What this can accomplish is much faster and more postive equilibrium for the stream system (e.g., the increased energy can be utilized to create deeper pools and increased spawning gravels in the pool tailway).

Integrated Storm Drainage Master Plans – Capital Improve Projects (CIPs)

The above integrated stormwater master planning elements will result in changing the traditional definition of what a CIP is. Traditionally it has been structural controls located within the municipally owned stormwater systems (e.g., the streets and street drainage structures and at creek crossings, etc.) Now CIPs can include property or property rights acquisition, buffer areas, protection and enhancement of natural resource sites and preservation of the open channel drainage system.

Integrated Storm Drainage Master Plans – Public vs. Private Solutions

Another element of master planning can include the evaluation of the trade-off of requiring private solutions (e.g., on-site design requirements) versus implementing public stormwater system measures. Figure 11 shows schematically that on a watershed basis, one could employ a combination of both to achieve the overall most cost-effective system. This can be addressed in modeling and cost-estimation for both approaches and then one or some combination employed.

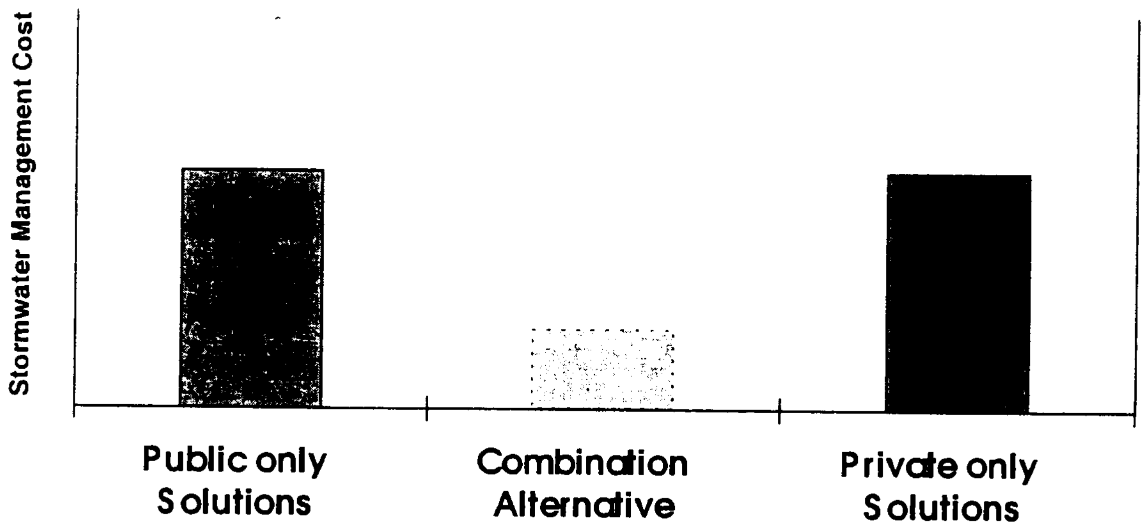

Figure 11. Conceptual Comparison between On-site Private Stormwater Solutions and Public Solutions.

Summary

In summary, urban stormwater management involves a complex set of phenomenon to manage and our stormwater science is lacking to support solely science-based decisions. Urban stormwater master planning needs to be conducted as an integrated planning and implementation process that considers water quality, habitat, and aesthetics along with urban flooding in order to meet increasing regulatory and environmental demands of the public. Typically, BMPs will only reduce the increase in small-storm hydrology that impacts physical stream habitat and stormwater pollutants; in-stream stability measures are needed as a part of master planning and urban system. Master planning and implementation needs to be thought of as an iterative process that will require adaptive management over time. A balanced approach that places the proper emphasis on problem definition, priority and goal setting, selection of measures/controls, participation by stakeholders, implementation, and monitoring/feedback/plan refinement is needed.

Conservation Design: Managing Stormwater through Maximizing Preventive Nonstructural Practices

Wesley R. Horner
Environmental Management Center
Brandywine Conservancy
Chadds Ford, Pennsylvania

Abstract

Unlike conventional methods of stormwater management that prioritize peak rate control to mitigate post-development downstream flooding effects, Conservation Design first aims to prevent or minimize the creation of stormwater from the outset. *Preventive* Conservation Design methods are defined in this paper as those that integrate stormwater management into the initial stages of project design, instead of waiting to consider them in the final steps of the site planning process. *Mitigative* Conservation Design techniques will be explored that use natural processes performed by vegetation and soil to mitigate unavoidable stormwater runoff impacts once prevention has been maximized to the greatest extent possible. Underlying these techniques—whether preventive or mitigative in nature—is a comprehensive perspective of water resources that views stormwater as an asset to be managed, not a waste for disposal.

This paper summarizes a recent project which the Brandywine Conservancy undertook for the Delaware Department of Natural Resources and Environmental Control, with support from USEPA Section 319 funding. For interested readers, *Conservation Design for Stormwater Management: A Design Approach to Reduce Stormwater Impacts from Land Development* (Delaware Department of Natural Resources and Environmental Control with Brandywine Conservancy, 1997) further details all aspects of the Conservation Design program described here. This manual is referenced throughout this paper and is available by contacting DNREC at 302-739-4411 in Dover DE.

Introduction

Most Stormwater management programs place a heavy reliance on implementation of structural stormwater management facilities: detention basins, conveyance piping and inlet/outlet structures. These facilities—though created to mitigate negative stormwater impacts by controlling flooding—cannot in and of themselves eliminate adverse impacts of urban development throughout a watershed. In fact, because these systems fail to acknowledge and plan for critical system-wide water cycle processes, stormwater management itself can become a problem, rather than a solution. This is especially true when conventional stormwater management systems are combined with conventional large-lot subdivision designs.

The negative effects of this type of development and conventional stormwater management have been described in a variety of recent studies and reports, including the *Pennsylvania Handbook of Best Management Practices for Developing Areas* (CH2MHill, 1998) and a variety of other state stormwater manuals; Center for Watershed Protection publications such as *Better Site Design: A Handbook for Changing Development Rules in Your Community* (Center for Watershed Protection, 1998) and *Planning for Urban Stream Protection* (Schueler, 1995); the Northeastern Illinois Planning Commission's *Reducing the Impacts of Urban Runoff: The Advantages of Alternative Site Design Approaches* (Northeastern Illinois Planning Commission, 1997), and *Urban Stormwater Best Management Practices for Northeastern Illinois* (Northeastern Illinois Planning Commission, 1993). These effects include:

- Altered site hydrology and reduced groundwater recharge
- Reduced stream base flows
- Altered stream geomorphology (resulting in damaged aquatic habitat)

- Loss of site area for other uses (e.g.; recreation)
- Single purpose: disregards site resource conservation benefits
- Lack of attention to water quality
- High construction costs
- Maintenance burdens and costs
- Negative visual appearance (e.g., basins often fenced off)
- Limited number of stormwater discharge points
- Less flexibility in design

Conservation Design reflects a totally different philosophy toward land development that integrates stormwater management into the very core of site design, as opposed to considering it a problem to be resolved after the design has been completed. This philosophy regards stormwater as a key component of the hydrologic cycle and critical to maintaining the water balance—and groundwater reserves—for a particular watershed.

Recently we have come to realize that land development's impacts to water resources are not one-dimensional. They include, in addition to flooding, the multiple concerns of water quality, groundwater quantity, stream and wetland characteristics, in-stream habitat, and biodiversity. Therefore, stormwater management and site design must be approached much more comprehensively. At the foundation of this comprehensive approach lies an understanding of the relationship between land development and our water resources. In order to better comprehend this relationship, we must understand the water cycle itself—the amount of rainfall, evapo-transpiration, groundwater infiltration, and runoff—and how this cycle is affected by the characteristics of an individual site such as soil types, topography, and vegetation.

The Water Cycle and Landscape Dynamics

Appreciation of the water cycle is especially important to achieve successful, comprehensive stormwater management (Figure 1). In fact, only through understanding full water cycle dynamics, can we hope to achieve some sort of system balance and minimize negative stormwater impacts. Figure 2 displays a generic flow chart of the water cycle that highlights the various components of this cycle and how they are interconnected **(Conservation Design for Stormwater Management, 1997)**. It is important to appreciate that the system itself is a closed loop: what goes in, must come out. If inputs to infiltration are <u>decreased</u> by 10 inches, then inputs to surface runoff and/or depression storage must be <u>increased</u> by this same amount. Furthermore, infiltration <u>outputs</u> must also be decreased: following along on the flow diagram, the groundwater reservoir, evapo-transpiration and soil moisture elements together will be reduced by this 10 inches, which will reduce stream baseflows.

The logical first step in any discussion of the water cycle is *precipitation*—in all its various forms. In southeast Pennsylvania, and indeed throughout much of the Mid-Atlantic states, the climate is relatively humid **(*Conservation Design for Stormwater Management* 1997, based on Hydrosphere 1992 database).** Substantial precipitation tends to be distributed throughout the year in frequent events of modest size. This consistency in rainfall throughout the year indicates that this region does not have a defined wet or dry season as do other areas of the country. This rainfall potential throughout the year has significant implications for consideration of stormwater runoff. For example, having rainfall throughout the year indicates that sediment laden runoff can occur at any time; therefore, it is important to establish some sort of erosion-controlling groundcover during all seasons of the year.

Also important is the distribution of rainfall by size of event. Based on analysis of 35 years of data from a Wilmington, Delaware rain gage (***Conservation Design for Stormwater Management* 1997**), it is clear that the precipitation occurs mostly in small "events" or storm intensities. Ninety-eight percent of the total *number* of events during this extended period were classified in the "less than 2 inches" category. Even more important from a water cycle perspective, 96% of the average annual rainfall *volume* occurred in storms of less than 3 inches (which is less than the 2-year, 24 hour

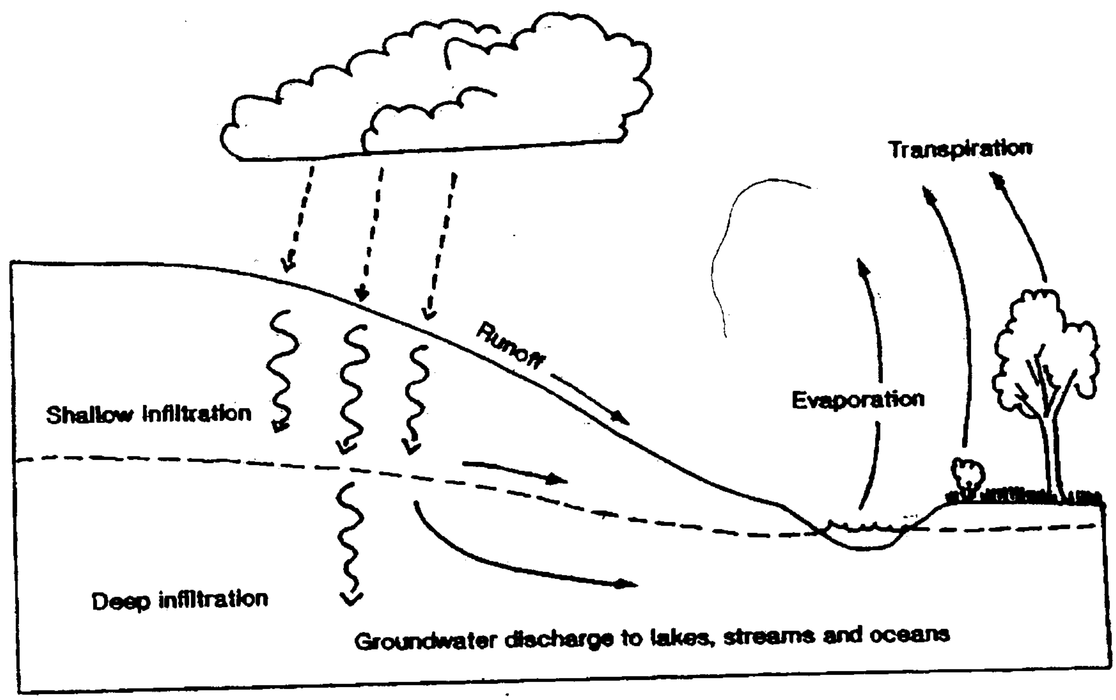

Figure 1. The Water Cycle.

storm). This understanding of storm size distribution is critical for a variety of reasons in stormwater management. For example, if our concern is keeping the water cycle in relative balance, capturing and recharging the 1- or 2-year storm as the basis for design will encompass the vast bulk of precipitation and stormwater runoff volumes in the average year and provide adequate water cycle balance. This leads to very different design criteria than if flooding (peak runoff rates) is the only concern addressed.

Another key component of the water cycle is the linkage between stormwater infiltration, groundwater recharge and stream baseflow. As land is developed and impervious coverage increased, less water is recharged to groundwater aquifers **(Thomas Dunne and Luna Leopold's *Water in Environmental Planning* [Dunne and Luna, 1978] is an excellent background text in addition to the above referenced reports).** As these subtractions continue acre-by-acre, development-by-development, their cumulative effects grow larger. Also, as development occurs, more water is often withdrawn from the underground reserves for drinking, irrigation, or commercial uses. As subtractions are made from the groundwater reservoir flow, the impact will be seen in the form of a lowered water table and reduced stream baseflow discharge. Headwater springs and first-order streams—the lifeblood of our stream systems—may even dry up. The baseflow from headwater zones is critical to maintaining a diversity of aquatic plant and animal life, as well as terrestrial animals dependent on certain aquatic species for survival. In some cases the groundwater reservoir does not discharge to a stream, but rather to a wetland. In these instances, reduced infiltration and a lowered water table ultimately translate into a loss of wetlands themselves, and an elimination of their rich and vibrant ecological function.

A final component of the water cycle that must be addressed is overland runoff. This is the component most frequently addressed in conventional stormwater management approaches, for it is the cause of increased downstream flooding. Three major elements determine the volume and character of stormwater runoff for a given storm intensity: soil type, land cover (including vegetation and debris), and slopes. Soils vary widely in their ability to infiltrate stormwater and

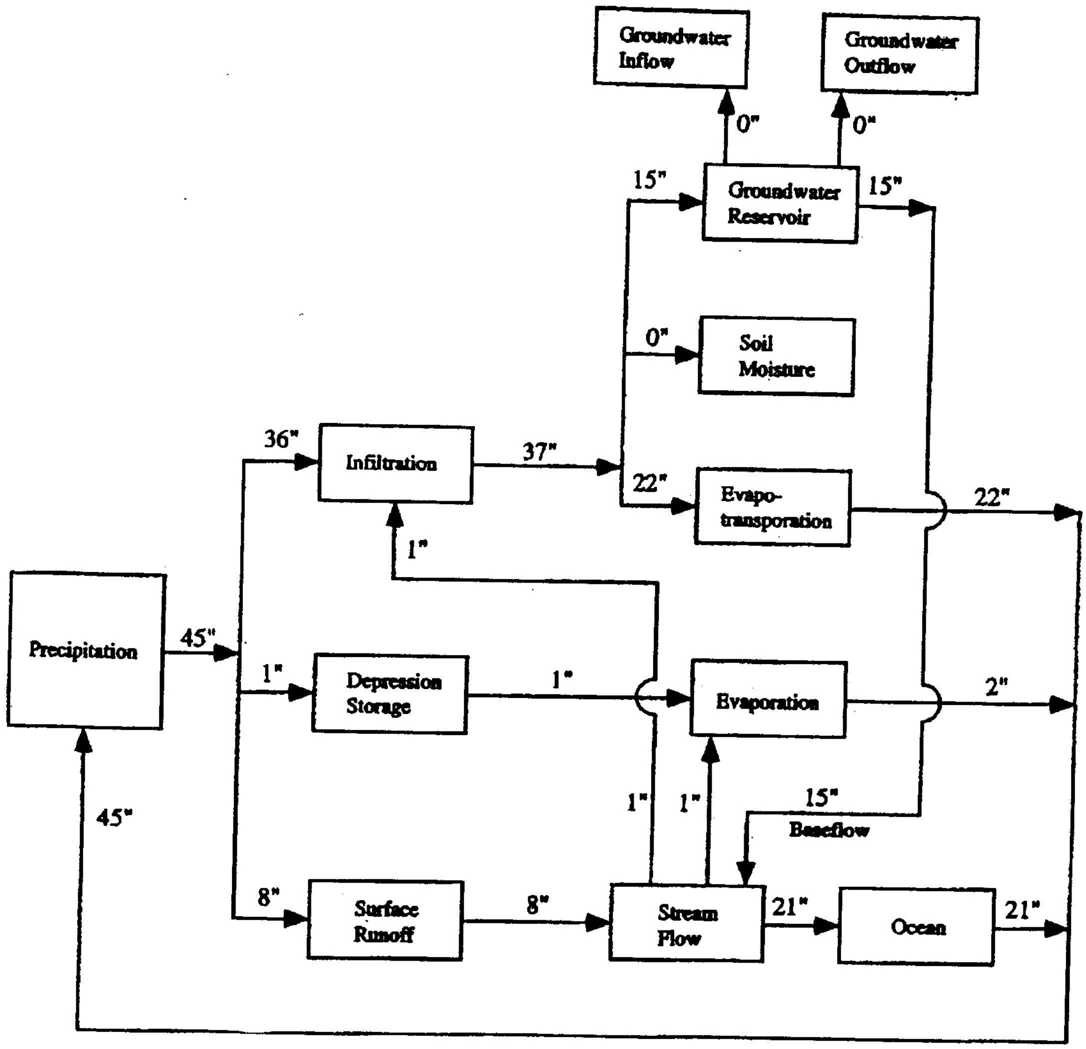

Figure 2. Water Cycle System Flow Chart.

minimize runoff and are classified accordingly by the USDA Natural Resources Conservation Service (NRCS) into four categories based on their permeability rates (Hydrologic Soil Groups A through D, with A having best permeability).

Land cover greatly affects the rate and volume of stormwater runoff and has significant water *quality* impacts as well. Obviously, the landcover of greatest concern for stormwater management is impervious coverage created through the development process. Interestingly, compacted lawns and cultivated fields can have significant runoff rates as well, especially when no crop covers the bare soil. The landcover in this region best suited to retard stormwater runoff and assist in its infiltration is the natural one: the piedmont forest. A mature forest can absorb much more water than an equivalent area of turf grass due to the presence of an organic litter layer and herbaceous and woody plant material. The organic litter layer on the forest floor provides a physical barrier to sediments, maintains surface soil porosity, and assists in denitrification and other water quality functions. The vegetation, both herbaceous and woody, physically retards runoff and erosion with its spreading root mats and also assists in maintaining soil permeability and water quality by taking up nutrients through its root systems.

Finally, slopes are another critical component of the stormwater runoff equation. Steeper slopes can accelerate runoff and increase the erosive force of the water. Therefore, removing vegetation on steeper slopes can have dramatic impacts on downslope aquatic systems.

As seen above, the water cycle and the implications for stormwater management are complex and comprehensive. The process of urbanization dramatically impacts the functioning of this water cycle. Conservation Design has been developed to address the issues of comprehensive stormwater management and to address the land use patterns that impact it.

Land Use and Site Development Impacts

Throughout much of the United States, farmland and natural areas are converted to suburban development at an ever accelerating pace. In fact there is hardly a city in America that does not occupy at least two to three times more land area than in 1970, even if population has not increased proportionately. This history of land use change is certainly true of the Mid-Atlantic states, where communities continue to grapple with the effects of unmitigated suburban sprawl.

The dynamic nature of wet-weather flow regimes and landscape ecology make it difficult to assess the impact of urbanization on aspects of the water cycle such as groundwater reserves and aquatic habitat. However, studies have indicated that the biological community in urban streams is fundamentally changed to a lower ecological quality than what was there before development occurred. In one study in Delaware, approximately 70% of the macroinvertebrate community found in streams of undeveloped forested watersheds was comprised of pollution sensitive mayflies, stoneflies, and caddisflies, compared to 20% for urbanized watersheds (Maxted and Shaver 1996). Other studies suggest that the decay in stream quality is very rapid in the early stages of watershed urbanization; watersheds with less than 10% impervious cover are the most susceptible to the adverse effects of urbanization. Therefore early intervention as a watershed begins to develop is critical, and furthermore, this intervention should include measures to address stormwater management and land use in a connected, comprehensive manner.

In addition to in-stream habitat impacts, the issue of land development and water resources also has great implications for our human communities well beyond the issue of flooding. Reduced stream baseflows and groundwater resources means decreased availability of drinking water supplies. Also, reduced baseflows result in less available water for diluting the pollution output from industrial or municipal waste systems. As stormwater runoff increases, water quality can be greatly impacted by stream bank erosion, re-suspension of sediment, runoff of chemicals and fertilizers from lawns and fields, and increased stream temperatures. Stormwater-linked pollutants vary with type of land use and intensity of use and have been shown to include bacteria, suspended solids, nutrients, hydrocarbons, metals, herbicides and pesticides, toxins and organic matter. Not only are these pollutants increased, but the landscape's natural capacity for filtering and chemical uptake through vegetation is decreased as land is cleared and paved. All of these pollutants can impact both drinking water supplies and natural aquatic systems.

Thus it becomes evident that if the negative effects of land development on our water resources are to be minimized, we must find alternatives to the conventional structural approach to stormwater management. Moreover, these alternatives must address the issue of land use and patterns of development in a comprehensive fashion, one that strives to maintain a hydrologic balance on site and replicate the pre-development hydrologic regime to the greatest extent possible. One approach—or collection of approaches—that can accomplish these goals is *Conservation Design.*

Conservation Design Principles

Stormwater management throughout the Commonwealth (and elsewhere) can be markedly improved by approaching stormwater differently than has been the practice in the past, where "stormwater management" has been defined largely as stormwater disposal. This different perspective challenges us to maximize prevention, even before stormwater becomes a problem, and to avoid highly engineered structural solutions that are expensive to build and maintain. In their place, Conservation Design focuses on utilization of natural systems and processes to achieve stormwater management objectives where feasible. At the same time, this new approach is intended to work with site resources—woodlands, soils, wetlands, etc.—to enhance their stormwater functions. The end result is a site design which minimizes stormwater generation and then mitigates the remaining stormwater in a low-impact manner, with an emphasis on groundwater recharge. Conservation Design is not so much a singular approach or solution as it is a *collection* of approaches and practices that are flexible enough to effectively address any given site and development program. Common to all these approaches and practices are several basic principles.

Achieve multiple objectives. Stormwater management should be comprehensive in scope, with techniques designed to achieve multiple stormwater objectives. These objectives include both peak rate and total volume control (i.e., balance with the hydrologic cycle), as well as water quality control and temperature maintenance. These objectives should include maintaining or improving the pre-development hydrologic regime.

Integrate stormwater management early into the site design process. Stormwater management tacked on at the end of the site design process almost invariably is flawed. To optimize comprehensive stormwater management objectives, stormwater management must be integrated into the first stages of the site planning. Stormwater impacts may even be a factor in determining type of use, extent of use, and location of the development on a site.

Prevent first, mitigate second. Approaches to site design which can reduce stormwater generation from the outset are the most effective approach to stormwater management. For example, effective clustering of units significantly reduces length of roads when compared to conventional development. Reduction in street width and driveway length can minimize impervious coverage. These type of approaches are rarely thought of as stormwater management practices, yet they achieve powerful stormwater quality and quantity benefits.

Manage stormwater as close to the source of generation as possible. From both an environmental and economic perspective, redirecting runoff back into the ground as close to the point of origin as possible, is preferable to constructing elaborate conveyance systems that increase flows and suffer from failures over time. Avoid concentrating stormwater. Disconnect, rather than connect, where feasible.

Engage natural processes in soil mantle and plant communities. The soil mantle offers critical groundwater recharge conveyance and pollutant removal functions through physical filtration, biological action, and chemical processing. Understanding how much of what type of soil is in place on any given site is essential when assessing stormwater management/water quality impacts and opportunities. Vegetation similarly provides substantial pollutant uptake/removal potential and can assist in infiltration by maintaining soil porosity and retarding runoff. In addition, naturally vegetated areas improve their stormwater functions over time as leaf litter and debris builds a richer organic soil layer. Areas of good soil permeabilities (A and B soils) and intact vegetative communities should be prioritized in prevention strategies.

A Conservation Design Procedure

The Conservation Design principles outlined above, though greatly simplified, can offer valuable guidance when approaching a particular land development project. In fact, these five principles form the basis for a Conservation Design Procedure. This Design Procedure incorporates both Preventive Approaches and Mitigative Practices. Preventive Approaches tend to be broader in geographic scope than other techniques and typically may influence some of the major decisions regarding a particular development project. Approaches may even transcend the site itself, involving an entire planning jurisdiction or area, or even an entire region. Also, Preventive Approaches attempt to reduce impervious coverage or minimally disturb the existing vegetation and soils in prime recharge areas. For example, a reduction in road width from 30 feet to 18 feet means an immediate 33.3% reduction in roadway imperviousness, which typically comprises a large portion of site imperviousness.

Mitigative Practices include mitigative techniques which are often more structural in nature. These practices encompass a rapidly growing array of biofiltration and bioretention methods that maximize the stormwater management potential of soils and vegetation. Mitigative Practices include vegetated swales for stormwater conveyance, vegetated filter strips and riparian buffers, grading, berming, terrraforming, and level spreading stormwater in natural areas. These practices should mitigate as close to the source as possible and achieve multiple objectives. For example, a berm, which is used to retain stormwater runoff on a forested slope, can double as a walking trail, thus decreasing the expense of two separate individual systems.

Figure 3 graphically displays the Design Procedure as a flow diagram. The procedure itself can be thought of as a series of questions which must be asked as Conservation Design is applied to each site. If site designers rigorously address all of these questions, the "answers"—the Conservation DesignPreventive Approaches and Mitigative

R0019520

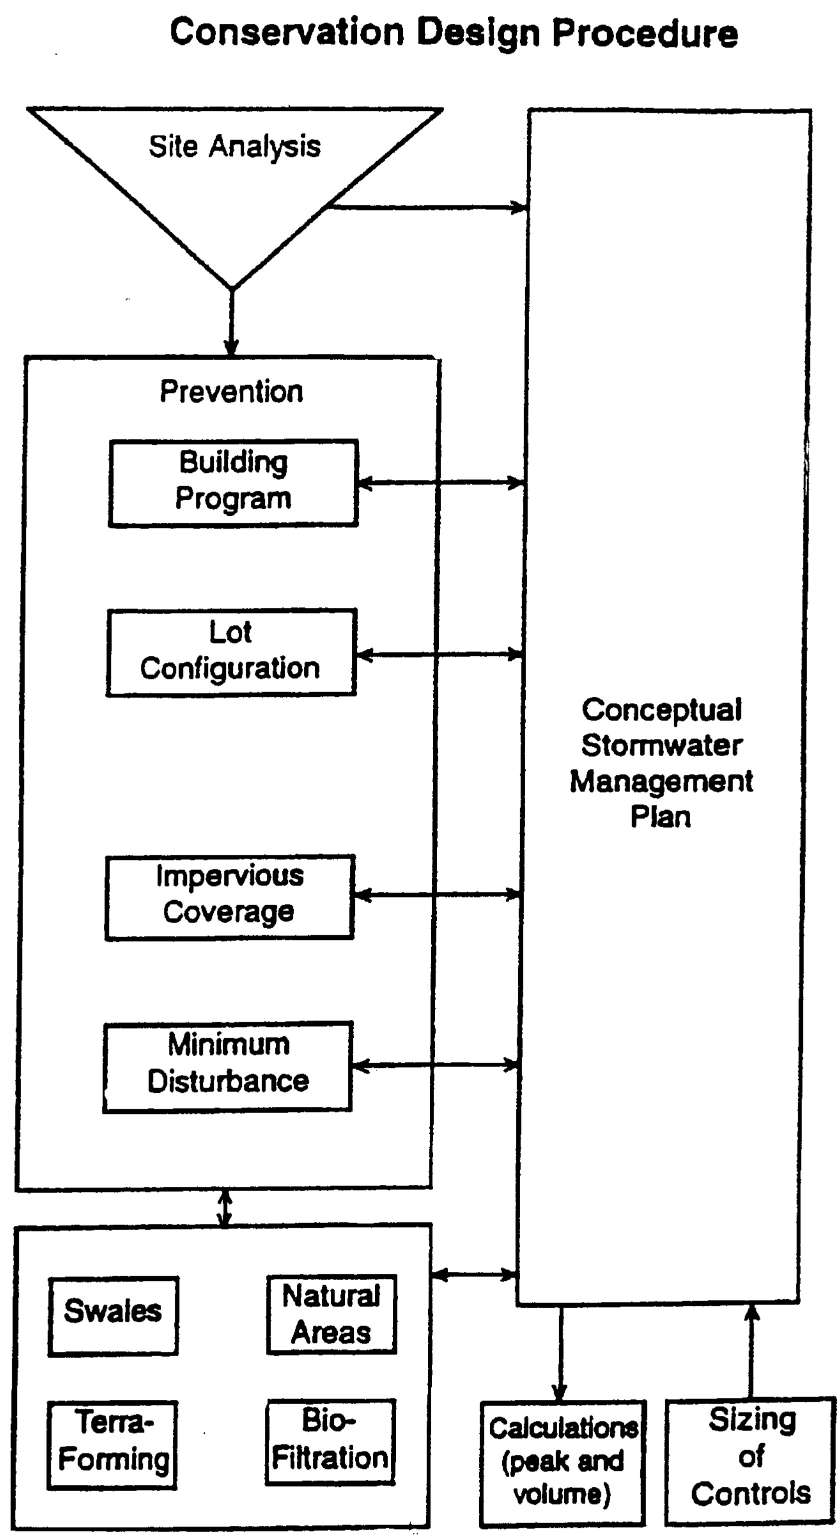

Figure 3. A Conservation Design Procedure.

Practices—will successfully be identified for each site. The overriding objective ultimately is to achieve a new way of thinking about site design. The procedure begins with an effective and complete Site Analysis, which can help identify both areas of concern and resources for opportunity in regard to stormwater management. The procedure then flows from macro, larger-scale preventive questions (i.e., how can the design be clustered to reduce site disturbance) to micro, small-scale mitigative questions (i.e., can stormwater be infiltrated in bioretention areas?). Probably the most important aspect of the procedure in Figure 3 is its positioning of the Conceptual Stormwater Management Plan as a concurrent task with the entire site design process. This reinforces the notion that stormwater management should be an integral part of the entire design process, including the site analysis.

In order to better understand the Conservation Design Procedure, each of its components (the Preventive Approaches and Mitigative Practices) is discussed in more detail below.

Site Analysis

Three major aspects need to be addressed in the Site Analysis process:

Site Background and Context

What is the surrounding context?

What is its location in the watershed?

In which geologic/geographic region is it located?

What is the site size?

What are adjacent uses and landcover?

Critical Natural Features

Existing hydrology?

Wetlands? Floodplains? Riparian buffers?

Steep slopes? Special habitat areas?

Stormwater Opportunity Areas

Where are soils that are best suited for stormwater recharge? Worst?

Where is existing landcover optimal to prevent stormwater?

What opportunities exist to use vegetation and soils in mitigation?

On what soils and slopes is this vegetation?

What is depth to bedrock or water table?

Preventive Approaches

The Preventive Approaches include a range of hierarchical questioning:

Building Program

What is the current zoning and density for this tract?

Is there currently an open space design option for the site?

Can the proposed building program be reduced in terms of density?

Can the type of unit or lot size be modified to promote open space?

What are the possibilities for water and sewer supply?

Lot Configuration

Have lots been reduced and open space been maximized?

Have lots been clustered to avoid critical areas of recharge?

Have lots been configured to take advantage of mitigative practices?

Impervious Coverage

Has development been clustered to reduce impervious surfaces?

Have road widths been minimized?

Have building setbacks been minimized to reduce driveway lengths?

Have parking ratios and needs been carefully examined?

Have needs and sizes of walkways been examined?

Minimum Disturbance

Has maximum total site area, including soils and vegetation, been protected from clearing and disturbance?

Are zones of undisturbed open space maximized?

Have buildings been sited carefully to reduce vegetation removal?

Can no-disturbance buffers be installed to limit zones of soil compaction?

Mitigative Practices

The Mitigative Practices include a tool box of options that promote groundwater recharge and improve water quality. These practices have been assigned to several groupings, although in many cases the practices overlap. Virtually all of these techniques make maximum use of vegetation and soil functions, so although they are all technically structures, they are of lower complexity and more rooted in natural process than conventional approaches.

Vegetated Swales

Vegetated swales are effective means of stormwater conveyance. At low slopes, they can recharge modest amounts of stormwater, filter it through vegetative processes, and slow it down.

Terraforming

Terraforming comes in a variety of techniques. These include constructing subtle berms along contour below undisturbed areas. The berms act as modest "dams" retaining the water for up-slope recharge. Also, subtle grading of depression areas promote retention and recharge throughout a site.

Level Spreading/Natural Areas

With a level spreader, stormwater spills over the lip of a long trench or berm, creating sheet flow across a broad area. The level spreaders slow down the intensity of runoff and discharge it over a large, adjoining vegetated area with good soils, which in turn filter it and assist in groundwater recharge. Filter strips are planted vegetated strips through which runoff passes that filter it and slow it down. Riparian buffers are vegetated zones along stream corridors that filter the stormwater passing through it and help minimize erosion. These techniques are most valuable when used in conjunction with preventive strategies that leave larger natural areas undisturbed in order to handle these additional stormwater inputs.

Bioretention/biofiltration

Bioretention is a popular name given to just about any type of device that utilizes vegetation and soil to manage stormwater flows. They can be subtle depressions that exist naturally and receive stormwater or depending on soil conditions, they may be physically constructed "pits" that are filled with permeable soils and planted with native vegetation that adapt to both wet and dry conditions. These systems can either be "on-line" (part of the stormwater conveyance flow) or "off-line" (separate from the rest of the stormwater management/mitigation system). In either case, they have modest ponding storage that is recharged over the course of time.

Other mitigative devices

Not all of the required volume storage to meet peak rate requirements for a given site may be attained through the practices outlined above. At times, it may be necessary to put in "structural" systems such as in-ground infiltration trenches, infiltration pipes, or stormwater wetlands. However, these systems should be explored only after both Preventive Approaches and Mitigative Practices of Conservation Design have been maximized to the greatest extent possible.

Conclusion

The Conservation Design Procedure is perhaps best characterized as a "check list" or protocol of questioning during the site design process. The key to this approach is its range of innovative, yet effective options, not afforded in conventional systems which tend to be standardized irrespective of the particular site. With Conservation Design, the approaches and practices can be combined in a variety of ways to minimize the impacts of development on the water cycle and still meet regulatory stormwater management criteria such as peak rate control. Often, because these approaches and practices tend to favor multiple objectives and nonstructural techniques, Conservation Design can be less expensive to install and maintain than conventional systems. Also, because they are largely based on soil and vegetative processes, conservation design techniques tend to improve in function over time, while conventional detention basin systems tend to diminish in function over time. In terms of water quality, Conservation Design Approaches and Practices can outperform conventional systems. For example, filter strips and biofiltration areas can remove over 90% of the suspended solids, 40% of the phosphorous, and 20% of the nitrates (Dillaha et al. 1986 and 1989; Yu et al. 1993). In addition, reduced yard areas and increased forested zones prevent chemical runoff from lawns—a great contributor to non-point source pollution—at the outset.

Conservation Design is limited only by the creativity of the designer and the flexibility of the developer and regulatory agencies. It must be emphasized that the Conservation Design approach will not eliminate a need for structural systems in all cases; however, more often than not, Conservation Design can replace or reduce the need for structural practices while providing attractive site amenities. And in the process, the water cycle will be balanced, and forests and other sensitive resources will be preserved. In short, Conservation Design can do more with less, and more for less, than conventional approaches to stormwater management.

Low–Impact Development Design: A New Paradigm for Stormwater Management Mimicking and Restoring the Natural Hydrologic Regime An Alternative Stormwater Management Technology

Larry S. Coffman, Associate Director
Department of Environmental Resources
Prince George's County, Maryland

Abstract

Whether complying with federal or state regulations or addressing local vital watershed protection/restoration objectives, local jurisdictions are confronted with the daunting task of developing, administering and funding complex effective multi-objective stormwater management programs. Today's comprehensive stormwater program not only has to deal with runoff quantity and quality control but, may also have to address such complicated issues as ecosystem restoration, combined sewer overflow reduction, fisheries protection, potable surface/ground water source protection, and wetland, riparian buffer and stream protection. As our understanding of the technical and practical limitations of conventional stormwater management technology has increased over the past two decades, and as watershed protection objectives have changed, many jurisdictions have begun to question the efficacy and cost-effectiveness of conventional stormwater approaches in meeting today's complex environmental/water resources objectives. Older communities with existing extensive stormwater management infrastructures are also struggling with the economic reality of funding the high costs of maintenance, inspection, enforcement and public outreach necessary to support an expanding and aging infrastructure. Still more challenging are the exceptionally high costs of retrofitting existing urban development using conventional stormwater management end-of-pipe practices to restore and protect receiving waters and living resources.

With growing concerns about the limitations of conventional technology and to address the changing objectives of watershed protection, in 1990 Prince George's County's Department of Environmental Resources (PGDER) began exploring alternative stormwater management practices and strategies. The development of bioretention or "Rain Gardens" (using the green space to manage runoff within small depressed landscaped areas) led to an understanding of how to optimize and engineer the landscape to restore hydrologic functions by uniformly integrating micro-scale management practices and impact-minimization measures into the development landscape. In 1997 PGDER released the Low Impact Development (LID) Design Manual demonstrating the principles and practices of LID to create a hydrologically functional landscape (PGDER, 1997).

LID stormwater management technology can maintain or restore a watershed's hydrologic regime by fundamentally changing conventional site design to create an environmentally and hydrologically functional landscape that mimics natural hydrologic functions (volume, frequency, recharge and discharge). This is accomplished in four ways. First: minimizing impacts to the extent practicable by reducing imperviousness, conserving natural resources and ecosystems, maintaining natural drainage courses, and reducing the use of pipes and minimizing clearing/grading. Second: recreating detention and retention storage dispersed and evenly distributed throughout a site with the use of open swales, flatter slopes, depression storage, rain gardens (bioretention), water use (rain barrels), etc. Third: maintaining the predevelopment "time of concentration" by strategically routing flows to maintain travel time. Fourth: providing effective public education and socioeconomic incentives to ensure property owners use effective pollution prevention measures and maintain management measures. With LID, every site feature is multifunctional (green space, landscaping, grading, streetscapes, roads and parking lots) and helps to reduce stormwater impacts or provide/maintain beneficial hydrologic functions. The cumulative beneficial impact of using the wide array of distributed LID techniques allows the site designer to maintain or restore watershed's natural relationship between rainfall, runoff, infiltration and evaporation.

The effective use of LID site design techniques can significantly reduce the cost of providing stormwater management. Savings are achieved by eliminating the use of stormwater management ponds, using less pipe, inlet structures, curbs

and gutters, less roadway paving, less grading and clearing. Where LID techniques are applicable, and depending on the type of development and site constraints, stormwater and site development design construction and maintenance costs can be reduced by 25 % to 30% compared to conventional approaches.

The creation of LID's wide array of micro-scale management principles and practices has led to the development of new tools to retrofit existing urban development. Micro-scale management practices that filter, retain and detain runoff can be easily integrated into the existing green space and streetscapes as part of the routine maintenance and repair of urban infrastructure. LID retrofit techniques may lead to drastic reductions in the cost of retrofitting existing urban development. Reducing urban retrofit costs will increase the ability of cities to implement effective retrofit programs to reduce the frequency and improve the quality of CSOs and improve the quality of urban runoff to protect receiving waters. LID represents a radically different approach to controlling stormwater runoff that provides effective tools to restore or maintain a watershed's hydrologic functions for new or existing development.

In 1998 EPA provided grant funding to assist PGDER in their efforts to develop a general manual describing LID principles and practices, and share this technology with other local governments throughout the nation. Efforts are currently underway with EPA to further advance LID technology by improving the sensitivity of current hydrology and hydraulic analytical models for application with small watersheds and sites and to develop new micro-scale control approaches and practices for urban retrofit. Additional efforts are also underway to demonstrate how LID micro-scale management and multifunctional infrastructure principles and practices can be used to control highway runoff within existing rights-of-way. It is hoped that the LID national manual will help to stimulate debate on the state of current stormwater, watershed protection and restoration technology and its future direction. The lessons learned about LID planning, principles, practices and research are described in detail in the reference documents listed at the end of this paper. Copies of these reference documents can be obtained by calling the Prince George's County's Department of Environmental Resources at (301) 883-5832.

Background

Typically, adverse stormwater impacts are mitigated through conservation of natural resources (forests, streams, floodplains and wetlands); zoning restrictions to direct densities and increase open space; and the use of structural or non-structural control technologies (best management practices - BMP's) to treat and manage runoff quantity and quality. Many conventional stormwater mitigation approaches, such as management ponds, exhibit a number of inherent practical, environmental and economic limitations including inability to replicate predevelopment watershed hydrology, elevated water temperatures, costly maintenance burdens, and accelerated stream erosion due to the increased duration and frequency of runoff events. Furthermore, because current mitigation practices only lessen development impacts, there is concern about the cumulative impacts of the widespread use of conventional mitigation practices that may fundamentally alter a watershed's hydrologic regime and water quality, adversely affecting receiving waters and the integrity of their ecosystems. Many highly urbanized jurisdictions are beginning to question the efficacy of current technology and are finding it harder to ensure, enforce or fund stormwater programs and maintain the massive infrastructure created by conventional approaches.

Currently every site is designed with one basic overriding goal - to achieve good drainage. As we develop a site reshaping the landscape inch by inch, its hydrologic functions are altered on a micro-scale level. The cumulative impacts of micro-scale changes to the landscape drastically alter watershed hydrology. If sites can be designed to achieve good drainage, destroying natural hydrologic functions, why not design sites with the opposite objective to maintain predevelopment hydrologic functions? If inch by inch, sites are carefully and intelligently engineered to maintain hydrologic functions, would the cumulative beneficial affects result in the preservation of a watershed's hydrology? Can a site be designed in a way to remain as a functional part of a watershed's hydrological regime? To achieve a hydrologically functional development there must be a radical change in our thinking. We must not think in terms of impact mitigation as the stormwater management objective, but rather preservation of hydrologic and environmental functions. We should design sites to maintain hydrologic functions not just to mitigate impacts. Can our current stormwater management technology adequately meet our regulatory objectives and water resources/ecosystem protection needs? No one can answer that question for sure. However, it has not been shown that conventional ponds replicate predevelopment hydrology nor is there any evidence to suggest that conventional technology can ensure the ecological integrity of ecosystems. In fact, recent studies suggest that conventional approaches can not meet our water/natural resources and ecological objectives.

Introduction

With growing concerns about the economics and efficacy of conventional technology, in 1990 Prince George's County Maryland's Department of Environmental Resources began exploring alternative stormwater management practices. The success that was achieved through the development and use of bioretention (filtering or infiltration runoff in small depressed landscaped areas) led us to understand that perhaps changing the form and function of the developed landscape could be important in mitigating urban stormwater impacts. Later it was realized that through intelligent site design and uniform distribution of LID micro-scale management controls it was possible to maintain or restore hydrologic functions in a developed watershed. What is not known is how much of a watershed's hydrologic functions can be maintained or restored within a given development type (residential, commercial or industrial)? The one limiting factor to maintaining/restoring the hydrologic regime for highly urbanized development is the lack of available micro-management tools. Much of the current research underway is to expand the number of practices applicable in highly urbanized areas.

LID's objective is to preserve the natural predevelopment hydrologic regime. If predevelopment hydrology and water quality can be maintained, this would provide the best level of protection possible to receiving waters and aquatic living resources. Experience over the last 20 years has demonstrated that maximizing the efficiency of conventional conservation measures and the use of conventional end-of-pipe stormwater management practices can not reasonably be used to restore watershed functions. What is needed is a new philosophical approach to site development, an approach that will allow the designer to retain a site's hydrologic functions.

The approach used in LID designs is really an old one. LID borrows its basic principles from nature - uniform distribution of micro-management controls. In a natural setting, stormwater is controlled by a variety of mechanisms (interception by vegetation, small depression storage, channel storage, infiltration and evaporation) uniformly distributed throughout the landscape. LID mimics these mechanisms by uniformly distributing small infiltration, storage, and retention and detention measures throughout the developed landscape. What we soon began to see is that every development feature (green space, landscaping, grading, streetscapes, roads, and parking lots) can be designed to provide some type of beneficial hydrologic function.

Low - Impact Development General

LID controls stormwater at the source creating a hydrologically functional landscape that mimics natural watershed hydrology. Low impact development (LID) achieves stormwater management controls by fundamentally changing conventional site design to create an environmentally functional landscape that mimics natural watershed hydrologic functions (volume, frequency, recharge and discharge). LID uses four basic management planning and design principles. First: minimize impacts to the extent practicable by reducing imperviousness, conserving natural resources/ecosystems, maintaining natural drainage courses, reducing use of pipes and minimizing clearing and grading. Second: provide runoff storage measures dispersed uniformly throughout the landscape with the use of a variety of small decentralized detention, retention and runoff practices such as bioretention, open swales and flatter grades. Third: maintain the predevelopment time of concentration by strategically routing flows to maintain travel time and control discharge. Fourth: implement effective public education and incentive programs to encourage property owners to use pollution prevention measures and maintain on-lot landscape management practices. A developed site can be designed to become a hydrologically functional part of the watershed with comprehensive and intelligent use of LID practices and principles.

LID Basic Site Planning Strategies

The goal of LID is to design the site in a way that mimics hydrologic functions. The first step is to minimize the generation of runoff (reduce the change in the runoff curve number (CN)). In many respects, this step is very similar to traditional techniques of maximizing natural resource conservation, limiting disturbance and reducing impervious areas. The major difference with LID is you must carefully consider how best to make use of the hydrologic soil groups and site topography to help reduce and control runoff. These considerations would include how to:

1. maintain natural drainage patterns, topography and depressions,
2. preserve as much existing vegetation as possible in pervious soils; hydrologic soil groups A and B,
3. locate BMP's in pervious soils; hydrologic soil groups A and B,
4. where feasible construct impervious areas on less pervious soil groups C and D,
5. disconnect impervious surfaces,
6. direct and disburse runoff to soil groups A and B,
7. flatten slopes within cleared areas to facilitate on-lot storage and infiltration and
8. re-vegetate cleared and graded areas.

Where ground water recharge is particularly important (to protect well, spring, stream and wetland flows) it is important to understand the source and mechanisms for ground water recharge. When using the LID design concepts to mimic the hydrologic regime you must determine how and where ground water on the site is recharged and where necessary, protect and utilize the recharge areas in the site.

LID Hydrologic Analysis/Response

The objective of LID site design is to minimize, detain and retain the post development runoff volumes uniformly throughout the site close to the source to simulate predevelopment hydrologic functions. Widespread use and uniform dispersion of on-lot small retention and/or detention practices to control both runoff discharge volume and rate is key to better replicating predevelopment hydrology. Using LID practices also produces runoff frequencies that are much closer to existing conditions than can be achieved by typical application of conventional BMP's. Management of both runoff volume and peak runoff rate is included in the design. This is in contrast to conventional end-of-pipe treatment that completely alters the watershed hydrology regime.

The LID site analysis and design approach focuses on four major hydrologically based planning elements. These fundamental factors affect hydrologic and are introduced below.

1. Curve Number (CN) - A factor that accounts for the effects of soils and land cover on amount of runoff generated. Minimizing the change in the post development CN by reducing impervious areas and preserving more trees and meadows to reduce runoff storage requirements, all to maintain the predevelopment runoff volume.
2. Time of Concentration (Tc) - This is related to the time runoff travels through the watershed. Maintaining the predevelopment Tc reduces peak runoff rates after development by lengthening flow paths and reducing the use of pipe conveyance systems.
3. Permanent storage areas (Retention) - Retention storage is needed for volume and peak control, water quality control and to maintain the same CN as the predevelopment condition.
4. Temporary storage areas (Detention) - Detention storage may be needed to maintain the peak runoff rate and/or prevent flooding.

Minimizing the Change in CN

Reducing the change in CN will reduce both the post development peak discharge rate and volume. Calculation of the LID CN is based on a detailed evaluation of the existing and proposed land cover so that an accurate representation of the potential for runoff can be obtained. This calculation requires the engineer/planner to investigate the following key parameters associated with LID including:

1. land cover type,

2. percentage of and connectivity of impervious cover,

3. hydrologic soils group (HSG), and

4. hydrologic conditions (average moisture or runoff conditions).

The following are some of the LID site planning practices that can be utilized to achieve a substantial reduction in the change of the calculated CN:

1. narrower driveways and roads (minimizing impervious areas),

2. maximized tree preservation and/or afforestation,

3. site finger-printing (carefully siting lots/roadways to avoid disturbance of streams, wetlands and other resources), greater use of open drainage swales,

4. preservation of soils with high infiltration rates to reduce CN,

5. location of BMP's on high-infiltration soils and,

6. construction of impervious features on soils with low infiltration rates.

Maintaining the Predevelopment Time of Concentration Tc

The LID hydrologic evaluation requires that the post development Tc be close to the predevelopment Tc. Minimizing the change in pre and post Tc will help maintain the same frequency of runoff discharges, assuming there is uniform distributed micro-scale retention and detention of LID practices. The following are some of the site planning techniques can be used to maintain the existing Tc:

1. maintain predevelopment flow path length by dispersing and redirecting flows using open swales and vegetated drainage patterns,

2. increase surface roughness (e.g., preserving woodlands, vegetated swales),

3. detain flows (e.g., open swales, rain gardens, rain barrels etc.),

4. minimize disturbances (minimizing soil compaction and changes to existing vegetation /drainage patterns),

5. flatten grades in impacted areas,

6. disconnect impervious areas (e.g., eliminating curb/gutter and redirecting down spouts) and,

7. connect pervious areas to vegetated areas (e.g., reforestation, afforestation).

The combined use of all these techniques results in cumulative impacts that modify runoff characteristics to effectively shift the post development peak runoff time and frequencies to that of the predevelopment condition, and lower the peak runoff rate.

Maintaining the Redevelopment Curve Number and Runoff Volume

Once the post development Tc is maintained at the predevelopment conditions and the impact of CN is minimized, any additional reductions in runoff volume must be accomplished through distributed micro-scale on-site stormwater management techniques. The goal is to select the appropriate combination of management techniques that simulate the hydrologic functions of the predevelopment condition to maintain the existing CN and corresponding runoff volume. The target design volume is equal to the initial abstraction of rainfall that would have occurred in the predevelopment condition.

LID site designs maximize the use of small retention practices distributed throughout the site at the source to provide the required volume storage. The required storage volume will be reduced when the change in the pre and post CN is minimized.

Retention storage allows for a reduction in the post development volume and the peak runoff rate. The increased storage and infiltration capacity of retention LID BMP's allow the predevelopment volume to be maintained. The most appropriate retention BMP's include:

1. bioretention cells (rain gardens),
2. infiltration trenches,
3. water use storage (rain barrels and gray water uses) and,
4. roof top storage.

Other possible retention BMP's include retention ponds, cisterns and irrigation ponds but it may be difficult to distribute these types of controls throughout a development site.

As retention storage volume is increased there is a corresponding decrease in the peak runoff rate, in addition to runoff volume reduction. If a sufficient amount of runoff is stored, the peak runoff rate may be reduced to a level at or below the predevelopment runoff rate. This storage may be all that is necessary to control the peak runoff rate when there is a small change in CN. However, when there is a large change in CN, it may be less practical to achieve flow control using volume control only.

Potential Requirement for Additional Detention Storage

In cases where very large changes in CN cannot be avoided, retention storage practices alone may be either insufficient to maintain the predevelopment runoff volume or peak discharge rates or require too much space to represent a viable solution. In these cases, additional detention storage will be needed to maintain the predevelopment peak runoff rates. A number of traditional detention storage techniques are available that can be integrated into the site planning and design process for a LID site. These techniques include:

1. swales with check dams, restricted drainage pipes, and inlet/entrance controls,
2. wide, low gradient swales,
3. rain barrels/cisterns,
4. rooftop storage and
5. shallow parking lot/road storage.

Determination of Design Storm Event

The hydrologic approach of LID is to retain the same amount of rainfall within the development site as was retained prior to any development (e.g., woods or meadow in good condition) and then release runoff as the woods or meadow would have. By doing so, it is possible to mimic, to the greatest extent practical, the predevelopment hydrologic regime to maximize protection of receiving waters, aquatic ecosystems and ground water recharge. This approach allows the determination of a design storm volume that is tailored to the unique soils, vegetation and topographic characteristics of the watershed. This approach is particularly important in watersheds that are critical for ground water recharge to protect stream/wetland base flow and ground or surface water supplies.

LID BMP's

Site design techniques and BMP's can be organized into three major categories as follows; 1) runoff prevention measures designed to minimize impacts and changes in predevelopment CN and Tc, 2) retention facilities that store runoff for infiltration, exfiltration or evaporation and 3) detention facilities that temporarily store runoff and release through a measured outlet. Table 1, below, lists some of a wide array of LID BMP's and their primary functions. Placing these BMP's in series and uniformly dispersing them throughout the site provides the maximum benefits for hydrologic controls.

Table 1. Examples of LID BMP's and Primary Functions

BMP	Runoff Prevention	Detention	Retention	Conveyance	Water Quality
Bioretention		X	X		X
Infiltration Trench			X		X
Dry Wells		X	X		
Roof Top Storage		X	X		X

Water Quality

LID maximizes the use of the developed landscape to treat stormwater runoff. Not only can the landscape be used to store, infiltrate and detain runoff, the unique physical, chemical and biological pollutant removal/ transformation/immobilization/detoxification capabilities of the soil, soil microbes and plants can be used to remove pollutants from runoff. For example, bioretention basins or rain gardens are designed to use the upland soil/microbe/plant complex to remove pollutants from runoff. Rain gardens which look and function like any other garden except they treat runoff are designed with a layer of 2–3 inches of mulch, 2–3 feet of planting soil and vegetation (trees shrubs and flowers). Figure 1 shows a parking lot landscape island rain garden (bioretention practice) that uses a high rate filter media with plants to filter and treat 90% of the annual volume of runoff from the parking lot.

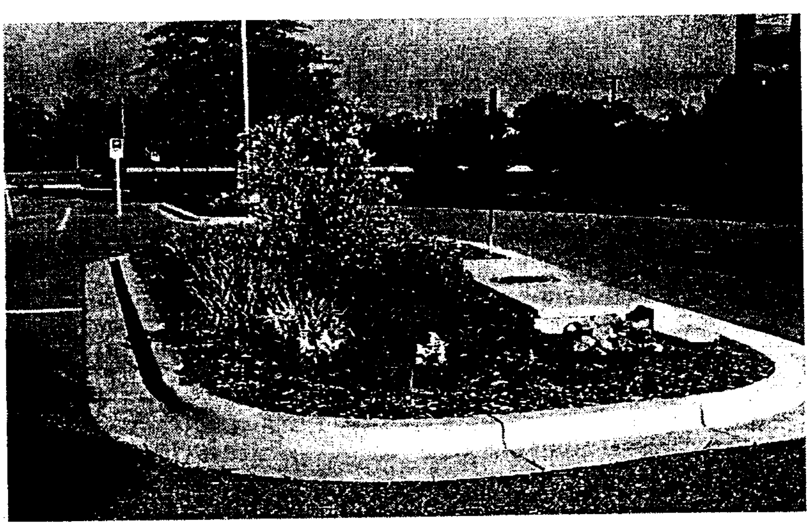

Figure 1. Parking Lot Rain Garden.

Studies conducted by the University of Maryland have shown rain gardens to be very effective in removing pollutants. The percent pollutant removal of various contaminants is shown below in Table 2. The results shown represent the average removal rates under a wide variety of flow rates and pollutant concentrations.

Table 2. Percent Pollutant Removal by Rain Gardens

Cu	Pb	Zn	P	TKN	NH4+	NO3-	TN*
%	%	%	%	%	%	%	%
93	99	99	81	68	79	23	43

* Removal varied as a function of depth in the soil. Percent removal shown is at a depth of approximately 3 feet.
Testing Conducted by the University of Maryland, Department of Engineering

The variety of physical, chemical and biological pollutant removal mechanisms available in the complex rain garden system is staggering. A description or explanation in any detail of these mechanisms is beyond the scope of this paper. A more detailed description can be found in the 1998 "Optimization of Bioretention Design" study conducted by the University of Maryland. Mulch has been found to be very effective in removing heavy metals through organic complexing with the hydroxyl and carboxyl sites on the organic molecules. Soil bacteria can metabolize (use as a carbon energy source) oil, grease and gasoline into C02 and water in the presence of adequate nutrients and oxygen. Soil bacteria have been used for years for the remediation of contaminated soils. Plants are known to uptake, transpire, accumulate and detoxify heavy metals and many other toxic compounds. The physiologic and metabolic processes of plants are used to clean contaminated soils through phytoremediation. A goal of LID is to maximize the use of upland landscape with its soil/ microbes/ plant complex to treat runoff. Using upland systems to trap and remove pollutants allows one to more easily control the fate of contaminants and prevent them from entering the water column where they are almost impossible to contain and remove.

Public Outreach and Pollution Prevention

Pollution prevention and maintenance of on-lot LID BMP's are two key elements in a comprehensive approach. Effective pollution prevention measures can reduce the introduction of pollutants to the environment and extend the life of LID treatment BMP's. Public education is essential to successful pollution prevention and BMP maintenance. Not only will effective public education complement and enhance BMP effectiveness, it can also be used as a marketing tool to attract environmentally conscious buyers, promote citizen stewardship, awareness and participation in environmental protection programs and help to build a greater sense of community based on common environmental objectives and the unique character of LID designs.

Costs

LID case studies and pilot programs show that at least a 25% reduction in both site development and maintenance costs can be achieved by reducing grading and the use of pipes, ponds, curbs and paving. In one subdivision called Somerset which used the rain garden LID technique for water quality controls, the developer saved $4,500 per lot or a total of $900,000 by eliminating the need for curbs, ponds and drainage structures. Maintenance costs are also reduced in scale and magnitude by using the small LID practices. LID site designs require only routine landscape care and maintenance of the vegetation. This eliminates the high costs of pond maintenance associated with dam repairs and dredging.

Road Blocks to LID

In the development and acceptance of the LID site planning approach, a number of roadblocks had to be overcome. Regulating agencies, the development community and the public all had concerns about the use of new technology. The

LID design manual represents the culmination of four years of work to address all of these concerns and issues. Some of the major components of the LID approach, which addressed the many concerns, include:

1. develop an hydrologic analytical methodology to demonstrates the equivalence of LID to conventional approaches,
2. develop new road standards which allow for narrow roads, open drainage and cluster techniques,
3. streamline the review process for innovative LID designs which allow easy modification of site, subdivision, road and stormwater requirements,
4. develop a public education process which informs property owners on how to prevent pollution and maintain on lot BMP,
5. develop legal and educational mechanisms to ensure BMP's are maintained,
6. demonstrate the marketability of green development,
7. demonstrate the cost benefits of the LID approach,
8. provide training for regulators, consultants, public and political leaders and,
9. conduct research to demonstrate the effectiveness of bioretention BMP's.

Summary

LID is a viable economically sustainable alternative approach to stormwater management and the protection of natural resources. LID provides tangible incentives to a developer to save natural areas and reduce stormwater and roadway infrastructure costs. LID can achieve greater natural conservation by using conservation as a stormwater BMP to reduce the change in CN. As more natural areas are saved, less runoff is generated and stormwater management costs are reduced. This allows multiple use and benefits (environmental and economical) of the resource.

Additionally, developers have incentives to reduce infrastructure costs by reducing impervious areas, and eliminating curbs/gutters and stormwater ponds to achieve LID stormwater controls. Reduction of the infrastructure also reduces infrastructure maintenance burdens making LID designs more economically sustainable. Superior protection of aquatic and riparian ecosystems can be achieved since a LID developed watershed functions in a hydrologically similar manner as the predevelopment conditions. Recreating the predevelopment hydrological regime is a better way to protect the receiving waters than the conventional end-of-pipe mitigation approaches.

LID promotes public awareness, education and participation in environmental protection. As every property owner's landscape functions as part of the watershed, they must be educated on the benefits and the need for maintenance of the landscape and pollution prevention. LID developments can be designed in a very environmentally sensitive manner to protect streams, wetlands, forest habitat, save energy, etc. The unique character of a LID green development can create a greater sense of community pride based on environmental stewardship.

A National Menu of BMPs for the Phase II NPDES Storm Water Program

James H. Collins
Tetra Tech, Incorporated
Fairfax, VA

John A. Kosco, P.E.
USEPA/Office of Wastewater Management
Washington, DC

Introduction

Implementation of the Phase II NPDES Storm Water Program, which is presently "proposed," will be enhanced by the development of several tools used to help reduce discharges of pollutants from regulated small construction activities and from regulated small municipal separate storm sewer systems (MS4s). One of the tools being developed by EPA is a national menu of best management practices (BMPs), from which regulated Phase II municipalities can select as they develop their stormwater management programs.[1] The purpose of the national menu of BMPs is to provide a list of options available to regulated Phase II municipalities as they develop a stormwater programs. The national menu of BMPs may be adopted or modified by each NPDES permitting authority, or the permitting authority may develop its own menu of BMPs for use by the Phase II municipalities under its jurisdiction. This paper describes the process of developing the national menu of BMPs and measurable goals for each of the six minimum measures required to be in the stormwater management programs.

Process of Development

The process used in developing the menu was to first list appropriate BMPs for each minimum control measure, with subcategories under certain control measures.[2] Then, a basic format for presenting the information about each BMP was established. Information being provided for each BMP in the menu consists of BMP name, description, an illustration, applicability and design considerations, limitations, operation and maintenance, effectiveness, cost, and references. The menu is being prepared by EPA, with support from Tetra Tech, Incorporated, and the Center for Watershed Protection. A peer involvement/peer review group has been selected and will provide review and input to the process of developing the menu over the course of the next year. The menu is currently being reviewed and developed as a traditional hard copy document. Following development, there are plans to make the menu available as an interactive Web-based tool. The menu of BMPs is scheduled to be released by October, 2000.

Descriptions of Six Minimum Control Measures, with Lists of BMPs

1) Public Education and Outreach

This measure in the proposed rule calls for the creation of a public education program to inform citizens about the impacts that stormwater runoff can have on water quality. It includes the preparation and distribution of educational materials to the community, describing these impacts and steps that can be taken to reduce pollution from discharges of stormwater. Examples of such steps include proper septic system maintenance, limitations on use and runoff of household and garden chemicals, proper disposal of used motor oil or household hazardous wastes, and involvement in local stream restoration activities. The following BMPs have been identified (in the Draft Rule) under four major subcategory groups in the menu for the Public Education and Outreach minimum measure:

Public outreach/education for homeowners

- Lawn and garden activities, including proper pesticide use and disposal practices

- Water conservation practices
- Proper disposal of used materials or household hazardous wastes
- Pet waste management

Targeting public outreach/education

- Education/outreach for commercial activities (parking lots, gas stations, etc.)
- Tailoring outreach programs to communities, including minority and disadvantaged, as well as children
- Classroom education on stormwater
- Distributing stormwater educational materials (how, to whom)

Public Outreach Programs for New Development

- Low-impact development (includes buyer awareness, legal documents, and settlement documents)

Pollution Prevention Programs for Existing Development

- Educational display, pamphlet, booklet, utility stuffer
- Using the media (includes newspaper, magazine, radio, television, public service announcements, and Internet messages)
- Promotional giveaway

2) Public Participation/Involvement

This measure in the proposed rule includes compliance with state and local public notice requirements, but goes beyond that to encourage municipalities to seek public involvement in the development and review of their stormwater programs. Opportunities for members of the public to participate in the development of their municipality's stormwater management program may include serving as citizen representatives on a local stormwater management panel, attending public hearings, working as citizen volunteers to educate others about the program, assisting in program coordination with other pre-existing programs, or participating in volunteer monitoring efforts. The following BMPs have been identified under two major subcategory groups of practices in the menu for the Public Participation/Involvement minimum measure:

Activities/Public Participation

- Storm drain stenciling
- Stream cleanup
- Volunteer monitoring
- Reforestation program
- Wetland plantings
- Adopt-A-Stream program

Involvement/Public Opinion

- Watershed organization

- Stakeholder meetings (includes local stormwater management ponds)
- Attitude surveys
- Community hotlines

3) Illicit Discharge Detection and Elimination

This measure envisions the creation of an illicit discharge detection and elimination program. Specific program elements include developing a demonstrated knowledge base of the MS4, using maps or other documents to identify major outfalls and pipe networks on a topographic basis; developing a plan to address illicit discharges into the MS4, including appropriate enforcement procedures to the extent allowable by law; and developing a process for informing the public about the hazards associated with illicit discharges and the improper disposal of waste. For example, recycling programs and other public outreach activities could be developed to address sources of illicit discharges, including used motor oil, antifreeze, pesticides, herbicides, and fertilizers. The following BMPs have been identified for the menu for the Illicit Discharge Detection and Elimination minimum measure:

- Failing septic systems
- Industrial connections
- Recreational sewage
- Sanitary sewer overflows
- Identifying illicit connections
- Wastewater connections to the storm drain system

4) Construction Runoff Control

This measure provides for the enforcement of a program to reduce pollutants in storm water runoff from construction activities resulting in the disturbance of one acre to five acres of land. The program would apply to the individuals responsible for activities at construction sites and should include an ordinance to control sediment and erosion; a mechanism to ensure control of other wastes at construction sites, such as discarded building materials, concrete truck washout, and sanitary waste that could impact water quality; requirements for the implementation of appropriate BMPs, such as silt fences, temporary detention ponds and hay bales; provisions for preconstruction review of site management plans; procedures for receipt and consideration of comments and other information provided by the public; regular inspections during construction; and penalties to ensure compliance. The following BMPs have been identified under 11 major subcategory groups of practices in the menu for the Construction Runoff Control minimum measure:

Minimize Clearing

- Land grading
- Permanent diversion
- Preservation of natural vegetation (includes tree preservation and protection)

Stabilize Exposed Soils

- Chemical stabilization
- Mulching

- Permanent seeding
- Sodding
- Soil roughening

Protect Steep Slopes

- Geotextiles
- Gradient terraces
- Soil retention (includes slope stabilization, retaining wall, reinforcement)
- Temporary slope drain (a.k.a. - pipe slope drain)
- Temporary storm drain diversion

Stabilize Drainage Ways

- Check dam (a.k.a. grade stabilization structure)
- Filter berm
- Grass-lined channel
- Riprap

Protect Waterways

- Temporary diversion
- Temporary stream crossing (bridge, culvert)
- Vegetated buffer

Phase Construction

- Construction sequencing
- Dust control

Install Perimeter Controls

- Temporary diversion dikes, earth dikes, and interceptor dikes (includes temporary fill diversions)
- Sand fence and wind fences
- Silt fence
- Brush barriers

Install Sediment Trapping Devices

- Sediment basin/rock dam
- Sediment filters and sediment chambers

- Sediment traps

Inlet Protection

- Stabilized construction entrances
- Storm drain inlet protection (includes block and gravel, excavated drop, fabric drop, and sod drop inlet protection)

Education and Awareness

- Contractor certification and inspector training
- BMP inspection and maintenance

5) Post-Construction Runoff Control

This measure uses post-construction controls as part of a program to address stormwater runoff from new development and redevelopment projects using appropriate structural and non-structural BMPs. Non-structural BMPs are preventive actions using management and source controls, such as policies and ordinances that result in protection of natural resources and prevention of runoff. Non-structural BMPs might include requirements that encourage growth in identified areas while protecting sensitive areas such as wetlands and riparian zones, minimizing impervious surfaces, maintaining open space, and minimizing clearing, grading, or other disturbance of soils and vegetation. Some of the typical structural BMPs include storage practices (wet ponds, extended-detention dry ponds, or other storage facilities with outlets); infiltration practices (infiltration basins, infiltration trenches, and porous pavement); and filtration practices (grassed swales, sand filters, and vegetated filter strips). This measure should also ensure effective and reliable performance by providing for the long-term operation and maintenance of the selected BMPs. The following BMPs have been identified under eight major subcategory groups of practices for the Post-Construction Runoff Control minimum measure:

Ponds

- Extended detention dry basin or pond (with or without permanent pools or shallow marshes near the outlet), includes tank storage
- Wet pond

Infiltration Practices

- Infiltration basin (a.k.a. - recharge basin)
- Infiltration trench (a.k.a. - infiltration galley)
- Porous pavement

Filtration Practices

- Bioretention
- Filters, including organic media filter (peat sand or compost-type), sand filter, multichamber treatment train (MCTT) system, and inlet filtration systems

Vegetative Practices

- Constructed wetland, shallow marsh
- Grassed swale

- Vegetative filter strip

Runoff Pretreatment Practices

- Catch basin
- In-line storage, includes flow regulator information
- Manufactured systems for water quality inlets

Experimental Practices

- Alum injection system

On-lot Treatment

- On-lot treatment includes information on dry wells, roof downspout systems, rain barrels, exfiltration storage systems, french drains, and dutch drains

Better Site Design

- Conservation easements
- Infrastructure planning
- Buffer zones/setbacks
- Open space development
- Narrow streets
- Curb elimination
- Green parking lot
- Alternative turn-around
- Urban forestry
- Alternative pavers

6) Pollution Prevention/Good Housekeeping

This measure in the proposed rule envisions the creation of an operation and maintenance/training program to prevent or reduce pollutant runoff from municipal operations. The program should include training for municipal staff to address prevention measures in government operations, such as park and open space maintenance, fleet maintenance, planning, building oversight and stormwater collection system maintenance. Other possible pollution prevention activities that might be relevant include controls for reducing or eliminating the discharge of pollutants from streets, roads, highways, municipal parking lots, maintenance and storage yards, and waste transfer stations; programs to promote recycling and pesticide use information; procedures for proper disposal of waste removed from municipal systems and public areas (such as streets) including dredge spoil, accumulated sediments, floatables, and other debris; and new flood management projects to assess the impacts on water quality and examine exiting projects to determine if they need additional water quality protection devices or practices. The following BMPs have been identified under two major subcategory groups of practices in the menu for the Pollution Prevention/Good Housekeeping minimum measure:

Source controls

- Animal waste collection
- Automobile maintenance
- Car washing
- Illegal dumping control
- Landscaping and lawn care
- Pest control
- Parking lot and street cleaning
- Roadway and bridge maintenance
- Septic system controls

Materials Management

- Alternative products
- Hazardous materials storage
- Household hazardous waste collection
- Road salt application and storage
- Spill response and prevention
- Used oil recycling

Conclusion

As part of the Stormwater Phase II Tool Box, the Menu of BMPs should help municipalities develop, implement, and enforce the Phase II program. The menu will be available in time for regulated municipalities to use in complying with stormwater management program requirements under Phase 2 permits and might also benefit other jurisdictions and individuals.

Urban Drainage and Flood Control District
Denver, CO

Abstract

The overall purpose this US EPA funded cooperative research program with the American Society of Civil Engineers (ASCE) is to develop a more useful set of data on the effectiveness of individual best management practices (BMPs) used to reduce pollutant discharges from urban development. BMP performance data gathered at a particular site should not only be useful for that site, but also be useful for comparing studies of similar and different types of BMPs in other locations. Almost all BMP effectiveness studies in the past have provided very limited data that is useful for comparing BMP design and selection among individual BMP types (e.g. sand filters). This paper overviews some of the problems of past BMP effectiveness studies from the perspective of comparability between studies. It suggests some of the ways that data should be collected to make it more useful for assessing factors (such as settling characteristics of inflow solids and physical features of the BMP) that might have led to the performance levels achieved. It briefly presents the database that has been developed by this project, which not only serves as a tool for storing data from existing studies, but as a tool for entering and storing data collected from future studies. Discussed are considerations that affect data transferability, such as effectiveness estimations, statistical testing, etc. It overviews the efforts to establish and analyze the data base for existing studies and overviews proposed analyses for the future, when more studies that have followed the protocols are available. The database has specifically pointed out the need for additional BMP performance studies, as the current data is very sparse in terms of studies that have recorded enough information to be useful in assessing BMP type performance.

Introduction

Many studies have assessed the ability of stormwater treatment BMPs (e.g., wet ponds, grass swales, stormwater wetlands, sand filters, dry detention, etc.) to reduce pollutant concentrations and loadings in stormwater. However, in reviewing and summarizing the information gathered from these individual BMP evaluations, it is apparent that inconsistent study methods and reporting make wider-scale assessments difficult, if not impossible. For example, individual studies often included the analysis of different constituents and utilized different methods for data collection and analysis, as well as varying degrees of information on BMP design and inflow characteristics. Just the differences in monitoring strategies and data evaluation alone contribute significantly to the range of BMP "effectiveness" that has been reported. These differences make combining these individual studies almost impossible to assess what design factors may have contributed to the variation in performance (Strecker et al., 1992). Urbonas (1994 and 1995) and Strecker (1994) summarized information that should be recorded regarding the physical, climatic, and geological parameters that likely affect the performance of a BMP and considerations regarding sampling and analysis methods.

Efficiency, Effectivness, and Performance

In order to better clarify the terminology used to describe the level of treatment achieved and how well a device, system, or practice meets its goals, definitions of some terms often used loosely in the literature are provided here. These terms help to better specify the scope of monitoring studies and related analyses:

- Best Management Practice (BMP) - A device, practice, or method for removing, reducing, retarding, or preventing targeted stormwater runoff constituents, pollutants, and contaminants from reaching receiving waters

- BMP System - A BMP system includes the BMP and any related bypass or overflow. For example, the efficiency (see below) can be determined for an offline retention (Wet) Pond either by itself (as a BMP) or for the BMP system (BMP including bypass)

- Performance - measure of how well a BMP meets its goals for stormwater that is treated by the BMP

- Effectiveness - measure of how well a BMP system meets its goals in relation to all stormwater flows

- Efficiency - measure of how well a BMP or BMP system removes pollutants

The ASCE project team is working with available data to determine efficiency of BMPs and BMP systems. In addition, effectiveness and performance are being evaluated, acknowledging the limitations of existing information about the goals of specific BMP projects. Quantification of efficiency only evaluates a portion of the overall performance or effectiveness of a BMP or BMP system. Calculation of the efficiency helps to determine additional measures of performance and effectiveness, for example the ability of a BMP to meet any regulatory goals. A list of typical goals and the current ability of the ASCE/EPA project to help evaluate them is shown in Table 1.

Problem: BMP Performance Study Inconsistencies

Studies of BMP effectiveness have utilized significantly different:

- sample collection techniques (e.g., from sample collection types--grab, composite, etc., flow measurement techniques, to how the sample was composited, etc.);

- water quality constituents, including: chemical species, methods (detection limits), form (e.g., dissolved vs. total, vs. total recoverable, etc.), and treatment potential;

- data reporting on tributary watershed and BMP design characteristics (e.g., tributary area or watershed attributes such as percent impervious, land use categories, rainfall statistics, etc.);

- effectiveness estimation techniques (there are at least four common techniques that have been utilized to assess effectiveness that can cause significant differences in pollutant removal reporting, with the same set of data), and potential alternatives to reporting just concentration/loading reductions; and

- statistical validation of results (typical lack of statistical tests to determine if the reported removal efficiency can in fact be shown to be statistically different than zero).

Monitoring strategies that could be employed to monitor BMP effectiveness include:

- New BMP installation with new development- input/output (e.g., monitor new detention pond of newly developed watershed and evaluate inflow concentrations/loads vs. outflows) or conduct a "control" watershed comparison

- Retrofit of existing or new single BMP within existing watershed--input/output, and/or, before/after (e.g., retrofit of an existing flood control basin for water quality)

- Watershed-wide new structural or non-structural--"control" watershed comparison (e.g., new BMP catch basins in developing area)

- Watershed-wide structural retrofit or application of non-structural - before/after, and/or, "control" watershed comparison (e.g., catch basin retrofit on watershed scale)

Input/output monitoring is the typical approach utilized. However, control watersheds and before/after approaches have also been employed. All of the other potential factors that could be contributing to differences in performance must identified and accounted. On the other hand, it is beneficial to be able to show that a watershed-wide difference is or is

Table 1. Goals of BMP Projects and the Ability of the National Stormwater BMP Database to Provide Information Useful for Determining Performance and Effectiveness

Goals of BMP Projects Category		Ability to Evaluate Performance and Effective
Hydraulics	•Improve flow characteristics upstream and/or downstream of BMP	-
Hydrology	•Flood mitigation, improve runoff characteristics (peak shaving)	✓
Water Quality (Efficiency)	•Reduce downstream pollutant loads and concentrations of pollutants	✓
	•Improve/minimize downstream temperature impact	✓
	•Removal of litter and debris	✓[1]
Toxicity	•Reduce acute toxicity of runoff	✓[1]
	•Reduce chronic toxicity of runoff	✓[1]
Regulatory	•Compliance with NPDES permit	-
	•Meet local, state, or federal water quality criteria	✓[2]
Implementation Feasibility	•For non-structural BMPs, ability to function within management and oversight structure	-
Cost	•Capital, operation, and maintenance costs	✓[1]
Aesthetics	•Improve appearance of site	-
Maintenance	•Operate within maintenance, and repair schedule and requirements	✓[1]
	•Ability of system to be retrofit, modified or expanded	✓
Longevity	•Long-term functionality	-
Resources	•Improve downstream aquatic environment/erosion control	-
	•Improve wildlife habitat	-
	•Multiple use functionality	-
Safety, Risk and Liability	•Function without significant risk or liability	-
	•Ability to function with minimal environmental risk downstream	-
Public Perception	•Information is available to clarify public understanding of runoff quality, quantity and impacts on receiving waters	✓

✓ can be evaluated using the ASCE/EPA Database as information source
✓[1] will be able to be evaluated using the database as primary source of information after enough studies have been submitted
✓[2] can be evaluated using the database the primary source of information combined with a secondary source of comparative data

not being detected with BMP implementation. These differences in monitoring approach certainly effect the ability to compare studies.

Any of the above topics would require an in-depth discussion beyond the scope of this paper. Therefore, this paper will present only a brief overview of each and some potential solutions for improving how data is collected. The ASCE project team has developed a set of protocols and a database on BMP performance studies with the purpose of improving the consistency of BMP monitoring information. The project includes:

- Developing protocols for BMP monitoring and reporting
- Developing a database on BMP performance studies
- Conducting an evaluation of existing information to assist EPA in providing guidance to the regulated community

The database specifies a chosen set of reporting information, but does not guide users on how to develop such information. For example, it does not specify in detail what a flow-weighted composite sample is and how it should be collected. The next step beyond the EPA protocols and database effort should be a guidance document on monitoring data collection strategies and techniques to improve their consistency and ultimate transferability. A few of the issues related to proper guidance are discussed in the next two sections. It should be recognized that, with the development of the database and the protocols, it will be a number of years (5 to 10) before a significant number of new studies on BMPs are conducted utilizing the protocols. Therefore, a rigorous evaluation of BMP selection and design factors will need to take place in the long-term future.

Recommended Parameters for Assessing BMP Performance

In developing a method for quantifying BMP performance, it is helpful to look at the objectives of previous studies seeking such a goal. BMP performance studies usually are conducted to obtain information regarding one or more of the following objectives:

- What degree of pollution control does the BMP provide under typical operating conditions?
- How does performance vary from pollutant to pollutant?
- How does performance vary with various input concentrations?
- How does performance vary with large or small storm events?
- How does performance vary with rainfall intensity?
- How do design variables affect performance?
- How does performance vary with different operational and/or maintenance approaches?
- Does performance improve, decay, or remain the stable over time?
- How does the BMP's performance compare relative to other BMPs?
- Does the BMP reduce toxicity to acceptable levels?
- Does the BMP cause an improvement in downstream biotic communities?
- Does the BMP have potential downstream negative impacts?

The monitoring efforts implemented most typically seek to answer a subset of the above questions. This often leaves larger questions about the performance of the BMP, and the relationship between design and performance, unanswered. Standardization of BMP data collection and evaluation methods (i.e., guidance and the ASCE/EPA database) allows this broader set of questions to be examined.

There has been a very wide variety of pollutants analyzed in BMP and characterization studies. The protocols established under the EPA-funded cooperative research program recommend a standard set of constituents for BMP testing programs. Table 2 presents the recommended constituents developed from the review of previous studies with an understanding of costs and likelihood of providing meaningful results. A discussion of how these constituents were selected and a detailed description of each can be found in Strecker (1994).

There are some practical and technical considerations regarding data reporting which would facilitate data usefulness, including consistent formatting of data, the clear indication of QA/QC results, standard comparisons to water quality criteria, reporting of tributary watershed characteristics, and BMP design information. The last two items are considered critical for evaluation of what contributed to BMP effectiveness in one location over another.

Data Reporting. It is recommended that all constituent concentration data be reported as event mean concentrations (EMCs). These statistics should be based on use of the lognormal distribution. The NURP and FHWA studies (EPA,

Table 2. Recommended Standard Analytical Tests for Urban Stormwater BMP Assessment

Lab Analysis	EPA Method Number	Detection Limit (mg/l)
Conventional		
TSS	EPA 160.2	1
TDS	EPA 160.1	1
TOC	EPA 415.1	3
COD	EPA 410.4	1
Total Hardness	SM 314-A	1
Nutrients		
(NH^3 - N)	SM 417-AD	0.1
Total phosphorus (as P)	SM 424-CE	0.005
Ortho-phosphate (as P)	SM 424-E	0.05
Nitrate + nitrite (NO_3 + NO^2 - N)	EPA 353.1 or .2	0.05
Total Metals		
Cd (cadmium)	EPA 7131	0.0002
Pb (lead)	EPA 7421	0.0003
Cu (copper)	EPA 6010	0.001
Zn (zinc)	EPA 6010	0.001
Dissolved Metals		
Cd (cadmium)	EPA 7131	0.0002
Pb (lead	EPA 7421	0.0003
Cu (copper)	EPA 6010	0.001
Zn (zinc)	EPA 6010	0.001

1983a; Driscoll et al., 1990) identified that the lognormal distribution is suitable for characterizing EMC distributions. The high degree of variability is why proper statistical techniques should be employed to evaluate whether a measured difference between BMP before/after or input/output is significant. The recommended inclusion of outlet data as a part of any paper or report will allow comparisons of typical outlet concentrations and may allow the determination of the lowest or average expected concentration from a particular type of BMP. For example, it may be that wet ponds may only be able to treat to some minimum concentration range at the outlet and the "effectiveness" is greatly impacted by the inlet concentrations.

Quality Assurance/Quality Control (QA/QC). All monitoring studies should include a QA/QC program. The details and results of the QA/QC program should be reported in monitoring study reports and summarized in papers. It is especially important to discuss when data are characterized as estimates due to QA/QC results and when detection limits were affected. Too often this information is not included.

Comparisons to Water Quality Criteria. A method to gage effectiveness could be to monitor how the BMP affects the number of times (frequency) that EPA water quality criteria are exceeded in both the inflow and the outflow, to assess how the BMP reduces (or does not reduce) the frequency of potentially toxic events. For heavy metals analyses, it is recommended that hardness be collected for all storms monitored and that comparisons to criteria be made utilizing the dissolved fraction with the computed aquatic criteria as modified by EPA (1993b).

Watershed and BMP Design Parameters. Table 3 presents a summary of these parameters. These parameters (more detailed parameter lists are available on ASCE's Web page at http://www.asce.org/peta/tech/ nsbd01.html) have been selected with the purpose of being able to utilize this information to evaluate what BMP design attributes and tributary watershed characteristics can be linked to BMP effectiveness information.

The primary goals of the ASCE/EPA database development process were to facilitate efficient data entry, provide useful queries of stored data, and output information in a comprehensive and applicable manner through a user-friendly interface. The database was written in Microsoft® Access incorporating Access relational database engine and features and the Visual Basic® for Applications programming language for customization of the functional aspects of the front end. Distribution will take place initially as an Access run-time version on CD-ROM, but will be available in the near future over the Internet.

Table 3. Parameters to Report with Water Quality Data for Various BMPs

Parameter Type	Parameter	Retention (Wet) Pond	Extended Detention (Dry) Basin	Wetland Pond Basin	Grass Swale/ Wetland Channel	Sand/Leaf Compost Filter	Oil & Sand Trap/ Hydro-dynamic Device	Infiltration and Perc..
Tributary Watershed	Tributary watershed area, average slope, average runoff coefficient, length, soil types, vegetation types	•	•	•	•	•	•	•
	Total tributary watershed impervious percentage and percent hydraulically connected	•	•	•	•	•	•	•
	Details about gutter, swer, swale, ditches, parking, roads in watershed	•	•	•	•	•	•	•
	Land use types (res., comm., ind., open) and acreage	•	•	•	•	•	•	•
General Hydrology	Date and start/stop times for monitored storms	•	•	•	•	•	•	•
	Runoff volumes for monitored storms	•	•	•	•	•	•	•
	Peak 1-hr intensity	•	•	•	•	•	•	•
	Design storm/flood recurrence intervals and magnitude	•	•	•	•	•	•	•
	Peak flow rate, depth, and Manning's roughness coefficient for the 2-year storm				•			
	Depth to seasonal high groundwater/impermeable layer		•		•			•
	Saturated hydraulic conductivity, infiltration rate, soil group				•			•
	Average annual values for number of storms, precipitation, snowfall, min./max. Temp., from appropriate weather station	•	•	•	•	•	•	•
Water	Alkalinity, hardness and pH for each monitored storm	•	•	•	•	•	•	•
	Water temperature	•	•	•	•	•	•	•
	Sediment settling velocity distribution, when available	•	•	•	•	•	•	•
	Facility on- or off-line?	•	•	•	•	•	•	•
	Bypassed flows during events	•	•	•	•	•	•	•

General Facility	Type and frequency of maintenance	•	•	•	•	•	•	•
	Types and location of monitoring instruments	•	•	•	•	•	•	•
	Inlet and outlet dimensions, details, and number	•	•	•	•	•	•	•
	Media or granular material depth, type, storage volume, and porosity					•		•
Wet Pool	Volume of permanent pool	•		•		•	•	
	Length of permanent pool	•		•		•	•	
	Permanent pool surface area	•		•		•	•	
	Littoral zone surface area	•						
	Solar radiation, days of sunshine, wind speed, pan evaporation, from appropriate weather station	•	•	•	•			•
Detention Volume	Detention (or surcharge) and flood control volumes	•	•	•		•	•	•
	Detention basin's surface area and length	•	•	•		•	•	•
	Brimful and half-brimful emptying time	•	•	•		•	•	•
	Bottom stage/infiltrating surface area and type			•	•			•
Pretreatment Plant	Forebay volume, surface area	•	•	•		•	•	•
	Relationship to other BMP's upstream	•	•	•	•	•	•	•
Wetland Plant	Wetland/swale type, surface area, and length, side slope lbottom width for swales and channels)			•	•			
	Percent of wetland surface between 0-12", 12-24", and 24-48"			•	•			
	Plant species and age of facility	•	•	•	•			

Estimation of BMP Pollutant Removal Effectiveness and Effectiveness

BMP pollutant removal effectiveness estimations are not straightforward and a wide variety of methods have been employed. Martin and Smoot (1986) discussed three types of methods to compute efficiencies, including an efficiency ratio, sum of loads, and regression of loads. Many researchers have utilized an efficiency measure based upon storm pollutant loads into and out of the BMP on a storm-by-storm basis. This weights the effectiveness considering that all storms are "equal" in computing the average removal. However, it is readily apparent that all storm volumes and their associated concentrations are not equal.

One factor that complicates the estimation of the effectiveness is that for wet ponds and wetlands, (and other BMPs where there is a permanent pool), comparing effectiveness on a storm-by-storm basis neglects the fact that the outflow for a particular event being measured may have little or no relationship to the inflow for that same event. Based upon a national characterization of rainfall (Driscoll, et. al., 1989), if a basin were sized to have a permanent pool equal to the average storm, about 60 to 70% of the storms would be less than this volume. Therefore, in many cases, flows leaving may have little or no relationship to flows entering the pond. Storm-to-storm comparisons are probably not valid. It is probably more appropriate to utilize statistical characterizations of the inflow and outflow concentrations to evaluate effectiveness or, if enough samples are collected (i.e., almost all storms monitored), to utilize total loads into and out of the BMP.

Table 4 compares three of the methods, including percent removal by storm with a statistical characterization of inflow/outflow concentration and a simple comparison of total loads in and out for the sampled storms for an example site. The removals estimated differ by up to 18 percentage points. In this record, there are several storm events where inflow concentrations were relatively low and therefore the system was not "efficient." However, it was effective at maintaining the effluent quality.

Table 4. Comparison of BMP Pollutant Removal Efficiency Techniques

Storm	Volume of Flow (ft^3) Inflow = Outflow	Concentration (mg/l) In	Concentration (mg/l) Out	Load (lbs) In	Load (lbs) Out		% Removal by storm
1	445,300	352	24	9780	670		93%
2	649,800	30	25	1220	1010		17%
3	456,100	99	83	2820	2360		16%
4	348,111	433	141	9410	3060		67%
5	730,261	115	63	5240	2870		45%
	Med	139	65			A	
	Cov	1.48	.86	28,470	9,970	V	48%
	Mean	249	85			G	
		Conc 66%		Loads 65%			

note: 1 lb_m = 2.2046 kg and 1 ft^3 = 0.028317 m^3

Based on these factors, it is recommended that a statistical characterization of inflows vs. outflows be utilized. Use of the log-transform of EMCs is recommended. Tests of the applicability of a log transform should be made to support the transform of data when sufficient data is available. Standard descriptive statistics, box-and-whisker plots, and normal probability plots of the transformed data for both the inflow and outflow should be employed to clearly demonstrate not only the differences in the mean EMCs, but also the effectiveness of the BMP throughout the range of influent and effluent EMCs. This approach provides the ability to determine whether any apparent differences in inflow and outflow EMC populations are statistically greater than zero. If enough data on storms is collected, (e.g., continuous samples over an extended period including base flow measurements where significant), the total loads in and out may also be an acceptable method. A graphical look at the distribution of contributing storms will often provide insight into the applicability of the method, (e.g., do a small number of large storms dominate the resulting effectiveness value).

The variability in runoff concentrations from event to event is large. In attempting to statistically characterize a BMP influent concentration (and outflow), the more data the better. As mentioned above, there are a number of types of BMP evaluations that can be conducted: (1) standard evaluation of a single BMP, testing input and output, (2) evaluation of multiple BMPs within a basin (before/after or control basin), and (3) evaluation of a BMP with multiple inlets (where it might be very difficult and expensive to evaluate the BMP utilizing input/output). All methods should require that a rigorous statistical approach be applied in selecting the number of samples to be collected to help assure detection of a given level of change.

As an example of the number of samples required to detect a "true" difference, Table 5 presents an analysis of two of the Portland monitoring stations (WCC, 1993) where 10 flow-weighted composite samples were collected. The Fanno Creek station is a large (about 1,200 acres) residential catchment that is in an open channel, while the M1 station is a smaller (about 100 acres) mixed land use station that is in a pipe. An analysis of a variance-based test was utilized with the existing data to determine how many samples are estimated to be needed to detect a 5%, 20%, and 50% change in the mean concentration at the station. The test was performed considering an 80% probability that the difference will be found to be significant, with a 5% level of significance (Sokal and Rohlf, 1969). This analysis does not consider potential seasonal effects on the collection of data as a factor. Even so, quite a large number of samples would be required to detect a 5% to 20% difference in concentrations. In many locations, given that there may be only 10 to 20 storm events per year that are large enough to monitor, it would take a number of years of sampling all storm events to be able to detect small differences.

Table 5. Analysis of Sample Sizes Needed to Statistically Detect Changes in Mean Pollutant Concentrations from 2 Stations in Portland, Oregon

		Number of Samples Required to Detect the Indicated % Reduction in Site Mean Concentration*		
Monitoring Site	Parameter	5%	20%	50%
R1 - Fanno Creek	TSS	202	14	4
Residential	Copper	442	29	6
	Phosphorus	224	16	4
M1 - NE 122nd	TSS	61	5	2
Columbia	Copper	226	15	4
Slough Mixed Use	Phosphorus	105	8	3

*80% certain of detecting the indicated % reduction in mean of the EMCs.

There are numerous examples in the literature where small differences (2 to 5%) have been reported based upon fewer samples than indicated by this analysis. This highlights the need to be more rigorous with regard to statistical testing of reported effectiveness estimates. To detect larger changes, the number of samples becomes reasonable. The mixed land use catchment in Portland is currently being studied for the effectiveness of the implementation of a number of source controls and other controls that do not lend themselves to input/output testing. Examples include maintenance changes (catch basin cleaning, street sweeping); education (business and residences); tree planting, and others. Post-BMP monitoring will be conducted along with qualitative evaluations.

Another approach that this study will be evaluating is the use of effluent data to compare to design criteria. It has been suggested by some researchers that BMPs may be able to treat only to a given concentration and therefore, if relatively clean water is entering a BMP, performance based upon efficiency may not fully characterize whether a BMP is well-designed. An example of this is based upon Rushton et al. (1997). The pond was located at the Southwest Florida Water Management District service office in Tampa. The drainage basin is 6.5 acres with about 30% of the watershed covered by roof tops and asphalt parking lots, 6% by a crushed limestone storage compound and the remaining 64% as a grassed storage area. The pond was modified twice after initial construction; therefore, there are three periods of performance data for three different designs. The first pond had an average retention time of 2 days, the second 5 days and the third 15 days. The second design added wetland features, while the third utilized deeper and larger pools.

Figure 1 shows the input and output median concentrations in log based 10 scale as well as the 95% confidence limits. The study reported that performance of the pond (defined as removal efficiency) decreased after the first modification. What appears to be evident is that the average inflow concentrations were much lower during the second period, while the outflow concentrations were about equal (less, but not statistically different from the first design). It appears that with the original and first modified designs that the effluent level was not decreased. However, one could not say that the BMP was any poorer in efficiency. The last design appears to have lowered the potential effluent concentration, but the major difference in efficiency came from the significantly higher inflow concentrations during the sampling period. This example points out the need to carefully think about whether pollutant removal efficiency is an accurate representation of how well a BMP works or does not.

In many cases, there is a need to conduct dry weather analyses between storms on BMPs with dry weather flows. It may be that pollutants captured during storms are slowly released during dry weather discharges.

Biological and downstream physical habitat assessments such as aquatic invertebrate sampling and habitat classification should be explored as an alternative to just utilizing chemical measures of effectiveness (Maxted, 1999). Long-term trends in receiving water quality, coupled with biological assessments, would likely be a much better gage of the success of the implementation of BMPs, especially on an area-wide basis.

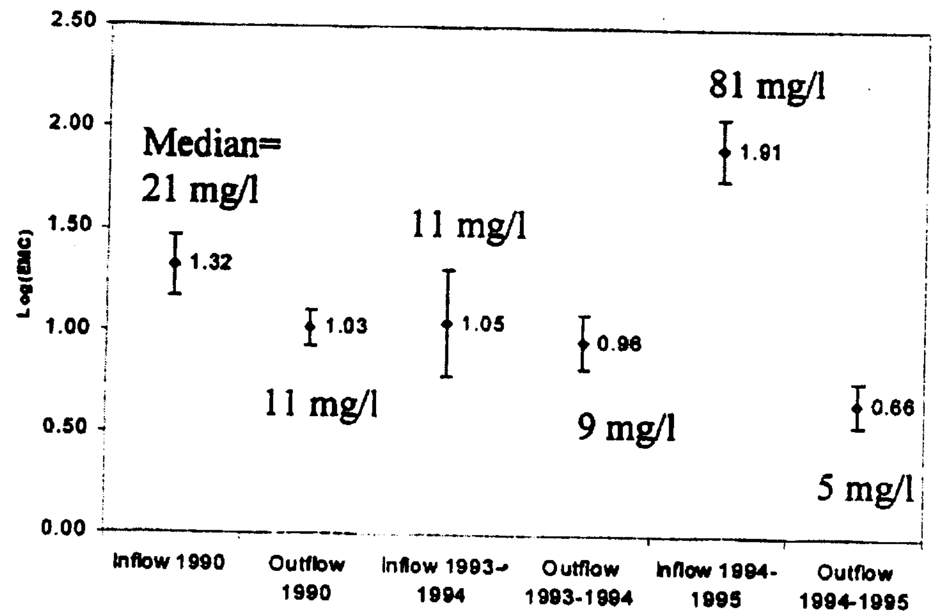

Figure 1. Inflow and Outflow Log Mean TSS Concentrations (mg/l) and 95% Confidence Limits for Different Designs of a Wet Pond Located at SWFWMD Service Office in Tampa, Florida.

Summary and Recommendations

There is a great need to have consistency with the constituents and methods utilized for assessing BMP effectiveness. This paper has presented only some of the consistency issues. It is recommended that researchers who undertake BMP effectiveness studies consider the recommendations suggested here, by Urbonas (1995) and other recommendations based upon further analysis of this subject. It is the authors' opinion that EPA should require studies receiving federal funding to conduct BMP effectiveness studies that utilize standard methods as suggested here, together with much still-needed detailed guidance on data collection and sampling methods to improve data transferability.

Acknowledgments

The authors wish to thank Gene Driscoll, Jonathan Jones, Bob Pitt, Bill Snodgrass, and Larry Roesner for their helpful discussions and comments on the subject. Jonathon Jones, Jane Clary, and John O'Brien from Wright Water Engineers developed the Database Structure and Platform as members of the ASCE project team. The Urban Water Resources Research Council has provided very beneficial support and feedback. Finally, the assistance by EPA in funding this cooperative agreement is acknowledged as well as the helpful participation of Eric Strassler and Jesse Pritts in reviewing our work.

Summary

The *Texas Nonpoint SourceBOOK* is an Internet-based resource that has been developed to assist public works officials across Texas with storm water management. The *SourceBOOK* provides basic information about storm water quantity and quality impacts, outlines how to develop and implement a local storm water management program, identifies localized water quality issues, and provides an interactive database of more than 100 Best Management Practices (BMP's) to use in a variety of situations.

The *Texas Nonpoint SourceBOOK* provides information for the novice as well as the experienced storm water manager. The project was funded by the Environmental Protection Agency and matching funds from 20 local governments across Texas. The North Central Texas Council of Governments (NCTCOG) served as project administrator. The *SourceBOOK* was developed by a consulting team lead by Camp Dresser & McKee Inc. (CDM). A Project Management Committee of local governments provided project oversight. After extensive review via the Internet, the *SourceBOOK* was officially endorsed by the Executive Committee of the Texas Chapter – American Public Works Association (APWA). Five training workshops were conducted across the state. The *SourceBOOK* is intended to be a living resource, with additions and changes occurring continually in response to input from users. A feedback page allows direct input from the Internet.

Why a *Texas Nonpoint SourceBOOK*?

Recognizing the need for improved communication, cooperation, and education statewide on stormwater issues, a *Statewide Storm Water Quality Task Force* was established by the Executive Committee of the Texas Chapter - American Public Works Association. At an organizational meeting in February 1994, a Steering Committee and subcommittees were formed. The various subcommittees immediately tackled the task of identifying current issues and needs regarding storm water quality and nonpoint source pollution, particularly with respect to the needs of public works officials across Texas.

Already known was that nonpoint sources, including stormwater, contribute to water pollution problems. The Water Quality Subcommittee began to review data from the Texas Clean Rivers Program, available nonpoint source monitoring data, and the State's Nonpoint Source Water Pollution Assessment Report. They presented this assessment at subsequent meetings of the Task Force. Water quality problems were known, but not how best to address them.

What was not known was the applicability and cost-effectiveness of Best Management Practices (BMPs) for addressing many of the typical water quality pollutants: bacteria, pesticides, nutrients, metals, toxic chemicals, and others. The Best Management Practices (BMP) Subcommittee surveyed local governments across Texas on BMP implementation but found little technical data. It was evident that until questions such as applicability and cost-effectiveness could be answered, local governments would not invest limited public funds on storm water controls.

A project was formulated that would provide the assistance local governments needed by developing an internet-based resource of storm water management information. At the time it was a striking idea, since the Internet was very new and few local governments had any "on line" experience. Using the emerging Internet would provide ready electronic access and would allow for the use of new technologies in communication. This resource was to be called the *Texas Nonpoint SourceBOOK*, and would be developed in both "hardcover" and electronic form. A grant application, submitted to the Texas Natural Resource Conservation Commission under the Section 319(h) Nonpoint Source Program, was awarded in the spring of 1996. Work on the project began in September, 1996.

How Was the *Texas Nonpoint SourceBOOK* Developed?

The North Central Texas Council of Governments provided staff support and general administrative oversight. To guide the development of the *SourceBOOK*, a Project Management Committee was established from the Texas Chapter-APWA membership. Among its first tasks was issuing a Request for Proposals for professional consultant assistance, and selecting the consultant finalists. From the finalists the Committee selected a consultant team led by the firm Camp Dresser & McKee Inc., in association with Espey Huston & Associates, Inc.; Center for Watershed Protection; Booth, Ahrens & Werkenthin, P.C.; Carter Burgess; and Pavlik & Associates. Together, the committee and consultants used the State's Nonpoint Source Water Assessment Report and supporting information to identify particular pollutants from priority watersheds and related pollution prevention BMPs.

During FY97, the Project Management Committee worked with the consultant to establish the format of the *Texas Nonpoint SourceBOOK* on the Internet. Presentations on local BMP experiences were made at the TX-APWA Short Course at Texas A&M in February, 1997. Initial consultant materials were reviewed by the TX-APWA general membership at its summer, 1997, Annual Meeting. A draft of the *Texas Nonpoint SourceBOOK* was presented to the TX-APWA general membership at the February 1998 Short Course, and local government comments were solicited.

The TX-APWA Executive Committee endorsed the *Texas Nonpoint SourceBOOK* in February, 1999. It is available through the Internet and on CD-ROM for use by local governments across Texas. The Committee and consultant conducted technology transfer and training workshops on storm water management and the *Texas Nonpoint SourceBOOK* at five regional one-day workshops across Texas during February and March of 1999.

How is the *Texas Nonpoint SourceBOOK* Organized?

The *SourceBOOK* is designed to make use of the capabilities of the Internet. This includes the ability to organize and present textual and graphical information through common browser formats, as well as providing active links to related sites. The design of the content of the *SourceBOOK* maximized the use of existing web sources wherever possible.

The content of the *SourceBOOK* consists of a set of modules:

Introduction and Overview

- About This Site
- Frequently Asked Questions (FAQs)
- Related Links
- Nonpoint Source News

- Post Your Feedback

Module 1 -- Nonpoint Source Management 101

- History of Nonpoint Source Management
- Urban Nonpoint Source Primer
- Controlling Urban Runoff--Guidance for Beginners
- Selecting the Right BMP -- Guidance for Beginners
- Planning Your Stormwater Management Program - Guidance for Beginners
- Glossary

Module 2 -- Urban Runoff Management Programs

- Introduction
- The Planning and Goal Setting Process
- Planning and Program Approaches
- Funding Mechanisms
- Measuring Effectiveness of Management Programs
- Implementation Strategies
- Case Studies
- Bibliography
- Additional Resources

Module 3 -- Characterizing Urban Waterways

- Urban Runoff Flow and Water Quality
- Assessing Urban Waterways
- Water Quality and Other Watershed Physical Characteristics in Texas

Module 4 -- Runoff Quality Best Management Practices

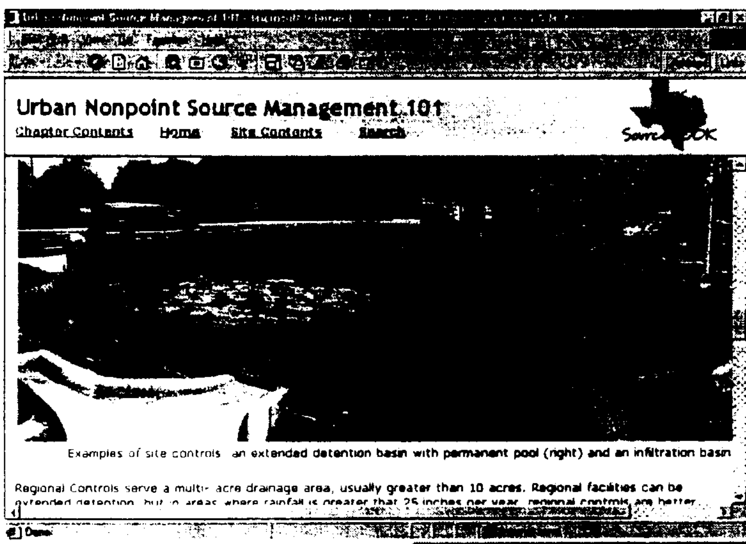
- Selecting Management Practices
- Housekeeping Practices
- Source Control Practices
- Treatment Control Practices
- Interactive BMP Selector

What Does Each Module Provide in the *Texas Nonpoint SourceBOOK*?

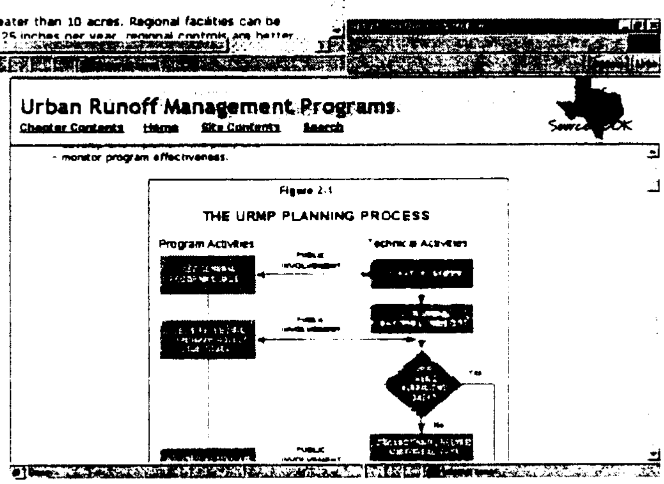
Module 1, "Nonpoint Source Management 101," is a primer for beginners on urban stormwater management. It quickly establishes that storm water quality <u>and</u> quantity management need to be addressed as one integrated program within a local government. It provides guidance on regulatory issues, basic axioms of runoff control, and the use of pollution prevention, source and treatment controls.

Module 2, "Urban Runoff Management Programs," describes the process to be used to manage urban runoff within the overall framework of the city, county, or special district. Particular attention is placed on the key institutional and financial components necessary for a successful ongoing program.

Module 3, "Characterizing Urban Waterways," begins with a generic discussion of urban runoff flow and water quality relationships. Considerable attention is then given to proper techniques for monitoring urban waterways and stormwater runoff. The majority of the module focuses on Texas-specific information. Descriptions of known water quality problems can be accessed for the entire state. Each regional planning area and basin has specific information on water bodies,

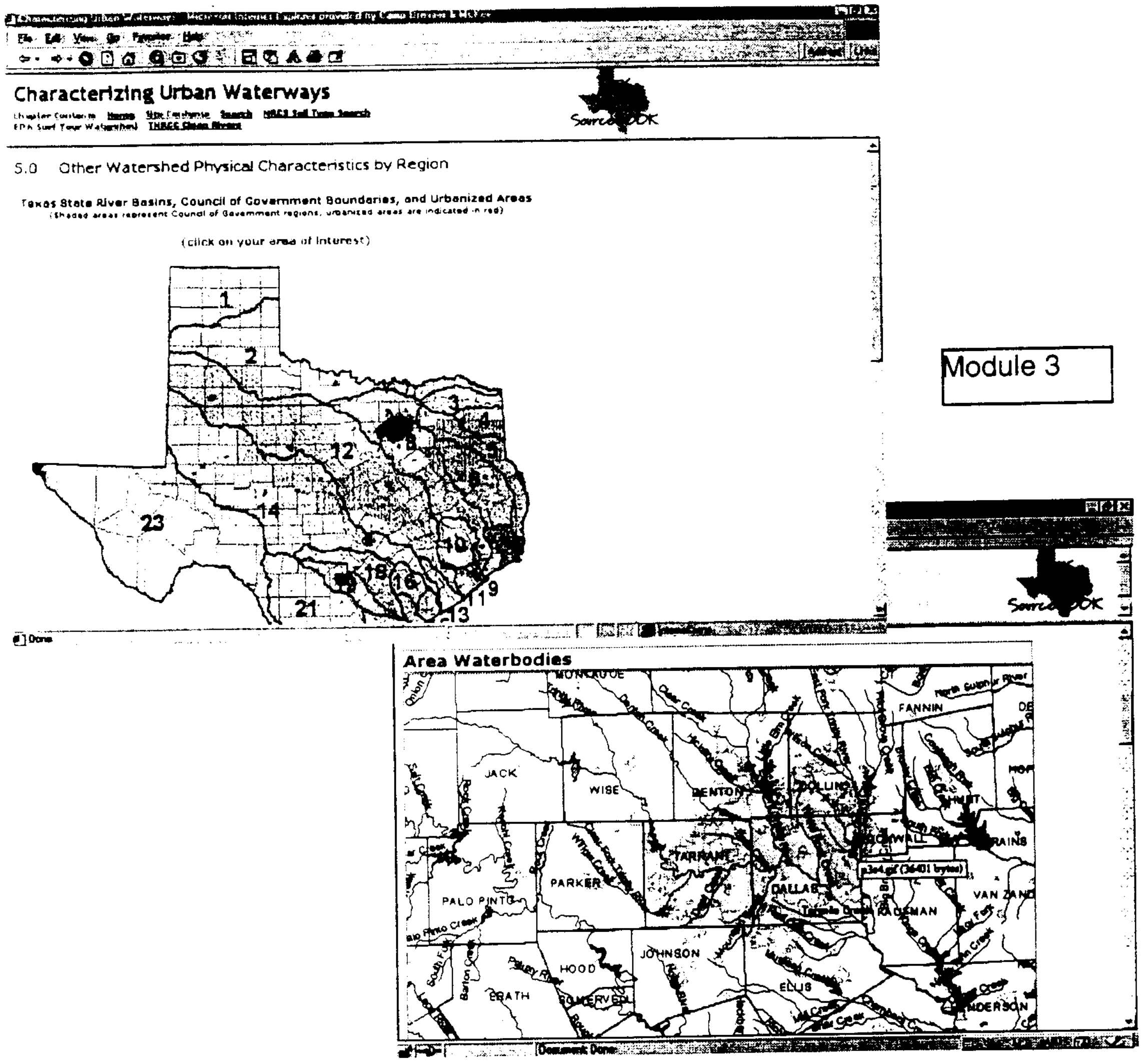


Module 1



Module 2

R0019557



watershed characteristics, annual precipitation and runoff, major soil types, and the like. There are many "hot" links to real-time gauging stations, local programs, and state/federal sites, such as EPA's *Surf Your Watershed*.

Module 4, "Runoff Quality Best Management Practices," provides guidance on the selection of Best Management Practices for pollution prevention, source control, and treatment control. Considerable effort was placed on gathering the most current information on more than 100 BMPs and review by the Project Management Committee of local governments. Each BMP includes detailed information, such as performance data, photographs, and relevant reference citations. An innovative BMP Interactive Selector was developed for the *SourceBOOK*. It enables the user to peruse BMP's in each category, or to input several characteristics specific to their situation and request a set of the most applicable BMPs.

A Comparison of the Long-Term Hydrological Impacts of Urban Renewal versus Urban Sprawl

Jon Harbor, Suresh Muthukrishnan, and Shilpam Pandey

Abstract

Recent concern over environmental and economic impacts of urban sprawl has focused renewed attention on the importance of making full use of existing urban areas. Revitalizing former industrial, commercial, and residential areas often involves changes in land use type or intensity of use. It is important to have the ability to evaluate the long-term hydrological impacts of such changes. These impacts can then be placed within the context of impacts that similar land uses would have if a decision were made to place them in the urban fringe (urban sprawl) rather than in existing urban areas (urban renewal).

In this study, we illustrate how the Long-Term Hydrological Impact Analysis (L-THIA) tool can be used to compare the hydrological impacts of land use change in existing urban areas versus change in the urban fringe. L-THIA is a simple, comparative tool that requires the user to provide information on land use and soil type for existing and future/planned conditions. The tool combines this information with local rainfall data to calculate long-term average annual surface runoff under existing and future/planned conditions. L-THIA analyses can be run directly at our web site for locations throughout the U.S. where the curve number technique is already routinely used (http://danpatch.ecn.purdue.edu/~sprawl/L-THIA). By performing analyses of renewal versus conversion of agricultural land at the urban fringe, it is possible to provide a comparative assessment of impacts. This initial comparison can be helpful in educating the general public and decision-makers, thereby raising awareness of this element of the set of variables that are considered in land use decisions.

Introduction

Because almost every major North American city had been founded by 1900, the dominant form of urban development during the 20th Century has been growth on the outer edges of existing cities, or just beyond city limits (Orum, 1995). With improvements in transportation and communications, the need for people to be clustered in high-density central areas has decreased (Chinitz, 1991), encouraging decentralization, suburbanization, and sprawl. In the United States, 87% of the population now lives in metropolitan areas and their hinterlands (Angotti, 1995), and steady infilling between urban areas has resulted in the development of megalopolises such as the Philadelphia - Boston - Washington DC - New York urban corridor. Even metropolitan areas which are stagnating or declining in terms of total population are still growing in terms of total built area because of low-density suburban growth (Johnston, 1982).

Decentralization and suburbanization have changed the relative importance of the core areas of cities (Richardson, 1982). Although these central areas were the sites of initial city growth and development, many cities are now faced with the challenge of revitalizing these once vibrant central industrial, commercial, and residential areas that have been in decline in recent decades:. The following quote reflects efforts to slow the tide of migration from urban centers.

"To combat the number of people fleeing [Chicago] for the suburbs, developers have lured middle-class home buyers back with promises of safe neighborhoods and affordable homes. Chicago also leads the nation in converting office and warehouse property into residential space such as condominiums and rental units, often targeted to low- and moderate-income buyers." (Heavens, 1999)

At the same time that city administrations have been coping with the challenges of urban core renewal, suburban and rural communities have become increasingly concerned about the environmental, economic, social, and aesthetic impacts of continued urban growth at the fringes of developed areas (these later concerns are often grouped under the term urban sprawl). Preservation of prime farmland and protection of rural areas have become important concerns, alongside a growing emphasis on combating the impacts of continued sprawl on flooding, groundwater recharge, air pollution, climate, ecology, and habitat fragmentation (Schueler, 1994). Although there is considerable interests in revitalizing urban cores, especially if this reduces urban sprawl, to accomplish this requires that the decision-making process for urban and suburban planning include consideration of the environmental as well as the economic aspects of land use.

Land use decisions are highly complex, involving consideration of economics, infrastructure, politics, labor and population dynamics, and the environment. The planning process requires collection and comparison of a wide array of data, usually with the goal of providing a planned solution that meets goals based on sustainable growth in industry and commerce. However, increasing public and political concern over the environmental aspects of urban development has raised the profile of efforts to develop efficient and environmentally sustainable urban environments. The key components of environmentally sound urban development include land use patterns that minimize environmental impacts (Arendt, 1996), efficient automobile and pedestrian traffic, and the use of energy saving and environmentally sound building designs. When attempting to balance economic and environmental concerns, it is important to quantify the differential environmental impacts of alternate land-use scenarios. Objective measures of differential impacts provide a rational basis for decision-making. In addition, they can be used to educate the public and key decision-makers in government and the private sector about the level of environmental benefit that can be gained from alternative land-use decisions.

The aim of the work presented here is to demonstrate the application of an impact assessment tool in evaluating the long-term hydrologic impact of development consistent with urban renewal versus the impact of an identical development located at the urban fringe. Although the general outcome of such a comparison is unlikely to surprise anyone, the advantage of quantifying differential impacts is in providing an objective numeric measure that is much easier to include in decision-making than vague subjective assessments of environmental benefits.

Long-Term Hydrologic Impact Assessment (L-THIA)

In response to concerns from local planners that they had no simple, objective way to assess the impacts of alternate development plans on surface water runoff and groundwater recharge, a Long-Term Hydrologic Impact Assessment tool (L-THIA) has been developed (Harbor, 1994; McClintock et al., 1995; Ogden, 1996; Grove, 1997; Bhaduri et al., 1997; Bhaduri, 1998; Minner, 1998; Minner et al. 1998; Lim et al., 1999; Leitch and Harbor, in press). L-THIA uses readily available data on soils, climate, and land use to estimate long-term surface water runoff. By running the model for current conditions, and then with changed land uses, the user can simulate the potential impact of land use change. The method, initially developed as a simple spreadsheet application (Harbor, 1994), is based on the U.S. Department of Agriculture's curve number (CN) method for relating precipitation and runoff as a function of land use and soil type (USDA, 1983, 1986). The CN method was selected because it forms the basis of other commonly used hydrologic models, thus the data required for its use is readily available in most planning settings. Because of the reliance on the CN method, L-THIA applies directly to those areas where the CN method is routinely used. Subsequent development of the L-THIA method has included provision of a Geographic Information System (GIS) version (Grove, 1997), addition of nonpoint source pollution loadings to land uses (Bhaduri, 1998), and development of an Internet-accessible version of the method (Lim et al., 1999).

In the curve number technique, the land use and hydrologic soil type of an area are used to derive a CN value (values typically range from 30 to 98). For any given daily precipitation, surface runoff is then computed from empirically based relationships between rainfall, CN, and runoff. Although most commonly used to estimate runoff for extreme storm events, in L-THIA the CN technique is used to determine daily runoff for a 30-year time series of daily precipitation values.

Average annual runoff is calculated for each CN to provide a measure of long-term average impact, rather than simply impact on isolated extreme storm events. To compare different land use change options, pre-development and post-development average annual runoff can be calculated for each scenario. The L-THIA method is freely available at http://danpatch.ecn.purdue.edu/~sprawl/LTHIA. This site includes information on the technique and its application, as well as access to US climate and soils data necessary to run analyses. Users can submit land use and soil information through a spreadsheet-style interface (Figure 1). Analyses are performed on a server at Purdue University and results are delivered back to the user in the form of tables and graphs.

A Comparison of Core Renewal versus Fringe Development

Study Scenario

The L-THIA tool can be used to examine the relative impact of land use change in the form of an urban renewal project; replacing underused or abandoned commercial, residential, and industrial buildings in an urban core region; versus an urban sprawl project; replacing agricultural land at the edge of a city. For the sake of illustration, consider planning a 70 Ha major commercial development with urban core and urban fringe location alternatives. Although the location decision-making process will be driven by economic and infrastructure concerns, also assume that differential environmental impact is important in decision-making, perhaps as a result of political or regulatory pressure. In the context of improving urban environments then, an important question is the extent to which placing this development in an urban core region would have different hydrologic impacts than placing it at the city fringe.

To simulate this situation, consider two possible sites in the Chicago area. The first is in the urban core, and currently consists of a mix of residential, industrial, and commercial properties that are unused or underused (Figure 1). The second possible site is on the urban fringe, and currently is used for agriculture. For simplicity we assume that both sites are on the same type of soil (from a hydrologic perspective), although in a real world example this might not be the case. In each case, we use the L-THIA web tool to analyze how average annual runoff will change if the site is converted to solely commercial use (Figure 1). In the L-THIA input and output, the urban core site is labeled "YEAR 1", the urban fringe agricultural site is labeled "YEAR 2" and the commercial land use for both sites is labeled "YEAR 3." The L-THIA web tool uses the "YEAR" designation for different scenarios because analyses are typically for land use changes over time.

Results

For the example described here, placing a commercial development in an urban core region, replacing an existing mix of urban land uses, increases average annual runoff by 58% compared to the initial situation (Table 1 and; Figure 2). Note that the levels of impact given in Table 1 do not depend on the size of the commercial development; the same percent increase applies regardless of area. Runoff increases because land uses with less impervious cover, such as residential, are replaced by commercial land use that has a higher percentage of impervious area. In contrast, for the urban fringe location, replacing agriculture with commercial use increases runoff by 670% (Table 1 and Figure 2), a ten-times greater impact. Runoff increases so dramatically because agricultural use on relatively permeable soil is replaced by very extensive impervious surfaces.

Table 1. Average annual runoff depths and change for commercial development (post-development) in the urban core versus the urban fringe. Results are for the specific example described in the text.

	Pre Development Average Annual Runoff (mm)	Post Development Average Annual Runoff (mm)	Increase in Runoff (%)
Urban Core	81.8	129.3	58
Urban Fringe	16.8	129.3	670

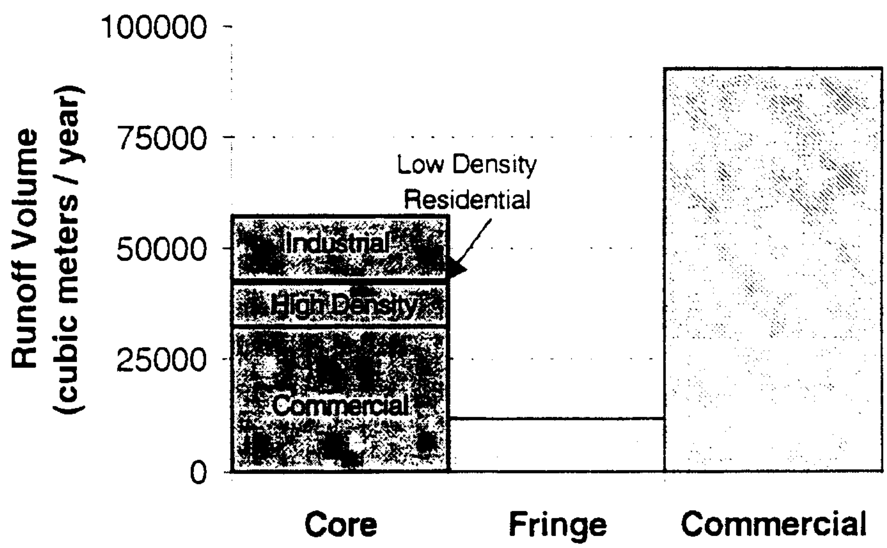

Figure 2. Average annual runoff volumes for commercial development, the urban core mixed-use, and the urban fringe agricultural use. The much larger difference between the fringe location runoff volume and the commercial case indicates that fringe development will have the largest hydologic impact. Note that the runoff volume is simple the average annual runoff depth (Table 1) multiplied by the site area. Results are for the specific example described in the text.

Discussion and Conclusions

The straightforward example presented here indicates that developing a commercial site in an urban core versus and urban fringe location can have a very significant impact on the level of disturbance of the hydrologic regime. For the Chicago example presented here, the urban fringe location produces an approximately ten times larger impact than the urban core location. Clearly, from a solely hydrological standpoint, the urban core location is a better choice than the fringe location. Although this is a hypothetical example, it illustrates the relative ease of use of the L-THIA tool, and more importantly demonstrates an accessible way to provide a quantitative estimate of the relative impacts of different land use decisions. More complex land use mixes and soil types can be run on the L-THIA web tool, either in the spreadsheet version or in a GIS version also available at the web site. Thus, more sophisticated comparative analyses can be performed.

In most cases, an L-THIA analysis provides a result that shows that renewal of existing areas has less hydrologic impact than development of an area with rural use. This is not a surprise, rather the value of the tool is that it provides a context for understanding and considering the magnitude of this difference in the decision-making process. For areas where problems such as groundwater supply and downstream flooding are important, the scale and magnitude of the hydrologic impact can be of considerable importance and can be considered alongside other concerns, such as infrastructure and economic viability. We suggest use of tools such as L-THIA as part of the planning process, to ensure that land use decisions are made after consideration of a full range of concerns, including environmental parameters as well as economic, infrastructure, and political issues.

Acknowledgements

Development of the L-THIA tool is being supported by grants from the Environmental Protection Agency, Region 5.

Comparative Nutrient Export And Economic Benefits of Conventional And Better Site Design Techniques

Jennifer Zielinski, Deb Caraco, and Rich Claytor
Center for Watershed Protection
Ellicott City, Maryland

Better site design describes a fundamentally different approach to the design of residential and commercial development projects. It seeks to accomplish three goals at every development site: to reduce the amount of impervious cover, to increase the amount of natural land set aside for conservation, and to use pervious areas for more effective stormwater treatment.

When designing new residential developments, planners have the opportunity to reduce stormwater runoff and pollutant export through better site design techniques. The better site design techniques applied to these developments are referred to here as "open space design," and present an alternative to conventional residential subdivisions. Also known as cluster development, open space design concentrates density on one portion of a site in order to conserve open space elsewhere by relaxing lot sizes, setbacks, frontages and road section and other lot geometry. Open space design also consists of:

- installing narrower streets and shorter driveways
- spreading stormwater runoff over pervious areas
- using open channels rather than curb and gutter
- clustering development to conserve forests and natural areas
- reducing the area devoted to turf
- protecting stream buffers
- enhancing the quality of septic system effluent in areas where sewage is disposed of on-site

When these techniques are applied together, the cumulative benefits of better site design can be impressive. Documenting the precise benefits is difficult, however, since few developments incorporating better site design techniques have been built, let alone monitored.

As most better site design techniques are non-structural in nature, the achievable benefits will vary depending on the unique characteristics of each development site and the actual site planning practices applied. Also, since better site design techniques are commonly applied together, it has been difficult to accurately quantify their individual nutrient removal benefits. Many local governments, consultants, and developers have expressed a strong desire for clear documentation of these presumed benefits.

To help meet this need, the Center for Watershed Protection (CWP) recently completed a study to document the comparative nutrient export and economic benefits of conventional and better site design techniques. The simple assessment methodology analyzed both the residential and commercial environment through four real-world development case studies in the Chesapeake Bay watershed. This paper presents the results of the residential component of that project, including the incorporation of open space design techniques into the redesign of two residential case studies; the resultant hydrologic, nutrient export, and economic benefits; and finally, the implications of our findings for the watershed manager.

Methodology

The basic method used in the *Nutrient Loading from Conventional and Innovative Site Development* project (Caraco, et al., 1998) conducted by CWP is a redesign analysis that compares conventional and better site design at actual project sites using a simplified model.

CWP first assembled plans of previously developed sites representative of typical development scenarios across the Chesapeake Bay, including a medium-density residential development from Virginia's Piedmont, a large-lot single family residential subdivision from Maryland's Eastern Shore, a retail strip mall from Frederick County, Maryland, and a commercial office park located outside of the District of Columbia in suburban Maryland. Each site was then "redesigned" using better site design techniques.

The Simplified Urban Nutrient Output Model (SUNOM) was then used to compare each conventionally designed site to the redesign. SUNOM is a spreadsheet model that computes the hydrologic budget, infrastructure cost and nutrient export from any site, using common site planning variables. The model provides watershed practitioners with a simple tool to compare the costs and benefits of better site design. It is not meant to be used as a method for determining actual stormwater runoff and nutrient loading from a development site. To obtain accurate numbers for this, a more detailed model should be used or on-site monitoring should be conducted.

Model input includes basic site planning variables that can be directly obtained or measured from a typical development submittal to a land use authority, including total drainage area, length of sidewalks, total impervious cover, linear feet of roads, lawn cover, utilities (length and type), forest cover, size, type, and length of stormwater conveyance, riparian forest cover, size and type of stormwater practices, soil type(s), and method of wastewater treatment. Default data are provided for many parameters and many of these assumptions can be changed based on site specific information.

SUNOM is governed by the principles of a simplified water balance. In addition to annual runoff and infiltration, SUNOM computes the annual nutrient load from each development site in pounds. In brief, the surface nutrient export from each site is estimated using the Simple Method (Schueler, 1987). This export is then adjusted to reflect the mean removal capability of stormwater BMPs where present (Schueler, 1997). The subsurface component of the model utilizes annual subsurface recharge rates (based on the site's prevailing hydrologic soil group) and monitored baseflow nutrient concentrations in the receiving water to estimate the annual subsurface nutrient export from urban areas. These values are then adjusted for the area of the site that cannot recharge (i.e., impervious cover) or are hindered from infiltrating by other conditions (e.g., compacted urban turf). The model also calculates the cost of development utilizing previously published or user-specified unit costs and predictive equations for infrastructure, stormwater management, landscaping, and septic systems.

For each case study, SUNOM was used to compare the annual hydrologic budget and annual nutrient export under five development scenarios: pre-developed conditions, conventional design without stormwater practices (uncontrolled), conventional design with stormwater practices (controlled), design incorporating better site design techniques without stormwater practices (uncontrolled), and design incorporating better site design techniques with stormwater practices (controlled). The cost of development associated with each design was also estimated.

Case Study #1: Duck Crossing, A Low Density Residential Subdivision

Duck Crossing, a large-lot residential development, is located in Wicomico County on Maryland's Eastern Shore. Prior to development, the parcel was representative of the typical terrain on Maryland's coastal plain, with very little gradient. The site contained tidal and non-tidal wetlands, natural forest, meadow, the 100-year floodplain, as well as three existing dwellings with on-site sewage disposal.

The large-lot subdivision of single family homes, constructed in the 1990's, (Figure 1) contains eight new residential lots, each of which are 3 to 5 acres in size with houses set far back from the street. The street is wide given the few homes that are served, ends in a large cul-de-sac, and is lined with a sidewalk. Each lot has an on-site private septic

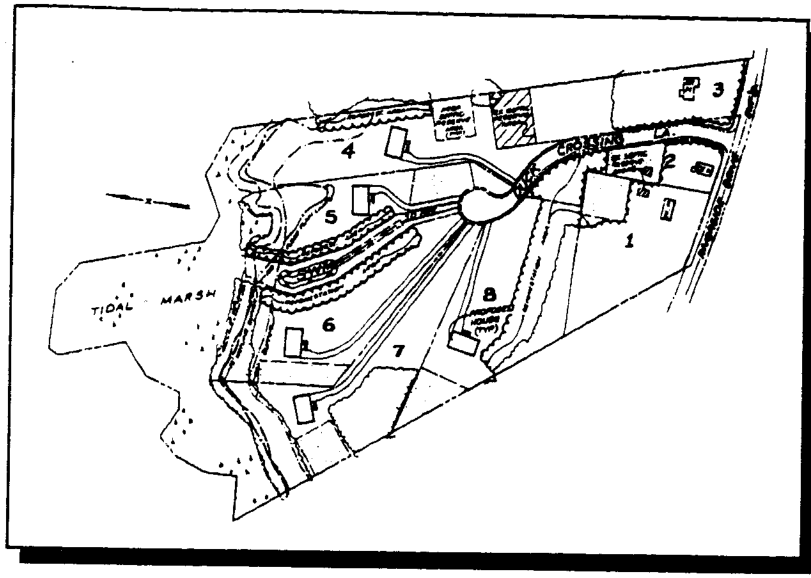

Figure 1. The conventional design of Duck Crossing, a low density residential subdivision on Maryland's Eastern Shore.

system, with a septic reserve field of about 10,000 square feet. Individual home property lines extend to the protected tidal marsh, which is the only common open space on the site. Stormwater management consists of street runoff conveyed by curb and gutter to a storm drain system that discharges to a small wet pond.

The major better site design techniques applied when redesigning this site (Figure 2) included:

- conservation of tidal and non-tidal wetlands and forested areas
- a 100-foot buffer along tidal and non-tidal wetlands
- clustering development to provide additional open space
- identification of potential development and open space areas based on location of sensitive areas, 100-year floodplain, and potential septic field areas
- distribution of stormwater treatment practices throughout the site
- use of a narrower access road; shorter, shared driveways; and wood chip paths through community open space instead of sidewalks along the road
- use of shared septic systems utilizing more advanced re-circulating sand filter technology

The open space design resulted in reduced impervious cover, reduced stormwater runoff, increased stormwater infiltration, and reduced infrastructure cost over the conventional design.

Case Study #2: Stonehill Estates, A Medium-Density Residential Subdivision

Stonehill Estates is located in Stafford County just north of Fredericksburg, Virginia. The original site was almost entirely forested in a mix of mature deciduous hardwoods, with perennial and intermittent streams, and non-tidal wetlands. An existing network of public water and sewer lines serves the site and road access to the subdivision is by two existing streets.

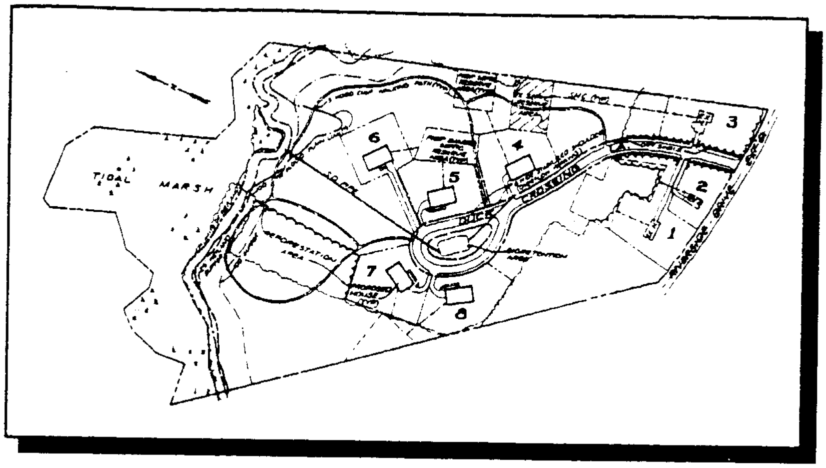

Figure 2. The open space design of Duck Crossing.

The conventional design produced a total of 108 house lots, each of which are about 9000 square feet in size (Figure 3). The subdivision is quite typical of a medium-density residential subdivision developed in the last two decades in the Mid

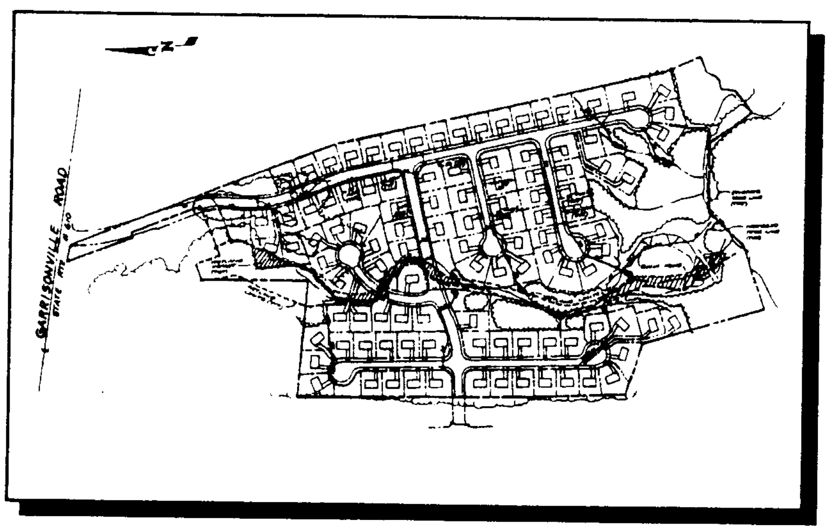

Figure 3. The conventional design of Stonehill Estates, a medium density residential subdivision in Stafford County, Virginia.

Atlantic with uniform lot sizes and shapes, and generous front setbacks. The streets were 34 and 26 feet wide, numerous cul-de-sacs were used as turnarounds, and sidewalks were generally installed on both sides of the street. With the exception of a small tot-lot, the majority of the open space is unbuildable land, such as floodplains, steep slopes, wetlands, and stormwater management areas. Street runoff is conveyed by curb and gutter to a storm drain system that discharges to the intermittent stream channel. It then travels to a dry extended detention pond, which is primarily used to control flooding, but also provides limited removal of stormwater pollutants.

The open space design also results in 108 lots, but these were slightly smaller with an average size of 6,300 square feet. The design also incorporates many techniques of open space design as advocated by Arendt (1994). The design techniques employed in the redesigned site (Figure 4) include:

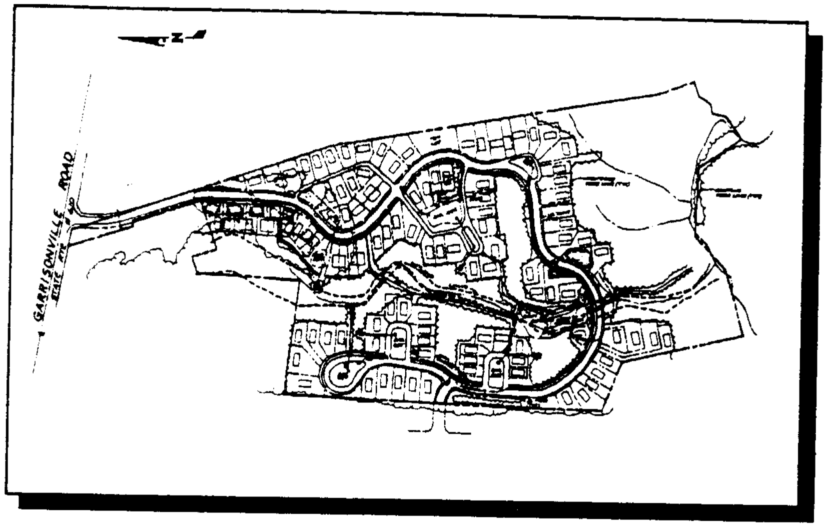

Figure 4. The open space design of Stonehill Estates.

- identify sensitive natural features, including mature forest and wetland, to be protected
- incorporate a minimum 100-foot buffer along all perennial and intermittent streams
- maximize the amount of community open space and preservation of natural areas
- maintain the same number of lots as the conventional design
- provide open space adjacent to as many lots as possible
- incorporate stormwater management attenuation and treatment throughout the site
- use narrower streets, loop roads, shorter driveways, and fewer sidewalks
- allow for irregular shaped lots and shared driveways
- manage stormwater in a "treatment train" with bioretention facilities that discharge to a small but more effective wet pond

The open space design resulted in reduced impervious cover, reduced stormwater runoff, increased stormwater infiltration, and reduced infrastructure cost over the medium density subdivision conventional design (Table 1).

The Benefits of Open Space Design

For both of these case studies, application of the open space design techniques resulted in reduced impervious cover, which translates directly to reduced stormwater runoff. Other "redesign" studies recently conducted in Delaware, Maryland, and Virginia have provided similar results. These combined results consistently demonstrate that better site design can reduce impervious cover by 25 to nearly 60% and stormwater runoff by 4 to over 60% for a range of subdivisions (Table 1).

Table 1. Redesign Analyses Comparing Impervious Cover and Stormwater Runoff from Conventional and Open Space Subdivisions

Residential Subdivision	Conventional Zoning for Subdivision	Impervious Cover at the Site			% Reduction in Stormwater Runoff
		Conventional Design	Open Space Design	Net Change	
Duck Crossing	3 - 5 acre lots	8%	5%	- 35%	23%
Stonehill Estates	1/3 acre lots	27%	21%	- 24%	24%
Remlik Hall [1]	5 acre lots	5.4 %	3.7%	- 31%	20%
Tharpe Knoll [2]	1 acre lots	13%	7%	- 46%	4%
Chapel Run [2]	½ acre lots	29%	17%	- 41%	31%
Pleasant Hill [2]	½ acre lots	26%	11%	- 58%	54%
Prairie Crossing [3]	½ - 1/3 acre lots	20%	18%	- 20%	66%
Buckingham Greene [2]	1/8 acre lots	23%	21%	- 7%	8%
Belle-Hall [4]	High Density	35%	20%	- 43%	31%

Sources: [1] Maurer, 1996; [2] DE DNREC, 1997; [3] Dreher, 1994; and [4] SCCCL, 1995.

For both Duck Crossing and Stonehill Estates, the conventional design results in the highest annual volume of runoff and the lowest volume of infiltration, as was expected. Of particular interest is the fact that the controlled conventional design results in a higher annual runoff volume and a lower infiltration rate than the uncontrolled open space design. This, however, should not imply that better site design alone, without structural stormwater management, is sufficient in controlling stormwater runoff from this site since the open space designs do not come close to replicating pre-developed hydrology.

Less impervious cover and stormwater runoff, in turn, translates directly to smaller pollutant loads. Reducing the impervious cover, preserving natural areas, and providing multiple stormwater practices in series reduced nutrient export for both case studies. However, neither open space design meets pre-development nutrient loads.

One area of particular interest for Duck Crossing is the implication of on-site sewage disposal systems. The conventional design included a standard septic tank and field for each lot, which resulted in phosphorus and nitrogen loads that far exceeded pre-development levels. Recirculating sand filters were used in the open space design, instead of conventional septic systems, because they yield better nitrogen removal efficiencies and are actually less expensive to construct. This resulted in a much lower nutrient output from the entire site. However, even in the open space design, the septic systems are the predominant source of nutrients.

For both case studies, the total infrastructure costs include the sum of the estimated costs of stormwater management, storm drainage, paving, sidewalk, curb and gutter, landscaping and reforestation, water, sewer and septic systems. In both cases, the open space design resulted in a cost savings. Costs associated with grading, erosion and sediment control, building construction and other incidental costs associated with land development were not analyzed. In general, these costs should be comparable between the two development options. If anything, the grading and erosion and sediment control costs should be lower with the open space design since less land is disturbed.

Several other studies have also shown that open space development can be significantly less expensive to build than conventional subdivision developments. Most of the cost savings are due to savings in road building and stormwater management conveyance costs. The use of open space design techniques at a residential development in Davis, California provided an estimated infrastructure construction costs savings of $800 per home (Liptan and Brown, 1996). Other examples demonstrate infrastructure costs savings ranging from 11 to 66%. Table 2 lists some of the projected construction cost savings generated by the use of open space redesign at several residential sites.

Table 2. Projected Construction Cost Savings for Open Space Designs from Redesign Analyses

Residential Subdivision	% Construction Savings	Notes
Duck Crossing	12%	Includes roads, stormwater management, and reforestation
Stonehill Estates	20%	Includes roads, stormwater management, and reforestation
Remlik Hall [1]	52%	Includes costs for engineering, road construction, and obtaining water and sewer permits
Tharpe Knoll [2]	56%	Includes roads and stormwater management
Chapel Run [2]	64%	Includes roads, stormwater management, and reforestation
Pleasant Hill [2]	43%	Includes roads, stormwater management, and reforestation
Buckingham Greene [2]	63%	Includes roads and stormwater management

Implications for the Watershed Manager

Better site design reduces impervious cover, conserves larger contiguous natural areas, and incorporates more advanced stormwater treatment, which results in reduced stormwater runoff, increased infiltration, and reduced nutrient export. Hopefully, the results of this study, as well as other redesign analyses, will answer some of the questions of local governments, consultants, and developers as to the benefits of better site design.

However, there may still be difficulties to overcome before better site design becomes a reality and common practice in many communities. Once there is a willingness to incorporate better site design techniques into new developments, many communities may find that their existing development codes and ordinances are in conflict with the goals of better site design. For example, many local codes and ordinances require excessive impervious cover in the form of wide streets, expansive parking lots, and large-lot subdivisions. In addition, there are generally few, if any, incentives or requirements for developers to conserve natural areas. When obstacles to better site design are present, it is a sign that a community may want to reevaluate and consider changing some of its local codes and ordinances.

In 1997, CWP convened a national site planning roundtable to address this very issue. During the 18-month consensus-building process, a diverse cross section of national planning, environmental, home builder, fire and safety, and public works organizations (as well as local planning officials) crafted 22 model development principles to help further better site design at the local level. This national roundtable is serving as a model for local government implementation of better site design principles.

Recently, Frederick County, Maryland, initiated a local roundtable to take a critical look at its own development rules. Members of the development community in partnership with local planning and zoning and public works staff are meeting to identify and overcome impediments to better site design that are embedded in the county's codes and ordinances. The outcome of the consensus process should be development rules that encourage rather than discourage the application of better site design techniques.

Changing local development rules is not easy. Progress toward better site development will require more and more local governments to examine their current practices in the context of a broad range of concerns, such as how changes will affect development costs, local liability, property values, public safety, and a host of other factors. Advocates of better site design will have to answer some difficult questions from fire chiefs, lawyers, traffic engineers, developers, and many others in the community. Will a proposed change make it more difficult to park? Lengthen response times for emergency vehicles? Increase risks to the community's children? True change occurs only when the community addresses these and other questions to the satisfaction of all interests.

Abstract

The Universal Soil Loss Equation (USLE) was developed for estimating sheet and rill erosion from agricultural fields under specific conditions. Parameters used to estimate erosion include rainfall energy, soil erodibility, slope length, steepness, surface cover, and management practices. Traditionally, urban conservation planners have not used the USLE for estimating soil loss and evaluating conservation measures and have relied on intuition alone to locate erosion control practices on constructions sites. The results of this process are often subjective and may vary with the skill of the planner. A USLE-based equation would provide a valuable, objective method for all planners, regardless of skill, to tailor specific construction site practices to existing conditions. A method to predict soil loss from construction sites was developed by adapting existing data for USLE erosion calculations to construction site conditions. In addition, the construction site procedure was used to create a user-friendly computer-based program to assist planners in developing erosion control plans. The computer program was distributed to engineers responsible for erosion control planning in Dane County, Wisconsin. Implementation of the USLE-based equation has proven to be a valuable tool for assessing alternatives for site management and erosion control. Planners are able to uniformly implement the equation on construction sites throughout the county, decrease the time necessary to complete a USLE calculation, and reduce human error.

Keywords:

Universal Soil Loss Equation (USLE), urban erosion control.

Background

Soil erosion, detachment of soil particles from the soil surface, results when soil is exposed to the power of rainfall energy and flowing water. Soil erosion causes a loss of productivity in the land, delivers millions of tons of sediment into waterways, and provides a substrate for toxic chemicals which are carried into receiving waters. Construction site erosion has been identified as a significant source of suspended solids in runoff in many parts of the United States (Hagman, et al., 1980; Yorke and Herb, 1976; Becker, et al., 1974). In the State of Wisconsin, sediment is the largest pollutant by volume (Wisconsin Department of Natural Resources, 1994). When erosion is compared on a rate basis, construction site erosion generates more erosion in a short period of time than any other land disturbing activity (Johnson and Juengst, 1997). While it is not possible to urbanize a watershed without exposing soil to erosive forces, it is possible to plan construction to control the production of sediment through the use of erosion prevention and reduction practices.

The Universal Soil Loss Equation (USLE) (Equation 1) was developed by the United States Department of Agriculture (USDA) for estimating sheet and rill erosion from agricultural fields under specific conditions (Wischmeier and Smith, 1978). The USLE enables planners to predict the average annual rate of soil erosion for combinations of seeding and management practices in association with a specified soil type, rainfall pattern, and topography. The equation groups interrelated physical and management parameters influencing erosion rate into six major factors whose site-specific values can be expressed numerically. More than a half century of erosion research in many states has supplied information from which the USLE factors were determined.

The Universal Soil Loss Equation.

$$A = R \times K \times (LS) \times C \times P \qquad \text{(Equation 1)}$$

Where:

A = average annual soil loss
R = rainfall and runoff factor
K = soil erodibility factor
L = slope length
S = steepness factor
C = cover and management factor
P = support practice factor

A The computed soil loss in tons/acre/year.

R The rainfall and runoff factor is the number of erosion-index units in an average year's rain. The erosion index is the storm energy in hundreds of foot tons times the 30 minute storm intensity.

K The soil erodibility factor is the soil loss rate (tons per acre) of a specific soil type and horizon as measured on a standard plot of land.

L The slope/length factor is the ratio of soil loss from the actual land slope length to that from a standard plot (726 feet in length) of land. Slope length is defined as the distance from the point of origin of overland flow to the point where either the slope gradient decreases enough that deposition begins or runoff water enters a well defined channel that may be part of a drainage network or a constructed structure.

S The slope/steepness factor is the ratio of soil loss from the actual land slope gradient to that from a standard plot of land (9%).

C The cover and management factor is the ratio of soil loss from an area with specified cover and management to the corresponding loss from a clean-tilled, continuously fallow condition.

P The ratio of soil loss with a support practice such as contouring, stripcropping, or implementing terraces compared to up and down the slope cultivation. The support practice factor does not usually apply to soil loss on construction sites.

Soil losses computed with the USLE are best available estimates, not absolutes. The USLE will generally be most accurate for medium-textured soils, slope lengths of less than 400 feet, gradients of 3 to 18%, and consistent seeding and management systems represented in the USDA erosion studies. The USDA research shows that in comparing actual soil loss to computed soil loss, 84% of the differences in long-time average soil losses were less than 2 tons/acre/year (Wischmeier and Smith, 1978). The accuracy of a predicted soil loss depends on how accurately physical and management conditions on the particular site are described by the parameter values. Large-scale averaging of parameter values on mixed drainage areas reduces accuracy.

Traditionally, urban conservation planners have not widely used an equation similar to the USLE for estimating soil loss and evaluating conservation measures. They have relied on intuition alone to locate erosion control practices on construction sites. A USLE-based equation provides a valuable, objective method for all planners, regardless of skill, to tailor specific construction site practices to existing conditions. Erosion control is more efficient when it focuses erosion control practices in areas on the site identified by the USLE as being the most susceptible to erosion.

The objectives of this project were to: 1) develop a method to predict soil loss from construction sites by adapting existing data for USLE erosion estimation to construction site conditions and 2) create a user-friendly computer-based program to assist planners in developing construction site erosion control plans with the USLE.

Implementation Area

The project was conducted in Dane County, located in south-central Wisconsin. Dane County has extremely diverse and vast water resources with 475 miles of rivers and streams and 37 lakes, but these resources are threatened by rapid urban growth. Within the next twenty years, it is conservatively estimated that an additional 72,000 people will live in the county. Residents recognize how impacts to water quality affect their standard of living, and are interested in protecting water resources.

Due to the value that the citizens of Dane County place on water quality, a very restrictive erosion control ordinance was adopted in 1995. Any land disturbance greater than 4000 square feet must comply with the Dane County Erosion Control Ordinance (Dane County, 1999). As part of this ordinance, applicants must prove that the erosion rate on their project will not exceed 15 tons per acre over the construction period for non-sensitive areas. In sensitive areas, including sites adjacent to, or directly draining to, lakes, streams, and wetlands, the soil loss is limited to 7.5 tons per acre over the construction period. In order to prove the soil loss rate is below the county standard, applicants need to calculate the USLE for their site from the start of construction until the site is stabilized. The Dane County Land Conservation Department reviews erosion control plans for accuracy of the plan and compliance with the ordinance.

Methods

Adapting USLE to construction site conditions

Our first objective was to develop a method of predicting soil loss from erosion on construction sites based on the guidelines given by the USDA for the USLE. In order to adapt the USLE to urban conditions, each variable in the equation was examined (see Equation 1).

The rainfall factor, R, is the first factor modified. Published R values represent erosivity during an average year. Most construction sites do not remain disturbed for exactly one year. In addition, the time of year that the site is open is critical in determining the amount of rainfall energy that will occur. In the Midwest, over half of this rainfall energy occurs during July, August, and September. Projects that take place in the summer will experience higher intensity storms than projects constructed in the winter. For these reasons, the R factor needs to be adapted to the construction schedule of the project (Table 1).

Table 1. Percent of R occurring after January 1st for Dane County, Wisconsin.

	January	February	March	April	May	June
1st	0	0	2	4	9	20
15th	0	1	3	6	14	28
	July	**August**	**September**	**October**	**November**	**December**
1st	39	63	80	91	97	99
15th	59	72	87	94	98	100

Once the percent R is calculated for the interval of time that the land will be open, it is multiplied by the annual R factor for Dane County (150).

$$R = (\% \text{ of } R \text{ to date}) \times (\text{Annual } R \text{ factor})$$

The soil erodibility factor, K, represents a soil's ability to resist erosion. The factor is determined by documenting erosion of a soil in a bare condition on a unit test plot. The higher the erosion rate, the higher the K factor. On construction sites, the subsoil K factor is often used because the topsoil is usually stripped. Subsoil K factors can be found in USDA

Soil Interpretation Records. The soil properties that affect erodibility include: soil structure, soil particle size distribution, permeability, organic matter content, and iron content.

The slope length/steepness factor, LS, relates the length and steepness of the slope (Equation 2). The rate of erosion increases exponentially as the length of the slope becomes longer. Erosion rates rise even more drastically as the steepness of the slope increases. The percent slope is a representative portion of the disturbed area, representing overland flow, not channel flow. The slope length is measured along the flow path from the top to the bottom of the slope of the disturbed area.

Formula used to calculate the LS factor.

$$LS = (L/76.6)^M(65.41\sin^2\theta+4.56\sin\theta+0.065) \qquad \text{(Equation 2)}$$

Where: L = slope length in feet

θ = angle of slope (in degrees)
M = 0.2 for slopes < 1%
M = 0.3 for slopes 1.0 to 3.0%
M = 0.4 for slopes 3.0 to 4.5%
M = 0.5 for slopes > 4.5%

The cover and management factor, C, is based on the type and condition of the cover on the soil surface. In construction site erosion control, the cover is extremely important. The vegetative cover provides protection from rainfall impact and runoff water. If the condition of the cover is poor, the C factor will be high. Conversely, when the vegetation is well established, the erosion and C factor will be reduced. C factors for construction sites can be found in *Predicting Rainfall Erosion Losses* (Wischmeier and Smith, 1978). The C factors for seeding, seeding and mulching, and sod represent the average cover over the establishment period. Once the site is seeded or sod is installed, a period of sixty days during the growing season is automatically assumed for cover establishment. If the end of the sixty-day cover establishment period falls after the recommended seeding dates, the calculation must be carried out to the following spring to allow for adequate growth.

Commonly Used C Factors:	Bare ground	1.00
	Seeding	0.40
	Seeding and Mulching	0.12
	Sod	0.01

The support practice factor, P, is not used to calculate soil loss on construction sites.

The product of the R, K, LS, and C factors equals the computed soil loss per acre over the construction period. In Dane County, if this number is greater than the required standard, the project must reduce erosion below the standard by using erosion control practices or by changing the management schedule. This assumes that 100% of soil loss is transported and deposited off-site for relatively small areas of less than 40 acres with no intervening obstructions or flattening of the land slope.

Developing the Spreadsheet to Calculate the USLE

Implementation of the USLE in erosion control plans was required for all land-disturbing activities greater than 20,000 square feet in Dane County after January, 1995. The calculation of soil loss was difficult for the consulting engineers responsible for submitting plans. In addition, the USLE calculations were often done incorrectly or the wrong data were used as inputs. For these reasons, a user-friendly computer-based program was developed to assist erosion control planners with the USLE calculation. The program uses Microsoft Excel 97*, a spreadsheet program that is commonly used among the engineering community.

The worksheet (Figure 1) uses the following variables and inputs (Table 2) which are either entered by the user or automatically calculated in the non-shaded rows.

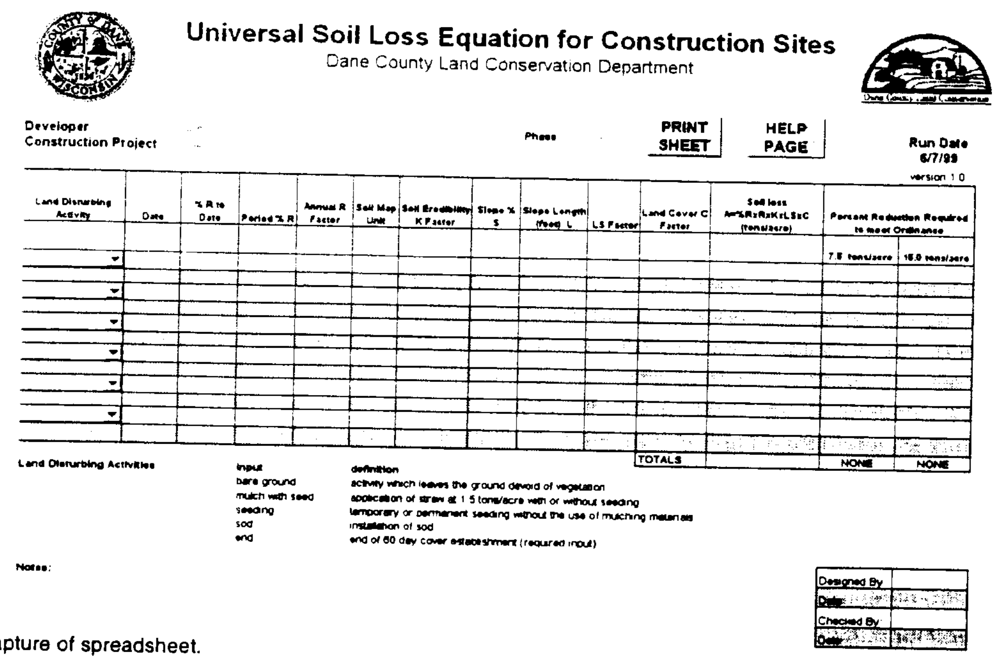

Figure 1. Screen-capture of spreadsheet.

Table 2. Variables used in the spreadsheet.

Column #	Variable	Type
1	Land Disturbing Activity	entered by user
2	Date	entered by user
3	% R to Date	automatically calculated
4	Period % R	automatically calculated
5	Annual R Factor	automatically calculated
6	Soil Map Unit	entered by user
7	Soil Erodibility K Factor	automatically determined
8	Slope % S	entered by user
9	Slope Length L	entered by user
10	LS Factor	automatically calculated
11	Land Cover C Factor	automatically determined
12	Soil Loss	automatically calculated
13	Percent Reduction to Meet Ordinance	automatically calculated

Variable/Input Descriptions:

Land-Disturbing Activity

The land-disturbing activity relates to the type of disturbance that is occurring on the ground and must be selected by using a pull down menu. Activity Inputs:

*Use of the commercial product name is for the convenience of the reader and does not imply endorsement of the product by either the Dane County Land Conservation Department or the University of Wisconsin.

R0019578

bare ground	Usually the initial disturbance and occurs when the ground is left bare due to stripping vegetation, grading, or other actions that leave the ground devoid of vegetation.
seeding	The application of permanent or temporary seeding without the use of mulch. Seeding requires that the user allows 60-days during the growing season for cover establishment.
mulch with seed	The application of a minimum of 1.5 tons/acre straw or other comparable mulching. This input is entered if the seeding and mulching are done at the same time. It is not necessary to also enter *seeding* if this input is used. This input also requires a 60 day cover establishment period during the growing season.
sod	The installation of sod for cover establishment.
end	*End* is a required input at the end of the 60-day cover establishment period. If the site is stabilized by a method other than vegetative cover, *end* should also be entered.

Date

The date the planned land disturbing activity begins, e.g. 5/15/99. The activity is assumed to continue until the next activity is entered. When seeding dates are later than the dates recommended for permanent cover establishment, the *end* date must be carried out to the next spring, rather than 60 days.

% R to Date

The percentage of the annual R factor from January 1st to the entered date.

Period % R

The percentage of the annual R factor calculated for the period from one land disturbing activity to the next.

Annual R Factor

The rainfall factor, R, is the number of erosion-index units in a normal year's rain. The erosion index is a measure of the erosive force of a specific rainfall. In Dane County, Wisconsin the rainfall factor is 150.

Soil Map Unit

The soil map unit for the predominant soil type in the area of the land disturbing activity.

Soil Erodibility K Factor

The erosiveness factor of the subsoil for the specified soil map unit.

Slope % S

The percentage slope for the representative portion of the disturbed area, representing overland flow and not channel flow.

Slope Length L

Slope length (in feet) is measured along the overland flow path from the top to the bottom of the slope of the representative disturbed area.

LS Factor

The LS factor is calculated using the equation for LS described previously (see Equation 2).

Land Cover C factor

The cover and management factor is the ratio of soil loss from an area with a specified cover and management practice to that of a unit plot of bare land. The input for the land disturbing activity corresponds to this factor.

Soil Loss

The predicted value of soil loss (tons/acre) which corresponds to the time period of each land disturbing activity. This value is calculated using the equation:

$$A = \%R \times R \times K \times (LS) \times C$$

Percent Reduction Required to Meet Ordinance

The percentage value in the total row corresponds to the reduction of soil loss necessary to comply with the Dane County Erosion Control Ordinance. It is required that the cumulative soil loss rate not exceed 15 tons/acre for non-sensitive areas and 7.5 tons/acre for sites that are located adjacent to or directly drain to sensitive areas.

Typical Spreadsheet Example for Dane County, Wisconsin

Figure 2 shows a sample USLE calculation using the spreadsheet. The assumptions are that construction will begin on July 17, 1999, and the site will be seeded and mulched on October 31, 1999. The representative pre-existing slope is 10% over 100 feet and the slope after grading will be 5% over 250 feet. The soil type is Dresden Silt loam (DsC2). The estimated soil loss rate for this site is 15.9 tons/acre. If this site is located near a sensitive area, the soil loss must be reduced by 53% to comply with the 7.5 tons/acre standard; on the other hand, if the site was not located near a sensitive area, the soil loss only needs to be reduced by 6% (15 tons/acre standard).

Results and Discussion

There are several advantages to using the adapted USLE for erosion control planning on construction sites. One advantage is being able to locate areas with the highest erosion rates, which results in more effective erosion control. If one portion of a construction site is predicted to have a higher erosion rate, more or larger erosion control practices may be targeted in that area, while less intensive practices may be required elsewhere on the site. The adapted USLE also facilitates the design of sediment ponds and other erosion control practices. The predicted amount of soil loss exceeding the standard can be used to calculate the percent reduction necessary to comply with the ordinance.

Another advantage is that the adapted USLE brings in the important element of time. In Wisconsin, the majority of the year's rainfall erosion occurs during the summer months. Summer is also the time of year that most construction is occurring. The USLE accounts for the date and duration the development project occurs and predicts the soil's vulnerability to erosion at that time. The USLE may show that staging the construction project will help to reduce the soil loss on the site.

The spreadsheet program has proven to be a valuable tool for calculating the soil loss. The program has been distributed for more than a year, free of charge, to the planners and consultants in Dane County. The County's review of the calculation in the erosion control plans has become easier and quicker by having a printout that summarizes the variables used. An advantage of having tables and formulas included in the spreadsheet, is the consistency that is achieved by everyone using the same parameters. Not only have the calculations of soil loss been more precise and time schedules more realistic, but planners and consultants have stated that it has saved them time and simplified the calculation process.

Public Involvement Programs That Support Water Quality Management

Josephine Powell
Wayne County Department of Environment
Detroit, Michigan

Zachare Ball
Karen Reaume
Environmental Consulting & Technology, Inc.
Detroit, Michigan

The Rouge River, a tributary to the Detroit River, in southeast Michigan, has been documented as a significant source of pollution to the Great Lakes System. The Rouge River Watershed spans approximately 438 square miles in 48 communities and three counties and is home to over 1.5 million residents. The eastern portion of the watershed contains much of the older, industrial areas of Detroit and Dearborn. The western and northern portions contains newer suburban communities and areas under heavy development pressure.

This paper discusses the programs used by the Public Involvement Team of Wayne County's Rouge River National Wet Weather Demonstration Project (Rouge Project) to (1) increase watershed awareness of Rouge River Watershed residents and business owners, (2) educate them about pollution sources to the Rouge River and (3) involve them in restoration of the Rouge River by showing them that small changes in their daily activities can help improve water quality and restore the river.

The Rouge Friendly Neighborhood Program was piloted over a two year period in watershed neighborhoods in three distinctly different areas of the watershed. All neighborhoods were surveyed to determine the initial level of knowledge about water quality issues, lawn care maintenance, and pollution prevention practices. Survey results were used to fashion a neighborhood program for each area. All three neighborhoods received Rouge Friendly brochures, newsletter articles, and other materials.

The Rouge Friendly Business Program, a companion program to the neighborhood effort, sought to educate small-to-mid-sized businesses about how they can positively impact the Rouge River by making small changes to daily business practices. Since auto-related businesses are very common in the Rouge River Watershed, an automotive services roundtable was convened. The partners included representatives of automotive service associations, the local chamber of commerce, and businessmen who met periodically for a year to review draft materials, make suggestions about the program's promotion, and to help mold the program before it was implemented. Once implemented, the industry representatives promoted the program in their publications and recruited businesses to participate in the program.

This paper will describe both of these pollution prevention programs and discuss how the Brightmoor neighborhood in the Rouge River Watershed was impacted by the Rouge Friendly Neighborhood and the Rouge Friendly Business Programs.

The Rouge Friendly Neighborhood Program

The Rouge Friendly Neighborhood Program was designed to be carried out by responsible neighborhood organizations. Preferred prerequisites were:

1. The group participating in the program must represent a defined area or neighborhood.

2. The group would participate in the Friends of the Rouge River Watch Program. The river system need not pass directly through the neighborhood for participation. An assigned segment could be identified for the group by Friends of the Rouge.

3. The group would participate in the Friends of the Rouge Storm Drain Stenciling Program. The stenciling of storm drains should include, but is not limited to, all the storm drains within their designated neighborhood or area.

4. The group should actively participate and/or encourage proper household hazardous waste management. This could occur through:

   - Reduced purchasing of hazardous house chemicals
   - Proper use of household hazardous chemicals
   - Proper disposal of hazardous household chemicals
   - Use of less-toxic alternatives to household hazardous chemicals

   The group can accomplish this requirement by distributing information concerning proper household hazardous waste management to their designated neighborhood.

5. The group would facilitate education of residents regarding non-point source pollution. Information would be provided by the Rouge Project Team for distribution to the designated neighborhoods.

6. Submittal of semi-annual reports discussing the activities that have been taking place could be a requirement to maintain Rouge Friendly Neighborhood status.

Three Rouge Project area neighborhoods representing different demographics and development history were chosen as pilots for the Rouge Friendly Neighborhood Program. They were the (1) Brightmoor area of Detroit, an older, developed area of the watershed along the Main Branch of the Rouge River; (2) Golfview Manor subdivision in Dearborn Heights, a newer subdivision along the Middle Branch of the Rouge River; and (3) West Bloomfield Place, a subdivision in West Bloomfield Township, a developing area along the Upper Branch of the Rouge River. These three pilots represented communities with diverse demographics and concerns.

The Brightmoor neighborhood was a deteriorating area with strong community activism regarding neighborhood problems and concerns. The neighborhood also showed strong stewardship for the Rouge River, which serves as a western boundary to the neighborhood and flows through a nearby park. Golfview Manor in Dearborn Heights was a more upscale, manicured neighborhood that was very active through its subdivision association, but did not have a real connection to the River. West Bloomfield Place in West Bloomfield Township was an upper income, less urban area bounded by a wetland.

Meetings were held with a core group of representatives from each neighborhood to garner support from the neighborhoods' leadership and to discuss what the program was and what the expected outcomes were.

The residents of all three pilot areas were sent a survey, distributed by mail or door-to-door, to document their knowledge of Rouge River water quality, storm water issues, and household hazardous waste disposal. In addition, respondents were asked for demographic information. The survey information was used to determine what the Rouge Friendly Neighborhood Program should focus on in each particular neighborhood.

Educational materials that had been developed about storm water pollution, household hazardous waste (and its disposal), and watershed awareness were reviewed by each group. Each core group helped develop the particular program that would be implemented in their neighborhood, because Rouge Project staff knew that no program would be a success without the core groups' support and endorsement. These core group members were relied on to explain the program at neighborhood meetings.

The Rouge Friendly Business Program

The Rouge Friendly Business Program was developed as a partnership between Wayne County, local government, and the business community to restore and protect the Rouge River. To accomplish this goal, information and assistance are provided to small business owners to teach them how they can positively affect the water quality of the Rouge River by changing some of their everyday practices. The education process is not about major contaminants, but those little things that slip the mind, such as keeping the dumpster lid closed and storing materials under cover. These simple actions can affect water quality because they stop pollutants from entering the storm system. As an incentive to participate, Wayne County embraced the concept that businesses in the watershed that demonstrate stewardship and a strong environmental ethic should be recognized by the community for their voluntary participation. As such, these businesses should enjoy greater name recognition through the efforts of the local and regional media as well as specific program materials, such as decals and magnets that identify the business as Rouge Friendly.

The Rouge River Watershed has approximately 42,000 businesses in its 48 communities and three counties. To design program materials that would have the greatest impact, three criteria were developed to target business types. They are:

- The business has a high incidence of illicit connections to storm drains
- The business conducts a significant number of pollutant-generating activities outdoors
- The business is found in large numbers in the watershed

Using these criteria, six types of businesses were selected and specific activities identified. They are:

- Vehicle Service Industry
- Food producers, grocers, and eating establishments
- Metal Machining
- Earth Disturbing Construction
- Remodeling and Repair Contractors
- General Business

Pollution control criteria were established for each kind of business. These criteria were used to create a self-assessment form to be used by business owners to evaluate how "Rouge Friendly" their businesses are. Best Management Practices (BMPs) were also written that correspond to each activity and this information was put into the booklet along with a self-assessment form for distribution.

Representatives of various trade organizations were invited to participate in a Vehicle Service Industry Roundtable. The roundtable was asked to review and comment on the educational materials, the self-assessment form, the BMPs, and the best way to conduct program outreach. Rouge Project staff sought to engage businesses in an ongoing dialogue to determine what approach would work best, with a secondary goal of determining how to get businesses to participate. Feedback from this group resulted in a name change from the "Clean Business Program" to the "Rouge Friendly Business Program." This was not a quick process, but took approximately six months of meetings to (1) form a Vehicle Service Industry roundtable, (2) explain the purpose of the Rouge Friendly Business Program, and (3) refine the program and products. The Rouge Friendly Business Program elements were finalized as follows:

- Self-assessment form and action plan
- Best Management Practices

- Site visits by technical staff
- Recognition materials for participating businesses (stickers and magnets)
- Business pledge and newspaper recognition

After these materials were finalized, Wayne County and Rouge Project staff promoted the Rouge Friendly Business on a pilot basis and recruited businesses through the following mechanisms:

- Business Roundtable contacts
- Letter and telephone contacts
- Door to door contact with businesses
- Contact through homeowner/neighborhood associations
- Integration of Business and Residential Programs

By the end of the pilot period, the Wayne County Department of Environment had recognized 20 businesses as Rouge Friendly.

The Brightmoor Community Pilot

The Brighmoor area of Detroit was developed in the 1920s as a neighborhood for working-class families. Most houses are frame, with the newer areas of the neighborhood (1940s and 1950s) of brick construction. Over the past 15 years, the Brightmoor area has deteriorated. Its once vibrant business strip is dotted with boarded, vacant buildings, graffiti, trash, and debris. Whole blocks of residential land are vacant and overgrown and illegal dumping is abundant. Environmental abuses ranged from a myriad of abandoned vehicles to illegal car repair businesses on residential streets. The Rouge Friendly Neighborhood Survey (Attachment A), distributed in Brightmoor in 1996, showed that the top two environmental concerns in the area were illegal dumping and abandoned housing.

Despite these challenges, the Brightmoor neighborhood had two characteristics that made it a viable pilot for the Rouge-Friendly Programs. One, Eliza Howell Park, located on its western edge, was traversed by two branches of the Rouge River. Second, Brightmoor had a wealth of grassroots organizations who were working to make the neighborhood better. Some annually removed log jams and other debris from the Rouge River in Eliza Howell Park during Rouge Rescue, sponsored by Friends of the Rouge, a grassroots organization serving the whole watershed.

Initial contact was made with the Brightmoor Concerned Citizens and other neighborhood representatives in January, 1996. The group agreed that they would like to participate as a Rouge Friendly Neighborhood pilot. A month later, the same group met again with Rouge Project staff. This time, city parks staff were present. They were told about the possibility of grant funding for storm water projects by the Rouge Project. The group brainstormed the kinds of things they would like to see happen at the park, which had suffered from spotty maintenance. They agreed that they would like to see wildflowers and prairie grass planted, nature trails restored, and a community garden created. The parks department later applied for and was awarded a $180,000 grant to plant wildflowers and prairie grasses and to install nature trails in the lower end of the park, near the Rouge River

The next step in the program was to survey residents about their knowledge of pollution entering the river and household hazardous waste disposal, their neighborhood environmental concerns, and demographic information. The survey was created with input by the core neighborhood group. The major data extracted from the survey were:

- 78% thought the Rouge River was polluted or very polluted, and 20% thought the river was getting worse.
- 38% did not know that the storm drains lead directly to the Rouge River. However, 56% understood that sanitary sewers go to the wastewater treatment plant.

- 18% correctly answered that industry pollutes the Rouge River the least and 66% thought stormwater pollutes the least.
- 87% maintained their own lawn. There was an even distribution among those who never fertilize their lawns and those who fertilize 1-2 times per year.
- 75% did not change their own motor oil.
- 80% took their cars to a car wash instead of washing it themselves.
- 92% claimed indicated that they know what household hazardous waste is, and 73% correctly identified motor oil as a household hazardous waste. However, 54% did not properly dispose of their wastes.
- 83% said they were committed/very committed to make small changes to prevent pollution.

Following are neighborhood issues, in order of importance:

1. Abandoned buildlings
2. Illegal dumping
3. Household hazardous material disposal
4. Infrequency of street sweeping and storm drain cleaning
5. Recycling
6. Do-it-yourself car repair/illegal car lots on residential streets
7. Overuse of garden/lawn pesticides
8. Overuse of fertilizer
9. Composting

Wayne County Rouge Project staff, Friends of the Rouge, and Brightmoor Concerned Citizens leadership made a presentation, including survey results, to the general membership in May, 1996. The general membership was enthusiastic about the program. The annual Rouge Rescue held in Eliza Howell Park on June 1, 1996, was expanded to include other activities, including storm drain stenciling, a tour of a newly constructed combined sewer overflow basin, and children's games.

Subsequent meetings with the Brightmoor group were used to brainstorm what the specific program elements should be and what outcomes were expected. The following elements were supported by the core group:

- Urban gardens on vacant lots
- Composting education
- Attempting to get rid of the massive log jam at the confluence of the Upper and Main Rouge River in Eliza Howell Park
- A tour of the area for the Detroit Environmental Court judge
- Lawn signs that read "I support the Rouge Friendly Neighborhood Program"
- Early recognition of well-maintained lawns and gardens; Brightmoor's "Resident of the Month"

- A Brightmoor Rouge-Friendly Business Program
- A renters' workshop to educate tenants about their rights and responsibilities and the responsibilities of landlords
- Educational materials in the various neighborhood newsletters

All of the activities were implemented except the lawn signs, the recognition of well-maintained gardens, and the renters' workshop. By the fall of 1996, the focus had shifted to conducting a monthly combined resident/business owners' meeting to include businesses, which were primarily vehicle service oriented, into the Rouge-Friendly initiative.

Results and Outcomes

Rouge-Friendly Neighborhood Program: Because of the enthusiasm and commitment of Brightmoor residents and business owners, many activities were conducted. They were:

- Thousands of educational brochures and children's materials were distributed in community centers, businesses, schools, and newsletters.
- A local business owner successfully sued a public utility that was pumping hundreds of gallons of polluted stormwater into the Rouge River.
- The local community organization not only enthusiastically participated in the annual Rouge Rescue event, but conducted another such event on its own.
- Through a partnership with the city parks department, the Greening of Detroit, and the Brightmoor Concerned Citizens, 100 trees were planted in Eliza Howell park by 200 local elementary school students.
- City officials agreed to conduct an environmental ticket blitz in the neighborhood, which resulted in the following tickets being written: 179 parking tickets, 71 abandoned cars tagged for removal, 8 stolen cars being towed, 15 public works tickets for bulk garbage being put at the curb too early, 2 environmental protection tickets, and 47 tickets for inoperable vehicles.
- A monthly meeting that included neighborhood residents, business owners, non-profit organizations, city officials (including police commanders), and county officials focused on environmental issues.

Rouge-Friendly Business Program: While many outstanding initiatives were accomplished by meeting with the Brightmoor stakeholders monthly, only one Brightmoor business was recognized as Rouge Friendly after ten months of monthly meetings. The meetings were well-attended and business owners felt comfortable discussing their environmental concerns. In June, of 1997, the approach for recruiting Brightmoor businesses as Rouge Friendly was changed. A community leader was paired with a technical staff member and they proceeded to visit neighborhood businesses. They visited 14 neighborhood businesses several times over a two-month period. Information about the program was left with the business owners, as well as an offer from the technical staff member to help the business owner with the self-assessment form. Through this effort, Wayne County recognized six additional Brightmoor businesses as Rouge-Friendly. This was a successful (43% participation), but labor intensive, method of recruiting businesses.

ATTACHMENT A

THE ROUGE RIVER PROJECT
A WORLD CLASS EFFORT

BRINGING OUR RIVER BACK TO LIFE

Are you willing to **prevent pollution** in your **neighborhood**?

Start **today** by filling out this questionnaire.

We are working with the **Rouge River National Wet Weather Demonstration Project** to make our subdivision a more attractive place to live. We have been chosen as one of three pilot neighborhoods in the Rouge River Watersheds to participate in a pollution prevention program that may be used as a model for other urban watersheds across the country. In order to design a program that best fits our needs, we need you to answer a few questions. The following survey is voluntary and confidential. Use the enclosed pre-stamped envelope to return the questionnaire by **April 22, 1996**.

1. Do you think the Rouge River is polluted?
   Very polluted 5 — 4 — *Somewhat polluted* 3 — 2 — *Not polluted* 1
2. Do you think the Rouge River is getting cleaner,staying the same, or getting worse?
   Getting cleaner 5 — 4 — *Staying the same* 3 — 2 — *Getting worse* 1
3. Where does water go when it enters an outside storm drain in your neighborhood?
   - ☐ To a storage tank under the ground
   - ☐ To the Rouge River
   - ☐ To the waste water treatment plant
   - ☐ Don't know
4. Where does water go when it is flushed down the toilet or sink?
   - ☐ To a storage tank under the ground
   - ☐ To the Rouge River
   - ☐ To the waste water treatment plant
   - ☐ Don't know
5. What pollutes the Rouge River the LEAST?
   - ☐ Combined sewer overflows *(a mixture of sewage and stormwater that flows into the river when it rains.)*
   - ☐ Stormwater *(water that runs off the ground and enters the river)*
   - ☐ Industry
6. How do you maintain your lawn?
   - ☐ Paid professional company
   - ☐ Paid neighbor
   - ☐ Someone in the household maintains it
7. How often is your lawn fertilized?
   - ☐ 1 to 2 times per year
   - ☐ 3 to 4 times per year
   - ☐ More than 4 times per year
   - ☐ Never
8. Where do you change the oil in your car?
   - ☐ Auto Repair Shop/Quick Oil Chnage
   - ☐ Yard ☐ Street ☐ Driveway
9. Do you usually wash your car or take it to a car wash?
   - ☐ Wash it myself
   - ☐ Car wash
10. If you change your oil at home, how do you dispose of it?
    - ☐ In the garbage
    - ☐ In the sewer
    - ☐ Don't know
    - ☐ On the ground
    - ☐ Take to facility that accepts used oil
11. Do you know what household hazardous materials are?
    - ☐ Yes
    - ☐ No
12. Which of the following is a household hazardous material?
    - ☐ Baking soda
    - ☐ Motor Oil
    - ☐ Lemon oil
    - ☐ Vinegar

13. How do you dispose of your household's hazardous materials?

- ☐ Put it in the trash
- ☐ Dump it down the sink
- ☐ Dump it on the ground
- ☐ Don't know
- ☐ Take it to a Household Hazardous Drop-off Area

14. Indicate whether the following environmental issues are very important, important, or not important to your subdivision.

	Very important		*Important*		*Not important*
Overuse of fertilizer	5	4	3	2	1
Composting	5	4	3	2	1
Abandoned buildings	5	4	3	2	1
Frequency of street sweeping and storm drain cleaning	5	4	3	2	1
Overuse of garden/lawn pesticides	5	4	3	2	1
Recycling	5	4	3	2	1
Household hazardous waste	5	4	3	2	1
Illegal dumping	5	4	3	2	1
Do-it-yourself car repair / Illegal car lots on residential streets	5	4	3	2	1
Other (specify: ______________________)	5	4	3	2	1

15. You can make small changes to prevent pollution (i.e. the type of fertilizer you purchase, how you dispose of your motor oil, etc.). What is your level of commitment to make these changes?

Very committed		*Somewhat committed*		*Not interested*
5	4	3	2	1

16. How many people, including yourself, live at this address?

- ☐ 1
- ☐ 2
- ☐ 3
- ☐ 4
- ☐ 5
- ☐ 6
- ☐ More than 6

17. How many of these are children?

- ☐ 0
- ☐ 1
- ☐ 2
- ☐ 3
- ☐ 4
- ☐ More than 4

18. How many pets do you own?

- ☐ 0
- ☐ 1
- ☐ 2
- ☐ 3
- ☐ 4
- ☐ More than 4

19. What is your gender?

- ☐ Female
- ☐ Male

20. What is your age group?

- ☐ Under 18 years
- ☐ 18–30 years
- ☐ 31–45 years
- ☐ 46–60 years
- ☐ Above 60 years

21. What was the last grade you completed in school?

- ☐ Some high school
- ☐ Completed high school
- ☐ Post-high school training
- ☐ Some college
- ☐ Completed college
- ☐ Graduate or professional school

Thank you for doing your part in cleaning up our subdivision! Remember, return the questionnaire in the pre-paid envelope by **April 22, 1996**.
Any questions should go to John or Shelley Mlynarczyk at 533-3453

The Water-Wise Gardener Program: Teaching Nutrient Management to Homeowners

Marc T. Aveni
Virginia Cooperative Extension
Manassas, Virginia

Introduction

The Water-wise Gardener program was developed by Virginia Cooperative Extension (VCE) seven years ago with funding from the Cooperative State Research, Education, and Extension Service (CSREES) of the U.S. Department of Agriculture (USDA). It is an educational program aimed at reducing non-point source pollution from suburban residential areas. The educational focus is upon nutrients, especially nitrogen and phosphorus from lawn fertilizer over-application or misuse. The program seeks to reduce such nutrient pollution to Virginia waterways, and eventually the Chesapeake Bay, through the recruitment of homeowner participants from impaired watersheds. Participating homeowners attend educational seminars on lawn best management practices, are partnered with a Master Gardener volunteer, and are expected to keep accurate records and implement recommended practices. The program, which is currently being implemented in 12 urban/suburban Virginia counties, is supported by a combination of local county funds, grants from the Virginia Water Quality Improvement Act, and funds from USDA. Cooperative Extension Units in North and South Carolina have replicated the program.

How the Program Works

The Water-wise Gardener program begins by recruiting homeowners from watersheds with impaired streams or other identified problems to participate in a year-long lawn care educational program. The most successful recruitment method to-date has been to conduct a "reverse search" on the Internet by street name. Once names and addresses are identified, a recruitment letter is sent personalized for the watershed; e.g., "Dear Resident of the Bull Run Watershed." The letter invites the homeowner to participate in the program and lists the benefits of participation, such as free seasonal seminars with regional experts, visits from a Master Gardener (volunteers trained by VCE in various aspects of horticulture), a free soil test, and Virginia Tech publications. In order to be enrolled in the program, the homeowners must return a completed pre-survey and a signed agreement form that details their obligation to the program. The pre-survey asks questions about their lawn care practices and attitudes before program involvement, as well as demographic information such as race, gender, income, and education levels. A stamped, self-addressed envelope is included for ease of return. For every 100 letters sent out, between 20-30 are typically returned. A simple database program keeps track of participants and their lawn care data. A reporting system on the Virginia Tech Intranet is currently being designed to record this information on a statewide basis by hydrologic unit.

Once enrolled, participants are assigned a personal Master Gardener. The Master Gardener schedules a visit with the homeowner to discuss his or her lawn. All Master Gardeners are instructed to stay outside on the lawn and not to go inside anyone's home. Some choose to bring along a spouse, friend, or another Master Gardener. At this visit, the Master Gardener works with the homeowner to correctly measure the square footage of lawn area, determine the type and variety of grass, collect a soil sample, and ascertain previous fertilization practices and amounts previously applied, if known. This information forms the basis of a personalized lawn care plan for the homeowner. Master Gardeners also answer other questions the participant may have; common questions include weed and pest identification, what plant grows best where, and why certain plants are not thriving. The Master Gardener leaves a business card with a phone number or e-mail where he or she can be reached for further questions throughout the program year. All Master Gardeners receive 50 hours of classroom training as well as supplemental field training before being assigned to homeowners. Typically, a Master Gardener will be assigned to between 5-10 homeowners.

In addition to the one-on-one visits from Master Gardeners, homeowners attend seasonal seminars on timely topics of interest to those with lawns. In Northern Virginia, where cool-season grasses like Fescue and Bluegrass predominate, fall topics include soil testing, fertilization, core aeration, and over seeding. Spring topics include mowing and pruning, integrated pest management, and proper watering and planting. Popular locations for seminars include parks with covered pavilions, school auditoriums, county buildings, and libraries. Any easily accessible public location large enough to hold 50 to 100 people comfortably, and accessible to wheel chairs, will work. If held inside, cold temperatures, rain, or wind are not a problem; however, an outside area for demonstration purposes is essential. State and regional Cooperative Extension experts are recruited for the seminars to answer questions. Master Gardeners are also present, with various displays, to answer questions and to meet with their assigned participants.

A professional-quality newsletter is sent to all participants approximately six times per year. A grant-paid editor solicits articles that reinforce or complement topics taught at the seminars. Articles on various aspects of watershed management are also introduced. The newsletter is made available electronically to other Extension Agents for editing and reproduction elsewhere.

After participants have attended fall and spring seminars, they are visited again by their Master Gardener to collect final lawn data and conduct a post-survey of practices and attitudes. The most important piece of data collected is the amount of fertilizer now being applied. Square footage of turf can be re-checked, if needed, and questions answered.

The homeowner may chose to participate again the following year, or to offer their lawn as a demonstration lawn, and erect a sign in their yard to promote the program in the community. The post-surveys and data sheets are collected from all participants annually. Results are compiled and analyzed by a grant-paid technician and a final report generated for each Cooperative Extension unit as well as an overall report for statewide efforts.

Results

Data for the period March 1998 to June 1999 for the Virginia counties of Arlington, Loudoun, and Prince William shows 326 individual homeowner participants. These 326 homeowners managed 57.1 acres of turf in 11 different hydrologic units in the Northern Virginia area. Between 100-200 additional individuals attended seminars but did not participate in the pre- and post-survey and data collection.

Accurate information on amounts of nitrogen and phosphorus applied by participants before program involvement is difficult to get. Most did not remember how much fertilizer they had applied in the previous year. Many stated the reason they joined the program was in order to understand how much fertilizer to apply. A total of 72 participants reported pre-program fertilizer application of 1,062 pounds of nitrogen. The same 72 participants reported 762 pounds of nitrogen applied after program involvement, or a reduction of 300 pounds. Information on pre- and post-phosphorus was not collected.

Pre-surveys indicated that only 12% of all participants had soil tested for their lawns prior to applying fertilizer. Homeowners not testing soil are more likely to apply excess fertilizer. For this reason, Virginia Tech recommends soil testing as a nutrient management practice for home lawns. Post surveys show 95% of participants returning surveys tested soils after program involvement. Another important nutrient management practice for homeowners with cool-season turf is to fertilize in the fall, when uptake by roots occurs best. Pre-surveys indicated that only 32% were fertilizing at this time of year, while post surveys indicated that 64% were fertilizing in the fall. Similar increases were also observed for recommended practices such as aeration (from 34% to 83%), and over-seeding (from 35% to 76%). An increase in the number of participants not watering the lawn at all in the summer also increased (from 18% to 44%) (Figure 1).

Demographics from the program indicate that 72% of participants were male and 28% female. Participants were overwhelmingly white (89%); followed by black (7%), Asian (4%), and Hispanic (1%). The majority (42%) had a four-year college degree and a gross family income of over $70,000 a year (54%). More than one-third of the lawns were between 5,000 and 10,000 square feet (35%).

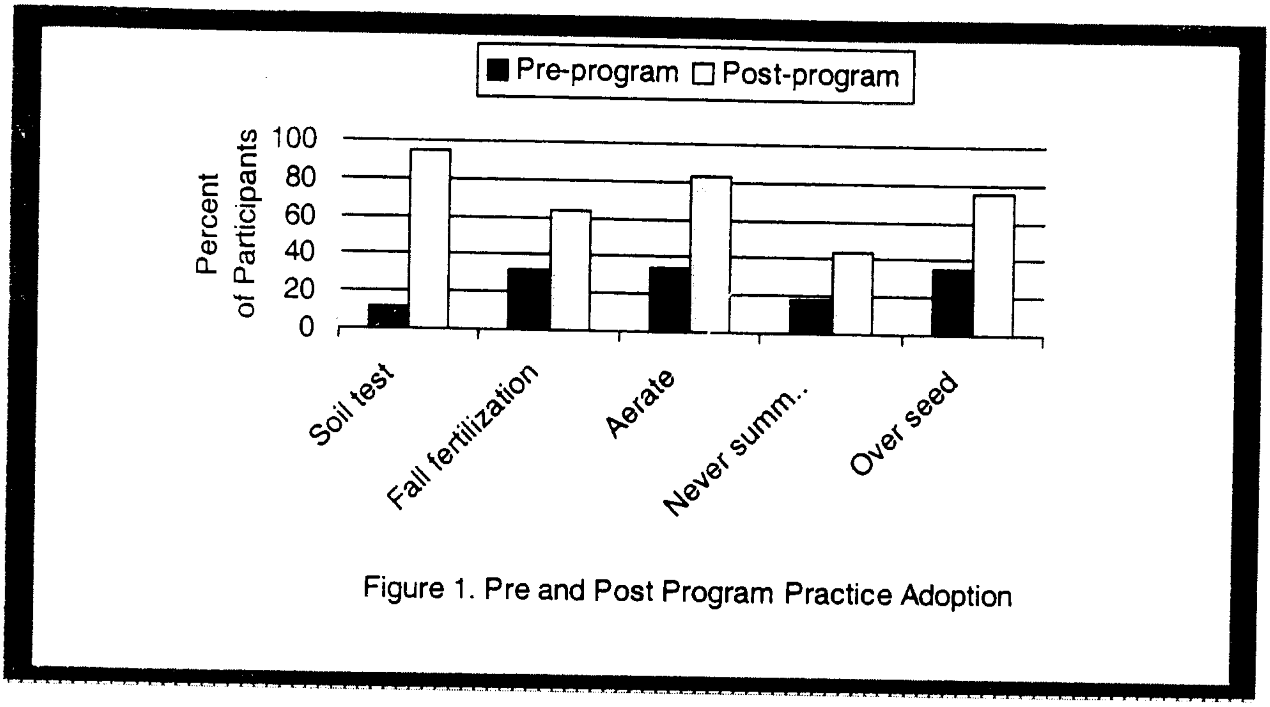

Figure 1. Pre and post program practice adoption.

Conclusions and Lessons Learned

The Water-wise Gardener Program was successful at reaching the intended audience and achieving adoption of nutrient management practices. Based on the success of the program, it appears that suburban homeowners can be recruited to maintain their lawns according to recommended practices. Homeowners are willing, with the help of Master Gardener volunteers in some cases, to keep records on their nutrient use as a part of program participation. Although 326 individuals and 57 acres of turf may seem low for an area like Northern Virginia, it is significant for a populace that does not traditionally participate in water quality educational programs. Considering that most lawns in suburban subdivisions have a turf area of around 5,000 square feet, clearly many individuals will need to be enrolled to reach meaningful numbers.

The study showed that it is difficult to obtain information on pre-program nutrient use for most participants. Most homeowners cannot provide accurate nutrient use data from the previous 6-12 months. They simply do not remember how much nitrogen and phosphorous was in the fertilizer bag applied last spring or fall. However, after program involvement, they do appear to understand how much nitrogen they applied and the square footage of their turf. From a water quality public policy perspective, it may be preferable to record nutrient use after program involvement and consider participants' turf square footage as the urban nutrient management measurement. In this way, the focus could be upon recruiting more and more individuals to participate in nutrient management educational programs like the Water-wise Gardener, thus increasing the number of acres addressed by urban nutrient management efforts. Such an approach could easily be integrated into local Geographic Information Systems, providing localities a simple method of accounting for and reporting on urban nutrient management. Localities interested in a program like the Water-wise Gardener should contact their local Cooperative Extension office to see if a similar project is already occurring or could be developed. As this program is being continued and expanded in the 1999-2001 time frame, the opportunity to better define what is realistic as an urban nutrient management measurement for homeowners will hopefully occur.

Chicago Wilderness; Toward an Urban Conservation Culture

U.S. Fish and Wildlife Service
Barrington, IL 60010

Chicago Wilderness - Origin and Purpose

We in the Chicago conservation community have been using the word "wilderness" in a highly unconventional context since 1996. We have coined the term "Chicago Wilderness" to refer to the rich biodiversity which resides in and around this huge, sprawling metropolitan area, extending from southeast Wisconsin, through the six-county metropolitan area in Illinois, and around Lake Michigan to northwest Indiana. This is a region which most people think of as anything but "untrammeled by man, where man is a visitor who does not remain," in the words of the Wilderness Act, which has defined our modern concept of wilderness.

This is an area that is associated with--indeed, defined by--humans and their cultural footprint. Although the "wilderness" is scattered throughout the region, mostly in parcels that would be considered slivers of land by conventional wilderness standards, it totals over 200,000 acres of land protected within a complex of national tallgrass prairie, national lakeshore, county forest preserves, city and township parks, and similar preserved public lands. Its protected lands and waters range from half-acre remnants to the 15,000-acre Midewin National Tallgrass Prairie,

Within this system of preserves can be found some of the largest and best woodlands, wetlands, and prairies in the Midwest. These lands are set in a much larger matrix of public and private, developed and undeveloped lands that support nature and the region's 8 million people.

We have called these lands "wilderness," in part to draw the attention of people who are focused on Chicago's cultural attractions to the existence of these lands in their own metropolis, and in part to deliberately blur the distinction, or conversely, emphasize the connections between formal wilderness in remote and inaccessible places and wild lands in the places where people live and work. The biotic connections exist on the land, and they ought to exist in people's minds, as well.

The boundaries of the Chicago Wilderness region do, in fact, capture a spectacular concentration of rare ecosystem types. These ecosystems harbor a high diversity of species, including a large number of those listed as threatened or endangered in the states of Illinois, Indiana, and Wisconsin. Outside of the metropolitan area, particularly in rural Indiana and Illinois, diversity decreases sharply as agriculture dominates the landscape.

"Chicago Wilderness" is also the name we have given the collaboration of over 90 organizations in the Chicago region that have banded together to better protect, restore, celebrate, promote, and publicize our rich biodiversity. An unfortunate and perhaps somewhat inevitable consequence of urban life is a detachment from the land; thus, a principal goal of the partnership is to reconnect a landless urban population, in Aldo Leopold's words, to the "raw material out of which we have hammered that artifact called civilization."

Despite the richness of nature and opportunity for conservation in the region, evidence suggests the Chicago region is experiencing a decline in native species and communities. Prior to protection, much of the region's current base of protected land was subject to agriculture, drainage, and other human influences which reduced or eliminated native plant and animal communities. These areas are often fragmented and isolated from healthy lands which could otherwise serve as immigration sources for native species.

Small fragments are also subject to influences beyond their boundaries, such as urban runoff. Keystone species like wolves and mountain lions, predators which formerly kept prey species like whitetailed deer in check, have been eliminated, and deer now threaten to destroy some of our finest lands through overbrowsing. Many of our protected sites are too small to sustain populations of area-sensitive species, or to retain their full complement of species in the face of random population processes like immigration and emigration. Exotic plant and animal species pose major threats to nearly all of our native communities. Landscape level processes, like fire, that shaped the fundamental character of our ecosystems do not occur with the frequency or to the extent they once did, resulting in shifts in community composition that usually result in a decline in biodiversity.

Chicago area residents are the beneficiaries of farsighted leaders early in the 20th century who established a tradition of setting aside natural land in the urban matrix for the public good, a tradition that our forest preserve districts continue today. The early model was not based on sophisticated concepts of biodiversity conservation, or of ecological processes, but on the museum approach of setting nature aside and not meddling. We now are the beneficiaries of the science of ecology, which begins to tell us how the land mechanism is constructed and how it operates. It is dynamic, not static, and changes occur when landscape processes are interrupted. The science of ecology also reinforces the connections between humans and the rest of nature.

This allows us to reexamine the old model of setting nature aside and leaving it alone. That removes the most immediate threat of development, but it does not address the aforementioned degenerative loss of biodiversity due to fragmentation and alteration of landscape processes. These processes clearly must be reintroduced into our preserves if biodiversity is to be preserved or restored. Prescribed fire must be intelligently applied, invasive species must be controlled, plant and animal species must be reintroduced where they have been eliminated, hydrology must be restored where altered, and science must be improved where our understanding of ecosystem processes is deficient. Perhaps most fundamentally, the people who must support the greatly increased levels of land management and research necessary to restore and maintain our public lands in a healthy condition must have a basic understanding of land health and the value system to commit public resources toward attaining it. Chicago Wilderness, the coalition, is committed to working on all of these fronts.

Quite understandably, the Chicago region's system of public lands was, and perhaps still is, the core of Chicago Wilderness, the initiative. It is what members rallied around during the coalition's formation in 1996. But the vision quickly expanded beyond public lands, for two reasons.

First, our public lands do not exist in isolation. They are part of a much larger land base, and the protected 200,000 acres are affected by what happens on the remaining 6 million acres of the Chicago metropolitan land area. The preserves form the core, but they cannot preserve all the biological parts by themselves since much biodiversity resides on private unprotected land and because they are subject to outside influences.

Biodiversity considerations need to infuse all of the region's land use decisions much more extensively that they do now. Private lands work either in harmony or discordantly with our network of preserves. The link between the two is most apparent in the case of wetland or aquatic habitats, which in many cases are sustained or impacted by runoff from distant areas. Streams, rivers, lakes, and wetlands defy the "protect by fencing" approach. Overall watershed characteristics determine aquatic and wetland habitat quality quite independently of whether the habitat is in a formal preserve or not.

Second, many high-quality, biologically rich pieces of nature persist outside of our preserve system and are threatened by development, along with other stresses like lack of management. Identifying these biologically important areas within proposed developments, redflagging them, designing development with their sustainability in mind, and doing all this with equity for the landowner, is one of our greatest challenges. Nature in the places where we live contributes so much to quality of life, yet maintaining it through the development process resists standard regulatory approaches. There are questions now asked routinely in the subdivision design process: does the plan conform to drainage code, are storm water basins sized properly, is it consistent with surrounding development, does it have proper standards of landscaping? A standard question should be: does it leave the land biologically richer or poorer? We are not yet routinely asking this question, although there are development approaches available that can allow us to answer this question affirmatively.

This question could properly be asked for aesthetic reasons alone, but there are practical reasons for doing so. Native landscapes hold enormous potential for managing storm water and preventing flooding. They hold enormous potential for cleaning up surface waters so that urban waters become fishable and swimmable, instead of the neighborhood joke or eyesore. Finding and applying the template for development that preserves and restores biological diversity, and which serves both aesthetic and utilitarian purposes, is one of the objectives of Chicago Wilderness.

Chicago Wilderness - Structure and Function

Chicago Wilderness formally began as an initiative with the signing of a memorandum of understanding (MOU) by 34 founding members. Members included landowners and land managers; local, state, and federal agencies; centers for research and education; and conservation organizations, among others. These institutions pooled their resources and strengths to form the Chicago Region Biodiversity Council, which has grown to include nearly 100 members.

By signing the MOU, the members of this innovative partnership have pledged a commitment to the protection, restoration, and management of biodiversity in the Chicago region. Four teams focus on central lines of action: science, land management, policy and strategy, and education and communication. The teams attract the participation of many non-member institutions, which adds to the scope and strength of the coalition. Chairs of the teams and other member organization staff form the nucleus of a coordinating group that develops central strategies and maintains momentum. A steering committee of executives oversees the direction of the overall initiatives. Despite this organizational structure, Chicago Wilderness has not become legally incorporated under state law, but remains a loose partnership bound by common goals and objectives.

The potential for Chicago Wilderness to serve as a model for urban conservation attracted the early attention of several federal agencies, including the U.S. Forest Service, U.S. Fish and Wildlife Service, and U.S. Environmental Protection Agency, who have provided significant operating grants. State and private grants have supplemented federal dollars. Direct grants have totaled over 4 million dollars since 1996. This total does not include members' matching funds or funds attracted by members for projects catalyzed, but not directly supported by, Chicago Wilderness.

Chicago Wilderness Accomplishments

The Chicago Region Biodiversity Council funds projects on an annual cycle. The Council's four teams set priorities for these projects; core staff ensure broad participation from team members. Reviewed and approved by a proposals committee, funded projects result from collaboration between member institutions and address critical conservation needs in the region. Since its launch in April 1996, Chicago Wilderness has funded over 130 collaborative projects. In addition to projects funded directly by the Council, the work of our individual member organizations in their own initiatives is central to the success of Chicago Wilderness. Projects completed or underway fall into six categories: characterization and information management; ecological inventory and monitoring; ecological restoration; planning and policy; education, outreach, and public participation; and communications and publications.

Individual projects have included a NASA-supported land cover mapping project; development of models of pre-settlement savannas, woodlands, and forests to guide restoration; assessment of restoration effects on bird communities; a vegetation monitoring workshop; assessment of garlic mustard impacts on native woodland ground flora; development of model restoration interpretive programs; a biodiversity educators workshop; and creation of a Chicago Wilderness Atlas of Biodiversity. An early pilot project supported by Chicago Wilderness was the launching of Chicago Wilderness magazine, a glossy, popular publication on nature in the Chicago area which since has been incorporated as a 501(c)(3) and has over 7,000 paid subscribers.

Chicago Wilderness Biodiversity Recovery Plan

In 1909, the Commercial Club of Chicago released the "Burnham Plan," a landmark of urban planning that proposed, among other things, a network of public parklands to be set aside for nature and passive recreation. This led to the legislative establishment of a system of such publicly owned preserves for the Chicago region which has continually expanded, and now forms the core of the protected lands that currently comprise Chicago Wilderness.

The Biodiversity Recovery Plan, completed in late 1999, takes the open space component of the Burnham Plan to the next step by creating a vision of sustainability, not only for the core of protected land, but for all of nature and its human inhabitants in the urban area. The recovery plan is a comprehensive statement of what Chicago Wilderness is about, and it is clearly the most ambitious and significant accomplishment of the coalition to date.

This plan is the result of three years of assessment and planning by representatives of the Chicago Region Biodiversity Council. The plan identifies the ecological communities of the greater Chicago region, assesses their condition, identifies major factors affecting them, and provides recommendations for actions needed to restore and protect them into the future in a sustainable condition. In short, the recovery plan outlines the steps necessary to achieve the overall goal of the Chicago Wilderness collaboration, which is to protect the natural communities of the Chicago Region and to restore them to long-term viability, in order to enrich the quality of life of its citizens and to contribute to the preservation of global biodiversity.

To achieve this goal, the recovery plan identifies the following objectives: 1) involve the citizens, organizations, and agencies of the region in efforts to conserve biodiversity; 2) improve the scientific basis of ecological management; 3) protect globally and regionally important natural communities; 4) restore natural communities to ecological health; 5) manage natural communities to sustain native biodiversity; 6) develop citizen awareness and understanding of local biodiversity to ensure support and participation; 7) foster a sustainable relationship between society and nature in the region; and 8) enrich the quality of the lives of the region's citizens.

The plan has many recommendations, some specific and some general, and identifies roles and specific actions for Chicago Wilderness members and the greater public that must be engaged to help implement the plan. The plan's intended intended audiences include the many staff members and general members of Chicago Wilderness institutions, public agency decision-makers, large landowners, and all concerned and active citizens who vote and otherwise influence biodiversity conservation in the region.

The recovery plan is both a plan and a process guided by its many sponsors. It is intended as a living document that will continue to evolve as new ideas and information arise. It is intended to complement the many other planning efforts completed or underway in the Chicago metropolitan area that are guiding the region to a better and more productive future. Its ultimate success probably rests on its successful integration into a broader, mainstream regional planning framework that has economic, cultural, social, and environmental components.

Strategic Visioning

After the second year of operation, the Biodiversity Council saw the opportunity to step back and evaluate the structure and function of the coalition during the first two years, consider expectations of members at the outset and evaluate to what extent they were met, and reprioritize its work for the next two years. This process consisted of development of a member questionnaire, convening of a focus group representing a cross-section of members, and a weekend retreat by Chicago Wilderness Steering Committee members and other leaders. It culminated with the development of six priority functions for the next two years, and associated budget requirements.

Some of these functions represent an intensification and refinement of activities the Council is already involved in; in other cases, they represent new endeavors. They include 1) facilitate networking among Chicago Wilderness members, including new orientation materials, workshops, symposia, and lectures; 2) establish an integrated information clearinghouse, including the development of regionwide resource databases, enhancement of the existing web site, and development of more communication resources; 3) increase publicity and outreach to broader audiences; 4) influence key actors outside Chicago Wilderness, including the establishment of a Conservation Policy Committee to develop position statements on regional issues; 5) develop and implement a funding strategy, focusing on large grants from foundations; and 6) implement, promote, and monitor the Recovery Plan.

The Urban Conservation Culture

Conservation efforts in urban areas are often frustrated by the complexity of land use issues, countless players, tangled politics, ecologically wrecked land, and a public dispossessed of nature. Yet it is crucial that we focus on urban areas because of the strong political forces concentrated in urban centers that need to be engaged in national conservation decision-making, and because there is no other way to engage the great majority of people other than to take the messages to them. Moreover, urban residents are still plain members of Leopold's land community, regardless of how obscure the connections, and these connections are best illustrated in the places where they live. Fortunately, the Chicago region has an added bonus of harboring world-class biodiversity, which creates a local, immediately compelling reason for public involvement and action.

Some writers have argued that the American ideal of wilderness has tended to shape our dominant view of nature itself as a place that can only be corrupted by human influence. In urban areas, this has created an assumption that "real" nature cannot exist in these places and it tends to absolve urban residents from local responsibility. Thus, it seems that Chicagoans are much more aware of the plight of Brazilian rain forests that they are of the plight of oak savannas, a globally rare community, in local forest preserves. In remote areas, the standard approach has been to specifically designate areas as wilderness, and then maintain as complete a separation between people and these areas as possible. Chicago Wilderness proposes to redefine wilderness to include local plant and animal communities, which can only be sustained through direct, creative human intervention. A premise of the recovery plan is that if we do not adequately enlist people to directly or indirectly support management and restoration of our lands, they will not become or remain healthy.

It is appropriate to recognize that humans in the Midwest always <u>have</u> influenced landscapes, for better or worse, and that people can be a positive force in maintaining ecosystem health. It may be that by calling a 200-acre patch of prairie in a sea of development wilderness, and by involving people in its stewardship, we can promote a correct sense of unity between the places that we live and remote places we may never see except as pictures on calendars. Restoration and stewardship can be the antidote to dualistic thinking. Remote wilderness and Chicago Wilderness can perhaps then be seen as simply examples of nature, as part of a single system that includes people.

From a relatively straightforward beginning that focused on public land management issues, this, I think, has become the broader goal of Chicago Wilderness--to reconnect people with nature and to make a societal commitment to sustain and nurture nature--for utility, for aesthetics, for spirituality, for all of the equally valid reasons for doing it, on all of our urban lands and in all of our land-use decisions. It begins with a process of educating the public about the natural wealth in the Chicago area, and hopefully ends sometime in the future with the development of an urban conservation culture of concern and personal responsibility for the health of all of our lands, both public and private.

A Survey of Resident Nutrient Behavior in the Chesapeake Bay Watershed

Chris Swann
Center for Watershed Protection
Ellicott City, Maryland

In recent years a handful of communities have attempted to craft education programs to influence our watershed behaviors. These initial efforts have gone by a confusing assortment of names, such as public outreach, source control, watershed awareness, pollution prevention, citizen involvement, and stewardship, but they all have a common theme -- educating residents on how to live within their watershed.

Many communities will need to develop watershed education programs in the coming years to comply with pending EPA municipal stormwater NPDES regulations. Indeed, half of the six minimum management measures prescribed under these regulations directly deal with watershed education – pollution prevention, public outreach and public involvement. Yet, many communities have no idea what kind of message to send, or what media to use.

In the following presentation, we review the prospects for changing our behaviors to better protect watersheds. We begin by outlining some of the daunting challenges that face educators who seek to influence deeply rooted public attitudes. Next, we profile research on the outreach techniques that appear most effective in influencing watershed behavior. Special emphasis is placed on media campaigns and intensive training programs. Lastly, recommendations are made to enhance the effectiveness of watershed education programs.

Challenges in Watershed Education

Watershed managers face several daunting challenges when they attempt to influence watershed behaviors. Some of those challenges include:

A lot of minds to change

The most pressing challenge is that there are simply a lot of minds to change. Some notion of the selling job at hand can be grasped from Table 1, which contains provisional, but conservative, estimates of potential residential "polluters" in the United States by various categories. It is clear that we are attempting to change deeply rooted attitudes held by millions of people. While most people profess to support the environment, only a fraction actually practice much of a watershed ethic on the small parcels of the environment where they live.

Table 1. Provisional Estimates of Potential Residential Polluters in the United States

Watershed Behavior	Prevalence in Overall Population	Estimates of Potential Residential Polluters
Over-Fertilizers	35%	38 million
Bad Dog Walkers	15 %	16 million
Chronic Car washers	25%	27 million
Septic Slackers	15%	16 million
Bad Mechanics	1 to 5%	3 million
Pesticide Sprayers	40%	43 million
Hosers	15%	16 million

Notes: estimates are based on 1999 U.S. population of 270 million, 2.5 persons per household, and average behavior prevalence rates based on numerous market surveys (See references).

Most Residents are Only Dimly Aware of the Watershed Concept.

It stands to reason that if citizens are asked to practice a watershed ethic, they will need to know what a watershed is. Surveys indicate, however, that the average citizen is unaware of the watershed concept in general, and does not fully understand the hydrologic connection between their yard, the street, the storm sewer, and (finally) local streams. Resident surveys also continue to show limited or incomplete understanding of terms such as "watershed", "stormwater quality" or "runoff pollution". For example, a recent Roper survey found that only 41% of Americans had any idea of what the term watershed meant (NEETF, 1999). The same survey found that just 22% of Americans know that stormwater runoff is the most common source of pollution of streams, rivers, and oceans.

At the same time, most of us claim to be very environmentally aware. For example, a Chesapeake Bay survey reported that 69% of respondents professed to be very active or at least somewhat active in helping to reduce pollution in the environment (SRC, 1994).

Resources Devoted to Watershed Education are Inadequate.

In recent years, several communities have developed education programs to influence the watershed behaviors practiced by their residents. Most of these efforts, however, are run on a shoestring. For example, CWP recently surveyed 50 local programs that have tried to influence lawn care, septic cleaning and pet waste behaviors (Swann, 1999). These education programs are typically run by the cooperative extension services, local recycling or stormwater agencies, or urban soil and water conservation districts. Most are poorly staffed (0.1 to 0.5 staff years), relatively new (within last five years), and have tiny annual budgets ($2,000 to $25,000). Given these limited resources, most watershed education programs have no choice but to practice *retail*, rather than *wholesale*, outreach techniques. Consequently, most watershed educators rely heavily on low-cost techniques such as brochures, posters, workshops, and demonstration projects to send their message out.

The Marketing Techniques We Can Afford Don't Reach Many People

Watershed managers need to send a clear and simple educational message that can attract the attention of the average citizen who is simultaneously bombarded by dozens of competing messages every day. A number of surveys have asked residents which outreach techniques are most influential in attracting their attention (Table 2). Messages sent through television, radio and local newspapers are consistently more influential in reaching residents than any other technique, with up to 30% recall rates by the watershed population for each technique. By contrast, messages transmitted through meetings, brochures, local cable and videos tend to be recalled by only a very small segment of the watershed population.

Table 2. Most Influential Methods of Getting Messages to Citizens, in 8 Citizen Surveys

	WA (Elgin, 1996)	OR (AMR, 1997)	CA (Assing, 1994)	CA (Pellegrin, 1998)	MI (PSC, 1994)	WI (Simpson, 1994)	MN (Morris et al., 1996)
TV	TV ad	Direct Mail	TV Ad	TV	TV	TV	Newspaper
TV ad	TV.	TV ad	Stencils	Paper	Paper	Paper	Direct Mail
Newspaper	Newspaper	Newspaper	Billboard	Radio	Cable TV	Newsletter	TV
Local paper	Radio Ad	Radio	Local paper	Magazine	Local paper	Brochure	Neighbors
Video	Brochure	TV	Brochure	Neighbors	News-letter	Site Visit	Ext Service
Brochure	Radio news	Bill Insert	Radio Ad	School	Video	Video	Radio
Local cable	Paper Ad	Newsletter	Bus Sign	Billboard	Meetings	Meeting	Meeting
Meeting	Billboard	Local paper	Direct Mail	Brochure	Brochure	- -	Local cable

One clear implication is that watershed education efforts must utilize a mix of outreach techniques if they are going to get the message across to enough residents to make a difference in a watershed. Most existing watershed education programs, however, cannot afford to use the more sophisticated *wholesale* outreach techniques that are most effective

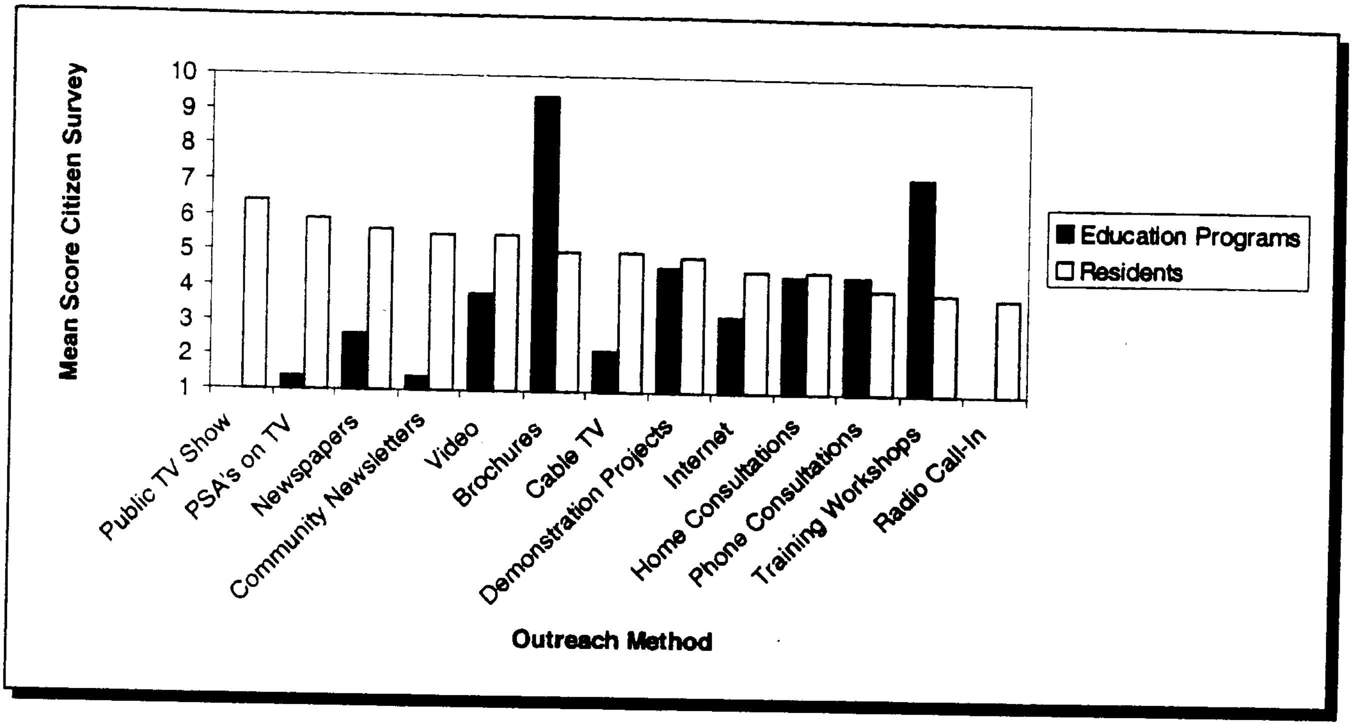

Figure 1. Outreach Methods Preferred By Residents Compared to Those Used by Education Programs.

at reaching the public with their watershed message. This gap is evident in Figure 1, which compares the outreach methods actually used by local watershed education programs with the outreach methods that residents prefer, based on responses from the Chesapeake Bay survey (Swann, 1999).

Crafting Better Watershed Education Programs

The first step in crafting better watershed education programs is to compile some baseline information on local awareness, behaviors and media preferences. Some of the key questions watershed managers should consider are:

Is the typical individual **aware** of water quality issues in the watershed they live in?

- Is the individual or household **behavior** directly linked to **water quality problems** ?
- Is the behavior widely prevalent in the watershed **population** ?
- Do specific **alternative(s)** to the **behavior** exist that might reduce pollution?
- What is the most clear and direct **message** about these alternatives?
- What **outreach** methods are most effective in getting the message out ?
- How much **individual behavior change** can be expected from these outreach techniques?

The best way to elicit this information is to conduct a market survey within the watershed. These market surveys are useful for two purposes: to gauge the level of watershed awareness and interest within the general population, and to determine if there is a segment of the population where education efforts should be focused to achieve the best returns in behavioral changes for the money spent.

Perhaps the most critical step in crafting an education program is to select the right outreach techniques to send the watershed message. Several communities have recently undertaken before and after surveys to measure how well the public responds to their watershed education programs. From this research, two outreach techniques have shown some promise in actually changing behavior – media campaigns and intensive training. *Media campaigns* typically use a mix of radio, TV, direct mail, and signs to broadcast a general watershed message to a large audience. *Intensive training* use workshops, consultation and guidebooks to send a much more complex message about watershed behavior to a smaller and more interested audience. Intensive training often requires a time commitment of several hours from residents.

Both media campaigns and intensive training can produce up to a 20% improvement in selected watershed behaviors among their respective target populations (Tables 3 and 4). Both outreach techniques are probably needed in most watersheds, as each complements the other. For example, media campaigns cost just a few cents per watershed resident reached, while intensive training can cost a few dollars for each resident that is actually influenced. Media campaigns are generally better at increasing watershed awareness, and sending messages about negative watershed behaviors. Intensive training, on the other hand, is superior at changing individual practices in the home, lawn and garden.

Table 3. Effectiveness of Media Campaigns in Influencing Watershed Behaviors: Four Surveys

Location and Nature of Targeted Campaign	Effectiveness of Campaign
San FranciscoRadio, TV and Buses (BHI, 1997)	Awareness increased 10-15% Homeowners who reduced lawn chemicals shifted from 2 to 5%
Los Angeles Radio and Newspapers (Pellegrin Research Group, 1998)	Best recall: motor oil and litter (over 40%) Worst recall: fertilizer and dog droppings (<10 %) Drop in car washing, oil changing, radiator draining of about 5 to 7% Greater self-reporting of polluting behaviors: dropping cigarette butts, littering, watering and letting water run on street, hosing off driveways into the street (10% or more)
Oregon Radio, TV (Advanced Marketing Research, 1997)	19% reported a change in "behaviors"–changes included being more careful about what goes down drain, increasing recycling and composting, using more nature-friendly products etc.
Oakland County, MI Direct Mail (Public Sector Consultants, 1994)	44% of mail respondents recalled lawn care campaign 50% desired more information on lawn care and water quality 10% change in some lawn care practices as a result of campaign (grass recycling, fertilizer use, hand weeding). No change in other lawn care practices as a result of campaign

Table 4. Effectiveness of Intensive Training in Changing Watershed Behaviors

Location and Nature of Training Campaign	Effectiveness of Intensive Training
Maryland Direct Homeowner (Smith, 1996)	10% shift from self to commercial car washing. No change in fertilizer timing or rates Better claims of product disposal.
Florida Master Gardener (Knox, 1995)	No significant change in fertilization frequency after program. Some changes in lower rates, labels, slow release (8 to 15%). Major changes in reduced pesticide use (10 to 40%).
Virginia Master Gardener (Aveni, 1998)	30 to 50% increase in soil testing, fertilizer timing and aeration. 10% increase in grass clippings and 10% decrease in fertilizer rate.

Both techniques work best when they present a simple and direct watershed message, are repeated frequently, utilize multiple media and are directly connected to local water resources that are most important in the community.

Other important suggested considerations for effectively marketing a watershed message are to:

Develop stronger connections among the yard, the street, the storm sewer, and the stream. Outreach techniques should continually stress the link between a particular watershed behavior and the undesirable water quality it helps to create (i.e., fish kills, beach closure, algae blooms). Several excellent visual ads that effectively portray this link are profiled in our watershed outreach award winners.

Form regional media campaigns. Since most communities operate on small budgets, they should consider pooling their resources to develop regional media campaigns that can use the outreach techniques that are proven to reach and influence residents. In particular, regional campaigns allow communities to hire the professionals needed to create and deliver a strong message through the media. Also, the campaign approach allows a community to employ a combination of media, such as radio, television, and print, to reach a wider segment of the population. It is important to keep in mind that since no single outreach technique will be recalled by more than 30% of the population at large, several different outreach techniques will be needed in an effective media campaign.

Use television wisely. Television is the most influential medium for influencing the public, but careful choices need to be made on the form of television that is used. Our surveys found that community cable access channels are much less effective than commercial or public television channels. Program managers should consider using cable network channels targeted for specific audiences, and develop thematic shows that capture interest of the home, garden and lawn crowd (i.e., shows along the lines of "This Old Watershed"). Well-produced public service announcements on commercial television are also a sensible investment.

Understand the demographics of your watershed. The middle-aged male should usually be the prime target for watershed education, as he is prone to engage in more potentially polluting watershed behaviors than other sectors of the population. Indeed, the most important audience for the watershed message includes men in the 35 to 55 year age group with higher incomes and education levels. Specialized outreach techniques can appeal to this group, such as radio ads on weekend sports events.

Another target group worth reaching includes what Pellegrin (1998) terms the "rubbish rebels"-- 18 to 25 year olds who tend to have low watershed awareness, engage in potentially polluting behaviors, and are often employed in lawn care and other service industries. This age group is hard to reach using conventional techniques, but may respond to ads on alternative radio, concerts, and other events that celebrate the watershed.

As communities become more diverse, watershed managers should carefully track the unique demographics of their watersheds. For example, if many residents speak English as a second language, outreach materials should be produced in other languages. Similarly, watershed managers should consider more direct channels to send watershed messages to reach particular groups, such as church leaders, African American newspapers, and Spanish-speaking television channels.

Watershed educators should also be careful about using the traditional environmental education model that uses schools to educate children who in turn educate their parents. While this model was instrumental in achieving greater rates of recycling, it may not be as effective in changing watershed behaviors. While it is important to educate the next generation of fertilizers, dog walkers, septic cleaners, and car washers, we need to directly influence the "boomer" generation now.

Keep the watershed message simple and funny. Watershed education should not be preachy complex, or depressing. Indeed, the most effective outreach techniques combine a simple and direct message with a dash of humor.

Make information packets small, slick, and durable. Watershed educators should avoid the ponderous and boring watershed handbook that looks great to a bureaucrat but ends up lining the bottom of a bird cage. One solution is to create small, colorful and durable packets that contain the key essentials about watershed behaviors, with contact information to get better advice. These packets can be stuck on the refrigerator, the kitchen drawer or the workbench for handy reference when the impulse for better watershed behavior strikes.

Educate private sector allies. A wide number of private sector companies may potentially stand to benefit from changes in watershed behavior. Better watershed behavior can drum up more sales for some companies, such as septic tank cleaners, commercial car washes, and quick oil change franchises -- although they may need some help in crafting their watershed marketing pitch.

Clearly, the potential exists for lawn care companies and landscaping services to shift their customers toward more watershed-friendly practices. Nationally, lawn care companies are used by up to 50% of consumers, depending on household income and lot size. Lawn care companies can exercise considerable authority over which practices are applied to the lawns they tend, as long as they still produce a sharp looking lawn. For example, 94% of lawn care companies reported that they had authority to change practices, and that about 60% of their customers were "somewhat receptive to new ideas" according to a Florida study (Israel et al, 1995). De Young (1997) also found that suburban Michigan residents expressed a high level of trust in their lawn care company.

Indeed, a small, but growing proportion of lawn care companies feel that environmental advertising makes good business sense and can increase sales (Israel et al, 1995). Clearly, intensive training and certification will be needed to ensure that watershed-friendly ads reflect good practice and not just slick salesmanship. It needs to be acknowledged that lawn care companies strongly committed to practices that reduce fertilizer and pesticide inputs need to be strongly endorsed by local government. Right now, it is not likely that such companies would be selected by the average consumer, as consumers primarily rely on direct mail, word of mouth, and cost when choosing a lawn care company (Swann, 1999 and AMR, 1997). For example, in the Chesapeake Bay survey, only two percent of residents indicated that they had chosen a lawn care company primarily on the basis that it was "environmentally friendly" (Swann, 1999).

Lawn and garden centers are another natural target for watershed education. Study after study indicates that product labels and store attendants are the primary and almost exclusive source of lawn care information for the average consumer. At first glance, national retail chains should be strongly opposed to better watershed behavior, since it would sharply cut into lawn and garden product sales and the lucrative profits they produce (even at the expense of the community and environmentally friendly image they often market). The key strategy is to substitute watershed-friendly products for ones that are not, and to offer training for the store attendants at the point of sale on how to use such products.

Summary

For the watershed manager faced with new regulatory requirements under Phase II of the NPDES program, the creation of an effective watershed education program should be a high priority. Not only is public education a mandated component of an NPDES permit, but in urbanized areas it may the most cost-effective tool available to achieve water quality goals. For smaller communities with scant budget and staff resources, it is imperative that these education programs be productive in terms of changing behaviors and raising awareness of individual actions on local water quality.

Perhaps the most important factor in creating an effective watershed education program is selecting the right outreach methods. Market surveys will often answer questions regarding the level of environmental awareness of watershed residents, what forms of informational outreach attract their attention, and resident willingness to change pollutant producing behaviors. This information allows the watershed manager to tailor outreach methods to specific target groups where behavior change is most likely. These surveys will also establish the demographics of the residents and determine whether multilingual outreach is required.

Watershed managers should also consider innovative approaches to sending out their pollution reduction messages. Pooling resources with other communities to create regional media campaigns and the use of outreach opportunities through private sector education are just two ways that program managers can reach broader audiences without spending large amounts of money.

Continued development of productive outreach methods and innovative techniques is necessary to relay the basic premise of watershed education - that we live in a watershed and how to properly live within it - in the most economical and effective manner.

Lawn Care and Water Quality: Finding the Balance

Jerry Spetzman
Minnesota Department of Agriculture
St. Paul, MN 55107-2094
email: Jerome.Spetzman@State.MN.US

Abstract

When land is converted from natural areas to developed urban areas, pavement and rooftops replace grass and trees. Water flows over driveways, streets and parking lots taking with it particles and debris in its path and depositing them, via storm sewers, into nearby lakes, creeks and rivers. This non-point source pollution can contain sediment, debris, fertilizers, pesticides, leaves, grass clippings, motor oil, or pet wastes. Small amounts of these materials entering a lake or river are not generally considered harmful. But when small amounts are multiplied by thousands or tens of thousands they can cause serious water quality problems.

Since 1993, the Minnesota Department of Agriculture, in cooperation with several other organizations, has been gathering information on homeowner use of pesticides and fertilizers in the Twin Cities metropolitan area. This information includes the amounts of lawn care products used by homeowners, where they are purchased, how they are applied, and whether or not they have an effect on nearby lakes, creeks or rivers.

Residents living in two watersheds were selected to participate in a focused study. Lake Harriet represents urban watersheds and Lake Alimagnet represents suburban watersheds. Based on survey results and water quality monitoring, education materials were developed to promote public awareness of lawn practices and their potential to affect water quality. These educational materials incorporate the concept that "everyone lives in a watershed" and that everyone has the potential to affect water quality, whether or not they actually live on a lake shore.

What are the Lake Harriet and Lake Alimagnet Watershed Awareness Projects?

The projects have two purposes: (1) to inform urban and suburban homeowners about living in a watershed, and (2) to help them learn how their lawn care habits can affect the quality of Twin Cities water. The project's goal is to improve water quality by reducing the quantity of pesticides and nutrients through responsible use of those materials.

How has this goal been achieved?

Project members have:

- Surveyed the current lawn care habits of homeowners and measured the effects of those habits by monitoring pesticide and nutrient runoff into Lake Harriet
- Informed homeowners about how their lawn care habits affect Twin Cities waters
- Asked homeowners how the projects have affected their lawn care practices
- Monitored runoff into Lake Harriet to quantify changes brought about by homeowner actions
- Drawn on detailed Lake Harriet experience to design urban watershed education materials for use throughout Minneapolis and Minnesota--these materials were tested in the Lake Alimagnet watershed

What is a watershed?

It is an area of land over which rain and melted snow flows to lakes, rivers, and wetlands. There are 46 major watersheds and 255 sub-watersheds in the Minneapolis-St. Paul metropolitan area.

The Lake Harriet watershed is a 1,139-acre area in a well-established residential neighborhood with almost 6,000 homeowners. The Lake Harriet study area is a 148-acre portion of the watershed. About 40% of the study area is covered with hard surfaces, such as pavement and rooftops. About 700 homeowners live in the study area, most in detached, single family houses built in the early 1900s. The water quality in Lake Harriet is very good for a Twin Cities lake.

A survey of 105 Lake Harriet watershed residents most familiar with lawn care done on their own properties, showed that:

- They are highly educated (college or post-graduate degrees predominate)
- Their average age is 47
- They have middle- to upper-level incomes
- They care for their lawns by mowing regularly and using fertilizers and herbicides
- A few use professional lawn care services

The Lake Alimagnet watershed has approximately 3600 suburban households. Of this number, a large proportion is made up of townhouse residents. The Lake Alimagnet watershed was developed in the 1960s. Homeowners are well-educated and have middle- to upper-middle incomes. The water quality in Lake Alimagnet is considered poor, algae blooms are common, and the predominant fish species is bullhead.

Why are we studying the Lake Harriet and Lake Alimagnet watersheds?

Because they provide good examples (respectively) of how urban and suburban development affect our water resources and because they are sources of year-round recreation for many Twin Cities residents. These residents are vitally interested in keeping the water clean.

What are we finding out?

Though Lake Harriet had some of the highest quality water in the Twin Cities, that quality has also declined over time. Lake Harriet has poor quality water and area residents want to reverse the trends.

These projects and others have monitored storm water, rainfall, and lake water to determine the levels of non-point source pollutants in Lake Harriet. Specifically, this project monitored two types of pollutants: pesticides, which can affect water quality, and phosphorus, which can increase lake algae growth and reduce water quality.

Pesticide monitoring

The Lake Harriet project monitored storm runoff, rainfall, and lake water. The water quality monitoring consisted of a permanent automatic sampling station installed in a storm drain outlet which carried watershed runoff into Lake Harriet; samples were taken during storm events, from which mass loading of pesticides and nutrients were calculated. In addition, a rainfall monitoring station sampled rain events. Finally lake monitoring samples were collected during the growing season. Several hundred samples were analyzed for more than 30 pesticides.

The education program included several methods of education, including homeowner meetings, direct mail, flyers, billboards, utility bill inserts, local newspaper articles and visits by Master Gardeners. Because monitoring preceded the education, and also followed it,reductions in pesticides can be measured. There was a decrease in average pesticide loads between the earlier and later monitoring periods. Therefore, the annual storm sewer runoff load of pesticides to Lake Harriet was reduced during the Lake Harriet project. The largest decreases came from the four compounds listed on this table:

Lawn Herbicides	Percent Decrease (1992-1995)
MCPA	86%
Dicamba	59%
2,4-D	58%
MCPP	56%

The most prevalent pesticides found during monitoring were herbicides (weedkillers). The eight herbicides listed on the following table accounted for 95% of all pesticide detections.

Lawn Herbicides	Agricultural Herbicides
MCPA	Alachlor
Dicamba	Atrazine
2,4-D	Cyanazine
MCPP	Metolachlor

- **Storm water runoff monitoring summary:**
  - Lawn herbicides were found in 80% of the storm runoff events sampled between April and October.
  - Agricultural herbicides were detected in 35% of the storm events sampled
- **Rainfall monitoring summary:**
  - The agricultural herbicides listed above (the only herbicides found in rainfall samples) were atmospherically deposited by wind and rainfall onto the watershed and the accompanying water bodies.
  - Lawn herbicides were not detected in rainfall samples.
- **Lake monitoring summary:**
  - The three most commonly detected compounds in lake water were MCPP, Atrazine, and 2,4-D. They were also the most frequently detected compounds in stormwater entering Lake Harriet.
- **Phosphorus monitoring:**

Analyses revealed the phosphorus in runoff peaks twice a year, in the spring and in the fall.

- In the spring, melting snow carries phosphorus attached to tiny particles of grit, sand, and organic matter as it enters the storm sewers.

- In the fall, phosphorus in leaves, grass clippings, and other organic debris enters the storm sewers. Studies conducted by other researchers established that only a small percentage of phosphorus in runoff results from appropriate use of fertilizer on lawns.

- **Water Quality Education**

Lake Harriet and Lake Alimagnet project participants have concluded that educating homeowners living in the watershed is one of the best ways of reducing pollution in the lake. Billboards, brochures, and water bill inserts have carried messages based on the following two concepts:

- **A healthy lawn and landscape promotes healthy waters.** Home landscaping with regionally adapted, healthy plants can help absorb and filter rainfall, irrigation, and runoff from melted snow.

- **Keep your lawn and landscape healthy as follows:**

  - Apply pesticides and nutrients according to recommendations
  - Aim roof downspouts onto lawns and gardens to filter and absorb runoff
  - Keep grass clippings and leaves off streets, sidewalks, and driveways
  - Leave grass clippings on the lawn or compost them
  - Use fallen leaves as winter or summer mulch, compost them, or shred them and leave them on the lawn
  - Keep lawn care products on the lawn and always follow label instructions
  - Clean up and reuse granular lawn care products that fall on streets, sidewalks, and driveways

Project Evaluation

- Based on feedback from homeowners living in the Lake Harriet and Lake Alimagnet watersheds, we have concluded the following:

  - Most homeowners in the Lake Harriet watershed apply significantly less lawn fertilizer than the University of Minnesota's recommended guidelines.
  - Most homeowners compost grass clippings or leave them on their lawns.
  - Homeowners would rather spot-treat weeds than apply herbicide to their entire yard or use non-chemical weed control methods.
  - Top soil in the Lake Harriet watershed is significantly deeper than that found in the Lake Alimagnet watershed. In many cases when suburban areas are developed, top soil is removed, but not replaced. This results in decreased plant vigor, and an increase in the need to fertilize, water, and maintain turf.
  - Most homeowners feel the educational initiative has increased their understanding of how lawn care habits affect water quality. Neighborhood newspapers and direct mail, the most common source of lawn care and water quality information, have the greatest impact.
  - Messages that are quick to read and easy to understand are the most effective in changing lawn care habits.
  - These messages are best delivered over an extended period. Homeowners have been reached through fliers, newspaper articles, brochures, direct mail, handouts, and personal contacts.

Feedback also shows that homeowners still need to hear the following messages:

- You can preserve water quality and have a healthy lawn by applying lawn care products in appropriate amounts, at the right times, and during suitable (or appropriate) weather conditions.
- By keeping leaves out of storm sewers, you can help reduce the amount of phosphorus carried to the lake in runoff water.
- Fall is the best season to apply turf fertilizers and lawn care products that control broadleaf weeds. The primary growth of turf grasses is early fall until late spring.
- Erosion, leaves, grass clippings, yard waste, pet waste, and rainfall all contain pollutants that can end up in lake water.

Lake Alimagnet Project Results

During the project period, the water quality in Lake Alimagnet improved significantly.

- Project cooperators achieved improvements in total phosphorus and chlorophyll-a.
- The best secci disk reading ever on Lake Alimagnet was recorded.
- The Citizens Assisted Monitoring Program improved the ranking of Lake Alimagnet from a "D" to a "C."

These results may be a result of the project, a curly leaf pond weed cutting, or may be credited to El Nino.

For more information on the Lake Harriet or Lake Alimagnet Watershed Awareness Projects and samples of homeowner education materials, please contact the Minnesota Department of Agriculture at (651) 297-7269.

San Francisco Bay Area's Pesticide Toxicity Reduction Strategy

Geoff Brosseau
Bay Area Stormwater Management Agencies Association (BASMAA)
Oakland, California

Introduction

Water quality research conducted by San Francisco Bay Area stormwater programs and wastewater treatment plants over the last several years has identified widespread toxicity in local creeks and wastewater treatment plant effluent (California Regional Water Quality Control Board, 1997; San Francisco Bay Area Pollution Prevention Group, 1998). The toxicity problem was ultimately traced to diazinon and chlorpyrifos–commonly used organophosphate pesticides available in hundreds of consumer products (Alameda Countywide Clean Water Program, 1997). Study results indicated that pesticide use according to label instructions could not be ruled out as a cause of wastewater and stormwater toxicity (Regional Water Quality Control Plant–Palo Alto, 1996). In May 1999, San Francisco Bay and 35 Bay Area urban creeks were listed by the U.S. Environmental Protection Agency (USEPA) as impaired by diazinon (USEPA, 1999).

Impact of 303(d) Listing on Local Governments

In its action, USEPA listed 53 waterbodies in California as impaired due to diazinon in urban runoff and 7 waterbodies as impaired due to chlorpyrifos in urban runoff. By definition under the Clean Water Act, this action means that there is a water quality problem, regardless of the problem definitions under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) (i.e., "unreasonable adverse effect") or the Food Quality Protection Act (FQPA). The listing action put over 100 municipalities in the San Francisco Bay Area and Central Valley at immediate regulatory, legal, and financial risk.

- Regulatory risk - The State Water Resources Control Board and USEPA can take enforcement action against, and fine, these municipalities for violating their NPDES (National Pollutant Discharge Elimination System) stormwater permits.
- Legal risk - Citizen and environmental groups can sue municipalities for the same reasons.
- Financial risk - These municipalities must now spend local public tax dollars proactively addressing this problem, and potentially reacting to fines and lawsuits.

Municipalities' Response

To comply with their NPDES stormwater permits, municipalities must meet two broad goals:

1. Effectively prohibit non-stormwater discharges into storm sewers.
2. Reduce the discharge of pollutants to the maximum extent practicable (MEP).

To meet these goals and to address the 303(d) listing, there are a number of actions Bay Area stormwater programs have taken or plan to take that may reduce pesticide-related toxicity in surface waters. These actions are packaged in a Pesticide Toxicity Reduction Strategy (BASMAA, 2000). The Strategy is a multi-faceted effort including:

- Education/outreach including:

- limiting or prohibiting pesticide use by municipal staff and contractors and/or requiring use of best management practices (BMPs) such as Integrated Pest Management (IPM)
- providing adequate and convenient options for disposal of unused pesticides and pesticide containers through household hazardous waste collection programs
- educating residents about pesticide-related toxicity and proper use and disposal through distribution of educational materials, and development and implementation of media and advertising campaigns
- educating residents about alternative methods and products through such programs as demonstration gardens and point-of-purchase campaigns in hardware stores and nurseries
- educating businesses about proper use and disposal, as well as alternative methods and products for use around their own properties and facilities
- educating pest control operators and working with them to develop BMPs protective of surface waters
- Regulatory – Identifying opportunities to reduce toxicity and advocating state and federal agencies to seize these opportunities through regulation and re-registration
- Monitoring - Investigating the extent and causes of toxicity, and assessing impacts on beneficial uses

The IPM Store Partnership

One exemplary part of the Pesticide Toxicity Reduction Strategy worth describing in more detail is the IPM (Integrated Pest Management) Store Partnership. In 1997, the Central Contra Costa Sanitary District (CCCSD), a wastewater treatment plant located in Martinez, California, jointly developed and successfully piloted the IPM Store Partnership with the Regional Water Quality Control Plant (Palo Alto, California) in four locally owned garden centers and hardware stores. In 1998, the Bay Area Stormwater Management Agencies Association (BASMAA) and the San Francisco Bay Area Pollution Prevention Group (BAPPG) joined together to fund the expansion of the IPM Store Partnership to more stores in the San Francisco Bay Area. By spring 1999, 116 stores in eight Bay Area counties were participating in the Partnership.

The Partners

BASMAA is a consortium of seven San Francisco Bay Area municipal stormwater programs. These programs represent more than 90 agencies, including 79 cities and 6 counties, and the bulk of the watershed immediately surrounding San Francisco Bay. BASMAA agencies agree to a memorandum of understanding and each year collect dues, prorated by population, from their members for a "baseline" program that provides for staff and finances projects–like the IPM Store Partnership–that are endorsed by all member agencies.

The BAPPG is a voluntary association of 39 wastewater treatment plants working together to prevent water pollution in the San Francisco Bay. These agencies represent all of the publicly owned municipal wastewater agencies that discharge into San Francisco Bay in the nine Bay Area counties, and almost all of the watershed immediately surrounding San Francisco Bay. BAPPG's decision-making is done by consensus. Each year, a work plan–with an associated budget–is developed. The budget is allocated among the 39 plants based on the average amount of treated wastewater discharged each day. Contributions are voluntary, although all agencies do contribute. These contributions are used to fund projects like the IPM Store Partnership.

Integrated Pest Management

There are many definitions of Integrated Pest Management. The definition used to guide the IPM Store Partnership was the following:

Integrated Pest Management is an approach that uses regular monitoring and cultural, biological, and physical methods to keep pests at acceptable levels. Only less toxic chemicals are used and only as needed.

IPM was used as the basis for the program because it: (1) focuses on effective alternatives to traditional chemical pesticides; (2) does not substitute another pesticide that may become tomorrow's problem, and (3) does not preclude the use of chemicals in all situations.

Although promotion of IPM was the basis for the program, the term itself is somewhat problematic. The terms "IPM" and "Integrated Pest Management" were used in speaking with experts and agencies familiar with the jargon, but these terms were avoided in communications with the non-initiated (e.g., general public). In addition, the term IPM was not very representative of the situation in the store between the customer and the store employee. Most customers go to a store for help when pests have already reached unacceptable levels, so store employees must start with controlling a pest problem, rather than preventing it, which is the first step in IPM. Despite this challenge, customers were exposed to the full range of IPM methods through the fact sheets and display materials, as well as less-toxic products.

Goals

The goals of the IPM Store Partnership are to:

- Educate the public about the value of IPM approaches to pest control and safe use and disposal of pesticides, when used
- Deliver IPM-related messages without negative messages about any products
- Develop partnerships with retailers so that they can help spread the word about water quality problems related to residential pesticide use
- Provide consistent messages
- Capitalize on economies of scale
- Prepare the stage for regional program expansion into chain stores

Program Elements

The IPM Store Partnership is an education program for employees and customers of locally owned garden centers and hardware stores. The project elements include:

- development and production of eight fact sheets on less-toxic pest management strategies for the public (*Naturally Managing Pests, Controlling Ants, Controlling Aphids in Your Garden, Keeping Cockroaches Out of Your House, Keeping Fleas Off Your Pets and Out of Your Yard, Living with Spiders, Tips for a Healthy Beautiful Lawn, and Safe Use and Disposal of Pesticides)*
- development of an extensive list of less-toxic methods and products preferable to diazinon and chlorpyrifos for various applications
- training sessions for store employees focusing on principles of Integrated Pest Management and successful application strategies for products on the less-toxic list
- design and production of a program logo and in-store promotion materials including "end cap" displays, posters, shelf-talkers, shelf signs, and vinyl banners
- program evaluation by a San Francisco State University-affiliated survey research and data analysis firm

Results and Discussion

Although the final evaluation will not be complete until the end of the 1999 in-store promotion season (late 1999), the sponsoring agencies expect it to be successful based on preliminary findings and on the success of the pilot project. Feedback from store owners and employees that participated in the pilot was uniformly positive. The sales data in the pilot IPM Store Partnership showed variations from store to store. One store found that sales of all but one diazinon and chlorpyrifos product dropped. At the same time, less-toxic product sales experienced an overall 17% increase and profits were not affected.

It is the hope of the participating agencies that the final evaluation and report on the 1999 Partnership will be useful as a model and primer for other agencies and jurisdictions concerned about pesticide-related toxicity in surface waters and interested in building educational partnerships with local businesses. While Bay Area water pollution prevention agencies have been coordinating their public education efforts since the early 1990s, the IPM Store Partnership is the first point-of-purchase program implemented regionally. All of the general benefits of inter-agency coordination (support for smaller agencies, cost savings, options for pooled advertising and media relations) are magnified in such a large undertaking.

Based on the partnership's success, all of the agencies that participated in the 1999 Partnership allocated funds for continuation of the program in 1999-2000. BASMAA and the BAPPG again contributed funds to regional coordination. Brainstorming sessions were held in late summer 1999 to determine how to improve the program, and minor modifications were made for 2000.

The IPM Store Partnership is one example of BASMAA and the BAPPG's commitment to use public resources efficiently. Given that philosophy, materials developed by the IPM Store Partnership are available to agencies interested in implementing a similar program.

Other Aspects of the Strategy

Despite the success of the IPM Store Partnership and many of the other educational aspects of the Pesticide Toxicity Reduction Strategy, it is clear to Bay Area water pollution prevention agencies that their efforts alone will not be enough to solve the problem. Study results indicate that less than 1% of applied diazinon runs off, yet it takes less than a fluid ounce of active ingredient flushed into stormwater runoff to cause toxicity in urban creeks (Regional Water Quality Control Plant–Palo Alto, 1996). Educational programs run by Bay Area water pollution prevention agencies are some of the most developed in the country and they have won numerous awards for their quality and effectiveness. Nevertheless, even the best education programs are not 100% effective. It is clear that education alone will not solve this problem.

San Francisco Bay Area stormwater programs are and will continue to address the problem of pesticide-related toxicity in surface waters by way of meeting the MEP requirement in their NPDES permits. These agencies have gone so far as to develop the Pesticide Toxicity Reduction Strategy described above that includes three elements–education, regulatory, and monitoring. The authority and ability of local governments to implement the strategy varies with each element. The most cost-effective and appropriate aspect for local governments to implement is education. For the regulatory and monitoring elements, local governments can, and have, identified the issues and opportunities to reduce pesticide-related toxicity, but they have limited ability or authority to actually implement corrective actions.

Regulatory

Regulation of pesticides including their registration for use in the Unites States is the responsibility of USEPA. California's Department of Pesticide Regulation (DPR) has responsibility for regulating the sale and use of pesticides in California. California DPR, with few exceptions, registers pesticides only after they have been registered by USEPA. California DPR can not register pesticides which have been denied registration by USEPA. At the local government level, the California Food and Agriculture Code grants some authority to county agricultural commissioners for local enforcement of pesticide regulations, record keeping, and outreach to applicators. However, with the exception of county agricultural commissioners, local governments are prohibited from regulating the registration, sale, transportation, or use of "economic poisons." This regulatory structure means that the ability and authority of local governments is limited to:

- identifying opportunities to reduce toxicity, such as eliminating potentially problematic uses, and advocating that state and federal agencies seize these opportunities through regulation and re-registration

- in the case of wastewater and stormwater agencies, regulating the discharge of pesticides to the sewer or storm drain to ensure local agencies' compliance with state and federal laws (e.g., Clean Water Act)

Monitoring

Local governments have some ability, authority, and responsibility to use monitoring to address the problem of pesticide-related toxicity of surface waters. To-date, San Francisco Bay Area municipalities have used monitoring to:

- identify and define the problem (Alameda County Urban Runoff Clean Water Program, 1995; Regional Water Quality Control Plant–Palo Alto, 1996; California Regional Water Quality Control Board, 1997; San Francisco Bay Area Pollution Prevention Group, 1998)

- characterize sources (Alameda Countywide Clean Water Program, 1997)

- recommend corrective actions (Alameda County Flood Control and Water Conservation District, 1997)

A review of monitoring data from around the country shows that municipalities in the San Francisco Bay Area and California Central Valley are not alone in their identification of this environmental problem.

- Orange County, California (Lee, et al., 1999) – Multi-year studies of stormwater runoff in San Diego Creek as it enters Upper Newport Bay have shown that the problem is not restricted to Northern California. Runoff from each stormwater event has been shown to be toxic, and about half of the observed toxicity is due to diazinon and chlorpyrifos used in urban areas for structural termite and ant control, and lawn and garden pest control.

- NAWQA (USGS, 1998) – Results from the United States Geological Survey's (USGS) National Water Quality Assessment Program from 1992 through 1996 show that the problem is in fact a national one. Over 300 samples have been taken from eleven urban streams scattered across the country, from Florida to Connecticut to Oregon, as part of the Pesticides National Synthesis Project. In a recent report on the first cycle of the program, USGS concluded that "urban and suburban areas are substantial sources of pesticides to streams" and that "most urban areas have similar pesticides in streams...and many urban areas may benefit from similar strategies for reduction."

- Publicly-Owned Treatment Works survey (USEPA, 1989) – Results from a survey done 10 years ago by USEPA show that pesticide-related toxicity is a wastewater problem as well as a stormwater problem. USEPA's Environmental Research Laboratory in Duluth, working through the National Effluent Toxicity Assessment Center (NETAC), reported on the occurrence of diazinon in 28 POTW effluents. Diazinon was found in sixteen (62%) of the effluents, and levels were greater than or equal to 250 ng/L for nine (32%) of the effluents. NETAC concluded in part "The frequency with which we have observed diazinon in the past, in this survey, and continue to find it in effluents is indicative of a widespread problem."

Clearly this is a national problem caused by products that are registered at the national level and sold across the country.

The pesticide registration process provides a built-in mechanism to use monitoring and science to address this national problem. During the registration process, USEPA must review and summarize the findings of studies conducted on each pesticide. During this step, USEPA may request that "registrants" (e.g., pesticide manufacturers) submit specific studies for review. Based on its review, USEPA can confirm, deny, or change the pesticide's registration including approved uses, sites of application, formulations, and label directions.

Local governments are willing to use monitoring and science to further investigate local impacts and sources, and to host case studies, if USEPA will provide financial and other support, with the goal of conducting representative case studies whose results can be extrapolated across the country. But given the established mechanism in the pesticide registration process, it would be inappropriate and ineffective for local governments to do more. USEPA must exercise its federal authorities and use monitoring and science information to make more informed, up-to-date registration decisions.

Conclusion

Rather than being a tool in and of itself, the Pesticide Toxicity Reduction Strategy is really a toolbox. It includes a number of effective tools for reducing pesticide-related toxicity of surface waters–an increasingly important part of urban water resource management and protection. Every job has its tool and in the right pair of hands, the job can be easy and cost-effective to complete. The wrong tool or the wrong hands can make the job difficult, if not impossible to finish. It is the responsibility of government agencies to be clear and disciplined about which tool and which pair of hands go with which job when fixing environmental problems. The extent to which they implement that concept will determine how successful the work of environmental protection will be.

Administering the NPDES Industrial Storm Water Program at the Municipal Level

Michael J. Pronold
Bureau of Environmental Services
City of Portland
Portland, Oregon

Abstract

As part of the EPA Phase 1 stormwater requirements, certain classes of industries are required to obtain Industrial Storm Water permits. The EPA, or a state agency that has been delegated by EPA, administers these permits. The Phase 1 regulations also require that municipalities develop a program to monitor and control pollutants in storm water runoff from industrial facilities. These are potentially non-coordinated requirements and can result in redundant efforts and a less than efficient program. In addition, EPA and/or state agencies may not have the resources to adequately administrate and enforce the permitting program while leaving the municipality liable for the discharges from the municipal separated storm sewer system (MS4).

The City of Portland, Oregon (City), met the requirement in its municipal storm water permit to control industrial stormwater sources of pollution by developing a Memorandum of Agreement (MOA) with the Oregon Department of Environmental Quality (DEQ), (which is the delegated authority) to administer the permit program. The MOA provided the City with the mechanism to administer the industrial stormwater permits for those facilities that discharge to the City's MS4. The City pursued this approach since it was responsible for the discharge from the MS4 and wanted to ensure that it had adequate oversight of these discharges. By coordinating this effort with other ongoing industrial water quality programs, the City could provide a more cost-effective program, considering the regulatory costs as well as cost to the industry. City Code was developed to support this approach.

When the City took over the administration of the permits in 1994, over 50% of the facilities with a permit had not met the requirements for the development of a storm water pollution control plan, the main requirement of the permit. In addition, nearly 60% of the permitted facilities had not performed the required stormwater sampling. Of the samples taken, approximately 30% violated standards in the permit. It was also evident that not all facilities required to obtain a permit had done so. Efforts since 1994, have shown that only 25–30% of the facilities required to obtain a permit had applied. A benefit of the local administration of the program is the detection of illicit discharges to the MS4. Approximately 15% of all industrial inspections have identified illicit discharges.

The City has also identified certain classes of industries and activities that can be significant sources of pollutants to the MS4. This has helped streamline the program efforts and redirect resources to where the greatest cost benefit will be realized.

Introduction

Stormwater discharges have been increasingly identified as a significant source of water pollution in numerous nationwide studies on water quality. To address this problem, the Clean Water Act Amendments of 1987 required EPA to publish regulations to control storm water discharges under NPDES. EPA published storm water regulations (55 FR 47990) on November 16, 1990 which require certain dischargers of storm water to waters of the United States to apply for NPDES permits. These regulations established NPDES permit application requirements for storm water discharges associated with large- and medium-size MS4s. The regulations also established NPDES permit application requirements for storm water discharges associated with industrial activity. EPA has defined this phrase in terms of 11 categories of industrial activity.

A requirement of the City's application process was "A description of a program to monitor and control pollutants in storm water discharges to municipal systems from municipal landfills, hazardous waste treatment, disposal, and recovery facilities, industrial facilities that are subject to Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA), and industrial facilities that the municipal permit applicant determines are contributing a substantial pollutant loading to the municipal storm sewer system." (40 CFR 122.26(d)(2)(iv)(C). This creates the potential for redundant efforts and a less than efficient program.

The stormwater regulations envision that NPDES permitting authorities and municipal operators will cooperate to develop programs to monitor and control pollutants in storm water discharges to MS4 from certain industrial facilities. The NPDES permits for industrial facilities establish requirements such as controls, practices, and monitoring of stormwater discharges, as well as provide a basis for enforcement actions. An integral part of the requirement is the adequacy of legal authority. This will allow the municipality to implement its program, which should include inspections, review of stormwater pollution control plans, monitoring, and implementation of control measures.

The municipality is ultimately responsible for discharges from its MS4. To meet the requirement in its municipal stormwater permit, and to provide the oversight necessary to protect itself from liability, the City developed new legal authority and entered into an MOA with the authorized NPDES state authority (DEQ), to administer the permits for those discharges to the MS4.

Program Elements

Legal Authority

The City did not have adequate legal authority to oversee discharges to the MS4. In response to this, the City developed code in February 1994. Some of the major provisions of the code are:

- Authority of the Director of Environmental Services to Adopt Rules
- General Discharge Prohibitions
- Discharge Limitations
- Reporting Requirements
- Storm Water Pollution Control Plan (SWPCP)
- Storm Water Discharge Permits
- Inspection and Sampling
- Enforcement

Key elements of the code include the requirement for permit holders to submit their SWPCP and monitoring results to the City, the authority for the Director to adopt administrative rules, make inspections, and undertake enforcements.

Memorandum of Agreement

The City entered into a MOA with the DEQ in March 1994. The MOA delineates the responsibilities for the implementation of the program between the two agencies. The MOA also prioritizes the implementation of the program to address those facilities that are of most concern first. Key elements of the City's responsibilities include:

- Development of an inspection and monitoring program
- Informing DEQ of any new or existing facilities that require a permit
- Enforcement of City Code

Key elements of DEQ's responsibilities include:

- Issuance of NPDES Industrial Storm Water permits upon referral or approval by the City
- Denial of permit applications for process wastewater discharge into the MS4
- Enforcement where the City lacks authority

Inspections and Monitoring

The section responsible for the implementation of the program is an autonomous work group. It is housed in the Source Control Division, which includes the pretreatment program. In November 1994, two inspectors were hired to implement the program under an existing supervisor. DEQ, which had been issuing permits since September 1992, provided a list of facilities with stormwater permits. A letter was sent to the permit holders requesting that they submit their SWPCP and all monitoring results. The letter referenced the MOA and included code citing the City's authority. Inspections were prioritized based on problematic outfalls as determined from information gathered in the Part 1 and 2 application process.

Inspections are usually scheduled in advance with the facility operator but can be performed without notice. Inspection forms are filled out during the inspection and any readily noticeable issues addressed during a post inspection meeting. Technical assistance is provided and information on Best Management Practices given in the form of verbal suggestions and reprints. Facilities are also evaluated for the presence of illicit discharges. All inspections are followed up with correspondence outlining the findings of the inspection and expectations of the industry. Any item where the industry is not in compliance with the permit is highlighted with a deadline to meet compliance before escalating enforcement is pursued. It is the goal of the program to perform annual inspections, at a minimum, of all permitted facilities.

Industries are also inspected if they are identified as potentially needing a permit. These facilities are identified through a systematic search using storm water outfall basins prioritized based on problematic outfalls. The basins are delineated for drainage, the industrial facilities identified within the basin using our database, and facilities selected by SIC Code. Inspections are also performed in response to referrals, drive-bys, complaints, and responses to an industrial survey performed in support of the pretreatment program. Prior to an inspection, building records, existing files from the pretreatment program, and plumbing records are reviewed.

Stormwater sampling of permitted facilities is performed by collecting grab samples at the sample point(s) identified in the facility's SWPCP. Analyses are performed by the City lab. This sampling does not relieve the facility of its stormwater sampling responsibilities. Files are developed on the facilities and maintained separately from the pretreatment files. An electronic database has been developed and is used by both pretreatment and storm water staff.

Enforcement

Enforcement capability was developed in City Code. Where the City does not have enforcement authority, it seeks voluntary compliance and refers enforcement to the permitting authority when necessary.

Funding

The program is entirely funded through a surcharge on the storm water fee for industrial and commercial accounts. The storm water fee is currently based on impervious area. This surcharge also funds portions of other programs that have work related activities because of industrial and commercial storm water discharges. The current staffing level is one supervisor and three technicians. Program costs amount to approximately $280,000 per year. This is primarily composed of salaries and benefits, but also includes approximately $25,000 for sample analyses. The budget also contains funds for the development of BMPs and educational materials.

Findings

Legal Authority

It is essential that legal authority be developed in order to be able to implement and support a municipal program. However, what is contained in the enabling legal authority (code) can vary drastically. It is important that the municipal permit holder review the NPDES Industrial Storm Water permit to determine its adequacy in meeting the municipal permit requirements. Most industrial storm water permits are general permits and they may not adequately address issues for which the municipal permit holder is responsible.

For instance, if the municipality is responsible for meeting TMDLs for a particular water body, the industrial permit may not even require that the facility monitor for these pollutants in its discharge. Provisions should be placed in code that allow the municipality to require the facility to conduct this monitoring. Another example would be the requirement to submit SWPCP and monitoring results to the municipality if this is not included in the permit. Nothing in federal regulations prohibits the municipality from requiring additional controls beyond the permit requirements. A review of the industrial stormwater permits can help identify elements that should be included.

Another provision that should be considered is the ability of the municipality to require a facility to obtain a permit. Currently, federal regulations base the requirement for a permit on SIC Code and exposure. There is a caveat that allows the permitting authority to require a facility to obtain a permit regardless of its SIC Code if that facility is impacting water quality. However, this could require that the municipality undertake sampling and additional work to prove an impact. This reduces the efficiency of the program in terms of resources and uniformity. It may even be necessary to include provisions in the code that allow the municipality to develop its own permit. Such a tactic is time consuming, however, and could create confusion for the regulated community.

Memorandum of Agreement (MOA)

The MOA should be developed to clearly outline the responsibilities between the permitting authority and the municipality. Language should be broad enough not to constrict how the municipality implements the inspection and monitoring program. This allows the municipality to alter the program as information is obtained from inspections without having to alter the MOA. Probably the most important element of the MOA is the delineation of enforcement. Since the municipality does not have authority to enforce permit conditions, language should specify that the municipality will enforce applicable requirements of the Code and seek voluntary compliance where it has no independent enforcement authority. If compliance is not obtained using these methods, enforcement would be referred to the permitting authority.

Inspections

The City has placed the responsibilities for implementation of the program within the Industrial Source Control Division. The section also houses the pretreatment program. It was felt that the responsibilities needed to be separate because of the large number of facilities that are to be addressed. The City has over 24,000 commercial and industrial facilities. Of these, nearly 3,000 have the SIC Code that potentially places them in the permitting program. In addition, a Stormwater Work Group is responsible for addressing other discharges to the MS4, such as pumped groundwater, boiler blow-down, water supply line flushing, washwater, and others.

For the City's situation, this arrangement has worked very well. The Work Group is able to develop expertise in the area while having access to existing information from the pretreatment program. Other municipalities have adopted this approach while others have incorporated the responsibility into the pretreatment program or other existing programs including fire and safety inspections. The municipality needs to consider several items when determining who will be responsible for implementing the program.

- The number and type of industries
- Existing oversight of the industries (pretreatment, hazardous materials,...)
- Existing programs within the municipality

If the municipality decides to place the responsibility in a Work Group that is not dedicated for this purpose, it needs to ensure that adequate resources exist to implement the program and meet the conditions of the MOA. The stormwater program may not be the priority of the assigned work section and if resources become inadequate, this work may be viewed as low priority and may not be addressed at the level that makes it effective.

The City has developed several "partnerships" to expand the inspection program. Informational flyers and a poster were developed for county sanitarians to use when they inspect restaurants. A simple storm water checklist was developed for City commercial recycling staff to use when inspecting retail establishments. In both of these cases, it is important to note that the facilities targeted would not ordinarily be inspected for storm water issues (unless a complaint was received) and that any issues of consequence would be addressed by storm water staff.

Permits

The DEQ has been issuing permits since September 1991. When the City took over administration of the permits in the fall of 1994, 63 facilities that discharged to the MS4 had permits. Since that time, an additional 65 facilities have been identified through inspections of non-permitted facilities. Non-permitted facilities are inspected based on SIC Code and prioritized by outfall basins that have been identified as problematic. This approach was necessary due to the large number of industries within the City that have the SIC Code included in the federal regulations. To perform a general survey of all facilities would have generated much more work than resources allowed. Each site would have to be evaluated prior to the issuance of a permit as the City is a mixture of combined sewers, sumps, and separated storm sewers. Staff members spend a considerable amount of time determining where stormwater drainage discharges. A municipality may be able to utilize this approach if the industrial base is smaller. Federal guidance states that a system-wide approach to establishing priorities for inspections should be developed.

Based on inspections of non-permitted industries to date (approximately 15% require a permit), and the remaining facilities that require inspections, it is estimated that an additional 50-100 facilities will be permitted. Based on these numbers, only 25-30% of facilities requiring a permit had applied when the City took over administration of the program. However, a large percentage of the facilities not requiring permits still had issues that needed to be addressed or were given BMPs that they were requested to implement.

SWPCP

The original general permit developed by DEQ did not require that the permit holder submit the SWPCP. When the City took over administration of the permits, the plans were to be submitted using provisions of the City Code. Over 50% of the facilities (33 of 63) had not developed a plan within the 180 days allowed in the permit, and of these, 14 (22%) had not even developed a plan. It is imperative that the municipality includes provisions in the code to obtain these plans if the provision does not exist in the permit. The requirement to submit the plan allows the City to track its development and review the plan prior to an inspection. Currently, only 5% of facilities have not met the requirement to develop the plan in the required time period.

Unfortunately, there is no requirement in the permit that the plans need to be approved. As long as they contain the necessary elements required in the permit they would be in compliance. This has proven problematic in the quality of some plans. It also restricts the City's ability to require that the facility implement certain pollution control activities. This emphasizes the need to include these provisions in the legal authority. The City has taken the approach of strongly suggesting that certain activities be implemented and incorporated into the plan. Once it is in the plan, it becomes part of the permit and provides a mechanism to require the facility to implement these measures. The City is then able to take the position of providing assistance in evaluating compliance with the permit. By noting these deficiencies and seeking voluntary compliance, the City believes it is assisting the industry in meeting the conditions of their permit and benefiting the environment through the implementation of the SWPCP.

Monitoring

When the City took over administration of the program in 1994, monitoring results were requested from permitted facilities. Nearly 60% (36) of the facilities had not performed the required monitoring for the previous year. Of these, 22 had not taken the required two samples, while the remaining 14 did not perform the complete analyses. Of the samples taken, 30% violated standards in the permit. Within the first year, the City was able to raise compliance on sample collection to over 80% and reduce violations of standards from 30% to 23%. Currently, over 90% of the facilities are in compliance with sample collection. It is more difficult to compare compliance with standards because a new permit was issued in 1998, that includes benchmarks for metals that were not in the original permit.

Monitoring results have limitations because they are grab samples taken from a discharge that is short-term in nature and highly variable. However, they can be used as a tool to measure effectiveness of BMPs and to identify sources of pollutants. Based on sample results, the City has identified several classes of industries that pose significant pollution concerns. These are, in order:

- Automotive recyclers (SIC Code 5015) – metals, oil and grease;
- Recycling industry (5093) - metals, oil and grease;
- Transportation facilities (various 4000) – metals, oil and grease, TSS;
- Heavy manufacturing (33--, 34--) – metals;
- Food industry (20--) – TSS, BOD, oil and grease.

Other SIC Code groups either represent a lower threat as a whole or are not present in the MS4. The City is now using this information to reprioritize their efforts in identifying industries that require a permit. While the City is still pursuing efforts based on outfalls, they are also developing a parallel effort to inspect all the facilities in these classes. In addition, investigation efforts by the City identified the Wholesale Distribution of Construction Equipment (5082) and Heavy Construction Equipment Rental (7353) as significant sources of pollutants. These classes are not included in the federal regulations, but any municipal program should evaluate these facilities.

Enforcement

Enforcement capabilities have been developed in code for those discharges to the MS4. However, the City does not have enforcement capability on permit provisions. The City must seek voluntary compliance and refer those matters to the permitting authority for which they don't have enforcement capability. This has worked to date, but requires coordination between the City and DEQ. When seeking voluntary compliance, the City uses the threat of referral to the permitting authority or third party lawsuits to obtain compliance. To make this effective, the permitting authority must be ready to follow up with enforcement upon the municipality referral.

Funding

As with a number of environmental programs, especially regarding storm water, it is very difficult to measure the cost/benefit until the program has been in place for a period of time. Costs have been identified, and certain benefits have been realized. Compliance with permit conditions, for both industry and the City, have been, for the most part, met. However, has this resulted in a benefit to the environment? City data have shown that industrial land use areas have significantly higher concentrations of pollutants than other land uses. Whereas the industrial land area in the MS4 is only 4%, it accounts for 11% of TSS, 15% of oil and grease, and 24% of metals. It would reason that a program aimed at the highest concentration of pollutants would produce a good return on the investment. Another benefit of the program has been the identification and removal of non-stormwater discharges. Approximately 15% of the inspections have identified non-stormwater discharges, primarily washwater, that were of concern.

Conclusions

The development of a program to monitor and control pollutants from industrial facilities is not one of the six BMPs that Phase II permit holders will be required to be developed. This may be due, in part, to the assumption that all industrial permits would be in place because of Phase I requirements. However, our efforts have shown that only 25-30% of the industries requiring permits had applied prior to the administration of the program by the City.

If a municipality decides to develop and implement a program, it is recommended that it utilizes the accomplishments of Phase 1 applicants. Phase 1 applicants can provide inspection forms, BMPs, MOAs, code language, and other necessary components to develop the program. They can also share results of their work to help prioritize the efforts of the municipality and help decide how to incorporate the work into existing programs. A municipality may also become a co-applicant with Phase 1 permit holders. If this occurs, the applicant will become subject to an industrial control program but may be able to utilize the existing program of the permit holder.

If a municipality does not develop a program, it is recommended that it at least work with the permitting authority to identify who has a permit and the status of their compliance. The municipality should also evaluate the industrial base in the MS4 and provide this information to the permitting authority if it identifies a facility that may be subject to the program. It may be prudent to incorporate these activities into the illicit discharge elimination program, which is a requirement of the permit. Whatever the municipality chooses, it needs to understand that it is ultimately responsible for discharges from its MS4.

Lessons Learned from Three Watershed-Sensitive Development Demonstration Projects in the Great Lakes Basin

Sarah Bennett Nerenberg
The Conservation Fund
Great Lakes Office
Chicago, Illinois

Introduction to The Conservation Fund

The Conservation Fund (TCF) is a national, non-profit conservation organization that purchases and protects land – more than 1.6 million acres since 1985. TCF also assists local communities, private landowners and government agencies with programs that balance conservation with economic development. TCF works with communities to improve water quality, build sustainable economic opportunities, and develop leadership skills, activities that put it at the forefront of conservation across America.

TCF has been active in the Great Lakes Basin since it opened a regional office in 1995. The initial focus of its work was the Great Lakes Watershed Initiative. This basin-wide effort was designed to raise the local visibility of the nonpoint source water pollution issue. The Initiative adapted many of the innovative solutions showcased in the National Forum on Nonpoint Source Pollution. TCF worked with many local partners to launch a network of community-based projects addressing nonpoint source water pollution in urban and rapidly urbanizing areas in eight states and Canada. The Initiative was conducted in partnership with the Council of Great Lakes Governors with major funding from the Great Lakes Protection Fund and Kraft Foods.

TCF expanded several projects as an outgrowth of the Initiative including the watershed-sensitive development work outlined in this paper and a sustainable development effort in Michigan. In Michigan, TCF facilitates a broad, community-based sustainable development effort in the Saginaw Bay watershed. The goal of the initiative, which engages local businesses, community groups, and government agencies, is to better link the environmental and economic well being of Saginaw Bay communities in order to sustain and improve the region's overall quality of life. This year, the project received the National Award for Sustainability from the President's Council for Sustainable Development and Renew America.

Introduction to Conservation Development Project

Currently, TCF is targeting one of the remaining threats to natural resource quality, enhancement, and preservation in urbanizing areas – conventionally designed subdivisions. In partnership with local developers, community groups, and government agencies, TCF is working in the Great Lakes Basin on the Conservation Development project. This project is designed to demonstrate the environmental and economic benefits of watershed-sensitive design through a series of model developments. In particular, we are working to demonstrate the benefits of watershed-sensitive site-planning and best management practices that reduce impervious cover and conserve open space. The current model projects are being developed in Huron, OH, Germantown, WI, and Niles, MI. The George Gund Foundation and the Great Lakes Protection Fund have provided major funding for this project.

We define watershed-sensitive development to include: open space design, significant reduction in impervious coverage, natural stormwater conveyance and storage to the greatest extent possible, and appropriate construction mitigation measures. Watershed-sensitive design can be used to build the same number of houses and still preserve a significant portion of the subdivision's original landscape. These open spaces serve important community and environmental functions. Agricultural land can be farmed, residents can enjoy recreational and aesthetic benefits, and important natural areas and systems can be preserved. Alternative designs also reduce the amount of impervious cover.

Techniques including narrower streets, porous surface parking areas, stream buffers, and open channels for stormwater conveyance minimize runoff from new development and its negative impacts on water resources.

When evaluating potential conservation development projects, The Fund considered the following criteria:

- Local community must be interested and open to new techniques, including flexibility on zoning and subdivision code issues;
- Property already slated for development and conventional development would have significant negative impacts on the site itself or adjacent natural resources;
- Project partners represent one of the dominant development paradigms in the Great Lakes (i.e., professional developer building homes in farm fields, lay developer seeking to hold and protect family or other special lands, government agency seeking to encourage sound practices); and
- Project site is suitable for demonstrating broad array of site design techniques and best management practices (BMPs).

Through TCF's work in the Great Lakes, we gathered many lessons-learned that may be applied to other regional and national efforts. This paper will review many of these lessons with the hope that other communities and organizations will be able to benefit from our experiences. The paper is organized into the four sections listed below:

I. Overall Lessons Learned

1. Not "One Size Fits All"
2. Measurable Criteria for Watershed-Sensitive Development
3. Adequate Oversight and Inspection
4. Incentive System Needed
5. Relationship to Other Smart Growth Movements

II. Lessons Learned about the Development Process

1. Pace of Development Often Incompatible with Innovative Site Design
2. A Greater Initial Investment in the Baseline Information is Necessary
3. Initial Cost of Watershed-Sensitive Developments
4. Deed Restrictions
5. Need Additional Lay Developer Education
6. Aesthetics Do Not Equal Ecology

III. Lessons Learned about Engineering/Site Design

1. Educate the Engineers
2. Lot Size Often Dictated by Septic Issues
3. Need Hard Science

IV. Lessons Learned about Working with Communities

1. Community Initiative
2. Local Official Knowledge Varied
3. Strong Local Partner is Key
4. Final Lessons Learned

Overall Lessons Learned

Not "One Size Fits All"

The approach used to create a watershed sensitive development must be tailored to the individual, organization, or developer creating it. The assistance needed by a private landowner that is seeking to preserve portions of family lands, for example, is quite different from that needed by a professional developer. We found that the models we developed need to take the different skills and goals of the project's initiator into account very early in the process. For example:

Lay developers (i.e., the individual landowners), not surprisingly, need help with the business aspects of the project, and are more inclined to make frequent changes to the preliminary site plan and architectural style of the development. These changes often reflect something the developer has "just learned" or "just considered." These new ideas can add value to the project, but they also require the technical assistants (e.g., landscape architects and engineers) to be more patient, more flexible, and firmer than they might be with professional developers.

Professional developers demand immediate turnaround on requests for assistance, and are looking for "the facts" on what is required to make a development watershed-sensitive. They can be somewhat impatient with the notion that there are not a fixed and specified set of best management practices and site design practices that, if employed, will "always" result in an "environmentally friendly" development.

Measurable Criteria for Watershed-Sensitive Development

As we began to design the model projects, it became apparent that there were no specific criteria available to measure the benefits of the watershed-sensitive design. A tool was needed to encourage developers to fashion environmentally friendly site designs, to help communities add flexibility to their local ordinances, and to provide a standard that can be understood by both homebuyers and existing community residents.

In response to this, TCF developed the Conservation Development Evaluation System (CeDES) as a rating system to evaluate a conservation development over the development's lifetime with emphasis on water quality and landscape impacts. The purpose of CeDES is to encourage developers to think about environmental concerns earlier in the planning process and to provide consumers and communities with a means of assessing the impact of better site design practices. It was developed with input from over thirty national professionals skilled in planning and evaluating conservation developments. It may be viewed at http://www.conservationfund.org/conservation/sustain/gloindex.html.

Adequate Oversight and Inspection

One of the biggest challenges is ensuring that the contractors are building in an environmentally responsible manner. Even if the developer is committed to minimizing the impact of the development on the environment, if contractors are not educated and committed it may not happen. This is a challenge for many local agencies and municipalities who have limited staff for constant inspections. Even if the communities have ordinances that require construction erosion controls etc., without constant inspection many contractors do not follow the requirements. The nonpoint source pollution from construction, especially the sediment loadings, can negate any benefits from the alternative site design. One recommendation is for the community to require that an environmental inspector be hired specifically for the site. The inspector may be from a consulting firm or from a local Soil and Water Conservation District.

Incentive System Needed

We expect that this process will proceed much more quickly in communities that have recognized the threats conventional developments pose and have begun developing strategies to address them. In order to expand conservation development practices to a broader constituency, state or county agencies may need to develop incentive programs that prompt local developers to undertake these projects. With each community, we encouraged the creation of incentives for watershed-sensitive development. These included density bonuses for the developer through credits for land preservation and minimization of impervious coverage. We also investigated the use of the Clean Water Act State Revolving Fund (SRF). Among other uses, these funds are used to reduce nonpoint source pollution and could encourage watershed-sensitive development. The State of Ohio has successfully used the SRF for this purpose and we hope to pilot the same use of the SRF loans in other states. Incentives such as Ohio's loan program, coupled with the higher financial returns these developments are expected to generate, are making watershed sensitive developments more the norm in the Great Lakes Basin.

Relationship to Other Smart Growth Movements

There are many "Smart Growth" movements currently being debating and promoted throughout the country. Watershed-sensitive development is just one part of the equation. At times, we were challenged to show how this fits into overall community sustainability efforts. The work that the National Site Planning Roundtable completed to develop "Better Site Design" principles has been invaluable in demonstrating how these different movement can work together (Center for Watershed Protection, 1998). We often say that watershed-sensitive development is one option for Smart Growth but that a community needs to find the correct planning principles to work for their residents and issues. Those in the Traditional Neighborhood Design (TND) movement challenge putting sidewalks only on one side of the street, which we recommend for reducing impervious coverage. We also suggest that if sidewalks are on both sides of the street at least one should be made of pervious materials. There also are environmental groups that challenge us for encouraging greenfield development instead of infill development. Again, watershed-sensitive development is only one option of many and if the market is going to demand suburban fringe growth, at least we can work with the communities and developers to ensure that it is done with maximum possible protection and enhancement of the natural resources.

Lessons Learned about the Development Process

Pace of Development Often Incompatible with Innovative Site Design

The pace of development and the pace of government decision-making often are absolutely incompatible. Developers with outstanding loans on land need to move quickly to ensure a development is economically viable. Government agencies, on the other hand, are very concerned about the impacts of development, but move very cautiously, especially when they are undertaking something new. The result is that it is easier for both government and developer to create conventional, environmentally harmful developments than to do something better.

On the demonstration projects, TCF took special care at the outset of the process to communicate the timelines of each participant to the other. In this way, we hoped to keep the parties from throwing up their hands and giving up. For the region, however, we explored possibilities to get communities to adopt "fast track" approvals for watershed-sensitive communities. The first need is to show municipal authorities that these developments deliver tangible benefits, then we can help them develop mechanisms such as a streamlined review process and updated subdivision and zoning ordinances that encourage their creation.

A Greater Initial Investment in the Baseline Information is Necessary

Before planning a watershed-sensitive development, fairly detailed baseline information including topography, soils, and wetlands delineations is needed. Although developers hope that they get enough of the baseline site information before beginning design work, inevitably the risk/benefit of doing extensive baseline work (e.g., soil borings) may preclude the developer from getting all of the necessary baseline data. The common practice is to use "engineering judgment" based on existing data and extrapolation to the rest of the site. Unfortunately, especially when the drainage plan is an integral part of the initial site design, relying on "engineering judgment" simply is not sufficient. For example, on the Ohio site we relied on the existing soils information to design the swale system. After presenting a preliminary site plan, the developer discovered through additional research and sampling that the available soil information did not accurately represent the existing soil conditions and the drainage plan had to be reconstructed.

Initial Cost of Watershed-Sensitive Developments

Planning and developing a watershed-sensitive development takes time and costs money. Both lay and professional developers often underestimate these initial costs. Professional developers often leave site planning to their engineers. The engineers typically obtain a wetlands delineation and examine soil and topography maps, but do not evaluate the site from a watershed or ecological perspective. Although lay developers may be more familiar with the special features of their properties than professional developers, both need help to catalog all the features and to understand the site's role in the surrounding landscape. Quite reasonably, professional developers often are unwilling to undertake these expenses until they have a sense of the project's scale and niche in the market. We believe, and existing watershed-sensitive developments indicate, that the costs of evaluating a property from an ecological and a watershed perspective will be recovered when the development is sold out.

Deed Restrictions

The deed restrictions (i.e., covenants, conditions, and restrictions) necessary to ensure that the development will continue as a watershed-sensitive development in perpetuity are a lot more extensive than typical deed restrictions. Early in the process, sample restrictions for various developments should be presented to the developer and to the community so that they understand the consequences of using some of the watershed sensitive techniques. The developer will gain an appreciation for the long-term commitment necessary for a successful development and local officials may be put at ease when they recognize that major additional responsibilities (e.g., swale maintenance) rest with the homeowners association and not the local government.

Need Additional Lay Developer Education

Private landowners need to be assisted and educated through the process. Although these initiators often have a deeper environmental commitment than professional developers, they often do not understand what kinds of activities on their properties will have negative watershed impacts. For example, on one of our projects, the lay developer suggested that a pond be built each time an area of low-lying ground is found to be wet most of the year. Once informed about the relationship of these areas to more prominent wetlands on the site, the developer agreed to treat these areas more appropriately (i.e., preserving and enhancing the existing wetlands). The professional developers understand stormwater and wetlands issues better because they operate in the regulatory arena. The lay developers may need to be educated about the significance of these issues and other issues that are common knowledge to professional developers.

Aesthetics Do Not Equal Ecology

Another aspect of landowner education is the principle that aesthetics do not equal ecology. Just because a development preserves or creates attractive green spaces does not necessarily indicate that it is not harmful to the surrounding watershed. Accordingly, the criteria we developed for watershed-sensitive development (see discussion above under Measurable Criteria) incorporate appropriate baseline evaluation of the site to insure key resources are protected, and a thorough analysis of the stormwater impacts after development.

Lessons Learned about Engineering/Site Design

Educate the Engineers

If any of the county, township, or city engineers are not comfortable with the techniques being used, they can turn down the project at any point in the review process. In all three of our projects, the "old-timer" engineers were extremely conservative and feared change more than any other local officials. We found that the developers' engineers need constant oversight and education to design the sites using the watershed-sensitive techniques. Unfortunately, without a broad effort to educate engineers, they will have to be educated one community or county at a time. Once these techniques become more commonplace, we assume that such a great initial effort will not be necessary.

Lot Size Often Dictated by Septic Issues

Wastewater issues often control the form, location, and economic feasibility of a new residential subdivision. In many parts of the Great Lakes region, heavy clay soils strictly limit the functioning of conventional septic systems. For this reason, lot size is frequently dictated by septic issues as much as by local zoning. Although there are some alternate systems (e.g., constructed wetlands and community systems) being piloted and used in the region, local health officials are very cautious about permitting them. This caution arises both from concerns about their technical functioning and about long term maintenance issues. Communities already feel burdened by the need to monitor individual septic systems. They are skeptical about a homeowner association's ability to reliably maintain a community treatment system.

Wastewater treatment issues should be considered up front in evaluating the feasibility of clustering homes on a particular site. If a public sewer does not serve the site, clustering probably will not work as well (i.e., the individual lot sizes will not be able to be reduced as much). There is the possibility of placing the leach fields in the common property to increase the overall open space percentage.

Need Hard Science

Although there is a great deal of national literature detailing watershed-sensitive development techniques, there is not a lot of research documenting the extent of the water quality benefits they provide in the field. The Center for Watershed Protection (CWP) recognizes that there is a lack of water quality monitoring data that evaluates the techniques in varied site conditions and is working to develop and encourage more studies. Through consultation with the CWP, the Northeastern Illinois Planning Commission, and the Wisconsin Department of Natural Resources (WDNR), we found that funding for long-term monitoring of these techniques is scarce. Without this data, many of these techniques may be challenged successfully by skeptical local officials. With the assistance of Old Woman Creek Estuarine Research Reserve, one of our local partners, we are monitoring the water quality at the Ohio site. We hope that they will be able to continue the monitoring after our grants are over. We also are working with the WDNR to secure funding for long-term water quality monitoring at the Germantown site. It is our hope that this information will continue to back up many of the claims of watershed-sensitive development and that funding will continue to support these efforts.

Lessons Learned about Working with Communities

Community Initiative

Without community buy-in and interest in these concepts, even the most enlightened developer is not going to be able to get a project approved. When we first started this project, we thought that the developers were going to be the "hard sell." In two out of three of the communities, it actually has been the communities that needed more education. In the Huron project, the developer was sold on many of the alternative site design techniques until he kept getting negative feedback from the township board. This site was chosen because of the commitment of the developer and the obvious benefits to the surrounding water resources. What was not realized was how much resistance there would be in the political arena. At this project, we had several informal meetings with local officials prior to presenting a conceptual plan, but because the process was developer-initiated, they continued to be resistant throughout the process.

Local Official Knowledge Varied

Municipal, county, and state officials with similar regulatory responsibilities often have very different views about the appropriateness of new techniques. Although there are no hard and fast rules about who is likely to be more progressive, disagreements are common and a primary cause of frustration among developers.

As development is now regulated, it is more expensive and time-consuming for a lay or professional developer to create a watershed-sensitive development. The only way for a developer to address this situation is to inform local regulators and planning officials about the project early on, and to involve them in the process. Unfortunately, this involvement will probably not speed up the process for the individual developer, but after a few such projects are launched, we believe the barriers for these kinds of developments will be lowered.

Getting everyone with a regulatory or permitting role on a project involved at the very beginning is absolutely vital. If a project that includes techniques that have not been implemented in the region before gets too far along before all the regulators and municipal officials are brought in, the "stranger to the deal" can feel left out and derail the project. Much of this problem will be allayed once a few watershed-sensitive developments are built, but until then, developers and regulators pushing for these practices need to make special efforts to get everyone to the table early. Of course, this process increases the costs of doing the development initially, but it can keep it from falling apart after significant site planning and related costs are incurred.

Strong Local Partner is Key

Throughout this project, TCF acted as a facilitator between the communities and developers and as a representative of the silent third party, the environment. We believe that as each community begins to look at this type of development, this third party is key to the success of a project. Although there are many merits to approaching communities as a national organization, without a primary local partner who is well-versed in the trials and tribulations of the development process (or willing to learn them), it is difficult to proceed. A preferable arrangement would be a local organization, such as a land trust, leading the effort with support from a regional or national organization or technical assistance center. A local organization will have a greater vested interest in and knowledge of the local environment, will know the local officials and political and personal histories, and will be able to track and monitor the day-to-day activities surrounding the development. In the long term, local land trusts may become a key player in this area. They understand land conservation and watershed issues, frequently have close ties with both local landowners and local government officials, and have some comprehension of the development industry.

Final Lessons Learned

Several realities of the development process that have little to do with the challenges of watershed-sensitive development are important to mention for groups and communities considering this type of project. One is that the personalities and reputations of the developers can make or break a project. On our project in Ohio, the developer apparently had a "history" with several of the plan commissioners. Our partners in the community think that the plan commission and the engineers were being unduly unfair during the review process. Also, one of the developers in Wisconsin has a reputation for "low-end" development. Because of this reputation, the Village is afraid that the developers will do their typical development in their town.

Another reality of the development process is that the Village Planner of Germantown estimated that 60% of submitted development plans are reviewed by the plan commission and less than 50% of zoning requests are approved. All of our projects include a zoning request because the current local ordinances do not include a provision for watershed-sensitive development.

Conclusion

At all three of our model sites there are already signs of new developments being proposed with many of the watershed-sensitive techniques. In Wisconsin, the developer was approached by neighboring communities to design similar subdivisions. In Michigan, several local officials have stated interest in adding language in their new ordinances that would encourage this type of development. In Ohio, our local agency partner, Old Woman Creek National Estuarine Reserve, was approached by a developer who has been watching the process and is interested in using some of the techniques at an adjacent site. While the review processes for all three projects have not been as easy as anticipated, it is expected that the next round of developments will have an easier time because of the trailblazing work done before them.

Continuous Deflection Separation (CDS) for Sediment Control in Brevard County, Florida

Justin Strynchuk, John Royal, and Gordon England, P.E.
Brevard County Surface Water Improvement
Viera, FL 32940

Abstract

In July 1997, Brevard County's Stormwater Utility Program installed a new type of trash and sedimentation control device called a Continuous Deflection Separation (CDS) unit. This was the first American installation to use the CDS technology, which was developed in Australia. After installation, autosamplers were placed upstream and downstream of the CDS unit and a year's duration of sampling data collected. Monitoring has shown that the CDS unit has provided an average 52% removal efficiency for total suspended solids and 31% removal efficiency for phosphorus.

Introduction

Stormwater sedimentation is a primary source of pollution to Florida's Indian River Lagoon. Suspended solids and turbidity reduce sunlight penetration in the lagoon which negatively impacts seagrass growth. Where land is available, detention ponds effectively reduce most of the suspended solids from stormwater flows. When land is not available, alternative, less effective, treatment methods must be used.

The CDS technology was initially developed in Australia to provide an effective method for trash and solids removal from stormwater flows. The screening action within the unit provides for 100% removal of trash and particles down to 4700 microns. In addition, the unique circular design creates centrifugal action within the round concrete box which propels suspended solids to the center of the box and down into the storage chamber.

Methods

The location chosen for the CDS unit installation was along a ditch at the north end of Brentwood Drive, south of Port St. John. The drainage basin for this location was 24.87 hectares (61.45 acres) in area. This basin has Type A soils along a sand ridge. The land uses are 24.87 hectares (6.7 acres) of roadway (US Highway 1), 8.04 hectares (19.87 acres) of industrial park, 9.47 hectares (23.39 acres) of vacant land, and 4.65 hectares (11.49 acres) of commercial property. The industrial area has a permitted stormwater system. A significant land feature is a 2.02 hectares (5 acre) dirt parking lot, 152.4 meters (500 feet) upstream of the site around a local restaurant. This parking lot has a steep slope and is composed of fine white base material. There is evidence of heavy silt buildup in the inlets and pipes downstream of this parking lot, along US 1.

There is an earthen ditch running eastward 76.2 meters (250 feet) upstream from the project location. At the project site, there is an existing 122 centimeter (48 inch) RCP driveway culvert in the ditch which discharges to a concrete channel running 152.4 meters (500 feet) eastward to the Indian River. The time of concentration to the site is 63 minutes, with a 10-year flow of 1,557.2 L/sec (55 cfs) and mean annual flow of 1,177.9 L/s (38.2 cfs). In Brevard County, the 10-year storm is 20.1 centimeters (7.9 inches) of rainfall and the mean annual storm is 13.97 centimeters (5.5 inches) of rainfall. There is no base flow at this location.

A diversion weir 68.58 centimeters (27 inches) tall is placed in front of the 122 centimeter (48 inch) culvert so as to divert flows over 254.8 L/sec (9 cfs) around the unit. In 18 months of observations, the water level has risen over the weir one time.

A 76.2 centimeter (30 inch) concrete pipe was constructed adjacent to the existing 122 centimeter (48 inch) pipe in order to divert flows to the CDS unit. The 76.2 centimeter (30 inch) pipe enters the CDS unit tangentially to start the circular flow within the unit.

The CDS unit consists of three circular, concrete chambers stacked on top of each other. The top chamber, where the water enters the unit, has a 1.524 meter (5 feet) inner diameter and is 188 centimeters (74 inches) tall. The middle chamber has a 2.44 meter (8 feet) inner diameter and is 127.54 centimeters (51 inches) tall. In the middle chamber is a 1.524 meter (5 foot) diameter stainless steel screen matching the walls of the top chamber. The screen has 4700 micron holes to filter larger materials. The bottom chamber has a 1.22 meter (4 foot) inner diameter by a 1.22 meter (4 foot) tall sediment sump.

Water enters the unit in a clockwise rotation. When the water passes through the screen, it flows counter-clockwise between the screen and outer wall until it reaches a 76.2 centimeter (30 inch) concrete pipe. This exit pipe is tangentially placed for smooth exit flows. The elevation of the exit pipe rises 96.52 centimeters (38 inches) from the lower chamber to the outflow channel downstream of the 122 centimeter (48 inch) culvert. This rise in elevation keeps the normal water level in the unit near the top of the second chamber at all times. There is no base flow at this location.

The top of the unit is flush with the surrounding ground and has a 0.91 meter (3 foot) square, lockable, stainless steel access cover. This feature allows for easy access with a vacuum truck for cleaning purposes.

The CDS unit was installed on July 17, 1997. Installation took two days with the precast structures. A large crane was required to lift the chambers into place. A 4.57 meter (15 foot) deep hole was excavated for the structure.

In conjunction with the CDS unit installation, County forces cleaned the ditch upstream of the unit. Two days later, a significant rainfall event occurred and 2,294 kilograms (6,600 pounds) of sediment from the upstream ditch was trapped in the unit. After that storm, the ditch was reworked and sod was laid. The sod greatly reduced the volume of sediment washing into the unit.

Cleanouts were also performed on November 17, 1997, removing 626.84 kilograms (1,382 pounds) of sediment and 2.88 meters (34 cubic feet) of trash and debris, and again on May 6, 1998, with 998 kilograms (2,200 pounds) of sediment. The solids removed from the unit are taken to the Brevard County landfill for disposal. The volume of water stored in the unit is greater than the vacuum truck capacity, so decanting is performed on nearby sandy soils to avoid a second trip to the landfill for disposal.

Evaluation of the CDS Unit During Storm Events

The intent of the sampling was to evaluate the effectiveness of the CDS unit in removing pollutants from a storm event prior to discharging stormwater into the Indian River Lagoon.

Five storm samples were collected at the CDS unit between April 1998 and March 1999. The storm events occurred after dry periods ranging between 7 and 75 days. Protocol for this program dictated that if the sample collection devices (autosamplers) were triggered at intervals of less than three days between storms, the samples were to be discarded. This situation did not occur during the year, and near-drought conditions were observed in the sample area throughout most of the year-long monitoring program.

Rainfall was measured at the sampling site by a tipping bucket rain gauge, and additional rainfall data obtained from the Orlando Utilities Commission (OUC) power generating plant 5.6 km (3.5 miles) to the north of the CDS installation.

Review of the rainfall data collected indicates that the majority of the water passing through this BMP was from precipitation falling on the upland, 18.72 hectare (46.25 acre) watershed. The variation noted in both coverage and amount of rainfall helps illustrate the localized nature of the storms occurring along the Lagoon coastline. During this sampling period, water flowing off the drainage basin contributed much more flow through the CDS unit than would have been expected based on the rainfall recorded at the sample site.

Samples were collected through the use of automated storm water samplers; one at the inlet and another at the outlet pipe of the CDS unit. All samples, associated blanks, and duplicates were collected in accordance with our state-certified Comprehensive Quality Assurance Plan.

The stainless steel intake strainers for the samples were mounted on the reinforced concrete pipe, slightly off center bottom, and both angled away from the flow. This was to prevent the strainers from becoming silted over by sediments and allow collection of representative water samples. Flow rates during the storm events were measured initially utilizing water level meters (ISCO bubbler type) in conjunction with a 90-degree V-notch weir, but eventually replaced with a Doppler area-velocity flow meter which provides a more accurate flow assessment. Initially, two bubbler meters were installed with both bubbler tubes mounted on the upstream weir. However, this led to difficulties in estimating just when to trigger (time delay) the downstream sampler in order to collect samples from the same "plug" of water.

During the first three sample events, water levels recorded were correlated to flow, and the samples were manually composited to give a flow-weighted composite sample from each sampler. Both inlet and outlet sample sets were composited identically, in accordance with the EPA NPDES Stormwater Sampling Guidance Document (July 1992). Discreet samples were collected for the fourth and fifth events.

It was intended that the third sample event would include a mass balance calculation. The CDS unit sump was thoroughly cleaned utilizing a VAC-truck to ensure that the material collected was a result of the one storm to be evaluated. Inlet and outlet stormwater composite samples were again collected, with the addition of a sediment (Table 1) and water column sample from the sump. Sediment depths were measured at five locations; four from the corners of the lid opening and one in the center. Based on a depth of 13.21 centimeters, a sump diameter of 1.22 meters (4 feet) and an estimated 1,410.6 kg/m3 (88 lb/ft^3), (based on previous sediment weight evaluation), approximately 217.3 kilograms (479.2 pounds) of sediment was collected in the unit from storm three. Based on the concentrations measured, 126.07 grams (4.443 ounces) BOD 5, 33.587 grams (1.184 ounces) of metals, and 122.81 grams (4.33 ounces) of Total Kjeldahl Nitrogen (TKN) were removed.

Table 1. Sediment Chemical Analysis For Storm #1

Parameter	Sediment Grab	Grab Duplicate	Average Value	Detection Limit	Units
Arsenic	0.096	0.11	0.103	0.069	Mg/Kg
Barium	3.4	2.9	3.15	0.14	Mg/Kg
Benzo(b)fluoranthene	260	ND*	250*	240	Ug/Kg
BOD5	650	510	580	2.7	Mg/Kg
Cadmium	0.03	0.033	0.0315	0.014	Mg/Kg
Chromium	1.1	1.1	1.1	0.027	Mg/Kg
Copper	1.2	0.95	1.075	.0.027	Mg/Kg
Iron	220	260	240	0.55	Mg/Kg
Lead	2	2.2	2.1	0.041	Mg/Kg
Nickel	0.4	0.36	0.38	0.069	Mg/Kg
Silver	0.16	0.059	0.1095	0.014	Mg/Kg
Total Kjeldahl Nitrogen	450	680	565	37	Mg/Kg
Total Phosphorus	79	230	154.5	9.2	Mg/Kg
Zinc	14	14	14	0.27	Mg/Kg

Notes:
Equipment Blank Water Yielded ND for all listed analytes.
*The benzo(b)fluoranthene mean value was calculated with the RDL as the lower value for the duplicate.

Only parameters with values above detection limit are listed. Many others were tested below detection limits.

For this third sample event, the upstream, or intake flowmeter bubble tube was mounted on the 90-degree V-notch inlet weir, as it was for previous sample events. The downstream bubbler, however, was moved and attached to the downstream discharge pipe. This change was necessary to account for the lag time between when the first sampler received flow at the beginning of the storm, the time required to fill the sump with 8,115 liters (2,144 gallons), and discharge to flow past the second sampler several minutes later. The problem encountered with this revised setup was that the upstream V-notch weir used to determine the flow was overtopped, allowing flow around and over it, preventing an accurate flow measurement. This led to disparity in the estimation of actual flow through the unit. Due to the questionable flow measurements, it was not possible to calculate the mass balance.

For the fourth sample event, an ISCO Doppler area-velocity flow meter was mounted in the bottom of the outfall pipe of the CDS unit. Upon registering a water level rise of one inch, this unit triggered both upstream and downstream autosamplers. The autosamplers were synchronized, collecting a bottle set in each ISCO at the same time. With this methodology and placement, overtopping the weir, flow bypassing, and pressurization were no longer potential sources of error. Since the samplers now triggered only when the sump was full, it was also somewhat easier to accept the premise of "what went in, must have come out."

Appropriate trigger points were selected in order to allow sufficient water depth for the velocity meter probe to operate properly. We found that the Doppler area-velocity flow meter probes appear to function erratically when covered by less than one inch of water, and believe that measurements taken when the water was at this depth are suspect. Two-bottle sample sets were collected at sampler initiation, and at 10-minute intervals during the storm. During previous sample excursions, samples were manually composited. Due to a high suspended solids content, (heavy particles including sand) that rapidly settled in the sample container, it was questioned whether the composite samples were truly representative of the solids collected. Therefore, discrete two-bottle sets collected every 10 minutes were sent to the laboratory without being composited.

For the fifth sample event, two-bottle sample sets were again collected at sampler initiation, and at 10-minute intervals during the storm. As with the previous sample event, sample sets were not composited but sent for analysis as six individual, two-bottle sets. The sample bottles for bottle sets six were not collected due to insufficient water to cover intake strainers, as the storm was not of adequate duration to produce the last 10-minute sample. Because of numerous problems encountered in the previous storm event samplings, along with refinements in sampler setup and flow measurement, the fifth storm sample event is considered the most accurate to determine what pollutant reduction is provided by the CDS unit for that storm. The individual two-bottle sets showed the variation in pollutant loadings throughout the storm event and the corresponding removal under the varying loads. Unfortunately, this was the lowest flow storm encountered, which may account for higher than normal removal efficiency. Maximum flow was estimated to be only 136 liters/sec (2.16 gpm). The average pollutant reduction between inlet and outlet samples for this event was: BOD5 53%, COD 52.6%, TP 36%, TSS 56%, and Turbidity 74.8%.

Sample results are presented in Tables 2 through 4 for the five sample events. Storm event 2 showed a 23% reduction in turbidity, but no reduction in the other parameters. Storm 4 showed an increase in most parameter concentrations between inlet and outlet that could not be attributed to resuspension due to a full sump, since the sump had been cleaned prior to the third event. Data for these two storms are therefore suspect. For events 1, 3, and 5, the average removal efficiencies for those parameters that showed a reduction were: TSS 52%, Turbidity 46.9%, BOD 34.2%, COD 35%, and TP 30.6%

After each sample event, field observations were made of the appearance of the sample jars, each containing a water sample that had been collected at progressive ten-minute intervals throughout the storm flow. Outlet samples typically appeared to be less turbid than the corresponding inlet samples, and also had less sediment on their bottoms. An observation was also made of the water surface inside the CDS unit proper. There was typically a thick layer of floating grass and other vegetation, an oil sheen, glass and plastic bottles, plastic sheets and bits, seeds and nuts, sticks, and a surprising amount of Styrofoam cups and particles.

Conclusions

While none of the sample events were a perfect combination of a good flow and everything working right, the data collected, and our observations, certainly indicate that the CDS unit is operating as intended and removing significant quantities of debris and suspended materials prior to discharge to surface waters. It was quite impressive to prevent this trash and sediment from washing out into the lagoon during a normal rain.

The phosphorus removals observed for the CDS Unit, as with any BMP of this type, will not have a high degree of accuracy, due to leaching of nutrients from grass, leaves, and other organic debris. If there are no base flows, these leached nutrients will be washed out with runoff and skew sample readings. A much more comprehensive analysis is available in the library of the web site www.stormwater-resources.com.

Future Evaluations

More data are necessary to further evaluate this BMP. Due to the inherent inaccuracies in water quality sampling, additional determination of the efficiency of this type of BMP could be made by conducting a mass loading and sediment evaluation. Much of the sediment collected in this type of BMP is invisible to current testing techniques since it is comprised of large particles that roll along the bottom of the pipe. Yet, known quantities of sediment are being collected.

A previous study of baffle boxes resulted in the same conclusion. Future sediment analysis from the CDS unit could be compared to the baffle box data previously collected. Brevard County will be conducting a sediment evaluation at three baffle box sites over the next 12 months that will provide additional comparison. As time permits, Brevard County will also collect additional sediment data from he CDS unit.

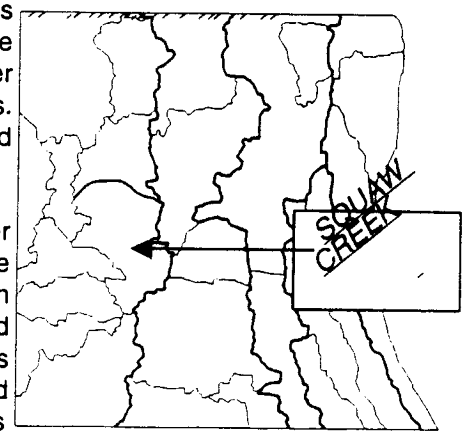
Use of Automated Technologies in Watershed Management Planning

Lake County Stormwater Management Commission (SMC)
Libertyville, IL

Introduction

The Lake County Stormwater Management Commission's (SMC) is working with many agencies to develop comprehensive watershed plans. These watershed plans involve data collection and collation, problem analysis, alternative solutions identification and action plan development. The watershed assessment includes hydrologic and hydraulic modeling; floodplain and floodway mapping; and water resource assessment. As part of a watershed management plan, one of the end results is to update floodplain maps and to map depressional storage areas. Other end products of this effort include location maps of water resources, including wetlands and regional detention sites, with identification of those needing preservation, enhancement or restoration. With this information, projects can be prioritized and cost estimates determined in order to assist local governments in implementing the action plans.

Lake County, Illinois is located in the northeastern corner of Illinois and is one of the fastest growing counties in the country. The county has 61,000 acres of wetlands (12) and 400 miles of streams and rivers throughout its 480 square miles. The combination of growth and the need to protect natural resources is driving the Lake County Stormwater Management Commission's (SMC) comprehensive watershed planning efforts. Plans are currently being developed for urbanizing watersheds between 2 and 50 square miles in area.



Map 1: Lake County, Illinois, Sub-Watershed

With limited personnel and funding, SMC is utilizing in-house computer capabilities and staff technical expertise to save time and money as we increase our ability to model and display watersheds. The Squaw Creek Plan is an example of how SMC is currently utilizing automated technology for watershed planning purposes. The Squaw Creek watershed is 25.5 square miles and is 75% undeveloped (includesagriculture, vacant and open space). The watershed is 17.3 percent wetlands. TheNorthern Illinois Planning Commission forecasts a 155% population change between 1990 and 2020. The Squaw Creek Watershed is located in the western portion of the county and drains into Fox Lake, on the Fox River.

SMC is integrating Geographic Information System (GIS) (2) technology with Computer Aided Design (CAD) and the Army Corps of Engineer's HEC-1 (10) and HEC-RAS (11) models to create an "automated" watershed closely resembling the existing Squaw Creek watershed characteristics. SMC used a variety of vendor software packages that include Environmental Systems Research Institute, Inc.'s (ESRI) ArcView (1) and its Spatial Analyst and Hydrologic Extensions, and Bentley's MicroStation.

Data Collection

It is very important to determine the methodologies for collecting, calculating, and analyzing data early in the automation process. Methodologies were determined for mapping floodplains, inventorying and analyzing water resources (8), and estimating runoff water quality. The floodplain mapping variables included time of concentration, precipitation runoff, stream storage, stream routing, sub-basin boundaries, and water surface elevations. These variables had to be determined before final data could be formatted and collated. We also had to determine how data could be documented in the report early in the study process.

Since considerable map data was available digitally, it was economical to perform many tasks on the computer rather than on hard copy. The Northern Illinois Planning Commission (NIPC) provided the digital land use map. Lake County Map Services provided digital copies of the Soil Conservation Service (SCS) hydrologic soil groups (HSGs) map, hydric soil map, United States Geological Society (USGS) orthophotos, Lake County Wetland Inventory boundary map, and Lake County parcel boundaries. In addition to this digital data, SMC contracted to obtain 2-foot topographic contours, detailed orthophotos, stream cross-sections, and field-surveyed hydraulically significant structures. Bridge and culvert information and stream cross-sections were also delivered digitally from Illinois Department of Natural Resource's (IDNR) land survey crew using Global Positioning System (GPS) and conventional surveying. Photogrammetry and cross-section control points were collected in the field utilizing a GPS with accuracy of 1:50,000 horizontal and +/- 0.03 feet vertical (5). Each USGS digital orthophoto map covers one quarter of a quadrangle and used 45 MB of computer storage. The topographic maps were delivered in GIS and CAD formats. Contracted data were delivered by square mile. This created a reasonable size data file, including:

Two foot topographic contours and breaklines	1.2 to 3 MB per square mile.
Orthophotos	35 MB per square mile
Digital Elevation Model	1 MB per square mile

The cost for the two foot contours overlaid on an orthophoto varied between $2200 and $3300 per square mile. Additional record drawings of hydraulically significant structures, such as road crossings and detention basin outlets, were collected from county and state highway departments and local communities. The townships and communities seldom had detailed information, so field investigations were undertaken, where necessary, using topographic mapping to establish a reference elevation.

The water resources inventory included a stream assessment, wetland inventory, and a wetland restoration assessment. The stream assessment data were collected in the field along with short community interviews. The stream inventory used an existing methodology created by NIPC (8). SMC created a methodology to identify potential wetland restoration locations.

Surface runoff water quality was estimated using typical measured pollutant loading data for several general land uses. NIPC had an existing procedure that assigned non-point runoff pollutant loads to general NIPC land uses. The typical pollutant loadings were entered into a worksheet so this procedure could be automated.

Creating Hydrologic and Hydraulic Data

Several hydrologic and hydraulic parameters and other data were used to analyze the surface water runoff and generate floodplain boundaries. These included delineating sub-basin boundaries; determining a runoff curve number, time of concentration and Clark's coefficient of runoff for each sub-basin; calculating reservoir data; formatting HEC-1 model; and creating HEC-RAS model geometry.

Sub-basin Delineations

The sub-basin boundaries were produced automatically using the following steps. First, a Digital Elevation Model (DEM) was produced from photogrammetry by a consultant. A DEM is a list of equally spaced data points with a defined easting, northing, and elevation. A spacing of the DEM points of 10 and 30 feet was evaluated. The 10-foot spacing would slightly increase the accuracy of the automated sub-basin boundary's but it used ten times the disk storage as the 30-foot spacing. Therefore, a 30-foot grid DEM was used to determine the sub-basin boundaries due to storage space limitations. Second, the DEM was loaded into ArcView and converted to a DEM grid using ArcView's Spatial Analyst. Third, the flow paths and the preliminary sub-basin boundaries were created using ArcView's Spatial Analyst and Hydrologic Extension along with the DEM grid, which delineated 180 preliminary sub-basin boundaries in 2.5 hours.

Fourth, these preliminary boundaries were edited with the digital contour map in the background to better model storage areas and road crossings. This editing entailed splitting basin boundaries and joining basins together to produce more accurate boundary lines. Editing was performed on portions of approximately 50% of the preliminary sub-basins that were automatically created and ultimately reduced the number of sub-basins. Edited boundaries were checked against hard copy maps and a field investigation of storm sewers and field tiles. A check of maps and field investigation identified three boundaries that needed additional modifications including the addition of one sub-basin. Finally, ArcView was used to automatically calculate each sub-basin's area and a sub-basin identification was assigned to each of the 140 sub-basin areas.

Runoff Curve Number

SMC created a methodology to estimate precipitation runoff. This required converting SMC defined land use categories to Soil Conservation Service (SCS) runoff curve numbers (RCNs) (9) using ArcView and Excel (6). RCNs were calculated using the following sequence. First, the 1990 NIPC land use polygons were converted to SMC land use categories based on land cover using 1996 orthophotos as a backdrop. Land cover was divided into six categories: 1) impervious, 2) graded grass, 3) natural grass, 4) graded forest, 5) natural forest, and 6) agriculture. Typically graded grass and graded forest land cover categories have increased runoff compared with their natural conditions as soils are compacted and depressions are removed during grading. A SMC land use was created for the calibration year of 1996 and for the model year of 2000. Second, concurrently with the land use conversion, the digitally mapped soil numbers were converted to HSGs using GIS queries. Third, the HSG map was intersected with the SMC land use categories to automatically create a land cover map. Fourth, the land use categories table and a land cover conversion table were joined so there was one RCN for each of the four HSGs.

Runoff Data

HEC-1 requires specific input data to generate runoff volumes for each sub-basin. The minimum input parameters for each sub-basin were identification, area, the time of concentration (Tc), Clarks Coefficient of Runoff (R), and weighted RCN. Sub-basin area was delineated as previously described.

The weighted RCN was determined in two steps. First, intersecting the finalized sub-basin boundaries with the RCNs boundaries using ArcView. This splits the RCN polygons with the sub-basin boundaries. This calculation took just twenty minutes. Then this table of RCN attributes for each sub-basin was exported from ArcView into Excel where the weighted curve number for each sub-basin was calculated in one day.

In addition, each sub-basin requires a length and slope of travel to generate the Tc and R. To determine the length and slope, a line with two points were needed, one upstream and one downstream. The line represented the direction of runoff from the farthest ridge to the outlet of the sub-basin. GeoAnalytics, Inc., a consultant, created a program to automatically generate a distance point 10% and 85% from the sub-basin outlet along this digitized line in 30 seconds. The point locations along the line were determined by the methodology used to estimate Tc and R. These points were queried individually with the DEM grid and checked against the topographic map to determine their elevation, which was entered into a table. ArcView calculated all sub-basin line lengths in less than a minute. The stream line and its two elevation points were associated with the sub-basin identification throughout this process. Next, the sub-basin boundaries, the associated line, and two points were joined into one table and exported as a database file. This database file was imported to an Excel worksheet where the slope, Tc, and R were calculated for each sub-basin.

Reservoirs

To model reservoir routing, the reservoir volumes were determined using ArcView and the 2-foot digital contours. The reservoirs consisted of a series of polylines in ArcView after conversion of the CAD contour map. The polylines were modified so they were completely connected and then converted to a polygon in ArcView. This documented the location of every reservoir that was modeled explicitly, as not all reservoirs could be modeled within the scope of our project. Second, the elevation for each contour was entered into a table. The topographic contractor now performs steps one and two. After all the elevation polygons were created, ArcView calculated the area of the polygons with one command.

Finally, the elevation and area tables were opened in an Excel worksheet to calculate the elevation versus storage relationship. This worksheet was referenced by the HEC-1 formatted worksheet described in the next section. Stage versus discharge relationship was determined for each reservoir when data was available using HEC-RAS or HY-8.

Hydrology Model Development

All of this data was combined into one Excel workbook to generate the input needed for HEC-1. The sub-basin data entry included: identification, area, weighted RCN, Tc, and R. Most sub-basins also needed reservoir or stream routing data. An Excel worksheet was edited with HEC-1 formatted column widths so the data could be saved into a file that the HEC-1 FORTRAN program can accept. Sub-basin data were entered automatically by referencing other worksheets in the same workbook. Once the first sub-basin referenced the other worksheets properly, the first formatted sub-basin data were copied to create another set of HEC-1 data for the next sub-basin. After the sub-basin identification was entered for this new HEC-1 input data set, the remaining data were automatically retrieved in the worksheet and correctly formatted, to avoid data translation errors.

Hydraulic Data

The stream cross-section data were initially generated in MicroStation. Each section was digitized as a series of connected line segments that were exported to a comma-delimited file of easting, northing, and elevation which was then imported into HEC-RAS's "Import/Export Files for Geospatial Data." The culvert and bridge data had to be coded in separately. The channel stationing was determined automatically using Intergraph In-Roads. This procedure not only provided data formatted to be exported directly in HEC-RAS, but also created a 3D map of the channel cross-sections and stream centerline to document the model spatially using MicroStation and ArcView. The cross-section segments had to be manually identified for use in the automated floodplain mapping.

Floodplain Development

Stream cross-sections and hydraulic structures were modeled using HEC-RAS to determine the water surface elevation along the stream. ArcView's Spatial Analyst Extension or ArcInfo could be used to delineate the floodplain from the HEC-RAS output. Final maps were generated in ArcView.

The HEC-RAS generated water surface profiles were exported by HEC-RAS's "Import/Export Files for Geospatial Data." GeoAnalytics Incorporated, Madison, Wisconsin, imported this data into an ArcInfo project that uses a 10-foot DEM grid. ArcInfo needs a line and an elevation for each cross-section to map the floodplain. The cross-section line and its identification were created in MicroStation, exported as comma delimited points, and then referenced into ArcView to create the cross-section line. The line with its cross-section identification was associated with the water surface elevation. The grid was then "flooded" between the two cross-sections with a linear slope between the appropriate water surface elevations. This creates a grid of the flooded area. For each flood profile that was to be mapped, a separate grid of the flooded area must be completed.

Reservoirs, such as lakes, ponds, and depressions, that have their Base Flood Elevations determined using HEC-1, were mapped automatically. The storage areas had the water surface elevation defined using HEC-1 then the grid was "flooded" for all points at or below that elevation.

The flooded grids were then converted to polygons and "smoothed" in ArcInfo for use in ArcView. Last the polygons were reviewed against the digital two-foot contours and adjusted as needed before final map production. Every reservoir outlet had to be manually mapped between its outlet and the downstream reservoir or stream floodplain.

Water Resource Assessments

A water resources inventory was completed that included a stream assessment, a wetland inventory, and potential wetland restoration site identification. All of the stream assessment data were collected in the field along with short community interviews and entered into a database. Several key stream characteristics were mapped using GIS. The stream inventory data were queried for specific stream conditions and key characteristics were mapped such as degree of bank erosion or sediment accumulation.

A county wetland Advanced Identification (ADID) study was completed in 1992 prior to the assessment. One of the criteria reviewed for each wetland was its storage potential, which was related to the area of the wetland. Querying the spatial data for specified wetland areas and creating a new set of data easily identified these wetlands. The wetland restoration and mitigation bank site identification methodology was developed by SMC in 1999. Several data sets were queried to identify the former wetland sites that have the greatest number of characteristics necessary to make them restorable and usable as a wetland bank. A less stringent set of criteria was used to define all former wetland sites with restoration potential. The potential wetland restoration sites included all Advanced Identified (ADID) wetlands. Potential wetland banking sites excluded ADID wetlands and restorable sites less than 20 acres.

Surface water quality 'hot spots" were estimated using non-point pollutant loading rates for several general land uses via NIPC methodology. Twelve pollutants were evaluated. The pollutant "hotspots" analysis employed land use, impervious surface area, annual runoff coefficients, and storm sewer conditions as surrogates to determine the annual pollutant loading by sub-watershed. The pollutant loading database was attached to the land use map database. It was then mapped in ArcView resulting in 12 maps, one for each pollutant.

The watershed advisory committee and NIPC identified which level of pollutant loadings should be labeled as detrimental. The pollutant load data were then grouped, using natural breaks in the data set, as low, medium or high. These were mapped and queried to determine where water quality enhancement projects would be most beneficial and highest priority.

Summary

The Lake County Stormwater Management Commission has invested a significant amount of time and funding in developing the hardware, software, and database necessary to perform floodplain analysis. By making this commitment and establishing the methodologies for manipulating data and analyzing watershed parameters, we have created a powerful analysis tool. Mapping accuracy, display flexibility and a wide range of GIS analysis ability has been created through this process. This technology coupled with other resource assessment efforts has created a strong foundation for future watershed planning in this watershed. The technology is transferable and will be used throughout Lake County as our agency resources allows.

Abstract

Fifteen small bare plots (1 meter x 1 meter) on a 10% slope were analyzed for runoff and sediment yield on a construction site. A rainfall simulator applied 6.32 centimeters of rainfall per hour to each plot after a polyacrylamide mix (PAM-mix CFM 2000*) treatment was applied. The following treatments: No PAM-mix applied to dry soil (control), PAM-mix in solution applied to dry soil, dry PAM-mix application to dry soil, PAM-mix in solution with mulch/seeding applied to dry soil, and PAM-mix in solution applied to moist soil. Each treatment was repeated on three plots. When a solution of PAM-mix with mulch/seeding was applied to dry soil and compared with the control (no PAM-mix application to dry soil), we found an average reduction of 93% in sediment yield. An average reduction of 77% in sediment yield was the worst performing PAM treatment, and occurred when PAM-mix in solution was applied to moist soil. The application of dry PAM-mix to dry soil reduced sediment by 83% and decreased runoff by 16% when compared to the control. Our results show that regardless of the application method, PAM-mix was effective in reducing sediment yield in the test plots. The ease of application, low maintenance, and relatively low cost associated with PAM make it a practical solution to the costly methods being implemented today

Introduction

One effect of rainfall is the initiation of the erosion process where individual raindrops fall and impact the soil surface. Soil detachment and particle transport by raindrop splash can lead to serious soil deterioration. Once soil is eroded and transported by surface runoff to lakes, rivers, and streams, a degradation of the aquatic habitat occurs. Sediment is the largest pollutant, by volume, in the State of Wisconsin (WDNR, 1994). In order to maintain a healthy watershed, it is critical to control erosion and sediment yield.

Maintaining soil structure and aggregate stability helps control erosion by increasing infiltration and maintaining less erodible-sized aggregates. Stable soil structures also help maintain a healthy environment. The use of polyacrylamides and polyacrilamide mixes (PAMs and PAM-mix) is a new tool to help maintain soil aggregate stability and reduce erosion caused by surface runoff. Such materials can be applied at a rate of 20 to 30 lbs per acre on construction sites, to stabilize such sites against erosion until they can be permanently protected through vegetation.

Water-soluble polymers and water polymer mixes do not create aggregates when applied to soil. However, they can stabilize existing aggregates when the aggregates are saturated with a solution of water soluble polymer mix. Increasing the aggregate stability with polymers reduces the effect of raindrop impact on the soil, thereby reducing erosion. Polymer application to the soil may also retard surface sealing, reduce particle soil detachment, reduce sediment in suspension, and compensate for low residue.

Objectives

The objectives of this study are to determine the optimum application methods and the effectiveness of the PAM-mix under moist and dry soil conditions. The different application methods were applied to a construction site in Middleton, WI. Data were collected to determine the most effective method of application and the effectiveness of the PAM-mix on construction sites.

Literature Review

The use of polymers as soil conditioners has been studied for decades. The most conclusive studies, done by Lentz et al. (1992), determined that negatively charged PAM is an excellent soil erosion deterrent for furrow irrigated fields. It was found to be a cost-effective and safe technology. Sojka and Lentz (1994) found that PAM, when applied in irrigation waters at rates greater than 0.7 kg/ha, reduced furrow erosion by an average of 80 to 90% and increased infiltration on Portneuf silt loam by an average of 15%. Trout et al. (1995) reported a 30 to 110% increase in cumulative infiltration. Roa et al. (1996) found that soils treated with PAM had infiltration volumes more than double that of untreated soils over a two-hour period. The infiltration volumes for the untreated soils averaged 231 ml/38.5 square centimeters while those for treated soils averaged 490 ml/38.5 square centimeters, or 98% of the volume of water to be infiltrated. Roa et al. (1996) also found that the high infiltration rate of the treated sample was associated with low concentration of sediment in the effluent or infiltrated water.

Nadler et al. (1994) found that PAM mobility in sandy loam, as well as clay loam soils, was limited to the top 25 cm 10 months after application. Clays were attached to anionic polymers more easily when salts were present in solution. With anionic polymers, flocculation was easier and more complete. When polysaccharides are present with anionic polymers in solution, fixation was also easier and more complete. Khamraev et al. (1983) reported that clay fixation is best achieved for PAMs with 30% anionic charges. The cementation provided by the clay flocculation stabilizes the aggregate at the surface. Roa et al. (1997) found that using polysaccharides, a calcium source with anionic polymers or polysaccharides with calcium nitrate and anionic PAM, increased the infiltration rate in saturated cores 5 times greater than with no soil treatment.

PAM use for erosion control provides a potent environmental benefit by halting furrow erosion by about half a ton of soil per ounce of PAM used. PAMs remove most sediment, phosphorus, and pesticides from return flows, and greatly reduce return flow BOD (Sojka and Lentz, 1996). The consequences of reducing sediment and nutrient loading of construction areas can ultimately be expected to reduce the frequency and intensity of algae blooms and reduce turbidity and sedimentation of stream channels.

Lentz et al (1992) in Kimberly, Idaho, reported that when applied at 10 ppm, PAM provided a 94% reduction in runoff-sediment in three years of testing. When used properly, PAM has no measurable toxicity to humans, plants, or aquatic organisms. Molash et al. (1997) state that the Polyacrylamide Allocation Standard for Reduction of Soil Loss is necessary because other best management practices (BMPs) are available and have varying degrees of effectiveness.

Sojka and Lentz (1996) summarized several advantages of PAMs over other erosion control BMPs: (1) PAM can be applied using irrigation equipment and can be effective for controlling erosion over large areas, as demonstrated in eastern Washington and Idaho; (2) PAM is very effective on fine silt/clay soils; (3) preliminary research conducted in

Kansas and California has indicated that PAM is effective at abating wind erosion; (4) PAM enhances precipitation of fine silts and clay particles, providing water quantity benefits; (5) PAM increases soil infiltration capacity that reduces runoff volumes; and (6) high benefit to cost ratio.

The types of PAM used for erosion control should have an approximate molecular weight of 12-15 Mg/mole, with an 8-35% negative charge density, and contain no greater than 0.05% Acrylamide monomer (Sojka and Lentz 1996).

A recent study done by King et al. (1996) focused on comparing the uses of polyacrylamides and straw mulch on dry bean yields. It was shown that the sediment loss was reduced for both straw mulch and the PAM treatment.

In three years of studies in construction sites using PAM for controlling soil loss, PAM has provided a 60-97% reduction in runoff-sediment (Roa et al. 1997).

Method

Five treatments were applied to soil test plots: (1) No PAM-mix application to dry soil [control], (2) PAM-mix in solution applied to dry soil, (3) Dry PAM-mix application to dry soil, (4) PAM-mix in solution with mulch/seeding applied to dry soil, and (5) PAM-mix in solution applied to moist soil. Three replications of each treatment were performed using a randomized block design on 1m x 1m non-vegetated plots in the Middleton Hills Development, Middleton, WI. The soil was a Dodge silt loam. The average slope of the test site was 10%.

Plot preparations included large boulder, cobble, and excess debris removal. The surface was raked prior to testing. Soil moisture prior to testing was about 9%.

The PAM-mix is a high molecular weight anionic granular polymer. The PAM-mix (2.25 g of PAM-mix added to 5 liters of water) was applied at a rate of 22.5 kg/ha, to the appropriate plots using a garden sprinkler. For the dry PAM-mix application, 2.25 grams of the PAM-mix was applied using a sifter. For the PAM-mix applied to moist soil treatment, the soil was pre-moistened by a 6.4 cm rainfall six hours before testing.

The sprinkler infiltrometer (Bubenzer and Patterson, 1982) was used to collect data for this study. A rainfall simulator was used that produces 6.4 cm per hour. Actual rainfall depths were recorded using eight rain gauges for each replication. Runoff from each plot was collected into a tank where the depth of the water was recorded at approximately 2-minute intervals during each test. The average trial time was 40-50 minutes or until the runoff collection tank was filled.

Runoff samples were extracted at approximately 10-minute intervals by diverting runoff into a collection container during each replication to determine sediment yield. A representative sample was also taken at the end of each replication from the tank. The samples were dried at 110°C for 24 hours and weighed to determine an average sediment load for each trial.

Results and Discussion

Mean sediment yield, infiltration, and runoff depth for the three replications and the controls are presented in Tables 1, 2, 3 and 4. For Replication 1, the PAM-mix solution was prepared the evening before field testing. It was noted that the viscosity of the solution decreased throughout the day. This change may have been due to UV light, reaction with the mix, and/or oxidative and photolytic interaction. Thereafter, the solution was prepared immediately before the rainfall simulation. After analyzing the results, a lower viscosity of the PAM-mix solution was determined to be less effective in controlling sediment yield. This difference is presented in Table 4. Future recommendations for commercial applications may need to take into account the time of preparation of the solution and handling before application.

During the first replication of testing, the largest sediment reduction occurred when PAM-mix in solution was applied to moist soil. The control yielded 184.4 grams per square meter and the PAM-mix in solution applied to moist soil yielded 36.4 grams per square meter resulting in a reduction of 80% in sediment yield (Table 1). The sediment yield reduction for the dry PAM-mix application to dry soil and PAM-mix in solution with mulch/seedling applied to dry soil were

Table 1. Summary of rainfall, infiltration runoff, and sediment yield for Replication #1.

Treatment	Rainfall (cm)	Infiltration (cm)	Runoff (cm)	Sediment (gm)	Soil Loss % of Control	Runoff Rainfall % of rainfall
Control	5.64	1.70	4.01	184.4	100%	71%
Dry PAM-mix/Dry Soil	5.79	1.91	3.89	68.3	37%	67%
Solution PAM-mix/Dry Soil	5.64	1.60	4.11	103.7	56%	73%
Solution PAM-mix/Moist Soil	5.72	0.05	5.66	36.4	20%	99%
Solution PAM-mix/Mulch/Dry Soil	5.72	1.57	4.14	67.3	36%	72%

approximately 64%. The sediment yield for PAM-mix in solution applied to dry soil was reduced by 44% when compared to the control.

In Replications #2 and #3, the lowest sediment yield occurred for the treatment of PAM-mix in solution with mulch/seeding applied to dry soil. A sediment reduction of 97% and 89% occurred, respectively. A sediment reduction for the treatment of PAM-mix in solution applied to dry soil was 87% and 57% respectively (Table 2 and 3).

Table 2. Summary of rainfall, infiltration runoff, and sediment yield for Replication # 2.

Treatment	Rainfall (cm)	Infiltration (cm)	Runoff (cm)	Sediment (gm)	Soil Loss % of Control	Runoff Rainfall % of rainfall
Control	4.57	0.51	4.06	377.67	100%	88%
Dry PAM-mix/Dry Soil	5.72	1.57	4.14	178.36	47%	73%
Solution PAM-mix/Dry Soil	4.72	0.61	4.11	48.77	13%	87%
Solution PAM-mix/Moist Soil	4.14	0.13	4.01	242.4	64%	97%
Solution PAM-mix/Mulch/Dry Soil	4.55	0.38	4.17	12.04	3%	92%

Table 3. Summary of rainfall, infiltration runoff, and sediment yield for Replication # 3.

Treatment	Rainfall (cm)	Infiltration (cm)	Runoff (cm)	Sediment (gm)	Soil Loss % of Control	Runoff Rainfall % of rainfall
Control	5.05	1.12	3.94	231.34	100%	78%
Dry PAM-mix/Dry Soil	5.38	1.96	3.43	43.29	19%	64%
Solution PAM-mix/Dry Soil	4.50	0.61	3.89	98.59	43%	86%
Solution PAM-mix/Moist Soil	4.42	0.28	4.14	47.65	21%	94%
Solution PAM-mix/Mulch/Dry Soil	4.39	0.38	4.01	26.58	11%	92%

When Replication #1 is excluded from the results, the average sediment reduction for PAM-mix in solution with mulch/seeding applied to dry soil increased from 87% to 94% (Table 4). The sediment reduction for PAM-mix in solution applied to dry soil was 76%. For dry PAM-mix applied to dry soil, the sediment reduction was 17%, and the sediment reduction of PAM-mix in solution applied to moist soil was 77%.

Conclusion

Our results show that, regardless of the application method, PAM-mix was effective in reducing sediment yield in the test plots. The most effective method of soil treatment throughout this study in reducing sediment yield is PAM-mix in solution with mulch/seeding applied to dry soil. The ease of application, low maintenance, and relatively low cost associated with PAM-mix makes it a practical solution to costly existing methods being implemented. The evidence from the field application in this study reflects that PAM-mix is a tool to reduce soil loss on bare soil until vegetation cover is established.

Table 4. Average summary of rainfall, infiltration runoff, and sediment yield for Replications 1, 2, and 3 and Replications 2 and 3, excluding Replication 1.

Treatment	Runoff (cm)	Sediment (gm)	Soil Loss % Replication 1, 2, and 3	Sediment (Gm) Excluding Replication 1	Soil Loss % Replication 2 And 3	% of Rainfall
Control	4.01	264.51	100%	304.51	100%	79%
Dry PAM-mix/Dry Soil	3.81	96.65	37%	110.83	36%	66%
Solution PAM-mix/Dry Soil	4.04	83.71	32%	73.68	24%	81%
Solution PAM-mix/Moist Soil	4.60	108.82	41%	145.03	48%	97%
Solution PAM-mix/Mulch/Dry Soil	4.11	35.32	13%	19.31	6%	84%

The primary factor that must be considered in future studies is the time of polymer solution preparation and application. It was noted that the optimal application procedure is to prepare the solution immediately prior to application. This procedure is necessary in order to limit the amount of degradation and maximize the performance of the PAM-mix.

Construction Site Planning and Management Tools for Water Quality Protection

Thomas Mumley
California Regional Water Quality Control Board
San Francisco Bay Region, Oakland, California

California is seemingly a developer's paradise. Population is on the rise, the economy is good, and there is little or no rain to interfere with construction for nearly eight months of the year. To top off these benefits, the California Regional Water Quality Control Board, San Francisco Bay Region (Regional Board) has a comprehensive Construction Site Planning and Management Program (Program). It is based on the integration of a strong regulatory and enforcement posture, an outreach and education strategy, and technical assistance. The keys to the success of the program are the balance of actions among these elements and implementation tools for actions within them.

Background

The Regional Board is the state agency in California responsible for protection of water quality and enforcement of water pollution control regulations, including National Pollutant Discharge Elimination System (NPDES) permits. The California Water Code provides the Regional Board with strong enforcement authority. This authority ranges from a notice to comply, to a notice of violation, to enforcement orders, to monetary penalties. Penalties can be as high as $10,000 per day of violation or $10 for each gallon of waste discharged. The Regional Board may also suspend part of a penalty in exchange for an environmentally beneficial project.

In the San Francisco Bay Region, the Regional Board is responsible for enforcement of a general NPDES permit for stormwater discharges from construction sites of five acres or greater. The general permit requires implementation of an effective Stormwater Pollution Prevention Plan (SWPPP) that includes best management practices (BMPs) for erosion and sediment prevention and control and management of equipment, materials, and wastes. The Regional Board is also responsible for enforcement of NPDES permits for municipal stormwater discharges that have been issued to all municipalities (regardless of population) in the urban areas of the region. These permits include requirements to control discharges from construction sites (regardless of size). There is an inherent overlap of Regional Board and municipality authority over construction of five acres or greater. The Regional Board's Program recognizes and takes advantage of this overlap of authority.

Inspections

The Regional Board initiated an aggressive construction site inspection and enforcement effort in 1997. This resulted in discovery of significant water quality problems associated with sediment discharges caused by minimal or token erosion and sedimentation control actions. Some of the most common observations were:

- No permit.
- SWPPP not developed, not implemented, or deficient, especially in terms of timing.
- Mass grading allowed to continue throughout winter months until rain and muddy conditions make further work impossible.
- Mass grading continues past the time when grasses will grow and germinate; first rains simply carry seed/mulch away with eroded soil.
- No erosion control measures; reliance solely on sediment basins.
- Sediment basins are frequently undersized, improperly designed, and not maintained.

- Site not monitored to assess BMP effectiveness.
- SWPPP not updated to reflect changes in site conditions.
- Hillsides stabilized with hydroseed, but no mulch (resulting in rains carrying seed material away with eroded soils).
- Control measures driven by "tokenism" with control measures intended to demonstrate good intentions rather than real effectiveness.
- Willingness to risk fines in order to maximize work during winter (rainy season) months.
- Local agencies, specifically planners and engineers with plan-approval authority, often unaware of "best" management practices.
- Sites approved by local authorities for mass grading during rainy season.
- Local authorities review and approve erosion control plans but do not inspect sites.

Enforcement Actions

Several types of enforcement actions evolved from these findings. The first consisted of the development and issuance of a "Notice to Comply" (Figure 1). Often (25 - 35 % of the time) operators at a site are unaware of their requirements or appropriate BMPs. The Notice to Comply is essentially a "fix-it" ticket that results in no further enforcement action if corrective action is implemented. Regional Board inspectors are authorized to issue Notices to Comply in the field, and use of this simple enforcement tool has proven to be an effective mechanism to gain timely corrective action at construction sites.

Other enforcement tools are used in circumstances where the severity of the problem warrants more intensive enforcement action. These include, in terms of progressive severity: a Notice of Violation, a Cleanup and Abatement Order, and a Cease and Desist Order. Violations of any of these actions typically lead to more aggressive enforcement action. The most aggressive enforcement action is imposition of administrative civil liability (monetary penalties).

During the 1997/98 rainy season the Regional Board imposed over $1 million in penalties, ranging from $10,000 to $230,000. A major consideration in determining penalty amounts is ensuring that it does not pay to pollute. Due to the economic and time pressures associated with many development projects, minor penalties may simply constitute a cost of doing business. The Regional Board has clearly stated its intolerance to this circumstance and intends to severely penalize repeat offenders. Clearly, such penalties not only get the attention of the violator, but the building industry as a whole. Substantive penalties have also provided opportunities to fund environmental education projects in lieu of direct payment of penalties. The Regional Board has favorably accepted development of technical assistance tools as appropriate mitigation projects.

Education and Outreach

The Regional Board recognizes that regulation without education is ineffective. Consequently, its program includes extensive outreach efforts. These include:

- Mass mailing to construction projects of more than five acres and projects permitted for winter grading summarizing requirements and findings on inadequate performance
- Meeting with development community and local agencies prior to the rainy season (August through September) to better communicate concerns and requirements and to establish a dialogue
- Providing detailed guidance and training for both developers and municipalities on their responsibilities and on effective control approaches

Figure 1. Notice to Comply

The objectives of these outreach efforts are:

- Commitment from the construction industry to include erosion control in their planning, scheduling, and (most importantly) project implementation

- Commitment from municipalities to play a greater role in SWPPP review and implementation, including training inspectors so that builders, municipal staff, and Regional Board staff are all on the same page - thereby allowing for consistent regulation of construction activities by applying a uniform standard.

In response, the building industry and municipalities have collaborated with the Regional Board on the production of training workshops on construction site planning and management for both building industry and municipal staffs. The workshops provide a review of regulations and responsibilities including:

- State responsibilities
- Permits for work in or near streams
- Local agency responsibilities
- Plan approval authority and requirements
- On-Site responsibilities (plans, permits,inspections)
- Inspector responsibilities
- Enforcement
- Field inspection coordination (i.e., state agency/municipality)

The workshops also include training on BMPs for erosion and sediment control (principles, tools, corrective measures, inspections, monitoring, reporting), non-stormwater discharge prevention and management, and a field trip to an active construction site where vendors demonstrate both proper and improper installation practices.

Production of the workshops has been funded in part through mitigations associated with administrative civil liability fines. Similarly, penalty mitigation funds have been used to develop education tools including:

- An 18 minute training video entitled "Hold on to Your Dirt: Preventing Erosion from Construction Projects" which provides information on BMPs for grading projects and for stabilizing disturbed land

- An 18 minute training video entitled "Keep it Clean: Preventing Pollution from Construction Projects," which provides information on BMPs to prevent water pollution from non-stormwater discharges from activities such as painting, stucco, concrete washout facilities and saw cutting

- A booklet of "Guidelines for Preparing a Storm Water Pollution Prevention Plan"

Erosion and Sediment Control Field Manual

The centerpiece of the Regional Board's Program is an *Erosion and Sediment Control Field Manual* (also developed with penalty mitigation funds). The *Field Manual* was produced in response to a common complaint by "field" personnel that there is a need for information on cost-effective and proven BMPs, and that existing references were too technical and difficult to read. The *Field Manual* contains concise descriptions of BMPs for erosion and sediment control and site management (Table 1). Overviews of regulatory requirements and inspection and monitoring responsibilities are also provided.

Table 1. Erosion and Sediment Control Field Manual BMPs

Erosion and Sediment Control Field Manual BMPs	
Erosion and Sediment Control Practices	
• Scheduling • Preservation of Existing Vegetation • Slope Grading • Temporary Seeding and Mulching • Permanent Seeding and Mulching • Hydromulching – Hydroseeding • Dust Control • Erosion Control Blankets and Geotextiles • Fiber Rolls • Temporary Stream Crossing • Stabilized Construction Entrance • Entrance/Exit Tire Wash	• Outlet Protection – Energy Dissipation • Check Dams • Silt Fencing • Temporary Straw Bale Dike • Sand/Gravel Bag Barrier or Rock Filter • Storm Drain Inlet Protection • Catch Basin Inlet Filters • Sediment Basin • Sediment Traps • Dewatering: sediments/toxic pollutants • Secondary Filtration
General Site and Materials Management Practices	
• Water Conservation Practices • Solid and Demolition Waste Management • Hazardous Waste Management • Spill Prevention and Control • Vehicle and Equipment Service • Material Delivery, Handling, and Storage • Paints and Liquid Materials	• Handling and Disposal of Concrete and Cement • Pavement Construction Management • Contaminated Soil and Water Management • Sanitary/Septic Waste Management • Landscaping Management

BMPs are described in a user-friendly format that features full-color graphics, including do and don't illustrations (Figure 2). Each BMP description includes its purpose, application, limitations, practices, inspection, and maintenance. There is a section on Corrective Measures that discusses what can go wrong and common installation problems. This latter section is essentially a troubleshooting guide that contains a table of common problems and corresponding corrective measures. Overviews of regulatory requirements and inspection and monitoring responsibilities are also provided. The *Field Manual*'s waterproof 9" x 9" binder and coated pages make it ideal for use in the field. As such, it provides the essential connection between the enforcement, outreach, and technical assistance components of the Regional Board's Program.

Overlap of State and Municipal Authorities

The Regional Board's Program provides a clear demonstration of how the Storm Water Phase II Program's construction requirements may be implemented. The Phase II rule allows states to recognize compliance with municipal program construction requirements as equivalent to compliance with a state-issued NPDES permit for construction, if it can be demonstrated that the municipal program requirements are equivalent. In such situations, a construction site deemed in compliance with a municipality's requirements would be deemed in compliance with the state-issued NPDES permit. The key is demonstration that the municipal program qualifies as equivalent.

In the San Francisco Bay area, as previously noted, the Regional Board has issued NPDES permits for municipal stormwater discharges that include requirements to control discharges from construction sites. In essence, there is an overlap of Regional Board and municipal authority where municipalities are in compliance with their permit requirements.

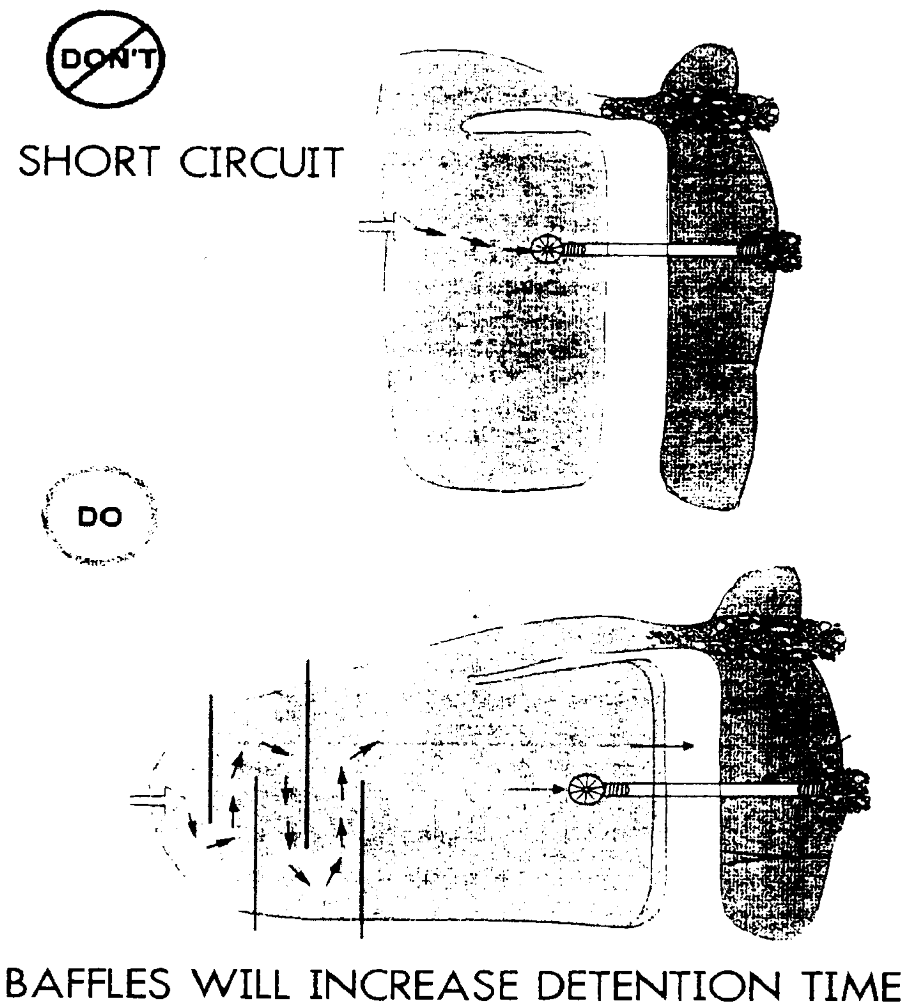

Figure 2. Sediment Basin Design.

Unfortunately, what may seem equivalent on paper may not be equivalent in practice. The case in point is that the Regional Board's inspection program noted above identified many construction sites out of compliance with their construction NPDES permits. Consequently, these same construction sites would be deemed in non-compliance with municipal requirements. In addition, the same inspection findings can be applied to the municipality. Since the municipality's NPDES permit requires it to control discharges from construction sites, construction site non-compliance means the municipality is not in compliance with its NPDES permit. In these circumstances, the Regional Board may (and has) taken enforcement action against both the construction site and the municipality.

To date, the primary enforcement tool used for the municipalities has been Notice to Comply. The Notice to Comply requires the municipality to report on the failure of its construction control program and to implement timely corrective actions. Most municipalities have been very responsive to this "wake-up-call," and have made improvements to demonstrate the desired "equivalency." The net result is a negative turning into a positive. The Regional Board's Program, with its balance between enforcement and education, has provided a *de facto* mechanism for recognizing municipal program equivalency allowed by the Phase II rule. By its design and implementation, the program essentially requires municipalities to demonstrate such equivalency. Consequently, the Regional Board will significantly reduce or eliminate its inspections in municipalities where Regional Board inspections find construction sites in compliance, thus providing incentive and reward to both the building industry and municipalities.

Lessons Learned

Lessons learned in the development and implementation of the Regional Board's Program are summarized in the following points:

- The only effective means of controlling erosion is erosion prevention, which requires careful planning and adherence to seasonal time-lines. Sediment capture should be used only as a secondary or back-up plan.
- Regulation without education is ineffective. Often, noncompliance is due to lack of awareness of the regulatory requirements and cost-effective, proven BMPs.
- Education without enforcement is impotent. Despite good intentions, the building industry is constantly trying to maximize its investment dollars, and environmentally sound BMPs are often superseded by time pressures to complete a project.
- Enforcement actions must be severe enough that they cannot be accepted as a cost of doing business.
- The balance between regulation and education is dependent on readily available technical assistance and implementation tools.
- Outreach and technical assistance needs to be directed to the right audiences. Workshop agendas and attendance were initially misdirected toward planners and local decision makers. Key attendees are municipal staff who actually review SWPPP plans and perform on-site inspections and building industry staff who are onsite. Evaluations revealed attendees wanted more technical information on installation and less time spent on municipal general plan/environmental plug. Audiences are especially responsive to builders discussing their experiences in implementing BMPs.
- Both the building industry and municipalities have historically short shrifted training. Workshop attendees expressed relief that practicable training is finally available - especially information on vendors, cost comparisons, and practical BMPs. The building industry and municipalities now realize costs of training are minimal relative to the benefit.

Conclusions

The bottom line is that environmental regulators, municipalities, and the building industry have different priorities that must be reconciled. Regulators seek no adverse impacts to waters. Municipalities seek economic growth. Builders want unfettered development. In the case of construction-related erosion, the means to each end is the same...effective erosion and sediment control. A little more work on the part of each party involved has proven that their different priorities are attainable and even harmonious.

Since the Regional Board made enforcement a top priority and began a collaborative effort with the building industry and municipalities to provide cost-effective outreach and training, construction site compliance with NPDES permit requirements has risen from 20% three years ago to greater than 90% today. Municipal compliance has risen similarly.

Regulating Sedimentation and Erosion Control into Streams: What Really Works and Why

Abstract

The overall objective of this project was to determine the effectiveness of different environmental policies, regulations, and incentives in reducing the ecological risks and consequences of sedimentation to streams. We were trying to learn which sets of regulations, enforcement strategies, and landscapes result in effective protection of stream communities from degradation, resulting from erosion and sedimentation from construction sites. By connecting erosion control efforts to environmental impacts, our aim was to create more effective management strategies that ultimately provide environmentally sustainable social and economic development in our watersheds.

We chose four replicate construction sites in each of three regulatory jurisdictions that varied in stringency of regulations and enforcement activities. At each site, we conducted instream assessments of water quality and biomonitoring of macroinvertebrates and fishes to determine the success of the regulators in protecting stream ecosystem health. We combined these results with evaluations of the regulatory environment to link the policies and management styles of the regulators to the effectiveness of protection of the streams. While all construction sites did some damage to the steams, we found that enforcement style and frequency of inspections were far more important than the nature of the regulations in preventing sediment pollution of streams.

Keywords: Development, enforcement, rivers, sedimentation, streams, regulations, regulatory effectiveness.

Introduction

A critical problem in American rivers and streams is sedimentation. Sedimentation degrades water quality, alters habitat for fish and macroinvertebrates, limits ecosystem functions and services, and reduces the aesthetic and economic value of rivers and streams. Many regulations and policy incentives have been devised to control sediment pollution of our rivers and streams. Yet there has rarely been an attempt to reconnect the policies with the ecology of the rivers. That was the goal of this research. This work integrates the regulatory environment, sediment ordinances, and policies with resultant ecological impacts of sedimentation on rivers and streams. The question the ressearch sought to answer was "What combinations of policies, regulations and on-site interactions between regulators and developers really work to enhance stream biota and stream ecosystem health?"

Research goals were accomplished by comparing similar streams in different regulatory jurisdictions (a comparative watershed approach). We tested the effectiveness of different intensities of sediment control regulations and enforcement. We used the streams to tell us what matters ecologically. The selected political jurisdictions differed in the stringency of their erosion and sediment control requirements and the nature and intensity of enforcement of the regulations. We chose 17 construction sites along streams in three different jurisdictions. We interviewed the regulators and developers at each site and we studied the regulations and the attitudes of the regulators and developers. At each site, we sampled the streams being impacted. Some projects are still unfinished. Therefore, we will present only the results of the 'before construction' and 'during construction' samplings.

We asked "Which erosion and sediment control regulations really work and why?" We have analyzed the erosion and sedimentation control regulations and compared them among the respective jurisdictions. Then we surveyed the attitudes and enforcement activities at all levels within each jurisdiction. This paper will briefly outline our findings and focus on what can be done to minimize sedimentation into streams from construction sites.

Methods

Site Selection

We selected three regulatory jurisdictions so they would vary across a range of two critical variables: (1) stringency of regulations (how strict and how rigorous the rules are) and (2) stringency of enforcement (i.e. frequency of inspections, severity of punishment of violations). A summary of some of the salient characteristics of the three regulatory jurisdictions is given in Table 1. Construction sites were selected from the array of applications for grading permits filed with the erosion and sediment control offices in each jurisdiction. The biggest constraint in locating study sites was the availability of construction sites on streams with riffle zones. One jurisdiction (District IV) extends eastward into the coastal plain as does Eastern Wake County. Therefore, many otherwise promising sites, which had sandy bottomed, slow flowing streams, were eliminated from our study. To be selected for this study, the construction sites had to have certain critical characteristics. For example, streams had to be within 100m of the site. There also had be a significant slope from the construction site down to the stream, so that if erosion occurred it would impact the stream. These factors made site selection extremely difficult. In this paper, we will discuss only the impact of large construction sites (>100 acres disturbed). We have located and sampled ten large sites.

Table 1. Selected Characteristics of Erosion and Sediment Control Jurisdictions Used for this Project

	Minimum Disturbed Area Requiring Erosion Plan	# Field Staff	Total Area (Miles^2)	# Active Projects	Site/Staff Ratio
Orange County	0.5 Acres	3	400	~100	33.3
Wake County	1.0 Acres	4	858	~400	100
District 4* (16 Counties)	1.0 Acres	4	8,116	~1000	250

* District 4, of the NC Division of Land Quality oversees all construction projects in all 16 counties without a Local Erosion and Sediment Control Program. It covers all governmental construction in the District 4 area, including Orange and Wake Counties. So, a single stream can have adjacent construction sites along the banks, one supervised by District 4 and the other by the Local Program.

Stream Sampling Procedures and Variables Sampled

We monitored at least three replicate sites per jurisdiction for the large construction sites. We sampled before, during, and after construction. We cannot control the timing of the construction projects, and since sampling must follow a rain of >1/2" in 24 hours (i.e., a rain with the potential to produce erosion and sedimentation), our sampling was dependent on the weather and the contractors. This means that the time between the before, during, and after sampling is highly variable. Since upstream and downstream controls were sampled on the same day as the "at the site" samples, this did not cause a significant analytical problem.

We sampled three sites on each stream, including >100m upstream, at the site, and >100m downstream. We took two replicate Surber samples for macrobenthos, identified to species whenever keys permitted, including chironomids. Chironomids are essential because they often constitute >90% of the individuals sampled, especially in the impacted reaches. The number of samples is small since our objective was not to analyze any one stream in detail, but to treat streams as replicates. In the overall analyses, multiple samples per site are pseudoreplicates. The mean of the replicate Surber samples was used in the analyses. We electroshocked for fish along one 50m reach of riffles and pools. We collected basic water chemistry data. Water quality parameters included D.O., turbidity, conductivity, Total N, NH_4^+, NO_3^{-1}, Total PO_4^{-1}, SRP, pH, and temperature. We also studied leaf litter decomposition rates. Five g leafpacks of *Cornus florida* (dogwood) leaves were incubated for two weeks *in situ* at all three sites in the "during construction" period to assess the critical ecosystem process of litter decomposition.

Environmental Policy Analysis

Surveys and semi-structured interviews were used to investigate both the regulatory agencies and developers. The surveys focused on the *capacity* of the agency, the external *commitment* that the agency receives, as well as the internal commitment toward the environment, and the *control* measures that are used. The surveys and interviews achieved a 100% response and participation rate. Although it has been harder to get their cooperation, we have nearly completed data collection from developers. The survey data is being augmented with documentary data from the sediment and erosion control offices in each of the counties.

The evaluation of implementation focused on (1) the extent to which developers comply with sediment and erosion control regulations and (2) the way that regulatory and organizational factors interact to shape compliance behaviors. The examination of outcomes combines social science and biological data to examine associations among regulatory styles, agency activities, and stringency of policy enforcement. We further analyzed how variations in sediment and erosion control enforcement are related to the ecological outcomes (including biological, chemical, and physical factors) in the impacted streams.

Hypotheses

Hypothesis 1. Greatest degradation will be evidenced at the construction sites, compared to upstream controls, with moderate to complete recovery downstream.

Hypothesis 2. Tighter enforcement of erosion and sediment control laws will result in less damage to streams.

Hypothesis 3. Stronger erosion and sediment control regulations will result in less damage to streams.

Results

Nearly all biotic and environmental variables measured tell the same story. Figure 1 shows the changes in the EPT Index for the during construction sampling. That is the species richness of the Ephemeroptera (the mayflies), Plecoptera (the stoneflies), and Trichoptera (the caddisflies). The tally of EPT taxa (i.e., EPT Richness or the EPT Index) is a well-established and universally accepted measure of stream health. These groups of aquatic insects are particularly sensitive to (and highly intolerant of) high temperature, low oxygen, toxic substances, a wide range of pollutants, and burial by sedimentation. An abundance of EPT species and individuals and high EPT diversity are clear indicators of good stream health. Reductions in EPT values demonstrate degradation of stream conditions.

EPT richness follows a pattern. The differences between jurisdictions are clear. The greatest decline in EPT values from upstream to at-the-site occurs in District IV. The EPT Index in Orange County changes little at any site. Wake County actually shows some enhancement of the EPT richness as you go from upstream to at-the-site. We sampled many other variables but the results parallel the EPT richness.

A short summary of the enforcement activities and attitudes of the regulators in the various jurisdictions is found in Table 2. These data show that these agencies differ in these aspects. Orange County had the strictest enforcement, penalizing nearly 25% of all construction projects, while Wake penalized ~22% and District IV penalized only ~ 4.5% of the projects they inspected. Orange County is most likely to use stop-work orders to halt construction due to sedimentation violations, while District IV relies on fines. District IV is perceived as being so understaffed that it is unable to make sufficient inspections. Consequently, some contractors do not feel obliged to follow their approved plans. Some contractors agree to a plan and then cut costs by not following the sediment controls. This laxity is detectable from the stream data (see Figure 1).

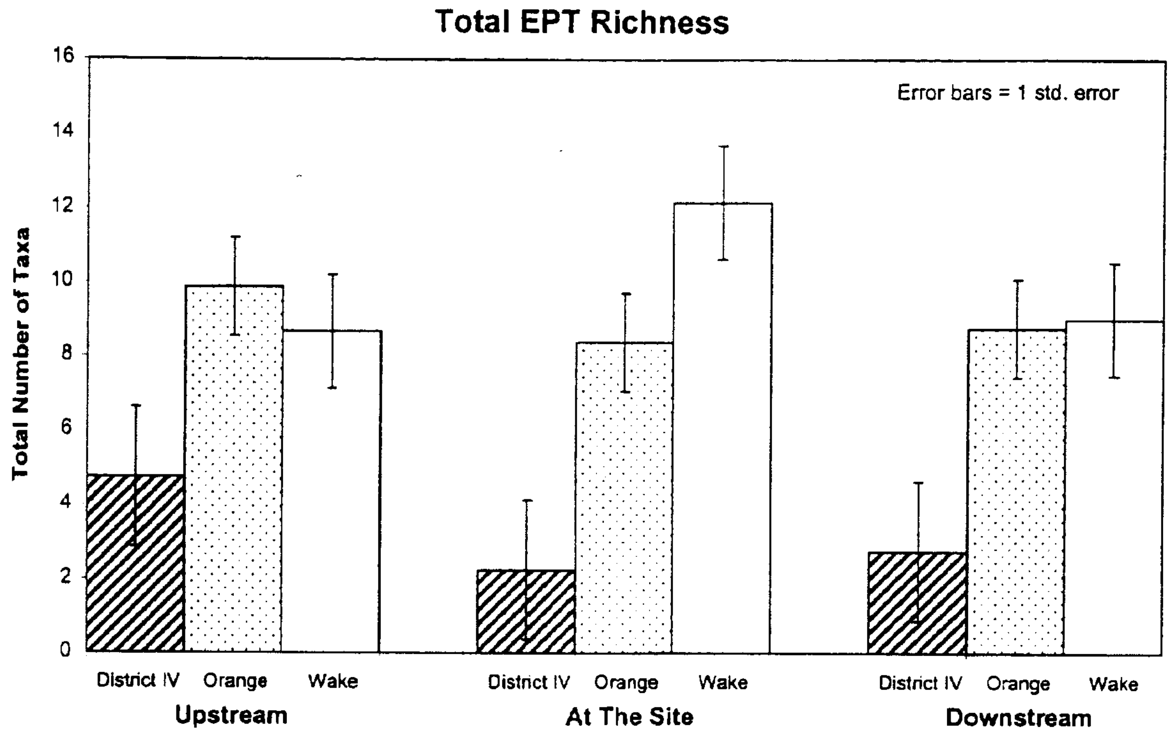

Figure 1. Total EPT Richness.

Table 2. Regulatory Environment

Agency/Variables	Orange County	NC District IV	Wake County
Enforcement Action	Very Strict	Average	Strict
Penalties enacted past year	24	44	88
Stringency of Penalties	High	Medium	Medium
Attitudes of Regulators			
Perception of official commitment	Supportive	Very Supportive	Indifferent
Percent of developers that regulators	8	40	10

Orange County and Wake County regulators generally think that developers will try to avoid complying with erosion and sediment control regulations. As the regulators' workload increases, their task becomes more difficult. This may result in regulators adopting a more forgiving attitude toward developers and less vigorous enforcement of the regulations. District IV regulators think that fully 40% of developers are trying to comply with the regulations.

Discussion

There is a clear link between the attitudes and enforcement activities of the regulators of erosion and sediment control ordinances and environmental outcomes in the streams near construction sites. If the regulations are completely effective, all sites should be similar to the upstream controls when the construction is completed and the site has been stabilized (i.e., revegetated). In our analysis, the degradation is clearly detectable in the benthic community data (see Figure 1). Benthic communities at the site are dramatically negatively impacted in District IV, unchanged in Orange County, and actually enhanced in Wake County. The effect is sometimes reduced downstream but the degradation persists downstream in District IV.

Wake County and District IV have identical regulations, while Orange County's regulations are more stringent. Comparison between the two jurisdictions with the same rules but different inspection and enforcement intensities will help us tease apart these factors. The stream data suggest that the laws, as written, are not particularly important. Wake County has the best environmental results while District IV has the worst stream degradation. Our analysis suggests that differences in laws and regulations have limited impact on the degree of degradation of stream biota.

The key factors seem to be the attitudes and enforcement behavior of the regulatory agencies. The frequency of on-site inspections is particularly important. In Orange County, every construction site is inspected every week. If it is a problem site, the inspectors may visit daily. In Wake County, the inspections are closer to every other week. In District IV, the goal is to visit every site once in the entire duration of the project. They also seek to respond to any citizen complaints within one week. In Orange County a complaint generates an inspection within one day. Another critical factor is topography. A very steep, erodible slope can undermine the best attempts at enforcement of erosion and sediment control regulations.

Our analysis suggests that differences in the nature and frequency of enforcement and inspections does matter. Developers tell us that a rigid, command and control approach to enforcement is less palatable to them than a flexible problem-solving cooperative approach. If the developers perceive that the regulators are really tying to help them keep sediment on site and out of the streams, they do a better job. Flexibility enters in as follows. If the sedimentation inspectors have enough time to analyze a sedimentation problem in detail, their suggestions will be better. Very often, the inspectors need the authority to implement solutions which are not exactly "by the book." When inspectors propose innovative solutions, which can really solve the problem, this encourages the developers to be more cooperative. More frequent inspections and a cooperative, flexible approach by regulators does ameliorate the stream damage among similar streams in different jurisdictions.

On the other hand, if the developers know that the regulators will in fact shut them down (with a stop-work order or a court injunction), it is easier for the regulators to get developers' attention. Fines are notoriously ineffective penalties in North Carolina. Presently the maximum fine is $500 per day. When developers are pouring millions of dollars into a project, this amount of fine is trivial. As one said, "It's just a cost of doing business." In essence, the effectiveness of erosion and sediment control depends more on enforcement than on how the regulations are written. Even with weak laws, the success of Wake County's Erosion and Sedimentation Control Program plainly depends on their on-site enforcement actions.

Recommendations

- Provide sufficient inspectors to visit each construction site at least weekly.
- Give inspectors the authority and knowledge to implement innovative solutions to erosion problems on a site-specific basis.
- Empower the inspectors to issue severe penalties (stop-work orders) in the case of sedimentation violations.
- Raise the maximum level of fines to a meaningful amount (we suggest $10,000 per day).
- Educate the development community to the damage that sedimentation does to stream communities.

Effectiveness in Erosion and Sediment Control: New Initiatives in Indianapolis

Since the late 1960s, when the severity of pollution from sediment from construction sites was first documented, many states and municipalities have worked to develop effective programs for erosion and sediment control. These state and local programs were augmented in 1987, when Congress required in the *Clean Water Act* that operators of all construction sites over five acres prepare erosion and sediment control plans and obtain National Pollution Discharge Elimination Permits (NPDES). At that time, some states, such as Maryland and North Carolina, already had well-supported, comprehensive approaches that were developed largely in response to state law. Other states, including Indiana, have relatively new programs that were adopted only after the federal mandate. In general, these newer programs are not as comprehensive, and managers are still working to develop systematic and effective methods for implementation.

This paper describes a new initiative in Indianapolis, Indiana, to increase the effectiveness of erosion and sediment control programs. The paper describes a general framework for evaluating erosion and sediment control programs. Next, it describes an intergovernmental, "S.W.A.T." team approach to inspection that was used in Indianapolis in the summer of 1998. The paper summarizes the results of the inspections and concludes with a discussion of the implications for managers of erosion and sediment control programs.

Effectiveness in Erosion and Sediment Control Programs

Managers and analysts in Maryland and North Carolina have used a general framework for evaluating erosion and sediment control programs (Clevenger, n.d.; Departments of Civil Engineering and City and Regional Planning, 1990). The framework comprises five criteria, each of which must be satisfied for sediment pollution to be controlled effectively:

- Complete coverage
- Competent plans
- Careful installation
- Continual maintenance
- Consistent enforcement

Overall effectiveness requires that the coverage rate (the proportion of construction sites with controls) approach 100%. Operators of development sites must know of regulatory requirements and make efforts to comply. Second, erosion and sediment control plans must be competent. Best management practices (BMPs) incorporated into plans by engineers or technicians must be able, if constructed properly, to control erosion and sedimentation. Third, BMPs must be installed completely and correctly. Improper installation may result in failure and off-site sedimentation. Fourth, BMPs must be maintained for the duration of the construction process. Finally, consistently effective approaches to enforcement must be developed to ensure compliance with substantive criteria. If any one of these criteria is not met, the objectives of erosion and sediment control may not be achieved.

When new programs are developed, these criteria can be considered sequentially. That is, when building a new program, managers must first make sure that developers and builders are aware of regulatory requirements. Next, they must work to ensure that developer's engineers are preparing good plans. If developers are aware of requirements and are submitting good plans, attention can turn to installation and maintenance. Use of enforcement tools always is a last resort.

An Initiative in Indianapolis

Although the City of Indianapolis has a sediment control ordinance that predates federal requirements, erosion and sediment control programs in Indiana have largely been developed in response to a state regulation [Title 327-IAC 15-5 (Rule 5)], that was adopted in 1992 to comply with EPA regulations. Since the adoption of Rule 5, managers generally have seen improvements in efforts to comply. Most developers and builders are now aware of requirements, and coverage is approaching 100%. With respect to plan review, the Division of Permits in the Department of Capital Asset Management (DCAM) is responsible for plan review pursuant to the city's ordinance, while, under a memorandum of understanding with the Indiana Department of Environmental Management (IDEM) and the Department of Natural Resources (IDNR), the Marion County Soil and Water Conservation District (District) is responsible for plan review pursuant to Rule 5. MCSWCD reviewers estimate that the quality of plans is improving, but that as many as 60 to 70% of all plans still must be returned and revised before approval. Most plans are approved on the second iteration.

Although the review process now assures that competent plans are being prepared, installation often remains inadequate, BMPs often are not maintained, and resources for inspection and enforcement are limited. IDNR has only seven inspectors in the Division of Soil Conservation for all 92 counties and 550 municipalities. IDNR inspectors generally work individually within regions, inspecting sites sequentially and in response to complaints. District personnel lack enforcement authority and mainly visit sites in response to complaints. In Indianapolis, sediment control has been a low priority with DCAM, which has no inspectors trained in or assigned exclusively to enforcement of sediment control requirements.

Managers have struggled to find ways to overcome resource limitations and to increase the effectiveness of implementation. In 1998, IDNR and District staff conceived of a "S.W.A.T." team approach to inspection. In this approach, all IDNR inspectors and District staff together focused their efforts on all open construction sites in the county. The objective was to visit all sites in a brief time period, thereby increasing the visibility of the program. Managers believed that intensive scrutiny of the county, if only for a brief time, would result in greater efforts at compliance. One of the assumptions on which this approach was based was that there are both formal and informal networks among developers and builders and that this approach would stimulate discussion about compliance issues.

In Indianapolis, IDNR and District personnel completed a county-wide survey of construction sites on June 23 and 24, 1998 (Hayes and Matthieu 1998). DCAM staff was invited to participate. IDNR, District, and DCAM staff visited more than 300 construction sites. Of these sites, 177 were active and were evaluated for compliance with Rule 5. Construction had not yet begun at 23 of the sites, construction had been completed at 61 sites, and the remainder were not evaluated because they were inaccessible or because construction was just beginning. This summary is restricted to the sites under active construction. The results provide a good picture of the current status of implementation and the general level of effectiveness of erosion and sediment control requirements in Indianapolis.

Inspectors evaluated sites for compliance in nine categories using a standardized checklist developed by IDNR. Sites also were checked for obvious evidence of off-site sedimentation. The nine categories were: (1) proper installation of erosion and sediment control measures; (2) perimeter erosion control measures; (3) erosion and sediment control measures on individual building sites; (4) protection of storm-sewer inlets; (5) stabilization of disturbed areas, (6) proper stabilization of drainage channels; (7) stabilization of drainage outlets; (8) maintenance of existing erosion and sediment control measures; and (9) tracking or accumulation of sediment on roadways. These criteria generally can be grouped within the installation and maintenance stages of the evaluation framework outlined above, although most involve aspects of both installation and maintenance. The first seven criteria primarily concern installation of BMPs; only two, maintenance and tracking, primarily concern maintenance.

Inspectors rated each applicable criterion at each site on a scale of Satisfactory, Marginal, Unsatisfactory or not applicable (NA). Items in compliance with Rule 5 were rated S, items that were in danger of becoming out of compliance were rated M and items in violation of Rule 5 were rated U. Because all criteria were not applicable at all of the sites, the number of sites evaluated for with respect to each criterion varies.

Disturbing Results from Disturbed Sites

The results of the inspections are summarized in Figure 1 (Hayes and Matthieu 1998). Overall the results show that installation is inadequate and that maintenance is worse. Improvements in implementation clearly are needed. Discussion of each of the nine items reviewed follows.

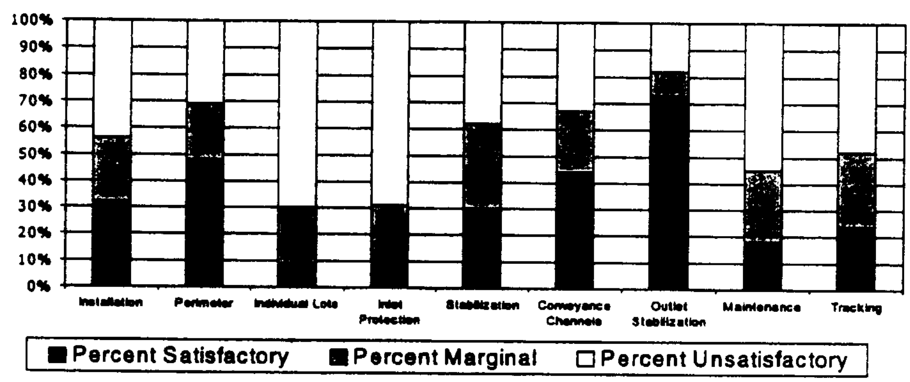

Figure 1. Rule 5 Compliance Summary-Percent of Applicable Sites.

Installation of Erosion Control Measures

Erosion control depends upon installation of appropriate control practices in given situations. Examples of these practices include silt-fence perimeter controls, sewer inlet and outlet protection devices, and the use of stone or mulch to stabilize slopes. Proper installation of these devices and practices helps reduce the risk of failure that may result in erosion and off-site sedimentation. Erosion and sediment control measures were installed correctly at only 32% of the active sites. Installation was marginal at 24% of the sites and had been done incorrectly at 44% of the sites. Proper installation was marked not applicable in cases where no erosion control practices were in use.

Perimeter Erosion Control Measures

Perimeter erosion control measures are designed to keep sediment from leaving a site directly at its perimeter through sheet or gully erosion. Perimeter erosion control devices/practices such as silt fence or buffer strips should be installed before land disturbance begins. The most effective and cost-efficient perimeter control practice is to leave existing vegetation in place, especially along waterways. Perimeter measures were installed and in compliance at 48% of the sites. Marginal conditions were found at 21% of the sites, and 31% of the sites were found to be out of compliance. Perimeter erosion control measures were not applicable at level or inward-sloping sites.

Individual Building Sites

Under Rule 5, erosion control is the responsibility of the site operator, either the developer or builder, throughout construction. At some sites, after the infrastructure has been installed and the lots have been sold to individual builders, the developer no longer has direct control over erosion and sediment control practices on those lots. Builders and contractors may or may not install and maintain erosion control practices. Erosion control on individual building sites is a serious problem in Marion County. Erosion and sediment control measures on individual building sites at developments were found to be adequate at only 9% of the active construction sites. Measures were in marginal condition at 21% of the sites, and 70% of the sites were found to be out of compliance. Most of these sites lacked proper construction entrances, storm-sewer protection, and perimeter protection. This category was not applicable for sites that had not yet begun construction of homes.

Storm-sewer Inlet Protection

Sediment entering storm-sewer inlets significantly reduces the capacity of retention/detention basins and drainage channels to store and convey stormwater away from flood prone areas effectively. If sediment is not removed prior to site closure, the specified volume and dimensions of retention/detention basins that were approved by the City can change. Inlet protection measures are especially important when sediment is tracked into or allowed to accumulate in roadways where it is conveyed directly to sewer inlets. Using measures such as seeding and silt fence adjacent to inlets will prevent sediment from clogging inlet protection devices and accumulating in the streets. Storm-sewer inlets were adequately protected from sediment at just 14% of the construction sites. Sewer inlets were marginally protected at 17% of the sites, and inlet protection measures were inadequate and not in compliance at 69% of the sites. Inlet protection was not applicable to sites that had not completed sewer installation.

Stabilization of Disturbed Areas

Stabilization of disturbed areas on construction sites may be the single most important practice for reducing erosion and off-site sedimentation. The best practice for achieving stabilization is to leave vegetation in place wherever possible. If soil must be disturbed, stabilization is relatively easily accomplished through temporary seeding or application of erosion control blanket. Rule 5 requires that disturbed areas that will be inactive be temporarily seeded. Stabilization by seeding results in higher perceived value by potential buyers, offering developers a financial incentive to vegetate land as soon as possible once the infrastructure is in place. Of active sites that were visited, 30% were in compliance with Rule 5 with respect to stabilization of disturbed areas, while 32% of the sites were marginal and 38% were not in compliance. This category of compliance was not applicable to sites that were being actively cleared or nearly completed at the time of the visit.

Drainage Channel Stabilization

Ditches and swales designed to convey storm water away from development to natural drainage ways or storm-sewers are subject to severe erosion and deterioration if not adequately protected. Erosion and damage to conveyance channels results in off-site sedimentation of waterways. This can be avoided by stabilizing the soil in conveyance channels immediately with permanent seeding of grasses, or with stone, mulch, or straw cover. Conveyance channel stabilization was satisfactory at 44% of the sites. Approximately 23% of the sites had marginally protected channels and 33% of the sites had channels in unsatisfactory conditions. Conveyance channel stabilization was not applicable at sites that did not have or require channels or at those that did not yet have them constructed.

Outlet Stabilization

Storm-sewer and drainage channel outlets from a site need to be properly stabilized to prevent erosion and sedimentation of the banks and waters they empty into. Outlet stabilization is best accomplished by protecting the soil around the outlet with stone riprap, geotextile fabric, or with well-established vegetation. Outlet stabilization was satisfactory at 73% of active sites. Outlets were in marginal conditions at 18% of the sites and unsatisfactory at 9%. This category was not applicable at sites that did not have outlets on the site or where infrastructure development was not yet completed.

Maintenance of Erosion Control Practices

Erosion control practices that have been installed properly must be maintained to be effective. In most cases, lack of maintenance results in the same effects as not employing erosion control practices at all. Examples of maintenance of erosion control practices include removing accumulated sediment from behind silt fence and reinforcing inlet protection after storms. Failure of erosion control practices allows sediment to leave construction sites via storm-sewers, drainage channels, roadways and sheet and gully erosion. An often-overlooked aspect of maintenance is removal of devices after work is completed. Maintenance of erosion control practices was satisfactory at only 18% of the sites. Maintenance was marginal at 27% of them, and there was little or no evidence of maintenance at 55% of the sites. Maintenance of erosion control measures was not applicable at sites that did not employ erosion or sediment control practices.

Sediment Tracking and Accumulation in Roadways

Soil and sediment in streets and roads are readily washed into sewers and drainage channels and can be a significant source of pollution. In addition, the sediment can be a traffic hazard with the potential for costly litigation against the local governments or developers. Sediment accumulated in roads is also unsightly and may discourage potential home buyers. Tracking and accumulation of soil in roads was kept to an acceptable level at 24% of the sites. Approximately 28% of the sites exhibited marginal compliance with the rule for keeping roads clear of sediment. Sites that were out of compliance with the rule made up 48% of this category. Large industrial sites where equipment was usually kept on site and residential sites that did not yet require extensive coming and going of vehicles were rated not applicable for sediment tracking.

Off-site Sedimentation

Sediment is the most abundant pollutant, by volume, in Indiana waters. Residential and commercial development sites are potential sources of high volume, sudden discharges of sediment that can cause problems for land owners down-stream of development. Besides the drainage and flooding problems caused by off-site sedimentation, sediment can obstruct and widen streams and erode stream banks. Sedimentation of the state's streams and rivers also causes habitat damage for many aquatic species. There were obvious signs of off-site sedimentation at 21% of the active sites. This figure is believed to be low, however, due to the large number of sites surveyed in a very short time. Only the most obvious cases were checked as displaying off-site sedimentation.

Observations and Implications: Priority-problem Solving

A number of observations that have important implications for managers of erosion and sediment control programs can be drawn from this inspection initiative. First, it is useful to consider the initiative in the more general framework for effectiveness in erosion control. Indiana regulations for erosion and sediment control first were adopted in 1992. Faced with implementation of a new regulation with few resources, IDEM, IDNR, and District staff first devoted efforts to education and ensuring complete coverage and competent planning. In late 1997 and early 1998, program managers determined that the plan review process was fairly well established and that additional effort needed to be devoted to installation and maintenance of BMPs. Because resource shortages preclude regular, periodic inspection, IDNR officials developed a S.W.A.T. team approach. Teams of state, district, and available municipal officials focused inspection efforts, visiting and inspecting as many sites as possible in a short time.

In Indianapolis, the results show that implementation generally is poor. Installation of erosion and sediment controls was unsatisfactory on 44% of all sites, and satisfactory on less than one-third. With the exception of outlet stabilization practices, which had been installed properly at nearly three-fourths of the sites, no practice was installed properly on more than half of the sites. Perimeter controls, a basic practice, were installed satisfactorily on fewer than half of the sites and they were unsatisfactory at almost one-third. Stabilization was satisfactory at less than one-third of the sites, inlet protection had been installed properly at less than 15% of the sites, and controls on individuals lots had been installed properly at just 9% of the sites where they were needed. It is clear that installation is deficient and that additional effort is needed to ensure that practices identified on plans are installed properly.

The inspections show that maintenance of erosion and sediment controls is even worse than installation. Inspectors determined that maintenance of controls was unsatisfactory on 55% of the sites and satisfactory on only 18%. Mud is being tracked on streets and washed into sewers and drainage channels on almost half the construction sites. Additional field work to ensure proper maintenance of BMPs is a critical need.

Although these results were disturbing, they were not unexpected. Program officials knew that implementation was inadequate and devised the S.W.A.T. team approach to provide a quick, comprehensive assessment of the status of implementation. Since the inspections, program managers have used the results as part of overall efforts to increase understanding of requirements for erosion and sediment control and to build commitment to the programs. City staff agreed to mail copies of inspection reports to all developers, and the district provided a summary of results to all city-county councilors.

The results provide information that program managers can use to establish priorities for problem solving and education. For example, installation of perimeter controls appears better than efforts to stabilize disturbed areas on site. Future inspections and educational efforts therefore can focus on the importance of stabilization. Similarly, since it appears that site operators are doing a fairly good job at stabilization of outlets, this requirement can be de-emphasized, and additional effort can be devoted to solving problems like installation of controls on individual lots that are not controlled by practices on the larger development site. More generally, as more people understand the different steps in the process of erosion and sediment control, implementation should become more effective.

The survey did not focus on discovering reasons behind compliance or non-compliance, but several inferences can be drawn from these data. First, the data and experience indicate that some developers are unaware of their obligation to control erosion and sedimentation and leave the permitting and erosion control planning to engineers and contractors. This can result in a lack of commitment to implementation. Second, some developers, engineers and contractors clearly do not yet understand the purpose and importance of implementing erosion and sediment control practices. Education is needed to increase their understanding and commitment. Third, some operators know the requirements of Rule 5, but do not take them seriously, ignoring the Erosion and Sediment Control Plan. For these individuals, enforcement action may be required. In addition, a general problem that was observed has to do with sequence of construction. All too often, land disturbance is beginning before erosion and sediment control measures are installed. More emphasis must be placed on installation of practices prior to earth disturbance, and site operators must learn to follow the sequence described on plans.

Given that resource shortages are likely to continue, problems in implementation are likely to continue and regulatory programs are likely to remain less effective than they could be. Steps that may be taken to increase effectiveness include making sure that the regulated community participates in on-site, pre-construction meetings that underscore the scope and importance of controls; increasing the visibility of IDNR and District staff and the frequency of their site visits; educating developers, engineers and contractors about erosion and sediment control practices and how to install and maintain them; and emphasizing the need for erosion and sediment control throughout the entire development process.

The S.W.A.T. team approach clearly does not solve the problems of a relatively new, understaffed erosion and sediment control program. But the approach is an effective way to obtain a significant amount of information in a short time, raise the visibility of erosion and sediment control programs, and help establish priorities for problem solving.

Abstract

Potential pollutants carried in stormwater runoff from urban surfaces are a major component of Nonpoint Source (NPS) pollution. NPS pollution is a leading cause of reduced water quality in US rivers and lakes, and there are major efforts underway to find innovative approaches to reducing NPS pollution from a wide range of sources. In urban areas, where much of the land has existing structures, a major challenge is to find ways to retrofit built sites to reduce NPS pollution associated with stormwater runoff. One component of this may be more widespread use of constructed wetlands that have value not only in terms of water quality improvement, but also in terms of urban ecology, aesthetics and education.

We have begun a long-term monitoring program of the performance of constructed wetlands in two settings: 1) On a commercial site where surface runoff is dominated by stormwater flow from parking lots and store roofs, and, 2) On a golf course that receives considerable surface flow from adjacent commercial, residential and highway areas. Monitoring includes both continuous measurements of flow, temperature, conductivity, pH and dissolved oxygen, and automated sample collection during storm events for more complete chemical analyses. Initial results suggest that the commercial site constructed wetland acts as an efficient trap during the spring and summer for suspended sediment and some dissolved matter. During the fall and winter dormant season trap efficiencies are much lower, and in some cases negative. The golf course site constructed wetlands also function as efficient traps during the summer, and plant growth in these wetlands has been helped considerably by the regular water supply provided by golf course irrigation. Both wetland systems also provide value in terms of improved aesthetics, their use by local educators, their diverse ecological assemblages, and the public relations benefits associated with visible efforts at improved environmental management.

Replacing portions of existing parking lots with carefully designed constructed wetlands, and adding constructed wetlands to urban recreational sites (such as golf courses and parks) should be viewed as one of several elements of an integrated approach for effective retrofitting urban areas to reduce NPS pollution from stormwater runoff.

Introduction

One of the major challenges facing urbanized areas is to find ways to improve environmental management in ways that do not involve major, costly impacts on existing infrastructure. Increasing recognition of the environmental impacts of built areas on parameters such as runoff amount and quality has increased regulatory and public pressure to develop and implement effective management practices. However, many of the best management approaches that can be integrated into the design of new developments cannot be implemented in existing built areas without prohibitive costs. Thus there is considerable interest in best management practices that can be used to retrofit urban areas for improved environmental performance.

Wetlands have the ability to store large amounts of water, reducing flooding of surrounding areas and in some cases recharging groundwater (Mitsch and Gosselink, 1993). In addition, wetlands are capable of improving runoff quality in many situations (Perry and Vanderklein, 1996) because they trap both solid and dissolved pollutants. Wetlands also can have considerable aesthetic benefits, and provide habitat for a wide range of plants and animals. Constructed wetlands are wetlands specifically designed and built for hydrologic and water quality management, as opposed to either natural wetlands or created wetlands. Created wetlands are designed and built to replace lost wetlands or to compensate for destruction of natural wetlands. Using constructed wetlands for water treatment attempts to take advantage of the benefits of wetlands without compromising natural wetland areas.

In urban areas there are unique challenges to be faced in proposing and designing constructed wetlands. Existing built areas rarely include extensive undeveloped space that can be converted to constructed wetlands. However, there are several opportunities that arise in many areas, including: 1) Making space by reducing the size of an existing parking lot; 2) Adding a constructed wetland to a redevelopment or urban renewal project; 3) Adding a constructed wetland to a park or green space; 4) Adding constructed wetlands to existing recreational facilities such as golf courses. A second major challenge in proposing constructed wetlands in built urban areas is to maintain adequate hydrology for long-term wetland survival. The extensive impervious surfaces of built areas generate large amounts of runoff during storm events, but this water is usually routed quickly away from the built area to prevent flooding. Because there is little opportunity for rainfall to infiltrate into the soil in urban areas (because most soil is covered by impervious surfaces), shallow groundwater flow is reduced. This means that wetlands in urban areas will receive far less between-storm water recharge from shallow groundwater than would be expected for a similar non-urban setting. In essence, wetlands in urban areas will experience a "flood and drought" hydrologic regime, which is poorly suited to an ecosystem that is based on extensive periods of wet conditions. One way around this problem is to look for locations where water is applied regularly to adjacent areas, in particular where extensive irrigation is used. Golf courses and lawns and gardens of major corporate complexes are potential sites where between storm irrigation might provide excess runoff and soil water drainage to adjacent constructed wetlands.

Given the potential use of constructed wetlands to improve water quality in built areas, it is important to evaluate how well wetlands function as pollutant traps in such settings. Such studies can be used to drive design improvements, and to evaluate the cost-effectiveness of using constructed wetland for NPS pollution control. Although there has been less work done in the area of stormwater constructed wetlands, in comparison to wetlands used as part of a wastewater treatment system (e.g. Hicks and Stober, 1989), limited results so far suggest that wetlands can be effective in treating stormwater for nonpoint source (NPS) pollution (Mitsch and Gosselink, 1993; Witthar, 1993; Livingston, 1989). Few data sets are available because of poor follow-up of constructed wetland performance through appropriate monitoring programs (Perry and Vanderklein, 1996). However, available studies to date and theoretical reasoning suggest that NPS pollution control is enhanced by maximizing the distance between the wetland's inlet and outlet, including deep and shallow sections in the wetland, selecting vegetation on the basis of climate and water quality and supply conditions, maximizing the ratio of treatment area to base flow, and minimizing the slope along which the water travels (Horner, *et al.*, 1994; Witthar, 1993). The idea in such a design is to model the constructed wetland after a natural wetland, which not only has the ability to slow down the flow of water (as does a detention or retention pond), but also can remove pollutants from the runoff water. The most important factor in the design and maintenance of constructed wetlands is hydrology (Mitsch and Gosselink, 1993). Without the proper water inflow and outflow, the newly created wetland will fail and be unable to accomplish its task of stormwater treatment.

Aims and Objectives

We are monitoring the performance of urban constructed wetlands in two settings, a constructed wetland incorporated into site development for a commercial facility and a series of constructed wetlands built into a recently renovated golf course that receives runoff from an adjacent urban area. Both sites are in West Lafayette, Indiana. The goal of long-term monitoring is to provide insight into seasonal and longer-term variations in trap efficiency, both as the basis for improved scientific understanding of constructed wetland processes and controls, and to form the basis for future improvements in design.

Study Areas

The commercial constructed wetland site occupies approximately 0.51 ha, with a water surface area of 0.26 ha and volume of 1300 m^3. This wetland is intended to treat the "first flush" of runoff, and so was designed to accommodate the volume of water corresponding to first half-inch of precipitation on the store's impervious surfaces (the parking lot and the rooftop). The mean depth of the constructed wetland is 0.5 m but this includes two deeper pools with a maximum depth of 1.8 m (Tatalovich, 1998). Conventional wisdom (which may not be correct) states that 90% of the annual pollutant load is transported in the runoff produced by the first 1.3 cm of precipitation (known as the first flush), and this has been shown to be true for the transport of most pollutants over impervious surfaces (Chang, 1994). At this commercial site, runoff that exceeds the first-flush equivalent is routed to a separate basin.

One motivating force behind use of a constructed wetland on this site was concern over potential impacts on a natural wetland (Celery Marsh) adjacent to the property. In addition to the constructed wetland, this site includes: elimination of a proposed auto care center, abstinence from chemical ice-clearing methods, and construction of additional ponds to treat stormwater runoff that could potentially include harmful pollutants. The constructed wetland receives runoff primarily from the 4.1 ha commercial parking lot, as well as minor additional input from an adjacent store, local access roads, and US Highway 52.

The golf course created wetlands are part of Purdue's new Kampen Golf Course and are positioned to intercept both runoff from much of the golf course and the adjacent urban area. The developed area includes two residential highways, a section of state highway, the parking lot of a motel, a gas station, and 200 residences. The water flowing through the Kampen Course eventually enters Celery Marsh, but prior to reconstruction this water flowed directly through drainage tiles and overland transport to the marsh, with no treatment. The golf course constructed wetlands serve several purposes: providing a water hazard and aesthetic component of the course, and enhancing environmental quality that can also be used in environmental education. Runoff from the urban area travels through three constructed wetlands prior to leaving the course. One particularly notable aspect of these constructed wetlands is that they have flourished even during long dry summer periods. Frequent watering of the greens and fairways, common on most courses, has the added advantage that it provides runoff and tile drainage to the wetlands throughout the summer.

Methodology

To determine the effectiveness of each constructed wetland in trapping potential pollutants, water samplers were installed at the inlet and outlet of the commercial constructed wetland (Figure 1), and at six locations in the golf course constructed wetland complex to track the progress of water as it enters the course, moves through the wetland system, and exits to the Celery Marsh. The samplers are equipped with ISCO® Submerged Probes that measure water levels, used in conjunction either with a weir or pipe of known geometry. The sampler uses these levels and the corresponding geometry of the sampling sites to calculate the flow into and out of the wetland. Each sampler also has a YSI® 600 Multi-Parameter Water Quality Monitor that measures dissolved oxygen, conductivity, temperature, and pH. The samplers record flow and water quality parameters every five minutes and are programmed to take water samples during storm events. Storm sampling is triggered in most cases by a change in water level, and at two locations, by rainfall intensity as measured with an automatic tipping bucket rain gauge. The trigger points were determined empirically, so that inlet and outlet samplers begin to sample at approximately the same time. The sampling programs for each sampler are split into two sections. The interval of time between samples in part A of each routine is closer together than those in the corresponding part B routines, so that sampling occurs more often during the "first flush." After that, the second stage

Figure 1. Sampling equipment at a constructed wetland. The laptop computer is downloading monitoring data from the sampler, and in the foreground is a set of 24 sample bottles for storm sampling.

of each routine samples at larger intervals to guarantee samples at times coinciding with the downward slope of the hydrograph.

Overall, the design of the experiment is to track flow and water quality into and out of the constructed wetlands continuously, both during storms and between storms, for a multi-year period. This allows for determinations of storm, seasonal and multi-year trends in constructed wetland trap efficiency. Trap efficiency can be defined in a number of ways, depending on the likely application of the results. In this work we are interested in concentration trap efficiency (percentage change in potential pollutant concentration between the inlet and outlet, both maximum and average values) and load trap efficiency (percentage change in potential pollutant load between the inlet and outlet for given points in a storm, for storm totals, and seasonally and annually). Selected samples from each precipitation event are analyzed by a Purdue University laboratory for total suspended solids (TSS), hardness, total Kjeldahl nitrogen (TKN), and total phosphorus (TP). These parameters are the same as those measured for seven other local sites as part of a larger analysis of water quality in rural and urban settings. In addition to the analyses performed at the Purdue laboratory, more complete chemical scans are performed once per season on selected samples by Heritage Environmental Services in Indianapolis, Indiana. The selection of tests is based on the pollutants that might reasonably occur at each site. The reason for this more complete scan is to determine whether any potential pollutants not routinely measured at the Purdue laboratory show up at unusually high levels. Any parameters that were not detected in the Heritage samples could potentially be excluded from future testing, but those parameters considered to be problems would need to be monitored on a consistent basis in the future.

Results and Discussion

To illustrate possible types of analyses and some major trends in the performance data, without reviewing the entire data sets available, this discussion includes three examples from the two sites. These include a complete storm record at the commercial site, between-storm sampling at the commercial site, and first-flush storm sampling at the golf course site.

Sample Storm at the Commercial Site

A 0.97 cm-storm occurred on 26 October 1997, with a double peak in intensity (Figure 2). As expected, the wetland acts to damp peak flows, so discharge values at the outlet slightly lag those at the inlet and are lesser in magnitude. Water temperature in the constructed wetland inlet is high and uniform (no diurnal variations) prior to the storm (Figure 3),

R0019674

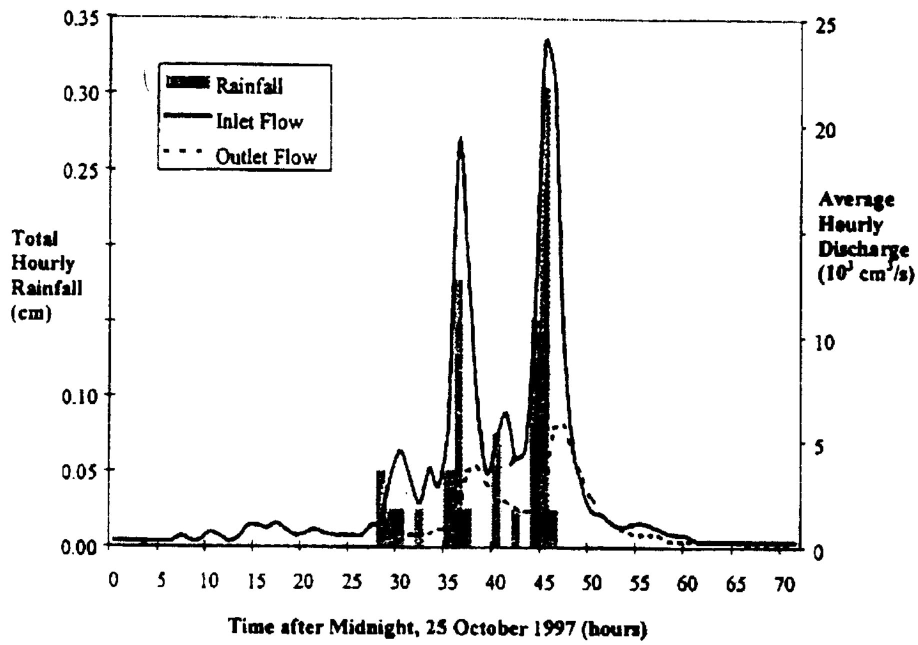

Figure 2. Rainfall and inlet and outlet runoff records for a storm event at the commercial site constructed wetland.

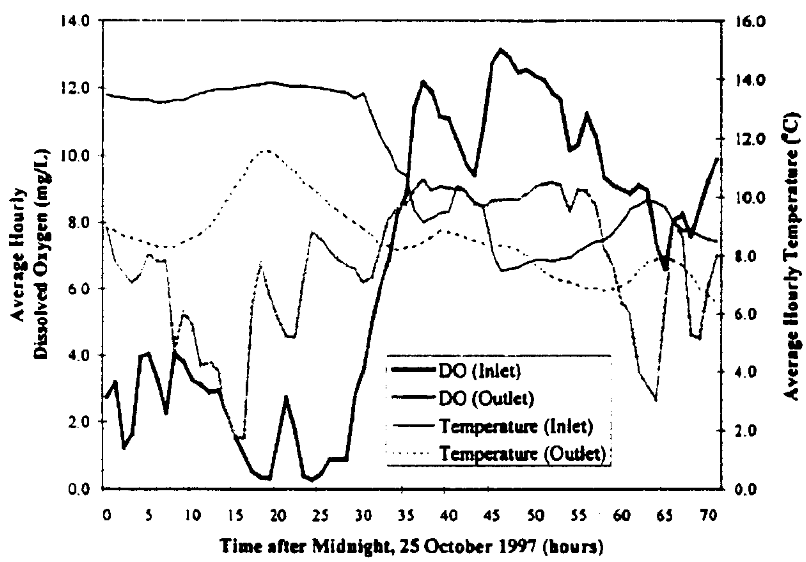

Figure 3. Dissolved oxygen and temperature records for the storm shown in Figure 1.

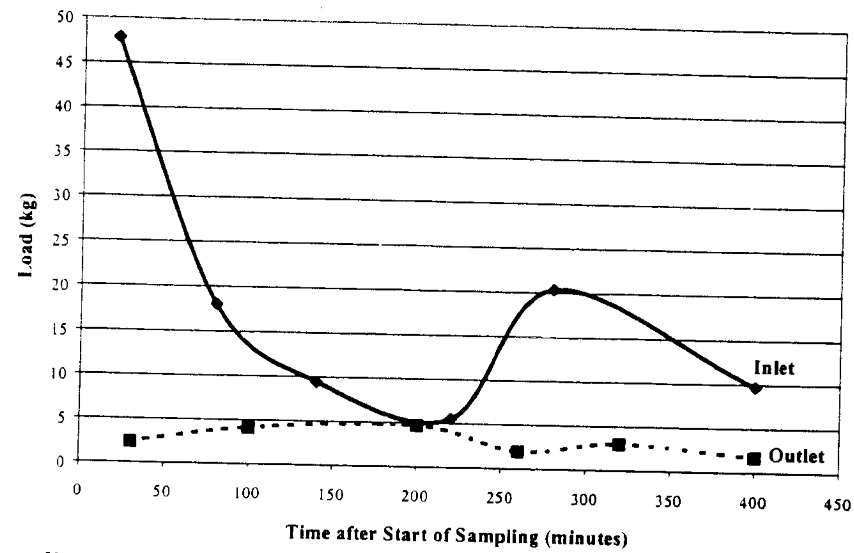
drops 6°C during the storm, and slowly climbs back 2°C in the 20 hours after precipitation stops. The outlet temperature shows a 4°C diurnal cycle prior to the storm, and a lower amplitude cycle after the storm. At the same time, the dissolved oxygen (DO) values climb during the storm (Figure 3). Inlet DO values vary within the 0 to 4 mg/L range before the storm, jump up to 9 to 13 mg/L during the storm, and fall during the 24 hours following the storm event. The outlet DO varies from 1 to 8 mg/L prior to the storm, is very stable between 8 and 9 mg/L during the storm, and has strong variations from 3 to 9 mg/L post-storm. High DO values during the storm are due to the increased mixing of the water, which causes oxygen to be introduced to the wetland, as well as the addition of "new" water that is higher in oxygen to the stagnant water.



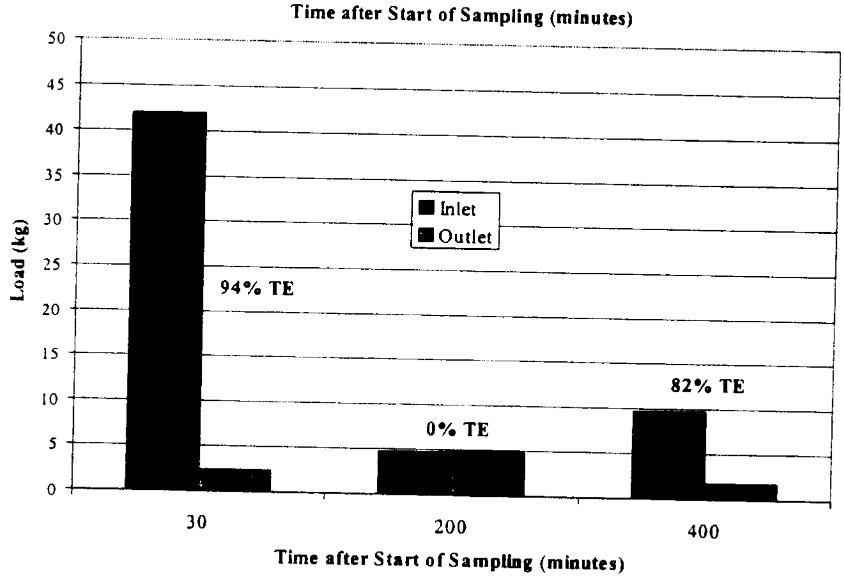


Figure 4. Total suspended sediment load for the storm shown in Figure 1 (upper), and calculated trap efficiency (TE) if only grab sampling had been used (lower). The actual load TE for the storm was 84%.

Initially, hardness data from the 26 October 1997 storm showed much higher values for the outlet than the inlet. This discrepancy relates to the movement of water through the wetland. Soon after the start of a storm, water begins to flow over the weir at the inlet and inlet sampling begins. This new runoff from the site has a low hardness, reflecting the naturally low hardness of rainwater. At the outlet, high hardness values show that the water initially being sampled is not new inlet water being displaced from the wetland; rather it is water that was stored in the concrete outlet box prior to the storm. Hardness values at the outlet fall throughout the storm, showing that hardness is lower in the wetland than in the concrete outlet box. Because hard water occurs when concentrations of Ca^{2+} and Mg^{2+} are high (Zumdahl, 1989), the concrete surroundings themselves can add to the hardness of the water. Ninety-five percent of all concrete used is made from Portland cement, which is prepared using finely ground limestone (Mindess and Young, 1981). The cement is made into concrete using admixtures such as calcium chloride. Also, the interaction of the surface water with groundwater, which in this geographic location is very hard due to infiltrating rainwater that dissolves the calcite-rich till from limestone in the region, can add to the hardness of the water in the wetland (Davis and Cornwell, 1991).

The hardness data suggest that the outlet record probably does not include water that enters and exits the wetland during the same storm. Other studies (e.g. Bhaduri, et al., 1997) have shown through chemical load distributions that the inflow and outflow from a basin are actually two different water masses, except in extreme storm events. The only way that the same water could appear at the inlet and outlet during the same storm would be if the inflow sheeted over the water in the basin, arriving at the outlet without significantly mixing with the water stored in the wetland prior to the storm; or if the storm produced enough water to completely displace the volume of water in the wetland.

Total suspended solids (TSS) concentration data and flow values for the storm are used to calculate TSS loading values, which depict the effect of the basin in reducing the overall sediment load. Total loads depict the actual physical amount of sediment entering the wetland and are important for planning activities such as dredging. TSS load values for the inlet are larger than the outlet (Figure 4). The inlet values start high, dip down, and then increase again. This indicates that the initial runoff has "first flush" (high load) characteristics, and then the load input rate decreases. A second, lower peak later in the storm could be the result of the later pulse of higher rainfall intensity (Figure 2). The values of TSS at the outlet remain fairly uniform throughout the storm. The initial value presumably represents between-storm ambient TSS loading in standing water in the wetland. During the storm, the increase in flow creates more turbulence, which can stir up some of the bed sediment, slightly increasing the TSS concentration and, therefore, the load. More importantly, though, the outlet values are lower than those for the inlet; thus there is a net decrease in TSS loading from the inlet to the outlet for this particular storm. In one sense, this traditional approach is a valid efficiency measure because the water going out is compared to that going into the wetland, but in another sense it is a skewed picture because the new inlet water is being compared with "old" outlet water that arrived in the basin during a previous storm (Bhaduri, *et al.,* 1997).

Multiple storm sequence sampling will provide a better view of overall trap efficiency (TE) than a single storm, just as a complete storm record is better than a grab sample. Standard grab samples do not always lead to accurate trap efficiency calculations (Figure 4). If one sample were taken each from the inlet and the outlet at exactly same time, the data could show a very high trap efficiency (30 minutes), no trap efficiency (200 minutes), or a fairly high trap efficiency (400 minutes). The overall load TE for this analysis was 84%. This is one of the reasons that this particular study samples several times after the start of a storm -- to bridge the gap between standard grab samples and actual events within the wetland. Continuous monitoring provides a more complete record of the constructed wetland's activity, more accurately depicting the trap efficiency of the wetland. From conductivity data, during the monitoring period, 137 kg of dissolved load entered the basin, and 59 kg left the basin, for a total dissolved solids (TDS) load TE over the storm of 57%. Further analysis of many storms can be used to determine an overall trap efficiency over longer periods of time. This type of analysis could be used to determine the effects of different storm intensities, seasonal variations, and increased urbanization in the area.

Detailed Chemical Scan at the Commercial Site: Between Storm Conditions

Samples for a detailed chemical scan were taken on 17 December 1997 using the sampler's grab sampling mechanism. At this time, there had not been a precipitation event in a couple of weeks, so these samples represent between-storm conditions in the wetland. Although these samples were tested for many possible pollutants, only a few were detected (Table 1).

Parameters which show reductions between the inlet and the outlet were chloride, sulfate, ammonia nitrogen, calcium, magnesium, sodium, silicon, strontium, and total dissolved solids (TDS). For instance, chloride levels fell from 210 to 160 mg/L, calcium levels fell from 95 to 54 mg/L, and strontium levels fell from 0.16 mg/L to below the detection level of 0.10

BDL = below detection limit

mg/L. Also, TDS levels fell from 720 to 490 mg/L. When compared to the values calculated using conductivity data from the sampler, these values are slightly higher than the values calculated for the 26 October 1997 storm event. The maximum TDS values calculated for the inlet and the outlet were, respectively, 568 and 365 mg/L, with average values around 337 and 263 mg/L. The higher between-storm values could be a result of the ability of sediments to dissolve in the wetland waters. Reductions in values between the inlet and the outlet indicate removal of certain pollutants within the wetland and also suggest that at the beginning of a storm, the outlet values will be lower than those of water near the inlet. Because of this, the best TE should be at the start of a storm, which is shown in the 26 October 1997 storm chemical data.

Not all of the detectable parameters were lower at the outlet than at the inlet. The ones that were actually larger at the outlet than at the inlet were: chemical oxygen demand (COD), aluminum, iron, potassium, total organic carbon (TOC), total phosphorus (TP), and total suspended solids (TSS). The increase in TSS is interesting, and may be the cause of increases in adsorbed pollutants. This could be attributable to the lack of growth of plants in the middle of December. Plants slow flow within the wetland, allowing sediments in the water to settle, and plants have the ability to take into their roots pollutants carried by the sediments (Pond, 1995). Because of this, as the plants die, they may release the sediments and pollutants trapped earlier in the year, as well as releasing products of the decay of the organic matter. Aluminum, iron, potassium, and phosphorus could have been attached to these sediments, especially the finer particles. Findings such as these agree with previous studies that noted a distinct reduction in the performance of stormwater wetlands in winter months (Oberts, 1994; Ferlow, 1993). Not only does plant death have an effect, but also the formation of ice on the water surface can scour the margins and resuspend the sediments and the pollutants that they carry (Oberts, 1994).

Detailed Chemical Scan at the Golf Course Site

First flush samples were collected for detailed chemical analysis during the first pulse of runoff from a storm in November 1998 and a second storm in June 1999 (Table 2). In November 1998, 14 water quality parameters declined in terms of a comparison between the urban input (Site 1) and the golf course output (Site 6). Four water quality parameters improved between the urban input and the water exiting the course during the same storm. This suggests that the constructed wetlands were not working well soon after initial construction, during the late fall. However, key parameters such as ammonia and nitrate-nitrite nitrogen and pesticide levels were either decreased as the water circulated through the golf course wetlands or were not detectable at either sampling site.

A distinctly different pattern of results is apparent in the June 1999 sampling (Table 2). Fifteen water quality parameters improved between the urban input and the water exiting the course, and only 4 parameters declined. This suggests that the golf course's created wetland system is functioning well to improve the water quality in the late spring when wetland plants have become established. Two parameters of particular interest for a golf course are nitrate-nitrite N and ammonia-N, which were undetectable in water exiting the course, but at 2.1 and 31 ppm, respectively, in water flowing onto the course.

* where contaminant was BDL, the detection limit was used for % increase/decrease calculations

No unusually high levels of any of a wide array of potential pollutants, including pesticides and metals, were detected at the golf course sampling sites. However, atrazine was detected in water exiting the neighborhood and entering the golf course (Site 1). Surprisingly, even from the urban runoff there was no measurable oil and grease. It is reassuring to note that heavy metals of concern, such as mercury and lead, are below detection limits in all samples.

Conclusions

Constructed wetlands can potentially be used to improve NPS pollution management in urban areas. Although finding space for constructed wetlands can be a challenge in developed areas, these management tools can be incorporated into the design of new or renovated commercial and industrial facilities. In some cases, they can be added to recreational facilities such as parks and golf courses. In each of these cases, good initial design and attention to continued water supply for long-term wetland survival is critical.

The constructed wetland monitoring program in West Lafayette, Indiana, includes both commercial and golf course constructed wetlands. Selected results presented here illustrate the complexity of developing a program to evaluate performance of such wetland systems. Traditional grab sampling can provide misleading results compared to continuous sampling, and it is clear that apparent trap efficiency varies both within storms as well as between seasons. The type of complete picture of constructed wetland performance that is needed to improve design and enhance understanding of chemical and biological processes in constructed wetlands can be approached by continuous monitoring through several years. Initial data suggest that the constructed wetlands studied here are generally performing well to reduce loads and concentrations of a range of urban NPS pollutants, particularly during spring and summer storm events after wetland vegetation has become established. However there is also a strong indication that trap efficiencies are much lower, and in some cases negative, during winter months. The implications of this depend on the context provided by the receiving area.

Constructed wetlands also provide important benefits beyond water quality control. They provide aesthetic diversity in urban settings, they represent islands of habitat types that are generally absent or underrepresented in older developed areas, and they provide important local educational resources in urban areas. Overall, constructed wetlands should be considered as a potential element of urban retrofit projects, if there are situations where water supply is available to maintain wetland hydrology.

Acknowledgments

The Purdue constructed wetland monitoring program would not be possible without generous support from the Showalter Trust, the United States Golf Association, Pete Dye, Inc., and Heritage Environmental. Equally important for the project has been the willing cooperation of Jim Scott, superintendent of the Birck Boilermaker Golf Complex, Wal*Mart Inc., and numerous undergraduate and graduate field assistants.

Advanced Identification (ADID) Techniques Used to Protect Wetlands and Aquatic Resources in a Rapidly Growing County

Dennis W. Dreher
Northeastern Illinois Planning Commission
Chicago, Illinois 60606

Abstract

McHenry County, Illinois, approximately 40 miles northwest of Chicago, is one of the fastest growing counties in the state. It also is home to many valued wetland and stream communities that are threatened by the impacts of new development. Because of this, county government officials, with funding from the U.S. Environmental Protection Agency, sought the assistance of resource experts from various local, regional, state, and federal agencies. Their task was to assess the quality of the aquatic resource and to develop strategies for improved wetland protection. The project initially involved the development of an up-to-date countywide inventory of wetlands, lakes, and streams. This inventory showed that over 11% of the county was covered with wetlands and waterbodies. These aquatic resources then were evaluated and rated based on the habitat, water quality, and stormwater storage functions that they provided. While only a small fraction of the total number of wetlands -- about 11% -- of the county's wetlands were designated high quality, these wetlands represented over 60% of the total wetland acreage. Inventory and assessment data were transferred to a customized CD-ROM mapping tool to provide ready access to project information by resource managers, planners, and local governments. The project team also developed a protection strategy for aquatic resources that was tied to the results of the Advanced Identification (ADID) study. In particular, it identified four critical protection components: improved education, regulations and best management practices, acquisition, and restoration. Though the ADID study is only recently completed, there are strong indications that this protection strategy is being taken seriously by officials in the county.

Background

McHenry County, Illinois lies approximately 40 miles northwest of Chicago along the Wisconsin border. Reflecting a history of glacial activity, McHenry County possesses an abundance of wetland types in a variety of physical settings. Predominant wetland types include palustrine, lacustrine, and riverine systems. Palustrine wetlands are found in a wide variety of geographic settings and terrains in the county and include marshes, bogs, fens, wet prairies, forested wetlands, and ponds. Lacustrine wetlands are less common. They are found mostly in eastern portions of the county and are exemplified by the wetlands of the Fox River - Chain O' Lakes. High quality rivers and streams, and associated riverine wetlands, are relatively common. In fact, McHenry County has some of the highest-quality stream ecosystems in Illinois, as exemplified by the Kishwaukee River and its tributaries.

While predominantly rural, McHenry County is one of the fastest urbanizing counties in the state. From 1990 to 1998, its population grew by 31.5% to 240,945. Population is forecast to grow to nearly 362,000 by 2020, an increase of an additional 50%. This rapid population growth has raised concerns over possible adverse impacts on the county's wetlands, lakes, and streams.

Historically, wetland and stream protection measures in McHenry County have included federal regulations, local government ordinances, and acquisitions by government agencies, primarily the McHenry County Conservation District and the Illinois Department of Natural Resources. However, with the recent rapid pace of urban development, unacceptable loss and/or degradation of wetlands and aquatic resources have been observed. Concerned over the possible environmental effects of rapid growth, the county board invited the U.S. Environmental Protection Agency Region 5 (EPA) to perform an "advanced identification" (ADID) study of its wetlands and aquatic resources.

An ADID project can have several objectives. One objective is to shorten permit processing, while providing increased predictability to the Corps of Engineers regulations under Section 404 of the Clean Water Act. ADID also provides information that can be used by state and local governments to aid in zoning, permitting, or land acquisition decisions. Another objective of ADID is to provide information to agencies, landowners, and private citizens interested in restoration or acquisition of aquatic sites.

Approach

The ADID study was initiated in 1995, under the coordination of the Northeastern Illinois Planning Commission (NIPC). The study was a cooperative effort among federal, state, and local agencies to inventory, evaluate, and map high-quality wetland and aquatic resources in the county. From the federal perspective, the primary purpose of this ADID study was to designate wetlands or other waters of the United States that are unsuitable for discharge of dredged or fill material. From the local perspective, the purposes of ADID were to improve the overall protection mechanism for wetlands via improved local regulation, improved predictability in the permitting process, identification of potential mitigation/restoration sites, and identification of potential sites for acquisition.

The scope of work for the ADID project included the following tasks:

- form a Technical Advisory Committee and a Planning and Policy Committee;
- develop ADID objectives for McHenry County and a strategy for protection and management;
- identify and map existing wetlands and aquatic resources;
- develop an evaluation methodology for identified functions of wetlands and aquatic resources;
- apply evaluation methodology utilizing Geographic Information System (GIS) technology and field inspection;
- map ADID sites for public review;
- develop a CD-ROM tool that contains both the project data and a customized GIS interface for display, query, and mapping; and
- produce a final report and brochure and conduct a workshop for local governments, landowners, and consultants.

The Technical Advisory Committee and the Planning and Policy Committee were formed soon after initiation of the project. There were two general purposes for these committees: 1) provide technical and policy assistance to NIPC and EPA, and 2) provide a forum for educating local interest groups regarding the value of wetlands and aquatic resources in the county.

The principal role of the Technical Advisory Committee was to advise project staff on scientific issues, particularly the development of evaluation methodologies for wetlands, lakes, and streams. Technical committee members provided expertise in wetland biology, soil science, hydrology, engineering, water quality, and computerized mapping. Technical committee members contributed substantial time evaluating wetlands, both in the office and the field. The technical committee consisted of the following invited agencies and organizations:

- U.S. Environmental Protection Agency, Region 5
- U.S. Army Corps of Engineers, Chicago District
- U.S. Department of the Interior, Fish and Wildlife Service, Chicago-Metro Wetlands Office
- USDA, Natural Resources Conservation Service
- Illinois Department of Natural Resources

- McHenry County Department of Planning and Development
- McHenry County Conservation District
- McHenry County Soil and Water Conservation District
- Fox Waterway Agency
- Northeastern Illinois Planning Commission

The principal role of the Planning and Policy Committee was to advise project staff on policy, particularly the determination of wetland functions important to McHenry County. The policy committee also provided advice on the development of a wetland protection and management strategy. The policy committee included all of the members of the technical committee as well as members of the following organizations:

- Homebuilders Association of Greater Chicago
- Illinois Audubon Society, McHenry County Chapter
- Illinois Environmental Protection Agency
- Land Foundation of McHenry County
- McHenry County Board
- McHenry County Defenders (a local environmental group)
- McHenry County Farm Bureau
- McHenry County Municipal Association
- McHenry County Realtors Association
- McHenry County Stormwater Committee
- Openlands Project (a regional open space advocate)

Developing an Aquatic Resource Inventory

Detailed inventories of wetlands, lakes, and streams were developed early in the project. Two principal existing inventories were considered for identifying and mapping wetlands: the National Wetland Inventory (NWI) developed by the U.S. Fish and Wildlife Service with the assistance of the Illinois Department of Conservation (1986) in the early 1980s, and an inventory by the Natural Resources Conservation Service (NRCS) that was being completed in McHenry County just as the ADID project began. While neither inventory was adequate alone (the NWI was becoming dated and the NRCS inventory, while more recent, and only a data set, focused principally on agricultural areas), in combination they served as a good starting point. In finalizing the inventory, numerous revisions and improvements were made based on reviews of aerials photos, field checks, and the knowledge of local experts.

The resultant inventory identified 2,535 wetlands, including lakes, covering 37,846 acres. The inventory identified an additional 1,250 *farmed* wetlands covering 3,839 acres. In total, there were 3,785 wetlands in all categories covering 41,685 acres, or nearly 11% of the county.

Lakes were identified as a subset of wetlands. Specifically, lakes were distinguished based on a criterion of 20 acres or more of open water. Fifteen such lakes were identified (excluding gravel pits).

Type	Number	Acreage	Percent of County Area
Wetland	2,518	33,003	8.4
Farmed Wetland	1,250	3,839	1.0
Lake	15	3,584	0.9
River	2	1,259	0.3
Total	3,785	41,685	10.6

Streams were identified and mapped based on an inventory developed by the EPA. EPA's Stream Reach File, Version 3 (1:100,000 scale), with minor revisions, provided an accurate and complete inventory of county streams. The inventory included over 570 miles of streams ranging in size from small, unnamed headwaters to large rivers like the Fox and Kishwaukee.

Evaluation of the Functions and Quality of Aquatic Resources

As the first step in developing a wetland evaluation methodology, members of the policy committee were asked to identify wetland and aquatic resource functions that were important to McHenry County. After considerable discussion, the committee recommended that the following functions be considered and evaluated: biological/habitat functions, water quality mitigation functions, stormwater storage functions, and groundwater functions. These functions then were evaluated and refined by the technical committee. Ultimately, it was concluded that groundwater functions of wetlands, while having important water supply implications, could not be evaluated because of insufficient data.

The project team and advisors then proceeded to develop evaluation criteria and methodologies for the following general categories: *biological/habitat functions* and *water quality/stormwater storage functions*. The development of a methodology for identifying high-functional-quality wetlands in McHenry County relied both on existing wetland evaluation methodologies and the technical expertise of members of the technical advisory committee. The resultant methodology builds on a methodology used in nearby Lake County, Illinois (Dreher, et al., 1992) as well as other documented methodologies, particularly the Wetland Evaluation Technique (WET) manual (Adamus et al., 1987), the Oregon Method (Roth et al., 1993), and the Minnesota manual (U.S. Army Corps of Engineers, 1988).

The methodology was designed to accomplish two objectives: 1) identify the functions that individual wetlands were performing, and 2) identify wetlands of such high quality that they merit special consideration for protection strategies. The evaluation of the identified functions for individual wetlands can be very complex and some of the referenced methodologies describe fairly elaborate approaches to perform thorough evaluations. However, because of the large number of wetlands to be considered in McHenry County, it was necessary to adopt a simpler evaluation procedure. The resultant methodology is fully documented in the final project report, "Advanced Identification (ADID) Study, McHenry County, Illinois" (NIPC et al., 1998). An overview of the evaluation criteria follows.

Biological functions include wildlife habitat, floristic diversity, stream aquatic habitat, and lake aquatic habitat. Wetlands were considered *high quality* for this function if they met one of several criteria. These criteria included:

- the presence of threatened or endangered plant or animal species;
- designation in the Illinois or McHenry County Natural Areas Inventory (NAI);
- field evaluation as a grade A, B, or C wetland community following NAI methods;

- streams with Index of Biotic Integrity (IBI) scores of 41 or greater;
- streams with high quality physical habitat; and
- healthy lake ecosystems with rich/diverse fish and plant communities.

Water quality/stormwater storage functions include shoreline and streambank stabilization, sediment and toxicant retention, nutrient removal and transformation, and stormwater storage and hydrologic stabilization. In order to be designated *high functional value* for water quality/stormwater functions, wetlands were required to meet three of the four following criteria:

- presence of stabilizing vegetation adjacent to an open waterbody or perennial stream;
- surface area larger than five acres and having characteristics indicating the propensity for sediment/toxicant retention;
- surface area larger than five acres, upstream of a lake or impoundment, and having characteristics indicating the likelihood of nutrient removal/transformation; or
- surface area larger than five acres, at least 50% outside the floodplain, and having characteristics indicating significant stormwater retention.

Alternatively, wetlands could be designated *high functional value* for water quality functions if they provided individual water quality functions adjacent to or upstream of wetlands, lakes, or streams that provide high quality habitat.

Individual wetlands and waterbodies were evaluated using a three-step procedure of GIS screening; aerial photo, map or desk-top evaluation; and field evaluation (as needed). Based on this evaluation, it was determined that 154 wetlands totaling 17,489 acres, or about 42% of the county's entire wetland area, met the criteria for high-quality habitats. Most of the high-quality wetlands tended to be large parcels, averaging 114 acres in size in comparison to the average wetland size of 11 acres countywide. An additional 274 wetlands totaling 8,292 acres (average size of 30 acres) met the criteria for high value for stormwater and water quality functions. Thus, while a relatively small number of wetlands (about 11%) were designated high quality or high functional value, these wetlands represent over 60% of the total wetland acreage.

Classification	Number	Percent of all Wetlands	Acreage	Percent of County Area	Percent of all Wetland Area
High Quality Habitat	154	4.0	17,489	4.5	42.0
High Functional Value	274	7.2	8,292	2.1	19.9
High Quality Lake	7	0.002	1,346	0.3	3.2

Of the 15 inventoried lakes, seven were determined to be high quality. A total of 572 miles of stream were evaluated and 170 miles (or nearly 30%) were designated high quality. Interestingly, high-quality stream segments were found on 18 different named streams and rivers scattered throughout the county.

Using ADID for Protection and Restoration

The ultimate measure of success for a project like the McHenry County ADID study is how it contributes to the protection and restoration of aquatic resources. With this in mind, the project scope included a work element to develop

R0019686

a strategy for protection and management of aquatic resources. With the assistance of the advisory committees, the project team developed a four-part strategy involving:

- improved education of local government officials, landowners, and the public;
- effective regulations and best management practices;
- expanded acquisition of aquatic sites and buffers; and
- restoration of degraded sites.

This strategy, which is described in detail in the project report (NIPC et al., 1998), is summarized below. Also described are some recent protection and management activities, although it is still too early to judge the long-term success of the project.

Improved Education: Educational initiatives are critical to improve awareness of wetlands and aquatic resources among local citizens, land owners, and elected officials. Improved awareness can enhance local support for protection, acquisition, and restoration programs.

- A 12-page brochure, *McHenry County's Wetlands, Lakes, and Streams*, was developed to educate the public and local officials about the value of wetlands and aquatic resources in their communities. The brochure also discussed the results of the ADID study and identified additional sources of information and agencies that can provide help. Over 1000 copies of brochure have been distributed by participating agencies, such as the county soil and water conservation district.
- Maps and information for all ADID sites were made available on a "user-friendly" CD-ROM. The CD-ROM includes simplified mapping software developed from a sophisticated GIS tool. The software enables querying and screening of various wetland characteristics at different geographic scales throughout the county. It also enables printing out detailed information on individual wetlands. Over 100 copies of the CD-ROM have been provided to local officials, consultants, and landowners in the county.
- The message of wetland, lake, and stream protection also is being carried to local officials and the public by county-based environmental groups and consortiums called "ecosystem partnerships" that have been established for the two main river watersheds in the county (the Fox and the Kishwaukee). ADID will be a useful tool in aiding the efforts of these organizations.

Effective Regulations: Effective regulations are needed to minimize the effects of new development on aquatic resources. Specifically, improved regulations are needed to fill in the gaps in existing federal, state, and local regulatory programs. It was the conclusion of both the ADID team and the *McHenry County Comprehensive Stormwater Management Plan* (McHenry County, 1996) that improved regulations are needed to address concerns such as buffers and setbacks, depressional storage volumes, pretreatment of stormwater runoff, and effective environmental mitigation for unavoidable disturbances.

- Current federal regulations authorized under Section 404 of the Clean Water Act require a permit for the discharge of dredged or fill material into wetlands or other waters of the United States. Federal guidelines also authorize the EPA and the Corps of Engineers to identify in advance of specific permit requests, aquatic sites that will be considered as areas generally unsuitable for disposal of dredged or fill material. The Chicago District of the Corps has indicated that it will apply this discretionary authority to high-quality habitat and high- functional value sites in McHenry County. The Corps also generally will require an individual permit (which allows public input) for proposed modifications of ADID sites.
- Stream and wetland regulations, based on a model ordinance developed by NIPC, also have been adopted by a number of local governments in the county. These regulations are intended to complement the federal regulations by discouraging development in buffers and setbacks adjacent to wetlands, lakes, and streams and requiring pre-

treatment of stormwater discharges. The City of Woodstock, the county seat, recently applied its wetland protection regulations in a residential development review that resulted in an innovative conservation design around a large wetland. Not only will the wetland be avoided, but the site design calls for clustering of homes and buffers adjacent to wetland areas. Also, drainage swales and natural landscaping will be incorporated on upland portions of the site to reduce hydrologic and water quality impacts of the development.

- ADID team members have worked closely with staff and consultants to the McHenry County Stormwater Committee in the development of a countywide ordinance for new development. It has been recommended that the countywide ordinance include provisions for stream and wetland protection that complement, but do not duplicate, federal regulations. While the ordinance adoption process has been challenged by financial constraints and political changes in the county, it appears likely that significant stream and wetland protections will be added to existing county and municipal regulations.

Acquisition: Acquisition of important wetlands and stream corridors is one of the best ways to assure their long-term protection. In fact, recent experience indicates that these areas are becoming high priorities for public land acquisition. Information developed in the ADID study, particularly the identification of high-quality habitats and high-functional-quality wetlands, will be valuable to land acquisition agencies, including park districts, the McHenry County Conservation District, the Illinois Department of Natural Resources, and local land trusts, in assessing acquisition priorities. In a recent example, the Plan Commission of Nunda Township in east-central McHenry County is developing a comprehensive land use plan that will utilize ADID maps to identify areas to be preserved as open space.

Restoration: Restoration of degraded wetlands, lakes, and stream corridors, and ongoing management of higher quality sites, are critical challenges for land management agencies. Management is needed to counteract the effects of disturbances such as site fragmentation, elimination of fire, invasive species, and hydrologic alterations. Notably, the McHenry County Conservation District has been a regional leader in restoring degraded streams and wetlands. The ADID data base will be very useful in identifying appropriate sites to continue this restoration. The availability of GIS data bases and mapping, particularly in conjunction with other digital data such as soils maps and data on seeps and springs, will greatly facilitate this objective.

Lessons Learned

ADID was a valuable experience in McHenry County that generally met its identified objectives. In considering ADID studies in other areas, there are several important lessons one can learn from the McHenry County experience.

1) *Engage local government sponsors and keep them informed throughout the project.* The McHenry County ADID began after the county board passed a resolution soliciting EPA's assistance. County staff and elected officials were invited to participate on advisory committees. When support appeared to waver at critical points in the process (e.g., staff changes and budget difficulties at the county), the project team reached out by convening special meetings reminding county officials of the benefits of the project with respect to adopted county objectives.

2) *Conduct an open study process involving both traditional supporters of stream and wetland protection efforts and potential adversaries.* Groups ranging from environmental organizations to developers and the agricultural community were invited to participate on advisory committees where issues and approaches were openly discussed. When a public meeting was held to present project results, over 200 individuals attended. The vast majority of those expressing opinions indicated support for ADID objectives and procedures, even though some had concerns over the ramifications of federal wetland regulations.

3) *Utilize the expertise and local knowledge of federal, state, and local resource agencies.* While EPA contracted with NIPC to coordinate the project, staff from numerous resource agencies contributed invaluable expertise in hydrology, soils, aquatic ecology, and botany. They also contributed countless hours in evaluating field sites. Scheduling such assistance from multiple agencies resulted in some time delays. However, without these voluntary contributions, the project could not have been completed.

4) *Define wetland and aquatic resource functions from a multi-objective perspective.* While there is a tendency sometimes to focus on just the habitat and recreational values of wetlands, lakes, and streams, it is important to consider a broader range of benefits to maximize local buy-in to the process. The McHenry County ADID specifically considered stormwater and water quality functions that were identified as being important in local plans, such as the *McHenry County Comprehensive Stormwater Management Plan.*

5) *Distribute end-products in user-friendly formats.* While ADID was a highly technical and complex project, efforts were made to provide products that were readily understandable by local governments, land owners, consultants, and the public. The product receiving the most interest was the CD-ROM containing ADID data, as well as a user-friendly GIS-based interface for querying and mapping. The CD-ROM promises to be much more useful than conventional paper maps.

6) *Engage the local press in covering the project.* Limited attempts were made to inform the local press during the course of the study. While there was some resultant news coverage in local newspapers, particularly around the time of the public meeting, this coverage was not particularly effective in informing the public about the benefits of wetlands and the importance of the ADID study. Focused efforts, such as targeted press releases, probably would have improved the frequency and quality of coverage.

Conclusions

The ADID study provides valuable information to advance the protection and restoration of wetlands and aquatic resources in McHenry County. It can aid residents and organizations desiring to protect high-quality resources or restore sites that have been degraded. It can inform landowners and developers about an appropriate course of action when they are considering disturbances in or adjacent to high-quality sites.

While the final ADID products have been available for only a short time, it is apparent that they will greatly facilitate ongoing efforts to educate county residents and officials, protect streams and wetlands from the effects of new development, preserve sensitive stream corridors and wetlands as public land, and restore degraded sites. While the ultimate success of county stream and wetland protection initiatives will depend on the will of landowners and local government officials, no one will be able to blame wetland loss on inadequate information.

Local Government Involvement in Mitigation Banking

Lisa T. Morales
Wetlands Division
U.S. Environmental Protection Agency
Washington, D.C.

Abstract

Mitigation banking is a valuable tool that can be used by local officials to achieve wetlands restoration and other local goals. Mitigation banks can be established by local governments to provide compensation for wetland losses that result from development projects. There are different strategies that local governments can use to establish a mitigation bank, depending upon their goals and objectives. The success of a mitigation bank is dependent upon several factors, ranging from bank location to the availability of funding. The Environmental Protection Agency conducted a survey of local jurisdictions to identify the different strategies that were utilized for effective development and implementation of mitigation banking. The findings of the survey are presented in case-studies that characterize the approaches that were used by local governments to achieve their mitigation banking goals and objectives.

Introduction

Mitigation banking is defined in the Federal Mitigation Banking Guidelines[1] as "wetland restoration, creation, or enhancement for the purpose of compensating for unavoidable wetland losses in advance of authorized impacts to similar resources." Under Section 404 of the Clean Water Act, applicants for permits must first avoid and minimize all impacts to wetlands and other waters of the United States. If there are still impacts, then applicants must provide compensatory mitigation through the restoration, creation, and the enhancement of similar type of aquatic resources. This "sequencing process" under the Section 404(b)(1) guidelines is a central premise of the Section 404 regulatory program, and mitigation banking can play a role in providing compensatory mitigation for unavoidable wetlands losses.

As a general matter, on-site and in-kind mitigation is preferred under the Section 404 Program. However, in those circumstances where it is determined, on a case-by-case basis, not to be practicable, then off-site, in-kind mitigation is acceptable.[2] Off-site mitigation can be accomplished using a federally-approved mitigation bank. Since the use of mitigation banking to offset permitted wetlands losses began in earnest in the early 1990's, local governments have been involved in developing banks to restore and replace lost wetlands functions and values within their jurisdictions. By simplifying the process for compensating for unavoidable wetlands losses, appropriate use of the banking concept can improve both permitting efficiency and environmental protection.

Mitigation Banking Objectives

- Local needs are best met when there are clear objectives and goals for establishing a mitigation bank. Examples of objectives for mitigation banking identified by local governments include:
- Use as part of a comprehensive watershed plan that addresses urban development and the need for preservation and restoration of wetlands
- Provide an incentive for economic growth by streamlining the process for providing compensation of unavoidable wetlands impacts
- Provide for restoration of degraded wetlands that otherwise might not be improved because of insufficient funding
- Use as part of a multi-objective strategy to manage stormwater, flooding, water quality, etc.
- Compensate for wetland losses from future local agency projects

Types of Mitigation Banks

Once the objectives for the proposed bank have been established by the local agency, the type of bank to meet the identified objectives must be determined. Local governments can establish a mitigation bank for their individual use or for credit sale as a commercial venture. The bank can be established solely by a public agency or as a joint venture with a private entity (e.g., entrepreneurial business). Mitigation bank types need not be mutually exclusive; for example a commercial mitigation bank may be established through public/private partnerships and still be part of a watershed management plan.

Commercial banks: A commercial mitigation bank is one in which the credits are sold to a party other than the bank sponsor (banker). The banker sells credits within the established service area to permittees who have approval from the U.S. Army Corps of Engineers (Corps); the agency responsible for issuing wetlands development permits; to compensate for wetland impacts through a mitigation bank.

Single-user: A single-user mitigation bank is established by a local agency to compensate only for wetland losses associated with activities conducted by the agency.

Factors Contributing to Mitigation Bank Success

Conditions for successful bank establishment

Local governments which have successfully established a mitigation bank have identified several conditions that need to be considered in order to successfully meet environmental and/or economic objectives.

- There must be a demand for compensatory mitigation within the local jurisdiction. Demand results from development pressure in a rapidly growing area where impacts to wetlands are expected to occur. The value of development in regions with rapid growth increases the willingness of the public agency or developer to pay for wetland mitigation. Potential bank sponsors should conduct a "needs" analysis to determine the demand for a mitigation bank in a given area. The analysis will show the extent of potential wetland impacts in the region and whether mitigation banking is a viable compensation option. Once demand for a bank is decided upon, the size of the bank can be determined.

- There must be a sufficient supply of available sites for restoration, creation, enhancement, or preservation.[3] The availability of appropriate sites will vary by geographic region. For example in Florida, large tracts of degraded wetlands have been impacted by previous land-use practices and by invasion of exotic plant species. Such large areas are conducive to restoration and enhancement. In some areas, there are mitigation banks where property is in high demand, resulting in high land acquisition costs. In other circumstances, finding an appropriate site may be difficult due to the lack of large wetland expanses. Land that is in public ownership can help lessen land acquisition cost, but may not have favorable physical attributes that would allow for a mitigation bank to be self-sustaining over time.

- Finally, regulatory coordination is important. The local agency needs to provide a prospectus to the Mitigation Banking Review Team (MBRT) established by the local Corps district.[4] The prospectus will serve as the mitigation banking instrument that identifies the objectives and administration of the proposed bank. As part of this coordination process, the local agency should identify the proposed bank site, the geographic service area, wetland types suitable for compensation at the site, the debiting and crediting system, performance standards, monitoring plan, contingency and remedial actions, and provisions for long-term management and maintenance.

♦ Proposing a mitigation bank in the context of a regional plan that integrates the bank into a comprehensive wetland or watershed management strategy may improve the likelihood of acceptance of the prospectus by the MBRT. A watershed management plan can provide greater certainty about the nature and extent of future wetland impacts and identify the most appropriate, environmentally beneficial options for offsetting the anticipated impacts. In this way, the MBRT has a level of assurance that the bank is a part of a broad goal to maintain or gain wetland functions in a given area or watershed.

Site selection criteria

Local agencies need to carefully consider the sites that are identified for potential mitigation banks. Site selection is one of the most important criteria affecting the successful establishment of a mitigation bank. The most significant site selection criteria is the potential that the site can be successfully restored or enhanced in a manner that will provide appropriate compensation for anticipated unavoidable wetlands losses. Selection of such ecologically important or desirable sites can further regulatory acceptance.

As identified in the federal guidance on mitigation banking, mitigation sites should be self-sustaining over time. Sites with naturally occurring hydrology are preferable to sites that require complex hydraulic engineering features that are costly to develop, operate, and maintain. Therefore, sites that can be restored without complex improvements should be the first option when establishing a mitigation bank.

Ideally, site selection would be undertaken in accordance with a watershed management plan under which existing wetlands have been surveyed to determine which sites are the highest priority for protection, the most suited for restoration or enhancement, and the most likely to be impacted by development. Through watershed planning, wetland functions that are lacking in a region can also be used to guide site selection. Additionally, planning at this level can help determine compensation requirements, because anticipated wetland impacts can also be identified. Two federal programs, the Special Area Management Plan (SAMP) and the Advance Identification (ADID) Program, can provide guidance and technical assistance to local sponsoring agencies that meet certain criteria and are interested in establishing a watershed scale planning effort.

---

[3] The Federal Mitigation Banking Guidance states that the use of preservation in a mitigation bank may be authorized by the federal agencies when it is demonstrated that the preserved areas contribute to the functions of the restored, created or enhanced aquatic resource.

[4] The Mitigation Banking Review Team is established as consistent with the Federal Mitigation Banking Guidance.

Mitigation bank site selection can also be targeted to address specific environmental objectives. For example, wetlands in several counties in Florida were overrun by exotic vegetation. Mitigation banking provided the funds to improve the wetland habitat through exotic species eradication and revegetation with native plants.

Site selection may also be influenced by a regional demand for mitigation opportunities and the availability of suitable restoration sites. Land acquisition is often cost-prohibitive for local agencies; land ownership, zoning restrictions, and allowable uses also are important factors in determining a mitigation bank site. Important functional characteristics of a potential restoration site include the presence of hydrology, hydric vegetation, and/or hydric soils; size of the site; historic conditions; and the degraded condition of existing wetland (e.g., exotics, fill, compaction, trash). Experts in restoration should be consulted regarding specific wetland requirements and regional wetland attributes prior to site selection.

Funding

The most common funding option used by local governments is the advance-credit sale option addressed in the Federal Mitigation Banking Guidance.With this funding mechanism, advance sale of a percentage of the total credits is allowed after certain criteria have been met by the bank sponsor, such as conservation easement, land acquisition, and/or design plan approval. By selling a limited number of credits in advance, the banker can collect sufficient funds to begin conducting wetland improvements, then sell more credits as they are certified by the regulatory agency. The advance sale of credits, however, involves a degree of risk; for example, problems can arise prior to mitigation bank implementation or completion, leaving the bank sponsor liable for any credits sold.

Local governments have also identified various other strategies for funding the establishment of their mitigation banks. Some of the options include:

- Completing the project in phases so that initial credit sales will provide funding for the remainder of the project
- "Borrowing" money from other local agency funds, then paying it back using money from credit sales
- Using available federal or state grant money for wetland improvement as seed money to establish the banks;[5]
- Partnering with a private company to share the costs
- Using combinations of the above mechanisms

Bank Administration and Operation

Several issues related to bank administration and operation pose a challenge to local governments. The geographic service area, credit ratios, credit valuation, monitoring plans, and long-term maintenance provisions are all issues that must be addressed by the local sponsor and approved by the signatory agencies. Information on these issues can be found in the Federal Mitigation Banking Guidance mentioned earlier, as well as in any existing state guidance. A partnership with a private entity that has experience in mitigation banking is one alternative for addressing bank administration and operation challenges.

The geographic service area for the mitigation bank should be established and presented in the mitigation banking planning document. The service area is the area in which credits from a mitigation bank can be used to compensate for unavoidable wetland losses. This area can be a watershed or a political boundary, such as a county or municipality.

The number of credits produced by a mitigation bank are generally determined by two factors, (1) the number of acres restored, created, enhanced, or, in exceptional circumstances, preserved, and (2) a quantified evaluation of the

---

[5] EPA has also identified the State Revolving Fund (SRF) as another potential source for funding the establishment of mitigation banks, subject to approval under each State's SRF regulations.

functional value of the wetlands in the bank. As a general matter, the greater the wetland improvement, the more credits generated. For example, more credits may be associated with restoration and fewer credits associated with enhancement. The second factor involves a functional assessment of the improved or created wetland, and a method for converting the functional units to credits.

To determine the appropriate compensation requirements for wetland losses, a mitigation ratio must be developed. This ratio can be based on lost wetland function and area, the rarity of the affected wetland, and the wetland replacement kind and function. The ratio will determine the number of credits required from the bank to replace the impacted aquatic resource. Generally, the mitigation ratio is greater than or equal to one; i.e., at least one credit (acre of restored, enhanced, or created wetlands) required to replace one acre of lost wetland resource.

As a general matter, the bank sponsor monitors the bank for a period of time (e.g., five years) to determine whether the bank is functioning at the level required by a previously determined set of performance standards established in the banking instrument. After the performance standards are met, the local agency may choose to transfer the mitigation bank to another entity (e.g., land trust) for the long-term maintenance and monitoring. An agency can also use volunteer labor to offset costs of monitoring and maintenance and to improve public awareness and citizen stewardship for the project. Among the local bank projects reviewed by EPA in the survey, local sponsors were usually responsible/liable for the performance of the mitigation site from the beginning, or after an established period of time if the project was a joint-venture.

Financial assurances for long-term maintenance and contingency plans for the bank most often take the form of additional fees added onto the cost of a credit, with a fixed amount from the sale of each credit put into an escrow account. The local agency then draws from the account for necessary maintenance expenditures. In some cases, completed banks become part of a park system or are turned over to a public agency for long-term management.

Mitigation Bank Approaches with Case-Study Examples

The following case-studies are examples of the different types of mitigation banks that can be established by a local agency, and highlight specific issues that are of concern to local governments. The banks discussed in the case-studies are not mutually exclusive, in that a given bank may fit into more than one "bank type" category.

Mitigation Banking in the Context of a Watershed or Wetland Management Plan

Local governments can use a watershed or wetland management plan as a means of addressing economic development and environmental concerns. An important aspect of such a plan involves compiling an inventory of existing wetlands in order to determine both coverage area and functions provided. This information can then be used to protect important resources, establish areas suitable for development, and determine the best sites for restoration. Mitigation banking is, therefore, a tool that can be integrated into a watershed plan to help meet resource management objectives.

Advantages of mitigation banking in the context of a watershed management plan are as follows:

- Sites to be restored and critical sites to be preserved are already identified in the plan
- Market demand for compensatory mitigation can be identified
- The extent and nature of potential impacts have been determined
- Likelihood of restoration project success is improved
- Uncertainty for regulatory agencies is lowered
- Multiple objectives can be attained

- Environmental benefits are maximize

West Eugene Mitigation Banking Program

Overview: The Eugene Wetland Mitigation Bank Program (Bank) was established in 1995. The program is operated by the City of Eugene, Oregon, under a separate fund within the City's financial structure. The goal of the Bank is to provide a mechanism to fund wetland mitigation projects, carry out the West Eugene Wetlands Plan (Plan) adopted in 1992, and meet other community needs. This program is being conducted in cooperation with the City's wetland partners (the U.S. Bureau of Land Management [BLM] and the Nature Conservancy [TNC]).[6] The objectives that the City seeks to accomplish with the mitigation banking program include:

- Creating credits in advance of wetland losses
- Meeting the mitigation needs of the community of Eugene
- Achieving community objectives, such as increased flood storage capacity, enhanced water quality, improved wildlife habitat, and establishment of education and recreation opportunities
- Targeting areas with high prospects for restoration success such as historic wetlands, disturbed agricultural wetlands, and areas adjacent to waterways
- Communicating the banking program's value to the community
- Operating the bank as part of a national model wetland program in cooperation with the wetland partners
- Establishing a permitting process familiar to businesses, environmental interests, and regulatory agencies

Funding for identifying wetland areas for the bank was provided through EPA's Advanced Identification (ADID) program. The West Eugene Wetlands Plan integrates wetlands protection and community development needs by identifying areas best suited for wetland preservation and areas with development potential. Thirteen hundred acres of wetlands were identified within the plan area, with more than 1,000 acres designated for protection or restoration and approximately 300 acres of lower value wetland designated as suitable for future fill and development. The Plan calls for the establishment of a mitigation banking program to compensate for unavoidable losses of wetlands through restoration and enhancement in conjunction with protection of important wetland resources.

All mitigation bank projects will be located within the Long Tom River watershed. Seven projects were initially constructed for a total of 56 acres. Three additional projects totaling 60 acres were in planning at the time of the EPA survey.

In this program, mitigation bank credits can be established in three ways

1. The City or its partners may undertake wetland mitigation work, then seek certification of credits by the Corps and Oregon Division of State Lands (DSL). The City provides documentation on a site prior to the mitigation work and after completing improvements to demonstrate an increase in wetland values.
2. The City may create more credits than are needed to compensate for permitted wetland losses as part of concurrent or advance mitigation work. If the Corps and DSL certify the excess credits, they will be added to the Mitigation Banking Program's ledger for sale.
3. Uncertified credits may be sold in order to fund initial mitigation work, which are later certified by the Corps and DSL when the initial hydrological and vegetative work is completed.

---

[6] City of Eugene, Public Works Department. 1997. West Eugene Wetland Mitigation Bank, Annual Report 1996.

The City Stormwater Fund provided money for acquisition of site properties. Additional capital for the projects came from the sale of uncertified credits. No uncertified credit can be sold unless the Corps and DSL have approved a mitigation plan.

As the bank sponsor, the City is responsible for monitoring and maintaining the bank sites. Monitoring is required for a minimum of five years and the sites will be inspected by the Corps and DSL on an annual basis. Monitoring goals are determined on a site-by-site basis. Maintenance will be conducted to ensure that the wetland functions and values are fully established and functioning. If the site is not meeting the performance criteria, corrective measures will be taken. Funding for these tasks is included in the credit price. At least an additional 20% will be added to the estimated credit cost and set aside to be used to monitor, maintain and, where necessary, conduct remedial measures.

Single-user Mitigation Bank

Local governments can establish a single-user bank. In this case, the local government initiates the bank, creates the credits, and is the principal credit user. Local sponsors with long-range project plans that involve potential impacts to wetland areas may establish a mitigation bank or banking program in anticipation of the need for compensatory mitigation. For example, a public works department with road expansion plans may know in advance that there will be unavoidable impacts and provide the funds necessary to initiate a bank in anticipation of the project.

An advantage of a single-user bank is that long-term planning provides advance knowledge of potential wetland losses associated with future projects. This reduces the uncertainty surrounding the demand for the bank and eventual funding. Funding may be available to initiate the bank based on the predicted future use.

Snohomish County Airport Mitigation Banking Program

Overview: The Snohomish County Airport (SCA) needed to address the multiple objectives of their 20-year Master Plan, the aviation needs of the airport, the economic growth of the region, and environmental protection. The Master Plan identified three development/construction projects that will occur over five years, each with anticipated wetland impacts. The objectives that the SCA seeks to accomplish through the banking program include:

- Creating a mitigation alternative for projected airport development
- Replacing or augmenting wetland functions in the watershed
- Replacing habitats that will potentially be lost, including open-water habitat that cannot be created on-site
- Creating recreational and educational opportunities

The SCA analyzed the three watersheds containing the project areas to determine missing wetland functions and values. Potentially impacted wetlands were then characterized according to acreage, wetland category, and function. Based on these analyses, two mitigation banks were designed to replace the wetland functions that would be lost by the airport projects. The SCA banking program creates a "reserve" of mitigation that accommodates Master Plan impacts for approximately seven years.[7]

Mitigation banking was an effective alternative for the SCA since the Federal Aviation Administration (FAA) prohibits the creation of bird attracting habitat within 10,000 feet of a runway. In this circumstance, on-site mitigation was determined not to be a viable alternative as it would attract waterfowl and migratory birds. The SCA created or enhanced a total of 32 acres and preserved an additional 23 acres.

Following a format developed by the Washington State Department of Transportation, the SCA Memorandum of Agreement (MOA) was established. The MOA describes the procedures for selecting, managing, monitoring, and

---

[7] Snohomish County Airport. 1997. Snohomish County Airport MOA/IM Executive Summary.

protecting mitigation banks. Additionally, an Implementation Manual was created by the SCA that presents agency recommendations for approval of the two specific bank sites. A technical oversight committee reviewed and advised changes to the MOA, and provides input for credit evaluation and ratio development.

Construction is nearly complete at both sites. One site has a nonprofit organization associated with it called the *Friends of Narbeck Wetland Sanctuary* that is working to promote citizen stewardship, protection of wildlife and wildlife habitat, native plant propagation, and environmental research.

Primary funding for the mitigation banks came from airport revenues. In addition, some funds were provided from the FAA, since the program will be used to mitigate for projects required by FAA safety regulations.

The SCA will be responsible for one of the sites in perpetuity. The other site will be donated to the City of Everett, Washington, Parks Department after all of the credits have been used. Monitoring will be conducted for five years in the emergent wetland and ten years in the forested wetland. Both sites have been placed in a conservation easement and a contingency plan will be executed if performance criteria are not met.

Public/Private Joint Venture

Public/private joint ventures can facilitate mitigation-bank establishment by providing investment capital and technical expertise. Mitigation banking is a complex process involving aspects of design, engineering, regulation, project management, biology, ecology, marketing, and long-term management. Because of this, a mitigation banking joint venture may be established to share the responsibilities and costs. A local agency role may be bank sponsor, bank creator, land owner, long-term manager, or all four. The private entity may conduct only the technical work, but can also assume any of the aforementioned roles. The EPA survey found that the local agencies partnered in joint ventures were most likely to provide the land for the mitigation bank and the private entity would provide funds and/or technical expertise.

City of Pembroke Pines and Florida Wetlandsbank, Inc.

Overview: In 1992, the City of Pembroke Pines in Broward County, Florida, entered into a partnership agreement with Florida Wetlandsbank, Incorporated to restore a heavily degraded site that was already overrun by exotic species and becoming further deteriorated by all-terrain vehicle use and illegal trash disposal. The City did not have the resources necessary to restore the site or to establish a mitigation bank. Concurrently, development pressures in the area were creating a demand for an effective mitigation alternative.[8] Florida Wetlandsbank agreed to design and construct a wetland system by eradicating the exotics and replacing them with a mixture of 10 typical Everglade habitats including cypress stands, emergent marshes, tree islands, and sawgrass prairie. Florida Wetlandsbank also provided the management for the bank, selling the first credits in 1994. In 1997, restoration was near completion, with 396 credits sold. The objectives for the Florida Wetlandsbank (the name of the mitigation bank) are to:

- Provide a mitigation alternative for the rapidly urbanizing City of Pembroke Pines
- Provide mitigation at a large site with high potential for ecological success
- Restore native wetland ecosystems in an area that was degraded and infested with exotic species

The mitigation bank provided a number of economic and environmental benefits, including the following.

[8] Paul Wattles, Assistant City Manager, City of Pembroke Pines, Florida. Personal communication, March 23, 1998.

- The project provided revenue for the City through the collection of franchise fees per acre (paid by Florida Wetlandsbank, Incorporated after credits were sold).

- Developers used the credits as quickly as they became available.

- The City plans to open part of the area as a park and offer public access and passive recreation opportunities.

- To date, the site is ecologically successful, with little reinfestation of exotic plants.

- Florida Wetlandsbank, Incorporated profited from the sale of credits.

The construction is completed and all credits sold for the original 350-acre site. An additional 100 acres has been added to the site with construction nearly completed and credit sales pending. The service area for the mitigation bank was kept at the county level rather than the basin level, which incorporates three counties. The County determined that mitigation for wetland losses should remain within the county.[9] The number of credits available in the mitigation bank were determined using a modified Wetland Rapid Assessment Procedure (WRAP).

Florida Wetlandsbank, Incorporated provided the capital for initiating the bank. Pre-project sale of credits allowed restoration work to begin. A trust fund was established to provide for the long-term maintenance of the site, with $1,000 per credit contributed to the fund.

Site monitoring will be conducted by Florida Wetlandsbank, Incorporated from the time that construction is completed for five years. Quarterly monitoring reports are required by the SFWMD. These reports contain information regarding the bank's performance criteria. A performance bond was placed with the SFWMD for each stage of construction. The bond will be used in the event that any of the performance criteria are not met. Once the performance criteria for the site are met, the money will be released to Florida Wetlandsbank.

Commercial Mitigation Banking

A local government can establish a commercial mitigation bank that sells credits to anyone who meets the requirements to use the bank for compensatory mitigation. The bank discussed here was established on public land, solely by public agencies, with credits for sale to the public. Optimally, a public commercial mitigation bank is part of a larger watershed plan.

A major advantage of public commercial banks is that they are in public ownership, which can better provide long-term management, and the funds generated from the bank can be used to further improve public resources. The disadvantage is that the up-front capital investment can be difficult for public agencies with limited availability of funds.

DuPage County, Illinois

Overview: DuPage County is a highly urbanized area located west of Chicago. Land development has negatively impacted the natural drainage system of the area by eliminating naturally occurring storage, reducing stormwater infiltration, and increasing the velocity and quantity of runoff. In response, the DuPage County Stormwater Management Plan (Management Plan) was developed in 1989, to reduce the potential for recurrent and increasing flood damage and to reduce further environmental degradation associated with development. The ecological assessment conducted during development of the Management Plan found that wetlands represented a significant portion of the natural watershed

---

[9] Desmond Duke, Project Administrator, Florida Wetlandsbank. Personal communication, June 19, 1998.

storage in the county, and are essential for adequate stormwater retention, conveyance, sediment control, and water quality enhancement.[10]

Individual watershed plans, within the larger DuPage County management plan, were developed to identify wetlands for protection, enhancement, and restoration. The County attempts to establish mitigation banks in the four main watersheds within the County. The service area for each bank will be the watershed in which the bank is located. The County also established an ordinance for stormwater management that requires developers whose development proposals will affect the function and values of wetlands to consider mitigation banking as an alternative to compensatory on-site mitigation. The objectives of the DuPage County commercial mitigation banking program are to:

- Manage and mitigate the effects of urbanization on stormwater drainage
- Enhance the quality, quantity, and availability of surface and groundwater resources and prevent further degradation
- Preserve and enhance existing wetlands, aquatic, and riparian environments
- Encourage restoration of degraded areas

Any investment in a bank must be at least equal to the cost of planning, acquiring lands, constructing, and operating and maintaining mitigated wetlands of equivalent or greater functional value than those lost to development.

The land for the bank sites was in public ownership. Funding for establishing the bank and initial project work came from an advanced credit sale. One-third of the credits were allowed for sale prior to work beginning at the site. One site, Winfield Creek, was in the process of selling credits for project initiation when public opposition to the site halted the project. The County is now in the process of finding another site but, in the interim, is liable for the credits sold.

The County has five banks that have been approved by the agencies and are in various stages of implementation. The oldest project, Cricket Creek, is in year two and, to date, is exhibiting successful hydrologic and vegetation conditions.

Conclusion

The use of mitigation banking by local governments can be an effective tool to restore and protect their community's valuable wetlands resources. The case-studies presented provide local governments with different mitigation banking strategies that could be used to address the needs of their community. As demonstrated in the case-studies, the establishment of sound objectives and goals by the local agency will help determine the type of mitigation bank that will best meet the local needs. In addition, there are several conditions that local governments must evaluate and consider for successful bank implementation, including (1) a demand for compensatory mitigation, (2) a sufficient supply of suitable sites for the bank, and (3) opportunities for working in partnership with the federal and state regulatory and resource agencies.

Mitigation banks that are established by local governments can address more than just the need for compensatory mitigation. Wetlands mitigation banks can achieve additional community needs by increasing local flood storage capacity, improving wildlife habitat, and providing educational and recreational benefits while restoring and enhancing important wetland resources.

Massachusetts Stormwater Management Policy/Regulations: Development, Implementation, and Refinement

Bethany Eisenberg
Vanasse Hangen Brustlin, Incorporated
Watertown, Massachusetts

Abstract

In March of 1996, the Massachusetts Department of Environmental Protection, in conjunction with the Massachusetts Office of Coastal Zone Management, released the Draft Version of the State's Stormwater Management Policy. The Policy includes nine specific Stormwater Performance Standards, which are to be met to achieve compliance. The Policy presented in two volumes: Volume One, the *Stormwater Policy Handbook,* which contains a description of the policy, its implementation, and descriptions of the nine individual stormwater management standards, and Volume Two, the *Stormwater Technical Handbook,* which contains more detailed information on Best Management Practices (BMPs), for stormwater management (i.e., detention basins, swales, etc.).

The policy is the result of three years of work by a Stormwater Advisory Committee that included representatives from regulatory offices (EPA, Department of Fisheries and Wildlife, Natural Resources Conservation Service, etc.), engineers and developers from the private sector, the highway department, and representatives of local conservation commissions. The Policy is to be implemented as an amendment to the existing Massachusetts Wetlands Protection Act, which is administered at the local level by local Conservation Commissions.

The nine performance standards are the key components of the policy. General descriptions of the standards include the following:

1. No new stormwater conveyances may discharge untreated stormwater directly to, or cause erosion in wetlands or waters of the Commonwealth.

2. Post-development peak discharge rates may not exceed pre-development rates.

3. Maximize recharge to groundwater: post-development must be similar to pre-development conditions.

4. Remove 80% of average annual load–post development of Total Suspended Solids (TSS).

5. Use specific BMPs for discharges from areas with higher potential pollutant loads; untreated infiltration prohibited.

6. Use specific BMPs for discharges to critical areas.

7. Redevelopment projects should not meet performance standards to the maximum extent practicable and at a minimum, improve existing conditions.

8. Erosion and sedimentation controls are required during construction.

9. Operation and Maintenance Plan for Stormwater Management required.

The Policy was introduced in March of 1996 for testing its effectiveness. Two Phases of training were provided over a two-year period across the state. The first phase focused on introducing the Policy and the second phase focused on detailed Engineering Companies, and local DPWs and planning departments.

Introduction

In March of 1997, the Massachusetts Department of Environmental Protection (MADEP), in conjunction with the Massachusetts Office of Coastal Zone Management (CZM), released a draft version of the state's Stormwater Management Policy (herein referred to as the "Policy"). Prior to the development of this policy, the control of peak stormwater discharges from development sites to prevent flooding and erosion problems was a fairly standard requirement across the country; and was well-implemented in Massachusetts. However, there were no state-level requirements for stormwater quality treatment, maintaining groundwater recharge processes, or maintaining stormwater treatment systems. The Policy was developed to provide standard minimum requirements for stormwater management that could be consistently implemented on development projects.

The Stormwater Management Policy is currently an amendment to the Wetlands Protection Act which is only applicable when a project proposes work within the boundary, or buffer zone, of a Wetland Resource Area. Hence, the Policy is not applicable to all developmental projects.

While the regulatory implementation of the Policy is through local Conservation Commissions, under the State's *Wetlands Protection Act,* the performance standards and design guidelines that define the Policy were developed for use by a larger audience. Development teams (typically the proponent and their engineers, architects, and planners) and the various reviewing agencies (Conservation Commissions, Planning Boards, DPWs, etc.) were expected to be users of the Policy. The goal was to provide guidance to ensure that negative impacts from stormwater runoff generated as a result of urban and suburban development would be minimized without placing an unjustifiable economic burden on developers for new projects, or preventing redevelopment of existing sites.

The Policy includes nine specific Stormwater Performance Standards for which compliance must be achieved on development projects. Included in these standards is a requirement to provide groundwater recharge, requirements for ensuring proper stormwater treatment prior to discharge to waters of the state, and provisions for waiving certain requirements if deemed infeasible for redevelopment projects. The Policy has been distributed as an Interim Draft to allow for refinements prior to its final promulgation as state regulations. In order to fully gage its effectiveness, however, the Interim Policy has been distributed and implemented as if the regulations were final.

The Policy is presented in two handbooks: Volumes One and Two. Volume One, the *Stormwater Policy Handbook.* contains a description of the policy, its implementation, and detailed definitions of the nine individual stormwater management standards. Volume Two, the *Stormwater Technical Handbook,* contains detailed information on Best Management Practices (BMPs), with guidelines for the design of standard stormwater management structures (such as detention basins and water quality swales).

Development

The Policy is a result of three years of work by a State Stormwater Advisory Committee. In addition to leaders from MADEP and CZM, this Committee included representatives from such regulatory offices as USEPA, Department of Fisheries and Wildlife, and the Natural Resources Conservation Service. Also on the committee were engineers and developers from the private sector (including the author) and representatives from the Massachusetts Highway Department and local Conservation Commissions.

The goal of the Committee was to provide a cohesive set of performance standards that addressed key issues associated with stormwater runoff control. The Policy was developed in such a manner that it provides adequate accompanying guidelines and recommendations, to allow for consistent implementation, while still allowing for flexibility in site-specific designs. Given the widely varying goals and perspectives of Committee members, the Policy published in 1997 was a result of group consensus and compromise.

The Committee was divided into two sub-committees, the Policy group, and the Technical sub-committee. The Policy group was tasked with developing the process for legal implementation and the Technical Committee was responsible for developing the specific technical requirements of the Stormwater Management Policy.

Some of the performance standards introduced completely new requirements for development projects and required detailed evaluation and discussion during the development stages. Some of the key issues that generated substantial debate include the following:

- ***Recharge:*** The loss of recharge to groundwater systems, which provide drinking water supplies and generate baseflow to streams and rivers, was a state-wide problem. A mechanism for requiring the maintenance of recharge after development was considered a high priority. The biggest issue relative to this requirement was: How much annual recharge should be required?

- ***Water Quality Treatment Volume:*** The quality and quantity of stormwater runoff from paved and unpaved areas can vary greatly. It was determined by the Committee that runoff from impervious areas was the highest concern and should require treatment. The largest decision relative to this concern was: What volume of stormwater runoff should be treated for water quality? Should it include runoff from both pervious and impervious areas?

- ***Critical Areas:*** The Committee felt that certain sensitive environmental areas should have the maximum practicable protection. Under the Massachusetts Stormwater Management Policy, "Critical areas" are defined as; shellfish growing areas, public swimming beaches, cold water fisheries, recharge areas for public water supplies and designated Outstanding Resource Waters (ORWs). ORWs are further defined to include surface drinking water supplies, certified vernal pools, and state designated Areas of Critical Environmental Concern (ACECs). The issue here was how to ensure that these areas are provided adequate protection and how to define what adequate protection is.

- ***Exemptions:*** Some Committee members expressed concern that stormwater management requirements may be too costly for small residential projects, or may be a deterrent for initiating redevelopment projects. The issue was what, if any, projects should be exempt from any or all of the standards?

- ***Operation/Maintenance:*** Maintenance of stormwater management practices is critical for their effectiveness. It is often difficult, if not impossible, to ensure that the operation and maintenance of BMPs will occur as necessary. The issue was: How can the necessary maintenance of BMPs implemented on the project be ensured?

A brief summary of the decisions on these key issues is as follows:

- ***Recharge:*** Annual recharge processes are permanently changed by the introduction of impervious areas to a site. In order to minimize this impact, it was agreed that the existing annual recharge should be determined and post-development annual recharge should maintain this to the maximum extent practicable. A preliminary methodology for determining existing recharge on the site was provided in the Draft Policy.

- Water Quality Treatment Volume:

  - For discharges to critical environmental areas (defined in the Policy), the volume of stormwater runoff to be treated for water quality control is defined as 1.0 inch of runoff times the total impervious area of the post-development project site.

  - For all other discharges, the volume to be treated is calculated as 0.5 inches of runoff times the total impervious area of the post-development project site.

  These volumes represent total runoff from the smaller, more frequent storms that occur annually, and the initial volumes of runoff from larger more infrequent storm events. The goal behind this decision was to fully treat the runoff from the majority of the storm events occurring annually, without approaching values where treatment system sizes would result in increasing costs with decreasing additional benefit.

  - ***Critical Areas:*** It was decided, as stated above, that 1.0 inch of runoff (as opposed to 0.5 inch) must be treated for water quality if the discharge is to a Critical Resource Area. Also, specific approved BMPs are recommended for use in particular critical areas. In addition, it was decided that spill prevention/containment methods must be included in the Stormwater Management System design.

- ***Exemptions***: Specific cases were provided exemption from the Policy, including: single family house projects, residential subdivisions with four or fewer lots that do not discharge to critical areas, and emergency repairs to highway/roadways or their drainage systems. However, none of these projects are exempt from the standard requiring sedimentation and erosion control requirements during construction activities.

  While redevelopment projects are not exempt, a redevelopment project may comply to the maximum extent possible if it can be proven that it is not practicable for the project to achieve full compliance.

- ***Operation/Maintenance***: All non-exempt projects require the development of a Stormwater Management System Operation and Maintenance Plan (O&M Plan). As defined in the Policy, the O&M Plan must contain the: names of the Stormwater Management System(s) owner and the person(s) responsible for implementing the O&M Plan, a schedule for inspection and maintenance, and a description of maintenance activities to be performed. Recommendations for specific maintenance practices and schedules are included in the Policy.

Stormwater Performance Standards

The nine Stormwater Performance Standards most accurately describe the key components of the policy that came out of the committee deliberations following resolution of the issues described above. The goal of the standards is to protect groundwater, surface water, and wetland resources from the impacts of stormwater runoff generated as a result of development and redevelopment projects. General descriptions of the standards are provided as follows:

1. No new stormwater conveyances may discharge untreated stormwater directly to, or cause erosion in wetlands or waters of the Commonwealth.

2. Post–development peak discharge rates must not exceed pre-development conditions for the 2-year and 10-year storm events under all conditions. The 100-year event must be analyzed to determine impacts and must be controlled if necessary.

3. Loss of annual recharge to groundwater should be minimized through the use of infiltration measures, to the maximum extent practicable. The recharge "requirement" which is to mimic existing annual recharge on sites to the maximum extent practical, has not been changed. However, a design methodology for estimating existing annual recharge at a site, and for designing recharge systems has been developed. The methodology uses soil classifications, soil gradation analyses and specific Massachusetts regional rainfall data as data inputs.

4. Stormwater management systems must be designed to remove 80% of the average annual (post development) load of total suspended solids (TSS). It is presumed that this standard is met when; (a) suitable nonstructural practices for source control and pollution prevention are implemented; (b) stormwater management BMPs are sized to capture the prescribed runoff volume; and (c) stormwater management BMPs are maintained and designed as specified in Volume Two. The Policy provides estimates of the percent TSS removal for individual BMPs when designed in accordance with the specified guidelines. Water quality treatment volume is 0.5 inches of runoff from impervious areas (1.0 inch if discharge is to critical environmental area).

5. Stormwater discharges from areas that are defined as having "higher potential pollutant loads" (as defined in the Policy) require specific stormwater BMPs. Infiltration of stormwater from these areas without pretreatment is prohibited.

6. Specific BMPs must be used for discharges to critical areas and the water quality treatment volume is 1.0 inch of runoff.

7. Redevelopment projects must meet the performance standards to the maximum extent practicable. It must be clearly stated why full compliance cannot be achieved and such projects must, at a minimum, improve existing conditions.

8. Erosion and sedimentation controls are required during construction.

9. An Operation and Maintenance Plan (O&M Plan) for Stormwater Management is required.

A detailed explanation of each of these Standards is available in Volume One, the Stormwater Policy Handbook.

Implementation

In order to test its effectiveness and identify potential problems, the Policy was introduced in March of 1997, prior to the promulgation of regulations. Copies of Volumes One and Two were distributed to each Conservation Commission office in the state, and to other relevant regulatory agencies. Two phases of training were provided across the state over a two-year period: first to introduce the Policy, and then to focus on detailed case studies and implementation issues. Training was made available to regulatory agencies, Conservation Commissions, local DPWs, planning departments, and engineering companies. During the training sessions, the largest turnout was from Conservation Commission representatives and engineering/consulting firms, with minimal attendance by the other groups invited.

At each of the training sessions, questions from the audience on the Policy were solicited and a list of most Frequently Asked Questions (FAQs) was developed. The FAQs provided an excellent basis for outlining where additional information and/or clarification was needed. Based on the number of recurring questions, the Committee decided to prepare a survey to solicit feedback from potential policy users. The survey was comprised of 23 questions for characterizing the respondent, determining the usefulness and ease of implementation of the Policy, identifying particular problems in understanding or implementing performance standards, and determining what type of BMPs were currently being implemented.

The survey was not designed to be a statistically valid data set, but rather to gain a practical working knowledge of what aspects of the Policy and/or its method of implementation needed to be refined. While this was generally evident from the FAQs, the survey further substantiated the specific areas where additional work was necessary. Some key findings from the 118 respondents to the survey were as follows:

- The overall sense of the Stormwater Performance Standards was that the Stormwater Policy implementation was good (63%) and that they consider the Stormwater Handbook to be a "useful resource for designing and reviewing systems (77%).
- In response to the standards, respondents were generally comfortable implementing peak discharge controls and sedimentation and erosion controls. This was not surprising since these were existing requirements in most municipalities that needed to be achieved for most development projects.
- Not surprisingly, new requirements for groundwater discharge, treatment of stormwater runoff water, and the preparation of stormwater Management O&M Plans were the standards for which additional clarification and technical support were most requested.

Feedback

The Draft Policy was issued prior to formal promulgation so that one to two years of interim implementation could be used for refinement. The FAQs, user survey, and ongoing feedback from the public defined those areas where refinements were especially necessary, including the following:

Standard No. 3 Recharge: The recharge requirement clearly created the most confusion, and required additional technical support. The original brief description included in Volume One was not sufficient for engineers or reviewers to prepare a comprehensive program for achieving the annual recharge requirement.

As a result, the technical sub-committee has focused on providing a more detailed definition of the recharge requirement and appointed a group to develop a design methodology for achieving compliance with this standard. The group has developed a methodology using soil groups and soils analysis and actual rainfall data to determine the existing annual recharge on project sites. Methodology for designing a recharge system to provide post-development recharge that best mimics pre-development conditions is being developed. This technical is currently in the final stages of development and is expected to be completed and distributed prior to December 1999.

Standard 4 - 80% TSS Removal: The Total Suspended Solids (TSS) removal requirement was not developed with the goal of removing only the TSS loads in stormwater runoff. Rather, it was considered an indicator parameter, whereby if 80% of the TSS is removed, a large portion of the additional pollutants carried in stormwater is also removed. This relationship does not hold true, however, if the proponent chooses to use only mechanical methods where settling of fines, assimilation of nutrients, or other biological processes that increase pollutant removal do not occur. For instance, a vegetated infiltrating swale, or wet pond, that is designed to provide substantial stormwater velocity reductions may greatly increase fine sediment removal and may also provide nutrient uptake in addition to gross TSS removal. A structure that removes solids only, and does not allow for detention or contact with plants or potential filtering areas does not comply with the goal/intent of the TSS removal standard.

In addition, users were having difficulty calculating TSS removals when numerous BMPs were to be used in a series. The specific percent removal rates provided in Volume One of the Policy are not additive and, as such, must be calculated as percents of the pollutant load that they receive.

In response to these issues, further definition of the goal of the TSS removal requirement and recommended practices for achieving the goal are being developed. A spreadsheet has been developed, which can be easily filled out by hand, to assist in calculating the percent TSS removal for a project based on the BMPs implemented.

Standard 9 - Operation and Maintenance: This standard has consistently raised the most concern relative to cost and implementation. Common questions were as follows:

- Who will pay for ongoing operation and maintenance of stormwater BMPs if it is not the town?
- How will the town fund the O&M requirements if they assume responsibility?
- What long-term mechanism is there to ensure that maintenance will be completed?
- What is the frequency of maintenance required for specific BMPs?

While these questions are difficult to answer, for a specific site or on a statewide basis, in terms of required maintenance, the Committee has responded by preparing operation and maintenance checklists, which may be used by the operator/owner. These checklists may be submitted to the local Conservation Commissions on an annual basis, if deemed necessary.

Specific maintenance practices and suggested frequencies have also been prepared and are currently being updated, as new information becomes available. It has also been noted that "one size does not fit all" in terms of required maintenance. For instance, an infrequently used residential guest parking area clearly does not warrant the same frequency of street sweeping as a commercial mall parking lot.

The question of financing stormwater management system operation and maintenance activities is also a site- and location-specific issue. The development of stormwater utilities and management districts is ever increasing and may be the option that some communities choose. The promulgation of the Policy as regulations will require the project proponent and/or towns and municipalities to develop a plan for ensuring O&M implementation. There are a variety of ways this may be achieved. Resolution may be somewhat facilitated in larger municipalities and/or USEPA-designated urban areas that must comply with the upcoming final USEPA NPDES Phase II Stormwater Regulations.

Summary

The development of the Massachusetts Stormwater Policy, which includes nine performance standards, was an integrated effort between state and local regulators, policy makers, engineers, developers, and the general public. The group effort and the implementation of the Policy as a Draft, to which refinements could and have been made, have contributed to the usefulness of the standards. While the development and implementation of the standards are still in the early stages, the Policy provides definitive goals for achieving stormwater water quality and quantity control, and addresses annual recharge on development sites. Until the development of these standards, there was no requirement to maximize groundwater recharge on sites or to mandate the development of the stormwater O&M Plan (unless required under other regulatory programs). These advances will provide an overall benefit to the natural resources of the Commonwealth of Massachusetts. The Stormwater Management Policy Volumes I and II may be obtained off the Internet or by request from:

Introduction

The Rouge River National Wet Weather Demonstration Project (Rouge Project) has made significant progress in restoring beneficial uses to a large, urban waterway using a holistic, "bottom up" watershed approach. This project was initiated in 1992, by the Wayne County (Michigan) Department of the Environment. The purpose of this document is to present a summary of the activities and progress of the Rouge Project; discuss the watershed approach being utilized in the Rouge Project, including the use of a general storm water permit; and summarize a community perspective on this entire effort.

Rouge Project Background and Summary of Progress to Date

The Rouge River National Wet Weather Demonstration Project is a watershed-based effort, substantially sponsored by the U.S. Environmental Protection Agency (USEPA), to manage wet weather pollution to the Rouge River, a tributary to the Detroit River in southeast Michigan (See Figure 1). The Rouge River Watershed is largely urbanized, spans approximately 438 square miles, and is home to over 1.5 million people in 48 communities in 3 counties. The Rouge River has been designated by the International Joint Commission as a significant source of pollution to the Great Lakes system.

The early focus of the Rouge Project was the control of CSOs in the older urban core portion of the downstream areas of the watershed. As a finite number of point source CSO discharges could be identified, and responsibility for each defined, the traditional regulatory approach of issuing National Pollutant Discharge Elimination System (NPDES) permits mandating corrective action worked relatively well. Additional monitoring of the river showed, however, that other sources of pollution needed to be controlled before full restoration of the river would be achieved throughout the watershed. These other sources of pollution include storm water runoff, interflow from abandoned dumps, discharges from illicit connections, discharges from failed on-site septic systems, and resuspension of contaminated sediment.

The Rouge Project is designed to identify the most efficient and cost-effective controls of wet weather pollution, while assuring maximum use of watershed resources. A great deal has been accomplished in these efforts. The following summarizes some of those accomplishments, focusing on CSO controls first. Approximately 50% of the watershed is served by separate sewer systems, with an additional 20% served by combined sewers (157 overflow points), and the

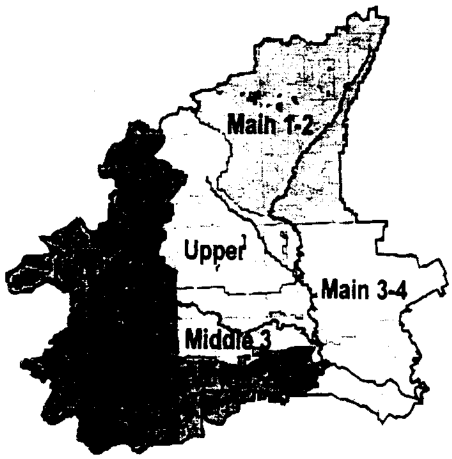

Figure 1. Rouge Subwatersheds & Location of Rouge Watershed in Michigan.

remaining area served by on-site sewage disposal systems. CSO controls are being implemented in phases. Under the first phase, six communities have separated their sewers and eight communities have constructed or are constructing 10 retention treatment basins. Each of these basins is sized for different design storms and several employ innovative technologies. A two-year evaluation study of the CSO control basins began on June 1, 1997. The results from the evaluation study, coupled with efforts to control storm water and other pollution sources in the watershed, will provide the basis for the second phase CSO control program for the remaining CSO sources in the watershed. The information gained from the evaluation of design storms and control technologies will be useful to others nationwide to determine cost-effective CSO controls to meet water quality standards.

The Rouge Project is also evaluating innovative stormwater control and watershed management technologies. Twenty-five different communities and agencies throughout the watershed are implementing over 100 pilot projects. Categories of pilot management projects currently underway include wetlands creation and restoration; structural storm water practices, such as grassed swales and detention ponds; erosion controls; stream bank stabilization; and habitat restoration, to name a few.

The Rouge Project also discovered that illicit connections and failing septic systems are major sources of pollution problems in the Detroit urban area. Creative ways to remediate these sources of pollution have been initiated.

A suite of computer models has been developed by the Rouge Project. These models simulate the water quality and quantity response of the Rouge River during wet weather events for existing and future conditions, and under various CSO and stormwater runoff management alternatives. This effort has resulted in a very useful public communication tool on water quality indices tied to actions needed to restore the Rouge River. A comprehensive geographic information system (GIS) and relational databases were designed and implemented to manage the wealth of data collected under the Project. In addition, a special data exploration tool, DataView, was developed to support routine analyses of large time-series data sets. DataView is user-friendly and readily transferable to other locations. Related to DataView is the Rouge Information Manager, also a user-friendly, readily transferable tool (an "electronic file cabinet") for accessing multi-media information about the Rouge River restoration effort.

Effective, readily transferable tools have been developed, employed by the Project, and are being shared with other cities and state agencies. Additional information on the Rouge Project can be obtained from the web site at *http:\www.rougeriver.com.*

Evolution of the Watershed Approach

The Rouge River watershed has seven subwatersheds that range in size between 19 and 89 square miles (See Figure 1). Older communities served by combined sewers dominate downstream portions of the Rouge River Watershed, while the headwater areas are typically open space, agricultural land, or low density residential developments that are undergoing rapid change due to growth pressures. Fully developed areas, typical of the middle portions of the Rouge Watershed, have separated storm sewers and limited opportunities to address stormwater problems with structural solutions.

Data gathered by the Rouge Project have shown numerous water quality and designated use problems, including high bacteria levels and low dissolved oxygen levels during wet weather events in all areas of the watershed. Fish consumption is prohibited in much of the watershed due to the threat to human health. Six of the seven subwatersheds have moderate to severe degradation of wildlife habitats, with fish populations suffering severe impairment in three of the subwatersheds. Aesthetic enjoyment is moderately to severely impaired throughout the watershed. Restrictions to small boat navigation resulting from logjams, garbage and sedimentation are a moderate to severe impairment in virtually all seven subwatersheds.

Based upon what was learned, the focus of the Rouge Project became more holistic to consider impacts from all sources of pollution and use impairments in receiving waters. The historic implementation of water quality management programs in the United States at the federal and state levels has been to focus on point sources, which are the most obvious sources of pollution to water bodies. This approach has worked well to control pollution from most point sources but has also left a patchwork of regulated and unregulated discharges of stormwater and nonpoint source pollution to surface waters. This patchwork is especially evident in most urbanized areas where multiple local jurisdictions are located in the same watershed. More subtle sources of pollution, such as stormwater, have emerged as the next priority for attention. The challenge for the Rouge Project became to develop innovative, coordinated solutions to achieve water quality objectives that may be: (1) be more cost-effective, (2) implemented in a more timely fashion, and (3) better able meet local needs.

It has become clear that water resources management must have the support of the general public in order to be effective and to become self-sustaining. A locally driven watershed approach to pollution management as a means to achieve management goals is an exciting concept discussed by many, but for which there is limited practical experience. This is particularly true in urban situations where there are multiple sources of impairment to a water body and stiff competition for limited local resources to address the pollution sources. The Rouge Project has provided a unique opportunity for a watershed-wide approach to restoring and protecting an urban river system by using a cooperative, locally based approach to pollution control.

The Michigan NPDES General Permit for Municipal Stormwater Discharges

As concern expanded to sources of pollution in the upper portion of the watershed above the CSO discharges, and water quality improvement focused more on watershed-wide approaches, the lack of a defined regulatory framework to address stormwater pollution and diffuse nonpoint source pollution became a major obstacle to further progress in improving water quality and restoring beneficial uses to the Rouge River. Beginning in 1995, the Michigan Department of Environmental Quality (MDEQ), the Rouge Project, and the communities in the Rouge Watershed jointly developed an innovative, watershed-based NPDES general permit ("General Permit") for municipal stormwater discharges. The permit was issued on July 31, 1997 (MDEQ, 1997). This collaborative process was outlined in a report entitiled "Adapting Regulatory Frameworks to Accommodating Watershed Approaches to Storm Water Management" (Fredericks, et al., 1997).

The MDEQ General Permit and USEPA's draft Phase II stormwater regulations (U.S. Environmental Protection Agency, 1998) due to be promulgated in September 1999, were developed during the same time frame. Wayne County, on behalf of the Rouge Project communities, was selected to serve on USEPA's Urban Wet Weather Flows Federal Advisory Committee, which (among other activities) assisted USEPA with the development of the Draft Phase II Stormwater Regulations. Participation on the federal advisory group on watershed approaches to stormwater management was invaluable to the development of the Michigan General Permit, and provides a high likelihood that the General Permit will be acceptable for implementing the forthcoming federal Phase II Stormwater Regulations in Michigan.

The General Permit incorporates the following elements:

General:

- Permit coverage is voluntary until the final EPA Phase II Stormwater Regulations are promulgated
- Public agencies who own, operate, or control stormwater systems are provided the opportunity for coverage
- Watershed size is established by the potential permitees during the application process
- Application and permit process have limited required actions; the focus is to establish desired outcomes.

Requires permittee to develop the following:

- *Illicit Discharge Elimination Plan* (IDEP) that has the goal of eliminating raw sewage discharges and includes addressing failing septic systems and improper connections of sanitary sewers to storm drains and open waterways.
- *Public Education Plan* (PEP) designed to inform residents and businesses about what actions they should take to protect the river.
- In cooperation with others, a *Watershed Management Plan* to resolve water quality concerns which includes: short and long-term goals for the watershed, delineation of actions needed to achieve the goals, estimated benefits and costs of management options, an opportunity for all stakeholders to participate in the process.
- *Storm Water Pollution Prevention Initiative*, which includes evaluation and implementation of pollution prevention and good housekeeping practices and the evaluation and implementation of BMPs to minimize impacts of new development and redevelopment.
- *Monitoring and Reporting Plan*, which includes a schedule for revisions to the Watershed Management Plan.

The IDEP and PEP are submitted to MDEQ at the time of application and the implementation of these plans begins when the MDEQ issues a certificate of coverage to a community/agency. Within six months after the issuance of a certificate of coverage to a community/agency, the General Permit requires the submission of a public involvement plan for approval by the state. This plan identifies the approaches that will be used within the hydrologic area to involve stakeholders in the development of a watershed plan that must be completed within 18 months after the certificate of coverage is issued. Once a consensus, long-term management plan has been completed, each agency and community within the watershed must prepare and submit for state approval its own pollution prevention initiative that identifies actions and schedules to address the pollution concerns identified in the consensus watershed plan. The watershed stormwater management plans developed by the communities and other public agencies do not require state approval; however, the individual pollution prevention initiatives emanating from the watershed planning process do require state approval, as the activities specified in the initiatives become permit requirements upon approval.

Rouge Community/Agencies Approach to Application and Permit Requirements

A total of 43 communities and agencies who own, operate, or control stormwater systems in the Rouge River Watershed have obtained coverage under Michigan's new watershed-based General Permit for municipal stormwater discharges. The result is that over 95% of the watershed is covered under this new program. The communities and agencies requested that, for purposes of the General Permit, the large Rouge watershed be subdivided into the seven subwatersheds shown in Figure 1. Long-term management plans will, therefore, be developed for each of these subwatersheds, with coordination of the plans provided by the MDEQ and the Rouge Project staff. The document "Implementing a Model Watershed Approach Through a State General Storm Water NPDES Permit" (Cave, et al., 1998) outlines key issues discussed and decisions reached by the communities as they developed their General Permit applications during 1998. The following section presents additional information regarding the application and permit requirements recently approved for the communities and agencies in the Rouge Watershed under the Michigan General Permit.

The Michigan General Permit for municipal stormwater discharges is quite flexible and allows those seeking coverage under the permit to use a wide variety of approaches to meet the public education, illicit connection/illegal discharge, and public involvement requirements. This flexible framework has allowed communities to experiment with various approaches that recognize local constraints and seize upon unique opportunities to meet the desired outcomes. While the basic requirements for what must be in the watershed plan are more detailed, the permitees within a watershed are allowed considerable freedom in deciding upon their own priorities, remedial actions, and schedules. Pollution prevention initiatives that are expected to be proposed by the communities will likely involve commitments to continue or expand current activities, like soil erosion and sedimentation control; implementation of new activities to address priority issues such as failing septic systems; and implementation of regional projects to reduce the frequency and velocity of storm flows in the river.

Table 1 and Table 2 outline the variety of public education and illicit discharge detection and elimination approaches identified by the communities and public agencies in the Rouge Lower 1 Subwatershed (Figure 1).

Across the watershed, communities actively sought ways to cooperatively address illicit connection/illegal discharge investigations and public education projects. In one subwatershed group, a community with experience in the production of videos agreed to make a river stewardship video that all other communities within the subwatershed could use on cable television, or through the distribution of cassette copies to local libraries and/or schools. In the same watershed, another community offered the use of a consultant to solicit bids for freestanding public information display boards and to develop stormwater information materials for the boards that could be used by all communities at public gatherings and inside public facilities. One community obtained the support of the local college to house and provide administrative support for a well-established non-profit organization, the Friends of the Rouge organization, whose public information activities were subsequently funded by several subwatershed groups to implement portions of their public education plans.

Advantages of Watershed Approach

The following section presents some of the lessons learned as the communities and agencies in the Rouge Watershed are beginning to implement the watershed-based, Michigan General Permit for municipal stormwater discharges.

Holistic Solutions/Local Ownership. There are distinct advantages in managing stormwater on a watershed basis. From the work already completed on the Rouge Project, it is clear that an integrated approach is needed to address all sources of water pollution and excessive flows in this urbanized watershed. By requiring those agencies and communities with responsibility for stormwater to work together at the subwatershed level to establish goals and objectives, local agencies and the state regulatory agency are forced to view solutions holistically. To achieve the desired level of river restoration, there must be integrated action plans that address not only stormwater but failing on-site sewage disposal systems (OSDS), CSOs, sanitary sewer overflows (SSOs), and significant nonpoint sources of pollution.

Ideally, a watershed-based regulatory framework should encompass all dischargers so that pollution sources can be addressed holistically. Practically, it must be recognized that prior NPDES permit programs at the state and federal level are already in place for municipal and industrial point source waste treatment discharges, and for many industrial and commercial stormwater discharges. While the Michigan watershed-based stormwater General Permit covers only public agencies that own, operate, or control stormwater conveyance systems not currently under a Phase I Stormwater Permit, the required watershed management plan does provide a framework for integrating activities under other permit programs. In addition, the General Permit gives communities and agencies the flexibility and encouragement to incorporate nonpoint source controls and pollution prevention activities as part of the required watershed management plan. For example, many

Table 1. Illicit Discharge Elimination Activities to be Implemented under Michigan Stormwater General Permit in Communities in Lower 1 Subwatershed, Rouge River Watershed

	Activity	Canton Township	Plymouth Township	Van Buren Township	Wayne County	Salem Township	Superior Township	Ypsilanti Township
Legal Basis	Existing ordinances for control of illicit connections and/or OSS have been determined sufficient or community/agency will evaluate existing ordinances	x	x	x		x	x	x

Utilize "Our Actions" display at various community events	x		x		x	x

communities have initiated pilot projects to evaluate how stormwater best management practices (BMPs) will control stormwater flow and prevent pollution. In some cases, these pilot projects have permanently changed the way communities and/or government agencies manage stormwater. These management practices will be included, as part of a watershed management plan, and credit will be given to the entities that are performing those functions.

Many of the subwatershed units selected in the Rouge River Watershed involve communities that have combined sewers, separated sewers, and OSDS. Some individual communities have all three within their corporate limits. Once the communities began to work together at the subwatershed level to establish goals to achieve water quality standards necessary to restore the river, each found that they had a significant role in the process and that the control of flow in the rapidly developing headwater areas was as significant as CSO problems in the lower portion of the watershed. Evaluating the sources of water quality problems and/or the threats to existing uses of the river at the subwatershed level by local agencies is leading to a better understanding of local constraints, opportunities for innovative solutions, ownership of the long-term river restoration effort, and interagency cooperation.

Overcoming Institutional/Regulatory Barriers. Local agencies and communities in urbanized areas have a long history of cooperative efforts to address the delivery of common public services. Recent trends in Michigan, and elsewhere in the country, to reduce the size and cost of government and limit local taxing power have accelerated efforts at the local level to integrate or share the cost of a broad range of government services. Local agencies are increasingly seeking ways with their neighboring jurisdictions to reduce the cost of police and fire protection, solid waste disposal, libraries, recreational facilities, infrastructure maintenance and repairs, public transit, water supplies, and sewage disposal. Unfortunately, except in a few isolated instances where a single authority has been created to oversee all aspects of water management, the legal responsibility for stormwater is widely dispersed among local communities, county health and drain agencies, road agencies, private developers, and autonomous school districts and public colleges. The creation of a new level of government in the form of a water management authority with broad powers has been resoundingly rejected in the Rouge River watershed by local agencies and is likely to receive the same reception in many other urban areas of the country.

State and federal water quality regulatory programs have traditionally focused on large point sources where responsibility for obtaining and complying with specific permit limits is easy to establish. The regulatory framework to control water pollution has generally discouraged rather than encouraged cooperative solutions among communities and has relied upon command and control to achieve results. The complexities involved in addressing wet weather pollution problems in urban areas, and the widely dispersed accountability for managing stormwater, demands a new regulatory framework that will encourage cooperation among the locally responsible public agencies to design integrated, holistic solutions. The watershed approach to stormwater regulation developed in Michigan offers an opportunity to overcome the institutional and regulatory impediments that have discouraged cooperative local approaches to restoring urban watersheds.

Institutional arrangements and financing options necessary to implement the General Permit and subwatershed management plans are among the many elements the local communities in the Rouge Watershed are addressing in their working groups. As part of the subwatershed planning process, communities and agencies are also identifying issues which cross subwatershed boundaries. Rouge Project staff and the MDEQ currently provide coordination of individual subwatershed efforts and assist subwatersheds in developing a comprehensive strategy for addressing watershed-wide issues. The subwatershed communities are also identifying those activities, such as public education and water quality monitoring, that may be most cost-effectively performed throughout the entire watershed by a single entity.

Increased Local Accountability and Political Support. Building a watershed restoration project from the bottom-up by helping local communities and agencies identify problems, set their own priorities for restoration, select their own remedial measures and propose their own schedules requires a sharing of power among federal, state, and local agencies not usually found in water pollution control programs. The General Storm Water Permit program in Michigan is voluntary at this time and it has allowed state regulators the ability to provide flexibility that might not otherwise be available. It has also increased the accountability of local agencies who no longer have the freedom to blame federal and state officials for the impositions of requirements, but now are responsible for convincing local elected officials that the programs proposed are in the best long-term interest of the local residents.

Opportunities for Cost Efficiencies/Innovation. As discussed earlier, the Rouge River communities that have obtained coverage under Michigan's General Storm Water Permit and are working in subwatershed groups have already developed more cost effective and efficient methods to meet public education requirements through cooperatively developed projects. Similar joint programs are underway to train local community and agency staff in illicit discharge elimination activities and in sharing staff and equipment to conduct river and enclosed storm drain surveys. The three county health agencies are developing common approaches to permitting and inspecting OSDS. The county road agencies are working with the state highway agency to address the design, construction, and maintenance of transportation drainage systems.

The county agencies in the three counties responsible for designated storm drains are working together and with local communities toward implementing common standards for stormwater management at new developments. County and local officials have worked together to establish protocols for rapidly developing independent GIS to assure that databases can be integrated to assist in watershed-wide water quality/quantity management. The economic and political cost for each community or county agency to develop these approaches has been an impediment in the past. The watershed approach has enabled these cooperative programs to be established. It is anticipated that the pollution prevention initiatives required following completion of the watershed management plans would also involve joint projects.

Establishing a broad range of cooperative programs to address stormwater problems across jurisdictional boundaries is, in of itself, innovative. However, with the development of comprehensive watershed plans, new practical approaches to implementing total maximum daily load (TMDL) requirements of the Clean Water Act and effectively using water pollution trading options created at the state level become possible. The Rouge River National Wet Weather Demonstration Project is funding a pilot program to verify that the watershed management framework under the Michigan Stormwater General Permit can be used to meet the TMDL requirements, ahead of state schedules (and at potentially lower cost), and the objectives of the Clean Water Action Plan program. In addition, the pilot program will demonstrate how the General Permit watershed framework can be used as a basis for the proposed statewide water quality trading program currently under development.

The top-down, command-and-control approach often requires repeated threats or legal action by state and federal regulators to ensure compliance with requirements due to lack of political will at the local level. Locally generated watershed plans containing specific action schedules that have been adopted by elected boards, commissions, and councils are less likely to be abandoned or require enforcement actions to assure compliance. Peer pressure and citizen support at the local level should be sufficient incentive in most instances for each local agency to complete their responsibilities on schedule. Where legal enforcement action is required, the state and federal agencies are more likely to find support among other local agencies who have met their obligations as outlined in the joint subwatershed plan.

Conclusions and Recommendations from a Community Perspective

Local communities in southeast Michigan and the state regulatory agency are attempting, for the first time, a consensus, cooperative approach to stormwater management and regulation under the NPDES program. The Michigan General Permit is a watershed-based, general stormwater permit issued under the National Pollutant Discharge Elimination System. The permit requires permitees to immediately initiate activities, such as illicit discharge elimination, and to participate in watershed management planning for a self-determined hydrologic unit. The watershed management plan forms the basis for implementing watershed goals and objectives, including improved water quality and pollution control. This new regulatory program implements the watershed approach endorsed by USEPA and others and should facilitate watershed-based integration of control programs for different pollution sources, such as stormwater CSOs which may be present within a large, urban watershed. In addition, it is believed that the new watershed-based stormwater program in Michigan will achieve the objectives of the TMDL program, the Clean Water Action Plan Program, and water quality trading programs under development across the country. From the perspective of local communities and agencies, this approach provides optimum flexibility to solve the most pressing problems in their subwatersheds by empowering them to identify problems, choose from alternative solutions, establish priorities and schedules, and develop common strategies with neighbors. Communities and others involved in this new program are also addressing issues such as coordination of subwatershed efforts within larger watersheds.

The Rouge Project (and others) have shown that by holistically addressing all sources of pollution, a cost-effective action plan can be implemented to address impairments and restore river uses. Storm water issues cannot be corrected in a vacuum, but must be integrated into an overall solution that addresses the physical, chemical, and biological stressors in a waterway. Stormwater adversely affects all three and, therefore, must be woven into the fabric of the overall watershed management plan and watershed control program. Without this integration, stormwater control will become another "add on" program that misses an opportunity to encourage an integrated program that addresses all sources of ecosystem stress in a cost-effective, prioritized manner. The approach being followed in the Rouge River Watershed should prevent misplaced efforts and, most importantly, result in a restored Rouge River on a much faster timetable.

A key objective of the Rouge River National Wet Weather Demonstration Project has been to demonstrate alternative methods to a "command and control," top down regulatory approach for water quality protection and improvement. The alternative methods sought by the Rouge Project leverage "bottom-up" approaches that put place-based needs in the forefront and use local initiatives to make progress on water quality restoration. This approach has led to a number of institutional changes in the watershed that will help sustain the watershed management efforts into the future. From the perspective of the communities involved, the cooperative, iterative approach being followed appears to be working and is a welcome change from traditional "command and control" relationships with regulatory agencies.

The Rouge Project approach demonstrates that watersheds can be "managed." When water quality objectives can only be reached through control of CSO, stormwater, and nonpoint sources, watershed management must involve the active participation of local units of government. From a community perspective, this local involvement is critical to the overall success of the Project and to stream restoration. Also, from a community perspective, undertaking a watershed effort is not a simple matter. Watershed planning and implementation takes a large commitment of time and effort.

The communities involved in the Rouge Project have a sense of overwhelming success with the watershed restoration efforts to date. Water quality and ecosystem health are improving, and the demonstration techniques have resulted not only in concrete and steel structures, but in real institutional changes that integrate the work of stormwater and watershed improvement into the basic institutions of government. Most importantly, the public is able to utilize new canoeing areas and other river-based amenities, which are now possible due the noticeable improvement in water quality, aesthetics, and other attributes of the river. It is hoped that this effort, and the work of the Rouge River National Wet Weather Demonstration Project, will continue to identify and quantify the benefits of cooperative, watershed-based efforts to protect and restore our nations water resources.

Acknowledgments

This paper represents a summary of select elements from the ongoing efforts of many individuals and organizations involved in the restoration of the Rouge River in southeast Michigan. The authors also gratefully acknowledge the assistance of Ms. Sandra Kiser during the preparation of this manuscript.

The Rouge River National Wet Weather Demonstration Project is funded, in part, by the United States Environmental Protection Agency Grant #X995743-01 through 04 and #C995743-01. The views expressed by individual authors are their own and do not necessarily reflect those of USEPA. Mention of trade names, products, or services does not convey, and should not be interpreted as conveying, official EPA approval, endorsement, or recommendation.

California's Model Urban Runoff Program (MURP): Urban Runoff Programs for Small Municipalities

Jennifer Hays, Assistant Engineer
Public Works Department
City of Monterey, California

Cy Oggins, Coastal Program Analyst III
California Coastal Commission
Central Coast District
Santa Cruz, California

Background

Monterey Bay is a crown jewel of the California Coastline and has received special protection under the National Marine Sanctuaries Act since September 1992, and the California Coastal Act since 1976. The 5,300 square mile Monterey Bay National Marine Sanctuary includes a number of small coastal communities, and ranges from the City and County of San Francisco on the north to Cambria on the south. The cities of Monterey and Santa Cruz have long recognized that protection of the unique marine resources within the Sanctuary is critical to the economic vitality and quality of life of their communities. Monterey Bay, with its world renowned Monterey Bay Aquarium, rich bird and marine resources, recreational opportunities that include the Santa Cruz Boardwalk, and commanding vistas has become a major tourist attraction.

The Cities of Monterey and Santa Cruz developed and implemented a Model Urban Runoff Program (MURP) in a cooperative team effort with the Monterey Bay National Marine Sanctuary, the California Coastal Commission, California Regional Water Quality Control Board-Central Coast Region, and the Association of Monterey Bay Area Governments (AMBAG) funded by an EPA 319(h) grant. The MURP was developed to address and support a number of environmental regulations and initiatives that applied to the Sanctuary and adjacent coastal areas including: the Sanctuary's Water Quality Protection Program, requirements of the Coastal Zone Act Reauthorization Amendment (CZARA), Coastal Commission plans and policies, the Regional Board's watershed management initiative and basin plans, the State Water Resources Control Board's Ocean Plan and Nonpoint Source Pollution Control Program, and EPA's proposed draft Storm Water Phase II Rule (Storm Water Phase II).

The concept of the MURP originated in the Sanctuary's Water Quality Protection Program for Monterey Bay National Marine Sanctuary-Action Plan Implementing Solutions to Urban Runoff and a State's Urban Runoff Technical Advisory Committee Report, developed to address Section 6217 of CZARA.

One of the most important drivers in the development and implementation of the MURP was an initiative of municipal leaders to address the value that the community places on protecting the local creeks, streams, and wetlands and the Sanctuary's marine biological resources.

Development of Model Urban Runoff Program

A key objective of the MURP was to produce a document that would assist other communities in the development of their own urban runoff programs by providing an off-the-shelf "how-to" guidebook building on the experience gained through the development and implementation of Phase I Storm Water Management Programs. A second objective of the project was the development of Urban Runoff Management Programs for the cities of Monterey and Santa Cruz that would address the community's values and achieve early implementation of and compliance with the various regulatory programs and initiatives.

Representatives from Phase I municipalities who were responsible for the development of their programs and had gained experience in implementation were consulted throughout the project. They participated in workshops when the MURP was presented to Monterey Bay municipalities and provided extensive information and examples of material used in their communities, including what worked and what didn't. Woodward-Clyde Consultants, with its extensive experience in working with Phase I municipalities, was selected to assist the project team in developing and producing the MURP.

The cities used a conceptual framework for developing urban runoff programs appropriate for their individual needs following the guidance recommended by the MURP. It included four major steps:

- Assessment – Institutional assessment and assessment of environmental resources and sources of pollutants of concern
- Development – Program management, institutional arrangements and coordination, legal authority, and fiscal resources
- Implementation – BMPs and model programs for each of the six control measures proposed in Storm Water Phase II and for control of commercial and industrial activities
- Evaluation – Progress reporting and evaluation, water quality monitoring, and program update.

Periodic meetings were held during the two-year grant period to share, review, and comment on individual city work products, review progress, prepare and validate the MURP, and discuss early implementation actions. The Sanctuary was instrumental in the early implementation effort by providing public information and outreach support and developing public education materials. The Coastal Commission played an active role in formulating strategies for addressing Sanctuary-wide water quality and land use concerns and providing support in the development of GIS-based land use maps. Project status reports were presented to the Monterey Bay Regional Stormwater Management Task Force, AMBAG, city councils, and Monterey Bay area public works officers.

The Model Urban Runoff Program

The MURP contains these four major steps for the development and implementation of an urban runoff program, and a corresponding appendix containing additional information, examples, models, references, and contacts for further information.

The Assessment Phase of the MURP describes the importance of information gathering and research to provide an early survey of the municipalities, current policies, programs, legal authorities, and fiscal resources applied to control urban runoff. A similar institutional assessment of existing regional storm water, watershed, and other water quality control programs is recommended to avoid duplication and to identify potential conflicts, opportunities for coordination, and areas not previously addressed. This phase also provides guidance and methods for (1) describing a community's water resources and activities that can be impacted by polluted runoff, (2) mapping the storm drainage system, (3) developing a relationship of pollutant sources/activities to pollutants of concern, and (4) developing a working map to assist in targeting problem areas or pollutant sources. Coordination with and building upon existing efforts, including joining Phase I programs, is encouraged.

The Development Phase of the MURP describes the (1) selection of the program management structure, (2) identifies individual and departmental responsibilities for management of individual program elements (public education, control measures, or BMPs) and (3) coordination with other internal and external programs and agencies. The legal authority to ensure implementation of BMPs and achieve compliance with the MEP standard of the Clean Water Act was developed through use of a model ordinance. The appendices include examples of language for the amendment of Local Coastal and General Plans as required by the State of California. Revisions to the California Environmental Quality Act checklist were recommended to provide planners an additional tool to evaluate impacts of runoff from both new development and re-development. This Phase includes an estimate of staffing resources to implement each element of an urban runoff program. It also describes the use of assessment districts, storm water utility fees, and other sources of funding program implementation.

The Implementation Phase of the MURP describes eight program elements including six required by EPA's Phase II draft regulations as minimum requirements MURP program elements include (1) public involvement/participation, (2) a public education and outreach program, (3) an illicit connection and discharge detection and elimination program, (4) a municipal operations control program, (5) a construction site discharge control program, (6) a new development/redevelopment control program, (7) an optional control program for commercial facilities, and (8) an optional control program for industrial facilities. The MURP recommends objectives, BMPs, implementation activities, and methods for program evaluation and documentation. This includes measurable goals for each of the eight program elements. The appendices contain numerous examples of public participation and education; BMPs for residential areas, food service operations, municipal operations, construction sites, vehicle service facilities, and shopping centers; sample SWPPPs for corporation yards and construction sites; and reporting forms.

The Evaluation Phase describes methods for (1) determining whether water quality is improving and whether the efforts and resources are directed at the right source and pollutants of concern; (2) reporting progress using the BMP measurable goals, and (3) the developing and implementing of water quality monitoring programs and volunteer monitoring programs. This phase provides and stresses the need for procedures for modifying and updating the urban runoff program using the evaluation tools.

Each section of the MURP contains an extensive list of references to assist municipalities in obtaining additional detailed supporting information on how these programs were developed.

Implementation of the Model Urban Runoff Program

Municipalities in California's major metropolitan areas were encouraged, and in some cases required, to file for NPDES' permit coverage on an area-wide basis. Numerous smaller municipalities are already regulated by Phase I requirements. There are now approximately 260 municipalities, with a combined population of 29 million, regulated by Phase I NPDES permits in California.

In California, 76 incorporated places and counties are proposed to be automatically designated and 38 areas outside urbanized areas that could be potentially designated under Storm Water Phase II. The Monterey Bay Area has 13 incorporated places and counties that would be automatically designated. The MURP will be of significant benefit to a number of smaller California municipalities, and particularly in the area covered by this project.

Undertaken as part of a 319(h) Grant, this project was required to conduct an outreach effort to ensure early implementation of urban runoff programs. Two workshops were held in April of 1998 for planning, public works, building, parks, public information/education, and general municipal operations staff in the Monterey Bay Area. These workshops, attended by approximately 120 individuals, covered an introduction to urban runoff pollution, and regulatory requirements. They featured presentations from individuals experienced in the development and implementation of Phase I storm water management programs and included four break-out workshops covering MURP development and implementation.

The agencies participating in the development of the MURP have undertaken a number of actions, described in the following paragraphs, to implement the project recommendations.

City of Monterey

During the development of the MURP, the City of Monterey mapped watersheds, major storm drains, key streams, creeks and channels. They also identified and mapped automotive servicing facilities, restaurants, several industrial sites, and pest and weed management activities as potential sources of runoff pollution. Fifteen potential sources or activities that could contribute primary pollutants of concern were identified. The City has adopted a water quality ordinance and established a monthly storm water utility fee, currently $3.43, to implement its urban runoff management plan.

In cooperation with the Sanctuary and Coastal Watershed Council, the City has also initiated a citizens participation program to label storm drain inlets and perform volunteer monitoring (Urban Watch Stormdrain Monitoring Program). This volunteer effort led to the development of a Restaurant Outreach program to educate employees and eliminate pollution. The City has commenced implementation of BMPs for new and existing sources, conducted water quality monitoring, distributed public education material, and is currently working to implement its construction site pollution prevention program.

In cooperation with the Sanctuary, the City has obtained a grant to install and test storm water treatment devices at the Monterey Harbor and Fisherman's Wharf parking lots to determine the effectiveness of removing oil, sediment, and trash.

City of Santa Cruz

The City of Santa Cruz developed a computer-generated map of watersheds and land uses to identify potential pollutant sources. The City adopted a storm water ordinance in April 1998, regulating all water entering the storm drain system, prohibiting illicit discharges and connections, and requiring implementation of BMPs published by the City. The City has drafted BMPs for vehicle service facilities, retail shopping areas, residential areas, and food service facilities. The City Industrial Waste Inspectors will conduct initial inspections of 100 vehicle service facilities in 1999 to determine any actions which must be taken to comply with the ordinance, with second inspections scheduled to formally determine compliance. The City hosted an outreach presentation of the program and the proposed BMPs for the business community during its Pollution Prevention Week.

City of Watsonville

The City of Watsonville began implementing a storm water program in 1991, through its industrial facilities Source Control Program, and completed a bilingual storm drain stenciling program in 1992. Subsequent to the development of the MURP, the City has completed a review of existing programs and policies, developed a new storm water ordinance, started an illicit connection program that has sampled 50% of the City's storm drain outfalls, and established a public education program in cooperation with the Sanctuary. The City plans to implement a municipal, industrial, and commercial source control program, a targeted educational outreach program, and a construction and new development program.

Monterey Bay National Marine Sanctuary

The Sanctuary's Water Quality Protection Program addresses a number of water quality issues in addition to urban runoff and targets nonpoint sources of pollution. The Sanctuary's program supports the cities' urban runoff programs by developing and distributing educational materials on urban pollution and co-sponsoring teacher training workshops with the Monterey Bay Aquarium. It also collaborates with the City of Monterey on volunteer monitoring programs and public education. The Sanctuary has prepared a plan for addressing polluted runoff from agricultural lands and has received commitments from the California Farm Bureau and six regional Farm Bureaus to form a coalition to address this issue. The Coalition will focus on educating its members on polluted runoff, establishing landowner committees and pilot projects in several watersheds, and strengthening farm management practices by developing grower self monitoring and serving as a liaison with the Sanctuary and the Regional Board.

The Sanctuary and the City of Monterey have a cost-sharing agreement, which funds a Sanctuary employee at half time in return for the development of a City public education program. This agreement is going into its third year, and has resulted in the development of public education brochures, posters, exhibits, BMP pamphlets, and the Restaurant Outreach Program. Current work is focused on the development of a Public Service Announcement, a construction site education program for developers and inspectors, and signage for Monterey's Harbor.

State of California - Coastal Commission and Regional Water Quality Control Board

Implementation of the MURP has been identified as a priority in the California Nonpoint Source Pollution Control Program's first 5-Year Implementation Plan, which the State Water Resources Control Board and California Coastal Commission developed pursuant to the Clean Water Act and Coastal Zone Act Reauthorization Amendments of 1990 (CZARA). Key actions that the State will undertake include the distribution of copies of the MURP Guidebook to California cities and the providing of technical support and training to cities developing Urban Runoff Management Plans using the MURP.

The Coastal Commission intends to review the experiences of Monterey Bay Area cities in implementing the MURP and coordinating with the Central Coast Regional Water Quality Control Board to revise the MURP Guidebook as needed. The document will be made available to other small coastal cities by printed copies, CD-ROM, or Internet web site.

Summary and Conclusions

The Model Urban Runoff Program project, which is funded through a 319(h) Grant has provided small communities in the Monterey Bay Area an excellent opportunity to develop their own urban runoff programs and to develop and validate an off-the-shelf " how-to" guidebook on development of urban runoff programs. The MURP will potentially benefit over 100 communities in California that will be required to develop urban runoff programs implementing the six minimum control measures contained in EPA's draft Storm Water Phase II Rule and the requirements of Section 6217 of the Coastal Zone Act Reauthorization Act.

Over 200 local governments in the Puget Sound watershed of western Washington require new developments to install stormwater treatment systems. The retrofitting of existing developments is also often required. With the guidance of the State of Washington[1], each local jurisdiction developed a list of approved treatment technologies, mostly public domain technologies such as wet ponds and swales, in the mid-1990's. Having an approved list raises the issue of how to add new unapproved technologies, in particular the manufactured technologies such as swirl concentrators and drain inlet inserts. A protocol is needed by which local jurisdictions can determine acceptability of "unapproved" treatment technologies. This paper presents a protocol[2] recently developed to assist local jurisdictions in the Puget Sound watershed.

Protocol Structure

The protocol has four parts:

1. Performance criteria to compare currently unapproved treatment technologies with currently approved treatment technologies.

2. Types of data to be used in the evaluation and methods of sample collection.

R0019722

3. Factors that are to be considered in the evaluation other than performance.

4. Content of the report provided to the local jurisdiction by the proponent.

Method to Compare Performance

There are many problems inherent in the development of a protocol, not the least of which is that there is no agreed-upon definition as to what constitutes acceptable performance against which to judge equivalency. An informal "standard" that is much discussed and that has been adopted by some jurisdictions outside the Puget Sound region is 80% Total Suspended Solids (TSS) removal over all storms less than a specified event.

A one-number standard of 80% may be inconsistent with two complementary observations about the performance of stormwater treatment systems. The first observation[3] is that removal efficiency of sand filters is directly related to influent concentration: the higher the influent concentration the greater the efficiency. This relationship may hold for other treatment technologies. The second observation[4] in Schueler (1996) proposes that there is a lower limit to the effluent concentration.

Further, a reasonably strong and direct relationship exists between runoff rate and TSS concentration[5]. This is particularly germane to our region with its mild storm intensities. A comparison of data from our region to areas with higher average rainfall intensities indicates that we tend to have lower TSS concentrations in untreated stormwater. It is therefore possible that over an aggregate of storms, we cannot achieve 80% TSS removal in the Puget Sound region.

A more appropriate method to compare approved and unapproved technologies may be to relate efficiency to the influent concentration. This approach allows the pooling of data from sites with different pollutant concentrations.

The protocol presumes that if we are satisfied with the technologies that are currently approved, we should approve an unapproved technology with similar performance. Therefore, the starting point is to identify the performance of currently approved technologies: swales, wet vaults, wet ponds, constructed wetlands, and sand filters. The results are presented in Figures 1 through 3. The data points in the figures are of flow-weighted composite samples from individual storms. Only data from studies conducted in the maritime climate of the Pacific Northwest are used.

Although this is a large region, from northern California to southwest British Columbia, comprehensive studies have been conducted only in western Washington. Data considered acceptable are from two wet ponds, three grass swales, and two sand filters. The protocol[2] provides detail on the studies that were reviewed. The reasons for using only Pacific Northwest data differ with the technology. With wet ponds there is concern about the possible effect of differences in regional climates on effluent quality. For sand filters, possibly because of differing sand chemistry, filters used elsewhere may be able to remove dissolved phosphorus[6] and zinc[7], a capability our sands do not have. Swales studies conducted elsewhere do not provide the information needed to judge whether they were sized to criteria similar to that used in our region.

Figure 1 for TSS is used in all comparisons, and is the first performance requirement that must be met. If the receiving water is nutrient sensitive, Figure 2 is also used. If the water body is of regional significance because it supports salmon, a central issue in our region, Figure 3 is also used. Zinc was selected to represent all toxics primarily because it is the only toxic with influent concentrations that are commonly high enough to allow for the evaluation of efficiency.

Each figure has a "Line of Comparative Performance," the origins of which are discussed later. Each line is drawn so that most of the data points fall above and to the left. This is called the region of acceptable performance. The data points of the unapproved technology under consideration would be plotted using the same format. If most of the data points fall above and to the left of the "Line", it can be concluded that the candidate technology is reasonably equivalent. What constitutes "most" is up to the local jurisdiction. The protocol does not specify a hard rule but offers these suggestions as to the percentage of data points falling above the "Lines": TSS, 90%; phosphorus, 80%; and zinc, 90%. Note that low efficiencies generally occur at low influent concentrations.

FIGURE 1 TSS Evaluation

PNW data - Individual storms

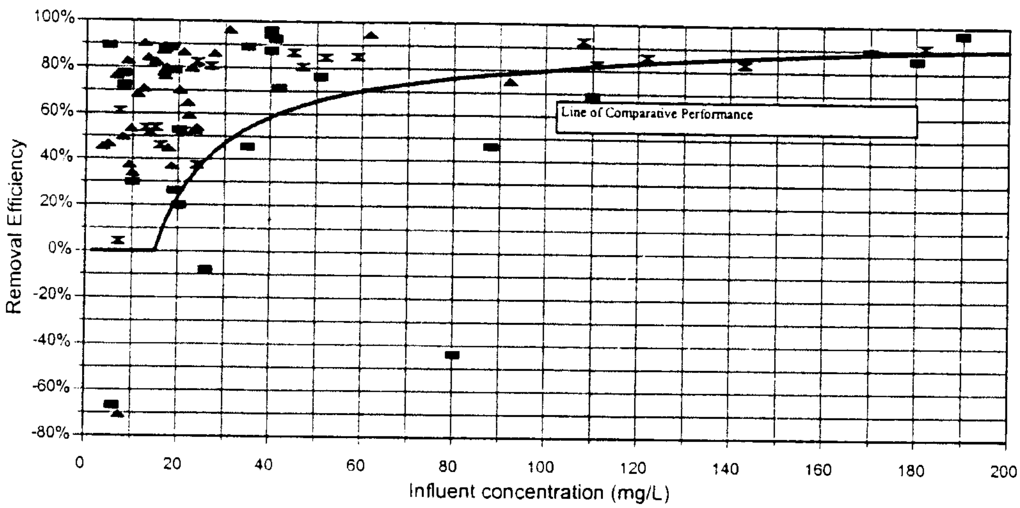

FIGURE 2 Phosphorus Evaluation

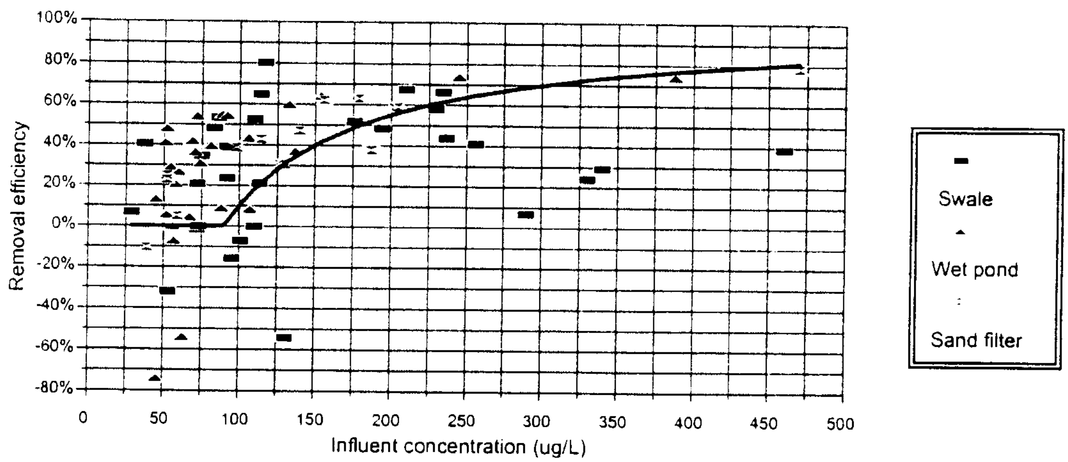
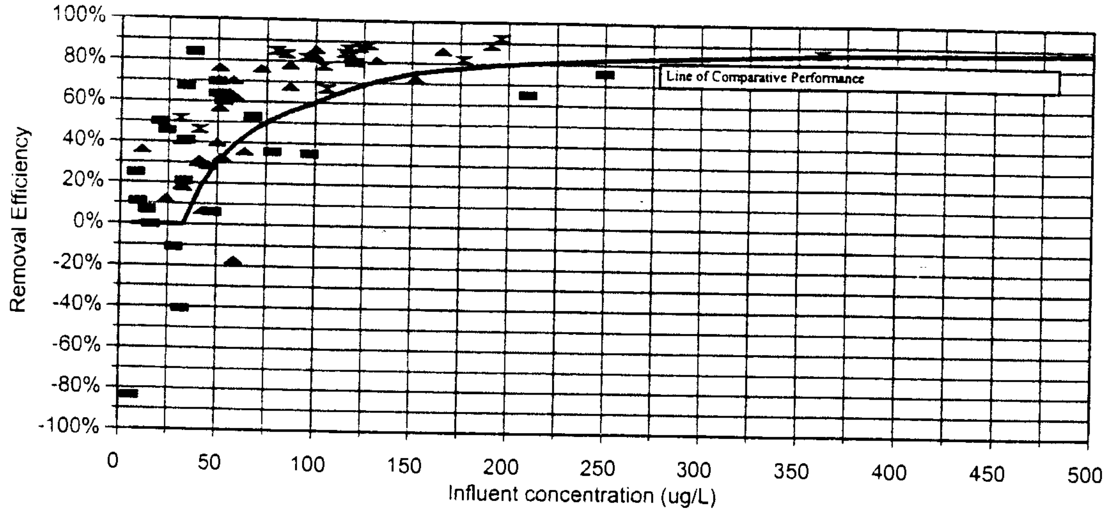
PNW data - Individual storms



How were the "lines" derived in Figures 1 through 3? Judgment was used to select a point of "irreducible" concentration, and to draw the line from this point to the upper right. Regarding "irreducible" concentrations: for TSS Tom Schueler has proposed[4] 20 to 40 mg/L, depending on the treatment BMP. A value of 15 mg/L was selected because the data in Figure 1 suggest that 15 mg/L is attainable. For TP (Figure 2), Schueler[4] proposed a concentration of 140 to 330 ug/L, depending on the treatment system. A lower value of 90 ug/L was selected for the same reasons as with TSS. Schueler[4] drew no conclusions with regard to zinc. However, his analysis[4] suggests "irreducible" concentrations of 36 ug/L for ponds and wetlands, so 35 ug/L was selected. It should be noted in Figures 1 through 3 that most of the incidents of low or negative efficiency occurred at low influent concentrations.

FIGURE 3 Zinc Evaluation
PNW data - Individual storms



Attempts were made to identify a line of best fit from which confidence limits could be derived under varying assumptions such as excluding all data below a particular influent concentration and/or removal efficiency. However, the relationships were so poor as to make confidence limits meaningless. It was concluded that basing the lines on some sort of statistical construct would give an air of rigor that is unwarranted at this time. Therefore, the lines were drawn using best professional judgment. It is expected that the Lines of Comparative Performance will change with time as additional data are collected.

Figures 1 through 3 can be used for inlet inserts if these pollutants are being considered. If, however, an insert is being considered for the removal of petroleum hydrocarbons, it must be compared to the effectiveness of oil/water separators. A graph comparable to Figures 1 through 3 is not provided for oil/water separators because of the lack of data. The criterion commonly used in the Pacific Northwest is that the concentration of individual samples shall not exceed 15 mg/L. This protocol could be used to generate data to compare to this criterion.

Data and Data Collection

It is the responsibility of the proponent of the unapproved technology, either the manufacturer or the development engineer, to obtain the required data. The protocol identifies the minimum requirements. Local jurisdictions are free to request more data. The protocol specifies the requirements for three sources of data: field studies with real storms, field studies with artificial storms, and laboratory tests. The protocol calls for discussion of advantages and disadvantages of each method. It is left to the local jurisdiction to decide the weight to place on each source of data. However, the protocol recommends that the local jurisdiction not rely solely on laboratory tests, particularly when considering the removal of dissolved pollutants or oil/grease and related products. It also recommends a size distribution of sediment for the laboratory tests.

The protocol is very specific with regard to the types and amounts of data that are to be collected. This aspect of the protocol is summarized in Table 1.

Table 1. Data Requirements

Item	Requirement
Number of test sites	One to three sites: medium density residential, retail commercial, and non-retail commercial.
Number of sampled storms	A minimum of 10 per site, total of 30 if one site
Storm depth	50% to the design storm depth (1.35" to 1.70")
Runoff duration	50% to 200% of the mean annual storm duration (7.5 to 30 hours)
Average rainfall intensity	50% to 200% of the mean annual intensity (0.02 to 0.08"/hour)
Type of samples	Flow-weight composite
Minimum aliquots per storm	10
Storm volume sampled	Samples are to be taken over not less than 75% of the total volume of each storm
Parameters	TSS, pH, total zinc, copper, and cadmium, TP, BAP, and TKN. Include dissolved metals and phosphorus if it is claimed that the technology can remove dissolved constituents. With catch basin inserts where the sole objective is the removal of petroleum hydrocarbons, measure oil/grease, TPH, TSS, and pH.
Additional	At the end of the test period, the sediment accumulated in the treatment system shall be removed, quantified, and anlyzed. The sediment shall be evaluated for total dry weight, moisture content, particle size distribution, organic content, and zinc. Use ASTM wet and dry sieve test procedures to analyze the particle size distribution. Also determine the amount of floatables, i.e. litter, and petroleum products.

The protocol states that for a data point to be used in the analysis of efficiency, the influent concentration of the parameter shall either be at least ten times its detection limit, or be greater than the "irreducible" concentration, whichever is greater.

Efficiency is to be calculated three ways.

Method 1: Removal in each sampled storm calculated as:

100 (average influent - average effluent)/average influent

Method #1 is required because it provides the data points to plot figures like Figures 1 through 3.

Method 2: Aggregate removal of the sampled storms as:

100(A-B)/A

Where: A = (influent conc. Storm 1)(flow Storm 1)+(influent conc. of Storm 2)(flow of Storm 2)

+ ... (influent conc. of Storm N)(flow of Storm N)

B = (effluent conc. of Storm 1)(flow of Storm 1)+(effluent conc. of Storm 2)(flow of Storm 2)

+ ... (effluent of Storm N)(flow of Storm N)

Method #2 is specified because it provides an overall efficiency of removal over the period of the research. If the amount of sediment that has accumulated in the bottom of the treatment facility has been determined from the separate lab test (See Section A.4), another calculation can be done to check the above estimate of efficiency. This second calculation is done as follows: subtract B from A, and then compare this difference to the amount of sediment determined from the separate laboratory test described in Section A.4. These calculations can also be done for zinc and phosphorus.

Method #3 Efficiency based on geometric mean:

100(A-B)/A

Where: A = geometric mean of all influent samples

B = geometric mean of all effluent samples

Method #3 is specified because it is the most correct method of calculating efficiency, although it has been used sparingly to-date. All influent and effluent data from multiple sites can be pooled.

Consideration of Factors Other than Performance

The protocol suggests that the local jurisdiction consider additional factors in making a decision should the technology pass the first requirement of acceptable performance. The protocol recommends the following factors, although the local jurisdiction is free to include other factors.

- Site characteristics
- Constructability
- Reliability
- Robustness
- Receiving water sensitivity
- Groundwater risk
- Operation and maintenance
- Habitat creation
- Thermal effect
- Aesthetics
- Recreational use
- Community acceptance

It is left to the reviewer to place a weight on the relative significance of each factor and to develop a scoring system. For example, the factors could be categorized and weighted as: "critical/ necessary," "important," and "desirable." A relative score, say 1 to 10, could be identified for each factor, and multiplied by the corresponding weight of each of the categories.

Content of the Applicant's Report

The proponent of the technology is responsible for producing a report for the local government conducting the evaluation. The protocol provides a very detailed list of items that are to be included in the report.

Explanation of the technology, such as:

- How it works, how it removes pollutants
- Where it is currently being used
- Available models
- Treatment and hydraulic capacities of each model
- Documentation of the treatment and hydraulic capacities
- Sediment storage capacities of each model up to the point of recommended maintenance
- Floatables storage capacities up to the point of recommended maintenance
- Sizing methodology

- Materials used in the construction of the product
- Recommended maintenance procedures and frequencies

Documentation of the field studies:

- A description of the test site including: total acreage, total impervious acreage, a description of landscaping if relevant, the acreage draining to the device if it differs from total acreage. A description of the drainage system including the size of the sumps, and whether the sumps were cleaned prior to or during the test period
- A description of the model used
- Complete drainage calculations showing the calculations to size the treatment device
- All raw data including laboratory reports. All data are to be reported including rejected data with an explanation for the rejection
- Statement from the analytical laboratory certifying that the appropriate procedures were followed in the preservation and analysis of the samples
- Calculation of efficiency of each storm by comparing influent and effluent concentrations
- Calculation of the efficiency for all storms by comparing the total aggregate inflow loading of all storms to the total aggregate outflow loading for all storms
- A graphic of data points showing influent concentration versus efficiency for each storm sampled for TSS, zinc, and phosphorus. Plot all data, including rejected data, with an explanation for the rejection
- Start and end times of the precipitation and runoff periods of each sampled storm.
- Start and end times of the sampling period of each sampled storm
- Antecedent conditions during the 72 hours prior to each sampled storm
- Total rainfall depth of each sampled storm
- Total runoff volume of each sampled storm
- Runoff volume that occurred during the period of sampling of each sampled storm
- Total rainfall during the period of all of the sampling, i.e. from the first storm sampled through the last storm sampled
- Total runoff that occurred during the period of all of the sampling, i.e. from the first storm sampled through the last storm sampled
- If artificial storms are used, identify the method and application rates of water and translate those rates into corresponding rainfall intensities
- Statement of certification signed by the proponent indicating that the protocol was followed

Additional considerations with inserts for drain inlets:

- Data showing the effect of accumulated litter and leaves on performance, flow capacities
- The point in the maintenance cycle that the field tests were run: i.e. were the units tested "fresh," without prior field exposure or were they in the field for some time

Documentation of laboratory studies:

- Description of the composition of the test water
- The size distribution of TSS in the influent and effluent
- The test flow rates
- The performance at each flow rate
- Mass balance of influent, effluent, and collected sediment

Conclusions

The protocol offers a reasonable and defensible approach that provides rationale for the consideration of technologies that are not currently approved for use in new developments as well as for public projects. The protocol is most suitable for the maritime climate of the Pacific Northwest. It is anticipated that the protocol will change over time, particularly as the data base for approved technologies becomes more extensive and as we learn from its use. More performance data are needed for public domain technologies located in our region, in particular wet vaults and constructed wetlands for which there are currently no data.

By Any Measure...

Thomas R. Adams, P.E., Vaikko P. Allen and Andrea Perley
Vortechnics, Inc.
Portland, Maine

The introduction of a diverse array of stormwater quality management tools in the last few years has created problems for the growing number of individuals and organizations who would like to compare the performance of these tools. Comparison is complicated by differences in treatment capacities, targeted pollutants, and treatment approaches. Several methods of evaluation have emerged in response to the need for verification of theoretical performance predictions; yet none of these "yardsticks" are appropriate in all situations and results from each are often not readily comparable to results from other measures.

Complicating the matter further is the confusion regarding what is being compared. In some cases, a technology will be compared with another technology. In other cases, the technology is compared to a performance standard. (Analogy: My maple syrup may be better than your maple syrup, but does that make it Grade A maple syrup?)

The confusion stemming from this is greater than meets the eye. For example, many specifiying engineers and hydrologists want to meet a performance standard of 80% TSS removal on an annual average basis. They go to guidance manuals and product manufacturers seeking something that will meet the standard. As the selection process develops, they grapple with cost, maintenance, the availability of land needed, and many other issues under the heading of "cost-effectiveness" for their clients. But by the time the selection has been made, it has become more a question of who has the better maple syrup rather than whether or not the selected product meets the standard. That is partly because 80% TSS removal on an average annual basis is virtually an impossible standard to achieve.

It ***is not the purpose*** of this paper to propose the adoption of one standard over another.

It ***is the purpose*** of this paper to review the merits of various measures of performance and, more importantly, to stress that any monitoring program that attempts to measure performance of a stormwater quality management system should begin with a consideration of how the observations will be reported.

Any monitoring program will consist of:

- Sampling
- Testing
- Reporting

Often, researchers start with the selection of samplers and procede with questions of deployment and maintenance of the samplers. Only when samples have been collected are the questions of testing, and eventually reporting, given much thought. We propose that the reporting aspect, even though it is "last" chronologically, should dictate how the testing and sampling are done. For example, if the report is considered most informative when its focus is the mass of pollutants removed, as is often the case, there is no need for samplers. To get those results usually requires only the very simple task of periodically measuring accumulations of precipitated sediments or floatable petroleum products (or other pollutants) and doing simple arithmetic calculations to determine the mass removed. We know of projects that went to the extraordinary effort that it takes to procure, set up, operate, and maintain automatic samplers to obtain influent and effluent concentrations, only to "back into" an estimate of the mass of pollutants removed by a convoluted set of "volume-times-concentration" calculations. This is a classic case of doing something the hard way, not to mention the very expensive way. So the first rule of thumb for any monitoring project is to ***decide first how to report the results***. Then design the sampling and testing around the information that is to be reported.

In this paper, we will present the following four "measures" of performance from which to choose in making those decisions. We consider these measures to be the current "status quo of the art."

- Mass of pollutants removed
- Event mean concentration (EMC)
- Lines of Comparative Performance (Minton, et. al.)
- Plotting efficiency versus operating rate

First, we would like to discuss in some detail some of the broader issues involved in monitoring stormwater treatment systems and measuring and reporting on their performance.

Setting

The setting is nearly always in the field or in a laboratory. We feel that the many benefits of testing in a laboratory are generally underestimated by technical professionals and non-professionals alike. What we refer to as the setting tends to be pre-determined well before a study gets underway. Since the setting tends to influence the important decision of what performance measure is best, this cursory overview is provided for perspective.

Field testing

The drawback with field testing is that it cannot be replicated very well. Every site is different. Every storm is different. There are "wet years" and "dry years." There are seasonal variations that can produce easily treated heavy sediment loads in winter and spring; hard-to-treat loadings, such as pollen and grass clippings, in summer; and moderately treatable loadings (leaves etc.) in the fall. It is poor science to compare the results of a field test of any treatment system to the results of a test of the same system at a different time and place.

Still, field testing has tremendous appeal because the stormwater and the sediments are "real."

- Field testing of individual facilities is usually adopted to evaluate the facility's performance in comparison to a performance standard (such as 80% TSS removal) to see if it "measures up." This setting is the simplest and most common, and is adaptable to any of the measures. The treatment system can be set up to treat all runoff or it can bypass flows that exceed the treatment capacity.

- "Side-by-side" field testing of several different facilities is increasingly popular, at least in concept. But, to our knowledge, this approach has not yet been successfully implemented. A key element is the design of the "flow-splitter" that takes all of the runoff and "splits" it into an equivalent discharge to each treatment system. The easy part of the design of the flow-splitter is achieving equal flow rates of ***water*** to each of the facilities (and even this "easy part" is not always all that easy). The hard part is getting equal discharge of ***pollutants*** to each of the facilities.

Whether testing an individual system or multiple systems, researchers have the potential to learn something very basic and very important from field testing that has, to our knowledge, eluded researchers to date. That is the determination of an appropriate threshold for bypassing peak flows. Consider a site that is estimated by conventional runoff modeling to discharge stormwater runoff at a rate of 3 CFS in a 10-year storm. Consider further two proposals for treatment. One claims efficiency of 90% and a treatment capacity of 1 CFS. The other claims 80% and a treatment capacity of 3 CFS. Which treatment option should be selected? If the prevalent standard of 80% is in place, the "safe" choice would seem to be treating all runoff from a 10-year event with 80% efficiency. But what if price is a factor? Maybe the system with 1 CFS capacity costs less. Even at the same cost, would 90% efficient be preferable to 80%? And with that consideration comes the $64,000 question. Will the system that claims 90% efficiency with a capacity of just 1 CFS even meet the standard of 80% overall? How much of the pollutant load will bypass the system altogether?

Some proponents of small-flow/high-efficiency technologies have stated that 90% of all storms are less than 1 inch of total rainfall and, therefore, treating 90% of all rain at 90% efficiency will yield a net annual removal of 81%. This argument is fundamentally flawed. It assumes that the 90% of rain from small storms carries 90% of the pollutants. This is simply not the case. The rate of mobilization of virtually all pollutants depends on rainfall intensity, not depth of rain. Therefore, it is important to treat high-intensity flows resulting from the ***infrequent event***, which tend to carry a disproportionately high pollutant load.

If 1 inch of rain falls in 24 hours, virtually any system that is reasonably proportioned, designed and, of course, maintained for the treatment of stormwater will do a good job. Efficiencies of TSS removal should be in the 90% range if the runoff is fairly dirty with silty-to-fine sandy sediments.

It is questionable, however, as to whether or not all of the runoff would be dirty if the rain that produced the runoff totaled 1 inch and fell over a 24-hour period. Intuitively, the "last flush" of such a storm would be very clean. But even the first flush may be very clean in comparison to what it would be if 1 inch of rain fell in 1 hour. This highly variable "dirtiness" gives rise to another interesting question when trying to measure efficiency. That is the question of how to account for the inevitable reduction in treatment efficiency when the water to be treated is clean in the first place. No treatment system can remove what is not there. So it has been argued that some accounting should be made for the fact that there is some lower limit to the physical treatment that can be provided. Minton's "Lines Of Comparative Performance" (see figure 2.) take this important consideration into account and are discussed later.

The "Double Whammy" of the "2-Month Storm"

Infrequent, high-intensity storms are important to the effective treatment of stormwater for two reasons:

- Over time, the higher intensity of less-frequent rainfalls, and the resulting higher stormwater runoff velocity, is what transports most of the sediment off of streets.
- The treatment facility is overloaded by the high flow of water that is transporting the sediment at the same time that most of the sediment is being transported to it.

Schueler and Shepp (1993) performed monthly observations documenting a random pattern of accumulation and loss of sediment in a study of 17 different oil/grit separators in Maryland. Overall, the losses of sediment "outnumbered" the accumulations. In other words, the observed systems lost previously accumulated sediments ***once every two months.*** We have inferred from their work that the "2-month storm" is a reasonable benchmark for stormwater treatment. To be "measurably" better than the poorly reputed conventional oil/grit separator, a system or a facility should be able to demonstrate, at a minimum, that it can continue to function in the 2-month storm. If a system is found to lose sediment in a 2-month storm, it should not be considered any better than conventional technology. Similarly, if a system needs a bypass to protect it from washing out in 2-month storms, it should be considered only marginally better than conventional oil/grit separators. Bearing in mind that high flows transport much of the total sediment, treatment systems should be able to handle more than ***the 2-month storm without bypass.*** Otherwise, much of the total sediment load may be discharged to the receiving waters that the system is supposed to protect.

Clearly the statements of the preceeding paragraph are more of a hypothesis than a statement of fact. One way to validate or invalidate the hypothesis is described in the following section on side-by-side testing in the field.

Side-By-Side Testing

Testing stormwater facilities "side-by-side" has recently become a very popular idea. The premise is that a well-run comparison of systems treating "the same stormwater and the same pollutants at the same rates of flow" will go a long way to reduce the tremendous "scatter" in the data that has been obtained to-date by testing individual systems at different sites. If two systems are evaluated at different sites, even if the study is carried out by the same researchers using the same protocol, the results will probably not be comparable. Every site is different, and from the point of view of stormwater treatment, differences that appear slight can actually be significant. We have observed a dozen systems installed on a single site (a large shopping mall parking lot) which were specified by the same engineer and installed by the same contractor at more or less the same time and, of course, subjected to the same weather. They exhibited decidedly different results when we measured sediment accumulations in the systems. The sediment depths ranged from a light dusting to accumulations of over two feet in less than a year.

So it is important in "side-by-side" testing that there be just one flow stream to the two (or more) systems being tested and that the flows be split, so that each system gets exactly the same rate of flow and the same pollutant concentration at all times.

The main benefit of "side-by-side" testing is that it can provide an answer to the question, posed earlier, of whether it is preferable to have, the arrangement should be as shown in Figure 1.

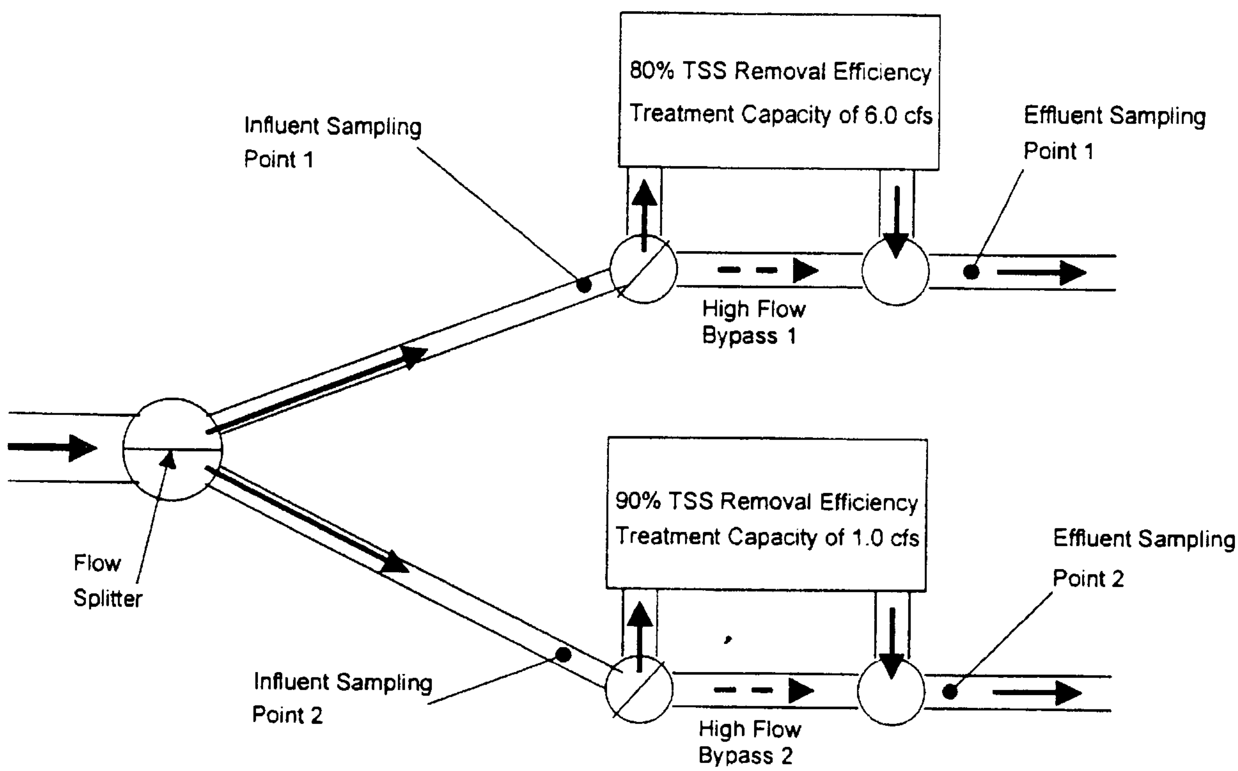

Figure 1. Recommended Arrangement For Side-by-Side Field Testing.

By sampling at points 1 and 2, the overall efficiency of the treatment system and bypass can be assessed objectively. Also, the question of "Which is the better system?" is answered. There are two shortcomings:

- Lack of repeatability. If one system gets 80% efficiency overall and the other gets 70% overall during one year of testing, there is no assurance whatsoever that either number will be repeated the next year. The test results should be regarded as indicative of performance. They are certainly not an assurance of performance over time. Such is the inconsistency, or "noisiness," of stormwater treatment data. A study like this should be conducted over a period of no less than two years. If the second year's results are reasonably close (in terms of statistical correlation) to the first, it can be considered complete. If not, it would be tempting to average all results. We feel that it would be poor science to do so, however. With the seasonal variability of stormwater pollutant loadings, one year's results will produce a single data point. A second year's results will produce a second data point. Many people seem to regard each storm result as a single data point, but as long as standards continue to be based on "average annual removal efficiencies," that is simply not the case.

- Variability with other sites. We have already mentioned the differences from one site to the next. The basic premise of side-by-side testing is to determine relative performance of two or more systems (i.e., which is best). As long as such a study is limited to this premise, the variability from one site to the next will not be a problem. But we know from experience that any "study," even the most cursory, tends to be overly generalized. We can only caution against doing so.

Laboratory Testing

Testing stormwater treatment systems in a laboratory setting offers some very significant advantages over field testing.

- It is repeatable and demonstrable.
- It is more productive in the sense that decades of rainfall can be simulated in a matter of days.
- It is more economical in terms of labor, sampling equipment, and flow-metering equipment costs.

Laboratory testing achieves these benefits by controlling operating rates, particle sizes, and pollutant loading. When influent concentrations are very low, removal efficiency will be low; but for concentrations that are generally recognized as representative for stormwater, all concentrations tend to produce comparable removal efficiencies.

In the lab, a set of tests can be run using one particle size (at representative concentrations) at operating rates from zero to the system's capacity. At the conclusion of these tests, a curve can be drawn plotting efficiency versus operating rate on the y-axis and x-axis, respectively. Such a curve typically slopes downward to the right, reflecting reduced efficiency and higher operating rates. Any point along a constructed curve should be reasonably reproducible when using the same influent sediment load.

Subsequently, a whole family of other curves can be constructed using different particles. Also, to more closely simulate "typical" sediment, a graded sediment sample can be developed and tested in the same way.

Laboratory testing should not be considered the "last word" in documentation of a system's performance, but can be considered a "benchmark" which is very useful in comparing systems operating at flow rates up to their capacity. Some field testing, where it is feasible, should supplement the work in the lab and, as previously discussed, side-by-side field testing is the only way to determine the impacts of bypasses on different systems.

The Four Most Common Measures of Performance

1. Mass of Pollutants Removed

This is easily the simplest approach to stormwater treatment measurements in the field. By measuring the depths of sediment accumulations in the facility on a periodic basis, it becomes a simple arithmetic exercise to calculate the volume and mass of sediments removed by the system.

Additional information is made available by this measurement. It may be recalled, from our earlier discussion of the 2-month storm, that Schueler and Shepp used measurements of sediment accumulations to document the poor performance of conventional oil/grit separators.

Researchers should consider using the same approach for the newer technologies that have come along since their important work was published. The approach can be made even more informative by correlating observations to such things as activities in the drainage area (e.g., winter sanding, sweeping, a spill, etc.) or meteorological events such as observed rainfall intensities or precipitation depths.

2. Event Mean Concentration (EMC)

These are sometimes referred to as "flow-weighted" or "flow-based composite" samples. They are nearly always obtained using automatic samplers, a flow-meter and a flow totalizer that arithmetically converts the flow rate measured by the flow-meter to flow volume over time and keeps track of the volume.

The sampler receives a signal that causes it to take a sub-sample when a programmed volume of flow is measured. For example, one sub-sample might be taken every 200 cubic feet of flow through the system. Over the course of the storm, all sub-samples would be combined into one large sample container from which the concentration will be obtained that represents the flow- weighted average for the entire storm.

Without a flow meter, the samplers could be set up to take a "time-based composite" sample; i.e., to sample every 30 minutes. Flow-weighted samples are much more representative, as a simple example will show. Consider a volume of 1,000 gallons with a uniform concentration of 300 mg/l flowing at a uniform rate past the sampling point in 15 minutes, followed by half as much volume (500 gallons) with a 100 mg/l concentration flowing by in the next 15 minutes. The correct representation of the concentration would be calculated as:

$$\frac{(1{,}000\,x\,300)+(500\,x\,100)}{1{,}000+500}=223$$

Flow-weighted sampling will more accurately reflect this. For example, if the sampler were programmed to pull a sample every 500 gallons, then 2 samples at the higher concentration would be taken and just one at the lower concentration. The average concentration would be calculated as:

$$\frac{300+300+100}{3}=223$$

Time-based sampling would, if the programmed time interval were 15 minutes, take one sample with a concentration of 300 and another with a concentration of 100, and the average would be calculated as:

$$\frac{300+100}{2}=200$$

Automatic samplers that can take flow-based composites have become a very valuable tool for sanitary engineers measuring concentrations of pollutants in wastewater. We believe that they have been too quickly applied to stormwater monitoring without regard for some of the inherent differences. Waste streams have "highs and lows" of both flow rate and concentration, but they are not nearly as wide as the variability of stormwater, which can change from flow rates of zero to a deluge in a matter of minutes and concentrations that can also exhibit a minimum of zero. These "spikes" can cause very brief periods of negative efficiency if a system is prone to washing out (as stormwater systems were shown by Schueler and Shepp to do regularly). If a wash-out occurs, it is an important phenomenon to note, but the briefly elevated concentration in the effluent will be "composited" with the rest of the (presumably lower) effluent samples. This will reduce the "event-mean-concentration," but will not reveal that a washout has occurred. Noting washouts, and the flow rate that caused them, is a very important aspect of a stormwater monitoring program; but they are not likely to ever be revealed by EMC data.

The second drawback of EMC data is that when influent concentrations drop to very low levels that cannot be further reduced by physical treatment, the efficiency, as measured by EMC's, will be reduced. This tends to obscure the fact that higher efficiencies can be achieved when they need to be achieved; i.e., when influent concentrations are higher.

3. Minton's "Lines of Comparative Performance"

It is widely acknowledged that there is a lower limit to the capabilities of physical treatment systems for stormwater. This means that it is very unlikely that effluent concentrations would ever be zero. It also means that very low concentrations would not be significantly reduced.

Minton et. al. has proposed the following mathematical expression to describe this lower limit:

$$\frac{Influent - LowerLimit}{Influent}$$

If the lower limit is 20 mg/l, then a plot of this expression is that shown in figure 2.

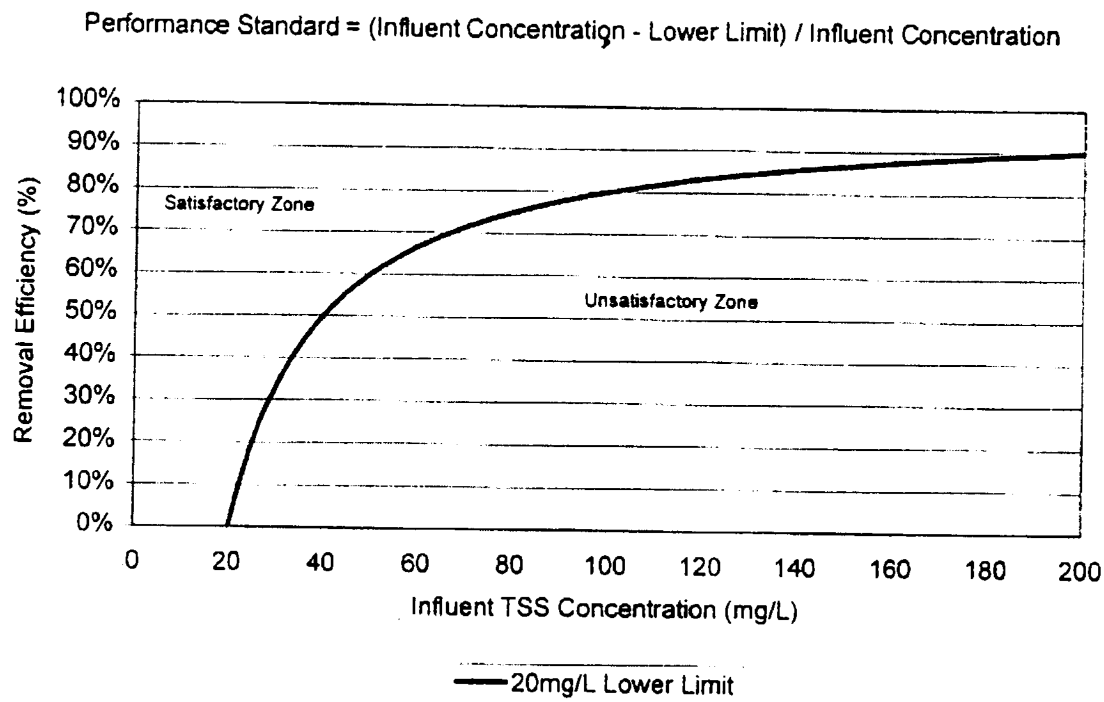

Figure 2. Line of Comparative Performance.

Plotting individual data points on such a graph can be very informative. Observed efficiencies above the line (designated a "line of comparative performance" by Minton) are considered satisfactory, while those below the line are unsatisfactory. Best of all, EMC's can be used without unfairly representing the efficiency. While the efficiency may be reduced by low influent concentrations, it may still be shown to be "satisfactory." More research will be needed to determine what is an appropriate lower-limit value to use in this approach.

4. Plotting efficiency vs. operating rate.

This approach was essentially described earlier under the heading of Laboratory Testing. By using discrete sediment particles in the laboratory, a family of curves such as those in Figure 3 can be developed.

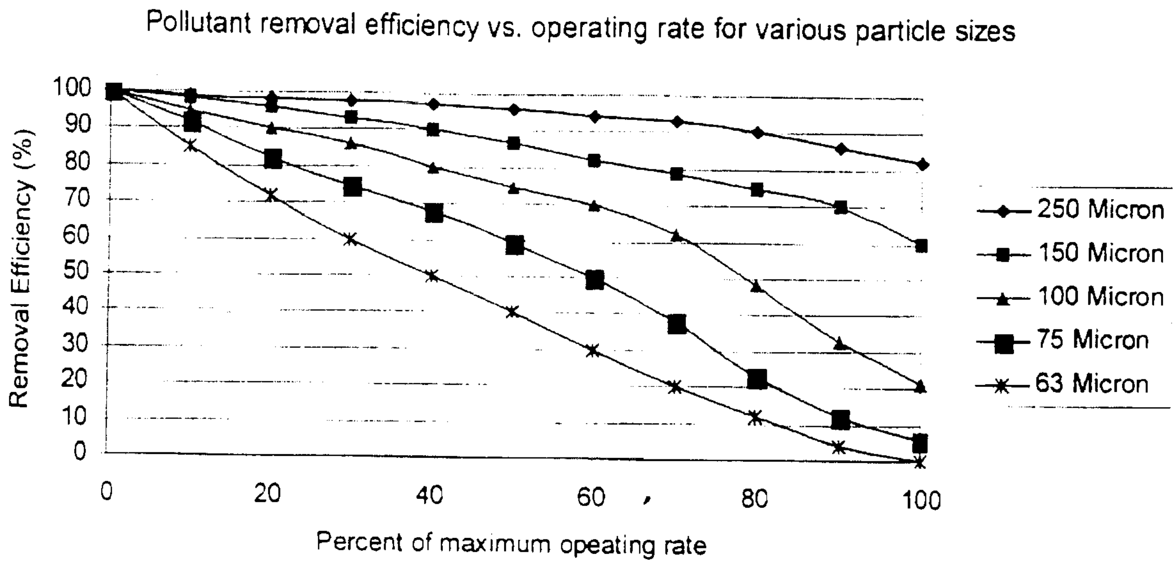

Figure 3. Removal Efficiency versus Operating Rate.

Field data is less likely to fit the relatively tight curves that can be generated in the lab. At the same operating rate, you may have vastly different influent concentrations, particle gradations, organic content, etc., depending on such factors as the time of the storm, antecedent dry period, and time of year. Removal efficiency is a function of all of these factors combined.

We feel that this performance measurement technique and presentation is the most informative. Its repeatability under controlled conditions makes it ideal for comparing one system to another. Certainly, if one system's performance curve on 100-micron particles, for example, is higher at all flow rates than another, it could reasonably be judged to be the higher efficiency system. If the curves are similar at low rates of operation, but either system drops down to zero efficiency at some higher flow rate, that flow rate should, of course, be considered the peak capacity for that system. This approach cannot show compliance with any standard for a stated percentage of TSS removal on an annual average basis.

Conclusion

To our knowledge, these four measures represent all of the techniques that have been used to measure the effectiveness of various stormwater treatment systems.

Measuring sediment accumulations in the field provides a good deal of useful information on mass removals and the ability to retain (or fail to retain) previously captured pollutants during periods of high flow. This approach costs very little to implement.

Event-mean-concentrations are the most widely accepted measure, but may not report all efficiencies and will almost certainly allow any failures to go undetected. This approach requires the use of automatic samplers at considerable cost, in terms of both time and money.

Minton's Lines of Comparative Efficiency are more fair to the treatment system because they account for the inability of any system to remove pollutants that are not present (or present in very low concentrations). If EMC data is collected to plot against the lines, then there are the same drawbacks of cost and automatic samplers allowing failures to go undetected. Both of those drawbacks can be overcome, but only with a very dedicated effort to take samples manually. Taking manual samples throughout the duration of all storms is very time-consuming and unpleasant work. For that reason, it is almost never done.

Plotting efficiency versus operating rate, whether in the field or in the laboratory, is arguably the most informative approach. In the field, automatic samplers are used (with individual samples in individual bottles and not composited), so there are those costs to consider. In the lab, samplers are needed but the construction of a model treatment facility, and the pumps and tanks to handle the required flow rates and volumes of water, will more than offset that cost saving.

Since none of these measures provides an ironclad confirmation that the widely prevalent standard of 80% TSS removal is being met, we submit that a different standard should be adopted by stormwater management jurisdictions.

Abstract

A model has been developed to estimate total suspended solids (TSS) removal using Stormceptor, an oil/sediment separator. The model was based on a commonly used, continuous simulation model United States Environmental Protection Agency Stormwater Management Model (USEPA SWMM) for hydrological processes. The suspended solids loading was estimated using build-up and wash-off equations. The solids were assumed to be distributed into five particle sizes for settling calculations. Simulations were conducted using various assumptions of loading and settling velocities to determine the sensitivity of the model to assumptions. Simulations were also conducted for a diverse range of geographic areas to determine the sensitivity of the TSS removal rates to regional hydrology. The model was sensitive to the selection of settling velocities and pollutant loading. The model was less sensitive to changes in hydrology, although significant changes in hydrology did impact TSS removal estimates.

Keywords: Stormwater; suspended solids; model; hydrology; Stormceptor, separator

Introduction

The Stormceptor is a mechanical water quality separator designed to remove oil and sediment from stormwater. A key feature of the design is an internal high flow by-pass to prevent scouring and re-suspension of previously trapped pollutants. Since the separator is based on treating "the everyday storm," the effectiveness of the separator is dependent on the distribution of pollution in stormwater and the frequency and magnitude of stormwater flows throughout the year.

In 1995, sizing guidelines were derived for the Stormceptor based on field monitoring of sludge accumulation over time in Toronto, Ontario, Canada. The accumulation data were used to derive estimates of annual total suspended solids (TSS) removal. Two key assumptions were made in the 1995 analysis to estimate TSS removal: (1) a TSS loading rate of 185 mg/l based on the USEPA's Nationwide Urban Runoff Program (NURP) median (U.S. Environmental Protection Agency, 1983), and (2) a sludge water content of 75% water. Actual Toronto rainfall data, combined with the NURP TSS concentration, provided estimates of annual TSS loading. Figure 1 shows the performance relationship derived from the Toronto monitoring, which forms the basis for the existing sizing guidelines.

Toronto rainfall time-series data (5 minute timestep) were input to a continuous hydrologic simulation model (SWMM Version 4.3) to determine the percentage of annual runoff treated based on the sizing criteria shown in Figure 1. The

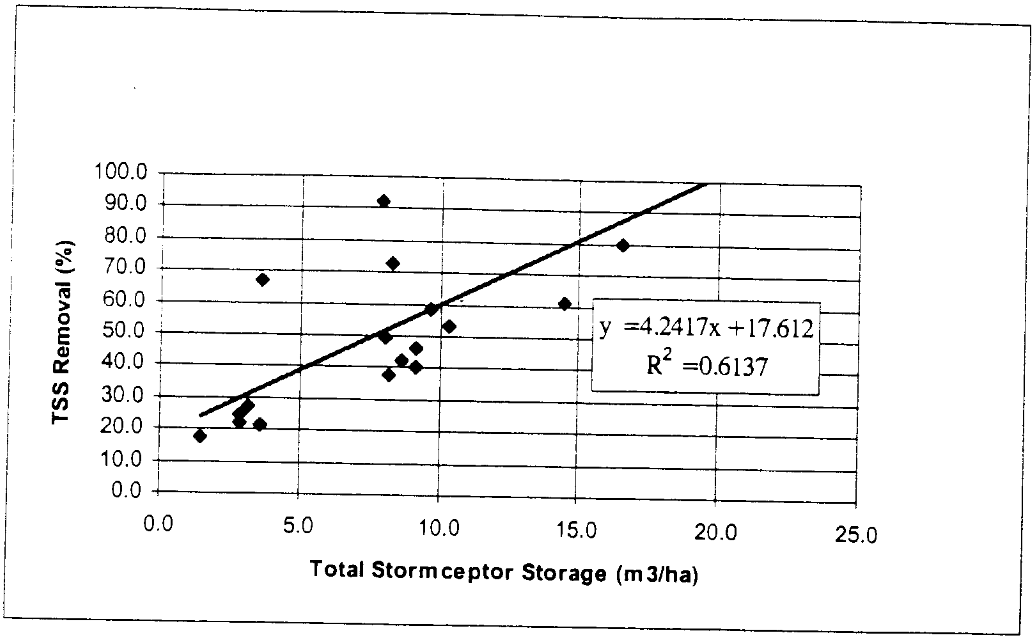

Figure 1. TSS Removal versus Stormceptor Total Storage (Toronto, 1995).

analysis of Toronto rainfall indicated that 80% - 90% of the annual runoff would be treated if the Stormceptor were sized according to these 1995 guidelines. This study was initiated to address concerns about the applicability of the Toronto-based sizing criteria to meteorological conditions in other regions.

Methodology

A computer simulation model was developed based on USEPA's SWMM Version 4.3. Solids build-up, wash-off, and settling calculations were added to the hydrology code to estimate suspended solids capture by the Stormceptor.

The model accommodates the use of either an EMC (event mean concentration) or build-up/wash-off calculations to estimate suspended solids loads. The build-up/wash-off model is more theoretically and physically correct. The EMC method has been shown to provide reasonable estimates of total solids loads (Charbeneau and Barrett, 1998) alone, if the distribution of the load is not important.

The distribution of pollutant load is important for measures that incorporate a high-flow by-pass (commonly known as "first flush" measures). Accordingly, preference is given to the build-up/wash-off calculations to correctly distribute the pollutant load with flow, recognizing the need to optimize the sizing of small-site stormwater quality measures.

In the model, solids build-up and wash-off are both approximated using an exponential distribution. The distribution of solids build-up is a function of antecedent dry days according to Equation 1 (Sartor and Boyd, 1972).

$$P_t = P_i + (PA-P_i)(1-e^{-kt}) \tag{1}$$

Where: P_t = solids accumulation up to day t (kg)
P = maximum solids build-up (2.4 kg/ha)
A = drainage area (ha)
P_i = initial solids load on the surface (not washed off from the previous storm) (kg)
k = exponential build-up factor (0.4) (days^{-1})
t = antecedent dry days

The maximum solids build-up (P) load was adjusted to provide similar long-term solids loading rates (124 mg/l) when compared to the EMC method. An exponential build-up factor (k) of 0.4 was used based on previous literature (SWMM 4.3 Users Manual). A k-value of 0.4 translates into 90% of the maximum solids build-up occurring after 5.66 days. Once the pollutant build-up reaches the 2.4 kg/ha limit, additional build-up is not allowed (assumed to be wind re-suspended/driven off the surface). Wash-off is estimated using Equation 2.

$$P_t = P_i e^{-kV} \tag{2}$$

Where: Pt = solids remaining on the surface at day t (kg)
Pi = initial solids load (from equation 1) (kg)
k = exponential decay factor (0.2) (mm^{-1})
V = volume of accumulated runoff from the surface (mm)

The exponential decay factor (k) of 0.2 was based on a review of previous literature that indicates k-values range from 0.03 to 0.55 (Alley, 1981; Charbeneau and Barrett, 1998).

Charbeneau and Barrett (1998) found that the simple wash-off model adequately described observed solids wash-off in Austin, Texas. Other researchers have cited that the wash-off Equation (2) is reasonable for fine material but may not be reasonable for larger solids that require a high rainfall intensity for mobilization (Metcalf and Eddy, 1991; Ball and Abustan, 1995). The SWMM model treats wash-off as a function of the runoff rate to account for mobilization. This correction is applied indiscriminately to the entire solids load and does not account for the variation in wash-off rate with particle size. If an "availability" factor is applied to all particle sizes uniformly, the model will underestimate the wash-off of solids with increasing runoff volume if the majority of particles are fine in size. The approach taken in this study was to use an availability factor for particles 400 μm in size or larger. Smaller particles follow the simple wash-off estimates given by Equation 2. The larger particles (≥ 400 μm) require greater runoff intensities to induce wash-off according to the availability factor provided in Equation 3.

$$A = 0.057 + 0.04(r)^{1.1} \tag{3}$$

Where: A = availability factor
r = runoff rate (mm/h)

Equation 3 is based on research by Novotny and Chesters (1997). The runoff rate is used instead of rainfall intensity, recognizing that the wash-off will lag the rainfall based on the time of concentration. The availability factor varies each timestep and is only applied to the runoff volume for that timestep, as dictated in Equation 4. The availabilty factor has an upper limit of 1.

$$V = V_i + A(V_t) \tag{4}$$

Where: V = accumulated runoff volume used in Equation 2 (mm)
V_i = accumulated runoff volume prior to current timestep (mm)
A = availability factor (equals 1 for particles smaller than 400 μm)
V_t = runoff volume for current timestep (mm)

The correction in Equation 4 effectively re-defines the accumulated runoff volume to be the runoff volume sufficient to mobilize the particles. This methodology requires more accounting in the model but provides a more physically correct wash-off model.

The separator was treated as a completely stirred tank reactor (CSTR). Alterations to the concentration of solids in the separator will vary according to Equation 5 (Tchobanoglous and Schroeder, 1987).

$$C'V = QC_i - QC_t - r_c V \tag{5}$$

Where C' = the change in concentration of solids in the tank with time (kg/m^3s)
Q = flow rate through the tank (m^3/s)
C_i = solids concentration in the influent to the tank (kg/m^3)
C_t = solids concentration in the tank (kg/m^3)
V = tank volume (m^3)
r_c = reduction in solids in the tank (kg/m^3s)

For gravity settling devices r_c can be estimated using Equation 6.

$$r_c = V_sC/D \tag{6}$$

Where r_c = reduction in solids in the tank (kg/m^3s)
Vs = settling velocity of solids (m/s)
D = depth of tank (m)
C = concentration of solids in the tank (kg/m^3)

Substituting Equation 6 into Equation 5, solving the first-order differential equation and integrating provides the general form of the non-steady state solution (Equation 7) for the concentration in the tank at time t.

$$C = QC_i/(V(V_s/D + Q/V))(1-e^{-(Vs/D + Q/V)t}) + C_te^{-(Vs/D + Q/V)t} \tag{7}$$

Where C = concentration in the tank at time t (kg/m^3)
C_i = concentration in the flow influent to the tank (kg/m^3)
C_t = concentration in the tank at the beginning of the timestep (kg/m^3)
Q = flow rate through the tank (m^3/s)
V = volume of water in the tank (m^3)
V_s = suspended solids settling velocity (m/s)
D = tank depth
t = time

Equation 7 was used to estimate the suspended solids concentration in the tank, and in the discharge from the tank each timestep. Equation 7 assumes the suspended solids are completely mixed within the tank volume.

During periods without flow (inter-event periods) the solids are not assumed completely mixed at the beginning of each timestep and the depth of suspended solids in the separator decreases each timestep until all of the solids are removed or there are subsequent flows into the separator. The concentration of solids in the tank during periods without flow was calculated using Equation 8.

$$C = C_t(1-V_st/ D) \tag{8}$$

Where: C = solids concentration in the tank (kg/m^3)
C_t = initial solids concentration in the tank at the beginning of the timestep (kg/m^3)
V_s = settling velocity (m/s)
t = timestep (s)
D = depth of solids in the separator (m)

The depth of solids (D) in the separator in Equation 8 decreases each timestep based on the settling velocity until all of the solids are removed or there are subsequent inflows to the tank.

The model can be used with either hourly or 15 minute rainfall data. Fifteen minute data are preferred, recognizing that the Stormceptor is only applicable for small drainage areas. Small drainage areas have short times of concentration and require data with a suitable timestep. Internally, the model performs calculations with a 5 minute timestep.

The choice of particle size distribution and settling velocities is a key part of the modeling exercise. Different settling velocities can be applied to the same particle size distribution, based on the specific gravity of the particles or to account for the effect of non-ideal settling or flocculation on settling. In this study, a typical stormwater particle size distribution (USEPA, 1983) was used for analysis (Table 1). The distribution given in Table 1 is commonly accepted by most regulatory agencies in North America.

The model allows the user to alter the percentages of each size based on site-specific conditions, if required. In most areas, it is anticipated that the particle size distribution will not vary significantly since it is primarily related to vehicle wear and atmospheric deposition. There may be certain instances, however, where the native soils contribute loading and the default distribution needs to be altered. The default percentages were used in our study.

Table 1. USEPA Default Particle Size Distribution

Particle Size (μm)	% by Mass
20	20
60	20
130	20
400	20
4000	20

Settling velocities were then assessed for each of the particle sizes provided in Table 1. Settling velocities were either calculated or based on empirical literature (USEPA, 1983). The calculation of settling velocities for small particles follows Stokes' law (Equation 9) since the Reynolds number (Equation 10) is less than 0.3.

$$Vs = g\,(p_s - p_w)d^2/18u \qquad (9)$$

Where
Vs = settling velocity for particle diameter d (m/s)
g = gravity (m/s^2)
p_s = density of particles (kg/m^3)
p_w = density of water (kg/m^3)
d = particle diameter (m)
u = viscosity of water (kg/ms)

$$N_R = V_s d p_w/u \qquad (10)$$

Where
N_R = Reynolds number
Vs = settling velocity for particle diameter d (m/s)
p_w = density of water (kg/m^3)
d = particle diameter (m)
u = viscosity of water (kg/ms)

If the Reynolds number is greater than 0.3, drag on the particles reduces the settling velocity. An iterative solution was used (solving for the Reynolds number, drag coefficient, and settling velocity until changes in the settling velocity were insignificant) for particle sizes with the Reynolds numbers. The drag coefficient is given by Equation 11, and the settling velocity is calculated by Equation 12.

$$C_D = 24/N_R + 3/(N_R 0.5) + 0.34 \qquad (11)$$

Where
C_D = drag coefficient
N_R = Reynolds number

$$Vs = (4g(p_s - p_w)d/(3C_D p_w))^{0.5} \qquad (12)$$

Where V_s = settling velocity for particle diameter d (m/s)
g = gravity (m/s^2)
ρ_s = density of particles (kg/m^3)
ρ_w = density of water (kg/m^3)
d = particle diameter (m)
C_D = drag coefficient

Table 2 provides a comparison of the settling velocities used in this study.

Table 2. Discrete Particle Size Settling Velocities (mm/s)

Particle Size (μm)	S.G. = 1.3 calculated	S.G. = 1.8 calculated	S.G. = 2.65 calculated	USEPA (1983) empirical
20	0.07	0.17	0.36	0.00254
60	0.59	1.57	3.23	0.02540
130	2.50	5.70	11.20	0.12700
400	16.00	37.00	65.00	0.59267
4000	180.00	300.00	450.00	5.50330

S.G. = Specific Gravity

The settling velocities that are based on the empirical USEPA data are 65 to 150 times smaller than the settling velocities based on a specific gravity of 2.65. A specific gravity of 2.65 is commonly associated with sand-size particles whereas the fines in stormwater are commonly associated with a lower specific gravity. The use of a higher specific gravity may be justified, however, if the values are considered representative of the settling velocities of fines in a flocculated or coagulated state. Research indicates that there is a high potential for coagulation amongst particles (Ball and Abustan, 1995) which will increase settling velocities and TSS removal rates. Furthermore, historical settling velocity calculations have been based on discrete particle methodologies (vertical settling column tests) that do not account for potential coagulation. Coagulation would effectively offset the settling velocity columns in Table 2 (i.e., discrete settling velocity for 60 μm represents coagulated 20 μm particle size).

Numerous field tests on the Stormceptor (Labatiuk, 1996; Henry et al., 1999; Bryant, 1995) have indicated a high percentage of fines in the Stormceptor. This empirical evidence lends credence to the coagulated settling theory, indicating that the USEPA discrete particle settling velocities may underestimate actual TSS removal rates. Settling velocities based on a specific gravity of 1.8 were chosen in this study as the default or benchmark selection. The solids loading was segmented into the particle size distribution and the concentration of solids in each particle size was tracked individually during the settling calculations.

Meteorological Data

Rainfall data from the City of Toronto (5 minute timestep, 0.25 mm resolution, 10 years record, 1987-1996) was agglomerated into 15 minute data for use with the model. Fifteen minute data were obtained for the entire U.S.A. from EarthInfo on CD ROM. Stations were selected based on location, period of record, data resolution and completeness within the period of record. Data were also obtained from CSR Humes for various stations throughout Australia. The rainfall data were converted into National Climatic Data Center (NCDC) format for input to SWMM.

Fifteen minute data were utilized, recognizing the small time of concentration that would typically be encountered in most Stormceptor applications. Simulations were also conducted using hourly data to determine the sensitivity of the results to the precipitation timestep. Numerous hourly stations were available on the EarthInfo CD for this purpose. The model uses a 5 minute timestep at all times regardless of the rainfall timestep.

Modeling Parameters

SWMM models catchments and conveyance systems based on input rain, temperature, wind speed, and evaporation data. Only rain data were used in these analyses. The default SWMM daily evaporation values (2.5 mm/day) were used. Evaporation data will not be important in this analysis since the catchment area is small (< 10 ha) and has minimal depression storage. The Horton equation was chosen for infiltration. The method of infiltration chosen is unimportant due to the small amount of pervious area (1%). Table 3 provides a list of the parameters used in the SWMM model.

Table 3. SWMM Area Parameters

Area - ha (ac)	variable
Imperviousness	99%
Width - m (ft)	variable
Slope	2%
Impervious Depression Storage - mm (in.)	4.7 (0.19)
Pervious Depression Storage - mm (in.)	0.5 (0.02)
Impervious Mannings n	0.015
Pervious Mannings n	0.25
Maximum Infiltration Rate - mm/h (in/hr)	62.5 (2.46)
Minimum Infiltration Rate - mm/h (in/hr)	10 (0.39)
Decay Rate of Infiltration (s^{-1})	0.00055

The width of catchment was assumed to be equal to twice the square root of the area.

Results

EMC versus Build-up/Wash-off

The suspended solids removal results based on the build-up/wash-off model were compared to those based on an EMC of 124 mg/l (USEPA, 1983) to demonstrate the sensitivity of the model to the different solids loading approaches. The use of an EMC assumes an equal concentration of suspended solids in all of the stormwater that is conveyed to the Stormceptor.

Figure 2 shows a comparison of results using an event mean concentration loading and build-up/wash-off loading, given the default particle size distribution and settling velocities based on a specific gravity of 1.8.

The results in Figure 2 show that the TSS removal rates using the EMC approach are lower by 14% when compared to the build-up/wash-off method even though the total loads are similar. This is expected due to the by-pass nature of the Stormceptor. The estimated TSS removals for the existing (1995) sizing guidelines, which are based on an early field study, are lower than both the EMC and build-up/wash-off estimates for low values (50% TSS removal) of separator storage/drainage area and are higher than the other estimates for larger values of separator storage/drainage area (80% TSS removal).

The range of TSS removal values based on computer modeling is smaller than the empirical TSS removal rates. Doubling the size of unit for the same area results in an increase of 30% for TSS removal, based on the current sizing guidelines, whereas the increase in performance based on the modeling is less dramatic (a 5% to 10% increase in TSS performance). This finding indicates that the modeling results will be less sensitive to changes in the model size for any given drainage area.

Selection of Settling Velocities

A comparison was made regarding the choice of settling velocities using Toronto rainfall data and the build-up/wash-off TSS generation methodology. Figure 3 provides the results of this analysis. The TSS removal estimates using the USEPA settling velocities are an average of 20% lower than the original TSS removal estimates, 29% lower than the estimates using the SG=1.3 velocities, and 39% lower than the estimates using the SG=2.65 velocities. These results indicate that the TSS removal performance results are very sensitive to the selection of settling velocities.

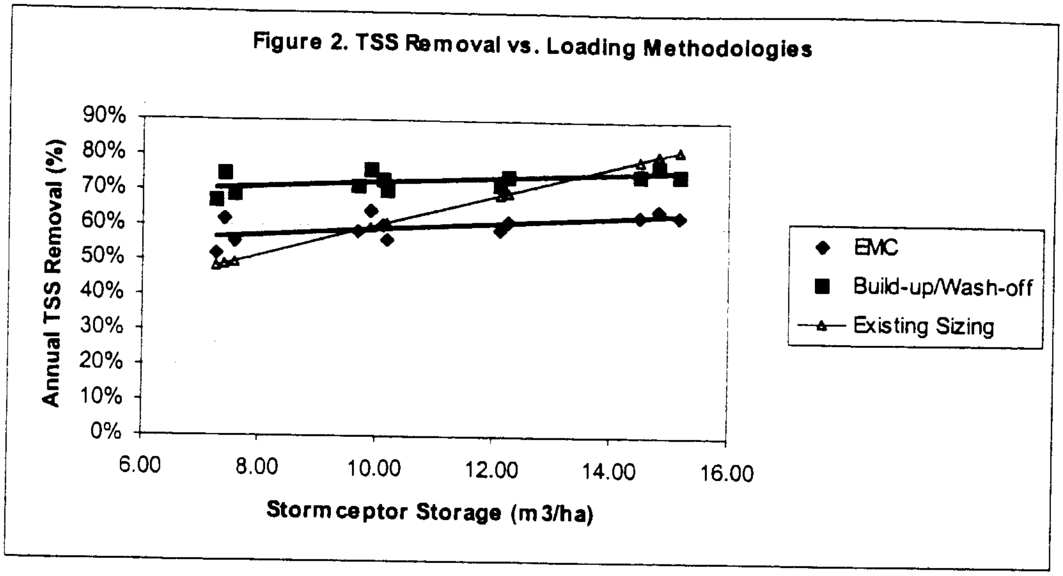

Figure 2. TSS Removal vs. Loading Methodologies.

Annual Flow Treatment

Numerous regulatory agencies design stormwater quality measures using a "design" event. The design event used generally ranges from the 25 mm storm, or annual storm, to the 25-year storm. The modified SWMM program was used to calculate the percentage of annual runoff that would be treated (not by-passed) with different by-pass flow rates. This analysis was conducted using the Toronto rainfall for a drainage area of 2.25 ha. Figure 4 shows that the volume of runoff that is treated prior to by-pass quickly becomes asymptotic with increasing treatment flow rate. A device that treats 30 L/s prior to by-pass would treat approximately 80% of the annual runoff. A device that treats 70 L/s (over 2x higher flow rate) only treats 10% more runoff (90%). Although the relationship between conveyance (% of annual runoff treated) and TSS removal is non-linear, Figure 4 shows that high-rate treatment devices are not required for small drainage areas.

The relationship provided in Figure 4 will vary with local meteorological conditions and is inherently accounted for in the TSS removal modeling.

Regional TSS Removal Performance Analysis

The model was used to compare results from different areas in North America and Australia to determine the effect of regional hydrology on TSS removal performance. All analyses were conducted using 15 minute rainfall data and based on the TSS build-up and washoff model and settling velocities for a specific gravity of 1.8.

Table 4 shows the results for various sized Stormceptors with a 2 ha drainage area. The locations of stations listed in Table 4 were selected to cover a wide geographic area, provide rainfall on a 15 minute timestep with a 0.25 mm resolution, and provide results representative of large nearby cities. Most data from city airports are recorded hourly, and therefore were not included in the comparison. The results in Table 4 are plotted in order of decreasing performance expectations in Figure 5.

Of the 16 stations analyzed, 12 stations provided TSS removal estimates within ±5% of the Toronto values.

Although the majority of stations provided similar TSS removal estimates, there were areas with significant differences. The performance estimates were lowest for the southeastern United States. This area is well know for its intense seasonal rainfall distribution. Figure 5 indicates that the TSS removal rates may vary up to 20% under different hydrological conditions on the same land use/site conditions. The use of local or regional rainfall data is therefore appropriate for design purposes.
