The extent of responses measured in stormwater samples with basic screening tests can be confirmed by conducting concentration-response tests. The derivation of $EC(LC)_{50}$ values from these tests can provide a better indication of the toxicity of stormwater samples than that available from the test responses in undiluted samples. For example samples taken at 12:00 and 12:20 during the 7/4/95 storm at KLSS showed 90% and 60% inhibition of fluorescence in the *C. dubia* IQ test and were subsequently tested using *C. dubia* IQ concentration-response tests. Table 7-11 shows the concentration ranges tested, the test responses, and the EC_{50} values derived. The lower EC_{50} value for the 12:00 sample compared to the 12:20 sample confirmed the pattern of response seen in the undiluted samples.

Table 7-11. *C. dubia* IQ Data from Concentration-Response Tests on Stormwater Samples from the 7/4/95 Storm at KLSS

Sample	% inhibition of fluorescence to *C. dubia* in undiluted samples	% inhibition of fluorescence at different concentrations (% sample)				EC_{50} (%)
		0	25	50	100	
12:00	90	5	45	75	95	28
12:20	60	5	20	45	80	52

The use of concentration-response tests is particularly valuable where a number of samples show the same level of response in undiluted samples but may show markedly different $EC(LC)_{50}$ values.

7.9.8 How Do I Use Advanced Screening to Identify the Cause of Toxicity?

The cause of moderate or highly toxic storm events can initially be investigated using the toxicity characterization element (Phase I) of the US EPA toxicity identification evaluation (TIE) procedure. Toxicity characterization involves separating the stormwater sample (and a dilution water control) into a series of fractions using processes, such as aeration, filtration through glass fiber filters, ^{18}C solid phase extraction, oxidant reduction, ethylenediamine tetraacetic acid (EDTA) chelation, and graduated pH adjustment. The KLSS consistently showed moderate toxicity during storm events, and a TIE was carried out on the 15:00 sample from the 4/25/96 storm, which initially caused 44% light inhibition in the Microtox test and 100% inhibition of fluorescence in the *C. dubia* IQ test. Toxicity characterization was carried out with the Microtox test according to the US EPA procedure described in Appendix B and indicated that the toxicity observed could have been due to a combination of volatile materials and heavy metals.

A TIE carried out on Cra storm sewer discharge (Waller et al., 1995) indicated that toxicity was due to the presence of elevated heavy metal levels, particularly zinc, which probably arose from a nearby metal plating facility. Subsequent analysis of heavy metal concentrations in discharges showed that these levels were sufficient to account for the responses measured in the Microtox tests (see Table 7-12).

Table 7-12. Comparison of Maximum Microtox Responses during Storm Events with Measured Zinc Concentrations

Date of storm	Maximum response (% light inhibition)			Zinc concentration in sample (mg/L)	EC_{50} for zinc (mg/L)
	5 mins	10 mins	20 mins		
5/24/95	16	23	47	1.27	1–2.5 (20 mins)
7/9/96	69	73	76	3.53	

The Microtox data show that light inhibition increased with increasing exposure time—evidence that the contaminants causing the response were probably dissolved heavy metals (see Section 6.3). As noted previously, information on the physicochemical parameters of samples is important in interpreting data and ascertaining the cause of toxicity. For example, sample pH and hardness have a marked effect on the toxicity of heavy metals.

7.9.9 How Do I Separate Wet Weather Effects from Other Watershed Influences in Receiving Water Samples?

The contribution of stormwater discharges to in-stream toxicity can be assessed by measuring responses in receiving water samples taken at both upstream and downstream sites as a time-sequenced series before, during, and after the storm. Identification of the impact of the storm water discharge is easiest where there is consistently limited toxicity measured at the upstream site. Analysis is complicated where there is considerable background variability in the responses observed in upstream samples outside of storm events.

Table 6-4 shows the responses in water samples from locations upstream and downstream at the KLSS measured with the Microtox and *C. dubia* IQ tests during an extended sampling program. The survey was carried out between 5/20/96 and 6/2/96 and 4 storm events. The upstream reference site

(CS REF) was on the Copper Slough approximately 50 m above the confluence with the KLSS basin, while the downstream site (DS MID) was about 100 m downstream of the confluence.

Responses in water samples at the upstream reference site were generally limited (<10 % change from pre-storm level) in both the Microtox and *C. dubia* IQ test with the exception of samples taken within a 4-h period of the start of the storms on the 5/23 (8:30) and 1/6 (17:20). These transient increases in toxicity above baseline levels probably resulted from the presence of contaminants which had entered the Copper Slough system upstream and been washed down to the reference site. Samples taken at the downstream site showed increased toxicity in the *C. dubia* IQ test immediately following the start of the 5/23 storm (that is in the 9:30 sample). Three hours after the start of the storm, the elevated toxicity seen in the *C. dubia* IQ test probably reflected the movement downstream site of contaminated water from the upstream site. Subsequent storm events resulted in no toxicity in water samples taken from the downstream site. The absence of toxicity at the downstream site following the 5/26 and 6/1 storms was consistent with the lack of toxicity measured in the samples from the storm sewer (see Table 6-3). The absence of toxicity in the storm sewer samples taken for the 5/26 storm probably reflects the limited availability of contaminants from runoff after the 5/23 storm. It indicates that it might not be worth sampling storms occurring rapidly after an initial event if that initial storm showed high toxicity (see Section 7.6.4).

Assessment of receiving water samples at the upstream (US) and downstream (DS) stations on the Copper Slough consistently showed an absence of toxicity (see Tables 6-3 and 6-4) probably due to the dilution of the storm-event discharges on the receiving water.

7.9.10 What is the Relationship of Wet Weather Toxicity to Dry Weather/Baseline Flow Toxicity?

The relationship of wet weather toxicity to baseline flow toxicity is site-specific and can be quite complicated. At one level, wet weather toxicity simply represents an acute response associated with the concentration and duration of exposure to contaminants during a storm event. Laboratory testing has verified that even short exposure durations can produce effects after the storm event has passed (see Chapter 5.0). Therefore, toxicity observed after an event, such as a fish kill days following a storm event, might be related to storm conditions and not base flow.

The relationship of wet weather flow toxicity to baseflow toxicity has been evaluated by Crunkilton et al., 1996. In their study, *Daphnia magna* and *P. promelas* were exposed for up to 14 days. Crunkilton noted, "There were no apparent differences in toxicity of organisms exposed to base flow and those that were exposed to high flow. Both were equally toxic." The critical finding in this research was the effect associated with extended exposure where seven-day tests indicated no effect and fourteen-day tests showed significant effect.

7.9.11 Does Toxicity Vary Seasonally?

At a particular location, seasonal differences in toxicity can result from event-specific characteristics, such as the length of the antecedent dry period, the intensity of rainfall, changes in the nature of deposition of materials on urban surfaces or the use of chemicals on residential or farm land, as well as receiving water characteristics (e.g., volume). However, given the potential interaction of these different factors, it might be difficult to clearly identify seasonal factors.

A simple approach would be to divide monitored storms into seasonal categories and examine the maximum responses observed in toxicity tests. This analysis was performed for data from KLSS, but no differences between seasonal toxicity were evident.

7.9.12 Does Toxicity Vary by Location within the Watershed?

For a specific event, differences in toxicity of runoff entering the receiving water system are found at various locations in a watershed due to the differences in the nature of the inputs. On a standardized loading basis, the magnitude of contaminants entering a receiving water varies according to land use and results in different levels of toxicity given the same degree of dilution. The general order of contaminant loading for different land uses from the highest to the lowest is: industrial and commercial > freeway > higher density residential > lower-density residential > open land (Horner et al., 1994). This pattern was found for basic screening tests on runoff samples collected from different land types in Fort Worth, Texas, during May, 1995 (Table 7-13). Samples were taken from the following watersheds:

- Cra, which is approximately 47 acres and dominated by industrial land use;
- Pylon, which is approximately 28 acres and contains and agricultural land use; and
- Eastern Hills, which is approximately 154 acres and consists primarily of residential areas.

The data showed that, for water samples collected from the three sites during a storm event on 5/24/95, the responses in the Microtox and *C. dubia* IQ test were most marked for Cra samples with less toxicity being recorded for the Eastern Hills and Pylon samples.

Table 7-13. Toxicity Data for Storm Event Samples Taken on 5/24/95 from Sites with Different Land Uses in Trinity River Watershed (Fort Worth)

Site	Toxicity (% response) for the 5/24/96 storm event	
	Microtox	*C. dubia* IQ
Cra	100	87
Eastern Hills	36	70
Pylon	0	30

In the receiving water, differences in toxicity at different locations can result from the volume of the receiving water and hence the available dilution at a given location.

7.9.13 Does Toxicity Vary by Region?

Toxicity differs between watersheds in different regions because of the different uses of land within those watersheds. However, for runoff samples derived from specific land uses in different regions, differences in toxicity can result from different storm event characteristics, such as rainfall intensity. In urban areas, snowmelt and the release of salt to receiving waters is a major issue in many States, but not Florida, Texas, etc., which are not subject to extreme climatic conditions.

The regional testing conducted for this project indicated that no fundamental differences in the characteristics of the toxic response to wet weather events could be attributed to specific regional characteristics. The differences in toxicity appeared to be source- and site-specific, and generally tracked a response pattern that identified both first flush and later responses, which can be attributed to resuspension of contaminants. In general, regional differences in toxicity are not of major concern, although adjustment of test procedures to accommodate regional differences in hydrology (see Table 2-1) might be needed.

CHAPTER 8.0

FIELD-BASED STORM EVENT ANALYSIS

8.1 Assessment Design Questions

8.1.1 When Do I Use In Situ Tests or Biosurveys?

Within the time-scale and biological tier testing framework, in situ tests and biosurveys find application in the event and long-term time scales and in the advanced screening and confirmatory testing tiers (see Chapter 3.0). In situ bioassays and biosurveys gives a measure of actual in-stream effects and serve as a link between laboratory-based measures (both biological and chemical) and possible ecological degradation. When a laboratory program identifies stormwater as being toxic, a second, critical step is to ascertain the actual environmental impact. In some situations, for example where receiving water dilution capacity is large, acute toxicity of stormwater might be of little or no consequence in terms of environmental degradation. Laboratory toxicity testing of receiving water samples obviously will give an indication of whether or not this is the case. However, any laboratory testing brings an artificiality to the analysis, thereby reducing its ecological relevance. Therefore, field assessments should be undertaken as a confirmatory exercise to evaluate in-stream impacts.

Studies of in-pipe toxicity at the KLSS site consistently showed moderate levels of toxicity occurring in most storms (see Table 6-4). Additionally, laboratory toxicity testing of in-stream water samples showed that toxicity was also present downstream and sometimes upstream of the point where the storm sewage discharge entered the main Copper Slough Channel (see Table 7-2). Biosurveys were undertaken at sites along the Copper Slough to ascertain the in-stream impact of the discharges (see Section 8.4), with invertebrates being sampled on three occasions using both Surber samples and kick samples.

8.1.2 When Shall I Perform an In Situ Test as Opposed to a Biosurvey?

The use of field-based assessments fits into a sequenced application of the tools available for wet weather event impact assessment. First, biosurveys should be used early in a wet weather assessment program to confirm that an in-stream impact exists. In fact, biosurvey findings often are the first indication that degradation due to storm events has occurred. Alternatively, following the identification of toxicity of a storm discharge through laboratory toxicity testing, a biosurvey can confirm whether or not receiving water is impacted. Biosurveys results can be used to tailor in situ or laboratory tests to the receiving water system by basing the choice of test organisms according to what is actually present in the receiving system.

Biosurveys generally provide the most ecologically relevant information of any type of biological testing. However, finding a receiving water impact downstream of a discharge does not necessarily imply a cause-effect relationship to a particular discharge, although it can provide strong evidence for such a relationship.

In contrast, in situ exposure experiments can be used to provide evidence of the impact of a wet weather discharge through a more controlled experiment. An exposure experiment yields the most direct evidence of a cause-and-effect relationship between storm events and in-stream effects. Exposure experiments can also be used in place of biosurveys where the natural fauna are severely impoverished due to degraded or poor quality habitat, or where marked differences in habitat preclude the selection of comparable sites for biosurvey sampling. See also Section 8.4.1.

8.1.3 Where Shall I Deploy In Situ Tests or Conduct Biosurveys?

Precise details of where to deploy in situ tests or conduct biosurveys depends largely on the study objectives and the constraints imposed by the receiving water system itself. However, a number of points must be considered.

For both biosurveys and in situ assessments, the position of sites relative to discharges is important. Firstly, appropriate reference sites are required (see Section 8.1.4). Secondly, downstream sites must take account of the physical mixing zones of discharges. A site within the immediate mixing zone might be required to examine maximum impact, but, for assessing the wider downstream impact, sites should be outside the immediate mixing zone. However, defining mixing zones is complex, and no simple guidance can be given. A third factor that should be considered when selecting sites is the danger of pseudoreplication (Hurlbert, 1988), which is the erroneous attribution of apparent differences between sites to some factor other than the true cause. This problem arises through inadequate sample replication. In situ tests and biosurveys are particularly prone to the dangers of pseudoreplication; for example, differences between a single upstream and a single downstream site could be ascribed to the impact of a discharge but in fact may be due to some other, unmeasured or unknown, factors, such as habitat differences. The use of multiple sites does not directly avoid this problem but goes some way towards avoiding erroneous conclusions.

For biosurveys, the prime consideration for selecting the exact sampling locations is site similarities. Since the objective is to compare the resident fauna or flora at two or more sites, and one of the major determinants of biological community structure is the physical habitat available, it follows that for comparisons to be meaningful, similar sites must be used. Indeed, the effects of changes in habitat can result in far greater differences in biological communities than the effect of considerable levels of contamination.

For in situ exposure assessments, site similarities are less critical but still of importance. Every effort should be made to select sites that are similar in physical factors that might effect organism health and survival, such as water depth, current velocity, shading. Figure 6-2 shows the deployment locations for in situ tests and biosurvey sampling locations on the Copper Slough Watershed.

8.1.4 What Constitutes a Reference Site?

A reference site is one that is used for comparisons with an impacted site. Two different types of reference sites exist and serve different purposes.

A **local or upstream reference site** is one that is used for direct comparison with an impacted site to infer the effect of a single discharge, multiple discharges, or runoff zone. Typically, this is a site that is upstream of the impacting discharge, or impacted area. The results from in situ deployments or biosurveys at this site are compared with results from the downstream, impacted site. Although an upstream reference site allows the identification of the impact of a particular input, it does not allow an identification of the impact of other input sources or a general degradation in water quality. Such a distinction may be assisted by use of a general or background reference site. In the KLSS system, the local reference site (CS REF) was located about 50 m upstream of the confluence of the outlet of the KLSS basin (see Figure 6-2).

A **general or background reference** site is one that is free from (major) anthropogenic influence and, as such is a measure of natural background conditions. By comparing the results of in situ deployments or biosurveys at a general reference site, an upstream reference site, and an impacted site, it is possible to infer the relative importance of the impact of the input under study in relation to that caused by other inputs. A reference site might be situated in the upper reaches of the watershed, above known inputs, or on a different, unimpacted stream. Clearly, the problems arising through pseudoreplication and the influence of other, unknown factors are likely to be greater for sites at some distance from each other, so greater care is required when interpreting results.

The Water Environment Research Foundation has published reports that discuss selection of reference reaches for use attainability analysis (Novotny et al., 1997; Michael and Moore, 1997). Much of that information would likely apply in this context. See also Section 8.1.5 of this report.

8.1.5 What Action Should I Take if a Suitable Reference Site Cannot Be Identified and Sampled?

A control site is essential for a meaningful interpretation of the results of in situ deployments of biosurveys. Without a control site, it is impossible to reliably attribute any measured effect to the storm water input(s) under investigation.

In the case of biosurveys, if a suitable control site cannot be identified (habitat dissimilarities), it might be appropriate to use an in situ technique instead. Another possibility is the use of artificial streams, but cost generally makes this an impracticable option.

With the advent of biocriteria, reference sites are now a critical component of water quality regulation and a focus of some controversy. Many States, in response to biocriteria development efforts, have identified reference streams and reference conditions. It might be possible to apply information from these non-degraded reference sites to evaluate biosurvey results.

8.1.6 When and Where Are Sediment Analysis/Assessment Efforts Needed?

Sediment toxicity assessment adds an important dimension to in situ water column toxicity assessments. Sediment toxicity is generally a chronic phenomenon resulting from sediment build-up over relatively long time scales. Thus, sediment assessments fall into the multiple event/ long-term area of the time-scale matrix.

Sediment assessments are most appropriate when significant sediment has accumulated in the receiving system and when there is interest in sediment-associated contaminants, such as heavy metals and organics. Sediment analysis might be also needed where resuspension of a significant amount of material that is known to, or suspected of, contributing to water quality problems has occurred. See also Section 8.5.1.

8.2 Sampling Questions

8.2.1 How Many Measurements Must I Take?

The number of measurements that must be made to answer a question is dependent on the precision required, the variability of the measurement process and the samples, and cost constraints (see Section 7.2). If the variabilities of the measurement process and of what is being measured are known, statistical techniques are readily available for calculating the required number of samples to attain a specified precision. This also allows estimation of the statistical power of the test to detect a given difference, i.e., the probability of concluding there is an effect when one exists. Discussions of the statistical aspects of sampling program design can be found in Mar et al., 1986; Reinelt, Horner, and Mar, 1988; Reinelt, Horner, Castensson, 1992; Horner et al., 1994.

A problem with in situ assessments and biosurveys is that the samples are usually highly variable, and variabilities are often unknown. A good starting point for deciding how many measurements to take or how many replicates to use is to assess what was done in other similar studies and how successful they were in achieving the stated objectives.

8.2.2 How Much Do Field Assessments Cost?

The cost of field assessments is quite variable and, again dependent on study objectives that define the effort and expertise required in a field assessment. The US EPA has developed Rapid Bioassessment Program (RBP) guidance (US EPA, 1989; also available from www.epa.gov/ OWOW/monitoring/AWPD/RBP/ bioasses.html) that has five protocols that require different levels of effort and expertise. These different levels of effort and expertise will have significantly different costs. For example, the level of effort for a RBP 1, a subjective analysis, is estimated to be 1 to 2 hours per station with an additional 0.5 to 1 hour for data analysis per station. Costs for this level of analysis might be as low as $200 to $500 per station. As assessment requirements increase, the level of effort and expertise costs increase. A typical screening level test involving macroinvertebrate sampling and analysis (e.g., identification to the family level for initial metric determination) costs from $500 to $2,500 per station. Addition of fisheries collections and identification of samples to the genus or species level add significantly to assessment costs. These estimates are for RBP sampling and would not include the cost of chemical analysis or supplementary toxicity testing.

8.2.3 Are Unique Devices Needed to Perform In Situ Testing or Biosurveys?

In situ deployments most commonly involve the placing of organisms in cages within the receiving system. There are no standard devices for this purpose but a number of workers have successfully used similar types of design (see Herricks, Milne, and Johnson, 1994).

For invertebrates, a small tube (usually perspex) is used, either with mesh over the ends or with sealed ends and mesh-covered openings cut into the tube. The precise size of the tube is not critical, and the number of organisms per tube can be adjusted according to the relative size of organism and tube, though many invertebrates are cannibalistic and, therefore, require individual cages. The individual tubes are usually aggregated into groups in some kind of cage or basket, which is fastened to the stream bed (e.g., with stakes) or attached to a weight (e.g., concrete block). The design and orientation of the cages in the stream must be such that sufficient water flows through but not at a velocity that might be excessive for small invertebrates, such as *Ceriodaphnia* (Sasson-Briskson and Burton, 1991).

For fish, larger cages are required and these can be constructed from a number of materials. The only important design requirement is that there is adequate flow of water and food particles.

Other types of in situ assessments include colonization samplers. These can consist of natural materials, e.g., stones held in a coarse mesh container or be of entirely artificial construction. Purpose-made colonization samplers are commercially available.

For biosurveys of invertebrates, a number of standard sampling devices are available. The commonest is a simple pond net used for kick sampling, which may have specified dimensions for the mouth and the mesh size. Others are devices, such as Surber samplers, that enclose a quadrant, with an integral net to trap dislodged organisms. For deeper water bodies, a variety of grab samplers can be used from the bank or a boat.

8.2.4 Which Organisms are Best for Field-Based Wet Weather Analysis?

In theory, any organism could be used for field-based wet weather event analysis. In practice, invertebrates and fish are most commonly used.

For in situ assessments, invertebrates are preferred over fish, because they are usually more easily collected and/or cultured and require smaller, simpler cages. Usually, organisms are deployed without food, and the maximum holding time before death ensues must be taken into consideration when selecting a test organism. For *Ceriodaphnia*, this period is 48 hours, while for *Hyalella* and similar species, and also for fish, it is around one week. Invertebrate shredders, such as *Hyalella*, can be provided with leaf material as a food source, allowing a longer deployment period.

For biosurveys, invertebrates are generally preferred to fish for several reasons. First, they are much easier to sample. Secondly, being less mobile, invertebrates provide a truer picture of recent water quality. Although invertebrates respond rapidly to adverse conditions and move away from an area by drifting, recolonization is a much slower process, requiring several weeks at least. In contrast, fish very rapidly move in response to short-term adverse conditions, such as a storm event. Also, there are well developed biotic indices based on invertebrates that provide a single index from a more complex data set. A disadvantage of invertebrates compared with fish is that sample processing and identification is much more labor intensive (see also Section 8.6).

8.2.5 How Long Should I Expect to Maintain a Sampling Program to Assess Effect?

The duration of a sampling program is largely defined by the study objectives. The use of in situ assessments and biosurveys is primarily be directed at multiple event/long-term time-scale analyses. There might be seasonal factors affecting toxicity of stormwater, (e.g., seasonal application of pesticides, seasonal storm patterns, snowmelt) which require a sampling program to cover a whole year or certain parts of the year. In situ assessments probably have a duration of weeks to months, while a biosurvey program might be ongoing for months to years.

8.3 Sources Questions

8.3.1 Do I Use Different Techniques for Different Sources?

Generally, sources are not a major factor in the selection of techniques, although knowledge of sources can direct choice. The presence of primarily non-conservative contaminants directs the focus of field assessments to event time-scale analyses, while the presence of conservative contaminants call for long-term analyses. Where a problem is known or suspected with heavy metals or organics that bind to particulate matter or accumulate in tissues, sediment tests or bioaccumulation studies might be necessary.

8.3.2 What Must I Know about Sources to Effectively Develop a Field Analysis Program?

It is desirable, but not essential, to know something about sources. Knowledge about possible toxicity sources (and, therefore, contaminants) can aid in the selection of the organisms for an assessment program. The presence of a particular contaminant should lead to the use of organisms with known sensitivity to that contaminant. For example, where ammonia is considered to be the causative agent of toxicity, fish should be used rather than invertebrates due to their greater sensitivity. In contrast, invertebrates would be more appropriate where pesticides are the suspected causative agent of toxicity.

8.3.3 How Do I Separate/Compare the Effects of Multiple Sources in a Field Analysis Program?

This is an area where understanding is poorly developed and relationships are not well understood. However, responses of particular in situ test systems and test organisms, as well as biosurvey results, might indicate differential effects of particular sources. For example, bioaccumulation studies might establish a link with a certain contaminant, possibly of particular origin. Similarly, differential responses of organisms in the community can lead to particular sources through knowledge of differing sensitivities to particular contaminants.

8.4 Wet Weather Event Questions

8.4.1 When and How Do I Use In Situ or Biosurvey Techniques for Event, Multiple Event, and/or Long-Term Analysis?

8.4.1.1 In Situ Tests

In situ assessments can fairly readily be used for event and multiple event analysis provided there is an intensive, rolling deployment program that extends over a number of months. Because events are unpredictable except in the very short-term, it is necessary to have a deployment in place, with frequent observations being taken before an event occurs so that pre-event observations can be compared with post-event observations. For long-term analysis of toxicity at a location, the rolling deployment program might need to be carried out for a year or longer. Where the time scale of interest is event, tests with relatively shorter induction times are most appropriate—for example lethality-based tests and feeding rate tests. For the multiple event and long-term time scales, these event-time-scale tests might still apply when deployed in a rolling program, as well as tests with relatively longer induction times, such as bioaccumulation tests and colonization chambers. The use of in-stream assessments is an important link between the laboratory measurement of toxicity in samples from a stormwater discharge and ecological effect, and these techniques are used primarily in a confirmatory role.

The effects of the 6/1/96 storm at KLSS were investigated using in situ tests with the invertebrates, *D. magna* and *H. azteca*, and fathead minnows (*P. promelas*). Organisms were deployed at the Copper Slough reference site (CS REF) and in the KLSS basin with sediment and without sediment (water column only) on 5/31/95 and recovered 48 hours later after the storm event. The results showed that for water column exposure, lethality was significantly higher (t-test, $P<0.05$) in the *D. magna* and *H. azteca* deployed in the KLSS compared to those at the reference site (see Table 8-1). However, no toxicity was measured in the discharge during this storm event, and the water column toxicity might have been due to the resuspension of contaminants present in the sediment at this site. For fathead minnows, there was no statistical difference between the lethality in organisms deployed at the two locations. Lethality in the organisms deployed at the reference site was less than 20% for all test species.

Table 8-1. Toxicity Data for In Situ Water Column Tests Deployed at KLSS for the 6/1/95 Storm

Location	Lethality (%) in different in situ tests		
	D. magna	*H. azteca*	*P. promelas*
CS - REF	20	17	10
KLSS Basin	100	46.7	6.7

A variety of caged invertebrates were deployed at the US and DS stations on the Copper Slough, but none showed storm-event-related toxicity responses. The lack of response at these stations suggested that the events did not cause toxicant concentrations that were sufficiently elevated to cause mortality over the short exposure periods during events.

During other studies, the project team has investigated the effects of CSOs at two sites in the United Kingdom: Pendle Water (Lancashire) and the River Trent (Staffordshire) (Milne et al., 1992). At Pendle Water, metal accumulation and mortality in caged amphipods (*Gammarus pulex)* and metal accumulation in resident mayflies (*Baetis rhodani*) were measured. On the River Trent, mortality in caged *G. pulex*, brown trout (*Salmo trutta*) and chub (*Leuciscus cephalis*) were used.

Deployments of caged *G. pulex* at sites above and below a CSO on Pendle Water for 7 to 44 days yielded evidence of acute toxicity on 3 of the 4 occasions a storm event occurred during the deployments. On the River Trent, four storm sewage discharge events during the three deployments of 33 to 44 days did not have a significant lethal effect on either caged *G. pulex* or caged fish.

8.4.1.2 Biosurvey Techniques

The use of biosurveys for event analysis is obviously more difficult and requires regular surveying to gain an insight into the impact of particular events, especially if these occur in isolation. Otherwise, biosurveys are most appropriate for assessing multiple events or long-term analysis. A series of biosurveys is generally needed at a location so that seasonal effects on community abundance and diversity can be accounted for in the analysis.

At KLSS, long-term impact has been assessed by conducting biosurveys at four locations over an 8-month period from October, 1995, to June, 1996 (see Section 8.1.1). Statistical analysis (see Figure 8-1) showed that the invertebrate community was significantly more diverse at US sites, was dramatically impaired at the point where the discharge entered the channel and showed some recovery DS.

During previous studies, the project team has investigated the effects of CSOs at two sites in the United Kingdom: Pendle Water (Lancashire) and the River Trent (Staffordshire) (Milne et al., 1992). The quality of the receiving water was assessed using the BMWP (Biological Monitoring Working Party) and ASPT (Average Score Per Taxon) scores (Armitage et al., 1983). The BMWP score is an index that combines into a single numerical expression both a qualitative or quantitative measure of macroinvertebrate species diversity depending upon the collection procedure and qualitative information on the ecological sensitivities of individual taxa (Metcalfe, 1989). Scores are based on the presence or absence of certain invertebrate families within a sample. The score is obtained by summing the individual scores of all the families present in the sample. Score values (maximum of 10 and minimum of 1) for individual families reflect their pollution tolerance based on a knowledge of distribution and abundance, with pollution intolerant families (such as the Ephemeroptera) having high scores and pollution tolerant families (such as Oligochaeta and Chironomidae) low scores. The average score per taxon (ASPT) is calculated by dividing the BMWP score by the total number of scoring taxa.

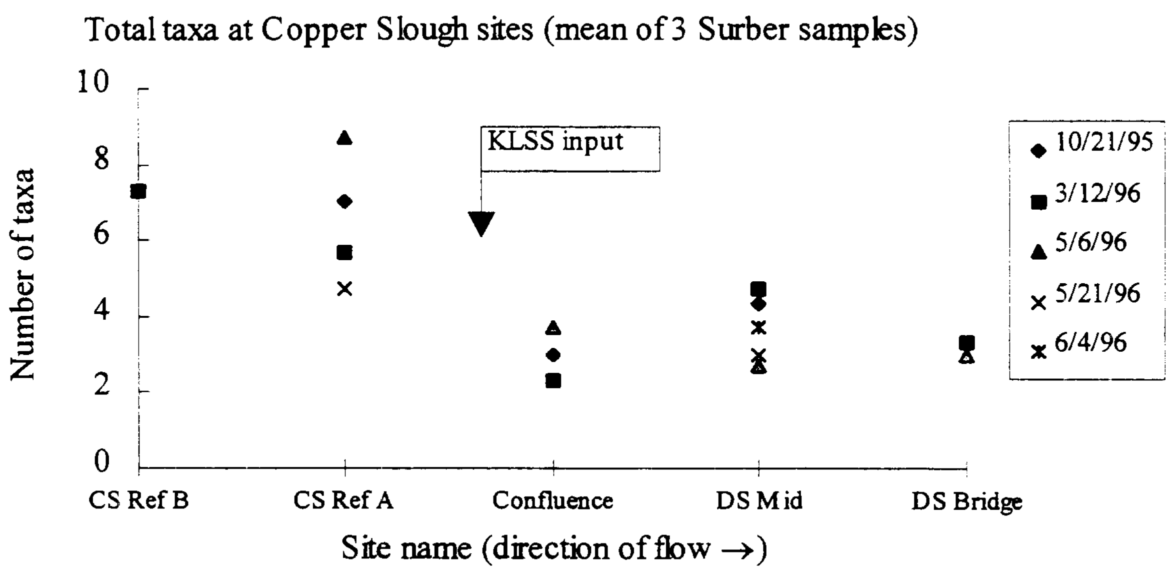

Figure 8-1. Summary of Biosurvey Data for Locations on the Copper Slough

At Pendle Water, sampling of invertebrate communities (by Surber sampler taken on 11 occasions between August, 1988, and July, 1990) indicated that discharges from a CSO exerted a chronic effect on the benthos downstream. However, the impact was limited to a zone of less than 250 m (820 ft) from the discharge. The numerical dominance of oligochaetes contributed to low species diversity downstream of the CSO. In addition, decreased BMWP, ASPT, and diversity were attributed to the absence of certain pollution sensitive species probably as a result of the toxic effect of discharges. Reductions in mean BMWP scores ranged from 2 to 27 when comparing a site 10 m (32.8 ft) upstream of the study CSO to a site 10 m (32.8 ft) downstream, and from 3 to 13 when comparing the upstream site with a site 100 m (328 ft) downstream (on the seven occasions within the study period that samples were taken at this site). Another observation was the reduction in invertebrate population densities following major storm events, although this trend was also observed at sites upstream and downstream of the CSO. Physical disturbance of the river bed during high flow was considered to be the major factor responsible.

Milne et al. (1992) also studied the River Trent (at Abbey Hulton, Stoke-on-Trent). BMWP, ASPT, and total taxa tended to be higher at sites upstream of a CSO. Reductions in mean BMWP scores (from samples taken on five occasions between August, 1991, to January, 1992) ranged from 14 to 27 when comparing downstream and upstream sites. High densities of oligochaetes found 200 m downstream from the CSO discharge suggested that the CSO discharges were causing chronic organic pollution. Tentative evidence of an acute impact was provided by the large reduction in mean densities of Baetidae (mayfly) downstream from a CSO following one storm event.

Whiting and Clifford (1983) investigated the impact of urban runoff in a small Canadian stream (Whitemud Creek) within Edmonton, Alberta. Seven sampling stations were used to assess the impact of six storm sewer overflows and samples were collected from each site at approximately 3-week intervals from April, 1976, to May, 1977. A number of invertebrate species common to a site upstream of the urban area were absent or rare within the city where oligochaetes and chironomids were very abundant. Species diversity calculated using the Simpson index (Simpson, 1949) and richness (number of taxa) were much lower downstream within the city than upstream. The changes in the urban invertebrate fauna were attributed to the discharge of organic materials and silt from storm sewer overflows. The magnitude of the effects of storm sewer runoff appeared to have been directly related to the area drained. Large faunal changes were found below the outlet of the second storm sewer system that drained 10.4 km^2 (2,570 acres), whereas little change was found below the third outfall discharge which drained 0.6 km^2 (148 acres).

Hoffman and Meighan (1984) studied the impact of a series of CSOs from San Francisco on various sites on the western shore of central San Francisco Bay. The study monitored the effects of three storm events between February and March, 1979, at 16 stations. Replicate benthic infauna samples were obtained using a 0.05-m^2 (0.538-ft^2) Ponar grab sample. Species diversity was calculated by the Shannon-Weiner index. A fisheries survey was also carried at six stations, 8 days after the end of the third overflow event using a 7.6-m (25-ft) otter trawl. The benthic infauna did not indicate any definitive decrease in the number of species or individuals per station as a result of any single overflow event. Species diversity was highest at those stations beyond the immediate degradation zone from the CSOs. Increased species diversity and biomass were considered to reflect the availability of food with increased organics in the sediments and increased suspended organic materials from the CSOs. Reduced fish abundance and diversity was found at the sites closest to the CSO discharges. This was considered to result from the unsuitability of these locations for most fish species due to the influence of CSOs on the sediment and the paucity of benthic invertebrates. A study of the effects of urban runoff on benthic macroinvertebrate community composition was conducted at eight sites along two branches of Shabakunk Creek (New Jersey) by Garie and McIntosh (1986). Quantitative sampling using a Surber sampler was carried out at six sites on the heavily developed West Branch and two sites on the lightly developed Main Branch during 1979/80. The analysis of the benthic collection was performed by examining changes in taxa richness and population density at the eight sites. Benthic macroinvertebrate samples collected by the multiplate artificial substrate samplers differed markedly in terms of community composition from those obtained by a Surber sampler and were not considered to be representative of those from the stream bed. On the basis of the Surber sampler data, the effects of urban runoff on the benthos of Shabakunk Creek included decreases in taxa richness and population density, along with shifts in community composition. Increased concentrations of heavy metals in the substrate were considered to be a contributory factor.

Pedersen and Perkins (1986) compared the benthic macroinvertebrate community of a Washington State stream in an urbanized watershed (Kelsey Creek) with that in a similar sized stream in a nearby rural location (Bear Creek). Buried colonization chambers containing natural rock substrates (Radford and Hartland-Rowe, 1971) were deployed at three sites on Kelsey Creek and two on Bear Creek. No significant difference existed between the urban and rural stream in terms of the average number of benthic invertebrates that colonized the samplers. However, a substantial difference existed between the composition of the benthos in the streams, such that the rural stream had nearly twice the functional diversity of the urban stream. The benthos of the urban stream was reported to be dominated by a few groups of invertebrates that could adapt to the erosional/depositional nature of the substrate and could utilize transient, low-quality food sources.

8.5 Water Quality Questions

8.5.1 What is the Relationship between Water Quality and Sediment Quality?

Relationships between water quality and sediment quality are complex and poorly understood. Chemically bound contaminants can re-enter the water column through chemical processes, particularly if resuspension occurs during storm flow events. Sediment toxicity is generally a chronic problem and relates to the long-term time scale. Therefore, it is in the context of this time scale that this question may be asked. Use of in situ exposure tests with designs that include and exclude sediment exposure can indicate differences between sediment quality and water quality. However, an insufficient understanding precludes reliable predictions of long-term water quality effects from either a chemical or biological assessment of sediment quality. More research is needed in this area.

A field deployment of caged *Hyalella azteca* was undertaken at the KLSS site with the objective of comparing water column toxicity and sediment toxicity (see Table 8-2). Groups of animals were caged out for 10 days, either in the water column only or with sediment contact. The results showed that the organisms in contact with sediment in the KLSS basin suffered significantly higher mortality than those in the water column at the contaminated site, but there was no significant difference between water- or sediment-related mortality at the reference site.

8.5.2 Where and When Do I Sample Water Quality to Support In Situ Testing?

Water quality analyses can strengthen the establishment of a toxicity cause-effect relationship, if mortality (or another endpoint) can be related to measured contaminant concentrations. It should be recognized, however, that this might not always be feasible where complex mixtures of contaminants are involved; indeed the whole rationale for stormwater toxicity testing rests on the inadequacy of chemical analysis alone as a tool for monitoring stormwater. See also Section 8.1.6.

Table 8-2. Toxicity Data for In Situ *H. azteca* Water Column and Sediment Tests

Location	Lethality (%)	
	Water column	Sediment
CS REF	10	20
KLSS	43	80

Where a particular contaminant is known to be a problem, perhaps from bioaccumulation studies, advanced screening tests, such as TIE (see Section 7.9.8 and Appendix B), might be able to trace the in-stream problem back to source.

To link in situ test results to storm event chemistry, continuous monitoring is clearly the most appropriate methodology, coupled with automatic samplers for parameters that cannot be continuously monitored. Ideally, monitoring points should be at, or in the vicinity of, the in situ testing site.

8.6 Test System/Assessment Procedure Questions

8.6.1 What Is the Best In Situ Test System?

The best in situ test system for a particular program is determined by the program objectives and the application of the test system selection methodology. The selection of test systems is based on time-scale considerations and the performance of the test against time-scale-specific criteria. Of the three time scales identified (intra-event, event and long-term), in situ tests systems are relevant to the event and long-term time scales. Where the time scale of interest is event, tests with relatively shorter induction times are most appropriate, for example lethality-based tests and feeding rate tests. For the long-term time scale (multiple event), these event-time-scale tests might still be applicable when deployed in a rolling program, as well as tests with relatively longer induction times, such as bioaccumulation tests and colonization.

8.6.2 What Is the Best Biosurvey Procedure?

As discussed above, the selection of test systems is based on time-scale considerations. Biosurveys are fairly exclusively directed at long-term time-scale assessments though they might be relevant in the event time scale (see Section 8.4.1). As such, time scale is not the major factor in assessing which biosurvey procedure is best for a particular program. Relevant considerations include:

- Which procedure will be most cost-effective and provide the most relevant information to meet study objectives?
- What organisms are present in the system and which are most appropriate? (see Section 8.2.4).
- Have any biosurveys been done previously (continuity will allow comparison with historic data)?

The RBPs developed by US EPA include three protocols for benthic invertebrates and two for fish. The appropriate biosurvey procedure depends on the study objectives. Benthic RBP I and Fish RBP IV are screening tools to help determine if biological impairment exists. Benthic RBPs II and

III and Fish RBP V are more rigorous and provide more objective and reproducible evaluations than RBPs I and IV. RBPs II, III, and V are semiquantitative and use an integrated analysis technique to provide continuity in evaluation impairment among sites and seasons. Each of the RBPs is summarized briefly in the following subsections.

8.6.2.1 Rapid Bioassessment Protocol I—Benthic Macroinvertebrates and Rapid Bioassessment Protocol IV—Fish

These RBPs are screening mechanisms to identify biological impairment. They are not intended to determine the degree of impairment nor provide definitive data to establish cause-and-effect relationships. They allow a cursory assessment, using cost and time efficiencies to evaluate a large number of sites, identify major water quality problems, and help plan and develop management strategies.

8.6.2.2 Rapid Bioassessment Protocol II—Benthic Macroinvertebrates

This RBP provides information to rank sites as severely or moderately impaired so that additional study or regulatory/management action can be planned. Like RBP I, this protocol can be used as a screening tool and allows agencies to evaluate a large number of sites with relatively little time and effort. The more documented procedures and integrated metrics of RBP II promotes better consistency and allows better comparison among sites.

8.6.2.3 Rapid Bioassessment Protocol III—Benthic Macroinvertebrates and Rapid Bioassessment Protocol V—Fish

These two RBPs provide a consistent, well-documented biological assessment. Like RBP II, they provide information for ranking site impairment and a way to compare repeatable results over time (trend monitoring). These RBPs include taxonomic identifications to the lowest practical level, thereby providing information on population, as well as community-level, effects. They include an integrated assessment of metrics and can be used to develop biocriteria.

8.6.3 Do I Use Different Tests in Different Regions?

The same categories of test systems are appropriate for all regions, although in some cases there may be seasonal constraints. What might differ between regions is the organisms used (see Sections 8.6.4 and 8.6.5).

8.6.4 Should I Use Indigenous Organisms as a Test System?

There are a number of arguments for and against using indigenous organisms (i.e., collected within the study system) for in situ tests, as opposed to using laboratory stock organisms. Using indigenous organisms gives a site-specific element to the testing program. It might also avoid problems of lack of tolerance to site-specific conditions (see below), and avoids any risk of the undesirable, or unlawful, release of nonindigenous species or strains. On the other hand, sensitive organisms might be absent due to previous exposure to contaminants, and it is often difficult to collect organisms of the desired age and condition.

The use of laboratory stock organisms has the advantage that standard species have known responses and tolerances to contaminants, and a large body of published information is available to aid in the interpretation of results. Additionally, quality assurance/quality control (QA/QC) procedures, such as stock sensitivity control, can be undertaken more effectively. Availability is another factor that influences the decision about which organisms to use.

8.6.5 What Must I Do to Successfully Deploy Common Laboratory Species, such as *Ceriodaphnia*, *Hyalella*, etc., in In Situ Test Systems?

To deploy laboratory species, a reliable source of organisms is required. If no local supplier can meet the requirements, a culture must be established and maintained. The other major requirement is equipment, mainly suitable cages (see Section 8.2.3).

To deploy caged laboratory stock species, the receiving water background physicochemical characteristics (such as pH, hardness, temperature, and dissolved oxygen) must meet requirements for their survival.

8.6.6 Are There Special Procedures—Water Quality or Toxicity Analyses—Supporting Certain Test Systems?

The extent of phototoxicity due to PAHs can be investigated by deploying test organisms with (in the sun) and without (in the shade) ultraviolet light. Ireland, Burton, and Hess. (1996) found a definite increase in mortality of *C. dubia* that were in contact with PAHs in the Little Scisto River and exposed to UV radiation.

Table 8-3 shows the results of deployments of *H. azteca* and *P. promelas* in the sun and shade at the CS-REF and KLSS basin sites. A degree of lethality measured at the *H. azteca* in situ test might have been due to the photo-induced toxicity caused by the presence of PAHs.

Table 8-3. Toxicity Measured in *H. azteca* and *P. promelas* In Situ Tests Located in the Sun and Shade

Location	Lethality in *H. azteca* in situ test (%)		Lethality in *P. promelas* in situ test (%)	
	Sun	Shade	Sun	Shade
CS REF	30.0	15.0	16.7	10
KLSS	46.7	26.7	6.7	10

8.7 Interpretation and Analysis Questions

8.7.1 What Does an In Situ Test Mortality Really Mean?

If mortality is observed at an impacted site following wet weather events, the first and most important thing to do is to ascertain that the observed mortality is significantly greater than mortality observed at the reference site, using appropriate statistical techniques. If there is no statistical difference, then no effect can be ascribed to the wet weather input under investigation. If there is a statistical difference, the observed mortality might be due to wet weather events. To aid in the interpretation of in situ mortality data, look to see if the mortality ties in with the findings of any biosurveys or laboratory biological test analyses.

8.7.2 How Should I Analyze Field Data? Must I Identify Species? Which Water Quality Index is Appropriate for Wet Weather Event of BMP Effect Analysis?

The analytical methods for field data should be established as a part of the initial study design. The study design includes specification of the type of data to be collected, either structural or functional data, or both. Measurements of structure focus on the numbers and kinds of organisms. Measurements of function focus on what organisms do.

The relationships between structure and function can be illustrated by what happens when a community is subjected to a contaminant—placed under stress. When a stress is imposed, a threshold in response is reached. Initial changes can result in species acclimation to the increased stress, producing changes in function but not structure. If stress is increased, more sensitive species are lost and replaced by more tolerant species; this transition is reflected by a corresponding change in structure but not necessarily function. Further stress affects even tolerant species so that with elimination of organisms, function is lost as well. The changes in structure and function can be modified by the initial stress level. An acute stress, one of high magnitude but short duration, can lead directly to the loss of structure and function. Therefore, field data should be analyzed in terms of both structure and function.

8.7.2.1 Structure

The analysis of structure requires identification of the organisms present. The first step in biosurvey data analysis occurs during study design. Study objectives define the taxonomic sophistication required for organism identification along with specification of data analysis methods or indices. Guidance for data analysis is provided in many sources; the analytical procedures accompanying RBP protocols provide a useful starting point for field data analysis of macroinvertebrate and fish data. The major caution in analysis is that most analytical procedures are designed for constant stress levels and might be inappropriate for time-scale analyses needed in wet weather discharge analysis. This is particularly true for condition and state indices (e.g., Ephemoptera-Plecoptera-Trichoptera (EPT) index; application of scraper/filtering collector or shredder to total taxa ratios; or application of biotic or community similarity indices) that have not been adapted to address specific time-scale issues.

A general rule of thumb is that more accurate identification of species present allows more complete and complex analytical procedures. Species level identifications are a basis for accurate community description and also provide a foundation for detailed identification and/or analysis of environmental factors that might be critical to the species, such as data on life history or other autecological requirements. Species identifications are not needed in all cases, but species identifications provide the best information to any assessment. RBP protocols offer good guidance for selection of taxonomic discrimination needed in the analysis of field data.

A fundamental property of an index is that it selects characteristics from a data set to summarize in the index value. In this summarization process, significant information may be lost or underutilized in field data analysis. The most common water quality indices (e.g., Hilsenhoff Index or the Index of Biotic Integrity—IBI) have been developed to provide only a general assessment of aquatic community state or condition. No indices specific to wet weather conditions are widely used.

In summary, the analytical procedures for biosurvey data should be established as part of the study design and meet all requirements of a quality assurance program. Analysis can be simple or complex depending on objectives and analysis criteria. Taxonomic sophistication in data analysis can also vary from identification of macroinvertebrates to order to confirmed species identifications. The level of discrimination in taxonomy is be set by analysis objectives. To date, no wet weather indices are widely used.

8.7.2.2 Function

The fundamental functional characteristics measured in biosurveys include biomass production (ecological energetics), trophic or systems regulation, and nutrient cycling. The most promising measures of these functional characteristics include:

- Changes in primary productivity/respiration;
- Changes in energy flow;
- Changes in decomposition;
- Changes in material cycling; and
- Changes in internal regulatory processes.

The usual focus of analyses for functional measures in biosurveys are listed in the following paragraphs:

Productivity and Respiration. Changing productivity leads to changes in the energy pool available and an alteration in turnover time of carbon/food resources. It is important in this analysis that time constants be carefully selected and correlations between photosynthesis and respiration are carefully developed.

Food Web and Functional Regulation. The regulation of energy and nutrient dynamics involves interactions among producers and consumers in an ecosystem. Measurements of these interactions are made by analysis of:

- Change in numbers of either a producer or a consumer;
- Movement of materials;
- Alteration of the environment; and
- Interactions with other consumers.

Material and Energy Movement. Energy transformation processes are regulated by essential element availability. Common measures include analysis of elemental retention for producers or consumers or analysis of the mobilization of essential elements and the regulation of these elements.

Decomposition and Element Cycles. In the cycling of materials, decomposition is an essential part of natural cycles. Measures of leaching, faunal breakdown, and microbial mineralization are typically performed to assess decomposition. The regulation of decomposition is of some importance. The factors that directly regulate decomposition include the physicochemical environment, available resource quality and quantity. Common measures include:

- litter accumulation and decomposition;
- Leaching, i.e., materials lost and rate;
- Nutrient export; and
- Nutrient and mineral cycling (emphasis active accumulation and storage).

Regulation Processes. A general measure often selected for functional measurement includes one or more of the above analyses, emphasizing the assessment of energy flow or nutrient cycling to generate some measure of "power" or the total energy movement through the ecosystem per unit of biomass. A number of <u>metabolic indices</u>, included in this category, have been proposed that respond to perturbation and are related to maximization of persistent biomass. Another measure is the frequency of response in analysis of some periodic character (including metabolism, biomass, and/or nutrient stability). This is often measured in terms of a <u>cycling index</u> or <u>path length</u>, and is typically based on the number of compartments present in the system. It might include quantification of processes, such as nutrient cycling.

8.7.3 How Do I Conduct Sample-Specific Analyses? (What Information Should I Extract from a Sample?)

The analysis of biosurvey results can be segregated into sample-specific analyses and comparative analysis between samples. A range of techniques are available for sample-specific analysis for both structural and functional data, with an emphasis on structural data analysis. The starting point is the definition of sample elements (e.g., organism identification). This identification can range from discrimination at the taxonomic level of an order to complete species identification. Selection of discrimination level defines an operational taxonomic unit (OTU). Once an OTU has been defined, then it is possible to identify which characteristics of the sample to measure. The analysis of sample characteristics usually includes:

1) organism specific analyses
   tissue studies (bioaccumulation)
   general health/condition (morphological abnormalities or tumors)
2) enumeration of numbers and kinds of organisms
3) enumeration of abundance and biomass of organisms
4) evaluation of population characteristics for each OTU
   size
   biomass
   trophic status
5) evaluation of community characteristics
   relative abundance of OTUs
   OTU dominance
   sample diversity

The first step is the preparation of a species or taxonomic listing. Then, counts will generally be made of the numbers of individuals in any OTU. It is the species list with individual abundances that provides the basic data for further analysis. In single samples, analysis will develop:

- The total number of species or OTUs;
- The total number of individuals (standing crop);
- A rank abundance tabulation;
- Frequency distribution.

It is now possible to relate the sample data to species-specific information, such as species autecology, niche analysis, trophic organization, OTU guild placement, pollution tolerance, etc. Once this information has been extracted from the data, it is possible to perform calculations on single samples using various indices:

- Pollution Indices— Pollution indices are generally developed based on some assessment of relative tolerance of certain species, using that information to assess pollution consequence.

- Diversity Indices—The most common indices used are diversity indices. A diversity index uses numbers of species and relative abundance to calculate a measure of diversity. The general assumption is that a more diverse community will be healthier.
- Biotic Indices—Based on concepts of integrity or a particular view of ecosystem organization or function, these indices are based on biotic characteristics. They can include ecological indices, such as niche overlap, interspecific association, and interspecific covariation. These indices usually require quantitative measures of species abundance.

8.7.4 How Do I Compare Samples from Different Sites or Different Times?

To compare in situ test or biosurvey data from a different locations on a watershed, it is necessary to incorporate a general or background control that is considered to be free from anthropogenic inputs. The values generated at this site can then be used to identify whether the extent of impact at study sites and local reference sites.

All of the information developed in single sample analysis can be compared between sites or through time. Typical sample comparison methods include correspondence or resemblance matrix calculation that allows clustering or ordinations and various multivariate analysis techniques.

8.7.4.1 Differences or Similarity

The identification of similarity (or difference) between samples is accomplished using either species lists (presence/absence or binary data) or abundance tabulations (quantitative data). Coefficients of similarity are available for either binary or quantitative data and selection of a similarity measure depends on the nature of the data, particularly the general correspondence of the species lists.

8.7.4.2 Binary Data

The most commonly used binary data, similarity analysis method is the use of the Jaccard coefficient. It can be used to discriminate between closely similar samples. It provides a direct comparison of species lists unbiased by species numbers but biased by the presence of rare species. Other coefficients of similarity identified include Kulezynski, Sorensen, and Mountford coefficients.

8.7.4.3 Quantitative Data

Coefficients of similarity based on binary data take no account of the relative abundances of the species at each station and tend to overestimate the importance of rare species and underestimate the importance of common species. This can be avoided by the use of coefficients that compare not only species lists but also the relative contribution made by each species. Some quantitative methods are biased by the numbers of individuals in a sample, so data transformations may be necessary.

Common quantitative similarity coefficients are derivatives of distance measures, such as the Bray-Curtis coefficient and distance coefficient. The Bray-Curtis index ranges from 0 (no species in common) to 1 (identical samples). The use of a geometric model to represent the relationship between species lists (communities) is accomplished in calculating distance coefficients. As an example, a comparison of two communities each with three species can be accomplished by representation in a three-dimensional space with the distance between positions in the three dimensions a measure of similarity.

Pedersen and Perking (1986) compared the benthic macroinvertebrate community of a Washington State stream in an urbanized watershed (Kelsey Creek) with that in a similarly sized stream in a nearby rural location (Bear Creek). The Canberra Metric index (Clifforde and Stephenson, 1975) produced groupings of sites on the urban and rural streams which were consistent with other measured data.

8.7.4.4 Cluster Analysis and Ordination

When community structure data are analyzed beyond simple similarity or correlation analysis, the influence of many variables can take a significant role in associations between samples. Green (1979) has reviewed multivariate approaches in the assessment of ecological similarity and identified two broad categories of multivariate analysis that are based on the similarity or resemblance matrices produced when a number of samples are analyzed. These two categories include cluster analysis and ordination. Both procedures allow visual interpretation of sample relationships and can be combined to increase analytical capabilities.

Cluster analysis associates in a dendrogram those samples which are most similar (or dissimilar) and provides a visual display of sample associations. A number of clustering techniques and procedures are available for both binary and quantitative data (used to calculate coefficients of similarity to generate the resemblance of dissimilarity matrix). Because the dendrogram provides a two-dimensional display of complex resemblance patterns measures of accuracy of the display are often presented with the dendrogram. A widely used indicator of display accuracy is the coephenetic correlation coefficient.

Cluster analysis allows discrimination of associations between samples while ordination techniques are often applied to identify possible causes for observed associations. Ordination assumes a relationship between species abundances and various environmental factors. Samples are separated or associated on one or more axes that are interpreted with knowledge of known environmental conditions. Other techniques, such as principal component analysis, factor analysis, principal coordinates, canonical correlation, and multidimensional scaling, provide additional multivariate analysis techniques.

8.7.4.5 Rank Comparisons and Correlations

Community comparisons can also be made using species ranks. Spearman's rank correlation coefficient and Kendall's coefficient have both been widely used. The major drawbacks of these methods are the presence of rank ties that reduce comparative strength and species absence that requires decisions on placement in the ranking list or exclusion from comparison. Correlation coefficients based on probabilistic models can be calculated from either binary or quantitative data. The point correlation coefficient and product-moment correlation are both useful correlation indices.

8.7.5 What Do I Do if In Situ Tests Disagree with Laboratory Testing Results?

The results from in situ tests might disagree with laboratory tests results due to the different exposure conditions experienced by the organisms under the two scenarios. Laboratory tests on sediment samples and in situ deployments with *D. magna* and *H. azteca* were carried out for the 6/1/96 storm at the KLSS system, and for both species, lethality was generally lower in the laboratory test rather than the in situ test (see Table 8-4). This finding is consistent with a study by Jacher and Burton (1993), who found that toxicity in *H. azteca* tests conducted in situ at agricultural and urban sites was greater than that measured in laboratory assays. The differences in lethality between laboratory and in situ tests might have been due to differences in flow rate, temperature, or higher dissolved oxygen levels in the laboratory than were typical of field exposures. Chemical partitioning of toxicants in the water at the site and consequently the continuous exposure of organisms to contaminants at this site could also cause a difference in response when compared to the laboratory test conditions in which uncontaminated, overlying water was used and renewed daily.

Table 8-4. Toxicity Data from Laboratory and In Situ Sediment Tests Using *D. magna* and *H. azteca*

Location	Lethality in *D. magna* tests (%)		Lethality in *H. azteca* tests (%)	
	Laboratory	In situ	Laboratory	In situ
CS REF	23	20	10	27
KLSS	63	100	53	83

In such cases where there are conflicting laboratory and field results, examination of both field and laboratory procedures, exposure conditions, and other location- and event-specific factors are needed. Field tests are less artificial than laboratory tests, although generally at the cost of less rigorously controlled conditions. Therefore, field test results should be considered to be a more reliable indicator of actual receiving system impact, while laboratory testing should be considered a more reliable indicator of toxic potential. Clearly, judgment will involve consideration of the degree of discrepancy between tests and possible reasons for observed differences.

CHAPTER 9.0

CONCLUSIONS

This project has involved analysis, laboratory studies, and field assessments. An extensive research record has been developed and is available in annual reporting, interim reports, and publications. The major conclusions of this research project, relating to each of the project objectives, are presented in the sections that follow.

Objective #1—Develop a database for frequency and duration of exposure for contaminants in CSO and stormwater runoff.

This research quantified the frequency of wet weather events at regional study sites, identified the presence of toxic contaminants in storm event samples, analyzed mechanisms that lead to the exposure of aquatic organisms to wet weather contaminants, and developed, from literature sources and field data, information on contaminant presence, exposure duration, and changes in frequency of exposure in wet weather discharges that are region, watershed location, or site specific.
This research also developed a conceptual model that quantifies relationships between chemical toxicity and the frequency and duration of exposure as defined by the hydrologic characteristics of storm events.

From this research, the following conclusions were reached:

- The description of the wet weather hydrograph is an essential first step in defining time scales for toxicity determination.

- It is essential to have a measure of hydrograph response in parallel with any toxicity assessment of stormwater.

- It was possible to develop a simple classification scheme for wet weather flow hydrographs and use this scheme to predict aspects of contaminant loading or exposure.

- Hydrograph peak values, stage duration, and frequency can all be used to predict aspects of contaminant loading or exposure.

- Contaminant concentrations present during wet weather events follow predicted patterns of a first flush high concentration, followed by lower concentrations later in an event due to dilution from rainfall/runoff.

- Variations on this contaminant concentration pattern are common, with a second peak occurring near the hydrograph peak.

- Other peaks in contaminant concentration might be related to first flushes of material from more distant points in the watershed or collection system with longer times of travel.

- Hydrograph and contaminant exposure conditions were comparable in the U.S. and Europe, although site-specific conditions determined actual contaminant presence and exposure conditions.

- Sediment contributions to time-scale toxicity are important, both in short-term exposure conditions associated with sediment resuspension and long-term exposure conditions associated with field sites.

- A simple conceptual model has been developed that defines hydrograph characteristics and calculates toxicity units from contaminant concentration data, providing a predictive tool for impact assessment.

Objective #2—Conduct a comprehensive review of the literature to identify biological test systems appropriate for detecting acute, chronic, and ecosystem effects caused by wet weather events.

In addition to an evaluation of available test systems, a comprehensive review of the literature dealing with the effects of episodic exposure on receiving system biota and ecosystems was completed as a part of this research.

From this review the following conclusions were reached:

- No test systems have been developed specifically for wet weather discharge monitoring.

- To assess the effects of wet weather events, it is necessary to move away from the organism-based approach used for continuous discharges to a "time scale of response" approach, which more realistically represents the intermittent exposure to contaminants with fluctuating concentrations. This means the time-scale characteristics of response, independent of the organism producing that response, is the major criterion for selecting test procedures and test systems.

- It is possible to identify criteria for the selection of test systems that will adequately assess the time-scale toxicity associated with wet weather discharges. Three time scales have been identified (intra-event, event, and long term), based on analysis of a database of frequency and duration of water quality changes developed from literature analysis of time-related contaminant change in wet weather events. These different time scales require different test criteria.

- An objective, criteria-based selection procedure has been developed to identify test systems that meet specific regional or other needs for testing to assess the effects of wet weather discharges on receiving system biota and ecosystems. The selection procedure evaluates test methods against criteria grouped into four main categories: time-scale criteria, measurement criteria, ecological relevance, and cost.

- No single test system adequately met all the criteria required for wet-weather event assessment.

- Modifications to standard toxicity testing methodologies have been developed as a part of this research, to produce new test systems that are more appropriate to wet-weather event time-scale toxicity assessment.

- The time-scale toxicity testing procedure developed as a part of this research accounts for post-exposure response of organisms to short duration exposures to contaminants.

- To meet criteria for a given time scale of exposure, a battery of tests is needed that provides complementary information in a cost-effective manner. For intra-event analysis, a test battery of Microtox, *C.dubia* or *H.azteca* IQ and *C. dubia* or *H. azteca*, and *P. promelas* time-scale lethality tests has been used to assess in-pipe or receiving system-single discharge toxicity. Standard WET tests using *C.dubia* and *H.azteca* are proposed for assessing whole-event toxicity.

- A tiered assessment system should be adopted for wet weather events, in which basic screening is carried out to establish the presence or absence of toxicity in discharges and allow a classification by degree of toxicity. Advanced screening can then be used to identify sources, characterize event toxicity, and define effect characteristics to guide both short- and long-term assessments of receiving water impact. Based on the results of basic and advanced screening tests, analysis can continue to a confirmatory tier that determines or confirms actual effects in the receiving water ecosystem. A key element of assessing the effects of wet weather events is relating the responses measured in samples taken in-pipe to impacts in the receiving water (using in situ tests and biosurveys). Further analysis can focus on long-term monitoring programs to identify the presence of any low level or cumulative effects on the receiving water ecosystem.

Objective #3—Conduct a series of field studies to quantify the relationships between chemical toxicity and the frequency and duration of exposure of aquatic organisms to contaminants in wet weather discharges.

Field study sites near Champaign, Illinois, in Fort Worth, Texas, and in Cleveland, Ohio were used in this research. The primary study site was the Copper Slough watershed, Champaign, Illinois, where comprehensive test batteries were used for storm event toxicity analysis, in situ testing, and biosurveys. Storm event toxicity analysis and limited in situ testing were completed at Fort Worth, Texas, while only storm event toxicity analysis was completed for Cleveland, Ohio. In addition to the field studies, an extensive laboratory testing program was implemented to assess time-scale toxicity. The following conclusions can be drawn from this research:

- Application of test systems to study sites revealed time-scale toxicity of varying degrees, depending on site characteristics and the nature of the storm hydrograph.

- An important adjunct to the determination of time-scale toxicity is the availability of continuous monitoring data for key water quality parameters. The availability of this information helps place samples taken in both an antecedent condition and a storm event context, provide data to focus costly analytical activities on critical samples, and key sampling to water quality transients. It is also important to evaluate toxicity data with regard to chemical monitoring data so that issues such as bioavailability can be considered.

- Discharges from a number of locations consistently showed moderate or high in-pipe toxicity, as measured with a battery of screening tests. However, the in-pipe toxicity did not always result in impact in the receiving water as measured by in situ tests or biosurveys due to the nature of the dilution of storm discharges in the receiving water. This was evident in data obtained from sampling downstream locations in the Copper Slough which indicated infrequent toxicity.

- The tests used to assess wet weather events need to be appropriate to the time scale of exposure likely to be experienced by receiving water organisms. The laboratory-focused research in this project has shown that even short-term exposure (< 1 h) to stormwater discharges can result in post-exposure toxicity even after baseline conditions have been restored.

- The changes in toxicity during the first flush of an event can occur rapidly and the sampling strategy needs to reflect this if maximum toxicity levels in a storm event are to be detected. This may mean sampling at intervals as short as five minutes or less.

- At the main study site (Kaufman Lake storm sewer) no seasonal differences in toxicity were evident although within a particular seasonal category there were differences in the toxicity of individual storms. The differences in storm toxicity during a season were due to such factors as the length of the antecedent dry period, the intensity of rainfall, changes in the nature and deposition of materials on urban surfaces, or the use of chemicals on residential or farm land, as well as receiving water characteristics. Consequently it is important to assess the toxicity of a number of storms. This is needed to evaluate the cumulative impact at a particular location and identify what watershed characteristics influence wet weather event discharge toxicity.

- At a single location, a sequence of storm events can produce varying levels of toxicity. Depending on antecedent rainfall, an initial event, which showed moderate or high toxicity, might be followed by events with low levels of toxicity. The observation of high levels of toxicity in samples from sequential storm events reflects source characteristics.

- The data obtained from different locations on the Trinity River watershed (Fort Worth, Texas) showed differences in toxicity of discharges depending on the location in the watershed and the nature of the inputs. The order of toxicity (highest to lowest) in basic screening tests was industrial > residential > agricultural, which is consistent with findings for contaminant loadings in other studies.

- The regional testing indicated that there were no fundamental differences in the characteristics of the toxic response to wet weather events that could be attributed to specific regional characteristics. The differences in toxicity appeared to be source- and site-specific and generally tracked a response pattern that identified both first flush and later responses.

- The toxic response later in events was related to samples with high levels of suspended solids. The observed toxicity is sometimes attributable to resuspension of contaminants. To this end, any assessment of the impact of wet weather events on receiving water organisms needs to consider the effects resulting from both the water column and the sediment. In general, regional differences in toxicity are probably not of major concern, although adjustment of test procedures to accommodate regional differences in hydrology is needed.

- In situ testing using caged organisms in the Copper Slough watershed produced variable results. Exposure at in pipe, or near source locations produced a toxic response, exposure at downstream locations did not indicate toxicity.

- Analysis of macroinvertebrate communities in the Copper Slough watershed indicated little short-term response to single events although macroinvertebrates did reflect the effects of identified sources of contaminants.

- Laboratory studies, in support of field analyses, resulted in the development of improved methods of time-scale toxicity analysis for time-sequenced samples taken from storm events.

- Regional evaluation of these laboratory test procedures using different water sources and stocks of organisms revealed consistent patterns of response although absolute values of toxicity varied.

- An event toxicity unit (ETU) has been developed from time-scale toxicity testing that accommodates variable exposure conditions during a storm event.

Objective #4—Develop a management context for wet weather discharges that integrates the need for both regulatory criteria and the protection of ecosystem health.

Although mainly focused on event-related time scales, this research did consider impact issues that involve longer time scales important in watershed/ecosystem assessments. Project activities included integration of event-related time scales with receiving system impact assessments. In these impact assessments, a range of issues must be addressed that consider new regulatory approaches (sediment criteria and biocriteria). This research evaluated time-scale effects of toxicants, linking source identification, physical effects assessments, and the identification of biological effects to link region or watershed conditions with magnitude, duration, and frequency metrics of wet weather events. Although no measures of ecological consequence are specifically recommended that integrate the response of ecosystem-level properties and processes with environmental variability and contaminant exposure, a new analysis paradigm was proposed.

When weighing management of wet weather discharges, the following are important considerations:

- The assessment, monitoring, and management of wet weather events must be carried out in a framework that considers the time scale of exposure relevant to the system under investigation (for example intra-event, event, or long-term). Establishing the time scale of exposure requires a careful analysis of location, storm characteristics, sampling needs, and receiving water issues. In particular, the available information on the hydrology of storm events at a location should be assessed to define the sampling regime to be adopted.

- The protocol for wet weather event assessment developed under this project provides a framework for wet weather event assessment and monitoring with a specific focus on storm event analysis and represents a starting point for the development of a management framework. The protocol is designed to be an integral part of the US EPA Watershed Protection Approach and WERF's Framework for a Watershed Management Program.

- A number of uncertainties must be resolved before it will be possible to develop a definitive ecosystem management context for wet weather events.

CHAPTER 10.0

FUTURE RESEARCH

The project team has explored a range of issues associated with time-scale toxicity and regional analysis of impacts from wet weather discharges. A number of research needs were identified during the conduct of this project, and several were addressed as part of the research effort. What can be summarized from the extensive literature review, laboratory, and field studies is that the special needs of wet weather discharge impact assessment are only now being defined in the context of time-scale toxicity, and research is needed in both fundamental and applied areas.

In fundamental areas, the effects of brief exposure to organisms, populations, and communities of organisms are poorly understood. This lack of understanding includes the identification of fundamental processes operating in the receiving system (e.g., transport, mobilization, transformation) and organisms (e.g., contaminant uptake/depuration, transformations and metabolic byproducts, detoxication), as well as the potential response spectra of exposed organisms or systems. In terms of fundamental processes in receiving systems, specific attention should be paid to contaminated sediments, mechanisms of contamination during storm events, and possibilities of resuspension of concentrated contaminants. In time-scale toxicity analysis, the effects of physical stress on organisms, or the effect of unstable habitat conditions are poorly defined. Of particular importance is the development of better predictive tools that will relate channel condition and stability to changing land use and hydrology, particularly when hydrology can be altered by detention-based best management practices. There has also been limited definition of the relationships between time scales of exposure in wet weather events as defined by hydrologic characteristics of the watershed, and relating specific contaminant concentration to land use and/or management practices intended to protect water quality. Of particular importance in the assessment of time-scale toxicity in relation to hydrology is the consequence to both organisms and their habitat of changing frequency of events of different magnitude or duration as land use changes and management practices are implemented.

The exploration of fundamental processes operating in organisms, populations, and communities is an extremely fertile area of research in time-scale issues. A primary element of time-scale toxicity determination is the availability of reference data to allow comparison with data from new research. Reference data can take the form of known responses for common test species, as well as reference properties and processes of communities or ecosystems to judge impact. In terms of common test species, there is extensive research on the response of commonly used test species to continuous exposures, but very little on the response to variable exposure, considering both concentration and frequency. For example, there is little research that adequately addresses the response of commonly used WET testing species to intra-event conditions (e.g., first flush high concentration transients) and multiple event exposure to both high and low concentrations of contaminants. This lack of fundamental understanding of organism response translates to an even greater gap in our understanding of community/ecosystem response where time-scale toxicity issues of wet weather events must be integrated with time scales of response of the communities and ecosystems under conditions of both constant and episodic exposure. Therefore, research is needed to address test system responses to variable exposure and exposure frequency of contaminants, monitoring fundamental organism processes, and identifying specific mechanisms of effect. Similarly, research is needed to define specific types of responses to time-scale toxicity in communities and ecosystems, and the development of metrics applicable to wet weather event discharges.

In the applied area, research is needed to translate advances in the fundamental understanding of the physics, chemistry, or biology/ecology of the environment into useful tools to guide management and regulatory programs. Fundamental issues persist in this applied arena, as well. For example, for most best management practices, few data address the effectiveness of contaminant removal through time and under different loading and hydraulic conditions. Because only a few standard measures of time-scale toxicity exist, research is needed to provide the detailed, management-practice-specific methods for impact analysis. Once a reasonable basis is provided for impact analysis, research is needed to validate management practice impact and, most importantly, develop predictive tools/models that will assist in the design of better management practices.

Although this research identified a test battery for time-scale toxicity analysis, additional research is needed to advance test systems testing in management programs. This will provide both specific guidance for selection of test systems and cost-effective methods to meet minimum information requirements for management and regulation.

APPENDIX A

STORM EVENT CHARACTERISTICS

Objective #1 of the research project supported a comprehensive time-scale toxicity analysis by identifying the conditions that lead to organism exposure to contaminants in receiving systems. To meet this objective, the project team developed a database for frequency and duration of exposure for contaminants in combined sewer overflow (CSO) and stormwater runoff. This database considered regional hydrologic characteristics that would assist in defining storm events. A library was assembled to provide information on storm event characteristics, lending a regional perspective on storm event characteristics and supporting analysis of specific studies conducted in various regions. Analyses have been performed on the Kaskaskia River near Champaign, IL; Johnson Creek in the Willamette River Basin at Sycamore, OR; the Cuyahoga River in Independence, OH (representative of Cleveland OH), Ware Creek near Toano, VA (representative of Virginia coastal areas); the Trinity River in Fort Worth, TX; and the Salt River in Phoenix, AZ. At each site the data gathered included the mean time between storms, categorization of storm events, and a hydrograph characterization of typical storm events. The search criteria for acceptable gauging stations included: proximity to the urban area; at least five years of stream flow record data; a data end date after 1980; and a drainage area less than 20 square miles. Because of the lack of suitable gauged streams in some areas, these criteria were modified slightly. The U.S. Geological Survey Daily Values database was provided on CD ROM by EarthInfo, Inc. and was used for the analysis.

Analytical Procedure

For each analysis, data were gathered for the most recent five-year period for which the data are complete. To determine seasonal affects, the data were divided into three-month blocks corresponding to the seasons of spring, summer, fall, and winter. The stream flow data corresponding to each season were then plotted as cartesian coordinates on a hydrograph with the mean daily flow as the ordinate (y-axis) values and the day of the month as the abscissa (x-axis) values.

For the analysis, it was assumed that a peak on the seasonal hydrograph was associated with a storm event that immediately preceded the peak. To determine the mean time between storm events, the abscissa value corresponding to a seasonal peak was subtracted from the value corresponding to the peak that preceded it, correcting the abscissa value for periods that extended past the end of one month into the next. The analysis was continued until the last peak of the season was reached. Because each season was analyzed separately, the first and last storm events of each season were used as the beginning and ending points, respectively, for the analysis. The mean and standard deviation for each data set and for the entire study period were then computed.

The project team found that the peak flow associated with a storm event was a useful criterion for differentiating large, medium, and small storm events. For storm size separation analysis, the relative flow of each urban watershed was examined separately. The storm size separation criteria were different for each watershed. This reduces comparability between watersheds, but is a useful tool in analyzing storm frequency within a watershed over the five-year period. The stream flow data were analyzed by year to determine the annual number of each type of storm event.

Hydrograph Characterization

A representative storm from each category was selected, based on peak flow and a relatively smooth return to base flow conditions. Following procedures outlined by Linsley, Kohler, and Paulus (1975), the representative hydrographs were analyzed to determine coefficients for the recession curves, as shown in Figure A-1. The shape of the rising limb of the hydrograph is influenced mainly by the character (duration, intensity, etc.) of the storm which caused the rise (Linsley, Kohler, and Paulus, 1975). The character of the storm events in this analysis is not known, due to the nature of the data available. Mean daily flow values do not supply enough information to accurately characterize the rising limb of the hydrograph. However, these data are sufficient to calculate recession constants for the various segments of the recession curve. The general equation for a recession curve is (Linsley, Kohler, and Paulus, 1975):

$$q_t = q_0 K_r^{\,t} \qquad \text{(A-1)}$$

where:

q_t	=	flow at time t units after time zero
q_0	=	flow at time zero
K_r	=	recession constant
t	=	time units after time zero (usually in 24-hour increments)

R0025576

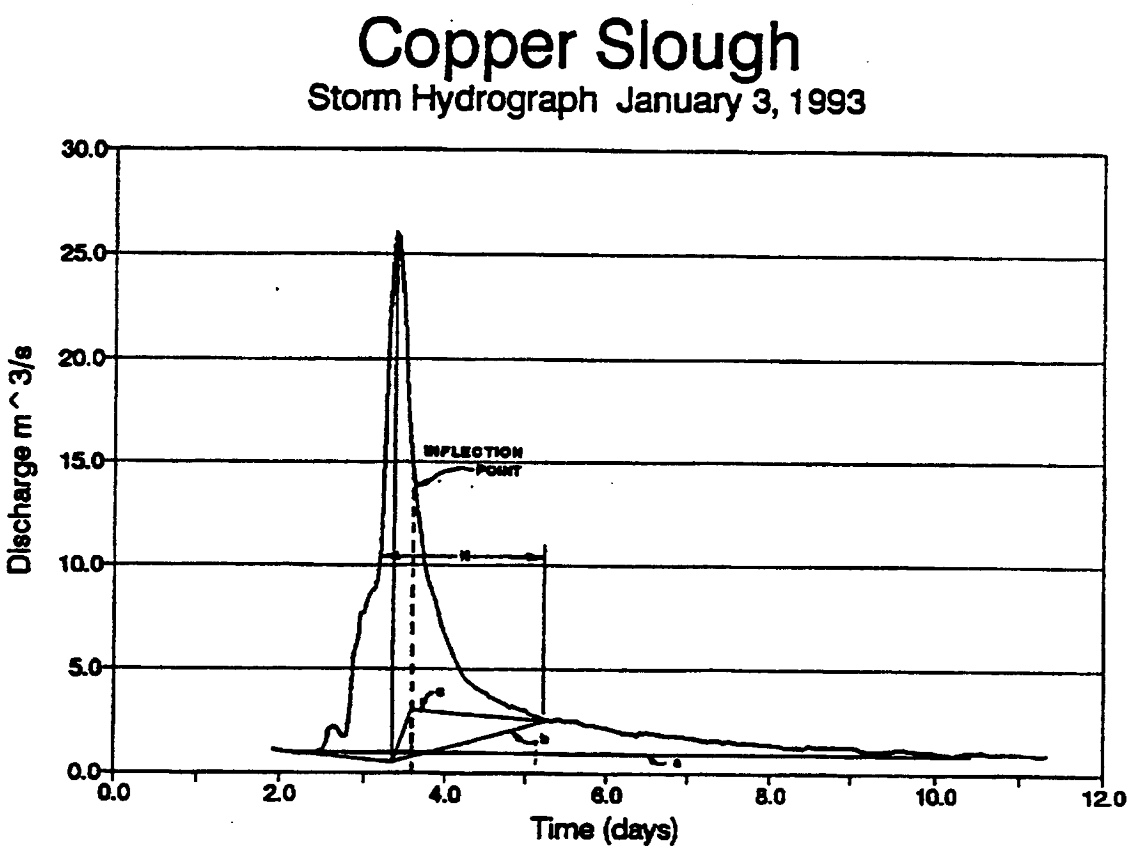

Figure A-1. Example Hydrograph from the Copper Slough, Champaign, IL, Providing an Illustration of Hydrograph Analysis for Base Flow Separation

If, in fact, the recession constant is constant throughout the recession curve, recession data can be plotted on a semilogarithmic graph as a straight line. The slope of this line corresponds to the value of K_r. However, normal recession curves include flow from three types of storage: stream channels, surface soil, and groundwater. Flow from each of these types of storage has different lag characteristics associated with the physical structure of the storage type. Actual data plotted on a semilogarithmic plot can be approximated by three straight lines corresponding to flow from the three types of storage (Barnes, 1940). The transition point between each type of flow is gradual, and graphical techniques are required to determine the recession constants for each section of the curve (Linsley, Kohler, and Paulus, 1975). These three recession constants correspond to base flow, interflow, and runoff.

Hydrologic Analysis Results

Champaign, Illinois. The gauging station selected for this urban area was Station No. 05590000, located on the Kaskaskia Ditch in the Kaskaskia River Basin at Bondville, Illinois. This gauging station has a natural drainage basin area of 12.4 mi^2 and is at an elevation of 689.89 ft above mean sea level. The Kaskaskia Ditch at Bondville is a second-order stream with land use dominated by agriculture. It is located at 40 degrees 6 minutes 47 seconds North latitude and 88 degrees 20 minutes 55 seconds West longitude. This station is located one mile east of Bondville, 3.8 miles west of Champaign at mile 289. Hydrologic data summaries are presented in Table A-1.

A small storm event would result in a peak flow in the Kaskaskia Ditch that was noticeable above the normal base flow on the hydrograph, but below 20 ft^3/sec. A medium storm event would result in a peak flow of between 20 and 100 ft^3/sec. A large storm event would result in a peak flow that exceeded 100 ft^3/sec. It should be noted that these definitions are based on a graphical interpretation of mean daily flows in the Kaskaskia Ditch and are not standardized for use in other climatic zones. The stream flow data were analyzed by year to determine the annual number of each type of storm event. The results are presented in Table A-2.

Table A-1. Summary of Mean Time Between Storm Events for Kaskaskia Ditch

Year and Parameter	Mean Time Between Storm Events (Days)			
	Spring	Summer	Fall	Winter
1986 Mean	7.00	6.67	7.09	15.80
1986 Standard Deviation	2.48	6.68	5.40	12.46
1987 Mean	4.06	8.50	9.33	7.33
1987 Standard Deviation	2.37	4.03	7.63	6.81
1988 Mean	7.00	5.62	7.80	6.15
1988 Standard Deviation	5.34	4.73	7.39	4.69
1989 Mean	6.92	6.21	14.40	6.15
1989 Standard Deviation	4.91	4.35	20.87	4.69
1990 Mean	6.38	6.77	11.60	5.25
1990 Standard Deviation	4.83	4.51	8.19	4.92
Mean for 5-Year Period	6.06	6.66	9.47	7.24
Standard Deviation for 5-Year Period	4.24	4.93	10.72	7.01

Table A-2. Number of Storm Events by Category and Year for Kaskaskia Ditch

Year	Small	Medium	Large	Total
1986	15 (40.5%)	17 (45.9%)	5 (13.6%)	37
1987	23 (48.9%)	23 (48.9%)	1 (2.2%)	47
1988	31 (72.1%)	10 (23.3%)	2 (4.6%)	43
1989	37 (78.7%)	7 (14.9%)	3 (6.4%)	47
1990	18 (51.4%)	9 (25.7%)	8 (22.9%)	35
Total 1986-1989	124 (59.3%)	66 (31.6%)	19 (9.1%)	209

A representative storm from each category was selected, based on peak flow and a relatively smooth return to base flow conditions. The representative hydrographs were analyzed to determine coefficients for the recession curves. Graphical analysis has been performed on the recession curves for a representative storm event in each size category—small, medium, and large. The representative small storm event occurred in the period January 1 to January 24, 1989. The representative medium storm event occurred in the period July 9 to July 29, 1986. The representative large storm event occurred in the period December 6 to December 31, 1986. The calculated recession constant data presented in Table A-3 are based on a 24-hour time interval.

Table A-3. Recession Coefficients for Storm Events in Kaskaskia Ditch

Storm Event	K_r		
	Base Flow	**Interflow**	**Runoff**
Small	0.93	0.69	0.11
Medium	0.89	0.68	0.45
Large	0.95	0.72	0.33

A second set of hydrologic data was analyzed from Champaign, Illinois for the Copper Slough, an urban stream that was the subject of intensive wet weather event analysis in this project. The hydrologic information used in this analysis was obtained from a stage recording station located approximately 20 m upstream of the confluence of the Copper Slough and the Kaskaskia River and is approximately 5 km west of the Champaign-Urbana city limits. The Copper Slough at the stage recorder was a third-order stream with a drainage area of 41 km^2. Land use in the watershed is approximately 40% urban and 60% agricultural.

Hourly stage data have been recorded for the Copper Slough from June, 1991, through December, 1995. The stage data were converted into discharges using a formula statistically derived from measurements of discharge and depth (Lawler, 1994). Hourly discharges were estimated for the period of October, 1991, through June, 1993. Baseflow for the creek is in the range of 0.5 to 1.0 m^3/sec.

A data set with beginning, peak, and end times of each storm were tabulated, as well as the peak discharge. With these data, it was possible to develop a histogram summarizing hydrograph duration, time between storm events, and the ratio of time to peak and the time of recession of each storm. In addition, baseflow separation techniques were applied to a storm event which occurred on January 3, 1993, to identify the surface and groundwater contribution to the stream hydrograph.

The January 3, 1993, storm event was chosen to demonstrate the three methods of base flow separation: straight line, fixed base, and variable slope. The runoff and base flow volumes were then calculated for each method and these are summarized in Table A-4.

Table A-4. Base Flow and Storm Runoff Volume for January 3, 1993 Storm Using Straight Line, Fixed Base and Variable Slope Methods

Method	Hydrograph Volume (m^3 x 10^6)	Base Flow		Storm Runoff	
		Volume (m^3 x 10^5)	% Total Volume	Volume (m^3 x 10^6)	% Total Volume
Straight Line	2.51	6.46	25.7	1.86	74.3
FixedBase	1.84	3.37	18.3	1.50	81.7
Variable Slope	1.83	5.19	28.4	1.31	71.6

Estimates of the base flow of the storm obtained via the three base flow separation analyses ranged from 18% to 28.4% of the hydrograph volume. The fixed base method tended to truncate the hydrograph and yielded the lowest hydrograph volume of the three methods. Even though the total hydrograph volume of the straight line and the variable slope methods varied by 30%, the percentage of base flow obtained through the methods was fairly consistent. The baseflow volume of 1.83 x 10^6 m^3 computed by the variable slope method is equivalent to a 3.2-cm depth over the watershed.

Hydrographs for the Copper Slough can be divided into small, medium, and large events. From baseflow separation of selected storm events, it was observed that the percentage of hydrograph volume as baseflow decreased as the magnitude of the storm event increased, since there was a limit of the storm runoff that could infiltrate into the groundwater. In this context, the percentage of base flow (28%) from a large event, such as the January 3, 1993, storm, is in agreement with the baseflow percentage of 33% obtained from a similar event on August 12, 1993.

A summary of hydrograph statistics for Copper Slough is shown in Table A-5. For the hydrograph duration and the time between peaks, there was no observable statistical pattern in the data. The histogram for peaks above base, indicated that peak discharge varied inversely with the number of storms. The parameter, time to peak (Tp) divided by recession time (Tr), which relates to the shape of the hydrograph, was evenly distributed between 0.1 and 0.5, indicateing that there is potentially a limiting factor in the shape of the hydrograph given a specific peak or recession time.

This time between peaks was compared to regional rainfall data. The analysis found that 30 of the 106 peaks (28%) were within 1 day of each other (Table A-5). According to rainfall data for the Champaign-Urbana, Illinois area, the mean annual time between rainfall events was 6.2 days (gamma distribution). Given the coefficient of variation for the rainfall data of 1.02, the probability of a storm event within 1 day of another is approximately 20%. This conflict would potentially indicate that a typical runoff event has multiple peaks due to timing of the runoff or that the area distribution pattern of rainfall for the watershed would create several runoff peaks.

Additional analysis was performed for the period from June, 1994, to October, 1994, to relate rainfall to hydrograph characteristics for a sampling station located approximately 2 km upstream from the confluence stage recorder. Level information at this site was obtained from a Datasonde 3 multiparameter monitoring probe fixed to a surveyed elevation in the stream. The length of time from the onset of a storm event to an increase in level varied from approximately 45 min to nearly 4 h, depending on the intensity-time pattern of the rainfall. The time to peak discharge varied less, generally being between 4 h and 4 h 40 min.

Table A-5. Summary of Hydrograph Statistics for Copper Slough for October, 1991, to June, 1993

	Peaks above Base (m^3/Sec)	Duration (Days)	Time Between Peaks (Days)	Ratio Tp/Tr*
# of Observations	110	50	106	50
Mean	2.51	0.92	2.83	0.26
Average	4.26	1.36	5.12	0.33
Standard Deviation	4.51	1.50	6.29	0.23
Maximum	26.1	7.88	37.5	1.20
Minimum	0.73	0.29	0.21	0.05

* Tp = time to peak; Tr = recession time

Portland, Oregon. The gauging station selected for this urban area was Station No. 14211500, located in the Willamette River Basin in Johnson Creek at Sycamore, Oregon. This gauging station has a natural drainage basin area of 26.5 mi^2 and is at an elevation of 228.47 ft above mean sea level. It is located at 45 degrees 28 minutes 40 seconds North latitude and 122 degrees 30 minutes 24 seconds West longitude. This station is located 2.5 mi east of the city limits of Portland at mile 10.2. The stream is 2/3-order with suburban/urban land use. The data chosen for analysis cover the years 1989 to 1993 (Table A-6).

A small storm event would result in a peak flow in Johnson Creek that was noticeable above the normal base flow on the hydrograph, but below 100 ft^3/sec. A medium storm event would result in a peak flow of between 100 and 200 ft^3/sec. A large storm event would result in a peak flow that exceeded 200 ft^3/sec (Table A-7).

The representative small storm event occurred in the period December 4 to December 18, 1989. The representative medium storm event occurred in the period March 8 to March 21, 1991. The representative large storm event occurred in the period January 2 to January 18, 1993 (Table A-8).

Table A-6. Summary of Mean Time between Storm Events for Johnson Creek

Year and Parameter	Mean Time between Storm Events (Days)			
	Spring	Summer	Fall	Winter
1989 Mean	4.78	5.64	5.21	4.41
1989 Standard Deviation	3.81	3.71	5.37	3.58
1990 Mean	4.21	4.83	4.50	4.33
1990 Standard Deviation	3.64	3.44	3.74	4.51
1991 Mean	4.30	8.44	3.39	4.81
1991 Standard Deviation	2.79	7.10	4.09	4.11
1992 Mean	5.47	8.38	4.26	4.42
1992 Standard Deviation	5.06	5.17	3.75	3.01
1993 Mean	3.56	7.09	4.83	4.32
1993 Standard Deviation	2.84	5.00	4.49	3.15
Mean for 5-Year Period	4.36	6.45	4.36	4.45
Standard Deviation for 5-Year Period	3.65	4.96	4.38	3.70

Cleveland, Ohio. The gauging station selected for this urban area was Station No. 04208000 on the Cuyahoga River at Independence, Ohio, a tributary to Lake Erie. This gauging station has a natural drainage basin area of 707 mi^2 and is at an elevation of 583.57 ft above mean sea level. It is located at 41 degrees 23 minutes 43 seconds North latitude and 81 degrees 37 minutes 48 seconds West longitude. This location is located 0.8 mi northeast of Independence, Ohio, and 3.0 mi downstream from Tinker Creek. The stream is a 5/6-order stream with agricultural/suburban/urban land use. The data chosen for analysis cover the years 1989 to 1993 (Table A-9).

Table A-9. Summary of Mean Time between Storm Events for Cuyahoga River

Year and Parameter	Mean Time between Storm Events (Days)			
	Spring	Summer	Fall	Winter
1989 Mean	4.53	4.72	4.11	4.94
1989 Standard Deviation	3.20	3.71	2.88	4.09
1990 Mean	5.50	4.44	5.13	4.58
1990 Standard Deviation	5.44	3.32	3.50	4.89

A small storm event would result in a peak flow in the Cuyahoga River that was noticeable above the normal base flow on the hydrograph, but below 2,000 ft^3/sec. A medium storm event would result in a peak flow of between 2,000 and 4,000 ft^3/sec . A large storm event would result in a peak flow that exceeded 4,000 ft^3/sec (Table A-10).

The representative small storm event occurred in the period July 5 to July 21, 1991. The representative medium storm event occurred in the period April 18 to May 3, 1990. The representative large storm event occurred in the period April 23 to May 18, 1993 (Table A-11).

Table A-10. Number of Storm Events by Category and Year for the Cuyahoga River

Year	Small	Medium	Large	Total
1989	53 (74.6%)	12 (16.9%)	6 (8.5%)	71
1990	50 (72.5%)	12 (17.4%)	7 (10.1%)	69

Williamsburg, Virginia. The gauging station selected for this urban area was Station No. 01677000, Ware Creek near Toano, VA. It is located in the York River Basin. This gauging station has a natural drainage basin area of 8.29 mi^2 and is at an elevation of 10 ft above mean sea level. The stream was a second-order stream with an urban land use. It is located at 37 degrees 26 minutes 17 seconds North latitude and 75 degrees 47 minutes 12 seconds West longitude. This station is located 0.8 mi upstream from France Swamp and 4.9 mi north of Toano, VA. The data chosen for analysis cover the years 1989 to 1993 (Table A-12).

A small storm event would result in a peak flow in Ware Creek that was noticeable above the normal base flow on the hydrograph, but below 10 ft^3/sec. A medium storm event would result in a peak flow of between 10 and 20 ft^3/sec. A large storm event would result in a peak flow that exceeded 20 ft^3/sec (Table A-13).

The representative small storm event occurred in the period June 21 to July 8, 1990. The representative medium storm event occurred in the period April 12 to April 25, 1989. The representative large storm event occurred in the period March 23 to April 11, 1992 (Table A-14).

Fort Worth, Texas. The gauging station selected for this urban area was Station No. 12030102, located on the Trinity River at 32 degrees 45 minutes 06 seconds North latitude and 97 degrees 17 minutes 21 seconds West longitude on the downstream side of the bridge on Beech Street. It is also located 1,700 ft downstream of the Sycamore Creek. This gauging station has a drainage area of 2,685 mi^2 and is 478.70 ft above the National Geodetic Vertical Datum of 1929. The stream order is 5-6 with a urban/suburban land use dominating the area of the gage. The data chosen for analysis cover the years 1989 to 1993 (Table A-15).

Phoenix, Arizona. The gauging station selected for this urban area was Station No. 09512190 on the Salt River at 24th Street in Phoenix, Arizona. It is located in the Gila River Basin. This gauging station has a natural drainage basin area of 13,391 mi^2 and is at an elevation of 1,074.80 ft above mean sea level. It is located at 33 degrees 24 minutes 56 seconds North latitude and 112 degrees 01 minutes 45 seconds West longitude. This station is located 3.6 mi southwest of the downtown post office in Phoenix, Arizona. The data chosen for analysis cover the years 1983 to 1991 (Table A-18).

A small storm event would result in a peak flow in the Salt River that was noticeable above the normal base flow on the hydrograph, but below 5,000 ft^3/sec. A medium storm event would result in a peak flow of between 5,000 and 10,000 ft^3/sec. A large storm event would result in a peak flow that exceeded 10,000 ft^3/sec (Table A-19).

APPENDIX B

METHOD DEVELOPMENT AND APPLICATION

Introduction

This Appendix documents the development and/or application of a range of techniques used for, or in support of, basic and advanced screening testing. The information contained here is summarized in Chapter 5.0. First, described under basic screening methodologies, is the development of a number of methodologies that can be used to classify toxicity. These methods are aimed at assessing or predicting the level of toxicity exhibited by a wet weather event or by individual samples taken during an event.

Section 4.6 highlighted the inadequacies of standard toxicity tests in addressing the range of time scales associated with wet weather events and the resulting need for modified test systems. A laboratory program to develop such modified test systems, based on a number of test endpoints, is described, together with a simple model by which an integrated measure of whole-storm toxicity can be derived from toxicity analysis of separate samples collected through a storm event. Also described are modifications of the enzyme-based Inhibitory Quotient (IQ) test for application to wet weather event toxicity assessment and the stimulatory response exhibited by the Microtox bacterial luminescence test in response to low levels of some contaminants.

Under advanced screening methodologies, the application of three methods is described that can be used to characterize toxicity following the identification of high or moderate toxicity through the initial application of basic screening procedures. The advanced screening methods described are a toxicity identification evaluation (TIE) procedure, which allows identification of specific contaminant groups giving rise to toxicity in a sample, a simple model that can be used to predict site-specific, receiving-system toxicity from hydrograph characteristics, toxicity prediction models applied to the prediction of toxicity due to heavy metals, and, finally, a simple storm sewer drainage model that can be used for estimating storm hydrographs and assist in identifying sources of contaminants.

Basic Screening Methodologies

An Introduction to Time-Scale Toxicity. As discussed in Section 1.2, existing standard methodologies for toxicity testing generally rely on test systems that operate on time scales that are not appropriate for the full range of time scales required for wet weather event analyses. A major thrust of this project has been to evaluate new methods and modify existing standard methods so that they apply to the shorter time scales relevant to wet weather intra-event assessment.

As noted previously, wet weather events are often associated with rapid changes in contaminant concentrations with peaks of high contaminant concentrations that extende for short periods of time (minutes). These concentrations can peak at levels that would be highly toxic over prolonged exposure durations (e.g., 48 hours or more). However, the relevant issue is how toxic they are over the actual exposure time in the receiving water. If concentrations are much higher than those causing toxicity on longer term exposure, another important question is that of post-exposure effects, that is toxicity caused by the short-term contaminant peak but manifested some time later, after non-polluted conditions are re-established.

This Appendix documents the laboratory program and a laboratory-based modeling effort, which were undertaken to address the above time scale and test development issues and to complement the field wet weather event assessment program.

Laboratory experiments were conducted to investigate the organismal effect of brief (or pulsed) exposures to a range of contaminant concentrations. The selected concentrations—higher than those that might be expected in wet weather discharges—provided a wide range of concentrations and would likely elicit responses in test organisms. These toxicity experiments were not intended to duplicate the full complexity of wet weather discharges, rather they were designed to assess brief exposure effects using contaminants known to occur in stormwater runoff. Toxicity testing methods were adapted to subject organisms to brief contaminant exposures (on the order of wet weather event time scales) and then remove the contaminant and monitor the post-exposure response. This research mainly investigated lethal effects but also included sublethal effects, such as reproduction, enzyme inhibition, and growth. Table B-1 shows a summary of the range of experiments performed. Concentrations were multiples of experimentally developed 24-hour LC_{50} concentrations. Organismal responses were compared between species, between contaminants, and between differing stock cultures and laboratory facilities. The research then attempted to connect the results to actual episodic pollution events, through the sampling and analysis of urban stormwater runoff events. A new test and metric for the analysis of episodic pollution events are described and demonstrated. Results are then discussed in the context of providing guidance for development of episodic pollution criteria and guidance for toxicity testing approaches to support episodic pollution monitoring and management.

Table B-1. Summary of Supplemental Time-Scale Toxicity Experiments Performed

Species	Location	Substance	Concentrations (mg/L)	Exposure Durations (min)	Endpoints Measured
H. azteca	UIUC	Cd	0.06, 0.19, 0.4, 0.6, 1.0, 1.9	15, 30, 60, 120, 180, 240	lethality

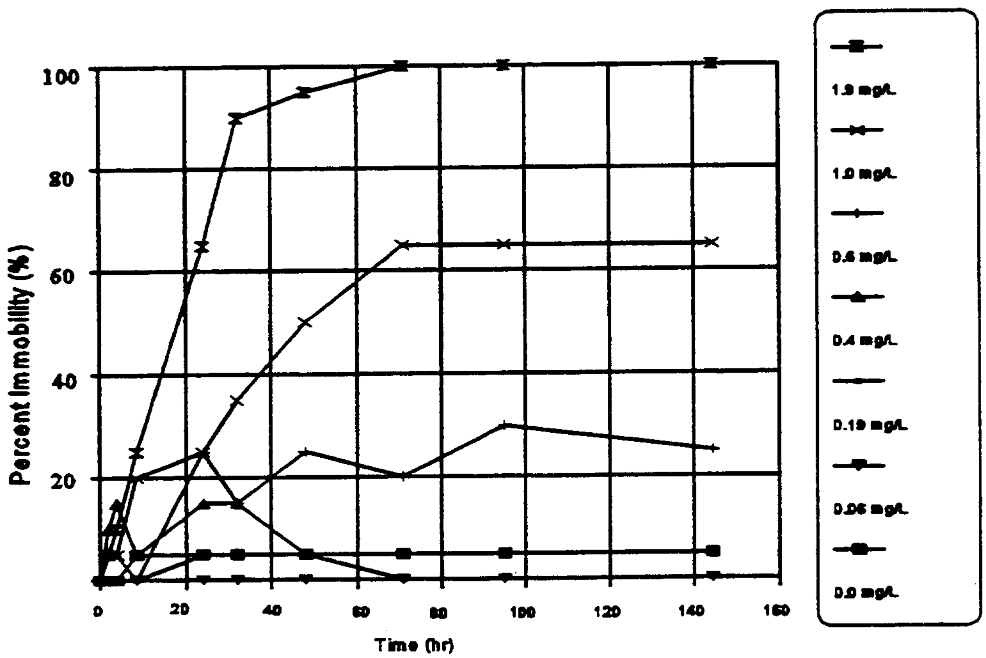
UIUC = University of Illinois, Urbana-Champaign, UNT = University of North Texas.

Brief Exposure Mortality Tests: *Cadmium Exposures: Hyalella azteca, Ceriodaphnia dubia, Pimephales promelas*. The test organisms were pulse-exposed to cadmium for durations ranging from 15 to 240 min. As noted earlier, the concentrations used were designed to elicit response and are much higher than those typically seen in stormwaters. In addition, soluble metal salts were used in the tests, wheras much of the metals present in stormwaters are particulate-bound and, hence, not bioavailable.

Figure B-1 shows the immobility curve of *H. azteca* after short-term Cd exposures. This graph is representative of immobility curves for *C. dubia* and *P. promelas*, as well. Immobility is used here as the surrogate measure of mortality. Immobility approximates, but is not equivalent to, mortality, since some organisms regain mobility. In most cases, organisms that were observed as immobile remained immobile and were obviously dead as indicated by signs of decomposition (loss of pigment, morphological alterations, and growth of decaying fungus).

Figure B-1. Percent Immobility of UIUC *H. azteca* after 60-min Cd Exposure



Note that in Figure B-1 time on the x-axis is in hours beginning at the initial time of exposure. Mortality did not generally occur during the exposure period; rather mortality was delayed and occurred after organisms were placed in clean water. Although exposure times lasted for only 15 to 240 min, mortality continued up to 70 to120 hr after the initial exposure period (longer for *P. promelas*). The maximum percent mortality increased with increasing Cd concentration and increasing time of exposure. The time at which the maximum mortality occurred with increasing Cd concentration and duration of exposure.

Information in mortality curves was summarized by calculating 12-, 24-, 48-, 72-, 96-, 120-, and 144-hour post-exposure median lethal exposure times (PE-LET_{50}) for each concentration. The x-hr PE-LET_{50} is the exposure time necessary to cause 50% mortality of the test population within x hours following the exposure. This x-hr PE-LET_{50} differs from normal LT_{50} values, which are based on time until death. This term instead refers to the time of exposure that causes eventual death even after the contaminant is removed. PE-LET_{50} values were calculated from linear regression lines from plots of percent mortality at x-hours versus the logarithm of the exposure duration (Figure B-2). This method is a modified version of the Litchfield and Wilcoxon (1949) method for determination of LC_{50} and LT_{50} values. Confidence limits were also calculated by the Litchfield and Wilcoxon method. As an example of this method, Table B-2 shows the results of a 1.0-mg/L Cd exposure on *H. azteca* at 48 hours post-exposure. Similarly calculated PE-LET_{50} values are plotted in Figures B-3 to B-5 for *H. azteca*, *C. dubia* and P. promelas.

Table B–2. Percent Mortality of *H. azteca* at 48 hr after a 1.0–mg/L Cd Exposure

Exposure Duration (min)	Percent Effect
15	0
30	25
60	50
120	85
180	100
240	100

Figure B-2. PE-LET$_{50}$ Determination for *H. azteca* Exposed to 1.0-mg/L Cd

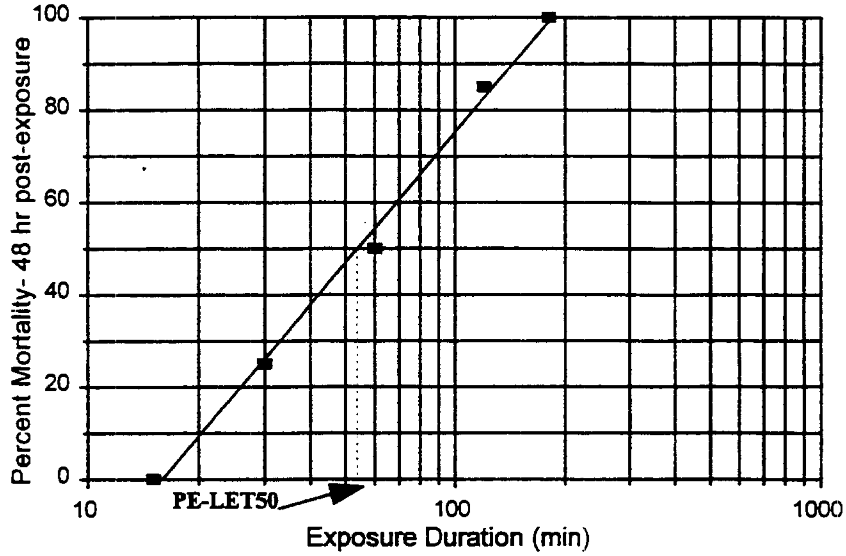


Figure B-3. Change in PE-LET$_{50}$ over Time for UIUC *H. azteca* Cd Exposure

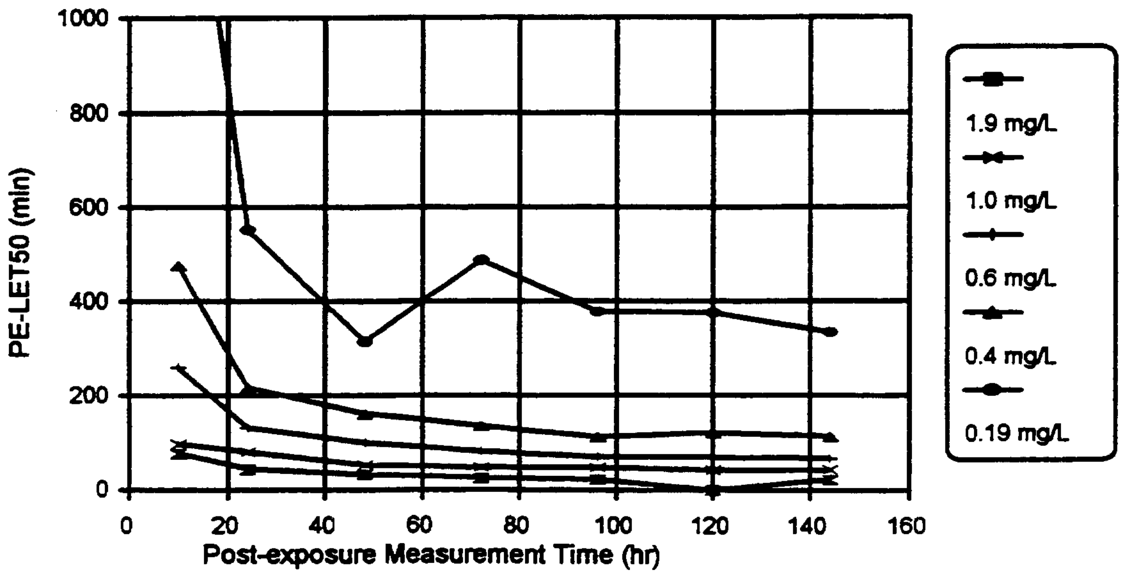

Figure B-4. Change in PE-LET50 over Time for UIUC *C. dubia* Cd Exposure

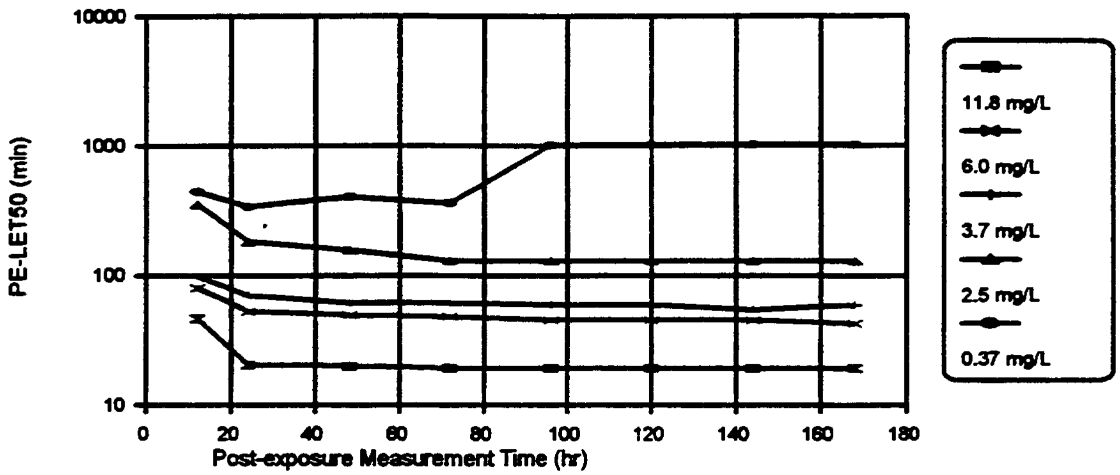

Figure B-5. Change in PE-LET$_{50}$ over Time for UIUC *P. promelas* Cd Exposure

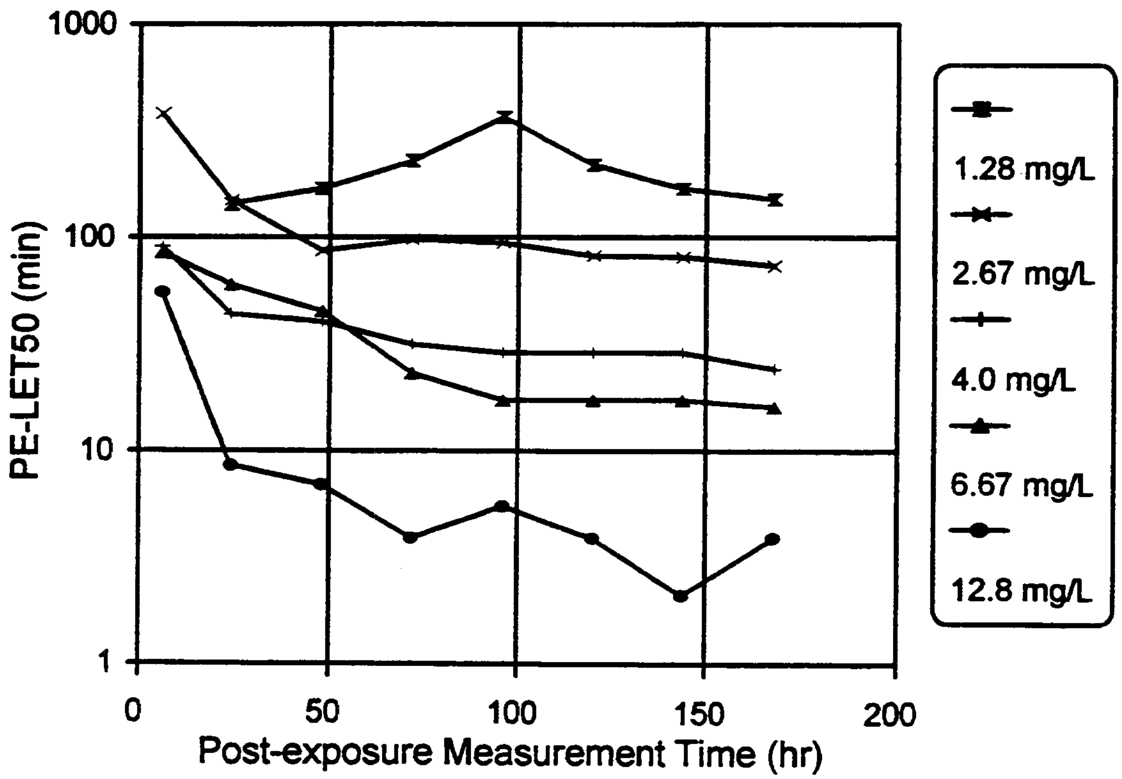
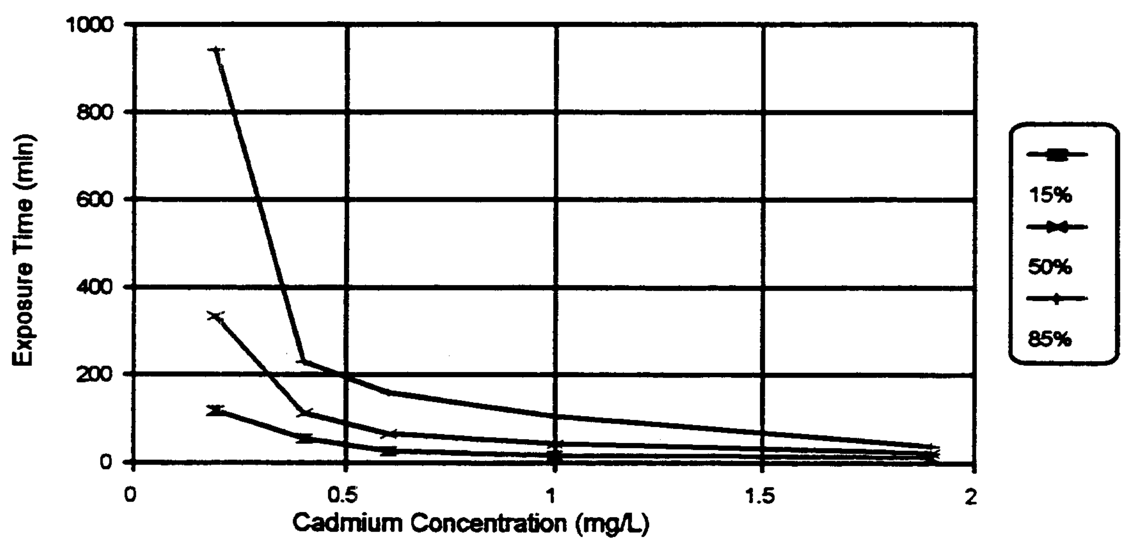


The observed delayed mortality caused PE-LET$_{50}$ values (an inverse measure of effect) to rapidly decrease soon after the exposure (Figure B-3). The curves then stabilized and approached a slope of zero, indicating that the maximum effect of the exposure was reached. The PE-LET$_{50}$ value at this point can be termed the ultimate PE-LET$_{50}$, which is the exposure time that ultimately will cause 50% mortality in the test population. The ultimate PE-LET$_{50}$ was generally reached by 120 hours after the exposure for *H. azteca* (Figure B-3), by 96 hours for *C. dubia* (Figure B-4), and not by 168 hours for *P. promelas* (Figure B-5). At higher exposure concentrations, this ultimate PE-LET$_{50}$ was reached more quickly than at low concentrations, indicating that the effects of high level stress are displayed quickly while low level stress might require some time for the effect to be developed (delayed effect). Figure B-6 illustrates the acute effect of Cd exposure as a function of exposure time and concentration. As the concentration of exposure increases, the duration of exposure necessary to elicit a particular percent effect decreases and vice versa. It is difficult to tell from these data if the curves asymptotically approach zero from both directions or if some other threshold exists.

Figure B-6. Percent Immobility of UIUC *H. azteca* as a Function of Exposure Time and Cd Concentration



Brief Exposure Mortality Tests: Zinc Exposures: H. azteca, C. dubia. Results of short-term *H. azteca* and *C. dubia* exposures to Zn were similar to those for Cd exposure (Figures B-7 and B-8). Organism mortality was delayed after the exposure period. The concentrations of Zn used in *H. azteca* exposures were much larger than for Cd exposures due to greater *H. azteca* tolerance to Zn. However, Zn concentrations used in *C. dubia* exposures were lower, which reflects the differences in species sensitivities to different contaminants. The ultimate PE-LET_{50} was generally reached by 120 hours after the exposure for *H. azteca* (Figure B-7) and by 96 hours for *C. dubia* (Figure B-8).

Brief Exposure Mortality Tests: Phenol Exposures: C. dubia. Representative results of brief phenol exposures are seen in Figure B-9. No significant delayed effects were observed for any of the phenol exposure regimes, which ranged as high as 240-min exposure to 500-mg/L phenol (50 times the 24-hr LC_{50} value). All exposure regimes caused less than 20% immobility; control immobility ranged from 0% to 25%. Exposure durations of 6 to 48 hours were required to produce any lasting effect on *C. dubia*. Interestingly, organisms in the 100-, 166.7-, 320-, and 500-mg/L concentrations were immobile at the end of each exposure period (15 to 240 min), yet quickly recovered when placed in the dilution water. This represents a tremendous potential for recovery from brief phenol exposures. It also indicates that short-term phenol toxicity has reversible effects, unlike the irreversible effects of cadmium and zinc.

Summary. Delayed lethal effects were observed for *H. azteca*, *C. dubia*, and *P. promelas* after brief cadmium exposure and for *H. azteca* and *C. dubia* after brief zinc exposure. Other authors have also documented the presence of delayed lethal effects in the amphipod *Gammarus pulex* after brief exposure to Lindane, permethrin, cadmium, and cyanide (Abel, 1980a; Abel, 1980b; Abel and Gardner, 1986) and in *P. promelas* after brief exposure to chlorpyrifos, endrin, and fenvalerate (Jarvinen et al., 1988). While delayed mortality was observed for cadmium and zinc exposures, recovery of *C. dubia* was observed after brief phenol exposure. Green et al. (1988) also reported the recovery of *Asellus aquaticus* after brief phenol exposure. These results suggest that care must be exercised when assessing wet weather discharge toxicity. Not only is there the possibility of delayed effects from brief exposure, there is a potential for recovery. Clearly, a modification of toxicity assessment procedures is needed that addresses both brief exposure issues and post-exposure effect analysis.

The PE-LET_{50} metric was effectively used to measure ultimate toxic effects with the consideration of delayed effects and recovery. Other metrics that incorporate delayed effects have been previously proposed. Although the calculation method is similar, the PE-LET_{50} differs from other commonly used or proposed toxicity metrics (Table B-3). The PE-LET_{50} differs from the LC_{50} and LT_{50} primarily in that it incorporates post-exposure observation. The PE-LET_{50} also differs from other metrics that do include post-exposure observation.

Pascoe and Shazili (1986) proposed a pe-LT_{50} (post exposure median lethal time), which is the time until 50 percent mortality, measured beginning after the exposure period. This metric sounds similar to the PE-LET_{50}, but is fundamentally different. The time that is actually measured in the pe-LT_{50} is the time to death, not the time of exposure which causes eventual death. While this metric incorporates post-exposure observation, it does not give information on exposure durations which cause ultimate effects;it simply provides information on the speed at which the toxicant produces an effect. Abel (1980b) proposed the use of a 20-day median lethal exposure time. This metric is very similar to the PE-LET_{50} and could actually be described as a 20-day PE-LET_{50}. There is more utility, however, in an ultimate PE-LET_{50} which will change in measurement time with a change in species used. For instance, as seen in this study, a 120-hour PE-LET_{50} is sufficient for estimating the ultimate effect (or ultimate PE-LET_{50}) for *H. azteca*, while *C. dubia* requires only a 96-hr PE-LET_{50}, and *P. promelas* requires greater than a 168-hr PE-LET_{50}. It was also seen that the time required for ultimate PE-LET_{50} determination decreased with increasing magnitude of exposure. Table B-4 summarizes the ultimate PE-LET_{50} values from tests performed at UIUC.

The plots of exposure time versus toxicant concentration showed curves of typical form. They agree with the form of the simple C x T model and the Mancini model (discussed elsewhere in this Appendix). Fitting the data to the C x T model yields the constant K1 for each of the species and contaminants; however, this constant has no physical significance. Data can also be fitted to the Mancini model, yielding the constants k_u/CD and k_r. The k_r constant (depuration rate) was generally very small (approaching zero) due to delayed effects. The delayed effects, however, do suggest that models such as the Mancini model used to estimate the effect of time varying exposures should use pulse exposure tests to fit data rather than continuous exposure tests (Hickie et al., 1995).

Table B-3. Comparison of PE-LET$_{50}$ Metric with Other Used and Proposed Metrics

Metric	Test conditions	Test characteristic measured	Information provided
LC50	Continuous exposure to range of concentrations	Lethality at end of set duration exposure	The **concentration** necessary to produce a lethal response within a set duration
LT50	Continuous exposure to single concentration	Lethality at set times during exposure	The **speed** of a toxic response
pe-LT50	Single concentration exposure, with subsequent post-exposure observation	Lethality at set times during post-exposure observation	The **post-exposure time** necessary to observe lethality
20 day LT50	Single concentration exposure for a range of exposure durations, with subsequent post-exposure observation	Lethality at 20 days post-exposure	The **exposure time** required to produce lethality within 20 days
PE-LET50	Single concentration exposure for a range of exposure durations, with subsequent post-exposure observation	Lethality at set times during post-exposure observation	The **exposure time** necessary to ultimately produce lethality

Brief Exposure Reproduction Tests. Tests were performed in which <24-hour old *C. dubia* were subjected to short-term Cd exposures followed by measurement of reproduction rates. Test results are summarized in Table B-5, and a representative plot is shown in Figure B-10. Each group of experiments (grouped by exposure time) was performed on a different day or at a different time, and control group data are provided in Table B-5. Neonate production was typically reduced at exposure concentrations just below lethal levels of 6 to 11.8 mg/L. However, these reductions were only statistically significant (one-sided Dunnett's t-test at α=0.05) for three exposure regimens. Other exposure regimens that reduced neonate production could not be statistically validated due to the low number of surviving individuals. This sublethal effect apparently occurred within a narrow range between indistinguishable effects and lethal effects. Delayed reproductive onset decreased neonate production for two concentrations after 240-min exposure. No neonates were produced until 6 or 7 days after 2.5-mg/L and 3.7-mg/L exposures, respectively.

Table B-4. Summary of Ultimate PE-LET$_{50}$ Values and Time after Exposure When Ultimate PE-LET$_{50}$ Values Were Reached for UIUC Organisms

Species	Substance	Concentration (mg/L)	Ultimate PE-LET$_{50}$ (min)	Time Reached (hr)

Brief Exposure Enzyme Inhibition (IQ) Tests. Results of the enzyme inhibition test also indicated potential for recovery from sublethal effects after the exposure period. Figures B-11 and B-12 show representative results of enzyme inhibition tests. Galactosidase enzyme activity was generally inhibited directly following the exposure period, yet recovery of enzyme activity was observed during the following 48 hours. Figure B-13 shows the maximum percent enzyme inhibition for each exposure regimes. The maximum percent effect generally increased with increasing exposure times and with increasing Cd concentrations. The mean time of maximum enzyme inhibition was 3.30 hours (with a 95% confidence interval of 2.65 to 3.96) after the onset of exposure. Since several of the exposure times were less than 3 hours, often the maximum percent effect was not reached until after the exposure period had ended. For these very brief exposure periods (Figure B-12), enzyme inhibition was actually lower directly after the exposure period, reached a maximum approximately 2-4 hours later, and then decreased as the organisms recovered. This time gives some indication of the total time for the transfer of toxicants to the site of action and response manifestation.

Figure B-14 shows organism recovery time—the time at which the percent enzyme inhibition of the population dropped below 20%—after brief cadmium exposure. Twenty percent was chosen since the control population response often fluctuated below 20% inhibition. Recovery time also was a function of exposure concentration and exposure time. The time necessary for recovery increased with increasing exposure time and with increasing cadmium concentration.

Brief Exposure Growth Test. *P. promelas* tests were initially designed only for PE-LET_{50} determination (lethality measurement). During the test, however, it was noticed that organisms surviving brief exposures were somewhat smaller than control populations, so growth of *P. promelas* was measured at the termination of the test. Since the experiment was originally designed only for PE-LET_{50} determination, organisms in each treatment were pooled for post-exposure observation and a pooled weight for each treatment was measured. The pooled weight was then divided by the number of survivors in each treatment to obtain a mean dry weight/surviving individual. This method meant that variances of mean dry weights could not be calculated except for control populations (since controls were conducted with each group of exposure duration treatments). Table B-6 shows the mean dry weights of *P. promelas* exposed to cadmium pulses. The mean dry weight for all control organisms was 0.159 mg with a 95% confidence interval of 0.078 to 0.241 mg. Statistical analyses could not be performed among treatments because of the lack of replication. However, in six treatments the mean dry weights were below the lower limit of the 95% confidence interval for control organisms. This decrease in mean dry weight occurred in treatments with exposure regimes just below lethal levels (generally high exposure concentrations and long exposure durations). Jarvinen et al. (1988) also showed that *P. promelas* exposed to pulses of chlorpyrifos experienced growth suppression. As with the effect of decreased reproduction in *C. dubia*, the effect of decreased growth in *P. promelas* appears to occur in a narrow range between indistinguishable effects and lethal effects.

Comparison of Brief Exposure and Continuous Exposure. For *C. dubia*, the results of brief exposure tests with post-exposure observation were compared to results of continuous exposure tests. PE-LET_{50} values were calculated for brief exposure tests, and LT_{50} values were calculated for continuous exposure tests. LT_{50} values represent time of continuous exposure at which 50% mortality occurs. Figure B-15 compares the PE-LET_{50} and LT_{50} values for cadmium exposures. At approximately 1,000 minutes of exposure, continuous exposure and brief exposure with post-exposure observation produce the same response. At times of exposure less than approximately 1,000 minutes, the two curves diverge. Brief exposure with post-exposure observation tests produced a more severe response than continuous exposure tests. Continuous exposure tests, since they ignore delayed effects, can underestimate the effect of brief toxic exposures, particularly for fast acting toxicants. At longer exposures times, the two methods approximate each other, since delayed effects are less important when exposure times are long. Abel and Gardner (1986) showed the same effect with *Gammarus pulex* exposed to pulses of cadmium. Median lethal exposure times (measured similarly to PE-LET_{50}s) were consistently less than median survival times (LT_{50}s), demonstrating an underestimation of effect by the continuous exposure regime. In assessing toxicity from brief exposures it is important to consider both mechanisms of toxic action, and the time required for response induction i.e., to understand the nature of the toxicants in relation to the time to induce response (Section 4.3).

Figure B-15. Comparison of PE-LET$_{50}$ and LT$_{50}$ Values for UIUC *C. dubia* Cd Exposure

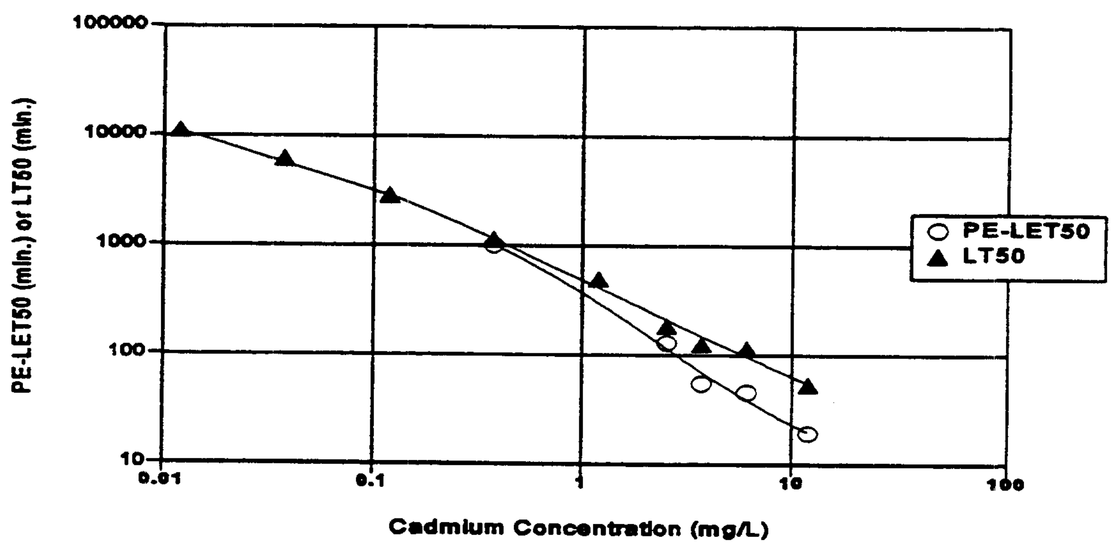

Figure B-16 compares the continuous exposure and brief exposure with post-exposure observation for zinc exposure. Brief exposure with post-exposure observation tests again show a more severe response than continuous exposure tests. For the case of zinc exposure, the difference between the PE-LET$_{50}$ and LT$_{50}$ values is much greater than for cadmium exposure. Again the continuous exposure method would underestimate the effect of brief toxic exposures. The two curves for zinc exposure also converge when the exposure time reaches approximately 1,000 minutes. At longer exposure times the results from each method are approximately the same.

Table B-6. Mean Dry Weight of UIUC *P. promelas* 7 Days after Brief Cd Exposure

Concentration (mg/L)	Exposure Time (min.)	N	Mean Weight/fish (mg)
0.4	Control	9	0.167
	15	9	0.233
	30	10	0.200
	60	9	0.144
	120	10	0.110
	240	7	0.171
1.28	Control	15	0.267
	15	13	0.231
	30	15	0.200
	60	14	0.214
	120	10	0.100
	240	8	0.125
2.67	Control	20	0.150
	15	20	0.150
	30	18	<0.056[a]
	60	11	<0.091[a]
	120	6	<0.167[a]
	240	2	<0.500[a]
4.0	Control	14	0.107
	15	16	0.063[b]
	30	5	0.040[b]
	60	3	0.067[b]
	120	0	0

	120	0	0
	240	0	0
12.8	Control	18	0.106
	15	5	0.040[b]
	30	2	0.050[b]
	60	0	0
	120	0	0
	240	0	0

[a] weight of fish was not detectable, so calculation was based on detection limit values.

[b] mean dry weight was below lower 95% confidence limit for control organisms.

Figure B-16. Comparison of PE-LET$_{50}$ and LT$_{50}$ Values for UIUC *C. dubia* Zn Exposure

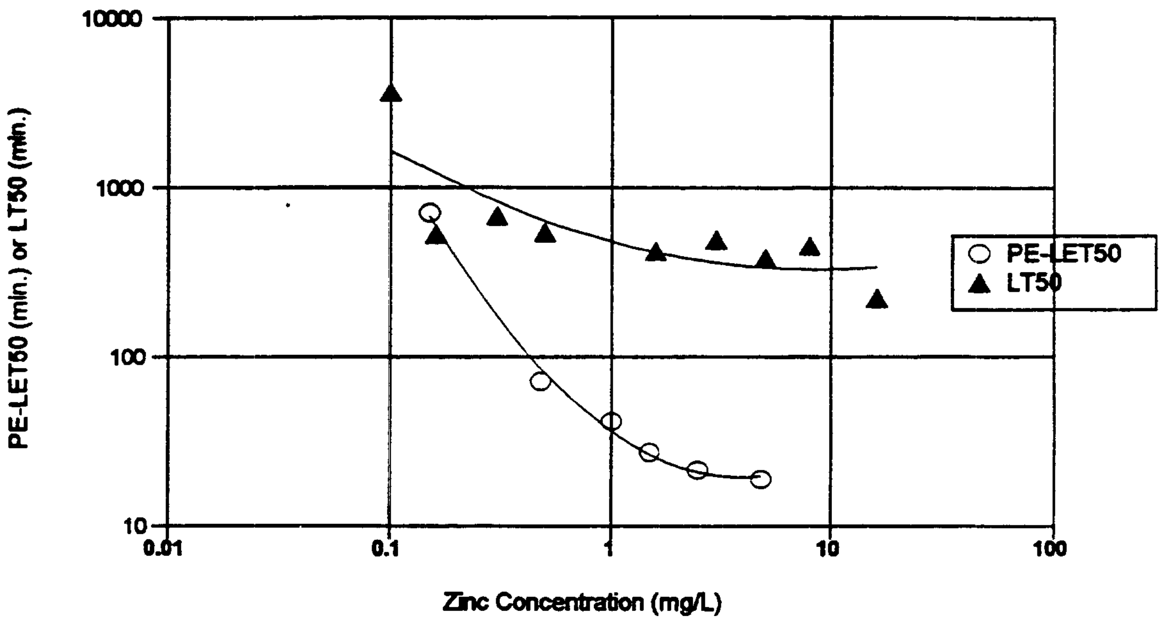

Figure B-17 compares the PE-LET$_{50}$ values and LT$_{50}$ values for phenol exposure. In this case, the brief exposure with post-exposure observation test produced a less severe response than the continuous exposure test. This is due to the fact of organism recovery after the phenol exposure. In this case, the continuous exposure (LT$_{50}$ method) would overestimate the actual effect of pulse exposure. The two curves again begin to converge as phenol concentrations drop below 10 mg/L and exposure times approach 1,000 minutes. Another interesting fact is that the PE-LET$_{50}$ curve is fairly flat. This indicates a possible minimum threshold for exposure time but this data does not support threshold determination. Even as phenol concentrations increase from 10 mg/L to 500 mg/L PE-LET$_{50}$ values do not decrease. A minimum threshold for 50% effect, in this data, occurs at approximately 200 minutes of exposure.

Between Species Comparison of Brief Exposure Tests: Cadmium Exposures. Brief exposure Cd tests were performed on *H. azteca*, *C. dubia*, and *P. promelas*. The results were compared to investigate differences in brief exposure response among species. Figure B-18 compares the brief exposure toxic response (in terms of PE-LET$_{50}$ values over the range of Cd concentrations used) among species. An analysis of covariance procedure was used to compare trends among species and contaminants (SPSS software). Tukey's honestly significant difference test was used to perform multiple comparisons among species. The alpha value for all tests was 0.05. Those curves which lie closest to the origin represent more sensitive populations, since a shorter time of exposure is required to produce a 50% response given a fixed cadmium concentration. *H. azteca* is the most sensitive of the three species to short-term cadmium exposures, with *C. dubia* being the least sensitive, and *P. promelas* falling in between. Each of the curves appears to be linear on a log/log scale within the range of observation. This indicates that if thresholds for cadmium exposure exist, they are very low and outside the range of concentration and exposure times examined (<0.06 mg/L and <3.93 min respectively). Notice also that the slope of the curves for *H. azteca* and *C. dubia* are approximately equivalent, but the slope of the *P. promelas* curve is considerably steeper. In fact, if the curve for *P. promelas* were extended, it would cross both other lines and would be the most sensitive species at short exposure times and the least sensitive at longer exposure times. This difference in slope is probably due to a difference in mechanisms of cadmium toxicity between the fish and the invertebrates.

Figure B-17. Comparison of PE-LET$_{50}$ and LT$_{50}$ Values for UIUC C. *dubia* Phenol Exposure

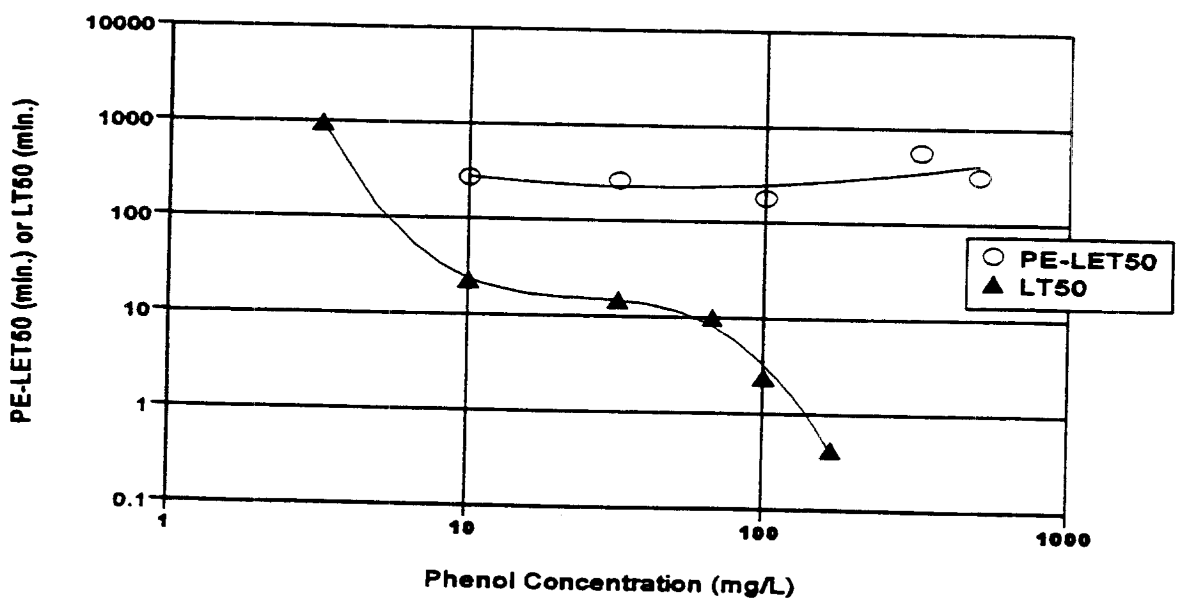

Figure B-18. Comparison of PE-LET$_{50}$ Values for Different Species over a Range of Cd Concentrations

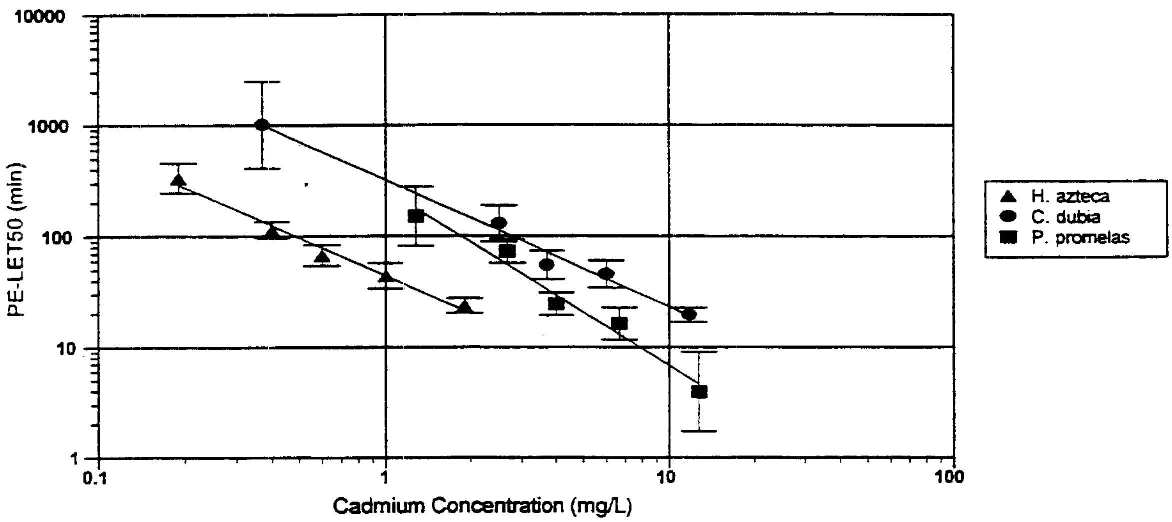
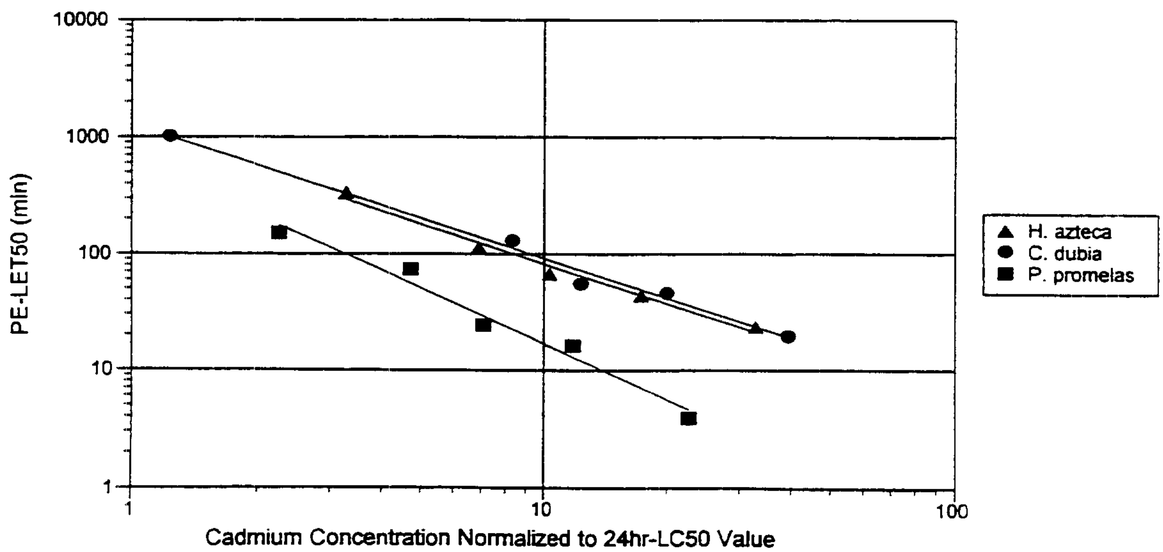


To determine whether differences in sensitivities observed among species were due to differences in their sensitivity to Cd or to differences in sensitivity to short-term exposures, the PE-LET$_{50}$ values were plotted against Cd concentrations which had been normalized to the 24-hr LC$_{50}$ values for that organism. Figure B-19 compares the species sensitivity on a normalized basis. Curves for *H. azteca*

Figure B-19. Comparison of PE-LET$_{50}$ Values for Different Species over a Range of Cd Concentrations Normalized to 24-hr LC$_{50}$ Values



and *C. dubia* lie directly on top of each other showing that the differences observed in short-term Cd exposure tests are entirely attributable to inherent differences in species sensitivity to Cd, and these differences are merely a reflection of differences observed at longer term exposures (24-hr LC_{50}). The response of *P. promelas*, however, was still different than for the two invertebrate species. *P. promelas* was considerably more sensitive to short-term Cd exposures than *H. azteca* or *C. dubia* on a normalized Cd concentration basis. This indicates that the 24-hr LC_{50} was not a good indicator of the short-term exposure response of *P. promelas* relative to other species. Even though *C. dubia* is more sensitive than *P. promelas* when 24-hr LC_{50}s are considered, *P. promelas* is more sensitive than *C. dubia* to short-term exposures (Figure B-19). This fact is related to the slope of the curves in Figure B-18. Because the *P. promelas* curve differs in slope from the other species, it is less sensitive (farther from the origin) at longer exposure times yet more sensitive (closer to the origin) at shorter exposure times. This is again probably due to a difference in the mechanism or multiple mechanisms of Cd toxicity between the *P. promelas* and the two invertebrate species.

Zinc Exposures. Figure B-20 compares the relative sensitivities of *H. azteca* and *C. dubia* to short-term zinc exposures. *C. dubia* is the most sensitive to Zn exposure, whereas *H. azteca* was more sensitive to Cd exposure. Notice that the curves are not straight lines as was the case with Cd exposures. The curves appear to reach asymptotes in both the x and y direction indicating that there is a threshold zinc concentration and a threshold duration of exposure below which no toxicity occurs. The thresholds for *C. dubia* appear to be much lower than those for *H. azteca*.

Figure B-20. Comparison of PE-LET_{50} Values for Different Species over a Range of Zn Concentrations

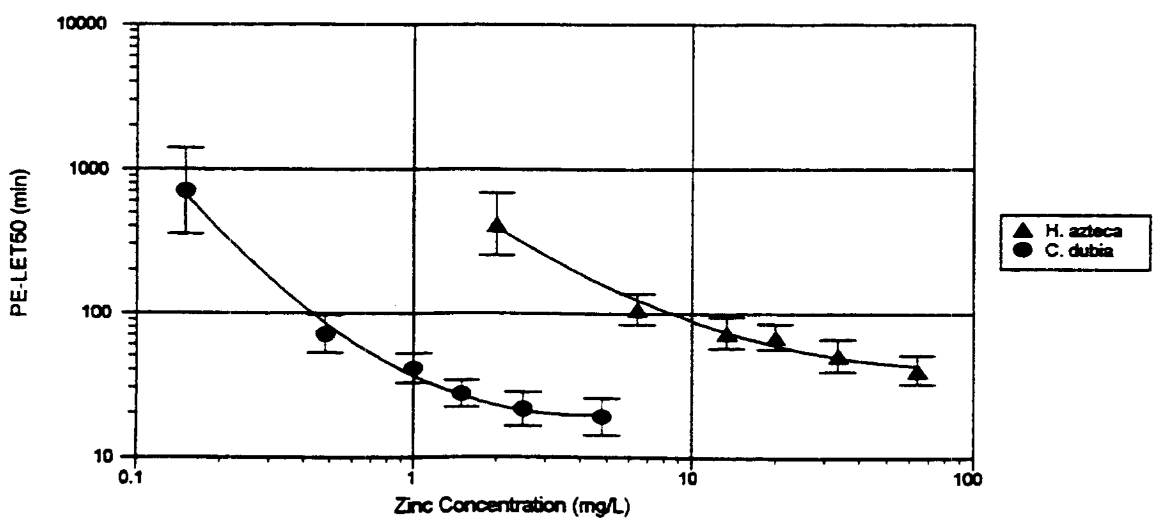


Figure B-21. Comparison of PE-LET$_{50}$ Values for Different Species over a Range of Zn Concentrations Normalized to 24-hr LC$_{50}$ Values

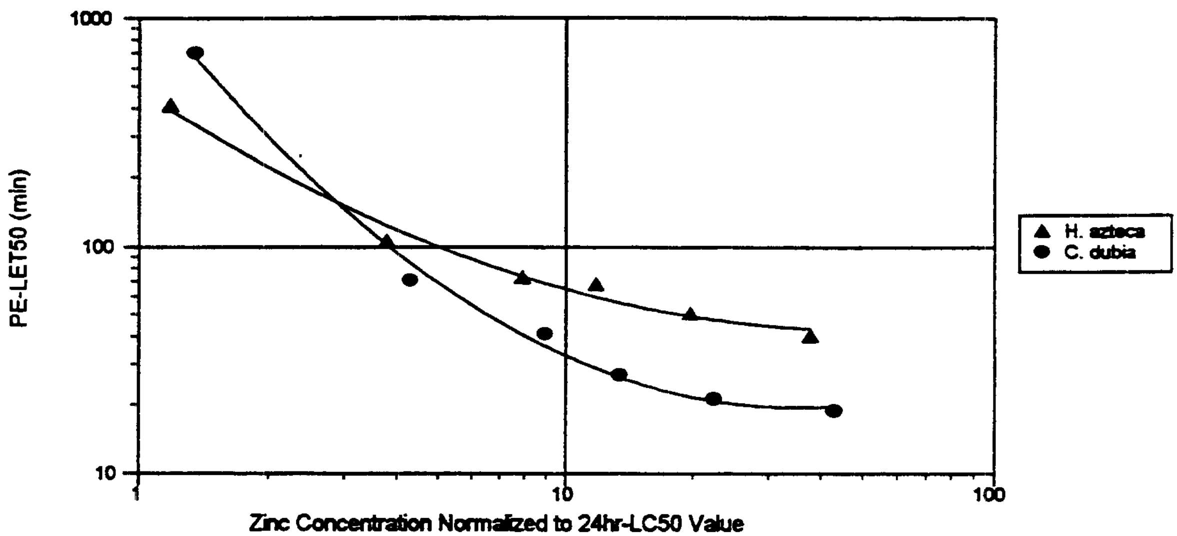

The Zn concentrations were again normalized using the 24-hr LC$_{50}$ values for each species to determine whether observed differences in short-term exposures could be explained by differences in 24-hr LC$_{50}$ values. For the case of Zn exposure (Figure B-21), the 24-hr LC$_{50}$ values do not entirely explain these differences. While the two curves are close to each other, they differ in slope. The disparity in the curves is not as great as it was between *P. promelas* and the other species in Cd exposure experiments (Figure B-19). The difference is probably due to the difference in thresholds. The curves would be altered by the proximity of the 24-hr LC$_{50}$ to the thresholds.

Between Toxicant Comparison of Brief Exposure Tests. Figure B-22 compares the *C. dubia* response to different toxicants. *C. dubia* is most sensitive to Zn exposure and least sensitive to phenol exposure. Notice also that *C. dubia* response to Cd is the most linear within the range observed. *C. dubia* response to Zn showed a curve that decreased in slope as it neared shorter exposure times, indicating the presence of a minimum threshold of exposure time. Phenol exposure strongly exhibited the presence of an exposure duration threshold.

Figure B-23 compares the *H. azteca* response to different toxicants. Only Cd and Zn were tested using *H. azteca*. While *C. dubia* was more sensitive to Zn exposure than Cd exposure, *H. azteca* was much more sensitive to Cd exposure. Zinc exposure to *H. azteca* also showed a curve that implies an exposure time threshold, and Cd exposure again showed a more linear response.

Figure B-22. Comparison of PE-LET$_{50}$ Values for *C. dubia* Exposure to Various Toxicants

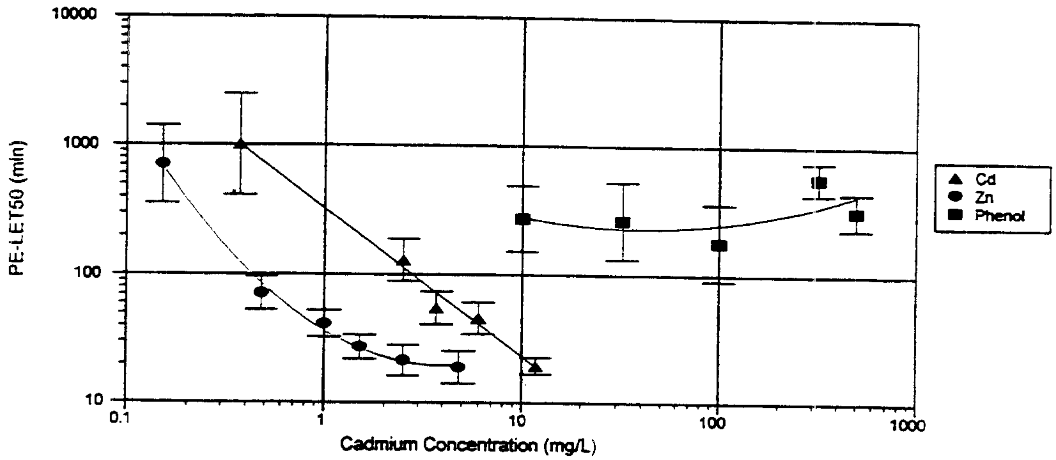

Figure B-23. Comparison of PE-LET$_{50}$ Values for *H. azteca* Exposure to Various Toxicants

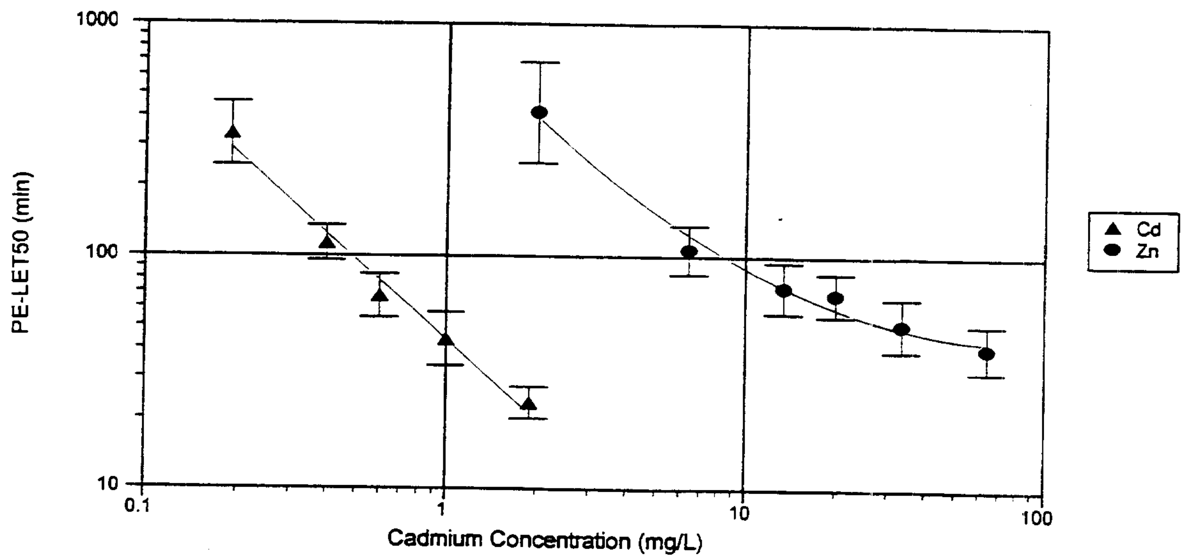

Between Stock Culture Comparison of Brief Exposure Tests. Brief exposure tests were performed using stock cultures of *H. azteca* and *C. dubia* from UIUC and the University of North Texas (UNT). Figure B-24 compares the results of brief Cd exposures between the UIUC and UNT stock cultures. *H. azteca* from both cultures were more sensitive to short-term Cd exposures than *C. dubia* from either culture. Within the same species, the UNT stock cultures were more sensitive than were the UIUC cultures. The slopes of the curves are relatively consistent between the different stock cultures and species. The differences in sensitivity between the stock cultures may be due to genetic variability in isolated strains, slight differences in culturing methods or practices, or simply differences in dilution waters between the two locations. The dilution waters used at each location were the waters in which organisms were normally cultured. Hard reconstituted water was used for *C. dubia* at both locations, dechlorinated tap water was used for UNT *H. azteca* stock, and filtered Copper Slough water was used for UIUC *H. azteca* stock. The characteristics of these dilution waters is seen in Table B-7.

Figure B-24. Comparison of PE-LET$_{50}$ Values for Different Stock Cultures over a Range of Cd Concentrations

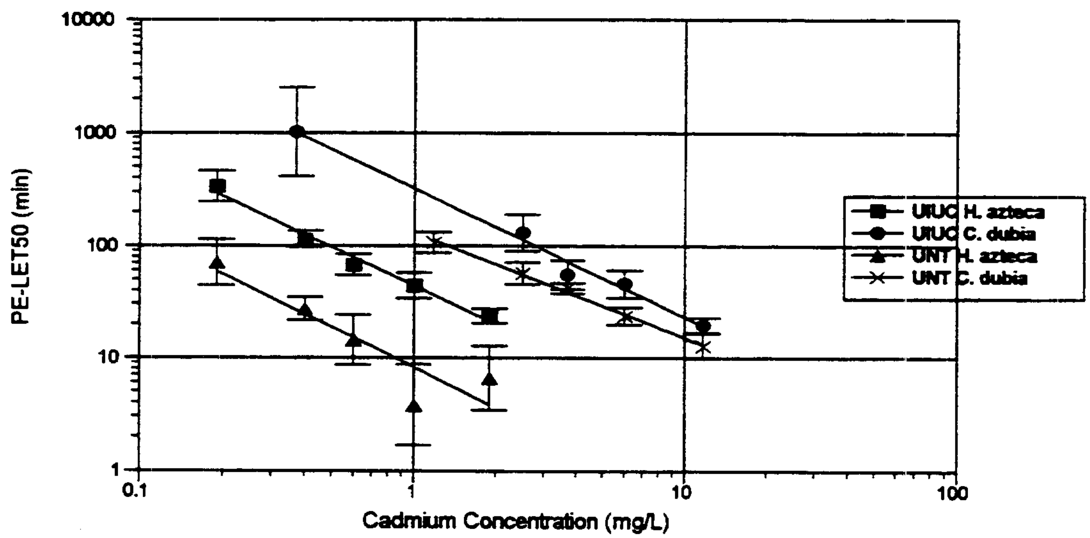

Table B-7. Chemical Characteristics of Dilution Waters Used

Dilution Water	pH	Hardness	Alkalinity
Reconstituted water	7.6 - 8.0	160 - 180	110 - 120
Dechlorinated tap	7.2 - 7.5	120	
Copper Slough	7.2 - 8.8	210 - 260	

Conclusions. Significant effects are indeed seen at very brief exposure times (even at durations of exposure as short as 15 minutes). Also, duration of exposure has a profound effect on the severity of the response. For these reasons, wet weather testing should use exposure times that match the duration of true wet weather exposures to adequately assess effects.

Secondly, there exists a potential for either delayed effects or organism recovery after brief toxic exposure. Delayed effects were seen for *H. azteca*, *C. dubia*, and *P. promelas* exposure to cadmium and zinc. Recovery from immobility was seen after *C. dubia* exposure to phenol. Delayed effects and recovery were even observed for the same contaminant. *C. dubia* experienced delayed mortality after cadmium exposure, yet organisms were able to recover from sub-lethal effects (enzyme inhibition). The potential for delayed effects and recovery indicate that wet weather testing should use methods which incorporate a post-exposure observation period. As comparisons of continuous exposures and pulse exposures with post-exposure observation indicated, measurement of endpoints only at the end of the exposure period can overestimate effects in the case of recovery and underestimate effects in the case of delayed effects.

Different species and even different stock cultures of the same species were seen to have different sensitivities to brief toxic exposures. This finding supports the test battery approach to wet weather monitoring used in this research. A battery of different species and different tests is necessary to adequately assess the effects of wet weather discharges where multiple contaminants and variable durations of exposure are present. In addition, it was also shown that sensitivity rankings done using longer exposure times do not always reflect sensitivity rankings of species exposed for short durations.

The research also found that certain duration of exposure thresholds exist for certain contaminants. A threshold of approximately four hours was necessary to elicit a response to phenol no matter what the exposure concentration. Zinc appeared to approach a threshold as exposure times dropped below 15 min. No exposure duration threshold existed for cadmium. This finding might affect wet weather monitoring, since the toxicity of certain contaminants need not be considered if exposure durations during the event are extremely short. Conversely, the toxicity of certain contaminants not displaying an exposure duration threshold would have to be of concern no matter how brief the duration of exposure.

Effects, such as growth suppression and reproductive impairment, which are generally considered the effects of chronic exposure, can occur after very brief (or acute) exposures. This research concluded that these chronic effects if present were observed on the margins between lethal exposures and no effect levels. Caution should be taken to not overlook effects typically deemed chronic even when brief, acute exposure conditions are present.

Event Toxicity Integration. As the project team examined frequency and duration issues in storm events, it became apparent that it was not possible to characterize toxicity in a storm event using traditional measurement and analytical techniques. Because toxicity stems from both contaminant concentration and the time-scale of exposure, both concentration and duration were critical issues in assessing toxicity in wet weather events. Results of the examination of storm event toxicity found variable toxicity for samples collected sequentially during a storm event. Another need became obvious: to provide a means of integrating the variable toxicity observed during a storm event into an integral measure of storm event toxicity.

The PE-LET_{50}, previously described, can determine a storm event toxicity that incorporates time varying concentrations during the event. This analysis combines PE-LET_{50} test results from samples collected during the event.

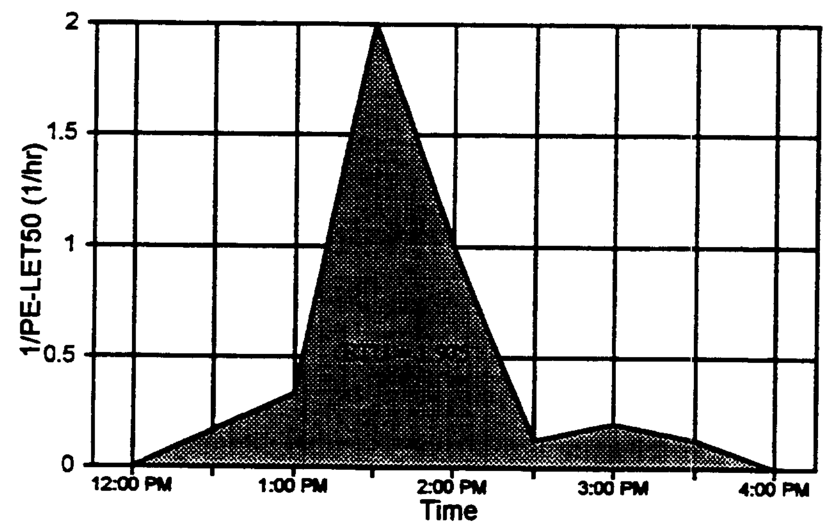
To complete this analysis, PE-LET_{50} values are determined for each sample collected during the event. For samples that showed little toxicity (that is less than 50% effect was measured in screening tests on 100% sample after 48 hours) the PE-LET_{50} for that sample is assigned a value >48 hours. Table B-8 shows example data for samples collected during a hypothetical four-hr episodic pollution event.

Table B-8. Example PE-LET_{50} Data for Event Toxicity Unit Analysis

Time of sample	PE-LET_{50} (hrs)	1/PE-LET_{50} (1/hr)
12:00	>48	0
12:30	6	0.167
1:00	3	0.33
1:30	.5	2
2:00	1	1
2:30	8	0.125
3:00	5	0.2
3:30	8	0.125
4:00	>48	0

The reciprocals of PE-LET_{50} values for individual event samples were then plotted based on the time of sample collection sequentially through the event (Figure B-25). Reciprocals of PE-LET_{50} values were used since PE-LET_{50} values decrease with increasing toxicity. For samples with low toxicity (PE-LET_{50} values >48 hours), the 1/PE-LET_{50} value was set to zero based on the assumption that the contribution to event toxicity from brief exposure to these samples would be negligible (since these samples produced low toxicity after 48 hours of continuous exposure). For consistency, PE-LET_{50} values and event time were plotted using the same units (minutes or hours). The area under the resulting curve was then numerically integrated using the trapezoid rule (Crosswhite, Hawkinson and Sachs, 1976). This integrated area, shown in gray in Figure B-25, then was termed the event toxicity unit (ETU).

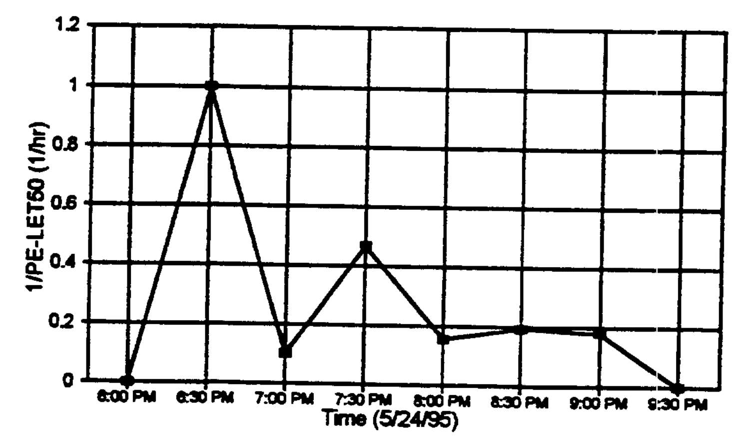
Figure B-25. Example Calculation of an Event Toxicity Unit (ETU)



The ETU is a dimensionless ratio that relates event characteristics to the exposure duration necessary to produce a 50% lethal effect, the PE-LET_{50}. An ETU greater than one indicates that the event would be expected to produce >50% lethality in the test population. An ETU less than one indicates that the event did not produce exposure conditions (magnitude, duration, or combination of both) necessary to produce 50% lethality. In the example given, the ETU was calculated as 1.975. Therefore, the hypothetical episodic pollution event, which lasted for only four hours, was predicted to have a greater than 50% effect. The value of the ETU is that it allows comparison of events that may differ in duration, intensity, and sequence of toxic conditions. Furthermore, the ETU can also be used to compare actual event conditions with reference exposure situations of known toxicity or experimental exposure conditions derived from event characteristics or event modeling.

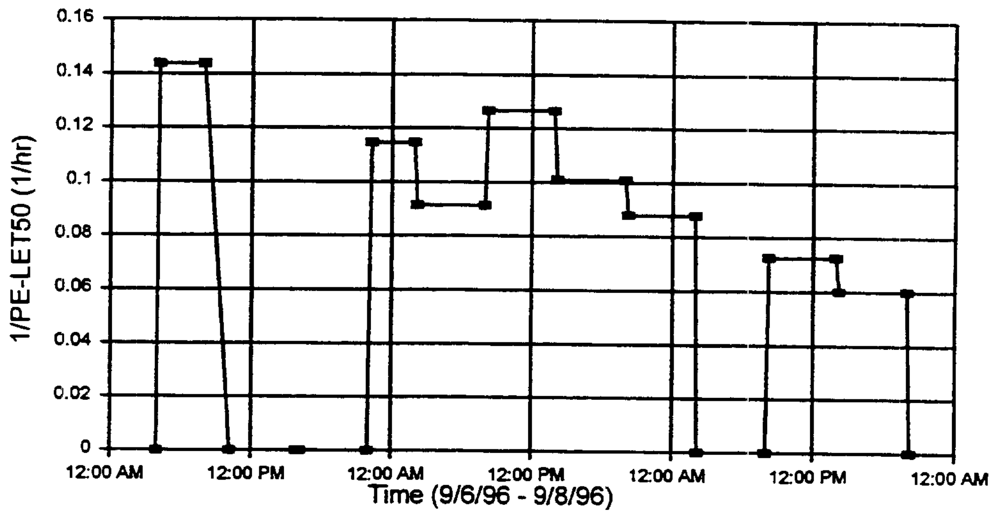
Testing of actual events was conducted for two events. The first was a storm event on 5/24/95 at the Cra site (Fort Worth, Texas). PE-LET_{50} values were calculated for six samples which showed significant toxicity in screening tests. Other samples during the event which showed little to no toxicity in 48 hour screening tests were assumed to have very high PE-LET_{50} values (>48 hrs) and therefore, the 1/PE-LET_{50} value was approximated at zero. The 1/ PE-LET_{50} values were plotted against the time of the event as shown in Figure B-26. The area under the curve was integrated to give a event toxicity unit (ETU) of 1.05. This indicates that the toxicity present during the 5/24/95 storm event at the Cra site was of a sufficient magnitude and duration to cause a greater than 50% lethal effect to *C. dubia*.

Figure B-26. 1/PE-LET_{50} versus Time for 5/24/95 Storm Event at Cra



Toxicity results for the 9/6/96–9/8/96 storm at the Cleveland #35 site appear in Figure B-27. Eight samples were tested for PE-LET_{50} values, while five samples throughout the event were estimated to have 1/PE-LET_{50} values of zero due to low toxicity in screening tests. At this site, the samples were composited over 6-hr periods. The 1/PE-LET_{50} value for each sample was plotted at the beginning and end of the composite period. This method assumes that the toxicity of the composited sample was consistent throughout the composite period. This minimizes toxicity peaks and gives the graph a step-change appearance, rather than the peak-and-valley appearance of the ETU graph for the Cra event. The ETU calculated for the Cleveland #35 event was 4.41. This event surpassed the magnitude and duration necessary for a 50% lethal effect by more than a factor of four. Even though the samples from the Cra event were more toxic than those from the Cleveland #35 site (based on 1/PE-LET_{50} values), the Cleveland #35 event was much more severe due to its longer duration.

Figure B-27. 1/PE-LET_{50} versus Time for 9/6/96 Storm Event at Cleveland #35 Site



Tables B-9 and B-10 show the LC_{50} values for the samples from the Cra and Cleveland #35 sites, respectively. The LC_{50} values for the Cra event showed greater toxicity, the LC_{50} does not reflect the duration of the event and, therefore, does not indicate the overall toxicity of the event.

Influence of Suspended Material on Inhibitory Quotient Test. In undiluted time series samples in which stormwater samples contained marked amounts of suspended material, the *C. dubia* IQ test consistently showed complete inhibition of fluorescence. It is possible that the organisms were feeding on the suspended material rather than the test substrate. If this occurred, any decline in fluorescence levels might not be toxicity related but simply because the organisms have not ingested a consistent amount of test substrate over all treatments. This hypothesis was tested by:

Table B-9. LC_{50} Values for Samples from 5/24/96 Event at Cra Site

Sample Date	Sample Time	LC_{50} (% of whole effluent)
5/24/96	6:30PM	18.58
	7:00PM	35.03
	7:30PM	not determined
	8:00PM	24.88
	8:30PM	12.07
	9:00PM	12.50

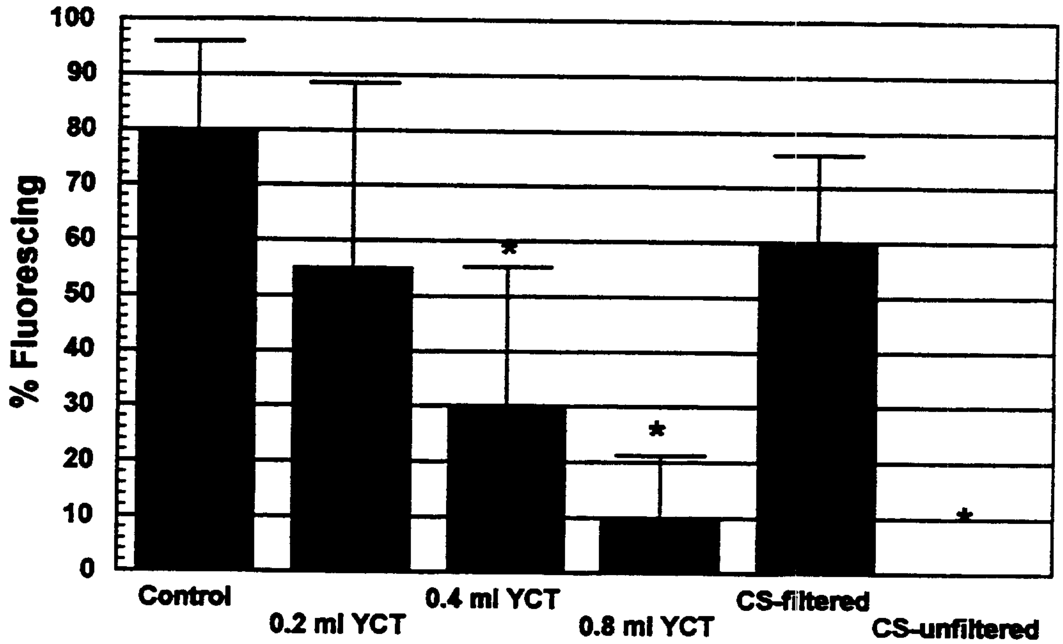
Table B-10. LC_{50} Values for Samples from 9/6/96 Event at Cleveland #35 Site

Sample Date	Sample Time	LC_{50} (% of whole effluent)
9/6/96	4:15AM	22.82
	10:15PM	34.02
9/7/96	2:15AM	39.23
	8:15AM	32.42
	2:15PM	35.36
	8:15PM	35.36
9/8/96	8:15AM	68.04

- Adding varying amounts of yeast-cerophyll-trout food (YCT) mixture into exposure vessels and monitoring changes in the level of fluorescence relative to controls;
- Adding varying amounts of kaolinite into exposure vessels and monitoring changes in the level of fluorescence relative to controls; and
- Comparing fluorescence in filtered and unfiltered stormwater samples.

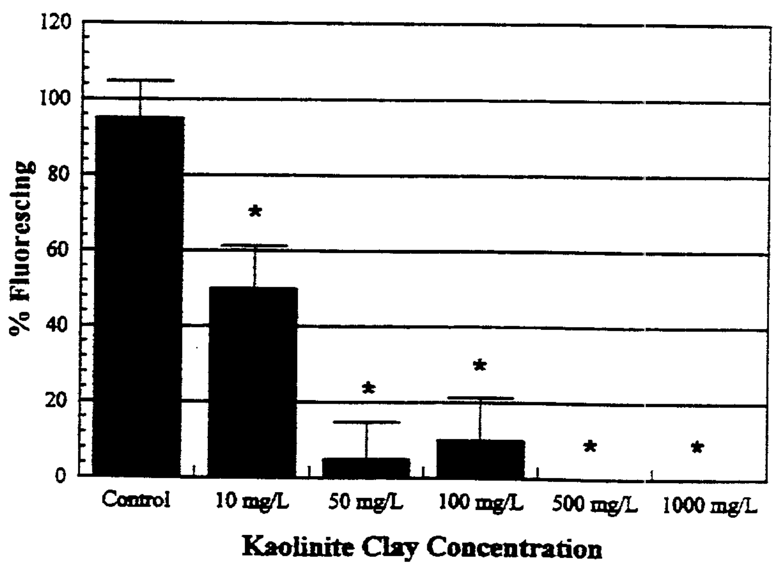
Adding 0.2, 0.4, or 0.8 mL of YCT to test vessels caused a concentration-dependent reduction in the level of fluorescence (Figure B-28). The addition of 0.4 and 0.8 ml YCT significantly reduced fluorescence relative to the control.

Figure B-28. IQ Test Results with YCT Added to Test Solution



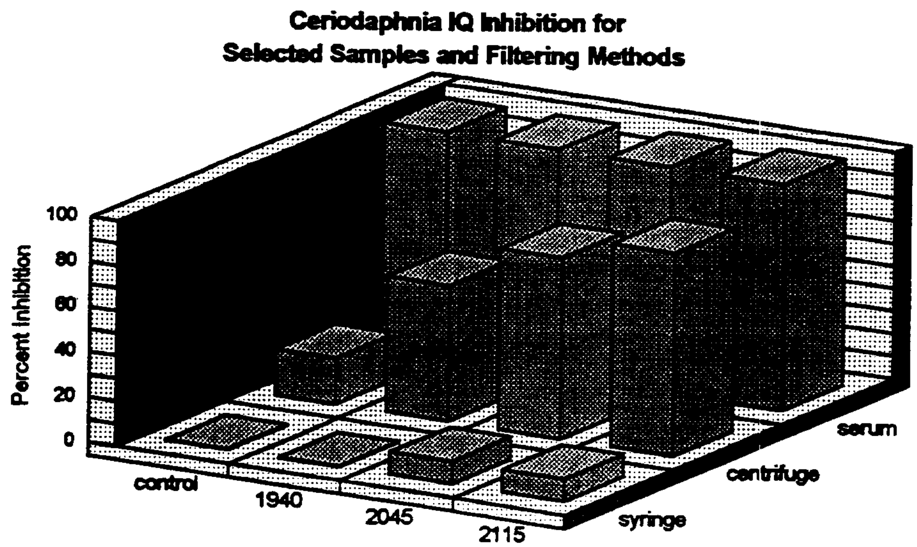
The addition of kaolinite clay to test vessels also showed a concentration-dependent reduction in fluorescence over the range 10 to 1,000 mg/L (Figure B-29). Fluorescence was significantly reduced, relative to the control at 10 mg/L with no fluorescence being evident at concentrations of >500 mg/L.

Figure B-29. IQ Test Results with Kaolinite Added to Test Solution



Comparisons of filtered and unfiltered water samples from the 2/26/96 storm at KLSS (19.40, 20.45, and 21.15) showed that for the IQ test there was a reduction in apparent toxicity with filtration of samples. However, the method of filtration proved to be important, and samples filtered though 0.45-µm membrane filters, Microtox solid phase filters, and centrifuged for 5 min at 5,000 rpm gave different results (Figure B-30). Filtering the sample through a 0.45-µm filter only minimally inhibited fluorescence in *C. dubia* exposed to all samples, whereas differences in inhibition were seen in some centrifuged samples. It is likely that filtering the samples through a 0.45-µm filter removes all the particulate material, but some toxicants might bind to the filter. Centrifuged samples will not be affected in this way and an equilibrium will be established between the water and solid phases. Filtering samples through the blood serum tubes still resulted in complete inhibition which may have been due to the presence of particulates or the leaching of toxic material from the tubes themselves.

Figure B-30. IQ Results for Different Filtering Methods



These findings indicate that all samples containing particulate material must either to be centrifuged prior to the *C. dubia* IQ test, or the test procedure must be modified so that animals were not exposed to particulates during testing. This could be achieved by taking organisms from the undiluted samples after 1-hr exposure and then exposing them to the test substrate in clean water for 15 min. Enzyme inhibition persisted for several hours after short-term exposure to cadmium, so recovery would not be expected during the 15-min exposure to the test substrate in clean water.

Microtox Stimulation/Hormesis. A common finding of Microtox assays of stormwater samples was the presence of stimulation rather than the expected inhibition of light output. Investigations indicated that the stimulation observed could be due to hormesis—a stimulation occurring as a result of exposure to mild toxicity. Hormesis has been documented repeatedly, although it is not necessarily understood. Stebbing (1981) collected numerous examples of hormesis involving a wide range of organisms, including algae, protozoa, vertebrates, and invertebrates. The stressors investigated ranged from heavy metals and organic compounds (including hydrocarbons), antibiotics, and ionizing radiation. The concentration-response curves tended toward a similar U-shaped form where there was a mild stimulation followed by an increase inhibition with increasing concentration.

Analysis of stormwater samples in this study produced a reasonably consistent stimulation in the Microtox assay. Figure B-31 illustrates Microtox results from a storm event sampled on July 4, 1995, at KLSS where the drop in conductivity can be used to show storm event onset and duration. Figure B-32 illustrates the results for all test systems used to evaluate this storm event. All other organisms exhibited an inhibition upon exposure to the storm samples, while the Microtox assay generally indicated stimulation, except in samples taken around the first flush, where reductions in light production of up to 87% were measured (Table 6-3). These results were consistent with data gathered from storm samples as a part of this project.

The consistency of response suggested a more detailed examination of low concentration response with the Microtox assay could identify an increased sensitivity of response not previously reported. A series of studies were initiated with the support of the Microbics Corporation (now Azur Environmental) to evaluate stimulation/hormesis in the Microtox assay. Six metal contaminants (Cd, Cr, Cu, Pb, Ni, and Zn) along with phenol and sodium lauryl sulfate were tested using procedures consistent with screening level testing used in this project. A dilution series of ten dilutions of each contaminant were tested simultaneously at two temperatures (15°C and 23°C). Light readings were recorded at 5, 10, and 20 minutes. Experiments were performed three times for each metal, each using a different lot of reagent. Thirty minutes after each vial of reagent was reconstituted, but prior to performing experiments, a test using a standard phenol solution was performed.

Statistical analysis was performed identifying the 95% double-sided bound of the controls. This was considered to be the natural variability of the test. Only data points occurring outside of this range were considered significantly different from controls. Table B-11 summarizes the results by contaminant and temperature for the contaminants tested, and Table B-12 provides the concentration ranges of stimulation by contaminant and temperature.

Figure B-31. Microtox Assay Results for the July 4, 1995, Storm at Kaufman Lake Storm Sewer

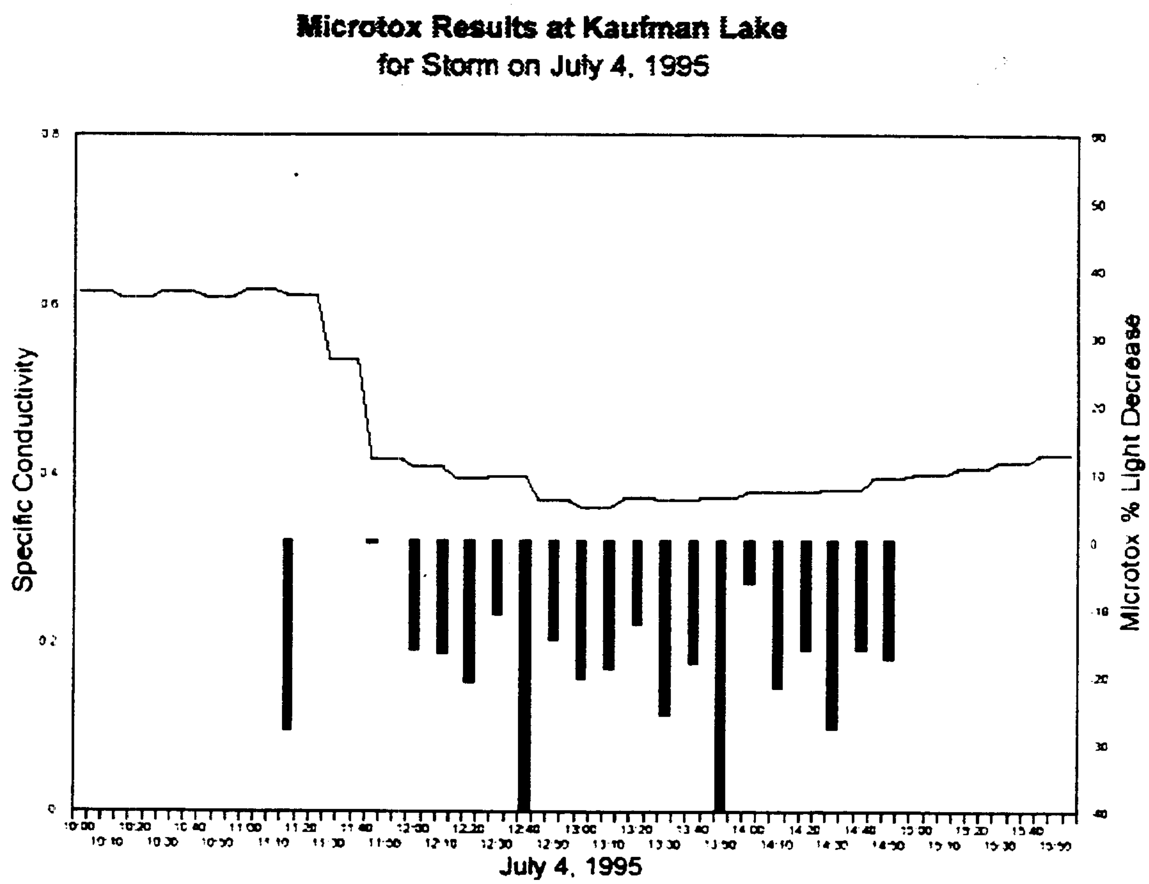


Table B-11. Summary of Hormesis by Contaminant and Temperature

Chemical	Evidence of Hormesis	Temperature of Occurrence
Cadmium	yes	15°C
Chromium	yes	23°C
Copper	no	
Lead	yes	15°C 23°C
Nickel	yes	15°C, 23°C
Zinc	yes	15°C
Phenol	yes	15°C, 23°C
Sodium Lauryl Sulfate	yes	15°C, 23°C

R0025626

Figure B-32. Test Battery Results for the July 4, 1995, Storm at Kaufman Lake Storm Sewer

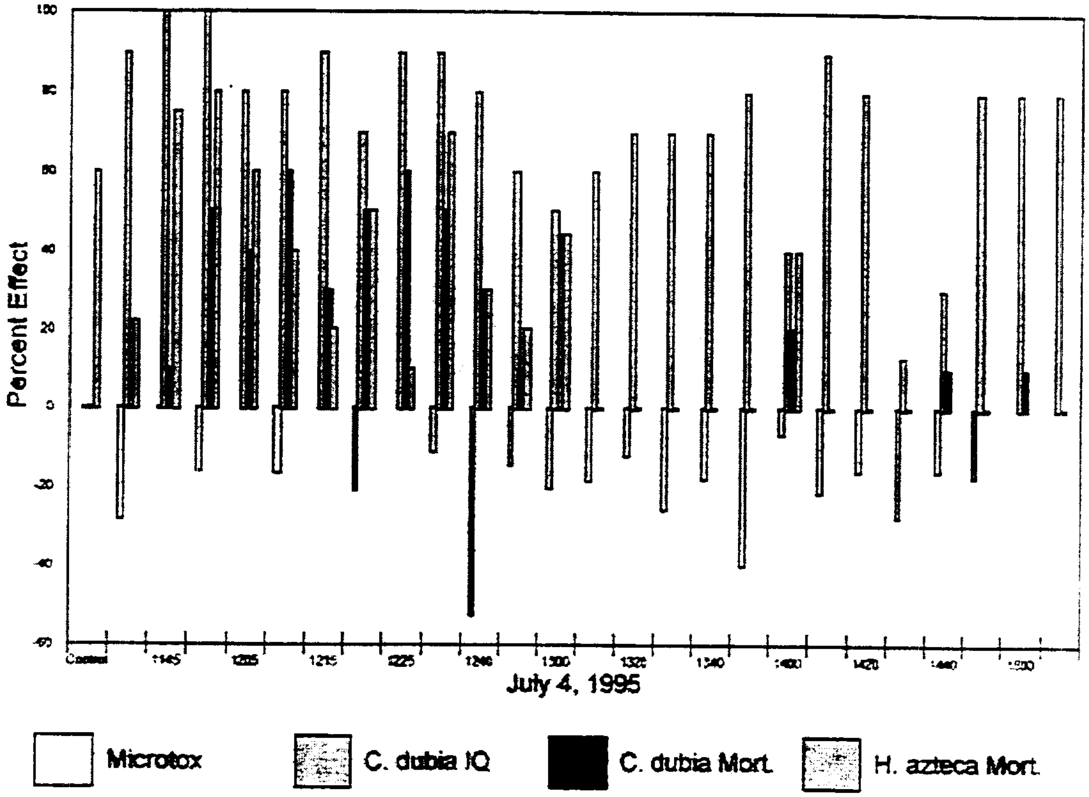

Table B-12. Concentration Ranges of Stimulation by Contaminant and Temperature

Contaminant	Range @ 15°C (mg/L)	Range @ 23°C (mg/L)
Cadmium	0.05, 0.5-2.5	–
Chromium	–	0.1-10.0
Copper	–	–
Lead	0.001-0.01	0.001, 0.05
Nickel	0.01, 1.0	0.1-1.0, 5.0-50.0
Zinc	0.001-0.1	–
Phenol	0.1-0.5, 2.5	0.05-5.0
Sodium Lauryl Sulfate	0.05-0.1	0.0001, 0.001, 0.05-0.5

The experiments supported the conclusion that it is possible to quantify stimulation at low exposure levels, and for several contaminants a concentration-response relationship could be identified for the range of exposure concentrations. It was also apparent from this research that the frequency of occurrence and magnitude of induced stimulation was affected by several factors. Some contaminants produced more stimulation than others, particularly chromium and the organic compounds phenol and sodium lauryl sulfate. When the stimulation levels observed in these experiments were compared with stimulation levels observed in stormwater sampling, no single contaminant produced maximum stimulation levels observed in stormwater (up to 60%). Further testing is needed with binary mixtures and simulated stormwater to determine if such high stimulation levels can be obtained experimentally. It is evident that the presence of certain contaminants in samples at low concentrations may cause stimulation of light production, with inhibition of light production being observed at higher concentrations. This pattern of response needs to be considered when interpreting receiving water toxicity data.

Advanced Screening Methodologies

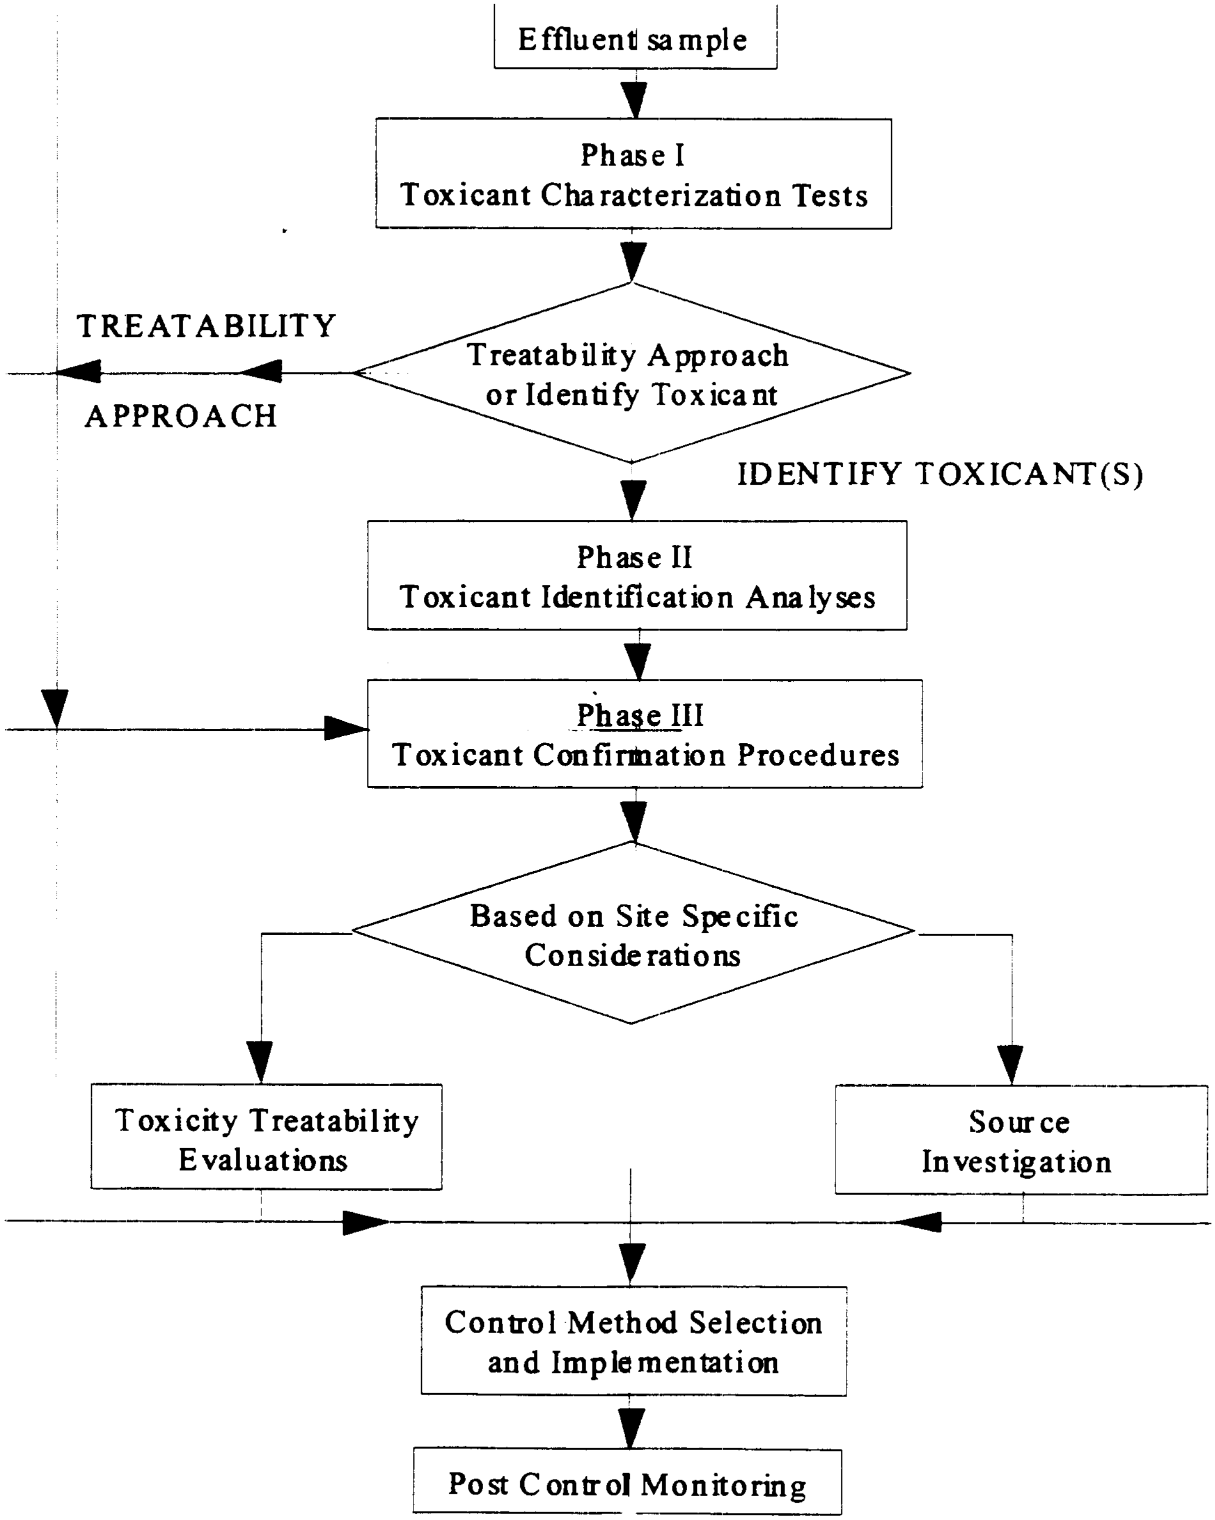
Once high or moderate toxicity has been identified using basic screening tests, then advanced techniques may be used to identify the causative agent(s) or source(s) of the toxicity.

Toxicity Identification Evaluation (TIE) Procedure. The TIE procedure forms part of a Toxicity Reduction Evaluation (TRE); it is designed to identify the cause of toxicity in environmental water samples. It encompasses three phases:

- Toxicant characterization (Phase I), where the objective is to identify the fraction(s) of the sample causing toxicity;
- Toxicant identification (Phase II), where the objective is to identify the toxicant(s) responsible for the observed toxicity;
- Toxicant confirmation (Phase III), where the objective is to confirm the true cause of toxicity.

Figure B-33 provides an outline of the toxicity reduction evaluation procedure and further details on each phase are provided in the relevant US EPA documents (US EPA 1988; 1989a,b).

Figure B-33. Flow Chart for Toxicity Reduction Evaluations (from US EPA, 1988)



R0025629

Toxicity characterization involves separating the environmental water sample (and a dilution water control) into a series of fractions using processes such as aeration, filtration (through glass fiber filters) and ^{18}C solid phase extraction, oxidant reduction, chelation with ethylenediamine tetraacetic acid (EDTA), and graduated pH adjustment. This process is designed to identify in which fraction or fractions toxicity is present before toxicity identification and confirmation is carried out to determine the specific toxicant(s) responsible for test responses. The aeration, filtration and ^{18}C solid phase extraction procedures are carried out at three pH conditions: acid (pH 3), unmodified (initial sample pH), and basic (pH 11). Table B-13 summarizes the objective of each fractionation step in the characterization procedure.

Table B-13. Objectives of the Different Fractionation Steps in Toxicity Characterization

Characterization step	Objective
pH adjustment	To provide information on the nature of the solubility, polarity, volatility, stability and speciation of the toxicant(s)
Aeration	To provide information on whether the toxicant(s) is volatile, sublatable or oxidizable
Filtration (glass fiber filters)	To provide information on whether the toxicant(s) is associated with filterable material
^{18}C solid-phase extraction	To provide information on whether the toxicant(s) is a relatively non-polar organic compound or metal chelate
Oxidant reduction addition	To provide information as to whether the toxicant(s) is reduced by the addition of sodium thiosulphate. This step will identify the extent to which toxicity is caused by substances such as chlorine, bromine, iodine, manganous ions, some electrophile organic compounds and some cationic metals
EDTA chelation addition	To provide information as to whether the toxicant(s) is removed by the addition of EDTA. This step will identify the extent to which toxicity is caused by certain cationic metals.
Graduated pH test	To provide information as to whether the toxicity of the toxicant(s) is pH dependent. This step will identify the extent to which ammonia causes toxicity.

The KLSS system consistently shows measurable toxicity during storm events and toxicity characterization (Phase 1 TIE) was carried out on the 1500 sample from the 4/25/96 storm which initially caused 44% light inhibition in the Microtox test and 100% inhibition of fluorescence in the *C. dubia* IQ test. The Microtox test was performed according to US EPA procedure, and the procedures for aeration, filtration through 0.45-μm glass fiber filters, filtration through a 2-ml ^{18}C solid phase column at the three pH values are summarized in Figures B-4 and B-5 for the stormwater and reference water samples. Table B-14 shows the timing of the stormwater sample manipulations and toxicity testing. The fractionation steps were mostly carried out on 4/27/96, and the resulting fractions were analyzed on 4/28/96. The effects of oxidant reduction and EDTA chelation were also assessed on 4/28/96 using the following concentrations of sodium thiosulphate (13 g $Na_2S_3O_3$ per liter stock) and EDTA (37.2 g per liter stock):

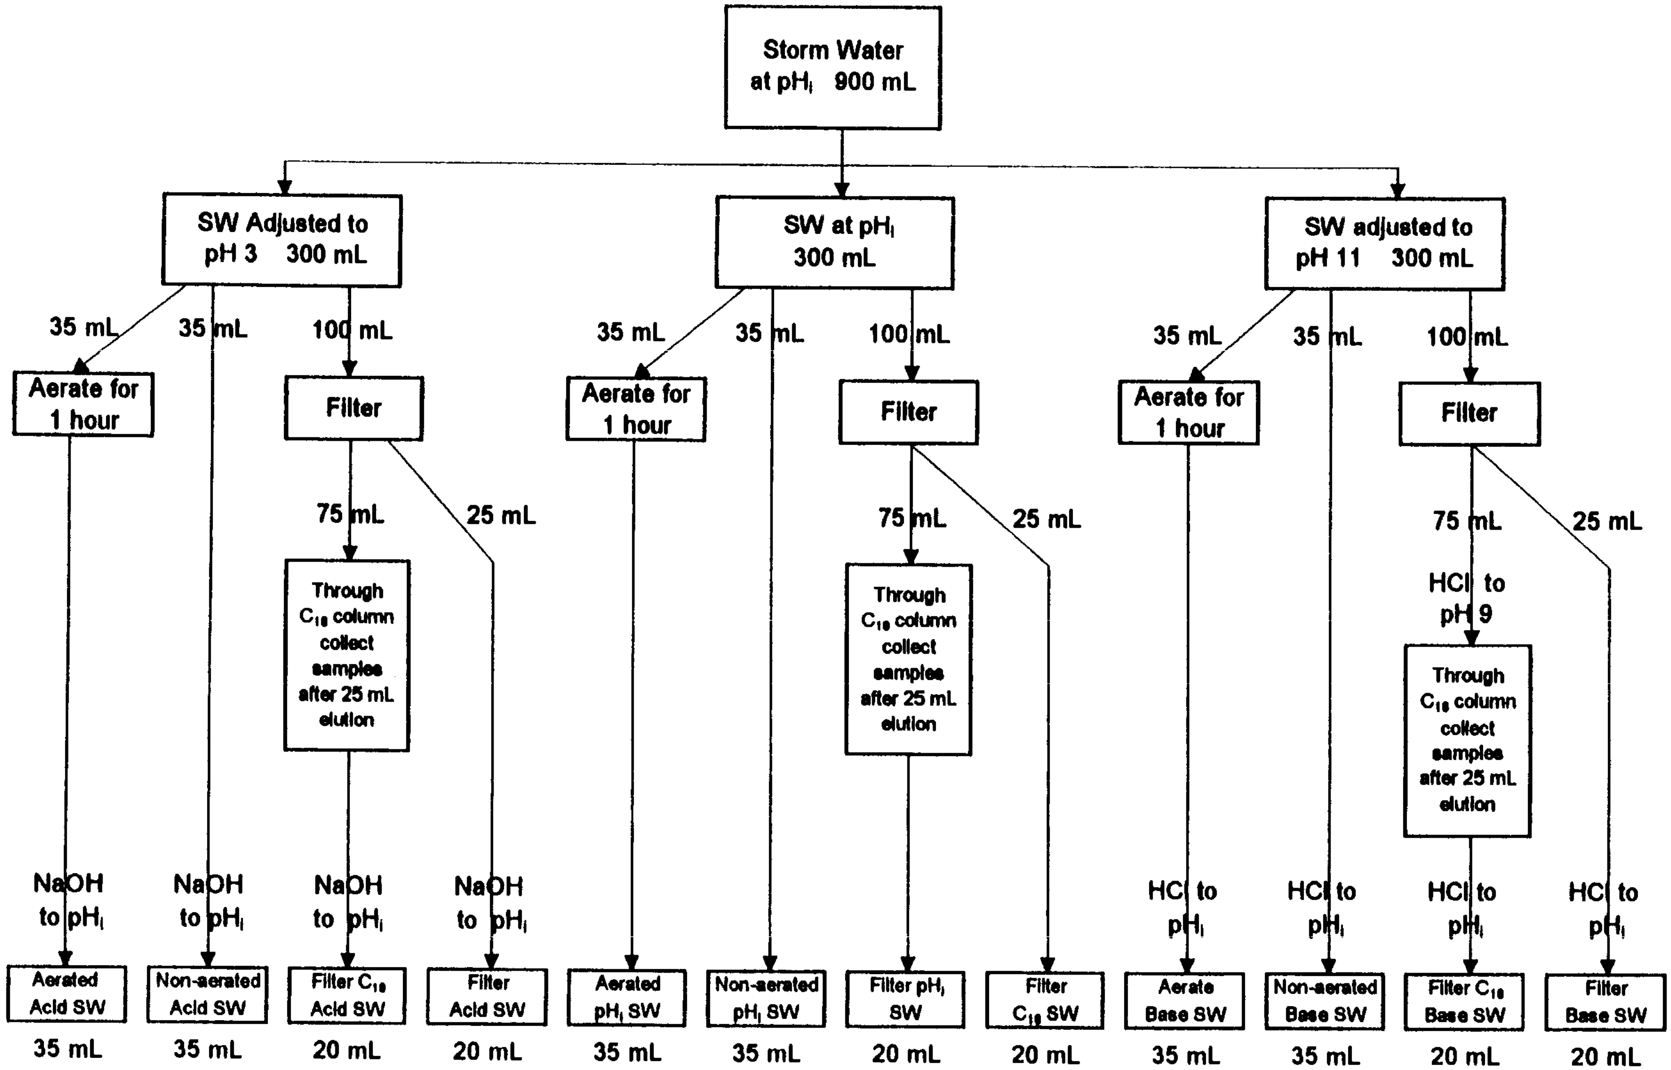
Sodium thiosulphate (g L^{-1}): 0, 0.05, 0.1, 0.2, 0.4, 0.6
EDTA (g L^{-1}): 0, 0.05, 0.1, 0.2, 0.4, 0.6

These concentrations were prepared by adding appropriate volumes of the stock solutions to volumes of the stormwater sample. The stormwater sample had a pH of 7.63, while the reconstituted reference water had a pH of 7.36.

Table B-14. Schedule for Conducting Toxicity Characterization on the 1500 Sample from the 4/25/96 Storm at the Kaufman Lake Storm Sewer

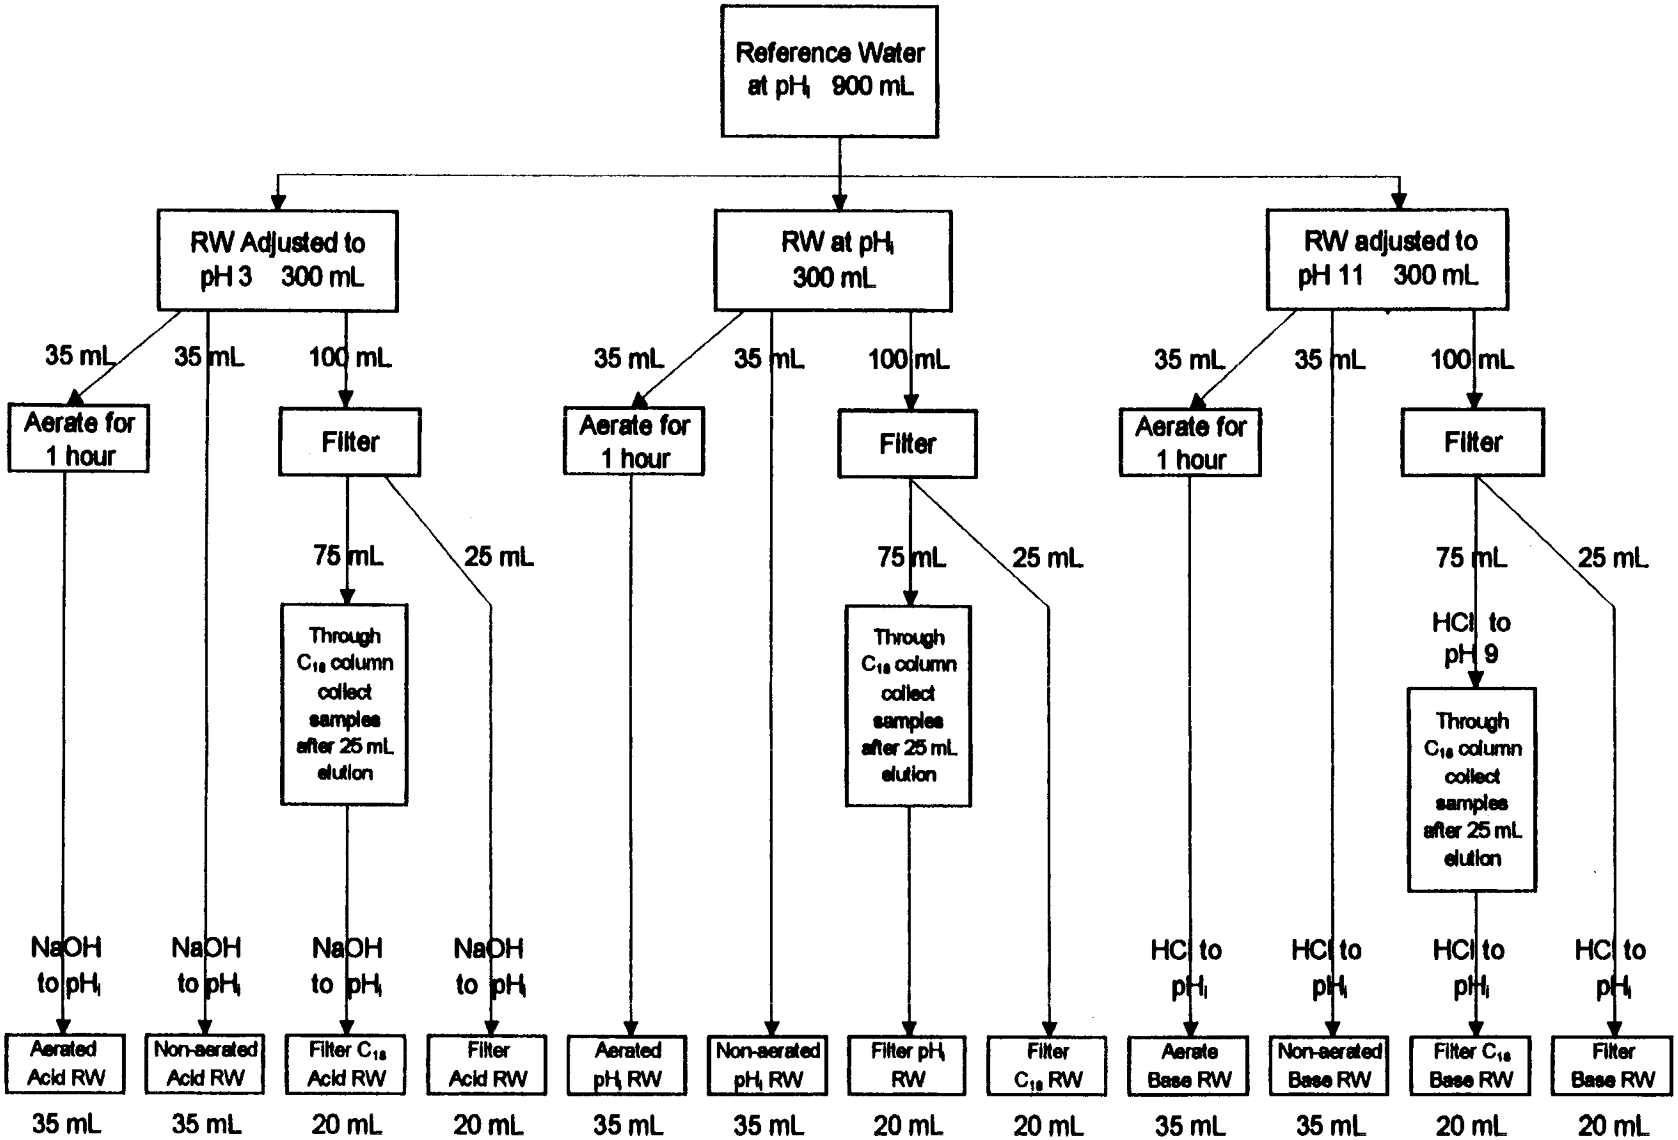
Date	Operation
4/25/96	Intra-event stormwater samples collected
4/26/96	Stormwater samples analyzed with Microtox and *C. dubia* IQ test, sample identified for toxicity characterization
4/27/96	Initial Microtox toxicity test Sample manipulations on stormwater and reference water samples: • pH adjustment (pH 3, pH 7.4, pH 11) • pH adjustment/aeration • pH adjustment/filtration • pH adjustment/ ^{18}C solid phase extraction
4/28/96	Microtox toxicity tests on: • Unmodified sample • pH adjusted samples • aerated samples • filtered samples • ^{18}C solid phase extraction samples • sodium thiosulphate addition samples • EDTA addition samples • graduated pH samples

Figure B-34. TIE Procedure for Stormwater Samples



R0025632

Figure B-35. TIE Procedure for Reference Water Samples



Microtox testing was carried out on undiluted samples and fractions, and light inhibition was measured on three replicates after 5, 10, and 20 minutes. Measurements were made after these different exposure periods since changes in the extent of light inhibition over time can provide additional information on the nature of contaminants present in a sample. For example an increase in light inhibition over time is indicative of the presence of heavy metals such as copper and zinc since these substances require longer exposure times than organics to exert any toxic effects (see Reteuna et al., 1986).

Table B-15 shows the light inhibition in the Microtox test measured in the different fractions of the storm water sample after 20 min exposure relative to the reference water fractions. Testing of the unmodified sample showed that light inhibition declined from 44% on 4/26/96 to 23% on 4/28/96, indicating the presence of non-conservative contaminants. For pH 7 fractions, no reduction in light production was evident after aeration while responses were reduced following the addition of EDTA. On the basis of the data the limited toxicity measured on 4/27/96 was probably due to a combination of volatile materials and metals.

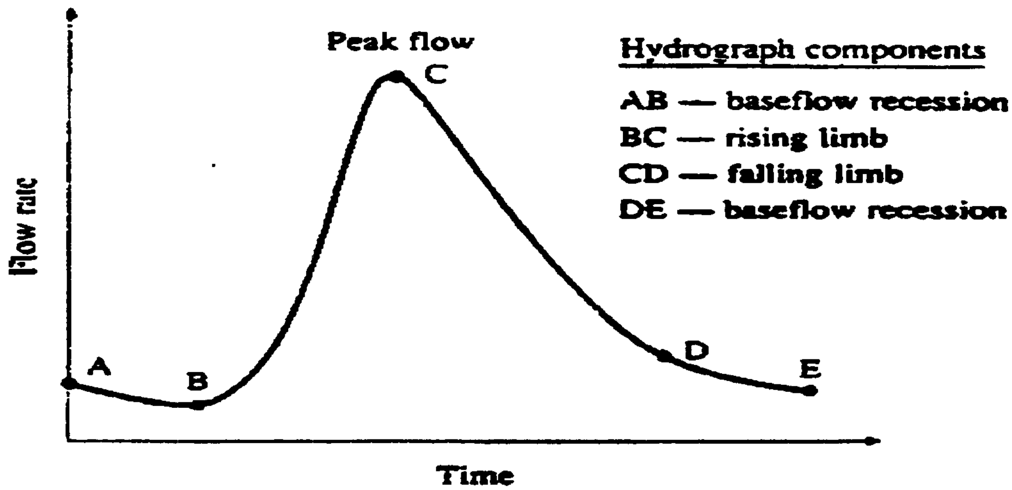
Hydrograph-Based Toxicity Prediction. Literature reports and observations made during field testing on this project, and a general analysis of contaminant/hydrograph relationships suggest that toxicity during a storm related hydrograph should be predictable. To this end, a simple predictive model of site-specific receiving system toxicity associated with storm events was developed. The underlying concept for the development of this model was that it was possible to use regional hydrologic information to describe hydrograph characteristics. Further, it was possible to translate expected contaminant concentration into a toxicity unit (TU), and provide an additive estimate of event toxicity.

The model completes an estimation of a hydrograph from a partial specification of hydrograph characteristics. On the basis of this projection, and estimates of contaminant input, the model then estimates the expected stream toxicity during runoff events. The hydrograph is a function of "total available overland flow supply, subsurface flow, groundwater flow, slope of the overland and stream segments, and geometry of channels" (Bras, 1990). The hydrograph can be separated into two elements, a rising limb and a recession limb (Figure B-36).

Table B-15. Microtox Data for the Toxicity Characterization of the 1500 Sample from the 4/25/96 Storm at the Kaufman Lake Storm Sewer

Fraction	% Light Inhibition in Stormwater Samples Compared to Reference Water Samples		
	5 mins	10 mins	20 mins
Aerated, acid	-2.6	-0.9	-1.4
Non-aerated, acid	-0.7	1.2	-5.6
Filter, acid	-5.9	0.2	5.8
Filter ^{18}C, acid	-11.5	-8.8	-6.9
Aerated, pH7	-19.7	-19.7	-10.5
Non-aerated, pH7	10.4	9.6	7.0
Filter, pH7	10.5	12.3	10.6
Filter ^{18}C, pH7	21.3	18.5	21.3
Aerated, base	-20.3	-20.3	-16.3
Non-aerated, base	-31.2	-29.9	-23.9
Filter, base	13.8	18.4	20.9
Filter ^{18}C, base	-0.2	-1.4	1.4
	% change in response relative to the control		
	5 min	10 min	20 min
0.05 g l^{-1} $Na_2S_30_3$	-3.8	-4.7	-1.9
0.1 g l^{-1} $Na_2S_30_3$	-5.1	-5.7	-4.1
0.2 g l^{-1} $Na_2S_30_3$	-2.1	-2.1	-0.8
0.4 g l^{-1} $Na_2S_30_3$	-0.9	1.0	0.4
0.6 g l^{-1} $Na_2S_30_3$	0	1.4	3.8
0.05 g l^{-1} EDTA	-11.3	-10.4	-10.4
0.1 g l^{-1} EDTA	-10.7	-8.9	-7.8
0.2 g l^{-1} EDTA	-7.8	-8.4	-8.5
0.4 g l^{-1} EDTA	-5.3	-6.8	-5.9
0.6g l^{-1} EDTA	-13.1	-13.5	-14.1

Figure B-36. Example Hydrograph, Illustrating Rising and Falling Limbs



Rising limb characteristics, such as the peak discharge and the time to reach the peak, are dependent on basin geometry and storm event characteristics. The recession limb of a hydrograph may be modeled according to:

$$Q_0 = Q_t K^t \qquad \text{B-1}$$

where t is the length of time between Q_0 and Q_t and K is the recession constant for a region where the units of time are minutes or hours for small basins and days to weeks for large basins (Viessman et al., 1989). Viessman et al. (1989) described the procedure for determining the appropriate value of the recession constant. First, a hydrograph is constructed to determine discharge at the beginning and end of a time interval. Second, these final and initial discharge values for each interval are plotted against other. Finally, a slope is determined as the value for the recession constant for the system. An example of hydrograph analysis is provided in Figure B-37 for a small storm event.

Meybeck et al. (1992) identified how water quality might change as a function of discharge. Figure B-38 illustrates how contaminant concentration might fluctuate with discharge. In the first figure (A), the lines represent the following: (1) A general decrease in concentration with discharge, which

R0025636

implies increasing dilution of a substance introduced at a constant rate. (2) Limited increase in concentration generally associated with the flushing of soil constituents. (3) a similar mechanism as curve (2), but a higher discharge causes dilution of the soil runoff water. (4) Increase in particulate matter due to sheet erosion and bed remobilization. (5) A hysteresis loop that is observed when time is introduced as an additional parameter in the sediment-discharge relationship. (6) Water source with a constant concentration, for example Cl^- in rainfall. Figures B and C provide illustrations for change in concentration with time for different, single, storm events. A common component of the single event illustration is the presence of a "first flush" of contaminants (Walling and Foster, 1975). Following the first flush, contaminant concentrations can vary. Concentrations may be low if diluted by storm flows, or show peaks of concentration through time due to different concentration times for different first flush flows in a basin, or increased concentration due to resuspension of previously settled contaminants.

To convert predicted or actual contaminant concentrations to effect estimates the toxic unit (TU) defined by US EPA (1991) was used. A TU is "a measure of toxicity in an effluent as determined by the acute toxicity units or chronic toxicity units measured: and are simply reciprocals of the LC_{50} or the No Observable Effect Concentration (NOEC). In this model, the acute toxicity unit was used.

A number of assumptions were made in model development:

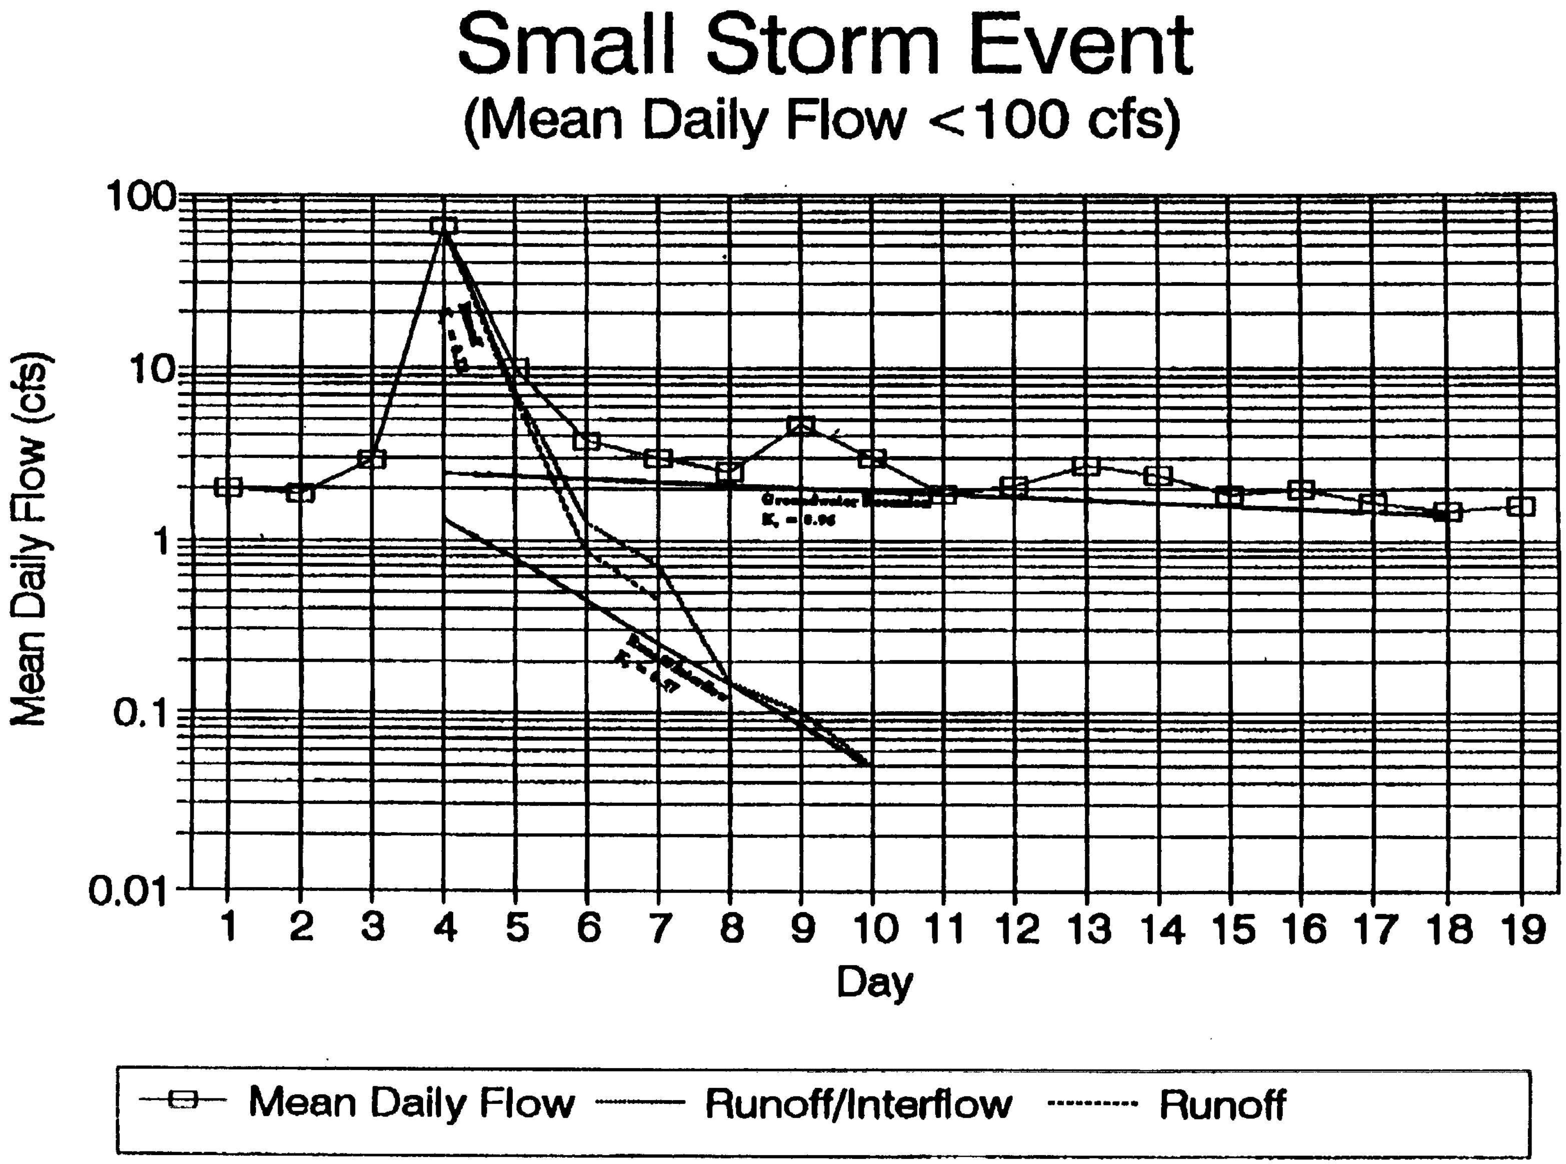
- The rising limb of the model was assumed to be linear.

- The period of hydraulic stress (important is considering the contribution of resuspension to contaminant concentration) was assumed linear along the rising limb and parabolic on the recession limb until an inflection point. Hydrographs are initially convex following the peak and concave after an inflection point. This inflection point is taken to be the end point of the period of hydraulic stress.

- The receding limb of the model following the period of hydraulic stress is based on a recession limb model proposed by Viessmann et al. (1989):

$$Q_0 = Q_t e^{-Kt} \qquad \text{B-2}$$

Figure B-37. Example of Methods Used to Define Recession Constants for Storm Hydrograph



This approach assumes a constant value for the recession constant, which is intended to provide a simplified implementation of K estimation in Appendix A.

- First flush contaminant introduction, expressed in toxic units is assumed to be instantaneous and completely mixed, with a steady state addition continuing with runoff after this pulse. The first flush in this model occurs at 30% of the time to peak.

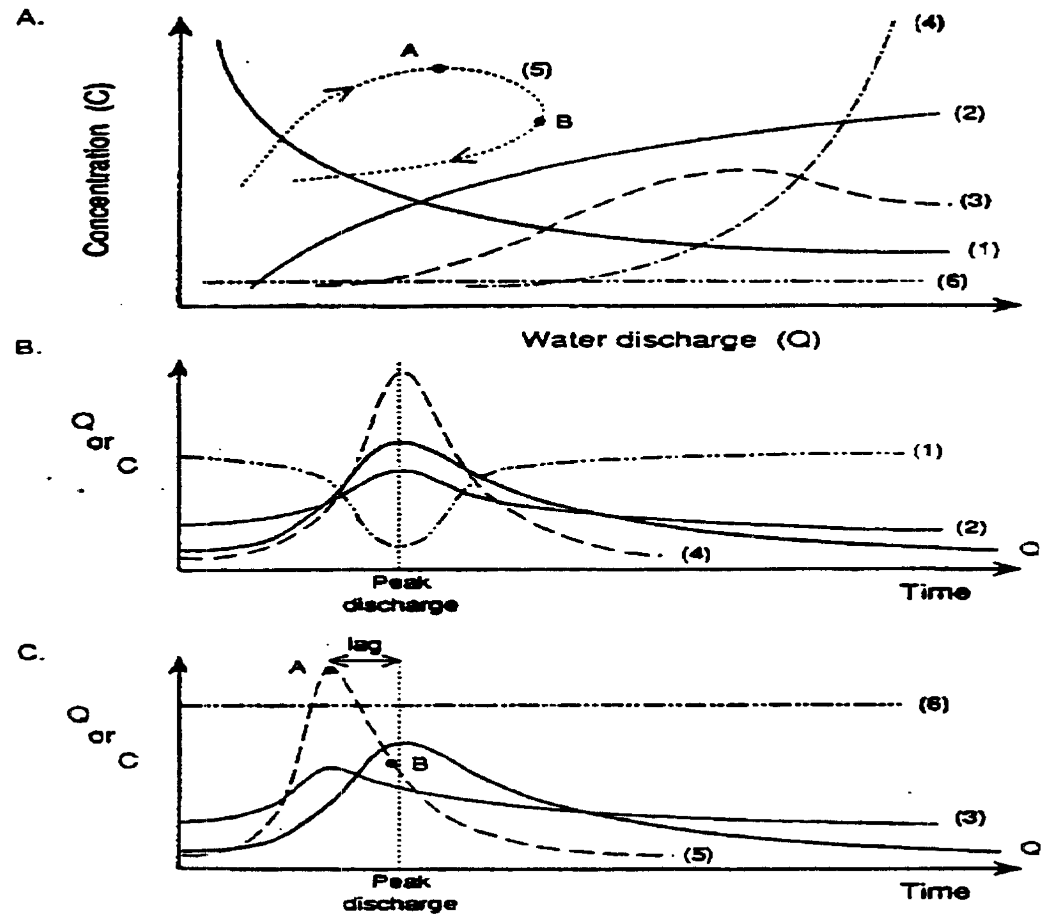
- A steady-state contaminant introduction is assumed to occur during the duration of rainfall. This steady state addition occurs from the time of the first flush through the peak of the hydrograph when direct runoff ceases. The magnitude of this addition is a variable determined by the user, and can be set to zero.

- The toxicity of the stream was assumed to be affected by both increases due to steady state additions and decreases due to dilution and first-order decay. Dilution occurs along the rising limb as discharge (and, therefore, dilution volume) increases. Decay may be set to zero for a conservative contaminant.

The initial model (Lawler, 1994) predicted TU values for only one contaminant where TU values were required as model input. The model was modified (Fitzpatrick, 1995) to allow prediction for five contaminants typical of stormwater discharges (Pb, Cr, Cd, Zn, and Cu), which used the concentration of a contaminant, as an input value, not a specified TU. The revised model calculates a cumulative toxicity using a simple additive assumption. A second revision added the ability to model storm events that produce multiple peaks.

Figure B-39 provides an example prediction for a two-peak storm event. The model was used as a tool to assist in developing a conceptual base for time-scale toxicity analysis. For example, a first flush might produce an initial peak in toxicity followed by a rapid decrease and low levels of toxicity in the remainder of the storm event. Another possible time-scale toxicity scenario finds a second peak of toxicity in a storm event when previously deposited contaminants are resuspended in the water column. When evaluated against storm event monitoring data, the presence of a first flush related toxicity was confirmed. Monitoring also confirmed toxicity later in the hydrograph. The model continues to be useful in providing a "what if" analytical tool to determine what changes are needed in initial assumptions to assist in interpreting possible causes of an observed time-scale toxicity result for a storm event.

Figure B-38. Expected Changes in Contaminant Concentration with Discharge; B and C Are Expected Changes Due to Single Storm Events
(from Meybeck et al., 1992)



Toxicity Prediction. Data collected as a part of this research identified heavy metals as important contaminants in the receiving waters studied (see also Horner et al., 1994). Assessing the toxicity of heavy metals in receiving systems is difficult due to the hydrologic, water quality, and organism variables. To account for some of these complexities, models may be constructed to predict toxic effects due to heavy metal exposures under field conditions. Many toxicity models appearing in the literature are based on first-order kinetics of toxic uptake and depuration. These models commonly represent the organism as a single compartment that can ingest, store, and excrete a toxicant. This is shown in Figure B-40.

Figure B-39. Example TU Prediction for a Two-Peak Storm

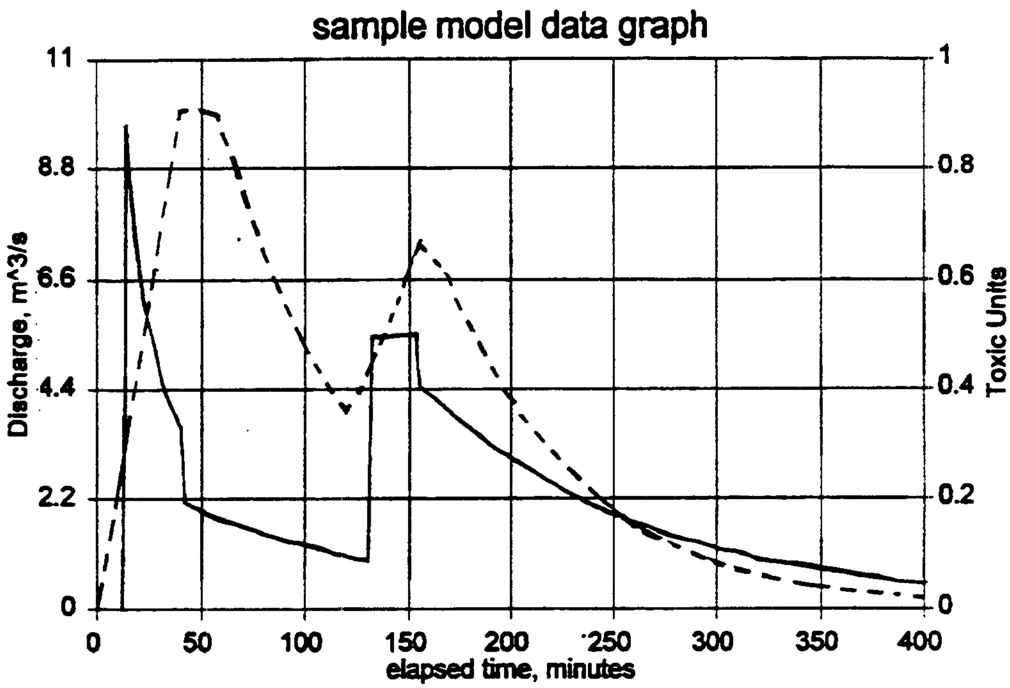


Figure B-40. One-Compartment Organism Representation Used in Some First-Order Kinetics Models

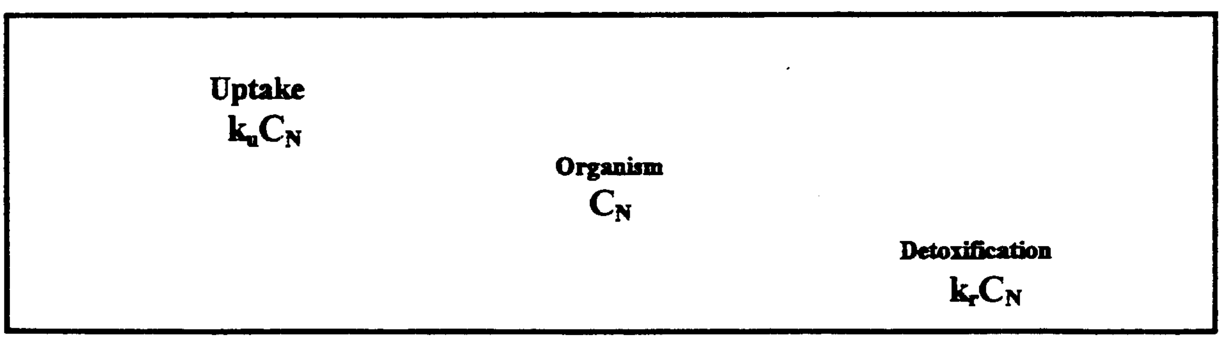


The following equation represents the change in toxicant concentration within the organism:

$$\frac{\delta C_N}{\delta t} = k_u C_w - k_r C_N \qquad \text{(B-3)}$$

where:

C_N	=	Concentration of toxicant in organism (mass of toxicant /mass of organism)
C_w	=	Concentration of toxicant in water (mass of toxicant / volume of water)
t	=	Time of exposure
k_u	=	Toxic uptake rate (volume water / mass of organism / time)
k_r	=	Detoxification rate ($time^{-1}$)

Assuming that there is no toxicant initially present in the organism (i.e., $C_N = 0$ at $t = 0$), Equation B-3 can be integrated to yield the following:

$$C_N = C_w \frac{k_u}{k_r} (1 - e^{-k_r t}) \qquad \text{(B-4)}$$

According to this model, a toxic endpoint, such as mortality, occurs when the tissue concentration reaches a critical concentration, C_D. The time at which this endpoint occurs is t_D. Substituting this boundary condition into Equation B-4 yields the following:

$$C_D = C_w \frac{k_u}{k_r} (1 - e^{-k_r t_D}) \qquad \text{(B-5)}$$

Several studies have used Equation B-5 to predict toxic effects due to time-variant exposures. Hickie et al. (1995) constructed a model to predict toxicity of pentachlorophenol (PCP) to larval fathead minnows, *Pimephales promelas*. In this study, Equation B-5 was rearranged thus:

$$\frac{1}{LC_{50}} = \frac{1}{CBR} \frac{k_u}{k_r} (1 - e^{-k_r t_{50}}) \qquad \text{(B-6)}$$

where:

LC_{50} = Median lethal concentration at time *t* (mass of toxicant / volume of water)

CBR = Median critical body residue (mass of toxicant / mass of organism)

Values for uptake and depuration rates, k_u and k_r, were estimated from each of three separate methods. In the first procedure, body residues of [^{14}C]PCP were measured through time in fish which were exposed to a 24-hour pulse of [^{14}C]PCP followed by a 24-hour recovery period. This provided direct measurements of CBR, k_u, and k_r. The other two methods involved fitting Equation B-6 to toxicity data obtained from continuous PCP exposure tests and the combined results of eight single-pulse exposure tests. The continuous exposure test lasted for 144 hours, while the pulse exposures ranged from 2 to 96 hours. The curve-fitting in each of these two methods yielded values of k_u/CBR and depuration rate, k_r. An uptake rate was estimated by multiplying k_u/CBR by the CBR value obtained from direct measurement of PCP body residues.

Using the kinetics parameters derived from each of the three methods, Equation B-6 was used to predict LC_{50} values for a variety of single and multiple PCP pulse-exposure sequences. Predicted LC_{50}s were compared with actual values recorded for each of these sequences. Out of the three sets of kinetics parameters derived, the best LC_{50} predictions were made using uptake and depuration rates obtained from the eight pulse-exposure tests. The kinetics parameters derived from continuous exposure tests provided the next best LC_{50} predictions. The assumed existence of a critical body residue, CBR, was supported by relatively constant whole-body residues of PCPs measured in dead fish (0.30 mol/kg). The researchers concluded that toxicity models based on Equation B-6 could provide reasonable estimates of toxic effects due to time-variant PCP exposures.

In another study, Meyer et al. (1995) applied Equation B-6 and two other models to predict monochloramine toxicity to the common shiner, *Notropis cornutus*, and rainbow trout, *Oncorhynchus mykiss*. The uptake and depuration rates, k_u and k_r, were estimated from continuous exposure tests involving these organisms and toxicant. A pulse exposure toxicity test subjected common shiners and rainbow trout to repeating cycles of two-hour monochloramine pulses followed by 22-hour recovery periods. The three models considered in this study were used to predict LC_{50} values for each of the first four pulses. Model predictions were then compared to actual experimental results. The researchers found that the best predictions were made using a modified version of Equation B-3:

$$\frac{\delta C_N}{\delta t} = k_u C_w^y - k_r C_N \qquad \text{(B-7)}$$

Assuming $C_N = 0$ at $t = 0$, Equation B-7 can be integrated to yield the following:

$$C_D = C_w^y \frac{k_u}{k_r}(1 - e^{-k_r t_D}) \qquad \text{(B-8)}$$

or:

$$\frac{1}{LC_{50}} = \left[\frac{k_u}{C_{L50}} \frac{(1 - e^{-k_r t_{L50}})}{k_r}\right]^{\frac{1}{y}} \qquad \text{(B-9)}$$

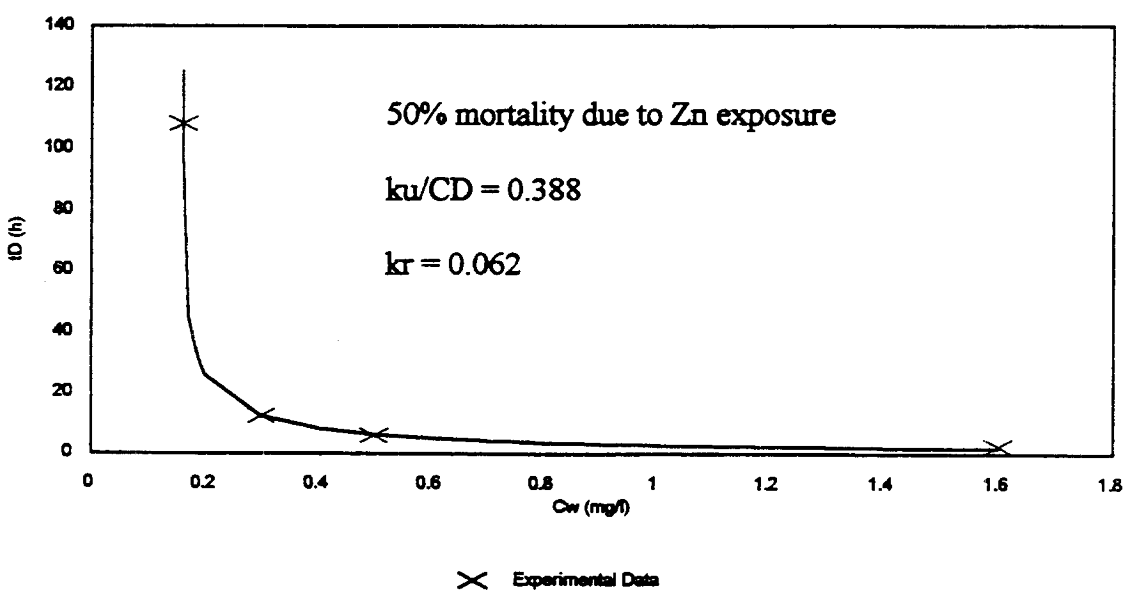
Using values of y = 1.557 and 1.342 for common shiners and rainbow trout, respectively, the predicted pulse CL_{50}s were all within 50% of the observed LC_{50} values.

To evaluate these possible models of heavy metal toxicity, toxic effects due to heavy metal concentrations were predicted using a single compartment first-order kinetics model. The procedure for developing this model is based on the work of Mancini (1983) who applied Equation B-3 to predict organism mortality when exposed to time-variant contaminant concentrations. As previously described, Equation B-3 can be integrated and rewritten as:

$$\frac{1}{C_W} = \frac{1}{k_r}\frac{k_u}{C_D}(1 - e^{-krt_D}) \qquad \text{(B-10)}$$

Equation B-10 contains two unknown parameters: the detoxification rate, k_r, and uptake coefficient, k_u/C_D, which can both be estimated from laboratory tests. Using a series of single-metal concentrations, values of C_w and t_D can be obtained by monitoring organism mortality under continuous exposure to a contaminant. The two unknown parameters may then be obtained by fitting Equation B-10 to experimental data as illustrated by Figure B-41:

Figure B-41. Curve Fitting to Obtain k_u/C_D and k_r Values from Experimental Data



Mancini (1983) assumed that a population of organisms can be divided into sensitivity levels, which are defined by survival-time variations occurring when the population is continuously exposed to the same metal concentration. Each sensitivity level of organisms is assumed to have common response characteristics to a toxicant. For example, if a population of organisms is continuously exposed to a range of metal concentrations, the first 10% of organisms that die in each metal solution would constitute the 10% sensitivity level. Because organisms of different sensitivity levels are assumed to possess different response characteristics, each sensitivity level has different toxic uptake and depuration rates. Thus, curves such as the one shown in Figure B-41 can be developed for each sensitivity level. Having obtained values of uptake and depuration coefficients, k_r and k_u/C_D, for each sensitivity level, the model may be used to predict toxic effects due to time-variant exposures. Using the following boundary conditions:

at $t = t_1$, CN $C_{N(t1)}$

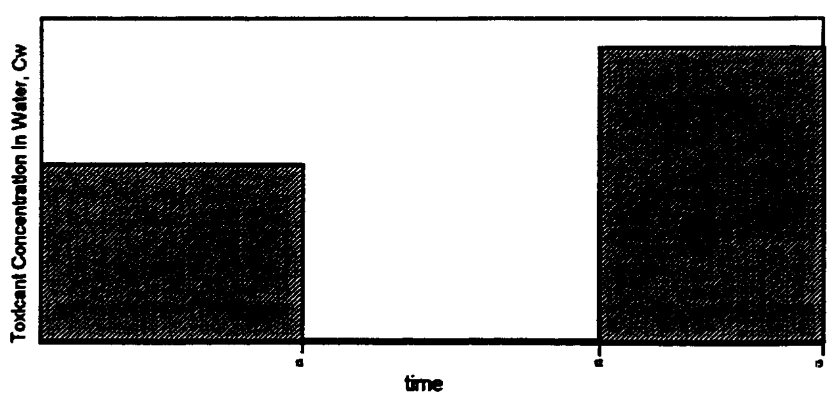
at $t = t_2$, CN $C_{N(t2)}$

Equation B-3 can be integrated to yield the following:

$$\frac{C_{N(t2)}}{k_u} = \frac{C_w}{k_r}\left(1 - e^{-k_r(t2-t1)}\right) + \frac{C_{N(t1)}}{k_u} e^{-k_r(t2-t1)} \qquad \text{B-11}$$

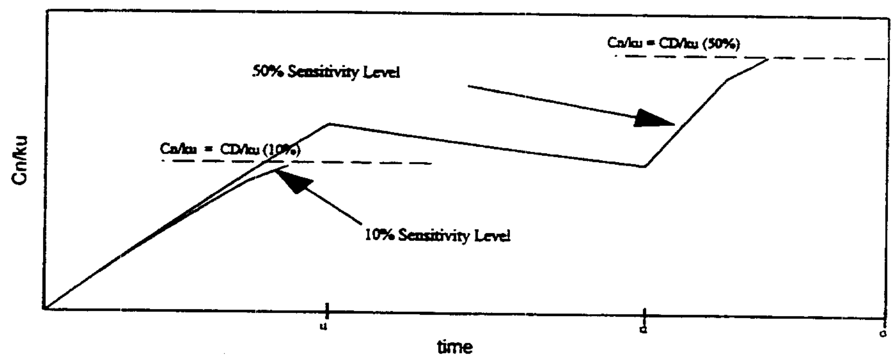
This equation represents the tissue concentration of a toxicant that results from an initial tissue contaminant concentration of $C_{N(t1)}$, a water contaminant concentration of C_w, and an exposure time of $(t_2 - t_1)$. For time-variant exposures (Figure B-42) Equation B-11 may be solved for each time interval over which C_w is constant.

Figure B-42. Example of a Contaminant Concentration Profile



Organism mortality for a given sensitivity level would occur when $C_{N(t2)}/k_u$ equals or exceeds C_D/k_u. The following series of graphs illustrates the use of the model. Figure B-43 displays a contaminant concentration profile through time. Using this profile, Equation B-11 may also be solved at the end of each time interval of constant C_w (i.e., at t_1, t_2, and t_3). Using uptake and depuration coefficients, k_r and k_u/C_D, corresponding to each sensitivity level, profiles of $C_{N(t2)}/k_u$ may be plotted through time. For a particular sensitivity level, each calculated value of $C_{N(t2)}/k_u$ is compared to the corresponding lethal tissue concentration of zinc, C_D/k_u, which is obtained from the model calibration discussed above. If $C_{N(t2)}/k_u$ exceeds C_D/k_u, mortality is assumed to occur in that sensitivity during that particular time-step. This is shown in Figure B-43.

Figure B-43. Calculated C_N/k_u Values for 10% and 50% Sensitivity Levels



By dividing $C_N(t2)/k_u$ by C_D/k_u at the end of each time interval, values of $C_{N(t2)}/C_D$ may be calculated for each interval. These represent the percent lethal tissue concentration (PLTC) for the *n%* sensitivity level at the end of each time interval:

$$(PLTC)_{n\%} = \left(\frac{C_{N(t2)}}{C_D}\right)_{n\%} * 100\% \qquad \text{B-12}$$

Mortality within the *n%* sensitivity level occurs when $(C_{N(t2)}/C_D)_{n\%} = 1$. For the concentration profile shown in Figure B-42, the following data are generated, Figure B-44. Mortality within the n% sensitivity level implies that a cumulative total of *n%* of the population have been killed due to the concentration profile. The percent population survival corresponding to the profile shown in Figure B-44.

Figure B-44. PLTC Values for the 10% and 50% Sensitivity Levels

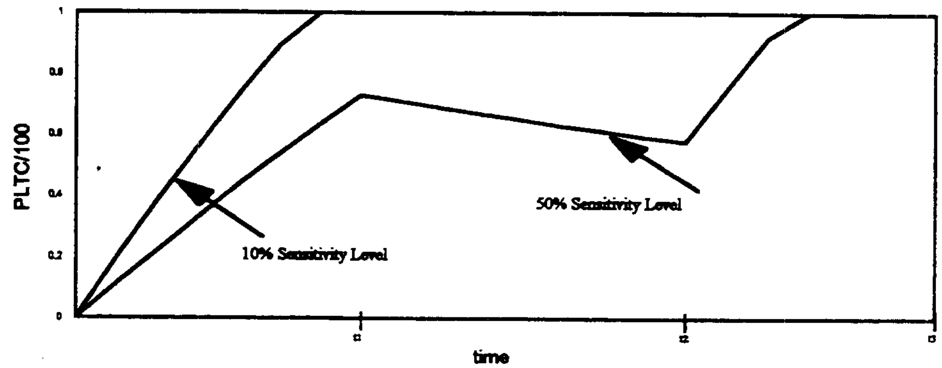


Figure B-45. Population Mortality Predictions Based on PLTC Values

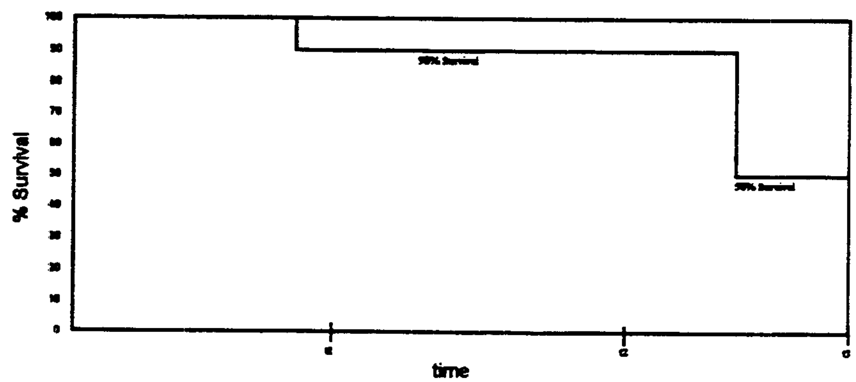


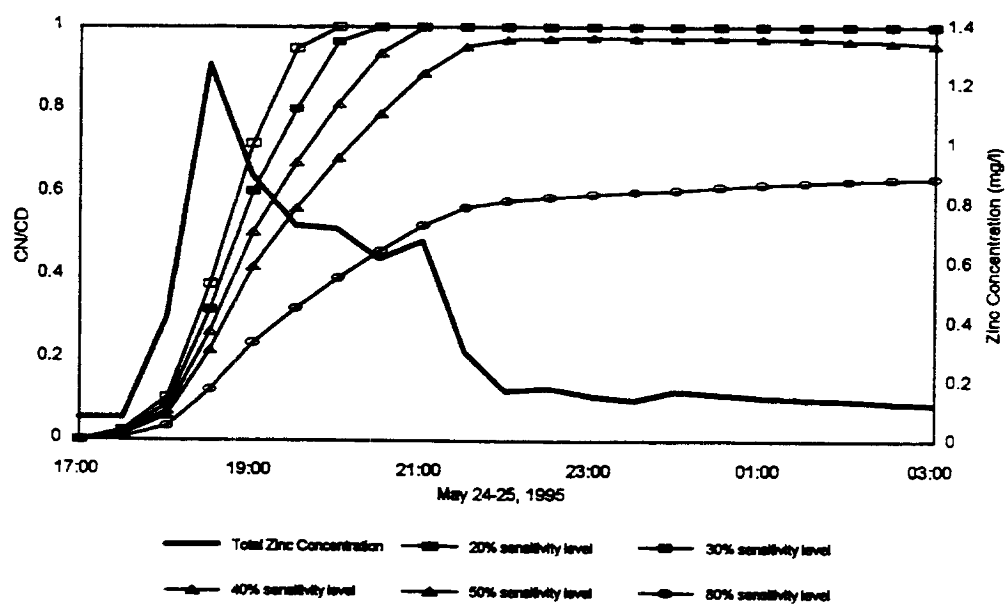
The model illustrated above was used to predict toxic effects of time-variant zinc concentrations to *Ceriodaphnia dubia* and *Vibrio fischeri*. Zinc concentrations were measured at discrete times. Therefore, Equation B-11 was modified to consider an average zinc concentration between every two measurements:

$$\frac{C_{N(t2)}}{k_u} = \frac{C_{w(t1)}+C_{w(t2)}}{2}\frac{1}{k_r}\left(1-e^{-k_r(t2-t1)}\right)+\frac{C_{N(t1)}}{k_u}e^{-k_r(t2-t1)} \qquad \text{(B-13)}$$

Equation B-13 was solved for each time interval between zinc concentration measurements. Values of C_w were obtained from dissolved or total zinc profiles measured at each of the Fort Worth sites. The depuration rate, k_r, for each sensitivity level was calculated in the model calibration discussed above. For each storm event and site examined, t = 0 corresponded to the time at which the first water sample was collected during the storm. The tissue concentration of zinc at t = 0, $C_{N(0)}/k_u$, was assumed to be zero. After the initial time step, values of $C_{N(t1)}/k_u$ were obtained from the solution of Equation B-13 for the previous time interval. Since all variables on the right side of Equation B-13 were known, $C_{N(t2)}/k_u$ could be calculated at the end of each time interval. Equation B-13 was solved for each sensitivity level using the Quattro Pro 6.0 software package. This spreadsheet compared each calculated value of $C_{N(t2)}/k_u$ to the corresponding lethal tissue concentration of zinc, C_D/k_u, to determine if mortality had occurred within the sensitivity level.

The model developed can be used to predict toxic effects resulting from time-variant zinc concentrations. From the model predictions listed above, potential zinc toxicity can be compared among the field sites, and toxicity associated with both dissolved and particulate-phase metals may be assessed. To test this application, the model was applied to data obtained from the Fort Worth field campaign in May, 1995. The model predicts significant zinc toxicity at the Cra site based on predicted total zinc accumulation, Figure B-46. These predictions are supported by toxicity tests which were performed on these samples, Figure B-47.

Figure B-46. Predicted Total Zinc Accumulation in *Ceriodaphnia dubia* at Cra During the May 24, 1995, Storm



R0025648

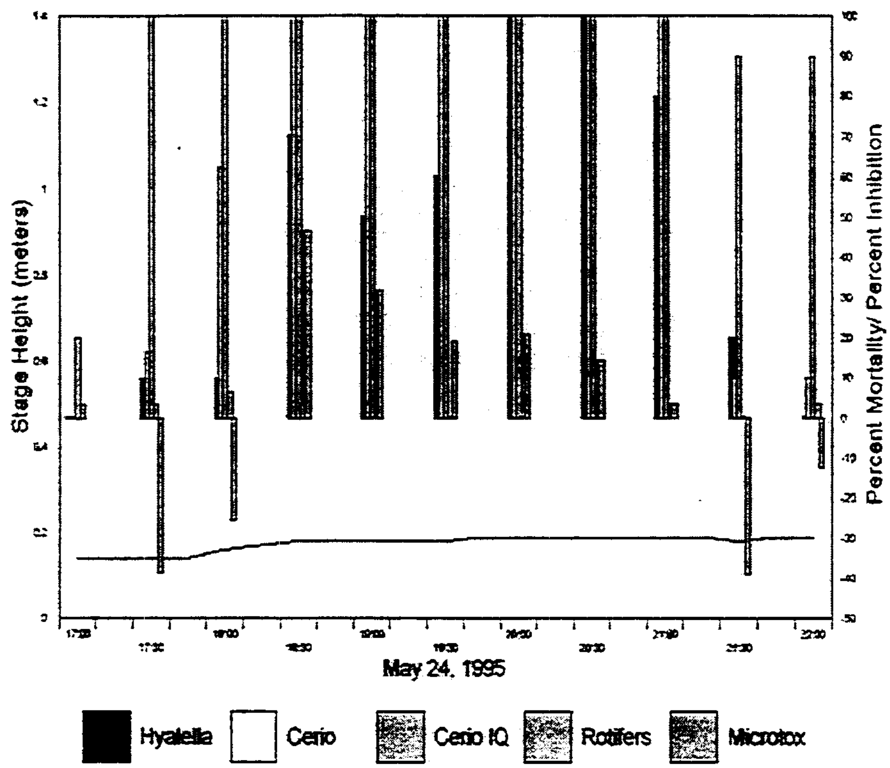
In the test battery *C. dubia* mortality was 100% for samples collected from 1830 through 2100 and the *V. fischeri* light inhibition ranged from 10% to 50% for this same period. These results are also consistent with the ETU determination that found a value of 1.05, which would indicate a highly toxic event.

In contrast to the finding for the Cra site described in Figure B-47, the model predictions indicate that zinc concentrations measured at Sycamore Creek, Eastern Hills, and Pylon will not cause toxic effects in populations of *Ceriodaphnia dubia* or *Vibrio fischeri*. These predictions are supported by toxicity test for *C. dubia*, where low numbers of mortalities (= 20%) were observed in samples collected from these sites. Microtox tests involving *V. fischeri* also indicate relatively low toxicity in these samples; light inhibition was observed in only a few samples, and this inhibition never exceeded 30%.

Although the toxicity tests appear to support model predictions, caution is advised when comparing these two data sets. The model predictions are based on time-variant zinc concentrations, while organisms in the toxicity tests were continuously exposed to relatively steady-state water quality conditions. Another major difference between the data sets is that the model considers only the effects of zinc concentrations, while the toxicity test results are influenced by multiple contaminants, such as copper and lead concentrations, which were observed in each of these samples.

Bioavailability is a critical factor determining the toxicity of metal concentrations within a receiving system (Horner et al., 1994). Bioavailable metals are associated primarily with the dissolved phase. Current heavy metal regulations, however, are based on total metal concentrations (Paulson and Amy, 1993). Because of this emphasis on total concentrations, the model was used to predict toxicity due to both dissolved and total zinc concentrations. By comparing the values shown in different tests it was found that the maximum predicted zinc accumulation in *C. dubia* is between 1.57 and 3.00 times greater for total concentrations than for dissolved concentrations. For *V. fisheri*, the maximum total zinc accumulation is between 1.32 and 2.95 times greater than the maximum dissolved zinc accumulation. These large differences suggest that current zinc regulations are over conservative, since only a portion of the total metal concentration may contribute to bioaccumulation and eventual toxic effect.

Figure B-47. Results of Toxicity Test Battery for the May 24, 1995, Storm at Cra



As with any model used to predict real-world phenomena, the toxicity model presented in this paper is subject to a variety of assumptions and limitations. These should be thoroughly understood before applying the model or interpreting its predictions. The equation governing this toxicity model is based on first-order kinetics of toxicant uptake and depuration. This equation assumes that the organism is a single compartment that accumulates the toxicant at a rate proportional to the contaminant concentration in the surrounding water. The rate of pollutant removal, or depuration, is assumed to be proportional to the tissue concentration of the toxicant. These assumptions might not accurately represent actual uptake and depuration mechanisms of an organism in the receiving system. For example, as a metal concentration in water increases, the uptake rate could decrease due to a reduced feeding rate or temporary immobilization of the organism (Luoma and Carter, 1991). In addition to contaminant concentrations in the organism and surrounding environment, water quality characteristics, such as pH or temperature, can also influence toxicant uptake and depuration rates. The effects of water quality properties are not incorporated in the model.

Another important assumption for the model is that a toxic effect occurs only when the contaminant reaches a critical concentration within the organism. This implies that an organism can completely recover from a contaminant exposure as long as the accumulated toxicant remains below the critical value. Such an assumption does not agree with the findings of Pascoe and Shazili (1985), who concluded that irreversible toxic effects can occur in the absence of toxicant bioaccumulation. Therefore, this model is appropriate only when the toxic effect results from tissue accumulation.

In calibrating this model and applying it to experimental data, a number of limitations became evident. First, the one-compartment first-order kinetics equation is not appropriate for all organisms and toxicants. In the *Vibrio fischeri* model calibration, for example, negative depuration rates were obtained for the 80, 90 and 100% sensitivity levels. In these cases, an alternative equation should be used for modeling toxic effects due to time-variant exposures.

Another limitation of the model is that it should be calibrated using solutions within the range of contaminant concentrations being examined. The lowest zinc concentration in the *V. fischeri* model calibration was 1.0 mg/l. From all of the samples collected at the Forth Worth field sites, only one contained zinc in excess of this lowest calibration concentration (1.27 mg/L Zn at Cra during the May 24 storm). As a result, model predictions of light inhibition were made by extrapolating the laboratory results to lower zinc concentrations that were observed in the field. This might have caused the model to overpredict light inhibition at low zinc concentrations. As mentioned earlier, negative light inhibition was measured in *V. fischeri* that were exposed to low zinc concentrations during the continuous exposure test. These light stimulation effects were not incorporated into the model, and this proved to be an important omission because stimulation was observed in many of the samples collected from the Fort Worth field sites.

Storm Sewer Drainage Model. Application of an available model is often a compromise between detail and availability of model input and the expected use of model output. As this project evolved from a focus on in-stream analysis of time-scale toxicity to a focus on in-pipe and near-outfall assessment, a need developed to model outfall hydrology to assist in both interpretation of toxicity during storm events, and prediction of toxicity as affected by storm sewer system characteristics. The focus on the KLSS system required an analysis of the sewer "tributary" system to identify possible sources of contaminants. Further, modeling suggested itself as a means to supplement toxicity testing with information on sewer dynamics that would assist in developing contaminant source and frequency and duration of exposure information.

The most widely used model for this type of analysis is the Stormwater Management Model (SWMM). Unfortunately, SWMM is a complex model that required input data detail that was not readily available. A second model, the Illinois Urban Drainage Area Simulator (ILLUDAS) was developed locally, had minimal input data requirements, and was supported locally. ILLUDRAIN (Ver 2.10) was applied to the KLSS system.

Information on storm sewers was obtained from the Champaign Department of Public Works (Figure B-48), and a general system configuration was identified that accurately represented actual system layout, which had the sewer network divided into branches and then subdivided into reaches with known contributing areas. Two storms were selected for modeling. A two-hour storm that occurred on June 23, 1994, and a four-hour storm on September 26, 1994, provided representative medium intensity storms of different duration. Model sensitivity was tested for different antecedent moisture condition (AMC) for these storms. The effect of rainfall amount was investigated using three storms, the one-year, two-hour rainfall, the June 23, 1994, storm and a storm of low intensity.

The results of this modeling are provided in Figures B-49 and B-50. Figure B-49 is the estimated hydrograph for a two-hour storm during which antecedent moisture conditions produced no change in hydrograph prediction. Figure B-50 provides model results for storms of different intensities. The model predicts a maximum discharge of 50 ft^3/sec with a maximum discharge occurring at approximately 45 minutes. Field measurements indicated a similar storm produced a maximum discharge of 40 ft^3/sec, and time to peak was generally observed within an hour of rainfall.

The application of ILLUDRAIN found that the model is sensitive to the percent grassed area in a watershed. Further, the model provides an option for identifying local surface hydrographs that assist in identifying sources of contaminants that vary through a single storm event.

Conclusions and Applications

In assessing the impact of wet weather events, time-scale considerations are the basis for selecting appropriate toxicity assessment procedures. If an acute toxic response is the indicator of impact, then short-term exposures (intra-event time scale) are most appropriate. In an intra-event analysis, concentration transients are sometimes very large (orders of magnitude), and the responses assessed need to match the time scales of exposure that occur during the storm event.

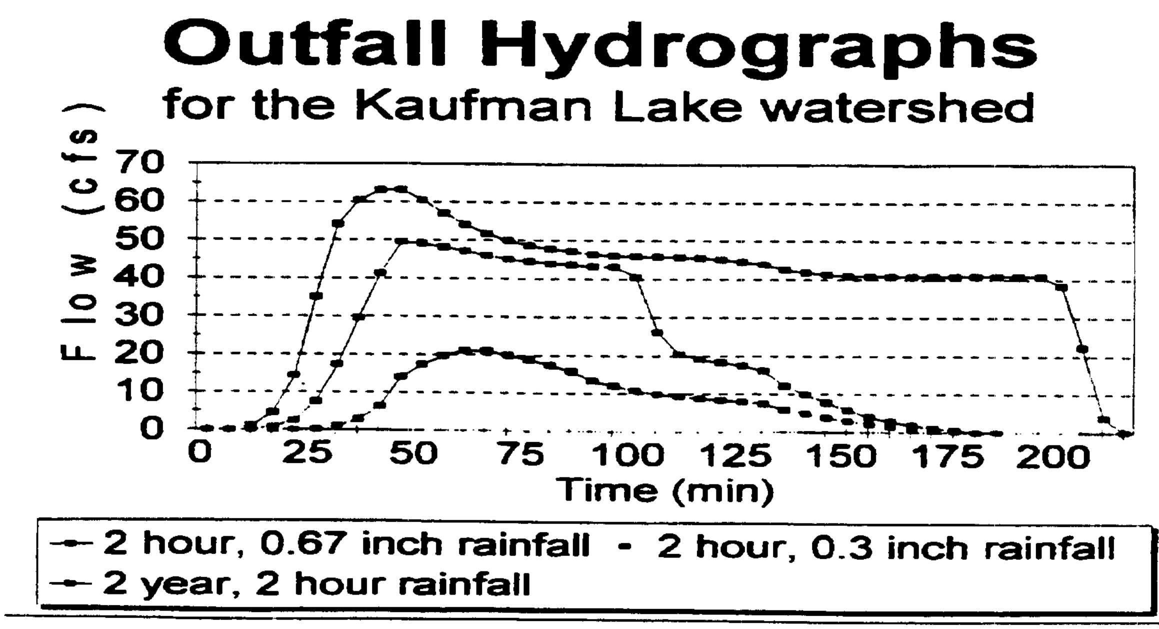
Figure B-50. Predicted Hydrographs for the KLSS Outlet for Different Intensity Storms



R0025654

Furthermore, since different test systems show different time scales of responses to toxicants, one test cannot be relied upon to detect toxicity in all wet-weather events. Consequently an optimized test battery is needed to accurately assess toxicity (e.g., minimize incidences of both false negatives and false positives in toxicity test results) associated with events of different duration. The need to use a test battery for time-scale toxicity testing is consistent with the consensus view of regulators involved in controlling point source discharges (US EPA, 1991; Environment Agency, 1996). The optimal test battery for assessing intra-event (and event or long-term toxicity) should be selected according to specific criteria and must be cost effective and accurate. Test batteries should avoid unnecessary redundancy (that is, tests that yield similar responses); if two or more tests consistently show the same response to samples and using both provides no additional information, there is clearly redundancy and using only one test improves cost effectiveness.

The identification of appropriate test batteries for each time-scale division has been a key element of the project and has been supported by the results presented in this section, which support the test systems selection procedure described in Chapter 4.0.

For intra-event analysis, test systems must be responsive to exposure durations in the order of minutes to as long as a few hours. Sequential sampling during an event assists in both identifying toxicity transients, which have been shown by laboratory testing to produce delayed response, and provides a basis for accurate ETU determination. Research conducted in this project has identified test methods, such the acute Microtox procedure and the Inhibitory Quotient (IQ) test using *C. dubia* and *H. azteca*, as being appropriate for intra-event analysis, as well as modified time-scale specific versions of WET tests using *C. dubia* and *H. azteca*, which simulate the pulsed exposure conditions found in storm events. These test systems provide a more appropriate means of assessing the effects of time-scale toxicity and account for both delayed effects and organism recovery.

The laboratory-based time-scale toxicity research also indicated:

- The need for modification of the existing IQ test method to ensure that high levels of suspended material in stormwater samples do not markedly reduce enzyme activity because organisms are ingesting these particulates rather than the test substrate; and

- The need to carefully assess the results of Microtox tests in view of the stimulation of light output seen in many receiving water samples before and after storm events due to the hormesis effect of low contaminant concentrations in the samples.

This battery of tests has been evaluated in the monitoring programs that assess intra-event toxicity during wet-weather events at different locations. This regional evaluation has demonstrated the applicability of WET derived time-scale toxicity tests and the clear need to implement specific time-scale toxicity testing for wet-weather discharge impact assessment.

The research has also identified a series of modeling and testing procedures approaches that can to predict toxicity, assist in sampling design, and identify the causative agent(s) and or sources of toxicity once high or moderate toxicity has been measured using the basic screening tests.

APPENDIX C

INTEGRATING TIME-SCALE ISSUES IN ECOSYSTEM MANAGEMENT

Ecosystem-Based Management

Objective #4 of the research was to "Develop an ecosystem-based management context for wet weather discharges, which integrates the need for both regulatory criteria and the protection of ecosystem health." An ecosystem context for time-scale toxicity was presented in Herricks, Milne, and Johnson (1994). Further conceptual developments have been made to develop a paradigm for integration of time-scale issues in ecosystem-based management.

Paradigm Description

The paradigm for integrated ecosystem management is based on scalar definition of critical ecosystem properties and processes that include both spatial and temporal issues in the disturbance/distance paradigm. This paradigm is the basis for development of an assessment template that defines critical ecosystem issues that must be addressed to: 1) assess success or failure of wet weather management programs without bias; 2) define critical measures of structure and/or function affected by wet weather flows to support management; 3) support modeling that follows a risk-based analysis for ecosystem management strategies; and 4) effectively integrates testing, assessment, and modeling to illuminate likely outcomes of a management strategy.

The disturbance/distance paradigm is based on the recognition that from the center point of a disturbance, there will be zones of decreasing effect with distance (Figure C-1). Because disturbance differentially affects ecosystem properties and processes in each of these zones, the measures necessary to assess effect also change with distance and reflect changes in complexity, disturbance dominance, effect type, etc. In addition to a disturbance control in this template, there is also an influence from undisturbed "natural" areas operating in a direction opposite to the disturbance, which leads to restoration. Since ecosystem properties and processes have a natural tendency to some equilibrium state, driven by homeostatic mechanisms, the combined influence of disturbance and restoration produce the ecosystem state or condition observed in an assessment. The disturbance/distance paradigm applies both damage functions and recovery functions in the assessment of sustainability in any zone.

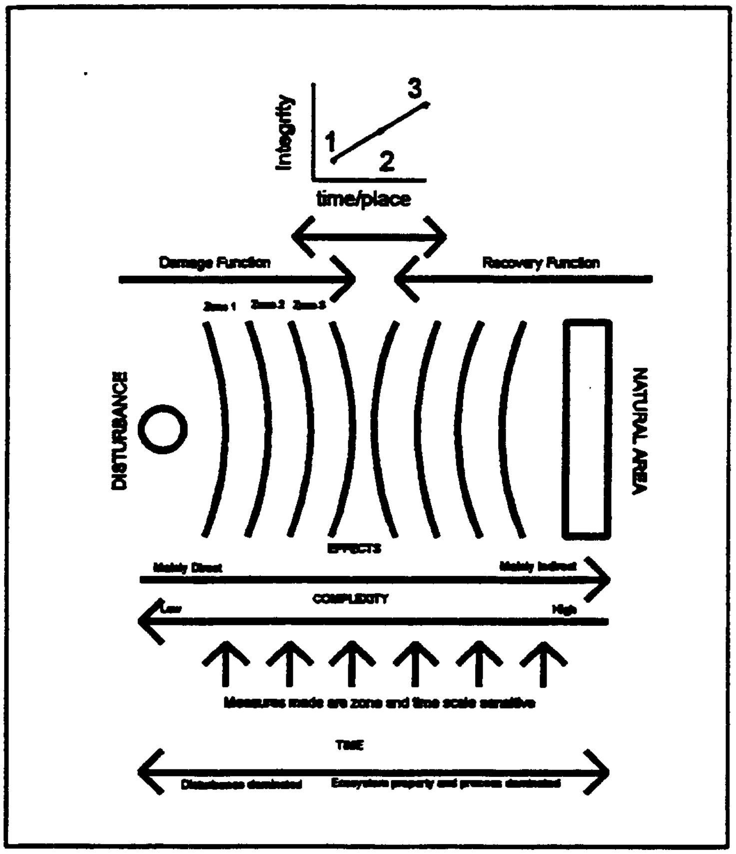


Figure C-1. Illustration of Distance Disturbance Paradigm, Coupling Spatial and Temporal Dimensions for Ecosystem Management

The mechanisms that sustain state or condition can be related to critical scalar constraints (spatial or temporal dimensions of ecosystem properties and processes) that are largely defined by internal ecosystem processes rather than some arbitrary divisions driven by external factors (location, climate, etc.). The disturbance/distance paradigm, based on these ecosystem processes and properties, also considers a temporal scale for analysis that is appropriate for each zone. A disturbance/distance temporal scale is established based on properties or processes dominant in each zone and a time scale of effect that is defined by the level of disturbance/concentration influencing each zone. For example, if the zone of analysis is close to a high level of disturbance (e.g., in-pipe or near pipe areas), the time scale appropriate for an effect analysis will be short, e.g., an acute response. As the distance from the disturbance increases, the time required to produce a given effect also increases because exposure concentrations are reduced, moving the response to a chronic response time frame. The disturbance/distance paradigm recognizes that, with distance, an effect analysis shifts from an emphasis on simple (direct, and short-term cause and effect) relationships to more complex (largely indirect, and long-term) mechanisms that produce change in an ecosystem. An alternative view of the disturbance/distance paradigm is produced when the analysis begins with a natural location, unaffected by the identified disturbance. In this "recovery-based" system, the distance from the natural location is also used to describe "relative influence" and constrain recovery mechanisms. In general, the distance and time scales appropriate to analysis are inverted in this recovery-based example; that is, restoration occurs rapidly in areas at some distance from the point of disturbance and require more time closer to the point of disturbance. The critical issue is still that ecosystems must be assessed recognizing the influence of both space and time on an observed state and condition.

Applying this disturbance/distance template to ecosystem management establishes critical spatial and temporal scale factors for ecosystem analysis. Furthermore, the template operates independently of regional differences and provides a basis for allocation of effort and expectations for success in management programs. To illustrate this point, consider a template based on an urban center as the focus for establishing a distance-based analysis. In the agricultural Midwest, general habitat heterogeniety can be considered low. Here, the spatial scales of natural ecotones are large and the basic scale of application from a single site might be large. Furthermore, the large scales associated with similar conditions suggests that few reference sites would be needed to adequately address ecosystem differences (note: thus this relatively large scale leads to the selection and application of fewer different assessment tools and approaches). If the Pacific Northwest is the focus for analysis, the spatial scale for analysis is much different because the landscape is highly variable. The spatial scales of natural ecotones in this setting are small so applicability of measurements made at a single site may be limited. The differences associated with selection of even small spatial scales in an assessment activity would require more reference sites. The result of the application of the distance-based template will be the redefinition of assessment and management needs that better reflect the reality of both natural conditions and the influence of human activity in each setting (or region).

The proposed disturbance/distance paradigm, and the assessment template, finds support in recent research agenda. Naiman et al. (1995) provide a comprehensive summary of the Freshwater Imperative (FWI), an effort to "identify research opportunities and frontiers in inland water ecology." They recognize that a clear need exists for an understanding of the causes of disturbance and degradation and how systems respond to, and recover from, disturbance and degradation. The FWI research agenda focuses on evaluation of responses to disturbance, pathways of recovery, measurement of progress to new equilibria, and identification of conditions under which systems shift to new equilibrium states. The Watershed Protection Approach (WPA) proposed by US EPA (1993) emphasizes environmental indicators, which are measurable features that singly or in combination provide useful evidence of ecosystem quality or reliable evidence of trends in. The environmental ndicator effort is particularly valuable, because it addresses the critical area of measurement utility and provides guidance for a range of indicators that can be used to both judge quality and assess the stage of restoration. The disturbance/distance paradigm can be the basis for focusing research to key questions in time-scale toxicity and wet weather discharge impact analysis.

Space and Time Integration

With the recognition of the need for integrated ecosystem management and the need for conducting ecological assessments at multiple ecological scales, particularly in regional assessments, there is a critical need for more exact definition of "scale" in ecosystems. In fact, a major element of the currently practiced ecosystem health paradigm is the argument that the fundamental unit in assessing ecosystems is an "area," such as a habitat, ecoregion, landscape, or a biome. In this health assessment, it is necessary to define an area and provide a corresponding identification of critical properties and processes. Examples of inexact coupling of spatial and temporal scales in the selection of critical ecosystem measures illustrates that an "area" is not fixed by size, rather it changes with time. Here, it may be valuable to consider the Schumm and Lichty time-scale synthesis (discussed in the following paragraphs), which suggests, as viewed from different time perspectives, how cause and effect relationships shift from internal to external. For example, internal factors, such as feedback (homeostatic) processes, operate in a time scale defined by equilibrium maintenance. External factors can operate over longer time scales as dependence and independence relationships change. It is the integration of temporal scale issues in analysis that allows productive assessment and successful management (Herricks et al., 1996).

To begin the process that selects measures of ecosystem state or condition, we need to define the boundaries of "areas" both in space and time. In analyzing these dimensional issues, we can advance ecosystem analysis by using concepts borrowed from geomorphology. As illustrated in Table C-1, scale issues are well-defined topographically in drainage basins/watersheds. For each scale, a system of measurement is available, and relationships between scales and among their spatial dimensions are defined. Geomorphologists have also developed an effective method of working with temporal scales. Three decades ago, Schumm and Lichty (1965) proposed a conceptual framework for geomorphologic time that classifies time span and the changing relationships among system variables that occur when temporal scales are changed. The three time spans they defined (cyclic, graded, and steady) do not have an absolute value, but differ in duration. Cyclic time is long, related to an erosion cycle of uplift and erosion to some level—this time span may be related to evolutionary time scales. Graded time is a short span of cyclic time that might be associated with a graded, or equilibrium, river profile—related to stable equilibria in ecosystems and defined by multiple generations of long- lived species. Steady time is a very short time period, applicable to processes that occur along a river reach—related to change within the life cycle of a long-lived species. With the definition of these temporal scales, Schumm and Lichty also provided a system that assists in relating variables in each time span by considering how independence/ dependence relationships change with the perspective of time scale. Table C-1 illustrates the changing status of variables as different time scales are considered. It is this insight into the changing independence/dependence relationships with time-scale perspective that directs an ecosystem assessment to consider the appropriate time scales of properties and processes, then define the independent variable(s) that are to be used in a cause-and-effect analysis.

Table C-1. Relationship of River Variables as Established by Time-Scale Perspective (After Schumm and Lichty, 1965)

		Status of variables during designated time spans		
	River Variables	Cyclic/Geologic	Graded/Modern	Steady/Present
1	Time	Independent	Not relevant	Not relevant
2	Geology	Independent	Independent	Independent
3	Climate	Independent	Independent	Independent
4	Vegetation	Dependent	Independent	Independent
5	Relief	Dependent	Independent	Independent
6	Palaeohydrology (long-term discharge of water and sediment)	Dependent	Independent	Independent
7	Valley dimensions (width, depth, slope)	Dependent	Independent	Independent
8	Mean discharge of water and sediment	Indeterminate	Independent	Independent
9	Channel morphology (width, depth, slope, shape, pattern)	Indeterminate	Dependent	Independent
10	Observed discharge of water and sediment	Indeterminate	Indeterminate	Dependent
11	Observed flow characteristics (depth, velocity, turbulence, etc.)	Indeterminate	Indeterminate	Dependent

Following the Schumm and Lichty (1965) approach, we propose that procedures be developed for integrated analysis that consider spatial and temporal scales for any "area" definition, e.g., in watersheds. At large spatial and temporal scales, the emphasis can be on multiple stressors, while time is related to ecological processes, such as evolution and succession. At smaller spatial scales, the emphasis can be on single stressors with a focus on concentration and duration of exposure where individual and population response is assessed. Furthermore, spatial and temporal scales define externalities, which are of importance in defining independence and dependence, and most importantly, cause and effect. As scales of analysis are reduced, more environmental and ecological variables can be considered independent, leading to a focus on individual, population, or community indicators that relate cause and effect, and direct management efforts to specific actions (Herricks et al., 1996; Wallin and Schaeffer, 1979).

Frissell et al. (1986) proposed a habitat-centered view of stream systems (Table C-2). Their view is based upon a hierarchical organization of habitat types. In this hierarchical organization, subsystems (stream segment, reach, pool/riffle, and microhabitat) develop and persist within a specified spatio-temporal scale. In this "systems" view, high frequency, low-magnitude geomorphic events predominate in the subsystems, while the system as a whole is subject to low frequency, high magnitude events. A critical issue in the hierarchy is that the setting within which components, processes, and dynamics are defined is provided by the next higher level in the hierarchy. These "nested" relationships in the hierarchy provide an example of the integration of Schumm and Lichty's (1965) time-scale perspective, illustrating the change in dependence relationships at different levels of the hierarchy. A recognition of this change in controlling variables with time-scale perspective is particularly important in ecological assessments.

The organizational framework provided by topographic, temporal, and system hierarchies provides a foundation for the examination of environmental system dynamics critical in defining and dealing with ecological assessment issues in wet weather discharge analysis and management practices for environmental protection. For example, a critical metric near the disturbance might be a rapid measure of direct toxicity while at a distance it may be a measure of recovery or succession. This is the foundation of a distance/disturbance-based paradigm that will select appropriate time-scale measures at defined distances where operational differences of processes are evident or where properties are consistent.

Table C-2. Expected Spatial and Temporal Scales, Events, Processes, and Water Quality Issues (Modified from Frissell et al., 1986)

Level in Watershed Hierarchy/Scale	Spatial scale (km)	Time Span	Expected Duration (years)	Landscape Change Characteristics	Process Characteristics	Water Quality Issues
Stream system/Basin	$10^3 - 10^4$	Cyclic/ Geologic	$10^6 - 10^5$	Tectonic uplift, subsidence, sea level changes, glaciation	Planation; denudation; drainage network development	Source materials established in watershed; weathering products dependent on parent materials and exposure conditions
Segment system/Network	$10^2 - 10^3$	Cyclic/ Geologic	$10^4 - 10^3$	Minor glaciation, earthquakes, very large landslides, alluvial or colluvial valley infilling; river meander pattern development	Migration of tributary junctions and bedrock nickpoints, channel downcutting, extension of first-order channels	Periodic exposure of unweathered materials may lead to water quality differences in basin; expectation of mid- to late-stage weathering products; more complete channel network increases potential for landscape change to affect water quality
Reach system/Channel Reach	$10^1 - 10^2$	Graded/ Modern	$10^1 - 10^2$	Debris torrents; landslides; channel shifts; river meander cutoff; channelization, diversion or damming by man	Aggradation/degradation associated with sediment storage structures; bank erosion; riparian vegetation succession	Loading emphasis; focus on input, output, and residence time of weathering products and contaminants; adjustment of channel form to sediment loading and corresponding storage of contaminated materials; exposure times changing from chronic to acute
Pool/Riffle system/Channel Cross-section	10^0	Steady/ Present	$10^1 - 10^0$	Sediment accumulation/washout; small bank failures; floodflow scour/deposition; thalweg shift; alternate bar change	Small-scale lateral or elevational changes in bedforms	Shift to concentration emphasis; presence of "hot spots" of contamination; water column/dissolved contaminants of greater importance; emphasis on acute exposure levels
Microhabitat system	10^{-1}	Steady/ Present	$10^0 - 10^{-1}$	Annual flow/sediment/organic matter transport, substrate scour; seasonal macrophyte/periphyton growth and scour	Seasonal depth, velocity changes; sediment accumulation; biological processes	Concentration and duration variability high; mixing zone issues important; emphasis on less than acute exposures that emphasize return frequency and timing of water quality alteration

R0025663

Issues associated with time scales can also be specifically addressed in the paradigm. For example, the episodic nature of wet weather flows can take advantage of the paradigm to more effectively perform a time-scale effect analysis in any more general system assessment. This requires that traditional toxicity testing procedures, which assume constant flow, are deemed inappropriate for the assessment of episodic exposures produced by, in particular, stormwater/wet weather discharges. In storm events, concentrations can vary over several orders of magnitude in very little time (seconds to minutes). In addition, the paradigm accommodates the situation where cumulative effects that include both the frequency of exposure and the accumulation/storage of contaminants leads to system degradation.

The issue of time in water quality can be addressed by a temporal scale segregation. Following Schumm and Lichty (1965), it is possible to establish three time perspectives. The first is short-term, a non-steady-state time increment. This time increment, at its shortest, includes episodic exposure and, at its longest, is based upon organism life span criteria that are used in an effect assessment. An acute, non-recurring fluctuation in water quality produced by a contaminant spill, or a less toxic, but more frequent episodic exposure will be typical of this time dimension. A second time perspective is a quasi-steady state. This time scale finds water quality conditions that are dominated by either a constant discharge or a constant release from stored components. The exposure conditions can vary as evidenced by decreasing concentrations with flow. The critical exposure measure is chronic toxicity or long-term population maintenance. The third time perspective is long, integrating water quality conditions through time that are associated with landscape change. Over this time frame, gradual change or a punctuated alteration that produces a new "stable" state, will find alteration in both system properties and the fundamental processes that control water quality.

In summary, the time-scale segregation adopted in the distance/disturbance paradigm is appropriate to the range of causes and a variety of sources. A short time scale will reflect the short-term variability typical of wet weather events. An intermediate time scale will accommodate the constancy of input, typical of baseline conditions. A long time scale will reflect cumulative effects and trends and is appropriate for determination of watershed/landuse influence on channel water quality, in particular the accumulation of contaminants in the receiving system.

- SOURCE CONTROL
- COMBINED SEWER OVERFLOW
- SANITARY SEWER OVERFLOW
- RISK ASSESSMENT

A Research Needs Survey for Urban Areas

WET WEATHER FLOW MANAGEMENT

Water Environment Research Foundation

FOLDER 5, ITEM 31
ADMIN RECORD
COPY 1

ABSTRACT

The results of a national assessment of research needs in managing urban wet weather flow are divided into three interrelated categories: combined sewer overflows, sanitary sewer overflows, and urban wet weather flow discharges. The initial compilation of 154 wet weather flow research projects was reduced to 69 higher priority projects for which detailed literature reviews were compiled. From this group, 26 topics were identified as high priority for research. The results of this assessment were organized into ten categories: (1) sources and monitoring; (2) receiving water impacts; (3) other impacts; (4) management; (5) models and decision support systems; (6) watershed management linkages; (7) regulatory policies and financial aspects; (8) source controls; (9) collection system controls; and (10) storage and treatment systems. Addressing the identified research would require an estimated $20 million to $40 million per year.

ENVIRONMENTAL STEWARDSHIP THROUGH INNOVATIVE SCIENCE AND TECHNOLOGY

The Water Environment Research Foundation (WERF) was established to advance science and technology for the benefit of the water quality profession and its customers. Funded through voluntary contributions, WERF manages research under four major Thrust Areas: Collection and Treatment Systems, Human Health and Environmental Effects, Residuals Management, and Watershed Management. WERF seeks cost-effective, publicly acceptable, environmentally sound solutions to water pollution control problems. A 15-member Board of Directors composed of water quality professionals; volunteers from utilities, academia, consulting firms, and industry; a Utility Council and Corporate Council composed of subscribing entities; and a Research Council of knowledgeable leaders in environmental sciences and engineering are actively involved in applied and basic research program management.

While WERF manages the research and coordinates the parties involved, the actual work is carried out by individual organizations, primarily utilities, universities, and industrial and commercial firms. To ensure objectivity, an independent advisory committee of distinguished scientists and engineers helps select researchers, oversees the studies, and provides periodic review and advice. Benefits accrue in the form of services, technological advances, and information for direct application by the profession for its customers.

The Water Environment Research Foundation is successfully building a cooperative research and development program serving the water quality profession. The Foundation's goal is to apply sound and objective scientific information to better serve the public.

The research on which this report is based was funded, in part, by the United States Environmental Protection Agency (EPA) through Cooperative Agreement No. CX 824468-01-3 with the Water Environment Research Foundation (WERF). Unless an EPA logo appears on the cover, this report is a publication of WERF, not EPA. Funds awarded under the Cooperative Agreement cited above were not used for editorial services, reproduction, printing or distribution.

WATER ENVIRONMENT RESEARCH FOUNDATION STAFF

Deputy Director:	Charles I. Noss, Sc.D.
Director of Technical Programs:	Raynetta Curry Grant, P.E., DEE
Project Manager:	Patricia J. Haddon

The project team gratefully acknowledges the invaluable insight and guidance provided by many people. Prof. Ed Herricks of the University of Illinois contributed background material for the receiving water impact section of this report. Also, many valuable ideas were drawn from a draft US EPA report by a team of researchers at the University of Alabama led by Prof. Robert Pitt. The following members of the ASCE Urban Water Resource Research Council extensively reviewed the draft US EPA research needs report and offered ideas during the early phase of this study:

Ed Herricks, University of Illinois at Champaign
Wayne Huber, Oregon State University at Corvallis
Jonathan Jones, Wright Water Engineers
Robert Pitt, University of Alabama at Birmingham
William Pisano, Montgomery Watson
Larry Roesner, Camp Dresser & McKee, Inc.
Roger James, Woodward Clyde
Peter Mangarella, Woodward Clyde
Eric Strecker, Woodward Clyde

The close cooperation of Richard Field of US EPA in circulating the draft Wet Weather Flow Research Needs report is appreciated. Finally, the WERF Wet Weather Advisory Panel provided many useful comments and suggestions.

The October, 1996, WERF Workshop was made possible by a concerted effort of WERF staff members Ron Ohrel and others. Tyler Richards of the Department of Public Works, City of Atlanta, moderated the workshop. Presentations were made by Robert Pitt of the University of Alabama at Birmingham, Ben Urbonas of the Denver Urban Drainage and Flood Control District, Bill Pisano of Montgomery Watson, and Ed Herricks of the University of Illinois at Champaign, Jon Jones of Wright Water Engineers, and Simon Clarke of the Water Research Centre. Afternoon discussions were coordinated by Richard Field of US EPA, Ed Wagner of CH2M HILL, George Barnes of Jordan, Jones, and Goulding, and Jon Jones of Wright Water Engineers.

The authors for the 1997 annual Water Environment Federation literature review on urban wet weather flows included several US EPA professionals (Field et al., 1997). This document provided a helpful, updated evaluation of the state of the art. Special thanks are owed Richard Field, Chi-Yuan Fan, Mary Stinson, Joyce Perdak, Michael Borst, and King Hsu of US EPA, and Richard DeGuida of Clough Harbour & Associates.

ACKNOWLEDGEMENTS, CONT.

The following participated in the urban wet weather flow research needs assessment during the September, 1997, Engineering Foundation Conference in Malmö, Sweden. Special thanks to Richard Ashley of the University of Abertay, Dundee, Scotland, who took notes during this meeting. This group gave an international perspective on the problem:

BENEFITS

- Reviews previous research needs assessments and offers a vision of gains expected from additional research;

- Examines closely such major topics as sources and monitoring, receiving water and other impacts, management, models and decision support systems, watershed management linkages, regulatory policies and financial aspects, source controls, collection system controls, and storage and treatment systems;

- Assesses 69 topics in the wet weather flow research. This assessment includes a literature review and statement of the problem, description of the research needs on the topic, and key references;

- Reviews innovative urban wet weather water management from an international perspective; and

- Prioritizes topics for additional, targeted research efforts according to cost effectiveness and provides cost estimates for identified research needs.

EXECUTIVE SUMMARY

This report presents the results of a national assessment of research needs in the management of urban wet weather flow. Three interrelated categories of urban wet weather flow management are covered: combined sewer overflows, sanitary sewer overflows, and urban wet weather flow discharges. The research needs assessment included the following steps: (1) extensive review of the literature; (2) review of previous research needs reviews, including US EPA's 1996 Wet Weather Flow (WWF) research program; (3) a one-day workshop to solicit ideas from interested professionals at the 1996 WEFTEC national meeting in Dallas; (4) extensive discussions with leading urban wet weather flow professionals; and (5) review of research needs with leading international experts.

The initial compilation of WWF research needs totaled 154 research projects. This list was reduced to 69 higher priority research projects, each summarized in one page. Each one-page summary consists of a statement on the importance of the problem including the relevant literature, research need(s), and key references. The final list of 26 topics is grouped into first and second priorities. Priority 1 topics, short- or long-term, should be initiated first. Priority 2 topics are also important but not as critical as the Priority 1 topics. In many cases, these final 26 topics are aggregations of the larger subset of priority research projects. Lastly, the final results of this needs assessment were organized into the following 10 categories (Table ES–1):

- Sources and monitoring;
- Receiving water impacts;
- Other impacts;
- Management;

- Models and decision support systems;
- Watershed management linkages;
- Regulatory policies and financial aspects;
- Source controls;
- Collection system controls; and
- Storage and treatment systems.

An estimated $20 million to $40 million per year would be needed to address the identified research needs.

The final list of priorities incorporates the following major principles and themes.

- WWF research provides an efficient way to bring innovations into the field in less time and thereby advance the state of knowledge in a more cost-effective and organized way.
- Source reduction or elimination, where possible, accompanied by treatment, provides a long-term, sustainable solution to WWF problems. A mass and energy balance approach is needed to characterize the nature of contaminants entering WWFs and to decide how best to manage them.
- The automobile is a major source of urban WWF problems and warrants special study of its overall impact.
- It is essential to evaluate all results of WWFs and to integrate these public health, physical, chemical, biological, socioeconomic, financial, and other considerations into an evaluation framework.

- Management of sediments associated with WWFs is a vital part of the management strategy.

- Subsurface impacts on groundwater and the vadose zones are becoming more of an issue in areas that are promoting infiltration as a management strategy.

- Innovative management strategies that are more compatible with bottom–up integrated watershed management must be developed.

- The US EPA Stormwater Management Model (SWMM) should be updated and expanded into a user friendly decision support system that interfaces with geographic information systems (GIS), relational database management systems, process optimizers, risk analysis capabilities, real-time control capabilities, and an expanded engine to incorporate other components of urban water systems.

- Real-time control provides an overarching framework for a data-centered approach for future WWF management.

- Methods are needed to integrate management of urban WWFs and watershed management.

- Policy research is needed to evaluate the feasibility of providing regulatory flexibility within a traditional command and control legislative framework that is regulated by individual media and individual constituents.

- Financing local WWF management programs is a challenge because of their multipurpose nature.

- Water quality standards issues related to wet weather flows must be reevaluated.

- Documented cases are needed of "success stories" of how a high level of environmental quality would enable communities to make their waterways focal points of redevelopment.

- On-site and local infiltration systems, including porous and permeable pavements, should be carefully evaluated for U.S. conditions, at the same time considering international experience.

- On-site and local wet weather flow re-use systems should be evaluated with particular attention to re-use for irrigation and cooling water.

- Innovations are needed in collection system design and operation including life cycle costing to avoid short-sighted approaches that reduce initial costs but leave a legacy of greatly increased operating costs. Unconventional sewer systems and flushing systems should be evaluated.

- More rigorous methods are needed to evaluate the efficacy of storage and treatment and other BMPs. Appropriate monitoring and modeling are essential components of these methods.

Table ES-1. Final List of Projects by Priority

Topic	*Priority*	
Sources and Monitoring		
Automotive pollutant source reduction or elimination	1	
Source control of heavy metals		2
Innovative monitoring methods	1	
Receiving Water Impacts		
Improved understanding of the physical, chemical, and biological processes		2
Defining beneficial uses for urban receiving waters		2
Urban stream and sediment geomorphology and restoration	1	
Stormwater-groundwater-vadose zone impacts		2
Other Impacts		
Evaluation of other performance measures for wet weather flow systems	1	
Management		
Opportunities for decentralized urban wet weather management	1	
Restructuring federal water agencies to better address urban water issues		2
Models and decision support systems		
Improve SWMM to include all aspects of contemporary decision support systems	1	
Incorporate real-time control into decision support systems	1	
Watershed Management Linkages		
Participate in integrated long-term experimental evaluation of urban watersheds	1	
Regulatory policies and financial aspects		
Determine areas where regulatory flexibility can achieve watershed goals		2
Innovative financing mechanisms for wet weather controls		2
Improved methods for evaluating the effectiveness of public education		2
Source Controls		
Feasibility of aggressive on-site and local infiltration of wet weather flows	1	
Feasibility of using porous and permable pavements		2
Feasibility of reusing wet weather flows for irrigation	1	
Collection System Controls		
Evaluation of role of separate and combined sewers including storage in sewers	1	
Deposition and scour in sewers		2
Improved infiltration/inflow control methods	1	
Benefits of sewer flow and quality monitoring		2
Storage and Treatment		
Improved high-rate wet weather storage treatment devices	1	
High-rate operation of wastewater treatment plants	1	
Effectiveness of best management practices	1

Acronyms and Abbreviations Used in this Report

AF	acre-feet
AGNPS	agricultural nonpoint source
AMSA	Association of Metropolitan Sewerage Agencies
ARMA	autoregressive moving average
ASCE	American Society of Civil Engineers
ASDM	atmospheric and sediment deposition model
AWRA	American Water Resources Association
BMP	best management practice
BOD	biochemical oxygen demand
BOD_5	5-day BOD
CD	compact disk
CDM	Camp Dresser and McKee, Inc.
COD	chemical oxygen demand
CSO	combined sewer overflow
CSUDP	Colorado State University Dynamic Programming
CWA	Clean Water Act (U.S.)
CWNS	Clean Water Needs Survey
DoD	U.S. Department of Defense
DOE	U.S. Department of Energy
DSS	decision support system
EA	environmental assessment
EDTA	ethylenediaminetetraacetic acid
EFAB	Environmental Financial Advisory Board (US EPA)
ERC	Environmental Research Center
ET	evapotranspiration
ETV	environmental technology verification
EXTRAN	extended transport model
FEMA	Federal Emergency Management Agency (U.S.)
FHWA	Federal Highway Administration (U.S.)

GB	Great Britain (U.K.)
GAC	granular activated carbon
GAO	U.S. General Accounting Office
GCM	global climatic model
GIS	geographic information system
GUI	graphical user interface
HEC	Hydrologic Engineering Center
HMS	hydrologic management system (replaces HEC-1)
I/I	infiltration/inflow
IAHR	International Association for Hydrologic Research
IAWQ	International Association for Water Quality
LTER	long-term ecological research
MCRS	minimum cost remaining savings
MTBE	methyl tert-butyl ether
NEPA	National Environmental Policy Act (U.S.)
NEXGEN	next generation
NOAA	National Oceanographic and Atmospheric Administration (U.S.)
NPDES	National Pollution Discharge Elimination System (U.S.)
NPS	nonpoint source
NSF	National Science Foundation (U.S.)
NTIS	National Technical Information Service (U.S.)
NURP	Nationwide Urban Runoff Program (US EPA)
O&M	operating and maintenance
PAH	polycyclic aromatic hydrocarbon
PC	personal computer
PET	potential evapotranspiration
R&D	research and development
RAS	river analysis system (replaces HEC-2)

RTC	real-time control
SCADA	supervisory control and data acquistion system
SCRB	separable cost remaining benefits
SCS	Soil Conservation Service (U.S.)
SS	suspended solids
SSO	sanitary sewer overflow
ST	storage treatment
SWMM	stormwater management model
TIN	triangular irregular network
TMDL	total maximum daily load
TSS	total suspended solids
TVA	Tennessee Valley Authority
U.S.	United States
U.S. COE	U.S. Army Corps of Engineers
US EPA	U.S. Environmental Protection Agency
UAA	use attainability analysis
U.K.	United Kingdom
USDA	U.S. Department of Agriculture
USGS	U.S. Geological Survey
UV	ultaviolet light
WEF	Water Environment Federation
WEFTEC	Water Environment Federation Technical Exhibition and Conference
WERF	Water Environment Research Foundation
WPCF	Water Pollution Control Federation (predecessor of WEF)
WWF	wet weather flow
WWTP	wastewater treatment plant

CHAPTER 1.0

INTRODUCTION

1.1 The Problem and Opportunities

Proper management of the quantity and quality of urban wet weather flow remains a major environmental problem. Estimated control costs for the United States range from several billion to hundreds of billions of dollars. The variation in these cost estimates stem from the magnitude of the source, the effectiveness of the controls, and the expected impacts on receiving water. On the positive side, communities that have successfully managed their water quality problems are now enjoying revitalized urban areas where receiving waters are major assets to the community, not perceived solely as components of the drainage and wastewater transport facilities. Cost-effective urban stormwater quality management should be integrated with urban stormwater quantity management and urban water management in general. Ideally, the urban water management system should be integrated with watershed management to take advantage of multipurpose opportunities. Urban wet weather flows come from three sources: combined sewer overflows (CSOs), sanitary sewer overflows (SSO), and stormwater discharges from storm sewers.

1.2 Intended Audiences for this Research Needs Assessment

The intended audiences for this wet weather flow (WWF) research assessment include the following:

- The local user community that supports WERF;
- Federal agencies including US EPA, NSF, COE, Federal Highways, FEMA, and other agencies involved with urban WWFs;
- The WWF research community in universities and other organizations;

- The WWF professional and research community, which is addressing many of the key issues defined in this research needs assessment; and

- People outside this field whom we hope to interest in addressing these important questions

1.3 Vision for the Benefits of Urban WWF Research

Concerted efforts since the late 1960s to clean up urban wastewater and stormwater have achieved impressive results. Previously, the accepted fate of urban watercourses was to serve as recipients of the unwanted by-products of urbanization including dry weather and stormwater-transported wastes from urban areas, in addition to receiving runoff from various industrial, agricultural, silvicultural, mining, and other activities. Also, these same receiving waters were ditched, drained, sewered, and subjected to a wide variety of manipulations to serve human needs. In addition to water quality changes, these waters underwent severe hydrologic changes due to hydropower development, navigation, water supply, flood control, recreation, etc. The end product of all of these abuses to our receiving waters was that citizens were conditioned to think of their waterways as undesirable kidneys of the city to be hidden and avoided.

Following the expenditure of billions of dollars on water quantity and quality improvements, we are beginning to see the long-term fruits of these investments. For example, the South Platte River flows through Denver from south to north. The South Platte has been subjected to virtually everu human influence. It is dammed upstream for water supply, hydropower, and flood control. Much of its flow is diverted for off-stream uses. Prior to modern water quality programs, the South Platte received poorly treated sewage, combined and separate sewer overflows and stormwater runoff, industrial wastes including meat packing wastes, and a variety of other insults. However, following aggressive cleanup and rehabilitation programs the South Platte switched from being a public health problem to a highly prized urban asset. The City of Denver is currently constructing a $60 million greenway along the entire stretch of the South Platte through Denver. Completed sections of this stream rehabilitation have stimulated major urban redevelopment in Denver with concurrent rapidly escalating property values along the South Platte because of its desirability as a recreational resource (swimming, fishing, boating) and as a vital link in the bicycle and pedestrian corridor through the city. Success stories, such as Denver's, are prompting many other communities and neighborhoods to integrate water into their overall plans for the future. This is the promise and vision for controlling WWFs. They are the last major uncontrolled source of pollution to our receiving waters. If we can manage this pollution source and provide a desirable hydrology for receiving waters, citizens can fully enjoy the benefits of this important investment for themselves and for posterity.

1.4 Preview of the Remainder of the Report

The next chapter of this report reviews previous research needs assessments and offers a vision for the expected gains from additional research. Individual research needs chapters give source characterization (Chapter 3.0), receiving water impacts (Chapter 4.0), management (Chapter 5.0), regulatory policies and financial aspects (Chapter 6.0), and control technologies (Chapter 7.0). One-page summaries of research needs are presented for each identified problem. The summaries are divided into three sections: statement of the problem, description of the research need(s) in this area, and key references. In the concluding Chapter 8.0, the 69 identified research needs topics are combined into 26 topics listed as priority 1 or 2. Lastly, we estimate the total cost of meeting these needs.

CHAPTER 2.0

PREVIOUS WET WEATHER FLOW RESEARCH NEEDS ASSESSMENTS

2.1 Literature Review

The literature review for the research needs assessment incorporates previous research needs assessments and their associated literature reviews. CH2M HILL (1990) summarized much of the literature as part of their research needs assessment. Also, the ASCE/WEF *Manual of Practice* (1992; 1998) and books by Debo and Reese (1995) and Novotny and Orem (1994) provide the reader with an overview, of the state of the art including extensive literature reviews. Field et al. (1997a, b) thoroughly review the wet weather flow (WWF) research results published in 1996. James (1996) edited a book of 18 papers dealing with the modeling aspects of urban stormwater. These papers address a variety of topics including the use of the models themselves, data management including GIS, and the interrelationships between BMPs and water quality. The two-volume proceedings of RIVERTECH96 (Maxwell, Pruel, and Stout, 1996) contains many papers related to urban stormwater management. The proceedings from a national conference on sanitary sewer overflows (SSOs) provide information on SSO problems generally and infiltration and inflow problems in particular (US EPA, 1996). The proceedings of the seventh international conference on urban storm drainage, held in Hannover, Germany, comprehensively describe new developments throughout the world (Sieker and Verworn, 1996; 1997). James (1997) edited a book of 28 papers on urban WWFs including a CD with 4,000 titles related to WWFs. The September 1997 Engineering Research Foundation Conference on Innovative Urban Stormwater Management, held in Malmö, Sweden, offers information on research needs (Rowney, Stahre, and Roesner, 1998).

2.2 Wet Weather Flow Research

Urban WWF quantity and quality has been studied since the late 1960s, initial interest focusing on combined sewer overflows. The US EPA Municipal Environmental Research Laboratory's Storm and Combined Sewer Program invested $60 million to $70 million in some 250 extramural projects until 1981 (Field 1982). The US EPA Nationwide Urban Runoff Program (NURP) sponsored $30 million in field studies in 28 cities between 1979 and 1983 (US EPA, 1983). Other federal agencies including the U.S. Geological Survey, the U.S. Army Corps of Engineers, and the Office of Water Research and Technology also had active urban stormwater research and demonstration programs during the 1970s. While the exact total remains uncertain, federal investment in stormwater research prior to 1983 probably exceeded $100 million. Subsequently, wet weather research funding by federal agencies in the United States disappeared in the early 1980s and has only recently begun to reemerge. This 15-year hiatus caused many gaps in U.S. research. Meanwhile, significant research efforts continued in Europe, Australia, Japan, and other foreign counties (Marsalek and Sztruhar, 1994). Thus, we must look to the international community to assess the current state of the art.

Roesner and Traina (1994) cite estimates of the American Public Works Association (1992) of urban stormwater control costs in the United States ranging from $147 million to $407 billion in capital costs and $1.2 biollion to $542 billion/year in annual O&M costs depending upon the assumed level of BMP control. Recently, the US EPA (1997) published results of the 1996 needs survey for wastewater and stormwater systems. This needs assessment estimated only the expected total cost of controlling combined sewer overflows. It gave partial estimates for sanitary sewer overflows (SSOs) and stormwater runoff. A rough estimate of wet weather control costs based on the 1996 needs survey and preliminary guesses at the cost of managing SSOs and urban stormwater yields a capital investment of $100 billion with annual O&M costs of $10 million per year.

The National Research Council (1993) evaluated future directions of wastewater management in coastal areas. Their report describes how a holistic approach can be taken to urban wastewater problems including wet weather flows. General research recommendations are related to improved source characterization, control effectiveness, and receiving water impact assessment.

2.3 Previous Research Needs Assessments

2.3.1 1986 Compilation by Torno

Torno (1986) summarized stormwater research needs as developed by conferees at an international conference on urban stormwater. The participants assigned priorities to the results of this assessment (Table 2–1) by voting. The number of votes received by each topic is presented in the right-hand column. The highest priority research topic was to conduct additional research to improve understanding of the processes of pollutant accumulation and transport in urban runoff. A total of 17 topics were selected, but not categorized.

Table 2–1. Urban Wet Weather Research Needs (Torno, 1986) (Prioritized)

No.	*Research Topic*	*No. of Votes*
1	The understanding of the processes and mechanisms, including the related mathematical models of pollutant accumulation and transport in urban runoff.	13 votes
2	The impacts of metals and other toxic pollutants on aquatic biota, including the means to monitor these impacts.	8 votes
3	The impacts of urban runoff pollution on receiving waters, including the impairment of beneficial uses. This includes the modeling of these impacts.	8 votes
4	Better understanding of the processes of sedimentation and scour of solid particles in sewers.	8 votes
5	Development of standards for sampling, analysis and data reporting for urban runoff pollutants.	8 votes
6	Performance of stormwater and combined sewer overflow treatment devices.	7 votes
7	The economic and institutional impacts of pollution control programs.	6 votes
8	The development of stormwater and combined sewer overflow discharge criteria based on receiving water impacts.	6 votes
9	The operation and maintenance of sewer and control technology systems, including the effects of O&M on system performance.	5 votes
10	The impacts of infiltrated urban runoff on groundwater.	4 votes
11	Improved techniques for rainfall forecasting, including the use of radar.	4 votes
12	Identification of sediment/water interactions in sewers and receiving waters.	4 votes
13	Identification and quantification of sources of error and uncertainty in model results.	3 votes
14	Development of criteria for model calibration and verification.	3 votes
15	The effects of real-time control systems on system performance and improved water quality.	3 votes
16	Case studies where complete planning, design, construction, O&M of storm and combined sewers demonstrate impacts on receiving water quality.	3 votes
17	Impacts of stormwater and combined sewage on the performance of wastewater treatment facilities.	3 votes

2.3.2 1986 Research Needs Assessment by Heaney

Under US EPA sponsorship, Heaney (1986) summarized research needs in urban stormwater pollution including the results of earlier studies of research needs. This assessment used an extensive literature review and informal contacts with leading experts in the field to develop the final list of 52 topics shown in Table 2–2. These topics were not ranked.

Table 2–2. Research Needs in Urban Stormwater Quality (Heaney, 1986) (Unprioritized)

No.	*Description*	*No.*	*Title*
1	**Sources**		
	Runoff Quantity	1	Relationship of runoff and basin structure
		2	Linkage of surface and subsurface phenomena
		3	Use of dense rain gages to describe storm patterns
		4	Integrate GIS to refine spatial analysis capabilities
		5	Flow meters to measure widely variable flows
	Runoff Quality	6	Flow-weighted sampling devices for variable flows
		7	Influence of land use on water quality
		8	Methods to distinguish wet and dry weather flows in combined sewers.
2	**Controls**		
	On-site	1	Effectiveness of swales
	Collection Systems	2	Instrumentation & monitoring to evaluate sewer hydraulics
		3	Cost-effective ways to rehabilitate & replace old sewers
		4	Laboratory & field studies of deposition & scour in sewers
		5	Use of simulation models in storm sewer design
		6	Calibration of transport models using improved databases
	Downstream Controls	7	Laboratory studies of high-rate treatment systems
		8	Effectiveness of disinfection with highly variable flows
		9	Design of storage/release systems to maximize pollutant control
		10	Evaluation of groundwater injection systems
		11	Engineering considerations in using wetland systems
		12	Application rates for land disposal of urban runoff
		13	Reuse of urban runoff as cooling water
		14	Probabilistic performance criteria for wet weather controls
		15	Treatment of heavy metals in urban runoff

Table 2-2, cont. Research Needs in Urban Stormwater Quality (Heaney, 1986) (Unprioritized)

No.	*Description*	*No.*	*Title*
		16	Sludge/solids disposal aspects of control options
		17	Process control systems to optimize performance of control
3	**Receiving Water Impact**		
	Quantity	1	Hydrograph separation techniques to estimate the origin of flow in rivers
	Quality	2	Quantify benefits of stormwater quality control
		3	Bioassay procedures for short-term intermittent exposures to urban runoff
		4	Bioassay procedures for long-term exposures to heavy metal accumulation in benthos
		5	Mass balance of urban runoff and receiving water fluxes
		6	Criteria for wet weather quality standards
		7	Behavior of urban runoff in mixing zones of rivers, lakes, & estuaries
4	**Institutional Arrangements**	1	Preparing effective and implementable NPS regulations
		2	Establish a mechanism for coordinating stormwater research across various funding agencies
5	**Watershed Management**	1	Understanding regional differences in receiving waters
	Linkages	2	Watershed response during winter conditions
		3	Watershed-based water quality standards
		4	Develop long-term watershed case studies
		5	Develop a watershed assessment methodology
		6	Feasibility of identifying "natural conditions" at the watershed scale
		7	Establish a network of urban research catchments
6	**Decision Support &**	1	Development of more robust parameter estimation methods
	Modeling	2	Add solids handling to simulation models
		3	Interface simulation and optimization models
		4	Refine statistical methods as preliminary screening procedures for simulation models
		5	Perform detailed statistical analyses of existing, NURP, U.S.GS, and other data
		6	Combine available databases into a single database

Table 2-2, cont. Research Needs in Urban Stormwater Quality (Heaney, 1986) (Unprioritized)

No.	Description	No.	Title
		7	Develop methods to properly allocate the costs of multi-purpose water projects
		8	Apply recently developed methods for evaluating public response to alternative control programs
		9	Develop user friendly integrated decision support systems
		10	Methods for estimating the probability distributions of sewage, urban runoff, and upstream flows
	Total no. of topics	52	

2.3.3 1990 WPCF Research Needs Assessment

WERF's predecessor, the Water Pollution Control Federation Research Foundation, sponsored a 1990 research needs assessment of nonpoint pollution (CH2M HILL, 1990). This assessment included agricultural and mining wastes in addition to urban runoff. The resulting 17 priority-assigned topics are shown in Table 2–3. The 1990 WPCF assessment reflected the emerging interest in watershed approaches. The other difference was in the interest in PAHs.

2.3.4 US EPA Research Needs Assessment

Shortly before this project began, US EPA released a draft of its urban wet weather flow (WWF) research plan for review (Field et al. 1997a). This major effort was reviewed by various groups including ASCE's Urban Water Resources Research Council (UWRRC). Several UWRRC members are also involved in this research needs assessment. Thus, the US EPA draft provided an excellent opportunity to involve a larger audience in the research needs process. It also heightened interest in the process because of the growing optimism that US EPA's WWF research program was being revitalized.

The final list of 77 projects (Table 2-4) were not assigned priorities. The US EPA divided the topics into the following five categories: characterization and problem assessment (13 topics); watershed management (16 topics); toxic substances impacts and control (5 topics); control technologies (36 topics); and infrastructure improvement (7 topics). However, many of them overlap, e.g., the Rouge

River Restoration, is a large demonstration project that encompasses virtually all areas. Many of these topics include a large technology transfer component. The US EPA WWF document was compiled by the Urban Watershed Management Branch of US EPA's National Risk Management Research Laboratory. This group is the designated lead in the WWF area. However, other EPA research organizations also participate in this program including (Field et al. 1996):

- Microbial Contaminants Control Branch
- Treatment Technology Evaluation Branch
- Water Quality Management Branch
- Subsurface Protection and Remediation Division
- Technology Transfer and Support Division.

Table 2–3. Research Needs from 1990 WPCF Assessment (CH2M HILL, 1990) (Prioritized)

No.	*Research Need*
1	Probabilistic performance criteria for wet weather controls
2	Improved knowledge of O&M costs
3	Determine decomposition rates for various PAHs
4	Bioassay procedures for long-term exposure to heavy metal accumulation in benthos
5	Mass balance of urban runoff and receiving water fluxes
6	Impact of snowmelt on receiving water quality
7	Establish a mechanism for coordinating stormwater research across various funding agencies
8	Understanding regional differences in receiving waters
9	Watershed responses during winter conditions
10	Watershed-based water quality standards
11	Feasibility of defining "natural' conditions at the watershed scale
12	Establish a network of urban research catchments.
13	Develop more robust parameter estimation methods
14	Add solids handling to simulation models
15	Develop user friendly integrated decision support systems
16	Methods for evaluating NPDES data
17	Methods for estimating the probability distributions of sewage, urban runoff, and upstream flows

5.4	Sanitary Sewer System Design
5.5	House Service Laterals
5.6	Reduced Impervious Cover
5.7	Swales Instead of Curbs

In addition to intra-agency coordination, US EPA coordinates with other federal agencies (e.g., Corps of Engineers), professional societies (e.g., ASCE, WEF), and international organizations (e.g., International Association for Hydraulic Research, International Association of Water Quality). Thus, a good infrastructure exists for coordinating research activities with the appropriate research and user communities.

Notable shifts in emphasis since the 1990 research assessment were the continuing growth of emphasis on watershed approaches, risk management, and toxics characterization and control.

2.3.5 1996 WERF/Bay Area Stormwater Management Agencies Wet Weather Research Needs Assessment

At the same time US EPA released its draft research needs document, WERF met with representatives of the Bay Area Stormwater Management Agencies to identify wet weather research needs. The 25 wet weather research needs, without priorities, are listed in Table 2-5.

This research needs assessment emphasizes the need to understand regional differences, e.g., technology applied in the Eastern United States does not necessarily perform well in the more arid Western United States. It also recommends a reevaluation of the environmentally friendly developments instituted during the past 30 years. Have they worked well? This needs assessment introduces the issue of environmental justice and how benefits and costs of these programs affect various socioeconomic groups.

Table 2–5. Urban Wet Weather Flow Research Needs Developed by WERF and Representative of Bay Area Stormwater Management Agencies, August 21, 1996 (Unprioritized)

No.	*Research Need*
1.	Acceptance of Eastern data in the West
2.	Hydraulic control BMPs
3.	Dry cycle contamination (agricultural issue)
4.	Atmospheric deposition
5.	BMP maintenance
6.	Biological indicators
7.	Can sand filters and other Eastern technologies work for Western storms?
8.	Limiting factors for ecosystems
9.	Better indicators of actual fecal contamination
10.	Impacts of BMPs
11.	Link decision making processes to quality measures: what is achievable given a particular degree of authorization?
12.	Characterization of non-stormwater impacts (cooling water pools, etc.)
13.	Vegetative management practices
14.	Environmental friendly development assessment: 20 years later
15.	Cross-media issues (e.g., Hg); pollutant cycling and how to break the cycle
16.	Sediment quality
17.	Dioxin/PCBs
18.	Turbidity studies, settleability, particle sizes, etc.
19.	Monitoring strategies for multiple point sources
20.	First flush impacts in the West
21.	Public perception; linking beneficial uses with the optimal distribution of funds
22.	Aquatic and non-aquatic vegetative management (e.g., techniques for killing algae in intake pipes)
23.	Distributing funds in developed and developing areas; "environmental justice"
24.	BMP cost-effectiveness
25.	Pesticide transport

2.3.6 October 1996 WERF WWF Research Needs Workshop, Dallas, Texas

Shortly after this project was initiated in September, 1996, a one-day workshop was held in Dallas on October 5 as part of the 1996 WEFTEC national meeting. Approximately 60 people participated.

Many of the participants had reviewed the US EPA Research Needs draft. Attendees received background information in an overview report entitled "Wet Weather Research Assessment." The format for the workshop was a series of presentations on the various aspects of urban stormwater management. In addition, Simon Clarke gave an overview of wet weather research in Great Britain and Don Weatherbe gave a similar overview of recent research in Canada. During the afternoon, all participants joined one of the four following groups: Wet Weather Sources; Controls; Receiving Water Impacts; or Institutional Arrangements, Watershed Management Linkages, and Decision Support and Modeling. During the final session, each group presented its topics and how it would assign priority to them. Most workshop participants represented the user community. The final results from this effort are shown in Table 2–6.

While the WERF workshop reiterated many of the research needs expressed in earlier needs assessments, some different themes were emerging. With regard to source characterization, there was significant interest in gaining a better understanding of the overall impactof the automobile including the need for increasing impervious area and pollutant load generation. Also, construction practices and litter control were topics of considerable interest. On the control side, there was strong interest in a more integrated approach to control effectiveness rather than examining each control in isolation. Another major shift in focus was a strong recommendation on the need for research directed to providing the technical and policy basis for more flexible regulatory programs. These recommendations are compatible with efforts within US EPA to reinvent itself to provide this additional flexibility. But, this is not an easy task for an agency whose entire history is based on regulating specific constituents in individual media (Government Accounting Office, 1997).

2.3.7 Recommendations from the 1997 Malmö Conference

Wet weather research needs were assessed as part of the Engineering Foundation Conference entitled Innovative Urban Water Management for the 21st Century, held in September 1997 in Malmö, Sweden (Rowney, Stahre, and Roesner, 1998). This week-long conference attracted 95 leading stormwater experts from throughout the world. Several suggestions for research needs emerged from the papers and discussions. Also, the senior author of this report organized an afternoon session on research needs with 16 attendees, most of whom are academics. Following a briefing on the ongoing WERF project, the attendees were asked to make their suggestions. Table 2–7 summarizes the results. The suggestions are not listed in any particular order.

Table 2–6. WWF Research Needs Identified by Participants at the October 1996 WERF Workshop (Partially Prioritized)

No.	*Sources*	*Votes*
1	Automotive fate and transport of inputs to water environment	8
2	Construction materials and practices	4
3	Litter generation, transport, fate, and control effectiveness	2
4	Improved methods of source controls	3
5	Buildup and washoff processes	2
6	Atmospheric deposition	
7	Urban drainage design improvements	
8	Ultimate fate of pollutants captured by BMPs	
9	Rainfall-runoff for small storms-micro-storm management	
10	Modifying urban surfaces to reduce hydraulic and pollutant loads	
11	How to measure and evaluate pathogens in stormwater	
12	Runoff quality monitoring protocols.	
13	Thermal pollution associated with urbanization.	
14	Isotope tracking techniques for characterizing the nature of WWFs	
15	WWFs from industrial sites	
16	Basic processes of buildup and washoff in developed urban areas.	
No.	*Controls*	*Votes*
	Most of the individual topics were subsumed under the first category	
1	Unified design protocols including local hydrology, catchment and water quality characteristics, performance measures, controls, stream impacts, and system optimization.	16
2	Trash, floatables control	7
3	Control of suspended solids	3
4	Integrated systems of flood and pollution control including reuse	
5	Collection systems	
	Rehabilitation	
	New designs for new areas:	
	Collection systems as reactors	
	Demonstration of sewer flushing	
	In-system storage	
	Real-time control	
6	Dissolved solids removal	

Table 2–6, cont. WWF Research Needs Identified by Participants at the October 1996 WERF Workshop (Partially Prioritized)

No.	*Institutional Arrangements, Watershed Management Linkages, & Decision Support Systems*	*Votes*
1	To identify those areas where it makes sense and is feasible for EPA to provide regulatory flexibility to achieve watershed goals. Possible areas: Compliance schedules Permitting innovations. Redefining water quality standards and metrics. Foster local accountability.	13
	Rationale: Current regulatory program is not consistent with the nature of the problem.	
2	To determine the costs/performance function data for stormwater controls as a function of operation, maintenance, and replacement costs. Rationale: Necessary to accurately project costs and benefits. Natural reluctance to spend money on maintenance. However, maintenance is essential to attain design objectives.	17
3	How do local governments make appropriate decisions to develop watershed? management/regulatory programs that will "withstand the test of time" and that all parties will buy into? Decision support tools Feedback on public involvement, participation techniques How to translate public desires into action? Common elements of successes and failures. Characterize and prioritize the factors that lead to "environmental integrity." Rationale: Without this approach, defer either to federal mandates or local political decsions.?	
No.	*Receiving Water Impacts*	*Votes*
1	If watershed is urbanized and changes in hydrology occur, what will the stream look like?	15
2	What are human health risk/ecosystem impact trade-offs?	8
3	What indices are needed to determine specific impacts of constituents, e.g., metals, BOD, pathogens?	3

With a theme of innovative urban water management for the 21st century, the Malmö conference was an ideal venue for receiving ideas for research. A major theme that emerged from the conference was the need to develop interdisciplinary teams that include engineers, scientists, landscape architects, and planners to develop new or redeveloped urban systems. As such we need to move away from the narrow view—especially in the United States—of forcing these urban developments to conform to narrowly focused regulations on how stormwater should be managed. Numerous case studies were presented by landscape architects showing how functional and beautiful designs could be developed with participation from all affected stakeholders.

Table 2–7. Wet Weather Research Needs from the Engineering Foundation Malmö Conference, September 1997 (Unprioritized)

No.	*Research Need*
1	Endpoints of toxicants in detention ponds
2	Need source control of toxics in automobiles, e.g., brake pads. Long-term solution is source control
3	Real-time control linking collection, treatment, and receiving waters
4	Integrating landscape architecture into urban water management programs. How to develop designs that show the beauty and spirituality, as well as the function of water in urban areas. Goal is not necessarily to make water system look "natural"
5	Develop improved decision support systems with better simulation engines, direct links with optimization techniques, explicit inclusion of RTC, and that incorporate sustainability and risk analysis
6	Long-term sustainability of infiltration systems. More efficient data collection techniques including transmission hardware and software are needed
7	Better understanding of health impacts of urban runoff
8	Better methods to quantify benefits of urban stormwater management
9	Groundwater pollution from highways
10	Quality of roof runoff and its fate in soil systems. Change roofing materials. Impact of grassed roofs
11	Development of stochastic models for urban stormwater
12	Measurements to track the movement of toxics through urban areas
13	Development of environmental ethics to reduce litter
14	Adaptive real-time control for entire urban water system including water supply, wastewater, and stormwater
15	Improve EPA use attainability studies to reflect the desire to provide innovative, flexible approaches to water quality management
16	Better define ecosystem-flow contaminant relationships for urban stormwater management
17	Cradle to grave tracking of urban water pathways and controls
18	Biofilm processes and biofiltration
19	Integrated urban water systems evaluation
20	Long-term performance of wetlands and ponds
21	Short and long-term performance of porous and permeable pavement systems. Need to support continuing experimental and laboratory studies
22	Techniques for reducing the demand for automobile travel, e.g., now pay a toll for entering Trondheim, Norway and Cambridge, England
23	Alternatives to current urban water management systems. Want to develop more sustainable systems. Need interdisciplinary teams
24	Urban stormwater management in cold climates

Table 2–7, cont. Wet Weather Research Needs from the Engineering Foundation Malmö Conference, September 1997 (Unprioritized)

No.	*Research Need*
25	Develop long-term experimental watersheds in urban areas. Australia has one that has been operated for 20 years. Hannover has one with 5 to 6 years of data. The new Munich project includes long-term monitoring.
26	Investigate the feasibility of decentralized urban water management and privatization. Use Great Britain, Australia, and New Zealand as case studies
27	Support large-scale international effort to evaluate the feasibility of sustainable urban water systems including careful consideration of demand management, recycling and reuse, and water management at the individual and neighborhood levels

Another striking observation from the U.S. perspective is the widespread use of stormwater infiltration systems in other parts of the world, e.g., Tokyo and many areas in Europe. These infiltration systems are able to totally contain smaller storms on site and reduce the impacts on local receiving waters. Another strong trend is the much more aggresive use of water reuse internationally. Finally, the amount of urban stormwater research in Europe greatly exceeds current activities in the United States. We need to learn from our international colleagues.

2.3.8 Compilation of Research Needs Efforts

The previous sections summarized the following seven research needs assessments:

- Assessment by international experts (Torno, 1986)—17 topics;
- Assessment by Heaney's (1986) literature review and discussions with experts—52 topics;
- WPCF assessment by CH2M HILL's (1990) literature review and workshop—17 topics;
- Assessment by WERF and Bay Area Stormwater Management Agencies—25 topics;
- Assessment by WERF workshop's 60 delegates—28 topics;
- US EPA assessment (Field et al., 1997a)—77 topics; and
- Engineering Foundation Conference recommendations—27 topics.

154	Sewer maintenance optimization								0

The number of topics for these seven research needs assessments totals 243. The net total of topics is smaller in that there is substantial overlap. To give an overview, all of these topics have been compiled in Table 2–8. The net total of 154 separate topics is listed under the following categories:

- Sources and Monitoring—23 topics;
- Receiving Water Impacts—22 topics;
- Management—23 topics;
- Regulatory Policies and Financial Aspects—19 topics; and
- Controls—67 topics.

2.4 Methods for Assessing Research Needs

Research needs can be assessed in a variety of ways. In a 1985 assessment of research needs in urban stormwater pollution sponsored by US EPA, Heaney (1986) relied on a thorough literature review. He culled research needs recommendations from various papers and reports and synthesized them into one comprehensive set. Torno's (1986) compilation of research needs represents the opinions of national and international experts obtained in open discussions as part of an urban stormwater conference. The 1990 WPCF/RF assessment of research needs in nonpoint pollution used a combination of literature review, expert panels, and user input in a one-day meeting (CH2M HILL, 1990). The 1996 US EPA research needs assessment used a combination of internal and external experts to develop the statements of unresolved problems and research needs.

The research needs assessment can be viewed as a portfolio selection problem wherein the objective is to maximize the present value of the expected net benefits from research activities. Research, by its very nature, is a risky investment. Thus, organizations make their best estimates of the potential payoff of various research investments and the probability of success of these research investments. The general objective is to select a mix of projects such that we have a high probability of a successful portfolio just as investors use in selecting among stocks, bonds, and other investment opportunities. While formal research planning models have been used for large research programs, such as the Department of Defense which is funding thousands of projects at any given time, most research funding organizations rely on less formal approaches.

2.5 Purposes of Urban Stormwater Research Program

Viewing research funding as a portfolio selection problem, the most fundamental question is: Exactly what is the purpose(s) of the program? Of course, this varies depending on the investor and his or her objectives, e.g. short-term high-risk, high-return investments or conservative long-term investments for retirement. Most investors select a mix of investments to ensure that the portfolio will achieve their goals.

Unlike traditional financial investments, research investments in the short-term are viewed as low risk, and conversely, long-term are viewed as higher risk. Wet weather research has many different clients. WERF is supported by organizations that would be expected to prefer applied research with well-defined tasks and a fairly high probability of success as measured by immediate value to the user community. These applied research projects are typically smaller, last a relatively short time (1 to 2 years), and are awarded based on responses to a formal request for proposals (RFP). These projects are open to a wide variety of groups including consultants and universities. At present, this model dominates research funding in the United States and Europe. The limitation of funding only short-term, low-risk applied research projects is that they tend to be less innovative since the problem, and often the solution, is prescribed in the RFP. These projects are also of limited value in supporting the training of graduate students in the wet weather area. US EPA is the primary source of wet weather research support in the United States. These funds come from various groups within US EPA and range from highly applied studies to more fundamental research. In the 1970s, the US EPA Wet Weather Research Program was more centralized and had a larger budget. Sponsored projects were a blend of fundamental and applied research and technology transfer. These projects supported many graduate students, many of whom are now leading professionals in the field.

The demise of this research program, along with companion urban water research programs in other federal agencies in the early 1980s, caused the U.S. WWF research community to dismantle and move into other areas where research support was available, e.g., hazardous waste. At present, only a handful of university faculty members have maintained an interest in WWF research and very few graduate students receive training in this area.

At the opposite end of the spectrum from highly applied, solicited research is basic research characterized by unsolicited proposals from universities and other research organizations wherein the proposer presents ideas and requests support for longer-term, basic research whose immediate utility may be unclear. Local utilities and agencies have difficulty supporting such activities. Even a federal agency, such as US EPA, may have trouble justifying such longer-term investments. The National Science Foundation (NSF) supports this kind of research, but until recently, their urban stormwater–related funding has been very small. A recent NSF/EPA/USDA cooperative initiative on watersheds offers hope of better support in this area.

Given a low level of current funding of WWF research in the United States, what mix of projects is appropriate? A popular tendency is to put all available resources into applied research with the hope of short-term payoffs and "success stories" that can be used to request higher levels of future support. As support levels increase, then some of the funding can be used to support longer-term, more fundamental research with increased support for graduate students. This approach did not work well for the water research community during the 1980s when funds were tight and researchers attempted to be more relevant. The result was continuously diminishing resources.

A possible new dimension for WWF research lies in international cooperation. The cost of supporting essential, long-term experimental research is high and requires a funding agency's multi-year commitment. For example, porous and permeable pavement is an important area of WWF research. Long-term experimental laboratory and field studies are essential to evaluate the efficacy of this approach, but at present, only a few such studies are being done in the world. International cooperation would make it possible to support these efforts with input from the international user community. The recent emergence of the European Union as a major funder of research in Europe offers real possibilities for establishing internationally funded projects in key WWF areas.

More detailed descriptions of WWF research needs are presented in the next five chapters.

CHAPTER 3.0

SOURCE CHARACTERIZATION

3.1 The Problem

Characterization of runoff pollutants is essential to understand impacts on receiving waters, to develop control strategies, to operate collection systems and treatment works, and to predict the ultimate fate of pollutants in the environment. Runoff is a common pathway for pollutants that originate in non-aquatic systems to enter aquatic systems. For example, results of Forster's (1996a, b) study of runoff from metal roofs in Germany show high metal concentrations in roof runoff. If this roofing material were replaced by a benign material, then the source would be eliminated along with the need for expensive controls to convert the metals into another form, e.g., sludge beds. Boller (1997) demonstrates that urban runoff control measures merely transfer metals from one destination to another. The fate and transport of metals were demonstrated in three scenarios: through a combined sewer, through a separate storm sewer, and through decentralized infiltration. In the combined sewer, the majority of the copper in urban runoff becomes bound with the sludge from the WWTP. In separate storm sewers, a large portion of the metals enters the receiving waters and becomes trapped in the benthic ecosystem. If on-site control measures are used, (e.g. decentralized infiltration), metals accumulate in the pervious ground. Thus, long-term control of metals (and all conservative pollutants) is accomplished by eliminating the source. The relative mass loads of copper from Boller's (1997) scenario analysis are shown in Figure 3–1.

The cases presented by Boller (1997) and Forster (1996a, b) highlight the need for pollutant source characterization to identify sources of contamination, and to design integrated means of eliminating them or eliminating their exposure to precipitation and runoff.

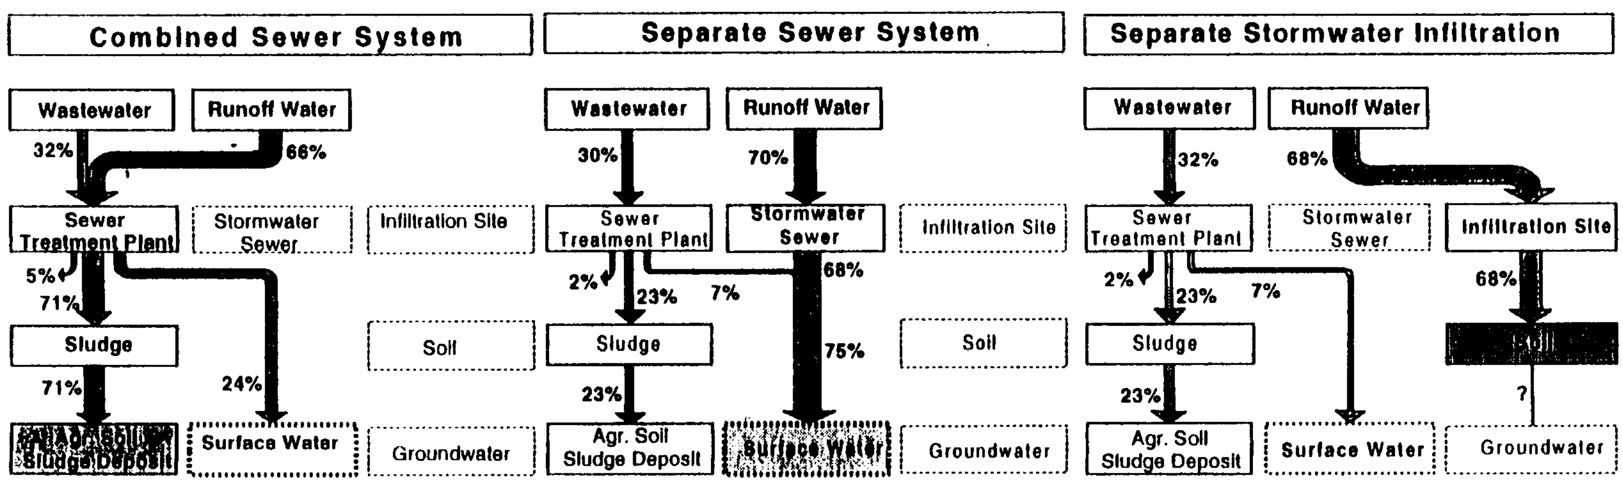

Figure 3–1. Relative Mass Flow of Copper in Different Urban Drainage Systems (Boller, 1997)

WERF

Aside from metals, urban runoff pollution consists of solids, nutrients, thermal effects, and toxic substances. The sources of these pollutants tend to be diffuse in nature; even when discharges occur at individual points (e.g., separate storm or combined sewer outfall), the source of the pollution tends to be dispersed over the urban land surface (Nix, 1994). Moreover, pollutants are only part of the problem; impervious surfaces found in the urban landscape increase runoff volume considerably, adding a physical hydraulic impact on the receiving waters.

Deposition of particles on land surfaces occurs naturally as part of atmospheric–lithospheric interaction. Atmospheric particulates are derived from natural processes (e.g. wind erosion), or from anthropogenic sources such as fossil fuel exhaust. This research area is primarily concerned with anthropogenic sources of pollution and their impact on urban runoff quality. Ball, Jenks, and Auborg (1996) stress the importance of wind in pollutant accumulation rates. Atmospheric depositional processes have been an active area of research; however, atmospheric scientists and water quality researchers have interacted relatively little.

Contaminant loading produced by wet weather flows has been studied extensively (Zison, 1980; US EPA, 1983; Hargesheimer, Lewis, and Seidner, 1986; Barr Engineering Company, 1987; Choi and Park, 1988; Birtwell et al., 1988; Driver and Tasker, 1988; Bartel and Maristany, 1989; Desbordes and Hemain, 1990). A reasonably high level of knowledge about source emissions has accumulated because of work of national scope (e.g., US EPA, 1983; Driver and Tasker, 1990; Driscoll, Shelly, and Strecker, 1990), as well as many regional and local studies to characterize urban runoff sources. In general, contaminant concentrations increase below discharge locations, but little is known about how they accumulate on the watershed and how they enter the runoff.

Heaney et al. (1998a) assess recent literature regarding overall impacts of the automobile on urban runoff. The automobile has caused urban sprawl in the United States over the past 50 years (Heaney et al., 1998a, b). The proliferation of the automobile has led to land-use changes and has directly contributed pollutants, making the automobile a major contributor to urban runoff pollution. The hydrologic effect of impervious surfaces is well known. A large fraction of impervious surfaces in the United States has been created to accommodate automotive transportation. These surfaces create near ideal wash-off conditions for accumulated pollutants. Research should track the total pollutant load that results from automobile transportation to aid in developing innovative control measures and, perhaps, lead to actual source reductions.

Contaminant loading has also been related to sedimentation conditions (Zison, 1980). The most common impact associated with sediment is the accumulation of large and heavy particulates near and downstream of runoff discharge locations and a corresponding increase in contaminant concentration in these "hot spots." Floatable solids, typically vegetative debris, partially decomposes and sinks to form organic mud deposits. An important mechanism of sediment contamination is the precipitation of soluble materials upon change of pH, oxidation reduction potential (ORP), or temperature. Rubin (1976) stated that when solutions of trace metals, or other dilute solutes, come in contact with solid phases, the concentration of the constituent in the solute usually decreases. It may take polluted solids a long time to pass through a contaminated stream. The transport of pollutants are, therefore, difficult to relate to specific runoff events. Much of the suspended contaminants during wet weather events may be resuspended sediment that had been deposited during previous storms (Wilber and Hunter, 1980).

Organization of research needs in this section follows the logic of characterizing urban land surface depositional processes and pollutants associated with urban land use, characterization of physical transport processes, and finally monitoring needs associated with source characterization. This typology is useful because the processes are the focus of research, and detailed sub-topics of importance are viewed in light of the overall physical processes associated with them.

Table 2–8 identifies 23 research needs topics as pertinent to source characterization. While differing in some details, many have common research elements. For this section, three overall topics were selected to cover source characterization needs. Ten topics listed in Table 2–8 relate to the characterization of pollutants having to do with urban land use. Six topics generally fit the category of fate and transport characterization, and seven have to do with monitoring issues related to source characterization. Not every research need identified in Table 2–8 is specifically referenced in the following sections (3.1 through 3.3), although all areas identified in Table 3–1 share common elements. Needs not specifically mentioned in Sections 3.1 to 3.3 may not be less critical, but were less represented in the literature. The literature base in the area of source characterization is not as broad as in other areas; nevertheless, this topic is equally important.

Research resources should be allocated to source characterization within the context of broad-based urban water-management goals. Characterization of pollutant sources is essential in understanding the fate and transport pathways through the urban hydrologic cycle. Knowledge of these pathways is essential to develop control and management schemes. The US EPA has designated a research team to investigate the life-cycle impacts of materials. The Systems Analysis Branch of the Sustainable Technology Division, under the National Risk Management Research Laboratory, conducts studies such as "Cleaner products through life-cycle design" and "Enhanced methods for life-cycle and total cost assessments." Researchers of urban runoff-quality projects, especially those involving source characterization, should cooperate with researchers working from the total systems viewpoint. Thus, research funded in this area should be performed in the context of overall systems improvement.

Table 3–1. Research Needs for Characterization of Sources (Unprioritized)

Section	*Table 2–8 ID #*	*Research Topic*
3.0 Source Characterization		
3.2 Urban Land Surfaces & Land Use	1	Atmospheric deposition
	2	Industrial sites
	3	Thermal pollution
	7	Automotive sources
	8	Construction sources
	9	Litter sources
	11	Influence of land use on water quality
	13	Toxics sources
	23	Quality of roof runoff
	14	Pesticide sources
3.3 Fate & Transport Processes	5	Watershed response during winter conditions
	6	Rainfall-runoff relationships for micro- storm management
	10	Build-up/wash-off processes in urban areas
	22	Cradle to grave tracking of urban water pathways and controls
	15	Determine decomposition rate for various PAHs
	17	Isotope tracing techniques for characterizing WWFs
3.4 Monitoring	12	Fecal sources, use better indicators
	16	Turbidity studies, settleability, particle sizes, etc.
	4	Use of dense rain gages and radar to describe storm patterns
	18	Cross media issues
	19	Flow meters to measure widely variable flows
	20	Flow-weighted sampling devices for variable flows
	21	Standards for sampling, analysis, and reporting for urban runoff pollutants

3.2 Characterization of Pollutants Associated with Urban Land Use

Pollutants on urban land surfaces may be dispersed over a wide area by means of atmospheric mixing and localized processes on urban land surfaces (e.g., residential impervious surfaces such as roof tops and road surfaces contributing pollutants directly from their construction material). Shepp (1996) estimates that runoff concentrations of petroleum hydrocarbons from automotive-intensive land uses typically range from 0.7 to 6.6 mg/L. Revitt et al. (1996) identified the sources of hydrocarbons in urban runoff through an extensive monitoring program. Recent studies of the quality of road runoff include Sakai, Sumiyama, and Tanaka (1996), Wada, Miura, and Muraoka (1996), and Ball, Jenks, and Auborg (1996). These studies help to understand the relationship between road use and pollutant generation. Roof runoff is generally considered to be "clean water" that may be usable for other on-site purposes such as lawn watering and toilet flushing. Cisterns have been used for many centuries to capture roof runoff for subsequent use. Recent studies in Japan confirm that roof runoff is of good quality for toilet flushing and landscaping (Sakakibara 1996). However, Forster's (1996) studies in Germany indicate high copper and zinc concentrations from metal flashings used on the roofs. Boller (1997) also reports high metal concentrations in urban runoff, which may accumulate in soils if infiltration-based BMPs are encouraged. Runoff pollution from industrial land uses differs from that of other diffuse pollution, in that it is derived from more localized activities. This may ease abatement measures somewhat; however, the toxicity of the pollution may be greater than from other urban land uses. Runoff from 10 industrial sites in North Carolina were evaluated for a broad list of conventional plus metal and organic toxicants (Line et al., 1996). Metal concentrations were highest from automobile salvage yard runoff, whereas wood-preserving sites had the highest chromium concentrations.

3.2.1 Research Needs

Two research areas concern the characterization of pollutants associated with urban land uses. Identification of pollutant sources associated with urban land uses is critical to improving source control. Also, knowledge of the physical processes occurring on the urban land surface is important to improving control measures and improving current models of pollutant accumulation and wash-off. In this area, rates of accumulation and entrainment into runoff are especially important in improving current models.

3.3 Physical Transport and Wash-Off Processes

The research area, physical transport and wash-off processes, concerns the physical processes that transport various pollutants from urban land surfaces. Pollutants deposited from the atmosphere or from previous runoff events are suspended in the runoff flow-stream. Transport from the land surface to the receiving water via runoff includes several runoff events or various depositional and resuspension transitions during one event. The processes include transport in storm sewer conduits; and pollutants may react physically, chemically, or biologically during transport. Nowakowska-Blaszczyk and Zakrzewski (1996) studied concentration changes of several pollutants through the urban water cycle in Poland. Comparing concentrations in rain water, runoff from roofing materials, parking lots, city streets, and drainage system conduits, the researchers found that pollutants were introduced into runoff from urban surfaces and storm drainage networks. Resuspension of deposits in pipes, as well as from roofs, demonstrated the wash-off process (Nowakowska-Blaszczyk and Zakrzewski, 1996). Sansalone and Buchberger (1996), Montrejaud-Vignoles, Roger, and Herremas (1996), and Parente and Hulley (1994) studied runoff quality from roadways and found significant increases in solids and COD. However, relationship between storm characteristics and pollutant concentrations was found to be slight, highlighting the lack of process-level knowledge regarding wash-off. Isotope tracing techniques show promise in tracking pollutants through the various runoff transport processes. Isotope tracing techniques use stable isotopes to determine the possible sources. Stable isotopes do not decay, and therefore may be used to trace the origin of the sample. Doll (1997) reports a research program on the Neuse River in North Carolina to trace the origin of nitrogen in the river. In this research, the ratio of ^{15}N to ^{14}N is measured and compared against the atmospheric ratio. This research is still in progress and results are not available, but, it is expected that sources of nitrogen, such as livestock runoff, can be identified. This information will then be used to calibrate a nutrient runoff model.

3.3.1 Research Needs

Research needs related to wash-off and transport processes are important for developing control and management schemes, and for long-term basin modeling analyses. Research should integrate sediment transport studies (Section 7.2.2) and innovative control needs with physical entrainment and wash-off phenomena. Doll (1997) shows that stable isotope tracing is promising for \identification of pollutant sources and how they are transported through urban areas. The focus of wash-off characterization should be the identification of sources by understanding pollutant pathways, and the characteristics of wash-off that may aid in the understanding of control measures.

3.4 Monitoring

Monitoring is composed of three main questions: how to monitor? what to monitor? and where to monitor? Work continues to develop more cost-effective sampling devices, e.g., Dowling and Mar's (1996) culvert composite sampler for obtaining flow-weighted wet weather samples. Fuchs et al. (1996) describe the use of biofilm samplers to indicate heavy metal variations in an urban area. The spatial and temporal variability in rainfall remains an important issue for wet weather management and monitoring. Mikkelsen, Arngjerg-Nielsen, and Harremoes (1996) have established a nationwide rain gauge network in Denmark for monitoring short and intense rain events. The U.S. NEXRAD radar system should prove useful for estimating point rainfalls in urban environments (Seliga and Chen, 1996). Philadelphia has modernized its rain gauge network to improve its database for operating the WWTP during wet weather periods (Day and Nicolo, 1996). Legg, Bannerman, and Panuska (1996) used a rainfall simulator to determine the rainfall-runoff relationship for 20 residential lawns in Madison, Wisconsin. The runoff coefficients for newer lawns were significantly greater than for older lawns. The effect of antecedent soil moisture on infiltration was unclear. Snowmelt may also be an important runoff-based transport mechanism. Based on 7 years of measurements in Norway, Thorolfsson and Brandt (1996) found the volume of snowmelt runoff to be much greater than typically considered in drainage designs, resulting in much more flooding and CSOs in winter than in summer. Measurements in Alaska of snow and snowmelt runoff (Saxton, Siftar, and Fowler, 1996) show that snow is, in general, more contaminated than snowmelt runoff.

3.4.1 Research Needs

Spatial and temporal variability of precipitation accounts for much of the uncertainty in hydrologic analysis. Therefore rainfall data should cover larger areas for longer times. A primary research need in water quality monitoring is the standardization of information (Urbonas, 1994; Strecker, 1994). Measurement techniques that characterize solids must be improved. Capturing a representative solids sample from runoff remains difficult, and settling velocity tests are widely variable and expensive. Efforts should be devoted to these fundamental areas of monitoring.

CHAPTER 4.0

RECEIVING WATER IMPACTS

This chapter covers surface and subsurface receiving water impacts. The research topics identified in Table 2–8 were organized into the outline as shown in Table 4-1. The grouping was necessary because some topics overlap, and others are not emphasized in the literature. Eight topics were combined in subsection 4.1.1; two each in subsections 4.1.2, 4.1.3, 4.1.4, and 4.3.1; and three each in subsections 4.1.5 and 4.2.1.

4.1 General Topics

The goals of controlling urban runoff remain elusive (Heaney and Huber, 1984; Heaney, 1988). Broadening the view of receiving water impacts to incorporate stream geomorphology has progressed significantly. This broader view has been helpful in designing effective urban stream restoration programs. During the past five years, the use of more formalized risk analysis methods to evaluate receiving water impacts has been much discussed (Heaney, 1995; Heaney, Wright, and Samsuhadi, 1996).

Because of its disperse nature, its complex impacts, and its difficult control in an urban setting, urban wet weather flows have attracted the attention of a diverse group of researchers over the past several years. Studies of the impacts on receiving waters have called for an increased understanding of biology and chemistry, transport mechanisms, BMP efficiencies, and regulatory effectiveness. To cost-effectively implement wet weather flow control measures, these disciplines must be integrated, from both a regulatory and a technical standpoint (Andoh, 1994). The National Pollutant Discharge Elimination System has not been effective across the board, and many industries have not met permit obligations (Hoag and Rossmiller, 1994), although many successful applications of innovative wet weather flow quality control technology have been used. Studies of the interactions between BMP installation and receiving water impact have addressed vegetative covers, impervious surfaces, sediment mechanics, storage and recycling devices, riparian strips, habitat, and land uses

(Startin and Lansdown, 1994; Argue, 1994; Fujita, 1994). Maxted and Shaver (1997) suggest that more data on the effectiveness of BMPs must be developed, particularly in going beyond the traditional evaluation of physical treatment characteristics to evaluating the effectiveness of biotic habitat protection. In their limited study, they found that at a high level of development, BMPs did not appear to be effective in protecting biologic diversity downstream; they suggest studying different levels of impervious cover, and different regions. Field et al. (1994) find that non-storm loadings from wet weather flow systems in urban areas are critical and must be addressed if substantial improvements are to be made in receiving water quality.

It is important to separate impact from effect. Impact is really a concept, often defined in the context of a regulatory or analysis framework that includes economic, social, and political considerations as well as scientific and technical issues. Effects can be defined as measurable changes from background or reference conditions. In the analysis of physical, chemical, and biological effects, it is appropriate to emphasize biological measures, which integrate receiving system physics and chemistry into a more general measure such as biological or ecological health, integrity, or quality. Furthermore, an emphasis on effect analysis assists in translating existing information from a descriptive, subjective assessment and qualitative analysis to an objective assessment and quantitative analysis of defined effects.

Land development physically alters the watershed. The magnitude of changes varies with the proportion of developed watersheds. Typical impacts of development, including urbanization, are modification of stream channels, increased erosion and sedimentation in the stream, modified hydrographs, and altered riparian vegetation which change the stream temperature regime. Urbanization of a watershed also changes the release and delivery of chemicals naturally produced in the watershed, resulting in an increase in macro- and micronutrients for some time after disturbance (Vitousek, 1977). After development, the stream usually receives a mix of chemical contaminants produced by human activities. The most severe modifications involve complete containment of stream channels and wholesale modification of all headwaters streams and small tributaries. Under less extreme conditions, the stream course may be modified to accommodate development or the stream may be channelized to provide for flood control purposes. Where natural channels remain in urbanized areas there are usually several reaches where the stream channel is constrained or efforts made to reduce erosion or channel movement by using revetments or rip-rap.

Table 4–1. Research Topics on Receiving Water Impacts (Unprioritized)

Section	*Table 2–8 ID#*	*Research Topic*
4.1.2 Rivers, Lakes, Estuaries & Wetlands	24	Behavior of urban runoff in mixing zones of rivers, lakes, and estuaries
	25	Feasibility of identifying "natural conditions" at the watershed scale
	26	Impact of snowmelt on receiving water quality
	29	Criteria for wet weather quality standards
	33	WWF physical stressors
	35	Indices to determine specific impacts of constituents, e.g., BOD, metals
	38	Large river impacts
	40	Understanding regional differences in receiving waters
4.1.3 Nutrient, Metals, & Toxicant Cycling	28	Fate of nitrogen inputs
	30	Mass balance of urban runoff and receiving water fluxes
4.1.4 Biomonitoring	27	Bioassay procedures for long-term exposures to heavy metal accumulation in benthos
	31	Bioassay procedures for short-term intermittent exposures
4.1.5 Benthic& Sediment Effects	32	Water quality response in water column & sediment
	37	Sediment impacts & control
4.1.6 Land Use & Urbanization	34	Effect of urbanization on stream geomorphology
	36	Small stream impacts
	39	Source water protection
4.2.1 Wet Weather–Groundwater–Vadose Zone Impacts	41	Wet weather-groundwater interactions
	44	Groundwater pollution from highways
	42	Vadose zone impacts
4.3.1 Ecosystem Risk & Human Health Risks	43	Human health risk/ecosystem impact trade-offs
	45	Evaluation of health risks

The impacts of wet weather discharges on aquatic biota have been well documented. Davies (1991) and McHardy, George, and Salanki (1985) have examined the impacts of heavy metals on aquatic organisms. Cook et al. (1983) and Benke et al. (1981) studied stream ecosystems in Georgia, and Pratt, Coler, and Godfrey (1981) compared benthic population trends along urban and nonurban areas of the Green River in Massachusetts. General findings included change in benthic community dynamics with the amount of urbanization and identification of urban runoff as the cause of community disruption. Although these studies point to wet weather discharges as an impact agent, few studies have examined direct cause and effect relationships of urban runoff for receiving water aquatic organisms (Heaney and Huber, 1984). Further, the general conclusion of the extensive work on urbanized and unurbanized streams in Washington State streams was that hydrologic changes (including the associated sediment release) were more important factors than chemical contaminants in determining overall stream health (Pedersen, 1981; Richey, 1982; Bissonnette, 1985) and fish populations (Scott, 1982; Steward, 1983). These hydrologic changes are particularly important in small streams down-gradient from hilly terrain undergoing significant increases in impervious surface because of development (Roesner, 1997a,b). According to Roesner, the effect of urbanization on these watersheds can result in a 6- to 12-fold increase in peak flow rate, with concurrent adverse changes in erosion, flooding, and water quality characteristics downstream. Figure 4-1 summarizes the multifaceted impacts of urban runoff on wetland receiving waters.

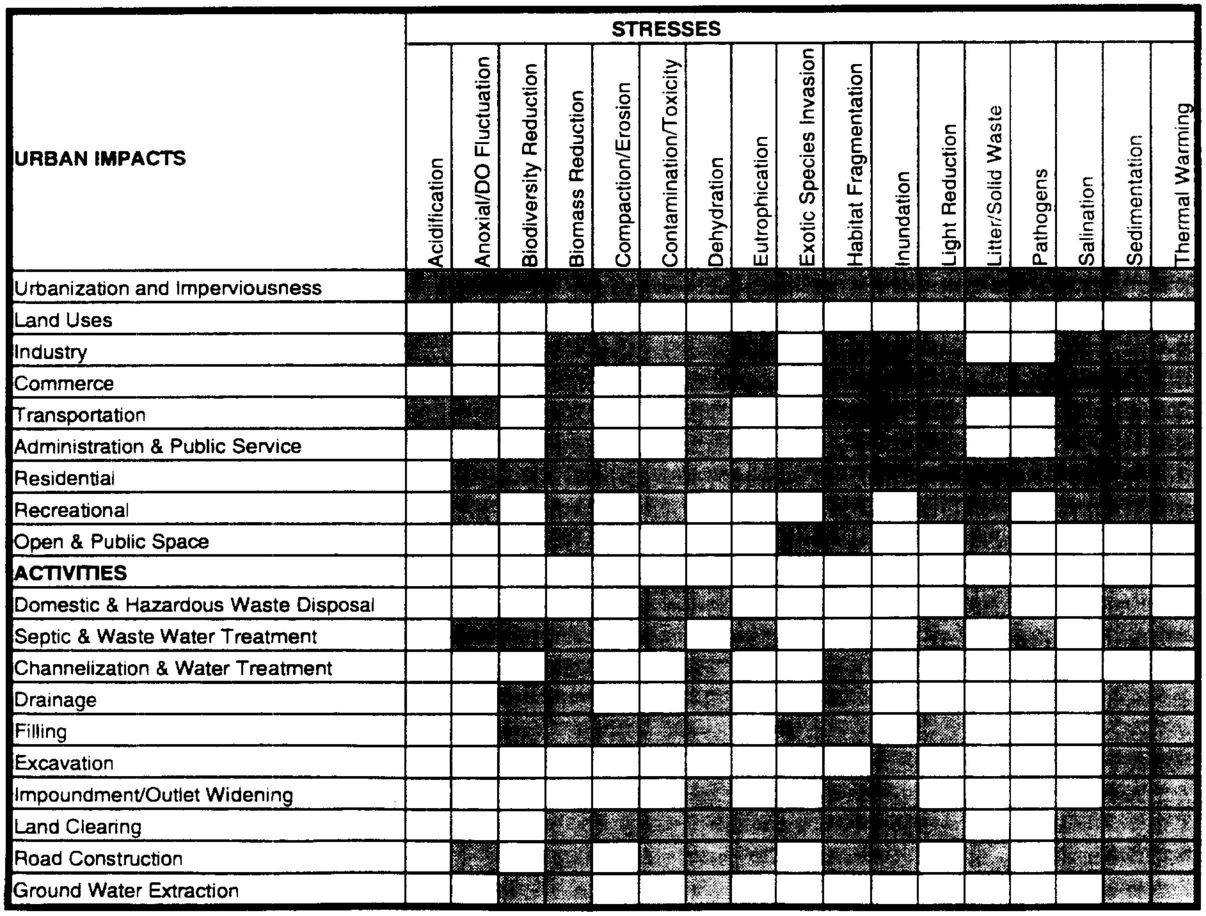

Figure 4–1. Impacts and Stresses on Wetlands Caused by Urbanization (Hicks and Larson, 1996)

Recent state-of-the art reviews include INTERURBA, a 1991 Engineering Foundation conference that addressed receiving system impact (Herricks, 1995) and a 1996 Engineering Foundation conference that addressed receiving water impacts (Roesner, 1997b).

Pitt et al. (1997) list the following categories of receiving water impacts:

- Sedimentation damage in stormwater conveyance systems and in receiving waters.
- Nuisance algae growths from nutrient discharges into quiescent waters.
- Inedible fish and undrinkable water caused by toxic pollutant discharges.
- Shifts to less sensitive aquatic organisms caused by contaminated sediments and destroyed habitat.
- Property damage from increased drainage system failures.
- Swimming beach closures from pathogenic microorganisms.
- Water quality violations, especially for bacteria.

The Center for Watershed Protection used 26 wet weather flow indicators to assess receiving water conditions (Claytor 1996; Claytor and Brown 1996). These 26 indicators were aggregated into six categories: water quality, physical/hydrological, biological, social, programmatic, and site.

US EPA's latest national water quality inventory (*Water Environment & Technology*, 1996) indicated only a slight improvement in the attainment of beneficial uses in the nation's waters. Agricultural runoff was the most important source of contaminated waters entering the nation's rivers and streams, while urban runoff ranked fourth. The latest US EPA National Water Quality Inventory indicated that problems in lakes were mostly caused by agricultural runoff, while urban runoff ranked third (*Water Environment and Technology*, 1996). These sources resulted in bacteriological growth, siltation, and excess nutrients. The latest US EPA National Water Quality Inventory indicated that urban runoff was the leading source of problems in estuaries, mainly as excess nutrients and bacteria (*Water Environment and Technology*, 1996). Continuing research on receiving waters should focus on the fundamental issue of the definition of a receiving water, and how to measure the impacts. The inclusion of groundwater and understanding the linkages between surface and subsurface waters is an important research need. Understanding interactions between the water column and the sediment bed in a stream, river, or lake is an important unresolved issue; the focus should be on what management techniques minimize sediment transport where this has been impacted by urbanization. The impact of urbanization and its increasing imperviousness on stream form and the practical management of these effects is an important question to be explored. Human health and ecosystem health studies should continue including the comparative risk field to better evaluate the significance of these risks. Lastly, impacts to the human economic system should also be explored.

4.1.2 Rivers, Lakes, Estuaries, and Wetlands

Hicks and Larson (1996) found a connection between wetland degradation and the increase of impervious surface from urbanization, and that at about 10% to 20% imperviousness, rapid degradation of wetlands occurs. The authors suggest that the "ecological integrity of wetlands is affected by the amount of impervious surface in the watershed, and that aquatic macroinvertebrate communities do serve as indicators of wetland condition." Heidtke and Tauriananen (1996) describe an aesthetic quality index for the Rouge River. Rauch and Harremoes (1996) contend that the primary indicators of acute urban water pollution are oxygen and ammonia. The authors conducted continuous simulations with a simplified deterministic model and determined that intermittent discharges from the sewer system or the wastewater treatment plant cause acute water pollution. Wada, Miura, and Muraoka (1996) explore the relationships between chemical oxygen demand (COD) and suspended solids (SS) and several hydrologic factors and found that the amount of the last rainfall and the inter-event time influence the concentrations of COD and SS. Shorter inter-event times decrease concentrations of pollutants, possibly because of build-up and wash off. Increases in highway traffic volume, particularly trucks and buses, and the relative emissions from each, also tend to increase concentrations. Yoder and Rankin (1997) describe indices and the biosurvey program developed for the state of Ohio. Livingston (1997) develops an interesting paradox. The author describes the innovative watershed-based pollution control and water management programs initiated in the state of Florida, but then focuses on the continuing degradation of the rapidly growing Tampa Bay area by urban stormwater runoff. The author argues that the complex sources of pollution in the Tampa Bay area require a more holistic approach to solve them, rather than a programmatic or disciplinary one.

4.1.2.1 Research Needs

Improved techniques are needed to assess urban runoff impacts. These would include modeling or analysis of the fate of pollutants or contaminants, considering the episodic nature of urban runoff and the time-related changes that integrate both the physical characteristics of the runoff and receiving system, and the chemical characteristics associated with multiple events and differential receiving storage and transport. Assessment procedures that monitor ecosystem conditions and accurately measure the ecosystem state are also needed. The development of a regulatory structure more appropriate to the episodic nature of urban runoff and to identify indices and indicators specific to urban runoff is also a significant research need.

4.1.3 Nutrient, Metals, and Toxicant Cycling

By means of an extensive literature review, Herrmann and Klaus (1996) trace pathways of water, nitrogen, and phosphorus in the urban hydrologic cycle and developed a budget for each constituent. The authors contend that sustainable systems involve the minimization of waste and the re-use of nutrients. This requires understanding of the entire life cycle of the nutrient within the urban hydrologic cycle. Novotny and Olem (1994) and Chapra (1996) extensively review toxicant conceptual and mathematical models. Chapra (1990) developed a conceptual model of toxicant loading budget for lakes. Decay and diffusive sediment feedback were ignored, however, sorption, volatilization, and sediment resuspension were included; this results in a conservative estimate of the net loss rate. Compounds were mapped in three zones based upon their sorption and volatilization characteristics. The water zone includes substances that sorb weakly and are soluble, and have low removal rates because sedimentation and volatilization are not significant. The air zone includes weak sorbers that are relatively insoluble, but are removed rapidly due to volatilization. The sediment zone includes compounds that sorb strongly and are subject to resuspension. Using a budget approach, Pettersen, Naef, and Broman (1997) determined the concentrations and flux of 12 petroleum aromatic hydrocarbons in settling particulate matter adjacent to a refinery on the Baltic Sea in Sweden. Concentrations and fluxes did not differ significantly from background levels, so either the refinery is an insignificant contributor of PAH loading, or the hydraulic residence time is low. Nizeyimana et al. (1996) used GIS and population data from the U.S. Census Bureau to develop nitrogen loadings to Pennsylvania surface streams from septic systems, developing a nitrogen budget model of these watersheds.

4.1.3.1 Research Needs

Insufficient information is available regarding the cycle of nutrients, metals, and toxicants through the urban hydrologic system. More work must be done similar to that of Herrmann and Klaus (1996) in tracing these pathways. Possible models of the cycle can be used as source management and control tools.

4.1.4 Biomonitoring and Bioassessments

Barbour (1997) advocates the use of bioassessments because they reflect cumulative impacts that might not be detected otherwise. The author summarizes state-by-state development of bioassessment approaches and the subsequent regional perspective that lends itself to watershed management. Herricks et al. (1997) assessed short-term exposure test systems, and found that, to be adequate, they must meet the following requirements:

- Fast response time with a time scale for the response matching the time scale for the exposure.
- Capacity to respond to changing conditions (e.g., track changing toxicity).
- Response to the effects of a single stressor, as well as integration of the impact of multiple physical, chemical, and biological stressors.

Peterson et al. (1996) argue that the lack of adequate toxicity testing for photosynthetic organisms inhibits regulation of toxics such as pesticides and heavy metals because they are relatively nonbiodegradable. The authors found that toxicity for plants may be several orders of magnitude more sensitive than the typical aquatic invertebrates tested. They argue that the inclusion of site-specific toxicity conditions and ecologically relevant organisms is needed to achieve the most appropriate testing at minimal cost. Maltby et al. (1995) conducted toxicity tests on stream water and roadway discharge water contaminated with hydrocarbons, carbon, and zinc on the amphipod *Gammarus pulex*. Significant short-term toxicity was found. An example of a long term in situ study of the response of an organism to urban runoff can be found in Crukilton et al. (1997). The authors describe short- and long-term toxicity testing of several macroinvertebrate species, including *Ceriodaphnia dubia* and *Pimephales promelas*. Crukilton et al. (1997) found that short-term (24 to 48 hour) adverse impacts were typically not noticed within the macroinvertebrate community, but longer term impacts (7 to 10 days) were. Nyholm (1996) discusses the interaction of biodegradable toxins with nutrients and the synergistic effect of toxics. The author suggests that "degradable toxicity is the toxicity of the fresh effluent less its persistent toxicity."

4.1.4.1 Research Needs

The development and acceptance of testing procedures is needed to effectively analyze the impact of both urban runoff and receiving systems on toxic response for single events, multiple events, and over time scales appropriate to changing watershed conditions.

4.1.5 Benthic and Sediment Impacts

Brick and Moore (1996) conducted hourly samplings of trace metals in an oxic, alkaline river with high levels of metals stored in bed sediments. Results indicate that most major elements and ions and alkalinity show no diurnal variation; however, particulate metal concentrations show substantial increases resulting from increases in suspended material at night. Scoullos, Dassenakis, and Zeri (1996) studied the Louros estuary in Greece, which has a very narrow mixing zone and, particularly in summer, exhibits a pronounced saline water wedge on the bottom. The authors found that particulate metals desorbed from riverine sediments and remained within the saline wedge, which acts as a sink. Spliethoff and Hemond (1996) reconstruct history with sediment core samples of the Aberjona River, north of Boston, finding direct correlations between concentrations of heavy metals and depth as key industries arrived in the watershed and left the area. Skipworth, Tait, and Saul (1996) describe a bench scale test to simulate the erosion process of solid deposits in sewers in the United Kingdom. The authors found that the erosion rate depended upon the initial rate of change of flow rate and the final flow rate during the experiment, and not on any steady state variable. Morrisey, Roper, and Williamson (1997) contend that the premise that urban stormwater outfalls cause observed chronic toxicity in fauna living in sediments to be mainly circumstantial. The authors conducted a detailed biological and chemical analysis of iron, lead, and zinc in sediment samples and found that sediment texture and the concentration of lead were main factors in influencing the faunal amounts; with pH and iron concentrations in pore water causing an effect in some cases. Di Toro et al. (1991) developed a model of sediment oxygen demand (SOD) of the anaerobic zone of sediments of freshwater lakes and streams. The model includes the flux of methane and ammonia from the sediment to the water above, and the methane and nitrogen gas fluxes in bubbles from the sediment to the surface.

4.1.5.1 Research Needs

More research is needed in identifying interactions between the sediment and receiving waters, both in sewers and in receiving waters. Effort should be concentrated on sediment impacts in the water column.

4.1.6 Land Use, Urbanization, and Geomorphology

Ferguson (1997) tracks alluvial stream response to urbanization in the Piedmont area of Georgia. According to the author, the process of urbanization can be separated into the following cycles: clearing and cultivation, then reclearing and urbanization. Examples of stream aggradation, incision, and possible reconstruction are given. Ferguson found that urbanization reduces the low flows in a stream, and in times of rain, makes the intensity and frequency of the peaks higher;

which is the worst of all hydrologic regimes, particularly for wildlife dependent upon stable stream hydrology. The effect on the stream is to increase the erosive power, and to "remold the entire riparian corridor in a brown flurry of erosion, sediment, and habitat loss." MacCrae (1997) found that, in an urban stream in Ontario, a channel adjusting to urbanization increased almost three times its original cross-sectional area because of the increased peak flow, and boundary shear stress along the streambank. The author argues that mitigation should also include a no net change of the transverse component of shear stress along the channel perimeter based upon an index method developed by the author. Sovern and Washington (1997) argue that returning to "natural" hydrologic conditions is impractical and cost prohibitive. These authors suggest that a "new urban stream" can be constructed by stabilizing the streambed, confining aquatic habitat microchannels, revegetating channel banks, reducing sediment discharge in the watershed (reduce channel width), and vegetating the channel bed. Case study examples are given. Harris, Saunders, and Lewis (1997) suggest that urban rivers in the arid west tend to be much more flashy than their counterparts in the east, and urbanization only increases this trend. The impact of man's activities (such as water diversions for agriculture) have a much more direct link to water quality in western streams. Less vegetation implies less buffering from solar radiation and temperature swings. Schueler and Claytor (1997) explore the potential of using the amount of impervious cover within a watershed as an index of stream health. This was based upon correlations between impervious cover and factors affecting stream quality such as "stream temperature, fish diversity, instream habitat, macroinvertebrate diversity, nutrient loading, channel stability, changes in stormwater flow peaks and frequency, spawning success, and bacterial contamination."

4.1.6.1 Research Needs

The ongoing development and evaluation of techniques to integrate urban runoff analysis in overall watershed management, particularly the impacts of urbanization on watersheds, is needed.

4.2 Groundwater and Vadose Zone

4.2.1 Stormwater–Groundwater–Vadose Zone Impacts

Pitt et al. (1996) summarize the potential contributions of urbanization to groundwater pollution. Groundwater flow may be reduced by urbanization; however, the remaining flow that percolates tends to be contaminated stormwater runoff. The authors describe the various urban wet weather flow pollutants, such as pathogenic microorganisms, toxicants, nutrients, pesticides, organic compounds, heavy metals, inorganic compounds, and salts and various treatment techniques for them. The authors advocate the use of stormwater infiltration to make up for the lack of recharge due to impervious surface buildup from urbanization. However, they caution that it should be restricted to less polluted areas, such as residential areas, and that the groundwater should be monitored. Mikkelsen et al. (1996a) and Mikkelsen, Jacobsen, and Boller (1996b) found that heavy metals and PAHs present little groundwater contamination threat, if surface infiltration systems are used. However, the more mobile pesticides and salts can be a problem. Squillace et al. (1996) and Zogorski et al. (1996) describe the potential of wet weather flow as a source of groundwater methyl tert-butyl ether (MTBE) contamination. Mull (1996) examines the connection between leaky sewers and surficial aquifers, which, particularly in industrial sites, can cause significant contamination of groundwater. Mull found significant increases in chemical oxygen demand (COD), ammonium, nitrate, chlorinated hydrocarbons, and pathogenic bacteria. Traffic areas are the third most important source of groundwater contamination in Germany (after abandoned industrial sites and leaky sewers). Trauth and Xanthopoulos (1996) developed a pilot groundwater monitoring network in Karlsruhe, Germany, finding oxygen depletion and increases in calcium, sulfate, hexazinone, potassium, boron, ethylene diaminetetraacetic acid (EDTA), and trichlorethene with urbanization. They found that the relative concentration of these pollutants increased by about 30 to 40% over 20 years. Gremillion et al. (1995) used isotope tracing methods in several central Florida watersheds and determined that rivers received about 75% of their flow from the surficial aquifer. This phenomenon may be caused by to the unique Florida limestone stratigraphy, however, the possibility of a tight coupling between surface and groundwaters in some regions is a research need to be explored.

4.3 Human Health

4.3.1 Human Health Risks and Ecosystem Impact Trade-offs

O'Shea and Field (1993) summarize wet weather flow quality and its relationship to potential for human disease, tracking pathogenic microorganisms from their sources such as driveways, roof runoff, sidewalks, paved parking areas, and paved roadways. The authors investigate receptor pathways such as agricultural use and recreational use, including bathing, and suggest that there is a significant potential for diseases to occur. Typical indicators such as *Escherichia coli* are not very useful. The authors also investigate disinfection technologies for wet weather runoff. They conclude that, due to the relatively high risk involved, if US EPA's policy continues to emphasize re-use of stormwater, disinfection requirements and bacteriological criteria must be reevaluated. Swimmers in front of wet weather flow outfalls at Santa Monica Bay, California, were 50% more likely to develop a variety of symptoms than those who swam 400 m from the same outfall (*Water Environment and Technology*, 1996). Human fecal waste was present in the stormwater collection systems. Eggleston, Keith, and DePasquale (1996) describe closures of the

Boston area's Tenean Beach because the limit for fecal coliform or enterococcus had been exceeded. Rempel et al. (1996) summarize the work of assessment of CSO impacts to the Red River near Winnipeg, Manitoba. The focus of their effort was coliform bacteria, and minimizing the public health risk, as the Red River is used extensively for recreational purposes. Reynolds, Gerba, and Pepper (1995) found human enteric viruses (a class of viruses associated with sewage pollution) adjacent to marine outfalls. Lack of an inexpensive and reliable testing method prevents these viruses from being routinely monitored in the United States. The authors compared traditional cell culture methods with direct reverse transcriptase-polymerase chain reaction amplification and successfully detected several enteric viruses, including polio virus.

4.3.1.1 Research Needs

Effective risk assessment and management techniques for urban runoff to assure protection of human health and provide a means of balancing human and ecological considerations is needed. A particular need is a better indicator of the relative harm wet weather flows pose to human health because of combined sewer overflows. Current indicator methods cannot sufficiently distinguish between harmful impacts and the possible presence of contaminants.

CHAPTER 5.0

MANAGEMENT

This chapter focuses on management tools of the urban wet weather flow management professional. Significant advances have been made in this area, particularly in terms of computer modeling and links between models and spatial and geographical databases. These areas are covered, as well as organizational structure, decision support systems, and watershed management linkages. The research topics covered in this chapter are outlined in Table 5–1. The more significant research needs identified in Table 2–8 are covered with single-page summaries of current work. Some areas were combined when research literature on the topic was not available. Some topics were added to fully cover the broader subject matter involved.

5.1 Organizational Structure

Jones, Clary, and Brown (1998) describe existing models of stormwater management institutions, such as watershed-based committees and institutions, stormwater utilities, local agencies, and private utilities. For each stormwater management institution, the authors identify its integration, flexibility, efficiency, effectiveness, and responsiveness. According to Jones, Clary, and Brown (1998) the key issues future institutions will have to address are: financing, staffing, administrative authority, clear regulations and standards, legal challenges, regional solutions, risk management, maintenance, monitoring and evaluation, non-structural source control strategies, retrofitting, technology transfer, practice guidance, and public involvement. A particular need is evaluation of the effectiveness of different models of management institutions.

Weather Flow Collection/Control/Treatment Systems for Newly Urbanizing Areas. Draft Rep. to US EPA. Cincinnati, OH: , National Risk Management Research Laboratory.

5.2 Models and Decision Support Systems

The goal of this section is to briefly review the existing models used in urban stormwater management, including noting critical deficiencies and strengths, then to evaluate technological advances in geographic information systems (GIS), decision support systems (DSS), real-time control, and artificial intelligence techniques and how they might assist in modeling urban stormwater. Following this overview, analyses of micro subjects within this field are presented. Much of this overview is from Heaney et al. (1998).

Within the United States, users continue to rely on existing urban stormwater models. Commonly used models are listed in Table 5–2 (Huber, 1997). TenBroek and Brink (1996) compared several continuous stormwater simulation models including STORM and SWMM. Donigian, Huber, and Barnwell (1996) compared the attributes of six urban and seven non-urban wet weather flow models. Mercer, Cave, and Kaunelis (1996) summarized the use of a variety of stormwater and receiving water models—including SWMM, WASP, the Watershed Management Model, and P8—as part of the Rouge Project in the Detroit area. Donahue, Breen, and Kublak (1996) summarized the use of modeling and evaluation tools to select a cost-effective CSO control plan within a watershed perspective. Shoemaker et al. (1996) compare the attributes of six stormwater models. Swarner and Thompson (1996) present the results of extensive measurements and modeling of SSO problems in Seattle, Washington. The results of an extensive SSO evaluation using XP SWMM for the Miami sewer system are described by Walch et al. (1996). Kachalsky and DeSantis (1996) describe modeling and evaluation methods for optimizing CSO control in New York City. Herrmann and Klaus (1996) developed general water and nutrient budgets for urban water systems which included stormwater.

A variety of international urban stormwater models have been released in recent years. Neylon et al. (1996) describe the first version of the HydroWorks stormwater quality management model being developed by Wallingford Software in the United Kingdom. Foller, Frentzel-Beyme, and Wittenberg (1996) show how MOUSE can be used to optimize a combined sewer system in East Germany. Dempsey, Eadon, and Morris (1996) describe SIMPOL, a simplified urban pollution modeling tool developed as part of the U.K. Urban Pollution Management Research Program. SIMPOL models the stormwater system as series of tanks. Bente and Schilling (1996) propose an object-oriented approach for an urban hydrologic simulation system. Davies (1996) discusses the importance of the appropriate blend of modeling and data for SSO evaluations including the advantages and disadvantages of SWMM and HydroWorks. An extensive evaluation of the Sydney, Australia, SSO problem was done with MOUSENAM and SEEKER to simulate and optimize control options (Hayes, 1996). Ji, Vitasovic, and Zhou (1996) describe a fast model for evaluating the hydraulics of sewers and open channels. This work shows the implicit solution scheme in the SUPERLINK model to be much faster than EXTRAN's explicit solution. Gent, Crabtree, and Ashley (1996) surveyed models that can simulate solids deposition and resuspension in sewers. They describe MOUSETRAP and HydroWorks QM that supersede WALLRUS and MOSQITO. Jack, Petrie, and Ashley (1996) describe several models for characterizing sewer sediments. They briefly describe the WALLRUS/HydroWorks PM hydraulics model, the STOAT wastewater treatment performance model, and the MOSQITO, HydroWorks-DM, and MOUSETRAP sewer flow water quality models. Imbe, Ohta, and Takano (1996) used a water budget to establish the impact of urbanization on the hydrologic cycle of a new development near Tokyo, Japan. This development focuses on reduction of hydrologic impacts by encouraging infiltration systems and storing rainwater. Mitchell, Mein, and McMahon (1996) describe a water budget approach to integrated water management in Australia. Budgeting is done at the individual parcel, neighborhood, and wider catchment scale. A current gap in urban stormwater modeling is the inability to properly incorporate the impact of rainfall on frozen surfaces in urban areas. Thorolfsson and Brandt (1996) describe a Norwegian experience in which "worst case" conditions occur during winter. They recommend development of new mathematical models to handle this special case.

Real-time control (RTC) systems will be an integral part of future urban stormwater decision support systems. Schilling (1996) summarizes the state of the practice regarding the use of RTC including applications around the world. Nelen and Broks (1996) summarize use of RTC in eight Netherlands cities. Lavellee, Marcoux, and Bonin (1996) report 30% to 60% reduction in the volume and frequency of CSOs in Quebec City using RTC. Rauch and Harremoes (1996a, b) describe an RTC system that includes optimization using genetic algorithms. Schmitt (1996) evaluates improvements in two German CS systems from using RTC. Volume reductions were 30% in one case and 9% in the other. Sirkin (1996) cautions that RTC should only be used after determining some necessary, preliminary information for the stormwater system. Kjaer, Wilson, and Mark (1996) describe using MOUSE ONLINE, an extension of the Danish Hydraulic Institutes's MOUSE model, for RTC.

Table 5–1. Research Topics on Urban Wet Weather Flow Management (Unprioritized)

Outline Topic	*Table 2–8 ID#*	*Research Topic*
5.1 Organizational Structure		
5.2 Models and Decision Support Systems	66	Criteria for model calibration/verification
5.2.2 Enhancements in Existing Models		
5.2.2.1 GUI/Object Oriented Programming		
5.2.2.2 Improvements in the Analysis of Rainfall Input Data		
5.2.2.3 Improved Parameter Estimation Techniques	58	Develop more robust parameter estimation methods
5.2.2.4 Data Centered Approaches to Enhancing Stormwater Modeling	50	Analyze existing NURP, USGS, NPDES, and other data
	54	Combine available databases into a single database
5.2.2.4.1 Real Time Control	61	Add real-time control to all aspects of SWMM
5.2.2.4.2 Stochastic Simulation	64	Methods for estimating the probability distributions of dry and wet weather flows
	51	Probabilistic performance criteria for wet weather controls
5.2.2.4.3 Neural Networks		
5.2.2.4.4 Calibration of Transport Models Using Improved Databases	67	Calibration of transport models using improved databases
5.2.2.5 Linking Surface/Subsurface Phenomena	48	Linkage of surface and subsurface phenomena
5.2.2.6 Linking with Atmospheric Models		
5.2.2.7 Solids Handling Capability/Sewer System Modeling	46	Add solids handling to simulation models
5.2.3 Development of Integrated Decision Support Systems	47	Develop user friendly integrated decision support systems
	55	Develop integrated decision support systems for overall watershed evaluations
	68	Decision support systems with real-time control and all aspects of urban water
5.2.2.1 Integrate GIS to Refine Spatial Analysis Capabilities	52	Integrate GIS to refine spatial analysis capabilities
5.2.2.2 Interface Simulation and Optimization Models	49	Interface simulation and optimization models
5.2.2.3 Development of Integrated DSS for Overall Watershed	56	Watershed ecosystem model
5.2.2.3.1 Watershed Models		
5.2.2.3.2 Ecosystem Models	65	Riparian forest management
5.2.2.4 Develop Risk Management Methodologies	53	Develop risk management methodologies
5.3 Watershed Management Linkages		
5.3.1 Watershed Assessment Methodology	59	Develop a watershed assessment methodology
	60	Case studies of integrated stormwater management
5.3.2 Development of Long-Term Watershed Case Studies		
5.3.3 Urban Research Catchment Network	57	Create and maintain an urban wet weather flow information repository
	62	Establish a network of urban research catchments
5.3.4 Development of Watershed-Based Water Quality Standards	63	Watershed-based water quality standards

MacArthur et al. (1996) describe a computer-based system for conjunctive operation of the WWTP and stormwater controls in Monroe County in upstate New York, which includes the city of Rochester. Cantrell et al. (1996) summarize an application of HydroWorks developed specifically to use with an existing RTC system in Lima, Ohio, an early RTC application in the United States. Miles, Moore, and Tarker (1996) describe methods and models for evaluating I/I problems associated with SSOs.

Models and decision support systems are incorporating GIS. US EPA recently released a package called BASINS, which includes a CD for each of the EPA regions (US EPA, 1996), BASINS links nonpoint models including HSPF and QUAL2E using ArcView. An AWRA conference proceedings contains several useful articles on evaluating urban wet weather flow management problems with GIS (Hallam et al., 1996). Shamsi and Fletcher (1996) describe how ArcView can be used for a variety of GIS-related links to urban wet weather flow models and data management including AM/FM systems. Haubner and Joeres (1996) describe using GIS as a preprocessor for the Source Loading and Management Model (SLAMM) to estimate pollutant loads in urban areas, including a case study of Plymouth, Minnesota.

Although the model is important, much of the focus has shifted to the related needs of database management, developing GISs, and a sophisticated user-friendly interface, all combined in a package called a decision support systems (DSS). These necessary components of a DSS are described in Figure 5–1 (Dunn et al., 1996). Reitsma (1996) defines DSSs as ".. computer-based systems which integrate state information, dynamic or process information and plan evaluation tools into a single software implementation." A DSS is a system that assists in bridging the gap between data and models to solve difficult partially undefined problems. Most of the current work in DSS in the water field has been in the simulation of complex reservoir operations, because of the financial impact of hydropower. A thorough description of this area can be found in Jamieson and Fedra (1996a, b) and Fedra and Jamieson (1996). This series of articles describes the conceptual design, planning capability, and example application of the Water Ware DSS, a complex river basin DSS that combines a "GIS, a geo-referenced database, groundwater flow, surface water flow, hydrologic processes, demand forecasting, and water-resources planning." Dunn et al. (1996) describe the hydrologic processes used within the DSS. The DSS mimics the hydrologic system in terms of its organization, as can be seen in Figure 5–2.

Table 5–2. A Variety of Urban Hydrologic, Hydraulic, and Water Quality Models (Huber, 1997)

Model	Agency/Source	Primarily Hydrology/ Hydraulics	Continuous Simulation or Storm Event	Complete Dynamic Flow Routing?	Quality Simulation?	Graphical User Interface

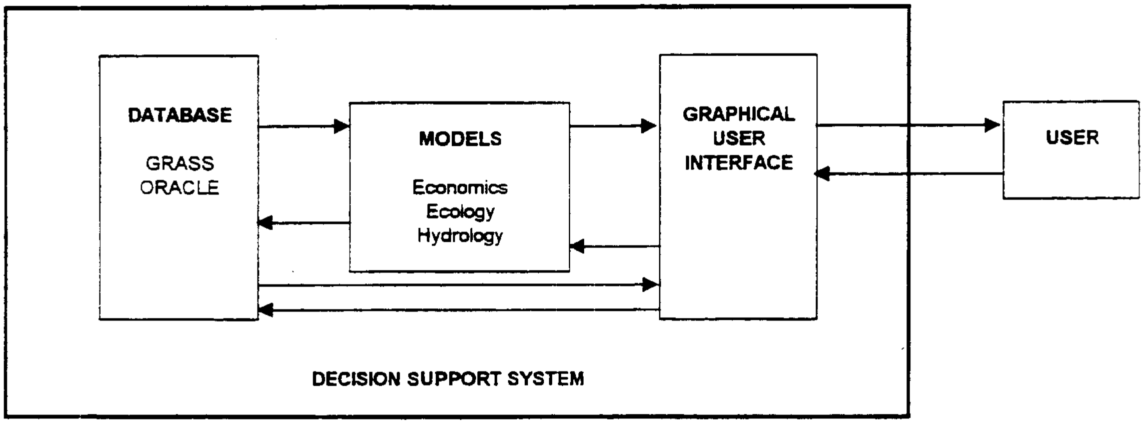

Figure 5–1. The Components of the NELUP DSS (Dunn et al., 1996)

DSSs are also used to enhance input of information. Griffin, Bauwens, and Ahmad (1994) describe an "intelligent assistant" which assists in training professionals in the interdisciplinary field of urban drainage modeling by providing definitions (in several languages), data on coefficients and parameters, and a graphical standard front end to several existing models. Illustrating the state of the art are an example of an input screen from this DSS (Figure 5–3) and an example of output from a DSS, viewed in conjunction with map information (Figure 5–4). A significant need is the application of this technology to the urban wet weather flow management field.

In summary, the area of models and DSS is evolving rapidly. Significant effort is still needed in developing graphical user interfaces (GUIs) and restructuring older model codes. This will enable them to be linked with other appropriate optimization and simulation software, GIS, DSS, and external databases. The complex, unstructured nature of the urban stormwater management problem makes it an interesting case for DSS. A particular subset of DSS for urban stormwater models is the issue of RTC. These systems are typically operated in a dynamic environment which uses real-time data in conjunction with optimization and simulation modules to maximize the volumes intercepted, and thence minimize the volume of CSO spills to the environment, in what is termed an integrated predictive control approach (Lavellee, Marcoux, and Bonin, 1996). Such systems' intensive use of data and the dynamic environment in which they operate demand DSS. An example of the organization of such an RTC/DSS system can be found in Figure 5–5.

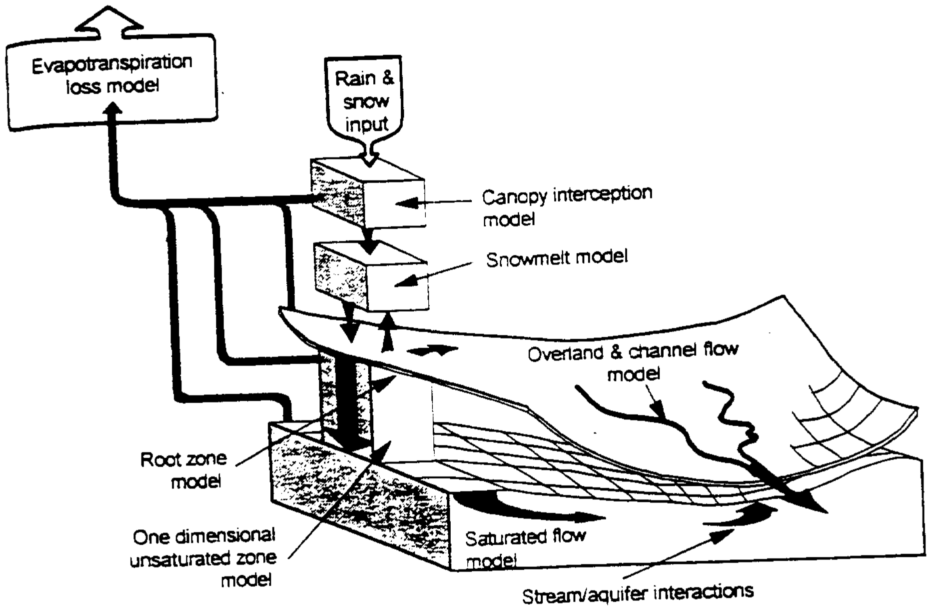

Figure 5–2. Schematic Diagram of SHETRAN Flow Model (Dunn et al., 1996)

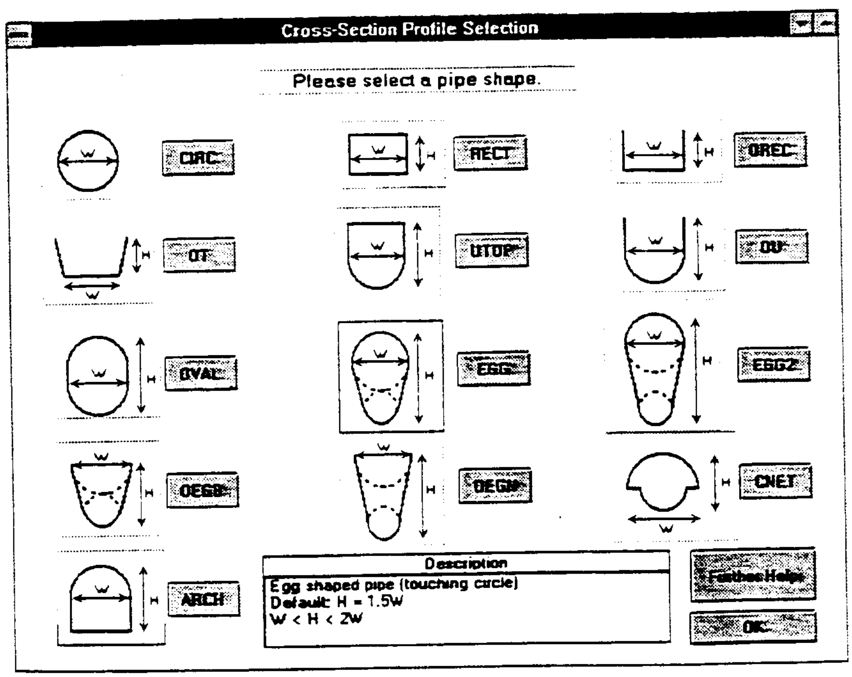

Figure 5–3. Creating an Input File, Selecting Cross-Section Profiles (Griffin, Bauwens, and Ahmad, 1994)

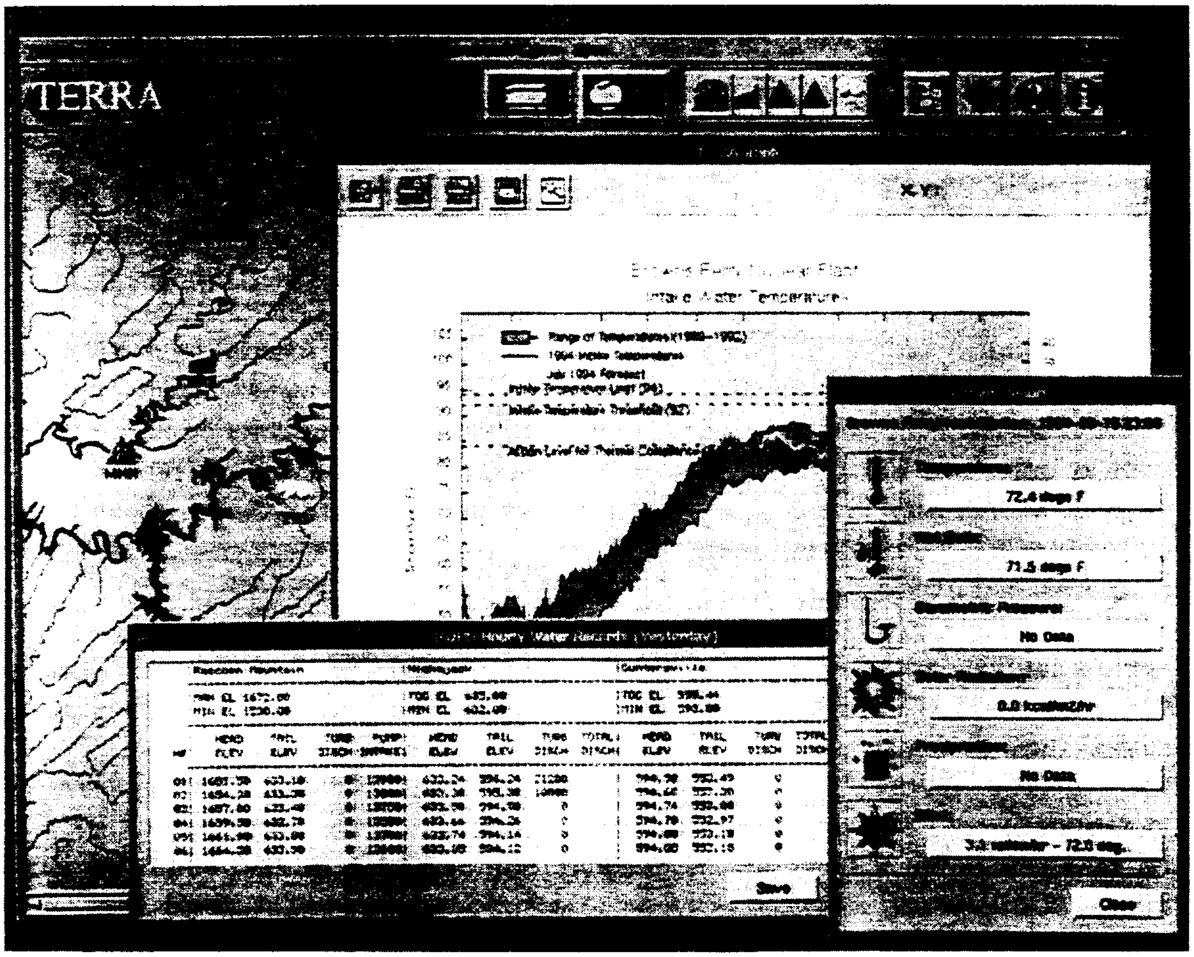

Figure 5–4. TVA Environment and River Resource Aid (TERRA) (Reitsma, 1996)

Lavellee, Marcoux, and Bonin (1996) summarize a feasibility study conducted before implementing the RTC system. The authors outline the major steps in the design strategy:

- Characterization of the existing network;
- Diagnosis of the existing CSO problem, usually through modeling and calibration;
- Design of a CSO control strategy (long-term plan); and
- Tests of the performance of the control strategy.

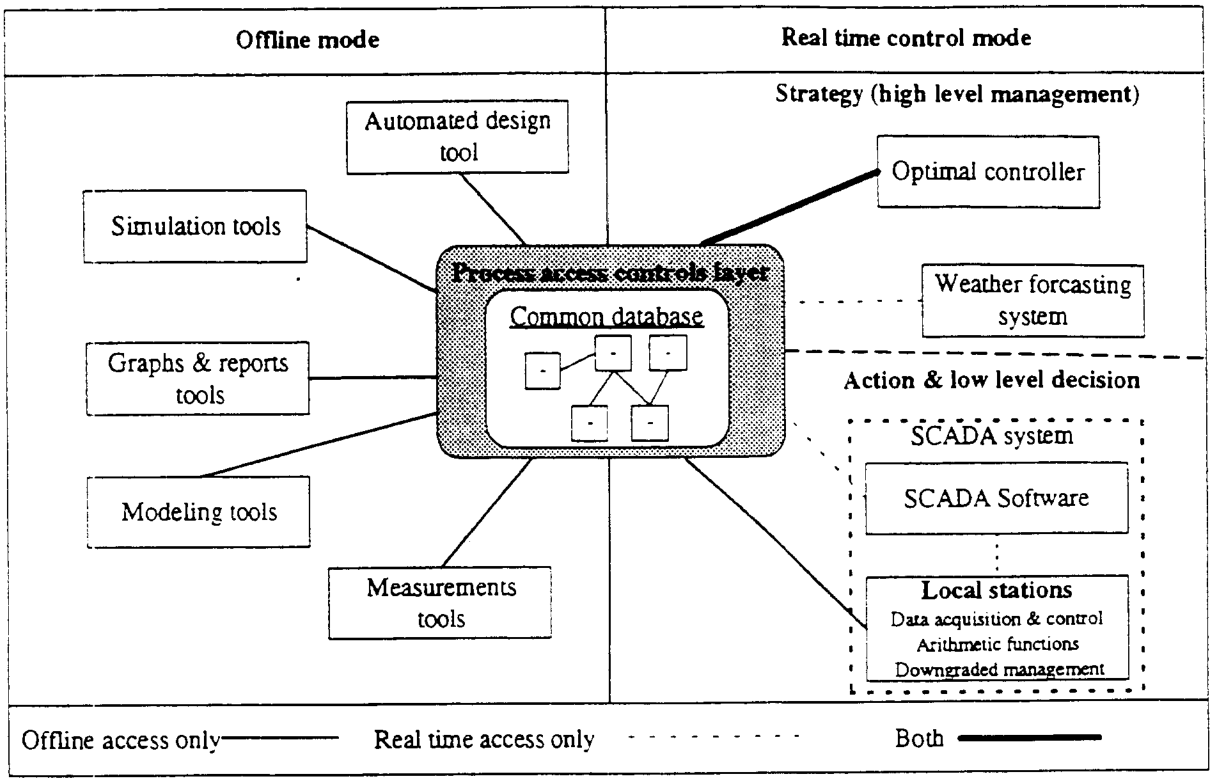

Figure 5–5. CSO Control Strategy Design Tools (Lavellee, Marcoux, and Bonin, 1996)

The authors describe the process and the design of the RTC system, including the configuration of local stations (sensors, flow regulators, data loggers, and communications devices), supervisory control and data acquisition system (SCADA), rainfall forecasting system, and optimal control system. The optimal control system must integrate the entire system and data inherent within each component. Integrating these data into optimized decision strategies that minimize CSOs requires decision-support tools. Several specific topics and research recommendations follow.

5.2.2 Enhancements in Existing Models

5.2.2.1 Graphical User Interface/Object Oriented Programming

For an overview of the object paradigm and its effect on modeling and programming, see *Environment International* (1995). Bente and Schilling (1996) offer an object-oriented software concept for development of hydrologic models. The advantage of using this system is the standardization of structural components, so they can be individually replaced or enhanced, and new components easily added. This concept usually includes, by definition, a graphical user interface (GUI). Shamsi (1997) presents an overview of currently available GUIs for the SWMM model. The GUIs are compared based on common tasks associated with SWMM modeling and rated in tabular form. Huber (1997) compares many of these same GUIs along with the European models. Ahmed (1994) develops an object-oriented stormwater planning model to allow the evaluation of BMPs in new developments. Such a tool is desirable in development planning because it allows the user total flexibility in choosing an appropriate BMP, its size, locations, etc. Djokik and Maidment (1991) developed an object-oriented urban stormwater model within the Arc Info GIS system, using the rational method for hydrologic analysis. The model uses the network of storm sewers to route flows, and generated drainage basins based upon triangular irregular networks (TIN).

5.2.2.1.1 Research Needs

Huber (1995) emphasizes the need for parallel advances in the fundamental modeling engine, particularly in the areas of model conceptualization, numerical techniques, databases, and integration with ancillary software such as GIS. A possible combination of the two points is that object-oriented software development may allow better modeling abstract objects more closely mimicking the behavior of physical objects. However, the continuity of this development with previous SWMM work can only be maintained by an extensive code rewriting of the model engine which is a significant expense. An alternate method may be to restructure only parts of the code, particularly the user interface and input/output modules to enable linkage with other programs and develop GUIs as an interim measure.

5.2.2.2 Improvements in the Analysis of Rainfall Input Data

Analysis of rainfall input data is a common task prior to stormwater modeling. Selection of a design storm from the data has been controversial. Zhu and Schilling (1996) suggest that design storm methods have the advantage of compressing data, which becomes particularly important for large stormwater systems. Essentially, each system must be modeled to determine what level or frequency of event results in surcharges or flooding of the system. Another technique is filtering. Zhu and Schilling (1996) suggest that the practice of compressing rainfall data to small increments of about 1 to 60 minutes, common in stormwater modeling, leads to filtering errors, which can underestimate peak flows. The model amplifies this error when predicting overflow volumes. The authors developed a method for estimating this error.

A new technology attracting much research effort is the use of radar to supplement and give a better spatial definition of rainfall gages. Faures et al. (1995) determined that, in a small, 4.4-hectare semiarid catchment, the largest source of variability was spatial. The authors point out that modeling at this scale using a single rain gage will yield significant errors due to spatial variability. Radar rainfall techniques help overcome this disadvantage. Auchet and Faure (1996) provide an overview of a technique of calibrating radar rainfall data to measured rainfall. Einfalt, Gustafsson, and Lumley (1996) find significant differences between measured rainfall amounts and those predicted using radar rainfall data. Lumley et al. (1996) compare modeled flow predictions using radar rainfall data and measured rainfall data.

Cowpertwait et al. (1996) applied the Neyman–Scott rectangular pulses rainfall model to many sites throughout the United Kingdom; the model was then regionalized by regression analysis of input parameters. A disaggregation technique was performed on the hourly rainfall series to allow output on a five minute level. The authors determined that using the regional model for ungaged sites yielded reasonable results.

5.2.2.2.1 Research Needs

More work should be done on calibration and processing of radar rainfall techniques to supplement rain gages. Is it possible, for a given area, to determine the optimum number of gages necessary for calibration? Better integration of this research with traditional stochastic hydrology research should be done as well.

5.2.2.3 Improved Parameter Estimation Techniques

Many parameters commonly used in hydraulic modeling are difficult to estimate or measure. Cowpertwait et al. (1996) developed a technique for reproducing statistical properties of hourly and daily rainfall series for different catchments in the United Kingdom with limited data. The reproduced series are created by analysis of regional models, probability analysis of available data, and regression analysis. Parameters commonly required by models can then be selected from the regional ranges based upon spatial criteria and professional judgement. Kenner et al. (1996) used a combination of models and geographic rainfall distributions to determine hydrologic coefficients with the least amount of error. Lee, Hoshi, and Masukura (1992) developed a set of dimensionless discrete runoff hydrographs for determining flow from a plane rectangular catchment. An advantage of this approach is that it is more suitable for use in urban watersheds, as the time scale varies with the intensity of runoff. King (1992) presents a literature review and database of methods for determining infiltration. The author found that many urban runoff models use empirical methods because researchers lack complete information necessary for physically based methods.

Kusuda and Arao (1996) determined the energy loss coefficients at drop structures (non-surcharged manholes), and Sakakibara, Tanaka, and Imaida (1996) developed energy loss coefficients for surcharged manholes. Aszetely and Lyngfelt (1996) modeled manholes in three dimensions with finite elements to also determine loss coefficients.

5.2.2.3.1 Research Needs

A possible approach is to incorporate parameter uncertainty, similar to first order error analysis, directly into new models. Then the models would give sensitivity ranges on the output. Another technique is to use genetic algorithms for assisting in calibration of models against known data, such as the study done by Liong, Chan, and ShreeRam (1995).

5.2.2.4 Data Centered Approaches to Enhancing Stormwater Modeling

5.2.2.4.1 Real-Time Control

A good introduction to the concept of real-time control in stormwater modeling can be found in Norreys and Cluckie (1996). The authors point out the advantages of dynamic, physically based stormwater models versus empirically based models developed via linear control theory. Because of the need to recalibrate to changing conditions, at this time physically based models cannot adapt quickly to real-time data, particularly in large systems. Empirical models simplify the drainage network, and as the authors point out, do not simplify hydraulic behavior any more than the kinematic wave theory. However, the linear approximation is only good for a narrow operating range. The conditions of pumping, pressure flow, and backwater effects are beyond the capability of linear control-based models, so a physically based simulation tool must be used in these conditions. Norreys and Cluckie's approach is to model the system in trunks, in a hybrid approach. Results indicate very close agreement with existing calibrated models. Pleau, Tremblay, and Colas (1996) describe an integrated system using three tools: a database management tool, a control tool, and a utility tool. Within these tools is information on the sewer networks, simulation parameters, meteorological models, hydraulics and storage models, real-time performance modules, and optimization modules. According to Cantrell et al. (1996), the city of Lima, Ohio, "operates one of the most sophisticated real time control systems in the U.S." The system is unusual in that the model, Hydroworks, incorporates real-time control as one of its modules. Cantrell et al. (1996) conclude that the use of real-time control in conjunction with a hydraulics model allows much more rapid testing of prospective conditions, compared with real-time control systems which use simpler transfer function models and must undergo extensive trial and error testing. A disadvantage of this approach is that use of real-time control adds a new source of complexity and possible numerical instability to the model. Cassar and Dettmar (1996) describe a real-time control system using EXTRAN as the transport model that determines the state of the system; the decision system is based upon optimization of a linear system once the state has been determined. Vitasovic, Swarner, and Speer (1990) describe the development of a combined real-time control system and dynamic stormwater system model for the City of Seattle. This model can handle surcharging of manholes and other nonlinear flow phenomena.

5.2.2.4.1.1 Research Needs

Nelen (1994) introduces a model to assess the performance of a system using real-time control. The optimal combination of models and real-time control in a hybrid approach still must be determined. Interaction with large-scale real-time control research activity in Europe would promote the use of this method in the United States. A possible link with existing research is that such hybrid models could be evaluated in the context of determining the possible optimal level of aggregation.

5.2.2.4.2 Stochastic Simulation

Trotta, Labadie, and Grigg (1977) describe a stochastic adaptive control model developed for the city of San Francisco for use in predicting runoff for use in an automatic control system. They found that, even with a high degree of error in the forecast, the system's overflow performance improved.

Todini (1988) provides a good overview of the classification of modeling, including stochastic models; and includes a proposal for future directions of modeling research. Scholz (1996) advocates using urban hydrologic and water quality data to fit an autoregressive moving average (ARMA) (also known as Box/Jenkins) stochastic model. An advantage of this technique is that the results are inherently grounded in real data; *i.e.*, unrealistic model predictions are avoided.

Schaarup and Hvitved (1994) used MOUSE-DOSMO to model dissolved oxygen depletion in rivers receiving combined sewer overflows. Known statistical distributions for rainfall and input parameters were sampled from a Monte Carlo analysis with repetitive runs of the model to find a range and probability of extreme events for the concentration of dissolved oxygen in rivers. Gyasi-Agyei and Willgoose (1997) developed a hybrid technique which combines two random process models. The two models were the jitter model, which attempts to improve the fit of a point process model, and either a nonrandomized Bartlett-Lewis rectangular pulse model or an autoregressive model. The hybrid model performed substantially better than the Bartlett-Lewis model alone.

5.2.2.4.2.1 Research Needs

Stochastic models must become more integrated with existing software, to make them more available. Then researchers will find their use in conjunction with statistical techniques more practical so that the linkage is better between the deterministic and stochastic processes.

5.2.2.4.3 Neural Network

Neural networks are a set of artificial intelligence techniques that are being used for function approximation and pattern recognition in wet weather flow research. Recurrent neural networks are the predominant subtype being used in the stormwater modeling field because these networks can simulate dynamic systems. The typical way in which neural networks are used includes an initial training phase in which the neural network adapts itself by testing itself against the available data record. After training, the model can then be used for prediction. Adaptive neural networks allow the system to modify itself based on the network's own performance at predicting events. Because of its reliance on data, and the empirical nature of neural network technology, it is frequently used in areas where physical processes are poorly understood. According to Bertrand-Krajewski et al. (1996) and Gong, Denoeux, and Bertrand-Krajewski (1996), the predictive effort is enhanced by introducing *a priori* information, or knowledge, or a kind of "gray box." The authors developed a neural network approach to assist in modeling the transport and flow of solids in sewer networks. Rabasso and Rosell (1996) use neural network techniques for quick forecasting of rainfall and flow within the sewer network. By enabling quick forecasts of peaks, it is possible for the decision framework of combined sewer overflows to be improved. Kroa and Chocat (1993) use neural networks to assist in the prediction of anticipated rainfall events within a real time controlled sewer system. Cancilla and Fang (1995) use neural networks, principal component analysis, and universal process modeling techniques to determine the concentration variability of selected complex organic constituents at and between specific locations along the Niagara River.

5.2.2.4.3.1 Research Needs

There are many applications of neural networks in which the network is used either in competition with or to complement a deterministic physically based model. There are very few instances of neural networks associated with stormwater modeling. More work needs to be done to determine the optimum combination of the two technologies; *i.e.*, when is it better to research the physical processes involved so that algorithmic models can be written as opposed to measuring the system extensively and using the neural net "black box" approach.

5.2.2.4.4 Calibration of Transport Models Using Improved Databases

Improved wet weather transport prediction is but one of many advantages that would result from a systematic, comprehensive wet weather database. Such a database would include critical measurements from a various climates, land uses, etc. Pollutant transport models may benefit from a comprehensive database by enabling researchers to access consistent data from similar situations. This may be especially important when using statistical relationships to predict gross wet weather pollutant transport to receiving waters.

Driver and Tasker (1990) report an example of a large-scale urban wet weather flow database constructed after data had been collected. The purpose of this work was to maximize the benefit from existing data and develop statistical models of runoff quality on a regional basis. The authors used a national database made up of data collected by the U.S. Geological Survey and the US EPA to develop statistical models of urban runoff concentrations and loads. The U.S. Geological Survey database was made up of two existing databases (Driver and Tasker, 1985; Mustard et al., 1987) and included data from 1,123 storms for 98 urban stations in 20 metropolitan areas (Driver and Tasker, 1990). The US EPA database included information from the Nationwide Urban Runoff Program and consisted of 1,690 storms for 75 urban stations in 15 metropolitan areas (Driver and Tasker, 1990).

A great deal of valuable information was gleaned from existing data collected by different agencies for different purposes. Such data should be standardized in recognition of possible future uses of the data, so that maximum benefit can be gained from the data.

5.2.2.4.4.1 Research Needs

Future improvements in wet weather performance could be assisting from use of a cross-sectional relational database. However, to maximize the usefulness of such a database, standards must be developed to guide monitoring. Ad hoc monitoring efforts have thwarted many attempts to develop a coordinated database spanning a wide range of applications. Care must be taken to ensure that data collected in the future meet rigid but cost-effective standards. Therefore, the first step in developing databases for use in wet weather applications must be the standardization of monitoring. This should be done in light of possible uses of the data once collected, such as model calibration. In addition, the applications, such as transport models, should be adaptable to this calibration data, i.e. both the databases and the applications should be standardized enough to ensure reliability, but flexible enough to allow project-specific modification.

5.2.2.5 Linking Surface and Subsurface Phenomena

Mull (1996) determined the range of discharge from leaky sewers to groundwater in Hannover, Germany, to be from 2.6 million to 9.4 million cubic meters per year using water balance, groundwater balance, and tracer studies. Morita, Nishikawa, and Yen (1996) developed the governing equations for the combination of surface flow and an infiltration trench. The authors' approach was to use a two-dimensional unsteady surface flow solution to the St. Venant equation coupled with a modification of the Richards equation for three-dimensional unsaturated unsteady subsurface flow. They introduce a new parameter, infiltratability, which is compared with rainfall intensity. The computer model based on this algorithm yielded reasonable results for this situation. SWMM (Huber and Dickinson, 1988) contains a one-dimensional, two-zone (saturated and unsaturated) groundwater routine to model infiltration. The purpose of this routine was to better handle areas, such as South Florida, where the primary means of runoff disposal is by infiltration rather than by surface transport.

Wada and Miura (1993) developed a simple, one-dimensional surface and unsaturated groundwater model to simulate a paved surface running off to an infiltration trench. Mushtaq, Mays, and Lansey (1993) developed a surface and subsurface model for operation of a series of recharge basins, and applied a nonlinear objective function and control theory to develop operational policies for the basins. The model was based on a Phillips/Green-Ampt infiltration model coupled with Darcy's equation for groundwater flow used for soil moisture redistribution, and a kinematic wave model for surface flow. Dunn et al. (1996) describe the NELUP decision-support system (DSS); this paper focuses on the hydrologic models used in the system. A groundwater flow component with coupled equations to river flow is included in the DSS.

5.2.2.5.1 Research Needs

Typically, recharge is the least known input variable in a groundwater flow model. It depends upon precipitation, infiltration, evapotranspiration, and various other factors that vary both spatially and temporarily. An unfortunate obstacle in this problem is the time scale; i.e., urban hydrologic models usually have time steps on the order of seconds or minutes, whereas groundwater flow models typically have time steps on the order of days, weeks, or even months. A more fundamental understanding of the water balance must be attained to formulate more general simulation tools. Until then, research of specific homogeneous sites will prove useful for limited situations.

5.2.2.6 Linking with Atmospheric Models

Thielen and Creutin (1996) linked an urban hydrologic model with an atmospheric model. The problems they encountered were describing soils, roughness, heat fluxes, and infiltration processes to the degree necessary to satisfy the atmospheric model.

Lin (1994) developed the atmospheric and sediment deposition model (ASDM), which is a combined water column and surface sediment advection and dispersion model capable of modeling transport processes that include sedimentation, sorption, and air–water diffusion, dry and wet deposition. The model was used to analyze several hot spots of mercury in the Detroit River.

According to Epstein and Ramirez (1994), global climate models (GCMs) work on a different scale which does not allow direct linkages to smaller-scale hydrologic models. To overcome this problem, the authors use daily spatial disaggregation techniques within the Upper Rio Grande River Basin in Colorado, preserving spatial variability, while analyzing temperature and precipitation records. The authors could then predict seasonal changes in runoff, soil moisture, evapotranspiration, as well as snowpack. An example of using a catchment model linked with an atmospheric model is given in Viney and Sivapalan (1996), and another can be found in Yates (1996). Both of these examples use water budget analysis to link the two modeling technologies on a spatially gridded scale.

5.2.2.6.1 Research Needs

More work must be done with respect to scaling issues between atmospheric models, water balances, and urban stormwater modeling. At present, the GCMs use a very large grid that does not refine or adapt itself over differing hydrologic regions, such as urban areas, so that much of the urban wet weather flow phenomena are lumped into larger regional hydrologic phenomena.

It is debatable whether urban hydrologic processes are appropriately simulated in this fashion, even at large time and space scales. More work must be done at the GCM level in terms of adapting to urban areas, and possibly to an adaptive grid size. Water budget analysis is the key link between atmospheric and urban wet weather flow models.

5.2.2.7 Solids in Sewers/Sewer System Modeling

Existing models cannot adequately handle the generation, deposition, settlement, erosion, and transport of solids within sewers. This is primarily due to a fundamental lack of understanding in the physics of solids behavior, according to Gent, Crabtree, and Ashley (1996). The authors review the current research in the area of sewer sediments, as well as implementation in sewer flow quality models, and suggest linking "field data collection, theoretical and laboratory studies, and model/software development" to assist in the success of current research. Schafer (1994) provides practical information necessary for use in models and design in the interim.

According to Bertrand-Krajewski et al. (1996), the predictive effort is enhanced by introducing *a priori* information, or knowledge, or a kind of "gray box." Bertrand-Krajewski et al. (1996) developed a neural network approach to assist in modeling the transport and flow of solids in sewer networks. The model compared favorably with predicted modeled results (MOUSE was the hydraulic model).

Schmitt and Zimmerman (1996) describe the model HAuSS developed to include micropollutant, sediment, and solids transport in sewers. Koelling (1996) used a finite element method to simulate the velocity field within an irregularly shaped sewer. This enables accurate flow estimation (typically depth is measured) even during backwater conditions. Swaffield and McDougall (1996) developed an unsteady flow model of a drainage system network using partially filled pipes capable of predicting flow depth and rate and solid velocity, and show how such a model can be used in decision making in the area of new development design. At present, the more empirical input/output and probabilistic characterization of solids behavior may need to be reevaluated. Studies in this area need to include some sampling and characterization of solids at the location in question.

5.2.2.7.1 Research Needs

To progress in this area, monitoring and modeling of solids transport in sewers must be developed conjunctively. Fundamental understanding of solids behavior in sewers is lacking, and research should be devoted to this area. Significant research is underway in this area in the United Kingdom, and modeling efforts in should proceed and should be supportive of the physical research on solids.

5.2.3 Integrated Decision Support Systems

A decision support system assists in bridging the gap between data and models to solve difficult, partially undefined problems. A thorough background on decision support systems and its application to reservoir decisions can be found in Jamieson and Fedra (1996a, b) and Fedra and Jamieson (1996). This series of articles describes the conceptual design, planning capability, and example application of the Water Ware DSS, a complex river basin DSS that combines "GIS, a geo-referenced database, groundwater flow, surface water flow, hydrologic processes, demand forecasting, and water-resources planning." Reservoir operation and management was one of the first areas in which DSSs were applied. Because of the complicated decision criteria governing urban wet weather flow management, Davis et al. (1991) studied a prototype DSS developed to analyze the impacts of different catchment policies. Driscoll (1993) developed a DSS to assist highway engineers in determining which construction sites would contribute to a receiving water quality problem. Azzout et al. (1995) discuss a DSS that would assist in the feasibility determination of alternative techniques in urban wet weather flow management. Lavellee, Marcoux, and Bonin(1996) describe a real-time control system developed for the Quebec urban area to manage a wet weather flow system to minimize CSOs. The unique data needs and system architecture of the real-time control system support many of the concepts of DSS because of the demand for timely decisions relating to large datasets.

5.2.3.1 Research Needs

Current work in decision support systems has focused on use of Unix-based minicomputer systems. Typical costs for these systems may be prohibitive for non-research–related activities. Software and development costs can also be high. Urban wet weather flow management has tended to focus more on PC-level technology, at a much smaller spatial and temporal scale, and at significantly smaller investment levels. This is primarily due to the fact that many of the users are small consulting firms or municipal governments. One aspect of current decision support systems is the lack of integration with existing stormwater modeling technology. Research in the development of decision support of urban stormwater systems should focus on use of personal computers linked to external databases over the internet. This has become possible recently with the increasing speed and processing power of personal computers, and advances in software such as GIS. DSS for urban stormwater needs to incorporate real-time control and the ability to effectively handle large databases and rapid evaluation of control options.

5.2.3.3 Integrate GIS to Refine Spatial Analysis Capabilities

The development of geographical information system (GIS) software technology is dramatically changing the practice of municipal engineering. According to Shamsi, Benner, and Fletcher (1995), more than 70% of the information used by local governments is geo-referenced. Shamsi, Benner, and Fletcher (1996) describe how ArcView, a GIS software package, can be used for a variety of GIS-related linkages to urban stormwater models and data management, including AM/FM systems. For an overview and description of GIS and hydrologic modeling, primarily focused on large-scale distributed watershed modeling, see Singh and Fiorentino (1996). Hauber and Joeres (1996) describe how GIS was used as a preprocessor for the source loading and management model (SLAMM) to estimate pollutant loads in urban areas. A case study of Plymouth, Minnesota, is included. Smith (1993) developed an urban hydrologic model using GIS with a distributed grid approach. Bellal, Sillen, and Zech (1996) use a digital terrain model approach, combined with a distributed grid, and compute a water balance within each grid cell. They found that the model compared well with other models, such as SWMM. Herath, Musiake, and Hironaka (1996) developed a GIS-based gridded urban area water budget, using simplified homogeneous units within each grid. They argue that the distributed hydrologic models capable of reflecting urban heterogeneity are needed although their model agreed well on a large scale. Litchfield (1994) compared various levels of abstraction in hydrologic models to observed data, using GIS to evaluate input parameters in finer levels of abstraction, i.e., down to the parcel level. The author found that the finest grid fit the pollutographs and hydrograph peak best, whereas the intermediate grid fit the storm volume best.

5.2.3.3.1 Research Needs

Several new GIS tools are now available that allow easier and better integration of GIS into stormwater modeling. A promising tool, mapobjects by ESRI, essentially allows a GIS object to be used in a Visual Basic or Visual C++ program. Similar tools from other vendors are also available. Either of these programs supports mixed language processing, including legacy Fortran 77, so development of an integrated GIS/stormwater model is probably easier now than it ever has been. Another avenue of research would be to continue the work of Litchfield (1994) with comparisons to continuously measured data, i.e., a real-time monitoring system in which GIS developed model parameters, and combined with a very fine rainfall/runoff spatial data system. An important research question is the effect of the finer grid on simulations—should some of the hydrogic algorithms or routing characteristics at this level be modified?

5.2.3.4 Interface Simulation and Optimization Models

Medina and Jacobs (1995) integrated simulation and optimization in a wet weather flow design modeling study that integrated failure and reliability analysis into its decision criteria. Nix and Heaney (1988) describe a procedure for continuous simulation and generation of production functions, which are then optimized by a variety of procedures. Segarra (1995) used a similar optimization analysis procedure. Production functions were developed for storage capacity and release rate, which were then optimized using runoff or pollutant trap efficiencies as a constraint. Gall, Averill, and Weatherbe (1997) describe a process modeling and simulation study with CSOs. They give an overview of dynamic simulation and optimization.

5.2.3.4.1 Research Needs

A promising research area of optimization is the use of genetic algorithms. This technique has already been applied to pipe network models (Dandy, Simpson, and Murphy, 1996), as well as river management decisions (King et al., 1995). The technology has yet to be widely applied to the complex optimization problems of urban wet weather flow. With the advent of Microsoft Windows and object-oriented programming, the interface between simulation and optimization has become easier to achieve. Tools are now available that permit off-the-shelf software for the most difficult portions of programs. Directed research into these areas may significantly increase the ability to link optimization and simulation.

5.2.3.5 Integrated DSS for Overall Watershed

5.2.3.5.1 Watershed Models

Watershed models combine the ability of hydrologic/hydraulic routing models such as SWMM with a receiving water model such as WASP or RIVMOD. This integration helps track sources of pollutants and nutrient loadings into receiving waters. Wool, Martin, and Schottman (1994) developed a linked watershed/waterbody model that integrates these models so that they can be run simultaneously. Kort and Cassell (1993) developed an object-oriented watershed model using STELLA, a process simulation language and program. Pabst (1993) outlines the objectives of the U.S. Army Corps of Engineers in the NEXGEN project. In this project, two hydrologic models, HEC-1 and HEC-2 are recast in an object-oriented manner as HEC-HMS and HEC-RAS. Both of these tools have been used extensively in watershed management. Schroeter et al. (1996) describe a long-term integrated watershed management study in southwestern Ontario, Canada. The authors developed a continuous in-stream temperature model that integrates information from runoff models, evapotranspiration, channel routing, reservoirs, recharge, and ecosystem information (such as vegetated canopy). Ford and Killen (1995) developed a DSS for the Trinity River watershed of Texas. The system combines a graphical user interface with HEC-1 and HEC-5 for runoff and reservoir system modeling, respectively, and, performs the following tasks:

- Retrieve, process, and file rainfall and streamflow data;

♦ Estimate basin area rainfall, update model parameters, and forecast runoff; and

♦ Simulate operations in order to forecast regulated flows basinwide.

The main objective of this system is to improve flood prevention and control.

5.2.3.5.1.1 Research Needs

Many of the existing tools are designed to analyze only a portion of the watershed. Cross-cutting, interdisciplinary models and decision support systems should be developed that cover entire watersheds and can enhance communication among professionals. All watersheds are complex, but, those in urban areas in particular have another layer of infrastructure and management practices to deal with as well. Heaney et al. (1998) offer the Boulder Creek watershed as a possible candidate for such study.

5.2.3.5.2 Ecosystem Models

Lhotka (1994) and Chapra (1996) describe an individual-oriented ecosystem aquatic ecosystem model capable of reproducing predator–prey relationships. Heringa et al. (1995) developed an object-oriented lake ecosystem model called LAKE. The model integrates most water resources processes with lake ecosystem processes. Berry, Hazen, and Flamm (1996) developed the LUCAS model, which "can integrate ecological and socioeconomic information for adaptive approaches to landscape management." The model is constructed with object-oriented techniques, and is combined with the GRASS GIS system. LUCAS predicts ecological impacts, such as spatial species distributions, as the result of projected land-use changes. Ford, Running, and Nemani (1994) developed the Rhessys model, a regional, hydro-ecological simulation system, which is a macro level biogeochemical model that uses raster-based input information, such as soils or leaf area index, to model ecosystem dynamics. Leonov, Litvinov, and Razgulin (1996) developed an ecological model of the Rybinskoe reservoir ecosystem based on the biogeochemical fluxes of organogenic elements (carbon, nitrogen, and phosphorus). Input parameters into the model included water surface temperature and illumination and hydrologic regime. Output includes carbon, nitrogen, and phosphorus fluxes, production, and destruction cycling. The authors explain several annual periodic variations, as well as regional peculiarities with the model.

5.2.3.5.2.1 Research Needs

A promising area of research is the use of satellite data measures to develop relationships on fluxes of nutrients, energy, and water within an ecosystem. A possible critique on the ecosystem models is the scale involved; i.e., the scale is usually large because satellites collect data on a large grid. As computer technology advances, the scale will decrease; and at some point it may be possible to use irregular grids such as watersheds and urban areas. Another area of integration is to use watershed models as building blocks in larger ecosystem models.

5.2.3.6 Risk Management Methodologies

Moser (1993) describes the U.S. Army Corps of Engineers' procedure to estimate flood damages based upon stage–damage–discharge curves. The author describes the use of new software and Monte Carlo simulation techniques to predict the relative uncertainty in each of these estimates. Arnbjerg-Nielsen and Harremoes (1996) applied these same techniques to urban storm drainage and found that, for most cases, the dominant contributor to uncertainty was the description of rainfall, followed by the prediction of runoff. However, in the case of extreme event prediction of chemical oxygen demand (COD) from CSOs, the uncertainty in the estimation of COD concentration was dominant. Novotny (1996) describes an analytic procedure for calculating the risk associated with wet weather discharges to aquatic ecosystems. Lei and Schilling (1996) use a combination of Monte Carlo simulation followed by multiple linear regression to estimate the undercertainty of models based upon the distribution of input parameters (uncalibrated). Heaney, Wright, and Samsuhadi (1996) describe an integrated risk management approach to urban wet weather flow quality management within the context of a multipurpose stream, Boulder Creek, in Boulder, Colorado, which also serves such additional uses as recreation, wastewater treatment dilution, agriculture, and instream flow augmentation and restoration. Risk analysis of the flow at the wastewater treatment plant shows that the covariance of concentrations of BOD and TSS are strongly related to flows, indicating that dilution ratio increases as the probability of an overflow increases. This increasing dilution ratio substantially decreases the risk of impacts from overflow events. Bulkley (1993) describes the process of developing acceptable criteria for determining permit requirements for combined sewer overflows (CSOs), based on the tradeoff between cost of increased storage and reduced risk from overflows. Finally, Line et al. (1993) review the risk-assessment methods appropriate to nonpoint-source pollution, balancing the economic risk of agriculture versus the environmental risk of nonpoint-source pollution.

5.2.3.6.1 Research Needs

US EPA (1996) set forth a strategic plan in the areas of characterization and problem assessment, watershed management, toxic substances impacts and control, control technologies, and infrastructure improvement. For the most part, these research needs are included within other areas.

5.3 Watershed Management Linkages

Interest in watershed management has waxed and waned over the past century. The concept of integrated water and land management was first articulated in the western United States by John Wesley Powell in a report to Congress in 1878 (Peterson, 1984). However, Congress rejected his idea and continued to use an ad hoc approach to authorizing projects. During the 20th century, interest in watershed planning has come and gone several times. Following World War I, unified planning at the river-basin scale flourished with major studies and implementation on numerous river basins, e.g., the creation of the Tennessee Valley Authority. The National Resources Planning Board provided the leadership for these efforts (Viessman and Welty, 1985). Increased environmental awareness during the 1960s and 1970s led to expanded efforts to evaluate water quality and related problems on a regional level. During the 1980s, water resources problems were addressed primarily by a command and control approach. A strong move back to the watershed management approach began a few years ago, e.g., see the *Proceedings of Watershed '93 and Watershed '96* (WEF, 1993; 1996). US EPA (1991) has taken a strong interest in the watershed approach. While it is axiomatic that integrated, holistic, sustainable infrastructure systems are desirable, demonstrated success stories of how such systems might function effectively are rare (Heaney, 1993).

St. John et al. (1996) described using hydrodynamic and water quality models to evaluate the overall impact of dry and wet weather loads on dissolved oxygen in receiving waters near New York City. Brosseau (1996) explained how the Bay Area Stormwater Management Agencies Association in the San Francisco area operates. This association's membership comes from seven stormwater agencies in the area. A major motivation for watershed-based approaches is economic efficiency. Brewer and Clements (1996) described how organizations formed a consortium to share the cost of monitoring at the watershed scale. Another source of savings from watershed management is to remove pollutants within the watershed in the most cost-effective manner. Market-based pollutant upstream/downstream trading has emerged as a potentially valuable mechanism. Methods for discharge trading and case studies were presented by Podar et al. (1996). Frederick et al. (1996) estimated the benefits of stormwater detention systems as increased property values due to the waterfront amenity value. They include the results of property valuations in many areas. Marx, Leo, and Heath (1996) described how a watershed-based approach has resulted in more cost-effective CSO control in Boston. Weiss and Lester (1996) outline how watershed ideas can be used to address sanitary sewer overflow problems within US EPA's regulatory program. Brady (1996) summarized the accomplishments of the first 5 years of US EPA's watershed protection approach. Stumpe and Hamid (1996) described how applying a watershed approach can develop more cost-effective SSO control programs. Urban wet weather flow is but one of many impacts in urban watersheds. Studies in Boulder, Colorado (Heaney, Wright, and Samsuhadi, 1996) and in Quebec city watersheds (Vescovi and Villeneuve, 1996) illustrate the complexity of urban watersheds. This complexity may be typical for urban areas because mankind invariably significantly modifies the watershed system. Roesner, Mack, and Howard (1996) describe an integrated master planning approach for wet weather flow management in a new development near Orlando, Florida.

Stephenson (1996) compares the water budgets of an undeveloped catchment with an urbanized catchment in Johannesburg, South Africa. The results show the expected increase in direct runoff and the need to import water for water supply. Nelen and Broks (1996) describe the planning of a new development for about 10,000 people in Ede, Netherlands. The three underlying environmental principles are sustainability, quality, and ecology. This area has a high groundwater table so groundwater management is an important part of the project. They plan to incorporate water-conserving hardware and divert the more polluted stormwater into the sanitary sewer. They are also considering a dual water supply system. Escartin (1996) provides an overview of Spain's use of the watershed approach since 1926 to manage water more efficiently.

Early watershed planning efforts focused on developing "master plans" which, once approved, served as a blueprint for management in the basin. Before computers, such efforts faced severe technological limitations in bringing together large amounts of information and systematically analyzing alternatives. The widespread availability of mainframe computers in the 1960s and associated computer-based simulation and optimization techniques led to large-scale efforts to develop "rational" master plans (Maass et al., 1962). Integrated river basin planning models were developed as early as 1971. Mays and Tung (1992) and Wurbs (1994) summarize these quantitative methods. The thrust in developing better planning methods was in devising ever-more complex models, e.g., three-dimensional lake models, nonlinear programming models. Unfortunately, the sophistication of models greatly outstripped the availability of data. Nevertheless, models have had a strong positive influence on water resources planning (Office of Technology Assessment, 1982).

In summary, research in watershed management is quite active, particularly in the modeling and DSS area. However, focused research is still needed in the development of a watershed assessment method, development of long-term watershed case studies, development of an urban research catchment network, and development of watershed-based water quality standards. A detailed literature review and summary of the needs in each of these areas follows.

5.3.2 Watershed Assessment Methodology

Brelot, Chocat, and Villessot (1996) describe a prediagnostic computer tool to determine the information needs to be addressed in a combined waterway/watershed impact/drainage system study. Lawrence (1996) emphasizes the need for ecosystems to be the building blocks of water management. Increasingly, biological indicators are being used as measures of watershed health. Development of streamflow and loading criteria require knowledge of geomorphological, hydraulic, and ecological sustainability. This emphasizes the need for total water cycle-based modeling. Young, Farley, and Davis (1995) describe an assessment model of a watershed that uses land-use changes in input values, and calculates average annual loadings within the catchment. This tool can be used to identify, within the context of public involvement, those areas where a more detailed model study should be conducted. Donigian, Huber, and Barnwell (1996) describe the available models of nonpoint-source water quality used in watershed assessment, such as SWMM, HSPF, STORM, CREAMS/GLEAMS, SWRRB, and AGNPS. VerBeek et al. (1996) describe a decision support system tool used for policy analysis decisions within a watershed.

5.3.2.1 Research Needs

To date, there is no generally accepted watershed assessment method. Researchers tend to address a problem from within a discipline, so the solution reflects their disciplinary bias. Modeling tools tend to be concentrated within a given discipline, as well. Simulation technology should be updated to current computer technology to reach a broader audience. This may include the use of decision support systems. Case studies could be used to evaluate such a method.

5.3.3 Long-Term Watershed Case Studies

Roth (1995) presents a watershed-based case study of Bear Canyon, in the Albuquerque, New Mexico area and describes the impact of past and present land use on the watershed, governmental measures to rectify these problems, and what best management practices can be employed to limit stormwater pollution. Jensen et al. (1995) discuss the Chain of Lakes, approximately 2 miles south of Minneapolis. The lakes are an important recreational resource; however, historical trends indicate long-term degradation. The authors discuss a watershed-based monitoring and assessment program, and what recommendations the program makes. Conry (1994) describes the Oyster Creek lake system, created by a series of dams, and its water quality. The author describes the citizen involvement—created as a result of the increased water level resulting in desirable waterfront property. Arteaga and Bartel (1994) describe a watershed monitoring study done for the city of Quincy, Florida. Water quality for drinking water supply is extremely variable due to turbidity and agricultural NPS pollution. Continuous stormwater quality modeling evaluated the effectiveness of control options, such as reservoirs and land-use controls. Wegener, Kunkel, and Wulliman (1990) describe the Shop Creek drainage outfall system, which was constructed at a cost of $671,000. The Shop Creek watershed comprises approximately 640 acres, draining into the Cherry Creek Reservoir, an important metropolitan recreation and drinking water resource. This project consisted of 3,000 feet of eroded stream stabilization and construction of a 4.8-acre-feet of continuously wet detention storage, with another 9.1 acre-feet of extended dry storage as well. The watershed was monitored extensively and it was determined that capturing phosphorus load, particularly the fraction of suspended phosphorus attached to fine sediments, was a priority. Scro (1994) describes the Navesink River Nonpoint Source Shellfish Protection Program, a multi-year monitoring effort, the goals of which were to reduce bacterial contamination of shellfish in the river, to improve agricultural productivity, and to mitigate nutrient and sediment loading in downstream reservoirs.

5.3.3.1 Research Needs

The most significant need is for a long-term commitment to monitor urban catchments. Shop Creek, in Aurora, Colorado, has an extensive water quality and quantity database of an urban watershed through the entire development cycle. However, gaps in this database result from limitations in funding, which has been almost exclusively funded on a local level. Many similar watersheds, such as the city of Boulder's, have some data; the limitations occur because of shifts in municipal priorities. Possible research funding into basic data collection and archiving would most certainly increase the amount of available data to evaluate long-term watershed impacts.

5.3.4 Urban Research Catchment Network

Huber et al. (1982) collected a storm event database of urban rainfall runoff quality data for 48 catchments in 16 urban areas. They provide hydrologic data for 25 catchments in 15 urban areas. They statistically analyze each parameters. Thorolfsson (1996) describes the Slandsli Research Catchment, a collaboration between the Department of Hydrologic and Environmental Engineering of the Norwegian University of Science and Technology, Trondheim, and the municipality of Bergen. Within the catchment are side by side conventional and infiltration systems for stormwater disposal. The results showed that using infiltration reduced surface runoff by 70%, maintained the predevelopment annual groundwater level after development, and cost about 30% less. Mitchell, Mein, and McMahon (1996) describe a water budget approach to integrated water management in Australia. They budgeted water at the individual parcel, neighborhood, and wider catchment scales. Jack, Petrie, and Ashley (1995) advocate the inclusion of the entire catchment in CSO modeling so that the optimal "hydraulic, economic, and environmental solution may be found."

5.3.4.1 Research Needs

In the United States, a few municipalities have established partial monitoring of catchments for water supply and pollution control needs (see section 5.3.3: Shop Creek, in Aurora, Colorado); however, there is no organized national effort; data for these types of sites are not widely publicized. Thus, this remains a pressing research need. This research could tie to the NSF LTER experimental watershed program. This could be combined with long-term case studies of environmentally friendly developments.

5.3.5 Watershed-Based Water Quality Standards

Stecker et al. (1994) summarize the South Carolina watershed-based water quality program. The watershed-based approach recognizes the need for coordination with activities such as "monitoring, problem identification and prioritization, water quality modeling, planning, and permitting." Schiff and Stevenson (1995) discuss the watershed-based monitoring approach of wet weather runoff in the San Diego, California, area. The findings were that the event mean concentrations of pollutants were lower than national averages. Monitoring also included 7-day chronic toxicity testing of *Ceriodaphnia*. During this study, fecal coliform bacteria from stormwater runoff resulted in closing the beach at Mission Bay.

The key aspects of nonpoint source pollution (NPS) in the context of watershed management can be found in Line et al. (1993). The authors review effluent trading to allocate pollutant loadings based upon a least-cost framework. They review impacts of NPS on receiving waters, as well as mathematical models appropriate to them; and controls and best management practices, as well as risk-assessment methodologies. Warwick, Cockrum, and Horvath (1997) give a method for estimating NPS loads and measuring water quality impacts using WASP5, a dynamic surface water quality model. Liao and Tim (1997) tightly couple an agricultural NPS model (AGNPS) with an Arc Info GIS system to develop an interactive watershed modeling environment.

5.3.5.1 Research Needs

A comprehensive statistical analysis of the performance of water quality-based standards in terms of both spatial and temporal dimensions must be done, with careful attention to intrastate as well as interstate variations, as program lines are set up along state levels. Watershed to watershed variability would make this analysis somewhat complex., but, common characteristics of watershed health could be used.

CHAPTER 6.0

REGULATORY POLICIES AND FINANCIAL ASPECTS

This chapter summarizes current work in regulatory policies and financing for management of urban wet weather flow, including regulations and permits, reuse and water resources, financing and cost analysis, benefits of urban wet weather flow management, and education and outreach. The research topics identified in Table 2–8 were organized into the outline as shown in Table 6–1. This grouping accommodates the overlap of some topics and the lack of available literature for others. Many of the other topics were combined into a single subsection. New sections, such as Section 6.3, were added where necessary to cover the broader nature of the field.

6.1 Regulations and Permits

During the 1960s and 1970s, after the initial passage of the Clean Water Act and subsequent amendments in 1972, the US EPA attempted to avoid regulation of wet weather flows. Perhaps this was because of the perspective at the time to focus on areas that would have the most impact, such as sewage treatment plants and industrial point discharges, but because of the sheer volume of WWF discharges in the United States. Although urban stormwater is usually a point discharge, it was classified with nonpoint source discharges because of their dispersed spatial nature and their lack of regulatory control. During the 1980s, the US EPA decided to selectively permit stormwater discharges; this effort was chosen based upon probable pollution potential. However, the Water Quality Act of 1987 required US EPA to initiate a new effort in the urban wet weather flow field, and US EPA promulgated these interim regulations in 1990. These rules required municipal stormwater discharge permits for the first time for areas whose population exceeds 100,000. Later rules pertain to less populated areas (Roesner and Traina, 1994).

Industrial stormwater dischargers can select an individual, group, or general permit, depending upon the nature of the discharge and preference (Field et al., 1997). Because little is known of the characteristics or quality variability of a given discharge, the program, at least initially, is primarily for monitoring.

Table 6–1. Research Topics on Regulatory Policies and Financial Aspects of Urban Wet Weather Flow Management (Unprioritized)

Section	*Table 2-8 ID#*	*Research Topic*
6.1 Regulations and Permits	86	Improve EPA use attainability study methodologies
6.1.1 Preparing Effective and Implementable NPS Watershed Goals	69	Preparing effective and implementable NPS regulations
6.1.2 Determining Areas Where Regulatory Flexibility can Achieve Watershed Goals	70	Areas where EPA can provide regulatory flexibility to achieve watershed goals.
6.2 Reuse and Water Resources	79	Wet weather flow management in new urban areas
	75	How to develop sustainable watershed management programs
6.3 Financing and Cost Analysis		
6.3.1 Methods of Financing		
6.3.2 Methods of Cost Allocation	71	Methods to allocate the costs of multipurpose water projects
6.3.3 Development of Cost and Performance Data for Controls	72	Cost/performance function data for wet weather flow controls
6.4 Benefits of Urban Wet Weather Flow Management	73	Quantify benefits of wet weather flow quality control
6.4.1 Contingent Valuation	74	Contingent valuation to estimate the benefits of wet weather flow projects
6.4.2 CSO Measures of Success	76	CSO measures of success
6.5 Education and Outreach	81	Common elements of successes and failures.
6.5.1 Public Involvement, Participation Techniques	77	Feedback on public involvement, participation techniques
	87	Environmental ethics to reduce litter
	78	How to translate public desires into action?
6.5.2 Coordination of Wet Weather Flow Research Across Agencies	85	Mechanism for coordinating wet weather research across agencies
	82	Retrospective assessments of existing environmentally friendly developments
	80	Feasibility of decentralized urban water management and privatization
	83	Environmental justice in management programs
	84	Recognition of regional differences in appropriate management strategies

Roesner and Traina (1994) and Moffa, Cabral, and Ford (1996) provide an overview of current federal regulations that pertain to urban wet weather flow. Because the program is relatively new, and because available information is lacking, US EPA has given permitees latitude. This is, in part, a concern for the sheer numbers of possible permits involved; however it also reflects US EPA's philosophy on watersheds. With the latitude comes a monitoring responsibility to establish background concentrations, both within the stormwater system itself, as well as the receiving water. Some of the requirements within the program, such as calculations of annual pollutant loads to receiving waters, require modeling technology that is still being developed (Pandit and Gopalakrishnan, 1997).

Many municipalities regulate wet weather flow quantity from the perspective of flood control or a nuisance regulation. This is mainly to protect neighboring property owners and rights of ways from being damaged by excess runoff. Mazich et al. (1990) describe basin-wide stormwater management ordinances. Another good reference in this area is Debo and Reese (1995). It would be interesting to examine areas of municipal regulation for stormwater quantity that could also be used for regulation of stormwater quality. Many municipalities have become responsible for water quality at the discharge point, thus providing incentive to develop authority to control water quality at the source as well. But, many of these municipalities are not now equipped for this responsibility. A key need is to educate the municipalities' existing professional personnel. According to Pitt et al. (1997), referring to the existing framework of local regulation, "without the institutional systems to set them up and enforce them, they will not be effective." Another key area of importance is municipal financing. Most of the urban wet weather flow infrastructure currently is funded at the local level; and, in most municipalities, serious deficiencies exist. New funding sources will be critical for the success of any new regulatory programs in this area.

An important aspect of US EPA's evolving program in this area is the potential for regulatory flexibility. In the development of US EPA's program, the agency has made some deliberate policy decisions to encourage watershed-wide planning and management of urban wet weather flows. Many new areas of water quality-based exchanges could benefit municipalities. These include the concept of effluent trading within a watershed (US EPA, 1996a, b). Effluent trading to maintain water quality on a watershed level has gained momentum recently; but, the system is complex (Kerns and Stephenson, 1996). US EPA (1996b) describes the benefits of pollutant trading among the various sources within a watershed as a means of reducing costs, and a framework for watershed-based trading was prepared (US EPA, 1996a). Little and Zander (1996) conducted a cost-effectiveness study on point sources and nonpoint sources control of phosphorus in Chatfield Basin, Colorado. Podar et al. (1996) summarized progress on trading programs across the nation. Taff and Senjem (1996) offered practical measures to resolve the uncertainties associated with nonpoint-pollutant trading systems.

The urban pollution management (UPM) manual and its products are being widely used in the United Kingdom for evaluating their flooding and CSO pollution problems (Morris and Clifforde, 1996). Brashear and Drinkwater (1996) compared urban wet weather pollution management approacies in the United States with those in the United Kingdom. Lindsey, Swietlick, and Hall (1997) summarize the application of US EPA's evolving watershed philosophy to urban wet weather flow management. According to the authors, urban wet weather flow pollution remains the single largest source of water quality degradation. US EPA introduces a key area of flexibility since the Water Quality Control Act of 1987 is the concept of "use attainability," which is a pragmatic realization that, in many urban areas, certain stream lengths do not and will not meet any significant water quality standard, no matter the technology used for urban wet weather flow. According to Title 40 CFR §131.3(g), "Use attainability analysis is a structured scientific assessment of the factors affecting the attainment of the use which may include physical, chemical, biological, and economic factors as described in Sec. 131.10(g)." Use attainability allows the users to develop alternative criteria and treatment requirements that balance the costs of compliance with the benefits of a realistic goal.

Novotny (1996) summarizes the new use attainability analysis (UAA) procedure found in Novotny et al. (1997) which is a guide published by the Water Environment Research Foundation. US EPA (1997) applied UAA to the development of TMDLs for a 15.5-mile stream section of Boulder Creek immediately downstream from the city of Boulder's wastewater treatment plant. This analysis is an attempt to bring a holistic viewpoint to the waste-load allocation procedure. The study found that the stream water quality is impaired by a combination of factors, including discharges, urban runoff pollution, agricultural runoff, and diversions of water that could be used for dilution, for water supply for people and agriculture. A wastewater treatment plant upgrade would not alone solve the problem, and would waste community resources without measurable environmental benefit. The study recommends a combination of modest plant upgrades, best management practices, and habitat restoration to achieve a reasonable water quality standard. Michael and Moore (1996) demonstrate that the UAA procedure can be used two ways: as a way of relaxing an unnecessarily stringent water quality standard to protect the aquatic ecosystem, as well as using the analysis to demonstrate the need to protect undesignated waters.

6.1.2 Preparing Effective and Implementable NPS Watershed Goals

Markowitz (1996) advocates continuous measurement and good communication with stakeholders to optimize water quality management including NPS and point sources. The author found toxicity testing to be of some limited value as a screening tool, but advocates the use of stream biological standards, recently established for the state of Ohio. Rumery-Betz and Taylor (1994) describe several priority lake projects in Wisconsin, including Camp and Center Lakes and Lake Mendota. The authors describe how urban land-based computer models such as WINHUSLE, BARNY, and SLAMM and lake water quality models are combined with GIS to assist in data integration as well as to keep track of land use changes within the watershed. After a 2- to 3-year planning process, a watershed plan is implemented, usually over 8 years, at a cost of $1 million to $6 million per project. Meals (1990) describes the 10-year monitoring and BMP control effort for the LaPlatte River. This project's main goal was to control shellfish pollution in downstream Lake Champlain by implementing land treatment, at a cost of $996,188, of which 71% was paid by government and 29% by landowners. Concentrations of TSS may have dropped from 10% to 60%. According to Wolf (1995), it is difficult to measure the success of an NPS program. The author presents possible measurements, including:

- Watershed water quality before and after implementation of BMPs;
- Program participation as measured by eligible vs. participating landowners, BMPs considered necessary vs. BMPs implemented, or dollars allocated to the NPS program vs. dollars expended; and
- Institutional goal coordination and management effectiveness.

Based upon these criteria, the voluntary NPS reduction program in Wisconsin has not succeeded in improving ambient water quality. Rector (1989) describes the evolving voluntary NPS programs nationally. The author advocates a negotiated, case-by-case agreement between the affected parties and regulators due to the unique nature of NPS discharges.

6.1.2.1 Research Needs

Possible research needs include a statistical analysis of watershed quality before and after adopting BMPs; and comparison of results nationally as well as within each state (because the program is developed along state lines).

6.1.3 Determining Areas Where Regulatory Flexibility Can Achieve Watershed Goals

Milne, Dempsey, and Morris (1996) describe intermittent river dissolved oxygen standards in the United Kingdom that are frequency based for short periods of low concentration events. Bailey

(1994) outlines the results of technical committees from the scientific and regulatory community in which clear recommendations were made to use cost-effectiveness criteria in implementing CSO permits and controls. This provides for site-specific permits, allowing for technical flexibility of each permit, rather than enforcing a costly technological control. Consideration is also given to water quality standards that focus controls where they are most needed. Murray, Cave, and Bona (1996) summarize the Rouge River National Wet Weather Demonstration Project in Michigan, which allowed alternative watershed-wide permits.

Hruby (1991) examines mixing zone possibilities in New Bedford, Massachusetts, using a dye study and fitting several models including a dilution model, two estuarine flow models, and a density flow model to the data. The extent of the mixing zone depended on quantity of receiving waters; tidal currents; wind; and the density gradient between fresh water and sea water. At this location, it was found that the mixing zone concept did not achieve much regulatory flexibility, primarily because of the small amount of receiving water and the strong tidal currents.

The use attainability analysis introduced in the previous section (Novotny et al., 1997) represents an important first step in determining realistic water quality goals in urban areas.

6.1.3.1 Research Needs

Apparently, no criteria have been defined for how to evaluate regulatory flexibility, nor any clear measures of performance that can be used to evaluate the effectiveness of using regulatory flexibility. More work must be done in these two areas so the absence of adequate information does not inhibit regulatory innovation. An evaluation of performance of the use attainability analysis procedure is also needed.

6.2 Reuse and Water Resources

As water supplies become more stressed, water conservation and reuse become more attractive options. Wastewater disposal costs also encourage more water reuse. Asano and Levine (1996) provide a historical perspective and explore current issues in wastewater reclamation, recycling, and reuse. A complete hydrologic cycle focusing on reuse can be found in Figure 6–1.

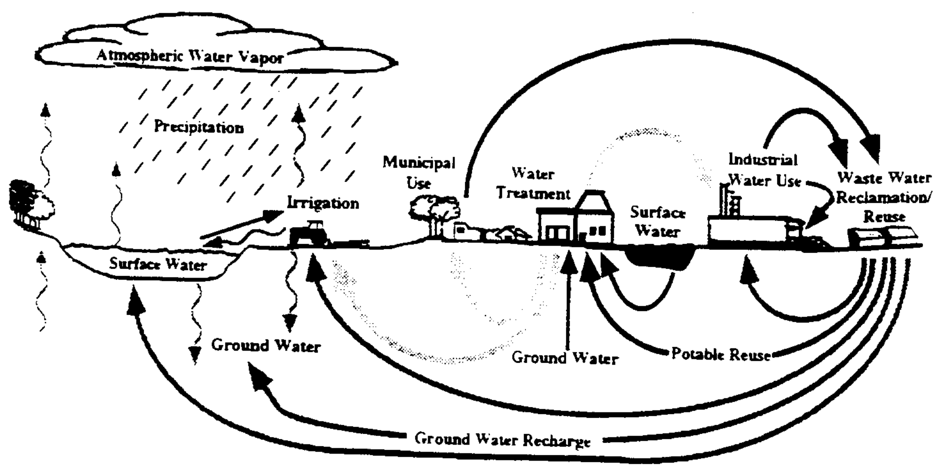

Figure 6–1. The Role of Engineered Treatment, Reclamation, and Reuse Facilities in the Cycling of Water through the Hydrologic Cycle (Asano and Levine, 1996).

R0025829

Urban wet weather flow management should be viewed within the context of overall urban water management. Such an integrated framework was proposed in the late 1960s and is regaining favor in the mid-1990s. Changes in urban water use are occurring thanks to aggressive water conservation practices which will significantly reduce indoor and outdoor water use. Based on recently collected data, per capita indoor residential water use is stable at an average of 60 gal/capita-day (Heaney et al. 1998). Aggressive hardware changes, such as low flush toilets, should reduce this usage rate to 35 to 40 gal/capita-day. Only a small proportion of this indoor waste is black water. Most of it is gray water that could be reused for lawn watering and other non-potable purposes. Peak water use in most cities is heavily influenced by urban lawn watering. This outdoor water use does not require potable quality. As the cost of water treatment continues to increase, dual water systems become more of a possibility, particularly with a decentralized infrastructure.

California has been a focal point of water reuse for some time. Ashcraft and Hoover (1991) found that reclaimed water in southern California is selling at prices ranging from $303/AF (acre-foot) to $366/AF, with costs of operation and maintenance of treatment facilities running from $10/AF to $95/AF. The authors argue that "avoided costs," such as those associated with wastewater disposal should be included in cost calculations. Requa et al. (1991) developed a wastewater reuse cost model for screening purposes in northern California. More recently, Tselentis and Alexopoulou (1996) describe a feasibility study of effluent reuse in the Athens, Greece, metropolitan area. Uses considered were: crop irrigation, irrigation of forested areas, industrial water supply, and domestic non-potable use. The most cost-effective scenario was distribution for crop irrigation near the route of the current discharge point. At the other extreme, Haarhoff and Van der Merwe (1996) describe direct potable reuse of reclaimed wastewater in Windhoek, Namibia. Law (1996) describes the Rouse Hill project in Sydney, Australia, in which a dual non-potable distribution system was installed in a new community in 1994. Oron (1996) developed an integrative economic model, arguing that the optimal cost of a reuse system is a function of: treatment method; cost of treatment; transportation and storage costs (pipelines and tanks); environmental costs; and the selling price of reused wastewater. Anderson (1996a, b) describes new initiatives for reusing stormwater flows for urban residential and industrial water supply systems in Australia. Mitchell, Mein, and McMahon (1996) used a water budget approach to integrate storage and reuse of urban stormwater and treated wastewaters for two neighborhoods in suburban Melbourne, Australia. Nelen, DeRidder, and Hartman (1996) describe the planning of a new development for about 10,000 people in Ede, Netherlands, that considers a dual water supply system. Storing the treated wastewater on-site during wet weather periods can be more attractive than reusing only black water (Pruel, 1996). Herrmann and Hase

(1996) describe rainwater utilization systems in Bavaria, Germany, that save drinking water and reduce roof run-off to the sewerage system. Imbe, Ohta, and Takano (1996) discuss the effect of urbanization on the hydrological cycle of a new development near Tokyo, Japan.

Much of this work has focused upon using treated wastewater from a single effluent plant. The problem then becomes one of locating demand centers for the wastewater, which are typically located some distance away. This becomes a nonlinear form of the transhipment problem, in which demand and distance are cost drivers in a nonlinear objective function. Many researchers have started to focus on less centralized systems, including Tchobanoglous and Angelakis (1996). Decentralized systems can take advantage of the segregation between wet weather flow, gray water, and black water, and possibly use less contaminated waters closer to their points or origin. Of the three, stormwater runoff is usually the least contaminated before central collection. This may avoid construction of additional treatment systems, pipelines, etc., and present significant cost savings. From the wet weather flow quality management perspective, there is much interest in local management of wet weather flow from smaller, more frequent events, as these events tend to have more pollutants associated with them. The primary on-site option is to encourage infiltration of this stormwater flow from roofs, driveways, parking lots, and streets. This infiltrated water increases the moisture in the unsaturated zone and raises the groundwater table which can provide benefits in terms of increasing base flows in streams and providing stormwater to help meet the evapotranspiration (ET) needs of the local vegetation.

One of the most prevalent themes advanced in the recent literature in wet weather flow management is to limit the generation of runoff from urban areas through the use of best management practices and on-site control of wet weather flow, a form of reuse, particularly in frequent small storm events (Mitchell, Mein, and McMahon, 1996). Butler and Parkinson (1997) suggest that reuse of stormwater provides a more sustainable urban drainage infrastructure by minimizing available wet weather flow that could possibly be mixed with wastewater; as well as attempting to minimize the use of expensive drinking water for irrigation. The diagram in Figure 6–2 indicates that reuse of stormwater closest to the point of generation is the highest and best use that will yield sustainable systems. Pitt et al. (1996) suggest that residential stormwater (i.e. roofs and driveways, not streets) generally has the least amount of contamination and advocate infiltration of residential stormwater as a means of disposal with few environmental impacts.

In keeping with this theme, a possible model of a residential on-site control system is shown in Figure 6–3. Precipitation falls on roofs and driveways and is channeled, with some losses, into a storage tank. The storage tank varies in size depending on the location. Water is taken from the tank for irrigation of landscape surfaces; some is used for ET, some is lost to infiltration, and some is lost to runoff. In essence, this model is an irrigation, or water deficit demand model. Irrigation demand is determined mainly from ET requirements. To calculate ET, water is budgeted daily or monthly. By examining the water balance of one residential parcel in differing climatic zones, the efficacy of the option of on-site reuse of stormwater can be evaluated across the United States. Heaney et al. (1998) performed such an analysis and found that, for many areas of the country, particularly humid ones, enough stormwater can be collected to satisfy average irrigation demands. Arid areas of the country with high ET requirements may not satisfy their irrigation demand by stormwater reuse alone; some combination of graywater and stormwater may need to be considered in these cases.

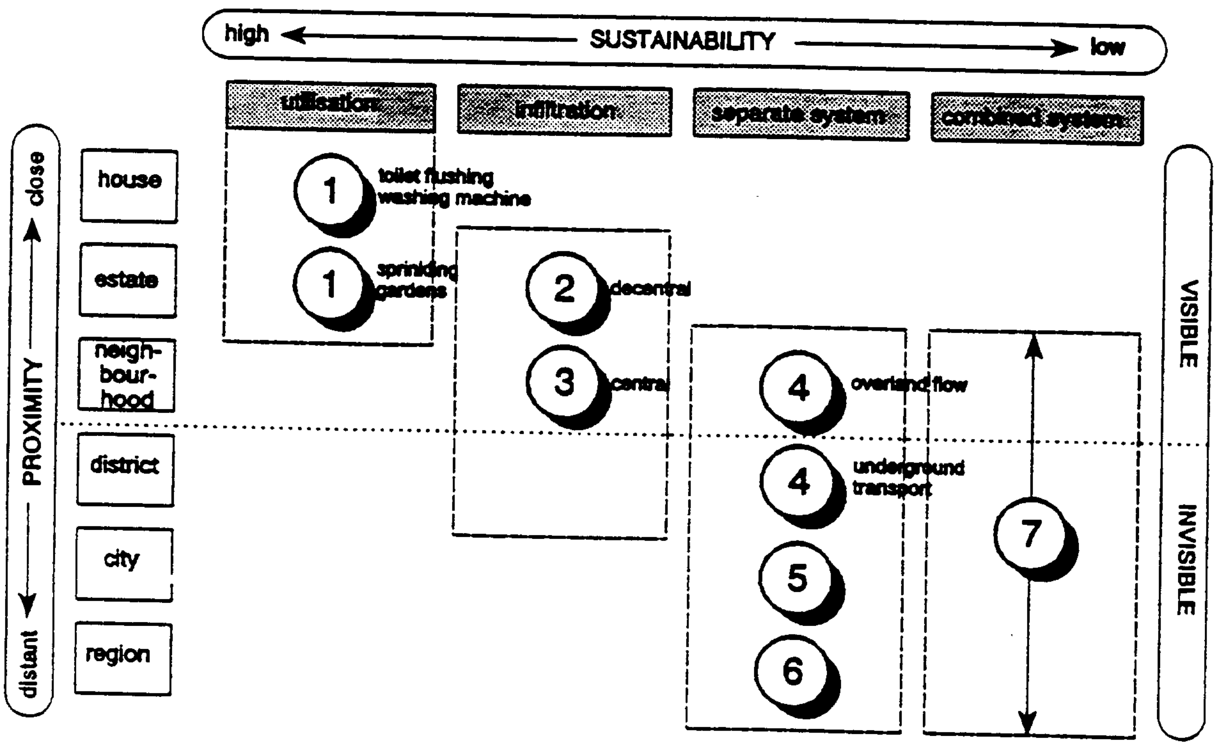

Figure 6–2. Stormwater Handling Priority Diagram, Based on Sustainability, Proximity, and Visibility (Veldkamp et al., 1997)

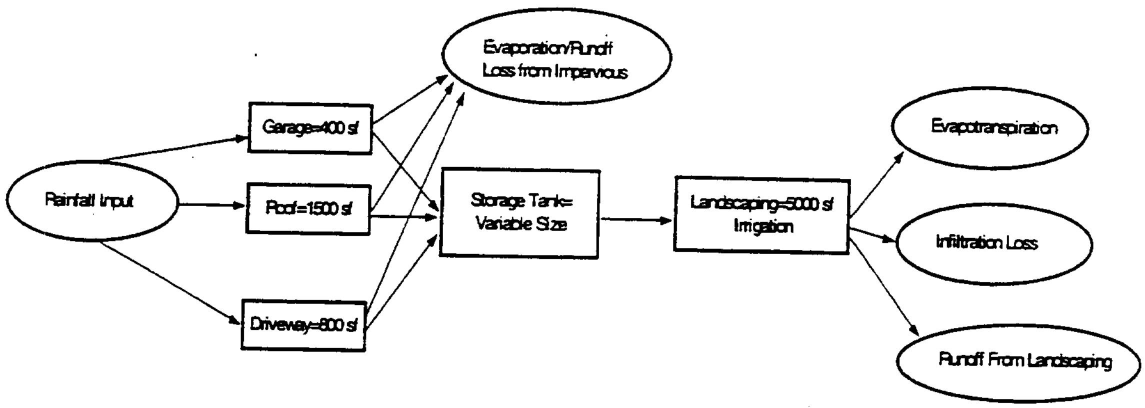

Figure 6–3. Concept of Stormwater Reuse Residential Storage System (Heaney et al., 1998)

Urban water reuse is an attractive possibility for 21st century systems. Stormwater from roofs and driveways has been shown to be of high quality and suitable for lawn watering, toilet flushing, showers, etc. Graywater from showers and baths can be used for lawn watering. Case studies of innovative systems such as the "Casa Del Agua" house in Tucson, Arizona (Foster, et al. 1988 and Karpiscak, Foster, and Schmidt (1990), the Rouse Hill Development in Australia (Law, 1996), and several in Germany (Herrmann et al. 1996) illustrate the potential of on-site water management. With aggressive on-site controls the need to import water for water supply is decreased significantly. Correspondingly, the amount of wastewater discharged off-site is also much less. Future work on both centralized and decentralized stormwater and graywater reuse systems needs to focus on economic evaluation; the area shows much promise due to the enormous amount of potential water supply available.

6.3 Financing and Cost Analysis

Stable funding is an essential ingredient in developing and maintaining viable urban water organizations, whether they are stormwater utilities, watershed organizations, or some other organizational form. Integrated management offers the promise of improved economic efficiency and other benefits from combining multiple purposes and stakeholders. However, the benefits from integrated watershed management exacerbate problems of financing these more complex organizations, since ways must be found to assess each stakeholder's "fair share" of the cost of this operation. Nelson (1995) provides a current overview of utility financing in the water, waste-water, and stormwater areas. At least 20 states have organized their activities, in varying degrees, around watersheds (Nagle et al., 1996). For many of these state programs, nonpoint pollution control is a primary objective. These state-based watershed water quality programs are supported by reallocating existing state program monies, some of which originate from US EPA. A major gap in funding at present is the inability of the federal government to "block fund" multipurpose local agencies such as watershed organizations. Local water agencies must deal with a large number of independent federal agencies with complex requirements for obtaining financial support.

US EPA used to maintain and widely distribute information on the cost of controls. The cost estimates for the EPA Needs Surveys give helpful data, e.g., Scott et al. (1992). However, much-improved accounting and cost-reporting methods are needed to learn the true costs of various parts of wet weather management. Many urban water control facilities are multipurpose. Hence, accurate methods to properly assign costs are essential. Newer methods such as activity-based costing are helpful in this regard., but, the longer-term solution is to directly link process simulators such as SWMM with accounting systems so that costs can be properly assigned as the wet weather flow moves through and out of the urban area.

The current interest in benefit/cost analysis as part of WWF evaluations demands improved methods of estimating benefits. This has been an active research area and relatively reliable methods are now available. With proper control of WWFs, many urban receiving waters are being rejuvenated and providing a focal point for large-scale urban redevelopment.

6.3.2 Methods of Financing

Fort Bend County, Texas, issued tax-exempt revenue bonds and impact fees to finance its drainage improvement projects (Gilligan, 1996). Urban stormwater utilities have been a successful way to fund wet weather flow pollution control systems (Benson, 1996; Reese, 1996). Roesner, Mack, and Howard (1996) describe a wet weather flow master plan that formulates an integrated way to finance necessary stormwater infrastructure for a new development near Orlando, Florida. Henkin and Mayer (1996) describe how US EPA's Environmental Financial Advisory Board (EFAB) and Environmental Financing Information Network (EFIN) can be used to create a financing strategy for implementing comprehensive conservation and management plans. One of the most promising financing alternatives for wet weather flow infrastructure needs has been the development of a stormwater utility which can assess user fees (Ferris, 1992; Reese, 1996; Benson, 1992). Debo and Reese (1995) provide a good overview of stormwater utility financing. Collins (1996) describes the formation of a county-wide stormwater utility in Sarasota, Florida. EPA used this county as its first stormwater NPDES permit in the state of Florida. Pasquel et al. (1996) describe the multifaceted funding mechanisms used by Prince William County, Virginia, to fund the county's watershed management program. The sources include a stormwater management fee based upon density and area of impervious surface and development impact fees. The authors include a detailed discussion of the major components of the fee structure. Nelson (1995) describes alternative methods for calculating system development charges for a stormwater utility.

6.3.2.1 Research Needs

Research is needed on innovative financing methods including financing urban stormwater as part of a watershed management organization.

6.3.3 Methods of Cost Allocation

Methods of finance and revenue generation cannot simply be used alone. Costs must be allocated among users in such a way as to preserve equity; otherwise users will pursue more reasonable alternatives. McDonough and Converse (1973) examine the trade-off between pipeline and treatment costs. They propose the "added pipe rule," i.e., that a community or group that causes a new trunk pipeline to be built should pay for it. Young (1982) develops fairness criteria for an allocation method, and finds that the generally accepted separable cost, remaining benefits (SCRB) allocation model does not meet these criteria. Young postulates that, as the size of a coalition grows, the cost savings exponentially increase up to a point, then approach a constant value, decreasing the impetus toward larger and larger groups. Heaney and Dickinson (1982) use cooperative *n*-person game theory to develop the minimum costs, remaining savings (MCRS) method, which satisfies many of the criteria Young (1982) proposes (*n* is the number of participants). Ng and Heaney (1989) further explore this method further. The method uses combinations of participants to determine an equitable allocation of the project costs. A major disadvantage of the method is that the number of coalitions to evaluate is determined by the following formula: (2^n-1), and consequently expands rapidly as the number of participants grows. Lejano et al. (1992) use some of these fairness criteria in allocating costs of a water reuse project in Los Angeles.

Strus and DeWitt (1996) developed an environmental charge cost allocation model, which allocates significant environmental costs to rate-payers by use of relational database technology. The algorithm is based on an activity-based percentage of use. Heaney (1997) summarizes this literature including applications to urban stormwater management. The area of cost allocation should be expanded to include the balance between rates and system development charges.

6.3.3.1 Research Needs

Fairly assigning system costs to users requires research to link activity-based costing models to urban hydrologic simulation models such as SWMM. Another area of possible research is the use of long-term economic and financial simulation to evaluate the sustainability of urban water management.

6.3.4 Development of Cost/Performance Data for Controls

Rudolph and Balke (1996) found that, in Zwickaw, Germany, an alternative stormwater disposal system was cheaper than connecting to the municipal storm sewer system by a factor of almost 2.5. This results primarily from connection fees due to the high costs of treating and storing urban stormwater without including social costs. Bautista and Geiger (1993) summarize the findings of a wetlands system that treats residential storm runoff before discharge into Lacamas Lake, Washington. The authors found that the system was effective at reducing sediment and nutrient loadings into the lake. Ferguson (1990) developed a monthly water balance model and applied it to 12 different infiltration basins in the Atlanta, Georgia, area. The basins differed by construction techniques and management objectives; results were reviewed in terms of costs and performance. Schmidt, Seta, and Averill (1997) describe a multi-agency pilot program for evaluation of controls in the Great Lakes area. Controls evaluated were vortex separator, a circular clarifier, a horizontal-flow plate clarifier, and an inclined rotary drum screen. Findings indicated that the vortex separator and plate clarifier achieved reductions of 50% in total suspended solids and 30% in biochemical oxygen demand (BOD), which is a possible goal of the province of Ontario. Wanielista et al. (1991) summarize research in the use of granular activated carbon (GAC) filter beds to remove trihalomethanes from an urban stormwater detention pond. Cost of treatment was approximately $4.39/1,000 gallons, annually. Li and Adams (1994) derived several analytic probabilistic models to predict from rainfall statistics the long-term performance of storage treatment devices.

Labadie et al. (1984) describe CSUDP/Sewer, and its stormwater control package, which is a model for conducting simulated real-time experiments in urban stormwater systems. The model can identify least-cost vertical layouts and sizings of storm drainage systems. The authors applied the model to identify optimal horizontal layout, which involves nonlinear programming and network flow theory; more testing on this problem is necessary.

6.3.4.1 Research Needs

Uniform information is needed on the total cost of wet weather flow controls and how to properly apportion these costs for multi-purpose projects. Information on costs and performance are typically the most difficult to get, so any new information gathered should be disseminated in the widest form available (e.g., World Wide Web).

6.4 Benefits of Urban Wet Weather Flow Management

Methods for assessing the benefits of wet weather flow quantity control, in terms of reducing flood damage by providing structural and non-structural controls, are well established, e.g., James and Lee (1971), Johnson (1985). Quantifying the benefits associated with water quality improvements or the dual problem of quantifying the damages associated with water quality degradation are more difficult, but a significant body of literature represents the subject. Heaney (1994) reviews alternative environmental valuation methods and proposes property valuation as a good integrative measure of the benefits or disadvantages associated with water quality. He includes the results of case studies in Florida of lakes that have a wide variety of water quality, size, and water level fluctuation. The same approach is used on the land side to evaluate the economic impact of providing flood control and drainage. Other ways to measure the direct user benefits include recreation travel costing, and defensive expenditures to ameliorate undesirable effects. A more recent approach is to evaluate non-user benefits, e.g. the benefits a person gains from knowing that a natural resource is being protected even if this person does not use or visit this resource. Cummings and Harrison (1994) present an evaluation of non-use values. Russell (1994) describes how these benefit assessment methods can be used in the decision making process.

Contingent valuation has been successfully applied to evaluate the value to customers of improved water supply reliability. The California Urban Water Agencies conducted a contingent valuation survey of 4,000 randomly sampled customers. Customers were asked to vote on a hypothetical referendum. If the majority voted yes, monthly water bills would be increased by a specified amount and there would be no future water supply shortages. If they voted no, utility bills would remain the same but shortages would continue (Hoag, 1997). The results (Figure 6–4) indicate a willingness to pay an additional $11 to $17 per month per customer to avoid future shortages of indicated frequency and severity. These results helped assess the economic value of reliability.

George (1996) discusses the pros and cons of using benefit/cost analysis (BCA) for environmental projects. Rudolph and Balke (1996) conducted a BCA of alternative wet weather flow management systems for new residential development in the cities of Dortmund and Zwickau, Germany.

Despite these advances, quantifying benefits in urban wet weather flow management has remained a difficult task. If benefits could be determined, cost/benefit analysis could be done quite easily, as typically cost data are available. For an overview of cost/benefit analysis in water resources, see Kneese (1993). There are indirect ways of determining benefits. One of these is real estate valuation, an example of which is given in Frederick et al. (1996). The authors describe ways of making urban wet weather flow management attractive; and, if this is done, give estimates from developments in which property was made more valuable than without it (Table 6–2).

Another problem related to evaluating benefits is assessing performance. Overall watershed and ecosystem health are determined by many synergistic and related factors that cannot usually be boiled down to a single indicator that is easy to measure. This problem is illustrated in Figure 6–5 from Holmes (1996). The author is not recommending giving up the quest for a performance measure, just suggesting that it is difficult to measure performance of a management system whose goal is to protect an ever-changing environmental system in which the interrelationships are not fully understood. The measuring process is something of a moving target.

It is possible, however, to develop broad criteria of performance that can be used to focus on the weaknesses suggested by Holmes (1996). Such studies may reflect the fact that our knowledge of the problem may not sustain the high degree of resolution typically required in scientific research. Such a system was developed by AMSA (1996), which ranks performance profiles by simple subjective criteria. This study categorizes performance measures and gives advantages and disadvantages, relative cost ratings, and key attributes of each (Table 6–3). Lindsey, Swietlick, and Hall (1997), reporting on a research project for the Water Environment Research Foundation, list key stormwater quality indicators (Table 6–4). Together, these begin development of performance systems for CSO control and urban water management. However, key technical and policy issues remain. Some of these issues are (Lindsey, Swietlick, and Hall, 1997):

- What incentives can serve as the impetus for water resource managers to move to a watershed management approach? How can states and US EPA afford to move to watershed management given shrinking resources?

- Watershed management and the use of environmental indicators may be more complex than traditional source-by-source management. How do managers and their agencies overcome these new complexities?

- Is the current statutory scheme under the Clean Water Act adequate to fully deal with urban wet weather problems? If not, in what respects should it be changed?

- What are effective strategies to address the challenges posed by watersheds that cross multiple jurisdictional boundaries? What roles should different levels of government, industry, and the public play?

- How can monitoring data and BMP performance information be comparably generated, usefully accumulated, and fully shared with interested parties?

- How can wet weather data and watershed information be used at a national level for decision making and future program direction?

- How do regulators ensure accountability under a watershed approach that may rely more on performance-based results and less on end-of-pipe compliance monitoring?

Location	*Base Costs of Lots/Homes*	*Estimated Water Premium*
Chancery on the Lake, Alexandria, VA	Condominium: $129,990 to $139,990	Up to $7,500
Centrex Homes at Barkley, Fairfax, VA	Home with lot: $330,000 to $368,000	Up to $10,000
Townhomes at Lake Barton, Burke, VA	Townhome with lot: $130,000 to $160,000	Up to $10,000
Lake of the Woods, Orange County, VA	Varies	Up to $49,000
Dodson Homes, Layton, Fauquier County, VA	Homes with lot: $289,000-$305,000	Up to $10,000
Ashburn Village, Loudon County, VA	Varies	$7,500 to $10,000
Weston Development, Broward County, FL	Home with lot: $110,000 to $1,000,000	$6,000 to $60,000 depending on lake size, location, and the percent of lakefront property in the neighborhood
Silver Lakes Development, Broward County, FL	Varies	$200 to $400 per linear foot of waterfront, depending on lake size and view
Highland Parks, Hybernia, IL	Waterfront lot: $299,900 to $374,900	$30,000 to $37,500
Waterside Apartments, Reston, VA	Apartment rental	Up to $10/month
Village Lake Apartments, Waldorf, MD	Apartment rental	$5 to $10/month depending on apartment floor plan
Lake Arbors Towers, Mitchellville, MD	Apartment rental	$10/month
Marymount at Laurel Lakes Apartments, Laurel Lakes, MD	Apartment rental	$10/month
Lynne Lake Arms, St. Petersburg, FL	Apartment rental: $336 to 566/month	$5 to $35/month depending on lake size
Sale Lake, Boulder, CO	Waterfront lot: $134,000	Up to $35,000
The Landing, Wichita, KS	Waterfront lot: $35,000 to $40,000	Up to $20,000
Fairfax County, VA	Commercial office space rental	Up to $1/square foot
Laurel Lakes Executive Park, Laurel, MD	Commercial office space rental	$1-$1.50/square foot

Water Quality Indicators:
Water quality pollutant monitoring
Toxicity testing
Nonpoint source loading
Exceedance frequencies of water quality standards
Sediment contamination
Human health criteria
Physical and Hydrological Indicators:
Stream widening/down cutting
Physical habitat monitoring
Impacted dry weather flows
Increased flooding frequency
Stream temperature monitoring
Biological Indicators:
Fish assemblage
Macroinvertebrate assemblage
Single species indicator
Composite indicators
Other biological indicators
Social indicators:
Public attitude surveys
Industrial/commercial pollution prevention
Public involvement and monitoring
User perception
Programmatic Indicators:
Number of illicit connections identified/corrected
Number of BMPs installed, inspected, and maintained
Permitting and compliance
Growth and development
Site Indicators:
BMP performance monitoring
Industrial site compliance monitoring

6.4.2 Contingent Valuation

The contingent valuation method of estimating benefits uses survey information in which respondents are asked to place a value on a given environmental benefit and how much they are willing to pay for it. Rogerson (1996) explains the concept of contingent valuation and how it would apply to the water field. Crase (1996) applies contingent valuation to establish a value for wetland and woodlot areas, created as a result of a wastewater reuse project to come up with estimates of benefits for the project. Loomis (1994) uses contingent valuation to establish values for whooping crane habitat, improved water quality along the Platte River wetlands, and instream flow needs. The author also suggests how these values can be integrated into the benefit/cost framework.

Whitehead and Groothuis (1992) apply contingent valuation to the Tar-Pamlico Basin of North Carolina, and found that the benefits of improved water quality were $1.62 million each year, and based upon this finding, a survey of voters determined that they were willing to pay $1.06 million per year to achieve these improvements.

Finally, Lindsey (1992), used contingent valuation techniques to estimate the benefit of two separate wet weather flow control plans resulting in 1% and 4% nutrient loading reductions to the Chesapeake Bay. The benefits were estimated to be $1.2 million and $4.2 million, respectively. Responders preferred user charges over property taxes to pay for these reductions, but, the charging vehicle did not appear to affect their value of the reduction. Notwithstanding, the author suggests that simultaneously valuing public goods as well as evaluating the method to pay for them may not be valid.

6.4.2.1 Research Needs

Innovative methods are needed to quantify the benefits of urban water management systems. Contingent valuation has shown some promise. Significant problems remain to be solved in using this technique, and more work is necessary.

6.4.3 CSO Measures of Success

Holmes (1996) describes the difficulty of measuring success of operation in water pollution control. In many cases, despite successful operation, other factors may cause ambient water quality may go down. There is a contradiction, however, in that the owners of treatment facilities often insist on such measures. The author suggests using quasi-biological systems as measures of effectiveness that value survival. Saget and Chebbo (1996) suggest that the following characteristics of discharges from storm sewers are important in measuring negative impacts:

- Annual loads (to determine cumulative effects);
- Loads per event (to determine acute effects over several hours); and
- Loading within events (to establish variation in small time intervals).

This work was based upon the database QASTOR, which contains both combined and separate storm sewer water quality data. Vanderkimpen, Diels, and Huberlant (1996) assess the different methods for estimation of CSO spill frequency such as:

- Spill frequency charts;
- High frequency synthetic storms;
- Composite high frequency synthetic storm; and
- Short historical rainfall series and continuous rainfall data.

The authors conclude that the spill frequency charts are relatively accurate for simple systems, but they make some assumptions that are unique for each chart and must be taken into consideration. High frequency synthetic storms may underestimate the spill frequency significantly. Composite high frequency synthetic storms correct somewhat for this, but the best method was the properly selected short historical rainfall series. Breur, van Leeuwen, and Dellaert (1996) developed a "discharge strategy" which is part of the decision model for an urban drainage system. Hedges (1994) used models for prediction of performance, and compared them with actual efficiency. In the United States, Lindsey, Swietlick, and Hall (1997) and AMSA (1996) developed broader, simpler versions of performance criteria.

6.4.3.1 Research Needs

More work in this area is needed to develop standardized measures of performance for CSO controls, particularly quantitative ones.

6.5 Education and Outreach

Education is an important nonstructural BMP component of an urban wet weather flow management plan, both in terms of the general public, and municipal, state, and federal professionals. The latter group is particularly important when there is an increasing burden on municipal government in terms of regulatory compliance, at a time of decreasing funding, and possibly mixed political commitments on the local level. US EPA has, in certain cases, required an educational component of a municipal stormwater discharge permit as a nonstructural BMP (Pitt et al., 1997). According to Urbonas (1998), the point of public education is to modify behavior, but the he finds that little is known about the effectiveness of such programs.

Schumacher and Grimes (1992) describe the public education program developed as part of the Charlotte, North Carolina wet weather flow planning process. This program consists of:

- Inform the public about regulatory requirements; and
- Formally involve special interest groups in the wet weather flow management process.

General guidance on education and outreach can be found in Beech and Dake (1992) and US EPA (1993). Fujita (1993) describes an extensive education program in Tokyo, Japan, to explain the new Experimental Sewer System (ESS). This education program convinced the public of the advantages of infiltration in reducing local flooding and restoring desirable groundwater conditions. The state of Illinois has prepared several education booklets to explain the watershed management program to the public (Water Environment and Technology, 1996).

Current studies in Austin, Texas, are the first to explicitly link investments in public education with improvements in receiving water quality (Pitt et al., 1997). While this link will probably remain difficult to establish directly, public education is an essential component of urban wet weather flow management.

A number of local public education programs for cities abating wet weather flow pollution were sponsored by US EPA (Austin, Latrou, and Rheams, 1996; Feuka, 1996). A multi-media public information campaign was an important part of efforts to achieve a 40% reduction of nutrients entering Chesapeake Bay (Leffler and Flagle, 1996).

Two important key areas of research are public involvement and participation techniques and coordination of research across agencies. A more detailed analysis of these areas follows.

6.5.2 Public Involvement, Participation Techniques

Lange (1991) suggests identifying important stakeholders most interested in decision making in river corridor planning, as well as developing an information and education program. The author also stresses that the planning effort should have a "clear vision" and should focus on budgetary concerns for implementation.

Terranova and Tice (1995) describe the public involvement in the NEPA analysis done for several towns in Illinois devastated by the 1993 Midwest floods; an environmental review of alternatives is required by NEPA and FEMA before construction. The process was an attempt to: 1) maximize public involvement, while maintaining a fast track toward environmental assessment (EA) adoption, through on-site and telephone interviews, 2) educate the public on the NEPA process, 3) prepare a site-specific summary of the draft EA for the community to review, 4) notify the public about pending meetings and deadlines, and 5) facilitate a public forum prior to finalization of the EA. In application, it was found that attempting to facilitate more public involvement earlier in the process would better assist local decision making that became protracted as a result of delays in public awareness of the issues.

Nazarenus (1995) describes the sometimes difficult process of increasing citizen involvement, first laying out several basic rules, including using layman's terms instead of technical ones, and discussing the project with those directly involved to attempt to increase their "ownership" of the project. Techniques the author used include: open houses, professional technical assistance, training sessions, marketing techniques, and better customer support.

Stiftel (1990) evaluates the North Carolina NPS pollution control program (see Section 6.1.2) and found significant disagreement between staff interpretations of public support and public survey results. The author suggests that this is caused by the undue influence of private interests, as well as inherent bias and tendency toward categorization. Stiftel also found that there are, with qualification, significant subgroups within the general population; however, the vast majority tended to be moderate on development and environmental issues. Marcy and Gerritsen (1996) describe the active, diverse citizen involvement in managing the Chesapeake Bay ecosystem.

6.5.2.1 Research Needs

Methods should be developed to evaluate the efficacy of public involvement and participation techniques. Case studies could be included.

6.5.3 Coordination of Wet Weather Flow Research Across Agencies

Simonovic and Bender (1996) describe a collaborative planning-support system (CPSS) which, by integrating models and databases from different areas in a user-friendly environment, enhances the iterative planning process by enhancing the communication between disciplines. Sherman (1995) advocates the need for inter-agency coordination to develop cost effective solutions to environmental degradation caused by wet weather flow management. Scott (1996) provides a literature review of wet weather flow research across Australia to assist in interagency coordination and avoid duplication.

Lesouef (1996) discusses water management institutions and the concepts of centralization versus decentralization; the author found that significant cultural and political context, geography, water surplus or shortage, and the necessity of a dynamic equilibrium were factors which influenced the degree of centralization chosen by the institution. Korf, Wilken, and Nel (1996) describe the formation of a wastewater management company in the East Rand of South Africa. They compare this model with other management organizations, including agencies, private companies, metropolitan boards, local governments, central governments, mix of public and private entities, and river basin management organizations.

6.5.3.1 Research Needs

Comparative studies of U.S. practices versus programs in other countries would be helpful. Countries such as Great Britain and Australia are conducting multi-purpose watershed research. It would be useful to compare coordination of research within this context. A collaborative effort with the public administration field in this area may be beneficial.

CHAPTER 7.0

CONTROL TECHNOLOGIES

Table 2–8 presents a master list of 67 research needs that involve control technologies to reduce wet weather impacts. These may be grouped into three general categories:

- Source control at the land-parcel or street-side level, e.g. on-site storm management and grass-lined swales;
- Collection system innovations, e.g. sewer rehabilitation; and
- Treatment and storage technologies, e.g., end-of-pipe, high-rate treatment systems.

Some of these technologies have been used in the field of urban wet weather management for some time but may be described as evolving because they are not widely used and are not fully understood at a process level; others may be more aptly described as being in their infancy. Recent work has focused on the integration of the urban water cycle (of which urban drainage is a component) with land use planning under the guiding principle of creating a more sustainable urban environment (Butler and Parkinson, 1997).

7.1 On-Site Control

Of the 67 control-oriented research needs listed in Table 2–8, 14 were identified as dealing primarily with on-site control. Section 7.1.2 covers two topics from Table 2–8, swales and swales instead of curbs. Section 7.1.3 covers three topics from Table 2–8, reduction of directly impervious surfaces, modification of urban surfaces to reduce hydraulic and pollutant loads, and performance of porous and permeable pavements. Two other, more generic, sections, toxic source reduction and improved source reduction are included in the section on modifying urban land-surfaces, but also involve many other research. Chapter 3.0 and Section 3.2 specifically cover characterization of toxic sources. Research needs associated with source reduction first require characterization of pollutants. However, the concept of pollutants associated with urban surfaces is generic, and research needs presented in Section 7.1.3 are indirectly relevant to toxic-source reduction. This section presents one-page summaries of nine on-site controls, and further research needed to improve their performance. The organization of research needs topics is shown in Table 7–1.

Control of urban wet weather impacts has traditionally been achieved through public drainage works; typically capturing urban runoff after it leaves privately owned lands. Drainage works on private lands are designed to collect runoff and transport it from urban land parcels to public drainage works as efficiently as possible. This "minor" drainage system typically provides drainage for events with recurrence intervals of 2 to 10 years (Table 7–2) and provides relief from nuisance flooding (ASCE/WEF, 1992). "Major" drainage ways are natural or improved channels that convey runoff that exceeds the capacity of the minor system, including emergency outfall facilities (ASCE/WEF, 1992). The level of service expected from conventional urban drainage works is shown in Table 7–2. The technologies described in this section are primarily concerned with modifications of the way parcel-level drainage interacts with the minor drainage system, and how the minor-drainage system operates. Therefore, on-site control technologies are designed to affect frequent storm runoff events: those with return periods shorter than 0.5 years. Candaras, Carvalho, and Koo (1995) refer to this category as micro-storm management.

With regard to urban runoff quality, traditional urban drainage works have exacerbated certain deleterious impacts of imperviousness: for example, nonpoint source (NPS) pollution accumulates on impervious surfaces and is transported via surface runoff directly to receiving waters (Schueler, 1995; ASCE/WEF, 1992). Impervious surfaces increase storm runoff volume and the peak flow rate and decrease the time-to-peak flow, effectively decreasing the level of service provided by stormwater infrastructure investment. In addition, a valuable resource has been "wasted" in areas where outdoor water use is a major component of the urban water cycle.

The impact of the automobile on urban runoff quality has been an especially important aspect of urban land use over the past 50 years. Imperviousness may be seen as a function of road width and lot density. Schueler (1995) highlights the importance of land-use planning in terms of pervious or impervious surfaces for urban NPS reduction.

Table 7–1. On-Site Control Research Needs (Unprioritized)

Section	*Table 2–8 ID#*	*Research Topic*
7.1 On-Site Controls		
7.1.2 Swales	88	Effectiveness of swales
	96	Swales instead of curbs
7.1.3 Modifying urban surfaces	151	Reduce directly connected impervious area
	90	Modifying urban surfaces to reduce hydraulic and pollutant loads
	109	Performance of porous and permeable pavements
	94	Improved methods of source reduction
	93	Toxics sources reduction
7.1.4 Reduce I/I from laterals	152	Reduce I/I in house service laterals
7.1.5 Design improvements for micro-storms	91	Urban drainage design improvements for micro-storms
7.1.6 Stormwater reuse	95	Stormwater reuse
7.1.7 Storm inlet devices	97	Storm inlet device
7.1.8 Industrial runoff control	98	Industrial runoff control
7.1.9 Reuse of runoff as cooling water	89	Reuse of urban runoff as cooling water
7.1.10 Roadway and airport deicing	99	Roadway/airport deicing

Table 7–2. Design Storm Frequencies for Minor and Macro Drainage Systems (ASCE/WEF, 1992)

Land Use	*Design Storm Return Period*
Residential	2 to 5 years
High value commercial	2 to 10 years
Airports (terminals, roads, aprons)	2 to 10 years
High value downtown business areas	5 to 10 years
Major Drainage System Elements	50 to 500 years

As a result of the impacts of impervious surfaces on runoff quality, wet weather researchers have investigated various means of reducing stormwater runoff and associated NPS pollution at the urban-parcel level. Researchers are attempting to implement broadly defined societal goals such as "sustainability" along with traditional goals of public health and safety and environmental protection. For example, recent work in Henze et al. (1997) and Sieker and Verworn (1996, 1997) highlight the problems associated with accounting for the future external costs of urbanization. The time scales relevant to the sustainability of urban drainage works are shown in Figure 7–1. Along with unforeseen scenarios, the difficulty in developing truly sustainable systems seems to lie in the uncertainty associated with forecasting the nature of the future urban environment within which the drainage infrastructure must operate.

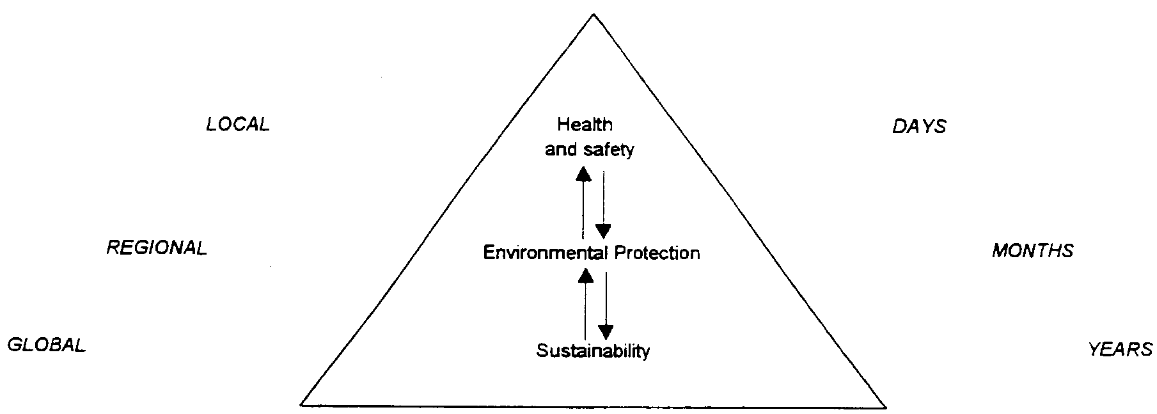

Figure 7–1. Hierarchy of Objectives of Drainage Systems Showing Increasing Extent of Spatial and Temporal Effects (Butler and Parkinson, 1997)

Larsen and Gujier (1997) describe the essential dilemma created by drainage works in dense urban land use:

> Urban drainage is fundamental for preventing flooding of many urban areas. Although urban drainage has serious consequences for the water cycle and for the quality of receiving waters during storm events, it is not possible to maintain present population densities without this service. In many urban areas a continuous draining of groundwater is necessary.

Urban drainage is therefore a necessary service for a rapidly urbanizing world. If we are to reduce long-term costs of urbanization and move toward sustainability, urban drainage works should move toward the following goals (Nelen, de Ridder, and Hartman, 1996):

- Control at the source;
- Control of the source;
- Minimization of flows;
- Use of sustainable materials; and
- Minimization of energy and other resources.

Figure 7–2 presents a conceptualization of these goals. On-site control strategies such as stormwater utilization (e.g., stormwater reuse) score high on the sustainability axis because reuse does not require the transportation of "wastes," and does not mix stormwater with that of other origins. The goals of on-site technologies may be summarized as follows (adapted from Pitt et al. 1997; Butler and Parkinson, 1997; Larsen and Gujer, 1997):

- Utilize stormwater as a resource;
- Minimize NPS pollution loads on a frequent-storm basis;
- Minimize quantity of runoff to better control flooding;
- Better satisfy short-term societal goals of public health and safety;

- Adhere to societal goals of minimized environmental impact; and

- Move toward satisfying long-term societal goals, such as sustainability.

7.1.2 Swales

Grassy swales have been recommended as a best management practice (BMP) in urban runoff control for some time, particularly for runoff from highways. Urbonas, Roesner, and Guo (1996) define a grassy swale as a component of a runoff treatment system that holds stormwater from one event until displaced by the next. Yousef et al. (1985) found that for highway runoff flowing over swales, ionic components of heavy metals and nutrients were reduced; possibly by "sorption, infiltration, precipitation, co-precipitation, and biological uptake." Urbonas (1997) documents the current literature on grassy swales as a BMP. Current research is consistent with past findings; namely that there is a significant removal of pollutants (e.g. from 20 to 40% removal of total suspended solids). Urbonas (1997) suggests that grass swales are most appropriate in areas where slopes are less than 3 to 4%, which tends to lower flow velocities. Even better performance is achieved in soils with very high infiltration rates. This indicates that infiltration is the essential removal mechanism, and, due to this characteristic, grassy swales may reduce the runoff volume as well as the runoff peak in certain cases. Pitt et al. (1997) also document the current literature on the use of swales and include reviews on studies of the potential for groundwater contamination from infiltration. The authors indicate that groundwater contamination is not a major concern for the majority of urban areas. Livingston (1993) reports on work from Florida in which equations were developed to aid in the design of swales to achieve a given level of performance.

Livingston (1993) provides a good first step in the development of quantitative analysis of swales. Pitt and Voorhees (1997) summarize the application of the source loading and management model (SLAMM) which, based on a simplifying method using the statistical characteristics of small storm hydrology, enables a user during planning to assess the performance of a variety of controls, including swales. A computer model of a grassy swale/perforated pipe urban runoff treatment system was developed by Paul Wisner & Associates (1994).

7.1.2.1 Research Needs

There seems to be more quantitative analysis for the performance of wet detention ponds than for grassy swales. More work should be done in this direction so that the mechanisms of pollutant removal in swales are better understood and swales can then be integrated into stormwater treatment systems.

7.1.3 Modifying Urban Surfaces to Reduce Hydraulic and Pollutant Loads

The impervious nature of urban surfaces is a well-documented problem associated with urban drainage (Schueler, 1995). Modification of these surfaces to improve runoff quality and reduce runoff volume and peak flow is an attractive land-use modification that has shown promise in several applications around the world. Two major forms of urban surface modification are:

increasing pavement porosity, and reducing directly connected impervious areas. Porous and permeable pavement has been developed in three forms: porous asphalt, porous concrete, and permeable modular locking concrete blocks with open cells (Urbonas and Stahre, 1993; Pratt, 1997). Of the three, modular blocks show the most promise, because this form does not clog as quickly as porous asphalt or concrete, and is easier to clean and maintain (Urbonas and Stahre, 1993). Kresin, James, and Elrick (1997) report decreased infiltration capacity of porous pavement with age. There has been concern in the United States regarding the ability of porous and permeable pavements to withstand freeze–thaw cycles (Urbonas and Stahre, 1993). However, Pratt (1997) recently cited work in Sweden and the United Kingdom that indicates that porous pavement performance exceeds that of impermeable pavement. In the United States, Florida has been a leader in the use of porous pavement; 90,000 m^2 of the pavement were constructed by 1990 (Ferguson, 1994). In Tokyo, Japan, it is estimated that 494,000 m^2 of both porous and permeable pavement have been constructed since 1984 (Pratt, 1997). Reduction of directly connected impervious surfaces in an urban catchment involves hydraulically breaking the connection of impervious surfaces and the minor or local drainage works (Urbonas and Stahre, 1993). For example, retrofitting existing roof drainage downspouts is a common example of disconnecting impervious surfaces (Urbonas and Stahre, 1993). New development may use more advanced techniques, such as porous driveways and roof drainage to landscaped ground or to onsite reuse facilities. Problems with draining impervious areas to pervious land include boggy mosquito-breeding areas, poor snow removal, and hazardous roadside ditches (Urbonas, 1997). If infiltrated water has drained from impervious surfaces that are sources of NPS pollution groundwater contamination may be a concern (Pitt et al., 1996).

7.1.3.1 Research Needs

Quantitative, long-term assessment of these BMPs is greatly needed. Effects of enhanced infiltration on the urban water budget including groundwater and runoff quality must be measured. Fundamental physical processes of infiltration through porous or permeable pavements remain poorly understood. Cooperation with experimental research in Canada and Europe would be helpful.

7.1.4 Reduce Inflow and Infiltration in House Service Laterals

Infiltration and inflow (I/I) represent a large portion of the nation's treated wastewater. Nation-wide estimates of annual I/I volume are as high as 50% of total wastewater flow (Petroff, 1996). Houston, Texas, has reported peak to average ratios of sanitary wastewater flow as high as 50:1 (Jeng, Bagstad, and Chang, 1996). I/I can cause sanitary sewer overflows (SSOs), with sewer system surcharging typically occurring as peaking ratios reach 4:1 or 5:1 (US EPA, 1990). Traditional I/I reduction strategies employ remedial actions on the sewer collection system. However, privately owned house laterals may introduce as much as much as 70 to 80% of the total infiltration in a sanitary sewer (Field and O'Connor, 1997). Elliot et al. (1997a, b) report that private sources contribute more than 60% of I/I in Lower Paxton Township, Pennsylvania. This poses significant problems for the owner of an aging sewer system. Expensive field monitoring is needed to isolate leaking laterals. Flow monitoring in conjunction with video inspection is typically used. Gokhale, Kaufmann, and Stein (1997) describe new techniques of testing water tightness in existing buried pipes using low-pressure air tests. Air is pumped into the sewer, and the rate at which inflow air is required to keep the pipe at constant pressure is measured (Gokhale, Kaufmann, and Stein, 1997). While there is no known fundamental relationship between the rate that air leaks out of a pipe and water leaks in, there is a direct correlation: sewers that leak more water in, leak more air out (Gokhale, Kaufmann, and Stein, 1997). This technology may prove economically feasible as test cases are performed and the technology develops.

7.1.4.1 Research Needs

The problem of service laterals leaking extraneous flow into sewers is a problem of economics: the shear number of privately owned laterals prevents rehabilitation on a scale large enough to effect a change in wet weather flows. Monitoring technologies noted above may prove important in identifying deficient laterals; however the problem of the number of laterals, each with an independent owner, remains. Therefore, this research problem lies largely in the area of sewer system administration. Building code enforcement, billing strategies, and incentives for private owners to fix deficient laterals must be investigated. As monitoring and control of sewers becomes standard practice for other reasons, an indirect benefit may be the ability of a sewer owner to monitor leaks at the parcel level. Future sewer billing strategies may include a charge for the volume of service rendered, similar to what is done in the water supply field. Research conducted in this area should be closely linked with research in sewer monitoring and control, and with institutional changes in sewer administration.

7.1.5 Urban Drainage Design Improvements for Micro-Storms

The concept of design improvements for micro-storms is that, by concentrating on these more easily controlled events, the first flush of pollutants into the urban drainage system can be eliminated. Candaras, Carvalho, and Koo (1995) studied the performance of an exfiltration/filtration system and determined that it was successful at meeting the goal of micro-storm elimination. O'Loughlin, Beecham, and Goyen (1996) emphasize the need for research into smaller storms and smaller catchments to avoid overdesign. Because of the wide spatial and temporal variation in runoff, storms of short duration are defined with measurement intervals of one minute or less, using pluviograph records for more than 10 years. In the absence of this type of data, extrapolations of intensity–duration–frequency (IDF) curves are made. Another method was developed by Pitt and Voorhees (1993), who attempted to reduce the data requirements by statistical techniques, noting the similarities in the rainfall-runoff interrelationships for different urban areas. This technique is the basis for the source loading and management model (SLAMM)), which was later extended in Pitt et al. (1997).

7.1.5.1 Research Needs

Candaras, Carvalho, and Koo (1995) describe the need to develop physically-based algorithms, methods, and computer models to facilitate the application of the BMPs in the Etobicoke study so that their use can be easily extrapolated to other areas. More research must be done in terms of the data requirements and statistical properties of small and micro storm hydrology; possibly in the area of aggregation/disaggregation analysis before model development. As O'Loughlin, Beecham, and Goyen (1996) indicate, extrapolations of IDF curves from known storms to smaller events typically results in overestimation of the smaller event, and subsequent overdesign of facilities.

7.1.6 Stormwater Reuse

This option is defined as the direct reuse of stormwater for beneficial uses, as opposed to a disposal option in which no value is obtained from the resource. Mitchell, Mein, and McMahon (1996) developed an urban water balance model to determine the effect of stormwater and wastewater reuse and suggested its application at a number of scales. They determined that water demand from reservoirs in Australia could be halved through the use of this resource. Herrmann et al. (1996) found that rainwater usage (using roof runoff water directed into a storage tank) could provide 30 to 50% of total water consumed in a residence, and reduce heavy metals (in stormwater runoff not reused) by 5 to 25%. Wanielista (1993) developed design curves to determine the storage retention volumes necessary to achieve given proportions of reuse. The design curves are based on a daily water-balance model. The main objectives for this practice in the State of Florida are the costs avoided of using municipal or pumped groundwater for irrigation; from the regulatory viewpoint, the main objectives are to discharge some of the stormwater onto the land and thereby get credit for 100% removal of this pollutant source. Field (1993) studied cost-effectiveness of the reuse of urban stormwater to meet a variety of differing demands for a hypothetical urban area. The proposed uses varied in their water quality needs, as did the corresponding treatment system designated for that use. Nowakowska-Blaszczyzyk and Zakrzewski (1996) project increases in suspended solids, nitrates, COD, BOD, and lead from rainfall routed through the following sources: roofing, parking areas, streets, storm sewers, infiltration through lawns, and infiltration through sand. The lowest values tended to be from roof runoff. Karpiscak, Foster, and Schmidt (1990) detail the application of stormwater and gray water reuse techniques at a single residence in Tucson, Arizona.

7.1.6.1 Research Needs

The effectiveness of stormwater reuse should be evaluated at a variety of scales and for a variety of climates, in terms of both cost and environmental efficacy. Information is needed on sizing on-site stormwater cisterns to capture the runoff and reuse it on-site for irrigation , toilet flushing, and other non-potable purposes. The expansion of experimental houses, such as Casa del Agua, to other climates and expanding these monitoring efforts to include evapotranspiration and water storage in the vadose zone is important. Other open questions are any possible measurable or modeled impacts on the urban wet weather system. The possible segregation of stormwater into roof runoff, driveways, residential streets, arterial streets, commercial or industrial site runoff and its possible use as a resource must be evaluated.

7.1.7 Storm Inlet Devices

Stormwater inlet devices are designed to intercept and convey surface runoff to closed conduit storm sewers (ASCE/WEF, 1992). The hydraulic capacity of an inlet is a designed feature that depends on the geometry of the structure (ASCE/WEF, 1992). Generally part of the "minor" drainage works described in Section 7.1, inlet devices are an important structural feature of the sewer. An extension of this concept of micro-storm management, as discussed in Section 7.1.5 includes inlet devices to promote rooftop and on-site storage (Urbonas and Stahre, 1993). As indicated by Urbonas and Stahre (1993), control devices used to promote storage tend to be maintenance-intensive and may promote nuisance flooding if not properly designed and maintained. As the entry point to the storm sewer, inlet devices play a role in treatment and control. As a hydraulic control point, inlet structures may be designed to statically control flow via grate geometry, pipe inlet control (such as weir, hydraulic brake, orifice, etc.); or as a dynamic control point as part of a control system (manual or automatic-real-time) using devices such as inflatable dams, motor-controlled gates (Field, 1996). Standard catch basins were monitored for solids capture effectiveness in Bellevue, Washington, and found to capture the largest portion of street solids (Pitt et al., 1997). Stormwater treatment devices may be added to inlet design to capture solids. Sumps added to the bottom of catch basins have been used in the United Kingdom and were also found to capture the largest-diameter fraction of solids in stormwater. Inlet devices using filter fabric to screen solids have been demonstrated in Stafford Township, New Jersey (Pitt et al., 1997). Significant solids and COD reductions were found (up to 50%); however, the filter medium tends to clog rapidly (Pitt et al., 1997).

7.1.7.1 Research Needs

Pitt et al. (1997) cite recent research that indicates that traditional catch-basin performance is fairly well understood. Modifications of the basic design (sumps, self-cleaning trash racks, etc.) have been demonstrated. Use of flow control devices in inlet structures is also a well-understood. Issues to be resolved regarding inlet structures pertain to the overall vision of future urban drainage works. What level of control and treatment is needed at the micro, minor, and major drainage system levels? The maintenance cost of catch basins is a major concern. As treatment is decentralized, maintenance becomes a problem. At the micro-level, rooftop storage by downspout inlet control is generally not a practical solution because the maintenance requirements become a burden to private owners (Urbonas and Stahre, 1993). In fact, Urbonas and Stahre (1993) report that rooftop inlet control devices have a tendency to disappear over time as they clog and create maintenance problems for the owners. Therefore, while performance data may not be a high-priority research item, the role that the inlet device may play in an integrated drainage system may be important.

7.1.8 Industrial Runoff Control

Precipitation that falls on industrial sites is usually of the same water quality as precipitation that falls on residential sites. However, the working practices of a particular industry and site may cause runoff to become contaminated by contact with various pollutants such as oils, greases, pesticides, heavy metals, suspended solids, as well as BOD from the overland flow surface of the site. According to Field (1993), thousands of toxicant laden stormwater discharges emanate from industrial sites. Hubbard and Sample (1988) describe a method of tracing toxicants in storm sewers to individual industrial sites. They used downstream water quality, stormwater system plans, land use information identifying the type of industry in each parcel in the area, and chemical analyses of the sediments in the storm drains.

Moffa (1996) develops a generic case study of an industrial site discharging stormwater to a small creek. The company becomes subject to NPDES regulation, selects a consultant, and begins a program of monitoring to establish dry weather baseline water quantity and quality near the discharge to the creek. Stormwater management model (SWMM) studies are performed to establish what pollutants may exceed regulatory standards at established frequencies of storm events. When a pollutant exceeds the regulatory criteria, the model is rerun with selected control or BMP options and consequent expected source reductions; this is repeated until the criteria are met. Weiss (1993) provides a concise summary of US EPA's permitting strategy, an overview of the regulations, options for treatment and control as well as minimization of contaminated stormwater. Due to the complex industry, and location-specific nature of the problem, US EPA's strategy is to tailor each permit to site-specific conditions (Weiss, 1993).

7.1.8.1 Research Needs

According to Field (1993), no research has been done in the area of assessment and control of industrial stormwater runoff. The mandate for regulatory compliance gives particular emphasis to this need. Claytor and Brown (1996) describe preliminary research on environmental indicators that may attest the effectiveness of industrial stormwater control programs. The US EPA industrial stormwater permitting program, due to its site-specific nature, will gather much information, including treatment and control options, type of industry, and so forth. As these data are collected, it would be possible to develop a database of this information, combine it with local site-specific information from available GIS databases, and develop performance evaluations of industry-specific control strategies.

7.1.9 Reuse of Urban Runoff as Cooling Water

Field (1993) determined, in a cost-effectiveness comparison, that cooling water reuse of treated stormwater ranks second only to irrigation, primarily due to the cost of meeting a higher water quality standard for cooling water purposes. This is especially important in that, according to Field and Fan (1981), cooling water is a substantial component of the estimated 53.5 billion gallons of water consumed per year. Ferguson (1987) discusses "harvesting" of urban stormwater for cooling water purposes, and gives site-specific formulas for the application of this technique.

7.1.9.1 Research Needs

Despite the cost-effectiveness of the reuse of urban runoff for cooling water purposes, there does not seem to be a large body of research in this field. More detailed treatability studies and pilot testing should be performed to determine whether this option is feasible. Industrial users may be employing this technique to control industrial runoff to avoid discharging it in accordance with an NPDES permit. If this is the case, then appropriate studies could be done across categories of industries employing this technique to determine the most efficient treatment, reuse, and management processes.

7.1.10 Roadway and Airport Deicing

Field and O'Shea (1992) document the problem of salt- and sand-laden stormwater runoff from roadways. The authors find the annual cost of damages resulting from this runoff to be $5.4 billion dollars. Research into alternatives to the use of salt as a deicing agent include hydrophobic pavements and highway coating methods. Lord (1988) summarizes an $8 million research effort into alternative deicing chemicals, reduced chemical usage, improved operation practice (including storage), pavement heating, pavement modification, and mechanical approaches. The author notes that promising research efforts include ice–pavement bond prevention and destruction, improved displacement plows, control of blowing snow, and management.

Madden (1995) details the current treatment options for airport deicing fluids (glycol) and associated stormwater. The options include disposal to an off-site or on-site wastewater treatment plant, on-site anaerobic treatment and disposal, and on- or off-site processing for reuse. The economics of the high cost of deicing chemicals and the large quantities used favor reuse. Alternative chemicals to glycol include urea, calcium and magnesium acetate, potassium acetate, and sodium formate.

7.1.10.1 Research Needs

Many of the research projects Lord (1988) mentions have come to fruition as many cities use alternative deicing chemicals to assist in the removal of snow and ice. Improved all season and specialized traction tires have also been introduced. Alternative chemicals come at an increased cost, however, primarily because sodium chloride is relatively inexpensive. Environmental education may be necessary to inform the public of the benefits of using more environmentally acceptable alternatives.

Airport deicing has become highly technologically sophisticated because it is typically subject to NPDES permitting. State-of-the-art recycling and treatment systems are the norm, particularly for new airports; however, even these systems are not fail-safe. The high cost of deicing chemicals used in airports creates a direct economic incentive to maximize the reuse of these compounds.

7.2 Collection Systems

Collection systems are an integral part of wet weather urban water management. Sanitary sewers as well as combined sewers and storm sewers provide drainage in some fashion; by draining groundwater via inflow and infiltration (I/I) in sanitary systems, or by providing designed drainage in combined and storm sewers. Research in the area of collection systems continues to be an area of interest, especially in Europe and Japan (Henze et al., 1997; Sieker and Verworn, 1996; Ashley, 1996; Bally et al., 1996). Practical experience from research in the United States is most active in the area of integrating technological advances and fundamental research findings into practice, as

R0025880

evinced by recent WEF technical conferences (WEF 1994a, b, 1995a, b, 1996) and a recent US EPA seminar (US EPA, 1996). Innovative researchers are rethinking the role of urban drainage from the ground up, as seen in recent research involving on-site drainage practices and the concept of micro-storm management (see section 7.1) (Candaras, Carvalho, and Koo, 1995)

Problems associated with collection systems during wet weather continue to be costly. Excessive I/I, sanitary sewer overflows (SSOs), and combined sewer overflows (CSOs) are common collection system problems in the United States. These problems are rooted in deteriorating infrastructure and past design practices based on rules of thumb to account for complex system functions (e.g. solids transport) and did not take into account modern system demands and performance standards.

I/I continues to be a costly problem. While rehabilitation costs, especially those requiring excavation, are costly, a fundamental problem is that of privately owned laterals. The expense of rehabilitating private sources of I/I can be as high as the treatment and conveyance costs of I/I. Current work on I/I is presented in Section 7.2.8. and shows that I/I control will be an area of research that will include technological innovations (e.g. trenchless technology) as well as administrative changes in the way private sources are handled. Field and O'Connor (1997) show that I/I rehabilitation for SO control may be more expensive than high-rate treatment technologies more commonly used for CSOs. This offers more evidence that engineered solutions to collection system problems should be viewed from the life-cycle cost perspective and that alternatives should be selected from a wide range of available technologies. Operation and maintenance (O&M) is an important area of collection system performance. Maintenance is a costly and necessary function system owners must provide to achieve acceptable performance. The effectiveness of preventive maintenance is an important research area for the near future, as the present infrastructure ages. Advances have been shown (see Section 7.2.9) in implementing data management in preventive maintenance scheduling; however, careful examination of the life-cycle costs of new rehabilitation techniques is needed.

Earlier research on infiltration focused on estimating the natural infiltration associated with rainfall runoff processes. The conventional wisdom was that the infiltration rate decreased over time during the storm event as the soil grew wetter and absorbed less moisture. In recent years, attention has shifted to using infiltration as an important on-site control. Infiltration can be induced by providing areas that are more porous, grading the land to encourage infiltration, and directing runoff from impervious to pervious areas. Increased attention to correctly depicting infiltration in urban areas revealed the gaps in our knowledge. No longer could infiltration be dealt with simply as a loss term in the water budget. Key gaps are listed below:

- Incorporating the effect of irrigation on infiltration rates. Existing continuous simulation models ignore the important impact of irrigation on antecedent conditions for wet weather models. Existing models simply assume that the antecedent conditions depend solely on the time since the previous storm event. In reality, lawns and gardens are watered frequently during the growing season. Thus, the antecedent conditions tend to be quite wet. The soil moisture budget for urban areas is fairly complex during the growing season because irrigation systems vary widely in terms of practices, e.g., automatic sprinklers vs. "hose-draggers," the ways in which these sprinklers are operated, etc. (Courtney, 1997).

- Estimating the effectiveness of run-on systems. Stormwater from impervious areas is directed to pervious areas for infiltration and perhaps later use as a source of evapotranspiration for plants.

- Correctly accounting for the fate of infiltrated water. Detailed on-site monitoring is needed to determine the final fate of infiltrated water. Does it go to deep percolation? Is it used by the local plants for evapotranspirative needs? Does it provide base flows for local receiving waters? Does it infiltrate into sewers?

- Accurately predicting infiltration for disturbed soils found in urban areas. For example, Pitt et al. (1997) cite the results of field sampling of infiltration rates in Oconomowoc, Wisconsin, vary widely in actual infiltration rates. They do not always decrease over time. Therefore, on-site monitoring is essential.

A corollary to a better understanding of infiltration is the general question of the effect of stormwater infiltration on groundwater quantity and quality. This topic is discussed in Chapter 3.0.

A major concern of system owners is the cost of operation. The traditional means of securing construction contracts has shown significant weakness in terms of costs over the project life of the sewer. The least expensive construction costs may result in increased operation and maintenance costs. Research into the administration of the life-cycle costs of sewers is needed to prevent unnecessary expenditures on rehabilitation. Institutional and legal changes are needed if progress is to be made in this area.

The behavior of solids in sewers is fundamentally linked to overflows, O&M costs, system performance, and treatability of wastes, especially for high rate treatment. The fate and transport of solids in sewers also has implications for design as well as operation and performance. The use of common design rules-of-thumb (e.g., ill-defined minimum velocities and grades) to ensure transport of solids has led to significant operational problems. Excess sedimentation in sewers may cause clogging and promote hydrogen sulfide production, both resulting in operational problems that affect the lifespan and performance of the sewer (Schafer, 1994). Research in Europe (Ashley, 1996; Ackers et al., 1996) shows that common design standards may not be enough, given the highly variable nature of solids load. Recent work on the behavior of solids in sewers is presented in Section 7.2.3.

New approaches for the design and operation of combined sewers to control sediment problems were presented by Blaszczyk and Ashley (1996). A 10-year, $331 million CSO sewer separation project was recently completed by the cities of St. Paul, South St. Paul, and Minneapolis. A total of 189 miles of storm sewers and 11.9 miles of sanitary sewers were installed, 168 miles of oiled streets were paved, and roof leaders at 21,900 residential properties were disconnected.

Further work is needed in several areas to improve collection system performance and to take advantage of recent technological advances. Other research needs discussed in this section are more fundamental in nature, and knowledge gained may be applied to many different types of sewers, i.e. solids behavior in sewers may be germane to sanitary, combined and storm drainage collection systems. Other needs, Such as section 7.2.4 "Use of Simulation Models in Storm Sewer Design," are system-specific. Another group of research needs relates to the application of computer technology. Innovations related to the computer information revolution are still being investigated and will require significant research resources in the future. For instance, data management capabilities are now greater than envisioned when most of the systems in use today were designed. Adapting design practices to take advantage of computer capabilities in system operation are critical. Data collection will be crucial to the properly designed collection system of the future.

Real-time control (RTC) of collection systems is an active area of research in Europe and Canada. Automatic control schemes to maximize in-line storage have been successful in many collection systems in the United States as well as in Canada and Europe (Vitasovic and Zhou, 1997; Schilling, 1996). While the United States has a 30-year history of using RTC, Canada and Europe are using more advanced control permitted by their more aggressive development and implementation of these methods during the past decade. RTC in the United States began in 1967 when demonstration projects were used for CSO control in Cleveland, Detroit, Minneapolis, and Seattle. These projects attempted to use RTC to increase collection system storage. U.S. cities that are either using or studying RTC systems include Cincinnati, Cleveland (Hudson, 1996), Detroit, Milwaukee, Lima (Cantrell et al., 1996), Philadelphia (Day, 1996), Rochester, and Seattle (Chantrill, 1990). This area shows significant promise, especially for large systems that have complex responses to wet weather conditions.

Future collection systems will be viewed more as an integral part of the urban hydrologic cycle. As such, fundamental knowledge gained in sediment transport and behavior will have a direct influence on modeling and design techniques, which in turn will play a role in system monitoring and operational control. These functions will be operated in the context of the urban water budget, which includes water use and distribution, indoor and outdoor use, water conservation, climate, receiving water quality, and beneficial uses. In addition, improved water management practices will be developed through integration with other urban systems, such as transportation and land-use planning.

In summary, this section covers areas of collection system research that will ensure that future design and operation of collection systems will be more efficient and more integrated with the management of the total urban water budget. Research areas cover fundamental physical knowledge such as sediment behavior, technological advances involving computer data management and modeling, and operational efficiency such as optimized preventive maintenance practices.

Of the 67 research needs identified in Table 2–8, twelve concern collection systems. Two needs from Table 2–8 are for better operation and maintenance of collection systems; these are covered together in Section 7.2.7. Two others concern solids handling—sewer flushing and solids disposal; these are covered together in Section 7.2.8. Two needs are associated with collection system design—design practices and innovative design; these are covered together in Section 7.2.10. The needs are grouped in Table 7–3.

7.2.2 Instrumentation and Monitoring to Evaluate Sewer Hydraulics

The complications of measuring flow in gravity sewers have frustrated sewer designers and operators since sewer measurements were first attempted in efforts to evaluate sewer hydraulics. The situation is complicated by the amount of solids and debris flow, sewer surcharging that results in pressure flow, highly variable flow rates, and limited physical accessibility. Primary measurement devices are the most reliable means of flow measurement, but are difficult to retrofit into existing sewers and may require significant maintenance. Most sewers were designed and constructed before the value of flow data was realized in sewer operation, and therefore do not have the appurtenances required for permanent monitoring. Many sewer owners resort to using temporary or semi-permanent velocity and depth measurements, usually in conjunction with a data logger. Measurement difficulties can be traced to problems associated with velocity measurements over the cross section of the conduit.

Monitoring technology has advanced along with the computer/information age. Digital data are recorded and efficiently transferred to databases for use in analysis. The problems associated with flow measurement, however, are more fundamental because the problems are physical in nature. Velocity sensor technology is advanced, but the problems noted above confound accurate measurement. Modern velocity sensor technologies include Doppler sensors (which rely on the change in frequency of sound waves reflected from suspended solids), electromagnetic sensors (which use the Farraday principle of current generated by a conductor flowing through a magnetic field), and transit time sensors (which rely on acoustic transmission across the width of the conduit). All of these have applications in which they excel, however all may be subject to relative error when used in actual sewers. Recent innovations include use of an array of Doppler sensors to better estimate mean velocity in large sewer pipes (Erb, Vander Heyden, and Kyser, 1994; Hughes et al., 1996). Accuracy was improved from ±20% for a single Doppler sensor to ±7.4% for an array of Doppler sensors (Hughes et al., 1996).

7.2.2.1 Research Needs

The research needs associated with monitoring and instrumentation are twofold: improving the characterization of velocity with reliable, low maintenance sensors; and developing design criteria for in-system monitoring stations to be included in all new designs. Research should focus on improving the relationship between measured (point or chordal) and estimated average velocity for all flow depths. Notwithstanding, over the long-term, higher priority should be given to developing design criteria for in-system monitoring stations. This will advance the evolution of collection systems to coincide with advances in data management, control, and simulation.

7.2.3 Laboratory and Field Studies of Deposition and Scour in Sewers

Characteristics of sewer solids are critical to wet weather pollutant transport and treatment in sewer collection systems. Sewer solids are typically characterized by settling velocity, size distribution, and concentration. Solids exhibit a wide range of variability in all of these measures, in addition to site-specificity. For these reasons, characterization of sewer solids by laboratory and field studies is crucial for complete analysis of the performance of sewers and treatment works, and receiving water impacts. Settling velocity is the most important physical property to measure because it determines the gravitational effects on the solids load, aiding in scour and deposition analysis and treatability. Pisano (1996) describes two methods of settleability tests: the method most widely used involves a large mechanically mixed settling column with sample extraction ports along the longitudinal axis; in the other method, developed in Germany, settleable solids are separated and then placed in an Imhoff cone with one outlet at the bottom. The former method is expensive and produces data with considerable "noise," while the latter method does not take into account non-settleable floatables and uses a much smaller (i.e., less representative) sample (Pisano, 1996). Aiguier et al. (1996) compare these two methods with a third method used in France that involves two tests, one for particles of less than 50 mm and one for particles of 50 mm and greater. The authors concluded that the German method always produces higher settling velocity results because of the extraction of the non-settleable portion of the solids (Aiguier et al., 1996).

In addition to the testing methods, there are also two methods of collecting solids samples from sewers. The most straightforward is to simply collect a sample of the flow; the method used more widely in Europe uses solids scraped from the wall of the sewer (Pisano, 1996). While the first method may appear to be the most representative, many hidden problems are inherent in that this method is very sensitive to the manner in which the sample is collected. Automatic samplers and hand pumps shear solids and may not produce enough intake velocity to collect heavier solids. Grab sampling techniques are effective but highly variable, and representative samples from the bottom of large diameter sewers are difficult to capture. Conversely, the scraping method is simple and inexpensive, but only captures solids that have already deposited, therefore the sample may not be representative.

7.2.3.1 Research Needs

Research is needed to determine proper equipment and procedures to conduct settleability tests in a uniform manner. Currently, a wide variety of data is collected, but the wide variation in techniques prevents comparison of information gleaned from them. Important design and operation questions can only be answered if solids data are comparable. This would greatly increase the applicability of design data across systems, e.g., the design experience of one sewer could more effectively be applied to design of another. Systematic solids measurement would also greatly aid modeling and transport studies, providing fundamental information on the physics of solids in sewers.

7.2.4 Use of Simulation Models in Storm Sewer Design

The use of mathematical models to simulate sewer performance for design and operation is common practice for major projects. However, for many of these projects, the simulator is used merely to mimic performance under design storm conditions. The limits of design storm simulation to represent life-cycle performance over a wide range of conditions is well documented (Davis, Moffa, and Dent, 1993; Nix, 1994, 1996; Heaney and Wright, 1997). Continuous, long-term simulation of the integrated wet weather environment (e.g. runoff surfaces, micro/minor/ major drainage works, storage/treatment facilities) is advantageous in that overall performance is measured over a wide range of real events (Nix, 1994). Models that can interface well with relational databases and time series information that represents system inputs and outputs over the simulation period are advantageous. In addition, models that interface easily with other programs, e.g. optimization routines, are advantageous in that they allow designers to change key parameters and measure the potential impact of the change. Unfortunately, the most widely used non-proprietary simulation package in the United States, the US EPA SWMM, does not easily facilitate database–GIS–optimization interfacing, although it does perform continuous simulation.

Models that do perform needed functions and take advantage of modern interfacing capabilities are proprietary. Based on experience with SWMM, public domain software is valuable if it can be trusted. Also, private interests may add value and usability to the software and resell it because software source codes are available in the public domain.

7.2.4.1 Research Needs

Efforts should focus on making continuous simulation a common design practice via integration with time series databases. The public sector has a vested interest in maintaining a usable, modern modeling framework that private vendors can work from to produce value-added packages. The simulation program of the future will ideally be integrated within a "tool-box" of decision and design software. This will allow design performance to be more accurately measured by making full use of available databases and decision support software. The model evolution should include: full use of 32-bit PC-based architecture, object-oriented programming to facilitate project specific integration, and available executable code for extensive modification and additions by users and private software companies.

7.2.5 Cost-Effective Ways to Rehabilitate and Replace Old Sewers

Aging sewers are prone to collapse, to clog, and to allow excessive inflow and infiltration (I/I). Approximately 600,000 miles of combined and sanitary sewers exist in the United States, and each 1,000 miles of sewer sustains approximately 50 major main breaks per year (WEF, 1994). As the sewer infrastructure ages, it will require extensive rehabilitation to maintain a desirable level of service. Unfortunately, if the rehabilitation requires digging and replacing, the costs of rehabilitation are very high, which leads to a less than satisfactory level of service and high O&M costs. Therefore incentive is strong to rehabilitate sewers without digging. Recent work in trenchless technology appears promising, and advances in this area are expected to continue. Current state-of-the-art trenchless technologies (Najafi, Varma, and Stutterheim, 1997) include :

- Cured-in-place pipe;
- Sliplining;
- In-line replacement;
- Close-fit pipe;
- Point source repair; and
- Sewer manhole replacement.

Larsen et al. (1997) presents comparative costs for some of these technologies in South Florida. They found costs for rehabilitation of a 300-foot sanitary sewer section to be:

- Chemical grouting, $3,000 (only for leaking joints);
- Fold and formed liner, $12,200;
- Cured in-place liner, $14,300;
- Slip lining, $21,000 (reduces hydraulic capacity);
- Pipe bursting, $24,000; and
- Full replacement, $30,000

In addition to the costs of the various technologies and the trade-offs for each, the local traffic and neighborhood disturbances may be more important than the sewer repair costs. This is especially true in urban areas where a high density of commerce may be critical for local businesses.

7.2.5.1 Research Needs

Research should evaluate laboratory and case study experience on trenchless rehabilitation technologies. While construction costs have been documented, long-term maintenance costs are not as available because these methods are relatively new. Long-term performance also must be measured for different sewer types, locations, etc. An impartial review of available technologies is needed that considers total life-cycle costs. Demonstration projects may be a useful tool, providing a controlled means of measuring performance and costs. In addition, as collection system monitoring and control technologies advance, rehabilitation may include construction of additional sewer appurtenances to accommodate data collection. The costs of not doing this during rehabilitation projects may prove to be costly over the extended life-cycle of the sewer. A new WERF research project will be underway in spring, 1998 entitled Innovative Materials and Techniques for New and Replacement Sewers.

7.2.6 Improved Inflow and Infiltration Control in Sanitary and Storm Sewers

Inflow and infiltration (I/I) is a costly and widespread problem in the United States. Petroff (1996) estimates that 50% of treated wastewater in the United States is derived from I/I. Besides increasing treatment and pumping costs, I/I is a major cause of sanitary sewer overflows. A review of 10 case studies indicates that peak wastewater flows ranged from 3.5 to 20 times the average dry weather flow (DWF) (US EPA, 1990). Maximum ratios have been reported as high as 50:1 in Houston, Texas (Jeng, Bagstad, and Chang, 1996). The US EPA (1996) estimates that 27% of SO occurrences result from excessive I/I. Costs of I/I may also be found in the design and construction of sewers. Designs must include allowances for future I/I, thus increasing construction costs. Heaney et al. (1997) estimate that the majority of sewer capacity currently in use in the United States is intended to accommodate extraneous flows.

While inflow is commonly lumped together with infiltration, the two are derived from different sources and result from different deficiencies in the collection system. Direct inflow sources commonly result from illicit connections, from unenforced building codes or absent inflow-related requirements, or from poorly designed or maintained interaction with the surface drainage system (e.g. flooded manhole covers resulting from poor street drainage). Infiltration, on the other hand, commonly results from deteriorating sewer infrastructure. This is complicated by the fact that much of the infiltrated volume may be from private sources such as privately owned, small diameter, service laterals. Elliot et al. (1997a, b) estimate that 42% of I/I in a central Pennsylvania community comes from private laterals during a peak I/I event. Elliot et al. (1997a, b) estimate the costs of I/I removal for the community. Rehabilitation costs range from $0.40 to $.36/gal. removed for sump pump removal and grouting manholes and sewer line, to $.20 to $3.72/gal. for lateral repairs. By comparison the conveyance and treatment cost for each gallon of I/I is estimated to be $3.81 to $18.80/gal.

7.2.6.1 Research Needs

Research related to I/I control should follow several paths. First, there is a need to examine feasible means of controlling inflow via proper sewer administration. Second, there is a need to develop design criteria for the sewer of the future that will include life-cycle costing, data monitoring, and infrastructure design compatible with the needs of the future. I/I control should play a major role in rethinking sewer infrastructure. Third, there is a need to demonstrate the life-cycle cost-effectiveness of current rehabilitation technology.

7.2.7 Sewer Maintenance Effectiveness

Maintenance of collection systems plays a major role in the overall performance of the system and usually contributes much of the life-cycle costs. As such it is critical to effective administration of maintenance operations. Innovative municipal owners are using computer databases and GIS systems to manage sewer maintenance operations. The city of Garland, Texas, a suburb of Dallas–Fort Worth, has integrated historical maintenance information with current GIS mapping to administer O&M (Hardin and Messer, 1997). Age of sewer, number of complaints, number of overflows, and preventive maintenance are recorded in a database and used to develop routine maintenance schedules. For example, problem sewer lines are scheduled for line cleaning every 0.8 years, while non-problem lines are scheduled for cleaning every 10 years. In this way, areas that have been problematic in the past are identified and scheduled for preventive maintenance. The city of San Diego, California, is using GIS and decision analysis software to set priorities for preventative maintenance and rehabilitation projects with the overall goal of reducing SSOs (Giguere, Kennedy, and Yackly, 1997).

This kind of information management is crucial to increasing the cost effectiveness of O&M programs. Combined with economic data, an optimal maintenance schedule is feasible. Using system-specific information, preventive maintenance is administered logically, taking into account local needs and conditions.

7.2.7.1 Research Needs

To achieve a level of maintenance that is cost effective, the effectiveness of O&M must be known in relation to the life-cycle costs. Therefore, research needs relate to a better understanding of overall sewer performance and costs, a need strongly tied into an integrated database such as that discussed in Section 7.2.5. Demonstration projects that carefully monitor costs and performance must be evaluated across different types of systems (e.g., sanitary systems, combined systems, large municipal systems, rural systems).

7.2.8 Sewer and Tank Sediment Flushing

The fate and transport of solids in sewers remains largely unknown to researchers and designers alike. Current design methods call for minimum velocity or grade requirements, much like sewer design guidelines at the turn of the century (WEF/ASCE, 1982; Metcalf and Eddy, 1914). Recent research in Europe has focused on the fundamental but misunderstood phenomena that drive sediment behavior in sewers (Ashley, 1996). The results of 100 years of inadequate design practices have left many sewer owners with large maintenance problems and costs.

Self-cleansing sewers have been attempted with some success since antiquity (Pisano, Grande, and Novac, 1997). However, with great variation in the properties of solids, unwanted deposition occurs frequently in many sewers. Many methods for cleaning sewers are available. Pisano, Grande, and Novac (1997) give an overview of current technology. These methods include: power rodding—mechanical rods turn and cut through pipe deposits and roots—adequate for sewers up to 300 mm in diameter; balling, poly pigs, kites, and bags—an inflated rubber ball, kite, bag etc. is introduced to the sewer line and increases flow velocities, scouring deposited solids and grease—adequate for sewers up to 600 mm in diameter; jetting—uses a high-pressure hose, dragged mechanically through the sewer line to dislodge solids—usually a truck-mounted machine; and power bucket machine—a mechanical cleaning device usually used for areas that cannot be scoured by hydraulic methods (Pisano, Grande, and Novac, 1997).

Pisano, Grande, and Novac (1997) also discuss recent successes in permanent flushing mechanisms installed in sewers. Generally these are tanks or dams built into the sewer that release an unsteady dynamic wave at prescribed intervals to flush deposited solids. Variations on this technology have been used since the 1800s, but better fundamental understanding of sewer solids and maintenance needs allow better design of flushing schemes tuned to specific sewer conditions.

7.2.8.1 Research Needs

Two research needs are associated with sewer flushing. The first is fundamental research that will integrate fate and transport of solids with continuous simulation of sewer performance. This research should include development of adequate data monitoring for long-term evaluation of maintenance effectiveness and costs. The second research task involves the development of design criteria for automatic sewer flushing mechanisms. These are permanent structural designed elements of the sewer system such as those discussed by Pisano, Grande, and Novac (1997).

7.2.9 Innovative Design of Sanitary and Storm Sewers

Aside from greater use of computers in sewer design, there have been few significant changes in modern sanitary sewer design in the last 30 years. Advances have primarily been in computer modeling of flows and system performance, but these are usually based on linear pre-computer methods such as the rational method and unit hydrograph methods for storm sewers and unit area design rates for I/I. The result of these design practices has had mixed results, with many over-designed sewers and some with less than acceptable reliability (Heaney et al., 1997). The lessons learned from the existing infrastructure should be used to develop a vision of future sewers that includes life-cycle costing, data management and control, I/I control, innovative technologies, source controls, etc. (Heaney et al., 1997). For this vision to be formulated, a logical estimate of future trends in land use and transportation must be made. Using the past as a guide, it is informative to look at the land use patterns of the last 50 years as a period in which the automobile dominated transportation, and this in turn helped drive land use patterns to zoned, separate uses and suburban sprawl (Heaney et al., 1997). Likewise, it is envisioned that the automobile will not disappear from the landscape in the near future. However, in another 50 years, land use and transportation are likely to be quite different than they are today.

Sanitary and storm sewer owners of the future cannot afford to repeat past mistakes. The long-term performance of the system must be maintained is services are to be cost effective. The effects of life-cycle costs driving the decision must be reckoned with; contracts that include a vested interest in the performance of the system over a long period will likely replace short-term construction contracts (Heaney et al., 1997). The control of the system will be synchronized with treatment plant operation and receiving water monitoring. This mandates that permanent monitoring stations be designed as an integral part of the collection system. The future sewer systems should be adaptable to new technology as it becomes available.

7.2.9.1 Research Needs

This research area is one of evolution in engineering design. In order to properly assess what the future may hold, lessons learned from current sewer infrastructure failures and successes must be assimilated into future design practice. The focus of future collection system design will be one of integration and control. The system will be viewed as an integral part of the urban water budget, urban land use, and the environment. To this end, the data analysis and control technology currently available should be used to create integrated models of the urban–environment interface.

7.3 Storage and Treatment

The economics of treating wastewater and stormwater during wet weather usually dictate that treatment be accompanied by some form of storage. Treatment costs for infrequent events generally outweigh storage costs, giving incentives to store some portion of the storm volume. The treatment used may take many forms, from combined sewage stored and released into the collection system for secondary or tertiary treatment at the wastewater treatment plant (WWTP), to simple sedimentation of stormwater in the storage facility itself. Storage also may be of several types, from use of existing pipe capacity to store wet weather flows in-line to off-line tanks or ponds. Another storage concept is the design and construction of new, oversized pipes to provide more system storage. This area has received little attention. The concept has several advantages over above-ground storage, in that the extra storage could be provided below-ground and constructed during rehabilitation and renovation projects. Auxiliary high-rate treatment may also be a cost-effective way to treat by-passed volume that would otherwise not be treated. This section introduces the rich history of research found in the engineering literature on storage and treatment.

High-rate treatment facilities have shown promise in treating wet weather flows in recent years. Sections 7.3.3 through 7.3.6 discuss areas of high-rate treatment that have been successfully demonstrated but require more fundamental knowledge of performance and costs before broad application of these technologies can be realized. High-rate treatment may be important for reducing wet weather impacts on receiving waters by providing greater treatment rate than traditional treatment methods, however this comes at the expense of (usually) providing a lower level of treatment. High-rate treatment may be divided into two areas: altered operating procedures of WWTPs to accept larger flows at reduced levels of treatment, and facilities specifically designed to accept high flow rates while providing a minimum level of treatment.

High-rate treatment may also be broken into two areas by the type of pollutant treated: solids or bacteria. Bacteria control through disinfection is a common goal of CSO control strategies (US EPA, 1993). Several technologies are available today, including chlorination, ozonation, and ultraviolet irradiation techniques (Moffa, 1996) (see Section 7.3.5. High-rate sedimentation is discussed in section 7.3.6. This technology involves use of chemicals to increase sedimentation rates. High-rate solids removal may also be accomplished through use of vortex separators, discussed in Section 7.3.4. These devices have successfully treated CSOs in the United States, Canada, and Europe (Field, 1990; Field and O'Connor, 1996; Pisano, Thibault, and Forbes, 1990; Pisano, 1994).

An area of research that shows significant promise, though it has had limited application in the United States, is the use of WWTPs to treat WWFs. High-rate operation of WWTPs involves changing the function of certain components of the WWTP to accept higher flow rates. This may be accomplished through step feeding (WEF, 1997), through the use of aeration tanks as primary settling devices (Nielsen, Carstensen, and Harremoes, 1996) or by other means of increasing treatment component capacity. This is a critical research area and highlights the importance of integrating the operation of collection systems with their associated WWTP.

Innovative work in storage-treatment system design and operation has been an active area of research. Van Buren, Watt, and Marsalek (1996) evaluated internal pond baffles in Kingston, Ontario, and found that extended hydraulic residence times and prevention of flow short-circuiting result in increased particulate settling and associated contaminant removal. Green and Martin (1996) evaluated the benefits of constructed reed beds in treating stormwater overflows in terms of reductions in discharges of BOD_5, TSS, ammonia, and total organic nitrogen. The design, evaluation, and application enhancements for swirl and vortex technologies for flow regulation and reduction of settleable solids were discussed by Field and O'Connor (1996). Booker, Ocal, and Priestly (1996) discuss the use of magnetite-assisted sedimentation and high-rate filtration for treatment of storm-induced sewer overflows. Werner and Kadlec (1996) evaluated the performance of constructed wetlands receiving wet weather runoff. Storage–treatment systems for storm-induced flows exhibit a wide range of configurations and treatment processes. These systems should be viewed in the context of integrated wet weather management, playing an important role in a system that includes source control, infiltration and reuse, conveyance, storage, treatment, and ultimate disposal. The literature reviewed in this section reveals a wide-ranging and rich history of active research and applications. The reader should refer to the citations in this section for a deeper appreciation of this field.

Listed in Table 2–8 are 31 research needs related to storage/treatment of WWFs. Many of the topics are specific to particular technologies or demonstration projects, but share important concepts. The 31 topics were grouped into 10 sub-topics, though not all sub-topics are specifically mentioned. This is because many areas are redundant from a research perspective, or little literature was found on the topic. That does not necessarily reflect the relative importance of the topics.

Section 7.3.2 covers research topics related to the problem of sanitary sewer overflows. Two areas from Table 2–8 are covered in this section: CSO concepts for SO control and SO corrective action. The next four sections, 7.3.3 through 7.3.6, cover different aspects of high-rate treatment. Section 7.3.3, high-rate operation of WWTPs, covers five subtopics identified by other research needs assessments. Laboratory studies of high-rate operation, process control systems, retrofitting for WWFs, demonstration of biofilters, and impacts of WWFs on WWTPs are all related to areas covered in Section 7.3.3. Vortex separation facilities for the treatment of CSO (though the technology may be used in other areas of WWF treatment) are covered in Section 7.3.4. Two topics from Table 2–8 are covered here: CSO vortex controls and vortex/disinfection demonstration. High-rate disinfection technology is discussed in Section 7.3.5, covering five topics from Table 2–8. The effectiveness under highly variable flow conditions, pathogen detection, vortex/disinfection demonstration, high-rate disinfection and high rate ozonation demonstration are covered. Innovative solids separation technology is discussed in Section 7.3.6, covering two topics from Table 2–8: high-rate sedimentation and magnetic separation. General aspects of solids handling are discussed in Section 7.3.7, covering three topics from Table 2–8. Design of release systems, the control of suspended solids and the control of dissolved solids are covered. Two topics are discussed in Section

7.3.8: treatment of toxins and treatment of heavy metals. Use of enhanced natural systems is covered in Section 7.3.9, specifically the use of enhanced infiltration and wetlands for treatment and disposal of urban runoff. This section covers five topics from Table 2-8: groundwater injection, application rates for land disposal, wetlands systems, constructed vegetation cells, and long-term effectiveness of infiltration systems. Best management practices are discussed in Section 7.3.10, which covers four topics from the table. Litter control systems, runoff control using compost systems, BMP effectiveness, and vegetative management practices are all discussed in the BMP section. The costs of operation and maintenance of storage treatment systems are covered in Section 7.3.11. The grouping of needs related to storage and treatment research is shown in Table 7–4.

One sub-topic listed in Table 2–8 was not covered in the 10 subsections of Section 7.3: the storage facilities design manual. Design manuals serve an important function in the transfer of information between researchers and practitioners. They also serve as a benchmark of engineering knowledge. Two important benchmarks have recently been published: *The Design and Construction of Urban Stormwater Management Systems* by the ASCE and WEF (1992); and *Stormwater Best Management Practices and Detention for Water Quality, Drainage and CSO Management* by Urbonas and Stahre (1993). These two volumes cover most of the state of knowledge regarding storage systems. The source of this topic in Table 2–8 is the US EPA report *Risk Management Research Plan for Wet Weather Flows* (Field et al., 1997). The discussion of this topic reveals that the scope of the project includes compiling existing data on the effectiveness of storage, verifying recommended approaches through modeling, and publishing a design manual. This topic was not included as a separate research topic because it would only be appropriate after significant progress had been made on the other aspects of storage and treatment of wet weather flows covered in this section. Upon completion of related storage topics, innovations in design should be included in a new "milestone" engineering guideline.

Another topic listed in Table 2–8 that is not covered in the following subsections is demand management for automobiles. This topic is covered in various forms throughout this report. See Sections 3.0, 3.2, and 3.3 for information regarding automobiles and wet weather pollution. Other items from Table 2–8 not covered in this section are the Environmental Technology Verification pilot project (ID# 145 from Table 2–8), and the performance of WWF controls in cold climates. The ETV pilot project is a project through the US EPA to provide performance and cost data on control technology. Evaluation is performed by a disinterested third party on proprietary control technology. This is an important project for wet weather control users, but it does not involve research. Cold climate research is a fairly active area, and the literature on the hydrologic effects of cold climates is considerable. However, little research has been done on the performance of WWF controls in cold climates, especially in urban areas. This area is important, and fundamental research that links known cold-climate hydrology and receiving water biology with performance information on controls should be done. The role of urban snowmelt is mentioned in Section 3.4.

Two broad topics in Table 2–8 that are not mentioned in the detailed sub-sections that follow are the integration of flood and pollution control works and the integration of landscape architecture in wet weather management systems. The integration of flood and pollution control works is a critical area of research and has been covered in Chapter 2.0. The integration of landscape architecture and wet weather management is covered in Chapter 8.0.

7.3.2 Sanitary Sewer Overflows

Sanitary sewer overflows (SSOs) are an important problem in the United States, especially in light of recent regulatory attention from the US EPA. The primary causes of SSOs are inflow and infiltration (I/I), pipe clogging, and pipe breaks. Jurgens and Kelso (1996) cite excessive wet weather flows as causing 20% of SSOs in Fayetteville, Arkansas, and Clemente and Cardozo (1996), 40%, in Miami, Florida. The proceedings of the 1996 national conference on SSOs shows that 27% of SSOs result from I/I, 43% from pipe blockages, 12% from pipe breaks, 11% from power failure, and 7% from insufficient system capacity (US EPA, 1996). These results were from a sample of six communities in the United States. Field and O'Connor (1997) address the implications of I/I rehabilitation as an SO abatement strategy. Sewer rehabilitation to remove I/I is very costly, as discussed in Section 7.2.7. Some systems report as much as 80% of I/I result from privately owned sources, so rehabilitation may not remove enough extraneous flow to alleviate the SO problem (Field and O'Connor 1997). Therefore, remedial actions using CSO treatment techniques may prove more cost effective. These actions include: maximizing the flow to the wastewater treatment plant (WWTP) using flow-equalization techniques, maximizing treatment capacity by retrofitting, installing parallel processes or designing new high-rate treatment plants, or installing satellite treatment facilities (Field and O'Connor 1997).

7.3.2.1 Research Needs

The research needs for control of SSOs are closely related to those for CSO control and other forms of high-rate treatment, including high-rate operation of WWTPs and flow maximization to the WWTP. In addition, it is important to look at rehabilitation costs and total benefits. While I/I control may not prove cost effective for controlling SSOs as argued by Field and O'Connor (1997), the combined benefits of improved sewer performance and reduced long-term pumping and treatment costs achieved from I/I control, in addition to SO reduction, may prove cost effective for some systems. Therefore this research area would greatly benefit from a careful accounting of the life-cycle costs of various rehabilitation/treatment alternatives.

Technical knowledge regarding SO abatement is also directly tied to maintenance effectiveness research as discussed in Section 7.2.7. I/I is not the only cause of SSOs that would benefit from other research topics. Other major causes of SSOs, e.g. pipe blockages, breaks and capacity limitations should be investigated to determine how much volume is lost from SSOs annually as a result of maintenance needs. Because it is not strictly a wet weather problem (dry weather SSOs may occur), research into this area should encompass all causes of SSOs, as dry weather discharges are generally more harmful to the environment. Elimination of a portion of SSOs may be an important result of an effective, preventive maintenance program, such as that discussed in Section 7.2.8. Once again, the economic benefit of life-cycle costing is an important factor in looking at all of the SO-abatement alternatives.

7.3.3 High Rate Operation of Wastewater Treatment Plants

Wastewater treatment plants (WWTPs) may be subject to high wet weather flows due to I/I or combined sanitary and storm flow from a portion of the collection system combined by design.

Abatement of overflows and system surcharges may be expensive, and could include system rehabilitation, construction of storage facilities, or end-of-pipe treatment works. Therefore, maximizing treatment plant capacity may be a very attractive option. This is accomplished by removing hydraulic restrictions in the collection system or the treatment works, or by using storage facilities to equalize flows (Field and O'Connor, 1997). However, additional storage needed to equalize flow may be reduced if the WWTP itself is operated in a fashion that allows high flow rates. High-rate operation of WWTPs may take several forms; including step-feed control (WEF, 1997), use of aeration tanks as settling basins (Nielsen, Carstensen, and Harremoes, 1996), and modification of treatment processes to allow for a higher rate of treatment (Booker, Ocal, and Priestly, 1996; Field and O'Connor 1997). WEF (1997) provides a case study of real-time control of WWTP operation in Hamilton, Ontario. During periods of wet weather flow, the WWTP switches operating policy to step feed the secondary clarifiers from the aeration basins. This avoids WWTP by-passes that would normally occur to prevent sludge blanket wash-out (WEF, 1997). Step feeding reduces the solids loading to the secondary clarifiers, allowing greater storm-generated volume to be treated without wash-out. This operating policy has reduced by-pass volume by an order of magnitude (WEF, 1997). Nielsen, Carstensen, and Harremoes (1996) detail a case study in Denmark that has shown improvements over the step-feed process control method. In this case study, careful data collection of system input and performance are used to control the WWTP at or near hydraulic and biologic capacity. Booker, Ocal, and Priestly (1996) provide information on increased settling efficiency achieved through use of chemical coagulation and magnetic-assisted sedimentation. Research is being conducted on magnetic sedimentation at a demonstration facility in Sydney, Australia (Booker, Ocal, and Priestly, 1996). While showing promise, this process is being refined to achieve lower operating costs and increased performance. Chemical coagulation is also being tested as a means of allowing for high-rate filtration (Booker, Ocal, and Priestly, 1996). Solids are chemically treated to enhance coagulation and flocculation, in turn enhancing settling and allowing for removal in filters that allow large hydraulic loading (Booker, Ocal, and Priestly, 1996).

7.3.3.1 Research Needs

High-rate operation of treatment works is a fertile area of research, with the potential for large economic benefits. Along with more demonstration of high-rate approaches, integration of high-rate treatment and control of the collection system is needed. This may lead to an eventual overall maximization of system resources, including collection system storage and maximized flow through the WWTP via high-rate operation and flow equalization. To achieve this objective, proper identification of high-rate performance is needed. This would allow life-cycle economic trade-offs between alternatives to be examined.

7.3.4 High Rate CSO Treatment—Vortex Separators

Vortex separators are a common means of treatment for combined sewage. Bernard Smisson, in Bristol, England, first conceived of Vortex separators (Moffa, 1993). Smisson began his work in 1946 and formulated an idea of treating combined overflows at the point of discharge. Two of these original devices were constructed in Bristol in 1963 and are still in use today. The design concept was to have a small device that would separate solids from overflow, with the concentrated solids being passed back to the interceptor sewer and ultimately to the WWTP. Overflow, cleansed of much of the gross settle-able solids, was allowed to discharge into the receiving waters. Vortex separators (or swirls) achieve these design concepts by routing the flow through a circular path to achieve a type of vortex. Heavier particles are drawn toward the outer diameters and allowed to be drawn downward through ever smaller diameter paths and ultimately out a bottom drain or foul sewer, to be routed to the interceptor (Moffa, 1990). Flow containing smaller particles is allowed to discharge over the top of the device, thus achieving the desired separation. After conducting extensive hydraulic research on the forces involved with these units in the 1970s, the LaSalle Hydraulics Laboratory reported that the units function with a combination of gravitational and vortex separation in a controlled manner (Moffa, 1993). Vortex technology has advanced since Smisson's original concept. The US EPA conducted research and demonstration projects in the 1970s, developing a design now known as the US EPA Swirl. German designers have modified this design and market a device known as the Fluidsep (Moutal, Kloman, and Gaffoglio, 1994; Pisano and Brombach, 1994). Engineers in the United Kingdom have also modified the vortex separator and produced a model known as the Storm King (Moutal, Kloman, and Gaffoglio, 1994). In addition to solids separation, vortex separators remove floatables via a trap near the top of the unit (Moutal, Kloman, and Gaffoglio, 1994).Currently in the United States more than 50 vortex units are in operation (Moutal, Kloman, and Gaffoglio, 1994). Many of these units are still being tested for removal efficiencies and are often used in conjunction with storage facilities and disinfection processes (Field and O'Connor, 1996). A project in Flushing Bay in New York City is testing the three major vortex designs, primarily for floatables removal (Moutal, Kloman, and Gaffoglio, 1994).

7.3.4.1 Research Needs

Because a number of vortex separators are actively monitored or are about to be actively monitored, it would be appropriate to develop an unbiased review and database of all existing data for the various incarnations of vortex separators. Existing designs could then be modified in detail and the pros and cons of each type identified. A detailed design manual should be compiled from existing installation experience which covers all modern design alternatives, and long-term monitoring should be continued to determine appropriate life-cycle costs and performance.

7.3.5 High Rate CSO Treatment—Disinfection

Pathogens are one of the primary pollutants of concern from combined sewer overflows (CSOs). Disinfection is an important part of reducing risks associated with recreational and potable uses of receiving waters. However, traditional means of disinfection at WWTPs are designed to handle relatively constant flows and are not well suited to reliably handling highly variable CSO flows (Field, 1990). Because of the characteristics of CSOs—the intermittency, quantities of suspended solids, temperature variations, and variable bacterial quality—disinfection at WWTPs typically involves chlorine gas or sodium hypochlorite exposure (Field, O'Shea, and Brown, 1993). Other concerns involving disinfection of CSOs are that chlorine residuals may not be acceptable to the receiving water ecology, the disinfection unit may have to be unmanned and must be able to handle intermittent flows, and traditional indicator species such as fecal coliform may not be acceptable because runoff quantities may increase without corresponding increases in pathogens (Field, O'Shea, and Brown, 1993; O'Shea and Field, 1992).

Other disinfection technologies have shown promise in CSO disinfection. Boner et al. (1995) describe a bench scale test that used an ultraviolet disinfection unit installed in conjunction with a modified vortex separator (MVS/UV). The effectiveness of the disinfection unit depended on the solids removal efficiency in the vortex separator, and this study recommended that the MVS/UV be demonstrated at a full-scale installation. This recommendation was heeded, and a full-scale demonstration of a number of CSO abatement technologies is being conducted in Columbus, Georgia. (Boner and Turner, 1996). This demonstration project includes UV, chlorination/ dechlorination, and peracetic acid disinfection. Results of this project have not been reported.

7.3.5.1 Research Needs

A primary research need is to develop better means of measuring potential pathogenic waterborne bacteria. Traditional indicator organisms are unreliable for health-risk measurement, especially in areas that receive CSO and stormwater runoff (O'Shea and Field, 1992, 1993). One indicator will likely not be appropriate for every watershed; therefore studies should include a wide variety of storm-generated pollution and receiving waters (O'Shea and Field, 1992, 1993). Before control technologies can be compared and design guidelines developed for the disinfection of wet weather discharges, reliable means of measuring performance are crucial. Demonstration of disinfection technologies is also important; however, conclusive results should be dependent on reliable measures of pathogenic control.

7.3.6 Advanced High Rate Treatment—Magnetic and Chemical Additives

The addition of chemicals to aid in sedimentation is standard practice in water and wastewater treatment, and is known to substantially increase sedimentation rates (Booker, Ocal, and Priestly, 1996). The intermittent, highly variable nature and the need for unmanned facilities makes treating wet weather flows with these processes more challenging (Field, 1990). Booker, Ocal, and Priestly (1996) give experimental results from Australia derived from chemical flocculation and magnetite-assisted sedimentation and high-rate filtration as a means to treat urban runoff. Another technology utilizing magnetic forces, high-gradient magnetic separation, has also been used to treat urban runoff with success (Field, 1990). A demonstration facility in Albany, New York used chemical additives to enhance treatment of CSO and raw sewage. Activated carbon was added to the flow to remove dissolved organics, then alum was added to aid in clarification (Field, 1990). Polyelectrolyte was added followed by a flocculation period. Gravity settling was then followed by filtration and disinfection. Reclaimed and reused chemicals were part of this demonstration (Field, 1990). Booker, Ocal, and Priestly (1996) report on use of polyelectrolytes to enhance flocculation and chemical coagulation. In pilot experiments, polyelectrolytes were added to SSOs, along with an inorganic coagulant (alum), and magnetite (iron oxide) to aid in sedimentation (Booker, Ocal, and Priestly, 1996). Initial results were promising for treatment of sewer overflows. Another phase of this study tested the addition of a coagulant (aluminum sulfate) and a high molecular weight cationic polyelectrolyte to raw sewage (Booker, Ocal, and Priestly, 1996). This mixture was then filtered using a more coarse filter than normally used for raw sewage. The flocculated and coagulated sewage was filtered at a high-rate at the pilot study scale (Booker, Ocal, and Priestly, 1996). These experiments showed promise in high-rate physicochemical separation. Delaporte (1996) reports on promising research in use of lamellar decantation in treating storm-induced flows. This process uses a flocculation and coagulation reactor in combination with lamellar modules, which are used in physicochemical treatment of water and wastewater. Results show COD and SS reductions of 60 to 85%. Averill et al. (1996) report on an integrated CSO treatment facility in Toronto. This pilot test used chemical coagulant additives, a vortex separator (Storm King Dynamic Separator), a clarifier, and UV disinfection. The average effluent TSS concentration was 65 mg/L when using the chemically assisted coagulant (Averill et al., 1996).

7.3.6.1 Research Needs

Research should focus on process refinement and interaction with other high-rate treatment processes, e.g., vortex separation and disinfection, as shown in Averill et al. (1996). The Toronto pilot test (Averill et al., 1996) is an excellent model in developing process demonstration facilities, as all processes may be removed or an additional process added in order to monitor operational performance on a wide variety of process train configurations.

7.3.7 Control of Solids

Removing suspended solids is perhaps the oldest method for controlling water pollution. If allowed to settle by gravity, suspended solids are removed relatively easily and do not require biological or chemical treatment. However, the treatment of suspended solids is still a complex engineering problem because of constraints related to the settling velocities of small particles in water. Removing solids is additionally important because other important pollutants are often either in solid form or adsorb onto solid particles. Nutrients, bacteria, synthetic organics, toxics, and heavy metals may all be part of the suspended solids load. Control of wet weather solids may be accomplished either by treatment or source control. Source control of suspended solids is covered in Section 7.1. Treatment of suspended solids may be broken into treatment utilizing strictly settling forces, or enhanced settling via chemical or magnetic additives (covered in Section 7.3.6). Gravitational settling treatment includes traditional detention and gravity settling, enhanced gravitational settling (i.e. plate settlers), or vortex separation (covered in Section 7.3.4).

Control and treatment of dissolved solids is a more complex engineering issue. Because they are not affected by gravitational forces, dissolved solids, along with colloidal particles, must be controlled by other means. Dissolved solids are more commonly treated by source control; e.g., BMPs related to erosion and site disturbance, or deicing salt management. However, Van Buren, Watt, and Marsalek (1996) report removing dissolved pollutants from a modified detention basin by using baffles to eliminate short circuiting. Wetland biota may remove selected dissolved pollutants. In an assessment of wetland treatment, Strecker (1993) reports that metals may form insoluble sulfides in wetland environments. Urbonas (1997) also cites biochemical reactions occurring in wetland and wet-pond environments that remove dissolved constituents. In general, dissolved solids treatment must rely on some form of reaction, while suspended solids may be treated chemically or physically.

7.3.7.1 Research Needs

The physics of particle behavior in water is fairly well understood; however, the added complications of flocculation, floatables, highly variable loads, and biologic activity make it difficult to accurately predict actual settling. Demonstration of innovations in outlet design, storage geometry, and the effects of loading variability should be encouraged. We must better understand physical aspects of settling basins, including mixing regimes, temperature effects, concentration effects, and velocity distributions. A better understanding of the physical processes may lead to more efficient designs and aid in other areas of treatment. Research on the treatment of dissolved solids should be part of a wetlands-treatment research program. This is a relatively active research area in the United States, and, in the monitoring of these systems, a better understanding of the biochemical reactions that take place in a wetland environment should be encouraged.

7.3.8 Characterization and Treatment of Toxics and Metals

Heavy metals (cadmium, copper, lead, and zinc) and many toxics (e.g., PCBs, dioxin) are environmentally persistent, and therefore accumulate in receiving water sediment, settled sludge from WWTPs or satellite treatment facilities, or in the surficial soils of permeable infiltrating areas (Boller, 1997). An estimated 50 to 80% of metals are washed off from roofs and streets (Boller, 1997). Forster (1996) found a prominent first flush of metals from urban roof runoff in Germany.

Physical treatment (e.g., gravitational settling, filtration, vortex separation) tends to transfer these pollutants from one segment of the urban waste stream to another. For example, settled metals accumulate in benthic environments such as the bottom of detention ponds (Ab Razak, Li, and Christensen, 1996). Routine maintenance may be performed by dredging the detention basin bottom. The result is contaminated soil waste that may have to be landfilled. Therefore, source control is a critical part of toxin and metal control (Forster, 1996; Boller, 1997). PAHs, PCBs, ^{137}Cs, and ^{210}Pb are among other persistent pollutants that associate with clay, silt, and organic carbon particles in runoff and may ultimately accumulate in sediment beds (Ab Razak, Li, and Christensen, 1996). Forster (1996) reported zinc and copper concentrations from roof runoff that pose an environmental hazard to aquatic fauna even after strong dilution. Bijlsma et al. (1996) conducted studies on canal sediments in the Netherlands and found high concentrations of metals. The top 15-cm layer had concentrations of zinc as high as 1400 mg Zn/kg, copper as high as 281 mg Cu/kg, and lead as high as 562 mg Pb/kg. The sediment over 15 cm deep had concentrations 20 to 50% higher, possibly indicating a diminishing load. Forster (1996) recommends that the first flush of roof runoff be conveyed to the WWTP via combined sewers. This management alternative assumes that the WWTP sludge will contain metals from other sources, and therefore the incremental metals added by diverting roof runoff will not add to the toxicity of the sludge. Boller (1997) indicates that innovative wet weather management systems such as enhanced infiltration are severely limited by the possible accumulation of heavy metals. Management alternatives such as combined sewers, separate systems, or infiltration schemes merely transfer metals to WWTP sludge, receiving water sediments, or local on-site soils, respectively (Boller, 1997).

7.3.8.1 Research Needs

Source control appears to be the only form of long-term control that will avoid build-up of persistent pollutants in the environment. Long-term, cross-disciplinary research—involving plumbers, automobile designers, architects, landscape architects, environmental and industrial engineers, and the public—is essential to effectively remove these pollutants from the urban environment (Boller, 1997). This research is critical and should be linked to on-site hydrology, infiltration and other re-use strategies, and wetland management. Aside from source control, it is important in the short-term to continue research into toxic impacts, bioaccumulation, and the fate and transport of waste through the urban hydrosphere, from the household level to its ultimate fate in the environment.

7.3.9 Wetland Treatment and Land Disposal of Urban Runoff

While, technically, different forms of wet weather management, wetland treatment systems and land disposal techniques share some important concepts. Both are less infrastructure-intensive than sewer-based/receiving water discharge systems, and have similar benefits; namely both reduce flood peaks, may increase the local groundwater table, and may reduce pollutant discharges to receiving waters. Land application has the additional benefit of reducing outdoor landscape irrigation needs, while wetland systems may be incorporated into beneficial land uses such as parks and wildlife habitat (Knight, 1997). Important considerations of both practices have also been identified, namely possible soil contamination of persistent toxins and metals (see Section 7.3.8).

Wetlands used for treatment are complex systems requiring a close interaction between hydrologists, biologists, engineers, land-use planners, and urban managers. They require maintenance and careful design to maintain sustained benefits (Urbonas and Stahre, 1993). The literature in the constructed wetland field is broad. Habrel et al. (1997) give an overview of wetland systems for water pollution control. This volume highlights the advanced level of research activity in this area. Shutes et al. (1997) report on wetland systems for runoff treatment; pre-treatment consists of oil separators, spillage interceptors, and wetland forebays. This example of integrating innovative treatment schemes is important for the long-term success of these methods. In the United States, concerns about groundwater contamination have engendered somewhat more resistance to the application of infiltration systems than to constructed wetlands. However, in Tokyo, applications have been extensive and the increased baseflow in urban streams has been beneficial (Fujita, 1997).

7.3.9.1 Research Needs

Wetland treatment and land disposal of urban runoff are active research areas and further knowledge should be encouraged. Specifically, long-term treatment capabilities of both infiltration systems and wetlands should be investigated. It is also important that these systems be part of an integrated land-use/runoff management scheme. The land value benefits of riparian parks and wetland systems may even outweigh improvements in water quality. These systems will be a vital part of urban land and water management of the 21st century and as such it is important that research be continued in this area. The hydrologic considerations in designing these systems are crucial. Application rates of infiltration and acceptable hydrologic loading of wetlands are important for sustaining these systems. Regional differences are more pronounced than for other forms of treatment, and therefore demand acceptable hydrologic loading. The research aspects of wetland and infiltration disposal should focus on engineering better overall systems that increase land values through parks, provide treatment of runoff, and are part of a plan that includes source control, infiltration systems, and detention/wetland systems.

7.3.10 BMP Effectiveness

Best management practice (BMP) is an ill-defined term in the urban wet weather literature. BMP is used to describe everything from true management practices to any type of control facility, including large capital projects, that go beyond the common meaning of the term management alternative. Urbonas (1997) defines BMP as any practice to control and manage the quality and quantity of urban runoff, including structural and non-structural BMPs. Non-structural BMPs include: discontinuing or preventing use of a pollutant (e.g., pesticides, phosphorus detergents); programs to reduce site disturbance and erosion; public education on proper uses and disposal methods of chemicals, oils, pesticides, etc.; effective street sweeping, deicing, and leaf removal; elimination of illicit connections of wastewater lines to storm sewer lines; and O&M programs for public and private wet weather management facilities (Urbonas, 1997; Pitt et al., 1997; Schueler, 1995). Structural BMPs may include: minimizing directly connected impervious area, water quality inlet design—including catch basin design (e.g., deflective litter control design), infiltration practices, filter basins and filter strips, solids separation by gravity or vortex forces in wet and dry detention basins and vortex separators, and wetlands (Urbonas, 1997; Pitt, 1997; Yu and Nawang, 1993).

Currently there is no meaningful direct measure of the effectiveness of non-structural BMPs, largely because they rely more on behavior modification than on hardware-oriented means (Urbonas, 1997; Pitt et al., 1997). Non-structural BMPs tend to be common-sense practices; however there is little information on the costs of the necessary behavior modification and benefits derived thereof. Field performance data are available from a wide variety of structural BMP facilities (Urbonas, 1997). However, there is no standard method of measuring performance, and much data are reported in the theoretically flawed measure of "percent removal" (Urbonas, 1997).

7.3.10.1 Research Needs

Several critical research needs are associated with the application of BMPs. Most critical is developing a better understanding of how various BMPs fit into an integrated urban water management plan. To accomplish this, three research needs are evident: (1) a meaningful standard to quantify performance; (2) long-term performance and cost data (using the standard developed in #1) to prove that BMPs in fact are "best"; and (3) a process-level understanding of the various BMPs to improve current design practice. Current BMP design is an art, relying on the designer's intuition about what is appropriate for a given situation.

7.3.11 Improved Knowledge of Operating and Maintenance Costs

As discussed in Sections 7.2.6 and 7.2.8 for collection systems, knowledge of actual costs of maintenance activities is crucial to developing a beneficial maintenance plan. This is also true for the operators of storage/treatment facilities to minimize life-cycle costs. For example, based on construction expenditures, detention ponds may be an attractive storage and treatment option in areas where land value is relatively low. However, the administration of maintenance of storage works is crucial to maintain performance over time (Urbonas and Stahre, 1993). Not only are the costs of cleaning and maintaining detention ponds important as settled solids fill the volume of the pond, but the administration of these activities must be planned during the design stage so facilities are not abandoned (Urbonas and Stahre, 1993). Further consideration must be given to the potential of disposing contaminated sediments, as discussed in Sections 7.3.8 and 7.3.9.

7.3.11.1 Research Needs

Knowledge of life-cycle costs must be better understood to accomplish integrated performance criteria for an entire drainage system. As with collection systems, storage and treatment works must include careful documentation of the trade-offs incurred between maintenance and performance. To accomplish this goal, standardized performance criteria should be developed to understand how well existing facilities perform, and standardized accounting procedures should be developed to allow for cross-comparison. Demonstration of these performance criteria in actual basins would then lead to a better design criteria for engineers, and a better understanding of the life-cycle costs for operators.

CHAPTER 8.0

SYNTHESIS OF RESEARCH NEEDS AND CONCLUSIONS

8.1 Summary

This chapter discusses the results of our assessment of research needs in urban wet weather flows (WWFs). Three interrelated categories are included: combined sewer overflows, sanitary sewer overflows, and urban stormwater discharges, and each research need is considered in the following steps: (1) reviewing of all relevant literature; (2) reviewing of previous research needs assessments, including US EPA's 1996 Wet Weather Flows research planning report (Field et al., 1997); (3) soliciting ideas from interested professionals at a one-day workshop at the 1996 WEFTEC national meeting in Dallas; (4) holding extensive discussions with leading urban stormwater professionals; and (5) reviewing research needs with leading international experts at the September, 1997, Engineering Foundation Conference in Malmö, Sweden (Rowney, Stahre, and Roesner, 1998).

8.2 Methods for Doing Research Needs Assessments

Research needs can be assessed in a variety of ways. Five of the seven research needs assessments cited in this report were done by polling experts during a professional meeting. The remaining two needs assessments used an extensive literature review and the professional experience of a few experts as the basis for selecting topics. The research needs assessment can be viewed as a portfolio selection problem wherein the objective is to maximize the present value of the expected net benefits from research investments. Research is a risky investment. The objective is to select a project portfolio with a high probability of success just as investors choose among stocks, bonds, and other investment opportunities. While formal research planning models have been used for large research programs, most research funding organizations rely on less formal approaches. This assessment uses a wide variety of U.S. and international expertise to develop a sense of research needs. The project team believes that the final list is a fairly well balanced view of the problem.

8.3 Purposes of Urban Wet Weather Research Program

Many different entities support wet weather research. Among them is the Water Environment Research Foundation (WERF), which is supported by participating cities that generally prefer to support applied research involving well-defined tasks and a fairly high assurance of delivering results to the user community within three to five years. Therefore, WERF projects typically address discrete, targeted topics that involve relatively short study periods (one to two years). WERF project funding is awarded based on responses to a formal Request for Proposals (RFP). At present, this model dominates research funding in the United States and Europe, because the results reach the funding organizations in a short time frame. Two potential drawbacks of funding only relatively applied research projects is that such projects may tend to be less innovative, since the problem and often the solution are prescribed in the RFP, and such projects usually provide only limited support for training graduate students in the wet weather area. [Editor's note: WERF has now created a funding program for innovative research under its Emerging Technologies Program.]

At the opposite end of the spectrum is basic research, characterized by unsolicited proposals from universities and other research organizations wherein proposers present their ideas and request support for longer-term, basic research for which immediate utility may be unclear. It is more difficult for local utilities and agencies to justify supporting such activities. Even a federal action agency, such as US EPA, may have trouble justifying such longer-term investments. The National Science Foundation (NSF) provides this kind of support. Until recently, their funding related to urban stormwater has been scant. A current NSF/US EPA/USDA cooperative initiative on watersheds offers hope of better support in this area.

A potentially new dimension of future WWF research lies in the area of international cooperation. These essential, long-term experimental research are expensive and it is difficult to obtain continuing support in lean budget times. The emergence of the European Union as a major source of research support offers real possibilities for establishing internationally funded cooperative projects in key WWF areas.

8.4 Vision for the Benefits of Urban WWF Research

Concerted efforts since the late 1960s to clean up urban wastewaters and wet weather flows have achieved impressive results. Before then, the accepted fate of urban receiving waters was to serve as recipients of the unwanted by-products of urbanization including dry-weather- and wet-weather-transported wastes from urban, industrial, agricultural, forestry, mining, and other activities. Also, these same receiving waters were ditched, drained, sewered, and subjected to a wide variety of manipulations to serve human needs. In addition to water quality changes, these waters were severely impacted by hydrologic changes due to hydropower development, navigation, water supply, flood control, recreation, etc. The end product of these abuses was that citizens were conditioned to think of their waterways as undesirable kidneys of the city that were to be hidden and avoided.

Consequent to billions of dollars of expenditures on water quantity and quality improvements, we can now see the long-term benefits of these investments come to fruition in terms of revitalized urban waterfront areas. With WWFs managed and a desirable hydrology provided for receiving waters, citizens can enjoy the benefits of this important investment for themselves and for posterity.

8.5 Summary of Research Recommendations

A synthesis of seven compilations of research needs and a selection from this listing were presented in the previous five chapters. The compilation resulted in the 154 research projects listed in Table 8-1. From this list, a subset of 69 higher priority research projects were selected and one page summaries were prepared for each of these topics. The selected 69 projects are shown in Table 8-2. During the final screening, several criteria were used in the selection process:

- Inherent importance of the topic;
- Topic is an emerging area of concern for which few research results are available; and
- Topic is an important component of an integrative approach to WWFs.

The final 26 selected research topics (Table 8–3), are divided into two priorities. Priority 1 topics should be initiated first. They may be short- or long-term efforts. Priority 2 topics are also important but not as critical as the Priority 1 topics. In many cases, these final 26 topics are aggregations of the larger subset of high-priority research projects. The final results of the research needs assessment were organized into 10 categories: (1) sources and monitoring, (2) receiving water impacts, (3) other impacts, (4) management, (5) models and decision support systems, (6) watershed management linkages, (7) regulatory policies and financial aspects, (8) source controls, (9) collection system controls, and (10) storage/treatment systems. Summary discussions regarding these topics are presented in the subsections that follow.

8.6 Sources and Monitoring

8.6.1 Automotive Pollution Source Reduction or Elimination

Cross-cutting research should be done by product, e.g., automobile, as well as by constituent, e.g., zinc, in order to understand how these constituents originate and move through urban systems. Among the many products and activities that affect urban WWFs, the automobile stands out as the most important generator of runoff. Much of the imperviousness in cities— streets, parking lots, driveways, garage and carport roofs—supports automobile-related activities. Also, automobiles generate a significant portion of the WWF pollutant load. An evaluation of WWF pollutant control opportunities by preventive methods associated with the automobile is recommended. This could be a major thrust area and would include not only pollutant load generation but also the feasibility of large-scale use of permeable and porous pavements. Lastly, the potential value of demand management techniques to reduce automobile dependency could be evaluated.

8.6.2 Source Control of Heavy Metals

Another major thrust area is to select a heavy metal and perform a source-prevention analysis with regard to urban WWFs. Heavy metals present a quandary whether they end up in sewage sludge, sediments in ponds and receiving waters, in soil, or groundwater. A vision for source management is that additional research will permit the gradual reduction or elimination of these urban WWF sources before they enter the system. This preventive approach is the preferred long-term, sustainable choice. US EPA has an active pollution prevention program; the WWF group of US EPA should explore joint funding opportunities.

Table 8–3. Final List of Projects by Priority

Topic	*Priority*	
Sources and Monitoring		
Automotive pollutant source reduction or elimination	1	
Source control of heavy metals		2
Innovative monitoring methods	1	
Receiving Water Impacts		
Improved understanding of the physical, chemical, and biological processes		2
Defining beneficial uses for urban receiving waters		2
Urban stream and sediment geomorphology and restoration	1	
Stormwater-groundwater-vadose zone impacts		2
Other Impacts		
Evaluation of other performance measures for wet weather flow systems	1	
Management		
Opportunities for decentralized urban wet weather management	1	
Restructuring federal water agencies to better address urban water issues		2
Models and decision support systems		
Improve SWMM to include all aspects of contemporary decision support systems	1	
Incorporate real-time control into decision support systems	1	
Watershed Management Linkages		
Participate in integrated long-term experimental evaluation of urban watersheds	1	
Regulatory policies and financial aspects		
Determine areas where regulatory flexibility can achieve watershed goals		2
Innovative financing mechanisms for wet weather controls		2
Improved methods for evaluating the effectiveness of public education		2
Source Controls		
Feasibility of aggressive on-site and local infiltration of wet weather flows	1	
Feasibility of using porous and permable pavements		2
Feasibility of reusing wet weather flows for irrigation	1	
Collection System Controls		
Evaluation of role of separate and combined sewers including storage in sewers	1	
Deposition and scour in sewers		2
Improved infiltration/inflow control methods	1	
Benefits of sewer flow and quality monitoring		2
Storage and Treatment		
Improved high-rate wet weather storage treatment devices	1	
High-rate operation of wastewater treatment plants	1	
Effectiveness of best management practices	1

8.6.3 Innovative Monitoring Methods

Monitoring continues to be an issue because of difficulties in getting accurate data under the complex dynamic conditions that occur during wet weather periods. A strong theme of future WWF management strategies is to move toward data-centered modeling. Direct measurements are fundamental to understanding these complex processes. The regulatory process must promote continuous monitoring activities to determine what actually happens as WWFs move through urban areas. Recent hardware and software improvements make it much more cost effective to monitor performance directly and to use this information for real-time control. In spite of these advances, fundamental data on how wet weather processes occur in urban areas remain lacking.

8.7 Receiving Water Impacts

From the early days of WWF research, the chronic question has been, "What's the problem?" Efforts to demonstrate clear cause-and-effect linkages between WWFs and receiving water problems did not yield clear evidence (Heaney and Huber, 1984). Several reasons may be cited for this difficulty including:

- No significant acute receiving water impacts occur, only chronic long-term impacts;
- Urban WWF impacts are masked by all of the other impacts including sewage effluents, upstream pollution, non-urban nonpoint pollution, and hydrologic modifications;
- Lack of studies that concurrently measure landside and receiving water fluxes; and
- Lack of agreement on how to define "impacts". Are they violations of water quality standards, impaired beneficial uses, geomorphologic changes in the receiving water, etc.?

Debate on these issues continues. Participants at a 1996 Engineering Foundation Conference that focused on receiving water impacts could not agree on how to measure receiving water impacts in a way that was acceptable to the scientific, engineering, regulatory, and user communities (Roesner, 1997). Roesner (1997) summarizes the current situation:

> What became clear to this engineer during the course of the conference is that engineers view habitat degradation and restoration much differently than does the

scientific community. Engineers, being concerned and trained to protect the public health and safety of the community from flood damages, tend to design systems with a high degree of integrity that will withstand the 100-year flood. This has resulted in channel straightening, lined channels, removal of vegetation, and debris removal that are detrimental to the resident aquatic ecology. Scientists on the other hand advocate the use of many techniques for aquatic habitat restoration that cannot withstand the forces of flood flows and thus pose a distinct threat to public health and safety. What is required is the development of soft engineering that simultaneously provides for drainage and flood protection, achieves the scientists' criteria for ecosystem protection or restoration, and looks and acts like the natural environment. The conference shows that there are a number of issues that need to be addressed to make this happen.

8.7.1 Physical, Chemical, and Biological Responses in Receiving Waters

Research concerns in this category are long-standing and include efforts to define "natural" conditions as a baseline, looking for an overall index or set of indices to measure receiving water impacts, and developing criteria for receiving water impacts. The inherent complexity of receiving water systems makes it essential to continue to seek a better understanding of the physical, chemical, and biological processes. However, other measures of effect must be explored.

8.7.2 Defining Beneficial Uses for Urban Receiving Waters

A fundamental unresolved issue is to unambiguously define "receiving water." Many, if not most, of the surface waters in urban areas have been severely modified by human activities. Indeed, many of these receiving waters are artificial canals and ponds that were constructed for a variety of purposes. Because the most severe impacts of urban runoff tend to manifest themselves in these smaller receiving waters, their water quality protection often dictates the required level of control to meet existing regulations. It is probably futile to use "natural conditions" as a benchmark for urban receiving waters since many of them have been severely modified for a variety of human uses including water supply, flood control, navigation, hydropower, wastewater transport, mining, and agriculture. A more meaningful goal may be to develop a consensus on the future vision for that water and then to design a management program accordingly. Case studies of river and lake rejuvenation can be used to illustrate this concept.

8.7.3 Urban Stream and Sediment Geomorphology and Restoration

Research and regulation on receiving waters has tended to focus on impacts measured in the water column. Sediments are considered as sources or as sinks relative to the water column. Many of the long-term effects of WWFs and other pollutant sources are manifested in buildup of pollutants such as toxics in sediments. Serious impacts can occur if and when this sediment is resuspended. The dynamics of sediment deposition and resuspension are complex and site specific. Thus, it is a challenging research area. An important research need is to demonstrate the cost-effectiveness of managing receiving-water sediment as part of control programs. Without managing sediments, we ignore perhaps the most important component of receiving water impacts.

A newer emphasis in receiving-water evaluations is to use physical change in the receiving water as a measure of effect. These impacts are especially noticeable in smaller urban streams. Urbanization causes a flashier hydrologic response into receiving waters, and tends to reduce groundwater levels that are essential to provide base flows in streams. Thus, physical changes in the stream can be used as indicators of impacts. Research is needed to better quantify these impacts including the effects of wet weather detention systems on stream and sediment dynamics.

8.7.4 Wet Weather–Groundwater–Vadose Zone Impacts

Interest in subsurface WWF impacts on the vadose and groundwater zones is relatively recent in the United States. International research has given these effects more emphasis, especially in Europe and Japan, because of their extensive use of infiltration systems as WWF controls. With the expected growth of interest in decentralized management of WWF in the United States, the need to better understand and model subsurface effect is apparent. The influence of urban irrigation on local water budgets must be included because irrigation has a significant effect on antecedent conditions in many areas.

8.8 Other Impacts

Recently developed multiple performance measures for WWF control systems—e.g., the Association of Metropolitan Sewerage Agencies' list of 24 elements—illustrate the need to expand the evaluation beyond the traditional concern with meeting water quality standards. Little definitive evidence shows that urban WWFs can seriously impair human and ecosystem health. Because of the dynamic nature of WWFs, it is quite difficult to perform the necessary risk assessments to evaluate public health problems. The problem of evaluating ecosystem health impacts is even more complex because of the lack of clear definition of terms with regard to what is meant by ecosystem health. A significant component of integrated impact analysis is the socioeconomic and financial effects. This subject has received little attention with regard to WWF water quality problems. Quantification of direct—e.g., degraded property values—and indirect—e.g., non-user values—economic impacts can be a significant portion of the overall evaluation. Numerous "success" stories of stream and lake rejuvenation are reported in the literature. These successes can be measured by the economic and social revitalization in neighborhoods and cities as once polluted and otherwise degraded surface waters become improved to the point where they are viewed as assets to the community and become a focal point of redevelopment efforts.

8.9 Management

8.9.1 Opportunities for Decentralized Wet Weather Management

The literature on sustainable urban systems strongly suggests the need to manage wet weather problems using decentralized systems with strong emphasis on local infiltration, detention, and reuse. The development of decentralized WWF systems would represent a shift away from the prevailing tendency to use large centralized controls. Decentralized WWF systems are most cost-effective if water, wastewater, and wet weather management functions are integrated at this local spatial scale. International efforts in this area should be reviewed as part of this research initiative.

8.9.2 Restructuring Federal Water Agencies to Better Address Urban Water Issues

Wet weather flow quality regulatory programs of the past 25 years have emanated primarily from the federal government. During the same period, urban wet weather utilities have been created in many cities and several metropolitan areas. Many of these agencies have quantity management as their primary, and often exclusive, mandate. Also, watershed-based organizations are emerging. It is too early to predict the influence of these organizations. Another new organizational concept is privatization of these activities as has been done internationally. The most radical departure from current U.S. organizational practice would be to decentralize current federal responsibilities down to state, local, and watershed levels. Aggressive movements in this direction have been made in Great Britain, Australia, and New Zealand. These decentralized organizations are typically watershed-based and handle all aspects of water. Thus, they are in a much better position to develop and finance multi-purpose programs. Federal wet weather flow management responsibilities in the United States are spread across several federal agencies with numerous, and often conflicting, mandates, e.g., to promote economic development vs. to protect the environment. Is it desirable to modify the missions of these agencies so that WWFs can be managed more consistently?

8.10 Models and Decision Support Systems

8.10.1 Improve Stormwater Management Model to Include All Aspects of Contemporary Decision Support Systems

US EPA support of the development of the US EPA Stormwater Management Model (SWMM) has resulted in major benefits in terms of improved methods of analysis of urban WWF problems. Developed around 1970, SWMM has been improved so it can now handle a wide variety of hydraulic boundary conditions. Contemporary users have come to expect a user-friendly environment, nice graphics, links to database management systems, links to real-time control, links to GIS, and seamless integration across modules, i.e., from runoff to transport to storage/treatment to receiving water. Also, they would like to link the simulators to optimizers that can help find good, if not optimal, solutions. Other desirable features include explicit considerations of uncertainty, and a benefit/cost element to evaluate the desirability of various alternatives. Lastly, linkages are desired between WWFs and urban water supply, wastewater collection and treatment systems, flood control, hydropower, and other aspects of water management so that an integrated view can be taken of urban watershed management.

Lacking continuous federal support during the past 15 years, SWMM has not kept pace with other, more recent, models such as MOUSE in terms of some technical capabilities—e.g., solids in sewers, real-time control—but more obvious is its comparatively unfriendly user interfaces. Commercial products such as XP SWMM offer much easier to use shells for running SWMM. Research is needed to develop a vision of SWMM for the 21st century that addresses key questions, such as whether US EPA should support a major development effort, whether SWMM should remain non-proprietary, and what new features are needed in the model.

8.10.2 Incorporate Real-Time Control into Decision Support Systems

Real-time control (RTC) provides an important overarching framework for future decision support system development. Ultimately, system performance should be measured directly and intelligent decisions made accordingly. Intensified research is needed in the United States to inventory the current status of using RTC, especially internationally, and then to develop innovative improved RTC techniques for WWFs.

8.11 Watershed Management Linkages

In spite of tremendous interest in the 1990s to use watershed-based approaches for evaluating urban water problems, little research has been done on methods for doing such evaluations. The notable exception is the US EPA/NSF/USDA program on watershed research, active for the past four years. More formal linkages to this program should be explored.

One striking gap in understanding urban water management is the absence of long-term experimental urban watersheds that can directly assess the impacts of urbanization. A possible initiative is to tie to the recently funded NSF Long-Term Ecological Research (LTER) urban watersheds efforts, for instance in Baltimore.

8.12 Regulatory Policies and Financial Aspects

8.12.1 Determine Areas Where Regulatory Flexibility Can Achieve Watershed Goals

During recent years, US EPA has been trying to offer more flexibility in its regulatory programs in order to achieve more cost-effective WWF programs (Lindsey, Swietlik, and Hall, 1996). Opportunities for more cost-effective programs include allowing multi-media analysis to see where pollutants can be more effectively controlled or eliminated at the source, allowing upstream and downstream trade-offs for control of a specific constituent of concern such as nutrients or allowing trade-offs with other water management activities, for example, changing the operation of a hydropower reservoir. As the GAO (1997) evaluation of these new regulatory thrusts points out, US EPA faces major challenges to make significant changes in the way it has done business for the past 25 years. Research is needed to evaluate the effectiveness of experimental programs to provide more regulatory flexibility.

8.12.2 Innovative Financing Mechanisms for Wet Weather Controls

During the early years of US EPA, financing of WWF control programs was relatively uncomplicated since the federal government had both the carrot and the stick. The carrot was very generous federal cost sharing for control projects. The 1990s brought a different financial situation with the federal government still wielding the stick of regulations but without a significantly smaller carrot in the form of financial incentives to pay the costs. The much ballyhooed watershed and integrative water management programs require sophisticated cost-sharing arrangements, a major hurdle. Research is needed on how to obtain sustainable financing to support these potentially expensive programs.

A significant constraint on developing innovative urban stormwater management programs is the fragmented funding policies of the federal agencies, the largest supporters of wet weather research. Under current funding patterns, it is difficult to take a holistic view of the problem because research funding is available only to evaluate specified components of the problem. It is hard to be optimistic about the prospects for cooperatively supported integrative research from our assertively independent federal water agencies—US EPA, the Corps of Engineers, FEMA, USDA, FHWA, USGS, NOAA, DOE, DoD, and other agencies.

8.12.3 Improved Methods for Evaluating the Effectiveness of Public Education

While education is an essential element in improved environmental management, it is difficult to quantify the cause-and-effect linkages without longer-term data collection. Litter control continues to be cited as a priority research need. Experience in evaluating the effectiveness of water conservation programs should be evaluated as a case study of related efforts to quantify the effectiveness of educational programs.

8.13 Source Controls

8.13.1 Feasibility of Aggressive On-Site and Local Infiltration of Wet Weather Flows

During the past decade demand-side management has taken hold in the water resources and related energy fields. Correspondingly, in the water quality field, attention has switched from end-of-pipe treatment of the unwanted by-products of urbanization to reducing the load entering the city through demand management. Water conservation efforts significantly influence the quantity and quality of domestic wastewaters. Also, local management of WWFs by infiltration and storage reduces the downstream load. Research is needed on the value of demand-management approaches and their long-term impacts; for example, will local infiltration of WWFs and using gray water for lawn watering cause public health problems?

Many innovative research areas have been suggested under the general category of on-site control. The most fundamental and sustainable approach is to reduce or eliminate the size of the problem at the source by preventive measures. With successful experience in Europe and Japan, interest in local infiltration systems is growing in the United States. These infiltration systems can provide local control that mimics the performance of the undisturbed natural system. Research to date indicates that these infiltration systems are safe if the infiltrated water comes from low-risk sources such as rooftops, residential driveways, and seldom-used parking areas. WWF can also be used for gray water in houses. Adequate monitoring is essential to properly evaluate the efficacy of on-site controls. Such monitoring should include the effect of lawn watering on the local water budget.

8.13.2 Feasibility of Using Porous and Permeable Pavements

The feasibility of using porous and permeable pavements, especially in low traffic areas, should be explored with a combination of laboratory, pilot, and full-scale monitoring systems. This significant effort should be coordinated with U.S. transportation agencies and international programs that have already established testing facilities.

8.13.3 Feasibility of Using Wet Weather Flows for Irrigation

A related area of on-site control is to reuse WWFs for local irrigation. This WWF can be stored on-site in cisterns or in neighborhood surface ponds. The option may be very attractive in areas with high irrigation demands and expensive water treatment costs. With lawn watering as a beneficial use, the economics of using large regional ponds vs. local ponds may switch to favor local ponds to reduce distribution system costs.

8.14 Collection System Controls

8.14.1 Role of Separate and Combined Sewers Including Storage in Sewers

The pros and cons of combined vs. separate sewer systems and fundamental design criteria continue to be debated; see for instance, "Two feet per second ain't even close" (Shafer, 1994). Research is needed to improve bases for design. Innovative options to be evaluated include oversizing sewers as a low-cost source of storage; and the inclusion of flushing systems as an integral part of sewer systems in order to optimize solids management. Sewer flow and quality measurements are essential to improve the state of art.

8.14.2 Deposition and Scour in Sewers

Existing simulation models can predict the behavior of WWF quantity in collection systems. However, they are much less adept at predicting water quality because of a high degree of uncertainty on the spatial and temporal variability in the quality of stormwater entering the sewers, and the complex sediment deposition and resuspension that occurs within the collection systems. Another long-standing gap in knowledge is understanding the nature of infiltration and inflow. The recently completed European initiative, entitled "Solids in Sewers" (Ashley, 1996), provides a prototype for future research programs organized to address these complex questions.

8.14.3 Improved Infiltration/Inflow Control Methods

Improved methods of I/I evaluation and control must be developed. Existing sewer design and construction practices still allow significant I/I to enter sewers. Innovative I/I controls for existing sewers are also needed. Current high levels of I/I are wasting valuable capacity in WWTPs.

8.14.4 Sewer Flow and Quality Monitoring

Professional and regulatory communities need to be convinced of the fundamental need to measure flows and quality in collection systems. A useful research project would be to document the benefits from such monitoring. A significant number of case studies have accumulated during a 30 year history of using real time control (RTC) to enhance the use of storage in combined sewer systems. The value of measurements as an integral component of RTC can be quantified from retrospective case studies.

8.15 Storage/Treatment

8.15.1 High-Rate Wet Weather Storage Treatment Devices

A wide variety of high-rate, wet weather treatment devices were developed and tested in the 1970s as part of an US EPA WWF research and demonstration program. This program supported a balance of laboratory and pilot plant testing of innovative technologies. It also provided support for demonstration projects and widely disseminated the results of these tests. Unfortunately, this program was sharply curtailed and much of this information is now obsolete and should be updated.

8.15.2 High-Rate Operation of Wastewater Treatment Plants

An important area requiring additional research is optimal operation of conventional wastewater treatment plants (WWTPs) in response to wet weather conditions. A significant reduction in sanitary sewer and combined sewer overflows could be achieved with high-rate operation of WWTPs during and following wet weather events. This is currently an active research area in Europe.

8.15.3 Effectiveness of Best Management Practices

The effectiveness of BMPs including ponds and wetlands continues to be debated. Even now, few experimental studies properly collect data to determine the overall effectiveness of these devices. A cursory look at the scientific basis underlying the widely reported "typical removal rates" in the literature reveals that we are on shaky ground. An important general research and technology transfer need is to develop a statistically meaningful database on actual performance of these BMPs that could be used in a systematic way to improve the state of the art.

8.16 Estimated Cost of U.S. WWF R&D Program

In the United States, research on urban runoff quantity and quality has been undertaken since the late 1960s, initial interest focusing on the problem of combined sewer overflows. The US EPA Municipal Environmental Research Laboratory's Storm and Combined Sewer Program invested $60 million to $70 million in some 250 extramural projects up to 1981. The US EPA Nationwide Urban Runoff Program (NURP) sponsored $30 million in field studies in 28 cities between 1979 and 1983. Also, other federal agencies including the U.S. Geological Survey, the U.S. Army Corps of Engineers, and the Office of Water Research and Technology had active urban WWF research and demonstration programs during the 1970s. While the exact total is uncertain, the federal investment in WWF research before 1983 probably exceeded $100 million (Heaney, 1986).

Roesner and Traina (1994) cite the American Public Works Association (1992) estimates of urban WWF control costs in the United States ranging from $147 million to $407 billion in capital costs and $1.2 billion to $542 billion/year in annual O&M costs depending upon the assumed level of BMP control. This extreme variation in the cost estimates reflects the high degree of uncertainty regarding future wet weather regulations. According to the 1996 US EPA Clean Water Needs Survey (CWNS), a total of $139.5 billion of capital cost is needed to satisfy all program categories eligible for state revolving funding for the design year (2016) population (U.S EPA, 1997).

Operation and maintenance costs are not included in this total. The breakdown of these total costs is shown in Table 8–4.

The only wet weather flow category comprehensively addressed in the 1996 CWNS is combined sewer overflows with a total capital need of $44.7 billion. According to US EPA (1997), sanitary sewer overflow control costs are probably underestimated in the 1996 CWNS:

> Although SO needs are not identified separately in the CWNS, some associated costs to address SO problems are included in Categories I, III, and IV. In general, EPA believes that the needs estimates in these categories related to SSOs underestimates the total costs associated with preventing SSOs. Therefore, the scale of the SO problem is currently being addressed by EPA separately from the CWNS.

In addition to excluding SSOs, the 1996 CWNS does not address control of urban runoff from storm sewers.

A conservative estimate of the expected capital costs for CSOs, SSOs, and stormwater quality management is about $100 billion. The expected amortized annual value of this capital investment is about $10 billion per year. Annual operation and maintenance costs would be comparable in size yielding an expected total annual cost of $20 billion per year.

The expected cost of managing wet weather flows can be used to estimate the needed expenditures for research and development to attempt to minimize these costs. A rule of thumb for the desired level of R&D is that it range from 2 to 6% of the investment depending on the type of technology. However, lack of funding during the past 15 years will require a few years to rebuild the necessary research infrastructure within US EPA and the university and professional research communities. Significant research efforts have been underway in Europe, Australia, Japan, and other counties during the past 15 years. Thus, we should look abroad to accurately assess the current state of the art. Using a conservative estimate of 1 to 2% R&D needed to support this WWF program yields an annual research funding need of $20 million to $40 million per year for the U.S. WWF program. Programs for international cooperation in research should be explored as a way to develop the most cost-effective R&D programs.

Table 8–4. Needs for Publicly Owned Wastewater Treatment Facilities and Other Eligibilities (US EPA, 1997)

Need Category	*Project Description*	*Total Capital Needs, $ billion*
Title II Eligible Projects		
I	Secondary Treatment	26.5
II	Advanced Treatment	17.5
III	Infiltration/Inflow Correction	3.3
IV	Sewer Replacement/Rehabilitation	7
V	New Collector Systems	10.8
VI	New Interceptor Sewers	10.8
V	Combined Sewer Overflows	44.7
VI	Stormwater	7.4
Total Categories I through VI		128
Other Eligible Projects (Sections 319 and 320)		
VIIA-C	Nonpoint Sources (agriculture and silviculture only)	9.4
VIID	Urban Runoff	1
VIIE-G	Groundwater, Estuaries, Wetlands	1.1
Total Categories VII		11.5
Grand Total		139.5

- PUBLIC EDUCATION

WATERSHED MANAGEMENT

Residential and Commercial Source Control Programs to Meet Water Quality Goals

SOURCE CONTROL

PROJECT 95-IRM-1

Water Environment Research Foundation

1998

ABSTRACT

A nationwide literature assessment was conducted to collect information on residential and commercial sources of wastewater and stormwater pollution. In most parts of the country, industrial sources of pollution have been effectively controlled through established pretreatment and industrial stormwater programs. To achieve further reductions in pollutant levels, communities are increasingly looking to nontraditional—commercial and residential—sources of pollutants.

The project team gathered information from around the country concerning wastewater and stormwater pollution prevention and public education programs that have been developed to address non-industrial sources. This research will provide a valuable resource for communities developing wastewater and stormwater pollution prevention programs. Also described herein are monitoring studies conducted to identify wastewater and stormwater pollutants and their sources. The report covers best management practices and program ideas for specific sources of pollutants. Public education programs and efforts to measure program effectiveness are also discussed. In addition, the report provides a list of program representatives who can be contacted for additional information on specific programs. Based on the results of the assessment, future research needs with respect to commercial and residential sources are identified.

WATER ENVIRONMENT RESEARCH FOUNDATION

RESIDENTIAL AND COMMERCIAL SOURCE CONTROL PROGRAMS TO MEET WATER QUALITY GOALS

PROJECT 95-IRM-1

Water Environment Research Foundation
Formerly Water Pollution Control Federation Research Foundation

ENVIRONMENTAL STEWARDSHIP THROUGH INNOVATIVE SCIENCE AND TECHNOLOGY

The Water Environment Research Foundation (WERF) was established to advance science and technology for the benefit of the water quality profession and its customers. Funded through voluntary contributions, WERF manages research under four major Thrust Areas: Collection and Treatment Systems, Human Health and Environmental Effects, Residuals Management, and Watershed Management. WERF seeks cost-effective, publicly acceptable, environmentally sound solutions to water pollution control problems. A 15-member Board of Directors composed of water quality professionals; volunteers from utilities, academia, consulting firms, and industry; a Utility Council and Corporate Council composed of subscribing entities; and a Research Council of knowledgeable leaders in environmental sciences and engineering are actively involved in applied and basic research program management.

While WERF manages the research and coordinates the parties involved, the actual work is carried out by individual organizations, primarily utilities, universities, and industrial and commercial firms. To ensure objectivity, an independent advisory committee of distinguished scientists and engineers helps select researchers, oversees the studies, and provides periodic review and advice. Benefits accrue in the form of services, technological advances, and information for direct application by the profession for its customers.

The Water Environment Research Foundation is successfully building a cooperative research and development program serving the water quality profession. The Foundation's goal is to apply sound and objective scientific information to better serve the public.

BENEFITS

- Provides a valuable resource for communities developing wastewater and stormwater pollution prevention programs;
- Cites monitoring studies that identified wastewater and stormwater pollutants and their sources;
- Describes best management practices (BMPs) and program ideas for specific sources of pollutants;
- Identifies public education strategies, approaches to different audiences, and types of materials developed;
- Discusses ways to gauge program effectiveness;
- Lists program representatives who can provide additional information on specific programs; and
- Identifies future research and program development needs with respect to commercial and residential sources.

R0025967

EXECUTIVE SUMMARY

A nationwide assessment was conducted to collect information on residential and commercial sources of wastewater and stormwater pollution. In most parts of the country, industrial sources of pollution have been effectively controlled through established pretreatment and industrial stormwater programs. To achieve further reductions in pollutant levels, communities are increasingly looking to nontraditional pollution sources (i.e., commercial and residential sources).

The project team gathered information from around the country concerning wastewater and stormwater pollution prevention and public education programs that have been developed to address non-industrial sources. This research will provide a valuable resource for communities developing wastewater and stormwater pollution prevention programs. Monitoring studies conducted to identify wastewater and stormwater pollutants and their sources are described in this report. Descriptions of best management practices (BMPs) and program ideas for specific sources of pollutants are included. Public education programs and efforts to measure program effectiveness are also discussed. In addition, the report provides a list of program representatives who may be contacted for additional information on specific programs. Based on the results of the assessment, future research needs with respect to commercial and residential sources are identified.

Over 200 people from wastewater, stormwater, and industrial pretreatment programs around the country provided information on pollution prevention activities being conducted in 25 states representing all ten regions of the United States Environmental Protection Agency. Findings are organized into the following areas:

- Monitoring and source identification efforts;
- Commercial and residential sources of pollutants;
- Public education programs; and
- Measurements of program effectiveness

Monitoring and Source Identification Studies

The pollutants evaluated during the review of monitoring and source identification studies are listed in Table ES-1. Metals were found to be the most commonly studied pollutants in the wastewater and stormwater studies reviewed for this assessment. Numerous studies have also evaluated levels of conventional pollutants and of nutrients. Pesticides and their sources were seen to be emerging as an area of more recent interest and activity. Fewer studies targeted organic pollutants (other than pesticides) and their sources.

Table ES-1. Summary of Pollutants Evaluated (Out of 48 Studies)

Category	Number of Studies	Pollutants Most Commonly Evaluated
Metals	36	Cu, Hg, Ni, Pb, Zn
Pesticides	14	chlorpyrifos, diazinon
Organics	13	polyaromatic hydrocarbons (PAHs), solvents, hydrocarbons
Nutrients	10	phosphorus, ammonia
Conventional	9	biochemical oxygen demand (BOD), total suspended solids (TSS), oil and grease
Others	5	cyanide, tributyltin

With respect to source identification, several studies have been conducted that evaluate wastewater or stormwater run-off from commercial or residential areas. However, few of these studies identify specific sources (e.g., individual businesses, specific residential activities) within the commercial or residential area. Studies that have investigated specific commercial businesses or residential activities have focused on evaluating operations and materials used rather than sampling wastewater or runoff. In most cases, the difficulty in obtaining representative wastewater or run-off samples from small businesses or residences hampered sampling efforts.

In addition to traditional monitoring efforts, new directions in stormwater monitoring were identified, including special studies, volunteer monitoring programs, and incorporation of environmental indicators into monitoring strategies.

Commercial and Residential Sources of Water Pollution

Several commercial sources of pollutants have been targeted by pollution prevention and stormwater programs around the country as shown in Table ES-2. Strategies that have been developed to address these sources include permitting, educational outreach, recognition programs, certification programs, and business assistance centers.

Many programs, all over the country, have developed programs for vehicle service facilities, construction activities, and food service businesses because most communities have several businesses that fall into these categories, and these businesses are subject to multiple regulatory programs (e.g., wastewater, stormwater, air quality, hazardous materials, health services, etc.).

Efforts have also been directed toward printers, painting contractors, dentists, laboratories, medical facilities, photoprocessors, landscape maintenance, dry cleaners, and machine shops. It should be noted that some of the programs addressing printers, dry cleaners and machine shops focus more on air emissions and hazardous materials generation than wastewater issues. Sources for which little work has been done include brake pads, existing development, new development, vehicle related activities, wood finishers, jewelry manufacturers, mobile cleaners, cooling water systems, and ceramics studios.

Residential sources of wastewater and stormwater pollution are less often the focus of outreach efforts as shown in Table ES–2. Most of the residential source programs focus on household cleaners and landscape maintenance. In most cases, landscape maintenance outreach targets general practices as opposed to specific products. With respect to household cleaners, much of the outreach targets products that have been determined to be of little concern to wastewater.

A moderate amount of work has been done to address water supply corrosion and home vehicle maintenance. Effective source control for corrosion has involved water purveyors to reduce the corrosivity of the water supply.

Table ES-2. Summary of Commercial and Residential Sources Evaluated

Source	Wastewater/ Stormwater	Number of Programs
Commercial Sources		
Existing development	Stormwater	2
Brake pads	Stormwater	3
Ceramics	Wastewater	3
Wood finishers	Wastewater	4
Jewelry manufacturing	Wastewater	5
Mobile cleaners	Stormwater	6
Cooling water systems	Wastewater	8
New development	Stormwater	9
Painting contractors	Both	10
Boatyards/ marinas	Stormwater	12
Landscape maintenance	Stormwater	12
Laboratories and medical facilities	Wastewater	13
Dentists	Wastewater	14
Machine shops	Wastewater	16
Dry cleaners	Wastewater	17
Photoprocessors	Wastewater	18
Food service businesses	Both	23
Printers	Wastewater	26
Construction and new development	Stormwater	28
Vehicle service facilities	Both	45
Residential Sources		
Pet care	Both	4
Laundry graywater	Wastewater	5
Pools and spas	Both	5
Painting activities	Stormwater	7
Indoor pest control	Wastewater	10
Corrosion	Wastewater	11
Root control products	Wastewater	12
Vehicle maintenance	Stormwater	15
Household cleaners	Wastewater	20
Landscape maintenance	Stormwater	24

Little work addresses laundry graywater, pools and spas, painting activities, root control products, and pet care. Laundry graywater appears to be a significant source of several metals in wastewater. Painting activities do not appear to represent a substantial source of metals or other pollutants currently under evaluation. Pools, spas, and root control products are associated primarily with copper. Pet care is likely to be a significant source of pesticides to wastewater.

Public Education

An extensive effort has been dedicated to educating the public about preventing stormwater and wastewater pollution. The messages are fairly uniform from program to program. These messages communicate what the wastewater and stormwater concerns are and what individuals can do about them. While the public is receiving the same key messages, there is no uniform catch–phrase or slogan (e.g., "Reduce, Reuse, Recycle" or "Give a Hoot, Don't Pollute). From a marketing point of view, a consistent message would help stormwater and wastewater pollution prevention programs achieve an even stronger public recognition of the issues.

Audiences targeted by public education campaigns include the general public, ethnic communities, commercial businesses, municipal workers, and school programs. Effective strategies used to approach these sources include the use of the media (i.e., television, radio, newspapers), participation in public events, presentations at workshops and trade shows, videos, course curricula, and advertisements and promotional items.

Emerging areas of development in public education are watershed management to promote pollution prevention and the use of social marketing and behavior change principles to develop wastewater and stormwater public education programs.

Program Effectiveness

While many agencies have indicated a need to evaluate the effectiveness of their wastewater, stormwater, and public education programs, little information is available concerning tools for measuring effectiveness. Some information is available on using water quality measurements, other environmental criteria, financial value, and surveys as indicators of effectiveness. Models have been developed to help predict program effectiveness based on such parameters as water quality data and demographic data. In general, there appears to be a lack of understanding of how to measure program effectiveness. More work developing the proper tools and understanding how to incorporate them into pollution prevention programs is clearly needed.

Conclusions

Based on the results of the literature assessment, recommendations concerning future research and program needs include:

- Developing a method for addressing issues beyond a local government's jurisdiction (e.g., reduction of copper levels in brake pads);
- Developing a research program and mechanism for addressing cross-media pollution prevention issues;
- Conducting a monitoring program to characterize non-stormwater discharges;
- Applying scientific principles to do public education;
- Establishing a wastewater/ stormwater pollution prevention information resource;
- Developing tools to measure program effectiveness;
- Developing a uniform catch phrase for stormwater and wastewater pollution prevention;
- Producing a CD-ROM containing examples of public education materials; and
- Focusing pollution prevention strategies and public education materials on locally important pollutants of concern.

Additional program development is needed for such commercial and residential sources as automotive brake pads, new development, vehicle related activities, pesticide users, mobile cleaners, and laundry graywater.

Acronyms Used in This Report

ACCWP	Alameda Countywide Clean Water Program

CHAPTER 1.0

INTRODUCTION

This report presents the results of a national assessment regarding commercial and residential sources of wastewater and stormwater pollution. The Water Environment Research Foundation (WERF) sponsored this project to identify existing activities and future research needs for stormwater and wastewater pollution prevention programs. This assessment focuses on pollution prevention programs for wastewater and stormwater that target commercial and residential sources. Pollution prevention programs targeting hazardous waste and air quality have also been developed but are not the focus of this report. This chapter discusses background information, the purpose of the project, the project methodology, and an overview of stormwater and wastewater pollution prevention projects in the United States.

1.1 Background

Regulations affecting publicly owned treatment works (POTWs) have increased over the years, and water quality standards have become more stringent. To comply with regulations and achieve water quality standards, POTWs have the choice of either implementing new treatment technologies or effectively reducing pollutant discharges through source control efforts. Very often treatment alternatives are not economically feasible, and source control represents the more cost–effective and reasonable option. While industrial wastewater discharges can sometimes be effectively controlled through pretreatment programs, the resulting reductions in pollutant loadings are not necessarily adequate to meet increasingly stringent water quality objectives. Communities are looking to nontraditional sources (i.e., residential and commercial sources) to achieve the necessary reductions. New regulations have also made it necessary for communities to evaluate discharges to their stormwater systems. Similar to wastewater, industrial regulation alone will not adequately reduce the levels of pollutants in stormwater. Control of non–industrial stormwater discharges might also become necessary.

To achieve improved water quality, significant sources of wastewater and stormwater pollutants should be identified, and effective source control strategies should be implemented. Some communities have conducted source identification studies and implemented source control strategies for non-industrial sources of wastewater and stormwater pollutants. However, the body of knowledge regarding types of non-industrial sources and appropriate control strategies remains incomplete.

A need exists to identify the significant non-industrial sources of stormwater and wastewater pollution and to critically assess source control strategies currently in use. This identification and assessment process will aid communities in their efforts to reduce water pollution. Ample evidence points to commercial and residential source control as an important step toward further reducing municipal pollutant loadings. In many communities, non-industrial discharges account for the major portion of loadings of several key pollutants in wastewater. For example, studies by wastewater treatment plants in the South San Francisco Bay Area show that about 80% of copper, a pollutant of great concern in the Bay, comes from non-industrial sources (Palo Alto Regional Water Quality Control Plant [PARWQCP] and Montgomery Watson, 1994; City of Sunnyvale and EOA, 1993; City of San Jose, 1993). Therefore, pollution prevention programs in the San Francisco Bay Area have targeted residential and commercial activities over the last few years to further reduce pollutant loadings. Additional studies conducted in other parts of California have confirmed the significant contribution of non-industrial discharges (Larry Walker Associates [LWA], 1994b; Montgomery Watson, 1994a).

Pollution prevention is the most promising approach to addressing non-industrial discharges that contribute to water quality issues nationwide. However, due to limited resources, future local efforts promise only a patchwork of information about individual facilities.

Pollution prevention efforts cannot be focused effectively without source identification information. A comprehensive non-industrial source identification study is necessary to avoid duplication of effort among local governments and maximize the resources available to implement pollution prevention programs. The analysis will start with a review and assessment of the work that has already been conducted concerning source identification. Once sources are identified, feasible pollution prevention measures (best management practices [BMPs] and other strategies) can be developed and implemented. Typical command-and-control efforts that are used for industrial sources are not easily applied to non-industrial sources. Source control strategies that can be effective for commercial and residential sources include public education, legislative approaches, and technical approaches. Compilation and evaluation of existing materials from a cross-section of communities will aid in the development of effective control strategies to address new sources of pollutants, as well as assist researchers to identify where new studies are necessary.

1.2 Project Purpose

This project report will serve as a resource for communities implementing pollution prevention and stormwater programs. A second objective was to identify future research needs with respect to commercial and residential sources of wastewater and stormwater pollution. This project was initiated to help communities effectively focus and plan their source control efforts by compiling and reviewing existing information, identifying information gaps, and recommending future directions and research needs. This project involved a review of research literature, as well as engineering and economic studies, a nationwide survey of public education and pollution prevention programs, and a comprehensive evaluation of information collected for different pollutant sources. The specific topics addressed include the following:

- Pollutants identified in different regions of the U.S.;
- Residential sources of pollutants;
- Commercial sources of pollutants;
- Source control strategies used to address commercial and residential sources;
- Effectiveness of these strategies based on environmental benefits and cost benefits;
- Factors contributing to regional similarities and differences; and
- Factors contributing to similarities and differences in stormwater and wastewater pollutant sources and source control strategies.

1.3 Project Methodology

To evaluate existing information regarding commercial and residential pollutant sources, a review was conducted in the following areas:

- Residential and commercial monitoring studies;
- Source control strategies used to address commercial and residential sources;
- Public education programs used to create general awareness and to target specific sources;
- Observed effectiveness of strategies which have been used to date to address commercial and residential sources.

To compile this information, literature searches were conducted through published databases and the internet. However, much of the information required is not available through published literature. A focused approach was used to contact leaders in stormwater and pollution prevention programs throughout the country. United States Environmental Protection Agency (US EPA) regional and national coordinators for stormwater and pollution prevention were first contacted and asked to identify the best programs in their regions. Representatives of the recommended programs were then approached for information about their specific projects.

Developing stormwater contacts through US EPA regional stormwater coordinators was an effective method of finding the leaders in stormwater pollution prevention. However, regional pollution prevention coordinators were often more aware of pollution prevention efforts targeting hazardous waste or air pollution rather than wastewater or stormwater. To supplement the gaps with respect to wastewater, additional contacts were made through the Water Environment Federation (WEF) pollution prevention committee, Association of Metropolitan Sewerage Agency (AMSA) 1996 pretreatment workshop participants, and US EPA regional pretreatment program coordinators.

Over 300 people were contacted throughout the U.S. Each contact was interviewed briefly via telephone about the program emphasis (i.e., stormwater or wastewater), pollutants evaluated, and efforts pertaining to commercial or residential sources. Based on the results of the phone contact, a questionnaire requesting more detailed information was sent. The contacts were asked to fill out the questionnaire and return it along with a list of reports or other literature available from their programs. The project team followed up to obtain the literature of interest. Approximately 60 program representatives returned completed questionnaires, which provided the basis for this report. A list of programs and contacts providing information for the source control assessment are listed in Appendix A. A copy of the phone interview and questionnaire are found in Appendix B.

While not every program in the U.S. was assessed, the programs included represent the current status of pollution prevention and stormwater programs targeting residential and commercial sources. Approximately half of the programs reviewed using this approach are located in California. The project team is located in California which may have resulted in a greater response from California programs. Even so, stormwater and wastewater pollution prevention contacts were made in every region of the United States. Regional differences are accounted for through the nationwide contacts that were established.

1.4 Wastewater and Stormwater Pollution Prevention Programs in the United States

As part of this WERF project, representatives of wastewater and stormwater pollution prevention programs around the country were interviewed regarding their programs. In some cases, contacts were difficult to establish and other avenues were explored to obtain a complete picture of nationwide activities. These avenues included literature searches, review of "home pages" on the Internet, and review of case studies (e.g., US EPA, 1994; National Pollution Prevention Roundtable, 1995). In several parts of the country, pollution prevention programs have been developed to target hazardous waste rather than wastewater or stormwater. In some cases, water pollution prevention programs have been developed that primarily target industrial activities. In general, these hazardous waste and industrial programs are not discussed in this report. This section provides an overview of wastewater and stormwater pollution prevention programs targeting commercial and residential sources in the U.S. according to US EPA region. Some national efforts are also highlighted. The U.S. is divided into 10 regions according to regional US EPA office jurisdictions as shown in Figure 1-1.

For each US EPA region, the following elements are discussed:

- Highlights of programs reviewed in this report; and
- Areas of focus (stormwater and/or wastewater).

Regional programs that are highlighted in this report are summarized in Table 1-1. A list of people contacted for the programs discussed in this report is found in Appendix A. In addition to the overview in this section, program activities are discussed in detail in the appropriate sections of the report.

1.4.1 Region 1

Region 1 includes the New England States of Maine, Vermont, New Hampshire, Massachusetts, Connecticut, and Rhode Island. Programs reviewed in Region 1 include the Massachusetts Office of Technical Assistance, the Massachusetts Water Resource Authority, the New Hampshire Department of Environmental Services, Narragansett Bay Commission, and Save The Bay.

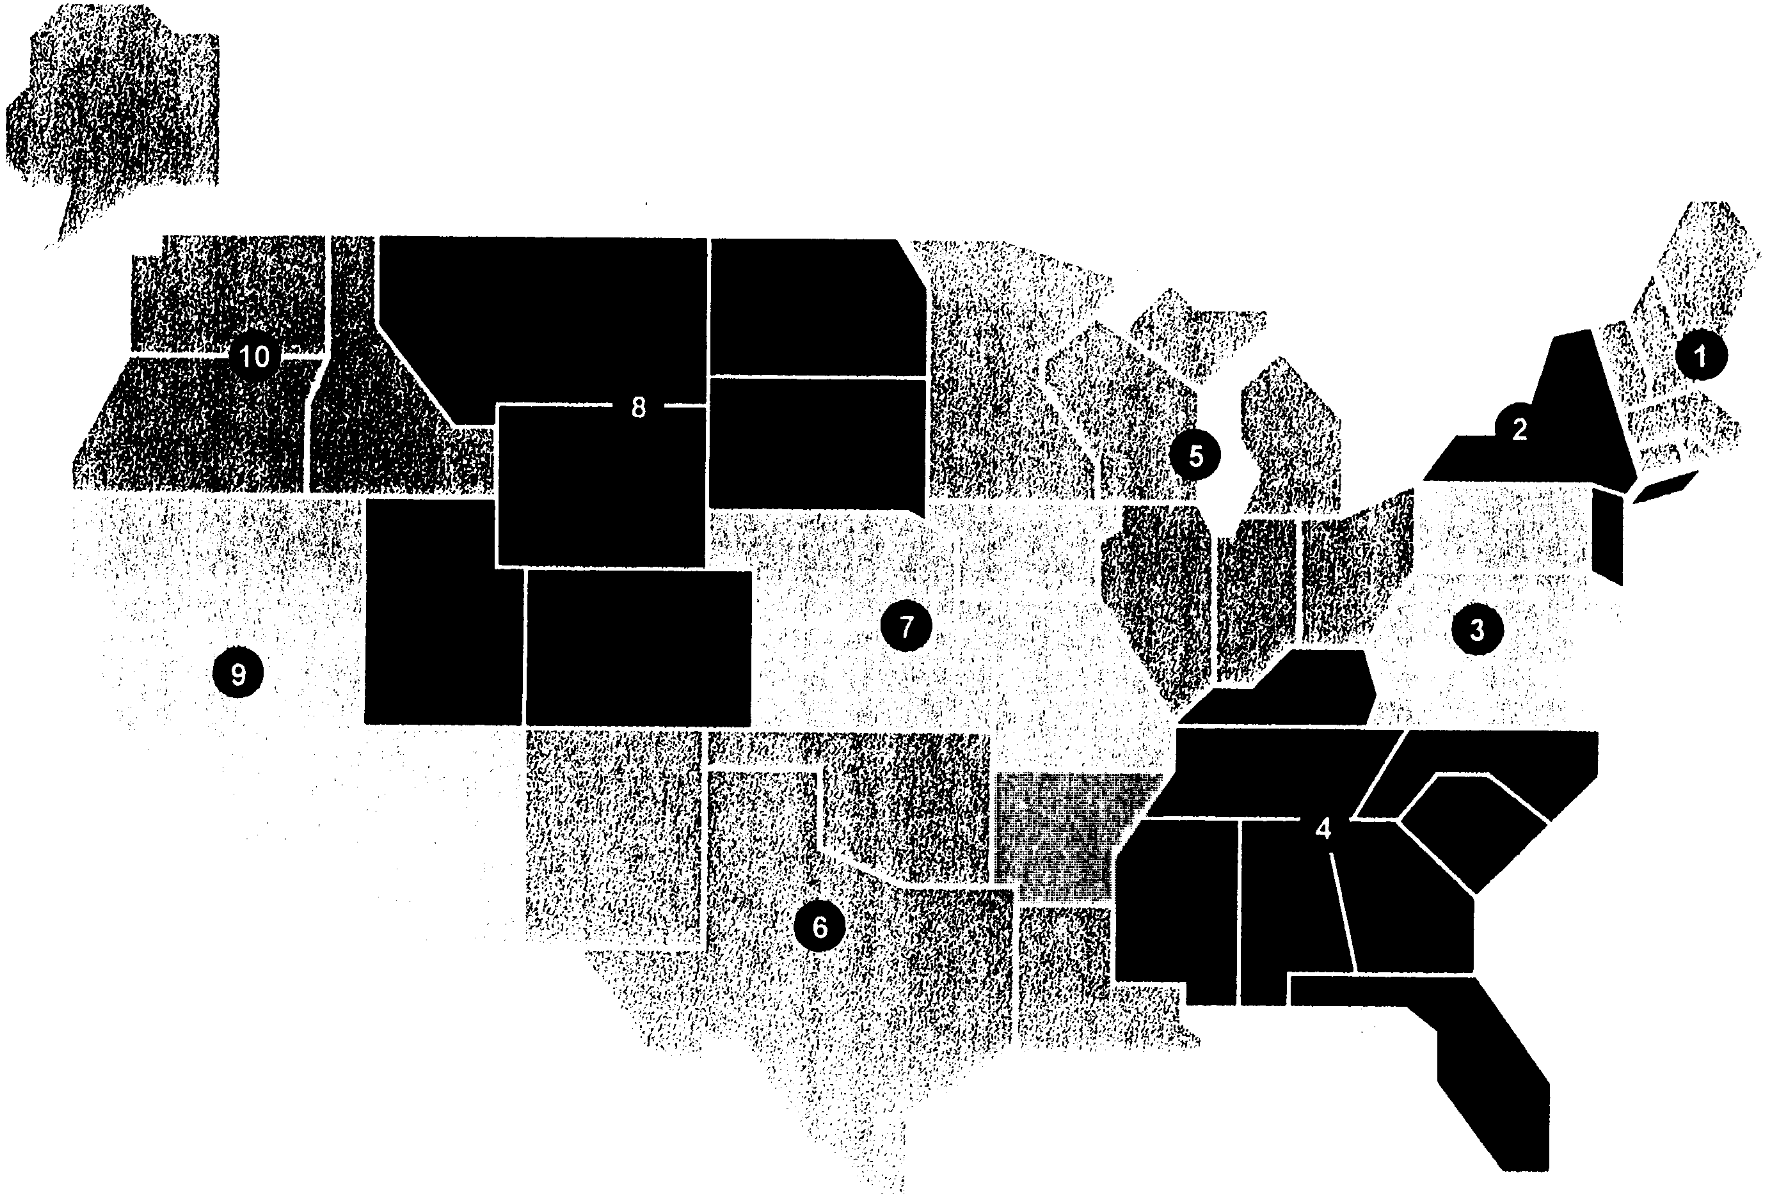

Figure 1-1. US EPA Regions

(1) P2 = Wastewater Pollution Prevention
SW = Stormwater Pollution Prevention

The Massachusetts Office of Technical Assistance (OTA) has conducted several pollution prevention programs working with POTWs (US EPA, 1994; Offen, 1996). The Critical Parameters project is a US EPA-funded project that developed programs for small businesses (Very Small Quantity Generators) and the general public. The program targets copper, cadmium, nickel, and zinc. Outreach to the general public included a half-hour video explaining the effects of water pollution and a guidebook concerning household pollution prevention opportunities. In addition, a school curriculum was developed for elementary age students.

The Massachusetts Water Resource Authority has a substantial pollution prevention effort targeting copper, lead, mercury, petroleum hydrocarbons, and pesticides (McManus, 1996). Activities so far have targeted household hazardous waste generation. Commercial efforts are starting with the sampling of car washes. In addition, this agency has conducted extensive residential and stormwater monitoring.

The New Hampshire Department of Environmental Services provided information regarding their stormwater program for new development and timber harvesting (Spaulding, 1996).

Save The Bay is an organization in Region 1 that seeks to "ensure that the environmental quality of Narragansett Bay and its watershed is restored and protected from the harmful effects of human activity" (Save The Bay, 1996). To help small-flow POTWs meet their NPDES permit limits, Save The Bay initiated the Toxic Diet Project as a model project in Northbridge, Massachusetts (Wilder, 1994). It involves a collaboration with residents, businesses, and local agencies to identify sources of metals from residential sources, commercial sources, and water conveyance piping (i.e., corrosion) and to implement source reduction. The Narragansett Bay Commission also provided information on source control activities in this region.

1.4.2 Region 2

Region 2 includes New York, New Jersey, Puerto Rico and the Virgin Islands. Information was provided by the Region 2 US EPA Office (Bosques, 1996) and the New York-New Jersey Harbor Estuary Program (Ausubel, 1996). In addition, a case study for Erie County, NY, was reviewed (NPPR, 1995).

Pollution prevention project information was provided by US EPA Regional Pollution Prevention Program (Sapadin, 1996). Grant projects targeting low income and minority communities were described. One grantee, the New Jersey Environmental Federation provided information on its projects (Goldsmith, 1996). These projects target residential sources of metals (lead and mercury in particular) and pesticides. Approaches include surveys, development of outreach materials, and work with local government. Information on stormwater projects targeting certain commercial activities was provided by the Region 2 US EPA office, as well.

A comprehensive plan has been developed to establish and maintain a healthy and productive ecosystem in the New York-New Jersey Estuary and New York Bight (NY/NJ Harbor Estuary Program, 1996). The plan includes actions to address toxic pollutants, management of dredged material, stormwater run-off, pathogens, floatable debris, and nutrients. The emphasis for toxic pollutants is on metals and pentachlorobenzenes (PCBs). Planned actions revolve around more stringent permit limits, sediment clean-up, additional source identification, and additional monitoring. Intensive public outreach is planned as this project moves into implementation.

The Erie County Office of Pollution Prevention provides technical assistance to small businesses and is currently working with local POTWs to promote pollution prevention (NPPR, 1995).

1.4.3 Region 3

Region 3 includes the Mid-Atlantic States of Pennsylvania, Delaware, Maryland, Virginia, West Virginia, and the District of Columbia. Stormwater programs are well developed in this region, with much of the activity centering around efforts to protect the Chesapeake Bay. The Chesapeake Bay Program, construction programs in Maryland and Delaware, and wastewater and stormwater pollution prevention activities in Virginia were reviewed.

Information regarding the Chesapeake Bay Program has been collected through the literature and the Chesapeake Bay Program's home page on the Internet. The Chesapeake Bay Program (CBP) began in 1983 through the cooperative efforts of the States of Maryland, Pennsylvania, and Virginia; the District of Columbia; the Chesapeake Bay Commission; US EPA; and advisory groups. (The Chesapeake Bay Program, 1996; Hudson, 1995) The CBP was initiated in order to restore the estuary and address three issues: nutrient over-enrichment, dwindling bay grasses, and toxic pollution. Specific actions initiated by the CBP include a phosphate detergent ban, introduction of agricultural BMPs, biological nutrient removal, a citizen's monitoring program, and an intensive public education campaign emphasizing the role of individual residents in the Bay's restoration. Substantial progress had been seen by 1993, including increases in acreage of underwater bay grasses, record setting numbers of young rockfish, and reductions of point source pollution. Nutrient reduction efforts have been expanded to include setting reduction targets for the Bay's tributaries in addition to the Bay itself.

Contractor certification programs in Delaware and Maryland are described in this report (Shaver, 1993; Non-Point Source News Notes, 1995a).

Pollution prevention activities in Virginia were summarized as part of a commercial business evaluation (MEB, 1994). Businesses targeted include printers, wood finishers, dry cleaners, and marine maintenance facilities. Stormwater and pollution prevention activities in Alexandria, VA, are also discussed herein.

1.4.4 Region 4

Region 4 includes the southern States of Kentucky, Tennessee, North Carolina, South Carolina, Florida, Georgia, Alabama, and Mississippi. Pollution prevention and stormwater programs in North Carolina and Florida were reviewed. Some information was also provided by programs in South Carolina and Tennessee.

Pollution prevention programs in Florida include State programs and those implemented in Broward, Dade, and Lee Counties (Opris, 1996; Cuniff, 1996; Nottingham, 1996). Targeted activities include hotels/motels, marinas, and salvage yards, in addition to some of the more common businesses (i.e., vehicle service, printers, photoprocessors). Broward County has developed pollution prevention and BMPs through a collaborative effort with marine facilities and automotive salvage yards (NPPR, 1995). Dade County has an extensive pollution prevention program targeting several business categories, as well as residents and visitors. Source control strategies for business include training, workshops, BMP booklets, and on-site audits. Businesses targeted include printers, dentists, radiator shops, and photoprocessors. Residential outreach has been conducted through schools, television, radio, newsletters, billboards, and through outdoor cleanup, and tree planting activities.

Pollution prevention and stormwater programs in North Carolina also appear to be comprehensive. The North Carolina State University Water Quality Group acts as a resource center and provides technical assistance with respect to stormwater issues. They have developed a comprehensive list of BMPs for activities impacting stormwater (NCSU, 1996). The North Carolina Office of Waste Reduction is a resource and technical assistance center for pollution prevention activities (Hunt, 1996). This office has an extensive library and database of articles and information relating to pollution prevention and conducts on-site audits and workshops and training for business.

1.4.5 Region 5

Region 5 includes the Great Lakes States of Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin. The Region 5 US EPA office identified contacts and provided background information on key programs. Stormwater program information in Region 5 was provided by the Wisconsin Department of Natural Resources (DNR), the Rouge Program Office, and the Northeastern Illinois Planning Commission. Pollution prevention activities in Minnesota and Wisconsin were also reviewed.

Wisconsin DNR has conducted extensive monitoring and source identification for stormwater pollutants (Bannerman, 1996). In addition, they have developed outreach materials pertaining to pesticide use and construction activities.

In Michigan, the Rouge River Stormwater Program has developed outreach on several fronts and has initiated a Rouge Friendly Business Program and a Clean Neighborhood Program to recognize efforts to control commercial and residential sources of stormwater pollution (Reaume, 1996).

The Northeastern Illinois Planning Commission has developed stormwater guidance materials including guidance information and an instructional video pertaining to sediment and erosion control.

With respect to wastewater pollution prevention, the Milwaukee Metropolitan Sewer District in Wisconsin and the Western Lake Superior Sanitary District in Minnesota have developed interesting programs with respect to mercury sources, including dentists, hospitals and laboratories (MMSD, 1991; Tuominen, 1996).

1.4.6 Region 6

Region 6 includes the Gulf Coast States of Louisiana, Oklahoma, Texas, Arkansas, and New Mexico. Pollution prevention programs were reviewed in Oklahoma, Texas, and New Mexico. Stormwater programs were reviewed in Texas.

Diazinon has been associated with whole effluent toxicity failures for several POTWs in Region 6 (APA, 1995; Erwin, 1996). Programs in Oklahoma and Texas targeting residential use of diazinon and other pesticides are discussed herein. The City of Albuquerque, New Mexico has an extensive pollution prevention program for small businesses, particularly those identified as sources of silver

(Hogrefe, 1996). Workshops, guidance manuals, and a recognition program are used to encourage businesses to meet the silver discharge limits.

With respect to stormwater, the North Central Texas Council of Governments has developed a regional stormwater program addressing pesticides, nutrients, sediments, metals and fecal coliform (NCTCOG, 1996). Program implementation includes an extensive public awareness effort, residential and commercial runoff monitoring, source identification, and industrial BMP development. Monitoring studies conducted in Galveston Bay, Texas, are discussed elsewhere in this report (Galveston Bay National Estuary Program, 1992).

1.4.7 Region 7

Region 7 includes the Midwestern States of Kansas, Iowa, Missouri, and Nebraska. Contacts in this region indicated that stormwater programs are in the initial stages of development with monitoring, brochure distribution, and storm drain stenciling being the extent of the activities undertaken to date (Coonley, 1996; Wurtz, 1996). In addition, POTWs have felt little pressure up to this point to implement pollution prevention because pollutant levels in their effluent are not of concern in most cases.

Pollution prevention activities in this region seem to focus on small businesses through assistance centers that have been developed at the University of Northern Iowa and the Iowa Department of Natural Resources. While these programs were largely developed in response to air quality and hazardous waste issues, programs and information have been developed that are useful for wastewater, as well. The Iowa Waste Reduction Center at the University of Northern Iowa has developed excellent guidance manuals for printers and vehicle service facilities (IWRC, 1995). The Iowa Department of Natural Resources has a non-regulatory assistance program staffed by retired industry professionals called the Waste Reduction and Assistance Program (WRAP) (Wnuk, 1996).

1.4.8 Region 8

Region 8 includes the Rocky Mountain States of Colorado, Montana, North Dakota, South Dakota, Wyoming, and Utah. Pollution prevention and stormwater programs in Colorado and Montana provided information for this study. Some program aspects in Fort Collins and Boulder, Colorado, and the Montana Pollution Prevention Program are highlighted in the paragraphs which follow.

The City of Fort Collins, Colorado is developing a stormwater program using a watershed approach (McBride, 1996). As part of this approach, pollution prevention strategies have been implemented including household hazardous waste collection, use of integrated pest management for public lands, and spill prevention plans. Public outreach efforts include a children's water festival, a master naturalist program, storm drain stenciling, and a citizen monitoring project.

The City of Boulder's pretreatment program has investigated commercial sources, including food service facilities, printers, photoprocessors, medical facilities, vehicle service facilities, and dry cleaners (Erickson, 1996). Outreach to these businesses includes a semi-annual pretreatment newsletter and small business pollution prevention seminars.

The Montana Pollution Prevention Program (called MT P2) at Montana State University has developed a variety of outreach materials and conducted training for several small business categories including dry cleaners, vehicle service, printers, hospitality industry, wood finishing, and construction (Montana State University, 1996). In addition, this program provides pollution prevention education to Native American communities.

1.4.9 Region 9

Region 9 includes the Western States of California, Arizona, Nevada, and Hawaii. Numerous programs in Arizona and California provided information for this project. Program elements are discussed in detail throughout the rest of the report. Some brief information about programs in Phoenix, the San Francisco Bay Area, the Central Valley, and Southern California is presented in the following paragraphs.

In Arizona, the Phoenix Pollution Prevention Program and stormwater program provided extensive information (Sundstrom, 1996; Menke, 1996). Both programs have comprehensive, creative public outreach materials. As one example, the Pollution Prevention Program has created an interactive, "Jeopardy" style game for businesses (Pollution Prevention Pays) and the general public (Be A Pollution Solution). These games are used at trade shows and public events. Other aspects of the Phoenix programs are described throughout the report.

The San Francisco Bay Regional Water Quality Control Board (SFRWQCB) requires the use of pollution prevention to address pollutants through its NPDES permits. Several agencies have developed innovative programs in response to this requirement. In addition, POTWs work together on projects of regional interest through the San Francisco Bay Area Pollution Prevention Group

(SFBAPPG). A few of the group's accomplishments are (1) regional outreach materials targeting copper sulfate root control products and vehicle service facilities; (2) a regional video explaining wastewater and stormwater issues; (3) a source identification study for copper in wastewater; and (4) a source identification study for toxic organic pollutants in wastewater (Louie, 1996). These and other SFBAPPG projects are discussed throughout the report.

A wide range of outreach to businesses, including vehicle service facilities, printers, medical facilities, cooling towers, and dentists, has been implemented by public agencies in the Bay Area. Some of the programs from this area that are highlighted in this report include the City and County of San Francisco (CCSF), the Palo Alto Regional Water Quality Control Plant (PARWQCP), East Bay Municipal Utility District (EBMUD), Union Sanitary District (USD), City of Sunnyvale, and Central Contra Costa Sanitary District (CCCSD).

Stormwater activities in the Bay Area are conducted in cooperation with wastewater pollution prevention activities in many cases. Such activities include programs developed for pesticide use, mobile cleaners, and construction activities. Regional outreach programs are developed through the Bay Area Stormwater Management Agencies Association (BASMAA). Stormwater programs in the Bay Area that are highlighted in this report include the Alameda Countywide Clean Water Program (ACCWP) and the Santa Clara Valley Nonpoint Source Pollution Control Program (SCVNSPCP). Some examples include pesticide source identification efforts and outreach targeting construction activities and new development.

In the Central Valley of California, projects addressing construction sources of pollutants and sources of organophosphate pesticides in stormwater are being conducted through the Sacramento Stormwater Program and the Central Valley Regional Water Quality Control Board (CVRWQCB). In addition, pollution prevention outreach for commercial facilities, such as dry cleaners, vehicle service facilities, printers, and wood finishers, has been developed by the Sacramento Regional County Sanitation District (SRCSD) and the Business Environmental Resource Center (BERC) (Harader, 1996).

In Southern California, wastewater pollution prevention efforts focus primarily on industry. Stormwater programs in Ventura County and Riverside County have extensive outreach targeting both commercial and residential sources. The Ventura Countywide Stormwater Management Program (VCSQMP) has developed outreach and recognition programs for vehicle service facilities and food service businesses (VCSQMP, 1995b). Riverside County has developed guidance for construction and new development and general awareness outreach for the general public (Ristow, 1996; Summers, 1996).

1.4.10 Region 10

Region 10 includes the Pacific Northwest States of Washington, Oregon, Idaho, and Alaska. The preponderance of activity reviewed for this report is located in the Seattle-King County area of Washington. Some stormwater program information was also provided by the Department of Public Works in Anchorage, Alaska.

Seattle METRO and King County Hazardous Waste Management Program work together to implement business inspection and assistance programs, pesticide public outreach programs, general awareness public outreach, and business recognition programs (Hildebrand, 1996). The Seattle Drainage and Wastewater Utility conducts public outreach and school programs targeting stormwater issues (Chandler, 1996). The City of Bellevue, Washington, developed business outreach materials discussed in this report (Woodward-Clyde, 1990). Washington programs targeting pesticides, dentists, vehicle service facilities, and general public outreach are discussed in more detail throughout this report .

The municipality of Anchorage provided a literature search and analysis of stormwater BMPs conducted in support of their stormwater program (Montgomery-Watson, 1994b; Montgomery-Watson, 1996a). This document provides a comprehensive list of stormwater BMPs divided into the following categories: source reduction practices; erosion, sedimentation, and drainage management practices; vegetative management practices; retention/detention management practices; filtration and infiltration management practices; and material and disposal management practices.

1.4.11 National Efforts

Some efforts have been initiated at a national level to address sources that are of concern to communities nationwide. Two such groups are the Water Environment Federation Pollution Prevention Committee and the Silver Coalition.

The WEF Pollution Prevention Committee is a group of wastewater and stormwater professionals from around the U.S. who work together on pollution prevention issues (Schweinfurth, 1996). They have coordinated national workshops on commercial sources, including photoprocessors and vehicle service facilities. In addition, they have written and produced guidance documents for controlling vehicle service facility discharges, silver discharges, and dry cleaners discharges to wastewater. Future activities include publishing guidance manuals for dental offices and industrial laundries and developing a source control training program for small municipalities.

The Silver Coalition, in cooperation with the Association of Metropolitan Sewerage Agencies (AMSA), has developed a code of management practice (CMP) for silver dischargers (Silver Coalition, 1995). It contains recommendations on technology, equipment, and management practices for controlling silver discharges that process photographic materials. This CMP will be used to develop a consensus among the regulated and regulatory communities for controlling silver discharges in a cost-effective and environmentally sound manner. The Silver Coalition worked with other agencies, including US EPA and WEF, to develop this manual. In addition, pilot efforts have been conducted in municipalities from different parts of the country. The CMP has been implemented in Hampton Roads, VA, Albuquerque, NM, and Colorado Springs, CO.

CHAPTER 2.0

MONITORING AND SOURCE IDENTIFICATION

Numerous monitoring programs have been conducted by Federal, State, county, city, and environmental agencies to determine the pollutants in wastewater and stormwater that ultimately impact receiving waters and to identify the sources of these pollutants. These investigations indicate that commercial and residential sources contribute significant amounts of pollutants to both wastewater and stormwater flows. As a result, several programs have monitored specific commercial and residential activities. This chapter includes information on monitoring of wastewater and stormwater discharges from commercial and residential land use areas in various regions of the U.S. This chapter is not a comprehensive evaluation of the available monitoring information, but a summary of selected studies that are representative of the types of investigations that have been conducted. Information presented is organized by program type (i.e., receiving water, stormwater, or wastewater) and then by region.

A summary of the studies reviewed in this chapter, including location, program type, affected water body, pollutants of concern, and the sampling site or commercial/residential source(s) identified, are presented in Table 2-1. Information on other monitoring and source identification projects identified during this study but not selected for review are presented in Table C-1 (Appendix C). According to Tables 2-1 & C-1, wastewater and/or stormwater monitoring of commercial and residential land use areas has been conducted in each US EPA region, and many of these investigations have targeted specific commercial and residential activities. The following sections discuss selected monitoring and source identification studies.

Table 2-1. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
1 Rhode Island, Massachusetts	WW[1]	Narragansett Bay	Cu Pb Zn	pipe corrosion not identified not identified
2 New York/New Jersey (NY/NJ)	WW, SW[2]	NY/NJ Harbor	Metals PCBs Cyanide	tributaries & municipal inputs tributaries municipal discharges
3 Chesapeake Bay	SW, receiving water, sediments	Chesapeake Bay	PAHs, As, Ni Cyanide, Cd, Zn Cr, Pb, pentachlorophenol Bis-(2-ethylhexyl)phthalate Cd, Cr, Cu, Zn nutrients	incomplete fossil fuel combustion (home heating units) automobile related activities exterior paints and stains plasticizer (garden hoses, food packaging, etc.) corrosion of metal alloys WW, agricultural land and developed land; sediment runoff from farms, construction sites & other lands
3 Chesapeake Bay	WW, SW, receiving water, sediments	Elizabeth River	PAHs TBT	dumping of oily wastes & creosote, combustion of fosssil fuel antifouling paint applied to watercraft
3 Maryland	SW	Maryland Piedmont	Hydrocarbons, PAHs, metals	service stations, convenience commercial, commuter parking lots

Table 2-1, cont. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
5 Wisconsin	SW	Milwaukee River and Sheboygan River watersheds	Pb, pesticides, bacteria	medium density residential areas
5 Wisconsin	SW, receiving water, sediment, whole fish & crayfish tissue	Madison surface waters	Zn Phosphorus Total solids, TSS, phosphorus, Cd, Cu, Cr, Pb, Zn As, Cd, Cr, Cu, Pb, Ni, Se, Ag, Zn Methoxychlor semi volatile organic compounds	roof runoff lawns and driveways street runoff detected at commercial & university sites detected at university site detected at commercial, high density residential, highway, and shopping center sites
5 Wisconsin, Michigan, Minnesota	SW	Lake Superior	Nutrients, metals, PAHs	runoff (non-specific)
5 Illinois	SW, receiving water	agricultural watershed surface waters	pesticides	runoff
6 Texas	SW	Galveston Bay	TSS, phos., nitrogen, BOD, oil & grease, bacteria, Cu, pesticides	most significant source areas were high density urban residential and barren areas
7 Dallas/Fort Worth, Texas	SW	not specified	Cd, Cr, Cu, Pb, Zn, Chlordane, Diazinon, bacteria, TSS	non-specific
7 Austin, Texas	SW	not specified	nitrate, Cu, ortho-phosphate, bacteria, sediment	not detected in first flush (first inch of stormwater runoff)

Table 2-1, cont. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
7 Iowa	SW,WW	Iowa's surface waters	pesticides, nutrients, bacteria, sediment ammonia, metals, nutrients, oil & grease, pesticides, BOD sediment, nutrients, bacteria	residential area runoff (SW, lawn watering, motor vehicle washing, fire hydrant flushing) commercial area runoff (SW, commercial facility drains, non-stormwater connections, CSOs) agricultural activites
9 San Francisco Bay Area Pollution Prevention Group	WW	San Francisco Bay and other California Waters	copper Toxic Organic Constituents	radiator repair, auto repair, car washing, cooling towers, dry cleaners, laboratories, laundries, hospitals, photoprocessing, printers, univ./schools, machine shops, metal fabrication, incinerator scrubbers non-specific
9 San Francisco Bay Area	SW, WW, receiving water, sediment	San Francisco Bay	Zn, Se Cu, Hg, Ni, DDE PAHs	runoff (non-specific) WW outfalls, atmospheric deposition, mobilization of sediments (non-specific) automobile exhaust (PAHs in sediment)
9 Santa Clara Valley Alameda County	SW	South & Central San Francisco Bay	Metals, TSS, TDS, hardness, TOC, oil and grease, nutrients, bacteria, toxic organic constituents	urbanized watersheds
9 City and County of San Francisco	WW	Central San Francisco Bay	Cu, Pb, Hg, Ni, Ag, Zn, cyanide Cyanide Toxic Organic Constituents	household use of motor oil and house paints printers, photoprocessors, vehicle service/repair shops, hospitals, laboratories, restaurants non-specific

Table 2-1, cont. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
9 Palo Alto (RWQCP)	WW	South San Francisco Bay	Diazinon Tributyltin	pesticide applications cooling water systems discharge
9 Novato Sanitary District	WW	San Pablo Bay	Cu Cu, Pb, Ni, Ag Ag, Zn	tap water sources (i.e., corrosión) commercial sources (non-specific) contribute more than residential or WWTP influent unmeasured non-residential sources
9 City of San Jose	WW	South San Francisco Bay	Zn Cu, Ni Ag	greatest contribution from residential & water supply sources (non-specific) corrosion, transportation (airport/terminal), machine shops, hospitals, misc. equip. rental, sheet metal work, lithographics, commercial printing, laundries, dry cleaners, car washes greatest contributions from commercial and residential sources (non-specific)
9 Union Sanitary Dist. (cities of Fremont, Newark, Union City, CA)	WW	Central San Francisco Bay	Cu, Ni	automotive machine shops, printers
9 Central Contra Costa Sanitary District (CCCSD)	WW	Suisun Bay	Chlorpyrifos, Diazinon metals	residential, self-service pet washers, pest control operators, kennels (flea shampoos) residential= laundry grey water, corrosion, root control, household products, vehicle service

R0025997

Table 2-1, cont. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
9 South Bayside System Authority (cities of San Carlos, Belmot, Redwood City & West Bay Sanitary District, CA)	WW	Central San Francisco Bay	Cd	auto repair, laundries, indoor household products, greywater
			Cr	laundries, indoor household products, greywater
			Cu	auto repair, photoprocessors, printers, dentists, labs, painting, laundries, cooling towers, indoor & outdoor household products, greywater, copper sulfate root killer, human body wastes
			Hg	hospitals, labs, painting, indoor & outdoor household products, human body wastes
			Pb	auto repair, photoprocessors, laundies, greywater, indoor & outdoor household products
			Mo	printers, painting, outdoor household products
			Ni	auto repair, labs, indoor household products, greywater, human body wastes
			Ag	auto repair, photoprocessors, printers, hospitals, dental offices
			Zn	auto repair, photoprocessors, printers, dental offices, painting, laundries, cooling towers, greywater, indoor & outdoor household products, human body wastes
9 City of Hayward	WW	Central San Francisco Bay	Cu, Diazinon	residential areas (non-specific)
			Pb, PAHs	not identified
9 Sunnyvale	WW	South San Francisco Bay	Cu	corrosion
			Ni	residential and commercial sources (non-specific)

Table 2-1, cont. Pollutants Evaluated and Sources Identified in Regional Water Quality Monitoring Studies

Region & Location or Agency	Type of Monitoring	Affected Water Body	Pollutants Evaluated	Location Sampled or Commercial/Residential Source(s) Identified
9 Ventura County, CA	SW	local rivers and sloughs	not specified	residential, commercial, industrial, agricultural illicit discharges - gas stations, auto service, commercial laundries, carpet cleaners, painters, pool cleaning, salvage yards, recycling facilities, restaurants, machine shops, outdoor storage
9 Orange County Sanitation District	WW		metals, organics, nutrients, oil and grease, TSS	residential sources (non-specific)
9 City of Los Angeles, CA	WW	Los Angeles Harbor	Cu, Zn	radiator & auto shops, dental offices
9 City & County of Sacramento, CA	SW	Sacramento and American Rivers	Cd, Cu, Hg, Zn Diazinon, Chlorpyrifos	acid mine drainage professional landscape maintenance, structural pest control, agricultural uses
9 City of Phoenix, AZ	WW	Phoenix area surface waters	As Hg	natural, commercial and residential greatest sources (non-specific) dentists (most significant source), also sampled printers, photoprocessors, hospitals, labs, auto repair shops, auto service stations, funeral homes, lithographics, glass cutters, ceramics, laundries
10 Washington	SW	Puget Sound	pesticides	drainages (non-specific)
10 Seattle, Washington	WW	not specified	Antimony, Ag, Zn, phthalate, chloroform, PCE, benzene Arsenic	nonindustrial sources (non–specific) dishwashing & powdered laundry detergents, bleach

[1] various sources, see Chapter 2.0 [2]WW = wastewater [3]SW = stormwater

2.1 Receiving Water Monitoring

Several receiving water monitoring programs have been conducted, and many have led to source identification investigations. Programs selected for discussion in this section include NY/NJ Harbor Estuary, Chesapeake Bay, San Francisco Bay, and Santa Monica Bay. Other receiving water investigations identified by the project team but not discussed in this report, include Narragansett Bay (Rhode Island and Massachusetts), Galveston Bay (Texas), Chesapeake Bay tributaries, and Kansas surface waters.

2.1.1 NY/NJ Harbor Estuary (Region 2)

An assessment of the impact of chemicals in the NY/NJ Harbor Estuary system was performed to guide development of future monitoring programs in the estuary (Squibb, O'Connor, and Kneip, 1991). The assessment was performed by collecting water, biota, and sediment samples. Chemicals of concern were determined for the estuary by comparing ambient concentrations observed in water and biota samples with Federal and State marine water quality criteria (WQC). The following chemicals are considered to be of concern for the NY/NJ Estuary based upon water monitoring results:

- Metals: arsenic, beryllium, cadmium, copper, lead, mercury, nickel, silver, zinc

- Pesticides: aldrin, alpha-BHC, gamma-BHC, DDD, DDE, DDT, dieldrin, endosulphan, heptachlor

- Organics: benzene, bis(2-ethylhexyl)phthalate, carbon tetrachloride, chlorobenzene, 1,4-dichlorobenzene, ethylbenzene, methylene chloride, napthalene, n-nitrosodi-n-propylamine, 1,1,2,2-tetrachloroethane, tetrachloroethylene, 1,1,2-trichloroethane, hexachlorobutadiene, PCBs, trichlorethylene

Other pollutants were deemed to be of concern based on fish tissue analysis. These pollutants include PCBs, TCDD, mercury, arsenic, DDT, DDD, DDE, chlordane, dieldrin, heptachlor, heptachlor epoxide, hexachlorobenzene, gamma-BHC, PAHs and tetrachlorodibenzofurans.

Another study, conducted as part of the NY/NJ Harbor Estuary Program, involved chemical analysis and toxicity testing of water column samples collected throughout the estuary (Science Applications International Corp., 1993). The purpose of the study was to assess both small-scale and broad-scale variability in toxicity. Water samples were collected in nonpoint source areas to determine general water quality of the estuary. Two different types of toxicity tests were performed, including the sexual reproduction test with the marine red alga, *Champia parvula*, and the fertilization test with the sea urchin, *Arbacia punctulata*. These methods were selected for several reasons. For example, discrete samples can be tested utilizing these methods, which provides a more detailed characterization of the variability of toxicity. Additionally, the two test species selected are sensitive to heavy metals (*Champia* is especially sensitive to copper), which can cause toxicity in the estuary. Both species were tested on over 130 water column samples from three sampling events (one small-scale event including 4 stations and 2 broad-scale events encompassing the entire Estuary). Water column samples were collected in conjunction with toxicity samples and analyzed for total silver, arsenic, beryllium, cadmium, chromium, copper, mercury, nickel, lead, antimony, selenium, thallium, and zinc, as well as total organic carbon (TOC) and total ammonia. The chemical analyses were performed so that chemical concentrations and toxicity could be correlated.

Results demonstrated that many of the ambient samples were toxic to the test species. Toxicity to either *Arbacia* or *Champia* was observed at each station during at least one of the sampling events. However, patterns in toxicity could not be attributed to heavy metals, in particular copper, as thought at the outset of the study. It was concluded that future work should be conducted, including toxicity identification evaluations (TIEs), which would help determine the pollutants present and possibly relate toxicity to potential point sources.

Sediment samples were also analyzed and were found to contain high concentrations of metals (organic chemical concentrations have not been as closely monitored). Chemical concentrations detected in sediment were used to determine potential sources (i.e., areas with high concentrations of metals in sediments were often surrounded by industry or near WWTPs).

An additional study, conducted as part of the US EPA National Estuary Program, determined pollutant loadings for NY/NJ Harbor Estuary. The objectives of this study were to determine the relative importance of each source of pollutants in the harbor, to provide information for a wasteload allocation analysis, and to determine future monitoring objectives (HydroQual, Inc., 1991). The study determined loadings for conventional parameters, nutrients, metals, PCBs, and cyanide from 6 different source classes. Sources included municipal discharges, industrial discharges, runoff loadings, tributary inputs, landfill leachate, and atmospheric deposition. Results demonstrated that metal loadings were primarily from tributaries and municipal inputs. Inputs from combined sewer overflows (CSOs) and atmospheric deposition, however, were also important sources of lead. Tributaries contributed significant amounts of PCBs (50% of the total load), and municipal discharges were responsible for the greatest cyanide inputs (89% of the total load). It is important to note that loadings for some parameters were estimated if actual assessment data were lacking.

2.1.2 Chesapeake Bay (Region 3)

Extensive monitoring studies have been performed in the Chesapeake Bay Area. In 1987, the Chesapeake Bay Agreement was finalized requiring development of a basinwide strategy to reduce toxic loadings to the Bay. As a result of this agreement, the Chesapeake Bay Basinwide Toxics Reduction Strategy was created. The strategy outlined efforts to define the nature, extent, and magnitude of Chesapeake Bay toxics problems and to initiate specific toxics reduction and prevention actions (Chesapeake Executive Council, 1989).

The most recent information is presented in the Chesapeake Bay Basinwide Toxics Reduction Strategy Re-evaluation Report (Chesapeake Bay Program, 1994). Objectives during the re-evaluation included identification of pollutants of concern, estimation of loadings to the Bay, pollutant source identification, source control and pollution prevention. A list of pollutants of concern was compiled for the report which included atrizine, benzo[a]anthracene, benzo[a]pyrene, cadmium, chlordane, chrysene, chromium, copper, fluoranthene, lead, mercury, naphthalene, PCBs, and tributyltin (TBT). A secondary list of toxics included alachlor, aldrin, arsenic, dieldrin, fenvalerate, metolachlor, permethrin, toxaphene, and zinc. Pollutants were included in the primary list if the pollutant had been measured in one of the environmental media in the past. Inclusion was not based upon evidence of potential or existing environmental impact. The list represents those pollutants that will be ranked and identified for future revisions of Bay toxics of concern. The secondary list includes those chemicals that might be considered for inclusion in a future list of toxics of concern.

Monitoring information presented in the re-evaluation report combines all past investigations and discusses results of pollutants detected in microlayer, water column, and sediment samples. Among the metals detected in microlayer samples are aluminum, arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, selenium, and zinc. Specific values were not presented in the report, but it was stated that microlayer concentrations were generally higher than bulkwater concentrations. Also detected in microlayer samples were TBT and PAHs in the concentration range from 0.005 to 1,171 ng/L and <0.05 to 20 ng/L, respectively. Pesticides and organic compounds were largely undetected, except for dieldrin (1 to 18 μg/L).

Water column concentrations were determined for metals, pesticides and organic compounds and are presented in Table 2-2 for the pollutants of concern. The magnitude of the metals data is an indication that significant widespread concentrations exceeding Federal or State water quality criteria (WQC) are not occurring in the mainstream Bay. However, questions have been raised concerning the quality of available metals data, e.g., dissolved concentrations were not determined; analytical methods might not have been appropriate for ambient conditions.

Table 2-2. Water Column Concentration Ranges of Pollutants of Concern in Chesapeake Bay[1]

Parameter	Concentration Range in Water Column (μg/L)[2]
Atrazine	<1.3 - 2,937
Benzo[a]anthracene	<1.1 - 27.2 ng/L
Benzo[a]pyrene	<2.0 - 137.2 ng/L
Cadmium	<0.2 - 4.7
Alpha-Chlordane	<0.1 - 17.2
Gamma-Chlordane	<0.1 - 9.5
Chrysene	NA
Chromium	<1.0 - 150
Copper	<1 - 68
Fluoranthene	<0.3 - 196.8 ng/L
Lead	<1 - 106
Mercury	<0.2 - 0.7
Naphthalene	<0.2 - 39.5 ng/L
PCBs	95% of the available PCB data were below detection limits
Tributyltin	<1 - 1,801 ng/L

[1] SOURCE: Chesapeake Bay Program, 1994
[2] unless noted otherwise
NA = not available

Pesticides were detected most frequently in the spring and summer months (months of heaviest use), and the highest concentrations detected in surface waters were associated with storms. The following pesticides have been detected in the Bay: 2,4-D, alachlor, aldrin, alpha-chlordane, atrazine, cyanazine, DDT, diazinon, dicamba, dieldrin, fenvalerate, gamma-chlordane, hexazinone, malathion, metolachlor, oxychlordane, picloram, prometone, simazine, and terbacil. However, over 60 pesticides included in the analysis were not detected.

Organic compounds in water column samples were not frequently detected. This might be attributable to sampling and analytical problems and the fact that most organics are readily absorbed to sediments and biota. High concentrations of TBT, however, were detected in several Bay habitats.

The Chesapeake Regional Information Service developed a factsheet for the Elizabeth River and Chesapeake Bay (Alliance of the Chesapeake Bay, 1994), which outlines the pollution problems and solutions for this area. According to the information provided, the Elizabeth River is one of the most polluted bodies of water in the entire Chesapeake Bay watershed. Loadings of lead, copper, and mercury were reported at levels 2 to 10 times higher that those in mid-Bay or the Potomac River.

Elevated concentrations of PAHs were detected in the Elizabeth River and were found to adversely impact fish species (e.g., skin lesions, cataracts, fin rot). Specific sources of PAHs in the river include dumping of oily wastes and creosote and combustion of fossil fuels. TBT was also detected at high levels and is attributed to TBT-containing antifouling paint applied to commercial and recreational watercraft. However, these paints has been banned. The report concluded that industrial and municipal wastewater discharge and urban runoff are the major sources of pollutant loadings to the river. Urban runoff is especially important in the South Hampton area, and as residential, commercial, and office space development increase in this area, control measures will be needed. In addition, monitoring efforts, including a mobile bioassay laboratory and a comprehensive long-term water quality monitoring/sediment contamination program, have been initiated. Further information regarding the identification of urban runoff sources to the Chesapeake Bay is provided in the stormwater section of this chapter.

2.1.3 San Francisco Bay (Region 9)

The Regional Monitoring Program (RMP), established in 1992, is a large-scale trace substance monitoring effort for San Francisco Bay. Participants in the program include numerous POTWs, local stormwater management agencies, the U.S. Army Corps of Engineers, Pacific Gas and Electric, and other industries (SFEI, 1995). The objective of the RMP is to answer questions about the state of the Bay including the level of pollution and if conditions (water quality, organism health, etc.) are improving or getting worse. During 1994, water, sediment, and/or bivalve tissue samples were collected from 24 stations. However, not all parameters were measured at all stations at all times in all three media.

Results of the 1994 effort identified PCB concentrations above WQC at all stations. Levels of total copper, mercury, and nickel were often above WQC, as were concentrations of PAHs and p,p'-DDE. In addition, diazinon was above the National Academy of Science guideline of 9,000 ppq at three freshwater stations. Efforts have been made to identify sources of these pollutants to the Bay. Seasonal differences in concentrations helped narrow down potential sources. Dissolved zinc and total selenium, for example, were higher in February and April, indicating runoff as the likely source. Conversely, pollutants detected during the dry season can be tied to continuous sources, such as riverine sources, waste discharges, atmospheric deposition, or mobilization from sediments. PAHs detected in sediments were attributed to automobile exhaust. The RMP will continue efforts to identify sources in future investigations.

An example of another regional receiving water monitoring effort is the compilation of diazinon data in the San Francisco Bay Area. Several Bay Area cities have identified diazinon as a pollutant of concern (Moran, 1995). Alameda County conducted toxicity testing that linked diazinon levels of 0.1 to 3 μg/L in local creeks to *Ceriodaphnia* toxicity (Hansen, 1995). Maximum diazinon levels in Palo Alto creeks were measured at 0.39 μg/L, with typical values ranging from 0.5 to 2 μg/L (Moran, 1995). A compilation of data from approximately 200 samples collected by several Bay Area cities found diazinon in most Bay Area creeks. Concentrations ranged up to about 3.3 μg/L, with typical values in the 0.1 to 0.3 μg/L range. The Palo Alto RWQCP and the Central Contra Costa Sanitary District have conducted source identification studies for diazinon, which are discussed in the stormwater section of this chapter.

2.1.4 Santa Monica Bay (Region 9)

The Santa Monica Bay Restoration Project recognized that an accurate assessment of pollutant impacts in the receiving water of the Bay was necessary to establish defensible long-term reduction targets (McDonald, 1996). In addition, it was determined that both loading estimates and sediment quality objectives must be established for pollutants that accumulate in the Bay's sediment. A first step of the assessment involved monitoring of water quality, sediment, and biota to determine pollutants of concern. Monitoring of these media in intertidal, open, wetland, lagoon, marina, and harbor locations of the Bay revealed 19 pollutants of concern, including DDT, PCBs, PAHs, chlordane, TBT, cadmium, chromium, copper, lead, nickel, silver, zinc, pathogens, TSS, nutrients, trash and debris, chlorine, oxygen demand, and oil & grease. Table 2-3 lists the pollutants identified at each sampling location along with the observed impacts.

Table 2-3. Pollutant Impacts to Santa Monica Bay

Location	Pollutants Identified	Impacts Observed
rocky intertidal areas	pathogens, debris, oil & grease	potential health risk near continually flowing drains (pathogens); aesthetic impacts (debris); toxic impacts from spills
open bay	DDT, PCBs heavy metals	contaminated sediments near municipal outfall sites; elevated fish tissue levels; localized health risks from seafood consumption contaminated sediments near municipal outfalls
wetlands	heavy metals, nutrients, debris	habitat impairment, impaired water quality; rare and endangered species impairment
lagoon	nutrients, pathogens	eutrophication; potential health risk to swimmers; fish kills
marina	Cu, Pb, Zn, PCBs, DDT, chlordane, TBT, chromium, PAHs	impaired water quality; contamination of sediment, water, and biota; chronic sediment toxicity
harbor	heavy metals	contamination of sediment; elevated contamination levels in shellfish

Loading estimates of the pollutants of concern from major point sources to the Bay were established through WWTP monitoring. However, loadings from other sources, including stormwater/urban runoff, atmospheric deposition and advection, were not determined, but they might be significant contributors of some toxic pollutants. Sediments were identified as the only source of banned or restricted chemicals including DDT, PCB, and TBT (McDonald, 1996).

2.2 Stormwater Monitoring and Source Identification

Stormwater monitoring and source identification studies selected for review are listed in Table 2-1 and discussed below. General stormwater monitoring results are presented in the first section, followed by a discussion of specific monitoring programs conducted in the various US EPA regions. New directions in stormwater monitoring are also discussed. Other stormwater monitoring and source identification efforts identified by the project team, but not reviewed in detail, are listed in Appendix C (Table C-1).

2.2.1 General Stormwater Monitoring

An early US EPA effort to characterize stormwater, the Nationwide Urban Runoff Program (NURP), involved analysis of 2,300 runoff samples collected at 28 locations across the U.S. (US EPA, 1983 as cited in Pitt & Field, 1990). Most of the data collected during the NURP study represented residential areas; however, some commercial/light industrial source areas were also sampled. The NURP study targeted priority pollutants including several trace metals and organic compounds . According to NURP results, as summarized by Makepeace, Smith, and Stanley (1995), 31 inorganic contaminants were identified in the stormwater samples. The inorganic chemicals of greatest concern were copper, lead, zinc, nickel, arsenic, beryllium, and cadmium. Over 100 organic contaminants were analyzed for NURP, and over 60 of these contaminants were detected. Groups of organic compounds analyzed included PCBs, PAHs, halogenated aliphatics, halogenated ethers, monocyclic aromatics, phenols and cresols, phthalate esters, nitrosamines, and pesticides. Bis(2-ethylhexl)phthalate and (∝-BHC) were detected most often (20% of samples). Lindane, chlordane, phenanthrene, pyrene, chrysene, pentachlorophenol, and ∝-endosulfan were detected in stormwater and were deemed to be of concern to human health and/or aquatic life. There were no significant differences in the pollutants detected and their concentrations among the 28 cities sampled. Along with NURP results, Makepeace, Smith, and Stanley (1995) presented additional information on urban stormwater quality. Their findings, including pollutants of concern in stormwater and their concentration ranges, NURP detection frequency, and potential sources, are given in Table 2-4.

Table 2-4. Summary of Pollutants Detected in Stormwater Based on NURP Results[1]

Parameter	Concentration Range in Stormwater Runoff (μg/L)	Detection Frequency During NURP (%)	Potential Commercial/Residential Sources
METALS			
Antimony	3.5 - 23.0	13	gasoline, paint pigments, plastics
Arsenic	1.0 - 210	52	laundry products, pesticides, weed killers
Beryllium	1.0 - 49.0	12	combustion of fossil fuels
Cadmium	0.05 - 13,730.0	48	wear & tear of vehicle parts, fertilizers, pesticides, corrosion of galvanized metals
Chromium	1.0 - 2,300	58	corrosion, paints, dyes, ceramics, paper, heating & cooling coils, fire sprinkler systems, pesticides, fertilizers
Copper	0.06 - 1,410	91	wear & tear of vehicle parts, corrosion (roofs, pipes etc.), fungicides, pesticides
Cyanide	2.0 - 33.0	23	chemical, biological, & clinical labs
Iron	80.0 - 440,000	NA	corrosion of autobodies & other steel
Lead	20.9 - 1,560	94	wear & tear of vehicle parts
Manganese	7.0 - 3,800	NA	wear of tires & brake pads, fertilizers
Mercury	0.05 - 67.0	NA	dental amalgam
Nickel	1.0 - 49,000	43	corrosion

R0026008

Table 2-4, cont. Summary of Pollutants Detected in Stormwater Based on NURP Results [1]

Parameter	Concentration Range in Stormwater Runoff (μg/L)	Detection Frequency During NURP (%)	Potential Commercial/Residential Sources
Silver	0.2 - 14.0	NA	photoprocessing, fungicides, dental, medical, and electrical wastes
Zinc	0.7 - 22,000	94	wear & tear of vehicle parts, corrosion of roofs,etc., galvanized steel, and other metal objects
ORGANICS			
BHC	α-BHC 0.0027 - 0.1 γ-BHC 0.052 - 11.0	20 11	γ-BHC used for commercial and domestic pest control
α-endosulfan	0.1 - 0.2	NA	agricultural and domestic pesticide
PAHs	0.0006 - 60.0 (for all compounds)	10-12 (fluoranthene, naphthalene, phenanthrene & pyrene)	combustion, leaching of creosoted wood products
PCBs	0.027 - 1.1	NA	leaching lubricants
Pentachlorophenol	1.0 - 115	15	wood preservative products

[1] SOURCE: Makepeace, Smith, and Stanley, 1995

NURP also included flow rates from storm drain outfalls during or following extended dry periods (i.e., dry-weather flow), and attributed this to possible illicit connections. To address these flows, US EPA developed a User's Guide for investigating inappropriate entries to storm drainage systems (US EPA, 1993). The User's Guide provides an investigative procedure for municipalities and other agencies that is helpful in identifying the most significant sources of non-stormwater pollutant entries into storm drainage systems (US EPA, 1993). In general, the procedure involves identification of contaminated outfalls, followed by an investigation of the associated drainage areas to identify sources, and development of controls once sources have been determined.

A background study, in which non-stormwater outfall discharges were examined, was conducted in conjunction with the development of the User's Guide (US EPA, 1993). This three-phase project was conducted to identify stormwater pollutants and sources (Phase 1), investigate the control of toxics in stormwater (Phase 2), and investigate source area control (Phase 3). During Phase 1, sampling was conducted in various source areas during different rain conditions. This sampling methodology allowed for evaluation of the impacts of different land uses and rain characteristics on pollutant concentrations. Samples were collected from parking areas, storage areas, roof runoff, street runoff, loading docks, vehicle service areas, landscaped areas, urban creeks, and detention ponds. Results revealed the presence of 13 organic compounds in more than 10% of the samples, with 1,3-dichlorobenzene and fluoranthene occurring with greatest frequency. Concentrations of organic compounds were highest in samples of roof runoff, parking areas, and vehicle service areas. Metals were detected in nearly all of the samples. Maximum concentrations of various metals were observed in different land use areas. For example, zinc was highest in roof runoff samples, nickel was highest in parking and storage areas, and cadmium and lead were elevated in samples from vehicle service areas and street runoff. Selected numerical results from Phase 1 of this study are presented in Table 2-5.

Phase 2 of this study involved an assessment of treatment processes using bench-scale testing (Pitt et al., 1993). The objectives of Phase 2 were to identify the most toxic source areas and determine relative toxicity improvements for various stages of each bench-scale treatment method. The Microtox® screening test was used to rate the toxicity of the samples. Parking areas, CSOs, and storage areas had the largest percentage of samples rated extremely toxic. According to Pitt et al. (1993), Phase 3 will use information from Phase 2 to develop a prototype treatment device to control runoff from automobile service facilities.

Another national effort was the evaluation of the effect of snowmelt on the quality of stormwater runoff (Oberts, 1994). Pollutants contributed from snowmelt can either occur from short-duration small quantity "pavement melt" or from more substantial end-of-season melt of the snowpack. Meltwater at the end of the season carries pollutants that have accumulated all winter in the snowpack and also gathers pollutants from street and soil surfaces. Pollutants in the snowpack are a result of atmospheric fallout, industrial activity, vehicular emissions/corrosion/fluid leaks, roadway deterioration, urban litter, and anti-skid grit and chemical deicers. In addition, rain events occurring simultaneously with end-of-season snowmelt can contribute substantial pollutant loads (i.e., greater than summer thunderstorms). Various studies have shown snowmelt runoff to be an important source of pollutants in Minneapolis-St.Paul, Minnesota; Durham, New Hampshire; Denver, Colorado; and Milwaukee, Wisconsin (Oberts, 1994). Constituents of concern identified in these studies include COD, TSS, nutrients, lead, chloride, oil & grease, and total zinc.

2.2.2 Monitoring Programs by US EPA Region

In 1990, in a report to Congress, the US EPA presented the National Water Quality Inventory. This report demonstrated that approximately one-third of U.S. waterways were impaired by stormwater runoff; subsequently, the US EPA published final regulations requiring stormwater permits for large municipalities and urban areas (> 100,000 population), and eleven categories of industry. A primary element of the municipal permits is the characterization of stormwater quality. The goal of permit-required stormwater monitoring data collected as part of this program is to determine the typical runoff quality from residential, commercial and industrial land use areas as well as identify particular sources of runoff pollutants (NCTCOG, 1996). Examples of municipal stormwater monitoring programs implemented across the country are discussed in the following sections organized by US EPA region.

2.2.2.1 NY/NJ Harbor (Region 2)

A recent study was conducted in the NY/NJ Harbor area to evaluate trace metals in CSO discharge and wet weather influent samples from sewage treatment plants (Battelle Ocean Sciences, 1994). The New York City Department of Environmental Protection (NYCDEP) collected six CSO and 23 influent samples during wet weather conditions. In addition, the New Jersey Department of Environmental Protection and Energy (NJDEPE) collected two CSO samples. Samples were analyzed for TSS, particulate carbon (PC), dissolved organic carbon (DOC), total silver, cadmium, copper, mercury, lead, nickel, and zinc. All of the metals were detected in the influent and CSO samples and several measurements were above WQC (as stated in the report). Zinc, lead, and copper, for example, exceeded WQC of 58 μg/L, 8.5μg/L, 2.9 μg/L, respectively in all samples. The maximum zinc and lead concentrations, 1,575 μg/L and 1,383 μg/L respectively, were observed in CSO samples. The maximum copper concentration, 499μg/L, was detected in plant influent. Sources of these metals were not determined during the study.

2.2.2.2 Chesapeake Bay (Region 3)

Commercial and residential sources discharging pollutants of concern to Chesapeake Bay have been identified as point sources (municipal), stormwater runoff, atmospheric deposition, pesticide mixing and loading facilities, household hazardous wastes, and agricultural and domestic pesticide application (Chesapeake Bay Program, 1994). Stormwater runoff was identified as the greatest source of metals loadings to the Bay, followed by point sources and atmospheric deposition. The greatest source of organic chemicals (PAHs and PCBs) and pesticides was determined to be atmospheric deposition, followed by stormwater runoff. The pollutants of concern measured in stormwater runoff were determined to be from a number of sources. Incomplete fossil fuel combustion, especially from wood and coal burned in residential home heating units, is a source of chrysene, fluoranthene, phenanthrene, pyrene, arsenic, and nickel. Automobile related activities contribute significant amounts of cyanides, cadmium, and zinc. Chromium, lead, zinc, and pentachlorophenol are components found in exterior paints and stains. Bis-(2-ethylhexyl) phthalate is a widely used plasticizer for garden hoses, floor tiles, plastic containers, and food packaging. Finally, corrosion of metal alloys contributes cadmium, chromium, copper, and zinc. Other potential sources that have not yet been evaluated are bulkheads, piers and pilings built with pressure treated (copper arsenate) wood, runoff from marina facilities, and antifoulant paint leachates, all of which can cause localized impacts.

Another stormwater investigation in the Chesapeake Bay Area included a modeling project to determine the loadings of ten pollutants present in urban runoff to Chesapeake Bay (Cohn-Lee & Cameron, 1992). The model was based on local land use data, regional annual precipitation, and local and national stormwater concentration averages. Results demonstrated that contamination of the Bay from urban runoff is comparable, if not greater than, contamination from industrial and sewage sources. However, the model contained a few uncertainties: it did not consider fate and transport, nor did it have detailed site-specific land use and pollutant concentration data. A major conclusion of the study was that more site-specific stormwater monitoring data are needed to make accurate loading estimates.

A monitoring study in Maryland conducted by the Metropolitan Washington Council of Governments determined concentrations of hydrocarbons, PAHs, and trace metals in stormwater runoff samples (water and sediment) collected in standard oil-grit separators (OGS) (Shepp, 1996). The OGSs served five automotive-related land use areas in the Maryland Piedmont. Facilities located in the study areas were gas stations, convenience commercial, commuter parking lots, streets, and residential townhouse parking lots. Gas station runoff had the highest concentrations of hydrocarbons, PAHs, and metals in both water and sediments, followed by convenience commercial and commuter parking lots. Streets and townhouse parking lot concentrations were relatively low. Pollutants were attributed to spillage or leakage of oil, gas, antifreeze, lubricating fluids, cleaning agents and other automotive-related compounds.

2.2.2.3 Wisconsin (Region 5)

Most of the stormwater monitoring in Region 5 has been conducted in the State of Wisconsin. For example, a toxics reduction strategy was established for the Greater Milwaukee Area (MMSD, 1991). One of the goals of the strategy is to improve the Milwaukee Metropolitan Sewerage District (MMSD) database to maximize the effectiveness of the ongoing toxics reduction program and to document progress in achieving toxics reduction goals. Several steps were outlined in order for the MMSD to reach this goal, including researching information from other sewerage districts to identify pollutants of concern (POCs); compiling information on stormwater inflow, residential sources, and commercial sources; developing and implementing a comprehensive monitoring strategy for POCs (including residential and commercial sources); and determining the need for additional stormwater monitoring.

In addition, the State of Wisconsin focused several monitoring efforts on identification of pollutants present in stormwater and the sources of these pollutants. A study conducted by the Wisconsin Department of Natural Resources (DNR) and USGS (Bannerman, Owens, and Dodds, 1993), determined the contaminant loads for representative sources in various study areas. Rainfall runoff samples were collected from various land use areas including residential and commercial locations. Samples were collected within these areas from streets, parking lots, roofs, driveways, and lawns. Streets were an important source of most pollutants in all areas, whereas parking lot runoff was more critical at commercial sites. Roofs in commercial areas were found to contribute significantly to zinc loads. Lawns and driveways in residential areas were reported to produce substantial phosphorus loads.

The USGS and the City of Madison, Wisconsin conducted monitoring and sampling of stormwater runoff from seven drainage basins in Madison from 1993-94 (Waschbusch, 1996). Rainfall and stormwater runoff samples were collected from various land use areas, including commercial, medium-density residential, light industrial, university, highway, and shopping center. Samples were analyzed for metals, pesticides, and semivolatile organic compounds (SVOCs) to determine the quality of storm runoff. Metals detected were arsenic, cadmium, chromium, copper, lead, nickel, selenium, silver and zinc. All of these metals were detected at the commercial, university, and light industrial sites, and all metals except arsenic, selenium, and zinc were detected at all locations. Methoxychlor was the only pesticide detected at any of the sampling locations (a maximum concentration of 3.9 $\mu g/L$ was detected at the university location). The SVOCs were only observed at commercial, high density residential, highway, and shopping center locations. Most often detected SVOCs were fluoranthene, phenanthrene, and pyrene. Volatile organics were not detected at any of the sampling sites. The reported numerical data are summarized in Table 2-6.

The impacts of stormwater runoff on urban streams in Milwaukee County, Wisconsin, were observed during another Wisconsin DNR study (Masterson and Bannerman, 1994). To determine the impacts, storm sewer outfalls, stream water quality, bottom sediment, whole fish and crayfish tissue, semipermeable polymeric membrane devices (SPMDs), benthic macroinvertebrates, and habitat quality were monitored. Chemical analysis results for stream samples were compared with end-of-pipe stormwater data collected by the City of Milwaukee. Receiving water and sediment samples and fish tissue analyses showed high concentrations of several pollutants, including heavy metals, oil and grease, bacteria, and PAHs. The SPMD results illustrated the bioconcentration potential of many of these pollutants. Potential sources of the pollutants were identified as commercial parking lots and highways, industrial sites, residential landscapes and construction site soil erosion. Findings of this study strongly suggest the need for BMPs and other control measures to improve the quality of Milwaukee's urban streams.

Monitoring is also an important aspect of nonpoint source control plans for the Milwaukee River South Priority Watershed Project (Wisconsin DNR, 1991) and the Sheboygan River Priority Watershed Project (Wisconsin DNR, 1993). Monitoring for these two projects helped to identify nonpoint sources, such as construction site erosion and runoff from established urban areas (e.g., freeways, industrial areas, commercial areas, and high density residential areas). Based on the monitoring results, it was determined that residential areas can generate significant quantities of lead, pesticides, and bacteria.

Table 2-6. Stormwater Runoff Data for Madison, Wisconsin 1993–94 [1]

Parameter	Maximum Detected Concentration ($\mu g/L$)

Water quality and aquatic habitat investigations were conducted to determine pollution reduction goals. Pollution reduction goals include a 50% reduction in sediment loading, a 50% to 70% reduction in phosphorus loading, and a reduction in the mass loading of heavy metals from future urban areas. BMPs for urban areas have been established for both of these river basins and include hydrologic alterations and good housekeeping practices (reducing sources of pet waste, road salts, lawn fertilizers, and pesticides). Ongoing water quality monitoring is being conducted to evaluate effectiveness of the programs.

2.2.2.4 Illinois (Region 5)

The Illinois State EPA (IEPA) conducted pesticide monitoring of surface waters in an agricultural watershed to determine the presence of commonly used herbicides and organophosphate insecticides (Moyer and Cross, 1990). Seven herbicides (alachlor, atrazine, butylate, cyanazine, metolachlor, metribuzin, trifluralin), seven organophosphates (chlorpyrifos, diazinon, fonofos, malathion, methyl parathion, phorate, terbufos), and one fungicide (captan) were included in the analysis. Monitoring was conducted from 1985 to 1988 and included collection and analysis of ambient and storm event runoff samples. Atrazine was detected at all surface water sampling locations and had the highest maximum concentration (39 μg/L). High concentrations of atrazine were also detected in the runoff samples (peak concentration of 160 μg/L). Pesticide concentrations during storms were found to depend upon the duration and magnitude of the event. As a result of this study, future monitoring objectives were set by the IEPA, including expansion of storm event intensive monitoring to better characterize occurrence of pesticides and their concentrations in stormwater.

2.2.2.5 Lake Superior (Region 5)

During a USGS monitoring effort, contaminant concentrations in stormwater were determined in several Lake Superior Basin Cities from 1993-1994 (Steuer, Selbig, and Hornewer, 1996). The USGS collected stormwater samples from eight Lake Superior Basin cities (in the States of Michigan, Minnesota, and Wisconsin) to determine the quality of urban runoff entering Lake Superior from urban areas. The eight cities sampled contained various land uses ranging from heavy commercial and industrial to residential dominated areas. The ultimate goal of the monitoring program was to obtain data that could be used to educate cities regarding the specific contaminants present in stormwater and determine whether small communities should be included in the stormwater permitting process. Samples were analyzed for nutrients, metals, and PAHs and the results are presented in Table 2-7.

Table 2-7. Contaminant Concentrations in Stormwater Samples Collected from Lake Superior Basin Cities [1]

Parameter	Median Concentration		
	Michigan	Minnesota	Wisconsin

2.2.2.6 Galveston Bay (Region 6)

As part of the Galveston Bay National Estuary Program (GBNEP), characterization of nonpoint sources and loadings were determined for the Bay (GBNEP, 1992). Key study components were nonpoint source load calculation, subwatershed ranking, evaluation of upper watershed influences, and mapping. A geographic information system (GIS) mapped the geographic characteristics of the study area, analyzed the land use data, completed nonpoint source estimates, graphically represented results, and helped design pollution control measures. The watershed consists of several land use areas: high-density urban, residential, open/pasture, agricultural, barren, wetlands, water, and forest.

Nonpoint source loads of TSS, total phosphorus, total nitrogen, biochemical oxygen demand (BOD), oil and grease, fecal coliform, dissolved copper, and pesticides were estimated. Loadings were calculated for various scenarios: a year with average rainfall, a year with high annual rainfall, and an individual storm event. High rainfall load calculations were 40% to 60% higher than those calculated for average rainfall. Estimates for a single storm event demonstrated that a significant amount of the annual loads occur during a few large rainfall events per year. High density urban land use areas contributed the greatest nonpoint source loads of all parameters. Major potential sources identified for each of the parameters analyzed are presented in Table 2-8.

Table 2-8. Major Potential Nonpoint Sources of Pollutants to Galveston Bay Watershed

Parameter	Potential Nonpoint Source
TSS	eroding urban areas, cultivated fields, streambanks
Total nitrogen	eroding soils, fertilizer application, leaking sanitary sewers, overflows, by-passes, natural organic matter
Total phosphorus	eroding soils, fertilizer application, leaking sanitary sewers, overflows, by-passes, natural organic matter
BOD	natural decaying organic matter, leaking sanitary sewers, overflows, by-passes, oil and grease
Oil & grease	motor vehicles
Fecal coliforms	leaking sanitary sewers, by-passes, overflows, pets, cattle, wildlife
Dissolved copper	corrosion of copper plumbing, algicides, eroding soils
Pesticides	urban and rural pesticide application

2.2.2.7 Trinity River Basin—Dallas/Fort Worth (Region 6)

Water quality monitoring of the Trinity River Basin (North Central Texas) has helped to identify pollutants of "concern," "possible concern," and "no detectable concern" in this area (NCTCOG, 1996). To make these determinations, eleven years (1982–1992) of receiving water data were compared to the most stringent Texas surface water quality standards (WQS) published for each stream segment or other appropriate reference. The constituents of concern identified during this study included trace metals, fecal bacteria, nutrients, and dissolved oxygen (DO). The constituents of concern determined via this study have been instrumental in identifying pollutants of concern in stormwater runoff in the Dallas/Fort Worth area.

A cooperative stormwater monitoring program encompassing seven cities in the Dallas/Fort Worth, Texas, area was designed to more effectively monitor stormwater quality than the administration of individual city programs (NCTCOG, 1996). The program involves runoff sample collection at 11 residential, 6 commercial, 9 industrial, and 4 highway sites (highway data were not presented in this report). Samples were checked for 186 constituents; 100 were detected. However, only 48 were detected in more than 10% of the samples analyzed. To determine the pollutants of greatest concern, several criteria were used—frequency of detection, existence of State of Texas surface WQS for the constituent, occasional exceedance of surface WQS, and a report of the constituent being a potential concern in the upper Trinity River and its tributaries. Based upon these criteria, several constituents were deemed priority pollutants of concern for the Dallas/Fort Worth region: cadmium, chromium, copper, lead, zinc, chlordane, diazinon, fecal coliform, fecal streptococcus, and TSS.

Four of the constituents, including TSS, copper, lead, and zinc, were detected in all three land use areas (residential, commercial, and industrial). Future monitoring activities will include sampling of mixed land use and instream sites which are expected to better characterize the urban landscape.

2.2.2.8 Austin (Region 6)

A study involving urban runoff monitoring at several sites operated by the City of Austin, Texas was conducted to examine first flush stormwater pollutants (Chang, Parrish, and Souer, 1990). First flush, a concept introduced in the early 1970s, suggests that most of the urban pollutant load is transported during the beginning of a storm. A general rule was adopted based on this idea that 90% of the annual stormwater pollutant load is transported in the first one-half inch of runoff. Several programs used this rule to develop BMPs. However, this study determined that the first flush rule is not as absolute as previously thought. First flush was found to depend upon the amount of impervious cover. Areas with 70% and 90% impervious cover had 78% and 64%, respectively, of the annual pollutant load present in the first flush. However, the first flush rule (90% of the annual pollutant load in the first flush) did hold true for areas with 50% impervious cover. Another major conclusion of this study was that first flush effects are especially weak or absent for certain pollutants including nitrate, copper, ortho-phosphate, bacteria, and sediment.

2.2.2.9 Iowa (Region 7)

The Iowa Department of Natural Resources utilized information from national and local studies to determine potential impacts of pollutants on Iowa's surface waters (IDNR, 1994). Specific land use areas in Iowa were correlated with pollutants of concern. Residential areas were reported to be a source of pesticides, nutrients, bacteria, and sediment; municipal areas contribute ammonia, metals, oxygen-demanding substances, nutrients, pesticides and oil & grease; agricultural areas add sediment, nutrients, bacteria, and pesticides to Iowa's surface waters. Sources of pollutants in non-stormwater urban runoff were identified as fire hydrant flushing, lawn watering, motor vehicle washing, drains within commercial facilities, non-stormwater connections, and CSOs. A conclusion of this study, based upon current monitoring program data and a review of past investigations, is that Iowa has good to excellent water quality. However, monitoring programs will continue. Levels of PCBs, chlordane, mercury, and cadmium, for example, will be monitored to determine the degree to which urban areas contribute to levels of pollutants in Iowa fish. In addition, the cities of Davenport and Des Moines will continue stormwater monitoring programs and will establish new programs to control stormwater contaminants originating from commercial and residential areas.

2.2.2.10 Bay Area Stormwater Management Agencies Association (Region 9)

The Bay Area Stormwater Agencies Association (BASMAA) consists of representatives from all of the stormwater programs in the San Francisco Bay Area. Several of these programs have been conducting stormwater monitoring programs, including the Santa Clara Valley Nonpoint Source Pollution Control Program (SCVNPS), the Alameda Countywide Clean Water Program (ACCWP), the Contra Costa Clean Water Program (CCCWP), and Vallejo and Fairfield/Suisun city programs (WCC, 1996). Data from these monitoring efforts are compiled and then made available to other BASMAA members to increase the database available for evaluating stormwater issues in the Bay Area. The SCVNPS and ACCWP have been monitoring since 1987 and 1988, respectively, and initially involved characterization of stormwater runoff quality and estimation of annual metal loads to the Bay. Samples were collected at stations that drained different land use areas during wet weather and at waterway stations during wet and dry weather. The CCCWP has been collecting samples since 1994–95 at two waterway stations. The cities of Vallejo and Fairfield/Suisun have conducted stormwater monitoring, but these data have not been added to the BASMAA database.

Samples collected as part of the ongoing SCVNPS and ACCWP are analyzed for total recoverable (and occasionally dissolved) metals, TSS, TDS, hardness, TOC, total oil and grease, VOCs, SVOCs, PAHs, organochlorine pesticides, and chlorinated herbicides. According to the 1996 Monitoring Data Analysis Report, which contains stormwater sample analysis results, most parameters were measured below the detection limits (WCC, 1996). In response to toxicity identification (TIE) findings, both programs recently added monitoring of diazinon and chlorpyrifos. However, results of the diazinon and chlorpyrifos measurements were not presented in the 1996 Monitoring Data Analysis Report.

Metal concentrations detected in SCVNPS and ACCWP waterway samples were hypothetically compared to current regulatory standards for San Francisco Bay, i.e., water quality objectives (WQOs) and water quality criteria (WQC). Chronic and acute WQOs represent criteria for total metals concentrations, whereas the recently adopted WQC are based upon the dissolved metal fraction. When data were compared to WQC criteria, several trends were recognized. For example, more hypothetical exceedances occurred in highly urbanized watersheds than in watersheds with more open space. Concentrations of dissolved copper, lead, and zinc exemplified this observation. In addition, mercury exceeded the chronic WQO and the WQC consistently. However, the hypothetical exceedances are probably related to the criteria being based upon the bioaccumulation potential of mercury. These criteria might not be appropriate for stormwater, because levels do not remain elevated long enough to be accumulated by aquatic species. Dry weather monitoring and fish tissue analysis are needed to validate this hypothesis.

In addition to the sampling describe above, SCVNPS has evaluated the effectiveness of modifications to a detention basin, and ACCWP has collected grab samples in an effort to identify industrial and residential sources of pollutants (WCC, 1996).

2.2.2.11 Ventura County (Region 9)

Stormwater monitoring, as part of the Ventura Countywide Stormwater Quality Management Program (VCSQMP), has been underway in Ventura County, California since 1993 (VCSQMP, 1995b). Runoff samples are collected at two residential land use stations, two industrial stations, one commercial station, two receiving water stations, and one agricultural runoff station. Station locations were selected based on the ultimate goal of characterizing runoff from predominant land uses in the county in order to estimate pollutant loads and refine stormwater management programs. At least three storm events are sampled during each wet season, a first-flush/early-season storm, a mid-season storm, and a late-season storm. Analytical parameters include nutrients, total and dissolved metals, bacteria, and organics. Monitoring results for the urban runoff sites during the 1994–95 wet season are presented in Table 2-9. All of the organic compounds were measured below the detection limit and insufficient data were collected at the agricultural site and receiving water sites during this time to report results. The values in Table 2-9 are similar to NURP values obtained for the same land uses and similar to stormwater monitoring data collected in other communities of California.

In addition, a countywide approach to determine illicit discharges was implemented in 1995 (VCSQMP, 1995a). The program design draws from the US EPA's User's Guide (discussed previously in this chapter) for identifying and determining the sources of illicit discharges. Sources under investigation included sanitary wastewater, septic tank effluent, household chemicals, gasoline filling stations, vehicle maintenance/repair, laundry wastewater, carpet cleaning wastewater, acid wash water, leaking tanks and pipes, miscellaneous process waters, loading docks, motor oil, wet sanding operation runoff, solvents, steam cleaning runoff, outside storage, landscape runoff, and leaking air compressors. Target businesses that contribute to these illicit discharges were identified as gas stations, automobile service facilities, commercial laundries, carpet cleaners, painting contractors, pool cleaning, salvage yards, recycling facilities, restaurants, machine shops, and facilities with outside storage. According to the program description, investigations involving field inspection and testing, were conducted to determine illicit dischargers. Investigations entail visual observations, field tests, and collection of samples for laboratory analysis. Once dischargers have been identified, education and follow-up inspections are initiated.

2.2.2.12 Sacramento (Region 9)

Pesticides, especially diazinon and chlorpyrifos, have been identified as primary pollutants of concern for the Sacramento/Central Valley region. In 1993, the U.S. Geological Service (USGS) studied the movement of diazinon through the Sacramento-San Joaquin delta. Diazinon was applied as a dormant spray pesticide in orchards in the Central Valley in the last two weeks of January, 1993. After a series of rainstorms in early February, diazinon concentrations were measured at different points along the Sacramento and San Joaquin Rivers. Concentrations of diazinon were measured at Freeport (near Sacramento) in the Sacramento River a few days after each rainfall. Diazinon concentrations peaked at 0.39 μg/L after the first rainfall and 0.19 μg/L after a subsequent rainfall. Similarly, concentrations in the San Joaquin River peaked a few days after each rainfall

Table 2-9. Median EMCs Based on 1994–95 Wet Weather Monitoring Data Collected in Ventura County, California

Parameter	Units	Commercial Station	Industrial Station 1	Industrial Station 2	Residential Station 1	Residential Station 2
BOD	mg/L	45.5	40.0	8.0	13.5	22.0

Total Zinc	µg/L	579.0	95.0	139.5	160.5	91.0
Dissolved Zinc	µg/L	43.5	52.5	44.5	45.0	25.0

"ND" = Not Detected; "ID" = Insufficient Detected data (<50% detected or less than3 values).
Medians were not estimated for parameters with less than 2 detected values
Data below the detection limit were set at the detection limit for estimating medians.

when measured at Vernalis (a site near Modesto). Diazinon concentrations reached a maximum of 1.1 μg/L approximately 2 days after the first rainfall. The movement of a diazinon "pulse" down each river was documented at several points. Where the Sacramento and San Joaquin rivers converge in the delta, diazinon concentrations increased steadily throughout February from 0.035 to 0.15 μg/L. The USGS also monitored pesticide levels from January, 1991, to April, 1994, on the Sacramento River at Freeport and on the San Joaquin River at Vernalis (MacCoy et al., 1995). Diazinon was detected primarily in the winter months each year in both rivers. Concentrations ranged from 0.02 to 0.7 μg/L during the winter months.

As part of a TIE performed on Sacramento and Stockton receiving waters, the Central Valley RWQCB collected samples after storm events during the 1994–1995 winter season and analyzed these samples for chlorpyrifos and diazinon (CVRWQCB, 1996). Toxic levels of chlorpyrifos and diazinon were detected in receiving water samples. The TIE confirmed that both chemicals were contributing to toxicity observed in the receiving waters. From the CVRWQCB's TIE, sources of diazinon in Central Valley urban stormwater were determined, based on reported use data, to be both urban and agricultural (CVRWQCB, 1995). Reported use of diazinon in the Central Valley in 1990 included professional landscape maintenance (33,000 lb), structural pest control (74,000 lb), and agricultural uses (560,000 lb).

Metals levels in Sacramento water bodies have also been evaluated. The County of Sacramento has identified inactive mines as a significant source of pollutants for the Sacramento River Basin (Larry Walker Associates, 1993). Over 800 inactive mines exist in the Sacramento River Basin, and many contribute acid mine drainage to basin surface waters. Acid mine drainage contains acid and heavy metals, such as cadmium, copper, and zinc. Additionally, drainage from cinnabar ore and gold mines can contain significant amounts of mercury. Regulatory actions and control strategies have been implemented to control discharge of heavy metals from the inactive mines within the basin.

2.2.2.13 Puget Sound (Region 10)

In 1990, PTI Environmental Services conducted a pesticide reconnaissance survey of Puget Sound (PTI, 1991). Water samples were collected during high–rainfall precipitation events from four Puget Sound drainages. Sampling was conducted to determine the pesticides present in stormwater runoff. Five pesticides were detected: diazinon, 2,4–D, dicamba, bromacil, and diuron. Diuron exhibited the highest concentrations ranging from 1.3 to 3.3 ug/L. Monitoring results for all of the pesticides detected in water samples are presented in Table 2–10. Future pesticide monitoring efforts were recommended, including routine monitoring, regional reconnaissance surveys, and detailed research studies.

Table 2-10. Pesticide Concentrations Detected in Surface Water of Puget Sound Drainages[1]

Parameter	Concentration Range (μg/L)
2,4-D	0.077–0.54
Bromacil	3.3 (only one detected value)
Diazinon	0.054–0.14
Dicamba	0.11–0.27
Diuron	1.3–3.3

2.2.3 New Directions in Stormwater Monitoring

Traditional stormwater monitoring efforts cannot always accurately describe existing conditions in receiving waters, evaluate overall integrity of aquatic communities, or assess the degree of improvement in stream systems. To better characterize urban runoff, stormwater monitoring efforts are expanding their scope to include special studies, BMP effectiveness studies, evaluation of programmatic measures and use of environmental indicators. US EPA's stormwater NPDES permit re-application guidance encourages the use of non-conventional monitoring to make monitoring programs more appropriate and useful to stormwater management decisions (Perciasepe, 1996). US EPA suggests in this guidance that municipalities consider using such non-conventional techniques as habitat assessments, bioassessment, and other biological methods. Examples of new directions in stormwater monitoring are discussed below and include modification to the NCTOG regional monitoring program, special studies in the San Francisco Bay Area, use of volunteer monitoring programs, and development of monitoring programs using environmental indicators.

To meet wet weather characterization requirements for the NCTOG regional monitoring program, 182 stormwater samples were collected at 26 stations in three types of single land use basins between February, 1992, and June, 1993, (Brashear et al., 1995). As part of the permit re-application process, the regional program assessed various monitoring alternatives with the objective of reducing costs and increasing the value of the information gained from the monitoring program. As a result of this assessment, the monitoring program was modified to maintain 14 of the 26 existing single land use sites and to add 7 new sites to monitor mixed land use sites, instream conditions, and undeveloped areas. In addition, two bioassessment projects have been initiated—one in Fort Worth and one in Dallas. The initial program monitored 190 parameters. Less than 30% of these parameters were detected in more than 10% of the samples. To be more cost effective, the parameter set was reduced to 20 parameters. These modifications should focus monitoring efforts more effectively and cut costs.

Several special studies of stormwater issues in the San Francisco Bay Area are being coordinated through BASMAA (Brosseau, 1996). The studies are being conducted by member agencies and the results are tracked and compiled through BASMAA. The special studies are divided into the following categories: impacts on creeks and bays; quality assurance/quality control; source identification and control; BMP evaluation; treatment control measures; and watershed management.

Volunteer monitoring programs are used around the country to encourage public involvement in watershed issues and to enable public agencies to collect more data with limited resources. US EPA has supported volunteer monitoring efforts since 1988 by publicizing such efforts and developing support materials, including monitoring methods manuals and guides to quality assurance project plans (Mayio, 1996). In 1994, 520 volunteer monitoring programs coordinated the efforts of over 350,000 volunteers.

Volunteer data are used by local agencies, as can be seen from the following examples from Minnesota, Maryland, and Tennessee. In Minnesota, volunteers have been collecting lake quality data since 1973 (Mayio, 1996). Planners and government agencies us data reports published by the Minnesota Pollution Control Agency to make decisions on lake management issues, including septic system upgrades, algicide treatments, dredging, and shoreline construction. Maryland's "Save Our Streams" program works with the State Highway Administration to monitor stream conditions before road projects are begun, to assess the impact of road projects on streams, and to determine whether sediment control regulations are being met. The Tennessee Valley Authority Clean Water Initiative was formed in 1993 to identify the causes of water resource problems and form teams of the appropriate people and organizations to address these problems (Lyon, 1996). The Clean Water Initiative teams have developed a framework for using volunteer groups to assist the teams by collecting data. Through this program, volunteers have participated in conducting biological stream assessments through evaluation of fish and benthic communities and riverine habitat quality; monitoring of fecal coliforms at swimming beaches; sediment monitoring by local fisherman of a river that supports trout and small mouth bass fisheries; and monitoring the effectiveness of acid mine drainage BMPs.

The Center for Watershed Protection in cooperation with US EPA has developed a methodology for using environmental indicators in stormwater monitoring programs (Clayton, 1996). Environmental indicators are select parameters and indices that can characterize overall conditions in receiving water and provide baseline information to allow the assessment of stormwater management efforts. Stormwater indicators can be organized into six categories: water quality indicators, physical and hydrological indicators, biological indicators, social indicators, programmatic indicators, and site indicators. Traditional water quality pollutant constituent monitoring is one indicator that can be supplemented with other indicators to develop an overall monitoring strategy. Other stormwater indicators identified by The Center for Watershed Protection are listed in Table 2-11. Monitoring programs incorporating the appropriate indicators can address the information needs of individual municipalities, provide baseline data, and assess the long-term effectiveness of stormwater management programs.

2.3 Monitoring and Source Identification

The project team identified several wastewater monitoring programs focused on commercial and residential sources (Table 2-1). General wastewater monitoring and source identification studies are presented in Section 2.3.1 followed by a discussion of specific monitoring programs conducted in the various US EPA regions.

2.3.1 General Wastewater Monitoring

The US EPA conducted a domestic/commercial loading case study to estimate characteristic pollutant levels in domestic wastewater and wastewaters from specific types of commercial sources (SAIC, 1989). Pollutant levels were determined from existing monitoring data from publicly owned treatment works (POTWs); municipalities were surveyed to obtain information on residential and commercial source monitoring data. Trunk line, specific commercial source, septage hauler, and landfill leachate monitoring data were requested. Approximately 38 POTWs responded to the survey, and all US EPA regions were represented.

Table 2-11. Stormwater Indicator Profile Categories

Major Categories of Environmental Indicators	Indicator Name
Water Quality Indicators	Water quality pollutant constituent monitoring Toxicity testing Nonpoint source loadings Exceedance frequencies of water quality standards Sediment contamination Human health criteria
Physical and Hydrological Indicators	Stream widening/downcutting Physical habitat monitoring Impacted dry weather flows Increased flooding frequency Stream temperature monitoring
Biological Indicators	Fish assemblage Macroinvertebrate assemblage Single species indicator Composite indicators Other biological indicators
Social Indicators	Public attitude surveys Industrial/commercial pollution prevention Public involvement and monitoring User perception
Programmatic Indicators	Number of illicit connections identified/corrected Number of BMPs installed, inspected, maintained Permitting and compliance Growth and development
Site Indicators	BMP performance monitoring Industrial site compliance monitoring

The survey results yielded data on such commercial sources as hospitals, automobile radiator shops, car washes, truck cleaners, photoprocessors, dry cleaners, and laundries. The main objective of the study was to enable POTWs to use these estimated pollutant loadings, in the absence of actual site-specific monitoring data, to calculate local limits. The information was also provided to aid POTWs in identifying commercial sources of pollutants and to help them decide which commercial sources require routine monitoring. As indicated in the report, however, no substitute exists for actual site-specific monitoring data.

The U.S. General Accounting Office (GAO) published a report containing recommendations to US EPA on how to better manage nonindustrial wastewater pollution. The report presents information regarding the range, sources, and seriousness of pollutants found in nonindustrial wastewater; strategies and programs developed by local and State governments to better manage and control these pollutants; and Federal options that might encourage or require better management and control of nonindustrial wastewater pollution (GAO, 1991). Using data collected from US EPA studies, it was demonstrated that household sources—pesticides, drain cleaners, toilet bowl cleaners, degreasers, detergents, gasoline, and motor oil—account for the majority of 12 of the 28 pollutants analyzed. Commercial sources also contribute to wastewater pollution. Data collected from several municipalities were used to determine the pollutants discharged to treatment plants from various commercial businesses. Pollutants that were associated with the different types of facilities are presented in Table 2-12 (US EPA, 1991 as cited in GAO, 1991). The main recommendation of GAO was to require major WWTPs to identify pollutants of concern and their sources and to report on effectiveness of strategies implemented to control pollutants.

Table 2-12. Pollutants Attributed to Specific Commercial Facilities

Type of Facility	Pollutants Discharged
Hospitals	TDS, COD, phosphate, surfactants, formaldehyde, phenol, fluoride, lead, iron, barium, copper, zinc
Radiator shops	COD, zinc, lead, copper
Car washes	COD, zinc, lead, copper
Truck cleaners	COD, TDS, cyanide, phosphate, phenol, zinc, aluminum, chromium, lead, copper
Photoprocessors	silver
Dry cleaners	TDS, COD, phosphate, butyl cellosolve, n-butyl benzene sulfonamide, iron, zinc, copper
Laundries	COD, ethyl toluene, n-propyl alcohol, isopropyl alcohol, toluene, m-xylene, p-xylene, ethylbenzene, bis(2-ethylhexyl)phthlate, iron, lead, zinc, copper, chromium, phosphate, sulfide

2.3.2 Monitoring Programs by US EPA Region

Wastewater monitoring studies conducted by individual municipalities are presented in this section. Municipal pretreatment programs throughout the country conduct residential monitoring in conjunction with development of their local discharge limits. In general, the studies discussed herein have been conducted for purposes other than limits monitoring.

2.3.2.1 Narragansett Bay (Region 1)

Save the Bay, a non-profit organization established to improve Narragansett Bay, has implemented a multi-phase project (Toxic Diet Project) to develop a national model to "improve the quality of the nation's waters by reducing toxic pollution loadings at the source." Phase I of the project involved identification of sources of pollutants and development of a reduction plan for these pollutants, specifically for the town of Northbridge, MA. Copper, lead, and zinc were identified as the pollutants of concern based upon comprehensive sampling conducted by the Northbridge POTW and evaluation of data from other studies. Sources for each of these pollutants were determined during a 1994 study conducted by Save the Bay, which involved sampling of Northbridge's drinking water supply, the drinking water conveyance system, and residential effluent. Copper was the only chemical directly tied to any of the sources sampled; and pipe corrosion was identified as the most significant source of copper. The sampled sources were not significant sources of lead or zinc, suggesting that commercial or industrial discharges are the primary source of these metals (Walsh, 1996).

2.3.2.2 NY/NJ Harbor (Region 2)

A study conducted in the NY/NJ Harbor involved evaluation of PCBs at point sources (Battelle Ocean Sciences, 1993). Ambient river water, and POTW influent and effluent samples were collected and analyzed for low-level PCB concentrations. Influent samples were collected during storm events (i.e., CSO), effluent samples were collected from five area POTWs, and ambient samples were collected from four major tributaries that discharge to the harbor. Samples were analyzed for 50 PCB congeners. Total (sum of all 50 congeners) maximum concentrations for influent, effluent, and ambient samples were 382 ng/L, 96 ng/L, and 25 ng/L, respectively.

2.3.2.3 San Francisco Bay Area (Region 9)

Recently, the San Francisco Bay Area Pollution Prevention Group (SFBAPPG) surveyed POTWs in the San Francisco Bay Area to gather information on toxic organic pollutants (TOPs) in the Bay Area. TOP limits, monitoring data, and studies were requested in the survey. About one-third of the POTWs that responded to the survey have sampled for toxic organic pollutants with most of the TOPs measured below the detection limit. Several of the POTWs, however, reported TOP concentrations that exceeded their permit limits. Tributyltin (TBT) exceeded its permit limit more frequently than any other TOP (Montgomery Watson, 1996b).

Information obtained from the surveys was used to determine the TOPs of greatest concern in the Bay Area. Based upon this data and information from the Ecological Overview of the Estuary Workshop (1995), tributyltin, chlorpyrifos, and diazinon were selected as the TOPs of concern for the Bay Area (LWA, 1996c). A nationwide literature review yielded information on monitoring and sampling studies, environmental impacts, and source identification and control measures for these pollutants (LWA, 1996c). The SFBAPPG will use information presented in this report to coordinate and plan pollution prevention efforts. Some POTWs, namely the City of Palo Alto's RWQCP and the Central Contra Costa Sanitary District (CCCSD), have identified sources of diazinon, and the Palo Alto RWQCP has also determined the source of TBT. The sources of these constituents are discussed in the Palo Alto and CCCSD sections in this chapter.

Copper is a concern for several Bay Area POTWs; therefore the SFBAPPG has also investigated source identification and control strategies for copper in wastewater (LWA, 1994b). The SFBAPPG distributed surveys to pretreatment programs throughout California in an effort to obtain information on copper sources, control strategies, and public education efforts. Copper source data included flows and concentrations of copper in POTW influent and effluent for the industrial, commercial, and residential sectors. Concentrations from each sector varied according to POTW size. For example, medium- and small-sized plants received significant loadings (51% and 87%, respectively) from the residential sector, whereas industry contributed the greatest loadings (67%) to larger plants. Several POTWs reported loadings from specific commercial sources, including auto repair shops, car washing, cooling towers, dry cleaners, laboratories, laundries, medical facilities (hospitals), photoprocessing, printing, radiator repair shops, and universities/schools. The highest average copper concentration was reported for effluent from radiator repair shops—22,337 $\mu g/L$. Average copper concentrations from all of the commercial sources monitored are listed in Table 2-13.

Conclusions drawn from this study include the need for increased sampling of commercial copper sources to further quantify the sources, standardize sampling methodologies, and conduct sampling efforts on a regional basis to obtain larger datasets.

Table 2-13. Copper Concentrations from Various Sources Based on Data from California POTWs

Source	Copper Concentration (μg/L)
Auto repair shops	375
Car washes	179
Cooling towers	91
Dry cleaners	129
Laboratories	120
Laundries	258
Medical facilities(hospitals)	183
Photoprocessors	118
Printers	442
Universities/schools	118

Numerous Bay Area cities have conducted individual studies to determine wastewater pollutants of concern and their sources. Palo Alto, San Jose, Novato, Sunnyvale, and Union Sanitary District (including the cities of Union City, Fremont, and Newark) are a few of the POTWs that have implemented pollution prevention and pretreatment programs to identify and control sources of some or all of the following constituents: arsenic, copper, cadmium, chromium, cyanide, mercury, nickel, selenium, zinc, and tributyltin. Descriptions of the monitoring and pollutant source identification studies conducted by these cities and others are presented in the following sections.

2.3.2.4 City and County of San Francisco (Region 9)

The NPDES permit for the City and County of San Francisco (CCSF) requires CCSF to implement BMPs to control sources of priority pollutants to the combined sewerage system. To develop BMPs, CCSF evaluated the loadings from four major sources: industrial wastewater, commercial wastewater, residential wastewater, and tap water (CCSF, 1993). Commercial facilities were found to contribute over half of the cyanide loadings. Residential sources were found to contribute half of the nickel loadings and almost half of the total mercury loadings. CCSF also conducted a consumer products heavy metals inventory in which the contribution of heavy metals from shampoos, soaps, toilet bowl cleaners, toilet paper, creme rinses, and deodorants was determined (CCSF, 1991). It was found that these products did not significantly contribute to total metals loadings.

In addition, CCSF conducted a survey of households to determine the use and disposal of common household hazardous products (CCSF, 1993b). The survey revealed that motor oil and house paints were used by the majority of residences surveyed. Therefore, CCSF conducted a study to determine the loadings of copper, lead, mercury, nickel, silver, zinc, and cyanide to the sewerage system from San Francisco residents disposing of used motor oil and latex paints to sinks and storm drains, from washing painting equipment in sinks, and from automobiles leaking motor oil onto CCSF streets. The study involved literature reviews on used motor oil and latex paint composition and disposal practices to drains, comparison of the estimated mass loadings from drain disposal and washing operations to dry weather influent data from CCSF's pollution control plant (Oceanside treatment plant), and comparison of the estimated mass loadings from the leaking of used motor oil to the Oceanside treatment plant annual wet weather influent and effluent data. Information gathered during the study suggests that used motor oil is not a significant source of CCSF's current total metals and cyanide influent loadings, i.e., less than 1% of the total metals and cyanide loadings were attributed to used motor oil. Latex paint discharged to sinks and street drains (directly and during washing of painting equipment) was also shown to contribute less than 1% of the total metal and cyanide loadings to the plant. According to the report, CCSF plans to quantify other sources of pollutants of concern including brake pads, tires, and gasoline exhaust.

CCSF conducted a study to determine sources of cyanide to the Southeast Water Pollution Control Plant (SEWPCP) (CCSF, 1992). As part of this study, CCSF evaluated both commercial and residential sources. Commercial wastewater sampling points for the project were determined by reviewing all of the drainage districts in the CCSF to ensure that selected sites were free of regulated industries. Five sampling sites were selected to represent the commercial sector. Additional sampling points were located at selected restaurants in order to estimate the percentage of the cyanide pollutant load from this particular commercial source. Average cyanide concentrations in commercial samples ranged from 5.0 μg/L to 8.6 μg/L, representing 23.8% of the cyanide load, and the contribution from restaurants alone was estimated to range from 2.5 to 19%. In addition, CCSF has inspected and/or monitored automotive service facilities, educational laboratories, medical facilities, photoprocessing labs, and printers and found that none of these businesses discharged detectable levels of cyanide.

In addition, residential streams were sampled at five designated sampling points in CCSF. Average cyanide concentrations in residential samples ranged from 5.0 μg/L to 6.5 μg/L.

In 1991, CCSF's Industrial Waste Pretreatment Program initiated a water pollution prevention program to identify City industries and businesses discharging pollutants that threaten the aquatic resources of the San Francisco Bay and Pacific Ocean (CCSF, 1996). Monitoring is an important part of the program. For example, effectiveness of the program is determined from the analysis of CCSF's two water pollution control plants' influent, effluent and biosolids data, industrial user discharge data, and individual sewerage drainage district discharge data. Monitoring has mostly focused on industrial dischargers, but CCSF has sampled, inspected and permitted several commercial photofinishers, printers, and graphic artists. Once these businesses were regulated by CCSF, the mass and concentration of silver in CCSF's SEWPCP's influent was substantially reduced. The SEWPCP's silver effluent also showed a significant improvement.

In addition, CCSF operates a monitoring program (i.e., City-Wide Collection System Monitoring Program), which identifies and maps all 52 drainage districts that comprise the two major drainage basins from which all wastewater flow is collected and transported to one of CCSF's two treatment plants. Contributory wastewater is sampled on a routine basis. This extensive monitoring program gives CCSF the ability to identify, by contributory district, significant deviations from background concentrations of targeted pollutants and also provides baseline data useful in determining effectiveness of implemented source control strategies (CCSF, 1996).

2.3.2.5 Palo Alto (Region 9)

As required by the NPDES permit, the Palo Alto RWQCP has completed several tasks to achieve compliance with discharge limits for toxic pollutants. For example, the Palo Alto RWQCP has evaluated pollutants of concern, calculated the maximum allowable headworks loadings for the pollutants of concern, conducted a headworks loadings allocation evaluation, and examined pollutants for local limit revision (Montgomery Watson, 1993a,b; 1994a).

A detailed discussion of each of these tasks is beyond the scope of this chapter. However, the Palo Alto RWQCP incorporated this information into their Clean Bay Plan to aid in the identification of wastewater pollutant sources (PARWQCP, 1995). A more recent version of the Palo Alto RWQCP's Clean Bay Plan (PARWQCP, 1996a) outlines the current pollutants of concern, their sources, and control strategies. The pollutants of concern for wastewater are arsenic, chromium, cyanide, nickel, cadmium, copper, mercury, selenium, zinc, and tributyltin, and those for stormwater are cadmium, chromium, copper, diazinon, lead, mercury, nickel, selenium, silver, and zinc. The plan involves continuing monitoring efforts to determine the effectiveness of control strategies and to modify the list of pollutants of concern if necessary. The following is a discussion of some of the source identification investigations conducted by the Palo Alto RWQCP.

Several monitoring efforts have been initiated by the Palo Alto RWQCP to identify sources of copper and perhaps reduce loadings to the plant. Efforts have been focused on corrosion of copper pipes, which is estimated to account for 51% of the copper discharged to the plant (PARWQCP, 1996b). In one study, the copper discharges to the sanitary sewer from the Stanford University Medical Center were evaluated (PARWQCP, 1995). The average amount of copper in the discharge was 0.17 lb/day. Four primary sources were identified including water supply, pipe corrosion, kitchen wastes, and human wastes. It was determined that 75% of the copper from the Center comes from recirculating hot water systems (i.e., pipe corrosion). Recommendations determined from the study were to continue monitoring corrosion and reduce the amount of corrosion with operational changes including reduced temperatures and flow velocities in hot water systems. Technical investigations on copper sources have also been conducted for the Palo Alto RWQCP, including *Linear Polarization Studies and Corrosion Rate Estimates* and *Copper Loading from Cooling Towers and Potable Hot Water Circulation Systems* both produced by Kennedy/Jenks Consultants.

Efforts to identify sources of diazinon have been initiated by the Palo Alto RWQCP, including an investigation of the types and uses of diazinon products registered in California (Cooper, 1996). There are 267 products containing diazinon registered for use with the Department of Pesticide Regulation. These products are classified by formulation type into the following categories: solution/liquid, emulsifiable concentrate, aqueous concentrate, pressurized liquids, sprays, flowable concentrate, dust/powder, wettable powder, granular/flake, impregnated material, and microencapsulated. Sixty of the products are impregnated materials (e.g., flea collars) and were not included in the Palo Alto RWQCP evaluation because they were unlikely to be a source of diazinon in wastewater or stormwater.

Recommended uses are provided on the DPR registry for each product. The indicated uses were divided into indoor and outdoor applications and into commercial and residential applications for the Palo Alto RWQCP study. Most of the products (202 of the 217) have outdoor uses, while the other 15 have only indoor uses. The Palo Alto RWQCP evaluated where each type of formulation is likely to be used. Ninety-six percent of the 72 granular/flake products registered are for outdoor use. Solution/liquid and pressurized spray products are generally used both indoors and outdoors. Over half of the products in the other categories are designated solely for outdoor use. This breakdown of product types might be used to focus source control efforts.

To gain more information about how the product is used, Palo Alto also surveyed retail stores in its service area that sell diazinon (Cooper, 1996). The survey results indicated the following:

- The target pests in the Palo Alto service area are ants, fleas, and grubs;
- Only 29 of the 246 registered diazinon products are available in stores in the Palo Alto service area;
- Formulations in significant use in the Palo Alto service area include granules, dusts, concentrates, and one ready-to-use liquid; and
- Diazinon sales occur primarily in the spring and summer.

Possible sources of tributyltin (TBT), as identified by Palo Alto RWQCP staff, included biocidal cooling water system additives, antifouling paints and stains, protective wood treatments, disinfectant commercial toilet bowl cleaners, and disinfectant carpet and upholstery cleaners (DPR, 1993 as cited in Davidson, 1995). Palo Alto RWQCP staff conducted surveys to determine the potential sources of TBT in the Palo Alto RWQCP service area. Surveys revealed that cooling water system discharge was the most obvious source of TBT (Moran, 1994 as cited in Davidson, 1995). It was calculated that one gallon of 2% TBT solution discharged to the sewer and treated with other wastewater at the Palo Alto RWQCP would contaminate more than 2.4 billion gallons of plant effluent. In addition, the Palo Alto RWQCP determined that even very small discharges from one or two cooling towers using TBT-containing products could cause the plant to violate their TBT effluent limit of 5 μg/L. Control strategies have been implemented to eliminate TBT in cooling water discharge, which are discussed in Chapter 3.0.

2.3.2.6 Novato (Region 9)

The Novato Sanitary District (NSD) established a source monitoring program to determine loadings of seven trace inorganic compounds in wastewater treatment plant influent and in commercial and residential wastewater (LWA, 1996b). Samples were collected from WWTP influent, residential trunk lines, commercial trunk lines, residential tap water, and finished tap water. The following parameters were measured under the Novato source monitoring program (NSMP): copper, lead, mercury, nickel, silver, zinc, cyanide, electrical conductance, pH, temperature, and TSS. Results of the monitoring program demonstrated that copper levels in commercial and residential samples were similar and that the majority (87%) of the copper present in the Novato WWTP influent is from tap water sources. Therefore, source control efforts in commercial and/or residential sectors are not likely to significantly decrease influent copper concentrations. Conversely, lead concentrations in commercial wastewater were significantly higher than either residential or WWTP influent concentrations, and tap water was not a significant source. The majority of mercury in NSD wastewater was unaccounted for; unmeasured non-residential sources accounted for an estimated 40% to 72%. In general, nickel and silver concentrations were higher in commercial wastewater and WWTP influent than in residential samples. In addition, the majority of silver loadings were attributed to non-residential sources. A high percentage (51%) of zinc loadings was attributed to unmeasured non-residential sources. Cyanide was largely undetected and loadings could, therefore, not be estimated.

2.3.2.7 San Jose (Region 9)

An evaluation of pollutant sources was conducted for the City of San Jose (CH2M Hill, 1995). The sources investigated included industry, nonpermitted industry (representing 37,000 commercial businesses in the Water Pollution Control Plant (WPCP) service area), residential, and water supply. Pollutants of concern evaluated in the report were arsenic, cadmium, chromium, copper, cyanide, lead, mercury, nickel, selenium, silver, and zinc. Zinc represented approximately 75% of the total metals load to the WPCP, with equal amounts contributed from residential and water supply sources. Copper represented the second highest contribution, 9%, with proportionate loadings from all sources. A significant percentage of nickel (59%) and silver (65%) came from commercial sources. Residential areas also contribute substantial silver (19%).

The City of San Jose investigated un-permitted sources of nickel and copper in Santa Clara/San Jose WPCP influent (EOA, 1991). The investigated sources were water supply, corrosion, human excrement, common household products, and commercial industry (automotive, photoprocessing, radiator repair, printing shops, and laundries). All source loadings were determined from existing data and a review of the literature; new site-specific data were not collected. The report was to present estimated loadings for assigning priorities to additional investigations. The majority of copper loading (55%) was reported to originate from the water supply and corrosion of copper plumbing. "Other" potential sources—pesticides, pigments, and medical/laboratory products—were estimated to contribute 29% of the total copper loadings. Nickel loading was mainly from water supply and corrosion (68%) with 13% contributed by commercial facilities.

The 1991 study served as the basis for a copper and nickel source control program for commercial facilities conducted by the City of San Jose (EOA, 1992). As part of the source control program, concentration data were collected from POTWs and summarized based upon the highest average concentrations of copper and nickel for commercial categories. Eleven significant commercial sources of these pollutants were determined: transportation (airports & terminal services), machine shops, hospitals, miscellaneous equipment rental, sheet metal work, lithographics, commercial printing, commercial laundries, dry cleaners, and car washes. Average copper and nickel concentrations determined for each source are summarized in Table 2-14.

Table 2-14. Summary of Copper and Nickel Monitoring Data from Commercial Businesses (Data Obtained from Surveyed POTWs)[1]

Source	Average Concentration (mg/L)	
	Copper	Nickel
Transportation facilities (airports & terminal services)	10.9	0.44
Machine shops	4.2	0.26
Hospitals	0.09	0.21
Misc. equipment rental shops	1.2	0.20
Sheet metal work shops	0.69	0.05
Lithographic	0.13	0.04
Commercial printers	0.44	0.06
Laundries	0.58	0.09
Car washes	0.39	0.15

[1] SOURCE: EOA, 1992

More recently, the City of San Jose developed the "Pollution Prevention Strategy for a Clean Bay" (City of San Jose, 1996). This program involves a commercial/residential sampling program to identify sources of copper, nickel, and cyanide. Current source identification programs are focusing on identification of the unaccounted for 20 to 40% of influent copper and nickel. Thus far, the program has determined that residential and commercial sources contribute significant amounts of copper, but do not add to nickel or cyanide loads. To identify sources of nickel and copper, trunkline sampling is being conducted to trace pollutants upstream of the WPCP. In addition, the largest discharger monitoring program is scheduled to continue through October 1997 and data will provide guidance for pollution reduction strategies.

2.3.2.8 Union Sanitary District (USD) (Region 9)

Union Sanitary District serves the cities of Fremont, Newark, and Union City. USD has collected treatment plant effluent monitoring data and has developed local limits. Based upon this information, copper and nickel were identified as the major pollutants of concern (USD, 1995). Mercury, cyanide, and PAHs were also selected as POCs in the Hayward Marsh NPDES permit, and diazinon was designated as a POC in the EBDA/Alvarado treatment plant NPDES permit. USD is targeting automotive machine shops and printers as the major sources of pollutants of concern. A pollution prevention plan has been established by USD and monitoring is being conducted to evaluate the effectiveness of the program.

2.3.2.9 South Bayside System Authority (Region 9)

Sources and loadings of pollutants of concern in wastewater were determined for the South Bayside System Authority (SBSA) as part of their waste minimization plan (LWA, 1992). The SBSA treats wastewater for the cities of San Carlos, Belmont, Redwood City, and the West Bay Sanitary District. Source identification included analysis of commercial and residential discharges. The following commercial sectors were evaluated: auto repair and auto parts cleaning facilities, radiator repair shops, photoprocessors, printing and publishing companies, laboratories, hospitals, painting contractors, laundries, and cooling towers. Residential sources identified were indoor household products, graywater, outdoor household products, copper sulfate root killer, and human body wastes. Pollutants associated with each commercial and residential source are presented in Table 2-15.

Table 2-15. Commercial and Residential Sources of Inorganic Pollutants as Reported by South Bayside System Authority[1]

Sources of Pollutants for SBSA	Parameter										
	As	Cd	Cr	Cu	Cn	Hg	Pb	Mo	Ni	Ag	Zn
COMMERCIAL											
Auto repair		x		x	x		x		x	x	x
Photoprocessors				x			x			x[2]	x
Commercial printers				x				x		x	x
Hospitals & clinics						x				x	
Dental offices				x						x	x

Human body wastes	x			x		x			x		x

[1] SOURCE: Larry Walker Associates (LWA), 1992.
ND = not determined
[2]Photoprocessing accounts for an estimated 40% of the silver discharged to the SBSA wastewater treatment plant.
[3] Loadings were insignificant for non-medical laboratories, therefore information is for medical laboratories.

2.3.2.10 Central Contra Costa Sanitary District (CCCSD) (Region 9)

The Central Contra Costa Sanitary District (CCCSD) has investigated sources of chlorpyrifos and diazinon (Brandenburg, 1996). Wastewater samples were collected from a residential community and from a number of commercial sources, including self-service pet washes, kennels, and certified pesticide applicators (Table 2-16).

Table 2-16. Sources of Diazinon and Chlorpyrifos
(Brandenburg, 1996)

Source	Chlorpyrifos (μg/L)	Diazinon (μg/L)
Residential	1.8 - 3.0	0.71 - 2.0
Self-service pet washers	0.38 - 7.0	0.045 - 0.099
Certified applicators	0.056 - 1.8	0.035 - 1.1
Kennels	3.1 - 4.8	0.068 - 16

In addition, CCCSD and DPR, with support from USD and Palo Alto, are sampling pesticides to determine the mass contribution to plant influent (Brandenburg, 1996).

CCCSD identified flea shampoos as a significant potential source of chlorpyrifos in wastewater effluent. Estimates were made concerning the number of pet washings that would result in enough insecticide to cause toxicity in the CCCSD effluent (a 35-Mgal/day plant). For flea shampoos containing D-limonene or pyrethrins, between 4,300 and 18,000 pets would have to be washed to put enough insecticide in the sewer system to cause toxicity in the effluent. In contrast, toxicity in the CCCSD effluent would result from washing 2 to 7 pets per day with a chlorpyrifos-containing product.

CCCSD also evaluated residential sources of metals in wastewater (LWA,1994a). The results of this study are discussed in Chapter 4.0.

2.3.2.11 Hayward (Region 9)

The City of Hayward has identified copper, lead, PAHs, and diazinon as pollutants of concern through analysis of influent and effluent monitoring data, review of the proposed San Francisco Basin Plan, new NPDES permit limits, and consideration of composting and beneficial use of POTW solids (Mendoza, 1996). The City evaluated print shops, large service facilities, and residential areas as possible sources of pollutants of concern. Surveys of print shops and large service facilities revealed that these businesses have already implemented effective pollution prevention practices. Therefore, the City decided that targeting these businesses would not result in significant reductions. Residential areas, however, are expected to discharge diazinon and copper and have been targeted through public education programs.

2.3.2.12 Sunnyvale (Region 9)

The City of Sunnyvale WPCP recently updated source loading calculations for the water supply, residential, commercial, and industrial sectors based on monitoring data from 1995 (EOA, 1996). Loadings were determined for copper and nickel, the pollutants of concern determined by the City's local limits development (City of Sunnyvale & EOA, 1993). To determine copper and nickel loadings from the residential sector, tapwater and residential sanitary sewer samples were collected. Tapwater samples were collected to estimate the contribution from corrosion of copper piping and fixtures in households. Based upon 1993–94 tapwater sampling data, the copper concentration from corrosion of residential plumbing was 30 μg/L. This represented a 33% decrease compared to the concentration (45 μg/L) calculated from 1991–92 data. Sanitary sewer lines were sampled in residential areas throughout the City of Sunnyvale during 1995 and were analyzed for copper and nickel. Annual mass loadings were calculated by multiplying the arithmetic mean concentration by the estimated residential flow (3,369 Mgal/yr). Average concentrations for copper and nickel were 0.036 mg/L and 0.006 mg/L, respectively, and mass loadings of 1,012 lb/yr and 169 lb/yr were determined, respectively.

To assess pollutant loadings of copper and nickel from commercial businesses, sewer line sampling was performed in representative commercial areas. Average concentrations of 0.089 mg/L and 0.009 mg/L were determined from the 31 samples analyzed for copper and nickel, respectively. Resulting mass loadings were 632 lb/yr of copper and 64 lb/yr of nickel.

The City also determined mass loadings of copper and nickel from industrial, infiltration and inflow, corrosion (copper only), and groundwater extraction. Calculated mass loadings for each source are presented in Table 2-17. As evidenced in Table 2-16, the residential sector is the largest source of copper (52% of the total) and nickel (47% of the total), and the commercial sector is the second largest source for both metals (33% of the copper and 19% of the nickel). In addition, the City assessed corrosion separately and concluded that, when viewed as a separate source, corrosion is the largest contributor of copper at 58% of the total.

Table 2-17. City of Sunnyvale WPCP 1995 Source Loadings of Copper and Nickel by Source Category
(EOA, 1996)

Source	Copper Mass		Nickel Mass	
	lb/yr	%	lb/yr	%
Water supply	42	2	37	12
Residential	983	52	142	47
Commercial	625	33	58	19
Industrial	221	12	38	12
Other (infil./inflow, groundwater extraction)	38	2	30	10

2.3.2.13 Los Angeles (Region 9)

The City of Los Angeles Department of Public Works, Bureau of Sanitation, conducted a study to mitigate silver, copper, mercury, and zinc in the effluent of the Terminal Island Treatment Plant (TITP) (Bureau of Sanitation, 1994). This study identified sources of silver, copper, mercury, and zinc in the TITP influent in an effort to ultimately reduce concentrations of these metals in effluent discharged to Los Angeles Harbor. Source identification involved sampling and analysis, a literature review, determining removal efficiencies across the plant, and calculation of maximum available headworks loading (MAHL) for each chemical to determine local limits. Sampling results demonstrated that determination of local limits for silver and mercury was not necessary. However, waste minimization programs were established for copper and zinc. Potential sources of copper and zinc were identified as radiator shops, auto shops, and dental offices.

2.3.2.14 Orange County (Region 9)

The sanitation districts of Orange County, California, implemented a nonindustrial source control project to determine the contribution of pollutants from domestic wastewater (County Sanitation Districts, 1995). Sampling was conducted in six residential neighborhoods representing various sociodemographic characteristics. The districts collected data to help determine appropriate local industrial discharge limits. A list of the POCs and their concentrations emanating from each residential source are presented in Table 2-18.

2.3.2.15 Arizona (Region 9)

In 1992, the Arizona Department of Environmental Quality established a navigable water quality standard for arsenic of 3.1 μg/L (Woodwick, 1995). This standard will become applicable to the 91st Avenue wastewater treatment plant (WWTP) (operated by the City of Phoenix) during the current permitting cycle. Several times over the past three years, the WWTP has reported arsenic concentrations above the WQC. In response, the City assessed sources of arsenic (Woodwick, 1995) and determined that a significant amount of the arsenic load emanates from natural and uncontrollable sources. For example, the Verde Formation contributes arsenic to the Verde River, which, in turn, contributes arsenic to the treatment plant. Commercial and residential sources, however, contribute an estimated 83% of the total arsenic load. Several alternatives to resolve the issue of elevated arsenic concentrations were presented by the City. One of the proposed alternatives was to implement a nonindustrial source reduction program and revise the local limit downward to the extent feasible.

In the development of a mercury local limit, the Cities of Phoenix, Glendale, Mesa, Peoria, Scottsdale, Tempe, and the Town of Gilbert identified, surveyed, inspected, and sampled potential mercury dischargers (City of Phoenix, 1995). Sampling was conducted for selected dischargers, including printers, photoprocessors, dentists, hospitals, animal hospitals, laboratories, auto repair shops, auto service stations, funeral homes, lithographics, glass cutters, ceramics, and laundries.

R0026049

Sampling results demonstrated that dentists discharged the largest amount of mercury to the WWTP. Measurable mercury levels were also detected in wastewater from analytical labs. In response to these findings, BMPs are being developed for dental facilities and analytical labs to reduce mercury loads to the WWTP.

2.3.2.16 Washington (Region 10)

The Municipality of Metropolitan Seattle conducted studies to determine the amount of certain pollutants entering WWTPs from nonindustrial sources. The studies revealed that nonindustrial sources contribute more than 75% of some pollutants (antimony, silver, zinc, diethyl phthalate, di-n-butyl phthalate, butyl benzyl phthalate, chloroform, tetrachloroethylene, and benzene) entering WWTPs (GAO, 1991). Other Seattle treatment plant studies demonstrated that 26% of the total load of arsenic came from powdered laundry detergents, dishwashing detergents, and bleach (GAO, 1991).

CHAPTER 3.0

COMMERCIAL SOURCES OF POLLUTANTS

Some businesses, if evaluated individually, discharge insignificant amounts of pollutants. However, when considered collectively, they can discharge substantial amounts of pollutants. Such commercial sources must be distinguished from industrial sources, which are subject to Federal pretreatment regulations.

Typically, there are many businesses in a community that all conduct the same type of activity (e.g., vehicle service, food service, photoprocessing, etc.). Therefore, these businesses can be addressed more efficiently on a collective, rather than on an individual, basis. Pollution prevention and stormwater programs have targeted several of these business categories as sources of pollutants. This chapter presents general approaches used to address commercial sources and information regarding individual commercial business categories.

3.1 Approaches to Control of Commercial Sources

Strategies used to control commercial sources include permits, zero discharge certification, educational outreach, financial incentives, technical assistance, recognition programs, and certification/training programs. Each of these strategies is discussed briefly below.

3.1.1 Permits

If a business is discharging non-domestic waste to the sanitary sewer system, a wastewater pollution prevention or pretreatment program may choose to allow this discharge. These permits typically have fewer requirements than a standard pretreatment permit, which is used for industrial dischargers. It will likely require the discharger to implement certain BMPs. Permit requirements may also include inspections and sampling, but often these activities are conducted less frequently than for an industrial discharger. The permit is likely to have a low fee or no fee.

3.1.2 Zero Discharge Certification

This strategy is often used in combination with a permit program. If the business can eliminate its non-domestic discharges, then no permit is issued. Many businesses view the option of not being permitted as a strong incentive to review their business practices to see if discharges can be eliminated.

3.1.3 Educational Outreach

Outreach informs the businesses about the pollutant issues, which practices need to be changed, and what alternatives are available. Outreach also informs businesses about new programs with requirements, including permits or zero discharge status. Businesses may also be encouraged to implement BMPs through a nonregulatory approach.

An example of effective business outreach comes from the Seattle Metro program (Carveth, 1993). Seattle has determined that the best publicity for the business community comes from working through existing business formats, such as trade associations and chambers of commerce. These organizations take advantage of the business owner's mindset that "business knows best how to market to business."

Following up on this idea, Seattle has determined that trade shows or trade fair formats are superior to public workshops when applied to the commercial sector. Vendors with products or equipment relevant to pollution prevention set up booths and publicize the event by sending invitations to small business owners. These trade shows are also publicized through local businesses and trade associations. At the trade shows, informative "shop talks" are given on topics of general interest to small businesses and on topics targeting specific industries. The small business trade shows have been held for the last 5 to 6 years, with recent ones having up to 80 vendors and over 1,000 participants.

3.1.3.1 Outreach Materials

The City of Bellevue, Washington, and the San Francisco Bay Area Pollution Prevention Group (SFBAPPG) and the Bay Area Stormwater Management Agencies Association (BASMAA) produce two good examples of outreach materials for vehicle service businesses.

The City of Bellevue program, "Business Partners for Clean Water," developed a manual for automotive businesses. The manual has 5 sections. The first section introduces the Business Partners for Clean Water Program and the Storm and Surface Water Utility. The second section describes how pollutants enter the stormwater and wastewater systems and the impact of these pollutants on local waterbodies. The third section describes pollutants associated with vehicle service facilities and their specific sources and briefly describes BMPs to address these sources. The fourth section describes the BMPs in detail. The fifth section provides the business with a checklist to help identify pollution prevention opportunities at their facility. The manual makes the information necessary to implement BMPs easy to find and easy to follow.

For vehicle service facilities, the SFBAPPG in cooperation with BASMAA developed a booklet, which provides an overview of the BMPs that should be implemented to protect wastewater and stormwater leaving vehicle service facilities (SFBAPPG/BASMAA, 1995). The booklet includes a comprehensive list of BMPs divided into sections dealing with specific activities that take place at vehicle service facilities. To complement the booklet, flyers address single topics in a straightforward style. These flyers were intended to deliver the message simply and assist the service staff in conducting their jobs in an environmentally responsible manner.

3.1.4 Financial Incentives

Financial incentives are used along with other strategies. In many cases, implementation of pollution prevention strategies is cost effective for the business by reducing waste disposal costs and reducing raw materials costs. Publicizing environmentally responsible behavior through recognition programs might also be viewed as a financial incentive if promoted as free advertising and a marketing tool for businesses. Another financial incentive is the use of a 'tiered' permitting system in which different classes of permits have different costs associated with them.

The City of Richmond uses financial incentives to encourage participation in its stormwater programs (Scarpa, 1996). Businesses and apartment complexes are charged a stormwater program fee based on parcel number. Rebates are offered to offset fees based on participation in the City's stormwater program. The business must implement BMPs and educate its tenants concerning the BMPs. In addition, the business is inspected annually and runoff is sampled by the City. Rebates are determined according to how "clean" the business's runoff is. This program is particularly attractive to apartment complexes that represent a large number of parcels and, therefore, have relatively high program fees.

3.1.5 Technical Assistance

Technical assistance is offered to small businesses through "small business assistance centers." Business assistance centers help individual businesses in addition to working with groups of businesses. Centers typically attempt to address all environmental media including air, water, and hazardous waste. They provide the business with information on how to implement certain pollution prevention strategies or BMPs in a cost-effective manner and on how to comply with various environmental regulations. Very often these Centers are associated with a University. Business assistance centers providing materials and information for this project are listed in Table 3-1. Two business assistance centers are described in the following subsections.

Table 3-1. Business Assistance Centers

3.1.5.1 Montana Pollution Prevention Program

The Montana Pollution Prevention Program (MT P2) is a non-regulatory technical assistance program, established in 1992, that works with small businesses and tribes to provide information on pollution prevention (MT P2, 1996). It is located at the Montana State University Extension Service and is funded through a US EPA grant and a grant from the state of Montana. The MT P2 works with all businesses but has targeted certain business types including dry cleaners, vehicle service facilities, printers, the hospitality industry, construction, wood finishing, educational facilities, and the agricultural community. It has developed resource materials, such as fact sheets, videos, and information packets; conducted outreach including workshops and teleconferences; provided on-site technical and research assistance; and worked to create business/government partnerships.

On-site visits were conducted at 28 businesses in 1995 to help businesses implement pollution prevention. Cost effectiveness of pollution prevention practices recommended by the MT P2 was documented for 10 of these businesses (3 dry cleaners, 4 printers, 1 automotive service facility, 1 furniture refinisher, and 1 aircraft business). Pollution prevention practices were implemented at these companies for a total investment of approximately $81,000. Estimated annual cost savings for these 10 businesses totaled $145,000. For examples, practices implemented by printers included replacing isopropyl alcohol (IPA) fountain solutions with low- or no-IPA alternatives, switching to less toxic inks, and converting to a digital prepress process (eliminating the need for photographic processes).

The MT P2 also provides assistance to Native American communities. A 10-week pollution prevention educational module was developed for tribal colleges. The MT P2 hosted the first National Tribal Pollution Prevention Conference with 67 tribes from 29 states represented. They have worked with three reservations to implement an 'environmental justice through pollution prevention' model. The project involves working with representatives from the reservation to conduct a reservation environmental assessment and educational program.

3.1.5.2 Iowa Waste Reduction Center

The Iowa Waste Reduction Center (IWRC) has been in operation since 1988 and is located at the University of Northern Iowa (IWRC, 1995). It is funded through Federal, State,and private funding,including US EPA, the Small Business Administration, and air permit fees. The goal of the IWRC is to help small business owners meet environmental regulations, reduce costs, and protect the environment. IWRC helps businesses with on-site visits and waste assessments. They provide such services as the Small Business Pollution Prevention Center and Mobile Outreach for Pollution Prevention (MOPP). MOPP takes technology and expertise to the small business in a 34-foot mobile unit equipped with the latest pollution prevention equipment. Comprehensive, well-organized guidance and resource manuals have been developed for vehicle service facilities and printers. These manuals address environmental issues for air, water, and hazardous waste. Wastewater and stormwater issues are dealt with effectively. Programs are also conducted with respect to toxic air pollutant studies, air emissions assistance, and a by-product/waste search service.

3.1.6 Recognition Programs

Recognition programs reward environmentally responsible behavior. A business that meets certain requirements is awarded a certificate. The incentive for participation in such a program is that the business' exceptional environmental behavior is publicized. To be effective, the business must perceive that the program offers a competitive advantage. A list of agencies with recognition programs and certification programs (described in the next section) which provided information for this project are listed in Table 3-2. Elements of recognition programs in Palo Alto and Santa Rosa, California are described in the following subsections.

3.1.6.1 Clean Bay Business Program

Palo Alto RWQCP implemented a vehicle service regulatory program in 1992 that targets approximately 330 businesses including auto repair shops, gasoline stations, fleet maintenance facilities, commercial car washes, parts cleaning and repair facilities, and autobody repair shops (Moran, 1995; Uribe, 1995). The program focuses on eliminating discharges to the storm drain and reducing or eliminating discharges to the sanitary sewer.

Businesses are issued permits if they discharge to the sewer. Permits are not necessary for businesses that have eliminated discharges to the sewer. Palo Alto RWQCP has included requirements for vehicle service facilities in their sewer use ordinance. A handbook listing recommended BMPs and explaining how to comply with the ordinance is distributed to all affected businesses. Businesses are visited annually for the purposes of education and inspecting for compliance. In 1994, in addition to the annual inspections, discharge monitoring requirements were implemented for permitted facilities.

R0026057

Palo Alto RWQCP developed the Clean Bay Business Recognition Program as an incentive for businesses to comply with the vehicle service facility requirements. A business may be designated as a Clean Bay Business based on the results of their annual inspection. Criteria for recognition as a Clean Bay Business are completion of an inspection, compliance with the ordinance requirements, and the lack of significant violations of other environmental regulations. A list of businesses meeting the recognition criteria is circulated to other agencies, including the local fire departments and the County Health Department, to determine if any of these businesses have outstanding violations that might contribute to surface water contamination. Facilities that meet the recognition criteria and receive approval from the other agencies are then designated as Clean Bay Businesses.

Clean Bay Businesses are provided with free advertising tools, such as stickers and placards to be displayed at their facility. In addition, the facilities are recognized publicly through press releases and lists published in the local newspapers.

Of the 330 vehicle service facilities, 55 continue to discharge and are permitted. The remainder have eliminated discharges to the sewer. In 1993, 179 businesses were designated as Clean Bay Businesses in the fall of 1993. Violations of ordinance requirements relating to employee training, spill prevention, and cleanup were found at 98 businesses. Requirements regarding secondary containment for vehicle fluid removal, vehicle washing, and containing vehicle leaks were violated at 39 facilities. Sanitary sewer-related violations were identified at 9 facilities. Of the permitted facilities, 18 businesses exceeded their discharge limits for one or more metals.

3.1.6.2 City of Santa Rosa

The City of Santa Rosa (Grimsrud, 1994) developed and implemented the Compliance Incentive Program (CIP) for the auto repair and service industry targeting approximately 275 businesses. The CIP consists of four elements: technical assistance, regulatory streamlining, recognition, and consumer awareness. Technical assistance takes the form of training and materials regarding BMPs and pollution prevention. A unified inspection checklist, which streamlines the inspection process, was developed through a collaborative effort involving eight regulatory agencies. Businesses that comply with all environmental regulations are presented with a regional sticker recognizing that they are a "Sonoma Green Business." A significant public outreach effort has been initiated to educate consumers about the program and the meaning of the recognition stickers. The CIP is a voluntary program; businesses must request the inspections leading to certification as a Green Business. It is used to supplement a more traditional enforcement program that incudes no-cost permits and annual wastewater discharge inspections. Of 150 inspections conducted during the first year of the program (1994), 33 businesses were found to be in full compliance.

Consumer awareness is viewed as an important element of the CIP. A multi-media campaign to educate the public consists of press conferences, radio ads, TV public service announcements, newspaper articles, public transportation ads, announcements in city billings, public meetings, and school presentations.

Another important component of the CIP is the coordination and communication among the eight regulatory agencies responsible for environmental compliance in Sonoma County. These agencies are the Santa Rosa Industrial Waste Section, Santa Rosa Fire Services, Sonoma County Fire Services, Sonoma County Environmental Health, North Coast Regional Water Quality Control Board, Bay Area Air Quality Management District, Department of Toxic Substances Control, and Cal-EPA. Representatives from these agencies meet once a month to discuss environmental compliance issues and share information on non-complying businesses. The Industrial Waste Section (Pretreatment Program) and the Environmental Health Department have coordinated their inspections to reduce the number of inspections conducted at any one business.

3.1.7 Training and Certification Programs

Training and certification programs are similar to recognition programs in that environmentally responsible behavior is recognized. However, these programs are more formal and require businesses or individuals to demonstrate specific knowledge about BMPs. Customers are then encouraged to only hire certified businesses. Certification programs for the construction industry and for mobile cleaners are described below.

3.1.7.1 Construction Certification Programs

The Maryland Department of the Environment (MDE) implemented a certification program for construction activities in 1980 (Non-Point Source News Notes, 1995a). The program targets earth-moving contractors primarily but has also been conducted for other groups, namely private building companies, land development companies, and the National Park Service. Training is provided by MDE environmental specialists in a 3.5 hour seminar. The training centers around erosion control and the negative impacts of sedimentation. In addition, it educates participants concerning potential erosion issues, such as sediment flow to a storm drain inlet and how inlet protection is used as a control measure. Once the training is completed, each participant receives a “Green Card”. The seminars are typically offered during the winter months when the participants’ workload is light.

To ensure that erosion and sediment control is effectively implemented on construction projects, MDE requires that at least one person on every construction site possess a Green Card. More than 7,000 people have been certified through the Green Card program since its inception. In 1995 alone, 1,350 people were certified as a result of 35 seminars. Although recertification is not required, many Green Card holders do attend additional training seminars.

The Delaware Department of Natural Resources (DNR) implemented a Contractor Certification Program in 1991 that is very similar to the Maryland Program (Shaver, 1993). The DNR regulations require that "responsible personnel involved in the construction project will have a certificate of attendance at an...approved training course." Half-day courses educate contractors about erosion and sediment control. In addition, DNR conducts a more intensive training course (4-day sessions) to certify construction reviewers/inspectors. These certified individuals review and oversee larger construction projects (involving more than 20 hectares) or projects experiencing significant sediment and stormwater problems.

3.1.7.2 Mobile Cleaners Certification Programs

Mobile cleaners (surface cleaners, janitorial services, auto detailers, carpet cleaners, window cleaners) are a significant source of discharges of material, wastes, and polluted waters to storm drain systems in the San Francisco Bay Area. The environmental impact, regulatory liability, and ubiquitous nature of discharges from mobile cleaners make them a seemingly ideal candidate for regulation. Yet, regulators and regulated agencies have found it difficult to address these discharges for several reasons. Consequently, the Bay Area Stormwater Management Agencies Association (BASMAA) has initiated a pilot program to help in breaking through the barriers to regulation and to establish a model for dealing with discharges of this type (Brosseau, 1996).

To develop the surface cleaners’ pilot program, meetings were held with surface cleaners and their customers in which the participants expressed opinions on what would constitute a successful program. The primary opinion was that the customers need educating, as well as the surface cleaners, to establish the value of hiring a responsible surface cleaner. As a result, a program consisting of education and recognition was produced. Surface cleaners that implement the prescribed pollution prevention practices are "recognized" and promoted to potential customers. Recognition is given to surface cleaners who attend an Outreach/Recognition Workshop and take a test based on the workshop contents. Recognition is conferred by BASMAA and the San Francisco Bay Regional Water Quality Control Board through issuance of a "recognition certificate." BASMAA maintains a database of the Recognized Surface Cleaners and provides the list to businesses and agencies that hire surface cleaners. Workshops held in July and November of 1996 resulted in over 200 surface cleaners receiving the certificate.

3.2 Pollution Prevention Control Strategies for Specific Commercial Sources

How the above control strategies are applied to individual commercial sources is discussed in the following section, which presents information on commercial sources for which programs have been developed. For each commercial source, the following elements are discussed:

- Associated pollutants;
- Recommended BMPs; and
- Program elements used to address the business category.

The commercial sources discussed fall into three categories:

- Sources of wastewater and stormwater pollutants;
- Sources of stormwater pollutants; and
- Sources of wastewater pollutants.

Commercial sources discussed in this chapter and pollutants associated with those sources based on information compiled for this report are listed in Table 3-3.

3.3 Sources of Wastewater and Stormwater Pollutants

Businesses with activities that are associated with both wastewater and stormwater pollution are discussed in this section.

3.3.1 Vehicle Service Facilities

Vehicle service facilities engage in many activities that have been linked to both stormwater and wastewater pollution. Pollutants associated with vehicle service activities are metals (particularly copper, zinc, chromium, nickel, and lead), oil and grease, solvents, and PAHs. Activities of concern include vehicle washing, parts and engine cleaning, fluid changing, vehicle fueling, autobody repair and painting, and radiator repair.

Table 3-3. Pollutants Associated with Commercial Sources

Commercial Source	Wastewater or Stormwater	Associated Pollutants
Vehicle service facilities	Both	Metals, oil & grease, nutrients,
Food service businesses	Both	Oil & grease
Painting contractors	Both	Solvents, metals
Construction and new development	Stormwater	Sediment, pesticides, solvents, metals
Boatyards/ marinas	Stormwater	Solvents, engine fluids, sewage, tributyltin
Existing development	Stormwater	Metals, pesticides, nutrients, vehicle fluids
Mobile cleaners	Stormwater	Solvents, metals, oil & grease, detergents
Landscape maintenance	Stormwater	Nutrients, pesticides
Brake pads	Stormwater	Copper, lead, zinc
Laboratories and medical facilities	Wastewater	Mercury, silver, selenium, copper, formaldehyde, phenolics, cyanide, solvents, xylenes, radioactive wastes
Printers	Wastewater	Metals, solvents
Dentists	Wastewater	Mercury, silver
Photoprocessors	Wastewater	Silver, selenium
Jewelry manufacturing	Wastewater	Silver, cyanide, copper
Cooling water systems	Wastewater	Copper, tributyltin, zinc, lead
Machine shops	Wastewater	Metals, oil & grease, solvents
Dry cleaners	Wastewater	Perchloroethylene
Ceramics	Wastewater	Metals, solids
Wood finishers	Wastewater	Solvents, metals

Not only are vehicle service facilities a potential source of several pollutants for both wastewater and stormwater, but most communities have many businesses that fall into this category. For example, Novato Sanitary District with a service area population of 53,000 identified close to 100 businesses that fall into this category (Selfridge, 1996). The Palo Alto RWQCP identified approximately 300 vehicle service facilities in their service area (population 200,000) (Moran, 1995). Even if each business has a relatively small discharge volume, the cumulative effect of all the vehicle service facilities in a community can be significant.

3.3.1.1 Other Vehicle-Related Activities

In addition to businesses that service vehicles (e.g., repair shops, body shops, car washes), other vehicle-related businesses have unique characteristics with respect to stormwater discharges. Two such business categories are auto parts stores and auto salvage yards. In both cases, water pollution from these facilities are primarily stormwater issues. Specific aspects of programs for auto parts stores and automotive salvage yards are discussed below.

Auto parts stores sell products to "do-it-yourselfers" who maintain their own vehicles. Improper use and disposal of these products can result in stormwater pollution. Auto parts stores can help reduce pollution by educating employees and customers concerning proper handling of vehicle parts and fluids (PARWQCP, 1994c). Customers and employees should be encouraged to recycle used fluids. In addition, special attention should be paid to maintenance of parking lots for these stores. Vehicle maintenance in store parking lots should be discouraged. In addition, parking lots should be inspected for drips and puddles and should be swept rather than hosed down for cleaning.

The impact of automotive salvage yards on stormwater quality has also been evaluated (Center for Watershed Protection, 1995). Salvage yards collect wrecked cars, strip them of their parts, and recycle the metal materials, as well as some plastics, glass, and fluids. Industry surveys indicate that over two-thirds of the salvage yards in the U.S. store vehicles outside and that few facilities (less than 20%) drain the vehicles before they are stored. Therefore, these facilities are likely sources of stormwater pollution.

To evaluate salvage yards as a source of stormwater pollution, stormwater runoff samples from over forty storms were analyzed for metals, oil and grease, and phenols over a 10-year period at an automotive salvage yard in Los Angeles (Center for Watershed Protection, 1995). It was determined, based on these data and data from other salvage yards in California, that salvage yards contain typically higher levels of oil and grease, BOD, metals, and some priority pollutants. Copper, lead, and phenols were present in the Los Angeles salvage yard's runoff at levels that cause acute toxicity to aquatic life (e.g., fathead minnows). Certain BMPs were implemented to improve runoff water quality. The primary, non-structural BMP was to drain the fluids from all vehicles prior to stripping or other processing. In addition, an oil-water separator was installed to treat wastewater from the dismantling area of the yard. Additional BMPs were to build a roof over the dismantling area and to build a berm around the dismantling area. Implementation of the these BMPs decreased runoff toxicity from 100% to 14%.

3.3.1.2 Best Management Practices

BMPs have been developed for activities conducted at vehicle service facilities to protect both wastewater and stormwater. The following list of BMPs summarizes the recommended practices used by several programs in the San Francisco Bay Area (SFBAPPG/BASMAA, 1995). They are divided into general practices applicable to most shops and BMPs targeting specific activities.

♦ BMPs for General Practices

Work associated with pollutants should be conducted in properly prepared areas. Whenever possible, work that might generate pollutants should be conducted indoors or under cover to prevent unintentional discharges to the storm drain. The work surface should be nonporous (i.e., concrete floors rather than dirt or asphalt). Absorbant mats should be provided for ourdoor work.

Prevent leaks and spills. Use drip pans to catch leaking fluids or spills. Use secondary containment when storing hazardous materials or hazardous wastes.

Liquid wastes and wastewater should be disposed of properly. Do not discharge toxic pollutants, rinse water or wastewater containing toxic pollutants to the storm drain. Toxic pollutants may only be discharged to the sanitary sewer after necessary treatment processes are installed (e.g., oil-water separators) and approval from the treatment plant is obtained. Non-domestic wastewater and rinsewater should be reused or recycled if possible.

Clean up spills properly. When spills occur, dry cleanup methods should be used. Spill cleanup should be accomplished by vacuuming, sweeping, using rags or dry absorbents first. Once dry cleanup is complete, floors and paved areas may be mopped. Avoid hosing down floors and paved areas.

Dispose of wastes properly. Recycle wastes, such as solvents, paints, oil filters, antifreeze, motor oil, batteries, and lubricants, using separate, well-labeled containers in convenient locations. Label sinks and other drains with reminders to prevent unintentional dumping of toxic pollutants and wastewater.

- BMPs for Specific Operations

Vehicle fluid removal. Conduct operations, such as changing oil, radiator fluids, or other vehicle fluids, in "bermed" or contained areas or use drip pans. Transfer fluids using pumps whenever possible to prevent discharges due to spills or leaks from entering the storm drain or sanitary sewer.

Engine, Parts, and Radiator Cleaning. Use self-contained sinks and tanks, allowing parts to drain and dry over tanks. Rinse parts over hot tanks when possible and use static or countercurrent rinsing to reduce rinse water discharges.

Vehicle Exterior Washing. Recycle wash water by running it through an oil/water separator and reusing it in washing operations. Avoid the use of acid-based or spray-on wheel cleaners. For occasional car washing, take cars to a commercial car wash.

Body Repair and Painting. Carefully calculate paint needs to reduce the amount of waste paint and thinner. Do not use water to control overspray or dust in the paint booth and clean spray guns in a self-contained cleaner. Wastewater emanating from painting operations should not be discharged to the sewer or storm drain.

3.3.1.3 Program Elements

Vehicle service facility programs are based on encouraging businesses to implement the BMPs described above through various control strategies. Strategies often used are permitting, zero discharge certification, recognition programs, and educational outreach. A voluntary program and a permit-based program are described in this section.

City and County of San Francisco (CCSF, 1996). CCSF's Water Pollution Prevention Program has developed a voluntary program for vehicle service facilities. CCSF identified approximately 1,000 vehicle service facilities, including gas stations with repair services, general repair, automotive repair, and glass installation shops. Car washes, although not considered significant industrial users (SIUs), are not included, because they are permitted under CCSF's Pretreatment Program.

Currently, CCSF's vehicle service program is completely non-regulatory. Visits were conducted with the purpose of educating the businesses with respect to pollution prevention opportunities at their facilities. A pollution prevention checklist was used to evaluate the businesses, and the results were shared with the business owner. A binder containing information on recommended practices was provided to each business. These binders contain a letter explaining the vehicle service program, a "Green Wrench Guide" containing BMPs (pollution prevention tips), a regulatory agency matrix, vendors of supplies and services for vehicle service facilities, and a checklist describing how to use and store hazardous materials at vehicle service facilities.

City of Benicia (Gregory, 1995). The vehicle service program in Benicia, California, is a typical example of a permit-based program conducted by a small community. The City of Benicia has 36 businesses that are inspected through their vehicle service program. This includes businesses conducting engine repair, autobody repair, and automotive repair and service. Car washes are permitted in a separate program as minor industrial users (Tier 3 permit) as part of Benicia's pretreatment program. Businesses in the vehicle service program are divided into three categories: businesses having zero discharge, businesses having a steam cleaning operation, and businesses discharging washdown water. Business that are zero discharge do not require permits. Businesses with steam cleaning are required to have an oil-water separator and a Tier 3 permit. Businesses discharging washdown water are not permitted but are required to redirect this discharge to the sanitary sewer eliminating washdown water discharge to the storm drain. Of the 36 businesses, 31 were zero dischargers, 2 had steam cleaning operations, and 3 businesses were discharging washdown water to the storm drain.

Many communities have targeted vehicle service facilities through pollution prevention or stormwater programs. The project team reviewed program information and/or outreach materials targeting vehicle service facilities from over 40 different agencies as listed in Table 3-4.

3.3.2 Restaurants and Food Service Businesses

Restaurants and food service businesses (grocery stores, delis, bakeries, etc.) have been targeted by both wastewater and stormwater programs with respect to oil and grease concerns. Other pollutants related to stormwater issues are food wastes and cleaning solutions containing bleaches or detergents. Activities that generate these pollutants include grease handling and disposal, equipment cleaning, spill cleanup, and pavement cleaning, and activities in dumpster and loading dock areas.

3.3.2.1 Best Management Practices

Oil and grease from restaurants are typically handled by installing a grease trap or interceptor. Restaurant BMPs often focus on proper use and maintenance of these items. BMPs are also developed for pavement cleaning, equipment cleaning, spill control, waste disposal, litter control and landscape maintenance. Typical BMPs for restaurants are summarized below and are based on those recommended by the Alameda Countywide Clean Water Program (Alameda County, 1994) and the Ventura Countywide Stormwater Program (VCSQMP, no date).

Oil and Grease Handling. Undiluted cooking oil, grease and meat fats should be recycled by a licensed waste hauler. Large volumes of grease or oily liquids (e.g., salad dressing, sauces) should not be poured down a sink, floor drain, or storm drain. A grease trap or interceptor should be installed and maintained to handle grease residues from cleaning activities.

Interceptor Maintenance. Grease traps and interceptors must be cleaned and maintained regularly to be effective. Licensed companies can provide this service. Traps should not be flushed with hot water or treated with detergents or enzymes. These practices discharge grease to the sanitary sewer.

Pavement Cleaning. Parking lots and paved areas should be swept. If cleaning with detergent is necessary, washwater should be collected and discharged to the sanitary sewer not the storm drain.

Equipment Cleaning. Washwater from equipment cleaning, either indoors or outdoors, should be collected and discharged to the sanitary sewer. This includes washwater from cleaning items, such as dumpsters, floor mats, and exhaust filters.

Spill Control. Prevent spills from entering storm drains or sanitary sewers. Use dry cleanup methods, such as sweeping, rags, or cat litter. If mopping is required, discharge mop water to the sanitary sewer.

Waste Disposal. Dumpster and outdoor waste containers should be covered to prevent stormwater from entering the containers. Dumpsters should be inspected for leaks and repaired or replaced by the leasing company. Paints, pesticides, and cleaners should be disposed of as hazardous wastes.

Litter Control. An adequate number of trash containers should be provided around the facility. Litter should be picked up daily in outside areas particularly near storm drain inlets.

Landscaping. The use of pesticides and fertilizers should be minimized and not at all in wet weather. Yard wastes should be composted or placed in a dumpster. Yard trimmings and waste should not be left in the gutter.

3.3.2.2 Program Elements

Many communities require the BMPs listed in the previous section and will often have ordinances requiring food service establishments to have grease removal devices, such as interceptors. The ordinance is typically enforced by the local wastewater authority through its pretreatment program or pollution prevention program. In addition to materials describing BMPs, outreach will often include information on obtaining and installing interceptors and information on local grease recyclers (LWA, 1996e). Program information and materials collected by the project team for food service businesses are listed in Table 3-5.

3.3.3 Painting Contractors

Latex paints, oil-based paints, and paint additives can cause stormwater or wastewater pollution if not handled and disposed of properly. Paint additives or old paint might contain mercury, lead, or tributyltin. Working with oil-based paints involves the use of thinners and other solvents that should not enter the sanitary sewer or storm drain. Paint removal and equipment cleanup are also activities that can contribute pollutants to wastewater or stormwater. Much of the program information and materials developed for painters is associated with construction activities and discussed in that section Some additional information is discussed in this section.

3.3.3.1 Best Management Practices

The following BMPs are used in outreach to painting contractors by the City and County of San Francisco City (CCSF, no date).

Paint Removal. Burlap sand bags or other barriers should be place around storm drain inlets when power washing is used to remove old paint. Residue from chemical stripping, as well as paint chips and dust containing mercury, lead, or tributyltin, should be collected and disposed of as hazardous waste.

Paint Cleanup. Rollers and brushes need only be cleaned when a job is complete rather than every day. During a job, equipment can be stored in plastic wrap in a cool place so that brushes and rollers remain pliable. When cleaning up, excess paint can be removed by scraping paint into the garbage. Latex paint should be washed off in a sink connected to the sanitary sewer. Oil based paints should be cleaned with thinner or turpentine away from sinks, floor drains, or storm drains. Paint thinner can be re-used by allowing the sediment to settle and decanting the clean thinner into another jar.

Materials selection. Latex paints should be used whenever possible. Organic additives should be used for mildew and algae control, not tributyltin or mercury-containing additives.

3.3.3.2 Program Elements

Some literature has been collected for paint formulators. Program information and materials collected by the project team for painting activities are listed in Table 3-6.

3.4 Sources of Stormwater Pollutants

Business activities that are conducted primarily outdoors and are typically associated with stormwater pollution are discussed in this section.

3.4.1 Construction

Construction activities are primarily outdoor activities and therefore are a concern with respect to stormwater pollution. Pollutants found in stormwater runoff from construction activities include sediment, paints, solvents, concrete, metals, oil, fuel, fertilizers, and pesticides. Contaminated sediment from construction sites can interfere with reproduction and feeding mechanisms of aquatic organisms and be toxic to certain organisms. High levels of nutrients (i.e., phosphorus, nitrogen) causes excessive growth of algae, which can impair aesthetics, water quality, and recreational use. Other concerns are bacterial contamination, salt contamination and elevated water temperatures (NIPC, 1992).

An emphasis has been placed on developing erosion and sediment controls for construction sites. In addition, construction activities that have been identified as sources of stormwater pollution are:

- Painting, solvent and adhesive application;
- Roadwork and paving;
- Repair and remodeling;
- Landscaping; heavy equipment operation;
- Earth moving activities; and
- Fresh concrete and mortar application.

3.4.1.1 Best Management Practices

BMPs for construction activities are divided into (1) erosion prevention and sediment control and (2) general site maintenance. Typical recommended practices are based on BMPs recommended by BASMAA and the Northeastern Illinois Planning Commission (NIPC, 1992).

- Erosion Prevention and Sediment Control (NIPC, 1992)

  Minimize the area disturbed and the time of disturbance. This is accomplished through effective site planning and design. The smallest area of land should be exposed for the shortest period of time practical during construction. Mass grading (i.e., topsoil removal) should be performed only when construction activities are imminent and should not be performed on areas that will not be constructed during the current season. In addition, development should follow the natural contours of the land whenever possible to create the least potential for erosion. Natural vegetation, such as woodlands, should be preserved whenever possible. This is particularly important for areas immediately adjacent to natural waterbodies and wetlands.

  Stabilize disturbed soils as soon as possible. To minimize erosion, soils should be stabilized within 7 days following the end of active disturbance (grading, construction, etc.). Erosion controls should be implemented and maintained during the entire construction project on all areas not undergoing active disturbance. This includes areas with stockpiled soil and landscape materials. Stabilization is accomplished by protecting exposed soil from the impact of rainfall and from water running off the surface of the land. It is best achieved by re-establishing vegetation through seeding or sodding. Temporary measures also include using mulch or erosion blankets.

Trap and filter eroded sediments before they leave the site. The objective of sediment control is to prevent eroded soil particles from leaving the construction site. The most effective sediment controls reduce runoff velocity and trap runoff allowing sediment to settle out. Eroded sediments are trapped by capturing runoff in a sediment basin and providing sufficient detention time for settling of sediment particles. Eroded sediments can also be filtered by forcing runoff waters to drain slowly through silt fences, straw bale barriers, or vegetated filter strips. Areas that require special attention are storm sewer inlets, culverts, and entrance roads. Storm sewer inlets and culverts should be protected with traps or filters. Roads and parking areas should be stabilized with gravel or the equivalent. In addition, a temporary stone pad with a filter fabric underliner should be installed near the site exit. This device removes dirt and mud and prevents construction vehicle tires from tracking soil onto nearby streets.

Control runoff onto and through construction sites. It is important that runoff from adjacent properties be controlled to prevent water from running across erodible areas. Offsite flow is typically addressed by diverting flow around or through disturbed areas using a stabilized channel and a stabilized outlet. In addition, provisions should be made for increased runoff caused by construction activities.

Routinely inspect construction sites and maintain control measures. Inspections will assess the adequacy of installed erosion and sediment control measures and verify that sediment is not causing onsite or offsite impacts. Maintenance is necessary to assure the continued effectiveness of erosion and sediment control measures.

- **General Site Maintenance (BASMAA, 1995)**

Prevent leaks and spills. Poorly maintained, leaking vehicles and heavy equipment are common sources of stormwater pollution and soil contamination. Site planning, preventive maintenance, and good materials handling can eliminate most spills and leaks. Specific areas well away from storm drains or creeks should be designated for parking and routine maintenance of vehicles and equipment. Maintenance, repair and washing should be conducted offsite if possible or in designated areas onsite. Vehicles and equipment should be routinely inspected for leaks. Drip pans or drop cloths should be used to catch leaks and spills during repair and maintenance activities. Fluids should be collected and recycled when possible.

Clean up spills immediately. Use dry cleanup methods, such as sweeping, absorbent materials or rags, for spilled materials. Spills on dirt areas should be dug up and disposed of properly. Spills should not be washed away or buried. Significant spills should be reported to the appropriate response agency immediately.

Store materials under cover. Wet and dry building materials should be stored under cover and/or surrounded by berms to prevent contact with rainfall and runoff. Containers of paints, chemicals, solvents, and other hazardous materials should be stored with secondary containment and under cover.

Cover and maintain dumpsters. Open dumpsters should be covered with a tarp or plastic sheeting. Dumpsters should be returned to the leasing company for leak repairs and cleaning. In addition to dumpsters, trash cans should be placed around the site to reduce litter on exposed surfaces.

Collect and properly dispose of paint removal wastes. Paint removal wastes include chemical paint stripping residues, paint chips and dust, sand blasting material, and wash water. Dust and paint chips should be swept up or collected in plastic drop cloths. When stripping or cleaning building exteriors with high pressure water, cover or berm storm drain inlets. Wash water should be collected and discharged to the sanitary sewer (if allowed by the local POTW) or onto a dirt area.

Clean up paints, solvents, adhesives, and cleaning solutions properly. Empty, dry paint cans, dry paint, used brushes, dropcloths and rags can be disposed of as garbage. Washwater from cleaning latex painting materials (e.g., brushes, rollers) should be disposed of to the sanitary sewer. Leftover oil-based paints, thinners and solvents can be filtered and reused or recycled. Unwanted paint, thinners, and solvents must be disposed of as hazardous waste.

Keep fresh concrete and cement mortars out of gutters, storm drains, and creeks. Avoid mixing excess amounts of fresh concrete or cement mortar. Wash out concrete transit mixers in designated areas. Washout water should be discharged to settling ponds or onto dirt. It should not be allowed to enter the street, storm drain or nearby waterbodies.

Service and maintain portable toilets. Leaking portable toilets are a potential health and environmental hazard. They should be inspected and maintained routinely and repaired promptly.

Dispose of cleared vegetation properly. Cleared vegetation, tree trimmings, and other plant materials should be composted or taken to a landfill. It should not be disposed of in a creek or drainage facility or left in a roadway where it could clog storm drain inlets.

Use pesticides and fertilizers properly. Do not over-apply pesticides and fertilizers. Follow the manufacturer's instructions for mixing, applying, and disposing of these materials.

Train employees and subcontractors regarding stormwater requirements and individual responsibilities.

3.4.1.2 Program Elements

Federal stormwater regulations require dischargers of stormwater from construction sites to apply for a permit or seek coverage under a promulgated general permit. Several municipalities have developed programs and materials to educate the construction industry regarding regulatory requirements and BMPs that will meet those requirements. Program elements include guidance manuals, brochures describing BMPs, recognition programs, videos, and workshops (Table 3-7).

3.4.2 New Development

New housing developments, roads, and commercial buildings have the potential to generate stormwater pollution through construction activities, post-construction activity, and through the increase in impervious surfaces. Effective planning for new development can address pollutants from parking lots, roads, compacted soils, and other impervious surfaces. Construction activities were discussed in the previous section. Post-construction activities of concern are those activities conducted outdoors on the developed site vehicle service facilities, cleanup for restaurants and food service businesses, painting, and landscape maintenance.

Practices discussed in other sections of this report relating to spill control and covering work areas and trash receptacles reduce the generation of pollutants from these sources. Pollutants generated from impervious surfaces and planning methods to reduce the generation of these pollutants are discussed in this section.

Impervious surfaces include rooftops and transport systems (e.g., roads, parking lots, and sidewalks). It has been estimated that transport surfaces constitute as much as 63% to 70% of the total impervious surface in urban and suburban areas (City of Olympia, 1996). In addition, the impervious area associated with medium density, single family homes can range from 25% to 60% depending on the layout of streets and parking areas.

Stormwater pollutants associated with impervious surfaces come from sources, including atmospheric deposition and fluids leaked from vehicles that are washed off the surfaces during storms. Impervious surfaces also elevate water temperatures and decrease biodiversity in streams. (Center for Watershed Protection, 1994).

3.4.2.1 Best Management Practices

Practices to reduce the impact of impervious surfaces include planning and design of new development to reduce imperviousness and practices to maintain impervious surfaces. BMPs based on those developed by the City of Olympia (City of Olympia, 1996) and Orange County (Orange County, 1993) are presented in the following subsections.

- **Planning and Design Recommendations**

  Integrate impervious surface reduction into local policies, goals and regulations, especially with respect to street and parking regulations. Reduce the size of parking areas. Encourage cooperative parking (e.g., park and rides, shared parking) through local policies and provide model legal agreements. Require evaluation of cooperative parking and transportation demand management before approving additional parking. Develop parking standards based on average parking needs instead of peak projections. Build multi-story parking or under the building parking.

  Reduce street coverage. Reduce residential street widths. Retrofit existing cul-de-sacs with vegetated islands designed to hold stormwater.

  Narrow sidewalk widths. Narrow low-use sidewalks to 4 feet in width. Build sidewalks on one side of the street only. Slope sidewalks to drain to vegetated swales or gravel strips.

  Design and locate buildings more effectively. Encourage cluster development that minimizes impervious surfaces. Build and use taller buildings, and modify policies to allow taller buildings.

- **Maintenance of impervious surfaces**

  Maintenance of common areas. Implement trash management and litter control procedures, including litter patrol, emptying trash receptacles, and noting and reporting trash disposal violations by homeowners or businesses. Inspect privately owned catch basins and, if necessary, clean catch basins prior to the storm season (mid-October in California). Streets and parking lots should be swept prior to the storm season.

  Commercial vehicle washing should be done with water only. Vehicle exteriors should be washed with tap water without soap or detergents. Wash water containing soaps and detergents should not enter the stormdrain. Solvents and degreasers can be used for spot cleaning but must be wiped off before the vehicle is rinsed.

Educate property owners, tenants and occupants. Outreach materials concerning general good housekeeping practices and proper use of chemicals should be distributed to homeowners and businesses and other occupants of a development. Outreach materials will differ depending on the type of activity or business (e.g., residential, office commercial, retail commercial, vehicle-related or industrial).

3.4.2.2 Program Elements

Programs for new development have recently been developed by some communities including the City of Olympia, WA and the state of Virginia. The City of Olympia has recently completed an Impervious Surface Reduction Study (City of Olympia, 1996). The goal of the study was to identify and gain community support for future impervious surface reduction techniques that result in increased stormwater treatment and groundwater recharge in the Thurston County region, without causing appreciable increases in development costs.

Based on the City of Olympia's study results, it appears that a 20% reduction in impervious surfaces throughout the study area (North Thurston County Urban Growth Management Area) is achievable. Several recommendations were made as a result of the study with respect to general policy development; vehicle-oriented pavements; construction practices and landscaped areas; design and placement of buildings; and community involvement and education. In particular, several recommendations focused on strategies to reduce the impact of parking areas. Fact sheets were developed regarding alternative, more pervious pavements, and methods of reducing parking. In addition, the City has developed and implemented a parking ordinance aimed at encouraging parking space reduction.

Virginia's new development program is an outgrowth of the Virginia Chesapeake Bay Preservation Act. The Act established a cooperative local government program to protect water quality in the Chesapeake Bay through improved land use management. It requires that development in designated areas meet certain criteria, including minimization of land disturbance, minimization of impervious cover, site plan review for all development, and control of stormwater runoff quality. Under the Act, runoff from redevelopment sites in designated areas must contain 10% fewer pollutants than existed before the redevelopment. Virginia's Stormwater Management Regulations were developed as a result of the Act and require the treatment of the first 1/2 inch of runoff from developments with more than one acre of land disturbance (Bell, 1996).

Program information and materials collected by the project team for new development are listed in Table 3-8.

3.4.3 Boatyards/Marinas

Pollutants from boatyards and marinas include paint, wood preservatives, solvents, degreasers, engine fluids, bilge wastes, and boat sewage (SCS Engineers, 1989). The pollutants are generated from hydroblasting (pressure washing) or stripping to remove paint, painting, engine maintenance, bilge pumping, sewage disposal, and onsite spills. Paint removal wastes constitute the major waste problem at boatyards. Hydroblasting yields runoff containing paint chips that can possibly reach adjacent waterways. Chemical stripping produces a toxic sludge that must be disposed of as hazardous waste. Larger boatyards sometimes have sheet metal shops and metal finishing shops to perform specialty repairs.

As mentioned above, paint related wastes are a major concern for boatyards. Numerous monitoring studies have identified TBT-containing antifouling paints, used to control nuisance organisms on the hulls of boats, as a primary source of TBT contamination in harbors, marinas, and other areas of commercial and recreational watercraft activities. Due to the high concentrations of TBT detected and the resulting impacts to aquatic organisms, State and Federal legislation has restricted the use of TBT-containing antifouling paints to control further degradation of coastal habitats (LWA, 1996b).

In mid-1987, several States, including California, Florida, Maryland, Maine, New Jersey, New York, Oregon, Virginia, and Washington, recognized TBT as a problem and implemented restrictions on the use of TBT-containing paints. Most State legislation was modeled after provisions established by the State of Virginia, which included a ban of TBT paints from non-aluminum-hulled boats shorter than 25 m long and a prescribed release rate of TBT no greater than 5 $\mu g/cm^2/day$ (Weis, 1989) State action eventually led to restrictions of TBT antifouling paints at the national level. In 1988, the "Organotin Antifouling Paint Control Act" established restrictions on painting vessels shorter than 25 m (excluding aluminum hulls) and a release rate of TBT no greater than 4 $\mu g/cm^2/day$ (Huggett, 1992). In addition, the Act prohibits the sale, delivery, or purchase of certain organotin antifouling paints and additives and requires continued monitoring and environmental impact assessment in representative coastal areas (33 U.S.C. § 2404 and 2406).

3.4.3.1 Best Management Practices

Most of the BMPs for boatyards and marinas were developed through hazardous waste programs designed to minimize the amount of waste generated and educate workers at these facilities about proper storage, handling, and disposal practices. However, the City of Phoenix and other communities have incorporated BMPs for boat builders and repairers into their stormwater programs due to the close proximity of these facilities to open waterways. The activities to be controlled are addressed by BMPs that have been developed for painters, vehicle service facilities, and machine shops. A summary of the approach taken for boatyards and marinas is presented in the following subsections and is based on work completed by King, Pierce, Snohomish, and Thurston Counties (Small Business Center for Education, 1990) and the City of Phoenix (City of Phoenix, 1996).

Pressure Washing and Surface Preparation. Prevent runoff from hydroblasting and any abrasives, dust, or paint chips from reaching waterways or storm drains. For boatyards without onsite settling tanks, lay tarps around the vessels and sweep up any remaining paint chips after the tarps are removed.

Painting. Train employees on proper spraying techniques. Mix paints in designated areas away from waterways.

Engine Maintenance. Use good housekeeping techniques, clean up spills thoroughly, and properly dispose of any wastes that are generated.

Materials Handling and Disposal. Store materials in protected, secure locations away from drain openings. Provide secondary containment when required. Label containers with correct information regarding the type and characteristics of its content. Do not commingle wastes.

Boat Sewage. Discharge sanitary wastes to a dockside pump-out station that is discharged to a sanitary sewer system or to a commercial waste disposal company. Most marinas provide this service. Another alternative is to arrange for pump-out service provided by commercial 'tank-boats.'

Bilge Water. Bilge water sometimes contains oils and solvents that should not be discharged to the sanitary sewer. Prior to discharge to the sanitary sewer, oil should be decanted. Decanted oil may be disposed at used-oil collection centers. Residual surface oil can be absorbed by an oil-absorbing blanket. Bilge water may then be discharged to the sanitary sewer.

3.4.3.2 Program Elements

Many community programs require implementation of the above BMPs through enforcement of hazardous waste regulations and through pollution prevention programs. To prevent the dumping of boat sewage, there is a Federal law and many State laws that make it illegal to dump untreated sewage into any U.S. water. In Florida, a law was passed to make it easier for boaters to properly dispose of human waste (Florida Clean Vessel Act Grant Program, 1994). Grant funds are being made available to provide pump-out and waste dump stations for every 100 boats. US EPA is also advocating specific strategies to be implemented at existing or new/expanding marinas. These strategies involve new designs for areas that generate pollutants, fish waste management, maintenance of sewage facilities, solid waste management, and public education.

Program information and materials collected by the project team for Boatyards and Marinas are listed in Table 3-9.

3.4.4 Existing Development

Existing development encompasses commercial and residential properties already constructed which might have to incorporate BMPs as retrofits or operational changes. This approach is the opposite of the one used for new developments which may be able to incorporate BMPs into the overall design of the project. Pollutant sources at existing developments include metals in cooling water and boiler discharges, pesticides, and fertilizers from landscape maintenance, vehicle fluids contained in runoff from parking lots and driveways, cleaners and paints used to maintain building exteriors, and chlorinated water from pool and spa maintenance. Activities of concern might be conducted inside or outside the establishment related to the specific type of business undertaken at the site. These activities are addressed in other sections of this report according to the type of business conducted.

3.4.4.1 Best Management Practices

Preventing pollution from existing development involves conserving water, properly maintaining heating and cooling systems, draining pools to the sanitary sewer, disposing of wastes in an appropriate manner, and minimizing runoff and the application of pesticides and fertilizers when maintaining landscape. These BMPs are described in detail in other more applicable sections of this report.

3.4.4.2 Program Elements

Some communities have prescribed BMPs for existing development by producing outreach materials for specific businesses, such as hotels/motels, office buildings, and apartment buildings (PARWQCP, 1995; City of San Jose, 1992a,b). This is a method of reaching those individuals who might not receive general public outreach materials at their residence or might not realize that implementation of BMPs is required at the workplace, as well as at home. Program information and materials collected for existing developments by the project team are listed in Table 3-10.

3.4.5 Mobile Cleaners

The category of mobile cleaners includes all types of cleaning contractors—carpet cleaners, auto detailers, surface cleaners, etc.— who travel to job sites. Usually, wash water is disposed of onsite and often to the storm drain system. These discharges have been found in Fort Worth, Texas, and the San Francisco Bay Area to be a significant source of pollutants to the storm drains. Pollutants include soaps, solvents, lead paint chips, restaurant grease, and vehicle fluids.

3.4.5.1 Best Management Practices

BMPs developed for mobile cleaners are based on the type of surface being cleaned and cleaning method used. Once these criteria are determined, the proper disposal method is specified. For example, if a building exterior is washed without soap and there is no loose paint, disposal to the storm drain may be allowed. In the San Francisco Bay Area, BMPs have been developed for surface cleaners, truck/auto washers, and food-related cleaning activities. A summary of those BMPs are presented below and based on work completed by the Bay Area Stormwater Management Agencies Association (BASMAA, 1996) and the Cleaning Equipment Trade Association (CETA, 1995).

Truck/Auto Washers. Most wash water generated from truck and auto washing must be contained and pumped to the sanitary sewer. Infrequent auto washing runoff may be left to evaporate on the pavement or discharged to landscaped areas. When removing dust from cars with water only, the runoff may be discharged to the storm drain.

Surface Cleaning. If cleaning sidewalks and plazas, unpainted buildings, or painted buildings with no loose paint is conducted without soap, discharge to the storm drain is allowed. However, filtering of the runoff to remove particulates may be required. If soap is used and/or paint is being removed during the cleaning process, the wash water must be contained and discharged to the sanitary sewer.

Food-Related Cleaning. No wash water associated with the cleaning of food-related equipment may be discharged to the storm drains. Runoff from cleaning dumpster areas, floor mats, exhaust filters, grease covered equipment, and lunch wagons/food carts must be discharged to the sanitary sewer system. If no soap is used for cleaning grocery carts, the runoff may go to the storm drains after filtering to remove particles.

3.4.5.2 Program Elements

Many communities have produced outreach brochures to inform mobile cleaning businesses of appropriate methods for wash water disposal. Program information and materials collected for mobile cleaners by the project team are listed in Table 3-11. The City of Fort Worth, Texas, passed a Cosmetic Cleaning Ordinance (Connor, 1996). Discharges to the storm drains are banned unless absolutely no cleaning substances have been added, the storm drain inlet is screened, and no oil sheen is present. Each cosmetic cleaner must have a permit and display the vehicle license registration numbers associated with that permit. The permit holder must ensure that all of its employees are knowledgeable of the discharge prohibitions and are using prescribed BMPs when engaging in cosmetic cleaning activities.

BASMAA initiated a pilot project to control discharges from surface cleaners (Brosseau, 1996). To develop the program, meetings were held with surface cleaners and their customers in which the participants were given a chance to express opinions on what would constitute a successful program. The primary opinion was that the customers need educating, as well as the surface cleaners, to ensure that the value of hiring a responsible surface cleaner is understood. As a result, a program consisting of education and recognition was produced. Surface cleaners who implement the prescribed BMPs are "recognized" by BASMAA and the San Francisco Regional Water Quality Control Board and promoted to potential customers. Recognition is granted to surface cleaners who attend an outreach/recognition workshop and take a self-evaluation exam on the workshop contents. Results of the surface cleaner program are being used as a prototype for developing materials and approaches for the remaining types of mobile cleaners.

3.4.6 Landscape Maintenance

Businesses that provide services to plant newly vegetated areas and maintain existing lawns, parks, and public areas can be sources of pollutants, including nutrients and pesticides. Source control strategies for landscape maintenance businesses are similar to those developed for home lawn and garden care and are discussed in Chapter 4.0. Other BMPs are presented in this chapter, under Construction and New Development.

With regard to pesticide use by landscape maintenance businesses, surveys have been conducted to obtain more information on pesticide handling. In Ohio, pesticide applicators were surveyed regarding pesticide application and disposal practices (Ozkan, 1992). Survey results were based on 1,380 responses received from applicators in 18 counties. Over two-thirds of the respondents reported that they calibrate their equipment at least once per year. Over 90% always rinse pesticide containers after emptying them. However, only 71% follow safe rinsing procedures (i.e., triple rinsing, pressure rinsing). Survey respondents indicated the use of several improper disposal methods.

The major portion of outreach material developed for landscape maintenance is directed at the homeowner and the general public. Much of the business outreach targets landscaping in conjunction with construction activities. Program information and materials collected targeting landscape maintenance by the project team are listed in Table 3-12.

3.4.7 Brake Pads

Disc brake pads contain varying amounts of metals including copper, lead, and zinc. Copper content in brake pads can range from less than 1% to as much as 20%. As the brake pad wears, metal dust is generated onto roadways. This dust is washed to storm drains with stormwater runoff. A study conducted by the Santa Clara Valley Nonpoint Source Pollution Control Program estimated that copper from brake pad wear may account for as much as 35% of the copper that enters the San Francisco Bay. While the initial brake pads studies have been conducted in the San Francisco Bay Area, addressing this source at a national level could help address copper pollution problems for water bodies in other parts of the country including the Chesapeake Bay, the New York-New Jersey Harbor, and the San Diego Bay.

An effort to address this source has been initiated through The Brakepad Partnership, formed under the auspices of Common Ground for the Environment (sponsored by Stanford University and Sustainable Conservation). Bay Area organizations provided seed funding. The goal of the Partnership is to identify and implement a voluntary business solution to reduce the levels of copper entering water bodies from brake pads. This solution will be reached through the cooperation of US EPA, California EPA, local governments, community members, automobile manufacturers, brake pad manufacturers, and the makers of friction materials used in brake pads.

Work with brake pads is in its initial stages, and little other information is available at this time.

3.5 Sources of Wastewater Pollutants

Business activities that are typically conducted indoors and associated with wastewater pollution are discussed in this section.

3.5.1 Laboratories and Medical Facilities

Medical facilities have been evaluated as sources of mercury and silver (Rourke, 1988). Hospitals have also been identified as sources of formaldehyde, phenolic disinfectants, selenium, zinc, lead, and cadmium (PARWQCP, Pollution Prevention for Hospitals and Medical Facilities). Specific sources within hospitals include instrumentation and equipment (e.g., temperature and blood pressure measuring devices) as sources of mercury, x-ray and photographic equipment as sources of silver and selenium, cold sterilization and disinfectant solutions as sources of formaldehyde and phenolics.

In addition to specific medical activities, hospitals have laboratory and facilities operations that may also generate certain wastewater pollutants. Laboratories can also be sources of cyanide, copper, solvents, xylenes, and low-level radioactive wastes. Facilities operations include plumbing, laundry, recirculating hot water systems, water softening and purification, and cleaning and maintenance. These activities can be sources of metals.

3.5.1.1 Pollution Prevention for Mercury and Silver

Based on the amount of information available, most communities are concerned with hospitals as sources of silver and mercury. The major source of silver is from x-ray and photographic equipment. BMPs and source control strategies for these areas are discussed in the section of this report entitled Photoprocessing Operations. Another source of silver is silver nitrate solutions used to treat burns. Solutions with high concentrations of silver should be collected and disposed of as hazardous waste.

The primary sources of mercury in medical facilities are equipment, such as measurement devices, lamps and electrical equipment. Proper handling and disposal of mercury-containing equipment should prevent mercury from entering the sanitary sewer. In most cases, alternative products that do not contain mercury are available (Terrene Institute). Mercury thermometers and manometers can be replaced by equipment with electronic sensors. Cantor tubes can often be replaced by Anderson tubes which contain no mercury. Electrical equipment containing mercury can be replaced by solid state devices and fiber optic equipment. Batteries can be replaced by lithium, zinc air or alkaline batteries. There are no effective substitutes for high energy fluorescent lights, but technology is reducing the volume of mercury required in such lights.

Mercury is also present in some laboratory chemicals and pharmaceutical preparations. The amount of mercury in antiseptics, diuretics, and skin preparations is low making these compounds unlikely to be significant sources. For other mercury-containing chemicals however, there are alternatives available.

3.5.1.2 Other Best Management Practices

The BMPs for sources of pollutants (other than silver and mercury) listed below are a compilation of BMPs recommended by Palo Alto RWQCP (PARWQCP, no date, Pollution Prevention for Hospitals and Medical Facilities), City and County of San Francisco (CCSF, 1995a), and the University of Tennessee (University of Tennessee, 1995).

Cold Sterilization. Formaldehyde and glutaraldehyde solutions must be treated and detoxified prior to discharge to the sewer. In certain cases, these solutions may be replaced with peracetic acid.

Laboratories. Wet chemistry methods may be replaced with automated chemical analyzers. Cyanide-free solutions may be available for cell sorting and counting analyzers. Alternatives, such as naphtha isoparaffinic hydrocarbons, may be used in place of xylenes. If xylenes must be used, spent solutions should be recycled and not discharged to the sanitary sewer.

Pharmacy. Neither medicines containing significant levels of metals nor expired medicines should be discharged to the sewer. Chemicals should be clearly labeled.

Utilities and Maintenance. Use automatic injection for laundry and boiler chemicals. Replace single pass cooling systems with recirculating systems. Avoid use of cooling water additives containing tributyltin or copper. Use latex paints instead of oil-based paints. Replace solvents with detergent-based cleaning agents. Replace phenolic disinfectants with quaternary amine disinfectants.

3.5.1.3 Program Elements

Program materials for hospitals have been developed in communities concerned with silver and/or mercury. A list of programs from which program information and materials have been collected by the project team are listed in Table 3-13.

3.5.2 Printers

The printing industry includes establishments that engage in printing by one or more of the five common printing processes: lithography, gravure, flexography, letterpress, and screen printing (US EPA, 1990a). A typical printing process includes the following steps: image processing, platemaking, printing, and finishing. Characteristics of image processing and finishing are similar for all the printing processes. Platemaking and printing characteristics depend on the type of printing process as summarized in Table 3-14. Each step and associated wastewater discharges are discussed herein.

Table 3-14. Printing Process Characteristics

Printing Process	Products	Plate Material	Printing Inks	Wastewater Discharges
Lithography	Books, brochures, flyers, periodicals	Aluminum or aluminum/ copper alloy	Petroleum or soy based	Isopropyl alcohol (from fountain solutions), cleaning solutions, trace amounts of ink, organic
Gravure	Magazines, catalogs	Copper plated steel	Solvent based	Metals (from platemaking)
Flexography	Packaging, labels	Acrylate polymer	Water based	Organic plate materials, inks
Letterpress	Books, stationery, business cards	Zinc, magnesium or copper	Solvent based	Metals (from platemaking), trace amounts of solvent
Screen Printing	T-shirts, posters, wallpapers	Organic emulsions	Solvent based	Trace amounts of solvent

Most programs for commercial printers focus on lithographic printers as they tend to predominate in most communities. Flexographic printers, while less common, are likely to have larger volume waste streams with higher metal content than lithographers. Flexography is an aqueous process using waterborne inks and should be considered as a potential source of metals in wastewater.

3.5.2.1 Best Management Practices

Pollution prevention programs based on BMPs have been developed for printers in several other areas. BMPs for printers tend to focus on reducing air pollutant emissions (primarily from volatile organic compounds [VOCs]), the generation of VOC-containing wastes and silver-bearing wastewater. Approaches to reducing VOCs often entail replacing solvents with aqueous materials that may impact the quality of wastewater.

Many BMP documents are available for printers. The BMPs listed below are typical and based on BMPs recommended by the City and County of San Francisco (CCSF, no date, Clean Image...) and Union Sanitary District (USD, 1993).

Photographic wastes. Silver is the primary pollutant of concern for wastewater. Typically, BMPs suggest (or agencies require) that silver-containing wastes are treated or collected by a certified waste hauling service.

Prepress (proofmaking and platemaking). The wastewater generated by these processes might contain significant levels of metals. Where this issue is addressed, documents typically note that metal-containing wastewater must be collected for disposal by a contract service rather than being discharged to the sewer.

Inks. Most documents indicate that petroleum-based inks should be replaced by soy-based inks whenever possible to reduce VOC emissions. Water-based inks are also recommended for this reason. Often, procedures are recommended to minimize waste generation from maintenance of ink delivery systems. These procedures include cleaning ink fountains only when changing colors, recovering and recycling used ink, and preventing inks from drying up or forming skins. Most documents highlight the air pollution issues associated with ink solvents rather than wastewater issues related to ink metal content.

Fountain solutions. Generally, it is recommended that fountain solutions containing little or no isopropanol (IPA) should be used to replace fountain solutions with standard levels of IPA to reduce air pollutant emissions. In addition, some fountain solutions have been found to be high in chromium (Greenwood, 1996). Chromium-free solutions are available and are recommended.

Press cleanup. Dry cleanup methods, such as using rags that are picked up for laundering and reuse, are usually recommended in preference to wet methods, which can be sources of air pollutant emissions (i.e., solvents) or wastewater pollutant discharges. Agencies usually recommend that liquid waste generated during cleanup be collected and disposed of by a contract waste disposal service.

3.5.2.2 Program Elements

Programs for printers are based on the BMPs listed above. Many agencies permit printers or encourage them to become zero dischargers. Printing industry trade organizations and suppliers may be helpful in developing the programs for printers. The printing industry and its suppliers are already aware that their discharges may have environmental impacts. Printing Industries of Northern California (PINC) has worked with several agencies in the San Francisco Bay Area to conduct workshops and inform local printers of regulatory requirements.

3M Corporation, for example, has developed materials and processes that are aqueous rather than solvent-borne for the printing industry. In addition, they have evaluated their materials and processes with respect to metals loadings in wastewater and make fact sheets covering this information available on request (LWA, 1996a).

Many of the programs and outreach materials for printers focus on reducing VOC emissions. However, CCSF, USD, EBMUD, and the IWRC are some examples of agencies that have addressed wastewater issues, as well. Program information and materials collected for printers by the project team are listed in Table 3-15.

3.5.3 Dentists

Dental activities have been associated with the discharge of mercury and silver to the sanitary sewer. Dental amalgam contains mercury and routinely enters the sanitary sewer as a result of dental work. Chair-side traps collect a major portion of the amalgam evaluated from a patient's mouth during restoration or placement of a filling. X-ray activities at dental offices generate silver that may be discharged to the sanitary sewer. Programs to control silver discharges are the same as those discussed in the photoprocessors section and are discussed there.

The City and County of San Francisco and Western Lake Superior Sanitary District have conducted monitoring studies evaluating mercury discharges from dentists. Based on monitoring results for effluent from nine San Francisco dental buildings in 1992, it was estimated that dentists contributed approximately 12% of the mercury loading in San Francisco's treatment plant influent (CCSF, 1993a). Western Lake Superior Sanitary District monitored discharges from a major dental building in Duluth, MN. Mercury loadings from dentists in this building were estimated to be 0.3 g per dentist per day (Tuominem, 1996).

3.5.3.1 Best Management Practices

BMPs for silver-containing wastes are the same as those recommended under the section entitled Photoprocessors in this report. BMPs for mercury-containing wastes revolve around recycling amalgam traps and treating wastewater containing amalgam particles. BMPs for handling of dental amalgam are listed below and based on practices recommended by Western Lake Superior Sanitary District and King County (WLSSD, 1996). WLSSD and King County produced these BMPs in 1996 after working with the dental community to revise versions of dental facility BMPS produced earlier (WLSSD, 1996; Foster, 1996).

Recycling amalgam traps. Waste amalgam should not be disposed of in the garbage or down a drain. Traps are changed after flushing the line overnight to disinfect the trap. Gloves, gasses, and masks should be used when handling the trap. The trap is stored in a plastic covered container labeled 'Amalgam for Recycling." Amalgam can be mailed to a recycler if proper shipping guidelines are followed. Local waste handlers are also equipped to provide the service of collecting the amalgam and shipping to a recycler.

Amalgam wastewater. Wastewater might still contain high levels of mercury even after passing through the chairside trap. Treatment systems are available to reduce mercury levels further. Treatment of the wastewater is not yet required in any of the municipalities working with dentists. Implementing wastewater treatment is being explored with equipment manufacturers and dental associations.

3.5.3.2 Program Elements

CCSF, King County Hazardous Waste Management Program, and Western Lake Superior Sanitary District (WLSSD) have all worked with dentists to address mercury discharges from amalgam waste. Programs emphasizing education and voluntary compliance have been found to be more effective with dentists than to implement a regulatory program. Programs have been developed through cooperative efforts with dental associations, equipment suppliers, and individual dentists. Guidance materials and BMPs are in the process of being revised in all three communities based on recent coordination efforts with dentists.

WLSSD initiated a Mercury Zero Discharge Project in 1995 with the goal of using pollution prevention strategies to control sources and determine which strategies are most effective (Tuominen, 1996). A targeted initiative for dental offices is part of the program, including outreach to dentists and development of mercury recycling/disposal procedures. WLSSD developed BMPs for dental offices by working with the local dental society. They have also worked with local dentists to evaluate and promote methods for collecting and removing amalgam from the wastewater stream. An important element of this program is the cooperative effort between the dentists and the sanitary district. Wastewater discharges from monitored dental facilities showed a 69% reduction in mercury loadings when 1996 levels (end of first year of Zero Discharge Project) were compared to 1992 levels.

The City of Albuquerque has developed BMPs for dentists and conducted a survey of dentists to evaluate mercury and silver disposal practices (Hogrefe, 1996). As part of this survey, it was estimated that only 13% of the dentists recycle the amalgam collected in traps. Albuquerque is conducting outreach to encourage dentists to recycle amalgam. In the Washington, D.C., area, the local dental societies have entered into a voluntary agreement with the Department of Public Works to educate its members regarding proper handling of amalgam wastes (DCDPW, 1995).

Other communities with concerns regarding mercury in wastewater have also developed programs and materials targeting dental facilities. Program information and materials collected for dental facilities by the project team are listed in Table 3-16.

3.5.4 Photoprocessors

Photoprocessing businesses conduct photographic or x-ray processes. Included are printers, medical and dental facilities, photofinishers, veterinary facilities, and laboratories. Silver is the primary pollutant of concern associated with photoprocessing and is typically of concern with respect to wastewater pollution. It is found in spent fixer solutions used in the developing process and wash water. Selenium is found in photographic toners and might present concerns in some communities with respect to wastewater discharges.

3.5.4.1 Best Management Practices

BMPs revolve around not discharging silver-containing or selenium-containing wastes to the sewer. The BMPs listed below are based on BMPs recommended by Sacramento Regional County Sanitation District (SRCSD, 1994), City of Albuquerque, and Palo Alto RWQCP (PARWQCP, 1995).

Silver-containing wastes. Spent fixer solutions cannot be discharged to the sewer. It must either be treated onsite with a silver recovery unit or collected by certified silver recycler. Most businesses choose to have the solutions hauled off-site. More dilute solutions like wash water are often allowed to be discharged to the sewer. Larger facilities with larger wastewater volumes would be expected to treat their washwater.

Selenium-containing wastes. Toners containing selenium should not be discharged to the sanitary sewer.

3.5.4.2 Program Elements

Programs developed for photoprocessors prohibit discharge of silver containing solutions to the sanitary sewer. Requirements of having silver wastes hauled off-site or treated prior to discharge are often enforced through ordinances and permit programs. Outreach to educate photoprocessors concerning these requirements is conducted through brochures and workshops.

The Silver Coalition has developed a Code of Management Practice for silver discharges that provides guidance on treatment alternatives, sample permit language and BMPs (Silver Coalition, 1995). Their recommendations have been implemented in several municipalities around the country, the City of Albuquerque among them.

As part of its silver program, the City of Albuquerque has developed a recognition program (Hogrefe, 1996). The program is called the 5 ppm Silver Program and was developed jointly with the New Mexico Silver Users Association. Businesses are presented with a certificate that recognizes accomplishment with respect to reducing silver bearing liquid wastes and meeting wastewater discharge limits of 5 ppm for silver.

Program information and materials collected by the project team for photoprocessors are listed in Table 3-17.

3.5.5 Jewelry Manufacturing

Jewelry manufacturing has been identified as a source of cyanide, silver, and other metals in wastewater. Some communities have addressed this as a significant source of these pollutants. The City of Albuquerque, New Mexico conducted a survey in 1995 that identified 163 businesses involved in jewelry manufacture in their service area (Hogrefe, 1996). Of these businesses, approximately 90% were considered small or medium businesses based on the number of employees and volume of metals processed. The City is working with jewelers to reduce silver discharges and address other pollutants associated with jewelers.

Activities conducted during jewelry manufacture that generate metals or cyanide-containing wastes are divided into the categories of casting, stripping, and finishing. Casting activities include wax mold production, dewaxing, devestment, and casting. Stripping activities include acid pickling and cyanide bombing to remove metal oxides and casting residues. Finishing activities include deburring, polishing, and electroplating. The specific processes most likely to generate wastewater pollutants are devestment, stripping and deburring (Southside Water Reclamation Plant, 1994).

3.5.5.1 Best Management Practices

The following BMPs are used by the City of Albuquerque for jewelry manufacturers (Southside Water Reclamation Plant, 1994):

Casting and Devestment Operations. Casting involves melting metal and pouring it into a mold to make the metal piece. While no liquid wastes are generated by this process, the use of deoxidizing casting alloys might reduce the need for stripping processes later. Devestment removes the casted piece from the mold and can be done by a wet process or a dry process. The wet process generates wet waste that is nonhazardous but its solids content could plug sewer lines. In addition, this wet waste might not be accepted by municipal waste haulers. The dry process is recommended because the dry wastes may be disposed of as solid waste.

Stripping Operations. Pickling uses strongly acidic solutions to remove oxidized metals. Waste pickling solutions contain high levels of metals. It is recommended that metals be recovered from the solution and the acid solution reused. Pickling solution should not be discharged to the sewer. Cyanide bombing is another stripping process that not only generates cyanide-containing wastewater but is also dangerous because of the potential worker exposure to cyanide fumes. It is recommended that other stripping processes be used. Alternatives are pickling or a two-step process involving oxide removal with trisodium phosphate followed by ultrasonic cleaning.

Deburring and Finishing. Deburring and finishing operations generate wastewater streams containing particulate metals. The recommended practice is to install settling tanks to recover the metals and allow reuse of the water.

3.5.5.2 Program Elements

Based on the information collected by the project team, fewer programs target jewelry manufacture than some other commercial sources evaluated. Fewer communities have many businesses that fit this category, although some larger cities might have significant numbers of jewelry manufacturers, and certain areas of the country are known for distinctive jewelry (New Mexico, for example). The programs evaluated focus on encouraging jewelers to recover metals wherever possible and to avoid using cyanide bombing. Program elements include BMPs, guidance manuals, recognition programs, and financial incentives. In the City of Albuquerque, jewelry manufacturers are included in the 5 ppm Silver Program described in the photoprocessors section of this report. Program information and materials collected by the project team for jewelry manufacturers are listed in Table 3-18.

There is a distinct financial incentive for jewelers to recover metals from wastewater streams as this not only reduces waste disposal costs but the recovered metals can be sold. For example, a large jewelry manufacturer (125 employees) in Massachusetts invested approximately $95,000 in a metals recovery process (Massachusetts OTA, 1990). In the first year of operation, the system recovered 263 troy ounces of gold and 2,144 pounds of copper. Revenues from the sale of the gold and copper were $107,200 and $879, respectively. Traditional waste treatment processes would have recovered less gold (~$40,000) and required payment for copper sludge at a cost of $1,350.

3.5.6 Cooling Water Systems

Zinc, TBT, and copper are the primary pollutants associated with cooling water system releases. The sources of copper include heat exchangers, condensers, and piping. Wood slats are sometimes impregnated with copper to preserve the wood, and copper is an ingredient in additives used to control algae growth (PARWQCP, 1996; Montgomery Watson, 1995). Zinc originates from galvanized steel structures and is sometimes added in the form of zinc orthophosphate to control corrosion. Palo Alto RWQCP has identified facilities utilizing tributyltin for algae control and the City of Los Angeles is concerned with the use of hexavalent chromium as a corrosion control additive (PARWQCP, 1996a; City of Los Angeles, no date). In analysis of water released from 14 cooling towers in San Francisco, copper and zinc were detected in all samples while cadmium, chromium, lead, mercury, and nickel were detected in some samples (Montgomery Watson, 1995). These pollutants end up in the waste stream after periodic blowdown from cooling tower systems. Blowdown prevents the buildup of dissolved substances in the recirculated cooling water which results in decreased heat transfer efficiency. The wastewater is typically discharged to the sanitary sewer system, however there are still some systems connected to storm drains.

Buildings and industries with cooling water systems were surveyed as part of a San Francisco study (Montgomery Watson, 1995). Of the 133 cooling towers surveyed, 42% were associated with office buildings, 11% were associated with hotels/motels, 26% were associated with unknown uses, and the remaining 21 % were affiliated with apartment buildings, hospital/medical facilities, municipal buildings, universities, industry, and commercial facilities.

3.5.6.1 Best Management Practices

The common approach to prevent discharge of pollutants from cooling water systems is to prevent corrosion and recommend acceptable types of treatment additives. Typical BMPs for cooling water systems are summarized below and are based on those recommended by the Palo Alto RWQCP.

Maintenance. Regular cleaning with brushes, pressurized water, or steam can reduce the need for chemical additives. After the physical cleaning, the system should be treated with a prefilming agent to prevent corrosion. Avoid using any additives that contain copper, chromium, tributyltin, and zinc, and only add the chemicals while the system is off-line to avoid discharge of untested waters to the sewer system. When required, replace parts with components that do not contain copper or zinc.

Monitoring. Regularly test the cooling water to determine the concentrations of copper, iron, zinc, carbon dioxide; chorine, chlorobromine, or ozone (if added); pH; conductivity; and water velocity in the piping. The concentrations might indicate operational problems, as well as noncompliance with discharge standards. Measure corrosion with corrosion coupons, corrosion rate meters, or other monitoring devices.

Operation. Maximize the "cycles of concentration" to reduce water use and minimize chemical additive use. Install and maintain a good automated control system to prevent overfeeding or underfeeding of chemicals. Filtration of the blowdown might improve the quality of recirculated water and thus decrease corrosion in the system. Treatment with metal absorbing devices might be warranted before discharge to the sanitary sewer.

3.5.6.2 Program Elements

BMPs to control the quality of blowdown water have been developed by the Palo Alto RWQCP. Some of the other programs have made operational recommendations for cooling water systems, but these have been primarily geared towards reducing water usage. Palo Alto RWQCP arranged public meetings to receive input from cooling tower operators and treatment chemical suppliers to prepare BMPs and ordinance requirements. Within the ordinance, implementation of several BMPs was required, and a threshold level of 0.25 mg/L copper set for cooling water discharges. Use of treatment additives containing copper, chromium, and tributyltin were prohibited in the Palo Alto RWQCP's service area. In December, 1995, use and sale of tributyltin was banned in nine Bay Area counties by the Despartment of Pesticide Regulations (PARWQCP, 1996). Program information and materials collected for cooling water systems by the project team are listed in Table 3-19.

3.5.7 Machine Shops

For purposes of program review, the category, "machine shops," was designated to describe all businesses that work with fabricated metal products. These businesses produce parts or process materials through contracts with other companies or they might be part of a larger manufacturing facility, performing work only for that company. Pollutants at machine shops include oils, metals, solvents, and metal coatings generated through machining, surface treatment and plating operations, metal cleaning and stripping operations, and paint application (US EPA, 1990a). Pollutants enter the waste stream when spent process solutions, filter sludges, rinse waters, and used oil are disposed.

Palo Alto RWQCP	Booklet, BMPs, fact sheet	CA	9
City of Los Angeles	Fact sheet	CA	9
City and County of San Francisco	Survey and report	CA	9

The Palo Alto RWQCP determined that the two major sources of pollutant discharge from machine shops are wastewater from parts tumbling and deburring and mop water from shop cleanup (PARWQCP, 1995). Machine shops inspected in San Francisco were also found to have limited discharges to the sanitary sewer. The operators were aware of the hazardous nature of their materials and have been implementing the required BMPs (CCSF, 1996).

3.5.7.1 Best Management Practices

BMPs for machine shops involve good housekeeping, proper storage and handling of materials, waste minimization, and proper disposal practices. The basic principles of pollution prevention at machine shops are summarized based on BMPs developed by the Palo Alto RWQCP (PARWQCP, 1995) and City of Phoenix (City of Phoenix, 1996). However, since a more intricate knowledge of the operation is required before making recommendations in process control, publications, such as the pollution prevention guide produced by US EPA (1990a), are suggested for adequate background information.

Housekeeping. Install secondary containment around machinery and use absorbents to clean up any spills that occur. Use dry cleanup whenever possible to minimize the volume of wash water generated.

Waste Minimization. Reuse, reclaim, or recycle cleaning fluids or rinse waters whenever possible.

Storage and Handling. Store materials indoors or under cover, place materials on pallets or off the ground, check frequently for leaks or corrosive activity, and properly label all containers. Secondary containment might be required for storage areas. Store and handle hazardous wastes in special hazardous waste containers or in drums with secondary containment.

Disposal. Test wastewater before discharge to the sanitary sewer to ensure compliance with local requirements. Pretreatment might help achieve the acceptable concentrations. Dispose through a legally licensed service all wastes generated by the operation that fit the legal definition of hazardous waste.

3.5.7.2 Program Elements

Many communities have issued BMPs for machine shops. Compliance with the BMPs is enforced through the local wastewater authority since disposal of wastewater generated is usually to the sanitary sewer system. BMPs determined to be critical have been added to sewer use ordinances in some areas. Unless materials are stored or handled outside, there are usually no risks to the storm drain system. Program information and materials collected for machine shops by the project team are listed in Table 3-20.

3.5.8 Dry Cleaners

Dry cleaning businesses are located in most cities. However, the actual dry cleaning might not take place at the business location. Businesses conducting dry cleaning on site are typically subject to hazardous waste and air program requirements in addition to regulation by a wastewater authority. Dry cleaning activities are primarily associated with perchloroethylene discharges to the sanitary sewer (Harader, 1994). Perchloroethylene is the solvent used in dry cleaning processes that cleans the clothes. Most of this solvent is recovered, and impurities, including water, soils, and body oils, are removed so that the perchloroethylene can be re-used. The water separator that removes impurities from the perchloroethylene is one source of concern to wastewater. Perchloroethylene's physical properties allow it to penetrate very small cracks giving it the potential to "leak" from sewers. It also passes through soil quickly, which can contaminate groundwater.

Many dry cleaners also have laundry facilities. Laundry graywater is a source of metals in wastewater. Pollution prevention strategies pertaining to laundry are discussed in Chapter 4.0. Dry cleaning activities are discussed in this section.

One recently-introduced alternative to dry cleaning is a computer-controlled wet cleaning process. Water temperature, heat, and agitation are carefully controlled to prevent damaging clothes. UCLA's Pollution Prevention Education and Research Center has been evaluating one shop using this process since early 1996 (San Jose Mercury News, 1996).

3.5.8.1 Best Management Practices

BMPs for dry cleaners revolve around preventing perchlorethylene from entering the sanitary sewer. Three waste streams have been identified as significant sources of perchlorethylene to wastewater: water-separator discharge, spills to floor drains, disposal of still bottoms. BMPs addressing these sources are listed below and are based on those used by the Sacramento Regional County Sanitation District (SRCSD, 1994).

Separator Water and Still Bottoms. Discharge of separator water and still bottoms to the sanitary sewer is prohibited. Instead, these wastes are collected in separate containers and disposed as hazardous waste by a certified waste hauler.

Spill Containment and Response. Dry cleaners must provide spill containment for machines containing solvents. The containment area should be impermeable, capable of holding 110% of the largest possible spill, should prevent the spill from reaching the sanitary sewer, storm drains, or soil. Spills should be cleaned up with rags that can then be run through dry cleaning equipment to recover the solvent.

Equipment. Closed-loop dry cleaning machines are available that produce a fraction of the waste that "vented" machines do. Closed-loop machines may generate less than one gallon of wastewater per month compared to 100 gallons per month for "vented" machines. Other equipment than can help minimize wastes are refrigerated condensers and cooling towers.

Operating Practices. Recommendations include not adding excess water or damp clothes to dry cleaning machine, tracking water usage to detect possible leaks in cooling equipment, and maintaining and steam stripping equipment regularly.

3.5.8.2 Program Elements

Programs for dry cleaners often include permits. Outreach is conducted describing BMPs and regulatory requirements through brochures and workshops. Program information and materials collected for drycleaners by the project team are listed in Table 3-21.

3.5.9 Ceramics

Glazes and clays used in pottery studios can be sources of wastewater pollution. Colored glazes typically contain metals, such as chromium, nickel, cobalt, copper, manganese, and iron (PARWQCP, 1995). Clays, while not associated with aquatic toxicity, can clog sewer lines if discharged in large amounts. Depending on the number of commercial ceramic studios in a community, this might not be a large source of wastewater pollution. However, communities with serious metal water quality problems might want to evaluate this source.

3.5.9.1 Best Management Practices

The Palo Alto RWQCP has developed the following recommendations for ceramic studios (PARWQCP, 1995):

Glazes. Glazes should never enter the sewer. If possible use a separate working area for glazes and for clays. Store glazes in covered containers away from sinks. Use secured shelves with lips or doors to help contain spills should they occur. Clean up glazing materials with a two-bucket sequential rinse rather than rinsing in the sink. When the initial rinse bucket contains too many solids, place it where the water will evaporate. Mix glaze wastes and rinse water with clay, fire and dispose of as trash.

Clays. Working water containing clay should be collected in a bucket and the clay should be allowed to settle out. Equipment should also be rinsed in this bucket before rinsing in the sink. Mop floors and pour mop water into collection bucket. Once the clay has settled out, water from the collection bucket may be poured in the sink. The clay may be reused or mixed with waste glazes, fired and disposed of as trash.

Housekeeping. Seal floor drains to contain spills. Install small settling buckets in each utility sink and put sediment traps in drain pipes. Minimize water use at each stage of the pottery process.

3.5.9.2 Program Elements

Because ceramic studios are not likely to be major sources of pollutants, programs are voluntary and consist primarily of educational outreach. Program information and materials collected for ceramics studios by the project team are listed in Table 3-22.

3.5.10 Wood Finishers

Wood finishing and furniture making activities are associated with the generation of wastes containing solvents, volatile organic compounds (VOCs), and some metals. In general, releases to air are the focus of pollution prevention programs for wood finishers. However, some processes that might present concerns in wastewater are the use of waterborne coatings (a suggested alternative to solvent-borne coatings), caustic stripping, and the use of methylene chloride (EBMUD, 1996).

3.5.10.1 Best Management Practices

The following BMPs for wood finishers are based on those recommended by EBMUD.

Stripping. Cleanup residues from methylene chloride stripping using a dry process, such as rags, before rinsing with water. Rinsewater generated from caustic stripping should be screened to remove paint skins prior to discharging to the sanitary sewer.

Housekeeping. Prevent spills and accidental discharges from entering the sanitary sewer by installing physical barriers or sealing floor drains. Soiled rags should be disposed of as hazardous waste or cleaned by an industrial laundry.

3.5.10.2 Program Elements

The pollution prevention program for wood finishers developed by EBMUD included permits and outreach through brochures and workshops to explain program requirements. Program information and materials collected for wood finishers by the project team are listed in Table 3-23.

CHAPTER 4.0

RESIDENTIAL SOURCES OF POLLUTANTS

Residential sources have been associated with wastewater and stormwater pollution, and in some cases, contribute more pollutants than industrial or commercial sources. This chapter presents approaches used to address residential sources of pollution and information regarding specific sources of wastewater and stormwater pollution.

4.1 Approaches to Residential Sources

Residential source control strategies can be divided into three categories, which are described in the sections that follow:

- Public education;
- Technology-based strategies; and
- Legislative strategies.

4.1.1 Public Education

Because a regulatory and enforcement approach is often not applicable in the residential sector, source reduction can best be accomplished through educating the public and attempting to change habits by raising awareness. Consequently, public education is the most commonly applied source control strategy for the residential sector. For the public education approach to be effective, the communicated information must be clear, concise, and targeted at the appropriate audiences. Methods of disseminating information include brochures, point-of-purchase displays, media advertising, school programs, event exhibits, and outreach to businesses serving the public. Public education is discussed further in Chapter 5.0.

4.1.2 Technology-Based Strategies

Technology-based strategies typically involve a process modification or the use of certain equipment to achieve discharge reductions. For example, changing a supply water treatment process by adding corrosion inhibitors might reduce metals loadings due to household plumbing corrosion, while installing household graywater systems would address loadings contributed by laundry graywater. The effectiveness of these strategies depends on how well the technology targets a particular problem, as well as on the level of cooperation and participation. For example, from a technical standpoint, graywater systems would effectively eliminate the discharge of graywater to the sanitary sewer. However, implementation of this strategy would require major, widespread changes in the practices of builders, developers, landscapers, and homeowners. Implementation of corrosion control, on the other hand, only requires the participation of a relatively small group (water purveyors) and, therefore, implementation would be more straightforward.

4.1.3 Legislative Strategies

Legislative strategies involve implementing new local ordinances or changing regional or State laws. These approaches include product bans through local ordinances, product bans through regional or statewide legislation, or changes in plumbing codes. The effectiveness of this type of strategy depends largely on the ability to enforce the ordinance or law and the ease or difficulty with which such a restriction can be circumvented.

One example of an effective legislative strategy has been the mercury ban in latex paints implemented nationwide in 1990. Prior to the ban, mercury was added to paint to improve mildew resistance, and mercury levels in paints were typically on the order of 125 parts per million (ppm) (CCSF, 1994). While the ban has only applied to indoor latex paints, a recent analysis of both exterior and interior paints shows the average mercury level to be 0.26 ppm and the maximum level to be 2 9 ppm. In addition, after-market additives that can be used for mildew resistance are also unlikely to contain mercury, even though the Federal mercury restriction does not apply to these products. Essentially, the mercury ban created an anticipation among manufacturers that mercury was an ingredient of concern, and was, therefore, likely to be banned in related products at some future time if the producers themselves did not act voluntarily.

4.2 Specific Residential Sources of Pollutants

Residential sources of wastewater pollution include corrosion, indoor pest control, pet care, household cleaners, and laundry graywater. Residential sources of stormwater pollution include landscape maintenance, vehicle maintenance, pool and spa discharges, and painting activities. Associated pollutants, studies, and strategies addressing each of these sources are discussed in the following subsections. Information for landscape maintenance, indoor pest control, and pet care is presented under one heading, Pesticide Use and Landscape Maintenance. Pollutants typically associated with each of these activities based on information collected for this report are listed in Table 4-1.

4.2.1 Household Plumbing Corrosion

CCCSD estimated that household plumbing corrosion accounted for about 9% of the CCCSD residential copper loadings and 4% of the CCCSD residential lead loadings. Other communities have estimated corrosion contributions to copper loadings to be much higher, ranging from 40% to 75% of total copper influent loadings (PARWQCP, 1996; NSD, 1996; Save The Bay, 1996). Factors influencing household plumbing corrosion contributions to metals loadings include water supply corrosivities, housing age distributions, and corrosion control practices.

Table 4-1. Pollutants Associated with Residential Activities

Residential Source	Concern to Wastewater or Stormwater	Associated Pollutants
Corrosion	Wastewater	Cu, Pb, Zn
Laundry graywater	Wastewater	heavy metals
Indoor pest control	Wastewater	pesticides
Pet care	Wastewater, Stormwater	pesticides (flea dips), animal wastes
Landscape maintenance	Stormwater	pesticides, nutrients
Vehicle maintenance	Stormwater	oil, heavy metals
Painting activities	Stormwater	heavy metals, solvent
Household cleaners	Wastewater	solvents, ammonia, bleaches
Pools and spas	Stormwater, Wastewater	chlorine, copper
Root control products	Wastewater	copper

Household plumbing corrosion is typically reduced using technology based strategies directed at the water supply and plumbing materials. Examples in Palo Alto and Novato, California are described.

A study conducted by Palo Alto RWQCP (PARWQCP, 1996) investigated copper piping corrosion and potential corrosion reduction measures. The study included the following elements: estimation of corrosion rates in copper piping; evaluation of corrosion in heating systems, cooling systems, and hot water recirculating systems; and the effect of addition of chemical corrosion inhibitors to the distribution system. Based on the results of this study, Palo Alto RWQCP is planning to implement the following measures: consider implementing the corrosion inhibitor strategy recommended by the study (i.e., add orthophosphate to the water supply at 1 mg/L), develop plumbing BMPs in cooperation with the Cities of Sunnyvale and San Jose, and develop educational materials to encourage the use of non-copper plumbing materials.

Novato Sanitary District (NSD) worked with its water purveyor, Sonoma County Water Agency (SCWA), to reduce copper loadings from corrosion by instituting pH control. NSD was experiencing difficulty meeting its NPDES effluent copper limits. Source identification studies indicated that approximately 75% of the copper loadings in NSD's plant influent could be attributed to household plumbing corrosion. Adjustment of the water supply pH has resulted in dramatic reduction in copper effluent loadings as discussed further in Chapter 6.0.

Corrosion of household plumbing has been evaluated as a source of copper and lead by several agencies and organizations including:

Massachusetts Office of Technology Assessment (OTA)
Save The Bay, RI
New Jersey Environmental Federation
Dade County Department of Environmental Management, FL
US EPA Region 5
City of Phoenix, AZ
City of Tempe, AZ
Central Contra Costa Sanitary District, CA
Palo Alto RWQCP, CA
Novato Sanitary District, CA
King County Water Pollution Control Division, WA

4.2.2 Laundry Graywater

A study conducted by Central Contra Costa Sanitary District (CCCSD) identified laundry graywater as a significant source of heavy metals, including arsenic, cadmium, chromium, copper, lead, mercury, nickel, and zinc (LWA,1994a). For most of the parameters examined, color laundry loads were shown to contain significantly higher levels of metals than did white loads. This might be attributable to leaching of textile dyes and/or to the fact that color clothes are more often outer clothes which tend to collect more dirt and to have more metal fixtures (i.e., snaps, zippers, etc.) attached to them. In addition to metals loadings attributable to the laundry itself, detergents and other laundry products can contribute significant amounts of arsenic, cadmium, and chromium to laundry graywater. Laundry graywater has also been evaluated as a possible source of chloroform from the use of chlorine bleach (Corsi, 1994).

Public education, technology-based strategies, and legislative strategies can all address laundry graywater as a source of residential metals. Public education would focus on an effort to modify residential laundry practices. Technology-based strategies include the use of graywater systems and reducing the use of metals-containing clothing dyes. Legislative strategies would involve passing a local ordinance requiring developers to install graywater systems in a certain percentage of new homes.

The washing of color loads in cold water rather than warm water could significantly reduce metals in graywater by reducing the amount of dye leaching from clothes during washing. (Energy conservation would be a secondary benefit of this option.)

The use of alternative, metal-free dyes would also help reduce residential metals loadings from laundry graywater. This would require a study to determine that dyes are indeed a significant source of residential metals. If this hypothesis is proved, a cooperative effort with dye manufacturers to develop and use acceptable alternatives (less toxic, metal-free dyes) would be in order. Such an effort may be beyond the capabilities of one municipality, and it would be more effective to refer this study to the state or US EPA for administrative and financial support.

Residential activities also impact loadings in commercial laundries. A source identification effort by a diaper service identified diaper rash ointment as a source of zinc in its laundry graywater (Massachusetts OTA, 1992). Outreach to its customers reduced zinc levels in the diaper service's wastewater.

4.2.2.1 Graywater Systems

Another technology-based idea that may be effective in reducing wastewater loadings from graywater is an on-site residential graywater system that can be used to collect graywater and recycle it to a subsurface drip irrigation system that can be used to water lawns, trees and shrubs. Graywater systems address all pollutants present in laundry wash water including those from dirt, clothing dyes and detergents. The potential to reduce metals entering the residential sewer wastewater through application of residential graywater systems complements water conservation as a justification for the use of such systems. To ensure that minimum standards for health and safety are met by residential graywater systems, graywater standards were added to the California State Plumbing Code in 1994 (California Department of Water Resources, 1994). Recent estimates indicate that it would cost the homeowner approximately $1,500-$3,000 to set up a typical graywater system, including piping and perforated tubes for the irrigation system (Sacramento Bee, 1994).

The graywater standards were adopted to allow systems to be installed in single family dwellings and were designed to provide consistent standards that meet minimum health and safety requirements. In addition, they were developed to provide relief for residential landscapes during water shortages and to enable the development of business and economic opportunities. Graywater systems have the advantage of addressing both water conservation and pollution prevention issues. In addition, the systems appear to be straightforward to install and maintain. However, to substantially reduce wastewater loadings, widespread use of graywater systems within a community would be necessary. This would require a substantial outreach effort.

Promoting graywater systems for larger sources, such as apartment buildings, laundromats, schools, and hotels might address wastewater loadings more effectively. The current graywater standards in California were developed for single family dwellings. However, a law was passed in 1995 to revise the graywater standards to allow for use by multiple family dwellings, commercial businesses, and other larger sources. These standards went into effect in January, 1997 (Prillwitz, 1995).

Agencies providing information on laundry graywater as a residential source of pollutants include:

Central Contra Costa Sanitary District, CA
Palo Alto RWQCP, CA
Eastern Municipal Water District, CA
City of Tempe, AZ
Seattle/ King County, WA

4.2.3 Pesticide Use and Landscape Maintenance

Pesticides are used by homeowners for landscape maintenance, indoor pest control, and pet care. Control strategies targeting general pesticide use and programs specifically targeting organophosphate pesticides are discussed in the following subsections. In addition, landscape maintenance can contribute nutrients and other pollutants. Programs addressing fertilizer use, water conservation, and native plant selection, in addition to pesticide use, are also described.

4.2.3.1 General Pesticide Use

With regard to pesticide usage habits, surveys conducted in Virginia, Maryland, and Minnesota indicate that about two-thirds of homeowners perform their own lawn care (Schueler, 1995). Approximately 20% to 40% of homeowners use insecticides, with the most common products used including diazinon and chlorpyrifos. The Maryland survey indicated that two-thirds of the homeowners who apply their own pesticides rinse their equipment over grass, pavement, or directly into gutters or storm sewers. One conclusion that can be drawn from these surveys is that a need exists for more public education regarding pesticide handling and disposal.

Strategies for controlling sources of pesticides include:

- Using integrated pest management (IPM) methods;
- Switching to less toxic pesticides, such as pyrethrins and insecticidal soaps, where appropriate and available; and
- Properly handling and disposing of pesticides to minimize the amount of pesticide entering the sewer or storm drain.

Integrated pest management is a program that is typically applied to agriculture, although its principles can also be applied to urban pest control (Robinson et al., 1995). IPM encourages the use of non-chemical controls, but allows for pesticide use under certain circumstances. The message of IPM is that alternatives to pesticides exist which can result in significant reductions in pesticide use. Many resources describe IPM practices and alternatives. One comprehensive resource is the Bio-Integral Resource Center and its 1996 Directory of Least-Toxic Pest Control Products (IPM Practitioner, 1995).

IPM is based on the implementation of four basic principles.

1. The pest causing the problem must be identified so that a pest control approach best suited to the particular pest can be chosen.

2. The applicator must decide what level of pest control is necessary. For example, a residential yard might not need to be completely free of insects and weeds.

3. Long-term strategies should be used to keep pests under control. Long-term strategies include introduction of disease-resistant plants, use of beneficial insects such as ladybugs, and removal of accessible food supplies for ants and cockroaches.

4. Short-term strategies are used when pests cannot be controlled due to unusual circumstances. Short-term strategies may include the use of pesticides, but the least toxic pesticide that will be effective is recommended.

Applying IPM to lawn care includes several practices (Schultz, 1990). Grass can be fertilized using organic fertilizers. IPM recommends fertilizing lightly and less frequently. Grass can be mowed higher leading to a healthier lawn that is more weed resistant, thus decreasing the need for pesticides. If pest problems occur, some damage should be tolerated and the least toxic controls available should be used. For example, biological controls, such as certain fungi or bacteria, can be effective pest controls. Also, the grass type chosen should be pest resistant and compatible with the local climate. Such practices can reduce the use of pesticides.

With respect to educating the public regarding these practices, Seattle METRO has developed a Green Gardening Program consisting of a multi-level education campaign encouraging pesticide use reduction and recycled materials use in urban landscaping. The program strives to educate people who currently use pesticides about easy, effective, and less toxic alternatives. Through public outreach, the program teaches people to look at their yards and gardens as a dynamic ecosystem and to curb all "preventative" calendar spraying. The program provides information on the dangers of pesticides and safest application techniques. Disposal of hazardous waste containers is also taught, but the emphasis is on preventing pest problems and choosing safer alternatives. In 1993, Seattle used four public education tools:

1. Workshops titled "Alternatives to Pesticides" were offered during the growing season at local nurseries.

2. A slide show called "Green Gardening" was presented to 23 community groups.

3. A "Green Gardening tour weekend" was held featuring 16 organic gardens open to the public.

4. Written brochures on alternative pest controls, pest and disease-resistant plants, and organic gardening were distributed at all Green Gardening events and at local nurseries.

In addition to these four tools, Seattle was also considering a program that would provide identifying signs for yards using Green Gardening techniques. The Green Gardening program also provides a consultant to train nursery workers on alternatives to pesticide use.

4.2.3.2 Public Education Programs for Organophosphate Pesticides

Sources of pesticides are likely to be unregulated commercial businesses or residential home and lawn maintenance. Public education programs have been implemented by several communities to encourage residents to implement the strategies discussed in previous sections. In particular, organophosphate pesticides, including diazinon and chlorpyrifos have been identified as pollutants of concern in both stormwater and wastewater around the country. Public education programs targeting diazinon or chlorpyrifos, as well as programs targeting pesticides in general, are described herein.

Diazinon was identified as the primary cause of wastewater whole effluent toxicity failures in several POTWs in US EPA Region 6 (Texas, Oklahoma, New Mexico) (Water, Environment & Technology, 1995). At the request of US EPA, CIBA Crop Production (diazinon manufacturer) conducted a study of 350 wastewater treatment plants in Texas, Oklahoma, and New Mexico, which are required to perform biomonitoring. The study results indicated that diazinon levels in effluent can be reduced through increased solids retention time and aeration capacity. However, public education efforts to discourage residents from pouring pesticides down the drain are more economical than treatment and have proven to be effective. A description of a public education program developed in response to toxicity failures in Oklahoma City, Oklahoma, follows. Greenville, Texas, also developed an effective public education program targeting diazinon which is described in more detail in Chapters 5.0 and 6.0.

Oklahoma City has a population of 480,000 and is served by four wastewater treatment plants with a total capacity of 81 Mgal/day (APA, 1995). Biomonitoring at all four plants identified toxicity which was linked to diazinon through toxicity reduction evaluations (TREs) conducted in 1992. Sources appeared to be residential; therefore, the City determined that a public education program represented the most economical and effective control strategy.

The initial task of the educational program was to conduct a series of user surveys. Separate surveys were conducted for the following groups: residential users; professional exterminators; lawn service and nursery professionals; veterinary clinics and groomers; animal shelters and kennels; janitorial services and carpet cleaners; apartments, motels, and hotels; food service establishments; and retail stores. The results of the surveys indicated that the public education program would be most effective by targeting residential users of pesticides. The City created its Public Education Program to inform the general public about the correct selection, handling, and disposal of pesticides. Program elements include brochures, bill inserts, public television programs, radio announcements, radio talk shows, information on buses and billboards, home and garden show exhibits, a home and garden club newsletter, and newspaper articles.

4.2.3.3 Landscape Maintenance

In addition to pesticides, landscape maintenance contributes other stormwater pollutants, including nutrients from residential fertilizer use and pet wastes. Programs have been developed to educate residents regarding landscaping activities and other residential activities generating pollutants. The Water Wise Gardener Program, Backyard Actions for a Cleaner Bay and Home*A*Syst are discussed below.

The Virginia Cooperative Extension has developed the Water Wise Gardener Program to encourage homeowners to implement best management practices that will reduce water pollution from fertilizers, pet wastes, erosion, and pesticide use (Aveni, 1996). Program goals that have been met include: 1) 85% of participants complete one year (1st and 2nd stages described below) of the Water Wise Gardener Program, and 2) documentation of a 40% reduction in nitrogen applied and a 25% reduction in yard wastes sent offsite, pesticides applied, and water used.

The Water Wise Gardener Program uses master gardeners to educate the public using a 5-stage process. The initial stage is to provide information to the public through seminars or workshops on topics including fertilization, IPM, plant selection, and composting. The second stage goes beyond the first stage of educating the public by encouraging individuals to participate at a deeper level of personal involvement. In the second step is the 'volunteer lawn' program in which homeowners sign an agreement whereby they volunteer to implement the recommended practices. A master gardener assists the volunteer in implementing at least 5 BMPs and to keep track of lawn and yard care activities. In the third stage, a volunteer lawn becomes a "demonstration lawn." After the homeowner has had a volunteer lawn for at least a year, they should be knowledgeable about how water quality relates to lawn care and their lawns should look well cared for. A yard sign is posted to highlight their efforts to the community. The fourth stage is training the homeowner to become a master gardener and thus expanding the program through this person's commitment to share knowledge with the community. The fifth stage is program evaluation which is conducted periodically to assess the program and determine future directions.

Backyard Actions for a Cleaner Chesapeake Bay is a public outreach program to: 1) inform citizens that their personal actions can impact the Bay; 2) provide hands-on information on gardening and lawn maintenance practices; and 3) show city dwellers and suburbanites how farmers are protecting the Bay (Leffler, 1996). Specific information was offered on wise fertilizer use, pesticide alternatives, and erosion control. The outreach strategy included video and radio public service announcements, and "Take It From Maryland Farmers" guides, posters, stickers, and displays. This 1995 outreach campaign resulted in the distribution of 5,000 guides and 3,500 calls to the Maryland Cooperative Extensions Home and Garden Information Center (advertised in the campaign).

Home*A*Syst is a national program that encourages homeowners to complete an assessment of pollution hazards in and around the home (Farm and Home Pollution Prevention Update, 1995). It is based on a program developed for farm assessments (Farm*A*Syst). These programs are intended to serve as a pollution risk assessment tool and a flexible implementation framework that builds interagency and private sector partnerships to support rural pollution prevention. A series of assessment worksheets identify pollution from a wide range of sources found on farms and in homes. Fact sheets and technical referrals are used to develop site-specific, voluntary action plans to prevent pollution.

Agencies and organizations providing materials and program information on landscape maintenance and pesticide use for the Source Control Assessment are listed in Table 4-2.

4.2.4 Vehicle Maintenance and Used Motor Oil

As discussed in Chapter 4.0, vehicle repair, maintenance, and washing generate pollutants, including heavy metals, oil and grease, and detergents that are discharged to the storm drain and the sanitary sewer. Residential vehicle maintenance has been addressed by pollution prevention programs and stormwater programs through public education efforts. These outreach efforts target used motor oil, residential vehicle maintenance, and residential car washing.

4.2.4.1 Used Motor Oil

Proper disposal of used motor oil has been targeted by many programs. Many communities have established household hazardous waste facilities where residents can dispose of hazardous wastes, including used motor oil. Many communities around the country provide household hazardous waste collection facilities and other means of collecting used motor oil. Some specific program aspects from the City and County of San Francisco (CCSF), Seattle/ King County, Ventura County, and Massachusetts OTA are described here as specific examples.

Massachusetts OTA established a recycling center to collect household hazardous wastes, including used motor oil, antifreeze, and photographic wastes as part of its Critical Parameters Project in Worcester, MA (US EPA, 1994). The recycling center received little use from business and moderate use from homeowners. It was felt that more publicity of the project would have increased the use of the recycling center. Even so, in the first year of operation, 1,400 gallons of waste were collected at the recycling center.

Service stations and auto repair shops sometimes accept used motor oil. The California Integrated Waste Management Board (CIWMB) encourages these activities through its used oil grants for local governments (CIWMB, 1994). Grants are provided to cities and other local governments to publicize used oil collection programs like the two described below. San Francisco and Ventura County have obtained these grants and used them to develop programs publicizing businesses that collect used motor oil. The City and County of San Francisco produced a map showing the 52 locations around the city that collect used motor oil. (CCSF, 1996) The map was developed to show that the locations were distributed throughout the city making it easy and convenient to recycle motor oil. Ventura County publicizes certified used oil collection centers (i.e., located at specified oil-change businesses, service stations, etc.) through a "Used Oil Recycling Month" and a used oil information center at public events, including the County Fair, Cinco de Mayo, Earth Day, and used car swap meets (Camacho, 1995). Other elements of Ventura's program include developing curriculums to be incorporated into adult education courses, such as auto repair courses, driving schools, and traffic schools.

Table 4-2. Information Collected on Landscape Maintenance and Pesticide Use

Program	Materials Reviewed	State	Region

4.2.4.2 Vehicle Maintenance and Car Washing

Car care guides for 'do-it-yourselfers' have been developed by agencies including CCSF and Eastern Municipal Water District. Home maintenance guidebooks and brochures developed by agencies including the San Francisco Estuary Project and the Alameda Countywide Clean Water Program include recommended practices for car care as well (SF Estuary Project, 1992; ACCWP, 1995). Recommended practices include washing cars on lawns or unpaved surfaces, recycling used motor oil and antifreeze, repairing leaking vehicles promptly, cleaning up spills with absorbants, such as cat litter. In addition, outreach materials remind residents never to pour used motor oil or antifreeze down an inside drain or a storm drain.

CCSF conducted an outreach program targeting young males, ages 16-25, based on research indicating that this is the group most likely to change their own motor oil. (CCSF, 1996) Elements of the program included advertising on youth oriented radio stations, conducting promotional events at auto supply stores and distributing recycling kits, including a map showing collection center locations; the car care guide, *Fix It!*; and a used oil recycling container. Street signs placed on utility poles were also used to encourage used oil recycling.

The following entities indicated that they have programs targeting used motor oil and residential vehicle maintenance activities and provided information for this project:

Palo Alto RWQCP, CA
King County Hazardous Waste Program, WA
Central Contra Costa Sanitary District, CA
City of Phoenix, AZ
Massachusetts Office of Technical Assistance
Montana Department of Environmental Quality
City and County of San Francisco, CA
Alameda Countywide Clean Water Program, CA
City of Davis, CA
San Francisco Estuary Project, CA
Dade County Department of Environmental Resource Management, FL
Alliance for the Chesapeake Bay, VA
Rouge Program Office, MI
Eastern Municipal Water District, CA
City of Sacramento, CA

4.2.5 Home Painting Activities

Paints are a source of certain metals and solvents as described in Chapter 3.0. Painting activities conducted by do-it-yourselfers should follow the same BMPs recommended for painting contractors in Chapter 3.0. Outreach to home painters is included in home maintenance guides such as those prepared by Palo Alto RWQCP, the Alameda Countywide Clean Water Program, and the San Francisco Estuary Project. The primary messages are to wash painting equipment in indoor sinks not outside near storm drains; reuse paint thinners; and to dispose of paints, solvents, and thinners at household hazardous waste collection centers (ACCWP, 1995).

A list of entities that provided information for this project and who indicated that they have programs targeting residential painting activities include:

Palo Alto RWQCP, CA
King County Hazardous Waste Program
City of Phoenix, AZ
Massachusetts Office of Technical Assistance
Montana Department of Environmental Quality
City and County of San Francisco, CA
Alameda Countywide Clean Water Program, CA

4.2.6 Household Cleaners and Other Consumer Products

Household cleaning products have been identified as being a significant source of arsenic, cadmium, chromium, and nickel (WTC, 1992). CCCSD estimated that household products accounted for 67% of CCCSD residential arsenic loadings, 35% of CCCSD residential cadmium loadings, 20% of CCCSD residential chromium loadings, and 10% of CCCSD residential nickel loadings (LWA, 1994a). Studies conducted by the Washington Toxics Coalition and the City and County of San Francisco provide a good summary of information regarding household products.

A Seattle study conducted by the Washington Toxics Coalition (WTC), in cooperation with Seattle Metro, examined metals content and consumer usage statistics for numerous household products, including laundry detergents, dish cleaning products, bleaches, general purpose cleaners, toilet bowl cleaners, and dandruff shampoo (WTC, 1991). This study determined that, with the exception of arsenic, dish and laundry cleaning products are an essentially insignificant residential source of metals. (These products were estimated to contribute 40% of the total loadings of arsenic to the residential sewer.) None of the metals examined were found in significant quantities in general purpose cleaners and toilet bowl cleaners. Finally, the WTC tested one brand of dandruff shampoo and found it contained significant quantities of zinc; however, no zinc loadings emanating from this product category were estimated because of insufficient information on metals content and overall usage.

The study also evaluated toothpaste, hair coloring products, bar soaps, bath crystals, and metal polishes. In addition, several brands of "ultra concentrated" laundry detergents were studied to supplement results obtained from the previous two phases of the study. Household products were analyzed for arsenic, cadmium, chromium, copper, lead, nickel, and zinc. Of the 7 different brands of toothpaste examined in the WTC study, trace elements were not found at significant levels in these products, with the exception of one brand which contained unusually high levels of zinc. However, because the market share of this brand was estimated to be only about 1%, it is not believed to contribute substantially to residential zinc loadings. Of the 15 different hair coloration products, trace elements were not found at significant levels in these products either, with the exception of one anti-graying product which contained unusually high levels of lead; however, because the overall usage quantities of this product are small, it is not believed to contribute substantially to residential lead loadings. Of bar soaps, bath crystals and metal polishes, none of the brands tested contained metals in quantities significant enough to contribute substantially to residential trace element loadings. Moreover, the examination of ultra-concentrated laundry detergents showed considerably lower levels of arsenic than those found in most other brands in earlier studies examining these products.

The Seattle study also examined 15 different brands of cosmetics, including eye and facial cosmetics of various colors. It was found that several of the brands were extremely high in zinc and chromium, while one brand was exceptionally high in cadmium. Arsenic, copper, lead, and nickel did not appear to be present in significant quantities. It was noted, however, that literally thousands of cosmetics products are on the market, and metals content (as judged from the small cross-section of products tested in the WTC study) is likely to vary greatly. Moreover, the amounts of these products entering the residential sewer are very difficult to quantify, and no attempt was made to do so. An accurate assessment of residential metals loadings from cosmetics products would therefore be a substantial research project all by itself.

CCSF conducted a study of household product contributions of heavy metals to the residential sewer (CCSF, 1991). The types of products investigated in the San Francisco study included hair products, toilet bowl cleaners, bath soaps, deodorants, and toilet paper. Information from previous studies was also incorporated into the analysis.

Using analytical results of consumer product trace element content, market share statistics, and existing data on residential and municipal wastewater, percent metals loadings to the residential sewer from household products were estimated. The San Francisco study found that the above product categories contributed less than 10% of the total residential loading of every parameter except arsenic (35%), and less than 2% of all the remaining parameters except chromium (6.9%), and silver (3.8%). Of the above product categories, powder laundry detergents were the major source of arsenic. These results indicate that, for most parameters, the above household product categories are insignificant sources of total residential trace element loadings to the sanitary sewer.

4.2.6.1 Green Cleaning Kit

An example of outreach to discourage the use of certain household products is Seattle's Green Cleaning Kit (Frahm, 1995). Since 1992, in a program funded by the local hazardous waste management unit, Seattle has given away or sold over 12,000 Green Cleaning Kits to its residents. The kits, which include spray bottles, recipes and some ingredients for non-toxic household cleaners, come in a box with instructions. Seattle instituted this program to raise citizen awareness and change behaviors. On the basis of follow-up surveys, Seattle determined that thousands of kit purchasers (up to 63%) now use the green recipes as a part of their regular household cleaning chores. Furthermore, the surveys determined that use of the Green Cleaning Kit reduced the quantity and use of hazardous cleaning agents by 15% to 30%.

Among the entities that provided information for this project and that indicated that they have programs targeting household products are:

Palo Alto RWQCP, CA
King County Hazardous Waste Program, WA
Central Contra Costa Sanitary District, CA
City of Phoenix, AZ
Massachusetts Office of Technical Assistance
Montana Department of Environmental Quality
City and County of San Francisco, CA
Alameda Countywide Clean Water Program, CA
City of Davis, CA
San Francisco Estuary Project, CA
Dade County Department of Environmental Resource Management, FL
Alliance for the Chesapeake Bay, VA

Rouge Program Office, MI
Eastern Municipal Water District, CA
City of Sacramento, CA
New Jersey Environmental Federation
Save The Bay, RI
City of Tempe, AZ
Union Sanitary District, CA
Alexandria Sanitary Authority, VA

4.2.7 Pools and Spas

Pool and spa water containing chlorine can be toxic to aquatic life. In addition, certain pool algicides contain copper which is of concern to both wastewater and stormwater systems. Public outreach has been conducted in some communities to encourage residents to dechlorinate pool water and not use copper-containing algicides. Recommendations regarding dechlorination include letting the water sit for two weeks or adding sodium bisulfate. Organic algicides are recommended as alternatives to copper-containing compounds. It is also recommended that filter rinsewater be disposed of on soil rather than down the storm drain. Some communities recommend discharging pool water to the sanitary sewer after contacting the local wastewater discharge authority (ACCWP, 1995; SF Estuary Project, 1992).

Several entities provided information about their programs targeting pools and spas, including:

Palo Alto RWQCP, CA
City of Simi Valley, CA
Alameda Countywide Clean Water Program, CA
San Francisco Estuary Project, CA
City of Sacramento, CA

4.2.8 Root Control Products

CCCSD evaluated copper sulfate root control products and estimated that these products contributed an average of 22% of the CCCSD residential copper loadings (LWA, 1994a). In the CCCSD service area, surveys indicated sales of about 3,400 pounds of root destroyer in 1992. This product is placed directly down the drain by homeowners in accordance with the instructions that come with the product. The intended use of this product is to inhibit root growth in sewers, although copper sulfate products are usually only moderately effective.

Because copper is a pollutant of concern to the entire San Francisco Bay Area, a regional approach discouraged using copper sulfate as a root control product (SFRWQCB, 1994). A regional brochure was developed describing the issue and alternative practices to remove roots from sewer lines. The brochure was distributed by POTWs throughout the Bay Area. Outreach was conducted to plumbers and hardware stores asking them not to use or sell these products.

In addition to outreach efforts, a legislative approach was used, as well (PARWQCP, 1996). During 1994, Palo Alto RWQCP staff developed and co-sponsored a bill, which was taken to the California State Assembly, that would have banned the sale and use of the copper-based root killer. This effort received support from several of the Bay Area public agencies through a letter writing campaign and participation in public workshops and legislative hearings. The legislative effort resulted in a commitment by the California Department of Pesticide Regulation to develop regulations relating to copper-based root killer. After a year of technical studies, public outreach, and regulation development, the Department of Pesticide Regulation adopted emergency regulations in December, 1995 prohibiting the sale and use of copper-based root control products in the nine Bay Area counties. In the summer of 1996, this became a permanent regulation.

CHAPTER 5.0

PUBLIC EDUCATION PROGRAMS

Educating a community's residents and businesses concerning wastewater and stormwater issues is an essential element of a nonindustrial pollution prevention or stormwater program. Public agencies throughout the country have developed public education materials. This chapter presents information regarding messages used in pollution prevention and stormwater education, audiences addressed, outreach approaches used, the watershed management approach, and use of behavior change principles.

Examples of public education materials and supporting documents were requested from agencies and private companies from around the United States. Nearly 500 brochures, flyers, door-hangers, videotapes, school program outlines, give-aways, posters, bumper stickers, and guide manuals were received from 75 public education program managers in 23 different states from all 10 US EPA regions. The agencies that provided public education materials for this project are listed in Appendix D. Several brochures, pamphlets, booklets, and other examples that were reviewed for this study have been copied and included in Appendix E. They illustrate how many agencies are communicating messages to their various audiences, including the use of regional characters, text and illustrations that target certain pollutants, activities, and audiences, and a discussion of creative outreach strategies. The appendix includes the names and telephone numbers of the agencies that produced each of the examples.

5.1 Stormwater and Pollution Prevention Messages

Public education programs heighten general awareness of stormwater and wastewater issues and communicate messages concerning specific pollutant sources. Elements of these messages, including general message themes, regional flavor of messages, and specific messages used in stormwater and wastewater pollution prevention programs, are covered in the following subsections.

5.1.1 General Message Themes

Materials provided for this study related to stormwater and urban runoff pollution typically focused on educating the general public that, as individuals, *they* are the nonpoint sources contributing every day to the most significant water pollution problems still remaining in the country. The materials usually stressed that the protection and future enjoyment of local bodies of water depend upon the individual's efforts to make the changes necessary to reduce their portion of the pollutant load. Most of the public education materials included lists of activities that people could do to reduce pollutants.

Public education programs also submitted materials that target the prevention of pollution to local wastewater treatment plants and subsequent effluent discharges to rivers, lakes, or bays. Similar to the stormwater and urban runoff programs, the messages for the pollution prevention public education programs emphasized the role and responsibility of the individual. Instead of warning people not to pollute local bodies of water via storm drains, these public education materials emphasized toxic materials that should not be discarded down house drains. Messages also informed that alternative products were readily available to replace the use of toxic cleaning and pest control materials in the home. The public education programs also emphasized taking left-over toxic wastes, including motor oil and paint, to household hazardous waste collection facilities.

5.1.2 Regional Flavor of Messages and Graphics

While basic messages on the need and how to reduce water pollution are fairly uniform throughout the U.S., the means of communicating this information have definite regional flavor. In Palo Alto, California, Flo the Raccoon is a delightful mascot. Clean Water Raingers (sic) in Trenton, New Jersey, include Claudine Crab, Diesha Diamondback (turtle), and Howie Heron. Materials from Miami, Florida, feature Officer Snook and communicate issues about the high water table and manatee protection. Some materials from Albany, New York, reflect the local interest in the arts by showcasing paintings of scenes in New York's watersheds. Fact sheets from Providence, Rhode Island, relate urban runoff pollution to the loss of shell fishing areas. The most exciting materials key into the local interests of their audiences and use regionally appropriate graphics.

Different regions of the U.S. focus on different pollutants in their public education programs. Nutrients are the focus of most programs in the East and for inland watersheds. Urban and coastal watersheds tend to focus on toxic pollutants.

The messages being conveyed to the general public are similar throughout the country. However, there is no single phrase that wraps everything up neatly—a phrase such as "Give a hoot- -don't pollute." The nationwide effort to educate the public on stormwater and pollution prevention issues would benefit greatly if such a common phrase were developed and uniformly used.

5.1.3 Specific Messages Used in Public Education Programs

Examples of messages illustrating both the similarities and the creative differences of stormwater and pollution prevention programs throughout the U.S. are presented in the following sections.

5.1.3.1 Stormwater/Urban Runoff Pollution Public Education Messages

As indicated above, public education messages either heighten general awareness of stormwater pollution or address specific sources of stormwater pollution. Messages being communicated by stormwater programs regarding general awareness include:

- ♦ Stormwater and urban runoff are not treated; therefore, as these surface flows reach local bodies of water, they contain all of the pollutants that accumulate from everyday living and commerce.
- ♦ By making changes in daily habits, individuals can protect the health of local creeks, streams, rivers, lakes, bays, and oceans.

Messages addressing specific sources of stormwater pollution include:

- ♦ Educating the general public that specific sources of stormwater pollution include automobile products, vehicle maintenance operations, litter, pet wastes, pesticides, fertilizer, erosion from construction sites, and illegal sewer connections.
- ♦ These pollutants enter the storm drain as water from rainfall, overwatering, or cleaning operations washes over outdoor surfaces.
- ♦ Specific outreach messages to businesses and/or groups typically revolve around encouraging the business to implement BMPs for their particular activity.

Examples of approaches to heightening general awareness from different parts of the country are:

California. Outreach to residents of multi-family buildings carries the following message.

"Storm Drain Pollution – Palo Alto's storm drains -- including drains in carports and parking lots -- flow directly into our creeks and San Francisco Bay with no wastewater treatment! *Remember that any substance dumped or spilled into a storm drain contaminates our local waterways and harms wildlife!*"(PARWQCP, no date, Guidelines for residents of multifamily buildings).

Washington. Outreach encouraging businesses to be aware of stormwater issues is expressed in a brochure with the following message.

"King County Promotes Your Business for Your Pollution Prevention Efforts -- Polluting is like pouring money down the drain -- it costs less to prevent it than to clean it up. It's also against the law. When it rains, water carries pollutants into storm drains that lead to lakes and streams. To prevent pollution, sweep your parking lots, cover dumpsters and stored materials, and wash cars in contained areas. Get recognized for protecting water quality -- Become a Business for Clean Water Today" (King County Surface Water Management Agency, no date, Stop Pouring Money Down the Drain).

Louisiana. Louisiana Department of Environmental Quality (DEQ) presents the following information regarding changing daily habits in a brochure entitled "Louisiana Storm Drain Stencil Program" (Louisiana DEQ, no date).

"Where should wastes go? Now that you know the dangers of dumping wastes, what is your alternative to getting rid of it? Recycle when possible. Most products like motor oils and paint thinners can be recycled and reused. Make these good habits in using household cleansers and materials: recycling, reusing and swapping. Contact local authorities for information."

The DEQ also has a series of pamphlets specifying BMPs for general audiences, urban area residents, contractors, agriculturalists, foresters, and residents with septic tanks.

Florida. Sarasota County developed a brochure called the "Bay Repair Kit" that has the following message.

"You can do something significant to improve this corner of the planet. Most pollution to our nearby bays and other waterways comes not from one or two big dirty industries, but from ... each one of us" (Sarasota County, no date).

New York. A brochure educating the public about New York watersheds uses this message:

"We all share the problem. We used to think that most water pollution in New York was caused by 'someone else' – the local sewage treatment plant, the factory down the street, the mysterious pipe emptying strange-smelling liquid into a stream. If we looked, eventually, we would find a pipe or a 'point source' of pollution.

Today, we know that the source of most water pollution is not as easily identified as a pipe ... in over 90 percent of the state's waters that are polluted, the cause can be traced to non-point sources of pollution ..."(Soil Conservation Service, 1994).

Chesapeake Bay. "A Citizen's Guide" distributed by the Chesapeake Bay Program states: "... the Chesapeake Bay is among the most productive estuaries in the world. But the Bay and its watershed are in trouble. Years of use — and abuse — have taken their toll...The future of the Bay depends largely on the choices we make today — not only for the 13.6 million people who currently live here, but for the 2.6 million more of us expected to make this region home by the year 2020" (Chesapeake Regional Information Service, no date).

Examples of stormwater messages targeting specific sources are shown in examples from Sacramento and Santa Clara Valley. The Sacramento Stormwater Management Program describes practices targeting several sources in the brochure, "Solution to Stormwater Pollution," which is available in English and Spanish.

"What Can You Do to Prevent Stormwater Pollution? You can make a big difference in keeping the creeks and rivers in the Sacramento area clean and healthy for fish, plants, birds, and wildlife, and ourselves by following these tips:

- Get involved! Stencil a storm drain with the message *'No dumping! Flows to river.'* Clean a creek. Call your local agency for more ideas about how you can help.
- Never pour anything down a storm drain that you wouldn't want to swim in!
- Try to use up toxic products or buy smaller quantities so you don't have to worry about disposing of leftover materials.
- Bring leftover toxic materials such as paint, cleaners, used motor oil, and pesticides to a household hazardous waste collection event in your community or to an authorized drop-off point.

- Never hose down spills into a storm drain. Use kitty litter or other absorbent material to clean up spills of toxic materials from pavement.
- Use pesticides, herbicides, and fertilizers carefully and sparingly, and do not apply if rain is forecast.
- Keep your vehicle and equipment well tuned to avoid leaks.
- Use public transportation or car pooling. When it rains, air pollution becomes water pollution!
- Keep yard clippings, detergent, trash and animal waste out of the gutter and storm drains."

The Santa Clara Valley Nonpoint Source Pollution Control Program presents information for a specific source in a poster for restaurants "Good Cleaning Practices to Protect Our Creeks and Bay" (SCVNSP, no date).

> "Clean all floormats, filters and garbage cans in the mop sink ...
> ... or outside in a bermed and covered area.
> Pour washwater into the mop sink
> Use a dry method for spill cleanup
> Keep dumpster area clean and the lid closed
> Handle and dispose of grease properly".

The poster is illustrated with large, interesting drawings that show how to perform each of the good cleaning practices specified. It is also accompanied by a packet of educational information for restaurant managers, with a checklist of BMPs for employees. The checklist has been printed in several languages.

5.1.3.2 Common Messages for Wastewater Pollution Prevention Programs

The three most commonly used messages related to wastewater pollution prevention (inside homes and businesses) are:

- ♦ To protect local bodies of water, it is important to avoid pouring toxic chemicals down drains that lead to the sanitary sewer system.

- ♦ Most informational materials emphasize alternatives that can readily replace household products that are toxic to the environment.

- There are properly designed and controlled facilities to safely dispose of household hazardous wastes in most areas of the country. The public is usually provided with the telephone numbers and other information necessary to make arrangements to properly dispose of common toxic wastes.

Several jurisdictions offer examples of how these messages are communicated:

California. East Bay Municipal Utility District (EBMUD) provides general information about the role of wastewater treatment in its brochure "Stopping Pollution at the Source."

"For living organisms from plankton to people, San Francisco Bay is a source of life, pleasure and nourishment. It's also a place where treatment plants, like EBMUD's, release highly treated wastewater from homes and industries. Discharges from our plant form a tiny part of the Bay's waters. Still to keep those releases free of harmful toxins, EBMUD created an award-winning Source Control Program. The District keeps pollutants out of the Bay by making sure homes, businesses and industries keep them out of sewers" (EBMUD, 1994).

The San Francisco Estuary Project describes household hazardous wastes in its brochure "Estuarywise."

"Inside your home ... Your cupboards and closets contain dozens of everyday cleaning, polishing, and painting products hazardous to our waterways. Under the sink lurk the drain openers, oven cleaners and insect sprays; out in the laundry room the chlorine bleaches and spot removers; down in the basement workshop the glues, paints and wood preservatives. Amazingly enough, these and other common household items can add up to a considerable source of pollution, once they find their way from our homes to the Estuary via drains, toilets and your local landfill. And don't forget that leaky faucet in the bathroom guzzling our scarce freshwater supply. ... Tackle it without toxics..." (SF Estuary Project, 1992).

Arizona. The cities of Phoenix, Glendale, Mesa, Peoria, Scottsdale, Tempe, and Gilbert produced a brochure called "Pollution Prevention Begins with You -- A Guide to Protecting the Salt River and Our Environment." Instead of reinventing the wheel, it adapted text and graphics used in a brochure that originated in the Santa Clara Valley Nonpoint Source Pollution Control Program. Its key messages are:

"How you use and dispose of products containing toxic substances has a direct impact on the environment and our quality of life ... Before you pour anything down the drain, stop and think" (City of Tempe, no date).

The City of Tempe has produced other good materials that inform the general public about pollution prevention in a program that "stresses a multi-media approach to reduction and control to prevent the transfer of pollutants from one medium (air, land, and water) to another" (City of Tempe, no date, Our Environment -- Our Choice). The public works department distributes a list of "Safe Alternatives to Common Household Chemicals" (City of Tempe, no date) for the residential population and a newsletter for its industrial dischargers (City of Tempe, 1996).

New Mexico. The city of Albuquerque relates household practices to local waterways in its brochure, "Are You Pouring Water Quality Down the Drain?"

"[The following are headings of sections in the brochure.] What goes down the drain does not simply go away... Did you know that many substances that enter the sewer system can't be removed during the treatment process?... It may surprise you to find out that the Rio Grande supports a riparian habitat along its banks. ... The natural life of this habitat is endangered by substances that cannot be removed in treatment. ... That's why your decisions count. ... Sometimes, the individual can make a big difference! ... A thoughtful home owner has many alternatives to pouring toxins down the drain" (City of Albuquerque, no date).

5.1.4 Best Management Practices for the General Public

One approach to communicating messages targeting specific sources is to develop BMPs for the general public. Much of the literature reviewed in this study includes BMPs or actions that people can take to reduce the flow of pollutants to their local water resources. These are often accompanied by illustrations to clarify how certain activities are done. The target audiences vary widely from community to community in the U.S. Some agencies provided public education materials that focus entirely upon the general public. Others had materials for a range of target audiences, with BMPs specified for their unique roles in the community. In general, BMPs for residents focus on using more elbow grease and fewer chemicals to clean up after ourselves.

Examples of BMPs recommended for stormwater and urban runoff pollution prevention are:

The New Jersey Department of Environmental Protection in Trenton, New Jersey, has developed a brochure, "How to be a Clean Water Rainger (sic)." Below is the approach used in the brochure to describe BMPs for the general public.

"Top Ten Things You Can Do to Help Keep Water Clean:

- Never throw anything down storm drains. They are for rainwater only.
- Don't litter. Always put trash where it belongs.
- Always clean up after your pets. Obey your town's 'pooper scooper' laws.
- Tell others how important it is to keep our land and water clean.
- Plant a tree. They take pollutants out of ground water, provide shade, and clean the air.
- Find out what waterway you live near. Where does your water come from?
- Precycle! Buy products that use the least amount of packaging.
- Recycle. Find out what is recyclable in your community. Buy products in recycled or recyclable containers.
- Learn about environmental issues. Get involved in local organizations.
- Conserve water whenever possible. For example, turn off the water while brushing your teeth and don't linger in the shower."

The City and County of San Francisco has developed a fan-style publication "Grow It! The Less-Toxic Garden. Control Pests & Plant Disease Using Less-Toxic Methods" educates the public on pesticide alternatives. It is available in several languages. Approximately 30 "less toxic control methods" are listed in this easy-to-use publication for common pests, mildews, and plant diseases. Among them are the following:

- "Aphids - - Spray with insecticidal soap (available in nurseries). Always test a small portion of foliage before treating the entire plant. Some plants are very sensitive to soap sprays.
- Cutworms - Hand pick during the day searching in widening rings around the stems of seedlings.
- Earwigs - Set out short lengths of bamboo or rolled up newspaper to trap earwigs. Check in the morning and shake earwigs into a bucket of soapy water.
- Powdery Mildew - Wash new growth with a spray of ordinary water. Powdery mildew thrives in cool, dry conditions."

5.1.5 Messages Targeting Specific Sources For Wastewater

Several agencies have developed materials addressing toxic pollutants coming from household and garden products. These are often directed towards reducing pollutants in the sanitary sewer system; however, most are applicable to stormwater/urban runoff pollution prevention, as well. Educational materials have been developed to give the general public information about natural alternatives to toxic products. These sometimes use a creative format, such as recipe cards, wheels to "dial" to the safer alternative, and posters for workshop or kitchen. The examples included below were selected to show the creativity that agencies have used to communicate natural (nontoxic) alternatives to the general public.

Examples of materials that describe nontoxic alternatives and disposal practices associated with prevention of pollution to the sanitary system are:

The City of Sunnyvale, California, has developed recipe cards for household activities (City of Sunnyvale, no date). Recipe cards are available for insecticidal soaps, odor removers, cut flower preservers, methods to apply flea powder, non-chemical drain cleaner, organic pest repellant, pantry pest repellants, baking soda play clay, air fresheners, wood furniture polish, metal polishes, abrasive cleaners, ant repellant, window cleaner, moth preventative, and roach repellant. One example is using olive oil combined with vinegar or lemon juice as furniture polish.

EBMUD produced a 'wheel' describing recommended alternatives to several household products (EBMUD, no date). For each product/chemical listed, the 9-inch diameter wheel includes hazardous ingredients, alternatives, hazardous properties, and proper method of waste management. The following are examples of alternatives for common hazardous products:

- "Paint thinners and turpentine -- Use water in water-based paints.
- Flea collars and sprays -- Herbal collar/ointment (eucalyptus or rosemary), or Brewer's yeast (call vet for amount).
- Herbicides -- Hand weeding, let grass grow 2-3 inches to shade weed seedlings."

A Florida brochure addressing pesticides, hazardous wastes and leftover paint presents the following BMPs (Florida Department of Environmental Protection, no date):

- "Follow label instruction on rinsing empty containers of garden chemicals. Apply the rinse water to the same plants that received the pesticide. Then, dispose of the empty, clean containers as solid waste. ...

- To properly dispose of leftover hazardous wastes, hazardous materials and other chemicals, take part in local 'Amnesty Days.' Call your local government. Many counties operate temporary hazardous waste storage areas which may be available to homeowners who have materials they need to dispose of.

- Donate half-full cans of paint to groups that can use them such as homeless shelters, Habitat for Humanity, or similar organizations."

5.2 Audiences

Every community has audiences composed of the general public, school children, businesses and industry, and municipal government. Subsets of these audiences vary by community. The target audiences identified for the Milwaukee area are representative of typical audiences in many communities (Southeast Area Water Quality Education, 1994). They include:

- **"Urban residents**
  - Residents with yards and gardens
  - Vehicle owners
  - Pet owners
  - Schools and youth groups
  - Community groups

- **Local governments**
  - Elected officials
  - Staff and consultants

- **Business and industry**
  - Automotive businesses
  - Building maintenance
  - Construction
  - Fleet maintenance
  - Landscaping and related businesses

- Marinas and boat maintenance
- Mobile cleaning services
- Outdoor storage and processing
- Parking lot and grounds maintenance"

This list represents the majority of audiences and more focused groups targeted by most of the larger communities throughout the country. Additional sub-groups reflect the character of a particular region—farmers in agricultural areas, foresters in the timber industry, homeless camps in big cities, and mining companies.

Certain sub-groups are just emerging as targeted audiences: ethnic employees of businesses who may not speak the same language or share environmental values with the managers/owners of the firm; new development, including architects, planners, engineers, and developers; customers of automobile parts stores who often arrive in the parking lots of these stores with problematic cars leaking oil and other pollutants; and watershed conservancies and stakeholders programs. These groups, which have unique roles in the social and business communities, are just beginning to be targeted by public education programs (Brosseau, 1996).

Approaches to different audiences including the general public, ethnic communities, businesses, municipal employees and the emerging sub-groups just mentioned are described below.

5.2.1 The General Public

Every agency that provided public education materials for this project included at least one item that targets the general public, "the average citizens of the community." In certain larger cities, key materials were translated to languages other than English (primarily Spanish and Chinese). When looking at the materials that were more successful than others in communicating stormwater and pollution prevention information to the general public, the following common threads stood out:

- ♦ Public education programs for the general public audience focused on communicating the key messages listed earlier in this chapter; the specific local creeks, streams, rivers, lakes, bays and/or oceans that were affected by pollution; and local, State, or national (US EPA) telephone numbers to call for more information.

- ♦ The best materials use layman's language, are highly visual, relatively brief, and focus on the tools for behavioral modification.

- Graphics did not have to be highly professional to be effective, but the materials that were easiest to read and understand have more graphics than text in the overall composition.

- The materials were designed to be succinct, deliver the key messages quickly and clearly, and provide the tools to go out and do the job right.

Some agencies are opting for the money-saving policy to "not reinvent the wheel" and have adapted public education materials that were originally prepared for another community (e.g., the City of Phoenix adapted its brochure "Pollution Prevention Begins With You -- A Guide to Protecting the Salt River and Our Environment" from a publication prepared for the Santa Clara Valley Nonpoint Source Pollution Control Program.) There are some limits to the ability to adapt materials produced by others, particularly if the item has a strong regional flavor that doesn't easily translate to another part of the country.

5.2.2 Ethnic Communities

Media coverage and workshops are two methods used to outreach to specific ethnic groups. Good examples are programs conducted by the cities of Los Angeles and San Francisco. The City of Los Angeles stormwater program prepared public service announcements targeting the Latino community and received overwhelming play on Spanish radio stations in Southern California. CCSF conducted workshops for the African American and Latino communities. Demonstrations on safer cleaning methods were conducted at supermarkets and house parties. San Francisco also held workshops for Latino house cleaners focusing on potential health problems associated with certain cleaning chemicals and their environmental impacts (CCSF, 1996).

Another strategy that has been used to reach certain demographic groups is to provide consumers with stormwater/urban runoff public education materials along with the products they buy in a point-of-purchase public education campaign. One example is a campaign that targeted not only a specific cultural audience, but a specific pollutant, as well. San Mateo County teamed up with Pennzoil in a campaign that featured, but did not focus exclusively on, an ethnic group and targeted the pollutants associated with used motor oil. This point-of-purchase campaign resulted in a 12% increase in the amount of waste oil collected locally.

Text of the campaign's printed material was presented in English only. Rich-looking visuals featured a Latino man. Research showed that, in the San Mateo area, most people who changed their own oil were young men, and many of them are Latino. Therefore, the campaign was designed to target this audience (Boyd, 1996).

As already mentioned, in larger communities, many print materials are prepared in multiple languages, using similar graphics and text. However, it appears that there is a tremendous opportunity to work even more effectively with ethnic communities in America by following the examples of Los Angeles, San Francisco, and San Mateo. This concept is more than translating a piece prepared in English to another language; it is having the targeted ethnic community in mind at the outset.

Surveys and focus groups help program managers understand the priorities of ethnic communities. For example, a public awareness survey conducted for the Los Angeles County Department of Public Works showed that Latino respondents were most concerned about reducing pollution in waterways than any other group; and that the greater concerns for all ethnic groups were reducing crime and gang violence, drug abuse, improving the quality of public schools, and creating jobs (LA County Department of Public Works, 1996).

5.2.3 Business Audiences

Public education programs approach businesses in various ways. The most direct of these is educating business managers and employees about how their practices may harm the environment and the changes they can implement to make corrections.

Many business education materials also cite regulations. For example, the (San Francisco) Bay Area Stormwater Management Agencies Association and the San Francisco Regional Water Quality Control Board produced a brochure targeting mobile cleaners called "Pollution from Surface Cleaning" (BASMAA, 1996). The brochure states:

> "Pollution from surface cleaning ... It harms the environment .... And it's against the law! Allowing polluting substances into storm drains is prohibited in California. Both the person who discharges the pollutant or leaves it behind, and the owner of the property where the material is generated are liable."

The brochure then describes the BMPs available to mobile cleaners.

At a recent training workshop for mobile cleaners in the San Francisco area, the cleaners stated that they were always "looking over their shoulders" because they didn't know whether or not they were following the correct procedures. The first of three training workshops provided BMP information using slides and a hands-on demonstration to educate over 90 people providing this service (Brosseau, 1996).

Other approaches to working with businesses are discussed below and include point-of-purchase displays, business recognition programs, educational materials, and ethnic employee training.

5.2.3.1 Point-of-Purchase

The greatest emphasis of public education programs oriented to the business audience is to win cooperation, save companies money, and to form partnerships that place businesses in a positive light in their community. Some of the most effective business outreach efforts are highly focused. One example is the point-of-purchase waste oil recycling campaign in San Mateo, California. Local oil distributors were provided with kits, stormwater education brochures, and a stand-up display, all of which encouraged the do-it-yourselfer to recycle motor oil. Retailers were responsible for distributing and replenishing the supplies of brochures and kits. Distributors were "on-board" as willing partners and have indicated that they want to participate in a repeat campaign (Boyd, 1996).

5.2.3.2 Business Recognition

Several pollution prevention programs use business recognition to encourage environmental stewardship. Examples include the King County Surface Water Management Program; Manhattan Beach, California's the Clean Bay Business program; the City of Los Angeles initiated the Ocean Safe Coalition of Businesses; and the Association of Bay Area Governments promotes the Green Business Program. The literature of the Alameda County Green Business Program, which is similar to many other clean business outreach efforts, states:

> "The Green Business Program recognizes businesses that are in compliance with environmental regulations and have taken steps to conserve water, energy, and other resources. Participating shops receive a number of benefits from the program including positive public recognition [and] streamlined compliance and pollution prevention assistance" (Alameda County, October 1996).

Another example of outreach that involves a city's recognition of environmental responsibility is the City of Palo Alto, California's official "Pollution Prevention Week," (September 16-22, 1996). The Mayor issued a proclamation that stated:

> "Pollution Prevention Week is an opportunity for government, industry, and environmental organizations to recognize the potential of pollution prevention and to work together to plan for a prosperous and sustainable future" (City of Palo Alto, July 1996).

5.2.3.3 Educational Materials for Businesses

Just as regions of the U.S. are quite unique from one another, types of businesses have particular characteristics, as well. Materials targeting businesses are more likely to be used if they use a design that is compatible with the industry. For example, a brochure prepared for the food service industry in the Santa Clara Valley area of California to communicate stormwater education/BMPs is subtly similar to menus found in fine restaurants (Santa Clara Valley Non-Point Source Control Program, no date, Good Cleaning Practices...). It included a poster of BMPs to be displayed in the kitchen where wall space may be a premium; therefore, both sides of the poster were used—the same graphics were printed in a horizontal format on one side and a vertical format on the other. This allows the restaurant managers to display where they have room on the wall, a cabinet, or door. Even more "restaurant-smart" thinking went into this poster: it is laminated so that kitchen grease and splatters easily wipe off.

5.2.3.4 Ethnic Employee Training

The restaurant package prepared by Santa Clara Valley was also designed to include training for employees who do not speak English. Inserts highlighting BMPs are included in Spanish, Vietnamese, Chinese, and English. The poster uses few words and, in fact, is so well-illustrated that it is not even necessary to be literate to understand what is required of the workers. The City and County of Los Angeles jointly produced a poster for training restaurant employees using a similar well-illustrated format. The text is in English and Spanish (City and County of Los Angeles, no date).

Efforts are also being made to provide environmental education/training for employees of the vehicle service industry for whom Spanish is the primary language. The City and County of San Francisco and the Commonwealth of Virginia, Department of Environmental Quality are two of the major programs in the United States that have produced training materials in Spanish for this targeted activity.

5.2.4 Municipal Audiences

Government offices are typically among the first to establish environmental policies for employees, including BMPs that apply to a cross-section of public service functions. Also, because government agencies often contract out certain services, BMP training and policies can be extended to private firms that are awarded those contracts. Examples from Florida, North Carolina, Cincinnati, and California are discussed below.

A three-phase program to reduce waste and pollution in County government offices in Broward County, Florida, is being conducted to deal with the area's problems with water pollution and dead fish (NPPR, 1995). These negative conditions affect the county's recreational boating and tourism industry. Initially, the pollution prevention education program targeted the business and industrial community. But the County decided that government workers should set an example by exploring opportunities and taking appropriate actions. The three phases include taking a survey of waste generating practices, preparing a summary report with recommendations for improvements, and implementation of a county-government wide waste reduction and pollution prevention program.

"Stormwater Fact Sheet No. 5, Municipal Pollution Prevention Planning", (Land-of-the-Sky Regional Council, no date) targets the municipal audience or government workers, including managers; the men and women who sweep streets, wash city trucks, maintain municipal landscaping, and who follow BMPs that prevent pollutants in stormwater and urban runoff.

The City of Cincinnati is attempting to conduct a model pollution prevention program in its own operations (NPPR, 1995). All departments and divisions have had training. The City invited other local and State government offices to participate in training and promotional activities. The City has adopted an "Environmental Preference" purchasing ordinance for all city purchases, such as lead-free, water-based paints for highway line striping. Cincinnati has also extended its training to the business sector.

The City of Sunnyvale Public Education staff makes presentations concerning pollution prevention to each city department annually. Presentations are geared toward information relevant to the specific department (City of Sunnyvale, 1996). Similar in-house education and training is also being done in North Carolina and other parts of the country to encourage municipal workers to serve as examples for others to follow in pollution prevention.

5.2.5 School Programs and Children

A great deal of work is currently underway targeting the audience of school children and their teachers. Materials and programs are typically directed to various age groups: grade school beginning with kindergarten, middle school/junior high, and high school.

Most school programs are targeted toward younger students. Like the campaigns to discourage smoking and encourage recycling, environmental educators hope to teach the young generation about healthy pollution prevention habits and that the students will then nag their parents and guardians to improve their own actions.

The content of school programs is extremely diverse:

The City of Los Angeles targets hundreds of grade school children at a time with its bilingual "Canopy" performances shown at assemblies in public and private schools (City of Los Angeles, 1994b).

Alameda County, California, has a popular "Kids in Creeks" teacher workshop program for grades K-12 (Alameda Countywide Clean Water Program, 1995).

The Central Contra Costa County Sanitation District's school education program goes into the classrooms with posters and displays, and a curriculum developed by a local environmentally-oriented museum. Students are enlisted in the "Central San Sewer Squad"(CCCSD, 1994).

The Seattle Drainage and Wastewater Utility distributes "Water You Doing?" for middle school classes. This has a teachers' manual, field trip directory, resource guide and activities, and three very funny and informative videos. The agency also provides equipment and training for grade school teachers in over 100 schools to raise salmon in their classrooms from eggs to fry, and then release the fry into local waters (Seattle Drainage and Wastewater Utility, 1996).

The King County Surface Water Management Division provides community stewardship grants to encourage watershed education and enhancement projects (King County Surface Water Management Agency, no date, Duwamish River Site Tour).

EBMUD, as part of its Pollution Prevention program outreach to schools, produced the student publication, "The Tardy Twins Meet Polluto," and an accompanying teacher's guide. This publication is designed to acquaint upper elementary students with the processes of the wastewater treatment and the importance of pollution prevention and controlling sources. It covers the processes of pollution and purification and the community's role in contributing to the problem and to the solution (EBMUD, 1996).

The City of Sunnyvale sponsors an environmental science fair targeting 4th to 7th graders. Projects are judged by educators and representatives from local businesses, and non-profit organizations. Projects entered in the Fair have included 'green' household cleaners, effects of urban runoff, and birds of the Bay (City of Sunnyvale, 1996).

Adopt-A-Watershed is a school education program that is used in many communities. It has curriculum and activities for grades K to high school that include long-term field studies, restoration projects, and community actions. An example of these for a kindergarten class is:

> What is a watershed? Concept -- The earth contains objects which are observably different and that change. Long-term field study--Tree height and diameter/succession study. Restoration project -- Tree planting. Community action -- Field trip booklet for family and community; children explain to family what a watershed is (Sacramento River Watershed Project, 1996).

The Water Environmental Federation is a partner with over a dozen other agencies and organizations in "Give Water a Hand — A Youth Program for Local Environmental Action." Youth groups select a problem of interest and conduct a project to solve it.

National Project WET (Water Education for Teachers) produces a wide range of materials for school programs. These include curriculum and an activity guide; science activities; booklets and handbooks on events, history, and stories; tee-shirts; and modules on the Everglades watershed, wetlands, groundwater, and water conservation (National Project WET, 1996).

The University of Wisconsin Extension, Environmental Resources Center has produced a resource series called "Blueprints for Educating Young People About Water". It encourages youth leaders to work with groups on water resource and protection projects (University of Wisconsin, no date).

The Global Rivers Environmental Education Network (GREEN) is an environmental education program that focuses on watersheds. The non-profit organization works with groups in 130 countries to promote watershed sustainability. Various materials are available through this organization: field manuals and kits for water quality monitoring, source book for watershed education, an educator's guide to toxic assessment, and several other publications and videos. Among the educational materials that are distributed by GREEN are those produced by National Project WET (see above) (GREEN, 1996).

The City of Santa Monica, California, had an interesting experience with high schoolers. These older students did not come through when they were recruited to distribute door hangers, apparently because the task felt like "make-work." However, these students were stellar when they volunteered to teach stormwater education principles to younger students in their school system. Their peer-teaching efforts were very relevant, and the benefit returned to the City of Santa Monica was quite valuable (Romain, 1996).

Public education programs targeting students should be age-appropriate, and as illustrated above, have relevance to the audience. Another thing to consider is that teachers are being overwhelmed with requests to use materials similar to stormwater education in their classrooms. How do teachers choose what to use? To avoid having resource materials gather dust on a classroom shelf, some research into the school's needs would be a benefit. For example, does the school need transportation for a field trip and could you provide that to get your program used in the classroom?

On the other hand, public education programs should also consider the cost per student. The City of Los Angeles believes that it gets great value in educating hundreds of students at a time with its exciting and sought-after performance of the "Canopy" program.

5.3 Effective Strategies for Different Audiences and Messages

A 1995 public awareness survey for the Los Angeles County Public Works Department asked people where they obtained information on the storm drain system. The responses were as follows:

Broadcast television	49%
Newspaper	47%
Radio	5%
Cable television	4%
Magazine	3%

Billboard	3%
Stenciling drains	3%
Brochure	1%
School child	1%
Other	8%
Don't know	6%

When these same people were asked where they received their information on local issues in general, they responded: newspapers (65%), broadcast television (63%), radio (24%), cable television (15%), magazines (12%), brochure (6%), newsletters (6%), billboards (5%), school child (4%), other (4%), and "don't know" (0%).

A survey conducted by researchers at the University of Wisconsin in the lower Milwaukee River Basin in 1989 showed similar results, but in addition to the media as a major source, pamphlets and newsletters were also rated highly effective.

5.3.1 Media (Newspaper, Television, Radio)

As just illustrated, using the media is one of the most effective ways to get information into the hands and minds of the general public. Effective media campaigns will adhere to the following principles:

- The viewing public needs to be rewarded, with things such as entertainment and/or information that directly helps them with a problem or saves them money. A public service announcement (PSA) that appears to serve only the needs of the sponsoring agency will fall flat.

- The piece prepared for the media needs to include basic information. The piece also needs to give people instructions; it should not simply tell the audience that water pollution is bad.

- Many agencies, when paying for advertising, are also asking for free time to increase coverage. When approaching television and radio stations to play PSAs, several agencies ask for "unsold" air time.

- ♦ When investing in the development of a PSA, public education managers may have more success if they work from the beginning with a particular radio or television station. This will not ensure that the PSA will receive good coverage, but it will help.

- ♦ PSAs have been developed to be shown in movie theaters before the previews. There is a hard and fast rule that PSAs shown in theaters must premiere at the movies. They cannot first appear on television or any other medium. Arrangements can be made with theaters that the PSAs may be shown at a later date in other venues.

Programs working effectively with media in Wisconsin and Texas are described below. As a result of the public awareness survey mentioned above, the Southeast Area Water Quality Education Program of the University of Wisconsin Extension concluded that a well-coordinated multimedia outreach program would be one of the most effective ways to convey stormwater information. The University prepared the following list outlining its media strategy:

1. Build on existing themes, mascots, and materials, especially the "It all adds up" and the "Stormie" cartoon character.

2. Target materials to reach all income, age, and cultural groups using appropriate languages, themes, music, media outlets, etc.

3. Use a variety of messages, times, and media to reach the critical threshold where people will remember and act on the information they have received.

4. Make the content and tone of messages positive.

5. Appeal to motivations, such as clean neighborhoods, health and safety, environmental quality, and convenience.

6. Build on what people already know and use sources they consider credible.

7. Use terms that people can easily understand such as "runoff" rather than "nonpoint source pollution."

8. Match the media to the message, keeping in mind that:

- Print media are most effective for more messages that require absorption of details and contemplation by the receiver;
- Television has the strongest emotional impact, but is the most costly; and
- Radio's advantages are flexibility and the ability to reach specific target audiences multiple times at a markedly lower cost than television.

9. Use graphics and sound to reinforce messages and make them more memorable.

10. Localize messages, but where appropriate, tie them to national and international events."

The efforts of Greenville, Texas, to reduce the level of the pesticide diazinon in wastewater effluent was described in a previous chapter of this report. Working with the media was a major reason why the overall pollution prevention program was successful (Erwin, 1996). Virtually every element of the total public outreach program was covered by the media. Articles were placed in the local newspaper, the City newsletter, and the "Texas Town & City" magazine. The message about diazinon use was covered in widely different ways: a local library program on the use of alternative pesticide controls, seminars given by recognized experts on fire ant control, flea and tick seminars, public awareness survey results, editorials about the public awareness survey, household hazardous waste announcements tied to diazinon use, environmental fairs, student programs, student-designed billboard contest, tours of the wastewater treatment plant, storm drain stenciling, small paid advertisements, monthly guest columns in the local newspaper, and radio PSAs.

In effect, Greenville, Texas "double-dipped": they gained public awareness through the various public outreach strategies (e.g., environmental fairs and student programs) and then gained far more exposure through publicizing their event and its message primarily in the local newspaper. As stated earlier, Greenville residents responded to this program by drastically reducing the volume of the toxic pesticide that previously caused chronic problems and violations at the community's wastewater treatment plant.

Effective media campaigns bring the issue to the forefront for the general public. Survey after survey confirms that people learn about environmental issues from newspapers, television, radio, and various publications. An effective media campaign capitalizes on opportunities for publicity. For example, the public can learn about stormwater and pollution prevention issues when they read newspaper articles about grass roots events, results of public awareness surveys, government employees featured for their efforts to implement BMPs, businesses being honored for their efforts to implement BMPs, a classroom field trip, or helpful educational materials that are available free to the public. Taken together in an effective media campaign, the message to encourage clean water practices is emphasized over and over.

5.3.2 Public Events

Earth Day was the original public event that drew the general public together to support protection of the environment. Today, agencies and organizations rarely miss participating in Earth Day festivities and often sponsor some form of outreach in a variety of public events each year. Examples of strategies using public events to promote awareness of wastewater and stormwater issues are discussed in the following subsections.

A self-guided bicycle tour of the Duwamish River was developed by the King County Surface Water Management agency in Seattle and is promoted by the Cascade Bicycle Club. A brochure, "Duwamish River Restoration Sites Tour," which includes a map for bicyclists, gives both environmental information and safety tips. This program targets the general public, bicycling enthusiasts in particular (King County, no date, Duwamish River Site Tour).

Several forms of cleanup days can be found around the country. In Sacramento, California, several groups including the Urban Creeks Council sponsor "Creek Week" that concludes with a creek cleanup with prizes for the most unusual things retrieved. This is a grass roots affair, that includes free lunch donated by a local fast food restaurant, live music, environmental education booths, and free tee-shirts. Approximately 500 people participated in the 1996 cleanup day. This type of program targets the general public with the message that individuals can contribute to cleaning up our water (Clark, 1996).

The City of Sunnyvale sponsors several public events throughout the year, including Coastal Cleanup Day for the South Bay, Pollution Prevention Week, Earth Day, and an Environmental Science Fair. On Coastal Cleanup Day, volunteers clean up local creeks and parks with 600 people volunteering in 1994 and 1,000 volunteers participating in 1995. Earth Day activities reached over 4,000 people with materials and interactive booths about nonpoint source pollution and pollution prevention (City of Sunnyvale, 1996).

CCSF recognized the diversity of its population of one million residents and prepared a catalog of all of the known community and cultural events held regularly. The catalog included information on the schedule of the events and how to contact the sponsoring organizations. The participation in these events targets the general public (CCSF, 1996).

Many cities make mini-public events from stenciling programs, bringing together people in a neighborhood to stencil their storm drains. These programs also target the general public. Almost every community that provided materials for this research study has a storm drain stenciling program. They all make a simple statement, such as "No Dumping. This drains to ocean (or bay, river, creek, or wetland)."

Major public events, such as Earth Day and the Great Coastal Cleanup, build awareness of environmental issues for large audiences. Given the large numbers of people involved and the lack of opportunity for thorough discussion of details, messages associated with these types of public events need to be simple. Smaller events, such as neighborhoods getting together to stencil storm drains, provide the opportunity for leisurely, thorough discussion of a range of environmental concerns.

5.3.3 Workshops, Trade Shows

Workshops are offered by agencies, ultimately to provide detailed information and demonstrations on how to implement BMPs. These programs often feature a related subject and piggy-back pollution prevention information.

CCSF offers workshops for the general public. Free gardening workshops are given in San Francisco to teach "less toxic gardening" to residents. CCSF also offer workshops on auto maintenance. The auto maintenance workshop features "low riders" and auto demonstrations to appeal to young males who were identified as most likely to work on their own vehicles. In addition to carrying an environmental message, the information offered is practical and useful thus filling a need of the people attending (CCSF, 1996).

A training workshop was given to mobile cleaners in the San Francisco Bay Area regarding BMPs to reduce the volume of pollutants from outdoor steam and pressure cleaning. The workshop concluded with a self-graded examination and distribution of recognition certificates. To encourage participation of mobile cleaners, the sponsoring agencies, RWQCB and BASMAA, also provided outreach to the cleaners' potential customers to encourage hiring of firms that completed this training program (Brosseau, 1996).

A conference for developers, businesses, local governments, and environmental organizations on planning for new development in Western Michigan was sponsored by the West Michigan

Environmental Action Council. It was attended by over 250 people (West Michigan Environmental Action council, no date).

Trade shows offer a forum for focused public education. For example, the City of Los Angeles developed a poster illustrating BMPs for restaurants and distributed free copies at a Restaurant and Food Industry trade show in Los Angeles. Because the cost and logistics of distribution of materials can be significant, trade shows that draw large numbers of targeted business audiences, such as restaurants, construction, and boating, are excellent venues for environmental education. The trick is capturing the attention of the participants. This can be accomplished with the same strategy as indicated for audiences reached through the media. Offer some kind of reward, such as information that will help solve a problem in their trade (Ellis, 1996).

5.3.4 Videos

Videos have also been produced pertaining to stormwater and wastewater issues. All of the videos reviewed for this study were professionally produced and targeted different audiences.

Where Does It Go? is a 12-minute video narrated by and featuring middle school age children. The video is a collaborative effort of schools in Petaluma, Novato, and Vallejo, California, with the Central Marin Sanitation District, other nearby agencies, and the California Integrated Waste Management Board's Used Oil Grants program. The key messages conveyed by this tape are that the wastewater and storm drain systems are separate; even with treatment, some pollutants still pass through the plant into the San Francisco Bay. The children narrating are clear and straightforward about what individuals can do to reduce their own pollution: wash cars at car washes instead of on the street, clean up a creek or storm drain, and use less toxic products. This is an excellent video that holds the viewers' attention, highlights the essential points related to preventing pollution in both the sanitary and stormwater systems, and provides helpful BMP suggestions. Along with the video is a lesson plan for 4th through 6th graders. The video cost $12,000 to produce. Each participating agency received 55 copies, a lesson plan, stickers, and a submaster of the video to produce additional copies (Bender, 1994).

H2O Improvements is a 20-minute program by the Massachusetts OTA (Massachusetts OTA, 1994). It focuses on pollution prevention and describes the wastewater treatment process. The video uses humorous vignettes to point out that it is less expensive to prevent pollution than it is to provide physical treatment, answers questions about the use and disposal of toxic materials, and addresses related issues

Storm Water, Clean Water Protection Program--Protecting Our Water is a 10-minute video that targets professions involved in new development: architects, developers, contractors, and maintenance (Riverside Flood Control and Water Conservation District, no date). The video was carefully made so that it has only limited reference to Riverside and, therefore, is easy to use in other regions. It uses a straightforward educational approach that combines illustrations with on-site visuals to demonstrate various BMPs that reduce stormwater pollution from design, construction, and maintenance points of view.

Water You Doing? is a 35-minute videotape with five segments. (Seattle Drainage and Wastewater Utility, 1992). Because these excellent presentations are heavily focused on Puget Sound, they are not readily adaptable for other areas. The program recognizes that to communicate water quality messages to what they call the "MTV generation," the video program would have to be different. The first segment uses a funny scientist to make the point about water sources and resources and the ways the Puget Sound is being polluted. The next segment brings together the weathermen of three local television stations to describe the watershed. The third segment uses a "Dragnet" theme to point out the difference between the sanitary and storm drain systems. The Flying Karamazov Brothers, a comic trio of jugglers, describe the differences between point source and nonpoint source pollution, and emphasize the importance of individual responsibility in the fourth video segment. The fifth presentation uses a teacher to lead into the school outreach program that features a call to action.

The Fantastic Journey, a 15-minute tape prepared by the City of Los Angeles, went behind the scenes with the video production crew to illustrate how stormwater pollutants travel through the storm drain system to the Santa Monica Bay. The video used the creative director of the City's 30-second PSA prepared for television to narrate this longer, more educational program. Visuals include the mountains of debris that accumulate in the Los Angeles storm drain system and end up on the beach. Viewers are shown various BMPs that the video production crew used to reduce their own contribution of pollutants (City of Los Angeles, 1994a).

Heal the Bay, an environmental organization based in Santa Monica, California, has produced several videotapes that have been shown on television and other forums. The latest is *Revenge*, which shows a car full of joyriders careening down a residential street, kicking grass and dirt onto private property, smashing into trash cans spreading litter everywhere, pouring oil on the ground, and even jumping out to light papers on fire on a doorstep. When the narrator asks if the audience would like this kind of treatment where they live, the camera pans to the joyriding occupants of the car: a dolphin and seals. The sound of the dolphin's call, which of course sounds like a cackling laugh, can be heard as the car drives away, and the narrator appeals to the audience to prevent pollution of storm drains (Heal the Bay, 1996).

5.3.5 Course Curricula

The Seattle Drainage and Wastewater Utility offered important insight (Seattle Drainage and Wastewater, 1996):

> "Meetings with Seattle middle school teachers were surprising. Teachers were quite blunt in saying they did not want or need more curriculum. There is more curriculum available than teachers know what to do with. Instead, new teaching tools are needed that can be integrated into the curriculum already being taught. It is important that the tools are flexible so that different teachers can use them in different ways."

With this in mind, a program was prepared with a teacher's manual, field trip directory, and resource guide. The teacher's manual includes activities and questions that correlate with the video "Water You Doing?" described earlier. The classroom can focus on the material for as little as one day and as many as five. Selected field trips are fully funded, including transportation, by the City of Seattle. The resource guide for teachers lists education centers, written materials, activities and lesson materials, audio/visual resources, and speakers willing to talk with classrooms of students.

The Central Contra Costa Sanitary District conducts school education using field trips to the wastewater treatment plant and in the third and fourth grade classrooms. The learning activities for the 3,000 3rd and 4th graders include pre-field trip materials and video, an activity folder, poster board and display board activities, and take-home materials (CCCSD, 1994).

The Center for Watershed Protection prepared a teacher's guide for creating a water monitoring program. Teachers of middle school students (10 to 14 years old) are provided with information, activities, and resources to create a unit about streams in the neighborhood. The class will adopt a segment of a stream, develop a monitoring program, and conduct field monitoring to study ecology. The guide points out that the class must have access to a stream. The guide teaches about watersheds, topographic maps, monitoring, and wild life (Center for Watershed Protection, no date).

EBMUD in Oakland, California, jointly with the California Water Pollution Control Association, Bay Section Public Education Committee, developed a science curriculum on wastewater treatment and pollution prevention issues for Roosevelt Junior High School in Oakland. EBMUD staff authored the chapters of the curriculum text, and the District provided funding for the project and tours of the main wastewater treatment plant for students (EBMUD, 1996).

5.3.6 Brochures, Pamphlets, and Other Written Materials

Several examples of effective messages have been included earlier in this chapter. There are many additional good themes and strategies for print materials as exemplified in the following paragraphs.

"Read this now. Or drink your old paint, chemicals, and pesticides later," a brochure by Metro Dade Solid Waste Management, Miami, Florida, reads in part. Having the reader's attention, the brochure tells how to safely manage chemicals, and provides several alternatives to toxic products. Clearly written information fits on a single 8 ½ x 11 page. Simple, but eye-catching, graphics deliver the message.

"What's Down That Dark Drain?" is a poster/publication produced just for kids by the Sacramento Stormwater Management Division. On one side, large text and simple graphics are used to tell children about storm drains and that nobody should pollute them with oil, litter, weed killers, and household toxics. The poster includes 10 different BMPs that children and their families can do. On the other side, there are several games and a simple test of knowledge.

Heal the Bay, an environmental organization in Santa Monica, California, produces several excellent print materials targeting the clean up of Santa Monica Bay. One of these is a fish-shaped door hanger that says "We're Healing the Bay One Neighborhood at a Time." The door hanger informs the reader that tens of millions of gallons of runoff daily end up in local coastal waters. Then the reader is invited to join in the stenciling program called the "Gutter Patrol." It includes a tear-off form to fill out with name and address in order to volunteer for the stenciling effort.

"Quick Guide to Car Care" for the do-it-yourselfer is a fan-style guide that informs people who maintain their own vehicles about ways to "help the car run better, save on fuel, prevent oil leaks, save on major repair costs, make your car safer to drive." The brochure also introduces "one more important benefit: good car care prevents water and air pollution." What is unique and especially effective about this item is its format. It is fashioned after the fans of paint or wood stain samples found in hardware stores: each page is 2" x 8" of laminated/heavy glossy paper; 12 pages are held together by a rivet that allows the user to fan to the selected "how-to" topic. It is convenient for do-it-yourselfers to keep by their side as they work on their cars, and because the paper is laminated, it is also easy to clean. This is prepared by CCSF and has been duplicated by other communities (CCSF, 1995b).

5.3.7 Advertisements, Promotional Items

Creative television ads and billboards can provide short, strong messages to the general public. For example:

Local cities and government agencies in King County, Washington, collaborated on a television ad that showed a man with a fertilizer spreader walking through the apparently shallow waters of Lake Sammammish. The words at the top of the screen said, "When you're fertilizing the lawn, remember you're not just fertilizing the lawn." This ad was part of a broader public education campaign focused on protection of the Lake Sammammish State Park.

The City of Los Angeles created a billboard that is a colorful, beautiful illustration showing the ocean full of marine creatures right below a city storm drain inlet. Text of the billboard states: "Storm drains lead directly to the ocean -- make the connection." This has been used on regular billboards, in bus stops, as posters and report covers.

Several communities have developed promotional items with stormwater or wastewater themes. The Riverside (California) Stormwater/Clean Water Protection Program has created a large plastic drawstring bag with storm drain illustrations and information on it, a visor, book cover, pencil, and smaller plastic garbage bags. Several communities produce refrigerator magnets with their logos or mascots. These magnets often encourage the reporting of storm drain violations. The City of Phoenix has post-it style note pads with the stormwater program telephone number and a cactus-shaped pencil. All of the promotional materials communicate the sponsor and the message to protect the environment in one form or another.

An interesting advertising strategy is used by the City of Phoenix. Callers who are put on hold when telephoning certain City departments listen to professionally produced pollution prevention tips (Louie, 1996).

5.4 Watershed Management/Stewardship Programs

Watershed management is becoming an important framework for environmental action in the '90s. People working together as stakeholders in a watershed are managing resources in a sustainable fashion. The concept of the approach is to build upon capabilities and overcome negative tendencies. In communities throughout the U.S., work is underway to bring different audiences together to work for the common goal of cleaner water. Some areas promote this as stewardship of a local water resource. Others promote the participation of stakeholders in a watershed management approach. Strategies promoting environmental stewardship include opportunities for training in grassroots fundraising, public speaking, legislative literacy, the policymaking process, and coalition building, as well as technical issues (Non-Point Source News Notes, 1995b). Other components of stewardship are cleanups of bodies of water and citizen monitoring. Examples of programs using the watershed approach are described below.

5.4.1 Lake Superior Binational Program

The States of Wisconsin, Minnesota, and Virginia and the province of Ontario, Canada, created the International Joint Commission (IJC) in 1989 to address boundary water quality issues (Larson et al., 1996). At the recommendation of the IJC, the Binational Program was launched to bring municipalities, native organizations, industries, environmental advocacy groups, academic community, and citizens together in forums to plan for a Lake Superior zero discharge demonstration program. Gradual pollutant reduction goals have been established by these stakeholders to achieve virtual elimination of pollutants by the year 2020.

5.4.2 National Cattlemen's Beef Association (NCBA) Water Quality Information Project

Beef cattle operations are commonly involved in forming partnerships in watershed management programs (Clawson, 1996). NCBA is also involved in forming partnerships at the State and national level among organizations and agencies. Cattle operators are concerned that they will lose control of their management operations. Crucial to successful watershed management efforts is recognition of property owners and their interests from the beginning, and not as an afterthought. The Water Quality Information Project started because of the lack of understanding of water quality assessment processes, potential impairments, and nonpoint source control programs. The project includes the NCBA Environmental Stewardship Award to winners in seven regions of the U.S.

5.4.3 The Rouge River National Wet Weather Demonstration Project

This project is an example of a watershed-based stormwater permitting process (Mercer, 1996). The river has been documented as a source of significant pollution to the Great Lakes system. The project developed a watershed-wide management program based upon the concept that each citizen has the right to expect clean water from their upstream neighbor and must extend the same courtesy to others downstream. A five-component strategy includes: 1) define working groups with a focused local purpose; 2) develop a common set of basic technical information; 3) identify and rank specific sub-watershed problems; 4) develop a long-term strategy and implementation process; and 5) allow for a watershed-wide NPDES permit or an alternative program.

5.4.4 St. Louis River Citizen Program

As part of a citizen monitoring program for the St. Louis River effort, students prepare slides of fish livers to assist US EPA in monitoring the condition of the environment. Residents count and identify frogs to track trends in the river's animal populations. Students also conducted a benthic macroinvertebrate study while others conduct water chemistry tests (Non-Point Source News Notes, 1994).

5.4.5 New York City Watershed Protection Program

An important element of a successful watershed management program is effectively representing the interests of all the stakeholders. Polarization had developed among stakeholders of New York City's watershed protection program to the extent that some stakeholders resorted to legal challenges (Stave, 1996). Participants viewed and valued watershed resources differently. Stakeholders included city water consumers, public agencies, farmers, tourism industry, and recreational users of the watershed. Understanding the basis for the differences was essential to bringing the stakeholders to some common ground. Closed door negotiations convened by New York's governor and lasting seven months initiated a resolution to the stakeholders' conflicts.

5.4.6 King County Department of Natural Resources

Another good example of the stewardship effort is described in the "1996 Community Stewardship Network Directory" distributed by the King County Department of Natural Resources, Seattle, Washington. It opens thus:

> "What you hold in your hands is a comprehensive directory of community and non-profit groups, government agencies and businesses involved in restoring and protecting the watersheds of King and other Puget Sound counties. This book will help you make new friends, seek assistance from government and business, and get connected with efforts to keep our local waters clean."

5.4.7 Puget Sound Water Quality Authority (PSWQA)

Beginning in 1987, the PSWQA entered into contracts with local groups for projects that solved local/regional environmental problems (PSWQA, 1993). The philosophy of this program is described by the following statement:

> "The watershed perspective offers another way of thinking, seeing, sharing responsibility and acting. The watershed is the big picture, comprised of an infinite number of smaller pictures. By seeing ourselves in the smaller picture, we can form the mosaic of the whole watershed and the roles and places of others.
>
> Watershed thinking requires new tools. Maps that answer questions like: What are our watershed's boundaries? Where does the water come from? Where does it go? Experiences like field trips that reacquaint us with our neighborhoods -- from a stream, storm drain, or sewer point of view.... Watershed thinking helps us sort big water quality problems into little ones -- the kind we can fix" (PSWQA, 1993).

The grant program enables various stakeholders to follow through with their smaller picture projects to address water quality concerns in the watershed. The program identifies key audiences as youth, homeowners, business, government, schools, nonprofit organizations, and Indian tribes.

Additional sources of information about watershed management programs include:

- Watershed '96: Moving Ahead Together, Preconference Workshop--Building a successful watershed framework, Clayton Creager, The Cadmus Group (workshop facilitator)
- The Rouge Project Catalog of Watershed Management Information, Rouge Program Office, 1996
- Lake Leelanau Landowner's Handbook, Our Lake, Our Responsibility, Fen's Rim Publications and South Lake Leelanau Steering Committee, no date
- Watershed Management Kit In a Box, Know Your Watershed - Conservation Technology Information Center, 1996.

5.5 Social Marketing/Behavior Change Principles

Environmental educators in some of the larger metropolitan areas are beginning to explore social marketing techniques to change the behavior of the public o stormwater issues, which is much more than simply increasing awareness. Social marketing is the process of selling behavioral change. Research is always used to help establish the educational strategies, much like the extensive research and tests that are conducted for product marketing before new items are offered and advertised for sale. Examples of programs that use social marketing strategies are anti-tobacco campaigns, AIDS awareness, and ride-share programs.

The anti-tobacco campaign offers an excellent illustration of how social marketing combines psychology, research, and public relations. Research showed that although smokers were well aware that they risked illness and death due to their habits, they still wouldn't quit. So a strategy was developed to attack the problem through public concerns for second-hand smoke because, while smokers were not willing to quit for their own health, many would quit if it would protect their spouses and/or children.

The Local Hazardous Waste Management Program in King County, Washington, researched behavior change literature from energy conservation, recycling, health education, and other fields (Frahm, 1996). The King County research found that information alone is not enough to change behavior. Developing a brochure providing the correct information will not, by itself, achieve the desired result. There are many barriers to achieving change besides lack of information. The recommended approach is to start a project by clearly defining the final objective, clearly identifying and understanding the audience, and addressing this audience's barriers to changing behavior.

Certain strategies effectively changed behavior. Insights from the King County research regarding these strategies are described.

Getting involved is the first step to making a commitment, and making a commitment makes people more likely to act. Small commitments lead to big ones. Start by getting the shop owner or resident involved in a visit. Then ask them to sign a form stating changes they will make. A study on improving recycling behavior asked residents to commit themselves to one, two, or three minor actions: complete a survey, save cans for a week, or send a postcard to the city council urging an increased recycling program. As the number of requested commitments increased, so did the recycling behavior. The effects were still observed 10 months later.

Feedback and follow-up are important. Feedback gives people cues about the impacts of their behavior changes. Additional contact is also very important in motivating people. Specific feedback (e.g., energy usage from hot water or turning on lights) and follow-up phone calls reminding people of a commitment are effective. In addition, comparative or social feedback appears to be useful. A large sign was posted alongside an expressway exit showing the percentage of drivers who were not speeding on the previous day. The sign reduced the number of speeding drivers by more than 50%. The same sign without any information about prior compliance had no effect.

People will listen first to their friends or relatives, or others they see as credible. What they hear at a dinner party often has more weight than a comprehensive data summary. Therefore, work through existing, trusted organizations; create a new, unbiased organization; share personal success stories; and arrange for people to meet those doing the desired behavior. One study found that farmers would not adopt a new hybrid seed corn, despite positive data from the U.S. Department of Agriculture, until one or two farmers who had tried the seed confirmed its value.

Change agents and role models are important. A few people in a group will typically adopt innovative ideas and behaviors first and spread them through the group. Find these people and help them successfully adopt a new behavior. The King County sewer utility works with farmers, often in rural areas far from the urban Seattle, to spread biosolids on their fields. Experience showed that reluctance to use urban biosolids was high until a local farmer would agree to provide a test site. The other farmers can see the results and talk with the local farmer and local extension agent about the benefits. This approach has been so successful that demand for King County's biosolids now far exceeds the available supply.

Changing attitudes may not change behavior. There is no strong direct or consistent relationship between attitudes and subsequent action. While 85% of respondents to a survey saw the energy crisis as serious, there was no clear relationship between energy related attitudes and conservation behavior. People who cited conservation as the most important strategy for improving our energy future were no more likely than others to take energy conservation actions.

Incentives may help change short-term, but probably not long term behavior. Incentives may be less effective at changing behavior than strategies that encourage people to internalize a behavior, such as commitment, norms or social recognition. People often respond to incentives by changing their behavior; but when the reward is removed, they generally revert to their original behavior. Researchers at an industrial complex gave drivers flyers that prompted seat belt usage and gave belt wearers the opportunity to win prizes. Seat belt usage increased in the afternoon when incentives were offered in the morning. However, after the incentives were withdrawn, belt usage returned to baseline levels.

If you need to provide information, present it effectively. People are more likely to pay attention to information that is vivid, personal, specific and concrete, stated in terms of loss rather than gain, told as a story, and emotional. Energy auditors used these concepts with good results. One study trained auditors to communicate vividly, personalize their recommendations, get homeowners involved in the audit to encourage commitment, and frame information in terms of loss instead of gain. The trained auditors had much greater success in getting people to follow through on their recommendations than did auditors without similar training.

CHAPTER 6.0

PROGRAM EFFECTIVENESS

Evaluating the effectiveness of pollution prevention, stormwater, and public education programs is critical to the success of source reduction efforts. Programs around the country seek tools to measure the effectiveness of their efforts. While it is crucially important, it is also a daunting and elusive task.

Despite the need to measure program effectiveness, to date, limited information is available in this area. Programs have not consistently incorporated evaluation into standard procedures for several reasons: a lack of adequate environmental data, scant developed performance measures, dearth of baseline information, and shortage of program evaluation tools. Evaluation procedures must be incorporated at the beginning of a project rather than tacked onto the end. This would allow the development of baseline information from which changes can be measured. In turn, environmental data or other performance measures must be available to develop good baseline information.

Most of the effectiveness measures reviewed for this project were based on water quality evaluations and public awareness surveys. In addition, there is an emerging interest in determining the effectiveness of programs based upon environmental indicators, such as those described in Chapter 2.0. Pollutant load reductions and water quality improvements are used by some programs to evaluate program effectiveness. Other environmental indicators that are used to measure effectiveness in studies reviewed herein include sediment quality and fish tissue analysis in the Chesapeake Bay and biosolids concentrations in the San Francisco Bay Area. Other effectiveness gauges are increased opportunities to reuse and reclaim effluent and biosolids, protection of worker health and safety, protection of operations at POTWs, and financial value/return on investment of pollution prevention equipment. Table 6–1 summarizes the measures of effectiveness for programs reviewed for this report.

Table 6-1. Examples of Program Effectiveness of Local Source Control Programs

Program/Municipality	Chapter Reference	Measure of Program Effectiveness
Palo Alto RWQCP (CA)	6.0	Pollutant loading reductions
East Bay Municipal Utility District (CA)	6.0	Pollutant loading reductions
Novato Sanitary District (CA)	6.0	Pollutant load reductions
Greenville (TX)	6.0	Decreased effluent toxicity Pollutant load reductions
New York/New Jersey Harbor	2.0	Ambient water quality conditions Fish tissue analysis Toxicity tests
Chesapeake Bay	2.0	Ambient water quality conditions Sediment quality Fish tissue analysis
City and County of San Francisco	2.0	Pollutant load reductions Biosolids concentration
Santa Monica Bay	2.0	Ambient water quality conditions Sediment quality Condition of habitat Potential health risk to swimmers Levels of contamination in shellfish
Erie County, New York	6.0	Value/return on investment in pollution prevention equipment

Efforts to evaluate program effectiveness based on the use of water quality and other indicators, development of models, and use of surveys are discussed below.

6.1 Program Evaluation Using Various Indicators

The ultimate goal of stormwater and wastewater pollution prevention programs is to reduce effluent loadings and improve water quality. However, using water quality to indicate program effectiveness is not always possible. It is difficult to see measurable differences in water quality when dealing with diffuse sources such as small businesses and homeowners. Reductions in effluent loadings or improvements in water quality can be observed when a specific pollutant issue can be traced to an individual source.

Pollutant load reductions have been indicators of program effectiveness with respect to vehicle service facilities, photoprocessing, corrosion, and pesticide use. Financial evaluation is another method of measuring program effectiveness.

6.1.1 Vehicle Service Facilities

The Palo Alto RWQCB and East Bay Municipal Utility District (EBMUD) each documented reductions in metals influent loading after the implementation of their vehicle service programs.

Of the 300 businesses in Palo Alto RWQCB's Vehicle Services Facilities Program, 65 are permitted for discharge while the remaining 235 facilities are zero dischargers. Based on sampling conducted by the Plant and the businesses, the Palo Alto RWQCB estimated that the 65 dischargers contributed 268 pounds of copper to the plant influent in 1993 (the first full year of the program). In 1994, sampling results indicated that the copper contribution from these facilities had dropped to 92 pounds (Louie, 1995).

EBMUD implemented its vehicle service program in 1992 issuing 251 permits to auto repair shops, fleets, and dealerships (EBMUD, 1996). Baseline levels of plant influent loadings were measured in 1988 for several pollutants, including cadmium, copper, lead, nickel, and zinc. Influent levels for these metals in 1993 (after program implementation) were substantially reduced. Copper levels went from 28 kg/day in 1988 to 20 kg/day in 1993. Cadmium levels were reduced to 0.6 kg/day in 1993 from 1.1 kg/day in 1988. Reductions in lead, nickel, and zinc between 1988 and 1996 were 76%, 51%, and 55%, respectively.

6.1.2 Photoprocessing

Prohibiting silver discharges from photoprocessors has effectively reduced silver levels in wastewater. Palo Alto RWQCB instituted its silver program in 1992 (PARWQCP, 1994b). Source identification studies determined that over 75% of the Palo Alto RWQCB's influent silver originated from approximately 350 relatively small commercial businesses. Palo Alto's sewer ordinance required these facilities to either haul spent fixer off-site for recycling or to recover the silver on-site and obtain a permit for the discharge of treated water to the sanitary sewer.

Due to this silver program, silver concentrations discharged to the San Francisco Bay by the Palo Alto RWQCB decreased from 14 μg/L in 1989 to 0.6 μg/L in 1993.

6.1.3 Corrosion

Novato Sanitary District was able to reduce its copper effluent loadings by working with its water purveyor, Sonoma County Water Agency (SCWA), to implement pH adjustment of the water supply. The water supply pH was approximately 7.5 prior to SCWA implementing corrosion control through pH adjustment in September of 1995. Adjustment of pH to 8.5 resulted in a dramatic reduction in copper loadings. Influent copper loadings were reduced by 55% with influent copper concentration decreasing from 140 μg/L prior to pH control in 1995 to 57 μmg/L in 1996. Effluent copper loadings decreased from an average of 29 μg/L in 1995 to 12 μg/L in 1996.

6.1.4 Pesticide Use

The City of Greenville, Texas, has a population of 23,000 and an average dry weather flow at its treatment plant of 3 Mgal/day (Erwin, 1996). In 1991 and 1992, the plant effluent failed 6 out of 7, and 11 out of 12 toxicity tests, respectively. Diazinon was identified as the cause of the toxicity, and monitoring indicated the diazinon was probably coming from residential sources. Diazinon levels ranged from 0.1 to 0.2 μg/L.

In late 1992, Greenville implemented a public education program. The program discouraged residents from using diazinon, encouraged the use of IPM practices, and recommended alternatives to pouring diazinon or even rinse water down the drain. Outreach methods included highway billboards, radio public service announcements, newspaper articles, school programs, and speakers for community groups.

Since 1993, Greenville has conducted toxicity testing monthly in the summer and quarterly in the winter. Toxicity failure has occurred no more than once per year from 1993 to 1995, with no toxicity failures through the middle of 1996. Since the public education program was implemented, diazinon levels in the City's effluent are primarily below the detection limit of 0.1 μg/L.

6.1.5 Financial Program Evaluation

The Department of Environment and Planning, Erie County, New York, evaluated the effectiveness of a pollution prevention program conducted by the Erie County Office of Pollution Prevention (Malcolm Pirnie, Inc., 1993). The program targeted small businesses and used a newsletter, conferences and presentations, site visits and follow-up reports, and an industrial advisory committee/focus group as primary methods of communication.

The evaluation process included reviewing materials and reports, contacting small businesses that had participated in the program, and a telephone survey. Results were compared to recommendations proposed by the Northeast Waste Management Officials Association and the National Roundtable of State Pollution Prevention Programs for evaluation of such efforts. The overall conclusions were that the program was valuable to its clients, did a good job of promoting awareness, and that the next step was to achieve measurable waste reduction. One-on-one site visits were perceived as the most successful element of the outreach program. The most prevalent barrier to implementation of pollution prevention measures was the cost of equipment. The evaluation report for the program recommended developing a case log of projects, particularly the financial aspects, to show small businesses the value and return of investing in pollution prevention (Malcolm Pirnie, Inc., 1993).

The Erie County evaluation report demonstrates that there are measures of performance other than water quality and awareness. In this case, the report stated that the documentation of financial value/return of investment in pollution prevention (case studies) is one important indicator of program effectiveness.

6.2 Using Models to Predict Effectiveness

Data can be compiled and used to develop models to predict program effectiveness. Two models, one based on demographic data and one based on water quality data, are described in this section.

The University of California at Berkeley, Department of Agricultural and Resource Economics, conducted an interesting study with a predictability model to correlate yard ownership and the use of chemicals associated with landscaping with residential socio-demographics (Templeton, 1996). There is widespread evidence of pesticides in creeks and other surface waters throughout the San Francisco Bay Area. Yet, based upon several factors, the study determined that up to

55.5% of San Francisco Bay Area households were using and/or disposing of pesticides in a manner that might make the quality of groundwater, surface runoff, and soil worse than it is. People were found to be primarily concerned with the appearance of their yard, and less concerned with underlying biological and physical processes associated with their landscaping. Choices related to pesticide use were also determined by constraints on information, time, and money (e.g., people generally did not take the time to read labels or disposal instructions.)

Conclusions of the study of the association of environmental behaviors with demographics include: the demands for yards and yard chemicals increase with family income; the impact of children on the use of chemicals depends upon how vulnerable to exposure they are and how able they are to help with yard maintenance; among those who keep yards, ownership (vs. renting) does not affect decisions related to chemical use. The authors noted that the predictability model would be of value to policy makers who regulate the use of yard chemicals and to sellers of pesticides and fertilizers as a marketing tool.

The County and City of Sacramento and Cities of Folsom and Galt developed a model to predict stormwater program effectiveness (LWA, 1996d). They jointly developed an analysis technique using specific statistics and modeling to assess trends and long-term effectiveness of the Sacramento Comprehensive Stormwater Management Program. The database was compiled from samples collected at three urban runoff monitoring locations during eleven storm events. The constituents included in the analysis were As, Cd, Cr, Cu, Fe, Pb, Zn, NH_3, BOD, coliform bacteria, hardness, nitrate and nitrite, oil and grease, phosphorus, organic carbon, TDS, TSS, and cyanide. The mathematical model predicted changes in stormwater quality as a result of program implementation ranging from 15% to 40% over a 20-year period.

6.3 Surveys

The effectiveness of public education programs is measured in different ways—improvements in water quality, number of calls received, number of participants in workshops and events. However, the most commonly used method of measurement with respect to public education is the survey. In this section are discussed surveys that have been used to measure general awareness and campaign effectiveness with respect to stormwater and wastewater pollution prevention issues. Table 6-2 lists the surveys reviewed for this project. (No surveys were reviewed that addressed either water quality evaluations or the cost effectiveness of a program.)

Table 6-2. Public Education Surveys

Agency	Survey Background	Summary of Findings
Chesapeake Bay Program University of Maryland 1994	Attitudes survey of awareness. Telephone survey of 2,004 residents in watershed.	85% of respondents are concerned about water pollution; 1/3 attribute pollutants to businesses. Only 7% thought individuals caused water pollution. Half of the respondents thought cleanup of Chesapeake Bay is very important. Opinions differed widely on how best to spend funds for Bay cleanup (e.g., funding for prevention vs. restoration).
Milwaukee River Program 1989	General awareness of stormwater issues, habits, and willingness to pay more to achieve water quality goals. Multi-page questionnaire mailed to 5,500 residents.	Public learns about environmental issues through media and other passive methods. Respondents do take actions to prevent pollution. They are willing to pay $50 to $75 per month to achieve goals.
City of Oklahoma, Oklahoma 1995	Survey of best management practices for pesticide use. Mailed survey to 17,000 residents. 3,002 were returned.	40% of the population do not use pesticides at all. Diazinon is a pollutant of concern causing toxicity for two of the City's treatment plants. The survey confirmed that residents in the service areas of these two plants use more diazinon products than other parts of the city.
Colorado Pollution Prevention Partnership 1994	Survey included in paper presented at Water Environment Federation annual conference. Telephone survey of 300 small and medium-sized (fewer than 500 employees) businesses across Colorado.	Conclusions were presented in text, not statistics. Businesses were found to comprehend what pollution prevention means, have implemented pollution-reduction practices, and consider suppliers to be among the most knowledgeable sources of information. Cost and economics were mentioned both as a barrier to pollution prevention and an incentive to increase the efforts of businesses.
Central Contra Costa County Sanitary District 1994	General awareness survey of water pollution causes and prevention. Telephone survey of 304 residents in ten cities.	83% were concerned about water pollution (top 2 or 3 environmental issues). Over half recognized that pollutants to storm and household drains are a major source of pollution.
Alameda Countywide Clean Water Program 1994	Survey of effectiveness of billboard campaign. Telephone survey of 300 county residents.	Billboards increased awareness of stormwater issues by 36%. 29% of respondents stated that they had changed their behavior as a result of the billboard campaign.

Table 6-2, cont. Public Education Surveys

Agency	Survey Background	Summary of Findings
Alameda Countywide Clean Water Program 1996	Survey of awareness of yard chemical use. Telephone survey of 1,200 county residents; conducted in English and Spanish.	More than one in three chemical users indicated that they followed proper use and disposal practices and that runoff from their property could safely go directly into the storm drains. Residents indicated that they would be willing to make additional behavioral changes as long as they were minor and convenient.
Santa Clara Valley Nonpoint Source Pollutant Control Program 1996	General awareness survey of urban runoff issues. Telephone survey of 1,200 valley residents.	58% said that pollution of the environment was very serious compared to 58% who considered traffic congestion as very serious. The majority believed that trash in streets, improper disposal of household hazardous wastes, and oil leaking from cars caused pollution in San Francisco Bay.
Los Angeles County Department of Public Works 1996	General awareness of do-it-yourselfers' 16 years and older. Telephone survey of 2,003 county residents.	Oil changers are predominantly male, largely from African American and Latino heritage, and frequently use Spanish as their primary language. Pesticide and fertilizer users tend to be largely from the English-speaking, non-Latino population over 45. 83% of do-it-yourselfers recycle aluminum cans; 74% recycle plastic bottles. The survey recommended a multi-media (newspaper and radio) campaign along with point-of-purchase outreach.
Los Angeles County Department of Public Works 1995	General awareness of storm drain system and background information to target audiences for public education campaign. Telephone survey of 2,400 adult residents in Los Angeles County.	Pollution of waterways is a major concern, but not at the same level as crime related issues. 88% believe waterways are polluted. 71% believe groundwater is polluted and half drink bottled water. Less than 25% had seen, heard, or ready anything about storm drains. Broadcast t.v. and newspapers were top two sources of information about stormwater.
City and County of San Francisco 1992	General awareness survey of best management practices. Telephone survey of 2,801 residents.	Majority of respondents blame businesses and industry for water pollution. 41% of households get information about environmental issues from newspapers. More than 2 out of 5 people associated great health risks with solvents, drain cleaners, and pesticides. The most commonly used toxic materials were nail polish removers (51%), motor oil (47%), and house paint (42%).

Table 6-2, cont. Public Education Surveys

Agency	Survey Background	Summary of Findings
City and County of San Francisco 1994	Survey of households -- use and safe disposal of household toxic products. Telephone survey of 1,886 households.	Respondents indicated a high level of awareness of environmental issues. Compared to 1992 survey, there was an increase in awareness that households are a major source of water pollution. 33% saw public education campaign signs.
City and County of San Francisco 1996	Survey of effectiveness of Clean It! campaign. Bi-annual telephone survey of 401 residents.	15% of respondents were aware of campaign; 11% recalled the message. Street sign ads and utility bill inserts were the most effective information sources.
City and County of San Francisco 1996	Survey of effectiveness of Clean It! and The Less Toxic Garden campaigns. Survey mailed with Water Warriors! City newsletter.	Data compilation underway.
City of Seattle Solid Waste Utility by the Seattle Tilth Association 1993	Final evaluation report of Green Gardening Program. Follow-up telephone survey of participants in Green Gardening educational events.	65% of participants used pesticides of which 11% used them regularly. 68% said that they had not taken steps to reduce the use of chemicals but 88% said they planned to try some techniques they learned in the workshops in the future. 45% of participants learned something about compost use and 85% would be very likely to attend a more detailed future workshop.
U.S. Environmental Protection Agency, Region 10 1994	Study of 12 nonpoint source public education programs, including survey techniques.	Cited among the more effective outreach techniques are peer-to-peer education, financial incentives, mobile signage posting BMPs, and newsletters.
U.S. Environmental Protection Agency, Region 3 undated	Manual on measuring effectiveness of state pollution prevention programs.	Compilation of methods, questionnaires, and surveys used by various projects to measure effectiveness of waste and pollution prevention programs.

Surveys are conducted by trained researchers, not amateurs. They are carefully designed to measure different things: public awareness and habits; success of a particular campaign; an evaluation of water quality; and cost effectiveness/analysis of source control strategies and outreach efforts. Typically, survey questions are asked in telephone interviews with a randomly selected audience or in questionnaires mailed to a particular group by zip code, newsletter mailing list, or a business association. Results are carefully summarized and reported to the sponsoring agency. In some cases, the research company interprets the results and/or recommendations.

6.3.1 General Awareness Surveys

Surveys of public awareness are used to determine how well public education programs are working and how public education programs should be focused to produce the most impact. Of the ten surveys of general awareness of stormwater and pollution prevention issues reviewed, there was only one set of "before-and-after" questionnaires for a specific public education program that allowed a comparison of results. CCSF conducted awareness surveys in 1992 and 1994 and found that within those two years, a larger percentage of the public had come to realize that households were a major source of water pollution (CCSF, 1994). The survey summary comparisons also indicated the following:

- "Use: Overall levels of household use of toxic products were about the same in 1994 as in 1992, except that the rate of the use of motor oil and antifreeze declined significantly during this period.

- Unsafe Disposal Practices (UDP): Where comparisons could be made for specific products, the rates of unsafe disposal of toxics down street or house drains were about the same in 1994 as in 1992. The UDP rate (all toxic products combined) increased from an estimated 3.49% in 1992 to 6.32% in 1994.

- Support for increased local government efforts to improve water quality and to educate the public. Household residents continue overwhelmingly to support increased efforts by CCSF to improve water quality and to educate the public about toxics and their safe disposal. The level of support was about as high in 1994 as it was in 1992, and that strong support is found in all areas of the city and in all demographic groups."

The survey shows that the public education program is working and producing results within two years. During the period between 1992 and 1994, CCSF conducted at least three major public education campaigns that targeted the general public and pollutants associated with household maintenance (Clean It!), gardening (The Less Toxic Garden) and used motor oil recycling. Household hazardous waste facilities were publicized. Workshops, utility bill inserts, newsletters, public events, and using the media were all part of the public education program to deal with the issue of San Francisco Bay pollution (CCSF, 1996).

The surveys of other programs included results that would help target public education efforts. Examples of survey results that lead to a targeted program are:

- The Milwaukee River Program learned that the media best provide environmental information to residents. In fact, through the survey, the program learned that the traditional methods used by agencies (meetings, brochures, fact sheets) are rejected by most people in the lower Milwaukee River basin. Watershed practitioners were encouraged to increase their access and use of local television, newspapers, and other media in their outreach campaigns (Simpson, 1994).

- The City of Oklahoma City concluded from its survey that a public education program that targets the general public audience would be the most effective plan for addressing the City's toxicity problems. The program would also educate specific user groups. A two-year plan was developed to inform the public about the proper usage of pesticides. Many decisions in the public education program were made based upon survey results (APA, 1995).

- The survey conducted for the Los Angeles County Department of Public Works recommended that the agency focus media dollars on a campaign that combines point-of-purchase and radio advertising efforts. The survey also indicated that do-it-yourselfers frequent only a few retail stores. Therefore, a public-private partnership developed with those retail stores to educate do-it-yourselfers on environmental issues has a good chance for success (LA County, Department of Public Works, 1996).

6.3.2 Surveys that Measure Effectiveness of Campaigns

There is tremendous creativity in public education concerning environmental issues. Agencies have developed campaigns that feature billboards, points-of-purchase efforts, radio and television

PSAs, series of workshops, and many print materials. Surveys have been conducted on several of these specific campaigns to determine whether or not a single approach (e.g. billboard) changed the public's level of awareness or behavior.

The Alameda Countywide Clean Water Program reported the results of pre- and post-advertising surveys conducted in 1994 regarding an advertising campaign that featured billboards, newspaper ads, and busboards on county transit buses. The outdoor billboards showed a couple running through fuscia-colored water discussing the effects of pouring paint in storm drains. The overall campaign showed snapshots of residents unknowingly "planning" to pollute the bay by various activities, such as dumping paint and oil in their nearby storm drain.

Telephone surveys of 300 residents indicated a pre- and post-advertising awareness of the issues of 46% and 70%, respectively. Furthermore, the post-advertising survey showed that more than 40% of the respondents stated they were more careful in handling pollutants.

According to Sharon Gosselin, the public information/participation coordinator of Alameda County's program, "It (the survey) also suggested that the next stage of communication efforts should focus more on the indirect ways that contaminants enter the storm drain as well as continue to promote alternatives to polluting and alternative behaviors and disposal methods. The post-advertising campaign survey validates this approach" (Alameda County, no date, Pure Water).

The survey that evaluated the City and County of San Francisco's **Clean It!** campaign yielded a great deal of information about the numbers of people who learned something about safer housecleaning, including:

- Of the respondents who stated that they learned something related to the campaign, 51% got their information solely from street signs. This meant that if street signs had not been part of the overall strategy, between 11,285 and 25,925 households would not have gotten the message.

- "Vinegar makes windows sparkle" was a campaign message that motivated 2.7% of the population to use vinegar instead of toxic cleaning products. This accounts for between 4,270 and 14,845 households citywide (CCSF, 1996).

CHAPTER 7.0

SUMMARY AND RECOMMENDATIONS

This chapter presents (1) the summary of project findings; and (2) recommendations for future research to address information gaps regarding stormwater and wastewater pollution prevention programs targeting commercial and residential sources.

7.1 Summary

Project results with respect to monitoring and source identification, commercial sources of pollutants, residential sources of pollutants, public education programs and program effectiveness are summarized in the following subsections.

7.1.1 Monitoring and Source Identification

Forty-eight monitoring studies conducted to identify wastewater and stormwater pollutants and their sources were reviewed (see Chapter 2.0). While this was by no means an exhaustive review, the results are representative of the current status of pollutant and source identification efforts for wastewater and stormwater. The pollutants evaluated in these studies are listed in Table 7-1.

Metals were the most commonly evaluated group of pollutants, with 36 of the 48 studies addressing metals. Metals studies have been conducted for both stormwater and wastewater. Metals that have commonly been measured at levels of concern include copper, mercury, nickel, lead and zinc.

Pesticides appear to be an area of emerging interest and recent activity. Fourteen of the studies evaluated pesticides or their sources for stormwater and/or wastewater. Organophosphate pesticides (e.g., chlorpyrifos and diazinon) are of particular concern because they have been linked to discharge and receiving water toxicity in many parts of the country.

Table 7-1. Summary of Pollutants Evaluated
(out of 48 studies)

Category	Number of Studies	Pollutants Most Commonly Evaluated
Metals	36	Cu, Hg, Ni, Pb, Zn
Pesticides	14	chlorpyrifos, diazinon
Organics	13	PAHs, solvents, hydrocarbons
Nutrients	10	phosphorus, ammonia
Conventional	9	BOD, TSS, oil and grease
Others	5	cyanide, tributyltin

A number of studies identified other organic pollutants at levels that have the potential to be of concern to wastewater or stormwater. These pollutants include bis-(2-ethylhexyl)phthalate, dioxins, PCBs, and PAHs. Solvents and hydrocarbons were also evaluated in some of these studies. Despite the number of monitoring studies that have addressed organic pollutants, the data are limited by the high cost of conducting laboratory analyses for many of these compounds and because, for a number of these pollutants, the analytical detection limits are higher than water quality standards. This makes it difficult to determine if many organic pollutants are present at levels of concern.

Numerous studies (19) evaluated levels of conventional pollutants and nutrients. Most of these studies addressed stormwater. Much of the effort regarding nutrients has been conducted on the East Coast, particularly in the Chesapeake Bay Area.

With respect to source identification, several studies evaluated wastewater or runoff from commercial or residential areas. Few of these studies have sought to identify specific sources (e.g., individual businesses, specific residential activities) within the commercial or residential area. In addition, little work has been done to identify the pathways that transport the pollutants of concern from commercial or residential sources to wastewater or stormwater.

In general, studies that have investigated specific commercial businesses or residential activities have done this by evaluating operations and materials used rather than through wastewater or runoff sampling. Some exceptions are the Central Contra Costa Sanitary District residential metals study and investigations of auto-recyclers described in Chapters 3.0 and 4.0. It is often difficult to obtain representative wastewater or runoff samples from small businesses or residential sources.

7.1.2 Commercial Sources of Pollutants

Several strategies have been developed to address commercial sources including permitting, educational outreach, recognition programs, and business assistance centers. These approaches have been well-developed throughout the country.

Commercial sources evaluated are listed in Table 7-2 along with the number of programs which evaluated each source. While this is not an exhaustive list of every program working with commercial sources, it is believed to be representative of the current status with respect to evaluating and controlling commercial sources.

Many programs all over the country have developed source control programs for addressing vehicle service facilities, construction activities, and food service businesses. Reasons for this are that most communities have many businesses that fall into these categories and that these businesses are subject to multiple regulatory programs (e.g., wastewater, stormwater, air quality, hazardous materials, health services, etc.).

Source control programs have also been developed for printers, painting contractors, dentists, laboratories, medical facilities, photoprocessors, landscape maintenance, dry cleaners, and machine shops. It should be noted that some of the programs addressing printers, dry cleaners and machine shops focus more on air emissions and hazardous materials generation than wastewater or stormwater issues. In general, there appears to be considerable information regarding these sources.

Sources for which little work has been done include brake pads, existing development, wood finishers, jewelry manufacturers, mobile cleaners, cooling water systems, commercial pesticide users, new development, and ceramics studios. Of these sources, the following have the potential to have discharges containing pollutants at significant levels: brake pads, existing development, new development, mobile cleaners, and pesticide users. These sources may be effectively addressed through pollution prevention approaches.

Table 7-2. Pollutants Associated with Commercial Sources

Commercial Source	Wastewater or Stormwater	Associated Pollutants	Number of Programs	Number of Regions
Existing development	Stormwater	Metals, pesticides, nutrients, vehicle fluids	2	1
Brake pads	Stormwater	Copper, lead, zinc	3	1
Ceramics	Wastewater	Metals, solids	3	2
Wood finishers	Wastewater	Solvents, metals	4	3
Jewelry manufacturing	Wastewater	Silver, cyanide, copper	5	3
Landscape maintenance	Stormwater	Nutrients, pesticides	12	3
Mobile cleaners	Stormwater	Solvents, metals, oil & grease, detergents	6	3
Cooling water systems	Wastewater	Copper, tributyltin, zinc, lead	8	4
New development	Stormwater	Sediment, nutrients, pesticides, solvents, metals	9	4
Painting contractors	Both	Solvents, metals	10	5
Laboratories and medical facilities	Wastewater	Mercury, silver, selenium, copper, formaldehyde, phenolics, cyanide, solvents, xylenes, radioactive wastes	13	5
Boatyards/ marinas	Stormwater	Solvents, engine fluids, sewage	12	5
Dry cleaners	Wastewater	Perchloroethylene	17	5
Machine shops	Wastewater	Metals, oil & grease, solvents	16	5
Food service businesses	Both	Oil & grease	23	5
Dentists	Wastewater	Mercury, silver	14	6
Photoprocessors	Wastewater	Silver, selenium	18	7
Construction	Stormwater	Sediment, nutrients, pesticides, solvents, metals	28	8
Printers	Wastewater	Metals, solvents	26	9
Vehicle service facilities	Both	Metals, oil & grease, solvents, PAHs	45	10

No information was collected during this project regarding programs addressing over-the-counter products containing ingredients that result in wastewater or stormwater pollution. Little information appears to be available concerning this topic. Some examples of products containing ingredients of interest include pesticides (e.g., copper stabilizers in cooling water additives) and cleaning products (e.g., zinc in floor waxes, tributyltin in toilet bowl and carpet cleaners).

Such products typically do not provide a complete list of chemical contents, primarily because manufacturers consider the formulations proprietary. While the Material Safety Data Sheet (MSDS) must list human health hazards, listing of water pollutants is not required. Further, for pesticides, inert ingredients (e.g., copper stabilizers in cooling water additives) need not be disclosed on the label or MSDS. In most cases, even if the presence of a pollutant of interest is noted on product information, the concentration of the material is not specified. These conditions make identifying product related sources difficult and expensive.

7.1.3 Residential Sources of Pollutants

Several approaches are available to address residential sources of pollutants, including public education, legislative strategies, and technology-based strategies. The most commonly used approach for residential sources is public education. In many cases, technology-based strategies or legislative strategies are beyond the jurisdiction of local governments, and therefore, are rarely used to address residential sources. Exceptions include pH control of the water supply to address corrosion and the product restrictions for copper sulfate root control products enacted in the San Francisco Bay Area.

Residential sources that have been evaluated for this project are listed in Table 7-3. This list is representative of the current status of efforts nationwide regarding residential sources. As is shown in Table 7-3, most of the programs developed targeting residential sources focus on landscape maintenance or household cleaners. In most cases, landscape maintenance outreach targets general practices as opposed to specific products. With respect to household cleaners, much of the outreach targets products that have been determined to be of little concern to wastewater.

A moderate amount of work has been done to address water supply corrosion and home vehicle maintenance. Effective source control for corrosion has been to work with the water purveyors to reduce the corrosivity of the water supply. Little work has been done to address laundry graywater, pools and spas, painting activities, root control products or pet care. Laundry graywater appears to be a significant source of several metals in wastewater.

Table 7-3. Pollutants Associated with Residential Activities

Residential Source	Concern to Wastewater or Stormwater	Associated Pollutants	Number of Programs	Number of Regions
Pet care	Wastewater, Stormwater	pesticides (flea dips), animal wastes	4	3
Laundry graywater	Wastewater	heavy metals	5	2
Pools and spas	Stormwater, Wastewater	chlorine, copper	5	1
Painting activities	Stormwater	heavy metals, solvents	7	4
Indoor pest control	Wastewater	pesticides	10	6
Corrosion	Wastewater	Cu, Pb, Zn	11	6
Root control products	Wastewater	copper	12	2
Vehicle maintenance	Stormwater	oil, heavy metals	15	7
Household cleaners	Wastewater	solvents, ammonia, bleaches	20	9
Landscape maintenance	Stormwater	pesticides, nutrients	24	8

Painting activities do not appear to represent a substantial source of metals or other pollutants of concern. Pools and spas and root control products are associated primarily with copper. Pet care is likely to be a significant source of pesticides to wastewater.

Much of the work regarding residential sources of pollutants has focused on identifying these sources. Outreach targeting residential activities tends to be focus on creating general awareness rather than targeting specific activities. Where outreach is specific, programs appear to be effective. Some examples include programs targeting used motor oil and the Greenville, Texas, effort to eliminate wastewater toxicity by educating the public regarding diazinon. Focused outreach efforts such as these are few.

Another limitation regarding residential sources is that, once a pollutant's source is identified as residential, effective control strategies can be difficult to implement. Control of residential sources requires effective public education to reach the right audience and elicit behavior change. Some residential control strategies would require the use of an alternative consumer product. Both of these approaches are difficult to implement effectively.

7.1.4 Public Education Programs

There is an extensive effort throughout the country to educate the public on preventing stormwater and wastewater pollution. The messages communicated are fairly uniform from program to program. The general public and targeted audiences are being told what the environmental concerns are and what they as individuals can do about them. However, while the public is being given the same key messages, there is no uniform catch-phrase. By comparison, other environmentally-oriented programs, such as recycling and litter control, have phrases that are consistently used to reinforce the central message: The "Three Rs of Recycling: Reduce, Reuse, Recycle" and "Give a Hoot, Don't Pollute" are examples. From a marketing point of view, a consistent message would help stormwater and pollution prevention programs achieve stronger public recognition of the issues.

Approximately 30 of the 75 agencies providing public education materials for this project developed materials that communicate general messages to the general public. Approximately half of the 30 agencies augmented the general message materials with brochures, newsletters, guides, and other printed materials that targeted specific activities, such as vehicle and household maintenance and gardening.

With respect to educational materials that have been prepared for businesses (15 of 75 agencies), it would appear that a moderate level of progress has been made. Business coalitions have been formed, grant programs implemented, training sessions conducted, and print materials distributed. In addition to educational materials, there are numerous brochures defining best management practices (BMPs) for businesses. Combining educational outreach to businesses with the BMP materials that have been produced and distributed, indicates a substantial effort to educate the business community.

Twenty-three agencies provided materials that showed their efforts to provide water quality information to school-age children. School children are not a major source of pollution; however, they serve as role models, reinforce environmental messages within their households, and carry what they learn into future generations.

Of the other public education programs, 8 agencies targeted employees of government agencies for stormwater and pollution prevention education in order to set an example for others in the community.

Public education programs are also being developed to target ethnic segments of communities. Public service announcements and articles are prepared for radio stations and publications targeting specific communities. Some programs have also researched values and cultural issues specific to a given ethnic community and used this information to develop effective campaigns.

Watershed management is increasingly being used as a framework for environmental action. This approach attempts to bring stakeholders representing different interests to the table together, recognizing the contributions and issues of each party. The watershed/stewardship approach broadens the outlook of the various participants in that they are encouraged to understand each other's issues and concerns. There are a number of models to help stakeholders and the public learn about watersheds and the mix of issues that are involved in keeping waterways clean.

Gradual improvement in the effectiveness of public education programs is expected from the increased use of social marketing and behavioral change principles. Research in these areas indicates that providing information alone will not change behavior. The better approach involves identifying the desired outcome, identifying the appropriate audience, learning about that audience, and understanding its particular barriers to change. Methods have been developed to overcome these barriers in other fields (i.e., energy conservation and health care) that can be applied to wastewater and stormwater pollution prevention.

7.1.5 Program Effectiveness

While many agencies have indicated a need to evaluate the effectiveness of their programs, little information is available concerning available tools for measuring effectiveness. Some information is available on using water quality measurements and surveys as indicators of program effectiveness. Other indicators include increases in opportunities to reuse effluent and biosolids, protection of worker health and safety, protection of POTW operation, and financial value.

One obvious method of measuring program effectiveness is through improvements in water quality. There is very little information available on programs that have used this as an indicator of successful commercial and residential programs. When dealing with diffuse sources, such as small businesses or homeowners, it is difficult to see measurable differences in water quality as a result of pollution prevention efforts. Notable exceptions include:

- Reduction of silver levels in the Palo Alto treatment plant effluent attributed to a pollution prevention program directed at photoprocessors;
- Reduction in copper levels in Novato Sanitary District treatment effluent attributed to corrosion control measures; and
- Reduction in whole effluent toxicity in the Greenville treatment plant effluent attributed to a diazinon outreach program.

In each of these cases, a specific pollutant issue could be traced back to a specific commercial or residential activity. This suggests that to use water quality improvement as an effectiveness indicator, it may be necessary to conduct focused programs such as these.

Models can be developed to predict program effectiveness using baseline information. Two such models, one using demographic data and one using water quality data, are discussed in Chapter 6.0.

Surveys are another indicator used to measure the effectiveness of public education programs. Surveys help either validate that the educational efforts are working or that they need to be fine-tuned to become more effective. In addition, surveys have helped identify the most effective tools for communicating with the public (e.g., the media, utility bill inserts, and street signs).

7.1.5 Program Effectiveness

While many agencies have indicated a need to evaluate the effectiveness of their programs, little information is available concerning available tools for measuring effectiveness. Some information is available on using water quality measurements and surveys as indicators of program effectiveness. Other indicators include increases in opportunities to reuse effluent and biosolids, protection of worker health and safety, protection of POTW operation, and financial value.

One obvious method of measuring program effectiveness is through improvements in water quality. There is very little information available on programs that have used this as an indicator of successful commercial and residential programs. When dealing with diffuse sources, such as small businesses or homeowners, it is difficult to see measurable differences in water quality as a result of pollution prevention efforts. Notable exceptions include:

- Reduction of silver levels in the Palo Alto treatment plant effluent attributed to a pollution prevention program directed at photoprocessors;

- Reduction in copper levels in Novato Sanitary District treatment effluent attributed to corrosion control measures; and

- Reduction in whole effluent toxicity in the Greenville treatment plant effluent attributed to a diazinon outreach program.

In each of these cases, a specific pollutant issue could be traced back to a specific commercial or residential activity. This suggests that to use water quality improvement as an effectiveness indicator, it may be necessary to conduct focused programs such as these.

Models can be developed to predict program effectiveness using baseline information. Two such models, one using demographic data and one using water quality data, are discussed in Chapter 6.0.

Surveys are another indicator used to measure the effectiveness of public education programs. Surveys help either validate that the educational efforts are working or that they need to be fine-tuned to become more effective. In addition, surveys have helped identify the most effective tools for communicating with the public (e.g., the media, utility bill inserts, and street signs).

solution might not be acceptable from a water quality retrospective. Successfully addressing these communication gaps between environmental programs is necessary.

In addition, it is becoming increasingly clear that a number of pollutants in stormwater and receiving water emanate from other media, such as airsheds above watersheds and groundwater basins near receiving water bodies. Airsheds have been identified as a significant contributor of nutrients to the Chesapeake Bay and acid rain to northeastern lakes. Pollutants, such as pesticides, dioxin, PAHs, and some heavy metals, also appear to be entering watersheds from the airsheds above them. Because environmental regulation in the U.S. is media-based, information on the existence, fate, and transport of pollutants from one medium to another is not necessarily covered by existing regulations and programs. A forum for communication between environmental programs would also help address this issue.

3. Conduct a monitoring program on non-stormwater discharges.

One of the two primary goals of the Federal stormwater regulations is to eliminate non-stormwater discharges to storm drain systems. However, very few data address the quality and quantity of the wide range of non-stormwater discharges (e.g., swimming pool discharges, vehicle washwater, pumped groundwater) present in most communities. This lack of data impedes the efforts of municipal stormwater programs to meet their Federal mandate. Representative monitoring data would allow stormwater management programs to focus their efforts on the non-stormwater discharges of most concern and facilitate the acceptance of these discharges by wastewater agencies.

4. Develop a wastewater/ stormwater pollution prevention information resource.

A mechanism for sharing information about water pollutant source control programs and public education materials should be created. This would allow agencies throughout the country to share information about pollutant sources and effective source control approaches. It would also allow public information materials already developed by others to be made available to all.

5. Develop tools to measure program effectiveness.

Very little information is available on the effectiveness of pollution prevention programs aimed at commercial and residential sources. Two factors contribute to this: (1) the difficulty of measuring the effectiveness of programs targeting such diverse sources; and (2) the unavailability of tools for this purpose. Research is needed to develop tools to measure the effectiveness of wastewater, stormwater, and public education programs. Measurements of effectiveness will help program managers focus their resources on the most effective control measures and improve the overall results of their efforts.

6. **Develop pollution prevention strategies for the following sources: automotive brake pads, pesticides, existing commercial development, mobile cleaners, laundry graywater, new development, and vehicle-related areas.**

These sources have been identified as potentially significant with respect to stormwater or wastewater pollution, but as yet, little work has addressed them. Effective reduction of the adverse water quality impacts from these sources requires future efforts to evaluate the sources and to develop effective control strategies as discussed in the following paragraphs.

Brake pads. As discussed in Chapter 3.0, automotive brake pads are a potentially significant source of copper. Research is needed to determine the fate and transport of copper from the brake pads to stormwater and then to surface water. The results of this research would help determine whether product modification would improve water quality. A voluntary partnership has been forged between local governments and industry to address these issues. The effectiveness of this partnership would be enhanced by national exposure and support of local governments nationwide.

Pesticides. There is increasing concern with pesticides in stormwater and wastewater. With respect to the water quality impacts of pesticides from these sources, there are three aspects of pesticides that could benefit from further research or program development.

First, there is a need to develop public outreach programs which target indoor pest control, pet care, and commercial users of pesticides (e.g., pest control operators, landscaping businesses, and small businesses with landscaping on-site). There has been a great deal of public outreach targeting use of pesticides for lawns and gardens, but little or none for these other potentially important uses.

Second, there is a need to develop outreach programs which target specific pesticides, rather than pesticides in general, where specific pesticides have been identified as sources of water quality impairment. It is increasingly common to find that specific pesticides are causing violation of water quality standards, in which case it is prudent to target those pesticides, rather than pesticides in general, for control.

Finally, there is a need for US EPA to investigate the feasibility of modifying its pesticides registration processes so that: (1) they consider potential water quality impacts resulting from pesticides in wastewater and stormwater; and (2) they consider inert, as well as active ingredients. US EPA's current pesticides registration processes require analysis of groundwater impacts for pesticides, but do not require the types of analysis necessary to determine whether the product could adversely impact surface waters through stormwater runoff or wastewater treatment plant discharges. In addition, US EPA's registration processes do not routinely consider the impacts of inert ingredients on surface water quality. In some cases, the inert ingredients (e.g., copper) can pose as great a water quality threat as the active ingredients.

Existing Commercial Development. Existing commercial development, such as office buildings, educational institutions, shopping malls, hotels and other buildings with a mix of business activities, can be a significant source of pollutants in wastewater and stormwater. Potential sources of wastewater or stormwater pollutants from such development include landscape maintenance, cooling water systems, food service operations, mechanical and auto repair facilities, parking lot cleaning, and other facility maintenance activities. Because of the variety of businesses involved, identifying and outreaching to this group is difficult. However, because of their potential contribution to wastewater and stormwater, programs need to be developed to identify and outreach to this group.

Mobile Cleaners. Surface cleaning operations, often performed by mobile cleaners, produce discharges that are of concern with respect to wastewater or stormwater, depending upon where the discharges are directed. The discharges contain both cleaning chemicals, such as soaps and solvents, and removed materials, such as oil and grease from parking lots and paint from building surfaces. Programs are needed to contact mobile cleaners, characterize their discharges, and develop effective pollution prevention programs. Mobile cleaners are challenging to identify and contact because they do not work at specific locations. The BASMAA pilot project described in Chapter 3.0 developed approaches to working with this group that might provide a successful model for other communities.

Laundry Graywater. Laundry graywater appears to be a significant source of several metals in wastewater. Control of this source would be either through the use of graywater systems or through the development and use of metal free dyes in clothing. Implementing either of these measures would be difficult at the local level. Use of graywater systems requires extensive public outreach and cooperation between the wastewater authority, building and planning departments, developers, landscape businesses, and plumbing unions. Development of metal-free dyes would require a national coalition of local governments and industry representatives. The effectiveness and feasibility of these potential control strategies needs to be investigated.

New Development. While BMPs related to construction activities are well developed, practices relating to planning and design of new development need to be evaluated. It might be feasible to lay out new development so as to reduce the potential for contaminating stormwater runoff. It might also be feasible to use building materials that would reduce the pollutants present in both wastewater and stormwater. For example, use of non-copper plumbing materials would reduce copper loadings in wastewater due to corrosion.

Vehicle Related Areas. Vehicles have been identified as a significant contributor of some of the most ubiquitous pollutants of concern in surface waters (e.g., oil and grease, PAHs, and heavy metals). A significant portion of these pollutants reach surface waters as a result of stormwater runoff from roads, bridges, parking areas, and driveways. These vehicle related areas take up considerable space in our communities, and in many cases, they are connected directly to storm drain systems. As a result, pollutants in runoff from these areas are transported directly to surface waters. Research is needed on how to reduce the pollutants in stormwater runoff from vehicle related areas.

7. Application of scientific principles to public education.

As evidenced by the results of this assessment, wastewater and stormwater agencies are beginning to use pollution prevention programs, as opposed to end-of-pipe treatment, to achieve additional pollutant reductions. Key to the success of these programs will be the ability of public education programs to bring about behavioral changes in society. Most public education programs aimed at reducing pollutant sources in wastewater and stormwater, however, are relatively unscientific. For public education programs to reach the majority of the population and effect behavioral changes, it will be necessary to incorporate psychological and marketing principles and techniques that have been successfully used in other fields. Research is needed as to how to apply these scientific principles and techniques to effect behavioral changes in the context of wastewater and stormwater pollution prevention programs.

8. **Produce a CD-ROM containing examples of public education materials.**

The project team collected many examples of public education materials directed at wastewater and stormwater programs. These materials could serve as a valuable resource to wastewater and stormwater agencies that are interested in developing new public education materials or in modifying existing materials. An efficient mechanism to make this material available to interested parties would be to place it on a CD-ROM. This would provide a single, easily accessible resource containing full color presentations of public education materials developed by others. The CD-ROM could be updated periodically and distributed through WERF. A catalog could accompany the CD-ROM.

9. **Develop a uniform catch phrase for wastewater and stormwater pollution prevention programs.**

Although there are numerous messages being communicated to the public with respect to wastewater and stormwater pollution prevention, there is no uniform catch-phrase or slogan (e.g., "Give a Hoot, Don't Pollute"). Efforts should be made to develop a uniform, nationwide catch-phrase for the wastewater and stormwater pollution prevention programs. This would result in stronger public recognition and thereby facilitate achievement of program goals.

10. **Focus pollution prevention strategies and public education materials on locally important pollutants of concern.**

Pollution prevention strategies and associated public educational materials have tended to be rather generic. They have typically focused on general pollutant classes (e.g., pesticides or motor oil) and/or specific pollutant sources (e.g., construction activities or vehicle repair facilities). Although it is desirable to reduce the discharge of all pollutants to all waters, the success of individual wastewater and stormwater pollution control programs will ultimately be judged on whether water quality standards are achieved. Local pollution prevention efforts, therefore, need to be focused more directly on the control of those pollutants which are responsible for exceedance of standards in local waters. This will involve: (1) identifying the pollutants which are responsible for violation of standards; (2) identifying possible community sources of those pollutants; (3) quantifying and prioritizing the sources; and (4) developing pollution prevention program to address the significant community sources of the pollutants of concern. Developing pollution prevention and public education programs in conjunction with the watershed approach should help focus these programs on locally important pollutants of concern.

7.2.2 Assigning Priorities to Workshop Recommendations

The findings of the project team and the resulting recommendations were presented at a workshop at WEFTEC '96 in Dallas, Texas, on October 5, 1996. The recommendations were discussed by the workshop participants, consolidated in some cases, and assigned priorities. The following recommendations were given the highest priority by the workshop participants:

1. **Develop and maintain a clearinghouse or information resource on wastewater and stormwater issues as described in Recommendation #4.**

This clearinghouse would be organized by specific pollutants and sources. It would contain information on monitoring data, control strategies, and the effectiveness of these control strategies. The CD-ROM described in Recommendation #8 in the previous subsection could be included as part of this clearinghouse.

2. **Develop monitoring and sampling protocols to be used for residential/ commercial wastewater and stormwater.**

The protocol would specify various parameters including equipment, sample type, sampling site criteria, sampling frequency and duration, clean techniques, quality assurance/quality control methods, data analysis methods, and detection limits. The developed protocols would allow data from different studies to be compiled and compared throughout the country.

3. **Characterize non-stormwater discharges through a monitoring program as described in Recommendation #3.**

Few data are currently available for the wide range of non-stormwater discharges present in most communities. Representative monitoring data would allow stormwater management programs to focus their efforts more effectively.

4. **Conduct research to identify motivators that are most effective in changing behavior as described in Recommendation #7.**

Other programs (e.g., energy conservation and health care) have successfully used social marketing techniques and behavioral change principles to achieve desired results with respect to behavior modification. Research is needed as to the application of these principles to public education efforts regarding wastewater and stormwater pollution prevention issues.

5. **Develop methods of assessing effectiveness of source control programs as described in Recommendation #5.**

Most agency staff contacted for this project expressed a need for tools to measure program effectiveness. Development and use of these tools will help program managers to focus their resources on the most effective control measures and improve the overall results of their efforts.

APPENDIX A

SOURCE CONTROL ASSESSMENT CONTACTS

WERF Source Control Assessment Agency Contacts

Region	State	Organization/Agency	Contact	Phone No.
1	Massachusets	MA Office of Technical Assistance, 100 Cambridge St., Suite 2109, Boston, MA 02202	Grace Offen HHW Coordinator	617-727-3260 x 696 (p) 617-727-3827

APPENDIX B

COLLECTING INFORMATION FOR THE PROJECT

The following guidelines were used to collect information in two parts. The first part was conducted over the telephone following the guidelines in the sections entitled Introduction and General. The second part consisted of the numbered sections and was conducted according to the contact's preference by phone, fax, or e-mail.

INTRODUCTION

(Introduce yourself and describe the project. Use the following paragraph as a guideline)

Larry Walker Associates (LWA) was awarded a grant from the Water Environment Research Foundation to conduct an assessment of existing information and programs concerning residential and commercial sources of wastewater and stormwater pollution. The first task in this project is to review the relevant literature and program information. Specifically, we are looking for information in the following areas:

- Identification of pollutants of concern from residential and commercial sources (e.g., data and descriptions of studies)
- Source control strategies used to address commercial and residential sources
- Effectiveness of these strategies used to address commercial and residential sources
- Stormwater and wastewater pollution prevention activities and public education programs

LWA and Harris and Company are developing a bibliography of this information. We would appreciate it if you would answer the following questions as they pertain to your program and provide us with a list of reports, articles, etc., that describe the information.

(Next, keep a record of each call. Start with the following basic information)

Name of person spoken to:

Title:

Organization:

Areas of expertise (e.g., stormwater, wastewater, pollution prevention, public education):

How do you want to receive and respond to our survey? (phone interview, fax, or e-mail)

GENERAL (Ask all contacts the following questions on the phone)

What are the pollutants of concern in your region (or for your agency)?

Which bodies of water are affected?

Which agencies, pretreatment programs, regional boards, other groups are considered leaders or have done the most work in **Water** (wastewater or stormwater) pollution prevention?

Who are contacts for these programs (phone number, address, fax number, e-mail)?

Stormwater contact?

Wastewater pollution prevention contact?

Outreach/public education contact?

The rest of the information can be obtained in a phone interview or faxed or e-mailed to the contact after the above phone conversation has been conducted. Wastewater and Stormwater contacts should respond to Sections I, II, III, IV, and V. Public education contacts should respond to Sections I, V, and VI.

WATER ENVIRONMENT RESEARCH FOUNDATION
RESIDENTIAL AND COMMERCIAL SOURCE CONTROL ASSESSMENT

Larry Walker Associates (LWA) was awarded a grant from the Water Environment Research Foundation to conduct an assessment of existing information and programs concerning residential and commercial sources of wastewater and stormwater pollution. The first task in this project is to review the relevant literature and program information. Specifically, we are looking for information in the following areas:

- Identification of pollutants of concern from residential and commercial sources (e.g., data and descriptions of studies)
- Source control strategies used to address commercial and residential sources
- Effectiveness of these strategies used to address commercial and residential sources
- Stormwater and wastewater pollution prevention activities and public education programs

LWA and Harris and Company are developing a bibliography of this information. We would appreciate it if you would answer the following questions as they pertain to your program and provide us with a list of reports, articles, etc. that describe the information. WE ARE NOT ASKING FOR COPIES OF THE MATERIALS AT THIS TIME, JUST A LIST OF WHAT IS AVAILABLE. We may ask to review the actual materials in the near future. We appreciate your assisting us with this project.

Please send your responses and lists to either person listed below:

Betsy Elzufon
Larry Walker Associates
509 Fourth Street
Davis, CA 95616
Phone: 916-753-6400
FAX: 916-753-7030
E-mail: lwa@davis.com

Christine Harris
Harris & Company
P.O. Box 72237
Davis, CA 95617
Phone: 916-7588-2100
Fax: 916-758-2211
E-mail: harcomp@aol.com

If your area of work or expertise is stormwater or wastewater or pollution prevention, please answer sections I through V. If your area of work or expertise is public education, please answer sections I, V, and VI.

I. CONTACT INFORMATION

Name:

Title:

Organization:

Address:

Phone number:

Fax number:

E-mail address:

Are there any other programs or people that you would recommend we contact?

II. SOURCES

How are pollutants of concern identified and prioritized?

How are sources of pollutants identified and prioritized (e.g., sampling, wastewater monitoring, other methods) ?

Which commercial sources (businesses, commercial activities - e.g., printers, cooling towers, auto repair shops, car washes) have been evaluated as sources of stormwater or wastewater pollution?

Which residential sources have been evaluated as sources of wastewater or stormwater pollution (e.g., home pesticide use, household products, laundry graywater)?

Has corrosion of plumbing been evaluated as a source of pollutants?

Has the source water been evaluated as a source of pollutants?

For any reports or articles on the programs/ materials described in this section, please provide the title, date, author & phone number, and a paragraph describing it if possible.

III. SOURCE IDENTIFICATION

Has monitoring of the sewer system or storm drain system been conducted to identify commercial or residential sources?

Has sampling been conducted for individual businesses or residential areas?

Has commercial or residential monitoring been conducted as part of a Local Limits evaluation?

Have specific products (e.g., printers ink, used motor oil, commercial pesticides, household cleaners) been analyzed or evaluated?

What other methods have been used to identify sources?

For any reports or articles on the programs/ materials described in this section, please provide the title, date, author & phone number, and a paragraph describing it if possible.

IV. SOURCE CONTROL STRATEGIES

What source control strategies or pollution prevention activities have been developed for each source (e.g., permitting, public outreach, focused business outreach, financial incentives, development of Best Management Practices)?

Have other pollution prevention activities been conducted that may not target a specific source?

Engineering studies?

Economic studies?

Evaluation of environmental benefits?

For any reports or articles on the programs/ materials described in this section, please provide the title, date, author & phone number, and a paragraph describing it if possible.

V. PROGRAM EFFECTIVENESS

Have public awareness surveys been conducted?

Have responses to outreach been tracked (e.g., logging phone calls made in response to a brochure, advertisement, etc.)?

Have buying habits been tracked?

Have surveys been conducted?

Has wastewater levels of pollutants been tracked?

Have cost analyses been conducted?

Other methods of measuring effectiveness?

For any reports or articles on the programs/ materials described in this section, please provide the title, date, author & phone number, and a paragraph describing it if possible.

VI. PUBLIC OUTREACH

What is the goal and/or purpose of the public outreach/ information program?

Methods of outreach - workshops, flyers, radio, newspaper, television, school programs.

Audiences - businesses, business groups, adults, students, environmental organizations, service organizations.

What types of public information materials have been used or are being used in the public information program? **(Please provide titles and brief description of these materials)**

Advertisements (magazine, billboards, other)

Brochures

Displays, exhibits

fact sheets

Guide books/ How-to booklets/ Manuals

Newsletters

Posters

Calendars

Press/ Media Kits

Public Service Announcements

School curriculum/ program

Slide shows/ speakers bureau

Specialty items/ give-aways

Storm drain stenciling program

Videos

Other materials

What languages are used in the public information materials?

Are the materials developed by the agency or by consultants?

Have you won awards or received other forms of recognition for the public information program?

For any reports or articles on the programs/ materials described in this section, please provide the title, date, author & phone number, and a paragraph describing it if possible.

APPENDIX C

ADDITIONAL MONITORING AND SOURCE IDENTIFICATION STUDIES

Table C-1. Summary of Additional[1] Monitoring and Source Identification Studies[2]

Region	Agency (and affected body of water, if specified)	Type of Monitoring	Pollutants Evaluated	Source ID Methods	Sources Targeted
I	MA Office of Technical Assistance for Toxics Use Reduction	WW, SW	oil & grease	sampling, literature	restaurants, household products
I	MA Water Resource Authority (MA Bay, Boston Harbor)	WW	Cu, Pb, Hg, Petroleum hydrocarbons, pesticides	sampling	• 5 yrs. strictly residential data • starting to look at commercial • some sampling of car washes
IV	NC Division of Env. Management	SW	not specified	sampling, MS4 programs, literature	those included in MS4 programs (unspecified)
IV	Dade County Dept. of Env. Resources Management	WW, surface water	Pesticides, Hg, PB, Organic Solvents	sampling=all businesses on sewer & septic are sampled regularly, citizen complaint results in residential sampling	residential (used motor oil, home chemicals, litering), lead in drinking water (corrosion)
IV	Lee County Div. of Natural Resources Management	WW	not specified	sampling, field assessment/verifications	commercial areas and indiv. businesses (unspecified)
V	City of Muncie	WW,SW	Cu, Zn, others (not specified)	monitoring urban sewers, residential areas	laboratories, other (non specified)
VII	Kansas Dept. of Health	WW	chlorine, ammonia, Cu, Hg	monitor streams & rivers	not specified
VII	Johnson Co. Unified Wastewater Dist. (Indian Creek)	WW, SW	Cu, pesticides (diazinon)	tox. testing during wet weather, monitoring inflow	not specified

R0026214

Table C-1, cont. Summary of Additional[1] Monitoring and Source Identification Studies[2]

Region	Agency (and affected body of water, if specified)	Type of Monitoring	Pollutants Evaluated	Source ID Methods	Sources Targeted
VII	Lincoln/Lancaster County POTW (Salt Creek)	WW	ammonia, Hg, diazinon, atrizene, chlorpyrifos	waste inventories	auto repair, photo processing, other (unspecified)
VIII	Denver Regional Council of Governments (South Platte River, all streams, etc.)	SW	dissolved metals, nitrogen, phos., ammonia, DO	not specified	abandoned mines
VIII	DEQ-WQD, Stormwater Program (Montana) (Ashley Creek, Flathead Lake, others)	SW	sediment, BOD, COD, hydrocarbons	permit sampling, research projects, complaint investigation sampling, SIC codes	commercial sources (unspecified), home pesticide/herbicide use, household products, paints, solvents, fuel, etc.
IX	East Bay Municipal Utility District (EBMUD) (San Francisco Bay)	WW	copper	EBMUD plant interceptor, Bay monitoring data, self monitor. data, literature	radiator shops, dry cleaners, photoprocessors, auto repair/body, printers, boatyards, furniture finishers
IX	City of Livermore (San Francisco Bay)	SW, receiving	not specified	limited sampling, knowledge of processes used at different facilities	vehicle service facilities, machine shops, analyzed "fountain" solution from printers
IX	City of Simi Valley	WW	Ag, Ammonia, Cu, Chloride, TSS	sampling specific businesses & residential areas, monitor. recv. water	Commercial: metal finishers, medical facilities, photoprocessors, automotive repair, retaurants, outdoor storage Residential: pools & spas, water softners

Table C-1, cont. Summary of Additional[1] Monitoring and Source Identification Studies[2]

Region	Agency (and affected body of water, if specified)	Type of Monitoring	Pollutants Evaluated	Source ID Methods	Sources Targeted
IX	Sacramento County Regional Sanitation District	WW	not specified	Residential: intensive sampling 1990-96, Comm.: sampling businesses	radiator shops, restaurants, dry cleaners, wood finishers, printers
IX	City of Tempe	WW	Hg, As, Cu, Pb	SIC codes, sampling	commercial printers, car washes, commercial laundries, auto repair shops, jewelers, home pesticide use, household products (Cu sulfate, TCE), laundry greywater

[1] Additional to studies discussed in detail in Chapter 2.0.

APPENDIX D

AGENCIES PROVIDING PUBLIC EDUCATION MATERIALS

Table D-1. Summary of Regions in United States that Provided Public Education Materials for WERF Study

State	Region	Agencies	Type/Focus of Materials
RI	1	University of Rhode Island	Computer-based curriculum for junior high school on water resources
RI	1	Save the Bay, Providence, Rhode Island	Print materials on activities related to stormwater pollution; reporter=s guide to water quality issues
NY	2	New York State Dept. Of Environmental Conservation, Albany	Materials on watersheds
MD	3	Center for Watershed Protection, Silver Spring, Maryland	Teachers guide on water monitoring program
VA	3	Terrene Institute, Alexandria Virginia	Newsletters and fact sheet on wetlands, urban runoff, and classroom materials
DC	3	Metropolitan Washing Council of Governments	Pamphlet on stormwater issues
VA	3	Alliance for Chesapeake Bay, Richmond, Virginia	Print materials on preventing pollution of Chesapeake Bay, including sediment/erosion control
MD	3	National Oceanic and Atmospheric Administration, Maryland	Fact sheet and article on toxics in Chesapeake Bay
DC	3	National Safety Council, Washington D.C.	Guide to media and reporters on coastal issues
VA	3	Water Environment Federation, Alexandria, Virginia	Various print materials on a range of environmental protection topics
MD	3	Ecosystem Recovery Institute, Freeland, Maryland	Pamphlet on education resources training programs
FL	4	Dept. Of Environmental Resources Management/U.S. Coast Guard, Metro-Dade County	Large number of materials, primarily focusing on things people can do to prevent stormwater and sanitary sewer pollution, recycling
AL	4	Reynolds Metals Company, Muscle Shoals, Alabama	Application award for stormwater program
FL	4	State of Florida, Dept. Of Environmental Protection, Tallahassee	Various materials on stormwater management

Table D-1, cont. Summary of Regions in United States that Provided Public Education Materials for WERF Study

State	Region	Agencies	Type/Focus of Materials
FL	4	State of Florida, Dept. Of Health and Rehabilitative Services	Booklet on radon in water
FL	4	Sarasota County Natural Resources Dept./Sarasota Bay Project	Booklet on various citizen activities to protect bay
WI	5	University of Wisconsin	Booklet on stormwater; various pamphlets on watersheds and characteristics of local water bodies, flood control, and stewardship; environment-oriented materials for children; various print materials for general public on activities that cause stormwater pollution
WI	5	Wisconsin Natural Resources	Booklet on Green Machine program
WI	5	Wisconsin Dept. Of Natural Resources	Various print materials on things residents can do to prevent stormwater pollution
MI	5	West Michigan Environmental Action Council	Print materials on stormwater pollution prevention
MN	5	Minnesota Pollution Control Agency	Various print materials on several environmental issues; fact sheets on environment-friendly products and practices; information on agriculture and water quality
MI	5	Lake Michigan Federation	Guide for citizens, educators and business on environmental issues related to Lake Michigan
MN	5	Western Lake Superior Sanitary District	Pamphlet on mercury
NM	6	City of Albuquerque, New Mexico	Pamphlets and advertisements on pollution prevention
TX	6	Lower Colorado River Authority, Austin Texas	Print materials on watershed management
OK	6	City of Oklahoma City, Oklahoma	Reports on BMPs, public education program, biomonitoring/diazinon

APPENDIX E

EXAMPLES OF PUBLIC EDUCATION MATERIALS

The following pages are sections of public education materials reviewed and discussed in this report. These publications illustrate a cross-section of the messages, regional styles, targeted pollutants and activities, audiences, and strategies used to communicate stormwater/urban runoff and pollution prevention issues today. Please note that only portions of the brochures, flyers, guides, and posters are reproduced in this appendix. The organizations that provided the materials are listed at the beginning of the appendix.

R0026229

Is your water quality going... ...down the drain?

What goes down the drain does not simply go away. Except for homes with septic tanks, all water washed down the drain or flushed down the toilet in Albuquerque goes to the City's Southside Water Reclamation Plant. At the plant, suspended solids, bacteria, and some treatable metals are removed. To destroy any remaining bacteria, the wastewater is chlorinated. Finally, this water is dechlorinated before being released to the Rio Grande, a cultural lifeblood for the state. The waters of the Rio Grande provide an indispensable resource for agriculture, wildlife, industry and communities downstream. Think about what might be going down the drain!

Did you know that many substances that enter the sewer system can't be removed during the treatment process? Those substances that enter the storm drain system are not treated at all! Anything poured into a gutter or a storm drain, such as used motor oil or antifreeze, flows directly to the Rio Grande, usually via neighborhood arroyos.

It may surprise you to find out that the Rio Grande supports a riparian habitat along its banks. Water birds, reptiles, amphibians, aquatic vegetation, and fish all inhabit the river downstream from the treatment plant. The Rio Grande also supports one of the largest cottonwood forests in the world.

The natural life in this habitat is endangered by substances that cannot be removed in treatment. The Albuquerque treatment facility does a great job, but current technology does not treat everything that could possibly be poured down the drain. Metals such as lead, silver and copper remain. If the effluent is heavily polluted by chemicals from products like used antifreeze or used motor oil when it reaches the plant, then the treated wastewater is also less pure as it enters the Rio Grande.

That's why your decisions count. Any time a toxic household or industrial product is poured thoughtlessly down the drain, it affects the quality of the habitats dependent on the river. In this state, due to the unique role of the Rio Grande, that includes many rural communities and wild areas.

Sometimes, the individual can make a big difference! While industry and business discharge is regulated by the Environmental Protection Agency and the City, for now household hazardous wastes are not. Voluntary individual responsibility is the most direct cure. Each time you decide not to pour, it counts!

A thoughtful home owner has many alternatives to pouring toxins down the drain. Be aware that many common household products, such as paints, cleaners, pesticides, herbicides and used oil, contain contaminants. Fixer used in home photo processing contains silver. Think before you pour!

Thanks for being part... of the water quality team!

Is what you're about to pour... ...giving you second thoughts?

Some Solutions:

Antifreeze Never pour antifreeze into a gutter! Recycling is available! Please call the Albuquerque Environmental Health Department at 768-2600.

Used Motor Oil Never dump oil on the ground or in a storm drain. Recycle this product! Find out about service stations and other sites in your neighborhood that will take in used oil for proper handling. Please call the Environmental Health Department at 768-2600.

Cleaners, pesticides and herbicides Make every possible attempt to use up leftover materials as specified on the label. Surplus can then be offered to others for their use. Try to use the less hazardous and non toxic products offered on the market, and buy only what you need. Finally, you can call the Albuquerque Environmental Health Department at 768-2600.

Paints & Solvents Use up as much of the leftover paint as possible. Offer unused portions to neighbors and theatrical groups, or use to cover graffiti. Cans with dried paint may be discarded in the trash. Paint thinner can be reused! Set aside the used thinner in a closed container until the paint particles settle out. The clear liquid may be strained for reuse. When the remaining paint sludge is dry, it may go in the trash. Photographic fixer with silver should be saved for recycling. Call the Environmental Health Department at 768-2600.

Car Washing Use low-phosphate soap or wax, or don't use soap at all, for washing your car. Try to wash the suds onto your lawn or desert landscaping instead of the gutter. Soap in small amounts will not damage a yard, but soap will harm fish and other aquatic wildlife in the river.

JUST FOR KIDS

STORMWATER POLLUTION SOLUTIONS

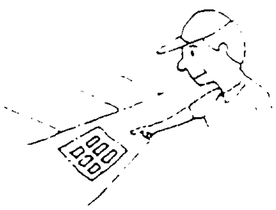
SACRAMENTO STORMWATER MANAGEMENT PROGRAM

YOU ARE THE

SOLUTION TO STORMWATER POLLUTION

KEEPING OUR YOUTH INFORMED OF WATER QUALITY ISSUES IN SACRAMENTO

WHAT'S DOWN THAT DARK DRAIN?



DO YOU EVER WONDER WHAT KIND OF "STUFF" GOES DOWN THOSE METAL GRATES ON STREET CORNERS? OR, WHERE THAT MYSTERIOUS DARK DRAIN LEADS TO? WHERE DOES IT GO?

WHEN IT RAINS OR WHEN YOU HOSE OFF YOUR DRIVEWAY OR SIDEWALK, THE WATER RUNS DOWN GUTTERS OR STORM DRAINS. THESE DRAINS CONNECT TO UNDERGROUND PIPES WHICH LEAD RIGHT TO CREEKS AND RIVERS. BUT A LOT OF OTHER STUFF, MOST OF IT TOXIC, WASHES INTO STORM DRAINS. LIKE MOTOR OIL AND ANTI-FREEZE FROM LEAKY CARS, TRASH, WEED KILLERS, PAINT, AND OTHER HOUSEHOLD TOXICS. YUCK! WE CALL IT **STORMWATER POLLUTION.**

WHEN YOU'RE RIDING IN A BOAT WITH YOUR FRIENDS, HAVE YOUR EVER SEEN GARBAGE FLOATING IN YOUR FAVORITE RIVER? THAT'S STORMWATER POLLUTION, TOO. SOME PEOPLE DON'T KNOW THAT STORMWATER POLLUTION CAN HURT FISH, BIRDS, AND CRITTERS THAT LIVE IN OUR CREEKS AND RIVERS. **BUT YOU AND YOUR FAMILY CAN HELP STOP IT!**

WHAT CAN YOU DO?

Tell your parents, teachers, friends, and relatives that you want to protect the Sacramento and American rivers! Here are some things you and your family can do to prevent stormwater pollution:

HOME

- Wash cars infrequently. Use biodegradable soap and a pistol grip nozzle on your hose.
- Recycle used motor oil and anti-freeze
- Once a month, remind your family to bring leftover toxic materials such as paint, cleaners, and pesticides to a household hazardous waste collection site.

SCHOOL

- Use water-based paints and wash up inside the classroom!
- Start a recycling center for paper, glass, and cans
- Always put trash in trash cans — never in the street!
- Ride your bike or the bus, or car pool with a friend. When it rains, air pollution turns into water pollution

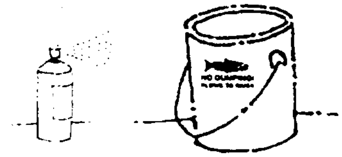
OUTDOORS

- Remind your parents not to apply fertilizer, pesticides, or weed killers if rain is forecast!
- If you see oil on your driveway, use kitty litter to soak up liquids, then sweep it up and throw it in the trash can.
- Use your pooper scooper for your pet and put poop in trash

WORKING TOGETHER, WE CAN ALL BE THE SOLUTIONS TO STORMWATER POLLUTION!

STENCIL A STORM DRAIN AT HOME OR AT SCHOOL

You can remind everyone who walks by a storm drain, "No Dumping — Flows to River!" so that everyone in Sacramento will know how important it is to protect our water. Call 433-6369 to borrow a stenciling kit and get more information.



PIPE MAZE

Follow the pipes to find out where rainwater goes after it runs down a storm drain. (Hint: There are two answers!)

Here is a list of some of the things you might find in Sacramento. Can you find them in the puzzle?

- FISH
- POLLUTION
- CREEK
- STORM DRAIN
- RIVER
- SOLUTIONS
- WATER
- GARBAGE
- RAIN
- STORMWATER
- WILDLIFE
- OIL

TEST YOUR ENVIRONMENTAL KNOWLEDGE!!

1. In Sacramento, like most cities, the water that runs down the street and into the storm drain:

a. gets cleaned at a treatment plant
b. goes to creeks or rivers
c. goes to a landfill

2. More than 1/3 of what we throw away is:

a. glass
b. cheeseburgers
c. paper

3. The biggest cause of stormwater pollution is:

a. industries
b. people
c. your dog

4. Putting used motor oil in the trash or pouring it down the storm drain:

a. is usually safe
b. bothers Oscar the Grouch
c. can pollute creeks and rivers

5. Most of our garbage is:

a. buried in landfills
b. made in New York City
c. put into the ocean

6. When the label on a product says, "poisonous" or "toxic" you should:

a. burn it in the fireplace
b. take it to a household hazardous waste collection site
c. use it on your house plants

Answers: 1. b 2. c 3. b 4. c 5. a 6. b

Special thanks to the City of Portland, Bureau of Environmental Services

If you have any questions regarding the Stormwater Management Program please call the **City of Sacramento, Department of Utilities,** (916) 433-6369, or write 5770 Freeport Blvd., Suite 100, Sacramento, CA 95822.

LOVE LOUISIANA

Save a Lake! or a Bayou! or a Stream!

Ready to make a difference? It's as simple as deciding you want to clean up our waterways by educating others about the importance of not using our storm drains for dumping chemicals or other wastes. And you can begin by stenciling storm drains in your area in cooperation with the Department of Environmental Quality. **The Louisiana Storm Drain Stencil Program is part of DEQ's nonpoint source anti-pollution program.** Waste that comes out of a pipe is called "point source pollution". A nonpoint source of pollution refers to rainstorm run-off from various urban, agricultural or forestry sources. Two of the major sources of nonpoint source pollution are used motor oil and household cleaners dumped into storm drains. Our program involves stenciling a storm drain, or a sign near the drain, with a simple message: **DUMP NO WASTE, DRAINS TO LAKE** . . . or stream, or bayou. This simple message will be a reminder that storm drains are not garbage cans and should not be used for dumping because the water from these drains goes directly to our water sources untreated. Other communities, like those in Washington State, have found this a useful program in fighting unnecessary waste.

HOW TO JOIN

DEQ'S DRAIN STENCILING PROGRAM

Who is painting drains?

Community groups, boy scouts girl scouts, school groups, parents clubs, garden clubs, environmental groups, civic organizations, men and women, boys and girls, young and old, kids with class projects, adults providing community service.

How easy is getting permission?

Once you have mailed a volunteer form to DEQ, you will be notified about who to contact in your area for permission to stencil drains.

If you are painting drains along public thoroughfares, usually you will be directed to call your city or parish Public Works Department. Ask for the drain utility or road maintenance division.

You will then get a letter of approval from the public works department.

If the drains are located on private property, such as an apartment parking lot, get a letter of approval from the management.

What paints should be used?

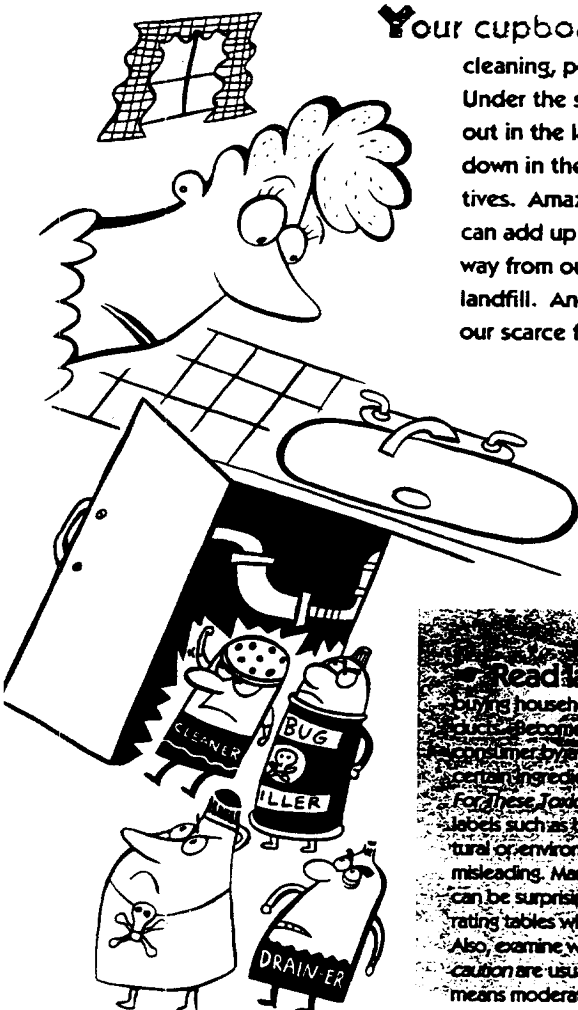
Suggested paints to be used are water-based, inverted tip marker, yellow traffic spray paints. An inverted tip can is more environmentally safe than aerosol cans because it is lead-free, contains no methylene chloride, it has lower volatile organic carbons and it is ozone-safe. One can of spray paint will stencil approximately 20 drains.

What other stenciling tips should be followed?

- Keep a record of storm drains completed on the stencil tracking form provided by DEQ.
- Make a record of drains you observe to be contaminated with wastes on your stencil tracking form. Have your project leader mail the tracking form to DEQ at the address listed in this brochure.
- Follow safety rules. Assign a traffic guard to wear a traffic vest. Do the project in groups.
- Wear old clothes and old, comfortable shoes.
- Clean up. Store the stencil in one plastic bag. Pick up all paper towels, rags or empty paint cans and dispose of in another bag. Dispose of all waste properly.
- Return the stencil, the stencil tracking form and paint cans to your project leader when finished.
- Maintain your drains and keep them free of debris.

estuarywise
100 tips on how you can prevent pollution of our bay and delta
I ♥ my
Estuary
Handbook for the San Francisco Bay-Delta Estuary

Inside Your Home



Your cupboards and closets contain dozens of everyday cleaning, polishing and painting products hazardous to our waterways. Under the sink lurk the drain openers, oven cleaners and insect sprays; out in the laundry room the chlorine bleaches and spot removers; down in the basement workshop the glues, paints and wood preservatives. Amazingly enough, these and other common household items can add up to a considerable source of pollution, once they find their way from our homes to the Estuary via drains, toilets and your local landfill. And don't forget that leaky faucet in the bathroom guzzling our scarce freshwater supply.

☛ **Read labels before** buying household cleaners and other products. Become an environmentally friendly consumer by avoiding products containing certain ingredients (see p. [illegible], *Watch Out For These Toxic Ingredients*). Be aware that labels such as biodegradable, organic, natural or environmentally friendly can be misleading. Many so called *green products* can be surprisingly toxic. Consult product rating tables whenever possible (see p. 32). Also, examine warnings. Products labeled *caution* are usually the least toxic, *warning* means moderate toxicity, and *danger*, *poison*, or the symbol of a skull and crossbones means it's extremely toxic.

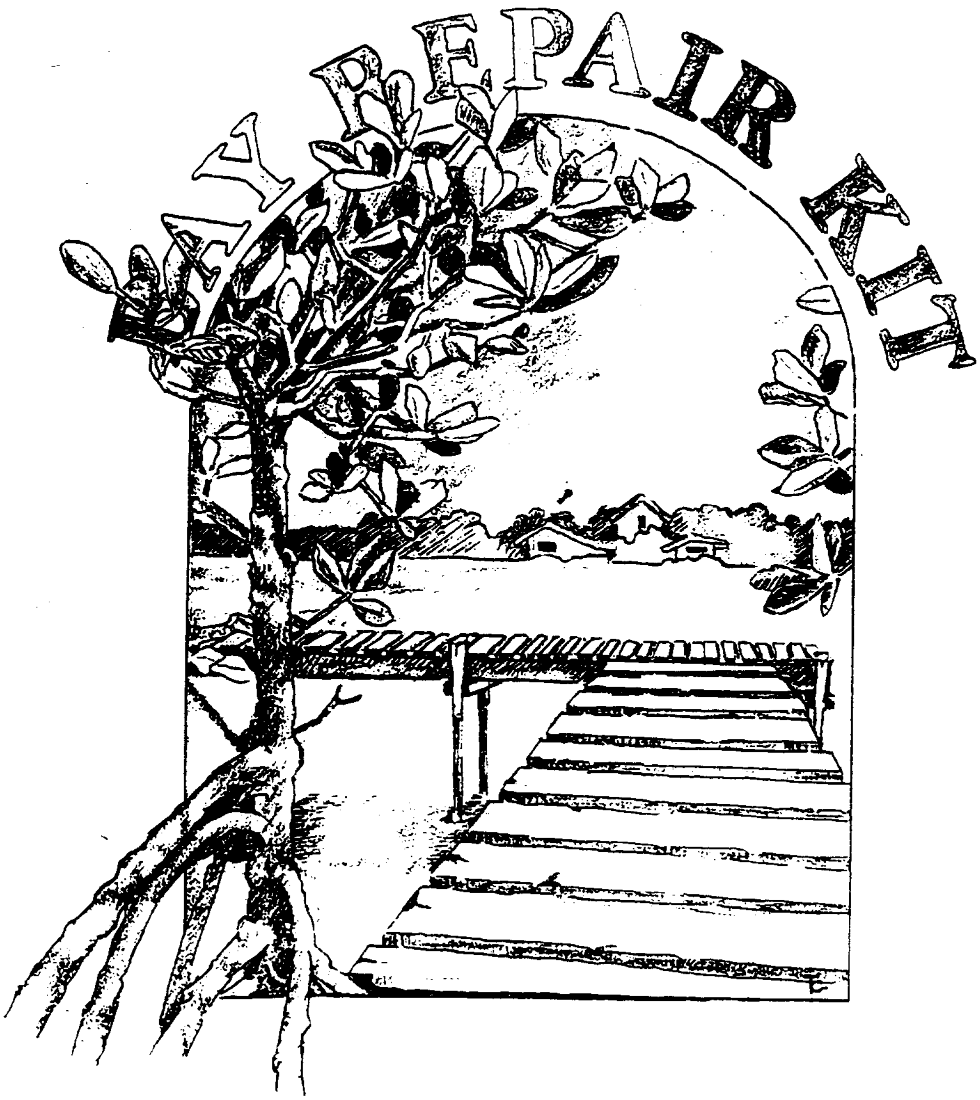
☛ **Use safe substitutes** [illegible]

☛ **Buy only as much** [illegible] Store [illegible] containers. [illegible]

☛ **Do not pour paints,** [illegible] preservatives, brush cleaners or solvents down the sink or toilet and never down storm drains. Clean up brushes and [illegible] buckets at the sink, not the gutter. [illegible]

Tackle it without toxics . . .

6

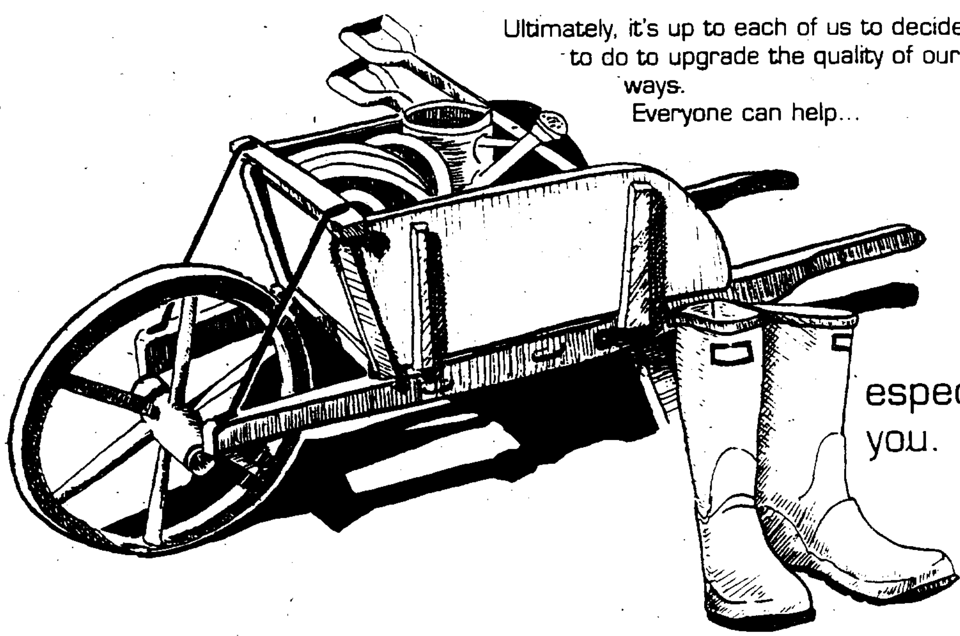


AY REPAIR KIT

Unknowingly, in the daily care of our households, we each may be polluting nearby bays and other waterways. This booklet offers practical steps to reduce that pollution in order to begin repairing our damaged coastal waters. Some suggestions are simple,cost-free,and require only a slight change of routine. Others are more intricate and car be implemented gradually over time. A few suggestions may even inspire you to re-landscape certain areas of your property.

Ultimately, it's up to each of us to decide what to do to upgrade the quality of our waterways.

Everyone can help...



especially you.

"Nobody ever made a greater mistake than he who did nothing because he thought he could only do a little."

Edmund Burke

R0026238

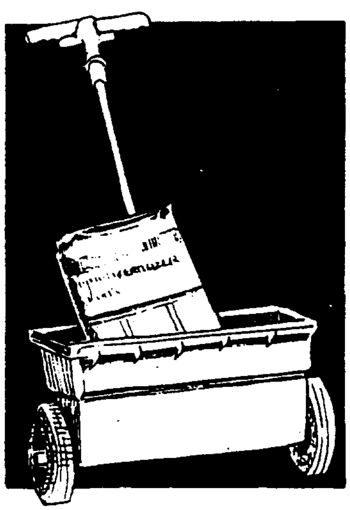
KEEP SURFACE RUNOFF CLEAN

Summertime • Late afternoon • Thunderstorms

Torrents of rain are pouring down onto your yard. It's virtually impossible to stop surface runoff now ...

The second line of defense is to **keep surface runoff clean**. The challenge is to prevent the runoff from picking up an array of contaminants from fertilizers, pesticides, bare ground, pets, pools, waste, cars and boats.

When fertilizing the lawn and landscape plants, remember the trade-off: the more you fertilize on land, the more you may be polluting the water.



Fertilizers

Fertilizers contain nitrogen and phosphorus, two elements which promote the growth of plants in water as well as land. Fertilizer-laden runoff can over-stimulate aquatic plant growth, causing algal blooms and fish kills.

WANTED

Your help is needed in locating the following notorious wastewater pollutants.

MERCURY

ARSENIC

And gang members Lead, Copper, Cyanide, Nickel, Cadmium, Zinc, Silver, Chromium, Beryllium, Thallium and Selenium.

City of Phoenix

WHAT CAN YOU DO

to arrest the use and hazardous disposal of these pollutants?

You can:

1 assess your industrial process to determine if any of these pollutants are present.

2 evaluate your industrial process to determine where you can reduce or eliminate the use of these pollutants.

3 contact your supplier and ask him to provide an alternate source of materials that does not contain harmful pollutants or heavy metals.

4 buy materials only as they are needed and in quantities which will be used before expiration dates.

5 schedule your production process so source materials are used effectively and efficiently.

6 institute a recycling program, either on or off site.

7 encourage your employees to identify ways to reduce or eliminate the use of these pollutants and heavy metals in your industrial process.

REWARD

By taking the steps recommended in this brochure, you will reduce the amount of pollutants and heavy metals you use in your production process and their disposal through the sewer. As a result, you will impress your customers, stockholders and boss by:

- saving your company money.
- reducing your company's potential environmental liabilities by avoiding costly lawsuits and/or penalties.
- displaying your company's environmental leadership by using waste-free processes and producing waste-free products.

- saving money for yourself, your business and your community by making it unnecessary for the city to install costly new equipment at its wastewater treatment plant, thereby keeping sewer rates reasonable.
- helping to keep our environment safe for you, your family and others to use, now and in the future.

I ♥ CREEKS

As Flo the Raccoon explains
to her boys Dwain and Rusty,

It's up to us
to keep pollution
out of storm drains!
What goes into the storm drains
(or street, or gutter) goes
right to our creeks and Bay.

If you see something dumped
or spilled near a storm drain,
call 329-2413 immediately!

Palo Alto Storm
Drain Program

415/321-2129

(Let's hope Rusty gets the message SOON!)

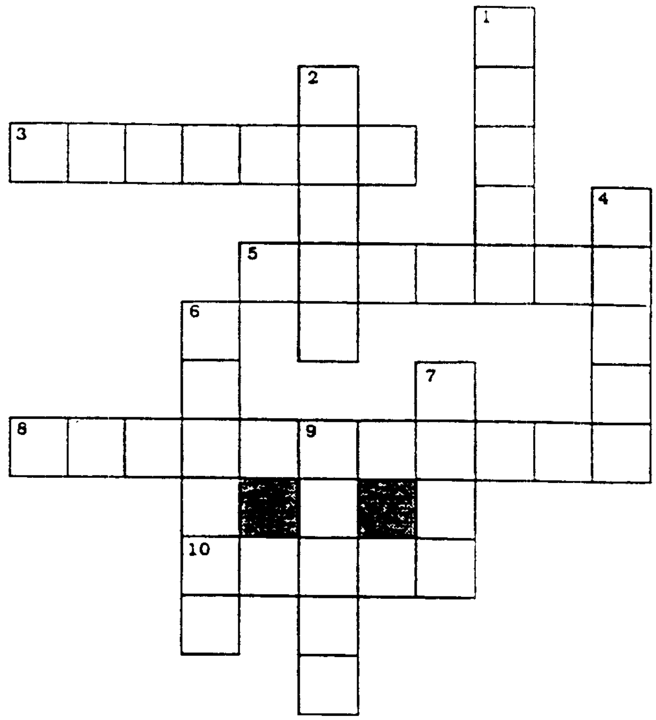
Printed on recycled paper, of course

R0026246

This activity book belongs to:

Water Wager: Have the Final Word

toxic
recycle
plastic
sludge
drain
glass
sewer
groundwater
cans
river



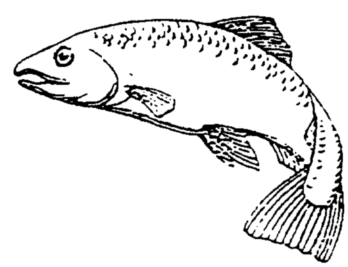
Across

3. A material sometimes made by humans that does not decompose and is very difficult to recycle.

5. What to do so that glass, aluminum and paper can be used again.

8. Water found in the earth.

10. A hard, breakable material which is good to recycle.



Down

1. Another word for poisonous.

2. A large stream that flows into a lake or ocean.

4. The pipe that carries wastewater to the treatment plant.

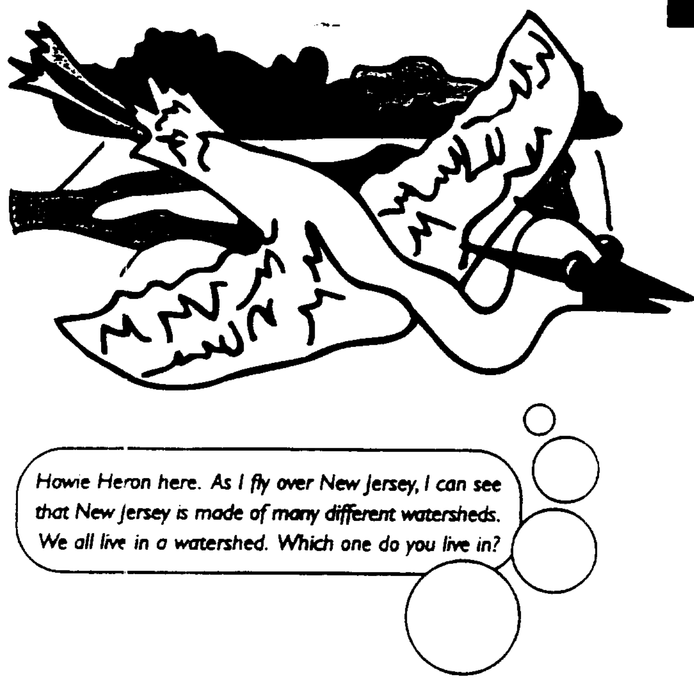
6. The name for the solid material that is taken out of treated water.

7. Another name for pop containers. (It's smart to recycle them).

9. Where the water goes down the sink or bathtub.

HOW TO BE A CLEAN WATER RAINGER

Save this booklet! It contains valuable information you can use!



WHAT IS A WATERSHED?

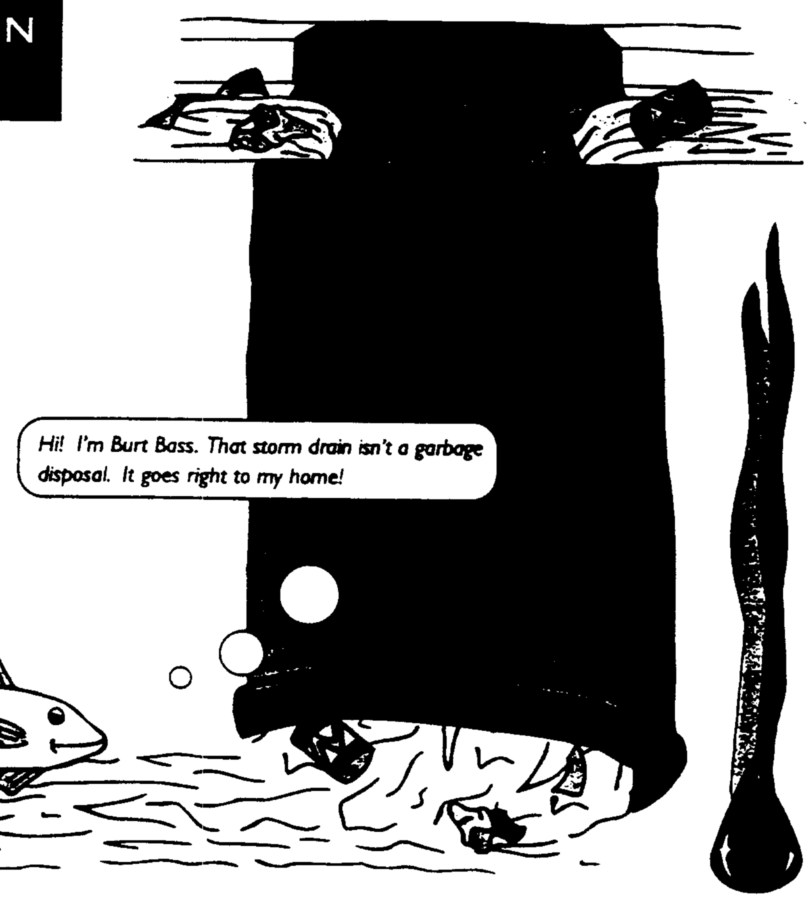
A watershed is the area of land surrounding a waterway that drains into it. A watershed includes not only the waterway itself but also the entire land area that drains to it. For example, the watershed of a lake would include not only the streams entering into that lake but also the land area that drains into those streams and eventually the lake.

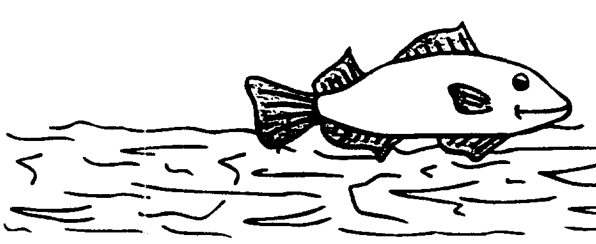
A watershed can be as small as a backyard that drains to a puddle or as large as the sections of New York, Pennsylvania, New Jersey and Delaware that drain into the Delaware River.

So what happens on the land in a watershed affects the waterway. For example if too many fertilizers are used on lawns, the extra fertilizer can end up in the local waterway. The same thing goes for ground water. The extra fertilizer could end up in ground water and maybe someone's well.

GET YOUR MIND IN THE GUTTER!

In urban and suburban parts of the state, manmade systems change the way water flows. Where does the water in the street gutter go? In most places in New Jersey, that gutter leads to a storm drain along the curb which goes directly to a local waterway. Whatever flows down the storm drain enters a series of underground pipes that lead to an outfall pipe that flows into a local waterway. The stormwater does not get treated. All the litter motor oil drippings, and other debris goes with it into the local waterway. That's why it's important to keep stormwater clean!





R0026250

TOP TEN THINGS YOU CAN DO TO HELP KEEP WATER CLEAN

- Never throw anything down storm drains. They are for rainwater only.
- Don't litter. Always put trash where it belongs.
- Always clean up after your pets. Obey your town's "pooper scooper" laws.
- Tell others how important it is to keep our land and water clean.
- Plant a tree. They take pollutants out of ground water, provide shade, and clean the air.
- Find out what waterway you live near. Where does your water come from?
- Precycle! Buy products that use the least amount of packaging.
- Recycle. Find out what is recyclable in your community. Buy products in recycled or recyclable containers.
- Learn about environmental issues. Get involved in local organizations.
- Conserve water whenever possible. For example, turn off the water while brushing your teeth and don't linger in the shower.

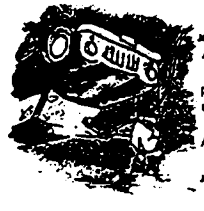
TARGETED POLLUTANTS AND ACTIVITIES

Plan your home maintenance projects to protect water quality

Here are some tips for protecting water quality, whether you do the work yourself or hire someone else. Remember, storm drains flow directly to our local creeks and on to San Francisco Bay!

Car Washing and Repair

If you do the work yourself:



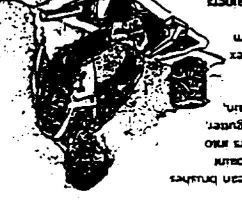
- Don't wash cars on a driveway or street where soapy water may flow to a storm drain. Wash on a lawn or unpaved surface. Dispose of leftover soapy water in a sink or toilet, not the street, driveway, or storm drain.
- If you change your own oil or antifreeze, recycle it! Never dump oil or any auto fluid onto the ground or into a storm drain or creek.
- Repair leaking vehicles promptly to help keep fluids off streets and out of storm drains. Soak up leaks and spills with an absorbent such as cat litter.

If you hire someone:

- Use a commercial car wash where water is recycled.
- Make sure mobile auto detailers use spill containment aids such as drop cloths when working in a street or driveway, and dispose of all wastewater in a sink, not the storm drain.
- Be sure your auto service center recycles oil and antifreeze, and follows shop cleanup practices that protect water quality.

Painting and Furniture Stripping

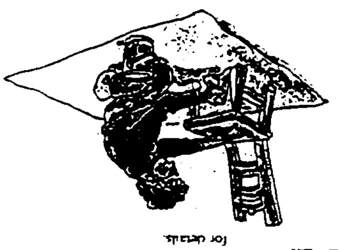
If you do the work yourself:



- Never clean brushes or rinse paint containers into a street, gutter, storm drain, or creek.
- Clean latex paint from brushes and containers in a sink. Filter, settle, and reuse thinners and solvents for oil-based paints.
- Dispose of unusable paints and thinners, thinner residue, and paint strippers through a household hazardous waste program.
- Empty, dry paint cans may go in household garbage, or they may be recycled in your city. Remove paint can lids before disposal.

If you hire someone:

- Make sure that painting contractors clean brushes and containers and dispose of paint residues properly — never in the street or storm drain.
- Professional painters must dispose of leftover paints and solvents as hazardous waste.
- Encourage your painter to use a special hazardous waste collection program for small businesses when it's available in your area. Call (408) 299-7300 for details.



Household hazardous waste collection

For information, contact your city's program or the Santa Clara County Household Hazardous Waste Program (408) 299-7300

City of Palo Alto (415) 496-6980
Drop-off first Sat. morning each month

City of Sunnyvale (408) 730-7278
Drop-off every 90 days; call for dates

City of Santa Clara (408) 984-3080
Drop-off twice a year

Home Maintenance Tips for a Cleaner Bay

Whether you do the work yourself or hire someone, you can help protect water quality

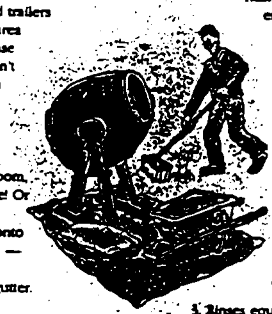
Santa Clara Valley
Nonpoint Source
Pollution Control Program

R0026256

Concrete, Masonry, and Asphalt Repair

If you do the work yourself:

- Set up and operate small mixers on heavy tarps or dropcloths.
- Hose down mixers, tools, and trailers in a dirt area where rinse water won't run into a creek or gutter.



- Clean up with a broom, not a hose! Or wash fine particles onto a dirt area — not into a street or gutter.
- Apply driveway sealants when no rain is forecast. Sweep first to prepare. Handle sealants with care and follow label directions.

If you hire someone:

- Explain to your concrete contractor that rinsing trucks or equipment in the street or near a storm drain endangers wildlife in our creeks and Bay — and it's illegal!

Make sure your concrete contractor:

1. Establishes a cleanup area before starting work.
2. Minimizes use of water in cleanup.
3. Rinses equipment onto an isolated dirt area, away from streets or creeks. Or, places a wheelbarrow under the chute and/or other equipment to catch rinsewater, and wheels it to a dirt area for disposal.
4. Rinses exposed aggregate concrete onto a dirt area.

Housecleaning and Window Washing

If you do the work yourself:

- Send dirty cleaning water down a sink or toilet, not into a street, gutter, or storm drain.

If you hire someone:

- Make sure people you hire understand that storm drains flow to the creeks and Bay with no treatment — so they won't dump anything into a storm drain.

Carpet/Upholstery Cleaning

If you do the work yourself:

- Dispose of dirty cleaning solution down a sink or toilet, not the storm drain.

If you hire someone:

- Ask professional carpet cleaners where they empty their tanks. Make sure they don't use the storm drain!
- Professionals should dispose of cleaning solutions down a sink or toilet, or return to their company for disposal to the sanitary sewer.

Pool/Spa Maintenance

If you do the work yourself:

- Control algae by regulating chlorine levels and by using a pool cover to block sunlight. Do NOT use copper-based algae control products.
- Always discharge pool or spa water to a sanitary sewer line cleanout. Never discharge pool or spa water to a creek, street, or storm drain. When it's time to empty your swimming pool, call your wastewater treatment plant for guidance. (See numbers on reverse.)
- Dispose of filter rinsewater and backwash into soil, not the gutter, creek, or storm drain. Or, call your wastewater treatment plant for guidance.

If you hire someone:

- Make sure your pool service contractor is not using copper products in your pool, and not disposing of filter backwash where it can run off to a storm drain.
- Make sure acid-wash rinsewater is neutralized before it is pumped to the sewer line cleanout. Call your wastewater treatment plant for guidance.

Lawn and Garden Care and Pest Control

If you do the work yourself:

- Don't use chemical pesticides or herbicides unless you have a major problem, and never in wet weather! Read labels carefully, and apply sparingly. Try to use products that are not hazardous to aquatic life.

- Don't blow or rake yard waste into the street or gutter. Follow your community's guidelines for curbside yard waste pickup, or start your own compost pile.

- Sweep up the leaves and litter in the gutter in front of your property.
- If your city has yard waste pick-up, sweep up any residue left on the street after pick-up day.
- For information about maintaining a healthy, pest-free lawn, call the U.C. Cooperative Extension Office, (408) 299-2638.
- For a free copy of "Pests Bugging You?" a simple brochure about less-toxic pest control methods, call the Santa Clara Valley Nonpoint Source Pollution Control Program at (800) 794-2482.

If you hire someone:

- Make sure your gardener does not blow or rake leaves into the street or gutter and collects yard waste for composting.
- If you contract with a lawn maintenance service, limit fertilizer applications to twice a year (fall and spring), and limit application of actual nitrogen on cool-season grasses to 4 lbs per 1,000 sq. feet. Chemical weed killers and other pesticides should not be necessary on a lawn that is appropriately watered, mowed, thatched, and aerated. Never apply chemicals when rain is forecast.

- Schedule excavation and grading projects for dry weather periods. Make sure your landscaper protects stockpiles and materials from wind and rain by storing them under secured sheeting or tarps.

If you like to change your oil yourself, make sure you finish the job right. Here's how:

1. Collect used oil in a clean, non breakable container that has a screw-on cap.
2. Don't mix other substances with your used oil such as paint, gasoline, solvents, or antifreeze. Your used oil must be free of contaminants in order to be recycled.
3. Mark "waste oil" on the container.
4. Place your used oil filter in a sealed plastic bag. Take it to a collection center that accepts oil filters.
5. Recycle your used oil by taking it to a used oil collection center. If your community has a curbside recycling program, place your used oil container on the curb.
6. Never dump used oil down the storm drain or in the gutter!

Recycling used oil is easy.
And it's **FREE!** Collection centers are popping up all over the County. To find out about convenient locations near you, call:

Reciclar aceite gastado es fácil y **¡GRATIS!** Se encuentran centros de colección en todo el Condado. Para más información sobre el centro de colección más cercano llame al teléfono:

1-800-94REUSE

This number will also provide you with information about disposal of household hazardous waste and stormwater pollution prevention.

This information is brought to you by:

PARTNERS IN PREVENTING WATER POLLUTION

Okay, you're through with the oil change. Ca[r] running smooth. Time to recycle your oil.

Why?— Because motor oil that drips, spill[s] is dumped on our streets and in the gutter [is] washed down storm drains during heavy rains. [Storm] drains are the express route to our creeks, the [Bay an]d the Ocean.

Of course, motor oil isn't the o[nly] ... pesticides, and trash that ... the year are destroying ... resources: the fish w... and the water we ...

Basically it ... your mot... around ...

Pollution From Surface Cleaning

It harms the environment . . .

In most parts of the San Francisco Bay Area, storm drains are pathways for pollution, traveling directly from streets, gutters, and other paved surfaces to local creeks or the Bay, Ocean or Delta. Wash water from surface cleaning activities often carries pollutants that can harm the numerous wildlife species that depend on healthy waterways for their survival.

. . .And it's against the law!

Allowing polluting substances into storm drains is prohibited in California. Both the person who discharges the pollutant or leaves it behind, and the owner of the property where the material is generated are liable.

This folder provides guidance for mobile cleaners to prevent pollution when cleaning flat surfaces such as sidewalks, plazas, building exteriors, parking areas, and drive-throughs.

This guidance is not specifically intended to be appropriate for other mobile cleaning jobs such as fleet washing and detailing, carpet cleaning, or cleaning of food-related equipment.

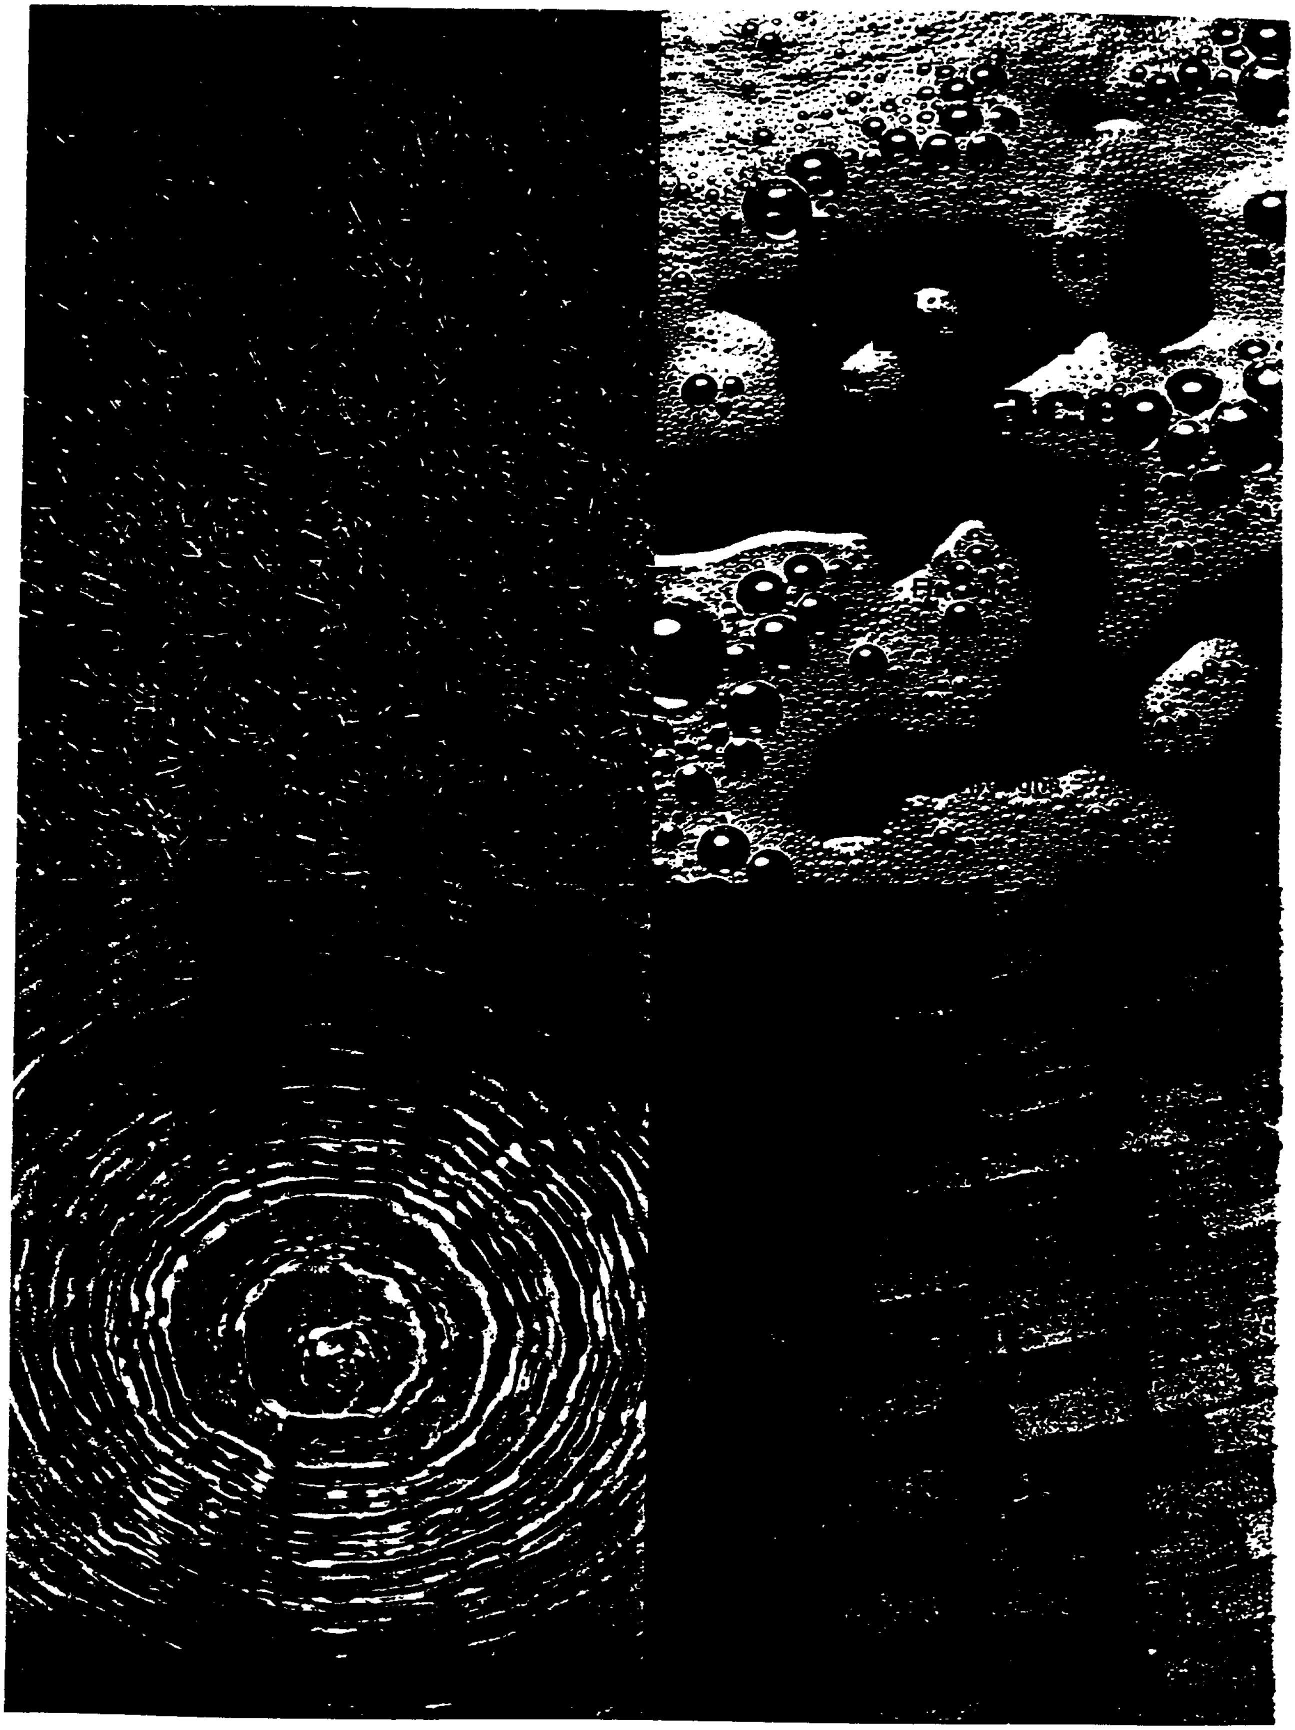
Where do these pollutants come from?

In general, three phases of the cleaning process can cause problems for the environment:

- Using harmful cleaning chemicals—including soaps as well as solvents
- Removing toxic materials such as oil, antifreeze, and grease from parking lots, sidewalks, or other surfaces
- Generating polluted wash water from activities such as wet sand blasting of buildings to remove paint

What sorts of hazardous waste can surface cleaning generate?

- Oil-saturated absorbents (but not oil-saturated rags, which can be cleaned at an industrial laundry)
- Wash water that contains lead paint chips
- Solvent cleaners



R0026264

So Where Should Wash Water Go?

Onto landscaping or unpaved surface

Wash water from cleaning unpainted building exteriors, sidewalks, or plazas, if:

- Discharge does not contain hazardous waste

AND

- Discharge will not cause flooding or nuisance problems, or flow to a creek

AND

- You have the owner's permission

Down a sink, toilet, or cleanout — through the sewer to a wastewater treatment plant

Wash water from surface cleaning of painted building exteriors, sidewalks, plazas, parking areas, drive-throughs, food service facility dumpster/grease containment areas, etc., if:

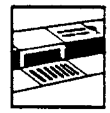
- You have used dry cleanup methods before washing with or without soap

AND

- Discharge does not contain hazardous waste

AND

- (For parking lots, traffic areas, food service facility dumpster/grease containment areas) You or the property owner have checked the local wastewater treatment plant's requirements before discharging to the sewer



To the street or storm drain

Wash water from cleaning sidewalks, plazas, and building exteriors, if:

- You have *successfully* used dry cleanup methods (described in the "tips" section of this folder to remove fresh oil stains, debris, and similar pollutants—before using water

AND

- Cleaning is done with water only—no soap or other cleaning chemicals

AND

- Water has not removed paint

Tips on proper cleaning and disposal methods

Avoid using soap!

- Even biodegradable soap is harmful to the environment. Before you use soap, test to see whether hot water under pressure will do the job.

Dry cleanup methods

- In many cases you can eliminate the need to collect and/or divert wash water if you follow this two-step process:
  1. Use absorbents (such as rags, absorbent mats or pads, rice hull ash, cat litter, vermiculite, or sand) to pick up greasy or oily spills.
  2. Sweep or vacuum to pick up litter, debris, or saturated absorbents
- Waste materials from dry cleanup such as absorbents, paint chips, etc. may often be disposed of in the trash. Check with the local solid waste authority to be sure. Rags may be sent to an industrial laundry.

Screening wash water

- When cleaning surfaces such as buildings and decks without loose paint, sidewalks, or plazas *without soap*, thorough dry cleanup should be sufficient to protect storm drains. However if any debris could enter storm drains or remain in the gutter or street after cleaning, wash water should first pass through a "20 mesh" or finer screen to catch the material, which should be disposed of in the trash

Collecting wash water

- A simple and acceptable method for collecting wash water on private property requires only a drain plug, small sump pump, and a length of hose. If a small parking-lot-type catch basin is available, remove the grate, plug the drain pipe (usually 2, 3, or 4 inches in diameter), and place the pump in the catch basin, attached to a garden hose. As wash water drains to this lowest spot, pump to landscaping, a sewer line cleanout, or a container for later disposal to the sewer.
- Vacuum booms are another option for capturing and collecting wash water.

Directing wash water to landscaping

- When routing wash water to landscaping, check the slope and area to be sure to avoid runoff into a street or gutter. If the soil is very dry, wet it down thoroughly before discharging so that wash water will soak into the soil instead of running off to the street, gutter, or storm drain.

Blocking storm drains or containing wash water

- Sand bags can be used to create a barrier around storm drains.
- Plugs or rubber mats can be used to seal storm drain openings.
- You can also use vacuum booms, containment pads, or temporary berms to keep wash water away from the street, gutter, or storm drain.

Hazardous waste disposal

- Be sure to read cleaning product labels before disposing of wash water. Follow use and disposal instructions carefully.
- Check with the city or county environmental health department to find out how small businesses can dispose of hazardous waste at a drop-off event (instead of hiring a hazardous waste hauler). In general, you must generate less than 27 gallons or 220 pounds of a particular type of waste each month to qualify to use these "Conditionally Exempt Small Quantity Generator" (CESQG) programs.

Equipment and supplies

- Special materials such as sheets of absorbent, storm drain plugs and seals, small sump pumps, and vacuum booms are available from many vendors. For more information check catalogs such as Pigalog (800-468-4647), Lab Safety Supply (800-356-0783), C&H (800-558-9966), and W.W. Grainger (408-433-9889), or call the Cleaning Equipment Trade Association (800-433-9889) or the Power Washers of North America (202-393-7044).

Remember, sending water that contains soap or any other type of pollution to a storm drain or water body violates state and/or local regulations!

Cleaning and Disposal

Type of Surface	Cleaning Method	Proper Disposal
Sidewalks, plazas	Dry cleanup* first, **wash without soap**	Screen wash water,* if needed, to catch debris THEN Discharge to landscaping,* or to a gutter, street, or storm drain
Sidewalks, plazas	Block the storm drain or contain runoff* Dry cleanup,* then wash **with soap***	Discharge to landscaping* OR Collect water and pump to the sewer*
Parking areas, driveways, drive-throughs	1. Block the storm drain or contain runoff* 2. Use absorbents to pick up oil; then dry sweep 3. Clean with or without soap	Collect water and pump to the sewer* *Check the local wastewater authority's requirements for discharge*
Restaurant/food handling dumpster areas, grease storage	Block the storm drain or contain runoff* Dry cleanup	If you must use water after sweeping/using absorbents, collect water and pump to the sewer* *Check the local wastewater authority's requirements for discharge*
Building surfaces, decks, etc., without loose paint	Use high-pressure water, no soap	Screen wash water,* if needed, to catch debris THEN Discharge to landscaping,* or to a gutter, street, or storm drain
Unpainted building surfaces, wood decks, etc.	Block the storm drain or contain runoff* Use soap or acid wash to remove deposits, wood restorer, or other chemicals	Make sure pH is between 6 and 10 THEN Discharge to landscaping* OR Collect wash water in a tank* and pump to the sewer *Check the local wastewater authority's requirements for discharge*
Painted surfaces being cleaned to remove paint or graffiti	Block the storm drain or contain runoff* Use any cleaning method	Collect wash water in a tank and pump to the sewer, or dispose as hazardous waste, as appropriate* *Call the local wastewater authority or the state Department of Toxic Substances Control (510-540-3732) for help in determining whether the paint contains toxic pollutants such as lead, mercury, or tri-butyl tin; or if the solvent cleaners you use are hazardous*
Graffiti removal	Block the storm drain or contain runoff* Wet sand-blast	Direct all runoff to a landscaped or unpaved area* OR Follow instructions above for painted surfaces

* *See tips section for ideas on how to do this!*

Pollution Prevention Voucher

____(cleaner company name), cleaner of the premises described below, has been trained by the Bay Area Stormwater Management Agencies Association in proper surface cleaning techniques for water pollution prevention.

We'll do the Job Right!

______________ is a Recognized Mobile Cleaner trained to prevent pollution of local creeks, the Bay, and Delta.

Cleaning water from

- Sidewalks
- Plazas
- Dumpster areas
- Building exteriors
- Parking areas/drive-throughs

pollutes our waterways when allowed to reach a creek or storm drain. Storm drain pollution is against the law in California. Liability is shared by the property owner and the actual discharger.

We've been trained to *Do the Job Right*. When we're finished, we'll provide you with a voucher declaring that your premises have been cleaned by a Recognized Mobile Cleaner.

Ask us about:

- Using dry cleanup methods before washing
- Blocking storm drains to protect them from pollution
- Directing wash water to landscaping if acceptable

Recognized by the Bay Area Stormwater Management Agencies Association and the San Francisco Bay Regional Water Quality Control Board.

For more information, call 510/286-0615.

CITYSCOPE

DIAZINON USE DISCOURAGED

The problem is not going away! Tests of Greenville's wastewater still show toxic levels of the pesticide diazinon. Unfortunately, an efficient, cost-effective method of removing the pesticide from water has not yet been developed. If diazinon continues to contaminate our wastewater, Greenville water utility customers will face major increases in their sewer bills to correct the problem.

The pesticide use survey conducted earlier this year showed widespread use of diazinon in the city. Even when applied properly, diazinon and other pesticides can still make their way into the wastewater system. Since even trace amounts are toxic to the test organisms it appears that proper usage isn't effective in controlling the contamination.

The only *guaranteed* way to co rect the water toxicity problem for all Greenville residents to st *using diazinon* and to decrease th use of other synthetic pesticides. less toxic, environmentally sour pest management program c control insect pests without creati dangerous residues which can co taminate wastewater or groun water.

The Office of Public Education : Water Utilities and the W. Walwor Harrison Public Library have join forces to provide residents wi information on such pest-ma agement programs.

Some of the books available at t library include ***Tiny Game Huntin*** *Environmentally Healthy Ways Trap and Kill Pests in Your Hou and Garden,* ***The Encyclopedia Natural Insect and Disease Contr*** *Dr. Pitcairn's* ***Complete Guide Natural Health for Dogs and Ca Rodale's Chemical-Free Yard an Garden,*** J. Howard Garrett's ***Orga Gardening*** and ***Plants of t. Metroplex III*** and ***Safety at Hon*** *A Guide to the Hazards of Lawn a Garden Pesticides and Safer Ways Manage Pests.*

For more information on the books and others about enviro mentally safe pest control, vi the Harrison Library at 3716 I Street, or contact the Office Public Education for Water Utilit at 457-3149.

A-8—Greenville Herald Banner, Sunday, April 10, 1994

Free seminar on fire ant control planned Tuesday

Fire ant control will the be topic of a special program Tuesday, sponsored by the Public Education for Greenville Water Utilities and the Hunt County Agriculture Extension Service.

The public seminar will begin at 7 p.m. at Crestview Christian Church, 5605 Wesley.

Dr. Michael Merchant, Texas Agriculture Extension Urban Entomologist will be on hand to describe the two-step method for fire ant control. Developed by the Texas Agriculture Extension Service, this method combines the broadcast application of a bait and treatment of individual mounds for effective fire ant control.

The Two-Step Method shows much promise, according to JoAnn Hall and Anita Mitchell, coordinators for the city's Public Education program. In 1993, volunteers from six counties in north central Texas participated in an evaluation of the method.

A survey of these volunteers found that 79 percent were satisfied or very satisfied with the level of fire ant control with the Two-Step Method, that 80 percent obtained better control than they had with the other methods tried in the past, and 84 percent planned to continue using the Two-Step Method.

Persons unable to attend the seminar but would like to receive information on the Two-Step Method should call Public Education for Greenville Water Utilities at 457-3149, or the Hunt County Extension Service at 455-4203.

Seminar to help fight pesky critters

By JoAnn Hall, Anita Mitchell
Special to the Herald Banner

Free
Flea & Tick Seminar
Thursday, July 7 at 7:00 p.m.
Fletcher Warren Civic Center

CLEAN GREENVILLE INC

Chances are, if you've got a pet, you've got fleas or ticks.

Our recent warm, humid weather has been ideal for the breeding of large flea and tick populations.

In an effort to provide area residents with the latest flea and tick control information, a free seminar will be sponsored by Public Education for Greenville Water Utilities and the Hunt County Extension Service on Thursday.

The public seminar will begin at 7 p.m. at the Fletcher Warren Civic Center, 5501 Hwy. 69.

Dr. Mike Merchant, Texas Agricultural Extension Urban Entomologist, will be the featured speaker. His presentation will cover indoor/outdoor flea and tick control as well as on-pet treatment.

Several local veterinarians and retailers will also be present to provide information on locally available products for flea and tick control.

Area residents who have been experiencing flea and tick infestations are encouraged to attend this free seminar.

No advanced registration is required.

For additional information on Thursday's seminar call Public Education for Greenville Water Utilities at 457-3149.

Hall and Mitchell are coordinators of Public Education for Greenville Water Utilities.

There are ways to control pests

By JoAnn Hall
and Anita Mitchell

There's an old saying that the only things that can't be avoided in life are death and taxes. This should probably be amended to include cockroaches. Cockroaches have been pestering humankind since Roman times. For many, the battle against cockroach invasions is never-ending. And a trip to the store to select a cockroach control product may only add to one's frustration.

A recent article in "Common Sense Pest Control Quarterly" provides invaluable information to those seeking relief from cockroach infestations.

Start by practicing cockroach prevention. Properly store food and keep dishes and food preparation areas clean. Take household trash out every day and use a trash can with a tight-fitting lid. Block insect entry points by screening windows and vents. Caulk or paint cracks or crevices and weatherstrip doors.

If cockroaches have already moved in, boric acid is a very effective control product. Place boric acid in and around cracks and crevices in areas where roaches have been sighted.

PUBLIC EDUCATION
Greenville Water Utilities
(903) 457-3149

Other locations for application are under kitchen appliances and around plumbing fixtures and pipes. Observe these safety precautions when working with boric acid: do not place it where children and pets can get into it, and wear goggles and gloves when applying.

Another effective control method is the use of bait stations. Bait stations are safe and easy to use. The control agent is housed in a small plastic disk that allows the cockroaches in, but blocks human and animal contact. Because cockroaches like to explore tight spaces, bait stations are very attractive to them.

Select bait stations that contain hydramethylnon as the active ingredient. Place bait stations near favorite roach hang-outs such as under the kitchen sink, behind or under the refrigerator and stove, in upper and lower kitchen cabinets, and in the bathroom behind the toilet and under the sink.

Not all bait stations contain the same amount of bait so consider placing two stations in each of these areas to provide greater control. Make sure the stations are positioned against the wall so that roaches will encounter them as part of their daily activities.

CLEAN GREENVILLE INC

Follow the manufacturer's recommendations for replacement and disposal.

Additional information on cockroach control is available from the Office of Public Education for Greenville Water Utilities at 457-3149. And remember, don't use Diazinon!

Hall and Mitchell are coordinators of Public Education for Greenville Water Utilities.

GUIDELINES FOR FOOD HANDLING FACILITIES

In the Santa Clara Valley, all storm drains flow directly to local creeks and the San Francisco Bay, with no treatment. Stormwater pollution is a serious problem for wildlife dependent on our waterways, and for the people who live near polluted streams or baylands.

Food handling facilities such as restaurants, institutional cafeterias, grocery stores, bakeries, and delis, contribute to this stormwater pollution mainly through improper cleanup practices that allow food particles, oil, grease, and cleaning products to flow into a street, gutter, or storm drain.

All of the cities in the Valley are required by the Regional Water Quality Control Board to enforce local ordinances prohibiting the discharge of pollutants to storm drains or local creeks. Also, the California Department of Fish and Game forbids any discharge of materials that could pass into creeks, rivers, or the Bay that would be "deleterious to fish, plant life, or bird life."

In addition, the Santa Clara County Department of Environmental Health and local wastewater treatment plants require that all grease traps and other grease removal devices be cleaned as often as necessary to prevent overflow and to meet local grease and oil limits in wastewater. Check with these agencies to find out about other requirements — see phone numbers on page 12.

Following the practices in this manual will ensure compliance with ordinance requirements with respect to both the sanitary sewer and the storm drains, and will help contribute to a cleaner Bay. Please share this information with any contractors that you hire.

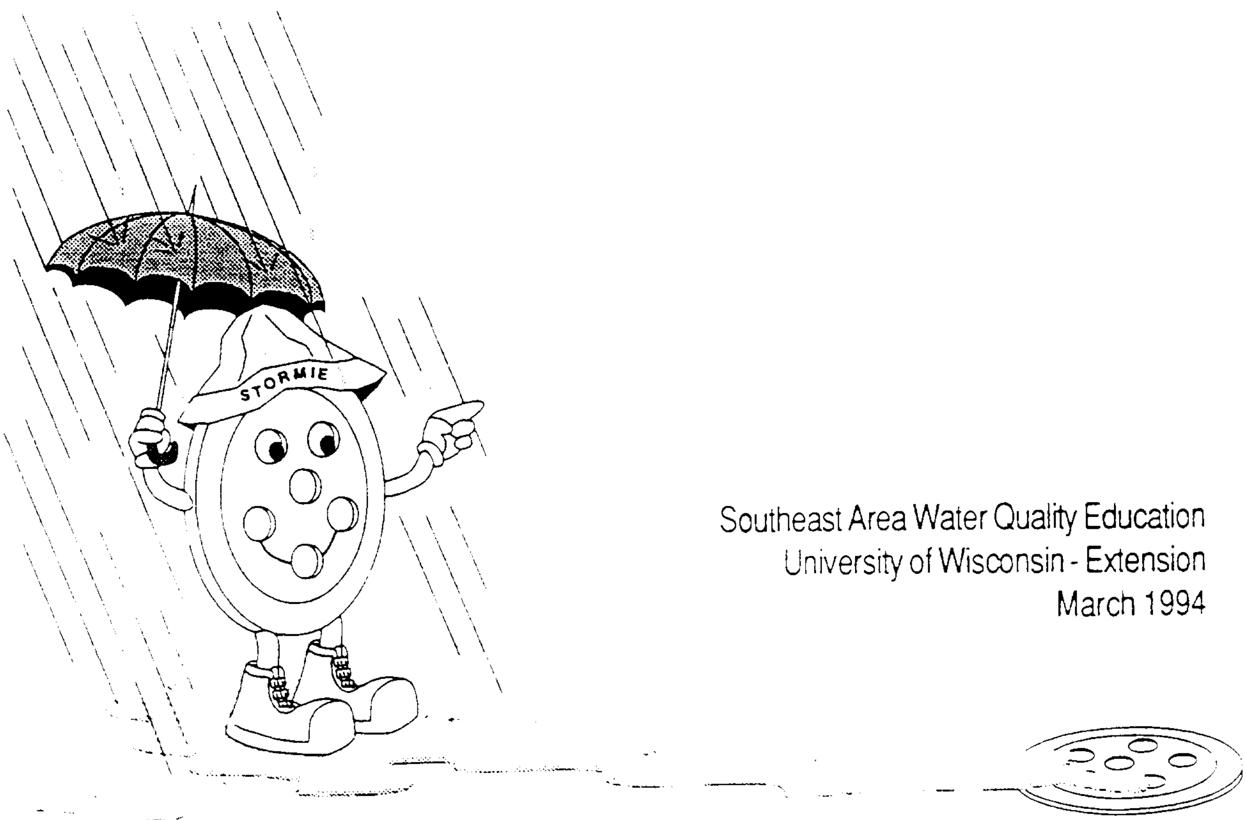
AUDIENCES

Spreading the Word On Storm Water

A Strategy for the Milwaukee Area



Southeast Area Water Quality Education
University of Wisconsin - Extension

March 1994

PROGRAM UNDERSTANDING: Increase understanding of the storm water permit program among affected local governments and industries.

SOLUTIONS ACCEPTANCE: Increase acceptance of and motivation to implement storm water controls and pollution prevention practices among local governments, business and industry, and urban residents.

SKILL DEVELOPMENT: Help local governments, business and industry, and urban residents develop the knowledge and skills needed to implement storm water controls and pollution prevention practices.

IMPACT EVALUATION: Provide information to and solicit feedback from local governments, business and industry, and urban residents about the impact of storm water cleanup efforts.

Target Audiences

Target audiences that must be reached to address these sources of polluted runoff include:

- URBAN RESIDENTS
  - Residents with yards and gardens
  - Vehicle owners
  - Pet owners
  - Schools and youth groups
  - Community groups
- LOCAL GOVERNMENTS
  - Elected officials
  - Staff and consultants
- BUSINESS AND INDUSTRY
  - Automotive businesses
  - Building maintenance
  - Construction
  - Fleet maintenance
  - Landscaping and related businesses
  - Marinas and boat maintenance
  - Mobile cleaning services
  - Outdoor storage and processing
  - Parking lot and grounds maintenance

The Chapter 3 discusses characteristics of each audience and recommends appropriate information and education programs.

FIGURE 5

Ten Keys to a Successful Media Campaign

1. Build on existing themes, mascots and materials—especially the "It All Adds Up" and the "Stormie" cartoon character.

2. Target materials to reach all income, age and cultural groups using appropriate languages, themes, music, media outlets, etc.

3. Use a variety of messages, times and media to reach the critical threshold where people will remember and act on the information they have received.

4. Make the content and tone of messages positive.

5. Appeal to motivations such as clean neighborhoods, health and safety, environmental quality, convenience.

6. Build on what people already know and use sources they consider credible.

7. Use terms that people can easily understand such as "runoff" rather than "nonpoint source pollution."

8. Match the media to the message, keeping in mind that:

    - Print media are most effective for messages that require absorption of details and contemplation by the receiver;

    - Television has the strongest emotional impact, but is the most costly; and

    - Radio's advantages are flexibility and the ability to reach specific target audiences multiple times at a markedly lower cost than television.

9. Use graphics and sound to reinforce messages and make them more memorable.

10. Localize messages, but where appropriate, tie them to national and international events.

1. Internal review during development
   - By author
   - By colleagues
   - By editing, layout, and illustration staff

2. External review during development
   - By staff in other agencies
   - By advisory committee members
   - By potential users

3. User feedback
   - Records of use (numbers distributed, audiences, types of events)
   - Suggestions, complaints, and comments (tracked for revisions or new materials)
   - Requests for further information (through storm water hotline or direct inquiries)

In some cases, a more formal review through mail-back forms, telephone surveys or focus groups will be appropriate.

Evaluating Programs

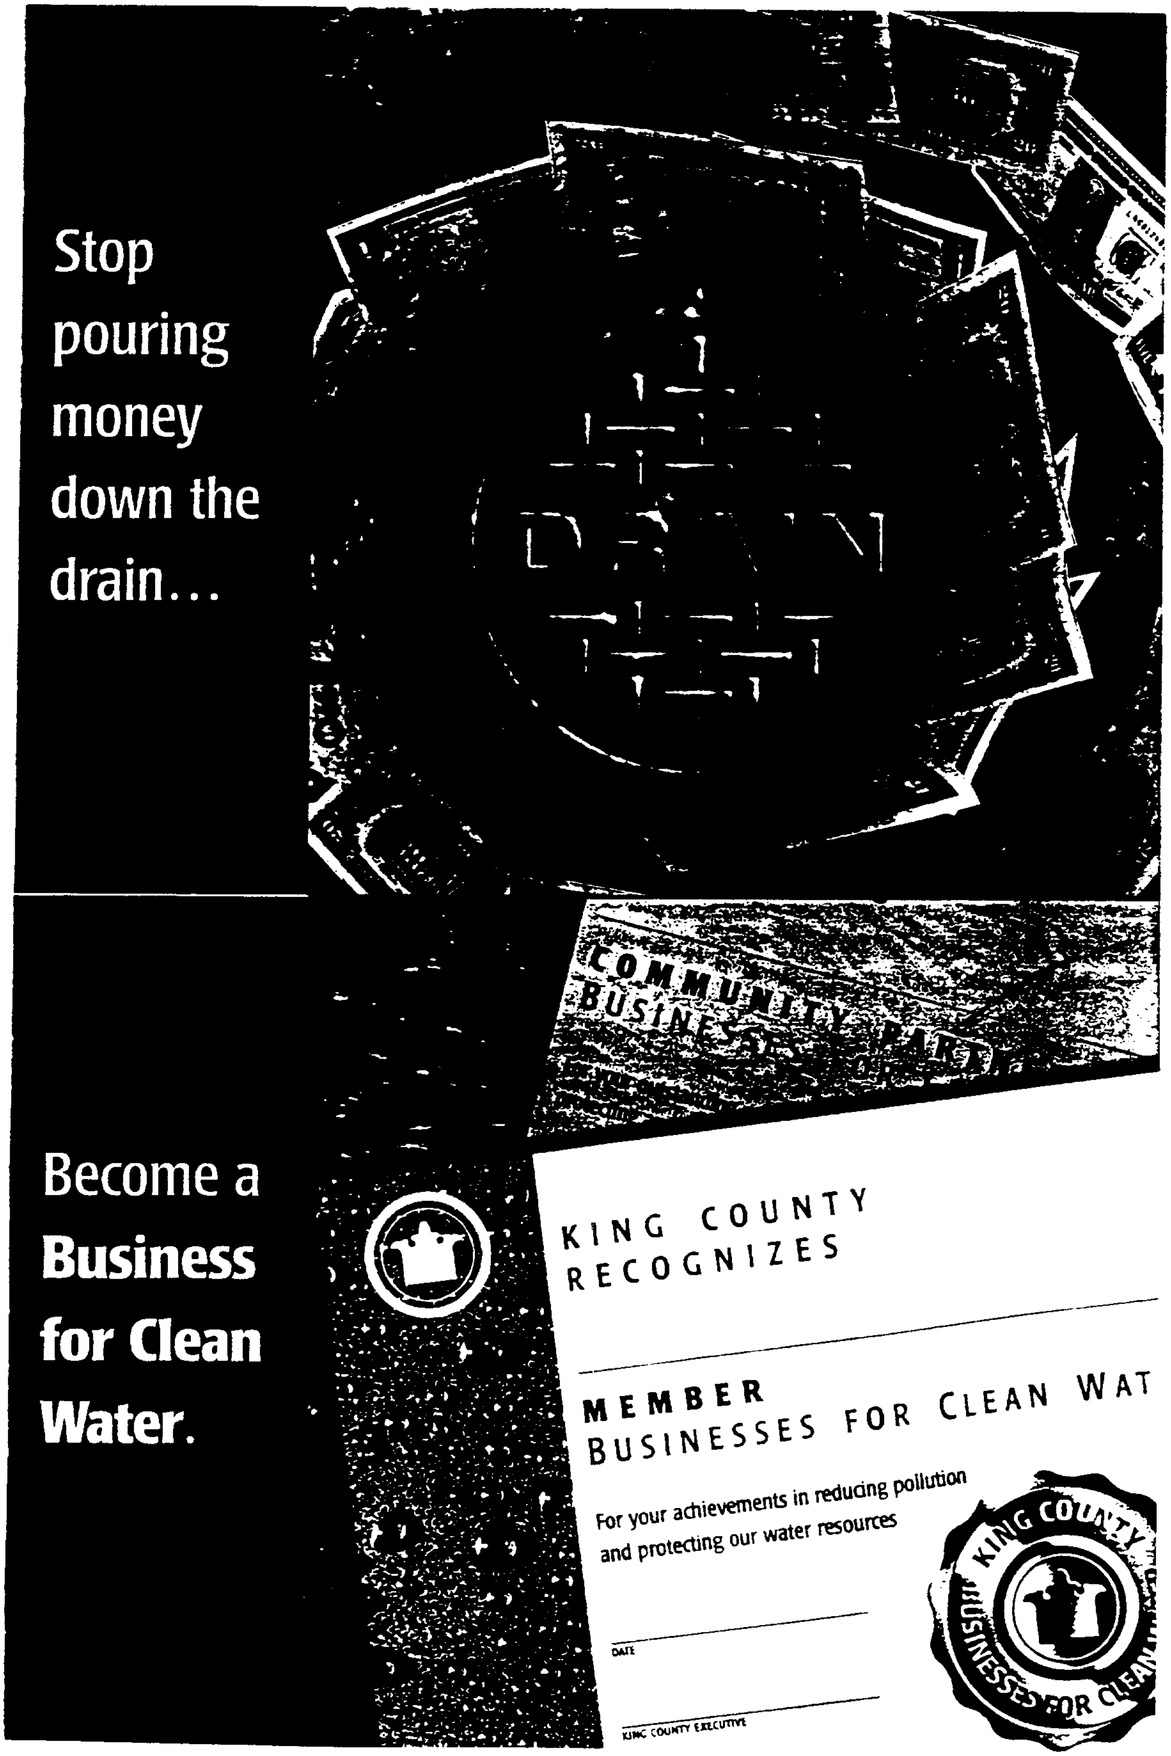
The evaluator's primary responsibility is to gather and interpret information that can help key individuals and groups improve efforts, make enlightened decisions, and provide credible information for public consumption.

Worthen and Sanders 1989

Educational programs such as workshops, staff training and school curricula require even more extensive evaluation. Evaluation typically begins with a planning or steering committee that identifies educational outcomes, oversees program development, designs evaluation tools, analyzes results and makes recommendations for future programs. Commonly used tools include:

1. Records of participation
2. Pre/post tests
3. Evaluation forms
4. Informal evaluation (discussion, show of hands, comments)
5. Records of requests for further information or additional programs
6. Telephone surveys or interviews of participants
7. Case studies of participants
8. Reviews by planning or steering committees
9. Reviews by external agencies

Evaluations methods must be selected for each program based on the type of information needed as well as available time and resources. Each



Stop pouring money down the drain...

BUSINESSES FOR CLEAN WAT
For your achievements in reducing pollution and protecting our water resources
DATE
KING COUNTY EXECUTIVE

R0026282

King County Promotes Your Business for Your Pollution Prevention Efforts

Polluting is like pouring money down the drain—it costs less to prevent it than to clean it up. It's also against the law. When it rains, water carries pollutants into storm drains that lead to lakes and streams. To prevent pollution, sweep your parking lots, cover dumpsters and stored materials, and wash cars in contained areas. **Get recognized for protecting water quality—Become a Business for Clean Water today.**

"I used to think rainwater went to the treatment plant—but only water in toilets and sinks goes to the sanitary sewer for treatment. Most outdoor drains go directly to streams and lakes."

—Yvonne Johnson, Property Manager
Yates, Wood & MacDonald, Inc.

How to get started:

Any business in **unincorporated King County** is eligible to become a member of Businesses for Clean Water by following these steps:

- Call 296-1900 to schedule a **free consultation** and learn what your business needs to do to protect water quality.
- Show us that you have implemented required practices to prevent pollutants from entering storm drains, lakes, wetlands and streams and become a Member.
- Be more than a Member—become a Community Partner—by educating other businesses and the community.

Become a Business for Clean Water and Receive:

- Free publicity in newsletters, newspapers, directories and more.
- A certificate and other materials that show your customers, community and employees that your business works to protect our environment.
- Best of all, you'll have a well-maintained business, reducing costs, time and liability.

"By becoming familiar with pollution prevention measures and properly maintaining your site you'll save money in the long run."

—Denise Hidano, Boeing Computer Services

Water You Doing?

Middle School Education Program

sponsored by the
Seattle Drainage & Wastewater Utility

This project is funded in part with a grant from the Washington State Department of Ecology Centennial Clean Water Fund

Seattle
Engineering Department

Gary Zarker, Director
Norman B. Rice, Mayor

November, 1992

Dear Educator,

Welcome to the Seattle Drainage and Wastewater Utility Middle School Education Program!

Mention Seattle to someone and immediately thoughts of water, water resources, and spectacular scenery come to mind. Puget Sound and all the surrounding lakes, rivers, and streams offer unparalleled recreation opportunities, commercial and sport fishing, one of the world's leading seaports, high quality drinking water, and even electricity. Seattle's residents value clean water and are willing to pay the cost of protecting and preserving this resource.

The Drainage and Wastewater Utility (DWU), a division within the Seattle Engineering Department, is the agency primarily charged with the responsibility for preventing water pollution in Seattle. To that end, DWU places a high value on environmental education of all age levels in an effort to promote non-polluting behavior. DWU is developing educational tools, such as this video and teachers manual, to assist Seattle and other school teachers with their environmental education programs. These tools will help school age children build a sense of respect for our natural water resources and provide them with the opportunity to develop clean water ethics within their school community, their family, and their neighborhood.

Sincerely,

Richard Gustav	Anthony Matlock	Carlton Stinson
Senior Planner	Education Specialist	Education Specialist

Seattle Engineering Department, Room 400, Seattle Municipal Building, 600 Fourth Avenue, Seattle, Washington 98104-1879 (206) 684-5000 TDD (206) 233

INTRODUCTION

This manual is part of an overall water quality education program designed by Seattle Drainage & Wastewater Utility for the students and teachers of Seattle middle schools. The material in this manual reinforces and enriches the concepts presented in the video entitled "Water You Doing".

Together, the video and this manual, along with the accompanying Field Trip Guide, can be used to instruct students of Seattle about some of the issues involved in managing and maintaining water quality within our city.

Because of the uniqueness of individual schools and classrooms, the materials were created to allow teachers maximum flexibility. The information can be taught in a variety of settings with a time commitment ranging from just one class period to an engrossing five weeks or more of in-depth studies.

THE VIDEO

The video is divided into five segments, each segment running an average of six minutes. One segment, followed by an activity and discussion, is structured for a 40-minute class period. The ideal or optimum approach would include a week of studying and interacting with the video and the manual's suggested activities.

THE MANUAL

The manual uses a matrix format. For each video segment, the matrix includes a selection of video foci, learning objectives, bridging questions and suggested activities. This menu-style format was adopted so the selection of approaches could be as effective as possible for various learning environments. At the very minimum, the topic of drainage and wastewater can be taught within one class period. The manual, however, includes other materials for the instructor who desires to extend the topic into a full five-week unit.

THE FIELD TRIPS

A field trip is a unique opportunity for students and teachers to visit and experience some of the lessons and activities offered in the various segments of the video and manual. The Select Trips are fully funded including bus transportation, admission fees and teacher substitutes. Special

(over)

arrangements will be made for any teacher who is interested in the Optional Trips. Further information can be found in the *Field Trip Directory*.

Produced through funding from the Public Involvement and Education Project, financed by proceeds from the Washington State Centennial Clean Water Fund and administered by the Puget Sound Water Quality Authority. This publication may be reproduced.

PUGET SOUND WATER QUALITY AUTHORITY

Introduction

In the end, we will conserve only what we love, and we will love only what we understand
— Baba Dioum, Senegalese conservationist

In 1987 the Puget Sound Water Quality Authority created one of the most powerful tools available for protecting and improving the region's water quality — the PIE (Public Involvement and Education) Fund. The success of this innovative approach lies in the fact that it provides funding to community-based projects that build stewardship for Puget Sound. In the last nine years, the Authority has provided more than $4 million for 230 projects. These projects have spread the message of clean water to at least two million people.

Local Problems, Local Solutions

At the heart of the PIE Fund is the belief that community-based organizations, businesses, local and tribal governments, and schools can involve and educate people about water quality in ways that government, by itself, cannot. Local groups best understand the needs within their own communities, and are best prepared to manage local resources. Through PIE, the Authority has provided direction, funds and technical assistance to enable project sponsors to act on local needs.

In 1987 this philosophy appeared risky and the PIE Fund was very much a pilot program. Today, after hundreds of successful projects have netted tangible improvements in Puget Sound and increased public understanding of water quality, the program has proven its merits as a valuable and responsible method for implementing water quality protection called for in the *Puget Sound Water Quality Management Plan*. The PIE Fund has been used by other states as a model in developing their own public involvement and education programs.

As the PIE program has grown and evolved, so have the PIE projects. Partnerships and alliances among groups with different missions and philosophies is becoming commonplace. Sponsorship from businesses and their related associations has grown. Projects aimed at involving a variety of ethnic groups, particularly non-English speaking people, has grown and, as a result, government agencies are learning how to bridge language and cultural barriers (though much work in this area remains).

Criteria for a Successful PIE Project

- Move beyond "us versus them" attitudes and emphasize that good water quality is in everyone's best interest.
- Emphasize interesting, innovative activities that involve people, put them in charge of decisions and lead to local action.
- Be well-designed and clearly articulate effective methods for reaching identified target audiences.
- Support cleanup and protection of Puget Sound waters.
- Be carried out by groups which have demonstrated their abilities to implement the project they propose.
- Clearly justify expenditures.
- Be guided by an advisory group, which includes a cross-section of affected people (for example, a mixture of business people, local government staff, citizen group representatives and technical experts) as needed for the particular projects.

Before qualifying for PIE funding, projects undergo thorough evaluation by Authority staff and a 12-member Education and Public Involvement Advisory Committee. The committee — which includes educators, business people, farmers, interested citizens, representatives from local and tribal governments, and at least one former PIE contractor — and staff review projects. The process is very competitive — only one of five proposals typically receives funding.

Raspberry Farm Improvement Clubs

This project established Raspberry Farm Improvement Clubs to enable raspberry farmers to experiment with techniques to reduce pesticide use on their farms and share their findings with other farmers.

Project Design

Project staff encouraged farmers to establish Raspberry Farm Improvement Clubs. Through the clubs, farmers developed and performed experiments designed to reduce pesticide use. The farmers received technical assistance from researchers to help develop research proposals. Each club designed an experiment to find a non-chemical solution to a pest problem and carried out the experiments on their own farms.

Results

- Three Raspberry Farm Improvement Clubs developed different experiments to meet their needs and reduce pesticide use. Farmers demonstrated their successes to other farmers through farm visits. The information from the experiments was shared at meetings and workshops and has advanced the knowledge base for alternatives to pesticides.
- Organic raspberry farmers who have been looking for information and help with organic growing techniques now have other farmers to talk to and new techniques to use.
- A strong coalition of farmers, environmentalists, private consultants and researchers formed to broaden support for integrated pest management and to disseminate information on production practices that reduce pesticide use on farms.
- An entirely new way of thinking about pests and pest management was introduced within the farming community and farmers themselves became the ones to find the best techniques and spread the word.

Notes

Peer learning is usually the best way for knowledge to spread. In this project, the farmers worked together to solve problems associated with pesticide use. As members of the Washington Red Raspberry Commission and other farming groups, the farmers became spokespersons for new methods developed in the project.

Perspective

"Six months ago you couldn't get someone to talk about alternatives to pesticides. Now there is a lot of interest." —*Jerry Dobbins, participating raspberry farmer*

Sponsor: Northwest Coalition for Alternatives to Pesticides, P.O. Box 1393, Eugene, OR 97403 (503) 344-5044

Coordinator: Gwendolyn Bane

PIE Funding: $9,015

Additional Resources: $1,200

Timeline: June 1994 - May 1995

Target Audience: Commercial and non-commercial red raspberry growers, researchers and industry representatives in Washington

DOWNSTREAM NEWS

King County Surface Water Management
Everyone lives downstream

VOLUME SIX · NUMBER TWO · SPRING 1996

Downstream News is dedicated to educating and inspiring people *like you* to protect and enhance King County's water resources.

County Executive awards 1996 Community Stewardship Grants with help from Westside School students

At a March ceremony hosted by Westside **School** in White Center, **County Executive Gary Locke** and Westside students presented grant awards to representatives from 12 schools and community groups. Funded both by SWM's Community Stewardship program and by Waterways 2000, the 1996 grantees received a total of $45,000 for a variety of stewardship and education projects in the coming year to protect and enhance King County's water resources.

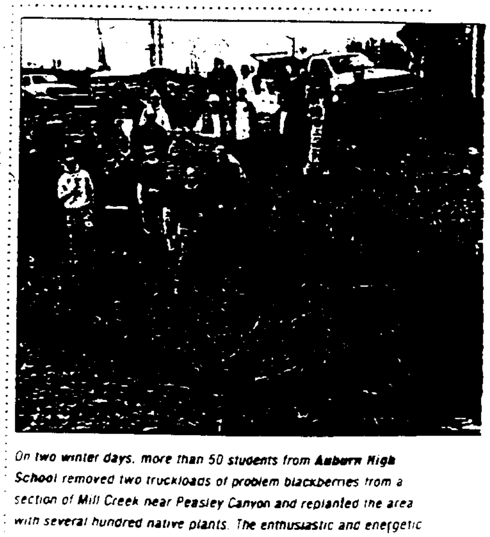
County Executive Gary Locke presents a grant award to teacher Ted Holmes and Westside School students.

With their grant awards, the groups plan to:

- Remove invasive weeds and plant natives along Bear Creek near Woodinville.
- Create and install an interpretive sign near Seola Creek.
- Continue community cleanups of the creek and create a web page.
- Protect, clean up and provide educational opportunities associated with the Shadow Lake bog east of Kent.
- Monitor water quality and educate residents about non-point pollution in the Lake Sawyer watershed near Black Diamond.
- Distribute a Duwamish watershed bike tour pamphlet and develop new educational watershed bike tours.
- Coordinate monitoring, teacher training and a watershed atlas for Thornton Creek.
- Create and distribute a student-made brochure to neighbors to encourage community stewardship in the Cedar River Watershed.
- Plant native riparian species and create an interpretive sign about invasive plants as part of a larger meadow restoration on Cougar Mountain.
- Recruit and train urban youth to do restoration projects in the Green and Duwamish Watersheds.
- Create a video on wetland birds as a tool to teach wetland monitoring.
- Build and maintain a native plant nursery to supply public restoration projects.
- Create an interpretive sign at a park beside the Cedar River, educate park neighbors and monitor the river.

The 1996 Community Stewardship Grant recipients are: **Westside School, Bear Creek Elementary School**, the **City of Black Diamond, Tahoma School District, Maple Valley Rotary, Rainier Audubon Society's Wetlands Group,** Lakeside School, Seattle Aubudon's WETNET, **Cascade Bicycle Club, Issaquah Alps Trails Club, Renton Fish and Game Club**, and the

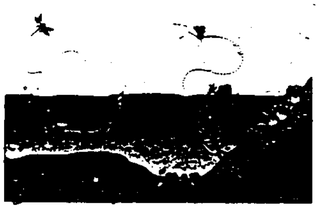
(continued on page 3)



*On two winter days, more than 50 students from **Auburn High School** removed two truckloads of problem blackberries from a section of **Mill Creek near Peasley Canyon** and replanted the area with several hundred native plants. The enthusiastic and energetic group came from the science classes of teachers **Stu Dick** and **Bob Rollins**.*

First, take a medium-sized stream....

Want to put on a community stewardship event but not sure where to start? Turn to SWM's Community Stewardship "How-to Kit", a collection of checklists, handouts and other resources groups can use to put on their own events. Compiled in an easy-to-use binder, the kit was put together by SWM staff as a result of their partnership with **Water Tenders**, a Bear Creek community group. If you're interested in a copy, call **Pat Johnson at 296-8029.**



Stewardship Grants

(continued from page 1)

Student Conservation Association.

As the 1996 grantees begin their Community Stewardship grant projects, last year's grantees are just completing their 1995 projects. More than 2,700 citizens actively participated in the protection of their waterways through last year's grants. They planted thousands of trees, installed more than 3,000 feet of fencing and built several hundred feet of trails. School students around the County learned about frogs and aquatic insects, grew native plants for a variety of restoration projects, and monitored and cleaned-up streams and wetlands near their schools.

With this year's grant awards, the Community Stewardship and Waterways 2000 grant programs have funded 88 projects since 1988 for a total investment of almost $200,000 in protecting the County's water resources. Stay tuned for more details on the 1996 Community Stewardship Grant projects. If you'd like to be notified when next year's grant applications are available, please call Pat Johnson at 296-8029.

Teachers: check out these environmental education resources

There's a wealth of classes and curriculum materials out there this summer to help you teach your students about water resources. Read on for details!

Classes, classes, classes!

- Sign up for one or all of the summer workshops for educators sponsored by the **Thornton Creek Alliance.** From June 22 to 27, learn about GIS, urban watersheds, monitoring and how to use data in the classroom. To find out if space is available, e-mail **Peter Hayes** at **peter_hayes@morrislakesidesea.wa.us** or call him at **440-2754.**
- **The North Cascades Institute** offers a variety of great workshops: check out *Watershed Week for Educators* (July 8-12 in North Cascades National Park), *Where the Forest Meets the Stream* (July 19-21 at Rockport State Park) or *Aquatic Insects: Riparian Habitats and Stream Ecology* (August 10-11 at Baker Lake Basin). For prices and availability, call **(360) 856-1934** or e-mail **nci@ncascades.org**. Or browse their catalogue at **http://www.ncascades.org/nci/**

- And it's not too early to mark your calendar for **TREE3!** The third annual TREE (Teaching Resources for Environmental Education) Fair is scheduled for **October 11** at **Eckstein Middle School** in Seattle. From workshops and exhibits, you'll get tips, lesson ideas and materials on a variety of topics, including watersheds, recycling, energy conservation and much more. For a flyer or more information on attending or exhibiting, call **Polly Freeman** at **296-8359** or e-mail her at **polly.freeman@metrokc.gov**
- Teach kids about rivers and forests! The **Nisqually River Education Project** has put together a guide for educators called *Where the Rivers Begin*, about the rivers and adjacent old-growth forests in **Mount Rainier National Park.** The park offers one-day teacher workshops on using the guide, which is now available in hard copy and on CD-ROM. Call the Park's Education Office at **(360) 569-2211, X3313** for more information.

BUSINESS ASSOCIATIONS CAN GET UP TO $7,500 TO KEEP WATER CLEAN

Business associations and Chambers of Commerce can apply for grants to fund projects in which businesses work together to improve and protect King County's water resources. Possible projects could include promoting pollution prevention practices, producing educational materials or educating and training employees. Target businesses must be located in SWM's service area (the western third of unincorporated King County). Applications are available now and proposals are due on July 1. For more information, call Sandra Kilroy at 296-8047.

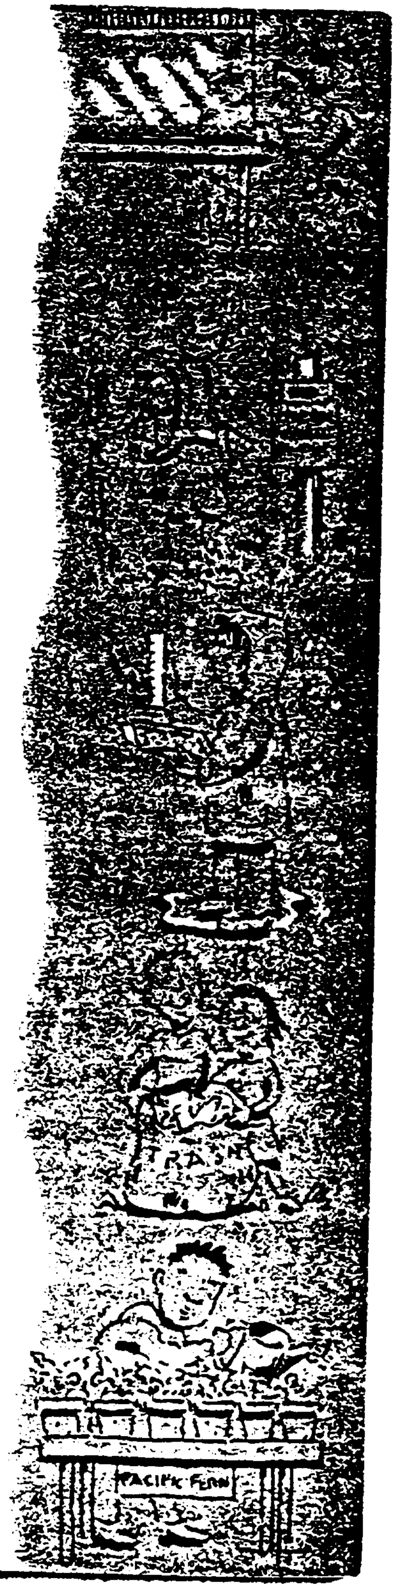
Have you seen this on TV?

ADS ON TELEVISION are just one of the ways local cities and government agencies are encouraging Lake Sammamish area residents to keep phosphorus out of the lake this spring and summer. Interpretive signs in Lake Sammamish State Park, doorhangers distributed around the watershed and low-phosphorus gardening displays at area nurseries are spreading the word to limit phosphorus inputs to the lake.

Why no "phos" for us? Excess phosphorus that reaches the lake stimulates dense growths of algae, turning the lake a cloudy green, causing ugly surface scums and ultimately harming recreational use, fish habitat and water quality. To keep phosphorus out of the lake, apply fertilizer to your yard sparingly, take your car to a commercial carwash, scoop pet waste and make sure your septic tank is in good repair.

Interested in helping get the low-phosphorus message out to your neighbors? Call Polly Freeman at 296-8359 to distribute doorhangers around Lake Sammamish or to learn more about the campaign to control phosphorus pollution.

1996 Community Stewardship Network Directory



King County
Department of
Natural Resources

King County
Surface Water
Management
Everyone lives downstream

What you hold in your hands is a comprehensive directory of community and non-profit groups, government agencies and businesses involved in restoring and protecting the watersheds of King and other Puget Sound counties. This book will help you make new friends, seek assistance from government and business and get connected with efforts to keep our local waters clean.

How to use this directory:

The directory is organized by watershed, city, and group (community/non-profit groups, schools, government agencies, businesses, and independent services). There are two ways to use the directory:

1. Look up the city closest to you. Learn your watershed and find the groups, schools, agencies, businesses and independents that are doing projects in your area. Each listing contains information on what is available and who to contact.

2. Use the group activity charts. At the end of the city and watershed listings, you will find charts that list cities and groups on one side and topics (like wetlands or revegetation) on the other. A dot at the intersection of the row and column indicates what topics are covered by what groups. See pages 58-75

Now that you have this directory, use it to protect our watersheds. Share it with your friends.

Analysis

This website provides an overview and analysis of the problem of storm water-related oil pollution in the US and how it is being addressed. Referring to a wide array of related sites, we describe and discuss the current US federal, state and municipal approaches to safeguarding cleaner and safer water resources in the United States.

PROBLEM

Home | Glossary | References

Why do we care about non-point source oil pollution?

In 1969, the Cuyahoga River in Ohio caught on fire because it became flammable after years of uncontrolled pollution. The horrifying event served as a wake-up call to the American public to address the deteriorating condition of many US rivers, lakes and estuaries. Three years later the Clean Water Act was passed with the objective to make all waterways of the US safe for fishing and swimming by the year 1983. Although this goal still has not been reached, water pollution control has come along way in the last 25 years.

In 1972, two-thirds of our water bodies were unfit for swimming or fishing. Thanks to extensive clean-up ef two-thirds of the water bodies in the country are considered clean and safe, but the remaining one-third of U waters are still considered unsafe. 99% of the five Great Lakes and more than 27,000 Midwest inland lakes advisories to the public that some fish are not safe to eat. While direct discharge from factories has been nea eliminated, our water continues to be poisoned by sources more difficult to handle: non-point sources of pol (Sierra Club Oct 1997).

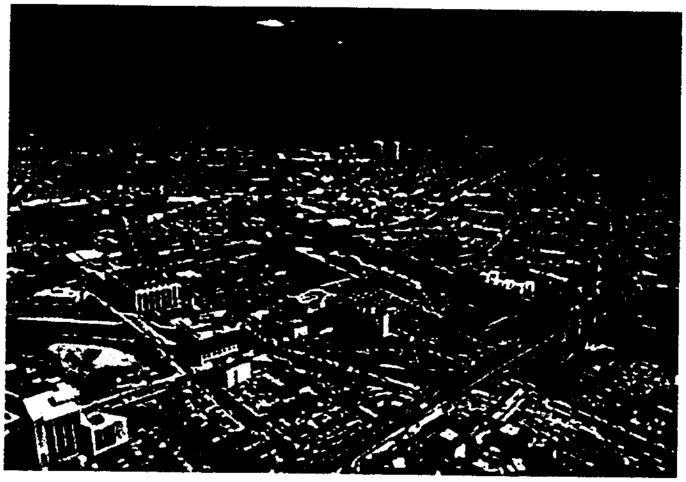
The problem

Polluted stormwater runoff creates surface water pollution. Surface runoff becomes polluted as it flows ove rooftops, paved areas, bare soil, and through sloped lawns. As it moves over these surfaces it collects soil, p waste, salt, pesticides, fertilizer, oil, grease, leaves, litter, and other pollutants to carry with it on its journey nearest body of surface water.

Stormwater may also collect in storm drains, surface ditches, and sewers, which carry these the substances u they reach a river, lake or estuary within its watershed. Contrary to popular belief, many storm sewers do no carry storm water to sewage plants for treatment.

Oil products in surface water are particularly troublesome. There are two main reasons for this.

- Chemicals in oil are so toxic that even small amounts are very harmful to living things.
- Oil pollution comes from non-point sources that are difficult to control because their origin is not associated with particular geographic locations.



Examples of non-point oil polluters of water inc cars, trucks, boats and machinery for agricultura forestry and construction purposes. Yet one of th greatest contributers to petroleum pollution is individual owners of motor vehicles. As we shal in the following section, illicit discharge of motc is a major casue of oil pollution of surface water

On the left: Brooklyn, NY

Although most such sources *individually* pollute only in small amounts, *collectively* they do serious har the natural environment.

Cleanup of oil-contaminated water can be extremely difficult and expensive. Efforts to control oil-polluted s water runoff is therefore focusing on preventive measures – to make sure that spills or leaks do not occur in first place - rather than trying to clean up polluted waters.

Nonpoint Source Pollution Control Program
U.S. Environmental Protection Agency — Office of Water

For more information on non-point source polluti see EPA's Office of Water's Nonpoint Source Pol Program:http://www.epa.gov/OWOW/NPS/roads

Environmental Chemistry of Waste Oil

When waste oil is released into the environment, its chemical and physical characteristics change through a process called weathering. Essentially, weathering occurs as a response to exposure to ambient environmental conditions. Weathering tends to remove the volatile, or aromatic constituents and those that are easily metabolized by microorganisms (Hall and Coon 1988).

The major constituents of concern in waste oil are benzene, toluene, styrene, benzo(a)athracene, napthalene, and benzo(a)pyrene (Mueller Asso. 1989). Each of these constituents is subject to the weathering process, and the exact weathering products of waste oil depend on ambient environmental conditions. For instance, in an aquatic environment, the breakdown products of benzene include butylphenylether, benzophenone, toluene, nitrobenzine, and aniline (Marchini et al. 1992).

After oil enters an aquatic environment, its constituents remain suspended in the water column for a few days. These constituents then migrate into sediments, where they can remain for years (Brown 1980).

In general, there are **seven processes** that can act on pollutants in aquatic environments (Barber et al. 1995)

1. Stick to sediments, where they concentrate (sorption and deposition),
2. Come loose from sediments and reenter the water column (desorption and diffusion),
3. Biological transformation into intermediate compounds or completely biodegraded.
4. Aromatic compounds may enter the atmosphere (volitalization),
5. Accumulate by way of bioaccumulation in animals,
6. May be broken down by sunlight (photolysis), or
7. May be broken down by interactions with water (hydrolysis).

Any or all of these processes can act on constituents of waste oil in surface water.

Biological Effects of Uncontrolled Waste Oil Pollution

HEALTH EFFECTS: WILDLIFE, HUMANS and BIOACCUMULATION

Toxicological studies of the effects of petroleum products on living organisms have focused mainly on the effects of spilled crude on marine organisms and on the effects of processed petroleum products on humans. Probably because waste oil varies depending on how it was used, relatively few studies that were available t us looked specifically at the effects of waste oil in surface waters on human and wildlife health. Nonetheless few studies have been done, and we will extrapolate from studies in marine environments to roughly assess effects in surface waters.

Health effects in wildlife

Brown (1980) performed a variety of experimental investigations into the effects of crude oil from various sources on aquatic plants and animals in southern Louisiana. He found that a measured amount of oil introduced into an experimental brackish marsh ecosystem reduced plant productivity by 88% and, because plants were not growing as quickly, that the oil had long-term effects on the addition of usable organic matt the ecosystem. Populations of zooplankton, which are microscopic animals that live water, declined immediately after the introduction of an oil load into Brown's study area, but these organisms recovered the numbers within two weeks. Crustaceans and fish suffered from behavioral changes and pathological effects. Both types of animals initially swim to the surface and show motor disturbances, both of which make them l able to avoid predators. Long-term, both types of animals suffered from lethal or sublethal skin diseases. Th diseases are thought to occur when oil constituents selectively kill beneficial bacteria that live on exposed tissue. This selective killing of beneficial organisms allows pathological organisms to proliferate, causing disease and death.

The effects of crude oil on birds has been extensively studied in marine environments. Ingested crude oil ca slower growth, damages internal organs, and decreases reproductive success (studies in Hall and Coon 1988

Other workers have found that benzene and its derivatives cause lethal and sublethal effects in freshwater minnows (Marchini et al. 1992).

Health effects in humans and laboratory animals

Summarized in chart below:

R0026334

Compound	Exposure pathway	Physiological targets	Acute effects	Chronic effects	Source
Benzene	Inhalation, skin contact	CNS, metabolized by liver	Severity of CNS depression ranges from confusion up to coma. Destroys bone marrow, may cause chromosomal abnormalities. Known carcinogen, aute myeloblastic leukemia is most common. Lethal to freshwater minnows at moderately high doses.	Accumulates in fat	Hume and Ho 1994, Hall and Coon 1988
Ethyl benzene	Inhalation, skin contact	CNS	Severity of CNS depression ranges from confusion up to coma	Not known	Hume and Ho 19
Toluene	Inhalation, skin contact	CNS	Severity of CNS depression ranges from confusion up to coma, may cause birth defects.	Not known	Hume and Ho 19
Xylene	Inhalation, skin contact	Kidney, body fat, nerves, lungs, brain, muscle, spleen.	(1) Severity of CNS depression ranges from confusion to coma-humans (2) Changes in brain chemistry	(1) 5% of inhaled product is stored in body fat.	(1) Hume and Ho 1994 (2) Studies in Burbacher 1993

Bioaccumulation

Bioaccumulation occurs when environmental contaminants are stored in biological tissues and transferred to other organisms through the food web. When this animal is eaten by another, its load of contaminant is transferred to the predator. Each animal can also transfer some of this contaminant to its offspring. Thus, ev if ambient concentrations of a contaminant are low, tissue concentrations in some animals in the ecosystem be quite high.

This process of bioaccumulation can have devastating effects on ecosystems—DDT was a bioaccumulating compound that caused almost total reproductive failure in birds of prey in the 1960's and 1970's. The bioaccumulative potential of petroleum products is reduced by two factors. First, the most abundant constituents are straight-chain hydrocarbons, which are readily metabolized and are not known to be highly toxic (Hume and Ho 1994). Second, the toxic aromatics in oil (benzene, toluene, xylene, etc) are light and volatilize quickly enough that they are unlikely to be ingested in water.

The waste oil constituents of most concern are those that are picked up during lubrication, or solvents that a mixed in during pre-disposal storage.

Uncontrolled pollution

Home | Glossary | References

Major Contributors

SOURCES OF POLLUTION | SURFACE RUNOFF POLLUTANT | MICHIGAN STUDY | AMOUNT C

Petroleum pollution of water is often associated with oil spills from big ocean liners like the now infamous Exxon Valdez. A recent report from the National Research Council reveals the truth about the most import sources of oil-pollution (Sierra Magazine 1999). It is clear from the diagram that illicit discharge and urban runoff are the major factors to be considered for control of hydrocarbons (Field 1997. Storm and Combined Sewer Overflow). The graph below illustrates the annual ammount of oil released into the environment worldwide in comparison with the Exxon Valdez.

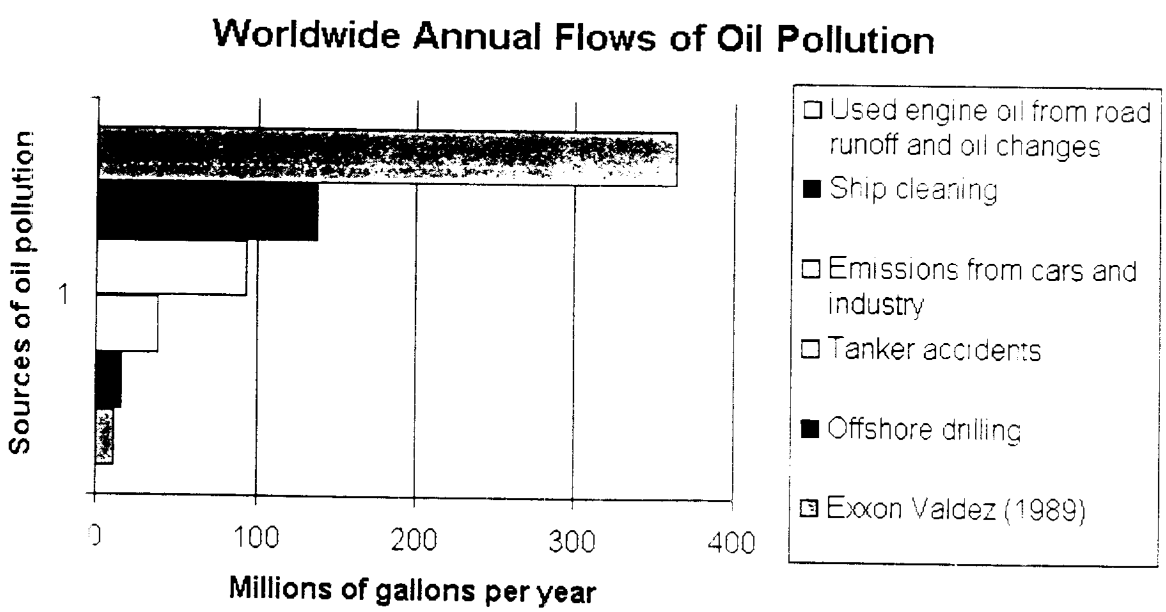

Table 1. Source: National Research Council 1999 (Sierra Magazine March/April 1999, p. 17)

The oil pollution problem in surface runoff

Ongoing studies by EPA have shown that polluted runoff is a major factor in the degradation of water resou in the US. Storm water runoff in particular is considered by the EPA to be the *biggest* current threat to heal national water resources.

In EPA's "National Water Quality Inventory" 1994 report to Congress, the EPA indicates that storm water discharges from a variety of sources, including separate storm sewers, construction, waste disposal, and resource extraction activities, are "major causes of water quality impairment. Roughly 46% of the identified cases of water quality impairment in surveyed estuaries are attributable to storm sewer runoff (EPA 1998. NPDES rule proposal, p. 2).

How does oil get into stormwater runoff?

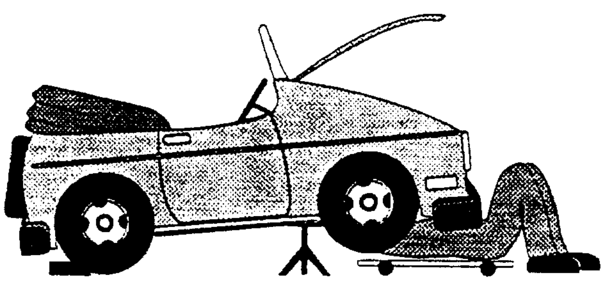
Leaks and dumping: In urban or construction contexts, oil and grease are may leak onto road surfaces from car and truck engines, may be spilled at fueling stations, and may be improperly disposed of instead of being taken to recycling stations.

Improper disposal includes dumping directly to a storm water sewer pipe materials, and dumping on the ground, where the material may drain directly to a storm sewer or be washed into a storm sewer during a sto event. Rain and snowmelt can also carry these pollutants directly to adjacent surface waters.

Runoff in storm sewers is usually carried to a wastewater treatment plant with other sewage. These wastew treatment plants treat water to remove conventional pollutants such as oil and grease. During heavy storm events, the quantity of stormwater runoff entering sewers can overwhelm treatment plants. These heavy stormwaters bypass the treatment plant and are discharged without treatment. This untreated discharge cont many contaminants, including waste oil.

Effects of bad and illegal plumbing: Studies have shown untreated storm water sewer discharges often include wastes and wastewater from *non*-storm water sources, commonly referred to as **illicit discharges**. These discharges are ``illicit" because the storm sewer systems are not designed to accept and discharge, or t process, such wastes. These discharges require government permits under the Clean Water Act. As a result, illicit discharges to storm sewer systems can create severe widespread contamination and water-quality problems.

Example: Michigan study on improper disposal of oil products by commercial facilities



The Ann Arbor and Ypsilanti municipal water qual projects in Michigan inspected 660 businesses, homes, and other buildings and identified **14 perce** of the buildings as having improper storm sewer dr connections. The program assessment revealed that on average, **60 percent** of automobile-related businesses, including service stations, automobile dealerships, car washes, body shops, and light industrial facilities had illicit connections to storm sewer drains. The program assessment also showed that a majority of the illicit discharges to the storm sewer system resulted from improper plumbing and connections, which had been approved by the municipality when installed. (Huron River Pollutio Abatement Program, Washtenaw County Statutory Drainage Board, 1987.)

Effects of actions by private citizens: Improper disposal of materials to street catch basins and other storm sewer inlets often occurs because many people mistakenly believe that disposal to such areas is an environmentally sound practice. Part of the confusion may occur because some areas are served by combine

R0026337

sewer systems, which are part of the sanitary sewer collection system, and people assume that materials discharged to a catch basin will reach an appropriate municipal sewage treatment plant; however, very few places in the United States actually treat their storm water. The vast majority of storm water sewers discharg effluent directly to surface waters.

The materials that are most commonly dumped on the ground or in storm sewers by the general public inclu

- used oil,
- household toxic materials,
- radiator fluid, and
- litter (disposable cups, cans, and fast-food packages).

Table 2. Percentage of respondents that reported disposal, in the past 12 months, of motor oil, paints, or chemicals at (a) county collection sites; (b) local service stations; (c) into sewer or storm drains.

	Number of Respondents	County Collection Sites	Local Service Stations	Sewer or Storm Drains
Total Number of Responcents	~200	90+	70+	approx. 40
Percentage of Total	+ + 100%	45%	35%	20%
County A	+ 60	67%	25%	8%
County B	+ 75	27%	53%	20%
County C	+ 65	31%	38%	31%
One-Person Household	+ 35	43%	43%	14%
Two-Person Household	+ 65	38%	39%	23%
Three-Person Household	100	50%	30%	20%
Owners	120	67%	25%	~ 8%
Renters	+ 80	13%	50%	37%

Source: http://www.epa.gov/owowwtr1/OCPD/ex_6-5t.html, *Measuring Progress of Estuary Programs* (EPA 1995)

Through recent community-level initiatives such as recycling and household pickup programs there h been increasing success in addressing these problems. (See Community Activities) The EPA seems increasingly aware that this is a necessary approach to deal with the problem of oil-polluted storm-wa runoff. When the general public is the main polluter then the traditional approaches developed mainl for industrial pollution are not sufficient. More on alternative approaches in the final section.

How much oil is in stormwater runoff?

R0026338

It is extremely difficult to quantitatively distinguish the individual impact of oil products from the impact of the rest of the set of storm water pollutants. From toxicological data, EPA estimates that oi products constitute one of the most damaging group of pollutants in urban runoff in the US. (EPA 19 Document code fr09ja98-23).

A lot of oil can enter surface waters through stormwater runoff:

- During one four-hour storm, 24,000 gallons of oil and grease, equivalent to a moderate crude oil spill bypassed New York City's Newton Creek treatment plant.
- A study of Jamaica Bay, New York, found that 50% of the petroleum derived materials contributed tc bay are due to wet-weather overflows. The major source of petroleum contamination in Jamaica Bay shown to be waste crankcase oil. This is in agreement with studies of Delaware Bay. Petroleum hydrocarbons and associated aromatic hydrocarbons are a cause of serious ecosystem degradation in New York Bight. Accumulation of polynuclear aromatics in sediments eventually may prove harmful benthic communities in the Bight.

Used oil as a major pollutant: According to a recent study conducted by the National Research Coun the largest source of petroleum-related pollution of water has been identified as storm water runoff (Sierra Magazine, March 1999). This graph was compiled from a diagram based on figures from the National Research Council (and published in Sierra Magazine April 1999) to illustrate the proportion oil pollution from road runoff and oil changes.

Leading sources of water quality impairment nationwide identified in a 1998 report by EPA include non-point and diffuse sources (i.e., urban storm water runoff--runoff from agricultural and urban sources, construction sites, land disposal of waste, and resource extraction), industrial process wastewaters, and municipal point sources.

Table 3. Leading sources of pollution for particular water bodies in the US (EPA1995)

Water Bodies	Urban runoff	Resource extraction	Waste disposal
Rivers/streams	12%	11%	
Lakes/reservoirs	18%		11%
Estuaries	46%		13%

The measured amounts of pollution from diffuse sources, including storm water runoff from agricult and urban sources, construction sites, land disposal of waste, and resource extraction indicate that diffuse sources are a leading cause of impaired waters, as follows (see table 2): The table should be interpreted as follows: Out of all rivers and streams surveyed, twelve percent of them were impaired l urban runoff/storm sewers as their main non-point source of pollution, and 11 percent were impaired resource extraction. Similarly, eighteen percent of the studied lakes, ponds, and reservoirs ere impair by urban runoff/storm sewers, and 11 percent were impaired by land disposal of wastes. Forty-six percent of estuaries were impaired by urban runoff/storm sewers, and 13 percent were impaired by la disposal of wastes.

Economic Damages

Home | Glossary | References

Economic Damage and Abatement Costs

ECONOMIC DAMAGE   ECONOMIC BENEFITS OF ABATEMENT

Economic damage of uncontrolled oil-polluted surface runoff

Loss of ecological services: Water polluted with oil damages aquatic and wetland ecosystems by degrading habitat and harming plant and animal populations. Many of the richest and most ecologically productive habitats occur at the edges of water--along the banks of rivers and streams and along the shores of lakes and oceans. Pollution of these waters can have negative effects on the ability of aquatic and wetland habitats to perform their functions in the ecosystem. These ecological functions can be thought of as services that the ecosystem provides.

By considering ecological functions as *services* they can then be associated with a value. One way to value these services is to find the commodity value of resources extracted from the ecosystem, for instance, the value of a commercial fishery. Another valuation method for ecological services is finding the value of a man-made substitute for the service. For instance, the water purification service of an acre of wetland may be valued at the cost that industry, agriculture, and municipal water suppliers would incur to perform the filtration themselves. Costanza et al. (1997) used both of these techniques in their calculation the value of global annual ecological services. They estimated that the 530 million acres of rivers, streams, lakes, and wetlands provide combined ecological services of $6.58 trillion.

Cost of clean-up: The costs of cleaning up major tanker disasters can be very, very high. For instance, the cleanup for the 11 million barrels of oil spilled by the Exxon *Valdez* has cost nearly $4 billion in environmental and legal damages.

Cost of lost recreational opportunities and asthetics: Oil pollution of aquatic ecosystems kills fish and poisons waterfowl. Oil-polluted water can also have an unpleasant odor and may have a film of oil at the surface. These effects combine to damage the recreation possibilities in an on oil-polluted waters, as well as making them unattractive. The cost of oil pollution in these inland waters can be measured as the damage to sport fisheries (which have been valued for marine systems, see EPA 1992) and waterfowl hunting as well as decreases in property values for properties adjoining or containing oil-polluted waters.

R0026341

Economic benefits of abating oil-polluted surface runoff

The economic benefits of abating oil pollution in inland surface waters are the avoided replacement costs for ecological services and the value avoided damage to natural resources commodity production. In other words, oil will not have to be removed from intake water by downstream industrial, agricultural, and municipal users, and commercial fisheries will retain their value. Additionally, recreational opportunities will persist and clean-up costs will not be incurred.

People pay a premium to live near clean water, and one of the technical options for addressing non-point source runoff pollution of surface waters both improves existing waterways and creates new waters. Stormwater retention ponds and constructed wetlands are both recommended as best management practices to control this contaminate. These ponds and wetlands filter out oil and encourage biodegradation and other forms of breakdown, which improve the quality of receiving waters. In addition, these artificial ponds and wetlands can have additional positive impacts on property values (up to $60,000, Frederick et al. Date unknown).

R0026342

Analysis

Home | Glossary | References

ANALYSIS and RECOMMENDATIONS

We have seen that non-point source waste oil pollution of surface waters causes economic and environmental damage. This pollution comes from numerous and diverse non-point sources, which have unique physical and regulatory properties. Because of these unique features, it is not practical to impose emissions charges or to use other emissions-based economic incentives for abatement. It is also unrealistic for any federal regulation to encompass all aspects of petroleum non-point source pollution. Even detailed and thourough legislation calls upon the need for public understanding and participation to address this issue effectively. Although the Clean Water Act is a good beginning, it is not comprehensive enough to remedy oil pollution problems on its own.

Command and control regulation can be used to require best management practices (BMPs) but these measures can only accomplish some abatement. Economic incentives should focus on markets for used and waste oil. As the current situation for the used oil markets is unstable, the incentive for new waste reduction and recycling technologies lies in the economic benefit of conserving oil.

Non-point Source Pollution

Non-point sources demand non-traditional approaches

On the previous pages on this web site, we have seen how the problem of oil pollution in US surface waters is closely linked to inappropriate consumer practices, such as illicit discharges and leaks from deficient motor vehicles. As shown in a 1998 report by the National Research Council, the most important source of oil-related water pollution is motor oil in storm water runoff - commonly washed off from oily parking lots or dumped directly into the storm sewers by ignorant car owners. These pollution-source characteristics pose a particular challenge to policy makers when trying to come up with an effective government regulatory response. As a government agency, how do you enforce a policy that aims at regulating the way millions of Americans handle used motor oil?

EPA's command and control policy instruments were primarily developed to curb industrial sources of pollution. Applying the same uniform standard approach to regulate non-point source oil-pollution of surface water is likely to have little effect and run into tremendous enforcement problems when applied to a non-point pollution problem. The EPA knows this and has therefore introduced programs such as the National Pollutant Discharge Elimination System (NPDES), which incorporate criteria for Best Management Practices (BMPs) for different actors.

Why the Clean Water Act is Not Enough

Water pollution control has come a long way in the US since the Cuyahoga River burst into flames 30 years ago. The Clean Water Act of 1972 should get most of the credit for accomplishing the observed improvements, but the command and control approach of the Clean Water Act can only take us so far. It may have been effective in curbing industrial discharge and other point sources of pollution, but the uniform standards approach has done little to reduce pollution from non-point sources (NPS) of inland surface waters. Non-point sources, however, remain a major problem for inland surface waters -- and for policy makers.

Why BMPs are Not Enough

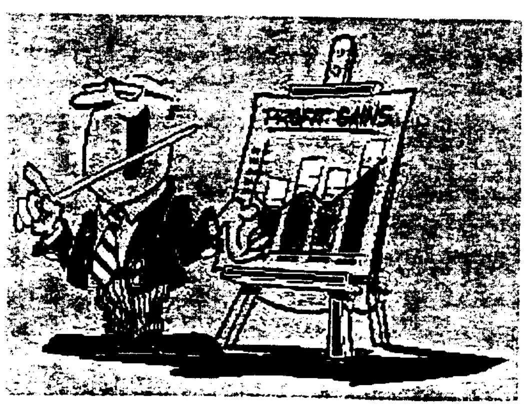
We believe that the EPA initiative to include Best Management Practices in the mainstream EPA non-point source programs represent an important step in the right direction for government interventions, especially when dealing with municipal non-point sources and agricultural runoff. The initiative recognizes the important role of local resource users and the decisions they make resource use.

These EPA programs are insufficient for controlling the most common non-point source of oil pollution in surface waters in the US - the millions of regular American individuals who handle motor oil on a daily basis. We cannot expect NPDES and similar programs to have any significant effect on oil-polluted storm water. Any command and control-based regulation - even if combined with BMPs - is doomed to fail when it is directed towards millions of individual American consumers. It would be unrealistic (and extremely costly) to enforce such a policy because the EPA cannot acquire complete and perfect information about the full extent of motor oil pollution of surface waters.

Although states have been given responsibility for implementing these NPDES permits, most states do not have the resources to monitor NPS pollution, which means that they can't find some of the less obvious hot-spots that contribute to pollution. The data collection programs that states have are usually designed to monitor point sources. While much NPS pollution may enter receiving waters from facilities that are also point sources, the monitoring equipment may not be set up to detect these different pollutants. The lack of state monitoring programs makes it impossible to measure the success of BMPs in controlling NPS pollution.

If imperfect information leads to limited and sporadic enforcement, then we can also expect low compliance as a likely policy outcome. Consequently, we can conclude that current legislation - even in combination with widely applied BMPs - is not enough to reduce oil-pollution of inland surface waters in the US. The present situation calls for new, complementary approaches that can better address the particular characteristics of oil our problem scenario.

Problems with the Used Oil Market

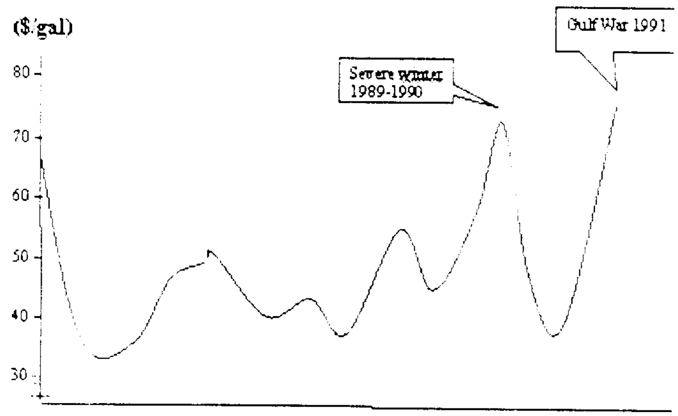


One of the major limitations for the used oil market is the direct impact the price of virgin oil has on the profit margin for recyclers. In order to compete, recycled oil products must be sold at a lower price than virgin oil products (Nolan in EPA 1994). In addition to pricing products below crude oil, recyclers bear the burden of collection costs while trying to maintain a profit. This can be especially problematic for recyclers when virgin oil prices are low.

R0026344

Figure 3. The effects of virgin oil prices on payments made t generators for used oil (EPA adaptation of Nolan et al. 1990

When virgin oil prices dipped below roughly $.50 per gallon, the generators of used oil experienced a loss from $.01 - $.10 per gallon of used oil. The area between the red and blue regions represents a free zone; no payment, no charge. Only at levels indicated by the green figures was it profitable to be used oil generator.



When prices for virgin crude are high, there is a stronger incentive for used oil processing and re-refining because recyclers and transporters will pay for it. Conversely, low virgin oil prices encourage onsite burning of used oil (EPA 1994). Because the value of virgin oil has fluctuated dramatically in the last decade, it is very difficult to create a stable used oil market.

Complementary Incentives for Increased Compliance

We do not argue that the US government should give up its command and control approach and the Clean Water Act and have it replaced by market-based policy instruments. We believe that the CWA is a good base for controlling a dangerous contaminant such as motor oil and that it should be taken further.

We argue that if the US government is serious about reducing oil-pollution of surface waters, then BMPs should be taken further and linked to a series of complementary market-based incentives. The goal of these market approaches is to create a market for waste oil that will make used oil too valuable to waste. Introducing a motor oil tax or a deposit/refund incentive would create incentives for DIYs to keep track of oil and will create incentives for commercial used oil generators to comply with BMPs. EPA proposed these and other market incentives in 1991 but have not put them into place. These market-based approaches, which rely principally on a self-regulating price mechanism to achieve a socially optimal market equilibrium, should reduce the need for the government to acquire perfect information and thus lower the costs of monitoring and enforcement.

Recommendations

Based on the above analysis, we would like to urge policy makers and all other motor oil users to consider and support the following steps for immediate action:

R0026345

- 1. Extend the current NPDES instrument for storm water runoff control to include all the major actors associated with oil-pollution storm water and develop appropriate BMPs for the expanded NPDES program. Although it is difficult to measure the direct environmental impact of such measures, it is nevertheless an important step to take.

  2. Introduce market incentives to achieve higher compliance for BMP standards for individual users. We specifically would urge policy makers to consider a policy mix consisting of a combination of some or all of the following instruments:
- A product tax on motor oil as to achieve a socially optimal market equilibrium and to raise revenue to finance incentive programs;
- A deposit/refund system on motor oil as to provide a direct cash incentive for user to recycle the used oil through an authorized agent;
- A price floor for virgin oil as to make recycling of used oil more profitable;
- A series of economic incentives to promote appropriate BMPs associated with private consumers' handling of used motor oil, such as providing opportunities for training and technical assistance on BMPs and introducing small grant programs to support the development of innovative local responses to address the used-oil problem at the neighborhood level;
- Tax incentives for petroleum and other related industry companies that engineer new products to efficiently manage new and used oil.

3. Expand the current efforts to inform the public about the adverse effects of illegally dumping used motor-oil into the street sewers, and

4. Conduct more studies on the economic damage of oil pollution of US surface waters, so that a quantitative benchmark can be established against which new policies can be evaluated.

In light of economic and environmental considerations, we feel these approaches to addressing the problem of surface run-off petroleum pollution would prove effective in significantly reducing the amount of oil in our waters. These recommendations are in no way the only instruments that may be employed to address this issue. By revising government regulation, market practices and public perception, the problem of oil pollution may be less threatening to human health and the environment.

38 About the UCLA Institute of the Environment

41 RC 1998 Revisited

From the Editors

The Southern California Environmental Report Card is produced once a year by UCLA faculty under the sponsorship of the UCLA Institute of the Environment. Each issue contains several articles addressing critical environmental concerns facing the fourteen million people in the Southern California region. The goal of every article is to provide an introduction and background to the science and policy, describe the current situation, and then evaluate in a balanced manner relevant performance of the public and private sectors, and the general public, in meeting the challenges of that particular environmental concern.

The environmental issues addressed in each Report Card will rotate over time. While the dominant environmental problems of the region dictate that various aspects of air and water quality will be ongoing themes, other important environmental topics will also be addressed. For example, in the first Report Card published last year (RC 1998), one of the articles discussed the state of wetlands in Southern California. In this year's Report Card (RC 1999), one article considers the impact and control of wildfires. Another assesses the state of environmental education in primary and secondary schools.

While faculty who write for the Report Card are all experts in their fields, they represent a wide range of academic disciplines, including social science, natural science, law, public health, engineering, urban planning, public policy, and others. Since environmental issues do not come neatly packaged by the usual academic disciplines, it is appropriate that the Report Card present a multidisciplinary perspective. But all of the authors share a common desire to draw on the best scholarship possible in order to help inform local and regional policy discussions.

The environmental problems facing Southern California are complex, and rarely are there simple solutions on which all stakeholders can agree. Therefore, each Report Card in the future as well as the present one will include reactions from knowledgeable commentators on the content of the articles from previous years. Our aim is to foster informed dialog from different points of view. In that spirit, we welcome constructive responses, whether in agreement or contradictory, from any readers who wish to share their views. All of us in Southern California have a stake in working together to find cost-effective and socially acceptable solutions to our major environmental problems.

Richard Berk, Ph.D.
Departments of Statistics and Sociology

Arthur M. Winer, Ph.D.
Department of Environmental Health Sciences

Editors, IoE Report Card

Letter from the Director

This is our second annual Southern California Environmental Report Card (RC 1999). It follows last year's Report Card (RC 1998) which was a great success, judging from the many positive responses we received from decision-makers, faculty, students and the public. Some of the responses we received from agencies are given in a final section (see RC 1998 Revisited) including an account of an important success story concerning wastewater treatment. In this year's Report Card we discuss Wildland Fire, Stormwater Impact, Groundwater Quality, and Environmental Education. All of these affect our local environment and have national implications as well. The grades range from "B" to "F."

Our objective in this and future Report Cards is to focus attention on environmental issues that affect the quality of our lives. We hope to issue a "call to action" when there are problems, as well as recognize decision-makers and the public when credit is due. In this edition of the Report Card, we have a mixed record of successes and failures. We also suggest actions that can be taken to further improve the environment.

As discussed in more detail by our Editors, we hope each Report Card is an accurate, unbiased and understandable account of environmental issues. We believe individuals, agencies and advocacy groups will find the report useful. Each section of the Report Card represents the assessment of an expert in the respective field, and has also been reviewed by senior faculty and others who have broad and penetrating knowledge. Still, we do not expect everyone will agree with all points of these articles. We welcome your responses and comments.

It has been a busy year for the UCLA Institute of the Environment (IoE). Within the Institute, we are practicing an increasingly more popular method of performing research. The complex problems we face are institutional as well as technical. Their solution requires more than a single discipline. Our approach is to integrate research among many disciplines. The Institute represents more than 50 professionals with knowledge spanning environmental fields from 20 different disciplines.

An example of this way of performing research is the Santa Monica Bay Watershed Project "Integrated Urban Watershed Analysis: The Los Angeles Basin and Coastal Environment," an NSF/EPA-sponsored grant. In this project, we are developing a more comprehensive understanding of Santa Monica Bay. Our scientific teams are studying pollutant inputs from all sources, including atmospheric, stormwater, point sources and the ocean itself. We are also studying the transformation and fate of the contaminants within the Bay. Meteorology, both short and long term, is important for this understanding. We recently held a one-day symposium at UCLA with invited guests from agencies responsible for managing activities that affect the Bay. Next year, we will have a second symposium to present our final findings. These results will lead to a greater understanding and new management tools to better protect Santa Monica Bay.

We look forward to your comments and hope you find this year's Report Card useful.

Wildland Fire

by Philip W. Rundel, Ph.D.

Professor, Department of Organismic Biology, Ecology and Evolution

Fire is an inevitable and periodic disturbance in the southern California landscape. The seasonally dry Mediterranean climate, coupled with the presence of flammable chaparral communities in the urbanized wildlands of the mountain areas of Southern California, make wildfire one of the most serious economic and life-threatening natural disasters faced by the region. The long summer drought in our Mediterranean climate results in a pronounced fire season that extends from summer into fall and even into January in unusually dry years. Why does chaparral burn so intensively? These woody shrubs dry considerably during the summer months, and small twigs and dead grasses provide flammable kindling to help a fire ignite. Volatile oils produced by several common species increase the ease of igniting a fire.

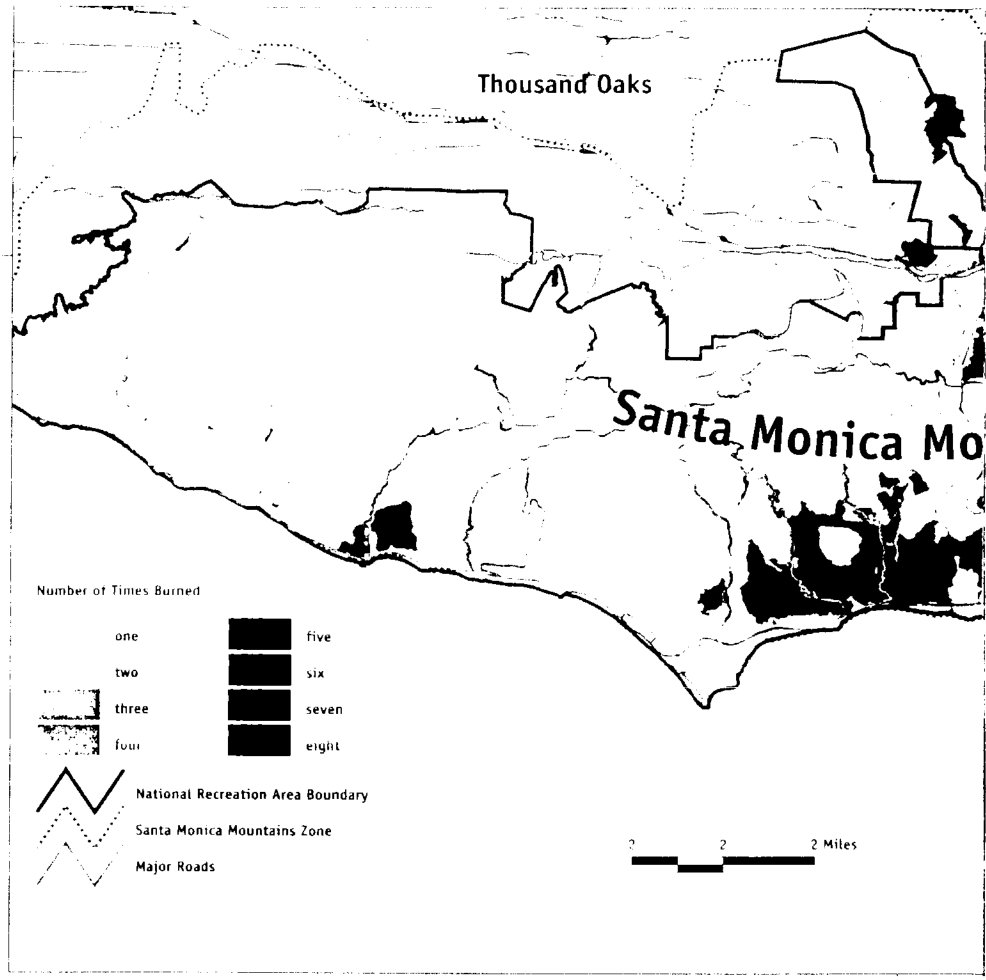
While the cause of chaparral fires was once rare lighting strikes in late summer, most fires today have a human origin through ignitions or regrettable deliberate actions. Human ignitions of fire are far from a random event, and instead occur with predictable high frequencies along specific road corridors. In the Santa Monica Mountains, for example, the [illegible] that [illegible] Ventura Freeway or the urbanized corridor of Mulholland Drive at the northern margin of the range.

The danger of wildland fire spread from many such sites is magnified greatly in the fall and early winter when strong and dry Santa Ana winds from the inland desert blow into Southern California. As these winds funnel through canyons in the transverse and coastal ranges of Southern California, wind speeds increase dramatically. Such winds, coupled with relative humidities that may be as low as 2%, can push firestorms through our foothill regions with alarming speeds and intensities.

Fire, however, is a natural process in our mountains and existed long before human populations arrived. Furthermore, fires perform important ecosystem functions necessary for the healthy maintenance of chaparral and woodland communities. This concept of fire as a natural component of our region is clearly indicated by the remarkable adaptations that exist in our chaparral communities to thrive under fire conditions. Fire, for example, is necessary for the reproduction of many chaparral plant species, and these species exhibit a variety of adaptations for re-establishment after fire, through resprouting from their woody root crowns and germinating new individuals from seeds stored for many years in the soil.

Annuals and short-lived woody species, whose seeds may have lain dormant in the soil for 50-100 years or more, become established in the first spring after a fire and help to stabilize soils against erosion and hold nutrients that might otherwise be lost. The diversity of chaparral species is highest in the first year after fire, and declines as the dominant chaparral shrubs become re-established.

Fire history of the Santa Monica Mountains, showing the number of wildfires that occurred for the range between 1925 and 1997. Note that the Central Malibu coast has received 6-8 fires over this period compared to much lower frequencies to the west and east.



Surprisingly, most animals in chaparral habitats also survive fire very well. Small animals such as snakes, pocket gophers and mice can survive nicely in underground burrows, while larger animals such as deer, coyotes, and bobcats will flee in front of an advancing fire. It is only the intermediate size animals such as small rabbits and woodrats with their stick nests that suffer from fires because they are too large to go underground but not sufficiently agile to flee.

The question of what is a "normal" fire frequency in chaparral and coastal sage scrub has been the subject of considerable debate. Typical estimates range from 30 to 50 years between fires, but in reality we have little knowledge of what such frequencies were prior to this century. Human activities have obviously affected natural fire frequencies. Fire was widely used by Native Americans in Southern California as a tool for maintaining wildlife habitat and for encouraging certain utilitarian plant species. From colonial Spanish times to the current century fire was frequently used by European and Mexican settlers to clear shrublands for farming and cattle ranching.

In recent decades, heightened human activity and arson have increased the fire frequency in some areas, particularly regions close to development and roads. Conversely, current policies of fire suppression that date back 75 years or more have reduced fire frequency in other areas. The irony of fire suppression is that it may have increased the likelihood of catastrophic fires by allowing large masses of flammable plant materials to accumulate with time. This process is reinforced when chaparral canopies suffer an extensive dieback of living tissues, as occurred, for example, during the long drought period from 1987-1993. Fire suppression has occurred at the same time there has been an increased penetration of urban development into chaparral vegetation, and thus increased danger to structures and human lives from wildfires.

FIRE AT THE URBAN/WILDLAND BORDER

The Southern California wildfires of 1993 and 1996 illustrate the dimensions of this problem from a human and urban perspective. Within a two-week period during the Fall of 1993, large parts of the foothill areas of Southern California erupted into flames. Within the Santa Monica Mountains, the Green Meadows and the Old Topanga fires of 1993 raced a linear distance of 25 km within a few hours, consuming a combined area of more than 50,000 acres before stopping at the Pacific Ocean. More than 21 major fires over these two weeks burned through 200,000 acres of chaparral and oak woodland, destroying more than 1,000 homes. Financial losses in the greater Los Angeles area during this period were estimated to be over $1 billion dollars, exceeding the property damage associated with the 1992 Los Angeles civil unrest. Four people died and 162 individuals suffered significant injuries. Added to this cost is subsequent damage from mudslides when heavy rains eroded bare hillsides.

Overall, more than 15,000 fire fighters from every county of California, and all of the western states joined to fight these fires, arguably making this the greatest mobilization of fire fighters in the history of the world. These events were repeated in the fall of 1996, when another fire erupted in the city of Calabasas and followed a similar pattern, burning uncontrollably across the Santa Monica Mountains until it reached the Pacific Ocean. This time, however, a rapid mobilization of fire fighters, a lower population density of homes, and improved levels of clearance around homes built with less flammable materials all combined to greatly reduce the level of property damage.

Throughout much of the Southern California region the buildup of fuels in remaining unburned areas make it inevitable that large areas will burn in the future. Large fires, driven by Santa Ana winds, will burn through vegetation of any age and are

Following chaparral fires, the living vegetation cover is totally burned, leaving only dead shrub skeletons and an ash layer. Most of these shrubs will quickly resprout, however, from underground buds.

Ongoing studies of fire behavior and ecology are providing important insights into the environmental role fire plays in chaparral and woodland ecosystems of Southern California.

exceedingly difficult to control. Without effective management policies and appropriate control on the nature of development, the loss of structures and human life will be an unavoidable consequence of intensive urban and suburban development in zones of flammable vegetation. The continued pressure to expand the urban fringe, and the continued difficulty of managing remaining chaparral fragments within the complex mosaic of land ownership in this area, ensure that fire will continue to be an important policy concern for the human and natural environments of our region.

The combined influence of increasing building regulations (e.g. less flammable building materials, shielding of overhanging decks, wider driveway access, water availability) and the encouragement of brush clearance and low flammability landscaping have done much to reduce danger to individual homes in the foothill areas. Newer homes built under such requirements are significantly less likely to burn than are older homes with flammable roofs and narrow driveways that restrict fire department access.

FIRE BEHAVIOR

Ongoing studies of fire behavior and ecology are providing important insights into the environmental role fire plays in chaparral and woodland ecosystems of Southern California. We know, for example, from 75 years of records that the central coastal areas of Malibu in the Santa Monica Mountains are subjected to far higher frequencies of fire than areas to the west and east. Such knowledge of past fire behaviors and extent are of great value in helping to develop mobiliza-

Fire management in the Santa Monica Mountains and the Los Angeles Basin has developed as a cooperative effort involving many government agencies.

The interfingering of urban development and wildlands in Southern California puts homes at potential risk from chaparral fires.

tion plans to fight future fires in the most effective manner. At the same time, these studies are raising many new questions.

If natural fires were largely ignited in the past from late-summer lightning strikes in August and September, these fires would typically have occurred before the onset of Santa Ana winds. The majority of such fires would be expected to have been low in intensity and relatively small in size. Such fires would produce natural mosaics of chaparral stands of differing ages. Central and northern California are shielded from Santa Ana winds by the Sierra Nevada and as a result have fewer large fires. However, if the seasons of natural fires in Southern California extended into the fall and were influenced by Santa Ana winds, then large catastrophic firestorms may be more typical of our landscapes. We lack the knowledge of fire histo-ies before this century to adequately resolve his question.

FIRE MANAGEMENT POLICIES

Fire management in the Santa Monica Mountains and the Los Angeles Basin has developed as a cooperative effort involving many government agencies. These include the Los Angeles City and County Fire Departments, California Division of Forestry, Ventura County Fire Department, National Park Service, USDA Forest Service, and California Division of Parks and Recreation. The active fire management policies of these agencies have been focused on goals of reintroducing fire as a natural ecosystem process to the degree possible, consistent with the safety of human lives and property, and reducing the amounts of hazardous chaparral fuels present through the use of prescribed burns under controlled conditions. While the cost of active fire management activities is substantial, it is far less in the long-term perspective than the consequent costs of property damage resulting from extreme wildfires. Much of the effort on fire management through prescribed fires is being focused on key areas where historical data suggests such program can be of significant help in reducing fire intensities in areas where fires commonly begin or where moving fires can be controlled.

Fire management policies have led to a number of controversial issues that have now largely been resolved. Early fears of liability issues for property damage associated with prescribed fires have now been surmounted by a California State program of indemnification for fire management agencies which carry out prescribed burns under what are termed *Best Management Practices*. Without indemnification, such prescribed burns would not be allowed.

Prescribed burning presents an effective means of reducing fire hazards in key areas. This technique reduces the build-up of flammable fuels through controlled fires carried out under conditions when fire intensities remain low and controllable.

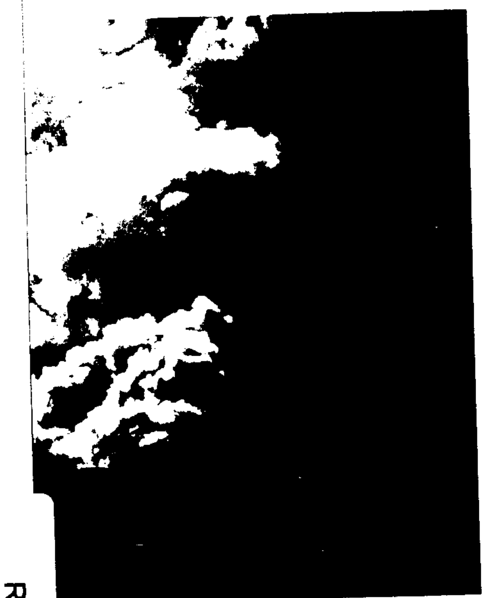
Another example of long-standing controversy resulted from a policy of active post fire reseeding with rye grass or other grasses. This has been a prevailing management practice for many years. The practice continued up until this decade despite a high cost and scientific studies indicating that such seeding offered little or no positive value in erosion control and impaired the ability of the native shrub and herb cover to become reestablished.

Brush clearance regulations remain another issue of contention as increased awareness of fire hazards in the foothill areas has led to more stringent city and county regulations on brush clearance around houses at the urban/wildland boundary. The potential for reduced homeowner's insurance rates through the California Fair Plan program has provided a strong financial incentive to comply with these regulations. Nevertheless, policies on recommended brush clearance practices and distances vary among agencies. There has long been an issue of the impact of new home construction along the boundaries of existing parkland where clearance setbacks extend into these public lands. New regulations now allow the Fire Department to review site plans for homes in the Santa Monica Mountains and many other foothill areas to encourage 200-ft setbacks of new homes from parkland boundaries.

Still other issues remain. In particular, the potential impact of prescribed burning on air quality has led to unresolved problems in evaluating the benefits of chaparral fuel reduction against the consequences of increased particulates in the atmosphere from smoke. Additionally, we still lack an understanding of the natural frequencies and intensities of chaparral fires before the arrival of human populations in Southern

Fire management policies have led to a number of controversial issues that have now largely been resolved.

California. Scientific studies are now using the latest in electronic and remote-sensing technology to permit better predictions of the frequency, intensity and rate of spread of wildfires. However, more improvements are needed.



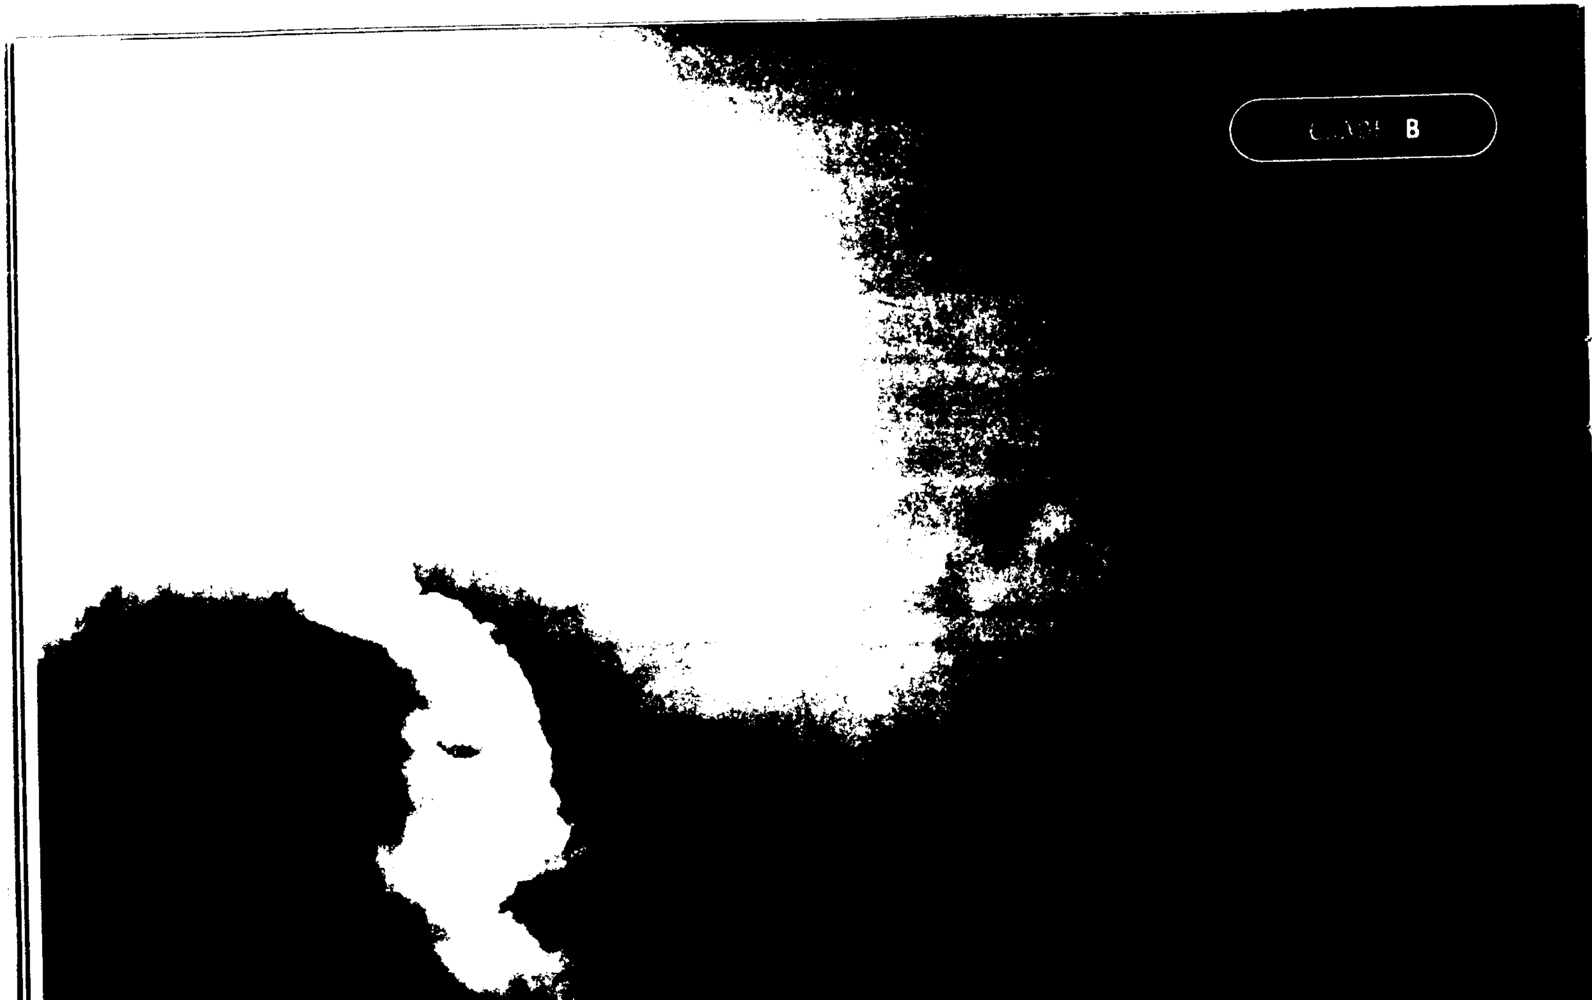
Prescribed chaparral burns create a management dilemma in that they reduce fire hazards but add smoke particulates which negatively impact air quality.

FIRE MANAGEMENT ASSESSMENT AND THE GRADE

The nature of fire management practices in the Los Angeles Basin and Santa Monica Mountains have shown significant improvement over the past decade. **Our previous efforts in wildland fire management deserve a "D".** A key to this progress has been the success of the Fire Alliance program that has brought together government agencies and private stakeholders (e.g. property owners and the insurance industry) to work cooperatively to develop the most appropriate policies for managing natural resources while protecting people and property from wildfires. This level of successful cooperation has been a model for other government/public programs.

In recent years, our overall program of wildland fire management has improved markedly, and now earns a rating of "B".

Philip Rundel is Professor of Biology in the Department of Organismic Biology, Ecology and Evolution at UCLA. He has been a faculty member in the University of California since completing his Ph.D. at Duke University in 1969. He has worked on a variety of studies of fire ecology and fire management in chaparral ecosystems and in mixed conifer forests in the Sierra Nevada. More broadly, his field of research investigates aspects of the adaptations of plants to environmental stress in Mediterranean-climate regions. He has actively worked with ecological studies of chaparral and related shrublands and woodlands in California, central Chile and the Cape Region of South Africa. Expanding beyond chaparral systems, he has also worked on a variety of programs related to the ecology and conservation biology of tropical regions around the world. This work has involved projects in Thailand and Indochina, Costa Rica, Brazil, Zimbabwe and the high Andean Altiplano region of Peru and northern Chile. In addition to his regular faculty duties, he is the manager of the UCLA Stunt Ranch Reserve, a field station for education and research in the Santa Monica Mountains.



B

Stormwater Impact

by Michael K. Stenstrom, Ph.D., P.E.

Professor and Chair, Department of Civil and Environmental Engineering

Coastal waters are one of our most important natural resources. Coastal water quality is the natural resource that gives Southern California one of its greatest reputations—beaches. California's development has affected our coastal environment in many ways. Partially treated wastewater discharges have impacted coastal waters by releasing tons of pollutants, such as DDT (a well known, now banned pesticide), suspended solids and many others. The previous Report Card (RC 1998) described wastewater treatment, our successes and failures, and the plans to reach full secondary treatment, which the City of Los Angeles achieved in December, 1998.

But wastewater treatment is only part of the story. Much more contaminated water reaches our beaches and coastal waters through stormwater discharges, or nonpoint sources. This water, usually called stormwater, crosses a variety of land uses, such as yards, roof tops, parking lots and freeways, before it reaches the ocean. Stormwater was previously thought to be clean and not a pollutant. We now know that stormwater, especially from highly developed urban areas, such as parking lots and highways, contains many pollutants that create problems on the beaches and in our coastal waters.

In the Los Angeles area, we average about 15 inches per year of rainfall, which occurs primarily between November and April. Therefore, we have long periods when no rain falls, allowing trash and pollutants to accumulate on land surfaces and in the storm drain system. The first large storm of the season washes a disproportionate amount of trash to the ocean. You may have seen pictures of "trash plumes" extending from major storm drains, such as Ballona Creek, well into the ocean. The first rain of the season, and the first portion of any rainfall, is called a "seasonal first flush" or "first flush." The first flush is always the most contaminated stormwater. Recent work by UCLA investigators, which was also described in RC 1998, has shown that the bulk of the pollutants entering Santa Monica Bay are from stormwaters, as opposed to treated wastewaters. Future efforts to improve the water quality in Santa Monica Bay, and by implication, most other coastal waters in California, must focus on improving stormwater quality. Unfortunately, stormwaters are more difficult to control than wastewaters. They are more dispersed, with a greater number of public agencies responsible for their regulation. It is not yet clear who "owns" stormwater and is responsible for its cleanup.

WHERE STORMWATER COMES FROM

Stormwater flow and quality are a function of many different factors in addition to the amount of rainfall. Hydrologists use a procedure called the "rational method" to estimate the amount and rate of stormwater flow. Historically, the rational method was used to estimate flows in order to design drainage systems to prevent floods. Flood prevention is an important activity of our public agencies, which has generally been performed well. The rational method assumes that the amount of stormwater that flows from a specific area is the product of the rainfall, surface area and a runoff coefficient. The runoff coefficient is related to the imperviousness of the land. Open areas, such as undeveloped land, have low runoff coefficients, indicating that most of the water percolates into the soil, replenishing groundwater sources. Paved areas have the highest runoff coefficient: virtually all the rainfall becomes stormwater.

Highly impervious areas are associated with urban development and failed ecosystems. When imperviousness (percentage of impermeable surface area) exceeds 20 to 30%, the ecology is affected and sometimes destroyed. The increased stormwater volume

Picture 1: Ballona Creek during dry weather. This picture shows Ballona Creek at the Fairfax Street Crossing. The small flow visible at the bottom is dry weather flow.

and flow rate cause streams to undercut their banks, creating erosion problems and destroying habitat for wildlife. Flow rate in streams draining urbanized areas can change from a small trickle to raging torrents in only a few minutes. Erosion problems require flood control agencies to stabilize stream banks, which turns streams and creeks into the concrete channels we see in movies.

Two areas in the Santa Monica Bay Watershed, which UCLA researchers have been studying with U.S. EPA sponsorship are illustrative. The Ballona Creek watershed, draining the west portion of Los Angeles, is highly developed and more than 60% of rainfall becomes stormwater. It is not surprising that Ballona Creek is a concrete channel with water depth that changes from just a few inches before a storm to as much as 20 feet during a large storm (Picture 1). The concrete channel is needed for flood control, but has destroyed the ecology of the creek. Notice the water level in the second picture (Picture 2) of Ballona Creek. Furthermore, the flowing stormwater cuts through downstream wetlands and natural habitats, and deposits silt where there should be none. In contrast, the Malibu Creek watershed is much less developed and only 30% of the rainfall becomes stormwater. Much of this runoff results from the hilly topography, as opposed to its imperviousness, which is less than 30%. Malibu Creek, while affected from urban development, still retains much of its ecology.

The water quality from the two areas is also different. Stormwater from urban areas transports pollutants associated with land uses. Lawns and gardens release nutrients and pesticides, while streets release hydrocarbons, oil and grease and heavy metals associated with motor vehicles. Ballona Creek stormwater is elevated in many pollutants, such as heavy metals (zinc, lead, copper, and nickel). Malibu Creek stormwater, by comparison, is much cleaner. Recent work by the Southern California Coast Water Research Project (SCCWRP), in partial collaboration with UCLA and USC, suggests stormwater from Ballona Creek is toxic to certain aquatic life forms. Heavy metals are the most suspect pollutants. Stormwater from Malibu Creek does not appear to be toxic.

Another problem with storm drains is dry weather flow. Most observers find it strange that storm drains usually have a small flow, even in the driest portion of the year. These small flows result from natural drainage and "nuisance" flows. The flow from excessive irrigation of lawns, leakage, car washing, hosing down of streets and sidewalks, and other small sources, is nuisance flow. There are also permitted discharges into storm drains from cooling towers and, unfortunately, illegal discharges. These flows all add up and become the unsightly trickle across beaches in summer weather. These dry weather flows represent special problems and require innovative solutions.

Picture 2: Ballona Creek during a large storm. This picture shows Ballona Creek at the same location during a large storm. Reference the water level in this picture to the level in the previous picture using the white pipe that crosses the creek. The violence of this storm is evident, and the noise from the flow was so loud that conversation between two people standing at the bridge was not possible. Urban development causes these high flows, which requires the concrete channels to protect property.

WHERE STORMWATER GOES

Stormwater makes its way from the street in front of your house or your roof drains directly to the ocean through a series of pipes, channels, creeks and rivers, which increase in size until they reach the ocean. There are no treatment plants between the stormwater generation point and the ocean. The time of travel in a major storm may be short (generally around five hours from downtown Los Angeles to Santa Monica Bay, via Ballona Creek) or lengthy in dry weather (more than 25 hours during dry weather flow). During the summer, mounds of plants and algae may grow in the concrete channels. Pollutants are often deposited in the stormdrains during low flow. All of this material is flushed out all at once during a large storm. This makes the problems worse, because the beaches are "slugged," and the large slug of pollutants is generally worse than evenly distributed pollutant discharge.

In the Los Angeles area, stormwater flow to Santa Monica Bay is primarily through two large drains, Ballona Creek and Malibu Creek. There are approximately 30 other storm drains that can affect Bay beaches. The Los Angeles River is another major drain, and discharges south of Santa Monica Bay.

The stormwater that reaches the ocean requires time and distance to mix with the saltwater. This occurs because the temperature and density of the stormwater are different from sea water. Observe that the dry weather spill (Picture 3) does not quickly mix with the sea, but meanders in a plume. Eventually, the plume will become fully mixed, but until this occurs, anything in the plume will be exposed to stormwater pollutants, almost without dilution. During wet weather, the volume of stormwater flow at very large drains such as Ballona Creek, is such that the salinity of the ocean near shore can be temporarily reduced.

BEACH CLOSURES

Beach closures are another symptom of stormwater problems. We are routinely told to avoid swimming near storm drains, and not to swim at all after storms (Picture 4). A recent study, partially sponsored and conducted by Heal-the-Bay, suggested that swimmers near storm drains were at greater risk than swimmers far from storm drains. The rapidly flowing stormwater scrubs bacteria and other pollutants from the land to create elevated concentrations on the beaches, and especially near stormdrains. Also, the greatest stress on sanitary sewers occurs during storms. The high water table causes infiltration, which is

Picture 3: Stormdrain showing a spill. This picture shows a spill from a small stormdrain that terminates at the surf. The brown color of the storm water reveals how it flows in a plume and is not immediately diluted. Our public health authorities have posted beaches, telling bathers not to swim close to stormdrains, for good reasons.

leakage of stormwater into sewers. The stormwater may overload the sanitary sewer and cause it to overflow at a downstream location. The overflow is a mixture of stormwater and sewage and contains bacteria and other pollutants, that can cause a serious health risk when it reaches the beach. Stormwater may in rare cases cause erosion problems, which may destroy a sewer or water line, creating a massive spill. The dry weather flow can also create high bacteria concentrations, especially if there is a sewer leak.

Our public agencies are required to monitor coastal water quality to detect leaks as well as assess the impact of stormwater. They use indicator organisms to determine water quality. Indicator organisms are non-harmful organisms that are associated with disease-producing or pathogenic organisms. Indicator organisms are more abundant and easier to measure than pathogens (pathogens are disease-producing organisms). We believe that monitoring indicator organisms is a more reliable way of assessing the safety of beaches than measuring the actual pathogens. Pathogens are more difficult to detect and less abundant, which means routine monitoring may not detect them.

Coliforms are the classic group of indicator organisms and are routinely measured by agencies that monitor beaches as well as those that operate water and wastewater treatment plants. When coliform concentration increases to a specific threshold, a beach is posted or closed. There are different types of coliform tests and new types of indicator organisms are being evaluated. Progress is also being made to more reliably and inexpensively detect pathogens. Rules for beach closures are evolving, and the limits and required responses by regulators vary across California.

A careful examination of beach closure data for the California's coastal counties reveals no significant upward or downward trend in beach closures. There is a definite trend that shows years with greater rainfall result in more closures, but this is expected. On average, less than 4% of "beach miles" are closed. A beach mile is a linear mile of shore line and is an attempt to standardize reporting. Obviously the closure of a single but very large beach is more significant than the closure of a small beach. At first, 4% of the beach miles being closed sounds like a large amount; however, one must realize that beaches adjacent to large stormdrains are always closed. San Diego County has the greatest number of closures but also has the greatest number of beaches. Does this suggest that beaches are getting better or worse?

In spite of the lack of quantitative data, beach water quality is improving. We are monitoring much more frequently than previously. We should expect to find more problems just because of more extensive monitoring. We also know that several long-term problems have been solved. The City of Los Angeles' efforts to upgrade the Hyperion Treatment Plant and replace aging sewers are resulting in far fewer sewage leaks. Other agencies are also making progress. It is now much more likely that a sewer leak will be quickly detected and fixed than 10 years ago.

Efforts are underway at the State Water Resources Control Board to create a statewide database of beach closures and postings. This is partially in response to a new law, AB 411, which requires greater monitoring and posting of beaches when indicator organisms exceed certain thresholds. Additional indicator organism types will also be monitored. The initial results of this law may be counterintuitive. Far more problems will be reported than before, and the stringent requirements will create more beach closures and postings. This will create a perception that beach water quality is worse, when it is actually the same or

Picture 4: Beaches are posted or closed when the indicator organism count exceeds a specific threshold. Beaches that are adjacent to a stormdrain are permanently posted. The public is also urged not to swim immediately after a storm.

improving. The additional monitoring over the next five to ten years will create a much better understanding of beach water quality.

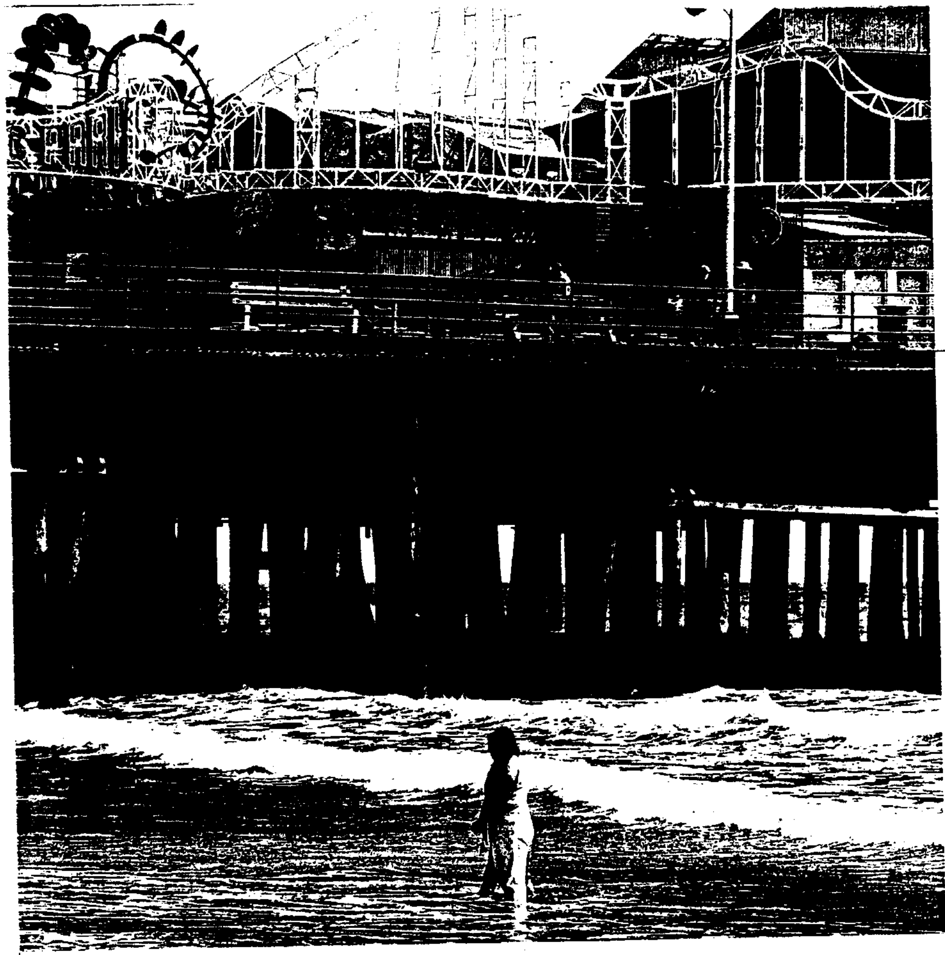
WHAT WE CAN DO ABOUT IT

Stormwater is not as easy to control as wastewater. We cannot simply require an agency to provide treatment. The episodic nature of stormwater precludes the use of treatment plants. One large rainfall, lasting perhaps a few hours, creates more stormwater flow to Santa Monica Bay than our new Hyperion treatment plant can treat in a month. Conventional treatment systems are not appropriate. Instead, we are developing alternative approaches, called Best Management Practices or BMPs. BMPs can be structural, such as stormwater detention basins, or non-structural, such as encouraging the public to practice pollution prevention.

Stormwater pollution prevention must be a joint effort between individuals and public agencies. We also need to rethink some of our building practices. The following section suggests some BMPs for Southern California.

Education: We need to educate the public so they understand that stormdrains are a "large slick pipe" to the ocean. A discarded cup or can will most likely end up on one of our beaches. At present there is no treatment system for stormdrains. Our public agencies have recently instituted stormdrain stenciling to inform the public not to discard trash or pollutants into stormdrains. Litter is infuriating. It is ironic that the same public that wants clean beaches also creates a large part of the problem. Caltrans reports that 20% of the material removed from freeway storm drain inlets is cigarette butts.

Porous Pavement: It is not always necessary to pave areas with 100% impervious material. In other locales, especially in Europe, porous pavements are used. Porous pavement results in more infiltration and less stormwater flow. A variety of forms exist. In some cases, porous pavement can be as simple as using loosely-arranged bricks or concrete blocks. Porous pavements are not applicable to all sites, such as well-traveled freeways. We need demonstration projects to show better the potential applications of this technology.



One large rainfall, perhaps a few hours, creates as much stormwater flow to Santa Monica Bay as our new Hyperion treatment plant treats in a month.

Biomass Injection: If you inspect a parking lot with green space (open space with vegetation), you will probably notice that stormwater is directed towards a drain and not to the green space. Infiltration can occur in the green space and, more importantly, the green space can actually provide treatment for some of the pollutants. Parking lot C at LAX is an example of a site where we should practice biomass injection. The stormwater can be directed to the green space where much of it can percolate into the soil. Excess can flow to a storm drain inlet that is in the middle of the green space. New construction techniques and building codes are required, but they should be no more expensive than existing approaches.

Wetlands, Ponds and Detention Basins: We have little opportunity in our inner city areas to construct wetlands and detention ponds. A wetland is a marsh or swamp (see RC 1998 for more information) in the drain system or coastal area. The natural processes in the wetland can treat many pollutants. Ponds and detention basins are used to capture a portion of the storm flow, especially the first flush. Pollutants can settle out and the stormwater can be gradually released, which avoids scouring pollutants and slugging of the beaches cited previously. These methods are land intensive; however, in developing areas, we can set aside a portion of each new development to provide for stormwater abatement. This is a more common practice on the East Coast.

Trash Screens and Racks: Recent approaches to screening stormwater to remove trash and debris are being evaluated in several places in Southern California. These new technologies may be able to remove trash and gross solids without excessive maintenance or flood control risks. The solutions are not cheap, but will probably provide a viable alternative for trash control. Figure 1 (p. 19, top) shows how these screens work.

Low Flow Diversion: It is possible to pump the dry weather flow from stormdrains to sanitary sewers. This BMP was suggested by the Pico-Kenter Stormdrain task force in the early 1980s. In dry weather, the small flow in the stormdrain is pumped to a sanitary sewer. It flows to the treatment plant and is eventually discharged through ocean outfalls. New treatment plants such as Hyperion have the capacity to handle these flows; furthermore,

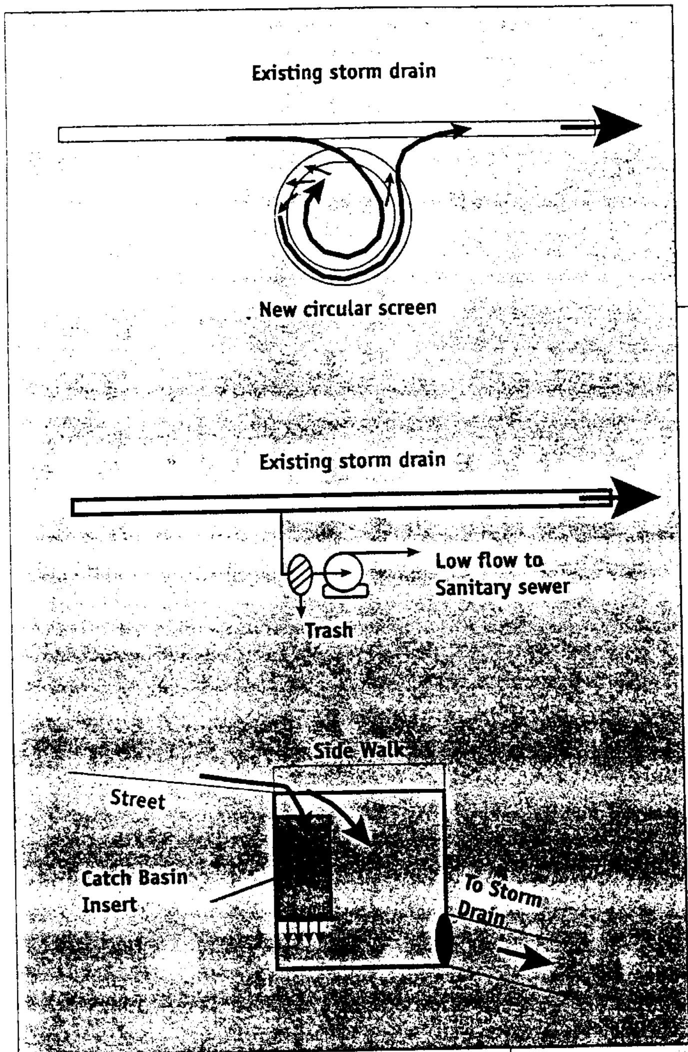


Figure 1

This figure shows three alternative Best Management Practices for stormwater. All have been investigated or proposed by researchers at UCLA.

The top of this figure shows a new type of screen being installed at several places with Proposition A funding. The screen is constructed next to an existing storm drain, represented by the two horizontal lines. A small diversion (weir) is placed in the storm drain to direct a fraction of the flow through the screen. The specially designed screen resists clogging and capture trash, debris and large solids. The captured material must be removed periodically and disposed to a landfill or other appropriate place. These devices are designed to treat the first flush and the smaller storms. Very large storms will bypass the screen.

The middle diagram shows a diversion for low flow. This low flow trickles across our beaches to reach the ocean. By installing a diversion, the low flow can be pumped to a sanitary sewer, then to a treatment plant, such as the Hyperion Plant, where it is treated and discharged several miles away from the cost.

The bottom figure shows a catch basin insert. Normally stormwater flows across the street to an opening in the curb, and from there into a small storm drain that eventually flows to a large drain such as Ballona Creek. Solids, trash and debris collect in the basin. One goal is to clean the basins before the wet season, which prevents the dry weather accumulation (trash, debris, road dust and particles) from reaching the ocean. During wet weather, small storms wash material into the catch basin which accumulates until it is flushed out in a large storm. The insert shown in the figure is a method of trapping the accumulated material so that it is retained in the basin. More advanced inserts have sorbents that will remove a large portion of the suspended solids and oil and grease. The inserts must also be periodically cleaned and replaced.

For over 90 years Civil Engineers have been separating stormwater from the sanitary sewer. Now we are telling them to put the low-flow stormwater back into the sewer.

dry weather flows occur when there is no infiltration (ground water that seeps into sanitary sewers), which reduces load on the treatment plant. The City and County of Los Angeles are planning several such diversions, and ten are in some state of planning or completion at present. Figure 1 (p. 19, middle) shows a diversion.

Street Sweeping and Catch Basin Cleaning: Street sweeping prevents trash and gross pollutants from entering stormdrains. Better sweeping methods to increase the recovery of small particles are being developed. Catch basins (the opening on the street where stormwater enters the stormdrain) can be more aggressively cleaned and maintained. Recent research conducted at UCLA and partially sponsored by a consortium of cities, lead by the City of Santa Monica, has demonstrated that catch basin inserts can retain pollutants and avoid flooding problems. Figure 1 (p. 19, bottom) shows an insert.

Product Replacement and Pollution Prevention: We now know that certain products are more polluting than others. Automobile brake pads are an example. Some brake pads have high metal content, which becomes a stormwater pollutant as the pads wear. Work is underway to provide brake pads with less metal content. There are numerous other examples. Many industries and businesses can practice pollution prevention. Simple measures, such as providing covered storage for product inventory, can significantly reduce stormwater pollution. The public needs to understand and practice pollution prevention techniques. Vehicle inspection programs to reduce smog also reduce stormwater pollution.

WHAT HAVE WE DONE?

How well are we doing? Unlike last year's report on wastewater treatment, the answer is not so clear. Stormwater management is a much more difficult problem than wastewater management. The reasons are both technical and institutional. Although stormwater management was required by the 1972 Amendments to the Clean Water Act, we are still struggling to create a regulatory framework. Successful stormwater management must be practiced by individuals as well as agencies.

The Santa Monica Bay Restoration Project has funded several significant studies to better understand stormwater and mitigate its impacts. This research is continuing, but there is still a long way to go. At least we can now estimate the mass of pollutants from stormwater and treated wastewater; five years ago we could not even do this.

Proposition A is funding a number of construction projects to demonstrate stormwater management approaches. These include screens and trash racks, catch basin inserts, low flow diversions and other management strategies. The successful projects will become models for long-term, full-scale projects and long term changes.

Monitoring programs are improving. The Los Angeles County Department of Public Works is creating a monitoring program, which should eventually be able to measure stormwater runoff from the entire County. Increased beach monitoring will also assist in isolating problems and encouraging solutions.

The rededication to wastewater treatment has resulted in new treatment plants and new sewers. We now have the capacity for low flow diversion in the City of Los Angeles' Hyperion Plant. Preventing sewage spills should have the highest priority. The technology exists to greatly reduce sewage spills.

The past record is not all good. In some instances our public agencies acted only after being sued by environmental advocacy

We previously thought stormwater was clean. Now we know that stormwater transports more pollutants to Santa Monica Bay than the treated wastewaters.

groups. Caltrans, which initially resisted efforts to clean freeway stormdrains, now has an aggressive program to develop solutions preventing freeway stormwater pollution. The U.S. EPA and the Regional Water Quality Control Board are now dedicated to developing a total management daily load (TMDL) for litter from stormwater. Other TMDLs will also be developed.

SUMMARY AND THE GRADE

Large challenges still exist. We lag behind many East Coast and Pacific Northwest communities in preventing stormwater pollution. We are better than many rapidly growing cities, particularly in Asia, where stormwater pollution is sometimes out of control. Unfortunately many of the challenges are not technical, but institutional, and therefore usually more difficult to address. We need to change building codes to improve stormwater management. In many cases, this will result in less development, and we must require developers to set aside land and resources for stormwater management. Agencies responsible for flood control must now understand that pollution control is an equal part of their mission. They must be proactive in developing alternatives that reduce stormwater pollution while providing flood protection. We must reconsider the assumption that the public is not willing to pay for environmental protection. There is ample evidence, especially in the Southern California region, that the public is willing to pay for protection, provided they understand the reasons and are assured the measures are economically and fairly applied. Our regulatory agencies do not have the staff to fully implement the required programs. Clearly, all individuals must practice stormwater pollution prevention in their everyday actions; the blunt truth is that one of our largest problems, litter, could be solved at no cost if people just behaved differently.

Our compromise grade is B. We have not protected the environment sufficiently to earn a B, but the problems are so challenging that we collectively deserve a B for our efforts.

Michael K. Stenstrom has been a professor in the Civil and Environmental Engineering Department for 22 years. During this time he has performed research and teaching in the areas of water and wastewater treatment. He is particularly interested in oxygen transfer, degradation of specific organic compounds and applications of control systems to biological processes. In the past several years he has worked on stormwater management. In this area he has developed a mass emissions model of stormwater-transported pollutants to Santa Monica Bay, and evaluated several best management practices for minimizing stormwater pollution.

Professor Stenstrom received his Ph.D. from Clemson University in 1976 and worked two years in industry before joining UCLA in 1977. He currently serves as chair of the Civil and Environmental Engineering Department. He has written more than 150 scientific publications and received more than $10 million in grants and contracts. He also serves as a consultant to municipalities and industries that wish to improve their treatment systems.

Groundwater Quality

by Tom Harmon, Ph.D.

Professor, Department of Civil and Environmental Engineering

INTRODUCTION

Southern California depends on subterranean water, or groundwater, to supplement its water supply, yet this valuable resource is often overlooked by the general public as an environmental issue. In Southern California, groundwater problems tend to be overshadowed by the more readily observable problems of air or water pollution. This attitude toward groundwater is probably more a case of 'out of sight, out of mind' than one of outright neglect. Nonetheless, ignorance concerning this resource has garnered a woeful legacy of groundwater contamination that will require decades of effort and billions of dollars to mitigate. Thus, it is timely to consider the historical demise of our groundwater resources and what we want to do about these resources in the future.

As Southern California's population and economy grew during the latter half of this century, so did the scope of its groundwater quality problems. Many new and useful chemicals were produced, including 'chlorinated solvents', such as trichloroethene (TCE) and perchloroethene (PCE), degreasing agents used in vast quantities wherever mechanical or electronic components needed cleaning. With their use came leaking tanks, spilling buckets and hasty, poorly monitored disposal of spent solvents. Such behavior appears negligent in hindsight, but was, in most cases, simply the standard practice at the time. This is not surprising for it was a remarkable era of growth for Southern California, and there was little time for environmental foresight.

The purpose of this article is to promote an understanding of groundwater quality as a topic of environmental concern, and to define relevant technical and legislative issues associated with groundwater and its degradation as a resource. Perhaps the most important point to be made is that groundwater quality problems develop over a long time, and require an even longer time for clean up. We illustrate this point by way of a historical narrative about the San Fernando Valley groundwater basin. Finally, the discussion turns to the state of this resource in Southern California today, and its future outlook.

HYDROGEOLOGY 101

Hydrogeology is the study of water quantity and flows in the subsurface terrain (see Figure 1). Groundwater is a generic term for water that has accumulated in appreciable quantities in the pore space of unconsolidated or loose sediments, or in the fractures associated with bedrock. This subsurface reservoir serves as the dominant source of fresh water in the hydrologic cycle. Indeed, groundwater comprises about two-thirds of the fresh water supply on this planet. This water percolates into the ground, a process referred to as groundwater recharge, mainly during the rainy season. It can exit the subsurface through the roots of plants, the beds of rivers, lakes and streams, or water production wells.

Like water in rivers or in pipes, groundwater flows from zones of higher elevation or pressure to zones located downhill, or at lower pressure. Under special circumstances, groundwater pressure differences develop vertically, giving rise to the upwelling of natural springs. However, groundwater flow is typically horizontal and slow, its progress constantly impeded by the surrounding filter material (the soil). In fact, a groundwater velocity of 100 feet per year is considered normal. A slow flow rate means the residence time, or the average time spent by a parcel of water in a groundwater system, may be years, decades or even longer.

Contaminant hydrogeology is the study of the fate and transport of chemicals in groundwater. We have a reasonable understanding of how chemicals pollute groundwa-

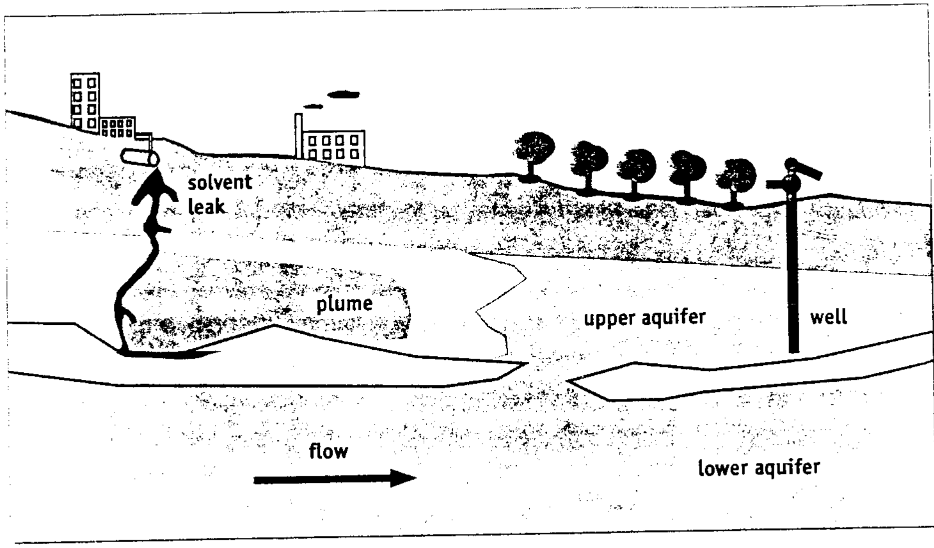

Figure 1: A schematic diagram of a subsurface environment where dissolving solvents are tainting the groundwater supply.

ter once they have been released into the subsurface. They first percolate through the soil until they reach the groundwater. There, they begin to dissolve very slowly into the passing flow, creating expansive plumes of tainted groundwater. The PCE plume shown in Figure 2 depicts this process in a carefully controlled laboratory setting. The slow bleeding characteristic of this chemical dissolution process is due mainly to the sparingly soluble nature of the chemical. PCE, for example, is soluble in the amount of about 150 milligrams per liter of water, or 150 parts PCE per billion parts water.

Regardless of its low solubility, PCE is legally regulated at an even lower level of just five parts PCE per billion parts water. This extremely low limit is due to adverse health effects thought to be associated with long-term exposure to this chemical. The definition of 'long-term exposure' gets fuzzy, but can be interpreted to mean regular drinking and bathing by a community will result in an increase in certain types of cancer and birth defects. Thus, even small spills of these chlorinated solvents can inflict enormous damage upon groundwater basins.

AN HISTORICAL PERSPECTIVE: THE SAN FERNANDO VALLEY

There are Southern Californians alive today who remember when Los Angeles was little more than a bustling town surrounded by picturesque rural scenery. As late as the 1960s, vast portions of the San Fernando Valley remained as part of that scenery. However, the post-war industrial boom and associated influx of population have drastically altered that picture of the Valley, and with it the underlying groundwater resources of the Valley.

To better understand the history of the San Fernando Valley with respect to groundwater, a brief mention of the underlying hydrogeology is in order. Figure 3 depicts a map of the San Fernando Valley floor nestled within the confines of the surrounding mountains. Large zones beneath the Valley floor are known as alluvial aquifers, water-bearing layers of sand and gravel deposited over thousands of years of erosion and deposition of the surrounding mountains. Regional groundwater generally follows the path of the Los Angeles River, flowing from west to east across the valley, then funneling south through the LA River Narrows. In the wider, western expanses of the basin, groundwater flow rates are as slow as 5 feet per year. At the Narrows, flow velocities on the order of 1300 feet per year have been estimated.

There are three key water-bearing zones in the basin which we can refer to as the recent or upper alluvium, the older or lower alluvium, and the Saugas formation, or deep zone. The upper alluvium extends from the

Even small spills of these chlorinated solvents can inflict enormous damage upon groundwater basins.

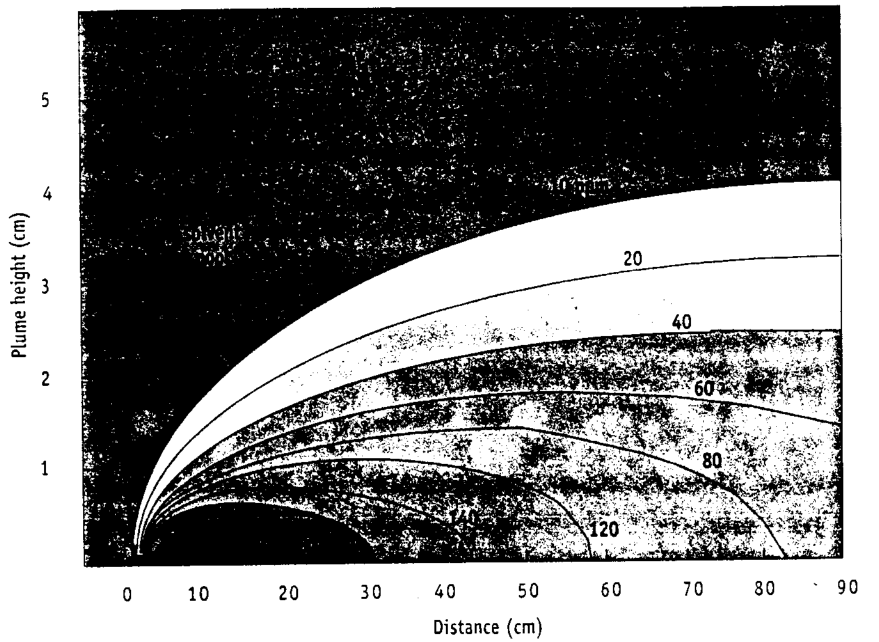

Figure 2: Contaminated groundwater pattern emanating from a dissolving solvent pool as observed by Dela Barre (1999)

ground surface to depths of roughly 200-250 feet. This zone is not fully saturated and the water levels there are quite sensitive to recharge and water usage. The lower alluvium extends to depths of 400-600 feet, and is separated from the upper zone by a layer of about 50 feet of finer sediments. This layer serves as barrier protecting the lower zone from water quality problems in the upper zone. However, the barrier is not failsafe because its thickness and the fineness of its sediments vary widely throughout the basin. Beneath the lower alluvium is the deep zone, which, due to its depths, has been the least-explored of the basin aquifers. It extends to at least 1,200 feet below the ground surface. Historically, groundwater extraction from the basin has been from the upper and lower alluvial zones.

The historical records for water levels in two San Fernando Valley production wells (Figure 4) provides an effective time-line for groundwater usage in that basin. Well 3700A is located in the southwest part of the basin, near Reseda, while Well 3914H is at the eastern end, near Glendale. For both wells, the record indicates consistently high water levels into the late 1940s followed by a steady decline. A severe drought during the late 1940s and early 1950s was responsible for the initial decline in water levels. However, drought alone cannot explain that the water levels for both wells continued to be depressed until the 1970s. Instead, these lower levels must be attributed to the increasing demands placed on groundwater in the basin over this period.

From the late 1970s forward, there was a rather rapid recovery in Well 3914H to pre-1940 levels, yet for the more westerly-situated Well 3700A, there was no such recovery. This difference is representative of the rapidly changing groundwater usage patterns in the San Fernando Basin during this period. Orchards had given way to the housing tracts needed for the growing army of factory workers of the post-war industrial boom. More significantly, this period of highly variable groundwater usage also serves to signal the beginning of historical groundwater quality problems in the San Fernando Basin.

In 1980, traces of industrial solvents, especially TCE and PCE, were detected in San Fernando Valley production wells. This discovery led to drastic reductions in

R0026373

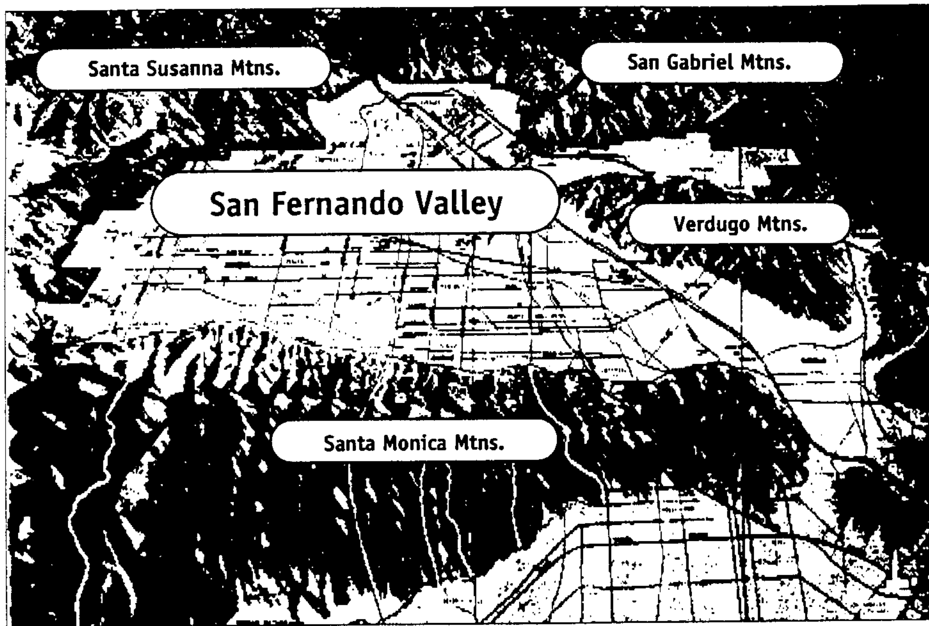

Figure 3: An overview of the San Fernando Valley and surrounding mountains.

groundwater extraction, particularly in the highly industrialized eastern end of the basin. As the 1980s progressed, it became apparent that the soils underlying many prominent factories of the Valley were affected by spills and leaks of these compounds and other toxic chemicals. Ironically, it may have been the reduced pumping of the late 1970s that first brought the groundwater in contact with many of these spills. In 1987, the U.S. Environmental Protection Agency (U.S. EPA) initiated a five-year remedial investigation of the groundwater contamination in the basin. The soils and groundwater underlying the streets and towns of the San Fernando Valley had become a gigantic Superfund site.

The plot in Figure 5 depicts the estimated extent of the upper aquifer TCE plume in the San Fernando Valley in the Spring of 1996. The creeping plume remains largely unchanged today. It is roughly 17 miles long and may contain more than 200 trillion gallons of contaminated groundwater. An interim strategy for extracting and cleaning groundwater at the front of the plume has been designed and will be implemented over the next 12 years while the responsibility and liability of various parties is assessed. However, the ultimate time-frame for cleanup is three decades or longer.

Unfortunately, the San Fernando Valley is not unique. The other major valleys, the San Bernardino and San Gabriel are also Superfund sites with problems very similar in size and scope to those associated with the San Fernando basin. Numerous landfills and military bases offer still other examples of Southern California's hazardous waste legacies in groundwater (see sidebar page 30).

OTHER CURRENT GROUNDWATER QUALITY ISSUES

Due to their ubiquitous usage and stability or staying power in the environment, chlorinated solvents such as those discussed above are the leading source of groundwater contamination in Southern California and the rest of the United States. However, there are many other groundwater contamination issues in our region, such as those associated with fuels, agricultural wastes, septic systems and sea water intrusion.

In the 1980s, it became clear most of the underground storage tanks at gas stations were leaking gasoline into groundwater. Of particular concern in gasoline leaks is benzene, a known carcinogen that is very mobile when released into the environment. As any Los Angeles motorist would suspect, repairing the tank systems and restoring the soil and groundwater around most corner gas sta-

The record for cleaning up contaminated groundwater in Southern California is not very strong.

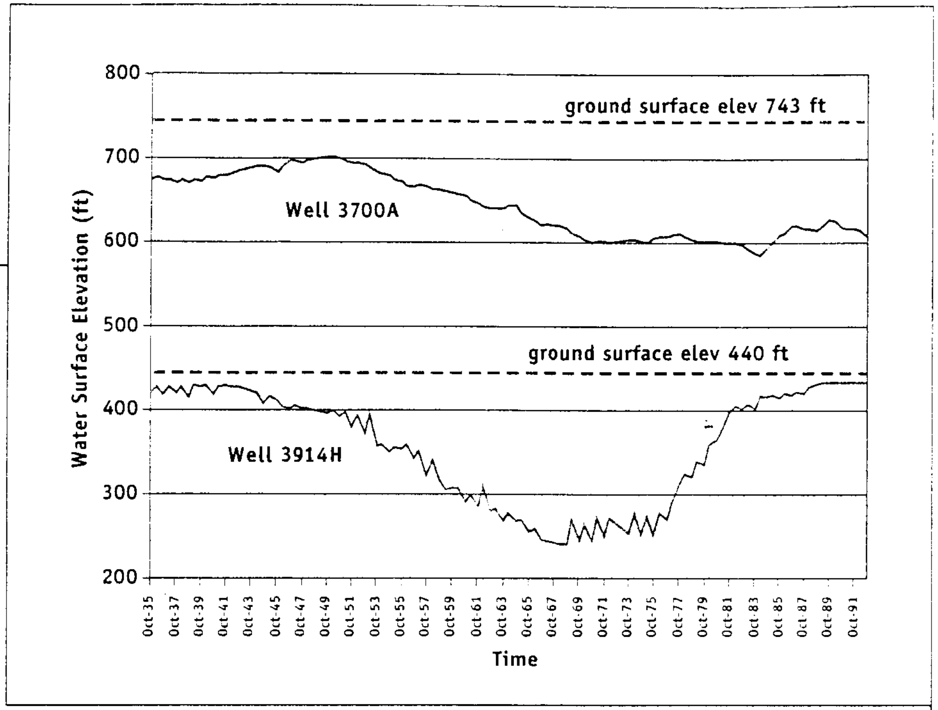

Figure 4: Historical depths to water for two San Fernando Valley drinking water wells (ULARA Watermaster Report, 1995)

tions in the region is an expensive proposition to say the least. Indeed, an estimated $2 billion dollars has been spent on this task in California throughout the early 1990s.

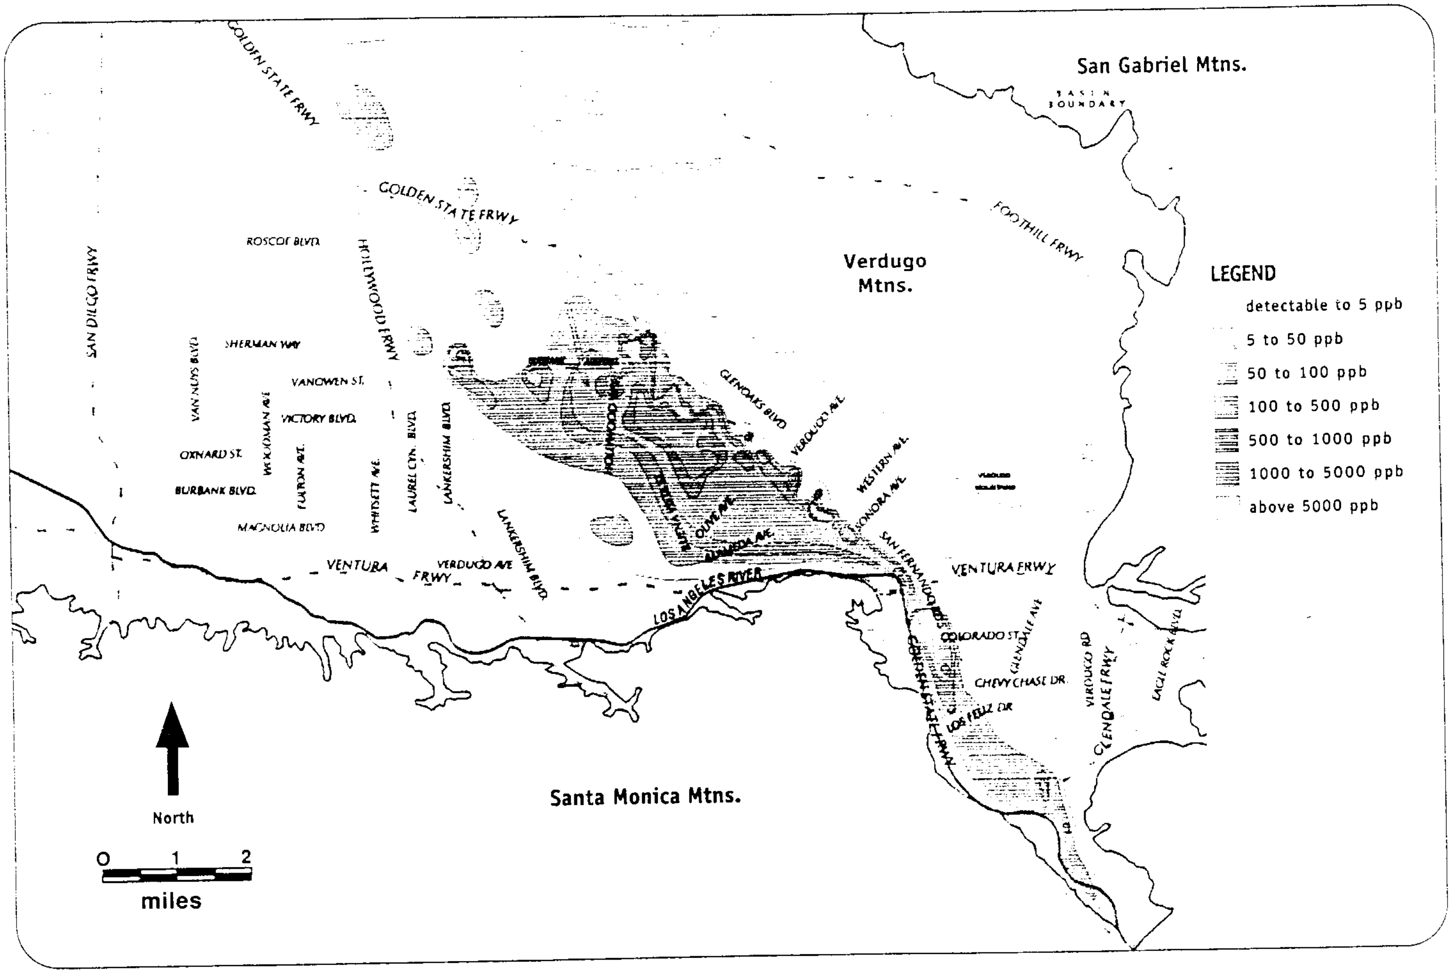
In the face of these costs, a movement toward more economically feasible strategies based on risk assessment was begun. A study regarding gasoline releases in the subsurface was commissioned by the state in 1995 and carried out by an advisory committee composed of scientists from several University of California campuses. The committee reported the human health risk associated with such gasoline releases was relatively small. They noted that plume reduction was generally already underway at such sites due to the biodegradability of gasoline components. Just as momentum was beginning to build behind the notion of worrying less about leaking underground gasoline tanks, a new problem arose in the form of cleaner burning gasoline mixtures.

Around the late 1980s, reformulated gasoline mixtures were introduced to help alleviate air quality problems associated with automobile emissions. A key ingredient in these mixtures was methyl tertiary-butyl ether (MTBE). Despite recent efforts to correct the problem of leaking underground storage tanks, MTBE has made its presence known in Southern California groundwater supplies, suggesting that even new tanks are leaking. In the city of Santa Monica, drinking water production wells in the Arcadia and Charnock well fields have been closed due to gross MTBE contamination. Based on its chemical properties and ubiquitous presence in California groundwater, MTBE is even more mobile than benzene, the previous gasoline component of interest. Based on a State-commissioned UC-wide study on MTBE in 1998, Governor Gray Davis proclaimed in March 1999, California will phase out MTBE over the next five years. Clearly, the full environmental impact of this chemical was not adequately assessed before it was introduced into our gasoline supplies.

HOW WELL ARE WE DOING?

Unfortunately, the record for cleaning up contaminated groundwater in Southern California is not very strong. There are many reasons for this poor progress. First, it can take years to gather sufficient information, through exploratory drilling and well sampling, to begin engineering proper cleanup strategies. Second, hazardous chemicals have had

Figure 5: Plume map showing the estimated extent of dissolved trichloroethylene (TCE) propagation in the San Fernando Valley's upper aquifer (adapted from U.S. EPA database)



R0026376

Groundwater quality problems are often a case of out of sight, out of mind.

decades to spread out in the subsurface. Given that federally mandated cleanup goals for many of these chemicals (MCLs) are extremely low, cleanup of major groundwater quality problems, even under the best of circumstances, is a decades long proposition.

In addition to these technical reasons, cost issues are prominent in our failure to complete the cleanup of our groundwater resources. One unsavory problem is that many of the responsible parties view cleanup as a long-term and expensive penalty for what they consider to have been standard operating procedures of a bygone era. As a business they prefer to pay to contest their problems in court rather than expend resources on the cleanup. While litigation costs may be substantial, they are dwarfed by long-term cleanup measures. Furthermore, if a case is stalled long enough, there is always a chance a responsible party's problem will disappear, either by natural dilution processes or through changes in our laws.

On a more positive note, groundwater-related legislation appears to be doing a good job of at least controlling present waste disposal practices. Federal and state agencies, like the Environmental Protection Agency (U.S. EPA), Cal EPA and Regional Water Quality Control Boards are generally aware of most hazardous waste problems with groundwater repercussions. This is not to say there are no longer any active hazardous waste landfills: there are many. These agencies now operate a system of checkpoints to help minimize, supervise and track the waste. And, as the final defense before our taps, Southern California drinking water agencies are also aware of potential problems and regularly screen drinking water for hazardous contaminants. Most of these chemicals are easily removable once identified.

THE FUTURE

Despite this apparent progress, there is still substantial room for improvement in all of these areas. If the recently installed checkpoints discussed above prevent the occurrence of new hazardous waste sites, then they will have served a purpose. However, as we noted at the outset of this article, groundwater quality problems are often a case of 'out of sight, out of mind'. This is also true when it comes to budgets, where funding for local, state and federal agencies, as well as that for education and research, has a tendency to disappear in favor of more visible problems. As a society we need to lobby local, state and federal officials to keep groundwater restoration and preservation in mind when making decisions affecting land and water usage. Some difficult decisions about our groundwater resources will be made in the not-so-distant future. First and foremost, we will need to decide whether we want to pay to clean our aquifers to the levels currently dictated by the law. Those in favor of the cleanup might point out it is a dangerous precedent to begin relaxing environmental standards for any resources. The major impediment to this alternative is it will force us to share the cleanup costs, both as conscientious citizens and as consumers of the products causing the

A glimpse of groundwater seeping from exposed fractures in cliffs along the Southern California coast.

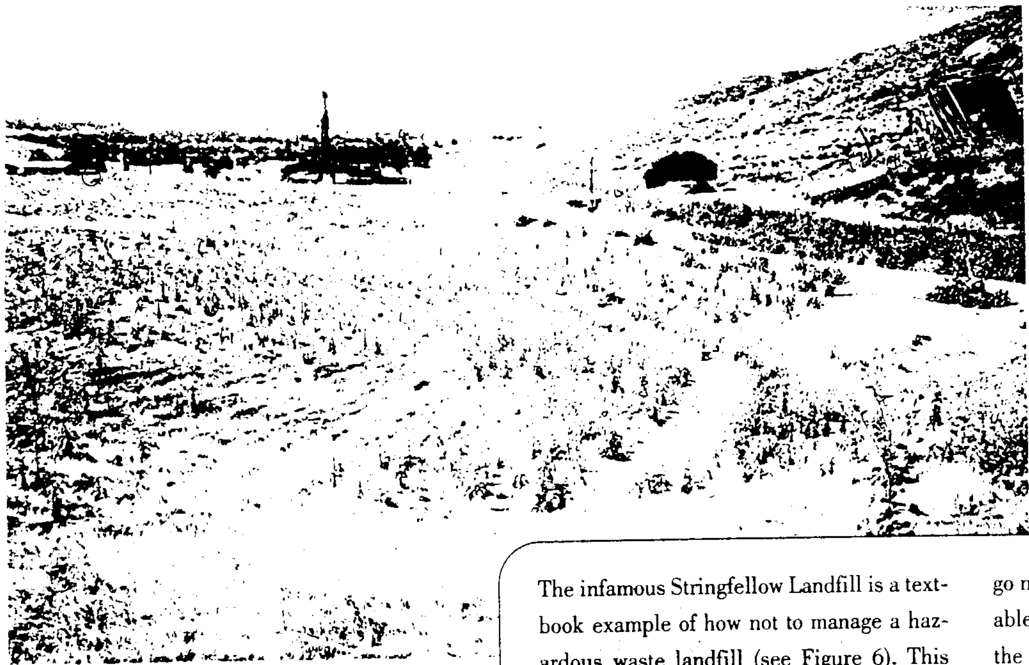


Figure 6: A recent view of the infamous Stringfellow Landfill site as it undergoes remediation.

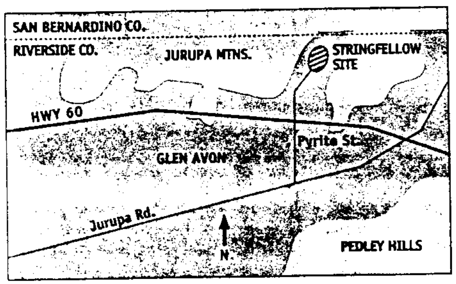

The infamous Stringfellow Landfill is a textbook example of how not to manage a hazardous waste landfill (see Figure 6). This remote, horseshoe-shaped canyon was designated as a potential hazardous waste receptacle by the State of California on little more than a 'drive-by' inspection in 1954. Under extreme pressure from the booming post-war chemical industry, the State lost no time in permitting landowner and quarryman, J.B. Stringfellow Sr., to operate the landfill. With little or no authoritative supervision, the site received an estimated 32 million gallons of hazardous waste between 1956 and its closure in 1972. At its peak operation, waste was dumped into the site's so-called evaporation ponds 24 hours a day. It was believed at the time that the hot, dry conditions would disperse the chemicals into the atmosphere at a rate greater than they were being delivered. It was also believed that any waste that did infiltrate into the subsurface would go no further than the underlying impermeable bedrock. To compound the problem, the waste was often dumped without regard to segregation of incompatible chemicals. The record is rife with horror stories of these ponds catching fire or erupting with toxic clouds. And beneath the surface more enduring problems developed as chemicals seeped through the pond bottoms and underlying sediments into the groundwater below. In hindsight, the reason for this seepage is clear: the bedrock contained a network of fractures which served as efficient conduits for conveying the toxic waste. The photograph in Figure 6 shows the site as it stood in 1992, after nearly 10 years of subsurface investigation and remediation design. Groundwater extraction and treatment, at an on-site treatment plant continues today. It is estimated that nearly half a billion dollars will have been spent on the site before work there is completed.

R0026378

It is a dangerous precedent to start relaxing environmental standards for any resource.

pollution. Those against cleanup might just as rightfully argue that any water marked for consumption is easily treated on an 'as-needed' basis. One impediment to this alternative is the negative public perception regarding drinking water that was formerly referred to as wastewater. If and when this impediment is overcome, we will again need to be prepared to share the cost. In this case, the cost will be associated with the more advanced water testing and treatment processes that such a policy will require.

GRADES

The grades on our protection and restoration of groundwater resources are presented on a historical basis:

Past History: F. The extent of the damage that was done from the 1940s through the 1970s was enormous. There were no watchdog agencies to protect the public interest. The only positive note is that, in most cases, we really did not know what we were doing. We can liken this grade to the one you would expect to receive when you find that you have been going to the wrong classroom for three weeks. Then, when you finally arrive at the right classroom, it's the day for the midterm exam.

Recent History: C. Despite the fact we now have the agencies and technology to address many of our groundwater problems, we remain satisfied with keeping the problems from getting worse. In part, this attitude has been brought about by the nature of subsurface problems, which are difficult and expensive both to characterize and solve. However, a large portion of this attitude is part of a pervading mood of ambivalence regarding what really needs to be considered when it comes to cleaning up groundwater: responsibility, risk, cost, time, or some as yet unknown combination of these factors.

WHAT IS ENVIRONMENTAL EDUCATION (EE)?

If we assume that education leads to literacy then the first question we should ask is "What is environmental literacy?" Earlier this decade, the Environmental Literacy (EL) Framework described environmental literacy as multi-faceted, including a cognitive dimension (knowledge and skill); affective dimension (attitude); and a behavioral dimension (individual or group involvement in environmental action). In 1992, C. Roth defined EL as "essentially the capacity to perceive and interpret the relative health of environmental systems and take the appropriate action to maintain, restore, or improve the health of those systems."

TOWARD ENVIRONMENTAL LITERACY FOR ALL

Should all our students become environmentally literate? A quick answer is "yes." Today's students, both from disadvantaged and non-disadvantaged groups, have listed many concerns, with their environment being high on the list. Students need opportunities to learn they are part of their environment—not observers of it, that it belongs to them as much as to anyone else; and that they, too, can understand it and have a role in its stewardship. In addition, many environmental advances have been made over the past two decades—Los Angeles' air is cleaner now than in the '70s (see RC 1998), and we must ensure that future generations maintain this progress. Students need not become ardent environmental activists nor research scientists, but literate voting citizens who can make decisions based on sound knowledge and evidence—even though some of these decisions may not be in tune with the local environmentalists' perspectives.

Environmental agencies and organizations (including the California Department of Education) that responded to a 1995 survey leading to the report *Pieces of a Puzzle: An Overview of the Status of Environmental Education in the United States* support EE for all:

- "Each individual should have a basic understanding of the environmental sciences"
- "Each individual should understand the relationships between human actions and the environment"
- "Environmental education should be integrated into all school curriculums"
- "Diverse environmental education opportunities should be available to the general public"
- "Environmental education in the state should be a cooperative venture, coordinated at all levels within the state and with national and international networks."

ENVIRONMENTAL RESOURCES

How can we, as educators, help students achieve environmental literacy? Over the past 10-15 years, diverse curricula projects have been developed from a variety of funding sources, each with their own agenda. For example, money from the California License Plate Fund has developed *Project WILD* and *Project Aquatic WILD*. These popular curricula provide classroom activities that model environmental concepts such as population fluctuations, impacts of toxins on food chains and webs, and the effect of the destruction of habitats on local species. Although designed for K-12 grades, they are most popular with elementary teachers. The California Department of Education (CDE) has supported the development of *A Child's Place in the Environment*, a K-6 curriculum that considers a specific environmental concept at each grade level. The Lawrence Hall of Science has

Teachers explore the ecology of Mono Lake.

developed environmental programs such as SEPUP (Science Education for Public Understanding Project) among their many programs for K-12 students. UC Santa Cruz has developed *Life Lab*, a program that uses school gardens as a vehicle for teaching science.

Local and state utility companies also provide a rich source of environmental education materials. The Los Angeles Department of Water and Power (LADWP) had a far-reaching education program until funding was reduced recently. Fortunately, many publications remain that promote understanding of water issues in the city, including transport to the city, purification, and delivery to customers. The Metropolitan Water District (MWD) had corresponding materials. Waste disposal concepts can be taught through *Closing the Loop*, a curriculum developed by the Los Angeles County Department of Integrated Waste Management, in which landfills provide the vehicle for teaching science concepts. Other programs include *Earth Resources*, a program developed by a consortium of oil companies in Texas. These latter two programs are geared toward teachers of secondary grades.

As well as published environmental education curricula, local school districts provide environmental instructional experiences for their teachers and students. For example, the Los Angeles Unified School District (LAUSD) works closely with the Los Angeles County Office of Education (LACOE) to take students to outdoor camps during the academic year. LACOE and LAUSD also offer the Yosemite Institute and Eastern Sierra program for teachers and students. In addition, there are marine science programs offered through Sea Education Afloat and the Roundhouse Marine Science Laboratory in Manhattan Beach. UCLA has developed a small aquarium, the Ocean Discovery Center in Santa Monica, and a marine science program at Fort McArthur that provide programs for students and teachers.

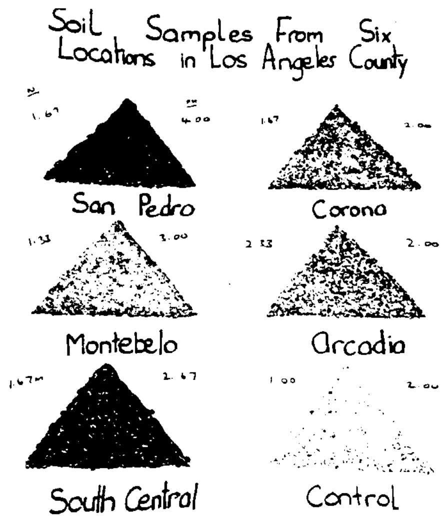
Care must be taken by teachers as they use environmental curricula, especially those published by strong activist groups that obviously further their own specific causes. It is easy to get caught up emotionally in these causes. Environmental issues are not black and white; there are many perspectives from which to study them. Teachers must remain even-handed whatever their own personal views. This does not mean that students should be shielded from activists. But they should be given opportunities to see issues from the perspectives of all stakeholders such as land developers, city councils, local water authorities, tax payers and others. One of the best teaching strategies is the classroom debate. Students must defend the perspectives of interested parties (such as those listed above), thus enabling them to see issues from all perspectives—an uncomfortable but illuminating exercise.

In addition, although it may not be the role of EE to develop activists, it is certainly the role of EE to help students learn actions they can take in their own personal lives that will support a healthier environment. They can learn how to conserve resources such as power and water, recycle, and dispose of toxic materials properly. Action must, of course, be linked to science and social science principles.

ENVIRONMENTAL EDUCATION IN SOUTHERN CALIFORNIA

Visits to local secondary school classes provide varying pictures. In some cases, you will see secondary and elementary students out on field trips to local areas such as the wetlands,

Children in elementary grades respond well to lessons on their environment. Such lessons provide concrete experiences upon which they can build more sophisticated understandings.



Tujunga Wash, the Los Angeles River, and Castaic Dam, learning to understand environmental issues first hand. Others may be reading about them from newspaper or Sierra club articles and debating issues as a means to seeing all sides of specific concerns. Others may never get to environmental science because it's usually the last chapter in the text.

At the elementary level, the approach to EE is somewhat different. Most published programs referred to earlier offer workshops to teachers to help them become familiar with the curriculum, the environmental issues addressed, and, to a greater or lesser extent, the science behind them. However, the report *Pieces of a Puzzle* finds the average length of an EE teacher training program is 2-4 days. Hence the depth of content and quality of teacher training is severely limited. Although follow-up is usually provided in the form of newsletters, Internet sites and telephone hotlines, the preferred method— providing mentor teachers as support—is not common.

University faculty and teachers (usually those of secondary grades) question whether one should introduce students to basic science concepts first and then relate them to the environment, or introduce students to environmental issues and then help them understand the science behind them. There seems to be no hard data on what works best. But, from observations of instructional practice, it is easy to see that environmental curricula are popular with elementary students and teachers for several reasons. Children in elementary grades respond well to lessons on their environment. Such lessons provide concrete experiences upon which they can build more sophisticated understandings. Many teachers, including those less-well prepared to teach science, feel more comfortable teaching science through environmental topics. They often feel more comfortable taking their students outside to explore and ask questions than setting up explorative activities in their classrooms. In addition, elementary teachers relate environmental lessons to those in social studies, thus making them more likely to include environmental lessons in their instructional programs.

In the case of secondary students, those who do not have a natural tendency to gravitate toward science courses often become interested in science through an environmental approach—the increase in popularity of integrated science courses and corresponding low numbers of students enrolling in traditional chemistry and physics courses illustrates this. This brings more students into the study of science. Although it is perceived by some that such courses "water down" science, it may be more challenging to teach science through studying an integrated system such as the environment. To do so, one needs a broad background in all the sciences, and to be able to link concepts across science disciplines. It seems that few faculty and high school teachers feel comfortable in doing this, perhaps because they have strong content understanding in quite narrow fields and thus, only feel comfortable teaching their own specific discipline. This compares to the same discomfort that elementary teachers feel at teaching science, for which they feel unprepared.

CURRENT STATUS OF EE IN TODAY'S EDUCATION SYSTEM

Despite the large selection of EE curricula now available, despite access to a whole wealth of EE information on the World Wide Web, and despite efforts of individual agencies and organizations to bring EE into the education reform efforts of Goals 2000, the majority of school districts list no subject

Hands-on learning at the UCLA Ocean Discovery Center.

called "Environmental Education" in their school curricula. Since most EE curricula projects have been developed by agencies outside the formal education system, the discipline tends to be relegated to the sidelines. Little effort has been made to bring EE into the core curriculum. In addition, despite the recent flurry of activity to develop content standards in academic disciplines, EE has received no such attention. Perhaps this is not all bad. If EE is to be included in the main curriculum, it must be included in the main curriculum standards and not separated by standards of its own. However, in the new State Science Education Standards, there is no mention of environmental science (although there is a very strong strand of ecological standards across the grade levels). It will be left up to the teacher to weave in the environmental perspective.

On a more positive note, one goal of the large NSF-funded Los Angeles Systemic Initiative (LA-SI) is to establish an Integrated Science Program in all LAUSD secondary schools. Since environmental studies provide a rich integrated system, teachers have designed many of their integrated programs around a study of the environment, especially the urban environment. An example of such a program is the Venice HS program on Urban Science. Integrated Science is now accepted as a science course in the A-F requirements for UC entrance. Another positive move toward implementing more EE in secondary classrooms is the new Advanced Placement (AP) Environmental Science course being offered for the first time this year.

COMPONENTS OF AN EE CURRICULUM

Consider again the three components of EL listed at the beginning of this article. We see that although EE curricula usually address the content behind environmental issues, it is more often the attitude and the action components that teachers and students alike will appreciate, get involved with, and remember. It is difficult and challenging, especially at the elementary level, for teachers to focus on science concepts behind the issues. Even at the secondary level, where curricula explain science concepts clearly, it is too often the social and behavioral components that students find interesting. This contributes to the myth that an environmental focus "waters down" the scientific content in EE courses, and leads to lack of support by more traditional departments. However, an environmental issue often provides an excellent way to motivate students to learn more—acid rain triggers student interest in understanding acids and pH. This triggers questions such as what does pH mean? What acids are formed in the environment? Why? How? Why and when are hydrogen ions dangerous? Teachers must then teach the traditional concepts about acids and bases. Too often this last step is not taken. But why?

PREPARATION OF SCIENCE TEACHERS

It is challenging to teach science well both in elementary and secondary grades. Not only must teachers have a strong, broad background in science and be able to identify and clarify science concepts they want their students to learn, but they must also present the material in a way that enables all their students to learn—not simply those who have a flair for the discipline. And as more information is added to the body of science, the task

An increasing number of opportunities for teachers and students to conduct investigative science are available through electronic networks linked through the world wide web.

escalates. Too often, teachers will stop when they have gained their students' interest and not pursue the more difficult challenge of teaching complex content.

Local science education reform programs have addressed this concern by offering environmental programs that strengthen teachers' backgrounds, while helping them identify and use effective instructional methods. The CSP-UCLA Science Project and Project ISSUES from UCLA/Center X, provide content background in urban science, and the UCLA Department of Organismic Biology, Ecology, and Evolution (OBEE) new program SSWIMS (Science Standards With Integrated Marine Science) updates participants' backgrounds in marine science. These programs help teachers develop leadership expertise for disseminating effective strategies to their peers. UCLA's Stunt Ranch Santa Monica Mountains Reserve is also developing opportunities for EE and research for local teachers and students. In addition, an increasing number of opportunities for teachers and students to conduct investigative science are available through electronic networks linked through the World Wide Web. Programs such as those administered by Cornell University encourage students to gather data on specific birds (http://birdsource.cornell.edu); students can track butterflies through Monarch Watch (http://www.monarchwatch.com); and schools can become involved in recording weather data across the nation through Project GLOBE (Global Learning and Observations to Benefit the Environment), a program initiated by Vice President Al Gore.

But in-service programs such as these cannot produce the required quality of science education alone. Universities must also help prepare teachers. This is especially true for environmental science where we are rapidly increasing our understanding of the science content.

GRADING LOCAL EFFORTS

Not every local EE effort has been mentioned in this report—there are many of note. There are also many individual teachers who make extraordinary efforts to ensure their students have opportunities to understand the environment, and the role they play in it. **Their individual efforts deserve an A grade. But EE has not yet taken the major place in the curriculum it deserves; hence current efforts in Southern California rate only a C.**

Janet M. Thornber, Director of UCLA Programs for Science Teachers at Center X in UCLA's Graduate School of Education and Information Studies, also co-directs the UCLA Science Project, one of 12 sites of the California Science Project (CSP) administered through the UC Office of the President. Ms. Thornber's work is dedicated to teachers and students in those schools targeted by UCLA to increase the pool of UC eligible students, especially those from traditionally disadvantaged backgrounds. Over the past 15 years, Ms. Thornber has received science education grants from the National Science Foundation, the Eisenhower Program, and other agencies to develop programs for Los Angeles teachers of all grade levels. Many programs have used environmental science as a vehicle for helping teachers and students relate academic science to their own world experiences. Ms. Thornber received a BSc Honors degree in Biochemistry from the University of London, England and an MSPH in Nutritional Sciences from UCLA's School of Public Health.

About the UCLA Institute of the Environment

Formally established in 1997, UCLA's Institute of the Environment grew out of the need for a campus unit dedicated to facilitating connections among the many different and divergent fields relevant to environmental research and teaching. Understanding the environment requires inquiry that transcends discipline-specific approaches. Whereas most university-based environmental programs are affiliated primarily with a single department or school, the IoE is an autonomous unit that works campus-wide to add new dimensions to environment-related research, teaching, and community outreach. The IoE brings together UCLA's diverse environment-related programs, providing coordination and integration, and making such programs more visible and effective on campus, as well as in the broader community.

THE IOE'S OBJECTIVES ARE:

- To develop multidisciplinary academic programs that address the full breadth of environmental issues facing today's society;
- To stimulate innovative and integrative interdisciplinary research on local, regional, and global environmental processes; and

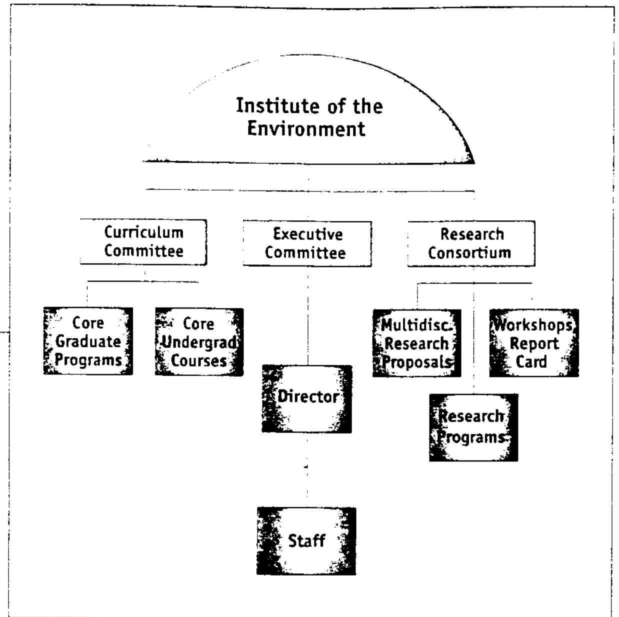
- To use collaborative problem-solving to strengthen UCLA's effectiveness in serving the community.

DISCOVERY-BASED LEARNING

To enhance the educational experience for UCLA students at all levels and in many fields, the IoE has the goal of incorporating environmental issues into every aspect of learning.

- The IoE played a major role in implementing a comprehensive overhaul of the general education curriculum in UCLA's College of Letters and Science. IoE faculty developed the first yearlong cluster course—Environment 1A, "The Global Environment: A Multidisciplinary Perspective"—which had its debut in the 1997-98 academic year.
- The IoE is developing environmental minors in six areas of concentration: engineering, life sciences, physical sciences, public health, public policy, and social sciences.
- In coming years, the IoE will initiate interdisciplinary graduate programs spanning a wide range of environmental topics.

Additionally, UCLA's Stunt Ranch Natural Reserve provides access to natural laboratory settings in the nearby Santa Monica Mountains, and the Marine Science Center's research vessel, "Sea World UCLA," enables students to collect data at sites in the Santa Monica Bay, Channel Islands, and Southern California Bight. The IoE encourages students to supplement classroom study by participating in field research throughout the Los Angeles area, gaining hands-on insights into air, land, and water issues affecting Southern California and beyond.



RESEARCH ACTIVITIES

The IoE fosters large-scale, multi-investigator, interdisciplinary environmental research by bringing together campus scholars as well as experts from local government and businesses. These broad-based investigations seek practical answers to complex questions about preserving natural resources, while still providing services for the community. They also present valuable opportunities for students to learn in the context of discovery.

- Our landmark Watershed project integrates the meteorology, hydrology, chemistry, biology, and coastal oceanography of the Los Angeles basin to address a host of issues related to water quality, availability, and management.
- The GLOBE (Global Observations to Benefit the Environment) project brings together faculty from the graduate School of Education and Information Studies and the Departments of Atmospheric Sciences, Biology and Geography to help local K-12 teachers lead students through scientific exercises, using actual instruments to record and interpret meteorological data.
- We have obtained funding from NASA to create an Environmental Remote Sensing Research Laboratory (ERRL) at UCLA. Offering state-of-the-art image-processing and computational services, the ERRL will support researchers involved in the growing field of environmental observation from space.
- The Lower Malibu Creek and Malibu Lagoon Resource Enhancement and Management Project is collecting data about the complex physical processes occurring in the largest watershed that drains into Santa Monica Bay. The aim is to identify strategies for preserving and restoring these vital and irreplaceable coastal resources.
- Over the past several years, researchers at the IoE in the natural and social sciences have been developing computer models that characterize various aspects of human-climate interactions in the Los Angeles Basin. One central theme has been the urban water cycle, which serves as an integrating metaphor linking five research sectors: human water use, coastal water quality, land use, regional meteorology, and regional air quality. With funding from the NSF, statistical tools are being developed to assess uncertainties in these computer models and provide statistical diagnostics to help improve how well they perform. The statistical procedures being developed also have wider applicability in part because they are embedded of a broad strategy for how to evaluate computer simulation models in a number of fields.
- Support from the California Sea Grant College System is enabling IoE researchers to design the first Model of the Southern California Coastal Ocean capable of resolving three-dimensional circulation patterns and integrating the most important features of biogeochemical and particulate dynamics.

UCLA Institute of the Environment

- Funded through the EPA, the Multi-level Statistical Models project extends existing methods to provide new techniques for working scientists. The goal is to assist in the process by which scientists try to generalize their findings from "case studies" or other special purpose investigations. Normally, generalizing from such research can sometimes be rather risky because it is difficult to know whether the findings apply to settings different from the ones actually studied. Since much of the research undertaken by the IoE is based in Southern California, the new statistical tools may help to indicate which finding only apply locally and which may have broader implications. The extension of statistical multilevel models include: 1) multiple response variables, 2) non-linear functional forms, 3) missing data, 4) disturbance covariance matrices allowing for temporal and spatial dependencies and 5) latent variables. At the end of the project, there will be software available for the techniques being developed that will run on a number of different platforms.
- With generous assistance from Intel Corporation, the IoE has built a Regional Environmental Assessment Laboratory and Geographical Information System (REAL/GIS) that will be accessible on campus as well as on the Internet. The REAL/GIS will provide scientists, planners, and the public with access to one of the largest and most diverse environmental databases for a major urban area.
- The IoE is collaborating with the Los Alamos National Laboratory to establish a Center for LIDAR environmental and atmospheric research. The center will develop a mobile, eye-safe system using lidar observations (a technique, similar to radar, that employs pulsed laser light instead of microwaves) to inform regional air quality forecasts.
- The IoE is a leader in earth system modeling, a holistic approach for studying global climate change by examining relationships among the atmosphere, land surfaces, oceans, and biogeochemical cycles.

"What is unique about the Institute of the Environment as an environmental program is its interdisciplinary breadth. It encompasses all of the major academic fields on a major university campus. Other university-based programs tend to focus on a single discipline, like engineering or agriculture. The IoE is broadly interdisciplinary to the same extent that our society is."

Richard P. Turco, Ph.D.
Founding Director, Institute of the Environment
Professor of Atmospheric Sciences

HOW TO REACH US:

The Institute has established a new web site. Our activities are routinely updated on the site, and we announce events and other activities of interest to those concerned about the environment. Contact us through our web site and sign our Guestbook. We welcome your feedback.

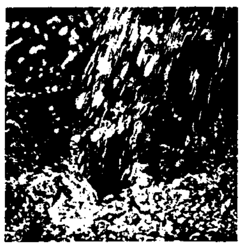
RC 1998 Revisited

WASTEWATER TREATMENT

We received several comments on the Wastewater article. The Los Angeles County Sanitation Districts (LACSD) (James Stahl) felt they had good reasons for delaying the decision to provide secondary treatment at their Joint Water Pollution Control Plant in Carson. They noted the DDT contained in the sediments off White's Point may someday be reintroduced into the environment, where they will do additional damage. Presently the DDT sediments are covered by sediment from the release of primary effluent. Continued release of primary effluent might keep the sediments covered and prevent their release. The U.S. EPA recognized the need to prevent DDT from reentering the environment, but felt the damage from primary effluent was greater than the risk of DDT release. A comment from Professor Stenstrom, the author of this article, is that the scientific merits of both sides of the debate were never entirely understood. This resulted from a lack of a disinterested third party. Scientific arguments offered by LACSD were never credible to the environmental community because of a real or perceived conflict of interest. The savings of avoiding secondary treatment would accrue to LACSD and its users. A proposal for an ocean waiver by a neutral third party, without financial interests, might have been received differently. The issue of DDT contaminated sediments remain, and will haunt us for some time to come.



The Bureau of Sanitation, City of Los Angeles (Judy Wilson) wrote to say they appreciated the "A" they received for inland plants, but believed they now deserve an "A" for the Hyperion Wastewater Treatment Plant. They cited the difficulties associated with its expansion and improvements, including differences of opinion with regulatory agencies about the design and method for its expansion. The Report Card was a retrospective look at the wastewater treatment by the Hyperion Plant since the Clean Water Act Amendments in 1972. The grade was based on the performance during this entire period, as opposed to more recent events, and the author stands behind this grade.

However, there is a new story to tell with respect to the Hyperion Plant. The plant began full secondary treatment in December, 1998, two months ahead of its final construction schedule. The City and guests celebrated the plant's opening on May 15 in a ceremony attended by 1500 people. The City announced that the plant was constructed ahead of schedule and at a cost significantly under budget. The completion of the plant will end a 22-year lawsuit over its construction.

The construction of the plant is a tribute to the City. It is a "top 10" plant in terms of its size. There are few plants larger in the United States. The most outstanding aspect of the Hyperion construction is the very tight construction schedule, and the small area occupied by the plant. The plant provides not only for secondary treatment, but anaerobic sludge digestion and sludge dewatering. The digesters produce methane gas which is burned at the Scatter Good Power station to produce electricity for Hyperion at significant savings. Hyperion also provides approximately 20 million gallons per day of reclaimed water for the West Basin project, and additional reclamation will occur in the future. Hyperion now has the capacity to treat the City's wastewaters, including the high flows that occur in winter, as well as low-flow diversions, which will protect our beaches in the summer.

Hyperion may not be the largest plant, but it is probably the largest plant in the smallest land area of any plant in the world. This results in part because of the use of high purity oxygen for aeration, but mostly from clever design. Its construction required delicate timing because there simply was not room for normal construction practices. It was also necessary to keep the old secondary plant operating until it could be replaced by the first completed portion of the new secondary plant.

In the late 1970's and early 1980's, engineers reviewed the old Hyperion Plant, the requirements for the secondary treatment, including sludge disposal, and said that "it can not be done." Now the City has done it, and we have to thank the City's new team for accomplishing this great task.

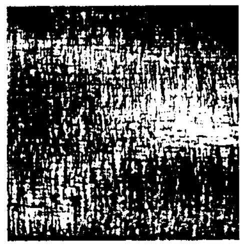
WETLANDS

Ballona Wetlands. Although there has been little change to the wetland area at Ballona Wetlands, there continues to be a great deal of political activity surrounding the preservation and restoration of the wetlands. A coalition of environmental groups continues to protest the plans for Playa Vista, a $7 billion residential and commercial development, and especially the involvement of DreamWorks. In summer 1998, a federal judge issued an injunction that stopped work on a 16-acre freshwater marsh being constructed to regulate and treat freshwater runoff before it enters the salt marsh, but not other construction activities; the ruling is being appealed. The plans for the salt marsh restoration have not yet been released.



Malibu Lagoon. UCLA has just completed a study of the Malibu Creek Watershed, led by Professors Richard Ambrose and Tony Orme. The study has improved our understanding of the hydrology and barrier beach dynamics as well as refined our ideas about the evolution of the wetlands. The study also evaluated numerous alternatives for managing the resources of the watershed and provided preliminary wetland restoration plans and recommendations for several areas in the lagoon area. The recommendations will soon be considered by the community. The Southern California Wetlands Clearinghouse has given Malibu Lagoon a high priority for funding for restoration, so planning for additional restoration in the area should begin soon.

AIR QUALITY

Response received from the South Coast Air Quality Management District

According to its opening *Letter From the Director*, the Institute's first Report Card was intended to "document progress and regression" in four environmental areas. However, significant strategic accomplishments were omitted from both the grading analysis and the discussion of our region's air quality programs. Taken together, these new tools quietly paved the way for increased public health benefits, continued reductions in ambient emission levels, and improved cost-effectiveness for air pollution control measures.

For example, unmentioned in the air quality article were two benchmark accomplishments that occurred in the year under review, 1997:

- **Early rewards from the AQMD Governing Board's Environmental Justice Initiatives**, including initiation of an unprecedented, comprehensive mobile monitoring effort measuring air toxics exposure to more than 50 compounds; targeted Town Hall meetings to resolve chronic nuisance emissions in previously under-represented neighborhoods (such as low-income communities of color); and enhancement of New-Source Review for cancerous and hazardous air contaminants.

- **Adoption of far-reaching fugitive dust controls, to address some of the worst fine-particulate pollution in the nation**, including measures to significantly reduce suspended road dust, which comprises one-third of the ambient particles smaller than 10 microns in diameter, known as PM10—strongly linked to respiratory disease and increased deaths. The measures adopted required a comprehensive approach tying together technical research and implementation among the construction industry, scores of street maintenance operations by local governments, and Southland agriculture.

In addition, that year also saw progress on reducing emissions from solvents, petroleum coke handling, restaurant chain-charbroilers, boilers and water heaters, and refinery flaring operations. Beyond these formal regulatory actions, progress was made on other fronts:

- Enhancement of socioeconomic assessment tools to provide decision-makers with more complete understanding of the potential benefits and costs of alternative air quality solutions;

- Market acceleration for a host of low-emission technologies and fuel systems developed through public-private partnerships under the internationally recognized Technology Advancement program; and

- Improved dialog to clarify enforcement priorities, highlight compliance issues, and streamline working relationships among regional, state, and federal bodies.

Finally, critical seedwork was taking place to improve the body of scientific knowledge on air pollution. This key seedwork included expansion of the region's air monitoring network, practical demonstrations of waterborne cleaners and low-emission paints, and important research on diesel exhaust—later declared as a toxic air contaminant and a significant public health threat.

1999's air quality successes have included heightened focus on ways to mitigate disproportionate impacts of poor air quality on children and those with pre-existing health problems, and a landmark rule controlling emissions from architectural coatings, a significant source of ozone-precursor emissions in the South Coast. Today's action focus would not have been possible without the active public and small-business feedback solicited over the past two years.

Southern Californians can measure their progress in the war on smog by comparing 1977's 121 Stage 1 smog episodes to the single episode in 1997. And though El Nino showers helped our air that year: so did diligent efforts that may have escaped the attention of the Institute. The prospect for the future is blue sky by the time that federally mandated clean air standards are to be achieved.

Barry R. Wallerstein, D. Env.
Executive Officer, South Coast AQMD

Response to SCAQMD

We welcome the SCAQMD's response as part of an open dialogue concerning critical environmental issues confronting the region. However, far from reviewing only a single year, 1997, as stated by the District, the Air Quality article in the 1998 Report Card provided a much larger perspective on the 50 year effort to reduce air pollution in Southern California. Within that larger framework it was not possible to list every recent accomplishment of the local air pollution agency, although most of its major achievements were cited. Clearly, many of the recent projects listed in the District's response to our article are laudable and, in several cases, long overdue. Nevertheless, it remains unclear whether the present overall efforts by the District will in fact produce "blue skies" in the next decade, as promised in their letter. For example, while taking credit for there being only a single Stage I ozone alert in 1997, the District's letter fails to mention that in 1998 the number of Stage I alerts surged to 12. Whether this represents a short-term setback, or the beginning of a reversal in the long-term decline in ozone, will only be revealed over time. We intend to revisit the District's Air Quality Management Plans, and the status of air quality in Southern California, no later than the 2003 Report Card. At that time, the additional years of air monitoring data will tell us whether the District's rosy projections were justified.

INTRODUCTION

Pollution of Malibu Creek and Malibu Lagoon has been causing concern for many years. In the late 1970's, an areawide plan for the South Coast area of California listed urban runoff, rural runoff, agricultural activities, recreational activities, septic tank systems, and unsewered communities as potential non-point sources of pollutants.

Nearly 20 years later these same sources are still a concern. The State of California, in its 1994 Water Quality Assessment, identified Malibu Lagoon, Malibu Creek and two of its tributaries, and several lakes in the Malibu Creek watershed as water bodies with at least some degree of water quality impairment. The assessment also identified "non-point" sources — sources such as overland storm runoff or seepage, which carry pollutants to the stream system via diffuse pathways -- as a major part of the problem. In addition, the use of imported water has greatly increased summer flows in the last 30 years.

Recognizing the problems, theResource Conservation District of the Santa Monica Mountains (formerly theTopanga-Las Virgenes Resource Conservation District) sponsored development of a natural resources plan for the watershed, with emphasis on water quality and quantity. The plan was prepared by the Natural Resources Conservation Service.

It was clear from the outset that a great many groups and individuals would be involved in the planning process. The RCD joined with the Santa Monica Bay Restoration Program to coordinate the efforts of the interested parties. Because of the diversity of viewpoints and concerns, a formal mediation effort was undertaken. That effort has led to a more widespread awareness of the connection between land use activities throughout the watershed and water quality in the creeks and lagoon.

The participants also developed a list of action goals. Some of these are addressed in the natural resources plan. Others are being pursued in other ways.

The plan:

1. Identifies and describes local water quality and quantity problems, including alteration of the flow regime.

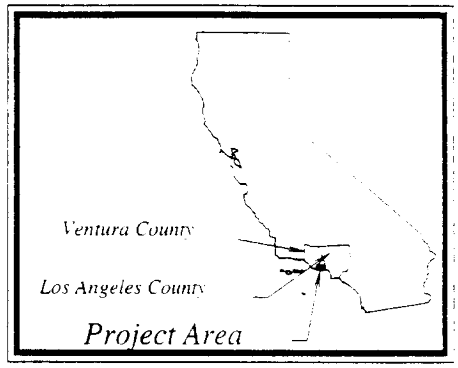
2. Evaluates and compares treatments to reduce the water quality problems linked to surface runoff.

3. Identifies possible implementation strategies and funding sources.

The complexities of the Malibu Creek watershed, the current level of understanding, and the differing points of view of interest groups means that there is no single combination of broadly applicable treatment options. Each site needs to have specific treatments designed for its particular conditions. The information and ideas in the plan will assist local leaders and land users in their efforts to improve water quality.

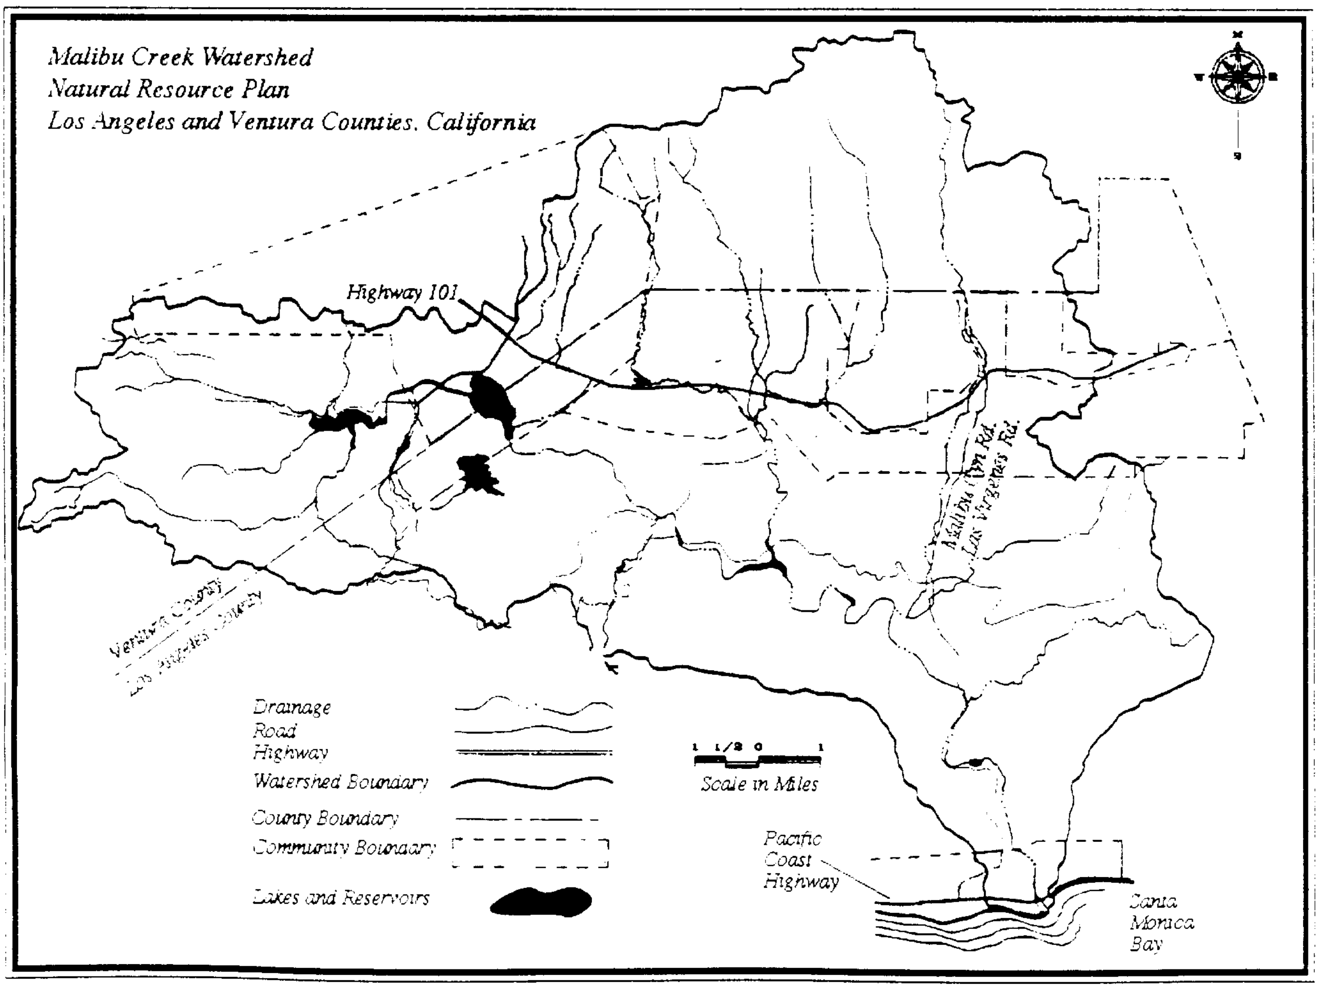
This report is a brief summary of the information in the natural resources plan. Copies of the complete plan may be obtained by contacting the RCD of the Santa Monica Mountains.

SETTING



The Malibu Creek Watershed is located about 35 miles west of Los Angeles. The creek and its tributaries drain a 109-square-mile area of the Santa Monica Mountains and adjacent Simi Hills. Approximately two-thirds of the watershed is in Los Angeles County and the rest is in Ventura County.

Malibu Creek drains into Malibu Lagoon and from there into Santa Monica Bay. Santa Monica Bay is one of three estuaries in California currently in the National Estuary Program. The program is an interagency effort administered by the U.S. Environmental Protection Agency. Its purpose is to protect and improve coastal water quality.



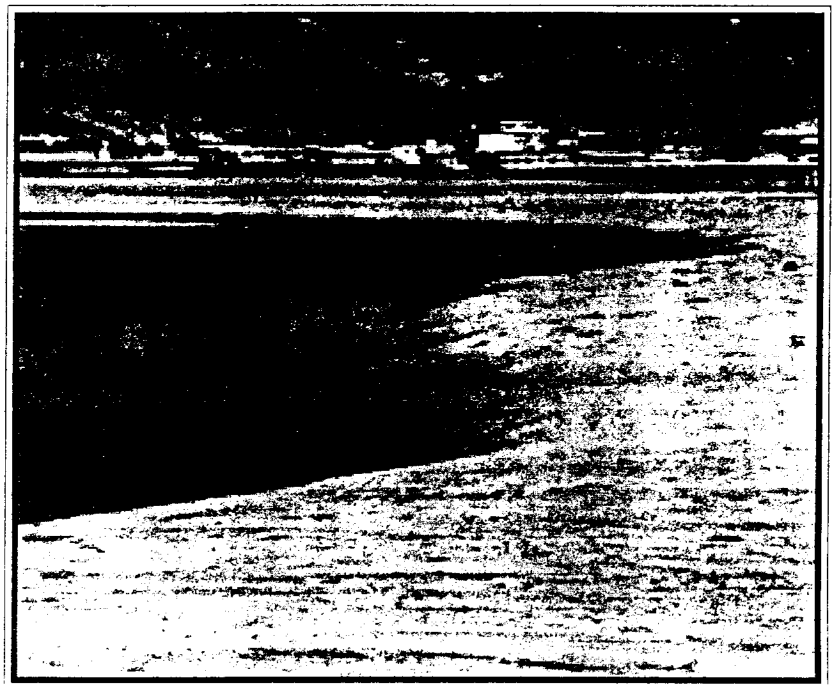
Location Map

R0026399

Malibu Beach is internationally known for its prime surfing conditions and is a popular destination for beachgoers and vacationers. The beach is part of the highly valued recreation area along the Santa Monica Bay coastline. Malibu Lagoon State Beach is located at the outlet of the lagoon.

Malibu Lagoon provides valuable estuarine habitat. It also serves as an outdoor classroom and offers many recreational opportunities. It is one of the few lagoon-type estuaries draining into Santa Monica Bay.

The lagoon's outlet to the ocean is closed off most of the year by a sand and gravel bar. It opens only when large storm flows come down the creek or when smaller or continuous flows cause the lagoon to overflow. The bar is often breached mechanically when there has been an extended period of low flow. The currents in the bay rebuild the bar after only a few weeks.



Sand and Gravel Bar

Two major highways cross the watershed: the Ventura Freeway (U.S. 101) and the Pacific Coast Highway (State Highway 1). More than 150,000 people commute along the Highway 101 corridor each day, and another 20,000 use the Pacific Coast Highway and the Malibu Canyon-Mulholland Highway corridors. The 1990 population within the watershed was about 90,000. Over 40 percent of the work force holds high-end white collar jobs, such as executive or professional specialty jobs. Forty percent of the housing in the watershed in 1990 was constructed after 1980.

The watershed consists of a number of subwatersheds. Land use and related resource issues vary significantly from one subwatershed to another. The subwatersheds are described later in this report.

LAND OWNERSHIP AND USE

Evidence indicates that the Malibu coast has been inhabited by humans for more than 10,000 years. Within recent history, grazing was the predominant land use in the watershed. Modern expansion of the Los Angeles metropolitan area and consequent development pressures have significantly reduced grazing and increased recreational activities and urban development in the watershed.

The watershed is located near a major metropolitan area, yet includes large areas of open space. Despite the extensive urbanization, large areas remain undeveloped in the upper watershed. A significant portion of the 69,900-acre watershed is in public ownership, including 6,700 acres in the Santa Monica Mountains National Recreation Area and 8,500 acres owned by the State Department of Parks and Recreation. The numerous parklands provide opportunities for hiking, mountain biking, fishing, horseback riding, camping, bird watching, and other outdoor activities.

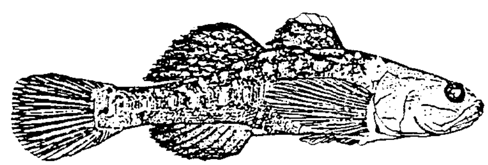
Land Use	**Acres**
Orchards	30
Pasture	1,520
Field Crops	260
Confined Animals	320
Urban	8,310
Rural Residental	2,800
Natural Areas	55,300
Golf Courses	540
Water	450
Other	380
Total	**69,910**

Recent development has resulted in the conversion of large blocks of middle and upper watershed open space to urban landscape. The cities of Malibu, Calabasas, Agoura Hills, Westlake Village, and Thousand Oaks lie partly or entirely within the watershed. All have expanded significantly in population since the 1990 census. Several additional large subdivision projects have been proposed and are now pending before the Ventura and Los Angeles County Planning Commissions. The city of Malibu lies along Santa Monica Bay at the outlet of Malibu Creek.

PLANT COMMUNITIES AND WILDLIFE

Over 600 native species and 200 introduced species of plants are known to exist in the watershed. The predominant habitat types include coastal oak woodland, mixed chaparral, coastal scrub, coastal salt marsh, and annual grassland, with inclusions of riparian and other habitat types.

The watershed supports an abundant and diverse wildlife community, which reflects the diversity of the vegetative communities. More than 450 species occur, including 50 mammals, 384 birds, and 36 reptiles and amphibians. The wildlife populations are unique in their proximity to one of the largest urban areas in the United States.



Tidewater Goby

Fish species include the southern steelhead, tidewater goby, and arroyo chub. Non-native fish include goldfish, largemouth bass, and bluegill. The steelhead run in Malibu Creek is the southernmost documented run in the United States.

At the time the natural resource plan was published, one plant, one fish, and nine bird species that are permanent or seasonal residents in the watershed were federally listed as threatened or endangered. Nineteen additional state-listed species may occur there. A number of additional species are candidates for listing. The tidewater goby, the federally listed endangered fish, had ceased to exist in Malibu Lagoon, but was reintroduced in 1991 by the Resource Conservation District of the Santa Monica Mountains. The goby is found only in coastal, brackish water habitats. The Malibu Creek population of the Southern California steelhead has been included in a recent addition to the federal list of endangered species.

CULTURAL RESOURCES

The Santa Monica Mountains have one of the highest densities of archaeological sites of any mountain range in the world. The National Park Service estimates that there may be over 300 sites within the watershed. There are at least two Chumash pictograph sites, and more are likely. These are of extreme public interest, yet are religious and sacred sites for Native Americans. Other sites include sacred sites, bedrock mortar sites, villages, middens, and burial sites.

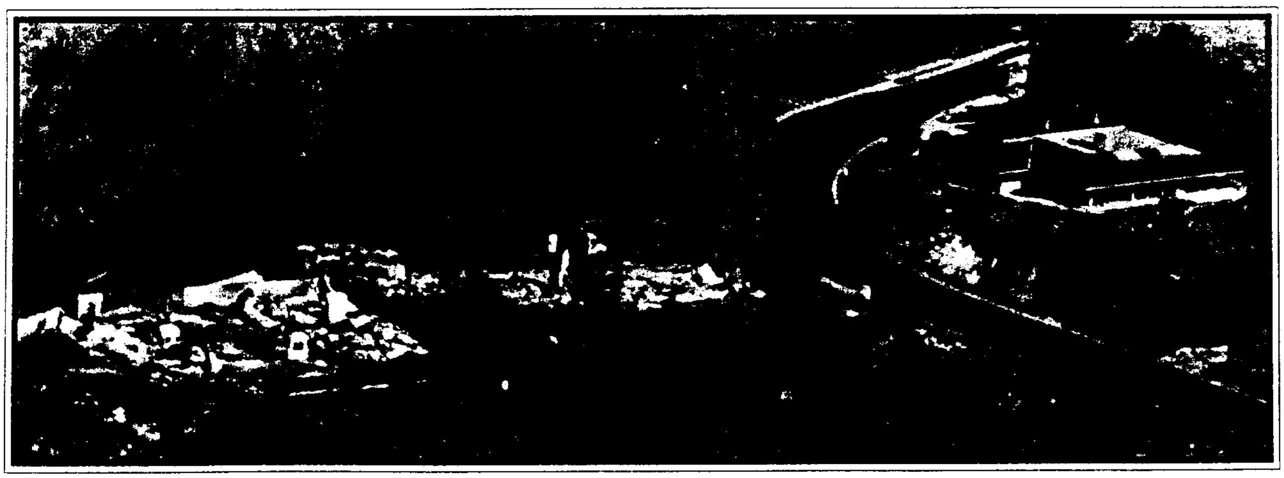
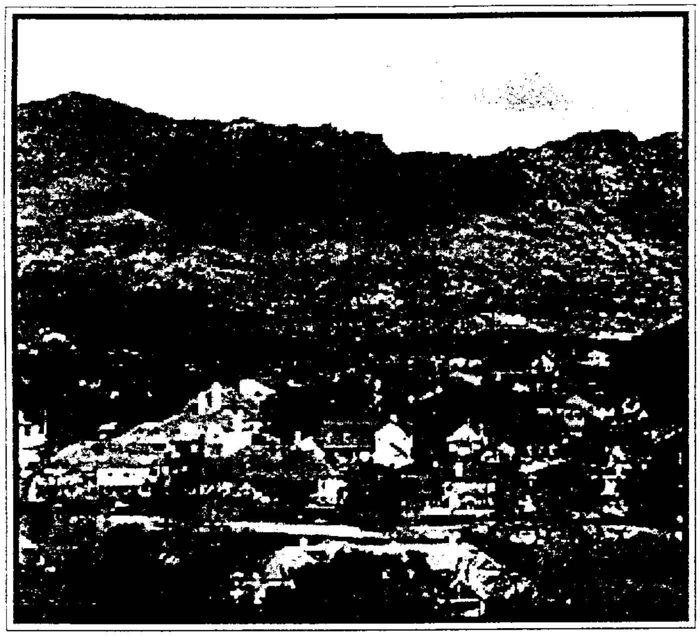
FIRE IN THE WATERSHED

Fire is one of the natural processes in the local ecosystem. Nearly all areas in the watershed have burned at least once since 1925, and a substantial portion has burned three or four times. The most recent fire was the Old Topanga fire of November, 1993. Human encroachment into fire-prone areas requires fire management planning that recognizes the reality of the fire regime.



R0026403

THE WATERSHED ECOSYSTEM



The development in the watershed has stressed and changed ecosystems. Buildings, pavement, lawns, and highways have replaced natural habitats. Imported water has allowed humans to increase their population beyond the watershed's natural sustainability. Increased stream flows have changed riparian and aquatic systems. Even though the increased flows are thought to benefit steelhead, they may also have adverse effects, such as elevated water temperatures caused by discharges, non-continuous stream flows, and water quality impacts.

IMPAIRED WATER QUALITY

Beneficial uses of the waters of the Malibu Creek Watershed, and especially those of the lagoon, are being threatened by accelerated sedimentation, runoff, salinity fluctuations, nutrients, and harmful bacteria. For example, coliform levels in the Malibu area stream system often reach concentrations higher than recommended for contact recreation, a designated beneficial use for the creek. The State Water Resources Control Board has identified eight water bodies in the watershed as impaired (not meeting standards) or suffering intermediate impairment (not meeting standards on some occasions).

Impaired Water Bodies
(as listed in the 1994 State Water Quality Assessment)

Malibu Lagoon	Twenty-nine acres, impaired; eutrophication, threat of recreational impacts, and fish kills.
Malibu Creek	Six miles, intermediate impairment, and three miles, impaired; fish population decline, spawning impairment, and sedimentation.
Lake Eleanor	Eight acres, intermediate impairment, eutrophication and urban runoff.
Malibou Lake	Fifty-five acres, intermediate impairment; elevated fish tissue levels, suspected eutrophication, and sedimentation.
Lake Sherwood	One-hundred-eighty-four acres, intermediate impairment: suspected elevated fish tissue levels.
Westlake Lake	One-hundred-fifty-six acres, intermediate impairment: suspected elevated fish tissue levels and eutrophication.
Triunfo Canyon	Seven miles, intermediate impairment: suspected sedimentation.
Lake Lindero	Fourteen acres, intermediate impairment: elevated fish tissue levels.

LAND MANAGEMENT TO IMPROVE WATER QUALITY

Water quality problems in this watershed are heavily influenced by land use activities. There are opportunities to reduce non-point source pollution by improving land management practices. Appropriate treatments vary, depending upon the land use.

- **Confined animal facilities.** These create a major problem in the collection, management, and disposal of waste products from the animals. Proximity to water bodies is also often a problem.

  Confined animal facilities are usually sparsely vegetated because large numbers of animals or large animals in a small area remove or trample the plant material. Nutrients from manure deposited on the ground surface in these areas will not only leach into the groundwater but will also be transported offsite by wind and water, along with the manure and soil particles. The problem is even greater where the confinement area includes part of the creek system.

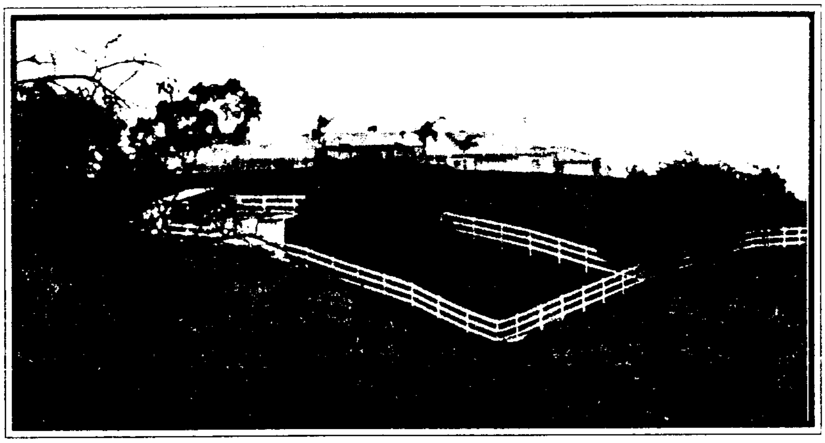
  An example of a conservation system to reduce nutrients, sediment, and runoff leaving a confined animal facility might include the following practices: a waste management system, waste utilization, roof runoff management, filter strips, and critical area planting.

- **Single-family residential areas.** Residential streets are deposition and storage areas for pollutants such as nutrients, sediments, dust, hydrocarbons and coolant from vehicles, and yard and pet wastes. These materials need to be removed from streets before rainfall carries them into the storm sewer system. This requires an effective street cleaning program.

  Nutrient use on lawns and landscaping is estimated to be two to three times the amount needed for growth. This is often due to lack of information. Water use in residential areas is also excessive for the same reason. The excess water and nutrients are either delivered directly into the storm drain system and the creeks or into the local ground water bodies. Reductions in nutrient and water use through better management and education can be cost effective for the land owner.

An example of a conservation system to reduce erosion, sediment and runoff from roads, and nutrients, sediment, and excess water leaving horse paddocks, lawns, and other landscaped areas might include the following: better road planning ,critical area planting, filter strips, a waste management system, waste transfer, residential street waste management, irrigation water management, nutrient management, and sediment basins.

- **Spaced rural residential areas.** This is a land use designation where the parcels may include a large house, landscaped ground, a horse paddock, and home orchards which are not associated with an agricultural operation. Horse paddocks averaging a half acre or more are common in the spaced rural residential areas. Water and nutrient use on lawns and landscaping is similar to that in single-family residential areas. The system of practices described for single-family residential areas could also be used in the spaced rural residential areas to reduce erosion, sedimentation, nutrients, and excess fresh water.



Spaced Rural Residential

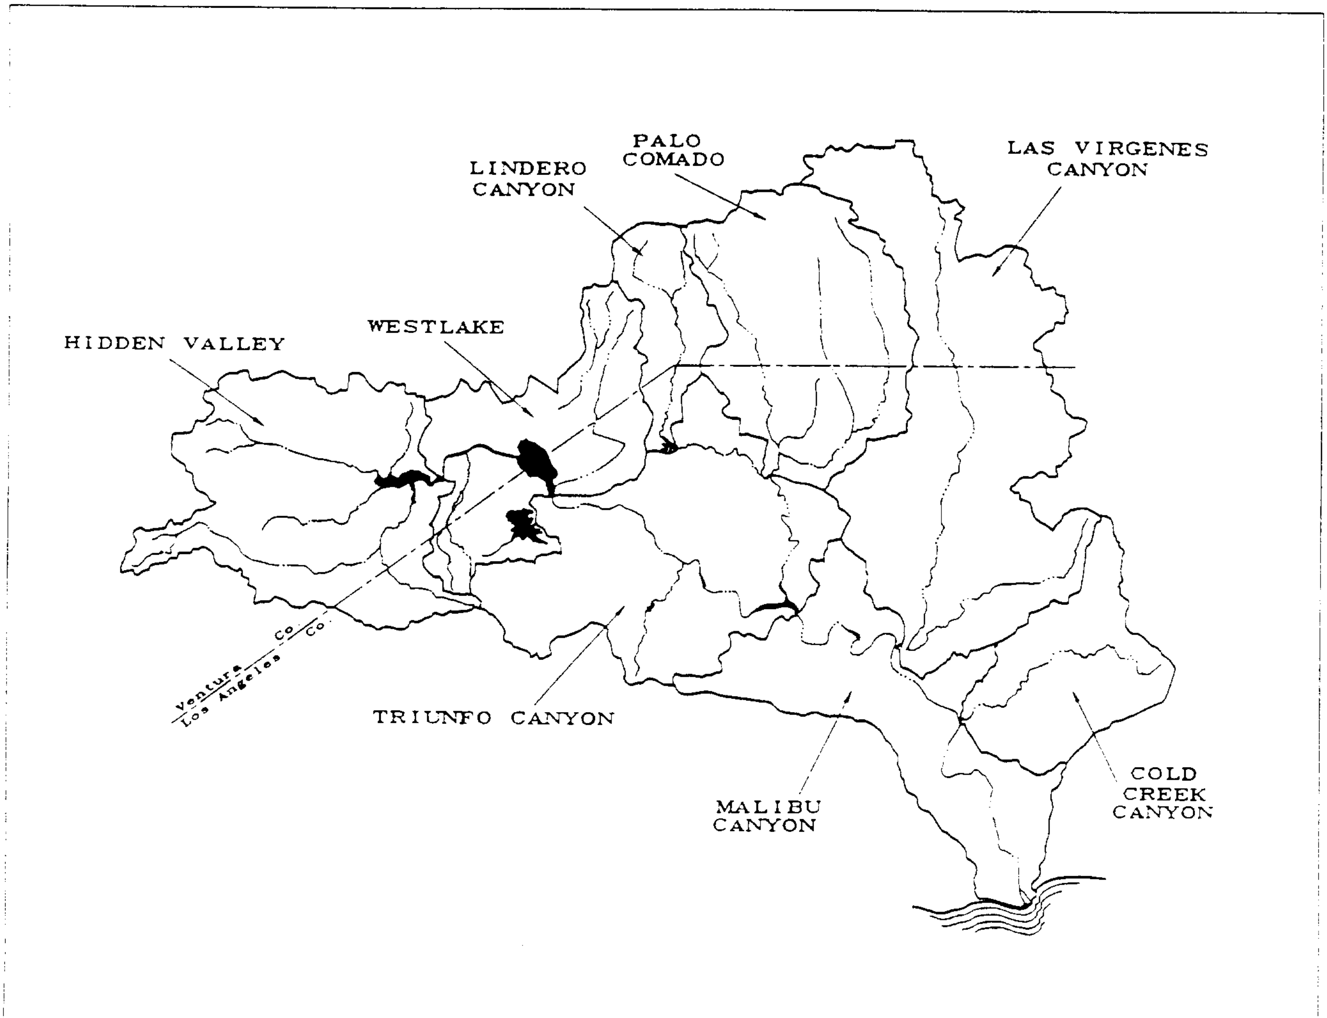
Horse paddock improvements could include distancing the paddock from streams and watercourses, controlling water from upslope areas and roofs, leaving cover on the soil surface, animal waste management and storage, and sediment control.

- **Natural areas, rural parks, and landfills.** Erosion from roads and trails in the natural areas of the watershed has been identified as a source of most of the sediment from land in this use. Similar rates are associated with roads and trails in the parks, and with landfills.

An example of a conservation system to reduce erosion and sediment caused by runoff from roads and other disturbed areas such as landfills might include the following practices: better road planning (including retirement of unnecessary roads and trails), critical area planting, sediment basins, and a program of prescribed burning.

SUBWATERSHEDS

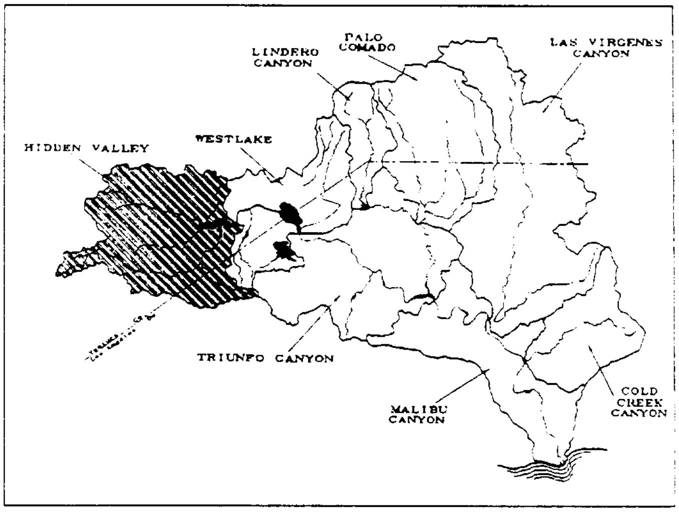
The Malibu Creek Watershed includes eight subwatersheds that contribute to the flow and quality of water in Malibu Creek. Each subwatershed can be viewed with its own land use and resource issues, revealing how it affects the whole watershed's ecosystem. The following pages provide an overview of each subwatershed with its land use, water quality issues, and the types of treatment that would be most useful in reducing pollution from non-point sources.



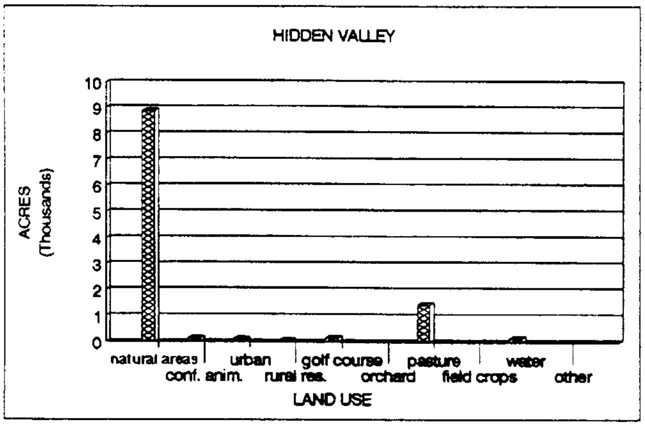
R0026408

SUBWATERSHED OVERVIEW

Located in the far west portion of the Malibu Creek watershed, the 10,975-acre Hidden Valley subwatershed has an approximate population of 1,200 (Census 1990). The subwatershed is predominately natural areas with a large acreage of pasture for the raising of livestock. A golf course is located adjacent to Lake Sherwood which is the outlet of the subwatershed. The majority of the residential area is situated around Lake Sherwood. Most of the existing buildup in the subwatershed occured prior to 1980.



LAND USE



WATER QUALITY ISSUES

Major Water Body: Lake Sherwood

Possible Concerns: High levels of nutrients causing increased algae growth in lake

Possible Sources: Fertilizers, animal wastes, wildlife wastes

Designated Beneficial Uses: Municipal water use, water contact recreation*, non-contact water recreation*, warm freshwater habitat*, groundwater recharge, navigation*, wildlife habitat

* may be affected by the possible concerns

POTENTIAL TREATMENT

For Rural Land Uses:

- Filter Strips
- Waste Management Systems
- Waste Utilization
- Livestock Exclusion
- Pasture and Hayland Management
- Fencing
- Irrigation Water Management
- Nutrient Management

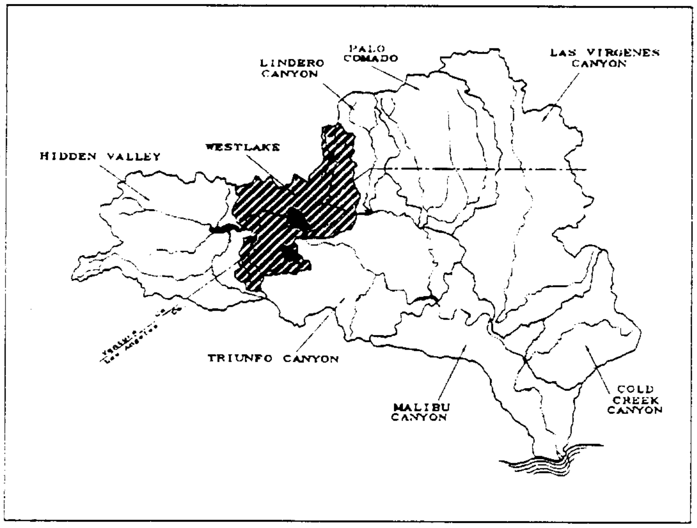
For Urban Land Uses:

- Nutrient Management
- Irrigation Water Management

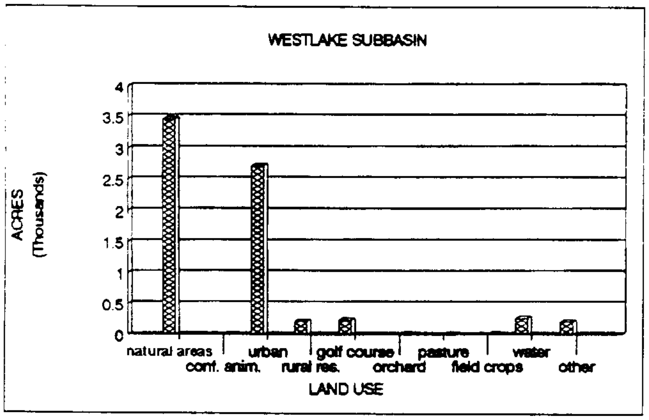
R0026409

SUBWATERSHED OVERVIEW

The 7,084-acre Westlake subwatershed contains the cities of Thousand Oaks and Westlake Village. This subwatershed is predominantly natural and urban areas. Much of the residential area is situated around the 157-acre Westlake Lake.



LAND USE



POTENTIAL TREATMENT

For Urban Land Uses:

Lawns, Golf courses, etc.

- Nutrient Management
- Irrigation Water Management

Stormwater Runoff

- Constructed Wetlands
- Filters
- Detention Basins

WATER QUALITY ISSUES

Major Water Body: Westlake Lake

Possible Concerns: Eutrophication impairment, high coliform bacteria levels have been recorded

Possible Sources: Fertilizers, urban runoff, wildlife wastes

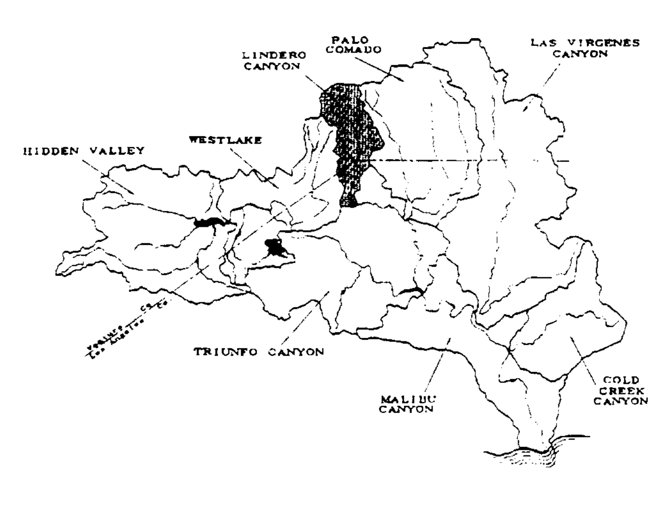
Designated Beneficial Uses: Municipal and domestic supply*, water contact recreation*, non-contact water recreation*, warm freshwater habitat*, groundwater recharge*, navigation*, wildlife habitat

* may be affected by the possible concerns

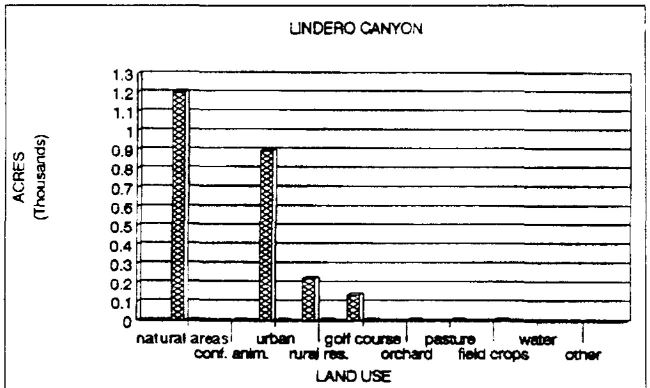
R0026410

SUBWATERSHED OVERVIEW

The Lindero Canyon subwatershed consists of 2,463 acres about equally divided between residential and natural areas. Golf courses occupy 138 acres of the subwatershed. Much of the development took place in the 1980s. The outlet for this subwatershed is the 14-acre Lake Lindero. As with subwaterhseds 1 and 2, much of the residential area is located around the lake with more residential acreage adjacent to the golf course in the northern part of the subwatershed.



LAND USE



WATER QUALITY ISSUES

Major Water Bodies: Lake Lindero, Lindero Creek

Possible Concerns: High levels of coliform bacteria, sediment deposition

Possible Sources: Urban runoff, wildlife wastes

Designated Beneficial Uses: Municipal and domestic supply*, contact and non-contact water recreation*, warm freshwater habitat, wildlife habitat

*may be affected by the possible concerns

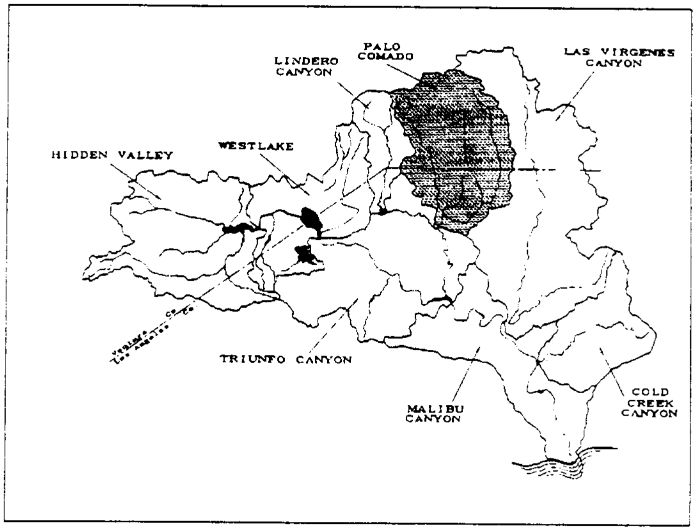
POTENTIAL TREATMENT

For Urban Land Uses:
- Irrigation Water Management
- Constructed Wetlands
- Filters
- Detention Basins
- Access Roads
- Critical Area Planting
- Sediment Basins

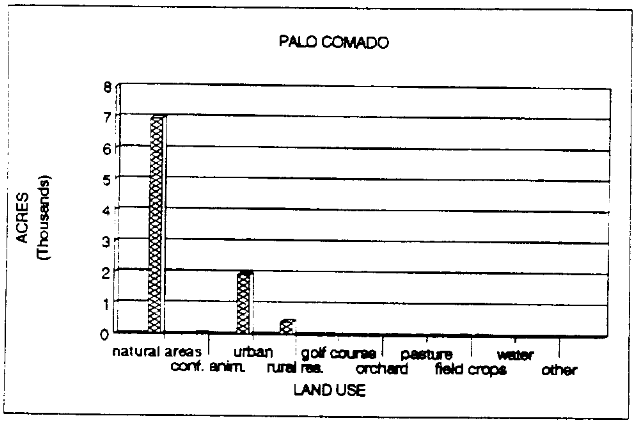
For Natural Areas:
- Road Retirement
- Critical Area Planting
- Streambank Restoration

SUBWATERSHED OVERVIEW

Located in the northern end of the Malibu Creek watershed, the Palo Comado subwatershed consists of 9,360 acres of mostly natural area with a large sprinkling of residential area and confined horse facilities. The majority of the population of this subwatershed lives in the City of Agoura Hills. The natural areas (6,958 acres) are in good condition and do not appear to have major problems.



LAND USE



POTENTIAL TREATMENT

For Urban Land Uses:

- Lawns, Golf Courses, etc.
  - Filter Strips
  - Irrigation Water Management
  - Nutrient Management
- Stormwater Runoff
  - Constructed Wetlands
  - Filters
  - Detention Basins

For Confined Animal Land Uses:

- Waste Management System
- Waste Utilization
- Waste Transfer
- Livestock Exclusion
- Fencing
- Pasture and Hayland Management

WATER QUALITY ISSUES

Major Water Bodies: Medea Creek, Palo Comado Creek

Possible Concerns: Nutrients and bacteria in creeks

Possible Sources: Urban runoff, confined animal waste, wildlife wastes

Designated Beneficial Uses:

Upper Medea Creek: Existing uses - wildlife habitat, rare and endangered species habitat, wetlands habitat; Potential uses - municipal and domestic supply*, cold freshwater habitat; Intermittent uses - groundwater recharge*, contact and non-contact water recreation*, warm freshwater habitat

Lower Medea Creek: Existing uses - contact and non-contact water recreation*, warm freshwater habitat, wildlife habitat, wetlands habitat; Intermittent uses - municipal and domestic supply*, groundwater recharge

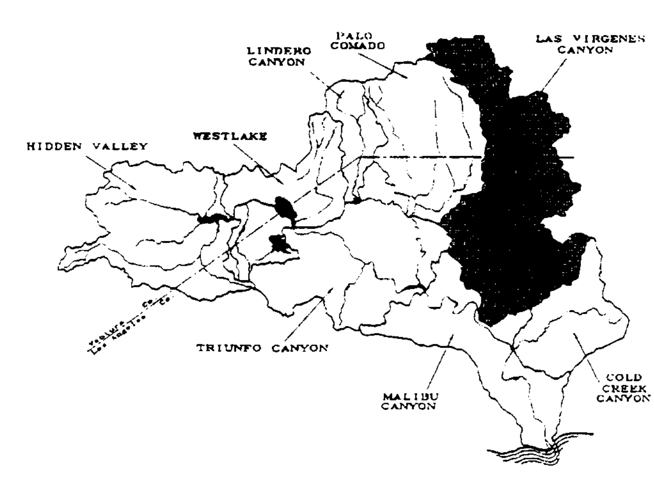
As a tributary to Medea Creek, Palo Comado Creek has the same beneficial uses as Medea Creek.

*may be affected by the possible concerns

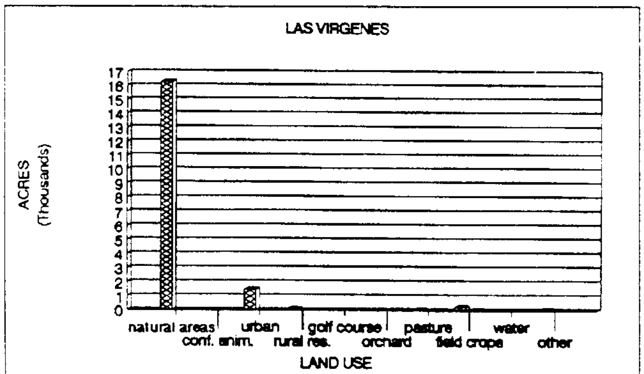
R0026412

SUBWATERSHED OVERVIEW

This 18,261-acre subwatershed is predominantly natural area with residential area as the second largest land use. There are also small amounts of orchard, pasture, and field crop acreage. Over 300 out of the total 3,766 households are on septic systems. The residential areas are scattered throughout the subwatershed as opposed to being congregated in one area. The outlet of this subwatershed is the confluence of Las Virgenes and Malibu Creeks.



LAND USE



WATER QUALITY ISSUES

Major Water Body: Las Virgenes Creek, Stokes Creek

Possible Concerns: Intermittent high bacteria and nutrient levels, low dissolved oxygen levels

Possible Sources: Runoff from natural areas, wildlife, urban runoff, septic systems

Designated Beneficial Uses: Existing uses - contact and non-contact water recreation*, warm frteshwater habitat, wildlife habitat, wetland habitat, rare and endangered species habitat; Potential uses - cold freshwater habitat*, migration*, spawning*

* may be affected by the possible concerns.

POTENTIAL TREATMENT

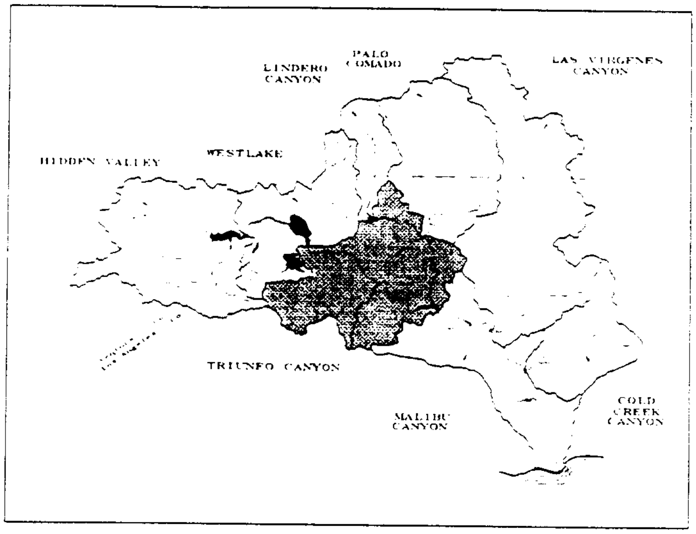
For Orchards, Lawns and Shrubs:
- Filter Strips
- Irrigation Water Management
- Nutrient Management

For Stormwater Runoff:
- Constructed Wetlands
- Filters
- Detention Basins

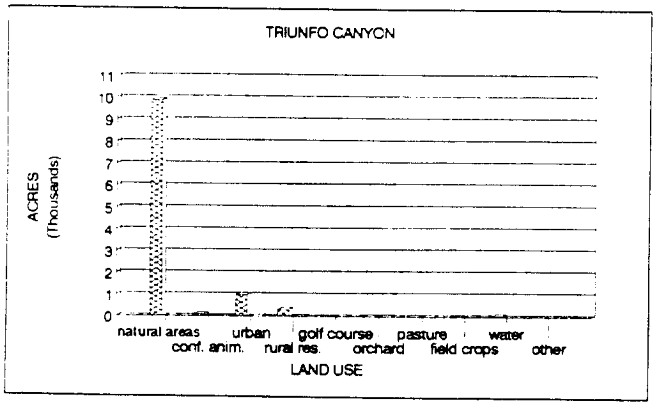
For Confined Animal Units:
- Waste Management Systems
- Waste Utilization
- Livestock Exclusion
- Fencing
- Pasture and Hayland Management

SUBWATERSHED OVERVIEW

The 11,349-acre Triunfo Canyon subwatershed contains 87 percent natural area, 9 percent residential area, 3 percent rural residential area, and 1 percent of the total area is comprised of confined animal units. Much of the residential area is located adjacent to Malibou Lake, which is the outlet of this subwatershed. The confined animal units appear to be concentrated along Triunfo Canyon and lower Medea Creek. There are 625 homes on septic systems in the subwatershed.



LAND USE



POTENTIAL TREATMENT

For Rural Land Uses:

- Access Road Improvements
- Critical Area Planting
- Sediment Basins
- Filter Strips
- Irrigation Water Management
- Nutrient Management

For Confined Animal Units:

- Waste Management Systems
- Waste Utilization
- Livestock Exclusion
- Pasture and Hayland Management
- Fencing
- Filter Strips

WATER QUALITY ISSUES

Major Water Bodies: Malibou Lake, Triunfo Creek, lower Medea Creek

Possible Concerns: Suspected sedimentation in Triunfo Creek, suspected eutrophication and sedimentation in Malibou Lake.

Possible Sources: Roads, streambanks, septic sysyems, confined animal units, fertilizers, runoff from upstream subwatershed

Designated Beneficial Uses:

Triufo Creek - Existing use - wildlife habitat; Intermittent uses - contact and noncontact water recreation*, warm freshwater habitat; Potential use - municipal and domestic supply

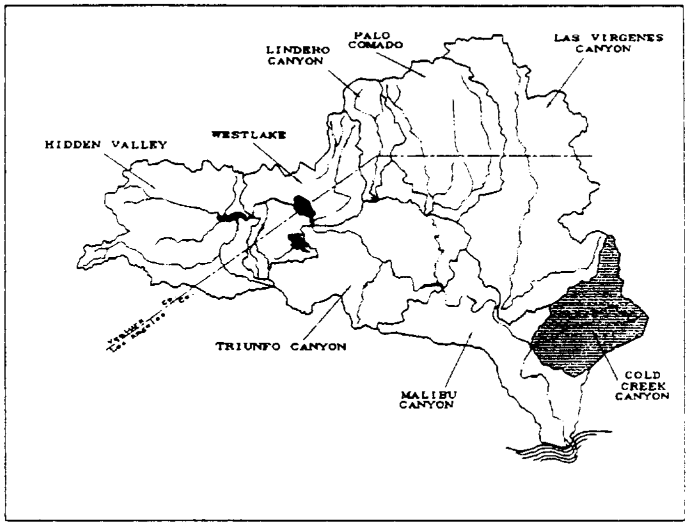
Malibou Lake: Existing uses - contact and noncontact water recreation*, warm freshwater habitat*, wildlife habitat, wetrlands habitat, rare and endangered species habitat*, navigation*; Potential use - municipal and domestic supply*

Lower Medea Creek: Existing uses - contact and noncontact water recreation, warm freshwater habitat, wildlife habitat, wetland habitat; Intermittent uses - municipal and domestic supply, groundwater recharge

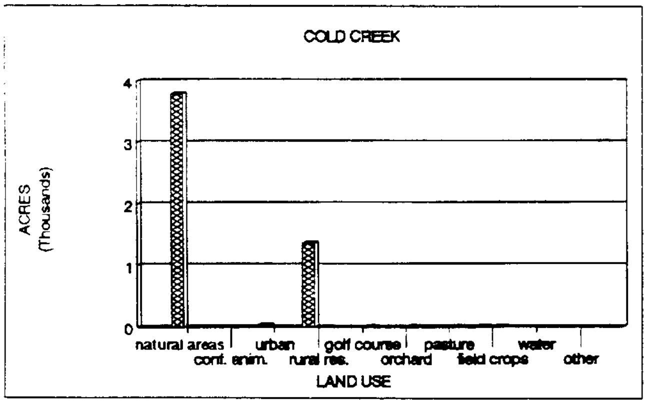
* may be affected by the possible concerns

SUBWATERSHED OVERVIEW

The 5,235-acre Cold Creek subwatershed consists mostly of natural area with scattered rural residences on private septic systems and 34 acres of confined animal units concentrated in the lower portion of the subwatershed. The outlet of this subwatershed is the confluence of Cold and Malibu Creeks.



LAND USE



WATER QUALITY ISSUES

Major Water Body: Cold Creek

Possible Sources: Runoff from natural areas, wildlife wastes, septic systems, confined animal units, fertilizers

Designated Beneficial Uses: Existing uses - contact and non-contact water recreation*, warm freshwater habitat, cold freshwater habitat, wildlife habitat, mitigation, spawning, wetlands habitat, rare and endangered species habitat; Potential uses - municipal and domestic supply*

*may be affected by the possible concerns

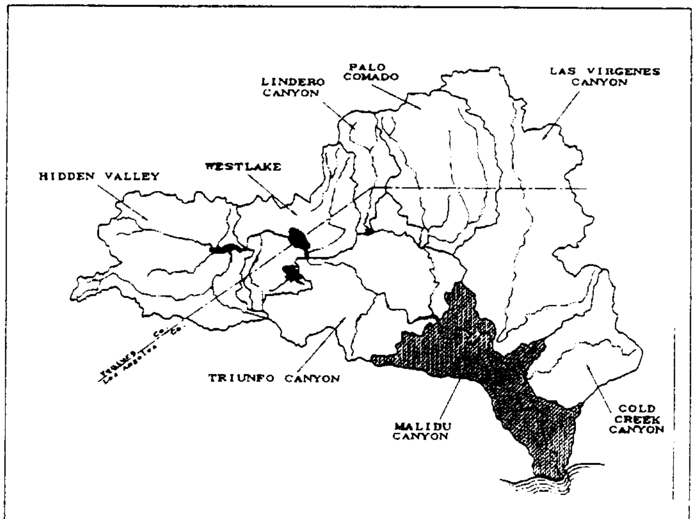
POTENTIAL TREATMENT

For Rural Land Uses:
- Filter Strips
- Irrigation Water Management
- Nutrient Management

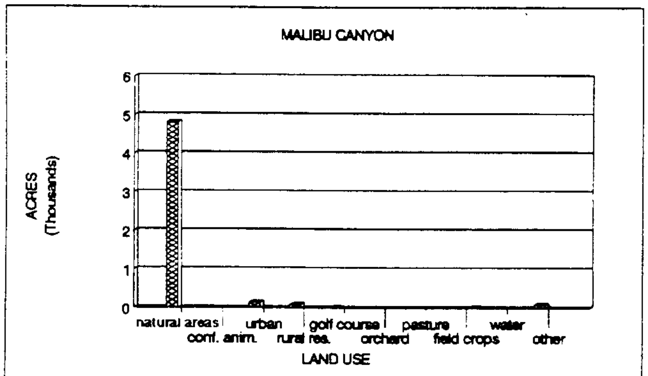
For Confined Animal Units:
- Waste Management System
- Waste Utilization
- Waste Transfer
- Filter Strips
- Livestock Exclusion
- Pasture and Hayland Management
- Fencing

SUBWATERSHED OVERVIEW

The Malibu Creek subwatershed is the southernmost subwatershed for the Malibu Creek Watershed and ends at Malibu Lagoon by the City of Malibu. A full 93 percent of the subwatershed is natural area, with 3 percent rural residences and 2 percent urban area. There are also small acreages of confined animal units and golf courses. This subwatershed contains the Tapia Treatment Plant and Rindge Dam.



LAND USE



WATER QUALITY ISSUES

Major Water Bodies: Malibu Creek, Century Reservoir

Possible Concerns: High nutrient and bacteria levels, fish population decline, spawning impairment, and sedimentation

Possible Sources: Urban runoff, septic systems, wildlife, runoff from natural areas, fertilizers, confined animal units, erosion from roads

Designated Beneficial Uses: Existing uses - contact and non-contact water recreation*, warm freshwater habitat*, cold freshwater habitat*, wildlife habitat, migration*, spawning*, wetland habitat, rare and endangered species habitat: Potential uses - municipal and domestic supply*

* may be affected by possible concerns

POTENTIAL TREATMENT

For Rural Land Uses:
- Access Road Improvement
- Critical Area Planting
- Sediment Basin
- Filter Strip
- Irrigation Water Management
- Nutrient Management

For Confined Animal Units:
- Waste Management System
- Waste Utilization
- Waste Transfer
- Livestock Exclusion
- Fencing
- Filter Strip

For Stormwater Runoff:
- Filter Strips
- Detension Basins
- Constructed Wetlands

TO: San Gabriel River Watershed Stakeholders

FROM: Shirley Birosik
Watershed Coordinator
LOS ANGELES REGIONAL WATER QUALITY CONTROL BOARD

DATE: June 29, 2000

SUBJECT: SAN GABRIEL RIVER STATE OF THE WATERSHED REPORT

The San Gabriel River has been one of this year's targeted watersheds in our watershed management permitting cycle. As it represents a major watershed, we have prepared a State of the Watershed report for the river. A draft copy of this report was distributed in May for review and comments received on the draft report have been incorporated into this final document to the extent possible.

The emphasis of the report is on a broad look at data from a number of surface water sampling programs and general observations on surface water quality. Recommendations for more focused monitoring are made. An overview of the watershed and its infrastructure is also given. Although termed a "final report", the document will be updated at least every five years in line with our watershed permitting cycle.

The electronic version of the document contains a number of hyperlinks; some links are to websites and some are to Excel files containing data and charts. This hardcopy contains a limited number of these charts and none of the data from the spreadsheet files due to their very large size. These files may be obtained electronically from this office by contacting myself at 213-576-6679 or sbirosik@rb4.swrcb.ca.gov.

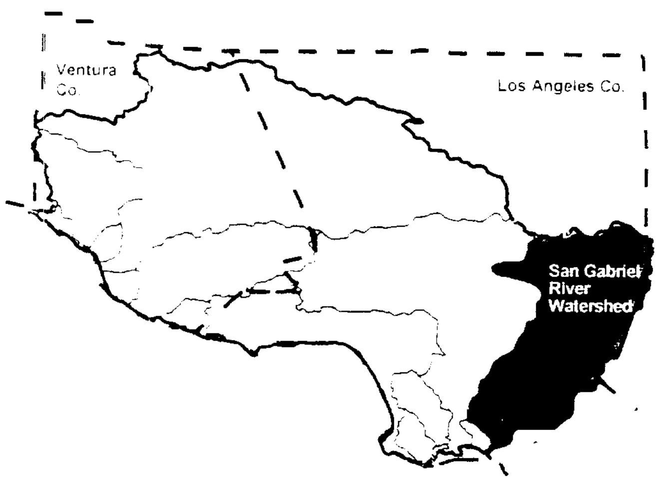
Executive Summary



The San Gabriel River receives drainage from a 689 square mile area of eastern Los Angeles County; its headwaters originate in National Forest lands in the San Gabriel Mountains. The watershed consists of extensive areas of undisturbed riparian and woodland habitats in its upper reaches. Much of the watershed of the West Fork and East Fork of the river has been set aside by the U.S. Congress as a wilderness area; other areas (particularly the East Fork and lower North Fork)in the upper watershed are subject to heavy recreational use. The upper watershed also contains a series of flood control dams. Further downstream, toward the middle of the watershed, are large spreading grounds utilized for groundwater recharge. The watershed is hydraulically connected to the Los Angeles River through the Whittier Narrows Reservoir (occurring mostly during high storm flows). The lower part of the river flows through a concrete-lined channel in a heavily urbanized portion of the county before becoming an soft bottom channel once again near the ocean in the city of Long Beach. Large electrical power poles line the river along the channelized portion and nurseries, small stable areas, and a large poultry farm are located in these areas (CRWQCB-LA Region, 2000).

Water Quality Problems and Issues

Pollutants from dense clusters of residential and commercial land uses have impaired water quality in the middle and lower watershed. Tertiary-treated effluent from several sewage treatment plants enters the river in its middle reaches (which is partially channelized) while two power generating stations discharge cooling water into the river's estuary. The watershed is also covered under the municipal storm water NPDES permit. Several landfills are also located in the watershed.

Existing Beneficial Uses designated in the watershed:

Estuary	*Above Estuary (various reaches)*
Contact & noncontact water recreation	Contact & noncontact water recreation
Industrial service supply	Industrial service supply
Protection of rare & endangered species	Protection of rare & endangered species
Wildlife habitat	Wildlife habitat
Spawning	Spawning
Marine habitat	Warm- & coldwater habitat
Estuarine habitat	Municipal water supply
Navigation	Groundwater recharge
Commercial & sportfishing	Industrial process supply
Migratory	Agricultural supply

Significant Issues:

- Sluicing of reservoirs
- Protection of groundwater recharge areas
- Trash
- Watershed-wide monitoring
- Mining/stream, modifications
- Ambient toxicity
- Urban and storm water runoff quality
- Nonpoint source loadings from nurseries and horse stables
- Estuary dynamics
- Restoration of wetlands

Three reservoirs, which were constructed primarily for flood control purposes, occur in the upper part of the watershed. Frequent removal of accumulated sediments is necessary to maintain the flood control capacity of these reservoirs. Some of the removal methods previously used have had short-term water quality impacts. Continued need for such maintenance could cause longer-term impacts (CRWQCB-LA Region, 2000).

Permitted discharges:

- Nine major NPDES dischargers (five POTWs)
- 25 minor permits
- 39 discharges covered under general permits
- 536 dischargers covered under an industrial storm water permit
- 170 dischargers covered under a construction storm water permit

IMPAIRMENTS: The upper reaches of the river (in the Angeles National Forest) are heavily used for recreational purposes and have been impacted from trash (303(d)-listed as an impairment), debris, and habitat destruction. Various reaches of the river are on the 1998 303(d) list due to nitrogen and its effects, trash, PCBs and pesticides, metals, and coliform (CRWQCB-LA Region, 2000).

State of the Watershed

This document is primarily a report on surface water quality in the San Gabriel River Watershed. However, topics such as a physical description of the river and structures, water resources and related issues, groundwater agencies, and other broader topics are also included as needed. The reader may need to consult other documents for more detailed descriptions of habitats, wildlife, and structures than this document is meant to provide. This document will be updated in future watershed cycles.

Physical Description of River, Tributaries, and Structures

The San Gabriel River receives drainage from a 689 square mile area of eastern Los Angeles County and has a main channel length of approximately 58 miles; its headwaters originate in the San Gabriel Mountains with the East, West, and North Forks. The river empties to the Pacific Ocean at Los Angeles/ Orange Counties boundary in Long Beach. The main tributaries of the river are Big and Little Dalton Wash, San Dimas Wash, Walnut Creek, San Jose Creek, Fullerton Creek, and Coyote Creek (LA County DPW, 1994).

The Upper Watershed

The watershed consists of extensive areas of undisturbed riparian and woodland habitats in its upper reaches, much of which is set aside as a wilderness area by the U.S. Congress. Other areas in the upper watershed are subject to heavy recreational use. The upper watershed also contains a series of reservoirs with flood control dams (Cogswell, San Gabriel, and Morris Dams, going downstream) (CRWQCB-LA Region, 2000). Cogswell Dam (formerly San Gabriel Dam No. 2) is located 22 miles north of the city of Azusa on the West Fork of the San Gabriel River. Construction of the dam was begun in 1932 and was completed in 1934. Its primary purposes are flood control and water conservation and it drains an area of 39.2 square miles. San Gabriel Dam (formerly San Gabriel Dam No. 1) is located 7.5 miles north of the city of Azusa on the San Gabriel River. Construction of the dam was begun in 1932 and was completed in 1939. Its primary purposes are flood control and water conservation and it drains an area of 202.7 square miles. Morris Dam is located 5 miles north of the city of Azusa on the San Gabriel River. Construction of the dam was begun in 1932 and was completed in 1935. Its primary purpose is water conservation and it drains an area of 217 square miles (LA County DPW websites). There are a number of "beneficial uses" designated for these reservoirs (as well as all the waters of this watershed) by the CRWQCB-LA Region; see page 5 for further information.

Santa Fe Dam

The river flows out of the San Gabriel Canyon and into the San Gabriel Valley entering first the Santa Fe Dam and spreading grounds. Santa Fe Dam and Reservoir is a flood control project constructed under the authorization of the Flood Control Act of 1936 and operated by the U.S. Army Corps of Engineers, Los Angeles District. Construction of the project started in 1941and was completed in 1949 (USACE LA District, Reservoir Regulation Section website).

The project is located on the San Gabriel River about 4 miles downstream from the mouth of the San Gabriel Canyon. The Rio Hondo, a distributary of the San Gabriel River, branches from the river just below Santa Fe Dam and flows westward to Whittier Narrows Reservoir. From Whittier Narrows Reservoir, the San Gabriel River flows south to the Pacific Ocean, and the Rio Hondo flows southwestward to the Los Angeles River (USACE LA District, Reservoir Regulation Section website).

Santa Fe Dam is an element of the Los Angeles County Drainage Area (LACDA) flood control system. The primary purpose of Santa Fe Dam is to provide flood protection to downstream communities along the San Gabriel River between the Santa Fe Dam and Whittier Narrows Dam, and , in conjunction with the Whittier Narrows Dam, provide flood protection along the Rio Hondo Channel, the Los Angeles River, and the San Gabriel River.. The second authorized purpose of the Santa Fe Dam is to provide recreation opportunities. The Santa Fe basin also includes a Wildlife Management Area, a designated sensitive habitat area. The flood control operation of Santa Fe Dam is also coordinated with the operation of other Corps dams in the LACDA system, namely Whittier Narrows Dam, Hansen Dam and Sepulveda Dam.

Although it has no authorized storage allocation for water supply, its flood control operation provides incidental water conservation benefits to the people of San Gabriel Valley and other parts of the Los Angeles Basin (USACE LA District, Reservoir Regulation Section website and USACE LA District, 1998).

Santa Fe Dam contains sixteen hydraulically operated gates set to pass low flows and build a debris pool during high inflows. Discharge rates within the debris pool range allows the Los Angeles County Department of Public Works to divert the flow to its spreading facilities, thereby enhancing water conservation. Once the reservoir level reaches elevation 456 feet, flood control releases are initiated and the flood pool is drained as rapidly as possible, consistent with the achievement of downstream flood control. As soon as the flood pool is drained, releases are reduced so that LACDPW can resume water conservation operation. (USACE LA District, Reservoir Regulation Section website).

The LACDPW has operated and maintained the Santa Fe Reservoir Spreading Grounds (SFRSG) since 1953 through an easement with the USACE. Stormwater and imported water diverted from the San Gabriel River are spread in the area. The spreading grounds are east and west of the San Gabriel River and occupy the northwest portion of the Santa Fe Reservoir. The SFRSG receives controlled releases from Morris Dam; also receives seasonal local flows originating in San Gabriel Canyon and imported water releases from the Upper San Gabriel Valley Municipal Water District's USG-3 outlet and from the San Gabriel Valley Municipal Water District's outlet to Beatty Channel (USACE - LA County DPW/Water Conservation Division, 1995).

The spreading grounds recharge water to the Main San Gabriel Basin underlying the San Gabriel Valley. The basin has an estimated storage capacity of 9.5 million acre-feet and is bounded by the San Gabriel Mountains on the north, the Puente Hills on the south, the San Jose Hills to the east, and the San Rafael Hills to the west. The Santa Fe Dam Recreation Area is located approximately one mile southeast of the SFRSG (USACE - LA County DPW/Water Conservation Division, 1995).

The Santa Fe Dam Floodplain has been designated as a LA County Significant Ecological Area (SEA No. 22) as defined by the County Zoning Code. This area has been designated as a Class 3 (5,7) SEA. Class 3 designates an area where the biotic communities, vegetative associations, and habitat of plant and animal species that are either one of a kind or restricted in distribution in LA County. Class 5 designates an area that contains biotic resources that are of scientific interest because they are either an extreme in physical/geographical limitations or they represent an unusual variation in a population or community. Class 7 designates areas that would provide for the preservation of relatively undisturbed examples of the natural biotic communities in LA County. The extensive alluvial fan sage scrub, lowland riparian, and freshwater marsh habitats located in the flood control basin are the major resources supporting the SEA designation (USACE - LA County DPW/Water Conservation Division, 1995).

The Area Between Santa Fe and Whittier Narrows Dams

The San Gabriel River Channel between Santa Fe Dam and the Whittier Narrows Basin is soft-bottomed with riprap sides. LACDPW has constructed a rubber dam in the San Gabriel River channel just downstream of the Walnut Creek confluence which can impound up to 400 AF (USACE LA District, 1998).

Walnut Creek is a tributary to the San Gabriel River above the Whittier Narrows area. Puddingstone Reservoir is located on upper Walnut Creek and is operated for flood control, water conservation, and recreation with a relatively small flood control allocation (USACE LA District, 1998).

San Jose Creek, a soft-bottomed channel, also enters the San Gabriel River upstream of the Whittier Narrows area, but downstream of the Walnut Creek confluence and its dry-weather flow is dominated by tertiary-treated effluent from a nearby treatment plant.

Whittier Narrows Dam

Whittier Narrows Dam is a flood control and water conservation project constructed and operated by the USACE, Los Angeles District. Construction of the project was completed in 1957. The Whittier Narrows are a natural gap in the hills that form the southern boundary of the San Gabriel Valley. The Rio Hondo and the San Gabriel River flow through this gap and are impounded by the reservoir (USACE LA District, Reservoir Regulation Section website).

The purpose of the project is to collect runoff from upstream along with releases into the San Gabriel River from Santa Fe Dam, thus, the primary authorized purpose of Whittier Narrows Dam is flood control. Subsequent Acts of Congress authorized the development of the area for park and recreational purposes. There is also a nature area located in the southeast area of the basin which was developed as mitigation for the established recreation facilities. The third authorized purpose of water conservation was granted in 1956 (USACE LA District, Reservoir Regulation Section website and USACE LA District, 1998).

If the inflow to the reservoir exceeds the groundwater recharge capacity of the spreading grounds along the Rio Hondo or the bed of the San Gabriel River downstream, this water is stored temporarily in a water conservation pool. The Rio Hondo and San Gabriel sides of the reservoir each have their own water conservation pools. If the water conservation pool on the Rio Hondo side is exceeded, flows are released into the Rio Hondo at a rate which does not exceed the downstream channel capacity of either the Rio Hondo or the LA River. If the water conservation pool on either side of the reservoir is exceeded a release of approximately 5,000 cfs can be made into the San Gabriel River. If the pool in the reservoir exceeds flood control storage, the gates on the San Gabriel River outlet begin to open automatically and emergency releases are made into the river (USACE LA District, Reservoir Regulation Section website).

The gates on the Rio Hondo outlet are normally wide open. On the San Gabriel side one gate is normally open about 0.5 feet with the remaining gates closed. The reservoir is normally empty and a weir within the reservoir keeps the flows from the Rio Hondo and the San Gabriel River separated. The natural flow to each river therefore normally passes through the dam unhindered. During the initial stages of a flood event, the gates on the Rio Hondo side are partially closed to build a water conservation pool. As long as the pool on the Rio Hondo side of the reservoir is below a certain elevation, releases are made to accommodate the capacity of the spreading grounds downstream along the Rio Hondo. All outflow to the San Gabriel River from Whittier Narrows Dam is through or over the spillway gates. Whittier Narrows currently provides greater than 100-year protection to areas downstream from the spillway on the San Gabriel River. There are plans to retain more water behind both Santa Fe and Whittier Narrows Dams, and in turn increase downstream water recharge, through increasing the size of the pools behind the dams and releasing water at a slower rate (USACE LA District, Reservoir Regulation Section website and USACE LA District, 1998).

Potentially occurring federal and state listed and candidate species in the riparian habitat of the Whittier Narrows Dam area include Least Bell's Vireo (federal and state listed) and tricolored blackbird (California species of special concern and a candidate for federal listing). The California gnatcatcher potentially occurs in the coastal sage scrub of the dam area and is a California species of special concern and federal threatened species (LA County DPW, 1994).

Recharge Areas Below Whittier Narrows

Further downstream, along the Rio Hondo and San Gabriel River, are large spreading grounds utilized for groundwater recharge. The stretch of the river below the Whittier Narrows area overlies the Central Basin groundwater basin which contains a number of shallow aquifers and three deeper aquifers (the Silverado, the Sunnyside, and the Lynwood). The deep and shallow aquifers are recharged by underflow through the Whittier Narrows from the north, and by percolation from the San Gabriel River and the Rio Hondo Channel, which flows into the Montebello Forebay just south of the Narrows. This surface and subsurface flow through the Narrows represents outflow from the upstream San Gabriel Basin. The San Gabriel River and Rio Hondo are unlined in this area, allowing for groundwater recharge at the San Gabriel Coastal Basin Spreading Grounds and the Rio Hondo Spreading Grounds, respectively (LA County DPW, 1994).

The Montebello Forebay is a recharge facility located immediately downstream of Whittier Narrows Dam and allows infiltration into the Central Basin aquifer. The Rio Hondo Coastal Basin Spreading Grounds are located on the banks of the Rio Hondo south of Whittier Boulevard, 2 miles downstream from the Whittier Narrows Dam. The spreading grounds are owned and operated by the LACDPW which uses gates across the Rio Hondo to divert flow to three separate intake structures. The San Gabriel River Coastal Spreading Basins are operated by the LACDPW. They are located on the west side of the San Gabriel River between Whittier Boulevard and Washington Boulevard. Water is diverted to the grounds by way of two rubber dams across the soft-bottomed river channel (USACE LA District, 1998).

Up to an annual average of 50,000 AF per year of reclaimed water is used to supplement local surface water and imported water for replenishing the Central Basin aquifer through the Montebello Forebay. The source of reclaimed water is from the following three water reclamation plants owned and operated by the County Sanitation Districts of Los Angeles County (CSDLAC): Whittier Narrows, San Jose Creek, and Pomona (CSDLAC, 2000).

The Lower Watershed

The lower part of the river flows through a concrete-lined channel in a heavily urbanized portion of the county before becoming an soft bottom channel once again near the ocean in the city of Long Beach. The concrete-lined Coyote Creek joins the San Gabriel River at the tidal prism in Long Beach south of Willow Street (CRWQCB-LA Region, 2000).

The Alamitos Barrier is an engineered freshwater pressure ridge and seawater trough located in the City of Long Beach. The Barrier is designed to protect the Central Groundwater Basin of Los Angeles County and the Orange County Groundwater Basin (which are geologically one basin) from seawater intrusion through an alluvium-filled erosional gap, commonly known as the Alamitos Gap. Currently, the Barrier is maintained through the injection of treated, imported potable water. The seawater trough is created by the extraction of brackish groundwater from four wells located on the seaward side of the injection well arc, and barrier performance is monitored through observations conducted at 230 wells located at multiple sites near the gap (Water Replenishment District of Southern California, 1998).

The combination of wells is designed to reverse the inland gradient of subsurface water and thus prevent further seaward intrusion. The Central Basin Municipal Water District supplies imported water to the Water Replenishment District of Southern California for groundwater replenishment and barrier injection (Water Replenishment District of Southern California, 1998).

The Watershed's Designated Beneficial Uses

The Los Angeles Regional Board's Basin Plan is designed to preserve and enhance water quality and protect the beneficial uses of all regional waters. Beneficial uses form the cornerstone of water quality protection. Once beneficial uses are designated, appropriate water quality objectives can be established and programs that maintain or enhance water quality can be implemented to ensure the protection of beneficial uses. The designated beneficial uses, together with water quality objectives, form water quality standards. Such standards are mandated for all waterbodies within the state under the California Water Code. In addition, the federal Clean Water Act mandates standards for all surface waters, including wetlands (CRWQCB-LA Region, 1994).

There are twenty-four beneficial uses in the Region as a whole; examples include wildlife habitat, municipal water supply, navigation, and marine habitat. These uses and their definitions were developed by the State and Regional Boards for use in the Regional Board Basin Plans. Beneficial uses can be designated for a waterbody in a number of ways. Those uses that have been attained for a waterbody on, or after, November 28, 1975, must be designated as "existing" in the Basin Plans. Other uses can be designated, whether or not they have been attained in a waterbody, in order to implement either federal or state mandates and goals (such as fishable and swimmable) for regional waters. Beneficial uses of streams that have intermittent flows, which can support some beneficial uses during dry periods through shallow ground water or small pools, are designated as intermittent. In addition, a use can be designated as "potential" if there are plans or potential to put the water to such future use among other reasons (CRWQCB-LA Region, 1994).

The beneficial uses of the San Gabriel River and its tributaries are listed in the table below as they appear in the Los Angeles Regional Board's Basin Plan

Beneficial Use Definitions

Beneficial uses for waterbodies in the Los Angeles Region are listed and defined below. The uses are listed in no preferential order.

Municipal and Domestic Supply (MUN)
Uses of water for community, military, or individual water supply systems including, but not limited to, drinking water supply.

Agricultural Supply (AGR)
Uses of water for farming, horticulture, or ranching including, but not limited to, irrigation, stock watering, or support of vegetation for range grazing.

Industrial Process Supply (PROC)
Uses of water for industrial activities that depend primarily on water quality.

Industrial Service Supply (IND)
Uses of water for industrial activities that do not depend primarily on water quality including, but not limited to, mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection, or oil well re-pressurization.

Ground Water Recharge (GWR)
Uses of water for natural or artificial recharge of ground water for purposes of future extraction, maintenance of water quality, or halting of saltwater intrusion into freshwater aquifers.

Freshwater Replenishment (FRSH)
Uses of water for natural or artificial maintenance of surface water quantity or quality (e.g., salinity).

Navigation (NAV)
Uses of water for shipping, travel, or other transportation by private, military, or commercial vessels.

Hydropower Generation (POW)
Uses of water for hydropower generation.

Water Contact Recreation (REC-1)
Uses of water for recreational activities involving body contact with water, where ingestion of water is reasonably possible. These uses include, but are not limited to, swimming, wading, water-skiing, skin and scuba diving, surfing, white water activities, fishing, or use of natural hot springs.

Non-contact Water Recreation (REC-2)
Uses of water for recreational activities involving proximity to water, but not normally involving body contact with water, where ingestion of water is reasonably possible. These uses include, but are not limited to, picnicking, sunbathing, hiking, beachcombing, camping, boating, tidepool and marine life study, hunting, sightseeing, or aesthetic enjoyment in conjunction with the above activities.

Commercial and Sport Fishing (COMM)
Uses of water for commercial or recreational collection of fish, shellfish, or other organisms including, but not limited to, uses involving organisms intended for human consumption or bait purposes.

Aquaculture (AQUA)
Uses of water for aquaculture or mariculture operations including, but not limited to, propagation, cultivation, maintenance, or harvesting of aquatic plants and animals for human consumption or bait purposes.

Warm Freshwater Habitat (WARM)
Uses of water that support warm water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Cold Freshwater Habitat (COLD)
Uses of water that support cold water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Inland Saline Water Habitat (SAL)
Uses of water that support inland saline water ecosystems including, but not limited to, preservation or enhancement of aquatic saline habitats, vegetation, fish, or wildlife, including invertebrates.

Estuarine Habitat (EST)
Uses of water that support estuarine ecosystems including, but not limited to, preservation or enhancement of estuarine habitats, vegetation, fish, shellfish, or wildlife (e.g., estuarine mammals, waterfowl, shorebirds).

Wetland Habitat (WET)
Uses of water that support wetland ecosystems, including, but not limited to, preservation or enhancement of wetland habitats, vegetation, fish, shellfish, or wildlife, and other unique wetland functions which enhance water quality, such as providing flood and erosion control, stream bank stabilization, and filtration and purification of naturally occurring contaminants.

Marine Habitat (MAR)
Uses of water that support marine ecosystems including, but not limited to, preservation or enhancement of marine habitats, vegetation such as kelp, fish, shellfish, or wildlife (e.g., marine mammals, shorebirds).

Wildlife Habitat (WILD)
Uses of water that support terrestrial ecosystems including, but not limited to, preservation and enhancement of terrestrial habitats, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), or wildlife water and food sources.

Preservation of Biological Habitats (BIOL)
Uses of water that support designated areas or habitats, such as **Areas of Special Biological Significance (ASBS),** established refuges, parks, sanctuaries, ecological reserves, or other areas where the preservation or enhancement of natural resources requires special protection.

Watershed Stakeholder Groups

Los Angeles/San Gabriel Rivers Watershed Council: This group was formed in 1995 following a large watershed conference held in the area which served to encourage other efforts. The Council has a board of directors and became incorporated as a nonprofit organization in 1996. The group is tracking watershed activities, but has primarily focused on flood control issues in the Los Angeles River as well as opportunities to create greenbelts and restore habitat. The Council's goal is to help facilitate a process to preserve, restore, and enhance all aspects of the double watershed. Currently, the Watershed council is heading up the Los Angeles County Task Force of the Southern California Wetlands Recovery Project. The Council is also initiating a Watershed Management Plan for both the Los Angeles and San Gabriel River. Their website is at http://lasgriverswatershed.org/.

Friends of the Los Angeles River: Friends of the Los Angeles River is a non-profit organization founded in 1986 to protect and restore the natural and historic heritage of the Los Angeles River and its riparian habitat through inclusive planning, education, and stewardship. Their website is at http://www.folar.org/.

Water Resources, and Groundwater Agencies and Issues

Groundwater in certain areas of the San Gabriel Basin has been impacted by volatile organics attributable to widespread industrial land use and associated contaminant releases over the last several decades. In

1979, VOCs were discovered in a number of public water supply wells in the San Gabriel Basin. As a result, the USEPA and the Regional Board entered into a cooperative agreement in 1989 to identify and cleanup the contamination. Subsequent investigations revealed more widespread soil and groundwater contamination in the Basin. During the last 15 years, more than one quarter of the approximately 366 water supply wells in the San Gabriel Valley has been found to be contaminated. The Regional Board, under authority of the California Water Code, locates and abates the sources of pollutants affecting these wells and oversees the remediation of the pollution. These investigations, conducted through the Well Investigation Program (WIP), are designed to identify and eliminate sources of pollutants in public water supply wells; identify dischargers by establishing a cause-and-effect relationship between the discharge of a pollutant and a polluted well; when necessary, take enforcement action against dischargers in order to force them to undertake site investigations and corrective actions; and oversee remediation of soils.

Soil and groundwater in the San Gabriel Valley are contaminated by volatile organic compounds such as PCE, TCE, and 1,1,1-TCA. Since 1997, new chemicals called emerging chemicals have been found in drinking water and groundwater monitoring wells. These chemicals include perchlorate, NDMA, and 1,4-dioxane which are carcinogens or suspected carcinogens.

The Regional Board has been the lead agency that oversees soil cleanup and "hot spot" groundwater cleanup. These are sites where groundwater contamination is so significant it warrants site-specific cleanup. USEPA is the lead agency for the regional groundwater cleanup. The various operable units (Superfund areas) in the Valley, such as Baldwin Park, Whittier Narrows, Puente Valley, El Monte, South El Monte, and Alhambra are at various stages of site assessment and cleanup.

Although the main goal of hot spot cleanups is the removal of high levels of contaminants, responsible parties are encouraged to reduce their cleanup costs by either sharing soil and/or groundwater treatment systems or reusing treated groundwater in their processes (CRWQCB – LA Region website).

Agencies with a vested interest in water resources in southern California:

- **Los Angeles County Department of Public Works** – The Los Angeles County Flood Control District was created in 1915 by the State legislature with the charge to control and conserve flood, storm, and other wastewaters. Since 1985 the LACDPW has been performing the functions of the flood control district. Under its conservation mission, LACDPW owns or operates 29 water spreading areas where groundwater is recharged. Several dams and reservoirs, including the U.S. Army Corps Whittier Narrows Dam, are operated to store water for post storm releases to downstream spreading grounds.
- **Metropolitan Water District of Southern California** – The MWD is a public agency and quasi-municipal corporation. Currently the MWD imports water from two sources, the Colorado River via the Colorado River Aqueduct and Northern California via the State Water project and its California Aqueduct.. MWD's primary purpose is to develop, store, and distributed water at wholesale rates to its member agencies. MWD is composed of 27 member agencies, including 14 cities, 12 municipal water districts, and one county water authority.
- **Department of Water and Power, City of Los Angeles** – The DWP imports water from the Owens Valley and Mono Basin through the Los Angeles Aqueducts. The remainder of the City's needs are supplied by local groundwater supplies and imported water from the MWD.
- **Water Replenishment District of Southern California** – The primary objectives of the WRD are to provide high quality water to its users, minimize adverse effects produced by years of groundwater pumping, and to oversee groundwater recharge operations in the Central and West Coast Basins. WRD purchases water imported through the State Water Project or the Colorado River Project and reclaimed water from CSDLAC to supplement storm runoff to replenish the groundwater basins. Direct groundwater recharge is accomplished through percolation at the spreading grounds adjacent to the Rio Hondo and the San Gabriel River; further replenishment is accomplished by injecting water at three freshwater barriers (West Coast Basin, Dominguez Gap, and Alamitos Barriers).
- **County Sanitation Districts of Los Angeles County** – The CSDLAC is a supplier of reclaimed water used during groundwater replenishment. Effluent from its facilities is a major part of the surface flow in the river during dry weather.
- **San Gabriel Valley Municipal Water District** – The District is composed of four cities and imports water to the San Gabriel Basin via the East Branch of the State Water Project.

- **West Basin and Central Basin Municipal Water Districts** – The West basin and Central Basin provide service to more than 40 cities and distribute wholesale water to approximately 50 separate water utilities. The Districts are involved in water conservation programs, water quality improvement projects, recycled water projects, and brackish groundwater desalting.
- **Upper San Gabriel Valley Municipal Water District** – The District was incorporated in 1960 by popular referendum and was annexed to the MWD in 1963. The District was formed to help solve water supply problems of the rapidly developing San Gabriel Valley.
- **Three Valleys Municipal Water District** – The Distract was formed in 1950 by popular referendum and was annexed to the MWD later in 1950. The District was formed to [provide supplemental imported water to serve growing needs of orchards and communities in the Pomona, Walnut, and eastern San Gabriel Valleys (LA County DPW, 1994).

Discharges into the Watershed

Major Dischargers

The Joint Outfall System (JOS) is the CSDLAC's integrated network of facilities which includes seven treatment plants, five of which are associated with the San Gabriel River Watershed. These five treatment plants (Whittier Narrows, Pomona, Long Beach, Los Coyotes, and San Jose Creek) are connected to the Joint Water Pollution Control Plant (JWPCP) which discharge off of the Palos Verdes Peninsula. This system allows for the diversion of desired flows into or around each "upstream" plant. Sludge (sewage solids separated from the wastewaters) from the upstream plants are returned to the trunk sewer for treatment at JWPCP (CRWQCB – LA Region files).

The Whittier Narrows Water Reclamation Plant is located within the Whittier Narrows basin on the west side of Rosemead Boulevard, between the Pomona Freeway and San Gabriel Boulevard. The facility discharges 10 MGD of tertiary-treated water into the Rio Hondo for groundwater recharge in downstream spreading grounds. Some reclaimed water is used to irrigate a nearby commercial nursery. The plant is constructed to be fully functional during flood events (USACE, LA District, 1998). Discharges from this facility normally are diverted to the Rio Hondo Spreading Grounds for groundwater replenishment. However, during heavy storm runoff, the effluent will enter the Los Angeles River through the Rio Hondo; there are times when discharges may enter the San Gabriel River depending on the depth of water behind the dam.

Two other water reclamation plants, the Pomona and San Jose Creek Water Reclamation Plants, discharge water into the middle reaches of the San Gabriel River. The Pomona plant discharges about 2.5 MGD to San Jose Creek which flows into the Whittier Narrows basin via the San Gabriel River. The San Jose Creek plant has three outlets to the river, one to San Jose Creek, one to the unlined portion of the San Gabriel River upstream of the San Gabriel River Coastal Spreading Grounds, and one outlet to the lined portion of the river downstream of the spreading grounds (USACE, LA District, 1998). The Los Coyotes and Long Beach Water Reclamation Plants discharge into the lower watershed.

In addition, two generating stations discharge into the tidal prism just north of Second St. (Westminster Ave.), the Haynes and Alamitos Generating Stations. Both draw in water from the nearby Los Cerritos Watershed Management Area.

<u>POTWs</u> (California Regional Water Quality Control Board – Los Angeles Region files)

County Sanitation Districts of Los Angeles County, Los Coyotes Water Reclamation Plant (Los Coyotes WRP) Order No. 95-077, CA0054011

- Located at 16515 Piuma Avenue, Cerritos
- Design capacity of 37.5 MGD
- Treatment is primary sedimentation, activated sludge biological treatment, secondary sedimentation, coagulation, inert media filtration, chlorination, dechlorination
- Tertiary-treated municipal and industrial wastewater is discharged into the San Gabriel River 1,230 feet upstream of the Artesia Freeway, above the estuary

- A portion of the treated effluent is reclaimed for landscape irrigation and is regulated under Order No. 87-51.

County Sanitation Districts of Los Angeles County, San Jose Creek Water Reclamation Plant (San Jose Creek WRP) Order No. 95-079, CA0053911

- Located at 1965 South Workman Mill Road, Whittier
- Design capacity of 100 MGD
- Treatment is primary sedimentation, activated sludge biological treatment, secondary sedimentation, coagulation, inert media filtration, chlorination, dechlorination
- Tertiary-treated municipal and industrial wastewater is discharged via three discharge points:
    - Discharge No. 001 to the San Gabriel River is the primary discharge outfall which is eight miles south of the plant near Firestone Blvd. From this point treated effluent flows directly to a concrete-lined, low flow channel in the river and travels about nine miles prior to reaching the estuary.
    - Discharge No. 002 to San Jose Creek is used for groundwater recharge at Rio Hondo and the San Gabriel Coastal Spreading Grounds. San Jose Creek is unlined from the discharge point to the San Gabriel River.
    - Discharge No. 003 delivers treated effluent to the unlined portion of the San Gabriel River as well as both the Rio Hondo and San Gabriel Coastal Spreading Grounds for groundwater replenishment.
- In addition to groundwater recharge, a portion of the treated effluent is used for irrigation and industrial process water and is regulated under Order No. 87-50. Treated effluent for groundwater recharge and discharged to lined channels is partially dechlorinated; that used for direct reuse is not dechlorinated. The discharge to the lined channel (No. 001) leaves the treatment plant at about 1 mg/l residual chlorine and is less than 0.1 mg/l upon discharge to the lined portion of the San Gabriel River.

County Sanitation Districts of Los Angeles County, Long Beach Water Reclamation Plant (Long Beach WRP) Order No. 95-076, CA0054119

- Located at 7400 East Willow Street, Long Beach
- Design capacity of 25 MGD
- Treatment consists of primary sedimentation, activated sludge biological treatment, secondary clarification, coagulation, inert media filtration, chlorination, and dechlorination.
- Tertiary-treated municipal and industrial wastewater is discharged to Coyote Creek at a point 2,200 feet upstream from the confluence with the San Gabriel River, above the estuary
- A portion of the treated effluent is reclaimed for irrigation and regulated under Order No. 87-47.

County Sanitation Districts of Los Angeles County, Whittier Narrows Water Reclamation Plant (Whittier Narrows WRP) Order No. 95-082, CA0053716

- Located at 301 North Rosemead Blvd., El Monte
- Design capacity of 15 MGD
- Treatment consists of primary sedimentation, activated sludge biological treatment, secondary clarification, coagulation, inert media filtration, chlorination, and dechlorination.
- Tertiary-treated municipal and industrial wastewater is discharged via four discharge points:
    - Discharge No. 001 to the San Gabriel River via a point 700 feet upstream from the Whittier Narrows Dam. The treated effluent generally flows down the river to the San Gabriel River Spreading Grounds
    - Discharge No. 002 to Zone 1 Ditch at a point 5,500 feet upstream from its juncture with the Rio Hondo. The treated effluent enters the Rio Hondo at a point about 4,000 feet upstream from the Whittier Narrows Dam and generally flows down the river to the Rio Hondo Spreading Grounds.
    - Discharge No. 003 to a test basin for the study of using reclaimed wastewater for groundwater recharge; there has been no discharge here since 1981 and no plans to discharge here in the immediate future.

- Discharge No. 004 directly to the Rio Hondo via a 27-inch diameter discharge line at a point 1,400 feet upstream from San Gabriel Blvd., above Whittier Narrows Dam. The treated effluent generally flows down the river to the Rio Hondo Spreading Grounds.
- All or a portion of the effluent is reclaimed and is regulated under Board Order No. 88-107. Reclaimed water directed to reuse is not dechlorinated.

County Sanitation Districts of Los Angeles County, Pomona Water Reclamation Plant (Pomona WRP) Order No. 95-078, CA0053619

- Located at 295 Humane Way, Pomona
- Design capacity of 15 MGD
- Treatment consists of primary sedimentation, activated sludge biological treatment, secondary sedimentation, coagulation, inert media filtration, chlorination, and dechlorination.
- Tertiary-treated municipal and industrial wastewater is discharged to the South Fork of San Jose Creek, a tributary of the San Gabriel River, at a point near the interchange of the Pomona and San Gabriel River Freeways, above the estuary.
- During dry weather, virtually all of the treated effluent is reclaimed for landscape and crop irrigation, as well as for industrial processes and is regulated under Order No. 81-34.

POTW Effluent Annual Averages

Constituent	Units	Pomona	Los Coyotes	San Jose Creek		Whittier Narrows	Long Beach
				East	West		
Flow	MGD	9.65	36.22	52.79	29.45	10.27	17.86
pH	pH units	6.98	7.23	7.00	6.97	6.98	7.18
Temperature	°F	76	76	77	77	76	76
BOD	mg/L	6	6	6	5	3	10
TDS	mg/L	506	843	583	560	538	661
Suspended Solids	mg/L	< 2	< 1	2	< 1	< 1	2
Settleable Solids	ml/L	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1	< 0.1

A total of nearly 39,000 acre-feet/year of reclaimed water from the Whittier Narrows, San Jose Creek, and Pomona WRPs were used for groundwater replenishment of the Central Basin in 1997-98. An additional 10,000 acre-feet/year were used for irrigation and industrial use at 390 sites. Thirty-six percent of the reclaimed wastewater produced by these facilities in 1997-98 was reused; the remainder was discharged to the watershed. Use of reclaimed water to recharge the Montebello Forebay has helped reduce the need for use of imported water or natural river water (imported water use decreased from 22,551 acre-feet in 1996-97 to 0 acre-feet in 1998-99 (LA/SG Rivers Watershed Council, in press).

R0026436

Types of permitted wastes discharged into the San Gabriel River Watershed:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
DCSOIL – nonhazardous contaminated soil	1	Minor
DCNWTRS – nonhazardous contaminated groundwater	1	Minor
DCONTAC – nonhazardous contact cooling water	1 2	Major Minor
DDOMIND – nonhazardous domestic sewage & industrial waste	5	Major
DMISCEL – nonhazardous wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	4 29	Minor General
DNONCON – nonhazardous noncontact cooling water	3	Minor
DPROCES – nonhazardous process waste (produced as part of industrial/manufacturing process)	1 1	Major Minor
DSTORMS – nonhazardous stormwater runoff	1 7	Major Minor
DWSHWTR – nonhazardous washwater waste (photo reuse washwater, vegetable washwater)	1	Minor
HCNWTRS – hazardous contaminated groundwater	7 6	Minor General
HPROCES – hazardous process waste (produced as part of industrial/manufacturing process)	1	General
HSTORMS – hazardous stormwater runoff	1	Major
IMISCEL – inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage)	2	General

(California Regional Water Quality Control Board – Los Angeles Region files)

Hazardous – influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards

Designated – influent or solid wastes that contain nonhazardous wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations

Inert – influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

In addition. approximately 70 oil wells are located in the Whittier Narrows below elevation 230 feet. The wells pre-date the construction of the dam and are part of the Montebello Oil Field discovered in 1918 (U.S. Army Corps of Engineers LA District, 1998).

R0026439

Overview of Existing Monitoring Data

Receiving Water Monitoring Data

What follows is an overview of the available receiving water monitoring data from 1988 to present; some figures are included in this document (electronically also as Figures.xls). All of the data and the rest of the figures are available electronically from the Regional Board as Excel 97 files (with the exception of one report) rather than as hardcopy due to the very large amount of information the files contain. As an informational note, the CRWQCB-LA Region ambient monitoring database contains sampling results from multiple agencies including the CRWQCB, US Forest Service, Department of Water Resources, and the Los Angeles County Department of Public Works. Due to its large volume of data, information in the ambient monitoring database has been separated into files based on broad categories of constituents. In some cases, data from the CSDLAC submittal were added into the constituent files in order to create one file with all chlorides data, for instance.

This overview of the data is not meant to represent an official Water Quality Assessment. Due to time constraints, no statistical analyses were performed. Rather, it is a qualitative review of available information on water quality. At some locations, only older data are available, while at other locations only more recent data exist. The intent of this overview is to generally describe patterns in various constituents which have been sampled in the watershed, to highlight where future data gathering may be most fruitful or needed, and to suggest where a more thorough data analysis could yield decisions for Water Quality Assessment purposes.

•**CRWQCB, LA Region ambient monitoring database:** SGRiverMetals_ambientonly.xls, SGRiverColiform_ambientonly.xls, SGRiverChloride_alldata.xls, SGRiverNutrients_alldata.xls
•**County Sanitation Districts of Los Angeles County electronic submittal of receiving water monitoring data previously submitted in report format:** SGRiver LACSD RW Data 1995-1999.xls
•**Los Angeles County electronic submittal of municipal stormwater monitoring data:** MunStormwaterSGRiver1997-98.xls **and** MunStormwaterSGRiver1998-99.xls

Monitoring frequency: Parts of the watershed have been monitored much more regularly and frequently than others **(see maps in Figures 1-6)**. The headwaters (based on the data available in the Regional Board ambient database) were monitored fairly intensively in the early 1990s but very infrequently since then. A large monitoring effort was conducted from 1988-1994 by the LA County Department of Public Works at a large number of sites; monitoring under the current municipal stormwater permit is much less intense and at fewer sites. For the most part, sampling is concentrated in the mainstem of the river and in tributaries near confluences (as well as in the vicinity of major point sources for which data from 1995-1999 were examined). As a consequence, much of the tributaries Walnut Creek, San Jose Creek, and Coyote Creek have not been monitored yet these, through the data available at the confluences, appear to be major contributors of pollutants to the mainstem of the river. Also of note are the large storm drains connecting to the mainstem below the spreading grounds which may be worthy of individual monitoring due to patterns seen in the data, particularly for coliform.

When one considers the unusual nature of this watershed, however, a fairly unusual monitoring program may be warranted. Waters from the upper part of the watershed often do not get past the Santa Fe Dam and its spreading grounds. Waters entering the mainstem from San Jose and Walnut Creeks may be diverted through Whittier Narrows area to the Los Angeles River. Those waters remaining in the San Gabriel River will often recharge at the downstream spreading grounds. From the beginning of the concrete portion on downstream is a continuously flowing river through discharges from POTWs as well as through urban runoff. It is joined by Coyote Creek just before meeting the unlined tidal prism.

General observations: The original datasets were in some cases reduced or streamlined to eliminate very infrequent sampling episodes or those not collected on the same date. At times, earlier and later datasets are compared; this is pointed out where it occurs.

- Nutrient and related data: Nitrate-N, nitrite-N, ammonia-N, total phosphate, and pH data are generally available for most of the sites monitored. Nitrate (as NO_3), BOD_5, chemical oxygen demand (COD),

R0026440

total organic carbon (TOC), and dissolved oxygen data are also sporadically available. For example, the County Sanitation Districts of Los Angeles County (CSDLAC) monitors BOD_5 and COD but not TOC. Other agencies have occasionally monitored for BOD_5 and TOC but never COD. This is unfortunate since the latter parameter has shown the most interesting patterns which will be discussed further below.

Certain parameters can appropriately be generalized into average values (nitrate-N, COD, and total phosphate are examples) since temporal fluctuations are not great in this dataset. Dissolved oxygen levels however fluctuate greatly and must be viewed on a finer scale.

Not surprisingly, nutrient concentrations tend to be quite low in the upper watershed (in the West, North, and East Forks). The average concentration of total phosphate in the North Fork, however, is a little higher than might be expected. pH averages slightly over 8.0 mg/l.

The next site where an array of parameters is collected is just above the confluence with San Jose Creek, many miles downstream. Here, nutrient concentrations are marginally higher than in the upper watershed. pH averages slightly under 8.0 mg/l.

A POTW discharges to San Jose Creek just upstream of its confluence with the main river. Ammonia and nitrate-N are already higher upstream of the POTW than in the upper watershed. Average ammonia, nitrate-N, and total phosphate levels increase noticeably below the POTW while pH averages just under 7.5 mg/l.

Sampling data for the mainstem below the confluence with San Jose Creek is again somewhat sparse until the San Gabriel Spreading Grounds, below the Whittier Narrows Dam. These data were collected from 1988-1994 and include mostly nitrite-N, pH, total phosphate, and TOC but comparisons to sites elsewhere in the watershed are difficult due to the availability of only this older dataset.

The next two sites with a large amount of data are each located downstream of a POTW within the concrete-lined portion of the main river. Nutrient concentrations have increased considerably by the lowermost of the two sites. COD also increases as one progresses downstream.

The next two sampling sites further downstream are much closer to the tidal prism and indeed the lowermost one is influenced at times by tidal overwash onto the concrete. Nutrient levels, particularly total phosphate, are considerably higher here than in the area above the concrete portion of the river. COD levels continue to rise. However, while BOD5 levels were rather high in the older dataset associated with the more upstream site, levels were considerably lower in the more recent data at the downstream site.

As previously mentioned, most of the monitoring in Coyote Creek is concentrated around the major point source, a POTW. An older dataset exists for a site further upstream. The greatest difference in parameters occurs in ammonia-N and total phosphate concentrations which rise downstream of the POTW and are rather low upstream. Nitrate-N levels however are rather uniform both upstream and downstream of the POTW.

Coyote Creek enters the main river at the tidal prism. COD rises sharply within the tidal prism. By contrast, after initially high levels, ammonia-N, nitrate-N, nitrite-N, and total phosphate levels fall sharply.

As described earlier in this document, various reaches of the river are 303(d)-listed as impaired for ammonia, toxicity, algae, or pH.

- Bacteriological data: Medians were calculated in order to evaluate bacteriological data for general trends. Total coliform was collected at all sites with fecal coliform and enterococcus collected at some. Coliform levels fluctuated greatly at many locations.

  What limited data there were for the upper watershed showed consistently low levels of total and fecal coliform. The tributaries Coyote and San Jose Creeks exhibited high median levels of total and fecal coliform as well as enterococcus (higher than the mainstem). Of particular interest is an abrupt increase in median total coliform levels in the concrete portion of the main river. A number of large storm drains enter the river in this stretch.

Various reaches of the main river, San Jose Creek, and Coyote Creek are 303(d)-listed as impaired for coliform.

- Metals data: Metals were generally not detected in the upper watershed and only occasionally detected elsewhere in the watershed; they were found most often in the lowermost part of the watershed. Arsenic and zinc were the metals most frequently detected. It can likely be assumed that the majority of sampling took place on dry weather days; wet weather storm sampling is discussed below and exhibited very different results. Various reaches of the river, its tributaries, or lakes associated with reservoirs are currently 303(d)-listed as impaired for lead, copper, arsenic (in tissue), silver, and mercury (in tissue).

- Chlorides data: Chlorides are higher in Coyote Creek than in San Jose Creek; chloride levels in the mainstem above the tidal prism are slightly lower than those in San Jose Creek. It's also clear from the data that full strength seawater is not reached until well into the tidal prism.

- Organics data: Except for lindane, other organics were rarely detected.

Specific findings

- Nutrients and related data: Dissolved oxygen is the most variable parameter related to nutrient concentrations. At times, average concentrations may be acceptable but extreme fluctuations may be occurring from week to week or from month to month (and probably daily although samples are generally not obtained that often).

  A fairly large amount of dissolved oxygen data were obtained for parts of the upper watershed in the early 1990s. Concentrations averaged 9.8 mg/l with little fluctuation. Availability of oxygen to aquatic life is temperature-dependent; with the generally low temperatures of the upper watershed, much of the oxygen was likely available for use.

  Dissolved oxygen levels fluctuate greatly in the rest of the watershed with concentrations in San Jose Creek fluctuating the least and those in Coyote Creek fluctuating the most, especially in recent years **(Figure 7)**. The fluctuations are extreme at some sites. Although some reaches are 303(d)-listed for algae, no part of the river or its tributaries are currently listed for low DO/organic enrichment or eutrophication.

  Ammonia-N concentrations were also evaluated in more detail. **(Figures 8 and 9)** Ammonia-N concentrations also fluctuate greatly at times. The graphed locations (other than those in the tidal prism and San Jose Creek) are in concrete-lined portions of the river. San Jose Creek water would likely not reach the lower river; however, it is clear that considerable ammonia enters the more sensitive tidal prism stretch of river and persists for some distance. Often, nearly half of the total nitrogen in the river is in the form of ammonia. Much of the lower reaches of the river and its tributaries are on the 303(d) list for ammonia exceedances.

  Chemical oxygen demand is higher in Coyote Creek than in either San Jose Creek or the upper parts of the concrete-lined portion of the main river. **(Figure 10)** Levels increase gradually at the more downstream stations until the tidal prism is reached where levels increase dramatically and continue to rise all the way to the mouth of the river. Also, COD levels have greatly increased over the past two years. This pattern is not consistent with that for BOD and indeed for many other parameters which tend to decrease partway into the tidal prism. COD in the effluent of tertiary treatment plants is generally less than 20 mg/l. There may be sources of industrial waste entering the lower watershed which are currently unknown and are apparently not associated with stormwater runoff since levels are high virtually year-round. Also of interest is an apparent decrease in overall BOD levels in the watershed when comparing the older dataset (1988-1994) with the later dataset (1995-1999) although the two datasets do not overlap sampling sites exactly (see later discussion on BOD levels in stormwater).

- Bacteriological data: Although highly variable, total coliform levels in San Jose and Coyote Creeks have rarely dropped below 1,000 mpn/100ml during the last five years. They are both currently on the 303(d) list for coliform exceedances. The lower reaches of the main river are also 303(d)-listed for coliform; however, there are some differences in total coliform concentrations among the current sampling sites (CSDLAC data). **(Figures 11 and 12)** Coliform levels below the SJCWRP discharge point (in the main river) are much lower than further downstream which may indicate a nearby source, possibly through a storm drain. Levels below the SJCWRP appear to fluctuate more with the seasons (and, presumably, with storm runoff) while levels further downstream are more consistently high. The beginning section of the tidal prism contains very high levels of coliform and rarely drops below 1,000 mpn/100ml. The estuary is not currently 303(d)-listed for coliform.

- Metals data: Coyote Creek is currently 303(d)-listed for silver bioaccumulated in tissue. Recent (non-stormwater) data are largely nondetect for metals. The estuary is also listed for arsenic in fish tissue through the state's Toxic Substances Monitoring Program. It is unclear from where arsenic may be originating since it is generally found in the water column at low levels. More intense monitoring (with appropriately low detection limits) would be useful to update the status of metals impairments.

- Chlorides data: It appears from **Figure 13** that the POTW discharge in Coyote Creek is ameliorating high chloride levels coming from further upstream.

LA County Department of Public Works, electronic copies of stormwater monitoring data for Storm Years 1997-98 and 1998-99 – specific findings

Sampling sites are located in Coyote Creek north of Willow Street (not a required site) and in the San Gabriel River south of the Whittier Narrows Dam.

- 1997-98 storm season

  Bacteriological data: Not surprisingly, very high total and fecal coliform as well as fecal streptococcus levels were found in the San Gabriel River during storm events (coliform samples were not collected in Coyote Creek).

  Nutrients (and related) data: In general, a "first flush" effect was seen where nutrient concentrations were higher following the first storm and gradually lower throughout the season. Nutrient concentrations were not outside the range found during dry weather although varied considerably from storm to storm. BOD and COD levels, however, were noticeably elevated over that found during dry weather and were higher in Coyote Creek than in the San Gabriel River.

  Chlorides data: It is clear from the chloride data that Coyote Creek in particular receives a considerable amount of storm runoff (relative to baseline flow) due to the greatly lowered chloride concentrations during some storms.

  Metals data: Metals data were compared with estimated water quality objectives for metals (hardness-adjusted). Potential metals exceedances occurred on 88% of the monitored days (at both an acute and chronic level) at the Coyote Creek site. Potential chronic objective exceedances occurred at the San Gabriel River site on 66% of the monitored days while potential acute exceedances occurred on 33% of the monitored days.

  Copper and zinc were the most common problem metals in Coyote Creek. Cadmium and lead were also occasionally at high levels. Many other metals were not detected. The creek is 303(d)-listed for silver only (in tissue) which did not occur at excessive levels in the water column sampling.

Potential exceedances at the San Gabriel River site involved copper, lead, and zinc to a fairly equal extent. The river (one reach) is 303(d)-listed for lead but not copper or zinc.

Semivolatiles and pesticides: These were detected very infrequently.

- 1998-99 storm season

During this storm season, some sampling occurred on non-storm days.

Bacteriological data: The Coyote Creek site was not monitored for coliform. At the San Gabriel River site, one sampling event occurred on a non-storm flow day. Coliform levels were much lower on that date than on early storm-year sampling dates (although still high relative to body contact standards). Later in the storm-year, coliform levels during storm days were much lower (compared to the beginning of the storm-year) and comparable to the one dry weather sample taken. Except for during the first two sample events, fecal coliform and fecal streptococcus were not exceptionally high; total coliform was always high.

Nutrients (and related) data: For Coyote Creek, this year also there appears to have been a "first flush" effect for some constituents (notably nitrate-N and ammonia-N). This effect appeared to occur during what were likely the first significant storm of the season in December. Levels were much higher than in the early season dry-weather sampling event for virtually all constituents except BOD which appeared to fluctuate independent of storm flows. Nutrient levels remained quite high in the second dry sampling event in January. Nutrient levels dropped somewhat throughout the rest of the storm season.

A "first flush" effect was harder to discern in the San Gabriel River data. It's possible that enough nutrients are carried during regular flows to mask storm effects.

Chlorides data: Chlorides levels dropped considerably during storms in Coyote Creek and more so than in the San Gabriel River.

Metals data: There were far fewer monitoring days with potential exceedances during this storm season than during the previous storm season. Twelve percent of the sampling days at the Coyote Creek site resulted in potential chronic effect level exceedances (copper, zinc, and selenium) while there was only one sampling day where potential acute level exceedances occurred (copper and zinc). Eight percent of the sampling days at the San Gabriel River site resulted in potential chronic level exceedances with no potential acute level exceedances.

Semivolatiles and pesticides: These were detected very infrequently.

Toxicity Study of the Santa Clara River, San Gabriel River, and Calleguas Creek, December 1996

Copies of this report may be obtained from the Regional Board. An electronic version is not available.

Much of the sampling took place in the early 1990s. Persistent toxicity problems were noted in Walnut Creek as well as in Coyote Creek and the San Gabriel River near their confluence; persistent toxicity was also seen in the tidal prism. Attempts were made to determine the causes of toxicity; an organophosphate (such as diazinon) and/or a metals (such as zinc) were implicated at times. A number of fish collected at several sites in the lower watershed exhibited abnormal histopathology associated with pollutants such as metals or certain organics. Coyote Creek and parts of the San Gabriel River are 303(d)-listed for abnormal fish histology. The San Gabriel River Estuary is not currently 303(d)-listed for toxicity.

Effluent Monitoring Data

The majority of this information is only available by visiting the Regional Board office by appointment for file review.

CRWQCB, LA Region NPDES (effluent) program monitoring and compliance inspection files

The POTWs in the watershed are generally meeting permit limitations and, except for ammonia-N (and nitrogen effects in general), do not appear to be greatly contributing to current 303(d)-listed exceedances.

Effluent monitoring data from a subsample of other types of discharges (minors) were also evaluated. A number of discharges are of treated groundwater from cleanup of volatile organic compounds. pH readings have been quite high (or at times low) at some sites. Nitrate levels were also elevated in some of these discharges although this parameter was not monitored regularly. A number of sites discharge stormwater runoff under individual NPDES permits. For the most part these permits do not contain limits for metals; they instead focus on parameters such as oil & grease, suspended solids, and pH. There is usually an annual metals scan required and some metals are fairly elevated at times. There are a few sites discharging condensate water with extra monitoring in one case revealing rather high levels of ammonia, COD, and oil & grease.

CRWQCB-LA Region. 1996-1997 Annual Report for Storm Water Industrial Activities General Permit – Analysis of the Sampling Results. August 1988. Final Draft.

The data analyzed in this report were submitted under a statewide General Industrial Activities Storm Water Permit which was initially issued in 1991 and reissued in 1997. The permit requires each regulated facility to prepare and implement a Storm Water Pollution Prevention Plan, develop and implement a monitoring program, and submit an annual self-monitoring report. There are approximately 500 facilities covered by the industrial storm water permit in the San Gabriel River Watershed. The report also addressed some data from 1992-1993. A large number of data exist for the period from 1993 to 1996 but the resources needed to make the data available electronically do not.

Results for the Los Angeles and San Gabriel Rivers Watersheds were combined in this report but it will be assumed that the combined data may be loosely representative of one or the other watershed. It was reported that out of the approximately 2,000 facilities reporting pH results, 13% were outside of the 6.0 – 9.0 mg/l benchmark level in 1996-1997; 24% were above the 100 mg/l benchmark level for total suspended solids; 25% were above the 200 μmhos/cm benchmark level for specific conductance; 14% were above 15 mg/l benchmark level for oil & grease; and 6% were above the 110 mg/l benchmark level for total organic carbon. Some of the samples exceeding the benchmark were orders of magnitude higher. The results in 1992-1993 were similar.

Recommendations for Future Monitoring

- Investigate potential contributions from storm drains of coliform and COD in lower San Gabriel River
- Investigate sources of high coliform in Coyote Creek
- In general, evaluate water quality in Walnut Creek, San Jose Creek, and Coyote Creek more intensively including using toxicity tests and Toxicity Identification Evaluations
- Investigate the need to continue 303(d)-listings for arsenic and silver
- Evaluate need to newly 303(d)-list reaches for copper and/or zinc
- Determine impairment status of lead in watershed
- Evaluate need to 303(d)-list estuary for low dissolved oxygen and ammonia
- Include nitrate monitoring for discharges of treated groundwater; in general, include COD monitoring for larger discharges

Potential Long-term Activities

The Regional Board considers these as issues of concern in the watershed for the agency over the long-term (California Regional Water Quality Control Board – Los Angeles Region, January 2000)

- Development of a coordinated watershed monitoring program
- Hydrologic study of the estuary to evaluate mixing dynamics and effects on water quality and beneficial uses
- Identification of seasonal variations in water quality
- Evaluation of fish tissue from fish in the lower river and estuary
- Determination of the fate of ammonia in the estuary
- Evaluation of habitats in the middle/lower river
- Evaluation of impacts from reservoir cleaning on water quality, particularly fisheries-related
- Evaluation of mining on instream beneficial uses
- Evaluation of success of trash TMDL efforts in upper river
- Evaluation of impacts from industrial stormwater in the watershed
- Identification of sources of contributing flows to reaches and tributaries
- Identification of dry segments in reaches and tributaries
- Consideration of TMDL-related issues
- Implementation of biological monitoring

[1]This conversion is true for concentration values <8,000 mg/L. The equivalent value in mg/L for concentrations ≥8,000 ppm can be calculated from table 1, American Society of Testing Material (2000), or by using the following equation:

$$C_{mg/L} = C_{ppm}/(1 - C_{ppm}(6.22 \times 10^{-7})$$

where:
$C_{mg/L}$ = sediment concentration, mg/L, and
C_{ppm} = sediment concentration, ppm

Comparability of Suspended-Sediment Concentration and Total Suspended Solids Data

By John R. Gray, G. Douglas Glysson, Lisa M. Turcios, and Gregory E. Schwarz

ABSTRACT

Two laboratory analytical methods — suspended-sediment concentration (SSC) and total suspended solids (TSS) — are predominantly used to quantify concentrations of suspended solid-phase material in surface waters of the United States. The analytical methods differ. SSC data are produced by measuring the dry weight of all the sediment from a known volume of a water-sediment mixture. TSS data are produced by several methods, most of which entail measuring the dry weight of sediment from a known volume of a subsample of the original. An evaluation of 3,235 paired SSC and TSS data, of which 860 SSC values include percentages of sand-size material, shows bias in the relation between SSC and TSS —SSC values tend to increase at a greater rate than their corresponding paired TSS values. As sand-size material in samples exceeds about a quarter of the sediment dry weight, SSC values tend to exceed their corresponding paired TSS values. TSS analyses of three sets of quality-control samples (35 samples) showed unexpectedly small sediment recoveries and relatively large variances in the TSS data. Two quality-control data sets (18 samples) that were analyzed for SSC showed both slightly deficient sediment recoveries, and variances that are characteristic of most other quality-control data compiled as part of the U.S. Geological Survey's National Sediment Laboratory Quality Assurance Program. The method for determining TSS, which was originally designed for analyses of wastewater samples, is shown to be fundamentally unreliable for the analysis of natural-water samples. In contrast, the method for determining SSC produces relatively reliable results for samples of natural water, regardless of the amount or percentage of sand-size material in the samples. SSC and TSS data collected from natural water are not comparable and should not be used interchangeably. The accuracy and comparability of suspended solid-phase concentrations of the Nation's natural waters would be greatly enhanced if all these data were produced by the SSC analytical method.

INTRODUCTION

The importance of fluvial sediment to the quality of aquatic and riparian systems is well established. The U.S. Environmental Protection Agency (1998) identifies sediment as the single most widespread cause of impairment of the Nation's rivers and streams, lakes, reservoirs, ponds, and estuaries.

Reliable, quality-assured sediment and ancillary data are the underpinnings for assessment and remediation of sediment-impaired waters. The U.S. Geological Survey (USGS) has protocols for the collection of sediment data (Edwards and Glysson, 1999) and for laboratory analysis of suspended-sediment samples (Guy, 1969; Matthes and others, 1991; Knott and others, 1992 and 1993; U.S. Geological Survey, 1998 and 1999a). Most of the laboratory analytical methods were adapted or developed by the Federal Interagency Sedimentation Project (1941), approved by the Technical Committee (Glysson and Gray, 1997), and used by most Federal agencies that analyze fluvial-sediment data.

Data collected, processed, and analyzed using consistent protocols are comparable in time and space. Conversely, data obtained using different protocols may not be comparable. The focus of this study is the comparability of suspended-sediment concentration (SSC) and total suspended solids (TSS) data. The terms SSC and TSS are often used interchangeably in the literature to describe the concentration of solid-phase material suspended in a water-sediment mixture, usually expressed in milligrams per liter (mg/L) (Gregory Granato, U.S. Geological Survey, oral commun., 1999; James, 1999). However, given that all other factors are held constant (such as particle density and shape), the analytical procedures for SSC and TSS differ and may produce considerably different results, particularly when sand-size material composes a substantial percentage of the sediment in the sample.

This report compares the SSC and TSS analytical methods and derivative data, and demonstrates which of the data types is the more accurate and reliable. The evaluation is based on historical SSC and TSS data collected and analyzed by the USGS and selected cooperators.

The authors appreciate the assistance of: Stephen S. Anthony, Donna L. Belval, James G. Brown, Ronald D. Evaldi, Herbert S. Garn, John D. Gordon, Stephen D. Preston, Daniel J. Sullivan, Richard J. Wagner and Henry Zajd, Jr. for providing the data used in this report. The formal reviews of Herbert S. Garn, Mary Ellen Ley, and Henry Zajd, Jr., were most appreciated, as were informal reviews by Anne Hoos and Harvey Jobson. Kenneth Pearsall's insights and research significantly enhanced the report. Patricia Greene's and Roger K. Chang's support for developing the tables and figures was invaluable.

FIELD TECHNIQUES AND LABORATORY METHODS

The paired SSC and TSS results used in this evaluation were derived from analyses of natural-water samples collected by the USGS and selected cooperators (table 1). Analyses of all SSC data from natural water were made by USGS sediment laboratories, and analyses of the TSS data were made by USGS and cooperating laboratories. Additionally, 53 quality-control samples were prepared by the USGS and analyzed by a laboratory that provides data to the USGS.

Field Techniques

The large majority of water samples were collected using either the equal-width-increment or the equal-discharge-increment method to obtain a composite sample that is representative of the discharge-weighted SSC (Edwards and Glysson, 1999). Some samples, including those obtained by at least one cooperating agency, were collected by dipping an open bottle to obtain samples for subsequent TSS analysis. Some of the paired SSC and TSS samples were collected in-stream sequentially and submitted to laboratories for analysis as whole samples. The remaining samples were split into subsamples by using a churn splitter or cone splitter (Ward and Haar, 1990; Capel and Larson, 1996; Capel and others, 1995).

Tests performed by the USGS demonstrate that the churn splitter and cone splitter can provide unbiased and acceptably precise (generally within 10 percent of the known value) SSC values as large as about 1,000 mg/L when the mean diameter of sediment particles is less than about 0.25 mm. At SSC values of 10,000 mg/L or more, the bias and precision of SSC values in churn splitter subsamples are considered unacceptable (U.S. Geological Survey, 1997; Wilde and others, 1999).

Cone splitters produce subsamples with SSC values that are adequately representative of the original sample at 10,000 mg/L, but not at 100,000 mg/L. The accuracy of the cone splitter for SSC values between 10,000 mg/L and 100,000 mg/L is unknown and is considered unacceptable at concentrations larger than 100,000 mg/L (U.S. Geological Survey, 1997; Wilde and others, 1999).

Subsampling will typically increase the variance and (or) create bias in the concentration and size distribution of solid-phase material in a subsample. Significant differences in the amount of solid-phase material in some paired samples may have occurred as a result of non-representative splitting of the original samples, or by collecting consecutive in-stream samples under conditions of rapidly varying SSC. Similarly, because the data were obtained by field personnel in eight States as part of unrelated studies, significant differences may have resulted because of differences in data-collection techniques. However, the probability of significant bias resulting from consistently selecting samples with larger concentrations of sediment for analyses by one of the methods would be small based on the large number of paired data used in the analysis. There is no evidence indicating that methods used for collecting, processing, or selecting subsamples for subsequent analysis introduced bias in the relations between SSC and TSS identified in this evaluation.

Laboratory Methods

Two standard methods are widely cited in the United States for determining the total amount of suspended material in a water sample. These are:

1. Method D 3977-97, "Standard Test Method for Determining Sediment Concentration in Water Samples" of the American Society for Testing and Materials (American Society for Testing and Materials, 2000), and
2. Method 2540 D, "Total Suspended Solids Dried at 103°–105° C" (American Public Health Association, American Water Works Association, and Water Pollution Control Federation, 1995).

The differences in these analytical methods, and some variations used to produce TSS data are described below.

Suspended-Sediment Concentration Analytical Method. ASTM Standard Test Method D 3977-97 lists three methods that result in a determination of SSC values in water and wastewater samples:

1. Test Method A – Evaporation: The evaporation method may only be used on sediment that settles within the allotted storage time, which can range from a few days to several months. If the dissolved-solids concentration exceeds about 10 percent of the SSC value, an appropriate correction factor must be applied to the SSC value. The precision and bias of Method A are shown as follows:

[mg/L, milligrams per liter]

Concentration Added, (mg/L)	Concentration Recovered, (mg/L)	Standard Deviation of Test Method (mg/L)	Standard Deviation of Single Operator (mg/L)	Bias, percent
10	9.4	2.5	2.3	-6
1,000	976	36.8	15.9	-2.4
100,000	100,294	532	360	0.3

2. Test Method B- Filtration: The filtration method is used only on samples with concentrations of sand-size material (diameters greater than 0.062 mm) less than about 10,000 mg/L and concentrations of clay-size material of about 200 mg/L. No dissolved-solids correction is needed. The precision and bias of Method B are shown as follows:

[mg/L, milligrams per liter]

Concentration Added, (mg/L)	Concentration Recovered, (mg/L)	Standard Deviation of Test Method (mg/L)	Standard Deviation of Single Operator (mg/L)	Bias, percent
10	8	2.6	2	-20
100	91	5.3	5.1	-9
1,000	961	20.4	14.1	-3.9

3. Test Method C - Wet-sieving filtration: The wet-sieve-filtration method also yields a SSC value, but the method is not as direct as Methods A and B. Method C is used if the percentage of material larger than sand-size particles is desired. The method yields a concentration for the total sample, a concentration of the sand-size particles, and a concentration for the silt- and clay-size particles. A dissolved-solids correction may be needed, depending on the type of analysis done on the fine fraction of the samples and the dissolved-solids concentration of the sample. The precision and bias of Method C are shown as follows:

[mm, millimeters; mg/L, milligrams per liter]

Mixture Number	Sieve Diameter (mm)	Concentration Added (mg/L)	Concentration Recovered (mg/L)	Standard Deviation of Test Method (mg/L)	Standard Deviation of Single Operator (mg/L)	Bias, percent
1	>0.062	1	3.4	2.8	2.4	240
1	<0.062	10	8.7	4.3	2.9	-13
2	>0.062	9	5	5.9	1.9	-44
2	<0.062	91	79	15.2	11	-13
3	>0.062	91	107	12.3	5.9	18
3	<0.062	909	832	87.2	61	-8

These three methods are virtually the same as those used by USGS sediment laboratories and described by Guy (1969). Only the Whatman grade 934AH, 24-mm-diameter filter is used for purposes of standardization. Each method includes retaining, drying at 103°C ±2°C, and weighing all of the sediment in a known mass of a water-sediment mixture (U.S. Geological Survey, 1999a).

Total Suspended Solids Analytical Method. According to the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1995), the TSS analytical method uses a predetermined volume from the original water sample obtained while the sample is being mixed with a magnetic stirrer. An aliquot of the sample — usually 0.1 L, but a smaller volume if more than 200 mg of residue may collect on the filter — is withdrawn by pipette. The aliquot is passed through a filter, the diameter of which usually ranges from 22 to 125 mm. The filter may be a Whatman grade 934AH, Gelman type A/E, Millipore type AP40; E-D Scientific Specialties grade 161, or another product that gives demonstrably equivalent results. After filtering, the filter and contents are removed and dried at 103° to 105° C, and weighed. No dissolved-solids correction is required. The percentages of sand-size and finer material cannot be determined using the TSS method.

The American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1995) describe the precision for this method as follows: "The standard deviation was 5.2 mg/L (coefficient of variation 33 percent) at 15 mg/L, 24 mg/L (10 percent) at 242 mg/L, and 13 mg/L (0.76 percent) at 1,707 mg/L in studies by two analysts of four sets of 10 determinations each. Single-laboratory analyses of 50 samples of water and wastewater were made with a standard deviation of differences of

2.8 mg/L." The standard provides no indication of the size of particles used in the testing for the method.

In practice, TSS data are produced by a number of variations to the processing methods described in the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1995). For example

- For the collection of TSS samples as part of the Chesapeake Bay Program, field staff pump water from a specified depth into a plastic gallon container. The container is vigorously shaken, and 0.2 – 1.0 L of the water-sediment mixture is poured for field filtering and subsequent analysis. (Mary Ley, Interstate Commission on the Potomac River Basin, the State of Maryland and the Commonwealth of Virginia, written commun., 2000).
- One State government laboratory produces TSS data by vigorously shaking the sample and pouring it into a crucible for subsequent analysis. All of the sample is poured into the crucible unless "there is a lot of suspended material," in which case only part of the sample is poured (Lori Sprague, U.S. Geological Survey, written commun., 1999).
- Another laboratory analyzed quality-control samples by using Method 2540D of the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1995), with the following variation: The sample is shaken vigorously and a third of the desired subsample volume is decanted to a secondary vessel. This process is repeated twice to obtain a single subsample for subsequent filtration, drying and weighing.

The reduction in TSS data comparability is not limited to lack of consistency in processing and analytical methods. According to James (1999), there is generally no agreed upon definition of TSS in regard to storm-water runoff, in part because the settleable part of TSS is not reported in most storm-water studies.

The problem extends to nomenclature. The terms "SSC" and "TSS", or variations thereof, are sometimes attributed to an incorrect data type. For example, a proposed Total Maximum Daily Load for sediment in Stekoa Creek, Georgia (U.S. Environmental Protection Agency, Region 4, written commun., 2000) is based on regional TSS data, which are compiled from U.S. Geological Survey records; the TSS data referred to are actually SSC data. Buchanan and Schoellhamer (1998) refer to "suspended-solids concentration data" for San Francisco Bay. Those data would more appropriately be referred to as SSC, because the total water-sediment mass and all sediment were measured in the analysis (Alan Mlodnosky, USGS, oral commun., 1999).

Part of the problem may be attributable to the origin of the TSS method and subsequent changes in the types of water for which it is recommended for use. Information available from the American Public Health Association and American Water Works Association (1946) makes it clear that the Suspended Solids Method was intended for use for wastewater effluents (Kenneth Pearsall, U.S. Geological Survey, written commun., 2000). This is more or less consistent with the Total Suspended Matter Method, which was "intended for use with wastewaters, effluents, and polluted waters," as listed in the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1971). A fundamental change took place in 1976, when the Total Suspended Matter Method was deemed suitable for "residue in potable, surface, and saline waters, as well as domestic and industrial wastewaters in the range up to 20,000 mg/L" by the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1976). The Suspended Solids and Total Suspended Matter Methods described above are predecessors of the "Total Suspended Solids Dried at 103°-105°C" Method, which first appeared in 1985 by that title in the American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1985).

In summary, the evidence indicates that the TSS method was originally designed for wastewater analyses, presumably on samples collected after a settling step at a wastewater treatment facility (hence the term "suspended" in TSS). The American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1976) expanded the TSS Method's applicability in 1976 to include natural water.

Differences Between the SSC and TSS Analytical Methods. The fundamental difference between the SSC and TSS analytical methods stems from preparation of the sample for subsequent filtering, drying, and weighing. A TSS analysis normally entails withdrawal of an aliquot of the original sample for subsequent analysis, although as previously noted, there is evidence of inconsistencies in methods used in the sample preparation phase of the TSS analyses. The SSC analytical method measures all sediment and the mass of the entire water-sediment mixture. Additionally, the percentage of sand-size and finer material can be determined as part of the SSC method, but not as part of the TSS method.

If a sample contains a substantial percentage of sand-size material, then stirring, shaking, or otherwise agitating the sample before obtaining a subsample will rarely produce an aliquot representative of the SSC and particle-size distribution of the original sample. This is a by-product of the rapid settling properties of sand-size material, compared to those for silt- and clay-size material, given virtually uniform densities and shapes as described by Stokes' Law. Aliquots obtained by pipette might be withdrawn from the lower part of the sample where the sand concentration tends to be enriched immediately after agitation, or from a higher part of the sample where the sand concentration is rapidly depleted.

The physical characteristics of a pipette used to withdraw an aliquot, or subsample, can introduce additional errors in subsequent analytical results. The American Public Health Association, American Water Works Association, and Water Pollution Control Federation (1995) specifies use of "wide-bore pipettes" to withdraw aliquots. The tip opening of those recommended for use is about 3 mm in diameter (Kimble-Contes Inc., accessed May 1, 2000). By definition, the upper limit of sand-size material, which is expressed as the median diameter, is 2 mm (Folk, 1980). A natural sediment particle's long axis is almost always larger than its median axis and can be substantially larger. Hence, a single coarse-grained sand particle or multiple sand-size particles, particularly when present in large concentrations, may clog a 3-mm tip pipette under suction.

If the aforementioned lack of consistency in the TSS analytical procedure extends to variability in diameters of pipette tips used to withdraw TSS aliquots, the size of particles being excluded from the subsample could vary with the type of pipette used. Hence, use of a pipette may cause concentration bias when subsampling if sand-size material is present in the sample.

Based on Stokes' Law, subsamples obtained by pouring sand-rich water-sediment mixtures should be deficient in sand-size material. Because the fine material concentration will not normally be altered by the removal of an aliquot, the differences between the two methods will tend to be more pronounced as the percentage of sand-size material in the sample increases.

Samples collected sequentially in-stream may have different concentrations and size characteristics of solid-phase material. This may be due to natural variations in the amounts and composition of solid-phase material in transport, and to variance and (or) bias that is introduced by sampling procedures. Likewise, a subsample may contain an amount and size distribution of sediment atypical to that of the original. However, any differences in SSC and size-distribution data from paired samples resulting from in-stream variations or sampling procedures would likely occur randomly among the 3,235 paired analyses used in this evaluation.

DESCRIPTION OF DATA USED IN THE EVALUATION

Results of analyses of natural-water samples and of quality-control samples prepared by the USGS were used for this evaluation. Natural-water samples for determination of SSC (parameter code 80154) were collected and analyzed by the USGS (table 1). Natural-water samples for determination of TSS, (parameter code 00530) were collected by the USGS and cooperating agencies, and analyzed by the USGS and cooperating laboratories. A total of 3,235 pairs of SSC and TSS data for natural water were obtained from the files of USGS District offices.

The paired SSC and TSS data were collected at 65 sampling sites in Arizona, Hawaii, Illinois, Kentucky, Maryland, Virginia, Washington, and Wisconsin. All but the 12 sampling sites in Kentucky were at USGS streamflow-gaging stations. The percentage of sand-size material was available for 860, or about 27 percent, of the SSC samples. The SSC and TSS natural-water data used in this evaluation were augmented by analytical results of 53 quality-control samples prepared by the USGS National Sediment Laboratory Quality Assurance Program (Gordon and others, 2000, U.S. Geological Survey, 1998; 1999a; 1999b; 2000b).

Arizona. A total of 122 SSC and TSS sample pairs were collected at a USGS streamflow-gaging station on Pinal Creek at Inspiration Dam near Globe (station number 09498400) in central Arizona from 1982-98. The samples were collected about monthly or bimonthly using techniques described by Edwards and Glysson (1999). A churn splitter was used to obtain subsamples of the water-sediment mixture. The USGS sediment laboratory in Iowa City, Iowa, analyzed the subsamples for SSC and TSS (James G. Brown, U.S. Geological Survey, written commun., 1999).

Hawaii. According to Hill (1996), 13 SSC and TSS sample pairs were collected at three streamflow-gaging stations in the Kamooalii drainage basin, Oahu, Hawaii, from 1985-89, as a component of a large-scale highway-construction study. The SSC samples were collected by a US PS-69 automatic pumping sampler. The TSS samples were collected by a Manning automatic pumping sampler. A churn splitter was used to obtain subsamples for TSS analyses. The SSC samples were analyzed by the USGS sediment laboratory in Oahu. The TSS samples were analyzed by the USGS National Water Quality Laboratory in Denver, Colorado (Stephen S. Anthony, U.S. Geological Survey, written commun., 1999).

Illinois. A total of 223 SSC and TSS sample pairs were collected at 8 USGS streamflow-gaging stations in the upper Illinois River Basin from 1988-90 (Sullivan and Blanchard, 1994). Samples were collected according to techniques described by Edwards and Glysson (1999). A churn splitter was used to obtain subsamples for SSC and TSS analyses. SSC samples were analyzed at the USGS sediment laboratory in Iowa City, Iowa, using the evaporation method. TSS samples were analyzed by an Illinois State laboratory using the nonfilterable residue, gravimetric method (Daniel Sullivan, U.S. Geological Survey, written commun., 1999).

Kentucky. A total of 95 SSC and TSS sample pairs were collected at 12 sampling locations in the Ohio River Basin in May 1999. SSC and TSS samples were collected at each site for one day over several hours at about 1-hour intervals. Samples were collected using an open-bottle sampler because of the low stream velocities. No splitting devices were used to obtain subsamples. The USGS sediment laboratory in Louisville, Kentucky, analyzed the SSC samples. A contract laboratory performed the TSS analyses (Ronald Evaldi, U.S. Geological Survey, written commun., 1999).

Maryland. A total of 1,561 SSC and TSS sample pairs were collected at 6 streamflow-gaging stations in the Patuxent River Basin, Maryland, as part of the USGS Patuxent Nonpoint Source study during the years 1985-98 (Preston and Summers, 1997). The sampling frequency was monthly, with additional samples collected during periods of storm runoff. The monthly base-flow samples were collected using the equal-width-increment method (Edwards and Glysson, 1999), and the storm-runoff samples were collected using an automatic sampler. A churn splitter was used for both monthly and storm samples of both SSC and TSS. The SSC samples were analyzed at USGS sediment laboratories in Lemoyne, Pennsylvania, and Louisville, Kentucky. The TSS samples were analyzed using a pipette and filtration method by a Maryland State laboratory (Stephen D. Preston, U.S. Geological Survey, written commun., 1999).

Virginia. A total of 188 SSC and TSS sample pairs were collected at 7 streamflow-gaging stations in Virginia during the years 1975-95. Paired SSC and TSS samples were collected every other month by the USGS except during some low-flow periods as part of the River Input Monitoring Program (U.S. Geological Survey, 2000a). Techniques described by Edwards and Glysson (1999) were used to collect all samples. A churn splitter was used to obtain subsamples for TSS analyses. The USGS collected most of the samples, except during some low-flow periods when the Virginia Department of Environmental Quality collected the samples. SSC analyses were performed by USGS sediment laboratories. A Virginia State laboratory performed the TSS analyses (Donna L. Belval, U.S. Geological Survey, written commun., 1999).

Washington. A total of 817 SSC and TSS sample pairs were collected at 25 streamflow-gaging stations in Washington during the years 1973-98, as part of various projects. Techniques described by Edwards and Glysson (1999) were used to collect all SSC and TSS samples. A churn splitter was used to obtain subsamples for TSS analyses. The SSC and TSS samples were analyzed at a USGS sediment laboratory in Tacoma, Washington, through September 1982. Thereafter, samples were analyzed at the USGS Cascades Volcano Observatory Sediment Laboratory (Richard J. Wagner, U.S. Geological Survey, written commun., 1999).

Wisconsin. A total of 216 SSC and TSS sample pairs were collected at 3 streamflow-gaging stations on streams in the Lake Michigan watershed, Wisconsin, as part of an evaluation of the differences in results of water-quality monitoring caused by differences in sample-collection methods (Kammerer and others, 1998). Low-flow samples were collected in August and October 1993, and high-flow samples were collected in April-July 1994. The SSC samples were collected using techniques described by Edwards and Glysson (1999). The TSS samples were collected concurrently with the SSC samples by the Wisconsin Department of Natural Resources using an open bottle. Subsamples for SSC and TSS analyses were obtained using a cone splitter. SSC samples were analyzed by the USGS sediment laboratory in Iowa City, Iowa. TSS samples were analyzed by a Wisconsin State laboratory (Herbert S. Garn, U.S. Geological Survey, written commun., 1999).

Quality-Control Data. The SSC and TSS natural-water data used in this evaluation were augmented by analytical results of quality-control samples from a cooperating laboratory. Known amounts of water and sediment were used to constitute quality-control samples as part of the USGS National Sediment Laboratory Quality Assurance Program. The National Sediment Laboratory Quality Assurance Program is designed as an interlaboratory-comparison evaluation to provide a measure of bias and variance of suspended-sediment data analyzed by laboratories operated or used by the USGS. The quality-control samples received by the participating laboratories were identified as such.

The quality-control samples were submitted in five batches to a cooperating laboratory during 1997-99. Of the quality-control samples, the first 35 were shipped as batch numbers 1997-1, 1997-2, and 1998-1 and were analyzed for TSS. Eighteen quality-control samples were shipped as batch numbers 1998-2 and 1999-1 and analyzed for SSC using the evaporation method (Kenneth Pearsall, U.S. Geological Survey, 1999, oral commun.).

COMPARABILITY OF SUSPENDED-SEDIMENT CONCENTRATION AND TOTAL SUSPENDED SOLIDS DATA

Natural-Water Data

The relation between SSC and TSS data was evaluated by comparing all available paired SSC and TSS natural-water data, and subsets of those data for each State. The number of paired SSC and TSS values for selected SSC concentration ranges with and without particle-size data are shown in figure 1.

Of the 3,235 natural-water SSC samples used in this study,

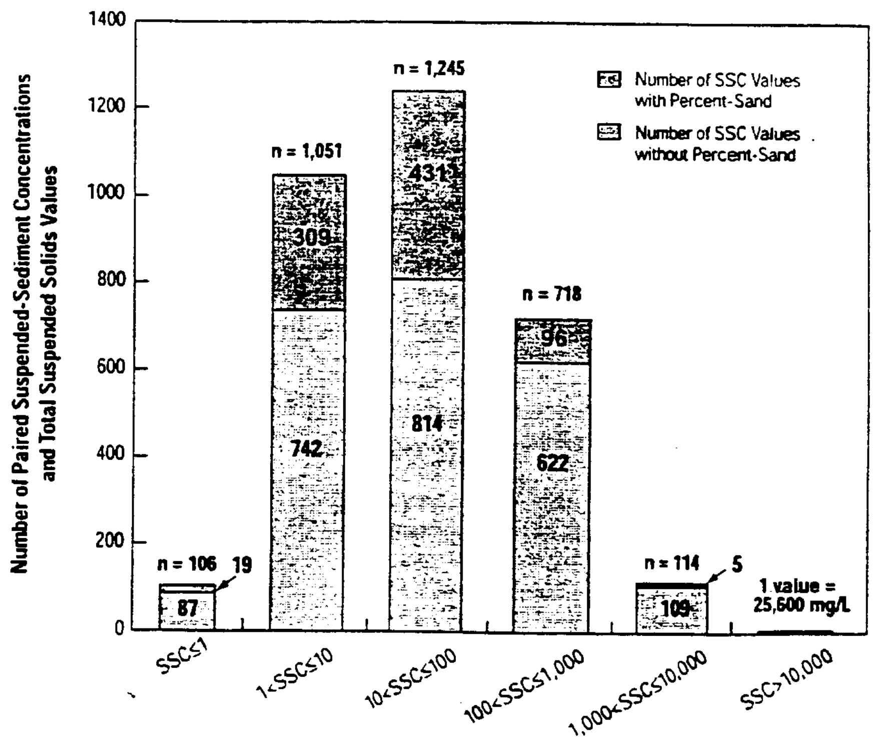

Figure 1. Number of paired suspended-sediment concentration (SSC) values and total suspended solids (TSS) values of the 3,235 data pairs for selected suspended-sediment concentration ranges, in milligrams per liter.

Table 2. Statistical characteristics of paired suspended-sediment concentration (SSC) and total suspended solids (TSS) data for each of eight States, and for the combined data from all States
[mg/L, milligrams per liter; >, greater than]

	SSC Values		SSC Minus TSS				
Source of SSC and TSS Paired Data	Number of values	3rd Quartile mg/L	Number of values >0 mg/L	Percentage of values >0 mg/L for all paired data	Number of values when SSC value is > 3rd Quartile value	Number of values >0 mg/L when SSC value is > 3rd Quartile value	Percentage of values >0 mg/L when SSC value is > 3rd Quartile value
Arizona	122	153.25	93	76%	31	30	97%
Hawaii	13	353.0	13	100%	3	3	100%
Illinois	223	48.5	111	50%	56	34	61%
Kentucky	95	10.2	28	29%	24	9	38%
Maryland	1,561	324.0	1,071	69%	390	328	84%
Virginia	188	16.0	105	56%	44	40	91%
Washington	817	30.0	518	63%	203	179	88%
Wisconsin	216	80.25	184	85%	54	54	100%
All Paired Data[1]	3,235	108.0	2,123	66%	809	672	83%

[1] Based on statistics using all 3,235 paired data; some values vary slightly from those calculated using summary statistics from the eight States.

74 percent had values less than or equal to 100 mg/L; only one value (25,600 mg/L) exceeded 10,000 mg/L (figure 1).

Statistical characteristics of SSC and TSS paired data for each State and for all paired data are given in table 2. Sixty-six percent of all TSS values are smaller than their corresponding paired SSC values. Eighty-three percent of all TSS values are smaller than their paired SSC value when SSC values exceed the 3rd quartile value. For each State except Kentucky (38 percent for 24 paired samples), 61 to 100 percent of the TSS values are smaller than their paired SSC value when SSC values exceed the 3rd quartile value. To summarize, SSC values tend to exceed their corresponding paired TSS values. This tendency becomes stronger at larger values of SSC.

Relations between all 3,235 paired TSS and SSC measurements are shown in figures 2 and 3. According to Glysson and others (2000), there is no simple, straightforward way to adjust TSS data to estimate SSC if paired samples are not available. Relations identified herein are not recommended for use in adjusting TSS data unless supported by additional research.

The data shown in figure 2 are plotted without transformation and include the two ordinary least squares regression lines obtained by regressing TSS on SSC (the lower line) and SSC on TSS (the upper line). Because of measurement errors associated with the collection processing, and analysis of the data, neither line can be interpreted as an unbiased estimate of the true relation

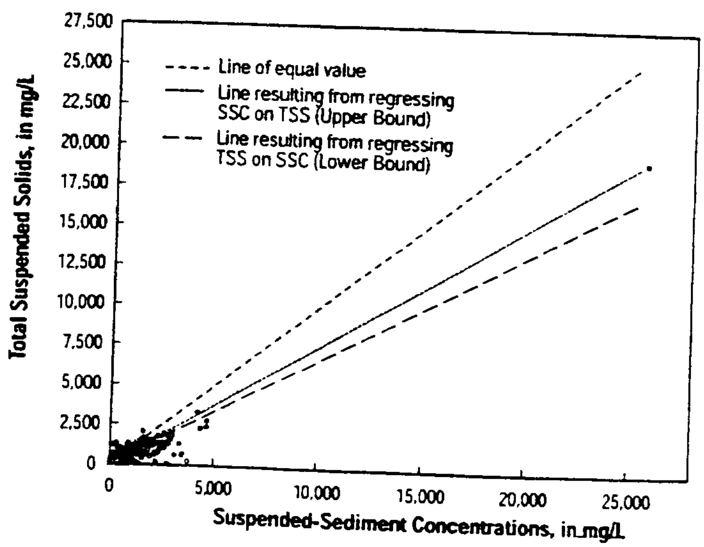

Figure 2. Relation between untransformed values of suspended-sediment concentration and total suspended solids for 3,235 data points.

between the two measurement methods. In fact, the existence of measurement error implies the system of equations describing the two measurements is insufficiently identified, making estimation of an unbiased relation impossible without additional information on the variance of the measurement error for at least one of the measurements (Klepper and Leamer, 1984). However, the two least squares regression lines can be used to bound the true slope and intercept coefficients (Frisch, 1934). In the case of TSS and SSC, the least squares intercepts are very small relative to the range of the data. Consequently, the two regression lines effectively form consistent upper and lower bounds on the true relation between TSS and SSC. These bounds imply that TSS is biased downward relative to SSC by a proportionate amount of 25 to 34 percent. Given the large skew apparent in the data, this finding is tentative and requires confirmation using a statistical or functional transformation yielding homoscedastic residuals.

The relation between SSC and TSS for all 3,235 pairs of transformed data using the base-10 logarithm and the line of equal value are shown in figure 3; the relations for each State and lines of equal value are shown in figure 4. Trends in the scattergrams plotted for all data compared to those with data that were segregated by State show some similarities, including a tendency for the data to plot to the right of the line of equal value, particularly at larger values of SSC.

As described previously, at least two factors associated with the TSS analysis can result in subsamples obtained by pipette or by pouring that are deficient in sand-size material. Rapidly falling sand-size material can be difficult to withdraw representatively, particularly if pipette subsamples are obtained from near the surface and (or) if the subsample is not withdrawn immediately after mixing. Also, coarser sand particles may plug the pipette intake, precluding withdrawal of a representative mixture. Subsamples obtained by pouring are also unlikely to contain representative amounts of sand-size material. In contrast, the amount or percentage of sand-size material in a SSC sample has no effect in bias because all sediment in the original sample is used in the SSC analysis.

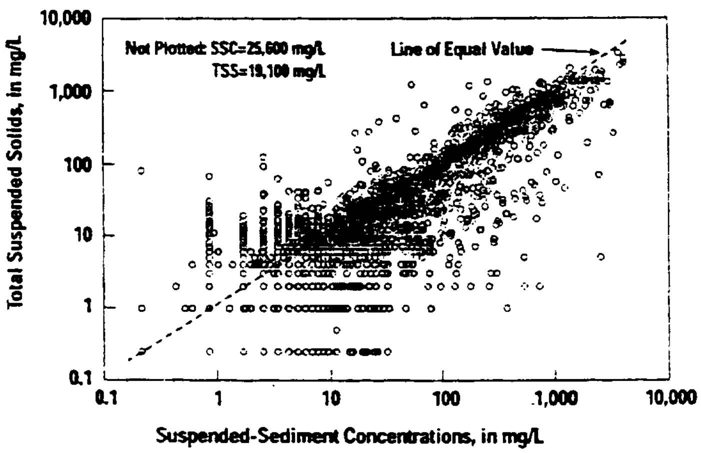

Figure 3. Relation between the base-10 logarithms of suspended-sediment concentration (SSC) and total suspended solids (TSS) for 3,235 data pairs in the scattergrams plotted. All SSC and TSS values less than 0.25 mg/L were set equal to 0.25 mg/L to enable plotting the data on logarithmic coordinates.

The relation between sand-size material and TSS bias was examined using the 860 paired SSC and TSS values for which the amounts of material coarser and finer than 0.062 mm in the SSC sample are known. Percent sand-size material, percent finer material, and the total mass of sand-size material were included in the analysis. All but one of the paired data associated with particle sizes are for streams in Illinois, Virginia, and Washington.

The relation between percent sand-size material associated with the SSC sample, and the SSC minus TSS remainder is shown in figure 5. No bias is apparent when sand-size material composes less than about a quarter of the sample's sediment mass. Above about a third sand-size material, the large majority of the SSC values exceed their paired TSS values. The increase in bias at larger SSC values as percent sand-size values increase is consistent with the observation that splitting original samples that contain a substantial percentage of sand-size material will rarely produce subsamples with a SSC or particle-size distribution similar to those of the original.

Splitting samples that contain small percentages of sand-size material are more likely to produce subsamples with concentrations and particle-size distributions similar to the original. The relation between TSS and the concentration of material finer than 0.062 mm for 860 of the paired SSC and TSS data with associated particle-size distribution data is shown in figure 6. The concentration of fine material was calculated as follows:

$$C_{<0.062mm} = SSC\,[1 - (Percent_{\geq 0.062mm}/100)]$$

$C_{<0.062mm}$ is the concentration of material finer than 0.062 mm in diameter,

SSC is suspended-sediment concentration, and

$Percent_{\geq 0.062mm}$ is percent sand-size material associated with the SSC value.

At TSS values that exceed about 5 mg/L of fine material, the SSC and TSS data are more or less evenly distributed around the line of equal value (figure 6). This suggests that the TSS method can provide relatively unbiased results when the large majority of material in a sample is finer than 0.062 mm.

The importance of bias in the relation between SSC and TSS characterized in figure 3 can be magnified when TSS data are used to compute sediment discharges. Sediment discharges increase when the product of water discharge and SSC increases (Porterfield, 1972). Additionally, the mobility of coarse material tends to increase with larger flow velocities. Because of the strong tendency for SSC to exceed TSS at larger values of SSC (see figures 3 and 4), calculating discharges of TSS will usually result in underestimates of

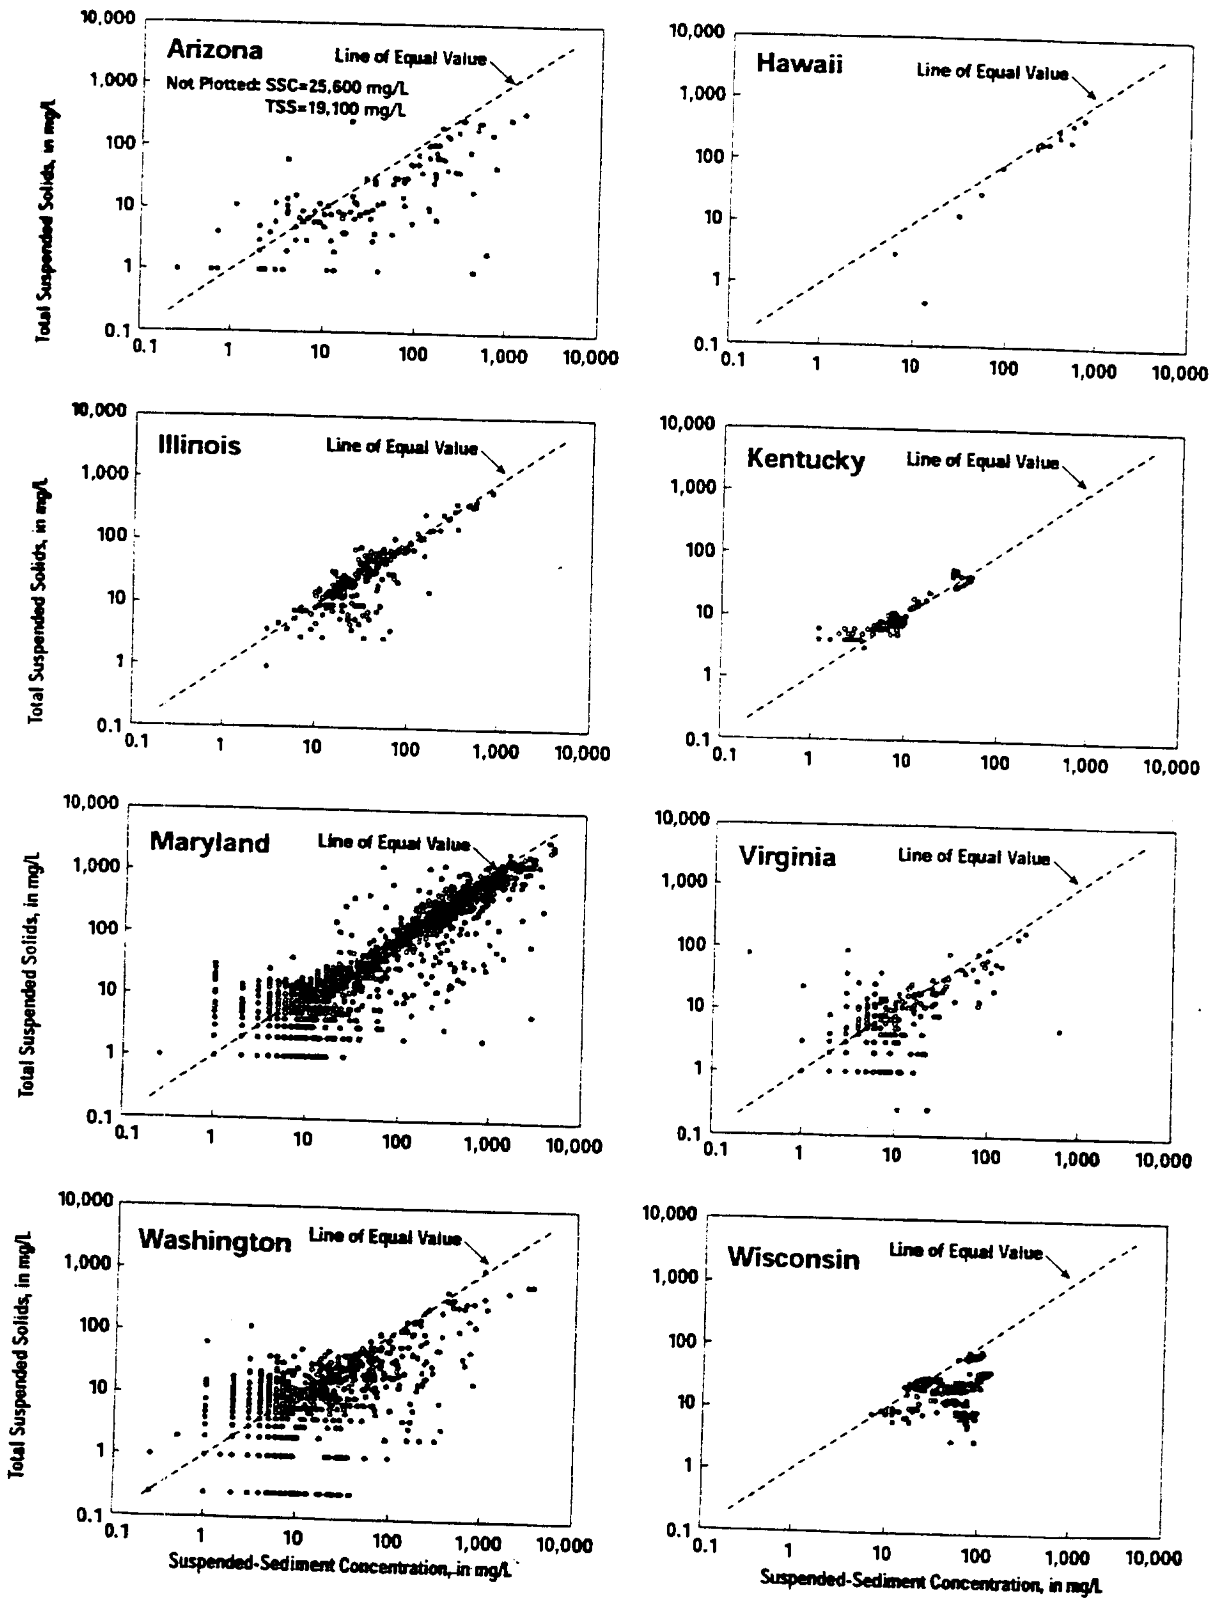

Figure 4. Relation between the base-10 logarithms of suspended-sediment concentration (SSC) and total suspended solids (TSS) for the data pairs from each State used in the analysis. All SSC and TSS values less than 0.25 mg/L were set equal to 0.25 mg/L to enable plotting the data on logarithmic coordinates.

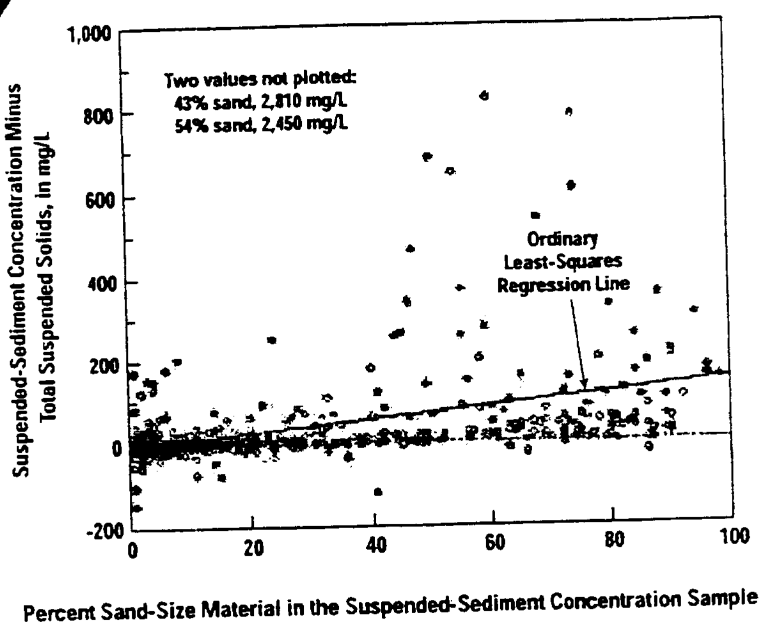

Figure 5. Relation between percent sand-size material in the sample analyzed for suspended-sediment concentration and the remainder of suspended-sediment concentration minus total suspended solids.

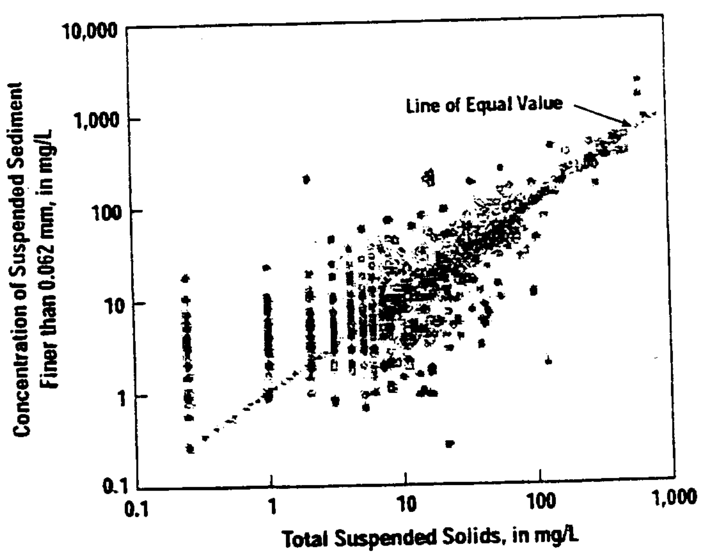

Figure 6. Relationship between total suspended solids and the concentration of suspended sediments finer than 0.062mm in paired suspended-sediment concentration samples. All SSC and TSS values less than 0.25 mg/L were set equal to 0.25 mg/L to enable plotting the data on logarithmic coordinates.

the suspended solid-phase discharges compared to those estimates that are computed from SSC data. TSS discharge underestimates may be negligible for streams conveying a predominantly fine material load over the range of discharges. Substantial underestimates of TSS discharges can be expected for streams conveying sediment loads that exceed about a third sand-size material in composition, and with percentages and concentrations of sand-size material that increase with discharge.

Figure 7 shows an example of the influence of bias resulting from using TSS data to calculate instantaneous sediment discharges for a stream in the northeastern United States. All the TSS and SSC samples used to compute sediment discharges from October 15 through December 24, 1998 were collected by a cooperating agency using an open bottle and analyzed by the cooperator's laboratory. The apparent order-of-magnitude change in sediment discharges between November and December 1998 was not related to any instream change in solid-phase transport, but to a change in analytical procedures (Henry Zajd, Jr., U.S. Geological Survey, oral commun., 2000). TSS analyses were performed on all samples collected in October and November 1998, and SSC analyses were used to produce subsequent data. The USGS did not publish daily sediment discharges for the pre-December period shown in figure 7 because the TSS data used in the computations were considered unreliable.

Quality-Control Data

Box plots that show the results of quality-control samples analyzed for SSC and TSS by a cooperating laboratory participating in the USGS National Sediment Laboratory Quality Assurance Program are shown in figure 8. The samples were analyzed in five sample sets. Box plots for sample sets 1997-1, 1997-2, and 1998-1 represent TSS analytical results. Box plots for study sample sets 1998-2 and 1999-1 represent SSC analytical results. This figure illustrates two important characteristics related to sediment-data quality.

First, both the SSC and TSS data tend to be negatively biased. The combined data for all samples analyzed as part of the Sediment Laboratory Quality Assurance Program from 1996 through September 2000 have a median concentration bias of -1.83 percent; the 25th percentile is -4.39 percent; and the 75th percentile is 0.00 percent. The bias primarily reflects a loss of some sediment, such as through a filter, or an inability to weigh accurately very small amounts of fine material in the SSC analytical procedure. The SSC median percent bias values for both study sets are about -2 and -4 percent of the known sediment mass. In contrast, TSS median percent bias values for the three study sets range from -6 to -23 percent from the known sediment mass; the mean difference in TSS median percent bias from the known sediment mass is -16 percent. Only for sample set 1997-2 does any quartile include the TSS value for the known sediment mass. The median percent bias in TSS sample set 1997-1 and in 1998-1 exceeds three F-pseudosigmas[2] from the mean value of all measured sediment mass measurements reported in the USGS National

[2]The F-pseudosigma is a nonparametric statistic analogous to the standard deviation that is calculated by using the 25th and 75th percentiles in a data set. It is resistant to the effect of extreme outliers.

Sediment Laboratory Quality Assurance Program. The analytical method used by the laboratory for determination of TSS in natural-water samples was deemed unacceptable by the U.S. Geological Survey (USGS, 1999b).

Second, the variances associated with the TSS quality-control data are large compared to those for SSC data (figure 8). The least variable data – those from sample set 1997-1 – range from -18 to -32 percent of the known value, and the difference between the 1st and 3rd quartile values is 9 percent. In comparison, the most variable SSC data – those from sample set 1999-1 – range from 0 to -5 percent; the difference in the 1st and 3rd quantile values is 4 percent.

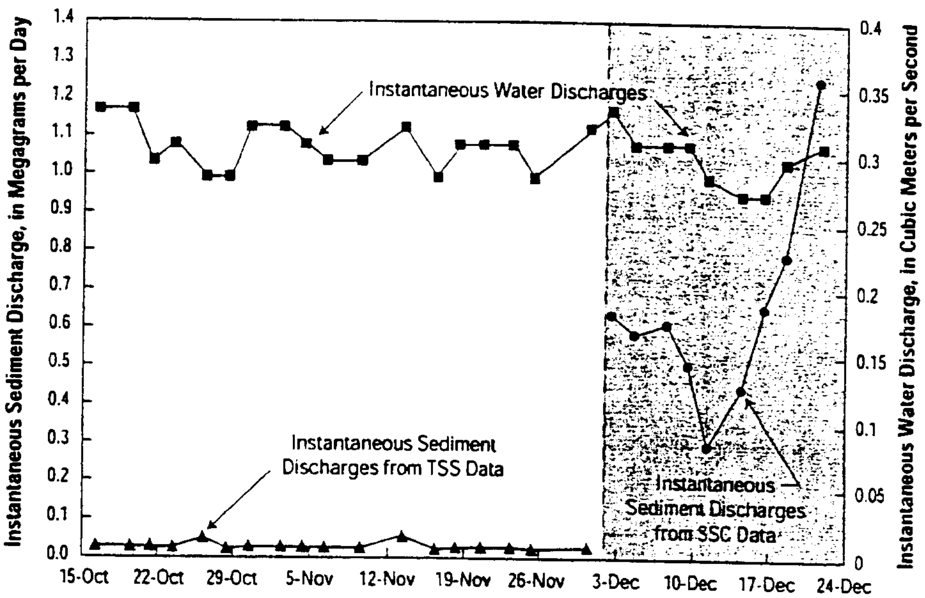

Figure 7. Instantaneous water discharges, and sediment discharges computed from total suspended solids (TSS) and suspended-sediment concentration (SSC) data for a stream in the northeastern United States, 1998.

In terms of bias and variance, the TSS results from two of the first three sample sets – 1997-1 and 1998-1 – were considered unacceptable by the U.S. Geological Survey (U.S. Geological Survey, 1998; 1999a). The SSC results from study sample sets 1998-2 and 1999-1, which were produced by the same laboratory, are considered among the most accurate of all laboratories that participated in the USGS National Sediment Laboratory Quality Assessment Program (John Gordon, U.S. Geological Survey, oral commun., 2000).

CONCLUSIONS

Of the two analytical methods examined for measuring the mass of solid-phase material in natural-water samples — suspended-sediment concentrations (SSC), and total suspended solids (TSS), — data produced by the SSC technique are the more reliable. This is particularly true when the amount of sand in a sample exceeds about a quarter of the dry sediment mass. This conclusion is based on the following observations:

1. The SSC analytical procedure entails measurement of the entire mass of sediment and the net weight for the entire sample. In contrast, only a part of the water-sediment mixture is typically used in the TSS analysis. Difficulties in, and variations for methods associated with obtaining TSS subsamples can result in determinations of solid-phase characteristics that are substantially different from those of the original sample.

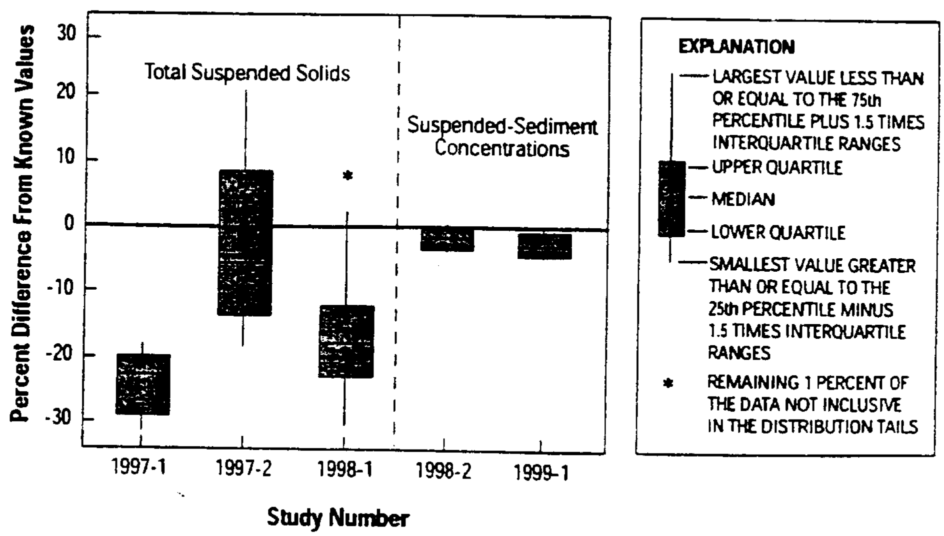

Figure 8. Variability in results of suspended-sediment concentrations and total suspended solids analytical methods in quality-control water samples analyzed by a cooperator laboratory. (John D. Gordon, U.S. Geological Survey, written commun., 2000).

2. Subsampling by pipette or by pouring from an open container will generally result in production of a sediment-deficient subsample. An analysis of 3,235 paired SSC and TSS natural-water samples from eight States showed that SSC values tend to exceed their paired TSS values, particularly at larger values of SSC. This is consistent with the assumption that most subsamples used to determine the TSS data were obtained by pipette or by pouring from an open container.

3. An analysis of 860 paired SSC and TSS natural-water samples for which relative amounts of sand-size and finer material are known for the SSC sample were used to determine the effect of sand-size particles on the TSS analysis. SSC values tend to be larger than their paired TSS values as the percentage of sand-size material exceeds about a quarter of the mass of sediment in the sample. Additionally, a relation between values of TSS and the paired SSC material finer than 0.062 mm showed that for samples with TSS values exceeding about 5 mg/L, the paired SSC and TSS data are more or less evenly distributed around the line of equal value. Sand-size material is more difficult to subsample than finer material due to the large fall velocity of sand-size material as described by Stokes' Law.

The tendency for SSC values to exceed their paired TSS values has important ramifications for computations of suspended solid-phase discharges; those computed using TSS data will often underestimate solid-phase discharges. This is particularly true for sites when the percentages of sand-size material in the water samples exceed about a third and where concentrations and percentages of sand-size material in transport increase with flow.

4. Fifty-three quality-control samples from a cooperator's laboratory — three sample sets totaling 35 TSS analyses of subsamples obtained by pouring from original samples, and two sample sets totaling 18 SSC analyses — were used to compare bias and variance introduced by use of the TSS and SSC analytical methods. Two of the three sample sets analyzed for TSS had unacceptably large mean negative bias. Variances associated with all three TSS sample sets were at least double those associated with the SSC quality-control results from the same laboratory. The two SSC sample sets analyzed by the same laboratory had small variances compared with those for the three TSS sample sets. The slight negative bias values associated with the SSC sample sets were consistent with data analyzed by most laboratories participating in the USGS National Sediment Laboratory Quality Assurance Program.

5. Review of the literature indicates that the TSS method originated as an analytical method for wastewater, presumably for samples collected after a settling step at a wastewater treatment facility. The results of this evaluation do not support use of the TSS method to produce reliable concentrations of solid-phase material in natural-water samples. The TSS method is being misapplied to samples from natural water.

Some SSC and TSS data may be comparable, particularly when the percentage or amount of sand-size material in the sample is less than about 25 percent. TSS values from analyses of samples collected following a settling step for coarser sediments, such as those obtained for compliance purposes at sewage treatment plants and water treatment facilities, may be reliable. However, because relatively few TSS data are associated with the percent sand-size and finer material from SSC samples, it is usually impossible to identify which if any TSS data may be biased. Some of the TSS data may reflect the mass of suspended solids in natural-water samples, but there are currently no absolute means to identify those data, nor a generally reliable procedure to correct biased TSS data.

The TSS method, which was originally designed for analyses of wastewater samples, is shown to be fundamentally unreliable for the analysis of natural-water samples. In contrast, the SSC method produces relatively reliable results for samples of natural water, regardless of the amount or percentage of sand-size material in the samples. SSC and TSS data collected from natural water are not comparable and should not be used interchangeably. The accuracy and comparability of suspended solid-phase concentrations of the Nation's natural waters would be greatly enhanced if all these data were produced by the SSC analytical method.

X. POLICY REVIEW AND REVISION 38

INTRODUCTION

The State Water Resources Control Board (SWRCB) and the Regional Water Quality Control Boards (RWQCBs) (together "Boards") are the principal state agencies with primary responsibility for the coordination and control of water quality. In the Porter-Cologne Water Quality Control Act (Porter-Cologne), the Legislature declared that the "state must be prepared to exercise its full power and jurisdiction to protect the quality of the waters in the state from degradation . . ." (California Water Code section 13000). Porter-Cologne grants the Boards the authority to implement and enforce the water quality laws, regulations, policies and plans to protect the waters of the state. Timely and consistent enforcement of these laws is critical to the success of the water quality program and to ensure that the people of the State have clean water. It is the policy of the SWRCB that the Boards shall strive to be fair, firm and consistent in taking enforcement actions throughout the State, while recognizing the individual facts of each case. Toward that end, it is the intent of the SWRCB that the enforcement actions of the RWQCBs be in accordance with the provisions of this policy.

Enforcement serves many purposes. First and foremost, it assists in protecting the beneficial uses of waters of the State. Swift and sure enforcement orders can prevent threatened pollution from occurring and can promote prompt cleanup and correction of existing pollution problems. It ensures compliance with SWRCB and RWQCB regulations, plans, policies, and orders. Enforcement not only protects the public health and the environment, but also creates an "even playing field," ensuring that dischargers who comply with the law are not placed at a competitive disadvantage by those who do not. It also deters potential violators and, thus, further protects the environment. Other benefits result from a strong enforcement program. Monetary remedies, an essential component of an effective enforcement program, provide a funding source for needed cleanup projects, provide a measure of compensation for the often unquantifiable damage that pollution causes to the environment, and ensure that polluters do not gain a substantial economic advantage from violations of water quality laws.

Enforcement determinations may be complicated fact-specific decisions based ultimately on experience and professional judgment. The purpose of this Policy is to provide a framework within which such decisions may be better made. In deciding which course of action should be pursued, RWQCB staff should consult with their supervisors. In many cases, the final decision will be left to the RWQCB.

It is important to note that enforcement of the State's water quality requirements is not solely the purview of the Boards and their staff. Other agencies (e.g., the California Department of Fish and Game) have the ability to enforce certain water quality provisions in state law. State law also allows for members of the public to bring enforcement matters to the attention of the Boards and authorizes aggrieved persons to petition the SWRCB to review most actions or in-actions by the RWQCB. In addition, state and federal statutes provide for public participation in the issuance of most orders, policies and water quality control plans. Finally, the federal Clean Water Act authorizes citizens to bring suit against dischargers for certain types of Clean Water Act (CWA) violations.

I. FAIR, FIRM AND CONSISTENT REGULATION AND ENFORCEMENT

Fair, firm and consistent enforcement depends on a foundation of solid requirements in law, regulations, policies, and the adequacy of enforceable orders, including waste discharge requirements (WDRs), cleanup and abatement orders, National Pollutant Discharge Elimination System (NPDES) permits, and other orders. The extent to which such enforceable orders include well-defined requirements and apply similar requirements to similar situations affects the consistency of compliance and enforcement. Whenever the circumstances of a discharge (including the nature and volume of the discharge and the beneficial uses of the receiving water) are similar, the provisions of the enforceable orders should be comparable.

The SWRCB, with assistance and advice from the RWQCBs will compile and maintain examples of standard enforceable orders. RWQCBs' orders shall be consistent except as appropriate for the specific circumstances related to the discharge and to be consistent with applicable water quality control plans. Such modifications must be consistent with applicable state and federal law. RWQCB Water Quality Control Plans may include unique requirements that apply within a region and must be implemented even if not consistent with other RWQCBs.

The Boards shall have a consistent and valid means to determine compliance with enforceable orders. Compliance assurance activities include the review of self-monitoring reports, facility inspections and complaint response. RWQCBs shall regularly review all discharger self-monitoring reports and document all violations and the subsequent response in the Boards' enforcement data management system. Where enforcement resources are limited, actions should be targeted to the highest priority significant violations. Enforcement actions should be initiated as soon as possible after discovery of the violation. Violations that are similar in nature and have similar water quality impacts should receive similar enforcement.

II. DISCOVERY OF VIOLATION

Violation of WDRs, Water Quality Control Plan prohibitions, enforcement orders, and other provisions of law administered by the SWRCB or RWQCBs can be discovered through discharger self-monitoring reports (SMRs), compliance inspections, facility reporting, complaints, or file review.

A. Self-Monitoring Reports

The Boards ensure compliance with WDRs by requiring dischargers to implement a monitoring and reporting program under California Water Code sections 13267 and 13383, and to periodically submit SMRs. Reporting frequency for regulated dischargers depends on the nature and impact of the discharge. The regulations that implement the CWA also specify monitoring requirements. WDRs shall explicitly require the discharger to clearly identify violations of their WDRs in the SMR.

B. Compliance Inspections

Compliance inspections are conducted on-site by the RWQCB staff under the authority provided in California Water Code sections 13267 and 13383. Compliance inspections address compliance with WDRs, laboratory quality control and assurance, record keeping and reporting, time schedules, best management practices, pollution prevention plans, and any other pertinent requirements. The inspections are also used as a verification of the accuracy of the discharger's SMR.

C. Direct Facility Reporting

Dischargers with regulated facilities should generally be required through their WDRs to report to the RWQCB by phone, usually immediately or within 24 hours, followed by a written report and a discussion in the next SMR, when certain events occur, such as:

- Bypass of raw or partially treated sewage or other waste from a treatment unit or discharge of wastewater from a collection system.
- Treatment unit failure or loss of power that threatens to cause a bypass.
- Any other operational problems that threaten to cause significant violations of WDRs or impacts to receiving waters.
- Discharges of oil or petroleum in or on waters of the State or where it will be discharged in or on waters of the State.

D. Complaints and Complaint Investigations

Often information regarding an actual or potential violation or unauthorized discharge is obtained through telephone or written notification from a member of the public, another public agency or an employee working at a regulated facility. Complaints may also involve nuisance conditions, such as noxious odors that extend beyond a wastewater treatment plant boundary. The SWRCB Office of Operator Certification also investigates complaints of operator misconduct at wastewater treatment plants. During the course of an investigation additional violations that are indirectly related or unrelated to the original investigation may also be discovered.

E. Case Record Maintenance and Review

WDRs and enforcement orders (e.g., cleanup and abatement orders, cease and desist orders, time schedule orders and California Water Code section 13267 orders) frequently mandate completion of tasks, which the dischargers must confirm by submission of appropriate reports to the RWQCBs. Failure to submit the reports or to complete the required tasks may be the basis for additional enforcement. RWQCBs shall use data management systems to track tasks and reports required of dischargers.

Often the RWQCB first hears about spills or other violations from the California Department of Fish and Game, the California Department of Toxic Substance Control or other enforcement agencies. District Attorneys are another source on information. The RWQCBs can use this information to decide whether to initiate joint or separate enforcement actions.

III. DETERMINING SIGNIFICANT VIOLATIONS

Enforcement actions shall be targeted toward the highest priority water-quality violations (significant violations). The general criteria below have been developed to assist the RWQCBs in identifying significant violations in order to help establish priorities for enforcement efforts. Depending on the circumstances, violations that are not included on this list could nonetheless be considered "significant" as well.

The following subsections comprise a non-exclusive list of violations that are considered "significant," will be identified as significant violations in the enforcement database, and will be considered high priority for enforcement.

A. NPDES Effluent and Receiving Water Limitation Violations

For facilities with NPDES permits, the following effluent and receiving water limitation violations are significant violations:

- Any violation of an effluent limitation for a Group 1 pollutant (see Table III-1) by 40 percent or more. (If the effluent limitation is zero, any detection necessarily exceeds the effluent limitation by 40 percent or more.) In addition, where the effluent limitation is lower than the applicable detection limit, the discharge must also equal or exceed the applicable detection limit in order to be considered a significant violation. The applicable detection limit is the Minimum Level for discharges of priority pollutants subject to the SWRCB's "Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California," and the Practical Quantitation Limit for all other Group 1 pollutants.
- Any violation of an effluent limitation for a Group 2 pollutant (see Table III-2) by 20 percent or more. (If the effluent limitation is zero, any detection necessarily exceeds the effluent limitation by 20 percent or more.) In addition, where the effluent limitation is lower than the applicable detection limit, the discharge must also equal or exceed the applicable detection limit in order to be considered a significant violation. The applicable detection limit is the Minimum Level for discharges of priority pollutants subject to the SWRCB's "Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California," the Method Detection Limit for total residual chlorine, and the Practical Quantitation Limit for all other Group 2 pollutants.
- Any waste discharge that violates a flow limitation by ten percent or more.
- Any waste discharge that violates a receiving water temperature limitation by three degrees Celsius or more.
- Any waste discharge that violates an effluent or receiving water limitation for pH by one pH unit or more.
- Any waste discharge that violates an effluent or receiving water limitation for any other pollutant or monitored parameter that is not listed in either Table III-1 or Table III-2 by 40 percent or more.

Table III-1. Group 1 Pollutants. This list of pollutants is based on Appendix A to Section 123.45 of Title 40 of the Code of Federal Regulations. For the purpose of data entry into the Permit Compliance System (PCS), the United States Environmental Protection Agency (USEPA) has identified an exhaustive list of those pollutants which are included as Group 1 pollutants under the various classifications of "other." The list is available on the SWRCB's Internet site (www.swrcb.ca.gov). The entire list, including any future amendments by USEPA thereto, is hereby incorporated into this Table III-1.

Oxygen Demand
Biochemical Oxygen Demand
Chemical Oxygen Demand
Total Oxygen Demands
Total Organic Carbon
Other

Solids
Total Suspended Solids
Total Dissolved Solids
Other

Nutrients
Inorganic Phosphorous Compounds
Inorganic Nitrogen Compounds
Other

Detergents and Oils
Methylene Blue Active Substances
Nitrillotriacetic Acid

Total Hardness
Other Minerals

Metals
Aluminum
Cobalt
Iron
Vanadium

Table III-2. Group 2 Pollutants. This list of pollutants is based on Appendix A to Section 123.45 of Title 40 of the Code of Federal Regulations. For the purpose of data entry into the Permit Compliance System (PCS), USEPA has identified an exhaustive list of those pollutants which are included as Group 2 pollutants. The entire list is available on the SWRCB's internet site (www.swrcb.ca.gov). The entire list, including any future amendments by USEPA thereto, is hereby incorporated into this Table III-2.

Metals
All metals not specifically listed under Group 1.

Inorganics
Cyanide
Total Residual Chlorine

Organics
All organics not specifically listed under Group 1.

B. Chronic Violations

Chronic violations are significant violations. A facility or discharger is in chronic violation when it has four or more similar types of violations during any six-month period, or it has violated a monthly average effluent limitation for a specific pollutant in the same season for two consecutive years.

C. Toxicity Violations

Two or more violations of numeric or narrative toxicity requirements contained in WDRs, Water Quality Control Plan prohibitions or other provisions of law within any six-month period are significant violations.

D. Violations of Prohibitions

WDRs, Water Quality Control Plans, and enforcement orders often contain prohibitions (year-round or seasonal) against certain types of discharges of waste. Violations of such prohibitions are considered significant violations.

E. Spills (including other unauthorized discharges)

Significant violations include:

- sewage spills that reach surface waters;
- sewage spills to soil that are a public health threat and/or are greater than 5000 gallons; and

- spills of other materials that cause a public health threat or cause toxicity to fish and wildlife (e.g., hazardous materials and oil).

F. Failure to Submit Reports

Failure to submit reports required by WDRs, California Water Code section 13267 and 13383 orders, California Water Code section 13260, regulations or Water Quality Control Plans within 30 days from the due date, or submission of reports which are so deficient or incomplete as to impede the review of the status of compliance are significant violations. In addition, failure to comply with the notification requirements contained in California Water Code sections 13271 and 13272 is a significant violation.

G. Violations of Compliance Schedules

Violations of compliance schedule dates (e.g., schedule dates for starting construction, completing construction, or attaining final compliance) by 60 days or more from the compliance date specified in an enforcement order or WDRs are significant violations.

H. Failure to Implement a Pretreatment Program

Failure of a publicly-owned treatment works to substantially implement its approved pretreatment program as required in its WDRs, including failure to enforce industrial pretreatment requirements on industrial users and failure to meet pretreatment program compliance schedules within 60 days is a significant violation.

I. Storm Water Program Violations

1. Industrial and Construction Discharges

Certain construction and industrial activities require compliance with either the General NPDES Permit for Storm Water Discharges Associated with Construction Activity (Construction Storm Water Permit) or the General NPDES Permit for Discharges of Storm Water Associated with Industrial Activity Excluding Construction (Industrial Storm Water Permit). Failure to submit a Notice of Intent for coverage under the general permits or a notice of non-applicability, after specific notification to the discharger, is a significant violation. Failure to either develop a Storm Water Pollution Prevention Plan (SWPPP), to substantially implement a SWPPP, to conduct required monitoring, or to submit annual reports is a significant violation.

2. Municipal Discharges

In most urban areas, discharges of storm water to and from municipal separate storm sewer systems (MS4s) require compliance with a Municipal NPDES Storm Water Permit. Failure to either submit a report of waste discharge, to develop a storm water management plan, to substantially implement the storm water management plan, to conduct monitoring, or to submit an annual report is a significant violation.

3. Failure to attain performance standards, failure to report and address violations and unauthorized discharges

Most storm water permits require the discharger(s) to comply with general performance practices or standards (e.g., best management practices, best available technology economically achievable, best conventional technology, and maximum extent practicable). If storm water and/or authorized non-storm water discharges cause or substantially contribute to an exceedance of an applicable water quality standard, the discharger is usually required to take specific actions (e.g., modify its Storm Water Management Plan) to resolve such exceedances. For storm water and/or authorized non-storm water discharges that cause or substantially contribute to an exceedance of an applicable water quality standard, significant violations include the failure to comply with the procedures to address exceedances required by the permit. Discharges of non-storm water that are unauthorized by the permit are significant violations. The criteria for significant violations in section III(A) of this policy apply to NPDES storm water permits that contain effluent limitations.

J. Clean Water Act Section 401 Violations

Discharges into waters of the United States that require a federal permit or license also require certification from the SWRCB or RWQCB that the discharge will comply with the State's water quality standards. Failure to obtain certification prior to a discharge that causes or contributes to a condition of nuisance or pollution or violates water quality standards is a significant violation. Failure to substantially comply with conditions specified in the certification is a significant violation.

K. Violation of Water Quality Objectives or Receiving Water Limitations

Any discharge of waste resulting in, or likely to result in, a violation of a water quality objective or a receiving water limitation in groundwater or surface water, or in the creation of a condition of nuisance, is a significant violation unless specifically authorized by the SWRCB or RWQCB. For storm water discharges, RWQCBs may allow the iterative approach discussed in SWRCB Orders WQ 91-03, 91-04, 96-13, 98-01 and 99-05.

L. Discharge of Biosolids to Land

The following violations of the SWRCB General WDRs for discharge of biosolids to land are significant violations:

- Any discharge in violation of the setback requirements;
- Any discharge that exceeds 1.4 times the agronomic rate for nitrogen, where the site is not a land-reclamation site;
- Any discharge of tailwater in violation of the requirements;
- Any discharge that exceeds the Background Cumulative Adjusted Loading Rate in the requirements; and

- Any violation of the specific Class B Discharge Specifications.

M. Other Discharges of Waste to Land (Non-Chapter 15 Facilities)

The following violations of requirements in WDRs for facilities regulated by the Non-Chapter 15 Program are significant violations:
- The failure to maintain required freeboard in ponds;
- Any discharge that exceeds flow limits by 20 percent or more;
- Any discharge that exceeds the effluent limitation for biological oxygen demand or total dissolved solids by 100 percent or more; or
- Any discharge where the dissolved oxygen is less than 50 percent of the effluent limitation;

N. Failure to Pay Fees, Penalties or Liabilities

Failure to pay fees, penalties or liabilities within 30 days of the due date is a significant violation unless an alternate payment schedule has been accepted by the RWQCB Executive Officer or the SWRCB's Division of Administrative Services.

O. Falsifying Information

Falsification or intentional withholding of information required by an order of the SWRCB or a RWQCB is a significant violation.

IV. ENFORCEMENT ACTIONS

The Boards have a variety of enforcement tools to use in response to non-compliance by dischargers. This section describes the range of options and discusses procedures that are common to some or all of these options.

A. Progressive Enforcement

An enforcement action is any informal or formal action taken to address the failure to comply with applicable statutes, regulations, plans, policies, or orders of the Boards. For some violations, an informal response such as a phone call or staff enforcement letter is sufficient to inform the discharger that the violation has been noted by the RWQCB and to encourage a swift return to compliance. More formal enforcement is often an appropriate first response for more consequential violations. If the violation continues, the enforcement response should be escalated to increasingly more formal and severe actions until compliance is achieved. Progressive enforcement is not appropriate in all circumstances, for example, where there is an emergency situation needing immediate response for which a cleanup and abatement order is appropriate or where the discharger is a chronic violator.

B. Standard Language

In order to provide a consistent approach to enforcement throughout the state, enforcement orders should be standardized where appropriate. The SWRCB intends to maintain model enforcement orders containing standardized provisions for use by the RWQCBs. RWQCBs should use the models and modify terms and conditions as appropriate for the specific circumstances related to the discharge and to be consistent with RWQCB plans and policies.

C. Informal Enforcement Actions

An informal enforcement action is any enforcement action taken by SWRCB or RWQCB staff that is not defined in statute. An informal enforcement action can include any form of communication (verbal, written, or electronic) between SWRCB and/or RWQCB staff and a discharger about a violation or potential violation. These actions may, in some circumstances, be appealed to the RWQCB or the RWQCB Executive Officer but cannot be directly petitioned to the SWRCB.

The purpose of an informal enforcement action is to quickly bring a violation to the discharger's attention and to give the discharger an opportunity to return to compliance as soon as possible. The RWQCB may take formal enforcement action in place of, or in addition to, informal enforcement actions. Continued noncompliance should trigger formal enforcement action.

1. Verbal Enforcement Actions and Staff Enforcement Letters

For many violations, the first step is a verbal enforcement action. Staff should contact the discharger by phone or in person and inform the discharger of the specific violations, discuss how and why the violations occurred, and discuss how and when the discharger will correct the violation and achieve compliance. Staff shall document the conversation in the facility case file and in the enforcement database.

A staff enforcement letter is often appropriate as follow-up, or in lieu of, a verbal enforcement action. Staff enforcement letters are signed by staff or by the appropriate senior staff. The letter should inform the discharger of the specific violations, and, if known to staff, discuss how and why the violations occurred and how and when the discharger will correct the violation and achieve compliance.

Verbal enforcement actions and staff enforcement letters should not include language that excuses the violation or that modifies a compliance date in WDRs or other orders issued by the State or RWQCB.

2. Notice of Violation (NOV)

The NOV letter is the highest level of informal enforcement action. An NOV letter shall be signed by the RWQCB Executive Officer or designee and shall be addressed and mailed to the discharger(s). In cases where staff normally work with the discharger's consultant, the consultant should also receive a copy of the letter. The NOV letter shall include the following information: description of specific violations, summary of appropriate enforcement options (including the potential daily or per gallon maximum Administrative Civil Liability (ACL) available), and a request for a written response by a specified date. The summary of applicable enforcement options shall include appropriate citations to the California Water Code and note that the RWQCB reserves the right to take any other enforcement action authorized by law.

D. Formal Enforcement Actions

Formal enforcement actions are statutorily recognized actions to address a violation or threatened violation of water quality laws, regulations, policy or orders. Formal enforcement orders generally shall contain findings that address the statutory requirements of the specific statutory provision being utilized.

1. Notices to Comply

Notices to Comply are issued pursuant to California Water Code section 13399 et seq., which requires the use of Notices to Comply as the sole enforcement option in most situations involving "Minor" violations.

The violations listed below are generally considered to be minor in nature:

- Inadvertent omissions or deficiencies in recordkeeping that do not prevent an overall compliance determination.
- Records (including WDRs) not physically available at the time of the inspection provided the records do exist and can be produced in a timely manner.
- Inadvertent violations of insignificant administrative provisions that do not involve a discharge of waste or a threat thereof.
- Violations that result in an insignificant discharge of waste or a threat thereof; provided, however, there is no significant threat to human health, safety, welfare or the environment and provided further that such violations do not violate any other order or prohibition issued by the SWRCB or RWQCBs. Significant threat means the threat of or an actual change in water quality that could result in a violation of water quality objectives or cause or contribute to a condition of pollution or nuisance.

A violation is not considered minor in nature if it is a significant violation as described in Section III of this policy or includes any of the following:

- It involves any knowing, willful, or intentional violation of Division 7 (commencing with Section 13000) of the California Water Code.
- It involves any violation of Division 7 of the California Water Code that enables the violator to benefit economically from noncompliance, either by realizing reduced costs or by gaining a competitive advantage.
- It cannot be corrected within 30 days.

2. Notices of Stormwater Noncompliance

The Stormwater Enforcement Act of 1998 (California Water Code section 13399.25 et seq.) requires that each RWQCB notify storm water dischargers who have failed to file a notice of intent to obtain coverage, a notice of non-applicability, a construction certification, or annual reports. If, after two notifications, the discharger fails to file the applicable document a mandatory civil liability shall be assessed against the discharger.

3. Technical Reports and Investigations

California Water Code sections 13267(b) and 13383 allow RWQCBs to conduct investigations and to require technical or monitoring reports in accordance with the conditions in the section. Failure to comply with orders made pursuant to Section 13267(b) may result in administrative civil liability pursuant to Section 13268. Failure to comply with orders made pursuant to Section 13383 may result in administrative civil liability pursuant to Section 13385. Section 13267(b) and 13383 orders are formal orders that are enforceable when signed by the Executive Officer of the RWQCB.

It is important to note that California Water Code sections 13267 and 13383 are not strictly enforcement statutes. They are the statutes that RWQCBs should routinely cite as authority whenever asking for technical or monitoring reports. It should also be cited in all WDRs as authority for the monitoring and reporting program.

4. Cleanup and Abatement Orders (CAOs)

Cleanup and Abatement Orders (CAOs) are adopted pursuant to California Water Code section 13304. CAOs are often issued to dischargers that are not being regulated by WDRs. CAOs are issued by the RWQCB, or by the Executive Officer under delegation from the RWQCB pursuant to California Water Code section 13223. RWQCBs should keep an accurate record of staff oversight costs for CAOs, because dischargers are liable for such costs. If staff costs are not recovered voluntarily or through civil court actions, the RWQCB may request that a lien be placed on the affected property.

RWQCBs shall comply with SWRCB Resolution No. 92-49 in issuing CAOs. CAOs should require discharger(s) to clean up the pollution to the most stringent levels that are economically and technically feasible. At a minimum, cleanup levels must be sufficiently stringent to fully support beneficial uses, unless the RWQCB allows a containment zone. In the interim, and if full cleanup cannot be achieved, the CAO should require the discharger(s) to abate the effects of the discharge. Abatement activities may include the provision of alternate water supplies. CAOs should name all dischargers for which there is substantial evidence of responsibility.

CAOs shall contain language describing likely enforcement options available for non-compliance and should specify that the RWQCB reserves its right to take any enforcement action authorized by law. Such language shall include appropriate California Water Code citations. Violations of CAOs should trigger further enforcement in the form of an ACL, a Time Schedule Order (TSO) under California Water Code section 13308, or referral to the Attorney General for injunctive relief or monetary remedies.

5. Section 13300 Time Schedule Orders (TSOs)

Pursuant to California Water Code section 13300, the RWQCBs or the Executive Officers can require the discharger to submit a time schedule which sets forth the actions that the discharger will take to address actual or threatened discharges of waste in violation of requirements.

6. Section 13308 Time Schedule Orders (13308 TSOs)

California Water Code section 13308 authorizes the RWQCB to issue a Section 13308 Time Schedule Order (13308 TSO) which prescribes a daily civil penalty if compliance is not achieved in accordance with the time schedule. The RWQCB may issue a 13308 TSO if there is a threatened or continuing violation of a cleanup and abatement order, cease and desist order, or any order issued under California Water Code sections 13267 or 13383. The daily penalty must be set based on an amount reasonably necessary to achieve compliance and may not contain any amount intended to punish or redress previous violations. Therefore, the 13308 TSO should contain findings explaining how the daily penalty amount will induce compliance without imposing punishment. For example, it could include a calculation of how much money the discharger is saving each day by delaying compliance. The 13308 TSO provides the RWQCBs with their primary mechanism for motivating compliance, and if necessary, assessing monetary penalties against federal facilities.

If the discharger fails to comply with the 13308 time schedule, the daily penalty is imposed when the RWQCB Executive Officer issues an ACL Complaint. The amount proposed in the ACL complaint should be equal to the daily penalty multiplied by the days of violation. If the amount of proposed liability in the ACL Complaint is less than the amount specified in the 13308 Order, the ACL Complaint shall include specific findings pursuant to California Water Code section 13327. The penalty may not exceed $10,000 for each day in which a violation of the 13308 TSO occurs.

7. Cease And Desist Orders (CDOs)

Cease and Desist Orders (CDOs) are adopted pursuant to California Water Code sections 13301-13303. CDOs may be issued to dischargers violating or threatening to violate WDRs or prohibitions prescribed by the RWQCB or the SWRCB. CDOs are often issued to dischargers with chronic non-compliance problems. These problems are rarely amenable to a short-term solution; often, compliance involves extensive capital improvements or operational changes. The CDO will usually contain a compliance schedule, including interim deadlines (if appropriate), interim effluent limits (if appropriate), and a final compliance date. CDOs may also include restrictions on additional service connections to community sewer systems.

CDOs shall contain language describing likely enforcement options available for non-compliance and specify that the RWQCB reserves its right to take any further enforcement action authorized by law. Such language shall include appropriate California Water Code citations. Violations of CDOs should trigger further enforcement in the form of an ACL, 13308 Order or referral to the Attorney General for injunctive relief or monetary remedies.

8. Modification Or Rescission Of Waste Discharge Requirements

In accordance with the provisions of the California Water Code, the RWQCB may modify or rescind WDRs in response to violations. Examples of cases where rescission of WDRs may be appropriate include: failure to pay fees, penalties or liabilities; discharges that impact beneficial uses of the waters of the state; and violation of the SWRCB General WDRs for discharge of biosolids due to exceedance of the Background Cumulative Adjusted Loading Rate. Rescission of WDRs generally is not an appropriate enforcement response where the discharger is unable to prevent the discharge, as in the case of a publicly owned wastewater treatment plant.

9. Administrative Civil Liability (ACL)

ACL means monetary assessments imposed by a RWQCB. The California Water Code and the Health and Safety Code authorize ACLs in several circumstances which are summarized in Table IV-1. Staff working on ACLs should consult the appropriate section of the California Water Code to review the entire text.

Table IV-1. Summary of California Water Code and Health and Safety Code Authority for Imposing Administrative Civil Liability.

STATUTE	COVERAGE
§ 13261 (California Water Code)	Up to $1,000 per day for failure to furnish reports of waste discharge or failure to pay annual program fees. ($5,000 per day for non-NPDES discharges if hazardous waste is involved and there is a willful violation.)
§ 13265 (California Water Code)	Up to $1,000 per day for discharging without a permit. ($5,000 per day for non-NPDES discharges if hazardous waste is involved and violation is due to negligence.)
§ 13268 (California Water Code)	Up to $1,000 per day for failing or refusing to furnish technical or monitoring reports or falsifying information therein. (Up to $5,000 per day for non-NPDES discharges if hazardous waste is involved and there is a knowing violation.)

§ 13271 (California Water Code)	Up to $20,000 or imprisonment for not more than 1 year or both for failing to notify the Office of Emergency Services (OES) of a discharge of hazardous substances or more than 1000 gallons of sewage.
§ 13272 (California Water Code)(Limitation: Does not apply to spills of oil into marine waters as defined in Government Code §8670.3(f).)	Imprisonment for not more than 1 year or a fine of not less than $500 and not more than $5000 per day for each day of failure to notify OES of a discharge of any oil or product in or on the waters of the state.
§ 13308 (California Water Code)	Up to $10,000 per day for violations of time schedules. Amount to be prescribed when time schedule is established.
§ 13350 (California Water Code)(Limitations: Must show intentional or negligent violation of cease and desist order or cleanup and abatement order; must also show that pollution or nuisance occurred if any other order, including waste discharge requirements, is violated. Strict liability with defenses if hazardous substances are involved.)	• Up to $10 per gallon of waste discharged (if no cleanup and abatement order has been issued). • Between $500 and $5,000 per day if a cleanup and abatement order has been issued. • If there is no discharge, but an order of the RWQCB is violated: Between $100 and $1,000 for each day of violation.
§ 13385 (California Water Code) (Limited in scope of NPDES permit program, e.g., point source discharges to surface waters. Strict liability applies.)	For NPDES permit program violations: Up to $10,000 per day of violation plus an additional liability of $10 per gallon for each gallon over 1,000 gallons where there is a discharge that is not cleaned up.
§ 13385 (California Water Code)	• 13385 (h) (1) … Mandatory minimum penalties of three thousand dollars ($3,000) shall be assessed for the first serious violation and each additional serious violation in any period of six consecutive months, except that the state board or regional board may elect to require the discharger to spend an amount equal to the penalty for the first serious violation on a supplemental environmental project or to develop a pollution prevention plan. • 13385 (i) Mandatory minimum penalties of three thousand dollars ($3,000) shall be assessed for each violation whenever the person does any of the following four or more times in any period of six consecutive months, except that the requirement to assess the mandatory minimum penalty shall not be

	applicable to the first three violations: (1) Exceeds a waste discharge requirement effluent limitation. (2) Fails to file a report pursuant to Section 13260. (3) Files an incomplete report pursuant to Section 13260. (4) Exceeds a toxicity discharge limitation contained in the applicable waste discharge requirements where the waste discharge requirements do not contain pollutant-specific effluent limitations for toxic pollutants.
§ 13399.33 (California Water Code) (Penalties may be reduced for specified reasons.)	• Not less than $5,000 per year or fraction thereof for failure to submit required notice of intent for coverage under stormwater permit. • Not less than $1,000 per year or fraction thereof for failure to submit notices on non-applicability, annual reports or construction certification as required by stormwater program.
§ 13627.3 (California Water Code)	Fines of up to $100 per day for persons operating wastewater treatment plants without the appropriate grade of license. Up to $1,000 per day for failure to provide reports on wastewater treatment plant operators.
§ 25284.4 (H&S Code) (Special provision covering underground storage tanks.)	For violation of tank integrity testing provisions, up to $500 per day.

California Water Code sections 13323-13327 describe the process to be used to assess ACLs. The California Water Code authorizes RWQCB Executive Officers to issue an ACL Complaint. Section VII of this policy provides specific instructions for staff to use when preparing ACL documents. The ACL Complaint describes the violation, includes a calculation of maximum potential liability, proposes a specific monetary assessment, and sets a hearing date (within 60 days after the Complaint is served). ACLs issued under section 13385 for violations of the CWA require that the hearing must be held at least 30 days after the issuance of the complaint in order to comply with public notice requirements.

ACL Complaint

Upon receipt of an ACL Complaint the discharger(s) may either waive their rights to a hearing and pay the liability; negotiate a settlement (usually memorialized in the form of an amended complaint) and comply with the terms of that settlement; or appear at the RWQCB hearing to dispute the Complaint. In the latter case, the RWQCB will consider whether to affirm, modify or reject the liability proposed by adopting an ACL order. If the RWQCB adopts an ACL Order, it may be for an amount that is greater or less than the amount proposed in the complaint but may not exceed the maximum statutory liability.

Suspended Liability

The RWQCB may, by various means, allow a portion of the liability to be satisfied through the successful completion of a Supplemental Environmental Project (SEP) and/or a Compliance Project (CP). The remaining portion of the liability shall be paid to the State Cleanup and Abatement Account. The specific procedures for suspending liability for SEPs and CPs are discussed in greater detail in Section VIII of this policy.

Staff Costs

The portion of the ACL amount that is intended to recover staff costs should always be paid to the State Cleanup and Abatement Account. Staff costs are discussed in greater detail in Section VII of this policy.

ACL Order

ACL Orders are final upon adoption and cannot be reconsidered by the RWQCB. Thus, the RWQCB may want to include a clause in the time schedule for completing SEPs or CPs that reserves its jurisdiction to modify the time schedule if it, or its Executive Officer, determines that the delay was beyond the reasonable control of the discharger. If the RWQCB fails to reserve jurisdiction for this purpose, the time schedule in the ACL Order can only be modified by the SWRCB pursuant to California Water Code section 13320. Another option that allows some flexibility in the time schedule for a CP is for the Board to adopt a CAO or a CDO at the same time it adopts the ACL Order. The time schedule in the CAO or CDO, subject to any future amendments to the CAO or CDO, would then be incorporated into the ACL Order by reference. All cash payments to the SWRCB or RWQCBs, including previously suspended liabilities assessed for failure to comply with CPs or SEPs, shall be paid to the State Cleanup and Abatement Account.

10. Referrals To Attorney General, District Attorney, United States (U.S.) Attorney or City Attorney

The RWQCB can refer violations to the state Attorney General or U.S. Attorney or request the appropriate county District Attorney or City Attorney to seek criminal relief. A superior court judge may be requested to impose civil or criminal penalties. In some cases (e.g., when the District Attorney or Attorney General is unable to accept a case), the RWQCB may find it appropriate to request the U.S. Attorney's Office to review potential violations of federal environmental statutes, including the CWA, the Endangered Species Act, the Migratory Bird Treaty Act, or the Resource Conservation and Recovery Act.

a. Attorney General

The Attorney General can seek judicial civil liabilities for a variety of California Water Code violations, essentially the same ones for which the RWQCB can impose ACL. Maximum per-day or per-gallon civil monetary remedies are two to ten times higher when imposed by the court instead of the RWQCB. The Attorney General can also seek injunctive relief in the form of a restraining order, preliminary injunction, or permanent injunction pursuant to California Water Code sections 13262, 13264, 13304, 13331, 13340 and 13386. Injunctive relief may be appropriate in emergency situations, or where a discharger has ignored enforcement orders or does not have the ability to pay a large ACL.

For civil assessments, referrals to the Attorney General should be reserved for cases where the violation merits a significant enforcement response but where an ACL would be inappropriate or ineffective. For example, when a major oil spill occurs, several state agencies can seek civil monetary remedies under different state laws; a single civil action by the Attorney General may be more efficient than numerous individual agency actions. A violation (or series of violations) with major public health or water quality impacts should be considered for referral in order to maximize the monetary assessment because of its effect as a deterrent. Referral for recovery of natural resources damages under common law theories, such as nuisance, may also be appropriate.

b. District Attorney, Circuit Prosecutor, or U.S. Attorney

District Attorneys may seek civil or criminal penalties under their own authority for some of the same violations the RWQCB pursues. While the California Water Code requires a formal RWQCB referral to the Attorney General, the RWQCB's Executive Officer is not precluded from bringing appropriate matters to the attention of a District Attorney. A major area where District Attorney involvement should be considered is for unauthorized releases of hazardous substances. In most of these cases, the RWQCB is not the lead agency, and the referral action is intended to support the local agency or another state agency that is taking the lead (e.g., county health department, city fire department, California Department of Fish and Game or the California Department of Toxic Substances Control). In many cases, RWQCB staff lacks the time to prepare an enforcement action, and a District Attorney referral is another option to seeing the matter pursued. Many District Attorney offices have created task forces specifically staffed and equipped to investigate environmental crimes including water pollution. These task forces may ask for RWQCB support which should be given within available resources. District Attorneys also have the resources to carry out investigations that may be beyond the expertise of RWQCB staff. For example, a District Attorney's investigator is skilled at interviewing witnesses and collecting evidence. Such assistance can help a RWQCB to determine if enforcement action is required and help with developing the evidence needed to prove the basis for enforcement.

The California District Attorneys Association has established the Environmental Circuit Prosecutor Project to provide experienced environmental attorneys to rural California counties. Circuit Prosecutors are deputized as needed in counties that lack the resources to have a prosecutor experienced in environmental law as a full time employee.

In addition to the criminal sanctions and civil fines, the District Attorney or Circuit Prosecutor often pursues injunctive actions to prevent unfair business advantage. The law provides that one business may not gain unfair advantage over its competitors by using prohibited tactics. A business that fails to comply with its WDRs or an enforcement order competes unfairly with other businesses that obey the law.

In cases where there is a serious violation of the CWA and additional investigatory resources are needed, the U.S. Attorney may be contacted.

c. Civil versus Criminal Actions

Enforcement actions taken by the RWQCB are administrative or civil actions. In cases where there is reason to believe that specific individuals or entities have engaged in criminal conduct, the RWQCB or Executive Officer may request that criminal actions be pursued by the District Attorney, Attorney General, or U.S. Attorney. Under criminal law, individual persons, as well as responsible parties in public agencies and business entities, may be subject to fines or imprisonment.

While criminal statutes differ, many require some type of intent or knowing behavior on the part of the violator. This intent may be described as knowing, reckless, or willful. In addition to the required intent, criminal offenses usually consist of a number of elements, each one of which must be proven. Determining whether the required degree of intent and each of the elements exists often involves a complex analysis. If a potential environmental criminal matter comes to the attention of staff, consultation with RWQCB management and counsel should take place first before making any contact with other enforcement authorities.

When evaluating whether a case should be referred for criminal investigation, particular attention should be given to the degree of intent and the gravity of the violation. A good rule of thumb is that if the conduct appears to be intentional or reckless and constitutes a serious threat to human health or the environment, careful consideration should be given to pursuing the case criminally.

E. Petitions of Enforcement Actions

Persons affected by most formal enforcement actions or failures to act by a RWQCB may file petitions with the SWRCB for review of such actions or failures to act. The petition must be received by the SWRCB within 30 days of the RWQCB action. A petition on the RWQCB's failure to act must be filed within 30 days of the date the RWQCB refuses to act or within 60 days after a request has been made to the RWQCB to act. Actions taken by the Executive Officer of the RWQCB pursuant to authority delegated by the RWQCB (e.g., cleanup and abatement orders) are considered actions by the Board and are also subject to the 30-day time limit. In addition, significant enforcement actions by a RWQCB Executive Officer may be reviewed by the RWQCB at the request of the

Discharger. Lastly, the SWRCB may, at any time and on its own motion, review most actions or failures to act by a RWQCB.

V. SPECIFIC RECOMMENDED ENFORCEMENT

It is the intent of the SWRCB that the following specific instances of non-compliance receive consistent enforcement responses from all nine RWQCBs. Decisions by the SWRCB and RWQCB to deviate from these specific recommendations should be based on extenuating circumstances that are documented in the discharger/facility record (e.g., file, databases, other records).

A. Knowingly Falsifying or Knowingly Withholding Information that is Required to be Submitted to State Regulatory Agencies

The foundation of the State's regulatory program relies on dischargers to accurately, and honestly, report information required by the Boards. This required information includes, but is not limited to: influent and effluent quality and flow data; surface and ground water data; spills of untreated or partially treated wastewater; and technical reports. Knowingly falsifying or knowingly withholding such information that would indicate violations of requirements contained in board orders, plans and policies erodes the State's regulatory program and places the health of the public and the environment at risk. The Boards shall respond to any instance of falsification or withholding of required information in accordance with this policy.

The discharger is responsible for compliance with orders and reporting of required information, including violations, to the SWRCB or RWQCB. The discharger is also responsible for ensuring that any employees, agents, or contractors acting on its behalf report truthful, accurate and timely required information. WDRs shall require training, specific signature authorization, audits, and procedures to ensure that dischargers, including their designees and employees are providing truthful, accurate, and timely reporting of required information.

The Boards shall consistently enforce the statutes pertaining to falsification or withholding of required information as follows:

- Initiate investigation of all instances of suspected falsification or withholding of water quality data within thirty days of becoming aware of the allegations. If the results of preliminary investigation suggest a possibility of criminal wrongdoing by the discharger, the SWRCB and RWQCB staff shall consult with management and counsel and inform the appropriate criminal investigative agency. The State and the RWQCBs may still pursue administrative actions against the discharger, however, prior to initiating any administrative or civil procedure, the criminal investigators and/or prosecutors must be consulted to insure that the administrative and civil process does not interfere with, or jeopardize, the criminal investigation.

R0026506

- Protect the confidentiality of all staff investigations of potential instances of knowingly falsifying or withholding required information. The RWQCBs shall protect the complainant's personal information such as name, address, phone numbers and employment data by providing a secure location for files about matters related to ongoing criminal investigations or licensing (e.g., treatment plant operator certification). The information in these files shall not be released to the public except as the law may require.

- Refer all cases where the investigation supports the allegation of falsification or intentional withholding of water quality data to the District Attorney, Circuit Prosecutor, Attorney General or the U.S. Attorney for criminal investigation.

- The SWRCB shall promptly consider, pursuant to California Water Code section 13627, suspension or revocation of the Operator Certificate of any operator who knowingly falsifies required information submitted to the SWRCB or RWQCB, withholds required information from the SWRCB or RWQCB, submits false or misleading information on an application for operator certification, or through threats, coercion or intimidation forces others to falsify or withhold required information from the SWRCB or RWQCB. Prior to initiating an investigation of potential operator misconduct involving falsification or withholding of information, the SWRCB's Office of Operator Certification shall insure that its investigation does not interfere with or jeopardize any potential criminal procedure.

- The RWQCB should assess civil liability against any facility where there is sufficient evidence of falsification or intentional or negligent withholding of required information.

- Where appropriate, the RWQCB shall, at a public meeting consider rescinding existing waste discharge requirements where the investigation supports the allegation of falsification or withholding of required information.

- The RWQCB should implement an intensive inspection schedule (e.g., semi-monthly inspections for a period of six months) for any facility where the investigation supports the allegation of falsification or withholding of water quality data. Inspections should involve thorough review of facility water quality records, procedures and processes, and sampling of effluent at regular intervals. Requesting the assistance of the District Attorney, Attorney General, or U.S. Attorney should be considered in complex cases.

B. Failure to Submit Reports and Submittal of Inadequate Reports

As stated above, the foundation of the State's water quality regulatory program relies on dischargers to report information specified in the WDR or in an order. If the discharger fails to submit a report, or submits a report that is inadequate (i.e., so deficient or incomplete as to impede the review of the status of compliance) the RWQCB should notify the discharger of the violation. At a minimum, the RWQCB should take an informal enforcement action if the discharger does not correct the violation within 30 days of the notification, and should issue an ACL if the discharger does not correct the violation within 60 days of the notification.

C. Mandatory Minimum Penalties for NPDES Violations

Mandatory penalty provisions are required by California Water Code section 13385(h) and (i) for specified violations of NPDES permits. A mandatory minimum penalty of $3,000 shall be assessed by the RWQCB. As an alternative to assessing $3,000 for the first serious violation in a six-month period, the RWQCB may require the discharger to spend an equal amount on a supplemental environmental project (SEP) or a pollution prevention plan (PPP). A serious violation is any waste discharge that exceeds the effluent limitation for a Group II pollutant by 20 percent or more, or a Group I pollutant by 40 percent or more. (See Tables III-1 and III-2)

If the RWQCB allowed the discharger to prepare a PPP pursuant to California Water Code section 13263.3 or an SEP in lieu of paying $3,000 for the first violation, the RWQCB must wait until the discharger has not had any serious violations for six months before it can allow the discharger to prepare an SEP or PPP in lieu of the mandatory penalty for additional serious violations.

The RWQCB shall assess mandatory minimum penalties of $3,000 per violation, not counting the first three violations, if the discharger does any of the following four or more times in any six-month period:

- exceeds WDR effluent limitations;
- fails to file a report of waste discharge or files an incomplete report of waste discharge pursuant to California Water Code section 13260; or
- exceeds a toxicity discharge limitation where the WDRs do not contain pollutant-specific effluent limitations for toxic pollutants.

The six-month time period shall be calculated as a "rolling" six months.

The intent of these portions of the California Water Code is to assist in bringing the State's waters into compliance with WDRs. RWQCBs should issue mandatory minimum penalties within seven months of the first qualifying violation, or sooner if the total mandatory penalty amount is $30,000 or more. This will encourage the discharger to correct the violation in a timely manner.

A single operational upset which leads to simultaneous violations of one or more pollutant parameters shall be treated as a single violation. EPA defines "single operational upset as "an exceptional incident which causes simultaneous, unintentional, unknowing (not the result of a knowing act or omission), temporary noncompliance with more than one CWA effluent discharge pollutant parameter. Single operational upset does not include... noncompliance to the extent caused by improperly designed or inadequate treatment facilities." "Issuance of Guidance Interpreting Single Operational Upset" Memorandum from Robert G Hess, Assistant Enforcement Counsel, September 27, 1989. The EPA Guidance further defines an "exceptional" incident as a "non-routine malfunctioning of an otherwise generally compliant facility." Single operational upsets include such things as upset caused by a sudden violent storm, a bursting tank, or other exceptional event and may result in multiple violations of the same effluent limitation. The discharger has the burden of demonstrating a single operational upset occurred. The RWQCB shall apply the above EPA Guidance in determining if a single operational upset occurred. It is not a defense to liability, but may affect the number of violations.

D. Failure To Pay Annual Fees

California Water Code section 13260 requires that each person prescribed WDRs shall pay an annual fee, except confined animal feeding or holding operations, which have a one-time $2,000 fee. Failure to pay the fee when requested is a misdemeanor and may be subject to an ACL imposed by the RWQCB of up to $1,000 per day pursuant to California Water Code section 13261. If the annual fee is not paid within 30 days of the invoice, the SWRCB staff shall issue a Notice of Violation for the annual fee which informs the recipient of the amount due and states that non-payment of the fee could result in one or more of the following:

- an ACL imposed by the RWQCB not to exceed $1,000 per day;
- a civil liability imposed by the superior court not to exceed $5,000 per day;
- recission of existing WDRs; or
- prosecution as a misdemeanor.

If the fee is not paid within 30 days of the Notice of Violation an ACL Complaint should be issued by the RWQCB Executive Officer. The amount of an ACL for nonpayment of fees should reflect an escalation of liability if there is a past history of failure to pay fees. In addition to the ACL, the discharger remains responsible for payment of the annual fees.

E. Failure To Pay Administrative Civil Liabilities

The SWRCB shall pursue collection of unpaid administrative civil liabilities. The California Water Code states that ACLs shall be paid within 30 days of the RWQCB's adoption of an ACL Order unless the recipient files a petition for review under California Water Code section 13320. When a petition is filed, payment is extended during the SWRCB review of the petition and shall be paid within 30 days of the SWRCB's decision on the petition. If the recipient fails to seek judicial review within 30 days of the SWRCB action, the SWRCB shall file for a judgment to collect the ACL pursuant to California Water Code section 13328. Application shall be made to the appropriate court in the county in which the liability was imposed, generally within 60 days of the failure to pay.

As an alternative to Section 13328, the SWRCB or RWQCB may pursue judicial collection for failure to pay an ACL imposed for CWA violations pursuant to California Water Code section 13385. After the time for judicial review has expired, the California Water Code provides that the Attorney General upon request shall petition the appropriate court to collect the liability. The person failing to pay the liability on a timely basis shall be required to pay interest, attorney's fees, cost for collection proceedings and a quarterly nonpayment fee of 20 percent for the liability and the nonpayment fees unpaid at the beginning of each quarter.

F. Acute Toxicity and Public Health

Where any violation can be shown to be the result of failure of a discharger to exercise normal care in handling, treating, or discharging waste, and that failure has resulted in acute toxicity to fish or wildlife and/or a public health threat, civil liability should be assessed.

VI. SPECIAL SITUATIONS

A. Violations at Federal Facilities

The CWA and the Resource Conservation and Recovery Act contain limited waivers of sovereign immunity. Due to sovereign immunity, the State cannot assess penalties or liabilities against federal agencies for past violations (e.g., no ACLs) under most circumstances. One significant exception is provided by the Federal Facilities Compliance Act of 1992 (42 USCA 6901 et seq), which allows the States to penalize federal agencies, under specified circumstances, for violations of state hazardous waste management requirements. In addition, under California Water Code section 13308, a RWQCB may seek an ACL, up to a maximum of $10,000 per day of violation, against federal facilities for any violation of a time schedule order. The time schedule order issued pursuant to Section 13308 prescribes a daily civil penalty which is based upon the amount necessary to achieve future compliance with an existing enforcement order. The RWQCB should take the action administratively, but if the federal government declines to pay, the RWQCB must refer the matter to the Attorney General's Office to file an action in state or federal court. Congress must waive sovereign immunity for the State to assess penalties or liability against the federal government.

B. Integrated Enforcement

SWRCB and RWQCB staff should cooperate with other environmental regulatory agencies, where appropriate, to ensure that enforcement actions are coordinated. The aggregate enforcement authorities of the Boards and Departments of the California Environmental Protection Agency (Cal/EPA) and the Resources Agency should be coordinated to eliminate inconsistent and inappropriately duplicative efforts. The following steps should be taken by RWQCB staff to assist in integrated enforcement efforts:

- participate in multi-agency enforcement coordination;
- share enforcement information; participate in cross-training efforts; and
- participate with other agencies in enforcement efforts focused on specific individuals or categories of discharges.

C. Oil Spills

Responses to oil spills to marine or estuarine waters should be coordinated through the Department of Fish and Game's Office of Oil Spill Prevention and Response (OSPR). OSPR staff may pursue enforcement action administratively or through referral to the local District Attorney. Staff should assist in an investigation by providing documentation, sampling, etc. If the discharger has not prepared a spill prevention plan or the plan is not acceptable to the RWQCB, the RWQCB should request a technical report under California Water Code sections 13267 or 13383. Major oil spills, those in excess of 10,000 gallons, usually involve a number of governmental jurisdictions. Such spills should be brought to the RWQCB for consideration of referral to the Attorney General for recovery of civil liability and other remedies.

Oil spills to inland (fresh) waters are not within the jurisdiction of OSPR. If formal enforcement actions are taken, they are usually enforced by either the county District Attorney under either the Fish and Game Code or Health and Safety Code, or by the RWQCB under the California Water Code. In general, if the District Attorney is interested in pursuing the case, the RWQCB should consult with the District Attorney before pursuing its own enforcement action to avoid any potential double jeopardy issues. However, staff should always request that any settlement by the District Attorney include recovery of staff costs and require any actions that appear necessary to prevent recurrence of a spill and/or to mitigate damage to the environment. If a District Attorney is the enforcement lead, RWQCB staff should generally focus their efforts on cleanup and prevention of future spills.

D. Hazardous Waste Spills

Hazardous wastes are those meeting the criteria specified in Title 22, Division 4.5, Chapter 11, California Code of Regulations. RWQCB staff shall coordinate enforcement actions involving hazardous waste spills with the California Department of Toxic Substances Control and/or any local or county hazardous waste program. Spills constitute unlawful disposal of hazardous waste pursuant to the Health and Safety Code. RWQCB staff should consider referring spills in all but the smallest amounts to the appropriate District Attorney. In addition, the RWQCB should consider assessing an ACL unless the spill was very small or limited in impact. Due to the nature of the materials discharged, the RWQCB should consider assessing an ACL in an amount at or near the legal maximum. If the California Department of Toxic Substances Control is seeking penalties or damages through a referral to the Attorney General, the RWQCB may consider joining that action in lieu of assessing an ACL.
Large spills of hazardous waste or hazardous substances, 10,000 gallons or more, should be treated like large oil spills, and should be considered for referral to the Attorney General. If appropriate, RWQCB staff should coordinate with the District Attorney or U.S. Attorney to determine whether criminal prosecution is warranted. In addition, such spills may constitute the unlawful disposal of hazardous waste pursuant to the Hazardous Waste Control Act (Health and Safety Code Section 25100 et seq.) and, in most cases,

should be investigated in conjunction with the California Department of Toxic Substances Control.

E. Spills of Non-hazardous Materials

Spills of materials that do not meet the formal criteria as being hazardous can still be highly toxic, such as some petroleum hydrocarbons or detergents, or of only limited toxicity, such as corn syrup. For this reason, such spills must be evaluated case-by-case for enforcement.

F. Solid Waste Facilities

Where a RWQCB has issued, or is likely to issue an enforcement action against a solid waste facility, it shall provide a statement to the local enforcement agency, the Integrated Waste Management Board, the air pollution control district or the California Department of Toxic Substances Control, if the violation involves the jurisdiction of that agency. This statement shall be provided at least 10 days prior to the date of issuance of an enforcement order which is not an emergency, within five days from the date of issuance of an enforcement order for an emergency, or within 15 days of the discovery of a violation of a state law, regulation, or term or condition of a solid waste facility's WDRs for a solid waste facility, which is likely to result in an enforcement action. The statement shall provide an explanation of and justification for the enforcement action, or a description of the violation (Public Resources Code (PRC) Section 45019).

The RWQCB shall inspect a solid waste facility within 30 days of receipt of an enforcement action or proposed enforcement action from one of the above agencies if such action stems from a complaint concerning a solid waste facility and if a water quality violation is at issue (PRC Section 45020).

- If a RWQCB receives a complaint concerning a solid waste facility, which is not within its jurisdiction, it must refer the complaint to the appropriate state agency within 30 days (PRC Section 45021).
- If a RWQCB receives a complaint concerning a solid waste facility, either directly or by referral from another state agency, it shall either take appropriate enforcement action, refer the complaint to the Attorney General, the district attorney, or city attorney, whichever is applicable, <u>or</u> provide, within 60 days, to the person who filed the complaint a written explanation as to why enforcement action is not appropriate (PRC Section 45022).
- RWQCB enforcement activities at solid waste facilities shall comply with the following (PRC Section 45020):
  - Enforcement activities shall eliminate duplication and facilitate compliance.
  - Facility operators must be notified before an ACL is assessed.
  - Prior to assessing an ACL, and upon the request of a solid waste facility operator, the RWQCB must meet with the operator to clarify regulatory requirements and to determine how the operator could come into voluntary compliance. The

operator may request a meeting with all agencies involved in the enforcement matter.

- The RWQCB must consider the factors listed in PRC Section 45016 in determining the appropriate enforcement action.

VII. ACL Procedures

The following provisions apply only to ACLs and do not apply to mandatory minimum penalties required pursuant to California Water Code sections 13385(h) and (i).

The RWQCB must make two important decisions in specifying the conditions of an ACL. First is the determination of the total liability considering the factors in law. These factors are described in the stepwise approach in section VII (A) below. Second is the determination of the appropriate distribution of that liability between payments to the SWRCB's Cleanup and Abatement Account (CAA), Compliance Projects (CPs), and Supplemental Environmental Projects (SEPs). This distribution is explained in Section VII(B).

A. Determination of the Total Liability

The California Water Code requires that the determination of the total liability include the consideration of a number of factors. Prior to issuing a complaint the RWQCB Executive Officer shall consider each factor. This consideration shall be documented in a staff report. If the RWQCB issues an ACL Order, the order shall contain findings explaining the Board's consideration of the factors. The documentation of elements such as the economic benefit, staff costs and avoided costs are necessary for the appropriate distribution of the total liability.

The California Water Code lists a number of factors that must be taken into consideration when setting ACLs. California Water Code section 13327, governing ACL amounts for a wide variety of violations, states that:

> [The Board] shall take into consideration the nature, circumstance, extent, and gravity of the violation or violations, whether the discharge is susceptible to cleanup or abatement, the degree of toxicity of the discharge, and, with respect to the discharger, the ability to pay, the effect on ability to continue in business, any voluntary cleanup efforts undertaken, any prior history of violations, the degree of culpability, economic savings, if any, resulting from the violation, and other matters as justice may require.

California Water Code section 13385(e), governing ACL amounts for violations subject to the CWA, has slightly different language, stating that:

> [The Board] shall take into account the nature, circumstances, extent, and gravity of the violation, and, with respect to the discharger, the ability to pay, any prior history of violations, the degree of culpability, economic benefit or savings, if any, resulting from the violation, and other matters that justice may require. At a minimum,

liability shall be assessed at a level that recovers the economic benefits, if any, derived from the acts that constitute the violation.

The California Water Code does not specify how these factors are to be weighed or combined when setting the actual dollar amount of an ACL. This section describes the procedure to be used to set ACL amounts based on the facts of the case. The steps in the procedure are shown in Table VII-1. This procedure applies to ACLs issued under both California Water Code section 13327 and California Water Code section 13385(e). The RWQCB staff should carefully document each step in the staff report for the ACL. The manner in which the RWQCB considers these factors for any given situation is up to the discretion of the RWQCB.

Table VII-1. Procedure to set ACL amounts

Step	Procedure
A. **Initial Liability**	Set an initial liability based on the extent and severity of the violation and the sensitivity of the receiving water. An initial liability should also be calculated for non-discharge violations.
B. **Beneficial Use Liability**	If possible, estimate the dollar value of any impacts of the violation on beneficial uses of the affected waters.
C. **Economic Benefit**	Estimate the economic benefit to the discharger. Economic benefit is any savings or monetary gain achieved by not preventing the violation.
D. **Base Amount**	The Base Amount a single amount that is a result of combining the figures derived from the first 3 steps. For many ACLs, the base amount will be the addition of the initial liability from step A and the economic benefit from step C because the calculation of the beneficial use liability may not be appropriate. For those instances where it is appropriate to calculate the beneficial use liability (step B), the initial liability may be reduced to reflect the extent that the impact of the violation is covered by the value estimated in Step B. The base amount reflects the extent and severity of the violation, its impact on beneficial uses, and takes away any monetary gain from the discharger.
E. **Adjustment for discharger's conduct**	Determine factors to adjust the Base Amount with respect to the conduct of the discharger's history of violations and other considerations. Apply these factors to the Base Amount from step D
F. **Adjustment for other factors**	Determine whether any other factors should be taken into consideration when setting the ACL amount. If appropriate, adjust the figure from Step E to include these factors.
G. **Staff Costs**	Estimate the SWRCB and RWQCB staff costs resulting from the violation. If appropriate, add this cost to the figure determined from steps A through F.
H. **Adjustment for ability to pay**	If appropriate, increase or reduce the figure from Steps A through G with respect to the discharger's ability to pay.
I. **Check against statutory limits**	Check the figure from steps A through H against the statutory maximum and minimum limits.

1. Step A. Initial Liability

Set an Initial Liability based on the nature, circumstances, extent, and gravity of the violation. This may include the consideration of information such as the pollutants contained in a discharge, the volume of the discharge, the sensitivity of the receiving water and its beneficial uses, known, suspected or threatened toxicity, threats to human health and the volume of the receiving water relative to the discharge. The way that this amount is calculated will depend on the type of violation. For spills, effluent limitation violations, and similar violations, the initial water quality liability can be based on a per-gallon charge.

For non-discharge violations such as late reports, failure to submit reports, and failure to pay fees, this initial water quality liability should be set considering the impact on the RWQCB's ability to effectively administer its water quality programs. These impacts include, but are not limited to, additional RWQCB staff costs beyond the normally required effort and the potential consequences of delayed clean-up, coordination, mitigation and enforcement response by the RWQCB due to late or omitted reports.

2. Step B. Beneficial Use Liability

Review the designated beneficial uses of the receiving water and determine whether the violation has resulted in any quantifiable impacts related to beneficial uses. Examples of quantifiable impacts are beach closures, fish kills, and reductions in wildlife populations.

To the extent that information is available, estimate the value of these impacts. It will rarely be possible to assign a value to all impacts on beneficial uses. However staff should review available information on values related to beneficial use of the receiving water and develop estimates of the impacts of the violation on these values.

For example, when a violation has resulted in a beach closure, this value could be estimated from a value per-person-per-visit of beach use, an estimate of how much the degradation in water quality has reduced this value and an estimate of the extent that the closure has reduced attendance.

3. Step C. Economic Benefit

Economic benefit is any savings or monetary gain achieved by not preventing the violation. In cases when the violation occurred as truly no fault of the discharger and it was demonstrated that the discharger exercised due care, there may be no economic benefit. In cases where the violation occurred because the discharger postponed improvements to a treatment system, failed to implement adequate control measures such as Best Management Practices (BMPs) or take other measures needed to prevent the violations, economic benefit could be estimated as follows:

a. Determine the actions that should have been taken to avoid the violation. Needed actions may have been capital improvements to the discharger's treatment system, implementation of adequate BMPs or the introduction of procedures to improve management of the treatment system.

b. Determine when these actions should have been taken.

c. Estimate the cost of these actions. The avoided costs may include expenditures that should have been made for capital improvements, adequate staffing, training, and the development of procedures and practices. If the discharger is now committed to implementing the actions needed to bring the discharger into compliance, the current costs should not be considered as part of the economic benefit but should be considered under Step F, "Other Factors", for a Compliance Project. The discharger's use of the money should be considered as part of the economic benefit under the next step d. The avoided ongoing costs such as needed additional staffing from the time determined under step b to the present should also be included in the economic benefit calculation.

d. Determine the value for use of the money. Convert the avoided costs to a present value at the time that the ACL is issued. This calculation reflects the fact that the discharger has had the use of the money that should have been used to pay to improve the treatment system. This calculation shall be done using the current version of USEPA's BEN computer program (the most recent version is accessible at http://www.swrcb.ca.gov/water_laws/index.html).

e. Determine whether the discharger has gained any other economic benefits. These may include income from continuing in production when equipment used to treat discharges should have been shut down or increased revenues gained as a result of competitive advantage.

f. The RWQCBs should not adjust the economic benefit for monetary efforts made by the discharger to abate the effects of the discharge.

On a case by case basis and to the extent that the information is available these figures should be estimated and used to calculate economic benefit. Any compound interest calculations must be done using USEPA's BEN computer program which is available at http://www.swrcb.ca.gov.

4. Step D. Base Amount

The Base Amount is the sum of the Initial Liability or the Beneficial Use Liability or a combination of the Initial Liability and the Beneficial Use Liability and the Economic Benefit. When it is appropriate to calculate the Beneficial Use Liability, the RWQCBs should assess the extent to which the Beneficial Use Liability represents the entire harm resulting from the violation. The RWQCBs may, at their discretion, find it appropriate to combine the amounts from Steps A and B in a way that reflects the significance of the impacts quantified in Step B relative to the total impacts of the violation.

The way that the Initial Liability and the Beneficial Use Liability should be combined will depend on how the violation harms the beneficial uses of the receiving waters and the extent to which this harm has been quantified. For example, a sewage spill will typically result in a wide variety of impacts, such as fish kills, degradation of wildlife habitat, and beach closures. For a sewage spill to the ocean in an urban area with high beach use, impacts on beach recreation may represent most of the harm resulting from the spill. If it is possible to estimate the value of the lost beach recreation in step B, it is appropriate to take this value and add it to some portion of the Initial Liability amount to reflect the total impact.

For a sewage spill contaminating a beach in a remote area, where beach use is relatively low, impacts on beach use are less important than other impacts, such as degradation of wildlife habitat and harm to a pristine environment. In such a case, the combined liability (steps A and B) should be based more heavily on the Initial Liability, because the impacts quantified in step B are less significant relative to the entire impacts of the violation.

Next, add the liability from steps A and/or B to the economic benefit from Step C to give the Base Amount. This calculation gives an amount that is the minimum appropriate to the violation. It reflects the nature, circumstances, extent, and gravity of the violation, and its impact on beneficial uses including toxicity, while taking away any economic benefit or savings to the discharger considering any expenditures associated with voluntary cleanup if appropriate.

5. Step E. Conduct of the Discharger

The Base Amount from Step D must then be adjusted to reflect the conduct of the discharger. This adjustment reflects factors such as the degree of culpability of the discharger, any voluntary cleanup efforts undertaken and the discharger's history of violations. This adjustment can be made by determining values for the four factors in Table VII-2, and using them to determine a conduct factor that is applied to the Base Amount. The RWQCB may apply the various conduct factors using percentages. A percentage less than 100 percent may be appropriate for a discharger that made exemplary efforts such as voluntary cleanup. Percentages greater than 100 percent are appropriate for dischargers that demonstrated less than exemplary behavior such as delaying notification of a spill. Large multiplier percentages 200 - 500 percent may be appropriate for cases involving falsification of data or other deliberate acts. This calculation is:

$$ACL = Base\ Amount \times CF1 \times CF2 \times CF3 \times CF4$$

Table VII-2. Conduct Factors to adjust ACLs

Factor	Adjustment for
Control Factor (CF1)	Amount of control that the discharger had over the discharge
Notification Factor (CF2)	Extent to which the discharger reported the violation as required by law or regulation.
Cooperation Factor (CF3)	Extent to which the discharger cooperated in returning to compliance and correcting environmental damage, including any voluntary cleanup efforts undertaken.
History factor (CF4)	Previous violations

6. Step F. Other Factors

If it is determined that there were avoided capital costs under the calculation of economic benefit and that the discharger is committed to take the necessary actions, the RWQCB may include the amount of those costs under "other factors" in the ACL. The RWQCB can also suspend that amount contingent upon implementation of a Compliance Project.

If the RWQCB believes that the amount determined using Steps A through E is inappropriate, the amount may be adjusted. Examples of circumstances warranting an adjustment under this step are:

- The discharger publicized the violation and the subsequent enforcement actions in a way that encourages others to violate water quality laws and regulations.
- The threat to human health or the environment was so egregious that the preceding factors did not, in the opinion of the RWQCB, adequately address this violation.

If such an adjustment is made, the reasons for the extent and direction of the adjustment must be noted in the administrative record.

7. Step G. Staff Costs

Staff costs are one of the "other factors that justice may require", and should be estimated when setting an ACL. Staff should estimate the cost that investigation of the violation and preparation of the enforcement action(s) has imposed on state government agencies. Staff costs should be added to the amount calculated from the previous steps.

8. Step H. Ability to Pay

The procedure in Steps A through G gives an amount that is appropriate to the extent and severity of the violation, economic benefit and the conduct of the discharger. This amount may be reduced or increased based on the discharger's ability to pay.

The ability of a discharger to pay an ACL is limited by its revenues and assets. In most cases, it is in the public interest for the discharger to continue in business and bring operations into compliance. If there is strong evidence that an ACL would result in widespread hardship to the service population or undue hardship to the discharger, it may be reduced on the grounds of ability to pay. The RWQCBs may also consider increasing an ACL to assure that the enforcement action would have a similar deterrent effect for a business or public agency that has a greater ability to pay.

a. Businesses

Normally, an ACL should not seriously jeopardize the discharger's ability to continue in business. The discharger has the burden of proof of demonstrating lack of ability to pay and must provide the information needed to support this position. This adjustment can be used to reduce the ACL to the highest amount that the discharger can reasonably pay and still bring operations into compliance. The downward adjustment for ability to pay must be made only in cases where the discharger is cooperative and has the business ability and the intentions to bring operations into compliance. If the violation occurred as a result of deliberate or malicious conduct, or there is reason to believe that the discharger can not or will not bring operations into compliance, the ACL must not be adjusted for ability to pay.

The RWQCBs may also consider increasing the ACL because of a business's ability to pay. RWQCBs should consider other ACLs for similar violations taken elsewhere in the Region or the State and adjust the amount up or down according to a discharger's ability to pay. This type of adjustment may serve to "level the playing field". For example, in order to have an equivalent deterrent effect for similar violations, the ACL for a Fortune 500 company should be significantly greater than one for a small business.

b. Public Agencies

ACLs paid by cities, sanitation districts and other public agencies are ultimately paid by their service populations, usually by taxes or user fees. The RWQCB may consider adjusting the total liability for cases of hardship or increasing the ACL if the agency has a large rate base and it is appropriate to increase the ACL to assure a similar deterrent effect for similar violations.

9. Step I. Statutory Maximum and Minimum Limits

The ACL must be checked against the statutory maximum and minimum limits to ensure that it is in compliance with the appropriate section of law. The maximum amount for an ACL issued under California Water Code section 13385 is $10,000 for each day in which a violation occurs plus $10 per gallon for amounts discharged but not cleaned up in excess of 1,000 gallons. The statutory maximum amounts for ACLs issued under California Water Code section 13261 are summarized in Table IV-1.

California Water Code section 13385, which applies to discharges regulated pursuant to the CWA, was amended effective January 1, 2000 to state that "At a minimum, liability shall be assessed at a level that recovers the economic benefits, if any, derived from the acts that constitute the violation". Therefore, for such violations occurring on or after January 1, 2000, the minimum amount for an ACL is the economic benefit.

It is the policy of the SWRCB that all ACLs shall be assessed at a level that recovers the economic benefit.

B. Distribution of an ACLs Liability

An ACL action may distribute the total, proposed liability determined above to three types of discharger-expenditures: implementation of CPs; implementation of SEPs; and cash payments to the State Cleanup and Abatement Account, including staff costs. If the

ACL action distributes liability to CPs or SEPs, it shall document that the amount of liability suspended is equal to the cost of implementing the CPs and/or SEPs and shall specify the date on which the CPs and/or SEPs are to be completed. The ACL action shall specify the amount of liability that shall be immediately due to the State Cleanup and Abatement Account. The cash liability shall, at a minimum, include the staff costs associated with the investigation of the violations and preparation of the ACL.

1. Compliance Projects (CPs)

ACL actions are intended to address past violations. If the underlying problem has not been corrected, the cost of returning to compliance constitutes an avoided cost (and thus an economic benefit) until the necessary improvements are actually implemented. Under these circumstances, the RWQCB may suspend a portion of the liability to compel future work by the discharger to address problems related to the violation. Compliance Projects (CPs) are projects designed to bring the discharger back into compliance in a timely manner.

a. Examples of CPs

CPs may include construction of new facilities, upgrade or repair of existing facilities, adding staff, training, studies, and the development of procedures.

b. CP Qualification Criteria

1) CPs are projects that are designed to bring the discharger back into compliance in a timely manner.
2) CPs are not SEPs
3) CPs shall have clearly identified project goals, costs, milestones, and completion dates and these shall be specified in the ACL action.

c. ACL Actions Allowing CPs

1) Either the RWQCB or the discharger may recommend specific CPs that could be included in the ACL action.
2) The ACL action shall only suspend the portion of the total liability contingent upon completion of a CP(s) that is equal to the discharger's economic benefit of the avoided costs.
3) CPs that are greater than one year shall have at least annual reporting requirements.
4) If the discharger expends at least the amount suspended and completes the CP by the specified date, the suspended amount is permanently suspended.
5) If the CP is not completed on the specified date the amount suspended becomes due and payable to the CAA.

2. Supplemental Environmental Projects (SEPs)

Supplemental Environmental Projects (SEPs) are projects that enhance the beneficial uses of the waters of the State, provide a benefit to the public at large, and that, at the time they are included in an ACL action, are not otherwise required or would be greatly accelerated by implementing the project. California Water Code section 13385(h)(3) allows limited use of SEPs associated with mandatory minimum penalties. In addition, the SWRCB supports the inclusion of SEPs in ACL actions, so long as these projects meet the criteria listed below.

a. <u>Examples of Supplemental Environmental Projects</u>

- Pollution Prevention
- Environmental Restoration (e.g., projects that involve the restoration or enhancement of wildlife and aquatic habitat)
- Environmental Auditing (e.g., projects that involve studies relevant to the discharge)
- Public Awareness (e.g., industry specific, public-awareness activity, or community environmental education projects such as watershed curriculum, brochures, television public service announcements, etc.)
- Watershed Assessment (e.g., citizen monitoring coordination and facilitation)
- Watershed Management Facilitation Services
- Non-Point Source Program Implementation

b. <u>SEP Qualification Criteria</u>

- An SEP should only consist of measures that go above and beyond the obligation of the discharger. For example, sewage pump stations should have appropriate reliability features to minimize the occurrence of sewage spills in that particular collection system. The installation of these reliability features following a pump station spill would not qualify as an SEP.
- The SEP should lead to improved water quality and enhanced support of beneficial uses of waters of the State.
- The SEP shall not directly benefit the SWRCB or RWQCB functions or staff. For example, SEPs shall not be gifts of computers, equipment, etc. to the SWRCB or RWQCB.
- The SEP shall not be an action, process or product that is ***required*** by any rule or regulation of any entity (e.g., local government, California Coastal Commission, United States Environmental Protection Agency, United States Army Corps of Engineers, etc.).
- The SEP shall contain specific performance standards, including milestones for achievement, and identified measures or indicators of performance. The ACL action shall specify that the discharger shall meet these standards, milestones and indicators.
- The SEP should, when appropriate, include documented support by other resource agencies, public groups and impacted persons.

- The SEP should, when appropriate, document that the project complies with the California Environmental Quality Act.

c. <u>ACL Actions Allowing SEPs</u>

- [For all ACL actions pursuant to any relevant California Water Code section other than Section 13385.] The discharger may propose to conduct an SEP in exchange a portion of the proposed liability, exclusive of the amount specified for a CP, in the ACL action. If the discharger opts to perform a SEP, the ACL action shall require the discharger to pay the remainder proposed liability, exclusive of the amount specified for a CP, to the State Cleanup and Abatement Account.
- The ACL action shall require the discharger to provide at least one progress report to the SWRCB or RWQCB at the completion of the SEP.
- The ACL action shall require the discharger to provide the RWQCB a post-project accounting of expenditures.
- If an SEP is accepted in an ACL action, the discharger shall hire an independent management company, which reports solely to the RWQCB, to audit implementation of the SEP. The company shall evaluate compliance with performance measures and make recommendations to the RWQCB about the successful completion of the SEP prior to the deadline(s) to complete.
- If the final cost of the successfully completed SEP is less than the amount suspended for completion of the SEP in the ACL action, the discharger shall remit the difference to the State Cleanup and Abatement Account.
- If the SEP is not successfully completed by the date specified in the ACL action, the discharger shall pay the amount that was suspended to the State Cleanup and Abatement Account.
- If the discharger successfully completes the SEP in a time specified, the portion suspended for the SEP will be permanently suspended.
- Because the RWQCB loses the ability to amend an ACL order, the ACL order shall contain reasonable milestones and compliance dates and the RWQCB should consider including a force majeure clause.

d. <u>Public Process</u>

The SWRCB will establish procedures to develop lists of candidate projects. The list of candidate projects shall be made available on the Internet in the form of a database containing information on candidate projects, completed projects, and in-progress projects. At a minimum, the RWQCBs shall provide public notice of adoption of ACLs Orders that include SEPs. In cases where the ACL includes a SEP and covers violations of the CWA, the RWQCBs shall provide a period for public comment prior to adoption. All ACL complaints that have been settled by the Executive Officer, with or without SEPs, shall be placed as an information item on the next, feasible agenda for the RWQCB.

VIII. DISCHARGER SELF-AUDITING

It is desirable to encourage self-auditing, self-policing, and voluntary disclosure of environmental violations by dischargers. Such self-auditing and voluntary disclosure of violations shall be considered by the Boards when determining enforcement actions and in appropriate cases may lead to a determination to forego or lessen the severity of an enforcement action. Falsification or misrepresentation of such voluntary disclosures shall be brought to the attention of the appropriate RWQCB for possible enforcement action.

IX. ENFORCEMENT REPORTING BY RWQCBS

In order to ensure greater consistency in the reporting by the RWQCBs on violations and enforcement actions, the enforcement reports for all Regions will be standardized. These reports will include a listing of facilities with a water quality violation during the reporting period or unresolved from a previous reporting period, including violations without a RWQCB response. This listing shall include at least the following information:

- The date of violation;
- An identification whether the violation is considered to be significant (see Section III);
- The RWQCB response, if any;
- The date of the response;
- The corrective action taken by the discharger, at least in cases of significant violations; and
- A listing of all previous violations for the facility which occurred in the previous 12 months and the associated RWQCB response.

The enforcement reports will be presented to the RWQCBs on an interval no greater than quarterly. The report format will be the format that is produced by the State Water Information Management (SWIM) data system and the RWQCBs will utilize the SWIM data system to track and monitor their violations and enforcement activities. Utilization of the SWIM data system by the Regions is essential in order for the SWRCB to comply with California Water Code section 13385 (m) which requires statewide reporting of violations to the Legislature.

A. Summary Violation and Enforcement Reports

All RWQCBs shall produce standard quarterly reports addressing significant violations. The SWRCB will specify the format of the summary reports.

B. Spill Reporting

All spills shall be entered into the Sanitary Sewer Overflow/Spills Module of the SWRCB's SWIM data system. In order to achieve consistent reporting of spills from regulated discharges all new and revised requirements and permits shall at a minimum contain the language requiring reporting of spills consistent with Table IX-1 below.

SUMMARY OF SPILL REPORTING REQUIREMENTS
TABLE IX-1

TYPE	VOLUME	DISCHARGE POINT	REPORTING PERIOD
Sewage	any	Waters of U.S./Impairment of Use	ASAP, but no more than 24 hours
Sewage	< 1000 Gals.	Soil	Quarterly
Sewage	=>1000 Gals.	Soil	ASAP, but no more than 24 Hours
Hazardous Materials	Any	Waters of U.S.	ASAP, but no more than 24 hours
Hazardous Materials	Any amount that poses a threat to beneficial uses.	Soil	ASAP, but no more than 24 hours
Oil	Any amount that produces a sheen.	Waters of U.S.	ASAP, but no more than 24 Hours
Non-hazardous materials (e.g., dirt, winery wastes, non-hazardous leachate, etc.)	Any amount that poses a threat to beneficial uses.	Soil or waters of the U.S.	Quarterly

X. POLICY REVIEW AND REVISION

It is the intent of the SWRCB that this policy be reviewed and revised, as appropriate, at least every five years.

OFFICE OF WATER QUALITY TECHNICAL MEMORANDUM NO. 2001.03
OFFICE OF SURFACE WATER TECHNICAL MEMORANDUM NO. 2001.03

Subject: Collection and Use of Total Suspended Solids Data

USGS Policy on Collection and Use of Total Suspended Solids Data:

1. The use of Total Suspended Solids data (TSS, parameter code 00530) resulting from the analysis of water samples to determine the concentration of suspended material in water samples collected from open channel flow and calculations of fluxes based on these data is not appropriate. Collection of samples to determine TSS requires concurrent collection of samples for suspended sediment concentration (SSC) analysis. Concurrent SSC analysis can only be discontinued after it is conclusively documented in a published report that the TSS data, on a site-by-site basis, can adequately represent SSC data over the whole range of flows that can be expected.

2. The SSC analytical method, ASTM D 3977-97, Standard Test Method for Determining Sediment Concentration in Water Samples (ASTM, 1999), is the USGS standard for determining concentrations of suspended material in surface water samples. This method is used by all USGS sediment laboratories, and by cooperating laboratories certified to provide suspended-sediment data to the USGS.

Background:

An important measure of water quality is the amount of material suspended in the water. The USGS has traditionally used measurements of suspended-sediment concentration as the most accurate way to measure the total amount of suspended material in a water sample collected from the flow in open channels. Another commonly used measurement of suspended material is the TSS analytical method. This method was originally developed for use on wastewater samples, but has been widely used as a measure of suspended material in stream samples because it is mandated or acceptable for regulatory purposes and is an inexpensive laboratory procedure. Using the TSS analytical method (parameter code 00530) to determine concentrations of suspended material in open channel-flow can result in unacceptably large errors and is fundamentally unreliable.

Summary of Recent Studies:

Studies on the accuracy of the SSC analytical method by ASTM (1999) and the USGS Branch of Quality Systems (Gordon and others, 2000) have shown that the SSC analysis represents an accurate measure of the concentration of the suspended sediment in a sample. Other measurements such as TSS, turbidity, and data obtained from optical backscatter instruments are often used as surrogates for suspended sediment and are often less expensive to collect and (or) analyze and some may be collected on a near-continuous basis. However, proper use of these surrogate measurements of suspended material requires that a relationship between SSC and the surrogate be defined and documented for each site at which the data are collected.

Differences between the TSS and SSC analyses were investigated using 3,235 paired TSS and SSC samples provided by eight USGS Districts (Gray and others, 2000), and with 14,466 data pairs from the USGS's NWIS data base (Glysson and others, 2000). The findings of these studies can be summarized as follows:

1. The TSS analysis is normally performed on an aliquot of the original sample. The difficulty in withdrawing an aliquot from a sample that truly represents suspended material concentration leads to inherent variability in the measurement. By contrast, SSC analysis is performed on the entire sample, thus measuring the entire sediment mass. If a sample contains a substantial percentage of sand-size material - more than about 25 percent - then stirring, shaking, or otherwise agitating the sample before obtaining a subsample will rarely produce an aliquot representative of the suspended material and particle-size distribution of the original sample.

2. TSS methods and equipment differ among laboratories, whereas SSC methods and equipment used by USGS sediment laboratories are consistent, and are quality assured by the National Sediment Laboratory Quality Assurance Program (OSW Technical Memorandum 98.05; Gordon and others, 2000).

3. Results of the TSS analytical method tend to produce data that are negatively biased by 25 to 34 percent with respect to SCC analyses collected at the same time and can vary widely at different flows at a given site. The biased TSS data can result in errors in load computations of several orders of magnitude.

Analysis of paired data for TSS and SSC (Glysson and others, 2000) indicates that in some cases, it might be possible to develop a relation between SSC and TSS at a given site. At least 30 paired sample points, evenly distributed over the range of concentrations and flows encountered at the site, would be needed to define such a relationship. There is no reliable, straightforward way to adjust TSS data to estimate suspended sediment without corresponding SSC data.

Because the TSS analytical method is widely used outside of the USGS for the determination of suspended-material concentrations in water samples for open channel flow, and because the TSS analysis is specified in several States' water-quality criteria standards for sediment, it would be appropriate for USGS District offices to share this information with their cooperators. The Offices of Water Quality and Surface Water are passing this information on to the U.S. Environmental Protection Agency's Office of Water and to other Federal agencies that are involved in using sediment data. For questions or additional information, contact Doug Glysson (OWQ, gglysson@usgs.gov) or John Gray (OSW, jrgray@usgs.gov).

EXECUTIVE SUMMARY
LOS ANGELES REGIONAL WATER QUALITY CONTROL BOARD WATERSHED MANAGEMENT INITIATIVE CHAPTER
December 2000

OVERVIEW

Water resource protection efforts of the State Water Resources Control Board and the Regional Water Quality Control Boards are guided by a five year Strategic Plan (last updated in 1997). A key component of the Strategic Plan is to utilize a watershed management approach for water resources protection.

To protect water resources within a watershed context, a mix of point and nonpoint source discharges, ground and surface water interactions, and water quality/water quantity relationships must be considered. These complex relationships present considerable challenges to water resource protection programs. The State and Regional Boards are responding to these challenges within the context of our organization's Watershed Management Initiative (WMI). The WMI is designed to integrate various surface and ground water regulatory programs while promoting cooperative, collaborative efforts within a watershed. It is also designed to focus limited resources on key issues and use sound science.

Previously, State and Regional Board programs tended to be directed at site-specific problems. This approach was reasonably effective for controlling pollution from point sources. However, with diffuse nonpoint sources of pollutants, a new regulatory strategy was needed. The WMI uses a strategy to draw solutions from all interested parties within a watershed, and to more effectively coordinate and implement measures to control both point and nonpoint sources.

For the initial implementation of the WMI, during the late 1990s, each Regional Board identified the watersheds in their Region, prioritized water quality issues, and developed watershed management strategies. These strategies and the State Board's overall coordinating approach to WMI are contained in the *Integrated Plan for Implementation of the WMI* which is updated annually. In following years, the Regional Boards have continued to build upon their early efforts to utilize this approach. The full version of our WMI Chapter outlines our ongoing efforts to continue implementation of the WMI.

The Los Angeles Regional Board and Watershed Management

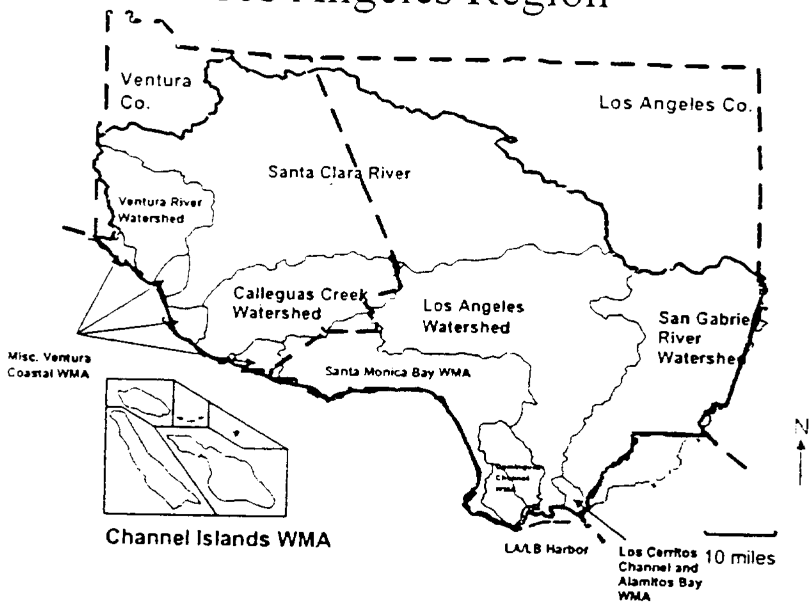
The Los Angeles Region has jurisdiction over all coastal drainages flowing to the Pacific Ocean between Rincon Point (on the coast in western Ventura County) and the eastern Los Angeles County line, as well as the drainages of five coastal islands (Anacapa, San Nicolas, Santa Barbara, Santa Catalina, and San Clemente). The Regional Board's jurisdiction also includes all coastal waters within three miles of the continental and island coastlines.

The Los Angeles Region is the State's most densely populated and industrialized region. Over 1,000 discharges of wastewater from point sources in this Region are regulated by the Los Angeles Regional Board. Over 700 of these point source discharges are discharged to surface waters, and are regulated under the National Pollutant Discharge Elimination System (NPDES). In addition, the Regional Board prescribes Waste Discharge Requirements (WDRs) for the remaining discharges, which are primarily to ground waters and landfills. However, the quality of many waters continue to be degraded from pollutants discharged from diffuse and diverse nonpoint sources. Future success in reducing pollutants from nonpoint sources and achieving additional reductions in pollutants from point sources requires a shift to a more geographically-targeted approach.

Our watershed management approach integrates activities across the Regional Board's many diverse programs, particularly permitting, planning, and other surface-water oriented programs which have tended to operate somewhat independent of each other. This approach enables us to better assess cumulative impacts of pollutants from all (point and nonpoint) sources, and more efficiently develop watershed-specific solutions that balance the environmental and economic impacts of our actions.

We have designated ten watershed management areas in the Los Angeles Region as shown in the figure below.

Watershed Management Areas of the Los Angeles Region



Initially, implementation of watershed management in the Los Angeles Region occurred in phases over a seven-year cycle for our pilot watersheds Ventura River and Calleguas Creek. We are now shifting to a five-year cycle to be in line with the standard permit life (of an NPDES permit) and to equalize workloads over the years. This shift in our watershed cycle is illustrated in the table on the next page. The majority of permit-related tasks such as permit renewals/revisions and regional monitoring program development as well as preparation of state of watershed reports, will occur during the first approximately twelve months of the watershed's five-year cycle. Much of the rest of the five-year cycle will be spent developing and implementing, with the input of stakeholders, measures for management of more complex pollutants from point and/or nonpoint sources. Many of the region's TMDLs will be implemented during the second cycle of permit renewals.

It should be pointed out that the involvement of stakeholders is critical to the success of watershed management; however, the process to involve stakeholders demands more of regulators in terms of public outreach, education, and consensus building.

Permit Timeline for Watershed Management Initiative

Santa Clara River Calleguas Creek	FY 2001/02
Dominguez Channel-LA/LB Harbor	FY 2002/03
Santa Monica Bay	FY 2003/04
Los Angeles River	FY 2004/05
San Gabriel River Los Cerritos Channel Channel Islands	FY 2005/06
Ventura River Misc. Ventura Coastal Santa Clara River Calleguas Creek	FY 2006/07
Dominguez Channel-LA/LB Harbor	FY 2007/08

NPDES permits in the Los Angeles Region are organized and scheduled by watershed. This workload must be integrated with that required under backlog reduction efforts or other regulatory or legislative requirements. Preliminary "State of the Watershed Reports" are prepared by watershed "teams" composed of permit writers, planning, TMDL, and nonpoint source program personnel, and those involved with groundwater protection.

The Watershed Management Initiative Chapter

This document is the fifth iteration of what we call our "Chapter" which is our Region's chapter of the WMI document for the whole state. The participants in implementation of the WMI in California (the nine Regional Boards, State Board, and USEPA) were asked in 1996 to begin preparation of a document which identified priorities and resource needs, across programs, in a watershed context. The Chapter is currently used both as an outreach and as a planning tool to identify the Region's priorities over the upcoming two fiscal years (FYs) and where we should spend our baseline resources, as well as where we need additional resources. The Chapter is organized into sections including the Introduction, Watershed Sections, and Region-wide Section. Included in each Watershed Section is an overview of that watershed, a description of its water quality concerns and issues, past significant Regional Board activities in the watershed, current (funded) activities, near-term (usually unfunded) activities that would benefit the watershed, and activities which may happen on a longer time-scale (usually unfunded). The Region-wide Section includes a description of activities not easily associated with particular watersheds.

Programs and Funding Under WMI

Programs covered under WMI include core regulatory (e.g., NPDES), monitoring and assessment, basin planning and water quality standards, watershed management, wetlands, TMDLs, 401 certifications, groundwater (as appropriate), and nonpoint source management activities (many of these programs also have region-wide components). It turns out most of our highest priority needs fall into areas that have little to no funding. **Areas with particular shortages include nonpoint source management (e.g., we see a need for an additional 14.0 PYs for FY00/01)**, CEQA review, monitoring and assessment, basin planning, **401 certifications (the statewide needs analysis from FY 00/01 indicated a shortfall** of 13.9 PYs), stormwater, and more than minimal work on NPDES pretreatment, enforcement, compliance, and monitoring report review. A majority of any additional monies that may become available would be dedicated to these programs in the targeted watersheds (then non-targeted watersheds) as well as allocated to upcoming TMDLs occurring throughout the Region. **For example, in FY00/01, we see a need for an additional 8.8 PYs to conduct TMDL work**. This watershed effort, which itself has

R0026533

consumed a lot of limited staff resources, will hopefully result in resource flexibility and augmentation to address these deficiencies.

Integration of Multiple Mandates Under WMI

While the Watershed Management Initiative strives to integrate and coordinate the various Regional and State Board programs and address the highest priority funding needs for those programs, there is also need to respond to and accommodate priorities established by the individual Regional and State Boards' members, priorities established prior to the WMI which run on their own timelines, legal or legislative mandates, or other new mandates which may affect the way the WMI is implemented in a Region. It is important to re-state here that the WMI is not a new program but rather a way to describe our approach to integrating existing and newly evolving programs and mandates.

For example, a high priority statewide mandate is management of nonpoint source pollution. High priority Regional Board activities include implementation of an effective enforcement strategy, development of a septic tank policy initiative, development and implementation of a strategy to assess nonpoint source loadings TMDLs, and better communication and coordination of Board programs and policies through improved outreach. More information is included in the Introduction of the full chapter. It is clear many of the Regional Board high priority activities are of primary importance in fulfilling not only the WMI but also the nonpoint source management initiative and other mandates.

However, some mandates present challenges to fully implementing watershed management. These include recent USEPA, State Board, and legislative requirements for reducing permit backlog, conflicts with the timing of scheduled TMDLs, lengthy delays incurred by the public processes e.g., hearings, workshops), ands insufficient funding or staff.

SUMMARY OF SIGNIFICANT WATERSHED ISSUES

The Region encompasses ten Watershed Management Areas (WMAs) which are the geographically-defined watershed areas where the Regional Board implements the watershed approach. These generally involve a single large watershed, within which exists smaller subwatersheds. However, in some cases they may be an area that does not meet the strict hydrologic definition of a watershed (e.g., several small Ventura coastal waterbodies in the region are grouped together into one WMA). Watersheds in the strictest sense are geographic areas draining into a river system, ocean or other body of water through a single outlet and includes the receiving waters. They are usually bordered, and separated from other watersheds, by mountain ridges or other naturally elevated areas.

Many of the watersheds in this Region range over large areas that are highly diverse. A Designated Wilderness Area may occur in one part of a watershed while extensive development dominates another part and possibly agriculture in yet different area of the watershed. This fact results in a great diversity of issues of concern to this agency in any particular watershed with the concomitant need to balance priorities among existing stakeholders. The following summarizes significant watershed issues in our watershed management areas. More detail may be found by consulting the full version of the WMI Chapter.

Watershed Management Areas
Significant Watershed Issues

1) Ventura River Watershed
- Eutrophication, especially in estuary
- TDS concerns in some subwatersheds
- One major discharger (POTW)
- Industrial storm water – 27 dischargers
- Impediments (dams, diversions) to steelhead trout migration
- Impairments: DDT, algae, diversions, selenium, other metals, trash
- Currently scheduled TMDLs: eutrophication FY04/05

2) Miscellaneous Ventura Coastal WMA
The harbors
- Accumulation of metals, PCBs, and historic pesticides in sediment and tissue
- Considerable marine life subject to impacts
- Impairments: DDT, PCBs, PAHs, metals, TBT, coliform
- Currently scheduled TMDLs: zinc FY04/05

The wetlands and coast
- Historic pesticide contamination
- Loss of quality habitat
- Impacts from oil spills and agriculture
- Use by endangered species
- Impairments: historic pesticides and effects, coliform
- Currently scheduled TMDLs: coliform FY01/02

3) Santa Clara River Watershed
- High quality natural resource
- Four POTWs
- Industrial storm water – 103 dischargers
- Construction storm water – 310 dischargers
- Impacts from exotic vegetation
- Impacts from agriculture
- Increasing urbanization, flows, and channelization in upper watershed; impacts on middle and lower watershed
- Impairments: nitrogen and effects, salts, coliform, trash, historic pesticides
- Currently scheduled TMDLs: chloride FY01/02, nitrogen FY02/03, eutroph. and trash FY04/05, coliform FY05/06

4) Calleguas Creek Watershed
- Six POTWs
- Industrial storm water – 82 dischargers
- Construction storm water – 100 dischargers
- Highly modified watershed
- Impacts from agriculture and naval facility
- Sediment inputs to Mugu Lagoon, one of the largest wetlands in southern California
- Competing urban uses; development pressures, particularly in upper watershed
- Severe lack of benthic and riparian habitat in watershed
- Impairments: nitrogen and effects, water-soluble pesticides and effects, salts, historic pesticides, PCBs, siltation, selenium, mercury, other metals, trash
- Currently scheduled TMDLs: chloride FY00/01, nitrogen FY01/02, other salts and water-soluble pesticides FY03/04, PCBs and historic pesticides FY04/05, metals FY05/06

5) Dominguez Channel/LA-LB Harbor WMA
- One POTW, two generating stations, six refineries
- Industrial storm water – 415 dischargers
- Historical deposits of DDT and PCBs in sediment
- Discharges from POTW & refineries
- Spills from ships and industrial facilities
- Leaching of contaminated groundwater
- Stormwater runoff
- Impairments: metals, PCBs, PAHs, historic pesticides, coliform, trash, nitrogen
- Currently scheduled TMDLs: coliform FY01/02

6) Santa Monica Bay WMA
- Key recreational resource (beaches)
- Three POTWs, one refinery, and three generating stations
- 21 minor discharges
- General permits – 166 dischargers
- Industrial storm water – 147 dischargers
- Construction storm water – 107 dischargers
- Impairments: mercury, selenium, other metals, historical pesticides, PAHs, PCBs, nitrogen, coliform, trash, TBT, habitat alteration, exotic vegetation, salts

Coastline
- Acute health risk associated with swimming in runoff-contaminated surfzone waters
- Chronic risk associated with consumption of seafood in areas impacted by DDT and PCB contamination
- Reduction of loadings from the two major POTWs in light of projected population increases
- Other impacts from urban runoff/storm water
- Historic deposits of DDT and PCBs in sediment
- Loadings of pollutants from other sources: sediment resuspension, atmospheric deposition
- The need to have a better understanding of the Bay's resources
- Currently scheduled TMDLs: coliform FY01/02; metals FY03/04; chlordane FY05/06

Malibu Creek Watershed
- Excessive freshwater, nutrients, and coliform in lagoon; contributions from POTW and other sources
- Urban runoff from upper watershed
- Impacts to swimmers/surfers from lagoon water
- Septic tanks in lower watershed
- Appropriate restoration and management of lagoon
- Access to creek and lagoon by endangered fish
- Currently scheduled TMDLs: nutrients and coliform FY01/02

Ballona Creek Watershed
- Trash loading from creek
- Wetlands restoration
- Sediment contamination by heavy metals from creek to Marina del Rey Harbor and offshore)
- Toxicity of both dry weather and storm runoff in creek
- High bacterial indicators at mouth of creek
- Currently scheduled TMDLs: trash FY00/01, coliform FY02/03PCBs and pesticides FY03/04 and 04/05, metals FY03/04 and 04/05

R0026535

7) Los Angeles River Watershed

- Six major NPDES dischargers (four POTWs)
- 30 minor permits
- 109 dischargers covered by general permits
- Industrial storm water – 1,327 dischargers
- Construction storm water - 147 dischargers
- Nitrogen and coliform contributions from septic systems
- Other nonpoint sources (horse stables, golf courses)
- Cross-contamination between surface and groundwater
- Protection and enhancement of fish and wildlife habitat and recreational areas
- Removal of exotic vegetation
- Balancing removal of vegetation for flood control with the need for urban habitat
- Attaining a balance between water reclamation and minimum flows to support habitat
- Leakage of MTBE from underground storage tanks
- Contaminated sediments within the LA River estuary
- Impairments: nitrogen, trash, selenium, other metals, coliform, PCBs, historic pesticides, chlorpyrifos
- Currently scheduled TMDLs: trash 00/01, nitrogen and coliform FY01/02, metals FY03/04, historic pesticide FY05/06

8) San Gabriel River Watershed

- Eight major NPDES dischargers (five POTWs)
- 23 minor permits
- 65 discharges covered under general permits
- 549 dischargers covered under an industrial storm water permit
- 175 dischargers covered under a construction storm water permit
- Sluicing and disposal of sediments from reservoirs
- Protection of groundwater recharge areas
- Ambient toxicity
- Excessive trash in recreational areas of upper watershed
- Mining/stream modifications
- Extensive stream modification for mining and water reclamation
- Urban and storm water runoff quality
- Nonpoint source loadings from nurseries and horse stables
- Lack of understanding of estuary dynamics (e.g. salinity profile)
- Septic systems
- Impairments: nitrogen and effects, trash, metals, historic pesticides, coliform, chlorides, PCBs
- Currently scheduled TMDLs: trash (completed), nitrogen (river) and coliform FY02/03; metals FY04/05, nitrogen (lakes) FY03/04; PCBs & pest. FY05/06

9) Los Cerritos Channel/Alamitos Bay WMA

- Four minor dischargers
- Loss of wetlands habitat in Los Cerritos area
- Impacts from antifouling paint in marinas
- Urban and storm water runoff impacts on isolated water bodies
- Loss of tidal exchange
- Impairments: ammonia, metals, historic pesticides and effects, PCBs, PAHs
- Currently scheduled TMDLs: coliform, ammonia, metals, PAHs, historic pesticides FY04/05

10) The Channel Islands WMA

- Five islands
- One major discharger, four minor dischargers
- Areas offshore of islands designated as Areas of Special Biological Significance
- High quality marine and rocky intertidal habitat
- Heavy use by marine mammals and endangered species
- No known impairments
- Lack of information on water quality

SUMMARY OF REGIONWIDE ACTIVITIES

There are many activities conducted at the Region which do not apply to a specific watershed; instead they represent ongoing regionwide strategies and policies, or programs which are not directly linked to the rotating watershed cycle. Also, statutory, regulatory, or funding requirements may dictate completion of some activities at odd intervals throughout the five-year watershed cycle (such as increased emphasis on pretreatment inspections). The table below gives examples of watershed versus non-watershed related activities.

Watershed Tasks	*Non-Watershed Tasks*
Renew permits	Issue new permits
	Develop new general permits, reduce backlog, pretreatment
Integrate municipal storm water program	Issue individual industrial and storm water permits
Conduct inspections for watershed permits	Conduct inspections on new permits
Enforcement (in-cycle compliance)	Enforcement (spills, out of cycle compliance)
Implement NPS controls	Develop regional strategies to address NPS problems
TMDL/WLAs	
Develop, coordinate and implement watershed monitoring	Coordinate monitoring on a regional scale
Water Quality Assessments (State of the Watershed Reports, partial updates to 305(b) by watershed)	Biennial 305(b) Reports to USEPA
Develop watershed policies	Develop regional policies
Watershed-specific Basin Plan Updates	Regional Basin Plan Updates, Triennial Reviews (as Currently required)
Data management (input and use by watershed)	Regional Database management (development and
GIS (input of watershed-specific layers and information)	GIS (development and input of regional layers and Maintenance of system)
Watershed-specific outreach/education	General outreach education
Incorporation of CEQA and 401 Decisions into watershed planning (as groups are formed, and as timing permits)	Timely review of CEQA documents, 401 certifications per statutory deadlines

While the Watershed Management Initiative strives to integrate and coordinate the various Regional and State Board programs and address the highest priority funding needs for those programs, there is also need to respond to and accommodate priorities established by the individual Regional and State Boards' members, priorities established prior to the WMI which run on their own timelines, or other new mandates which may affect the way the WMI is implemented in a Region. The following briefly describes our overall approach to implementing a subset of programs (some statewide mandates) and other Board priorities on a regionwide scale.

Core Regulatory – General Permits

There are many dischargers in this Region covered by general permits for discharges to surface water through a letter issued by the Executive Officer. This activity occurs independent of the watershed cycle as the need arises. Many of these are for short-term projects such as dewatering. 40 CFR §122.28 provides for issuance of general permits to regulate a category of point sources if the sources: a) involve the same or substantially similar types of operations, b) discharge the same type of waste, c) require the same type of effluent limitations or operating conditions, d) require similar monitoring, and e) are more appropriately regulated under a general permit rather than individual permits.

Core Regulatory – Storm Water Permits

Storm water activities include those involving the three municipal permits (and Standard Urban Storm Water Mitigation Plans associated with the two urban ones) in the Region, the approximately 2700 facilities regulated under the State's general industrial permit, and the approximately 950 construction sites regulated under the State's general construction permit.

Wetlands Protection and Management – Water Quality Certification

A key wetlands regulatory tool for the Regional Board is the CWA Section 401 Water Quality Certification Program which regulates discharges of dredge and fill materials to waters. The 401 certification program is one of the most effective tools the state has for regulating hydrologic modification projects, especially those which directly impact the region's diminishing acres of wetlands and riparian habitat.

Key program activities should include CEQA documents review/response, pre-construction meetings with applicants, site visits, application processing, follow-up monitoring and inspections, and enforcement. Unfortunately, the program is currently severely underfunded with only application processing being undertaken. **The program is currently funded at 2.1 PYs; the FY 00/01 statewide needs analysis for the 401 certification program indicated a needed augmentation of 13.9 PYs.**

Approximately 150-200 applications are processed each year. Information about projects and the program in general is available on the Regional Board website at http://www.swrcb.ca.gov/~rwqcb4/.

Management of Nonpoint Source Pollution

California's Nonpoint Source (NPS) Pollution Control Program has been in effect since 1988; it has recently been updated (January 2000). A key element of the Program is the "Three-Tiered Approach," through which self-determined implementation is favored, but more stringent regulatory authorities are utilized when necessary to achieve implementation.

Our long-term goal for the NPS program is to improve water quality by implementing the management measures identified in *the California Management Measures for Polluted Runoff Report (CAMMPR)* by 2013.

Major current nonpoint source program priorities are: 1) oversight of workplans for 319(h) and Proposition 13 projects, 2) establishment of regional strategies to address agriculture, marinas, and septic tanks (the latter will be focused on densely populated communities and areas where ground water is a source of drinking water), 3) investigation of loading contributions from agriculture, nurseries, golf course, and horse stables (in aid of TMDL work), and 4) expansion of our public education and outreach. It is anticipated our nonpoint source program implementation will heavily emphasize Tier 1, at least initially. **We see a need for an additional 14.0 PYs to fully implement our priorities.**

Enforcement Strategy

The statewide Water Quality Enforcement Policy adopted by State Board in 1996 is intended to make all enforcement consistent, predictable, and fair throughout the state. The Regional Board adopted a resolution in 1997 which confirmed the Regional Board's desire to carry out enforcement in a manner consistent with State Board's enforcement policy and that Regional Board staff prepare a regional enforcement strategy consistent with State Board's enforcement policy. The statewide enforcement policy is currently in the process of being revised.

The enforcement policy states that the Regional Board staff must bring to the attention of their Regional Board for possible enforcement action, at a minimum, an array of permit violations for a variety of dischargers as well as failure to submit reports or deficient reports, and spills. Our increased efforts have resulted in an improved enforcement record for the region and has contributed to increased compliance in some programs (e.g. industrial stormwater). The quarterly violations report is available to the public as part of the Executive Officer's Report; and is also available on the Board's web page.

Beaches/Coastal Watersheds Activities

Due to the great resource and economic value associated with the beaches and coastal watersheds of this Region, a number of activities occur that are specific to the coastal areas. Among these are a number of monitoring programs as well as a program to manage contaminated sediments. Monitoring programs include: several regional surveys of the Southern California Bight which evaluated a number of constituents to determine the spatial extent and magnitude of ecological disturbances, trend monitoring conducted through the State Mussel Watch and Toxic Substances Monitoring Programs, the recently formed Surface Water Ambient Monitoring Program (SWAMP), and a recently developed inventory of Coastal Ambient Monitoring Programs (CAMP).

Additionally, a Contaminated Sediments Task Force has been established to develop a long-term strategy to manage contaminated sediments found in the ports and marinas of Los Angeles County. This effort was funded by the Karnette bill.

FOR ADDITIONAL INFORMATION

Contact the Regional Board's Watershed Coordinator, Shirley Birosik, at (213) 576-6679 or sbirosik@rb4.swrcb.ca.gov for additional information or consult the Regional Board's website at http://www.swrcb.ca.gov/~rwqcb4.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 1 . INTRODUCTION

THE REGIONAL WATER QUALITY CONTROL BOARD - WHY THE WATERSHED MANAGEMENT APPROACH?

The nine Regional Water Quality Control Boards (Regional Boards) are each semi-autonomous and comprised of up to nine part-time Board Members appointed by the Governor. Regional Board boundaries are primarily based on watersheds. Each Regional Board makes water quality decisions for its region. These decisions include setting water quality standards, issuing waste discharge permits, adopting policies, and taking enforcement actions.

The Los Angeles Region has jurisdiction over all coastal drainages flowing to the Pacific Ocean between Rincon Point (on the coast in western Ventura County) and the eastern Los Angeles County line, as well as the drainages of five coastal islands (Anacapa, San Nicolas, Santa Barbara, Santa Catalina, and San Clemente). The Regional Board's jurisdiction also includes all coastal waters within three miles of the continental and adjacent island coastlines.

The Los Angeles Region is the State's most densely populated and industrialized region. Over 1,000 discharges of wastewater from point sources in this Region are regulated by the Los Angeles Regional Board. Over 700 of these point source discharges are discharged to surface waters, and are regulated under the National Pollutant Discharge Elimination System. Permits issued under this program are referred to as NPDES permits. In addition, the Regional Board prescribes Waste Discharge Requirements (WDRs) for the remaining discharges, which are primarily to ground waters and landfills. Up until recently, NPDES permits and WDRs were assessed on a case-by-case basis as they came up for renewal.

In recent years, watershed issues have become much more complex and the need to respond with more coordinated monitoring as well as development of cost-effective solutions has required us to rethink our "permit by permit" approach and move to a watershed approach. In addition, in light of economic constraints, dischargers of point source wastewaters are requesting more consideration of site-specific objectives. At the same time, environmental interests are requesting cumulative assessments of pollutant loadings to waterbodies and impacts to beneficial uses. This requires acknowledgment of the growing importance of nonpoint sources to watershed pollutant loadings. We also have the added need of conducting TMDLs for most of our Region's waters.

Managing water quality by watershed allows the Los Angeles Regional Board to address these varied demands in a more coordinated and effective manner. As the control of point source pollutants through NPDES permits and WDRs is central to the Los Angeles Regional Board's strategy to protect water quality, we have structured our approach to watershed management around the need to issue NPDES permits by watershed, in a timely and coordinated manner over a five-year cycle. This also allows for the gathering of input and coordination of nonpoint source issues within the same framework.

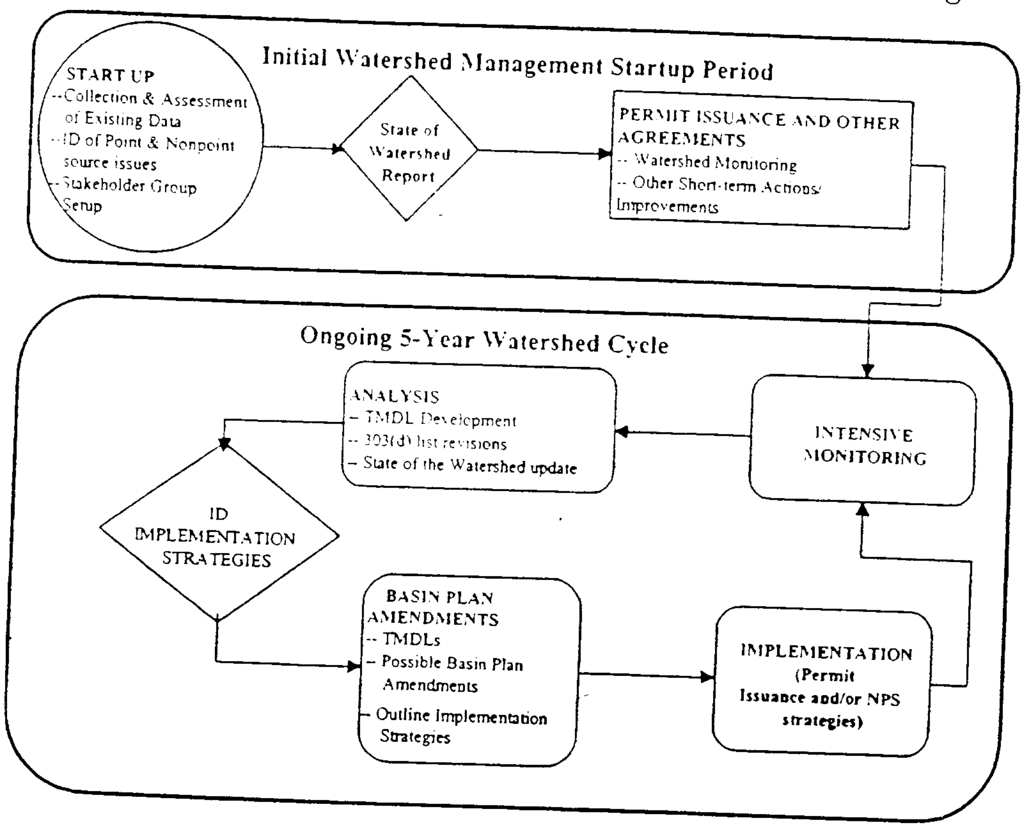
THE WATERSHED MANAGEMENT INITIATIVE

Watershed management is not a new program--it is a strategy for integrating and managing resources. The goal of the state's Watershed Management Initiative (WMI) is to integrate water quality monitoring, assessment, planning, standards, permit writing, nonpoint source management, ground water protection, and other programs at the State and Regional Boards to promote a more coordinated and efficient use of personnel and fiscal resources while ensuring maximum water quality protection benefits. The State's watershed work integrates and supports, to the extent possible, local community watershed protection efforts to implement cost-effective strategies for natural resource protection. As characteristics and resources vary widely from watershed to watershed, this approach customizes efforts to manage resources and address problems unique to each watershed while offering stakeholders the opportunity to implement the most cost-effective solutions to problems within their watersheds.

Watershed management represents a shift from a traditional approach that focuses on regulation of point sources, to a more regional approach that acknowledges environmental impacts from other activities. Over the last twenty-five years, permitting programs have significantly reduced pollutants that are discharged to California's waters from point sources. However, the quality of many waters continues to be degraded from pollutants discharged from diffuse and diverse sources, referred to as nonpoint sources, and from the cumulative impacts of multiple point sources. Future success in reducing pollutants from nonpoint sources and achieving additional cost-effective reductions in pollutants from point sources requires a shift to a more geographically-targeted approach.

Figure 1 illustrates an example of how permitting, planning, and other activities are integrated into our Regional watershed strategy. The upper part of the figure (initial start-up period) refers to work conducted mostly during the first time through the rotating cycle. The lower part of the figure addresses activities that occur during each cycle.

Figure 1. Elements of a Watershed Management Cycle - Region 4



R0026543

THE WATERSHED MANAGEMENT INITIATIVE CHAPTER

This document is the fifth iteration of the Chapter. The participants in implementation of the WMI in California (the nine Regional Boards, State Board, and USEPA) were asked in 1996 to begin preparation of a document which identified priorities and resource needs, across programs, in a watershed context. The Chapter is currently used both as an outreach and as a planning tool to identify the Region's priorities over the upcoming two to three fiscal years (FYs), describe where we should spend our baseline resources, as well as where we need additional resources (in support of Budget Change Proposals). It turns out most of our highest priority needs fall into areas that have little to no funding. This effort will hopefully result in flexibility and augmentation to address this deficiency.

The Chapter itself is not a commitment to complete work but provides a framework to identify priorities and resource needs which should form the basis for formal commitments which are made in fund source- and program-specific Workplans on an annual basis. Determinations of which activities will be funded by specific Workplans will be negotiated on the basis of the information in the Chapters. Annual program Workplans and grant applications will still be prepared by program managers to identify which activities are going to be funded in a particular year based on the fiscal decisions made.

The Chapter is organized into sections including the Introduction, Watershed Sections, and Region-wide Section. Included in each Watershed Section is an overview of that watershed, a description of its water quality concerns and issues, past significant Regional Board activities in the watershed, current (funded) activities, near-term (usually unfunded) activities that would benefit the watershed, and activities which may happen on a longer time-scale (usually unfunded). The Region-wide Section includes a description of activities not easily associated with particular watersheds as well as more detailed information on implementation of certain programs (such as nonpoint source) in the Region. The Appendix includes TMDL schedules and lists of permits to be reviewed or renewed each year. More detailed information on allocation of resources may be obtained by request from the Regional Board.

WMI DEFINITIONS

The following represent commonly used terms and definitions utilized throughout the document:

A **watershed** is the geographic area draining into a river system, ocean or other body of water through a single outlet and includes the receiving waters. Watersheds are usually bordered, and separated from other watersheds, by mountain ridges or other naturally elevated areas.

The **watershed management approach** is the specific method by which the Regional Board implements watershed management. Features include the targeting of priority problems, stakeholder involvement, developing integrated solutions, and evaluating measures of success. The entire watershed, including the land mass draining into the receiving water, is considered.

Watershed Management Areas (WMAs) are the geographically-defined watershed areas where the Regional Board will implement the watershed approach. These generally involve a single large watershed within which exists smaller subwatersheds but in some cases may be an area that does not meet the strict hydrologic definition of a watershed e.g. several small Ventura coastal waterbodies in the region are grouped together into one WMA.

State of the Watershed/Water Quality Characterization Reports are reference documents produced by Regional Board staff that describe the existing water quality conditions, data gaps, and sources of pollutants within a WMA. Strategies to resolve the water quality concerns, either in progress or proposed, are described. Preliminary versions of these reports are produced by the Regional Board in order to stimulate discussion and inputs on issues from other stakeholders. These documents will be updated as needed. First edition reports are available for Calleguas Creek, Santa Monica Bay, Los Angeles River, and San Gabriel River Watersheds.

A **Watershed Management Plan** is a planning document often produced by watershed stakeholder groups which addresses water quality, land use, economic, habitat, recreation, and other concerns and recommends specific management strategies to resolve identified problems in a cooperative and coordinated manner. Should stakeholder involvement be lacking, a plan which focuses on water quality concerns will be produced by the Regional Board and would emphasize a more regulatory approach to water quality improvement.

Nonpoint sources of pollution are those with no single point of origin. Pollutants may often be carried off the land by stormwater or be part of urban runoff. Common nonpoint sources are agricultural, urban (runoff from residential areas, parking lots, streets, etc.), and construction activities. **Point sources**, on the other hand, by definition originate from a discrete source such as a pipe or outfall through which a facility may discharge while regulated by a NPDES permit.

Beneficial uses are those uses of water identified in state and regional water quality control plans that must be achieved and maintained. Uses include contact water recreation, municipal water supply, navigation, agricultural supply, wildlife habitat, and groundwater recharge, among others. **Designated** beneficial uses, together with water quality objectives, form water quality standards as mandated under the California Water Code and Federal Clean Water Act. The California Water Code defines **water quality objectives** as "the allowable limits or levels of water quality constituents or characteristics which are established for the reasonable protection of beneficial uses of water or prevention of nuisance within a specific area." These objectives are both narrative (descriptive) and numerical and appear in each Regional Board's water quality control plan (**Basin Plan**) which also describes implementation programs to protect all waters in the Region.

Best Management Practices (BMPs) are intended to reduce the amount of pollutants and prevent pollutants from leaving a facility and reaching a waterbody. BMPs include good facility housekeeping methods and such things as scheduling certain types of work around periods of rainfall or high winds, controlling runoff from a facility and modifying practices to reduce the possibility of pollutants leaving a facility. These are often used in regulating stormwater and other nonpoint sources.

The **Total Maximum Daily Load (TMDL)** is a number that represents the assimilative capacity of a receiving water to absorb a pollutant. The TMDL is the sum of the individual wasteload allocations for point sources, load allocations for nonpoint sources plus an allotment for natural background loading, and a margin of safety. TMDLs can be expressed in terms of mass per time (the traditional approach) or in other ways such as toxicity or a percentage reduction or other appropriate measure relating to a state water quality objective. A TMDL is implemented by reallocating the total allowable pollution among the different pollutant sources(through the permitting process or other regulatory means) to ensure that the water quality objectives are achieved.

- **TMDLs** establish the loading capacity of a watershed, identify needed reductions, identify sources, and recommend allocations for point and nonpoint sources.
- The **Margin of Safety** is a required component of the TMDL that accounts for the uncertainty about the relationship between the pollutant loads and the quality of the receiving waterbody.
- **Grouping TMDLs** is a reasonable and logical way to collapse the total number of individual TMDLs to make the most effective use of resources we currently have and any which we may obtain in the future. This is largely due to the fact that some of the "pollutants" for which a water may be listed are actually "effects" of pollutants. The TMDL chart in each watershed section of this report reflects this collapsed approach. For example, many reaches of the Los Angeles River are listed for ammonia. Some of the same reaches are listed for pH problems while other reaches are listed for algae, scum, and odors. It is very likely the presence of these "pollutants" are interrelated. Excessive nitrogen (reflected here as high levels of ammonia) may lead to a condition of eutrophication (excessive nutrient loading) which can influence pH levels as well as promote increased algal growth. Scum may be evident due to floating algal material and odors may result when excessive algae starts to die off. Thus, it makes sense to group these approximately 95 TMDLs (calling it a "nitrogen and related effects" TMDL "group") and approach the problem by determining the sources of nitrogen loading into the watershed and the appropriate allocations in order to reduce loadings.

OVERVIEW OF ONGOING REGIONAL BOARD PROGRAMS AND ACTIVITIES

The Regional Board implements a wide variety of programs with different mandates, requirements, etc. Many of these (most surface water programs) are already fully or partially integrated into the watershed approach; others (primarily ground water) will be incorporated later and a few will likely remain separate from the WMI process. The following gives a brief description of these major program areas, current priority activities for each, and whether they are considered Category One or Two activities. **Category One** activities are those of high priority which are required by federal or state statute or regulation that need to be completed at least once during the 5-year planning cycle. **Category Two** activities are considered very important but are not required by statute or regulation. Additionally, more specific program objectives and implementation activities are included in the watershed or region-wide sections as appropriate. Updated information on Regional Board activities and programs may be also found on the Board's webpage at http://www.swrcb.ca.gov/~rwqcb4.

SURFACE WATER

Core Regulatory (Category One)

Core regulatory activities include NPDES (individual permits - updates and revisions, issuance of general permits, stormwater permits/program, enforcement actions, response to complaints, compliance and pretreatment inspections, pretreatment audits, and review of monitoring reports), groundwater protection activities (issuance of Waste Discharge Requirements), issuance of Water Reclamation Requirements, and land disposal under Chapter 15 California Code of Regulations. Issuance of new permits continues to be a high priority. Reduction of backlog and increased efforts in compliance and enforcement are also very high priorities. Permits are scheduled for reissuance to coincide with targeted watersheds on a rotating schedule of five years. Major NPDES permittees are inspected at least once annually while those in Significant Noncompliance are inspected at least quarterly until the noncompliance issue is resolved. Minor NPDES permittees are inspected at least once in each permit reissuance cycle (20% of the total per year). Those in noncompliance will be inspected annually until the problem is resolved.

Our FY01/02 focus in the core regulatory workplan will be on reducing backlogs, increasing inspections, and increasing our emphasis on pretreatment. Our watershed efforts will focus on coordinating receiving water monitoring and implementing bioassessment. Storm water will put an increased emphasis on compliance inspections and enforcement.

An additional core regulatory task follows adoption of the statewide Consolidated Plan for cleanup of toxic hot spots (in sediment). The Water Code requires reevaluation of those WDRs that may influence the creation of further pollution of known toxic hot spots.

Core regulatory must also implement waste load allocations established by TMDLs during renewal of existing permits or issuance of new permits.

Monitoring and Assessment (Categories One and Two)

Category One activities include the biennial Water Quality Assessment 305(b) Report, Surface Water Ambient Monitoring Program (SWAMP), and Los Angeles Basin Contaminated Sediment Task Force work. Category Two activities include involvement with the State Mussel Watch/Toxic Substances Monitoring Programs (SMW/TSMP), special studies, and volunteer monitoring.

Monitoring and/or assessment efforts are occurring on both regional and watershed scales. The State Mussel Watch and Toxic Substances Monitoring Programs (SMW/TSMP), the recently concluded Bay Protection and Toxic Cleanup Program (BPTCP), Los Angeles Basin Contaminated Sediment Task Force, and Regional Board ambient monitoring through the SWAMP are the major regional monitoring and/or activities with direct coordination provided by Regional Board staff (the SMW/TSMP, BPTCP, SWAMP, and Contaminated Sediment Task Force are described in more detail in the Region-wide Section of this document while activities specific to each watershed are described in the appropriate watershed sections). Also, every two years an update of the 305(b) report is required; emphasis will be put on updating targeted watersheds at those times. It should be noted, however, that an update to 305(b)/303(d) was not required in April 2000. The next scheduled update will be due to USEPA in April 2002.

Monitoring can have a number of goals. It may be used to assess trends over time and obtain general assessment information on a regional scale (ambient monitoring, TSMP, and, to some extent, the SMWP). It may be used to pinpoint "hot spots" and track sources on a watershed scale (BPTCP and ambient monitoring). It may also be used to assess loadings for TMDLs. An increasing use will be to better judge impairments of beneficial uses on a watershed scale and to assess effectiveness of nonpoint source BMPs and other water quality improvement strategies.

A major long-term monitoring and assessment goal is to increase utilization of biological assessments including incorporating them in monitoring requirements for dischargers.

Basin Planning (Categories One and Two)

Category One basin planning activities include conducting triennial reviews of planning priorities, development of water quality standards and implementation plans and policies, development of TMDLs, and preparation of Basin Plan amendments (some of which follow from development of TMDLs).

A triennial review is a fundamental planning function at Regional Boards. This activity provides the Board with the opportunity to review the status of water quality, identify issues and problems, and solicit direction and comment from concerned parties as well as the public in general. The triennial review process sets the stage for possible changes (i.e. amendments) to the Basin Plan, which may be needed to more effectively protect water quality. Amendments to the Basin Plan also ensure that the Regional Board's approach to protecting water quality is legally sound. A triennial review is currently underway.

Another important planning function is interaction with the public and other agencies that are planning projects that may impact the environment. Under the California Environmental Quality Act, the Regional Board has an opportunity and responsibility to work with the public to ensure projects that may affect water quality are properly designed to reasonably mitigate adverse impacts. This responsibility to participate in the planning processes at other agencies extends to the development of regulations (such as the California Toxics Rule and State Implementation Policy) and guidelines (such as irrigation practices). Review of environmental documents is a Category Two activity.

***Wetlands Protection and Management* (Categories One and Two)**

Wetlands acres in the Region have diminished greatly over the past several decades as coastal development, in particular, has increased. Wetlands provide habitat, serve to slow down water flow, decrease total volume through infiltration, and filter out a number of pollutants through active uptake by plants as well as deposition in sediments. Wetlands such as coastal estuaries are a buffer zone between ocean and inland water resources and are heavily utilized by aquatic organisms. Continuous stretches of riparian habitat function as wildlife corridors to allow animal movement between increasingly isolated populations. They also serve as popular recreational destinations for residents and visitors. Unfortunately, many of our Region's wetlands are impacted by varying kinds and amounts of pollutants and alterations.

The Regional Board participates in the Southern California Wetlands Recovery Project, which for the first phase effort, conducted an inventory of coastal wetlands from Santa Barbara to the U.S.-Mexico border. This inventory included information on twelve wetlands in seven watersheds for our region. When compared to estimated historical acreages, Los Angeles County has lost 93% of its wetlands while Ventura County has lost 58% of its wetlands. A 20-year regional wetland plan and strategy for prioritizing and restoring sites is being developed. Currently, the Project funds wetlands projects which involve planning, restoration, or acquisition. More information about the Project may be found on its webpage at http://www.coastalconservancy.ca.gov/scwrp/index.html.

Our wetlands regulatory tools include:

1. **Wetlands beneficial use designation**: The Region's Basin Plan now includes a beneficial use category for Wetland Habitat.

2. **Water Quality Objective:** The Region's Basin Plan has a narrative objective for wetlands protection which addresses the protection of hydrologic conditions and physical habitats to sustain the functional values of regional wetlands.

3. **Water Quality Certification (401) Program**: A key Category One activity associated with wetlands protection and management is CWA Section 401 certification which regulates discharges of dredge and fill materials to waters. The 401 certification program is one of the most effective tools the state has for regulating hydrologic modification projects, especially those which directly impact the region's diminishing acres of wetlands and riparian habitat.

4. **Wetland Grant:** Funding for mitigation monitoring has been requested.

***Nonpoint Source Program** (Categories One and Two)*

Nonpoint source Category One activities include coordination of 319(h) grant project activities, implementation of TMDLs and implementation of Coastal Zone Act Reauthorization Amendments provisions. Participation in stakeholder/watershed groups meetings and activities and public/agency outreach are Category Two activities.

California's Nonpoint Source (NPS) Pollution Control Program has been in effect since 1988. A key element of the Program is the "Three-Tiered Approach," through which self-determined implementation is favored, but more stringent regulatory authorities are utilized when necessary to achieve implementation. The NPS Program has been upgraded to enhance efforts to protect water quality, and to conform with the Clean Water Act Section 319 (CWA 319) and Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA). The lead State agencies for the NPS Program are the SWRCB, the nine RWQCBs, and the California Coastal Commission.

Our long-term goal for the NPS program is to improve water quality by implementing the management measures identified in the California Management Measures for Polluted Runoff Report (CAMMPR) by 2013. The short-term plan to achieve this goal is to identify, educate, and promote stakeholder involvement.

Current nonpoint source program priorities are: 1) oversight of workplans for 319(h) and Proposition 13 projects, 2) establishment of regional strategies addressing agriculture, marinas, and septic tanks (the latter will be focused on densely populated communities and areas where ground water is a source of drinking water), 3) investigation of loading contributions from nurseries, golf course, and horse stables (in aid of TMDL work), and 4) expansion of our public education and outreach. Certain sources (e.g., commercial and multi-family septics) may be regulated with waste discharge requirements.

GROUND WATER

The following programs under our Groundwater Division are currently not managed under our watershed schedule. Over time, we expect to integrate aspects of these programs with other watershed activities, particularly with regard to coordination of monitoring and assessment activities and GIS. Steps taken to date include the mapping of drinking water wells and underground storage tank AND Well Investigation Program (WIP) sites in a Geographic Information System (GIS).

***Underground Storage Tanks Regulation and Remediation** (Category One)*

Responsibilities include oversight of investigations into groundwater pollution and any corrective actions which may be needed which result from leaking underground storage tanks. Cases are roughly organized along watershed boundaries.

***SLIC Program** (Category One)*

Response to reports of unauthorized discharges, such as spills and leaks from above-ground storage tanks which may impact any of the region's waterbodies, are investigated through the

Spills, Leaks, Investigation and Cleanup (SLIC) Program and remediation actions are implemented.

DOD and DOE Sites Cleanup Program *(Category Two)*

The Regional Board works with a number of other agencies involved with remedial investigation and cleanups at U.S. Department of Defense (DOD) and U.S. Department of Energy (DOE) sites. Agreements with the DOD and DOE provide for accelerated cleanups at military bases and other Defense sites schedule for closure.

Well Investigation Program *(Category One).*

Followup investigation of volatile organic compounds in public water supply wells is conducted through the Well Investigation Program (WIP). Investigations focus on identification and elimination of sources of pollutants in public water supply wells, the identification of responsible parties, and oversight of soil and ground water remediation. In a way, this program is watershed-based as it focuses on two watersheds – San Gabriel and San Fernando (upper Los Angeles River).

FUNDING

Many high priority (in terms of Regional Board as well as statutory priorities) activities are unfunded or underfunded. For example, monitoring and assessment, basin planning, and nonpoint source activities are grossly underfunded (we see a shortfall of 14.0 PYs in resources needed to implement our priorities for the NPS program and a statewide needs analysis revealed a 13.9 PYs shortfall in the 401 certification program) . Some resources must be utilized for required activities such as triennial Basin Plan reviews and Water Quality Assessments. The latter activity tells us where our impaired waters are and there are federal requirements to conduct TMDLs on 303(d)-listed waters although more money is needed to do TMDL work on the problem waters (for example, we foresee a shortfall of 8.8 PYs and $650,000 in contract monies for FY00/01 TMDL work). If a TMDL is completed and a remediation strategy developed despite this, there is then little money for followup work, particularly with regards to dealing with nonpoint source contributions. This means that our involvement in nonpoint sources must be very time-conservative. While it may take years of work to cooperatively fix a nonpoint source problem, direct enforcement could take a lot less time and be an immediate action. However, the latter is contrary to the cooperative spirit of watershed management. Each watershed will require difference site-specific approaches depending on a variety of factors. Additionally, enforcement is another underfunded activity, particularly when dealing with nonpoint source discharges. On the other hand, priorities may shift due to the influx of "new" money to fund a previously underfunded, and often times, lower priority activity. Use of the new money may be specific to certain activities such as increased pretreatment inspections in the core regulatory program. See Table 1 for the funding status and priority of Regional Board activities and programs in greater detail.

Table 1. Funding Status of Major Regional Board Activities and Programs

Program/Activity (and Subcategories)	Import-ance (High, Med, Low)	Man-dated?	Current Funding	What We Can Do With Existing Funds	What Could Be Done with More Funds
Basin Planning					
Triennial reviews	M	Y	*Under-funded*	*Absolutely necessary updates; delayed and/or limited Triennial Reviews*	*Conduct regular comprehensive reviews of the Basin Plan and associated issues; act on an increased number of triennial review-listed items*
Evaluation of beneficial uses	H	Y	*Under- to unfunded*	*Field observations in conjunction with other activities*	*Comprehensive beneficial use surveys (necessary to set and refine use designations)*
Development of WQ objectives	H	Y	*Under- to unfunded*	*Utilize existing objectives.*	*Develop new and/or site-specific objectives; participate on State/Federal Task Forces; develop regional policies to implement water quality standards*
Development of watershed/ regional priorities	H	N	*Under-funded*	*Solve the easiest problems*	*Develop of complex watershed solutions*
Watershed Coordination and Plan Development	H	N			
Development of watershed plans	H	N	*Under to unfunded*	*Rely on stakeholders to do most of the work*	*Ability to provide staffing efforts to watershed groups to guide and prepare integrated plans for water quality along with flood protection, habitat protection, etc.*
Coordination	H	N	*Under-funded*	*Limited outreach*	*Provide staff to participate in all watershed groups*
TMDL Development	H	Y	*Under-funded*	*TMDLs with only the required elements in order to meet deadlines*	*More time spent developing TMDLs with site-specific information*

Program/Activity (and Subcategories)	Import-ance (High, Med, Low)	Man-dated?	Current Funding	What We Can Do With Existing Funds	What Could Be Done with More Funds
Water Quality Assessment					
Monitoring — Ambient watershed	H	Y (SWAMP)	*Under-funded*	*Do the basics required by the SWAMP; minimal staff sampling; rely on stakeholder sampling with minimal oversight; develop collaborative discharger watershed monitoring programs*	*Collect better data to assess impacts, assess for more constituents with more robust sampling; develop priorities, and evaluate successes; actively solicit and coordinate stakeholder monitoring; move beyond "snapshot" monitoring*
Lab support	H	N/A	*Under-funded*	*Evaluate small subset of waters; analyze inexpensive constituents; often inadequate for decision-making*	*Utilizing "better science" for decision-making*
Biomonitoring (training /field wk.)	H	N	*Under-funded*	*Use effluent chronic toxicity testing as surrogate*	*Real assessment of impacts to Beneficial Uses through field surveys*
Assessment	H	Y (WQA)	*Unfunded*	*Compile and assess as time permits ("back-burner")*	*Utilization as a critical element in watershed decision-making*
Computer data storage	H	N	*Unfunded*	*Data stored in many locations*	*More efficient and comprehensive analyses*
Analyze data	H	Y	*Unfunded*	*Simple statistics*	*More rigorous analyses*
State of watershed report	M	N	*Unfunded*	*Summarize available info*	*Info sharing/priority setting*
Biennial WQA Report	M	Y	*Unfunded*	*Limited to targeted watersheds (minimal info)*	*Regular and more comprehensive updates/ better data for quality decisions*
Reporting – *Water Quality Report Card*	H	N	*Unfunded*	*Encourage other groups to develop indicators that would be useful for our Region*	*Research and develop indicators and a "report card" format for Region*

Program/Activity (and Subcategories)	Importance (High, Med, Low)	Mandated?	Current Funding	What We Can Do With Existing Funds	What Could Be Done with More Funds
CEQA Review	M-H	Y	*Unfunded*	*Limited to highest priority projects with the greatest potential impacts*	*Provide early, meaningful comments; pre-401 coord.; early notification; be aware of piecemealing of projects*
401 Review	M-H	Y	*Under-funded*	*Review and process applications*	*Follow-up work (monitoring and enforcement), pre-construction meetings, site visits, review of draft CEQA documents, development of regional policies*
Nonpoint Source/CZARA					
Outreach	H	N	*Under-funded*	*Minimal effort - usually associated with group meetings*	*More active cooperation and outreach with individuals and groups in the watershed*
Contract/Project Management	H	N	*Under-funded*	*Minimum needed to get project through funding process*	*Receive better products and leverage from successful projects, hands on involvement and advertisement of successful projects*
Development of NPS Solutions	H	Y	*Under-funded*	*Little to none on our own; some involvement with others' work, and initiation of regulatory mechanisms (Tiers II and III)*	*Work with watershed communities to develop and implement nonpoint pollution control strategies, evaluate success of best management practices and management measures*
Permitting - Point Source (NPDES and WDRs)					
Permit development	H	Y	*Under-funded*	*Reduce backlog; process major and minor permits on watershed schedule/transfer minor permits to general permits as time allows*	*Have resources to solicit more stakeholder involvement; use higher level tools (modeling) to develop limits*
Inspections	H	Y	*Under-funded*	*Minimum required*	*More field presence/outreach/may reduce need for enforcement*
Enforcement	H	Y	*Under-funded*	*Only high profile major spills/violations*	*More enforcement actions taken on spills/violations that are not high profile*
Spill/complaint follow-up	H	Y/N	*Under-funded*	*Only major spills*	*Better customer service, follow-up on complaints, successful cleanups*

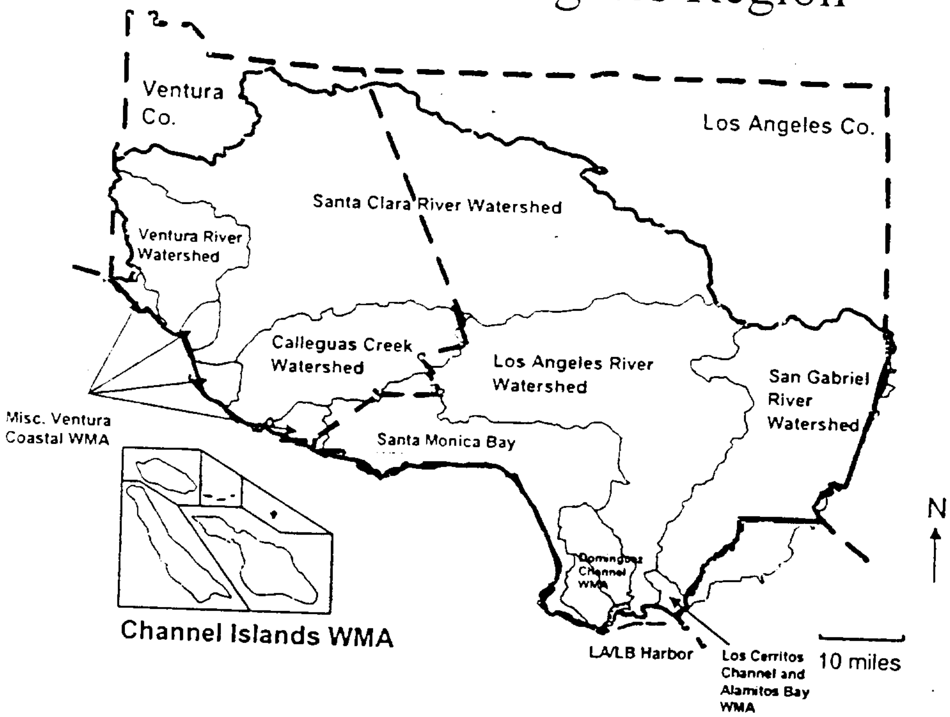
OUR REGION'S APPROACH TO WATERSHED MANAGEMENT

We have designated ten watershed management areas in the Los Angeles Region (Figure 2). Initially, implementation of watershed management in the Los Angeles Region occurred in phases over a seven-year cycle for each watershed. We are now shifting to a five-year cycle to be in line with the standard permit life and to equalize workloads over the years. This shift in our watershed cycle is illustrated in the table that follows. The majority of permit-related tasks such as permit renewals/revisions and regional monitoring program development as well as preparation of state of watershed reports, will occur during the first approximately twelve months of the watershed's five-year cycle. Much of the rest of the cycle will be spent developing and implementing, with the input of stakeholders, measures for management of pollutants from point and/or nonpoint sources. In some cases, nonpoint source activities may be occurring throughout the cycle due to the prior existence of stakeholder groups who have been meeting regularly on these issues. Toward the end of the five-year cycle (and prior to initiating the next cycle), we shall evaluate the success of our watershed efforts.

In light of limited schedules and resources, efforts during the 12-month start-up phase will target compilation and assessment of available data, identification of data gaps and the need for additional studies/monitoring, the development of a balanced stakeholder group, and issuance of permits for point source discharges. A by-product of these efforts will be a preliminary indication of pollutant problems from nonpoint sources; followup efforts to address these nonpoint source problems, as well as other water quality problems, will be undertaken during the cycle if efforts are not already underway through some other means.

NPDES permits in the Los Angeles Region are organized and scheduled by watershed. Preliminary "State of the Watershed Reports" are prepared by watershed "teams" composed of permit writers, planning and nonpoint source program personnel, and those involved with groundwater protection. These reports have become very useful tools for local watershed groups for general educational value and in setting priorities.

Figure 2. Watershed Management Areas of the Los Angeles Region



Permit Timeline for Watershed Management Initiative

Santa Clara River Calleguas Creek	FY 2001/02
Dominguez Channel-LA/LB Harbor	FY 2002/03
Santa Monica Bay	FY 2003/04
Los Angeles River	FY 2004/05
San Gabriel River Los Cerritos Channel Channel Islands	FY 2005/06
Ventura River Misc. Ventura Coastal Santa Clara River Calleguas Creek	FY 2006/07
Dominguez Channel-LA/LB Harbor	FY 2007/08

The formation of a balanced group of stakeholders for each watershed is critical to the success of watershed management, especially for resolving issues arising from nonpoint source pollutants. Accordingly, part of our approach is to initiate such groups of stakeholders and encourage active participation. Working in partnership with stakeholders, we expect that we can achieve the following goals (or have already done so during the watershed's first cycle) within each of our watershed management areas during the first five-year cycle of watershed management.

- **Establishment of a stakeholder group** or an infrastructure of stakeholder contacts which represents a range of key interest groups in the watershed; yet involvement is not a barrier to timely resolution of a water quality problem.
- **Compilation of reasonably available water quality data** and related information in the form of a 'State of the Watershed Report.'
- **Assessment of data gaps** and a plan to fill the gaps.
- **Development of a** coordinated, cost-effective **watershed-wide monitoring program.**
- **Identification of priority permit issues** and **coordinated issuance of NPDES permits** that addresses these issues.
- **Identification of other high priority issues**, including nonpoint source issues, and consensus among stakeholders as to how to proceed to resolve them.
- **Implementation of watershed-based solutions.**
- **Evaluate** success.

Many of the tasks noted above will not be limited to a particular part of the watershed cycle. Rather, some may overlap throughout the watershed cycle as may be the case with tasks such as review and assessment of monitoring data and permit compliance. Also, some tasks may have less emphasis than others depending on the watershed, its problems, and the relative influence of point versus nonpoint source contributors.

What is important is the basic tenets of watershed management are being implemented:

- *The effort has a geographic focus,*
- *The highest priority issues are being identified and addressed,*
- *Stakeholder involvement is occurring, and*
- *A scientific basis for water quality management decisions is being created.*

While this is an idealized model, many factors often change what can be done for each step. these include regulatory or statutory mandates, consent decrees, legislation, and changes in Board priorities or funding.

OUR HIGH PRIORITY ISSUES UNDER THE WMI

This Regional Board establishes priorities on an annual basis. While some of these priorities fall outside of the watershed management arena (it is acknowledged that some activities will likely always remain outside of the WMI), the bulk of these priorities are clearly of primary importance in fulfilling not only the WMI but also the nonpoint source management initiative and other mandates. For example, one major priority is, in fact, implementation of the watershed approach. In addition to Regional Board-directed priorities, priorities are mandated by legislation, statute, regulation, State Board, Cal-EPA, USEPA, and from sheer need to protect, restore, or enhance water quality. A list of the highest of these collective priorities follows. These are not necessarily arranged in priority order.

- **Point sources** – controlling compounds which continue to cause instream toxicity and/or accumulate in sediments or biota.
- **Industrial discharges** – ensuring compliance with either individual or general permits.
- **New/re-development** – proactively addressing water quality issues through CEQA, 401 certifications, or stormwater permits – ensuring wet weather compliance with construction permits.
- Addressing the **regional salt management**/salt imbalance issue which is becoming increasingly critical in the region. Also, balancing this issue with the need to promote the use of reclaimed water.
- **Municipal stormwater/urban runoff** – advancing stormwater and urban runoff programs through a variety of efforts. Current priorities include trash control and new development/re-development issues.
- **Watershed monitoring and assessment** – coordination of existing resources and participation in the Surface Water Ambient Monitoring Program. More use of bioassessment as a tool.
- **Water quality standards** program – although this is the cornerstone of all of our programs, it has been minimally funded for the last two decades. This is a critical need for our organization to address this deficiency.
- **Habitat loss/restoration** – even with strides in improving instream water quality, unless habitat is restored, in many cases beneficial uses can not be restored. Efforts which address this need are 401 certification, the Southern California Wetlands Recovery Project, and various watershed efforts. Removal of exotic species is also included in these efforts.
- Priority **nonpoint source** efforts – several areas have been targeted for accelerated efforts including development of regional strategies to address agriculture, septic tanks, urban runoff, and marinas as contributors of nonpoint source pollution as well as involvement with grant funding activities relating to CWA Section 319(h) and Proposition 13.
- **Toxic hot spots** (sediment) – many of the impairments in the Region, particularly in harbors, are related to contaminated sediments. While source reduction will decrease pollutant levels over time, remediation of these sediments will also be needed which will be a long-term project. An effort to help address this need is the Contaminated Sediments Task Force.
- **Beach closures** – other impairments in the Region are the result of elevated coliform levels or beach closures. Monitoring the water quality of recreational areas along the coast, identifying land uses or drainages which generate pathogens, and reducing pollution within these areas is a targeted activity.

These Board priorities are further highlighted in the watershed and region-wide sections as appropriate.

Section 2 . Activities Organized on a Watershed Basis

This section describes activities organized on a watershed basis. An **overview** of each watershed or WMA is provided, its **water quality problems and issues** are described, **past significant activities** (as appropriate), **current activities** (funded activities, in FY00/01 workplan), **near-term activities** (planned or projected high priority activities that may need funding, especially beginning in FY01/02), and **potential long-term activities** (long-term goals, beyond two years).

A table has been included in the Region-wide Section which describes non-TMDL-related resource needs for FY01/02. TMDL resource needs are also included in the Region-wide Section of this document.

THIS PAGE INTENTIONALLY LEFT BLANK

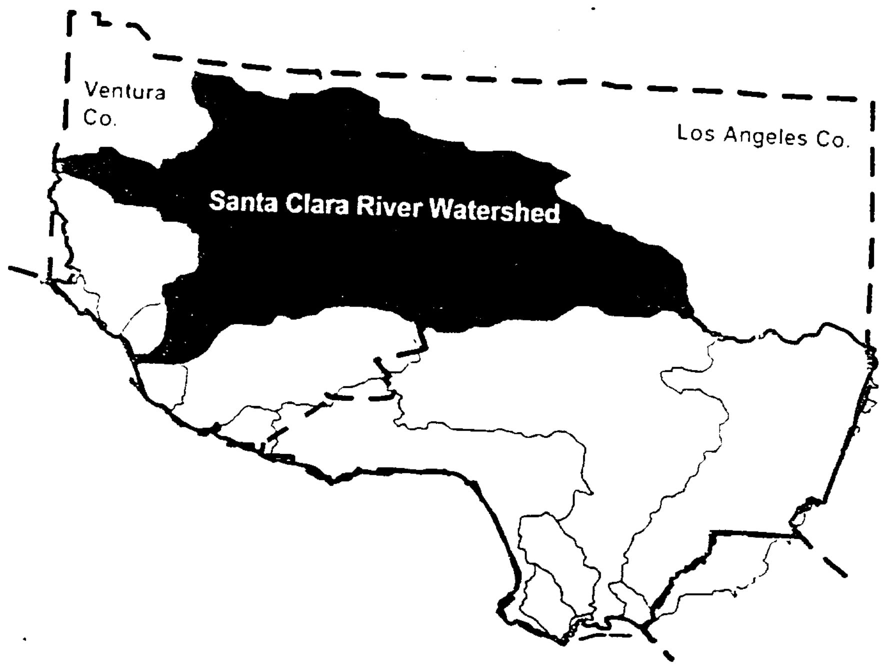
2.1 *SANTA CLARA RIVER WATERSHED*

This watershed will be targeted for permitting purposes in FY01/02.

Overview of Watershed

Size of watershed: approximately 1,200 sq. mi.

Length of river: approximately 100 miles



The Santa Clara River is the largest river system in southern California that remains in a relatively natural state; this is a high quality natural resource for much of its length. The river originates in the northern slope of the San Gabriel Mountains in Los Angeles County, traverses Ventura County, and flows into the Pacific Ocean halfway between the cities of San Buenaventura and Oxnard.

Extensive patches of high quality riparian habitat are present along the length of the river and its tributaries. The endangered fish, the unarmored stickleback, is resident in the river. One of the largest of the Santa Clara River's tributaries, Sespe Creek, is designated a wild trout stream by the state of California and supports significant spawning and rearing habitat. The Sespe Creek is also designated a wild and scenic river. Piru and Santa Paula Creeks, which are tributaries to the Santa Clara River, also support good habitats for steelhead. In addition, the river serves as an important wildlife corridor. A lagoon exists at the mouth of the river and supports a large variety of wildlife.

Water Quality Problems and Issues

Increasing loads of nitrogen and salts in supplies of ground water threaten beneficial uses including irrigation and drinking water. Other threats to water quality include increasing development in floodplain areas which has necessitated flood control measures such as channelization that results in increased runoff volumes and velocities, erosion, and loss of habitat. In many of these highly disturbed areas the exotic giant reed (*Arundo donax*) is gaining a foothold.

Beneficial Uses in watershed:

Estuary	*Above Estuary*
Contact & noncontact water recreation	Contact & noncontact water recreation
Wildlife habitat	Wildlife habitat
Preservation of rare & endangered species	Preservation of rare & endangered species
Migratory habitat	Migratory habitat
Wetlands habitat	Wetlands habitat
Spawning habitat	Municipal supply
Estuarine habitat	Industrial service supply
Marine habitat	Industrial process supply
Navigation	Agricultural supply
Commercial & sportfishing	Groundwater recharge
	Freshwater replenishment
	Warmwater habitat
	Coldwater habitat

Permitted discharges:

- Four POTWs (one discharge in estuary, one in middle reaches, two in upper watershed)
- 103 dischargers covered under an industrial storm water permit
- 310 dischargers covered under a construction storm water permit

Many of the smaller communities in this watershed remain unsewered. In particular, in the Agua Dulce area of the upper watershed, impacts on drinking water wells from septic tanks is a major concern. The community is undertaking a wellhead protection effort, with oversight by Board staff. Development pressure, particularly in the upper watershed, threatens habitat and the water quality of the river. The effects of septic system use in the Oxnard Forebay area is also of concern.

Types of permitted wastes discharged into the Santa Clara River Watershed:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	2 1	Minor General
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	6 8	Minor General
Nonhazardous (designated) noncontact cooling water	2	Minor
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	2	Minor
Nonhazardous (designated) stormwater runoff	1	Minor
Hazardous contaminated groundwater	1 1	Minor General
Nonhazardous (designated) filter backwash brine waters	1	Minor
Nonhazardous (designated) domestic sewage & industrial waste	4 1	Major Minor
Nonhazardous (designated) washwater waste (photo reuse washwater, vegetable washwater)	1	General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	12	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations

Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

Twenty-nine of the 43 NPDES discharges discharge into the mainstem of the Santa Clara River while the rest go to various tributaries.

Of the 130 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Motor Freight Transportation and Warehousing*, and *Motor Vehicle Parts, Used* categories.

There are currently 310 sites enrolled under the construction storm water permit with a similar number of sites located in the upper and lower watershed. The majority of these are residential sites 10 acres or larger in size.

IMPAIRMENTS: Limited data (beyond mineral quality and nitrogen) is available for much of the Santa Clara River. The Santa Clara River Estuary and Beach is on the 1998 303(d) list for coliform while a portion of the river upstream of the estuary is listed for ammonia and coliform. Portions of the river have chloride exceedances. The Estuary is also listed for DDT in fish tissue. Two small lakes in the watershed are also on the 1998 303(d) list for eutrophication, trash, DO, and pH problems. Two major spills of crude oil into the river have occurred in the last six years although recovery has been helped somewhat by winter flooding events. Natural oil seeps discharge significant amounts of oil into Santá Paula Creek.

The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
chloride	Basin Plan numeric objective: 80 - 100 mg/l	10 - 138 mg/l (mean of 105 ± 21)	Santa Clara River Reach 9 (Bouquet Cyn Rd to abv Lang Gaging) Santa Clara River Reach 8 (W Pier Hwy 99 to Bouquet Cyn Rd Bridge) Santa Clara River Reach 7 (Blue Cut to West Pier Hwy 99) Santa Clara River Reach 3 (Dam to abv SP Crk./blw Timber Cyn)

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3 - 28.0 mg/l to protect against acute toxicity	ND - 4.9 mg/l (mean of 1.4 ± 1.3)	Santa Clara River Reach 8 (W Pier Hwy 99 to Bouquet Cyn Rd Bridge) Santa Clara River Reach 7 (Blue Cut to West Pier Hwy 99) Santa Clara River Reach 3 (Dam to abv SP Crk /blw Timber Cyn)
nitrate + nitrite	Basin Plan numeric objective: no greater than 10 mg/l	0.3 - 15.4 mg/l (mean of 5.7 ± 2.4)	Wheeler Canyon/Todd Barranca Torrey Canyon Creek Brown Barranca/Long Canyon Mint Canyon Creek Reach 1 Santa Clara River Reach 8 (W Pier Hwy 99 to Bouquet Cyn Rd Bridge)
org. enrichment/ low DO	Basin Plan narrative objective Basin Plan numeric objective: annual mean greater than 7.0 mg/l no single sample less than 5.0 mg/l	0.8 - 11.0 mg/l (mean of 7.7 ± 2.5)	Santa Clara River Reach 9 (Bouquet Cyn Rd to abv Lang Gaging) Santa Clara River Reach 8 (W Pier Hwy 99 to Bouquet Cyn Rd Bridge) Elizabeth Lake
pH	Basin Plan numeric objective: 6.5 - 8.5 pH units	7.3 - 9.6 pH units (mean of 8.5 ± 0.7)	Elizabeth Lake
odors	Basin Plan narrative objective		Lake Hughes
coliform	Basin Plan numeric objective: Inland: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml Beaches: total coliform not to exceed 1,000 MPN/100ml in more than 20% of samples in 30 days and not more than 10,000 MPN/100ml at any time	20 - 24000 MPN/100ml	Santa Clara River Reach 8 (W Pier Hwy 99 to Bouquet Cyn Rd Bridge) Santa Clara River Estuary
sulfate	Basin Plan numeric objective: 150 mg/l		Santa Clara River Reach 9 (Bouquet Cyn Rd. to abv Lang Gaging)
Eutrophication	Basin Plan narrative objective		Elizabeth Lake Lake Hughes Munz Lake
algae	Basin Plan narrative objective		Lake Hughes
fish kills	Basin Plan narrative objective		Lake Hughes
trash	Basin Plan narrative objective		Elizabeth Lake Munz Lake Lake Hughes
ChemA*	National Academy of Science Guideline (tissue): 100 ng/g		Santa Clara River Estuary
toxaphene	State Board numeric objective (tissue): Max. Tissue Residue Level 8.8 ng/g		Santa Clara River Estuary

* ChemA refers to the sum of the chemicals aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, HCH (including lindane), endosulfan, and toxaphene

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
chloride	Santa Clara River Reaches 3, 7, and 8	01/02
nitrogen	Santa Clara River Reaches 3, 7, and 8 Wheeler Canyon/Todd Barranca Torrey Canyon Creek Brown Barranca/Long Canyon Mint Canyon Creek Reach 1	02/03
eutrophication	Elizabeth Lake Munz Lake Lake Hughes	04/05
trash	Elizabeth Lake Munz Lake Lake Hughes	04/05
coliform	Santa Clara River Reaches 8 and 9 Santa Clara River Estuary Santa Clara River Estuary Beach/Surfers Knoll	05/06

We see a need for an additional 2.2 PYs as well as $100,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Stakeholder Groups

Santa Clara River Enhancement and Management Plan Steering Committee The 26-member Project Steering Committee is currently directing preparation of an Enhancement and Management Plan. The Committee consists of representatives of the following individuals and agencies:

Acton Town Council * Aggregate Producers Agriculture/Private Land Ownership Beach Erosion Authority for Operations & Nourishment * Castaic Lake Water Agency Cities of Fillmore/Santa Paula * City of Oxnard City of San Buenaventura * City of Santa Clarita * County of Ventura - Resource Management Agency * Friends of the Santa Clara River * (environmental organization umbrella group) Los Angeles County Flood Control District * Los Angeles County Sanitation District	Los Angeles Department of Regional Planning - APIS Newhall Land & Farming Company Santa Clara Valley Property Owners Association State of California Coastal Conservancy * State of California Department of Fish and Game * State of California Department of Parks and Recreation * State of California Department of Transportation * - District 7 State of California Water Quality Control Board - L.A. Region * United Water Conservation District U.S. Army Corps of Engineers * U.S. Fish & Wildlife Service * Valley Advisory Committee Ventura County Flood Control District *

* Additionally indicated support for the river study by signing a Memorandum of Cooperation

Six subcommittees worked with a consultant to collect the information necessary for a river management plan: agriculture, flood control, water resources, aggregate industry, recreation, and biology were the areas focused on. These subcommittees worked on determining river dynamics and areas where the interests of diverse groups overlap along the river; the critical issues areas were identified. Reports were developed by the subcommittees that provide background information, goals, and recommendations for the river on the issue areas. A series of computer-based maps have been produced, which are currently being used in a GIS overlay process to identify conflicts and opportunities and facilitate decisions regarding use of the river floodplain. The stakeholder are currently looking for a consultant to put together a CEQA document for a watershed plan.

Friends of the Santa Clara River This non-profit stakeholder group has been involved with watershed activities along the length of the river with a focus on the protection, enhancement, and management of the river's resources. More information about this group may be found at their website http://www.FSCR.org.

Santa Clarita Organization for Planning the Environment (SCOPE) This group has been involved with educating the public about planning and environmental issues, including those involving the river, particularly in the area around the Santa Clarita Valley. More information about this group may be found at their website http://www.scope.org/.

Significant Past Activities

Santa Clara River Enhancement and Management Plan development evolved as the result of the efforts of former Ventura County Supervisor Maggie Kildee, representatives of the Ventura Office of the U.S. Fish and Wildlife Service, and grant funding provided by the State Coastal Conservancy. As far back as 1991, it was becoming apparent that the many proposed and conflicting uses of the river were heading for problems of rather large proportions unless the agencies that regulated the river and the various stakeholders along the river agreed on a consensus plan to manage the river and its resources. The increasingly complex regulatory process along the river, involving protection of river ecology and natural processes, was becoming a more difficult environment for stakeholders wishing to stabilize banks, develop urban projects, or mine river aggregate deposits. The river is a very complex natural system and agencies had been forced to be very conservative in analysis of projects because of incomplete understanding of the river's ecological processes. Large instream aggregate mining projects which had been proposed, plus several urban development projects in the making, led to the feeling that a giant "train wreck" was in store for the Santa Clara River. The options were to keep doing business-as-usual approaches, or to work together to develop a coordinated conservation plan for the river. Therefore, in 1991, Supervisor Kildee invited all concerned parties to participate in initiating the Plan. A Project Steering Committee was formed. Since that time, funding for consulting services associated with Plan development, totaling $510,000 to date, has been provided by the Coastal Conservancy, the State Wildlife Conservation Board, the U.S. Fish and Wildlife Service, the Cities of Santa Clarita and San Buenaventura, and both Ventura and Los Angeles County Flood Control Districts. In addition, a great deal of staff time and in-kind services have been contributed to this planning effort. This project also formed the primary basis for nomination of the Santa Clara River as an American Heritage River. Although the river is still under consideration, it has not yet been designated.

The Steering Committee began by identifying the river's critical issue areas. Reports were developed by subcommittees that provide background information, goals and recommendations for the river on the issue areas. A series of computer-based maps have been produced, which are currently being used in a Geographic Information Systems (GIS) overlay process to identify conflicts and opportunities and facilitate decisions regarding use of the river floodplain.

The Steering Committee initially identified nine main categories of critical resource issue areas and, over the past two years, subcommittees covering Biological Resources, Recreation, Water Resources, and Aggregate Mining have each developed reports providing background information, and goals and recommendations for their respective areas. In addition, two reports covering the History of the Santa Clara River and the Cultural Resources of the River have been published.

One downside to this effort is that the study and plan were limited to the mainstem of the river, not the tributaries or other watershed areas outside of the 100-year floodplain. If additional resources can be found, the study area can be expanded throughout the watershed. This will increase the chance of successful protection of this watershed.

Other important community-based efforts include Ventura County's Agriculture Policy Working Group's Agricultural Land Preservation Program, the Heritage Valley Tourism Development Program, Santa Clara River Valley Historic/Cultural Preservation Programs and the City of Santa Clarita's River Corridor Plan.

In 1990, the Regional Board adopted Resolution No. 90-004 (**Drought Policy**) which had a term of three years and provided interim relief to dischargers who experienced difficulty meeting chloride objectives because of a state-wide drought. The policy adjusted effluent limits to the lesser of 1) 250 mg/l or 2) the chloride concentration in the water supply plus 85 mg/l. In 1995, the Regional Board extended the interim limits for three years and directed staff to develop a long-term solution to deal with the impact of changing water supply, especially during droughts. In 1997, the Regional Board adopted Resolution No. 97-002 (**Chloride Policy**) which set the chloride objective at 190 mg/l except in the Calleguas Creek and Santa Clara River Watersheds where, due to the great concern for protection of agriculture, staff were directed to determine the chloride concentrations sufficient to protect agricultural beneficial uses.

Current Activities

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits and issuance of new permits. This will be a targeted watershed for the bulk of permit renewal purposes in FY 2001-02. There are four major dischargers, 16 significant or minor dischargers under individual permits, as well as 23 dischargers currently covered under general permits (additional information on permits may be found in the Appendix). Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue.

The one POTW discharging to the estuary conducted a limited-term receiving monitoring program to investigate whether toxic constituents (to be regulated under the CA Toxics Rule) are accumulating or bioaccumulating in the estuary.

We anticipate that NPDES permit renewals will focus on 1) compliance with the CA Toxics Rule, 2) nutrients, 3) coordinated monitoring, and 4) biomonitoring.

Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Ventura County Municipal Storm Water Permit (adopted in 2000). The "Discharger" consists of the co-permittees Ventura County Flood Control District, the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks. The Discharger is required to implement the approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) by January 27, 2001. The SQUIMP shall address conditions and requirements for new development and significant redevelopment.

To date, the storm water monitoring program has consisted of land-use based monitoring combined with receiving water monitoring and modeling. The Discharger intends to sign an agreement to participate in the Regional Monitoring Program established for Southern California municipal programs under the guidance of the Southern California Coastal Water Research Project.

The Santa Clara River receives municipal storm drain discharges from the City of Fillmore, City of Oxnard (part), City of San Buenaventura (part), City of Santa Paula, and unincorporated Ventura County (part).

MONITORING AND ASSESSMENT

The Santa Clara River will be a focus for SWAMP monitoring as the watershed comes up for targeting in the rotating watershed cycle. Currently, we plan on emphasizing stratified random sampling with the strata represented by stretches of river or tributary immediately upstream of confluences. Biological assessment work will be a major component of the program.

The upper Santa Clara River is monitored by the County Sanitation Districts of Los Angeles County under NPDES permits for the Saugus and Valencia treatment plants. Somewhat downstream, between the towns of Piru and Saticoy, water quality in the surface and groundwater is monitored by United Water Conservation District. Mid-river receiving water data is provided by the City of Santa Paula treatment plant under an NPDES permit and occasionally by the City of Fillmore when they discharge to surface waters under an NPDES permit. Otherwise, the City of Fillmore provides groundwater data that has not yet been integrated into the watershed picture. At the river's terminus, some water quality data is available from the City of San Buenaventura under NPDES permit for discharge to ponds adjacent to the river. The monitoring supports compliance evaluation; it is not part of a program for nonpoint source identification or TMDL development. In conjunction with the receiving water monitoring, land-use based monitoring is carried out as part of the Ventura County Municipal Storm Water Program. There is a long stretch of the middle river (surrounded by private property) that has had little to no monitoring because of limited access. Additionally, the Regional Board monitored a number of locations in the river and its tributaries until fairly recently when funding levels were reduced. The Regional Board has conducted some monitoring in the watershed also.

In support of upcoming TMDLs scheduled for the watershed, approximately one dozen sites will sampled along the length of the river this fiscal year for pesticides, nutrients, and minerals.

In addition, efforts to study impacts of chloride on groundwater supplies will require ongoing monitoring. A MOU has been prepared by staff and has been signed by several key stakeholders interested in this issue.

Ground water data are being collected by a number of agencies and should be compiled by the Fox Canyon Groundwater Management Agency. We should be acquiring some of this data over the next two years for use in our analysis of the Oxnard Plain nonpoint source contamination problems.

WETLANDS PROTECTION AND MANAGEMENT

Acquisition of parcels at the mouth of the river (wetlands, dunes and former riparian areas at the estuary as well as at the adjoining McGrath Lake and dunes) is a high priority for FY00/01 and future years funding by the Southern California Wetlands Recovery Project.

The Santa Monica Mountains Conservancy is a state agency created by the Legislature in 1979 charged with primary responsibility for acquiring property with statewide and regional significance, and making those properties accessible to the general public. The Conservancy manages parkland in the Santa Monica Mountains, Santa Susana Mountains, the Simi Hills, the Santa Clarita Woodlands, the Whittier-Puente Hills, the Sierra Pelona, the Los Angeles River Greenway, the Rio Hondo, the Verdugo Mountains, the San Gabriel Mountains, and the San Rafael Hills. The agency's goals are to: 1) implement the Santa Monica Mountains Comprehensive Plan, 2) implement the Rim of the Valley Trails Corridor Master Plan, 3) implement the Los Angeles County River Master Plan, 4) further cooperation with local governments in the region to secure open space and parkland, and 5) expand education, public access, and resource stewardship components in a manner that best serves the public, protects habitat, and provides recreational opportunities.

NONPOINT SOURCE PROGRAM

Santa Clara River Enhancement and Management Plan

A set of computer-based GIS maps has been developed to allow generation of a set of comparative overlay maps demonstrating the potential conflicting uses and compatible opportunities on each of 13 river reaches defined in the Plan.

Using the maps, extensive discussion of issues along the river will take place during a series of Project Steering Committee working sessions. Overlay layers are developed around the resource areas of water resources, flood protection, agricultural resources, aggregate resources, biological resources, cultural resources, recreation, and land use. Within each resource area, individual layers are being developed depicting selected parameters for comparison. For example, for biological resources, layers have been generated showing the various types of riparian vegetation, exotic species, and habitat values. The overlay analysis resulted in identification of the areas of greatest potential conflicts facing the river, and recommendations for addressing these issues, including (1) preserving and maintaining water conveyance and groundwater recharge functions of the river, (2) creating mitigation banks, enhancing significant biological areas, and providing public access opportunities, (3) enhancing populations of threatened and endangered species on the river, with the goal of creating viable and sustainable populations, (4) enhancement and preservation of agricultural land, (5) mitigation of beach erosion issues, (6) implementation of flood protection and bank stabilization facilities, and (7) identification of areas appropriate for development and for sand and gravel extraction.

Following completion in 1998 of the overlay analysis, a Draft Plan with reach-by-reach analyses was developed and public meetings held to discuss the Plan and its ramifications. Environmental review of the Draft Plan will also be carried out prior to developing the Final Plan.

Two demonstration projects under consideration for funding by the Coastal Conservancy would utilize a GIS overlay process for 1) a bank stabilization project using bio-technical methods to promote reduced bank erosion while increasing wildlife habitat, and 2) creation of a mitigation bank on a unique portion of river terrace riparian habitat for the protection and enhancement of wildlife habitat

In April 1999, the Project Steering Committee released preliminary river-wide and reach-specific recommendations for public comment. River-wide recommendations include those involving issues such as public outreach, private property rights, water quality, water rights, saltwater intrusion, water supply, river gradient, public flood protection facilities, maintenance of design flow capacity, private flood protection, cultural resource protection, fish passage, habitat conservation priorities, biological management, control of exotics, biological mitigation, public access and recreation, recreational property acquisition, and permit streamlining.

The group has also developed draft resource-based ranking criteria for parcel acquisition. There is one such parcel acquisition, funded by the State Coastal Conservancy, currently being pursued. The proposed acquisition includes 213 acres of river bottom, river terrace, and riparian habitat. Staff will remain involved with the Plan's development and implementation. During the fall of 1999, the Project Steering Committee reviewed proposals from consultants to prepare a CEQA document for the Plan for the river.

Regulatory-based Encouragement of Best Management Practices

Currently under consideration are agreements with sister agencies in regulatory-based encouragement of Best Management Practices. Most notably is the use of a GIS layer for pesticides application available from the Department of Pesticide Regulation (DPR). Reduction of pesticides identified as contaminants of concern for a watershed might be addressed through a Management Agency Agreement (MAA) with the DPR, or through waiving adoption of waste discharge requirements on an individual basis using information gathered in databases provided by the Ventura County Agricultural Commission office.

Regulatory involvement with the Agua Dulce septic tank problems is currently at Tier I but is moving into Tier II (see discussion of Nonpoint Source Program in the Regionwide Section for description of tiers). The rural community of Aqua Dulce is at the headwaters of the Santa Clara River in northern Los Angeles County. Previous studies have shown elevated nitrate levels in the groundwater due to animal wastes, septic systems, and some natural sources. Some drinking water wells are experiencing high levels of nitrate exceeding the MCL. The Regional Board requested the Aqua Dulce Town Council submit quarterly monitoring reports with a goal of testing 65 wells each quarter. Quarterly reports so far submitted have shown nitrate contamination.

Agriculture

There are a number of 303(d)-listed impairments in the watershed which may be attributable in part to agricultural practices, notably salts and nitrogen related as well as movement of historic pesticides. We will be focussing our 319(h) priorities for the upcoming application period on a number of areas of concern in the Region including development of an agricultural "strategy", education and outreach programs and implementation of management measures relative to nutrient management and erosion control.

Groundwater

The Oxnard Forebay is a prime groundwater recharge area that is impacted by nitrogen discharges, mainly from densely populated communities using septic systems, and agricultural areas. The Regional Board undertook a study of septic systems in the area during FY98/99; in August 1999 the Board adopted a Basin Plan amendment to prohibit septic systems in the Oxnard Forebay. The amendment immediately prohibits the installation of new septic systems or the expansion of existing septic systems on lot sizes of less than five acres. Discharges from septic systems on lot sizes of less than five acres must cease by January 1, 2008. This prohibition will affect up to 3,000 septic systems and ten to fifteen thousand people.

BASIN PLANNING

Chloride impairments in certain reaches of the river initially led to formation of a chloride committee to conduct a chloride TMDL by spring 2000. This stemmed from issues raised during development of a chloride policy for the region. Growers expressed concerned about increased chloride and effects on salt-sensitive crops, such as avocados. Staff propose going to the Board in December 2000 with two resolutions: one to extend the interim chloride limitation for discharges to the river until December 7, 2001; the other to amend the Basin Plan chloride objective for certain reaches in the river. The Board adopted the extension of the interim limitation at the December meeting, raised the Basin Plan objectives in Reach #3 from 80 to 100 mg/l, and determined the chloride objective for chloride in reaches #7 and #8 should remain unchanged from 100 mg/l. Reaches #3, #7, and #8 are currently 303(d)-listed for chloride. Reach #3, now with a higher objective for chloride, may be considered for de-listing in 2002. The Board has directed staff to complete a chloride TMDL on Reaches #7 and #8 within six to nine months.

Basin Planning activities will also include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

The Santa Clara River Watershed is being proposed for inclusion in a partial update of the Water Quality Assessment report due in 2002. This will require staff resources to collect and analyze data in 2000/01 in order to develop a State of the Watershed Report and update the Water Quality Assessment.
Future phases of the Santa Clara River Enhancement and Management Plan effort, to be carried out over the next one-to-five years, involve completion of the GIS overlay analysis, preparation of the Draft Plan, environmental and public review of the Draft Plan, publication of a Final Plan, and acquisition of funding for Plan implementation. Regional Board staff involvement will continue.

Our efforts to involve stakeholders shall also include exploration of funding options (especially for implementation of nonpoint source measures) and continuation of other outreach activities, such as speeches, meetings, and participation in environmental events. We shall continue out involvement in the watershed group's efforts to develop and implement a watershed management plan.

We are also proposing increased efforts in oversight and management of ground water resources. However, staff involvement in voluntary resolution of nonpoint source problems (Tier I) requires more resources than a regulatory-based approach. Tier II (regulatory encouragement) activities over the long-term include tracking nonpoint source inputs by supplemental databases such as DPR and the Department of Food and Agriculture (DFA), as well as increased sampling of the receiving water for contaminants of concern and toxicity. Tier III (effluent limitations) activities over the long-term include sampling, inspecting, and permitting priority contributors of contaminants of concern in watersheds not fully implementing a stakeholder-driven watershed approach.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. With additional resources we propose conducting a number of education and outreach activities including holding regional workshops and conferences with other Regional Boards as well as experts in the field. We also propose further refining our agricultural strategy to clearly delineate our goals and objectives with regards to reducing nonpoint source pollution from this sector and potential triggers for moving through the tiers.

The complexity of this watershed system, coupled with divergent goals among upstream developers, downstream farmers, and environmental interests, necessitate that extra planning resources be allocated to this watershed. It is imperative that the Regional Board actively participate in dialogue regarding water quality issues during the near-term, to ensure proper planning and development of the long-term projects that are being proposed. Among the various approaches that will be taken by the Regional Board is more active participation in CEQA and other planning efforts in this watershed to ensure protection of this valuable water resource, especially in light of the high growth projections in the floodplains and recharge areas of this watershed.

Potential Mid- to Long-term Activities

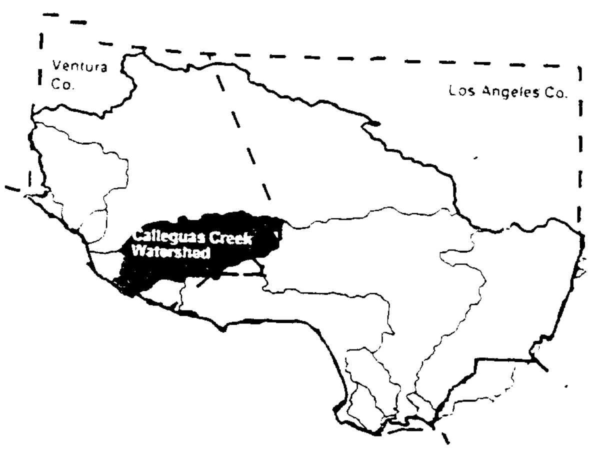
- Evaluation of potential impacts from mining in and around the river
- Evaluation of impacts from large-scale development in the upper river
- Identification of conflicts between ground water supply and water quality in lower watershed
- Identification of water quality and quantity issues for steelhead trout recovery
- Consideration of TMDL-related issues
- Implementation of watershed-wide biological monitoring which is a long-term goal for all of our watersheds

THIS PAGE INTENTIONALLY LEFT BLANK

2.2 *CALLEGUAS CREEK WATERSHED*

This was a targeted watershed for permitting purposes in FY95/96 and it will be targeted next in FY01/02.

Overview of Watershed



Calleguas Creek and its major tributaries, Revolon Slough, Conejo Creek, Arroyo Conejo, Arroyo Santa Rosa, and Arroyo Simi drain an area of 343 square miles in southern Ventura County and a small portion of western Los Angeles County. This watershed, which is elongated along an east-west axis, is about 30 miles long and 14 miles wide. The northern boundary of the watershed is formed by the Santa Susana Mountains, South Mountain, and Oak Ridge; the southern boundary is formed by the Simi Hills and Santa Monica Mountains.

Land uses vary throughout the watershed. Urban developments are generally restricted to the city limits of Simi Valley, Moorpark, Thousand Oaks, and Camarillo. Although some residential development has occurred along the slopes of the watershed, most upland areas are still open space, however, golf courses are becoming increasingly popular to locate in these open areas. Agricultural activities, primarily cultivation of orchards and row crops, are spread out along valleys and on the Oxnard Plain.

Mugu Lagoon, located at the mouth of the watershed, is one of the few remaining significant saltwater wetland habitats in southern California. The Point Mugu Naval Air Base is located in the immediate area and the surrounding Oxnard Plain supports a large variety of agricultural crops. These fields drain into ditches which either enter the lagoon directly or through Calleguas Creek and its tributaries. Other fields drain into tile drain systems which discharge to drains or creeks. Also in the area of the base are freshwater wetlands created on a seasonal basis to support duck hunting clubs. The lagoon borders on an Area of Special Biological Significance (ASBS)

Beneficial Uses in watershed:

Estuary	*Above Estuary*
Wildlife habitat	Wildlife habitat
Contact & noncontact water recreation	Contact & noncontact water recreation
Estuarine habitat	Industrial service supply
Marine habitat	Industrial process supply
Preservation of rare & endangered species	Preservation of rare & endangered species
Navigation	Agricultural supply
Preservation of biological habitats	Groundwater recharge
Wetlands habitat	Wetlands habitat
Migratory & spawning habitat	Freshwater replenishment
Shellfish harvesting	Warmwater habitat

and supports a great diversity of wildlife including several endangered birds and one endangered plant species. Except for the military base, the lagoon area is relatively undeveloped.

Supplies of ground water are critical to agricultural operations and industry (sand and gravel mining) in this watershed. Moreover, much of the population in the watershed relies upon ground water for drinking.

Water Quality Problems and Issues

Aquatic life in both Mugu Lagoon and the inland streams of this watershed has been impacted by pollutants from nonpoint sources. DDT, PCBs, other pesticides, and some metals have been detected in both sediment and biota collected from surface waterbodies of this watershed. Additionally, ambient toxicity has been revealed in several studies from periodic toxicity testing in the watershed (ammonia from POTWs and pesticides such as diazinon and chlorpyrifos are implicated). Fish collected from Calleguas Creek and Revolon Slough exhibit skin lesions and have been found to have other histopathologic abnormalities. High levels of minerals and nitrates are common in the water column as well as in the groundwater. Sediment toxicity is also elevated in some parts of the lagoon. Reproduction is impaired in the resident endangered species, the light-footed clapper rail due to elevated levels of DDT and PCBs. Overall, this is a very impaired watershed. It appears that the sources of many of these pollutants are agricultural activities (mostly through continued disturbance and erosion of historically contaminated soils), which cover approximately 25% of the watershed along the inland valleys and coastal plain, although the nearby naval facility has also been a contributor. Other nonpoint sources include residential and urban activities, which are present over approximately 25% of the watershed. The remaining 50% of the watershed is still open space although there is a severe lack of benthic and riparian habitat.

Permitted discharges:

- Six POTWs with NPDES permits (3 larger, 3 smaller)
- 82 dischargers covered under an industrial storm water permit
- 100 dischargers covered under construction storm water permit
- Municipal storm water permit

Mugu Lagoon as well as the Calleguas Creek Estuary is considered a candidate toxic hot spot under the BPTCP for reproductive impairment (the endangered clapper rail), exceedance of the state Office of Environmental and Health Hazard Assessment (OEHHA) advisory level for mercury in fish, and exceedance of the NAS guideline level for DDT in fish, sediment concentrations of DDT, PCB, chlordane, chlorpyrifos, sediment toxicity and degraded benthic infaunal community.

Primary issues related to POTW discharges include ammonia toxicity and high mineral content (i.e., salinity), the latter, in part, due to imported water supplies.

<u>Types of permitted wastes discharged into the Calleguas Creek Watershed:</u>

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	2	General
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	2 4	Minor General
Hazardous contaminated groundwater	4 4	Minor General
Nonhazardous (designated) domestic sewage & industrial waste	3 2	Major Minor
Nonhazardous (designated) domestic sewage	1	Minor
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	3	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

Discharges are fairly evenly spread around the watershed; nine of the 25 NPDES discharges go to the Arroyo Conejo, five each to the Arroyo Las Posas and Calleguas Creek, while four go to the Arroyo Simi.

Of the 82 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Electronic and Other Electrical Equipment and Components* and *Stone, Clay, Glass, and Concrete Products* categories.

There are 100 construction sites enrolled under the construction storm water permit. About 60 percent are located in the Simi Valley area and 40% in the Camarillo area. The majority of these are residential sites 10 acres or larger in size.

The table below gives examples of typical data ranges which led to the 1998 303(d) listings. See <u>Table 7</u> in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

IMPAIRMENTS:

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
nitrate + nitrite	Basin Plan numeric objective: no greater than 10 mg/l	11.9 - 70.0 mg/l (mean of 48.5 ± 13)	Fox Barranca Arroyo Las Posas Reach 1 (Lewis/Somis Rd. to Fox Barranca) Arroyo Las Posas Reach 2 (Fox Barranca to Moorpark Fwy (23)) Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Calleguas Creek Reach 3 (Potrero to Somis Rd.)
nitrogen	Basin Plan numeric objective: no greater than 10 mg/l		Rio de Santa Clara/Oxnard Drain #3 Calleguas Creek Reach 1 (estuary to 0.5 mi. S. of Broome Rd.) Calleguas Creek Reach 2(0.5 mi. S. of Broome Rd. to Potrero Rd.) Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.) Mugu Lagoon Duck pond agric. drain/Mugu Drain/Oxnard Drain #2
ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3 - 28.0 mg/l to protect against acute toxicity	0.1 - 20. 2 mg/l (mean of 2.7 ± 3.6)	Arroyo Las Posas Reach 1 (Lewis/Somis Rd. to Fox Barranca) Arroyo Las Posas Reach 2 (Fox Barranca to Moorpark Fwy (23)) Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Calleguas Creek Reach 1 (estuary to 0.5 mi. S. of Broome Rd.) Calleguas Creek Reach 2(0.5 mi. S. of Broome Rd. to Potrero Rd.) Conejo Creek/Arroyo Conejo N. Fork Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 4 (above Lynn Rd.)
algae	Basin Plan narrative objective		Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 4 (above Lynn Rd.) Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.)
low DO/org. enrichment	Basin Plan narrative objective Basin Plan numeric objective: annual mean greater than 7.0 mg/l no single sample less than 5.0 mg/l	2.6 - 10.9 mg/l (mean of 7.0 ± 1.8)	Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 4 (above Lynn Rd.)
chlorpyrifos (tissue)	Basin Plan narrative objective		Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.)
toxicity	Basin Plan narrative objective	0 - 100 % survival	Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 4 (above Lynn Rd.) Calleguas Creek Reach 1 (estuary to 0.5 mi. S. of Broome Rd.) Calleguas Creek Reach 2(0.5 mi. S. of Broome Rd. to Potrero Rd.) Duck pond agric. drain/Mugu Drain/Oxnard Drain #2 Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.)

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
chloride	Basin Plan numeric objective: 150 mg/l	78 - 230 mg/l (mean of 173 ± 31)	Tapo Canyon Reach 1 Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Arroyo Las Posas Reach 2 (Fox Barranca to Moorpark Fwy (23)) Arroyo Las Posas Reach 1 (Lewis/Somis Rd. to Fox Barranca) Calleguas Creek Reach 3 (Potrero to Somis Rd.) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 4 (above Lynn Rd.)
Boron	Basin Plan numeric objective 1.0 mg/l	0.4 - 1.4 mg/l (mean of 1.1 ± 0.3)	Fox Barranca Tapo Canyon Reach 1 Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Arroyo Simi Reach 2 (above Brea Canyon) Calleguas Creek Reach 3 (Potrero to Somis Rd.)
sulfate	Basin Plan numeric objective 250 mg/l	185 - 1000 mg/l (mean of 642 ± 278)	Fox Barranca Tapo Canyon Reach 1 Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Arroyo Simi Reach 2 (above Brea Canyon) Arroyo Las Posas Reach 1 (Lewis/Somis Rd. to Fox Barranca) Arroyo Las Posas Reach 2 (Fox Barranca to Moorpark Fwy (23)) Conejo Creek/Arroyo Conejo N. Duck pond agric. drain/Mugu Drain/Oxnard Drain #2 Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.) Mugu Lagoon Rio de Santa Clara/Oxnard Drain #3
dieldrin (tissue)	State Board numeric objective (tissue): Max. Tissue Residue Level 0.65 ng/g	4.7 - 6.6 ng/g (tissue)	Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.)
sediment toxicity	Basin Plan narrative objective	14 - 71 % survival	Calleguas Creek Reach 1 (estuary to 0.5 mi. S. of Broome Rd.) Calleguas Creek Reach 2(0.5 mi. S. of Broome Rd. to Potrero Rd.) Mugu Lagoon Rio de Santa Clara/Oxnard Drain #3 Duck pond agric. drain/Mugu Drain/Oxnard Drain #2
siltation	Basin Plan narrative objective		Mugu Lagoon
chromium (tissue)	Basin Plan narrative objective	0.51 - 0.58 ug/g (tissue)	Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd)

* ChemA refers to the sum of the chemicals aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, HCH (including lindane), endosulfan, and toxaphene

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
silver (tissue)	Basin Plan narrative objective	0.03 - 0.04 ug/g (tissue)	Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd)
nickel (tissue)	Basin Plan narrative objective	0.5 ug/g (tissue)	Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd) Mugu Lagoon
cadmium (tissue)	Basin Plan narrative objective	0.14 - 0.15 ug/g (tissue)	Conejo Creek Reach 3 (Tho. Oaks city limit to Lynn Rd.) Conejo Creek Reach 2 (Santa Rosa Rd. to Tho. Oaks city limit) Conejo Creek Reach 1 (confl. Calleguas to Santa Rosa Rd)
copper	USEPA water quality criteria 2.9 ug/l		Mugu Lagoon
zinc	USEPA water quality criteria 86 ug/l		Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Mugu Lagoon
Mercury	USEPA water quality criteria 2.1 ug/l		Mugu Lagoon
Selenium	USEPA water quality criteria 5.0 ug/l	11.0 ug/l (maximum)	Arroyo Simi Reach 1 (Moorpark Fwy (23) to Brea Cyn) Revolon Slough Main Branch (Mugu Lagoon to Central Ave.)
PCBs (tissue & Sediment)	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g	ND - 96.0 ng/g (sediment) 16.8 - 70.8 ng/g (tissue)	Calleguas Creek Reach 1 (estuary to 0.5 mi. S of Broome Rd.) Calleguas Creek Reach 2 (0.5 mi. S of Broome Rd. to Potrero Rd.) Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.) Mugu Lagoon Rio de Santa Clara/Oxnard Drain #3
Trash	Basin Plan narrative objective		Revolon Slough Main Branch (Mugu Lagoon to Central Ave.) Beardsley Channel (above Central Ave.)

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
chloride	Tapo Canyon Reach 1 Arroyo Simi Reach 1 Arroyo Las Posas Reaches 1 and 2 Calleguas Creek Reach 3 Conejo Creek Reaches 2 and 4	00/01
nitrogen	Fox Barranca Arroyo Las Posas Reaches 1 and 2 Arroyo Simi Reach 1 Calleguas Creek Reaches 1, 2 and 3 Conejo Creek/Arroyo Conejo N. Fork Conejo Creek Reaches 1, 2, 3, and 4 Revolon Slough Main Branch Beardsley Channel Mugu Lagoon Duck pond agric. drain/Mugu Drain/Oxnard Drain #2	02/03
pesticides (water-soluble)	Conejo Creek Reaches 1, 2, 3 and 4 Calleguas Creek Reaches 1 and 2 Duck pond agric. drain/Mugu Drain/Oxnard Drain #2 Revolon Slough Main Branch Beardsley Channel	03/04
Other salts	Fox Barranca Tapo Canyon Reach 1 Arroyo Simi Reaches 1 and 2 Arroyo Las Posas Reaches 1 and 2 Calleguas Creek Reach 3 Conejo Creek/Arroyo Conejo N Fork Conejo Creek Reaches 1, 2, 3 and 4	03/04

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
PCBs	Calleguas Creek Reach 1 Calleguas Creek Reach 2 Revolon Slough Main Branch Beardsley Channel Mugu Lagoon	04/05
pesticides (sediment-bound)	Mugu Lagoon Arroyo Las Posas Reaches 1 and 2 Conejo Creek/Arroyo Conejo N. Fork Conejo Creek Reaches 1, 2, 3 and 4 Calleguas Creek Reaches 1 and 2 Duck pond agric. drain/Mugu Drain/Oxnard Drain #2 Revolon Slough Main Branch Beardsley Channel	04/05
metals	Arroyo Simi Reach 1 Conejo Creek Reaches 1, 2 and 3 Mugu Lagoon Revolon Slough Main Branch	05/06

We see a need for an additional 2.5 PYs as well as $50,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Stakeholder Groups

Calleguas Creek Watershed Management Committee (and subcommittees) The committee and subcommittees have been actively meeting since November 1996 with the purpose of developing a watershed management plan. The technical subcommittees include Habitat/Recreation, Flood Protection/Sediment Management, Water Quality/Water Resources, Public Outreach/Education, and Geographical Information Systems (GIS). A Steering Committee attends to the details of management plan development. The full Management Plan Committee meets on a quarterly basis, generally conducting business in a half-day session. Two or three Regional Board staff attend these meetings. The Flood Protection and Habitat Subcommittees meet bimonthly; one Regional Board staff member attends each. The Water Quality Subcommittee is meeting bimonthly and 1-2 staff members attend. The Steering Committee is also meeting bimonthly with 1-2 staff members attending. Regional Board staff are not currently assigned to the Public Outreach and GIS Subcommittees. For further information concerning this group, please visit their website at http://www.calleguas.com/cc.htm.

A number of committee members were also on the *Mugu Lagoon Task Force* which was formed in 1990 in response to concerns about sedimentation filling in Mugu Lagoon which is at the mouth of the Calleguas Creek Watershed. A major focus of the early meetings was exchange of information on the extent of sedimentation with related concerns such as pesticide transfer. A sediment and erosion control plan was prepared for the Ventura County RCD ~~by~~ the U.S. Natural Resource Conservation Service (USNRCS) using Coastal Conservancy funds ("Calleguas Creek Watershed Erosion and Sediment Control Plan for Mugu Lagoon", May 1995). This group is not currently meeting; however, information gained from this effort continues to be used by the other Calleguas Watershed Committees.

Significant Past Activities

CORE REGULATORY

The majority of Calleguas Creek Watershed permits were revised in June 1996. This watershed, as well as the Ventura River Watershed, were pilot watersheds in our implementation of the watershed management approach. The Ventura County Municipal Stormwater NPDES Permit had most recently been adopted in 2000.

MONITORING AND ASSESSMENT

The Calleguas Creek Watershed was included in a partial update of the Water Quality Assessment report in 1998. Also, in 2000, the dischargers completed a short-term watershed characterization study which assessed a large number of sites for both biological and chemical parameters.

BASIN PLANNING

In 1990, the Regional Board adopted Resolution No. 90-004 (**Drought Policy**) which had a term of three years and provided interim relief to dischargers who experienced difficulty meeting chloride objectives because of a state-wide drought. The policy adjusted effluent limits to the lesser of 1) 250 mg/l or 2) the chloride concentration in the water supply plus 85 mg/l. In 1995, the Regional Board extended the interim limits for three years and directed staff to develop a long-term solution to deal with the impact of changing water supply, especially during droughts. In 1997, the Regional Board adopted Resolution No. 97-002 (**Chloride Policy**) which set the chloride objective at 190 mg/l except in the Calleguas Creek and Santa Clara River Watersheds where, due to the great concern for protection of agriculture, staff were directed to determine the chloride concentrations sufficient to protect agricultural beneficial uses.

NONPOINT SOURCE PROGRAM

Work on nonpoint source problems in the watershed has been a long-term effort, initiated in 1990, with the support of 319(h) funds and other funding from, and support by, stakeholders. The 319(h) grant projects, special studies, and other activities that have been completed to date include:

- ***Irrigation Demonstration Project***: In 1994, the Ventura County Resource Conservation District successfully completed an irrigation project that demonstrated the water quality and conservation benefits of drip irrigation. This project was funded through a 319(h) grant.

- ***Toxicity Testing***: In order to detect sources of toxicity, we have collected water samples under three sequential studies (toxicity testing by UC Davis). Results of this sampling indicated sporadic toxicity, generally during wet weather seasons, with strong implication of organophosphate pesticides.

- ***Calleguas Creek Watershed Treatment – Phase I***: The Ventura County Resource Conservation District served as contractor for this project which focused on Best Management

Practices that involved small, individual landowners/ farmers. This demonstration project was designed to implement streambed protection practices. This project was funded through a 319(h) grant.

Current Activities

The following is a summary of current regional board activities in the Calleguas Creek Watershed which are expected to continue as part of the Watershed Management Initiative.

CORE REGULATORY

Permits in this watershed will be targeted for renewal in FY 2001-02. Current regulatory activities include compliance inspections, review of monitoring reports, response to complaints, and enforcement actions, as needed.

A watershed-wide regional monitoring program was created to fill in data gaps and eliminate duplicative and unnecessary monitoring. POTWs contributed significant resources to do a surface and ground water characterization study. It also serves to assess nonpoint source pollution from a variety of land uses.

Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Municipal Storm Water Permit (revised in 2000). Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Ventura County Municipal Storm Water Program. The "Discharger" consists of the co-permittees Ventura County Flood Control District, the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks. The Discharger is required to implement the approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) by January 27, 2001. The SQUIMP shall address conditions and requirements for new development and significant redevelopment.

The Calleguas Creek receives municipal storm drain discharges from the City of Camarillo, City of Moorpark, City of Simi Valley, City of Thousand Oaks (part), and unincorporated Ventura County (part).

To date, the storm water monitoring program has consisted of land-use based monitoring combined with receiving water monitoring and modeling. The Discharger intends to sign an agreement to participate in the Regional Monitoring Program established for Southern California municipal programs under the guidance of the Southern California Coastal Water Research Project.

In fulfillment of NPDES permit requirements for one discharger, and in concert with other point and nonpoint source dischargers, a characterization study of primarily point source loadings for the pollutants of concern began in June 1998.

Regulation of groundwater protection activities is intended to eventually become fully integrated into the watershed management approach; currently, groundwater monitoring (for POTWs using ponds) is being coordinated with surface water monitoring.

Key regulatory staff continue to participate as past of the Calleguas Creek Watershed team for purposes of updating the State of the Watershed Report and for communication on the characterization study in development.

MONITORING AND ASSESSMENT

Calleguas Creek will be a focus for SWAMP monitoring as the watershed comes up for targeting in the rotating watershed cycle. Since extensive monitoring has already occurred here, particularly in the lower watershed, a more directed approach to sampling site selection will be taken.

As the first integrated watershed monitoring program in the Region, the six POTWs in the watershed are each implementing a portion of the monitoring program as described in their NPDES permits, and as further revised in their Characterization Study to also include other agencies in the effort. In conjunction with the receiving water monitoring, land-use based monitoring is done as a part of the Ventura County Municipal Storm Water Program. The monitoring supports compliance valuation, nonpoint source identification, and potential TMDL development. The expanded monitoring by the dischargers will also serve to evaluate beneficial uses. Additionally, the Regional Board is funding additional toxicity work in the upper watershed in coordination with the dischargers' monitoring.

The BPTCP has identified the lagoon and tidal prism as "toxic hot spots" based on sediment contamination. Staff have completed a cleanup plan for the areas which was adopted as part of a statewide consolidated plan by the State Board in June 1999. Cleanup/remediation alternatives identified include dredging, in-situ capping, and treatment. Continuing Regional Board activities include working with stakeholders to further characterize historical sources of pollution as well as the extent of existing contributions. While remediation of the lagoon (as part of a military facility) may proceed on its own timeline, in general, there is a concerted effort by all stakeholders to prepare a comprehensive watershed management plan to address all problems in the watershed.

Six TMDLs are currently scheduled for this watershed over the next five years and considerable resources will be needed to support their development.

NONPOINT SOURCE PROGRAM

We expect that stakeholders will continue work on developing a watershed management plan, which will include measures for reducing pollutants from nonpoint sources. Accordingly, our efforts in the Calleguas Creek watershed will focus on continuing the nonpoint source phase of the watershed cycle, including integrating results of our on-going nonpoint source efforts. The 319(h) grant projects, special studies, and other activities that are currently on-going include:

319(h) Grant Project

Calleguas Creek Watershed Treatment – Phase II: The Ventura County Resource Conservation District serves as contractor for this project which focuses on Best Management Practices that require the coordinated efforts of several small groups or a large landowner/

farmer (as a followup to Phase I concentrated on small, individual landowners/ farmers). This demonstration project is designed to implement streambed projects that were successful.

We continue to support as high priorities for FY2001/02 319(h) funding projects relating to comprehensive erosion control efforts, habitat enhancement/restoration, and reduction of a variety of pollutants (see Table 4).

205(j) Grant Project

205(j) monies have funded a component of the Surface Water Element of the Calleguas Creek Characterization Study Monitoring Program which is evaluating nonpoint source contributions in the watershed. The study seeks to identify nonpoint source loadings of nitrogen, salts, and pesticides and with the results of the Surface Water Element, conduct TMDLs on several of these pollutants. The study is currently in the data analysis stage.

Toxicity Testing

Followup work is being conducted on the sporadic toxicity found in previous studies conducted by UC Davis. Another contractor is investigating a procedure to distinguish toxicity due to organophosphate pesticides.

Participation in Stakeholder Groups

Calleguas Creek Watershed Management Committee and Technical Subcommittees: Recognizing that many of the water quality problems in the lagoon stem from land use practices and pollutant sources above the lagoon, members of these committees meet regularly to exchange data and discuss coordinated approaches to solving the many problems in this watershed, including development of a watershed management plan. The watershed group consists of about 130 stakeholders who have been meeting for about two years. As we expect that much effort will need to be focussed on resolving agricultural and flood control issues, we have made a concerted effort to include appropriate stakeholders. Besides the main management committee of stakeholders, five technical subcommittees deal with more specific issues such as water quality, flood control, habitat/natural resources, public outreach, and GIS. The group is working on development of a watershed management plan and are actively pursuing development and implementation of "early action" items. Staff have been and will continue to work with these committees.

During fiscal year 2000/01, we shall continue to work with stakeholders to complete a watershed management plan. In particular, we shall work toward integrating our past, on-going, as well as other appropriate nonpoint source projects into the stakeholders' watershed management plan.

Other NPS Activities

Our efforts to involve stakeholders also shall include exploration of funding options (especially for implementation of nonpoint source measures) and continuation of other outreach activities, such as speeches, meetings, and participation in environmental events.

In this watershed, particularly with regards to agriculture, voluntary nonpoint source management measures are taking place. Agriculture is being brought into the watershed process as an important stakeholder and have, under the various subcommittees, brought to the table a number of voluntary best management practices.

Currently under consideration are agreements with sister agencies in regulatory-based encouragement of Best Management Practices. Most notably is the use of a GIS layer for pesticides application available from the Department of Pesticide Regulation (DPR). Reduction of pesticides identified as contaminants of concern for a watershed might be addressed through a Management Agency Agreement (MAA) with the DPR, or through waiving adoption of waste discharge requirements on an individual basis using information gathered in databases provided by the Ventura County Agricultural Commission office.

BASIN PLANNING

A priority basin planning issue is continued work to determine the scope of water quality impacts from agricultural runoff in the Region. The majority of agricultural activities occur in the Calleguas Creek Watershed, especially in the Oxnard Plain and in the nearby foothills. Development of solutions to any impacts is also a high priority and will be a major concern of the nonpoint source program and, by extension, the watershed committee and subcommittees which will be addressing this as well as other problems. An evaluation of salt-sensitive agricultural resources will be done as part of the chloride TMDL.

Chloride impairments in certain reaches of the river led to formation of a chloride committee to conduct a chloride TMDL by spring 2000. This stemmed from issues raised during development of a chloride policy for the region. Growers are concerned about increased chloride and effects on salt-sensitive crops, such as avocados. In December 2000, the Board a resolution to extend the interim chloride limitation (190 mg/l) for discharges to the creek until December 7, 2001. A chloride TMDL for the creek is tentatively scheduled to go before the Board in March 2001.

WETLANDS PROTECTION AND MANAGEMENT

The <u>Southern California Wetlands Recovery Project</u> considers the lower Conejo Creek acquisition a high priority project for funding starting in FY00/01. The Habitat Subcommittee of the Calleguas Creek Watershed Plan Committee has also approved the acquisition as a priority. A conceptual restoration plan is being prepared.

<u>The Santa Monica Mountains Conservancy</u> is a state agency created by the Legislature in 1979 charged with primary responsibility for acquiring property with statewide and regional significance, and making those properties accessible to the general public. The Conservancy manages parkland in the Santa Monica Mountains, Santa Susana Mountains, the Simi Hills, the Santa Clarita Woodlands, the Whittier-Puente Hills, the Sierra Pelona, the Los Angeles River Greenway, the Rio Hondo, the Verdugo Mountains, the San Gabriel Mountains, and the San Rafael Hills. The agency's goals are to: 1) implement the Santa Monica Mountains Comprehensive Plan, 2) implement the Rim of the Valley Trails Corridor Master Plan, 3) implement the Los Angeles County River Master Plan, 4) further cooperation with local governments in the region to secure open space and parkland, and 5) expand education, public

access, and resource stewardship components in a manner that best serves the public, protects habitat, and provides recreational opportunities.

DOD SITE CLEANUP PROGRAM

The Regional Board is working with the Department of Toxic Substances Control (DTSC) to investigate soil and groundwater quality. Sites currently under assessment/remediation include Mugu Lagoon, a former landfill, the Naval Exchange gas station, two Installation Restoration Program (IRP) sites, numerous underground storage tanks, and the former oxidation sewage ponds.

The Navy disposed of inert, contaminated and hazardous wastes to an unlined unpermitted landfill constructed by depositing and compacting wastes into Calleguas Creek. An erosion berm was installed as an interim remedial measure to prevent further erosion of the former landfill by storm water flowing through the creek during storm events. Long-term groundwater monitoring will be required for this site. Sediments and surface water at IRP Site 5 are contaminated with chrome. An initial emergency removal action (sediment excavation) failed to adequately remediate all impacted sediments and additional sediment remediation and surface water monitoring is ongoing.

Soil and groundwater at IRP Site 24 is contaminated with chlorinated solvents. Groundwater is being treated by implementation of a new biodegradation technology. It is not yet determined to what extent groundwater remediation or monitoring will be required to restore this site.

It is anticipated the Navy will implement a base-wide groundwater/surface water investigation to evaluate the overall groundwater and surface water quality, evaluate the interactions of surface water and groundwater, and determine the cumulative risk of multiple groundwater-surface water contamination sites on the overall water quality of the area and the risk to human health and the environment.

Prior to 1979, the Navy was allowed to discharge partially treated wastewater to surface water oxidation ponds that were constructed in the Calleguas Creek tidal prism. The ponds were unlined and allowed to percolate unevaporated water to the underlying groundwater, which is located about four feet below grade. The Regional Board rescinded the Navy's discharge permit in 1979 and required the Navy to pump all wastewater to the Oxnard POTW. However, periodic unpermitted discharges of wastewater continued to the ponds during planned repairs of the wastewater discharge line and wastewater overflow conditions, which occurred during heavy rains.

To prevent additional wastewater discharges to the ponds, the Regional Board issued a Cleanup and Abatement Order to the Navy in 1998 directing the Navy to cease all unpermitted discharges, construct a lined emergency wastewater retention basin, upgrade the wastewater discharge line, and remove the sludge that has accumulated in the ponds.

Current funding for the investigation and remediation of contaminated solids, surface water and groundwater at the base is through the DoD/CalEPA funding agreement; however, this funding is not satisfactory for the investigation or control of contaminants from upstream sources for the protection of Mugu Lagoon and continued funding cuts have had significant impacts on the level of oversight by Regional Board staff on these areas.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

NPDES Permits in the watershed will come up for renewal in FY 2003/04. In the meantime, core regulatory activities will focus on permit compliance, monitoring report review, and enforcement as needed. In addition, integration of stormwater and nonpoint source issues will continue. Members of the watershed team will be involved with periodic updates of the State of the Watershed Report. Additionally, there will be on-going interaction with stakeholders and followup on goals established during the permit renewal phase. Pending results from the discharger pollutant characterization study, a decision on waste load and load allocations will be pursued.

A review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

We shall have made significant progress later in this watershed's first cycle, toward identifying and assessing problems (through the characterization study) and involving stakeholders. At that point we (and the stakeholders) may also enough information to get a headstart on establishing load allocations for certain pollutants of concern.

Additional monitoring and assessment tasks include continued involvement in updates to the baseline State of the Watershed Report, focusing on filling data gaps and evaluating cumulative impacts as monitoring data become available from dischargers, evaluating the results of the the Characterization Study, Regional Board ambient monitoring, follow-up on pollutants identified through toxicity identification evaluations, implement TMDLs to actually begin to solve problems found through monitoring, and implementing the municipal storm water program.

Our efforts to involve stakeholders shall also include exploration of funding options (especially for implementation of nonpoint source measures) and continuation of other outreach activities, such as speeches, meetings, and participation in environmental events. We shall continue our involvement in the watershed group's efforts to develop and implement a watershed management plan.

Additionally, we need to outreach more with the agricultural community. We are also proposing increased efforts in oversight and management of ground water resources. However, staff involvement in voluntary resolution of nonpoint source problems (Tier I) requires more resources than a regulatory-based approach. Tier II (regulatory encouragement) activities over the long-term include tracking nonpoint source inputs by supplemental databases such as DPR and the Department of Food and Agriculture (DFA), as well as increased sampling of the receiving water for contaminants of concern and toxicity. Tier III (effluent limitations) activities over the long-term include sampling, inspecting, and permitting priority contributors of contaminants of concern in watersheds not fully implementing a stakeholder-driven watershed approach. Staff are currently working on an agricultural policy for the board.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate Small Community Grant, State Revolving Fund, 205(j), and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

Potential Mid- to Long-term Activities

In the long-term, activities will include continued participation in both internal and external watershed planning efforts and further implementation of watershed-specific solutions. Several Basin Planning issues will be addressed through the Characterization Study and watershed planning efforts. More resources are needed for these activities in 2000/01 and beyond.

Other mid- to long-term issues include:

- Beneficial uses: Studies to evaluate beneficial use issues.
- Site specific objectives: Review studies conducted by dischargers or other watershed interests.
- Land use planning: Integrate water supply and quality issues with local land use planning and management.
- Groundwater: Integrate inter-related ground and surface waters--optimizing protection for both.
- Flood control: Institute better coordination of multi-agency reviews of environmental impacts for flood control and development projects, including the consideration of regional mitigation programs. Optimize the use of environmentally-friendly flood control facilities.
- Implementation of watershed-wide biological monitoring is a long-term goal for all of our watersheds.

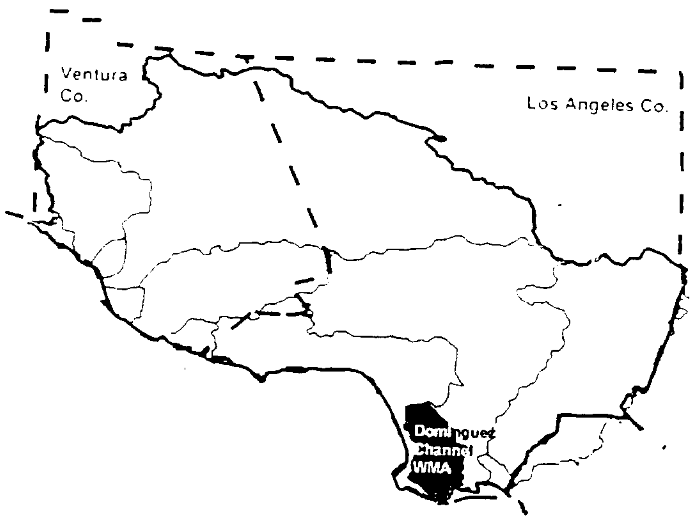
Review and comment on watershed issues in CEQA documents (for the highest priority projects) will also continue; however, this is currently an unfunded program.

Under the BPTCP, we estimated that about 20% of the Western Arm and 10% of the Eastern Arm of Mugu Lagoon contain contaminated sediments (about 725,000 cubic yards). We estimate that about 3 miles of Calleguas Creek contains 50,000 to 100,000 cubic yards of contaminated sediments. We want to work with local groups to develop remediation plans. Due to sensitive nature of Mugu Lagoon, we would suggest no action or in-situ treatment, rather than dredging, as remediation options. Treatment is expensive (probably would exceed $100 per cubic yard). Dredging could be used to remediate Calleguas Creek, although finding a suitable disposal site could be difficult; it would cost $1 to 5 million.

2.3 DOMINGUEZ CHANNEL AND LOS ANGELES/LONG BEACH HARBORS WMA

This watershed will be targeted for permitting purposes in FY02/03.

Overview of WMA



The Los Angeles and Long Beach Harbors are located in the southern portion of the Los Angeles Basin. Along the northern portion of San Pedro Bay is a natural embayment formed by a westerly extension of the coastline which contains both harbors, with the Palos Verdes Hills the dominant onshore feature. Historically, the area consisted of marshes and mudflats with a large marshy area, Dominguez Slough, to the north, and flow from the Los Angeles River entering where Dominguez Channel now drains. Near the end of last century and during the beginning of this one, channels were dredged, marshes were filled, wharves were constructed, the Los Angeles River was diverted, and a breakwater was constructed in order to allow deep draft ships to be directly offloaded and products be swiftly moved. The Dominguez Slough was completely channelized and became the drainage endpoint for runoff from a highly industrialized area. Eventually, the greater San Pedro Bay was enclosed by two more breakwaters and deep entrance channels were dredged to allow for entry of ships with need of 70 feet of clearance. The LA/LB Harbor complex together is now one of the largest ports in the country.

Both harbors are considered to be one oceanographic unit. Despite its industrial nature, contaminant sources, and low flushing ability, the inner harbor area supports fairly diverse fish and benthic populations and provides a protected nursery area for juvenile fish. The California least tern, an endangered species, nests in one part of the harbor complex.

Beneficial Uses in WMA

Dominguez Channel (above estuary)	*Domiguez Channel (in estuary)*
Noncontact water recreation	Contact & noncontact water recreation
Preservation of rare & endangered species	Preservation of rare & endangered species
	Industrial water supply
	Navigation
	Commercial & sportfishing
	Marine habitat
	Estuarine habitat
	Wildlife habitat
	Migratory & spawning habitat

Similar to LA Inner Harbor in many respects, LB Inner Harbor is dissimilar to the other Port in the higher number of privately-owned waterfront parcels which the Port has recently been in the process of the buying up and converting to Port-related uses, generally container terminals. Also, basins and slips in LB Inner

Harbor are somewhat more separated from each other than in LA Inner Harbor which may possibly prevent contamination from spreading easily.

The outer part of both harbors (the greater San Pedro Bay) has been less disrupted and supports a great diversity of marine life. It is also open to the ocean at its eastern end and receives much greater flushing than the inner harbors.

Water Quality Issues and Problems

A POTW discharges secondary-treated effluent to the outer LA/LB Harbor and is under a time schedule order to remove the discharge. The discharger's plan consists of achieving full reclamation (mostly for industrial reuse purposes) by 2020 which would eliminate the discharge completely. They plan on achieving about 80% reclamation by 2005. Two generating stations discharge to the inner harbor areas. Many smaller, non-process waste discharges also occur into the harbors and Dominguez Channel drains a highly industrialized area of the city resulting in very poor water quality.

Permitted discharges:

- One POTW
- Two generating stations
- Six refineries
- 415 dischargers covered under an industrial storm water permit
- 69 dischargers covered under the construction storm water permit

Types of permitted wastes discharged into the Dominguez Channel WMA:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	1 1 1	Major Minor General
Nonhazardous (designated) contact cooling water	2	Minor
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	1 6 30	Major Minor General
Nonhazardous (designated) noncontact cooling water	2 5 2	Major Minor General
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	1	Minor
Nonhazardous (designated) stormwater runoff	2 36	Major Minor
Hazardous contaminated groundwater	6 4	Minor General
Nonhazardous (designated) domestic sewage	1	Major
Nonhazardous (designated) filter backwash brine waters	2	Minor
Nonhazardous wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	2	General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	9	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

About one-half of the 120 NPDES discharges to Dominguez Channel; the rest go to the LA/LB Harbor.

Of the 415 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Motor Vehicle Parts, Used*; *Fabricated Metals Products, Except Machinery and Transportation Equipment*; and *Motor Freight Transportation and Warehousing* categories.

There are 69 sites enrolled under the construction storm water permit. The majority are along Dominguez Channel and are commercial sites.

Potential sources of pollution:

- Historical deposits of DDT and PCBs in sediment
- Discharges from POTW & refineries
- Spills from ships and industrial facilities
- Leaching of contaminated groundwater
- Stormwater runoff

Two areas within Los Angeles Harbor are considered to be toxic hot spots under the BPTCP: Dominguez Channel/Consolidated Slip, based on sediment concentrations of DDT, PCB, cadmium, copper, lead, mercury, zinc, dieldrin, chlordane (all exceed sediment quality guidelines), sediment toxicity, and degraded benthic infaunal community; and Cabrillo Pier area, based on sediment concentrations of DDT, PCB and copper, sediment toxicity and issuance of a human health (fishing) advisory for DDT and PCB in white croaker and exceedances of National Academy of Science guidelines for DDT in fish and shellfish. Several locations have been listed as sites of concern under the BPTCP: Inner Fish Harbor, due to sediment concentrations of DDT, PCB, copper, mercury and zinc and sediment toxicity (not recurrent); Kaiser International, due to sediment concentrations of DDT, PCB, PAH, copper and endosulfan; Hugo Neu-Proler, due to PCB sediment concentrations; Southwest Slip, due to sediment concentrations of DDT, PCB, PAH, mercury, and chromium, and sediment toxicity (not recurrent); Cerritos Channel, due to sediment concentrations of DDT, PCB, metal, chlordane, TBT, sediment toxicity and accumulation in mussel tissue; Colorado Lagoon, due to DDT, PCB, lead, zinc, chlordane, dieldrin, sediment toxicity and accumulation in mussel and fish tissue; Shoreline Marina, due to sediment concentrations of zinc, DDT, PCB, chlordane and PAH, and sediment toxicity (not recurrent); Long Beach Outer Harbor, due to sediment concentrations of DDT and chlordane and sediment toxicity (not recurrent); West Basin, due to sediment concentrations of DDT and PCB, sediment toxicity (not recurrent) and accumulation in clam tissue; Alamitos Bay, due to sediment concentrations of DDT and chlordane. There is need for further monitoring in all of these areas to clarify their status. Potential sources of these materials are considered to be historical deposition, discharges from the nearby POTW (especially for metals), spills from ships and industrial facilities, as well as stormwater runoff. Many areas of the harbors have experienced soil and/or groundwater contamination, which may result in possible transport of pollutants to the harbors' surface waters. Dredging and disposal of contaminated sediments and source control of pollutants in the harbors will be a major focal point for the Contaminated Sediment Task Force described further in the Region-wide Section of this document.

Los Angeles Inner Harbor

Although the area is dramatically cleaner now than twenty-five years ago, parts of LA Inner Harbor are still suffering the effects of historic deposits of pollutants in the sediment and current point and nonpoint source discharges. Fish caught in the East Basin have exhibited histopathological abnormalities (liver lesions). The abnormalities are indicative of aromatic and chlorinated hydrocarbon contamination. There is also significant degradation in the biological community of a part of Inner Harbor with high levels of PCB and DDT; and toxicity of the surface water microlayer of one part of the harbor to a test fish species (larval kelp bass). Additionally, Cal-EPA's Office of Environmental Health Hazard Assessment now advises against consumption of white croaker in the harbor and recommends no more than one meal every two weeks of black croaker, queenfish, and surfperches if caught in the harbor. On the other hand, the benthic community in many other areas of the inner harbor are healthy and sediments, though high in many pollutants, do not cause a great deal of toxicity in controlled lab tests.

LA Inner Harbor is on the 1998 303(d) list due to DDT, metals, PAHs, chlordane, TBT, and PCBs. Some of the contamination in sediment is historic with resuspension potential. Dominguez Channel was the recipient of runoff from the Montrose Chemical Facility which manufactured DDT several decades ago. There are also mostly nonpoint source inputs from several problem sites, spills, and storm drain runoff. The problems tend to be exacerbated by the poor circulation and flushing. The Port is in the process of filling in a large part of Outer Harbor and deepening some channels as part of their "2020 Plan". Pier 400, a 590-acre site of new land created by diking and filling harbor waters, was completed in April 2000. As a result, the potential exists for greater stagnation and more problems from deposition of new contaminants.

Data from the State Mussel Watch (SMW) Program have documented high levels of metals, PCBs, TBT, and PAHs in mussel tissue at several locations in LA Inner Harbor. The Bay Protection and Toxic Cleanup Program (BPTCP) has found a number of inner harbor areas with elevated pollutant levels but a smaller number of those have exhibited sediment toxicity.

Sediment data collected by Regional Board staff, the Port of LA, and various other researchers, have revealed several areas of heavy contamination with metals, PCBs, and DDT, and occasionally PAHs. Regional Board data show that the level of contamination within particular regions of the inner harbor vary considerably from site to site. Additionally, it is difficult to separate the effects of historic contamination from current inputs. Bight'98 included samples within harbors, including a number of stations in LA/LB Harbor; toxicity, sediment chemistry, and benthic data reports should be available early in 2001.

Dominguez Channel

Little recent data exist for the Channel itself even though considerable heavy industrial facilities (including the old Montrose site) are located within the watershed. However, a consultant for Montrose conducted sediment sampling for DDT in the Channel during 1990. EPA, in a letter to Montrose, cited this data and provided a comparison of those values with NOAA's "identified concentrations of DDT in sediment associated with adverse impacts. A sediment level of 3 ppb was associated with adverse impacts in 10% (ER-L) of the data reviewed by NOAA and a level of 350 ppb total DDT was associated with adverse impacts in 50% (ER-M) of the data reviewed by NOAA" (EPA letter to Montrose Chemical Corporation, November 27, 1991). The consultant found DDT levels of 300 - 13,000 ppb in the Channel. EPA stated that adverse impacts in the biological community of Dominguez Channel and Consolidated Slip would be expected.

A Regional Board study conducted in 1975 found that the aquatic biota of the Channel were largely marine in origin and were a continuation of LA Inner Harbor biota. The number and abundance of aquatic species declined with distance inland from the harbor. A fairly abrupt decline in benthic species between Alameda and Wilmington Streets was attributed to the effects of pollution. *Capitella capitata* was one of the most abundant benthic species in the area and is generally associated with polluted areas. An absence of benthic fish species adjacent to one oil refinery was considered to be indicative of oxygen-poor bottom water. There was a degraded benthic community at several stations in Consolidated Slip during BPTCP sampling.

Of major concern in the mid-1980s was discharge of zinc chromate as an additive in cooling water/boiler blowdown. There may have been some justification for that concern. Sediment sampling conducted by Regional Board staff in 1988 revealed zinc levels as high as 447 ppm, chromium as high as 67 ppm, and lead as high as 231 ppm.

Long Beach Inner Harbor

While historic contamination is a definite problem in the older parts of the harbor (including the naval base), Pier J has only recently been constructed, utilizing some highly contaminated dredge material. Some other likely problem sites include: Cerritos Channel with its inputs at times from Consolidated Slip (water generally flows from LB to LA Harbors), a creosote manufacturing site, several oil terminals, a defunct ship repair yard (and several active ones), and the naval base, which is closed, while the attached shipyard remains open.

Contamination in the LB Inner Harbor is known to be sporadic. Little information is available on contamination in Southeast Basin except for TBT water concentrations of up to 380 PPT found in a 1988 statewide study of harbors and low levels of PCBs found in mussel tissue in 1986. The most recent SMW data for the Inner Harbor show some areas of elevated DDT, most notably at those stations located in or near Cerritos Channel.

Moderate PCB levels were found in mussel tissue in front of the creosote facility located in Channel 2 and somewhat higher levels were found in Cerritos Channel which is likely related to its proximity to Consolidated Slip and other LA Harbor point and nonpoint sources. Long Beach Inner Harbor is on the 1998 303(d) list for DDT, PAHs, and PCBs, while San Pedro Bay is listed for DDT, PAHs, PCBs, and some metals.

The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

IMPAIRMENTS:

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Benthic comm. effects	Basin Plan narrative objective		Dominguez Channel Estuary (to Vermont) Los Angeles Harbor: Consolidated Slip Long Beach Harbor (part Main Ch., SE Basin, West Basin, Pier J, and breakwater)
ChemA* (tissue)	National Academy of Science Guideline (tissue): 100 ng/g		Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Machado Lake (Harbor Lake)
chlordane (sediment & tissue)	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 1.1 ng/g	100 ng/g (sediment) 5.0 - 11.3 ng/g (tissue)	Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Los Angeles Harbor: Consolidated Slip Machado Lake (Harbor Lake)
DDT (sediment & tissue)	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 32.0 ng/g	500 - 1,500 ng/g (sediment) 36 - 227 ng/g (tissue)	Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Los Angeles Harbor: Consolidated Slip Los Angeles Harbor (part Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Long Beach Harbor (part. Main Ch., SE Basin, West Basin, Pier J, and breakwater) Cabrillo Beach (Inner) San Pedro Bay nearshore and offshore zone: Cabrillo Pier area Los Angeles Harbor: Southwest Slip Machado Lake (Harbor Lake)
PCBs (sediment & tissue)	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g	500 - 1,000 ng/g (sediment) 42.5 - 90.7 ng/g (tissue)	Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Los Angeles Harbor: Consolidated Slip Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Los Angeles Harbor: Southwest Slip San Pedro Bay nearshore and offshore zone: Cabrillo Pier area Cabrillo Beach (Inner) Long Beach Harbor (part. Main Ch., SE Basin, West Basin, Pier J, and breakwater) Machado Lake (Harbor Lake)
aldrin (tissue)	State Board numeric objective (tissue): Max. Tissue Residue Level 0.33 ng/g		Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont)
dieldrin (tissue)	State Board numeric objective (tissue): Max. Tissue Residue Level 0.7 ng/g	0.9 - 2.1 ng/g (tissue)	Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Machado Lake (Harbor Lake)
sediment toxicity	Basin Plan narrative objective		San Pedro Bay nearshore and offshore zone: Cabrillo Pier area Los Angeles Harbor: Southwest Slip Los Angeles Harbor: Consolidated Slip Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Long Beach Harbor (part. Main Ch., SE Basin, West Basin, Pier J, and breakwater)
PAHs (sediment)	Basin Plan narrative objective	2,000 - 15,000 ng/g (sediment)	Dominguez Channel (above Vermont) Dominguez Channel Estuary (to Vermont) Los Angeles Harbor: Consolidated Slip Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Long Beach Harbor (part. Main Ch., SE Basin, West Basin, Pier J, and breakwater) San Pedro Bay nearshore and offshore zone Cabrillo Pier area
Chromium (sediment)	Basin Plan narrative objective	100 - 200 ug/g (sediment)	San Pedro Bay nearshore and offshore zone Cabrillo Pier area Dominguez Channel (above Vermont) Dominguez Channel Estuary (to Vermont) Los Angeles Harbor: Consolidated Slip

* ChemA refers to the sum of the chemicals aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, HCH (including lindane), endosulfan, and toxaphene

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Zinc (sediment & tissue)	Basin Plan narrative objective	150 - 510 ug/g (sediment) 110 - 510 ug/g (tissue)	Los Angeles Harbor: Consolidated Slip Dominguez Channel (above Vermont) Dominguez Channel Estuary (to Vermont) Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) San Pedro Bay nearshore and offshore zone Cabrillo Pier area
Lead (sediment)	Basin Plan narrative objective	120 - 122 ug/g (sediment)	Los Angeles Harbor: Consolidated Slip Torrance Carson Channel Dominguez Channel Estuary (to Vermont) Dominguez Channel (above Vermont) Dominguez Channel (above Vermont) Wilmington Drain
Copper (sediment)	Basin Plan narrative objective	110 - 140 ug/g (sediment)	Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Wilmington Drain Dominguez Channel (above Vermont) Torrance Carson Channel Dominguez Channel Estuary (to Vermont) San Pedro Bay nearshore and offshore zone Cabrillo Pier area
algae, eutroph.	Basin Plan narrative objective		Machado Lake (Harbor Lake)
odors	Basin Plan narrative objective		Machado Lake (Harbor Lake)
ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3 - 28.0 mg/l to protect against acute toxicity	ND - 18.0 mg/l	Machado Lake (Harbor Lake) Wilmington Drain Dominguez Channel (above Vermont) Dominguez Channel Estuary (to Vermont)
tributyltin	Basin Plan narrative objective	2,000 ng/g (tissue)	Los Angeles Harbor: Consolidated Slip Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater)
coliform	Basin Plan numeric objective: Inland: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml Beaches: total coliform not to exceed 1,000 MPN/100ml in more than 20% of samples in 30 days and not more than 10,000 MPN/100ml at any time	33 - 160,000 MPN/100ml	Dominguez Channel (above Vermont) Dominguez Channel Estuary (to Vermont) Torrance Carson Channel Wilmington Drain
beach closures	Basin Plan narrative objective	2 - 11 days/year closed	Los Angeles Harbor (part. Main Ch., Fish Hbr, Cabrillo Pier, and breakwater) Cabrillo Beach (Inner)
Trash	Basin Plan narrative objective		Machado Lake (Harbor Lake)

* Chem A refers to the sum of the chemicals aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, HCH (including lindane), endosulfan, and toxaphene

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	303(d) Listed Waters/Reaches	Year Scheduled for Completed (FY)
coliform	Dominguez Channel Dominguez Channel Estuary Torrance Carson Channel Wilmington Drain	01/02
coliform	Cabrillo Pier area Cabrillo Beach (inner)	01/02

We see a need for an additional 1.1 PY as well as $50,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Current Activities

The following is a summary of current regional board activities in the Dominguez Channel Watershed which are expected to continue as part of the Watershed Management Initiative on a watershed basis.

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits. This will be a targeted watershed for the bulk of permit renewal purposes in FY 2002-03. Many permits (refineries, in particular) are being renewed this year because of backlog issues, however. There are eleven major dischargers, 65 significant or minor dischargers under individual permits, as well as 37 dischargers currently covered under general permits (additional information on permits may be found in the Appendix). Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue. A watershed-wide regional monitoring program will be created in anticipation of the next cycle.

Due to limited resources, only the basic regulatory activities are performed: review of dischargers' monitoring reports, minimum necessary inspections and sampling, issuance/ renewal of permits, levels 1 and 2 enforcement actions (noncompliance and violation notification), case handling, and answering inquiries from the public.

MONITORING AND ASSESSMENT

In anticipation of the need for preparation of a State of the Watershed Report during the permit renewal time period, the Board's regional database's charting and mapping capabilities will be utilized to begin an assessment of available water and sediment quality information.

The BPTCP has identified two areas in the harbors as "toxic hot spots" based on sediment contamination. Staff have completed a cleanup plan for these areas; this plan is part of the Consolidated Plan for the state's toxic hot spots approved recently by State Board. Cleanup/ remediation alternatives identified include dredging, in-situ capping, and treatment. Continuing Regional Board activities include working to insure cleanup of contaminated land sites which may affect harbor waters, issuance of waste discharge requirements, where appropriate, and control/treatment of stormwater runoff. Of those areas identified as candidate sediment toxic hot spots, there is about 25,000 to 50,000 cubic yards of contaminated sediments in the Cabrillo Pier area; removal by dredging and disposal would cost 0.5 to $5 million; however, remediation there isn't recommended until Consolidated Slip contaminated sediments are cleaned up. The Consolidated Slip/Dominguez Channel area has about 50,000 cubic yards of contaminated sediments and would take $1 to 5 million to dredge. More sampling would be needed prior to any dredging in order to develop a detailed dredging plan. Also, post-remediation monitoring would be needed. This area is part of an EPA-designated Superfund site and should receive attention under that program within the next few years.

NONPOINT SOURCE PROGRAM

Staff will pursue starting a general stakeholder group in the watershed to address nonpoint source issues. Staff have performed inspections of commercial fishing operations in the Los Angeles Harbor area and educated personnel regarding negative impacts of discharges to the harbor. Since these inspections, staff have initiated some enforcement actions.

Staff is encouraging proposals for Proposition 13 funding for preparation of a watershed management plan.

BASIN PLANNING

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

Comments on watershed issues in CEQA documents for the highest priority projects will continue to be prepared; this is currently an unfunded program.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

Permits in this watershed will be renewed in FY 2002/03. Continuing core regulatory activities include compliance inspections, review of monitoring reports, response to complaints, and enforcement actions as needed relative to the watersheds NPDES permits. A watershed-wide regional monitoring program will be created in anticipation of the next cycle.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

As noted earlier, a large part of this watershed is on the 303(d) list for a variety of pollutants, especially in the sediment. Work conducted through the BPTCP has determined many of these areas support healthy benthic communities and acceptable levels of sediment toxicity. We will initiate discussions with stakeholders in 2000/01 on the best approach to take to resolve the problems noted on the 303(d) list.

The Dominguez Channel and Los Angeles/Long Beach Harbors Watershed is being proposed for inclusion in a partial update of the Water Quality Assessment report due in 2002. **Staff resources (0.75 PY/year) will be needed in 2000/01 and 2001/02 to collect, analyze, and store data for the Water Quality Assessment, State of the Watershed Report, and TMDL development.**

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

Potential Mid- to Long-term Activities

As may be the case in other industrial areas with extensive sediment contamination, development of regional sediment quality guidelines would be very valuable. The CSTF is developing an electronic database of relevant local sediment monitoring data to be used for this purpose. Development of sediment quality guidelines should be completed by January 2003. Basin Planning efforts may be focused on better defining beneficial uses in the area and implementing the State Bays and Estuaries Plan adopted in 2000. We also anticipate discharger requests for development of site-specific objectives for a number of constituents that will be included in the new Bays and Estuaries Plan. An assessment of existing data will be needed as part of this task.

Additional long-term activities include:

- Development of a watershed-wide monitoring program
- Consideration and implementation of TMDL-related issues
- Further evaluate beneficial uses throughout the watershed
- Restoration of habitat following improvements in water quality
- Implementation of biological monitoring
- Explore options for, and implement, sediment cleanup/removal

2.4 SANTA MONICA BAY WMA

This was the targeted watershed for permitting purposes in FY1996/97 and will be targeted again in FY03/04.

Overview of WMA

The Santa Monica Bay Watershed Management Area (WMA), which encompasses an area of 414 square miles, is quite diverse. Its borders reach from the crest of the Santa Monica Mountains on the north and from the Ventura-Los Angeles County line to downtown Los Angeles. From there it extends south and west across the Los Angeles plain to include the area east of Ballona Creek and north of the Baldwin Hills. South of Ballona Creek the natural drainage area is a narrow strip of wetlands between Playa del Rey and Palos Verdes. The WMA includes several watersheds the two largest being Malibu Creek to the north and Ballona Creek to the south. While the Malibu Creek area contains mostly undeveloped mountain areas, large acreage residential properties and many natural stream reaches; Ballona Creek is predominantly channelized, and highly developed with both residential and commercial properties.

As a nationally significant water body, Santa Monica Bay was included in the National Estuary Program in 1989. It has been extensively studied by the Santa Monica Bay Restoration Project (SMBRP) and a watershed plan was developed in 1994. A Santa Monica Bay Watershed Council was formed in 1994 to oversee implementation of the Plan. The Restoration Project staff will be coordinating with Regional Board staff to carry out the Board's watershed approach in the Santa Monica Bay Watershed.

Water Quality Problems and Issues

Though relatively small in its size compared with watersheds in other parts of the country, the Santa Monica Bay WMA embraces a high diversity in geological and hydrological characteristics, habitat features, and human activities. Almost every beneficial use defined in the Basin Plan is identified in water bodies somewhere in the WMA. Yet many of these beneficial uses have been impaired for years. While some of the impaired areas are showing signs of recovery, beneficial uses that are in relatively good condition face the threat of degradation.

Existing and potential beneficial use impairment problems in the watershed fall into two major categories: human health risk, and natural habitat (wildlife) degradation. The former are issues primarily associated with recreational uses of the Santa Monica Bay. The latter are issues associated with terrestrial, aquatic, and marine environments. Pollutant loadings that originate from human activities are common causes of both human health risks and habitat degradation.

Beneficial Uses in the WMA:

All of the beneficial uses defined in the Basin Plan for the Region occur somewhere in this Watershed Management Area except for BIOL (preservation of biological habitats)

Permitted discharges:

- Seven major NPDES permit discharges
- Three POTWs (two direct ocean discharges), one refinery, and three generating stations
- 21 minor discharges
- 166 dischargers covered under general permits
- 147 discharges covered by an industrial storm water permit
- 107 dischargers covered by a construction storm water permit

Of the major NPDES dischargers in the Santa Monica Bay WMA, the three POTWs (particularly the two direct ocean discharges) are the largest point sources of pollutants to Santa Monica Bay. Pollutants from the minor discharges have been estimated to contribute less than two percent of the total pollutants being discharged to the Bay.

Types of permitted wastes discharged into the Santa Monica Bay WMA:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	2 1 4	Major Minor General
Nonhazardous (designated) contact cooling water	1	Major
Nonhazardous (designated) domestic sewage & industrial waste	3	Major
Nonhazardous (designated) domestic sewage	2	Minor
Nonhazardous filter backwash brine waters	1	Minor
Hazardous stormwater runoff	1	Major
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	11 131	Minor General
Nonhazardous (designated) noncontact cooling water	4 1	Minor General
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	2	Major
Nonhazardous (designated) stormwater runoff	1	Minor
Hazardous contaminated groundwater	1 21	Minor General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage)	8	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain nonhazardous wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

The majority of the 196 NPDES discharges to the Santa Monica Bay WMA go to Ballona Creek (160).

Of the 147 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Fabricated Metal Products, Except Machinery and Transportation Equipment*; *Local and Suburban Transit and Interurban Highway Passenger Transportation*; *Motor Freight Transportation and Warehousing*; and *Scrap and Waste Materials* categories.

There are a total of 107 construction sites enrolled under the construction storm water permit. Forty-five of these sites are in the Malibu Creek Watershed with 62 in the rest of the WMA. The sites are fairly evenly divided between commercial and residential.

A considerable number of monitoring programs have been implemented in the Santa Monica Bay WMA, particularly over the last twenty years. Sampling efforts tend to center around assessing urban runoff effects in general along the coastline and reservoirs of PCBs and DDT contaminated sediment in the area of the Palos Verdes Shelf. Three statewide monitoring programs, State Mussel Watch, Bay Protection and Toxic Cleanup, and Toxic Substances Monitoring, focus on biological measurements.

The data from these programs indicate that in general the open coastline is much cleaner than the Bay's enclosed waters, except with regards to DDT and PCBs on the Palos Verdes Shelf. Pollutants of particular concern are chlordane, DDT, copper, and zinc. The BPTCP has listed the Santa Monica Bay - Palos Verdes Shelf area as a toxic hot spot for DDT and PCBs human health advisories (fishing) and NAS exceedances of DDT levels in fish. Marina Del Rey is listed as a toxic hot spot due to sediment concentrations of DDT, PCB, copper, mercury, nickel, lead, zinc and chlordane, and sediment toxicity; Marina Del Rey Entrance Channel (mouth of Ballona Creek) is listed due to sediment concentrations of DDT, zinc, lead, chlordane, dieldrin, and chlorpyrifos, and sediment toxicity. The BPTCP listed King Harbor as a site of concern, due to sediment concentrations of DDT and PCB and sediment toxicity (not recurrent).

Urbanization has had a significant impact on the riparian and wetland resources of the watershed, primarily through filling, alteration of flows, and decrease in water quality. It is estimated that 90% of the historic wetlands of the Santa Monica Bay WMA have been destroyed, with the remaining wetlands significantly degraded.

Although groundwater accounts only a limited portion of the Santa Monica Bay WMA's supply of fresh water, the general quality of groundwater in the watershed has degraded from background levels.

Greater Santa Monica Bay

Santa Monica Bay is heavily used for fishing, swimming, surfing, diving etc, activities classified as water contact recreation (REC-1). However, the ability for people to enjoy these activities has been lost to a certain degree because of the real or perceived risk to human health. The primary, and also the best documented, problems are acute health risk associated with swimming in runoff-contaminated surfzone waters, and chronic (cancer) risk associated with consumption of certain sport fish species in areas impacted by DDT and PCB contamination.

The general public has also been concerned about potential health risks associated with the consumption of contaminated seafood from Santa Monica Bay. This is the primary pathway through which humans are exposed to toxic chemicals found in the marine environment. While recent studies have shown that health risks are limited to consumption of certain seafood species found at certain locations, the public perception remains that all seafood in the Bay is contaminated.

One of the most evident impacts in marine habitats is sediment contamination and damage to marine life that the contaminants cause when they are released from the sediment (through natural fluctuations or through disturbance of the sediment) into the food chain. Organic compounds such as DDT, PCBs, polycyclic aromatic hydrocarbons (PAHs), chlordane, and tributyltin (TBT) are found in sediments in concentrations that are harmful to marine organisms at various locations in the Bay. Also found in Bay sediments are heavy metals such as cadmium, copper, chromium, nickel, silver, zinc, and lead. The major historic sources of sediment contamination have been wastewater treatment facilities; thus the accumulations are highest near treatment plant outfalls off of Palos Verdes and Playa del Rey.

Major Issues of Concern in Greater Santa Monica Bay

- Acute health risk associated with swimming in runoff-contaminated surfzone waters
- Chronic risk associated with consumption of certain sport fish species in areas impacted by DDT and PCB contamination
- Reduction of loadings from the two major POTWs in light of projected population increases
- Other impacts from urban runoff/storm water
- Historic deposits of DDT and PCBs in sediment; high levels in fish (Palos Verdes Shelf a Superfund site)
- Loadings of pollutants from other sources: sediment resuspension, atmospheric deposition
- The need to have a better understanding of the Bay's resources

Bioaccumulation of DDT in white croaker, dover sole, and California brown pelicans are well-known examples of the impacts caused by sediment contamination. Prior to the 1980s, high concentrations of DDT were found in muscle tissues of these organisms. DDT in these organisms are implicated in fin erosion and other diseases in fish as well as eggshell thinning and subsequent species decline in the California brown pelican.

Malibu Creek Watershed

The most recent Water Quality Assessment Report finds water quality in some streams within the Malibu Creek Watershed is impaired by nutrients and their effects, coliform and their effects, trash, and, in some instances, metals. While natural sources contribute, nonpoint source pollution from human activities is strongly implicated including ill-placed or malfunctioning septic systems and runoff from horse corrals. Nutrient inputs are also contributed by urban runoff and the POTW which discharges tertiary-treated effluent into the Creek about five miles upstream of Malibu Lagoon.

Major Issues of Concern in Malibu Creek Watershed

- Excessive freshwater, nutrients, and coliform in lagoon; contributions from POTW
- Urban runoff from upper watershed
- Impacts to swimmers/surfers from lagoon water
- Septic tanks in lower watershed
- Appropriate restoration and management of lagoon
- Access to creek and lagoon by endangered fish (steelhead trout and tidewater goby)

A nutrient TMDL for the mainstem of the Creek is in progress although ecologically-relevant nutrient objectives are lacking. A recently completed study produced a report which should lead to more effective management of the Lagoon and its resources as the restoration process continues.

Historically, the Lagoon was much larger than its current day size and although the flow dynamics of the Creek as well as the ocean's influence on the Lagoon in the past can only be extrapolated, it is likely Creek flow was much less than today during the dry season and a marine influence may have dominated, keeping the lagoon entrance open much of the year as occurs in the larger Mugu Lagoon to the north.. This also would have facilitated migration of the now endangered steelhead trout. And though Creek flow was likely less, more of the watershed was available for the trouts' use, at least prior to the construction of Rindge Dam in the 1920's. Most important, during the dry season there would be access to deep shaded pools in many parts of the watershed where the fish could mature until rain created the flows needed to reach the ocean.

Today, the flow regime is quite different and a major issue of concern. Both increased urban runoff from the more developed upper watershed and discharges from the POTW have increased baseline flows. However, recently the POTW which discharges to Malibu Creek came under a discharge prohibition starting each May 1, or at the first natural closure of Malibu Lagoon by sand buildup (whichever is later), through and including October 31 of each year, except during times of plant upset, storm events, or the existence of minimal streamflow conditions that require flow augmentation in Malibu Creek to sustain endangered species. In the long-run, this discharge prohibition may have many other implications on water quality and quantity in the Creek and Lagoon.

The lagoon size is much reduced from historic times and it currently remains closed much of the year except for during the winter when ocean influences breach the sandbar and Creek flows help maintain the opening. This had led to decreasing salinity or, at times, greatly fluctuating salinity which has disturbed efforts to restore the Lagoon. This also leads to elevated groundwater levels adjacent to the lagoon, assuring failure of septic systems in the area. Additionally, surfing and swimming is popular off the beaches in the immediate area and there is considerable concern over contaminated Lagoon water reaching these people.

Ballona Creek Watershed

The most recent Water Quality Assessment Report indicates impairment in this watershed due to coliform and its effects such as shellfish harvesting advisories; trash; PCBs and pesticides of historical origin such as DDT, chlordane, and dieldrin, as well as their effects such as sediment toxicity; metals such as lead, silver, arsenic, copper, cadmium, and zinc, as well as their effects such as water column toxicity; and tributyltin.

Ballona Creek is completely channelized to the ocean except for the estuarine portion which has a soft bottom. While at one time it drained into a large wetlands complex, it now has no direct connection to the few wetlands remaining in the area although tide gates exist in the channel which connect to Ballona Wetlands. However, Ballona Creek may more often affect the nearby wetlands due to wave action moving trash, suspended material and dissolved contaminants from the ocean to the nearby Ballona Wetlands and Marina del Rey Harbor within which complex Ballona Lagoon is located.

Major Issues of Concern in Ballona Creek Watershed and Wetlands
• Trash loading from creek • Wetlands restoration • Sediment contamination by heavy metals from creek to Marina del Rey Harbor and offshore) • Toxicity of both dry weather and storm runoff in creek • High bacterial indicators at mouth of creek

The U.S. Army Corps of Engineers (USACE) and Los Angeles County Department of Beaches and Harbors conduct routine dredging operations in order to keep the entrance to Marina del Rey Harbor open. Led by the Los Angeles Basin Contaminated Sediment Task Force (for further information on this Task Force, see the Regionwide Section of this document), the USACE is conducting a study to identify sources of heavy metals loadings within the watershed. The results of the study could provide useful information to develop a TMDL for selected heavy metals.

Both dry weather and storm runoff from the main channel and two major tributaries were found to be toxic to marine organisms. Toxicity was also found during storms in the ocean near the mouth of the Creek. Preliminary investigations show that the sources of toxicity vary, and were associated with metals on one occasion and with organic chemicals on another occasion. Further efforts are needed to identify the sources of toxicity.

Bacterial indicator levels measured at stations near the mouth of Ballona Creek frequently exceed the level of concern. As a result, warning signs are posted permanently on each side of the Creek. The number of beach closures due to sewage spills rose again in 1998 after a long declining trend over the last ten years.

The BPTCP lists the Marina del Rey Entrance Channel and Marina del Rey back channels as Toxic Hot Spots; however, since they are not high priority sites, we have not yet developed preliminary remediation plans or cost estimates.

Other Urban Watersheds

The most recent Water Quality Assessment Report indicates impairment in many of these smaller drainages, which discharge directly to the ocean, due to one or several of the following: coliform, ammonia, lead, copper (and toxicity likely associated with metals), trash, and low dissolved oxygen. Due to the frequency of high bacterial indicator levels, warning signs are posted permanently at many of these locations (i.e., storm drain outlets). It should be noted that there are plans to divert many of these storm drains to the sewer system during dry weather.

IMPAIRMENTS:

The table below gives examples of typical data ranges which led to the 1998 303(d) listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
beach closures	Basin Plan narrative objective	1 - 15 days/year closed	Marina Del Rey Harbor Beach
swimming restrictions	Basin Plan narrative objective		Santa Monica Bay beaches
shellfish harvesting adv	Basin Plan narrative objective		Malibu Lagoon

hist. PCBs, pest. and effects	Ballona Creek Ballona Creek Estuary	04/05
Metals	Marina del Rey Harbor - Back Basins	04/05

We see a need for an additional 4.2 PYs as well as $230,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Stakeholder Groups

- *Malibu Creek Watershed Advisory Council and Executive Committee (with subcommittees)* A number of stakeholder groups began meeting in the late 1980's/early 1990's in the Malibu area. One short-term facilitated group (in conjunction with the Advisory Council) formulated a list of priority issues that need to be resolved while the Executive Committee worked with the Advisory Council to exchange information and develop a Natural Resources Plan for the watershed prepared by the USNRCS. Separate task forces and subcommittees formed and reformed and eventually one group emerged with its associated subcommittees (and task forces as needed) as the main stakeholder forum. The Malibu Lagoon Task Force is currently quite active and the group is involved with offering advice on watershed-wide monitoring and coordination on development of a Malibu Lagoon Enhancement and Management Plan. Also currently active is the Volunteer Water Quality Monitoring Task Force, Monitoring and Modeling Subcommittee (tasked with developing a watershed-wide monitoring program), Human Health Subcommittee, and Wildlife Subcommittee. Joint Advisory Council/Executive Committee meetings occur quarterly with 1-2 staff members attending. Various subcommittees and task forces are active as needed but usually 1-2 other groups will be meeting quarterly with 1-2 staff members attending.

- *Santa Monica Bay Restoration Project (Watershed Council, Bay Oversight Committee, Implementation Committee, and Technical Advisory Committee)* The SMBRP was formed in 1989 under the National Estuary Program and is charged with the responsibility of assessing the Bay's problems, developing solutions, and identifying implementation procedures. A Bay Restoration Plan was developed and is in the process of being implemented. One or two Regional Board staff will attend the quarterly meetings of the Oversight Committee while another staff member will attend the quarterly Technical Advisory Committee meetings. More information about this group may be found at their website http://www.smbay.org/.

- *Topanga Watershed Committee* The committee was formed in 1998 as a followup to previous a community group working developing on alternatives to traditional flood control measures. Their focus has expanded to include general watershed management and protection activities as well as volunteer monitoring. More information about this group may be found at their website http://www.topangaonline.com/twc/index.html.

Past Significant Activities

Watershed Management

The first edition of a State of the Watershed Report was produced in June 1997 which assessed water quality using data from the SMBRP and the Regional Board as well as other data provided by Watershed Council members; this document will continue to evolve and be updated.

Nonpoint Source

A number of nonpoint source control strategies have been undertaken in the Malibu Creek Watershed. Those that involved restoration of aquatic life beneficial uses include streambank and riparian corridor habitat restoration projects funded by 319(h) monies undertaken by the Resource Conservation District of the Santa Monica Mountains and the Department of Parks and Recreation. Additionally, the Resource Conservation District has prepared a manual for horse owners in the areas detailing ways to prevent nonpoint source inputs from their land (funded by 319(h) monies).

Current Activities

The following is a summary of current regional board activities and strategies for dealing with point and nonpoint source pollution as well as other issues of concern in the Santa Monica Bay WMA.

CORE REGULATORY

Revisions of most of the major permits took place during 1997. Many of the minor discharges are now regulated under general permits. Portions of a regional ocean monitoring program are currently being implemented and other aspects of it are being developed (see Region-wide Section for additional details). Watershed (inland) regional monitoring programs are being developed with the dual purpose, in many instances, of both creating a more effective program and collecting the needed data to determine mass loading allocations. Ongoing work related to individual NPDES permits includes review and assessment of monitoring data, conducting compliance inspections, and pursuing enforcement actions if necessary. Due to limited resources, only the basic regulatory activities are performed: review of dischargers' monitoring reports, minimum necessary inspections and sampling, issuance/renewal of permits, levels 1 and 2 enforcement actions (noncompliance and violation notification), case handling, and answering inquiries from the public.

Core regulatory responsibilities also include administration of the consent decrees for full secondary treatment compliance by the City of Los Angeles and the County Sanitation Districts of Los Angeles County (CSDLAC) and a 1990 Settlement Agreement with the City of Los Angeles. Another responsibility is oversight of the approved pretreatment programs for the joint outfall system for the City of Los Angeles and the CSDLAC and oversight of the sewage collection systems.

In addition, although the permit for the Tapia Water Reclamation Plant in the Malibu Creek Watershed was renewed in 1997, there were appeals and changes which resulted in the permit being revised again in December 1999. Staff continue to spend significant effort on this permit due to contentious issues such as the summer flow prohibition and pending nutrient limitations.

The Santa Monica Bay WMA falls within Los Angeles County which was issued a renewed municipal storm water permit in 1996. There are 87 co-permittees covered under this permit including 85 cities, the County of Los Angeles, and the California Department of Transportation (Caltrans). Work on the permit will involve review of monitoring reports, evaluation of the storm water program's effectiveness, coordination with other watershed efforts, and modification of the permit as necessary. During 1997/98, discharger responsibilities under the permit concentrated on the evaluation of the five BMP model programs required in the 1996 permit: Illicit Connection/Illicit Discharges, Development Construction, Development Planning, Public Agency Activities, and Five-Year Public Education Strategy (including industrial/commercial site visits).

However, the Regional Board also needs to encourage and support the development and implementation of innovative structural and non-structural BMPs under the municipal storm water permit. In the Ballona Creek Watershed, over the next two years, many projects funded under Proposition A will be implemented. Promoted by the SMBRP, co-permittees within the watershed have collaboratively or individually conducted pilot projects to test new catchbasin retrofit devices and the effectiveness of street sweeping methodologies. The City of Los Angeles also conducted a study of impacts of street washing in homeless-aggregated areas. The results of these studies/pilot projects may lead to possible wide application of some new BMPs over the next two years. These projects would qualify to receive Section 319(h) funding.

An important requirement of the storm water municipal permit is implementation of the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Numerical Design Standards for Best Management Practices (BMPs) which were adopted in 2000. The SUSMP is designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating BMPs in the design phase of new development and redevelopment. It provides for numerical design standards to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways.

The numerical design standard is that post-construction treatment BMPs be designed to mitigate (infiltrate or treat) storm water runoff from the first ¾ inch of rainfall, prior to its discharge to a storm water conveyance system. Other standards also apply; additional information on the SUSMP may be found on the Regional Board website http://www.swrcb.ca.gov/~rwqcb4.

Also, given the recent surge in sewage spills into Ballona Creek, the Regional Board needs to exercise its authority through use of enforcement actions to require the City of Los Angeles to complete its planned infrastructure improvement and enhance its vigilance over the existing sewer system.

Key regulatory staff will also remain involved in the Santa Monica Bay team in order to stay focused on key watershed issues and contribute to updates of the State of the Watershed Report.

MONITORING AND ASSESSMENT

Portions of a regional ocean monitoring program are currently being implemented and other aspects of it are being developed (see Regionwide Section for additional details). Watershed (inland) regional monitoring programs are being developed with the dual purpose, in many instances, of both creating a more effective program and collecting the needed data to determine mass loading allocations. Bight'98 and 1994 SCBPP monitoring covered coastal areas (including harbors and marinas in Bight'98).

The SMBRP, with participation of the Regional Board, has been developing a new sources and loading monitoring design for point and nonpoint source ocean discharges from the Santa Monica Bay WMA/wasteshed. The overall objective of this monitoring program design, which applies to any watershed, is to produce improved estimates of loadings to the Bay in order to:

- make cost-effective trade-offs in reducing inputs of toxic pollutants
- evaluate the effectiveness over time of source control and treatment options taken to reduce inputs to the Bay
- assist in evaluating receiving water impacts

Because it is not practical to continuously monitor every stream/storm drain, the monitoring approach adopted by the municipal storm water permit is to rely on sampling of a set of mass loading stations in combination with a set of land use stations. Data collected through sampling of these stations will then be used to calibrate models that produce mass loading estimates for a specific watershed/subwatershed. This approach is further supplemented by several monitoring programs and research projects with narrower objectives. Under the municipal storm water permit, the Los Angeles County Department of Public Works (LAC-DPW) is conducting a critical source monitoring project to estimate the relative loading from five selected facilities/sites with high potential of generating pollutants. Caltrans conducts monitoring aimed at estimating loadings from highway runoff. For the last two years, LAC-DPW has funded USC/UCBS/SCCWRP to define the dispersion zone of storm water in the nearshore ocean and to study impacts from storm water runoff by measuring sediment contamination, toxicity, and the benthic community response index in the dispersion zone. The USACE has worked with UCLA to collect storm water samples in Ballona Creek to calculate relative contributions of pollutant loadings from each tributary and major land use types. SCCWRP also has on-going efforts to investigate the loading and impacts of storm water runoff throughout the Southern California region, including creeks in the Santa Monica Mountains.

Besides information provided by these existing efforts, there are still information gaps that hinder the fulfillment of the identified monitoring objectives. Specifically, the following needs to happen during the next two years:

- A project that develops methodology for and conducts status and trend analysis using stormwater monitoring data collected under the municipal NPDES permit.
- A study that uses more frequent monitoring during different periods of a storm to generate a "pollutograph." This information will greatly improve the accuracy of pollutant loading estimates generated by modeling efforts.
- A project that resolves the issue of consistency in detection limits used by different dischargers. The Regional Board needs recommendations and rationale on the proper detection limits for each measured constituent to estimate and make comparisons of loadings from various sources (point and nonpoint sources).
- The study and application of molecular markers for storm water runoff. The marker can be used to identify the area of storm water influence and therefore aid further study if the runoff impacts in receiving water sediments.
- Toxicity Identification Evaluations to identify the sources of storm water/urban runoff toxicity.
- A study of the effectiveness of structural BMPs that are implemented using Proposition A grant money funds. Since many pollution control devices are new and considered to be pilots in the Region, the review panel for the Proposition A funds recommended that the regional Board should take on the responsibility to both monitor the progress in implementing these projects and to evaluate the effectiveness of installed devices for regional applicability.
- A study of the effectiveness of non-structural BMPs (e.g. public outreach) implemented under the municipal storm water permit. The information will be useful for developing future storm water pollution control strategies.
- Development of practical sanitation survey tools.

These projects would require either additional staff time or need to receive funding from sources such as Section 205(j) grants, State Revolving Fund (SRF), or Proposition 13.

A marine resource inventory and habitat mapping (available on CD) are two projects recently completed for Santa Monica Bay. The objectives of these projects are to produce a detailed inventory of the Bay's habitats, especially the Bay's unique and sensitive habitats that have been overlooked in past monitoring and inventory including intertidal, kelp bed, short bank, Torrance Beach, and artificial reefs. It also provides necessary baseline for the valuation (and potential damage assessment) of the Bay's habitats, for special designation (e.g. ecological reserve) of certain areas, and for planning measures against abuse and depletion by pollution, development, or excessive harvesting. Additionally, it helps to identify the "habitats of concern" or "species of concern" and identify cost-effective methods for restoration and rebuilding efforts. It is anticipated that the initial mapping and inventory efforts planned by the SMBRP will identify many data gaps that need to be filled by special studies that:

- quantify the amount of substrate in the Bay and the Southern California Bight capable of supporting kelp beds
- assess the conditions of kelp habitats in the vicinity of Malibu
- analyze trends in the abundance of target species such as sea stars, owl limpets, and sea grasses based on historical surveys

- analyze trends in community composition and diversity of intertidal habitats in the Bay
- survey the abundance of resident species in the Bay
- assess the population sustainability of key commercial and sportfishing species

These studies could qualify to receive grant funding such as Section 205(j), SRF, or Proposition 13.

There are also a number of ongoing volunteer monitoring efforts underway in the WMA. They include storm event sampling at over 30 Bay storm drains coordinated by the Santa Monica BayKeeper, gutter patrol monitoring in inland neighborhoods and monitoring of Malibu Lagoon and the lower Creek for water quality and biological parameters coordinated by Heal the Bay, water quality and biological monitoring and surveys of Malibu lagoon coordinated by the Resource Conservation District of the Santa Monica Mountains, monitoring of the upper Malibu Creek Watershed, and coliform monitoring of the surf zone off of Malibu coordinated by the Malibu Chapter of the Surfrider Foundation.

WETLANDS PROTECTION AND MANAGEMENT

The wetlands priority in the Ballona Creek Watershed is Ballona Wetlands. Currently, the restoration process is stalled due to controversy surrounding approval of a large development in the area. Previous planning efforts have produced a wetlands restoration plan known as a "hybrid" plan, which contains elements of both full and mid-tidal alternatives in a manner that reduces environmental impacts and minimizes costs. Depending on the development plan approval process, the strategy is to ensure that adequate funding sources are secured for implementation of the restoration plan. The Regional Board participated in this activity through the 401 water quality certification process.

In the Malibu area, <u>The Southern California Wetlands Recovery Project</u> considers the Malibu Lagoon Water Level Control Project a high priority for FY00/01 or future funding. Also considered a high priority for funding is the Upper Malibu Creek Feasibility Study which would join with US Army Corps to study the feasibility of removing Rindge Dam. Two other high priority projects in the Santa Monica WMA is the Topanga Lagoon Restoration Feasibility Study and Solstice Creek Steelhead Enhancement work.

<u>The Santa Monica Mountains Conservancy</u> is a state agency created by the Legislature in 1979 charged with primary responsibility for acquiring property with statewide and regional significance, and making those properties accessible to the general public. The Conservancy manages parkland in the Santa Monica Mountains, Santa Susana Mountains, the Simi Hills, the Santa Clarita Woodlands, the Whittier-Puente Hills, the Sierra Pelona, the Los Angeles River Greenway, the Rio Hondo, the Verdugo Mountains, the San Gabriel Mountains, and the San Rafael Hills. The agency's goals are to: 1) implement the Santa Monica Mountains Comprehensive Plan, 2) implement the Rim of the Valley Trails Corridor Master Plan, 3) implement the Los Angeles County River Master Plan, 4) further cooperation with local governments in the region to secure open space and parkland, and 5) expand education, public access, and resource stewardship components in a manner that best serves the public, protects habitat, and provides recreational opportunities.

NONPOINT SOURCE PROGRAM

Nonpoint source pollution to the ocean (greater Santa Monica Bay) includes urban runoff, aerial fallout, spills, sediment resuspension, oil seeps, vessel traffic, and advection. Strategies for dealing with urban and storm runoff were discussed under the Core Regulatory section. In addition, a priority over the next two years is to divert dry weather flows from all problematic storm drains to the sewer system. Currently, diversions of six storm drains (Pico-Kenter, Ashland, Brooks Ave., Herondo St., Pershing Dr., and Thornton Ave.) have been fully or partially funded through Proposition A money. Therefore, more attention will be shifted to deal with Santa Monica Canyon, the only problematic drain that has not been scheduled for diversion, and Santa Monica and Redondo Piers, where measures to prevent sewer system leakage may be needed.

Strategies have been developed and efforts are underway to address aerial fallout, sediment resuspension, septic systems, marinas, and vessel traffic.

Septic Systems: In January 2000, the Santa Monica Bay Restoration Project (SMBRP) convened a Task Force to address the issue of septic system management throughout the northern Santa Monica Bay watersheds. The area of focus covers three jurisdictions: the City of Malibu, the City of Los Angeles, and areas of unincorporated Los Angeles County. In order to bring together the various perspectives and expertise on this issue, the Task Force was composed of representatives from various stakeholder organizations including: State Department of Health Services (SDHS); Los Angeles Regional Water Quality Control Board (RWQCB); California Coastal Commission; Los Angeles County Departments of Public Works, Health Services and Regional Planning; City of Los Angeles Department of Building and Safety; City of Malibu Environmental and Building Safety Department; Los Angeles County Board of Supervisors Office - Third District; and Heal the Bay.

The Task Force's goal has been to develop solutions to the problems associated with septic systems and their impact on water quality, while at the same time identifying the obstacles that must be faced in trying to mitigate the situation. By bringing an understanding of these obstacles into the formulation of its recommendations, the Task Force has tried to ensure that the solutions are implementable and still fully address the problem at hand.

After its review of the existing management and regulatory framework for septic system management in the Bay's watersheds, the Task Force's recommendations suggest that improving management of septic systems will require significantly greater oversight by both state and local agencies as well as improved coordination between them.

The Task Force recommends a comprehensive approach to septics system management in northern Santa Monica Bay that includes the following elements:

- **Issue waste discharge requirements (WDRs) for all existing multi-family and commercial establishments in northern Santa Monica Bay watersheds.**
  - The RWQCB should issue WDRs for all existing commercial and applicable multi-unit developments in northern Santa Monica Bay watersheds that are not currently permitted. It is estimated that there are approximately 380 systems that need permits in this area.
  - Develop general WDRs for common types of commercial and multi-unit residential units to facilitate the permitting process.

- Seek funding to increase RWQCB staffing to reduce the permit backlog.

- **Establish a comprehensive permitting program for operation, inspection and monitoring of all septic systems.**
  - Local agencies should require operational permits for all (commercial, multi-unit and single-family) septic systems. These permits would be issued on a five-year renewal basis, with shorter intervals for poorly performing systems.
  - Develop a comprehensive inspection and monitoring program that would be implemented through the operational permits. Require that initial inspections be conducted between six and 12 months after installation of new systems.
  - All properties served by septic systems should be permitted within five years of the adoption of these recommendations by local municipalities.
  - Develop computerized management systems to track and analyze permits, maintenance and inspection schedules.

- **Design and implement a comprehensive groundwater monitoring program to improve assessments of septic system impacts to receiving waters and groundwaters.**
  - Design a regional groundwater monitoring program in order to obtain information needed to better understand groundwater conditions and reduce the number of monitoring wells that may be required of permittees. This monitoring program would be implemented through WDRs.

- **Establish a coordinated approach for oversight of septic systems, including modification/update of the WDR waivers between the RWQCB and local agencies.**
  - The RWQCB and local agencies should establish agreements that ensure consistent implementation of a policy that all commercial and multisystems obtain WDRs before building permits are issued by local agencies.

- **Develop a grants program for qualified homeowners to provide financial assistance to upgrade failing systems.**
  - Establish a financial assistance program for homeowners for which the upgrade, replacement or repair of failing on-site waste disposal systems would be a significant financial hardship.

- **Develop more stringent requirements for installation and operation of wastewater management systems in environmentally sensitive areas.**
  - Utilize a risk-based approach in implementing the operational permit program, e.g. identify environmentally sensitive areas to be addressed as high priority, develop more stringent operating permits for wastewater management systems in these areas.

- **Establish local septic system maintenance districts to oversee and fund the permitting, inspection and monitoring activities.**
  - The process for establishing such a district is outlined in the State Health and Safety Code.

- **Conduct public outreach to residents regarding proper operation and maintenance of septic systems.**
  - Educational outreach to septic system owners should be conducted regarding proper operation and maintenance of septic systems and regarding the implementation of the proposed permitting and inspection programs.

The Task Force is currently seeking approval and support of these recommendations from the agencies responsible for their implementation. Finalized recommendations will be incorporated into the Santa Monica Bay Restoration Plan with the ultimate goal of implementation by all appropriate entities.

Aerial Fallout: Funded by USEPA, the SMBRP will conduct a study of air transport/deposition of toxic contaminants to the Bay over the next three years. This study will quantify the toxic materials and nitrogens emitted annually in the Los Angeles air basin that are subsequently deposited in the Bay and the Bay's watershed, and identify the sources of various airborne pollutants in the air basin and their relative contributions to total pollutant loading to the Bay. The Regional Board has been assisting the SMBRP by encouraging participation of the stormwater management agencies. The Regional Board can use this information to evaluate the effectiveness of air pollution control measures.

Sediment Resuspension: Currently, there is no study specifically planned to examine sediment resuspension as a source of pollutant loading to the Bay. However, the USEPA Superfund investigation on the Palos Verdes Shelf and the Contaminated Sediment Task Force are both looking into the sediment resuspension issue in order to evaluate the feasibility of capping as a remediation measure. USEPA initiated a pilot project in September 2000 to evaluate cap placement methods and cap stability at three test cells on the Palos Verdes Shelf. These two efforts will provide valuable information that will help evaluate relative contributions of pollutant loading from sediment resuspension.

Marinas and Vessel Traffic: Boating wastes (vessel traffic) are potentially a significant source of loadings into the Bay as well as into harbors of pathogens, trash, and some heavy metals. The SMBRP has organized a comprehensive boater education program for the southern California counties. In addition, the new Clean Marina 319h grant will further help educate boaters, facilitate clean-out practices, and promote recognition of successes.

Other NPS Activities: We will continue to manage a 319(h) project involving restoration of Zuma Lagoon. The goals of the project are: enhancement of existing native habitats, an increase in habitat diversity and expansion of freshwater marsh and willow riparian habitats through the use of native plantings, establishment of a sycamore alluvial woodland/coastal scrub habitat, and development of an interpretive area and trails that would serve to educate the public regarding the biological and cultural resources of the site. This project is projected to be finished by 2001.

A number of nonpoint source control strategies are being undertaken in the Malibu Creek Watershed. Those that involve restoration of contact and noncontact recreation beneficial uses include:

- An assessment of nutrient and bacteria inflow from septic systems adjacent to the Lagoon through the use of tracers, by the City of Malibu (a 205(j)-funded study).
- Development of a policy at the Regional Board to regulate/permit, if appropriate, septic systems in localized areas of Malibu and the Santa Monica Mountains area including Malibou Lake.
- Implementation of the waiver policy

Also, the City of Calabasas is using 319(h) money to develop and coordinate a watershed education center and library with a projected completion date of 2000.

We continue to support as a high priority for 319(h) program funding in FY2000/01 projects to restore wetlands in Malibu, Topanga, and Trancas Lagoons.

We anticipate a number of applicants will be pursuing Proposition 13 funding for implementation or restoration projects, particularly in the Malibu area.

Additionally, work will continue with the Bay Watershed Council, the Implementation Committees for Ballona Creek and Malibu Creek, with the Storm Water Santa Monica Bay Watershed Committees, and with other Santa Monica Bay Watershed stakeholder groups, in order to identify any necessary modifications and/or new nonpoint measures that should be implemented through the Bay Restoration Plan or individual Ballona Creek and Malibu Creek Plans.

BASIN PLANNING

As we are limited in resources and time to accomplish every watershed goal during the permit phase of the first cycle, the priority issues identified for the first cycle will need to be addressed during the remainder of the first cycle. We will continue to develop strategies for the implementation of priority actions identified under the Santa Monica Bay Restoration Plan, including protection of the Ballona Wetlands, as well as additional actions targeted by the Watershed Council for action. We will also integrate these into the Watershed Council's Plan and implementation activities.

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

Since most of the NPDES permits for this watershed were renewed in 1997, in general, core regulatory activities during the next four years will focus on permit compliance, monitoring report review, and enforcement as needed. Work continues on lower Malibu Creek issues. Members of the watershed team will be involved with periodic updates of the State of the Watershed Report. Additionally, there will be on-going interaction with stakeholders and followup on goals established during the permit renewal phase.

In particular, over the next two fiscal years, a number of issues need to be addressed that require additional funding. The major NPDES permits that were not renewed in 1997 (one POTW and the three generating stations) expired in 1999 (Scattergood, El Segundo and Redondo were renewed in 2000). The next watershed cycle when the Santa Monica Bay WMA will be targeted is in 2003/04. In the meantime, the POTW has completed construction of its secondary treatment facilities in order to achieve compliance with full secondary treatment requirements. There is a need to revise the facility's effluent monitoring program to include intermediate monitoring to determine removal efficiencies. There are also a number of major studies requested of dischargers have been submitted, are due soon, or are likely to take place which will require review and evaluation. Consolidation of non-storm water discharges into general permits specific to watersheds and development of a waiver program for de minimis non-storm water discharges also requires resources. **It is estimated the above activities will require an additional 2 PYs/year over baseline resources.**

Regarding resources needed to continue oversight of the Los Angeles County storm water permit (regulatory-based BMP management), regulatory personnel will be revising the annual program report format, auditing the permittees, evaluating the revised model programs, and reviewing reports and alternate programs submitted by permittees. The eighteen municipal program audits must be completed and matched with BMPs selected to address the pollutants of concern to facilitate development of TMDLs. The Caltrans storm water management program BMPs must be matched with pollutants of concern to facilitate TMDLs impacted by transportation land use. In addition, SWPPPs for all industrial storm water facilities in the WMA must be reviewed and BMPs matched with pollutants of concern to facilitate TMDL development. **These above activities will also require an additional 2 PYs.**

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

Issuing waste discharge requirements for all existing multi-family and commercial establishments in northern Santa Monica Bay watersheds not currently under permit (with any necessary followup work), as recommended by the Santa Monica Bay Restoration Project septic systems task force, will entail requiring **an additional 2 – 4 PYs per year for at least the next five years.**

There are a number of information gaps that need to be filled over the next few years such as:

- Review existing data and assess fish contamination levels in the entire Santa Monica Bay (not just the Palos Verdes Shelf).

- Analyze the link between contaminants in fish and biological impacts to shore birds, sea birds, and marine mammals.

- Continued involvement in updates to the baseline State of the Watershed Report, focussing on filling data gaps and evaluating cumulative impacts as monitoring data become available from dischargers.

- Regional Board ambient monitoring, and evaluation of monitoring data from the municipal storm water program.

- An important issue to address at some point in the future is the need to protect the populations of threatened and endangered species in the Bay which include the California least tern, Belding's savannah sparrow, western snowy plover, California brown pelican, El Segundo blue butterfly, steelhead trout, and tidewater goby. Depending on the level of existing efforts, the needs for each species range from monitoring and assessing current conditions, to developing or implementing strategies for population recovery.

- In the Malibu Creek Watershed, a number of long-term projects are being considered or are in progress which the Regional Board will be involved with to some extent. The Malibu Creek Watershed Council is projected to complete work on a Watershed Management Plan by 2001. This Plan would include implementation strategies to resolve concerns and issues in the watershed. The Department of Parks and Recreation and the City of Malibu are investigating development of a plan to reduce unseasonal breaching of the lagoon; a plan may be available by 2002. Also, the Rindge Dam Task Force is investigating the possibility and alternative ways to remove the dam in order to facilitate access to the upper watershed by steelhead trout. There is no projected end date for this project.

Additionally, although not a nonpoint source project per se, the POTW which discharges to Malibu Creek is under a discharge prohibition starting each May 1, or at the first natural closure of Malibu Lagoon by sand buildup (whichever is later), through and including October 31 of each year, except during times of plant upset, storm events, or the existence of minimal streamflow conditions that require flow augmentation in Malibu Creek to sustain endangered species. However, in the long-run, this discharge prohibition may have many other implications on water quality and quantity in the Creek and Lagoon.

- Develop a strategy for regulating septic systems in the Malibu area.
- A priority planning issue is to define water quality standards for nutrients in Malibu Lagoon and Creek.
- We will also continue our involvement with stakeholder activities and the pursuit of funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j), SRF, Prop. 13, Small Community Grant, and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.
- We plan on pursuing funding in FY00/01 in order to complete a nutrient TMDL in the Malibu Creek Watershed as well as start a coliform TMDL there. We also require funding for trash and coliform TMDLs in Ballona Creek and coliform TMDL in Marina del Rey Harbor.
- Comments on watershed issues in CEQA documents (for the highest priority projects) will continue to be prepared; however, there is currently no funding for this program.
- Implement biological monitoring in priority watersheds (e.g. Malibu, Topanga).

Potential Long-term Activities

In the long-term, Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

A wetlands management issue that will continue to impact core regulatory activities in Malibu Creek is the listing of the creek as critical habitat for the endangered steelhead trout. Water quantity will continue to play as critical a role as water quality in the issue.

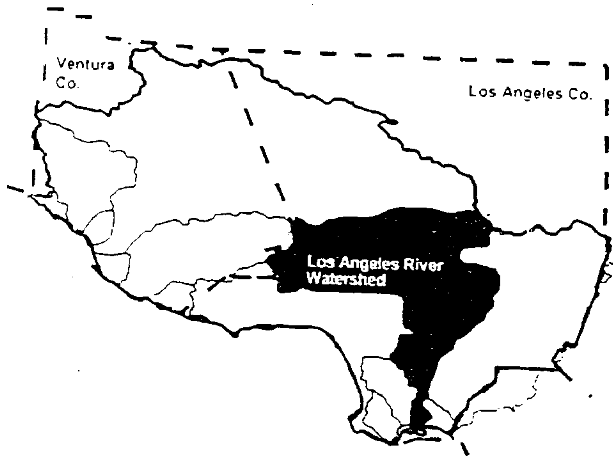
We will continue to develop strategies for the implementation of priority actions identified under the Santa Monica Bay Restoration Plan, including protection of the Ballona Wetlands, as well as additional actions targeted by the Watershed Council for action. We will also integrate these into the Watershed Council's Plan and implementation activities. Additional issues may include: 1) conduct or review studies to evaluate and refine (if necessary) the designated beneficial uses for certain waterbodies, 2) consider the establishment of wet weather criteria in some areas, 3) integrate water supply and quality issues with local land use planning and management, and 4) institute better coordination of multi-agency reviews of environmental impacts for flood control and development projects, including the consideration of regional mitigation programs.

THIS PAGE INTENTIONALLY LEFT BLANK

2.5 *LOS ANGELES RIVER WATERSHED*

This was the targeted watershed for permitting purposes in FY1997/99 and will be targeted again in FY 2004/05.

Overview of Watershed



Size of watershed: 824 square miles

Length of river: 55 miles

The Los Angeles (LA) River watershed is one of the largest in the Region. It is also one of the most diverse in terms of land use patterns. Approximately 324 square miles of the watershed are covered by forest or open space land including the area near the headwaters which originate in the Santa Monica, Santa Susana, and San Gabriel Mountains. The rest of the watershed is highly developed. The river flows through the San Fernando Valley past heavily developed residential and commercial areas. From the Arroyo Seco, north of downtown Los Angeles, to the confluence with the Rio Hondo, the river flows through industrial and commercial areas and is bordered by railyards, freeways, and major commercial and government buildings. From the Rio Hondo to the Pacific Ocean, the river flows through industrial, residential, and commercial areas, including major refineries and petroleum products storage facilities, major freeways, rail lines, and rail yards serving the Ports of Los Angeles and Long Beach.

Major tributaries to the river in the San Fernando Valley are the Pacoima Wash, Tujunga Wash (both drain portions of the Angeles National Forest in the San Gabriel Mountains), Burbank Western Channel and Verdugo Wash (both drain the Verdugo Mountains). Due to major flood events at the beginning of the century, by the 1950's most of the river was lined with concrete. In the San Fernando Valley, there is a section of the river with a soft bottom at the Sepulveda Flood Control Basin. The Basin is a 2,150-acre open space upstream of the Sepulveda Dam designed to collect flood waters during major storms. Because the area is periodically inundated, it remains in a semi-natural condition and supports a variety of low-intensity uses as well as supplying habitat. At the eastern end of the San Fernando Valley, the river bends around the Hollywood Hills and flows through Griffith and Elysian Parks, in an area known as the Glendale Narrows. Since the water table was too high to allow laying of concrete, the river in this area has a rocky, unlined bottom with concrete-lined or rip-rap sides. This stretch of the river is fed by natural springs and supports stands of willows, sycamores, and cottonwoods. The many trails and paths along the river in this area are heavily used by the public for hiking, horseback riding, and bird watching.

South of the Glendale Narrows, the river is contained in a concrete-lined channel down to Willow Street in Long Beach. The main tributaries to the river in this stretch are the Arroyo Seco (which drains areas of Pasadena and portions of the Angeles National Forest in the San

Gabriel Mountains), the Rio Hondo, and Compton Creek. Compton Creek supports a wetland habitat just before its confluence with the Los Angeles River. The river is hydraulically connected to the San Gabriel River Watershed by the Rio Hondo through the Whittier Narrows Reservoir. Flows from the San Gabriel River and Rio Hondo merge at this reservoir during larger flood events, thus flows from the San Gabriel River Watershed may impact the LA River. Most of the water in the Rio Hondo is used for groundwater recharge during dry weather seasons. The San Gabriel River drains approximately 689 square miles, which includes the eastern San Gabriel Mountains and portions of the Chino, San Jose, and Puente Hills.

Beneficial Uses in watershed:

Estuary	*Above estuary*
Industrial service supply	Groundwater recharge
Contact & noncontact water recreation	Contact & noncontact water recreation
Navigation	Warmwater habitat
Commercial & sportfishing	Wetlands Habitat
Protection of rare & endangered species	Protection of rare & endangered species
Wildlife habitat	Wildlife habitat
Marine habitat	
Migration of aquatic organisms	
Spawning	
Estuarine habitat	

The LA River tidal prism/estuary begins in Long Beach at Willow Street and runs approximately three miles before joining with Queensway Bay located between the Port of Long Beach and the city of Long Beach. The channel has a soft bottom in this reach with concrete-lined sides. Queensway Bay is heavily water recreation-oriented; however, major pollutant inputs are likely more related to flows from the LA River which carries the largest storm flow of any river in southern California.

Also part of the watershed are a number of lakes including Peck Road Park, Belvedere Park, Hollenbeck Park, Lincoln Park, and Echo Park Lakes as well as Lake Calabasas. These lakes are heavily used for recreational purposes.

Four basins in the San Fernando Valley area contain substantial deep groundwater reserves and are recharged mainly through runoff and infiltration although the increase in impermeable surfaces has decreased infiltration. Groundwater basins in the San Gabriel Valley are not separated into distinct aquifers other than near the Whittier Narrows. Active recharge occurs in some of these areas through facilities operated by Los Angeles County. Spreading grounds recharge two basins in the coastal plain of Los Angeles west of the downtown area.

Permitted discharges:

- Six major NPDES dischargers (four POTWs)
- 30 minor permits
- 112 dischargers covered by general permits
- Minor permits cover miscellaneous wastes such as ground water dewatering, recreational lake overflow, swimming pool wastes, and ground water seepage. Other permits are for discharge of treated contaminated ground water, noncontact cooling water, and storm water
- Two municipal storm water permits
- 1,327 dischargers covered under an industrial storm water permit
- 147 dischargers covered under a construction storm water permit

Water Quality Problems and Issues

Pollutants from dense clusters of residential, industrial, and other urban activities have impaired water quality in the middle and lower watershed. Added to this complex mixture of pollutant sources (in particular, pollutants associated with urban and stormwater runoff), is the high number of point source permits.

Types of permitted wastes discharged into the Los Angeles River Watershed:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	2 9	Minor General
Nonhazardous (designated) contact cooling water	1	Minor
Nonhazardous (designated) domestic sewage & industrial waste	3	Major
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	1 8 58	Major Minor General
Nonhazardous (designated) noncontact cooling water	3 13	Minor General
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	2	Minor
Nonhazardous (designated) stormwater runoff	1 9 1	Major Minor General
Hazardous contaminated groundwater	2 9	Minor General
Nonhazardous (designated) domestic sewage	1 1	Major Minor
Nonhazardous (designated) filter backwash brine waters	2	Minor
Nonhazardous wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	2	General
Inert contaminated groundwater	1	General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	16	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

A majority of the 148 NPDES discharges go directly to the Los Angeles River. Burbank Western Channel receives four discharges, Compton Creek receives five, and Eaton Wash receives three.

Of the 1,327 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Fabricated Metal Products, Except Machinery and Transportation Equipment*; *Motor Freight Transportation and Warehousing*; *Scrap and Waste Materials*; *Motor Vehicle Parts, Used*; *Primary Metal Industries*; and *Chemicals and Allied Products* categories.

There are a total of 147 construction sites enrolled under the construction storm water permit. About twice as many of these are in the upper watershed (which includes the San Fernando Valley) and the construction in this watershed is fairly evenly divided between commercial and residential.

IMPAIRMENTS: The majority of the LA River Watershed is considered impaired due to a variety of point and nonpoint sources. The 1998 303(d) list implicates pH, ammonia, a number of metals, coliform, trash, scum, algae, oil, chlorpyrifos as well as other pesticides, and volatile organics in that impairment. Some of these constituents are of concern throughout the length of the river while others are of concern only in certain reaches (see chart below). Impairment may be due to water column exceedances, excessive sediment levels of pollutants, or bioaccumulation of pollutants. The beneficial uses threatened or impaired by degraded water quality are aquatic life, recreation, groundwater recharge, and municipal water supply.

The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3 - 28.0 mg/l to protect against acute toxicity	ND - 34.9 mg/l (mean of 10.7 ± 4.8)	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reach 5 (within Sepulveda Basin) Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 3 (Riverside Dr. to Figueroa St.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Burbank Western Channel Rio Hondo Reach 2 (from Whittier Narrows Flood Cntrl Basin to Spreading Grounds) Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Lincoln Park Lake Echo Park Lake Lake Calabasas
nutrients (algae)	Basin Plan narrative objective Basin Plan numeric objective: nitrates-N + nitrites-N not greater than 10 mg/l	0.2 - 14.5 mg/l (mean of 2.7 ± 3.2)	Los Angeles River Reach 5 (within Sepulveda Basin) Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 3 (Riverside Dr. to Figueroa St.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Burbank Western Channel Verdugo Wash (Reaches 1 & 2) Arroyo Seco Rch 1 (d/s Devil's Gate Dam) & Rch 2 (W. Holly Ave. to Devil's Gate) Lincoln Park Lake Echo Park Lake Lake Calabasas
Scum, odors	Basin Plan narrative objective		Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reach 5 (within Sepulveda Basin) Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 3 (Riverside Dr. to Figueroa St.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Burbank Western Channel Peck Rd Lake Lincoln Park Lake Echo Park Lake Lake Calabasas
pH	Basin Plan numeric objective: 6.5 - 8.5 pH units	7.0 - 10.6 pH units (mean of 9.2 ± 0.9)	Los Angeles River Reach 1(u/s Carson St. to estuary) Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Compton Creek Echo Park Lake Lake Calabasas

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Low DO/organic Enrichment	Basin Plan narrative objective Basin Plan numeric objective: annual mean greater than 7.0 mg/l no single sample less than 5.0 mg/l	0.2 - 15.2 mg/l (mean of 6.0 ± 4.0)	Lincoln Park Lake Peck Rd Lake Lake Calabasas
Trash	Basin Plan narrative objective		Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reach 5 (within Sepulveda Basin) Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 3 (Riverside Dr. to Figueroa St.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Burbank Western Channel Verdugo Wash (Reaches 1 & 2) Arroyo Seco Reach 1 (d/s Devil's Gate Dam) & Reach 2 (W. Holly Ave. to Devil's Gate) Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Peck Rd Lake Echo Park Lake Lincoln Park Lake
Copper	USEPA water quality criteria: varies based on hardness but typically 12 - 47 ug/l	63 ug/l (maximum)	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Compton Creek Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Echo Park Lake Lake Calabasas
Lead	USEPA water quality criteria: varies based on hardness but typically 3.2 - 25 ug/l	140 ug/l (maximum)	Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Monrovia Cyn Creek Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Compton Creek Peck Rd Lake Lincoln Park Lake Echo Park Lake
Cadmium	USEPA water quality criteria: varies based on hardness but typically 1.1 - 4.0 ug/l	3 ug/l (maximum)	Burbank Western Channel
Zinc	USEPA water quality criteria: varies based on hardness but typically 106 - 414 ug/l	1,340 ug/l (maximum)	Lake Calabasas Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River)
Selenium	USEPA water quality criteria: 5.0 ug/l	9.3 ug/l (maximum)	Aliso Canyon Wash
coliform	Basin Plan numeric objective: Inland: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml Beaches: total coliform not to exceed 1,000 MPN/100ml in more than 20% of samples in 30 days and not more than 10,000 MPN/100ml at any time	ND - 93,000 MPN/100ml	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reach 6 (u/s of Sepulveda Basin) Los Angeles River Reach 4 (Sepulveda Dam to Riverside Dr.) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.) Los Angeles River Reach 1(u/s Carson St. to estuary) Verdugo Wash (Reaches 1 & 2) Arroyo Seco Rch 1 (d/s Devil's Gate Dam) & Rch 2 (W. Holly Ave. to Devil's Gate) Rio Hondo Reach 1 (Santa Ana Fwy to Los Angeles River) Rio Hondo Reach 2 (Whittier Narrows Flood Control Basin to Spreading Grounds) Compton Creek Bell Creek
chlorpyrifos	Basin Plan narrative objective		Los Angeles River Reach 5 (within Sepulveda Basin)
Chem A*	National Academy of Science Guideline (tissue): 100 ng/g		Los Angeles River Reach 5 (within Sepulveda Basin)
PCBs	State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g		Echo Park Lake
DDT	State Board numeric objective (tissue): Max. Tissue Residue Level 32.0 ng/g		Peck Rd Lake Lake Calabasas
chlordane	State Board numeric objective (tissue): Max. Tissue Residue Level 1.1 ng/g		Peck Rd Lake

* Chem A refers to the sum of the chemicals aldrin, dieldrin, chlordane, endrin, heptachlor, heptachlor epoxide, HCH (including lindane), endosulfan, and toxaphene

Potential sources of pollution:

- POTWs
- Industrial discharges
- septic systems
- landfills
- Nonpoint sources (horse stables, golf courses)
- Illegal trash dumping
- Cross-contamination between surface and groundwater

Ground water resources in the watershed are also impacted. Impacts, both real and threatened, include those from hundreds of cases of known leaking underground storage tanks that have contaminated soil and/or ground water with petroleum hydrocarbons and volatile organic compounds. There are also a number of cases of refineries/tank farms that have contaminated soil and/or ground water. Seawater intrusion (chloride) is of concern in other areas of the watershed which has necessitated wellhead treatment, shutdown, or blending. Finally, a number of wells have been shut down due to nitrate contamination with septic systems as a likely source.

ISSUES: The major issues of concern in the watershed include: 1) protection and enhancement of fish and wildlife habitat, 2) removal of exotic vegetation, 3) enhancement of recreational areas, 4) attaining a balance between water reclamation and minimum flows to support habitat, 5) management of storm water quality, 6) assessment of other nonpoint sources including horse stables, golf courses, and septic systems, 7) pollution from contaminated ground water, 8) groundwater recharge with reclaimed water, 9) contamination of ground water by volatile organic compounds, 10) leakage of MTBE from underground storage tanks, 11) groundwater contamination with heavy metals, particularly hexavalent chromium, and 12) contaminated sediments within the LA River estuary.. Some of these issues are only indirectly related to water quality but are those identified by stakeholder groups.

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
trash	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reaches 1, 2, 3, 4, 5 Burbank Western Channel Verdugo Wash Reaches 1 & 2 Arroyo Seco Reaches 1 and 2 Rio Hondo Reach 1	00/01
nitrogen and related effects	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Los Angeles River Reaches 1, 2, 3, 4, 5 Burbank Western Channel Verdugo Wash Reaches 1 & 2 Arroyo Seco Reaches 1 and 2 Rio Hondo Reaches 1 and 2 Compton Creek	01/02
coliform	Los Angeles River Reaches 1, 2, 4, and 6 Tujunga Wash (d/s Hansen Dam to LA River) Verdugo Wash Reaches 1 and 2 Arroyo Seco Reach 1 Rio Hondo Reaches 1 and 2 Compton Creek	01/02

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
metals	Tujunga Wash (d/s Hansen Dam to Los Angeles River) Compton Creek Burbank Western Channel Los Angeles River Reaches 1, 2, 4 Rio Hondo Reach 1 Monrovia Cyn Creek Aliso Canyon Wash	03/04
hist. pesticides	Los Angeles River Reach 5 (within Sepulveda Basin)	05/06

We see a need for an additional 1.9 PYs and $100,000 of contract monies for FY00/01 TMDL work conducted in this watershed.

Stakeholder Groups

Los Angeles/San Gabriel Rivers Watershed Council The group was formed in 1995 following a large watershed conference held in the area which served as a springboard. The Council has a board of directors and became incorporated as a nonprofit organization in 1996. The group is tracking watershed activities, but has primarily focused on flood control issues in the Los Angeles River as well as opportunities to create greenbelts and restore habitat. Three committees have been formed recently: water resources, water quality, and multi-use projects. The Council's goal is to help facilitate a process to preserve, restore, and enhance all aspects of the two watersheds. Preparation of a watershed management plan by this group is underway. This group is coordinating with other groups to seek Proposition 13 funding. Generally one staff person attends these monthly council as well as monthly board of directors meetings. More information about this group may be found at their website http://www.lasgriverswatershed.org/.

Los Angeles Basin Contaminated Sediment Task Force Contaminated dredged material disposal is a major issue in the Los Angeles Region due to its large commercial ports and the several major marina complexes and small vessel harbors. .Queensway Bay, at the mouth of the watershed, receives a large sediment load that impacts recreational uses. The U.S. Army Corps of Engineers frequently conducts maintenance dredging to remove accumulated sediments from this area. The need for a long-term management strategy for dealing with contaminated sediments in the Los Angeles area has been identified and the Task Force will prepare this strategy. Representatives on the Task Force include a number of federal and state agencies as well as port and environmental group representatives. More information about this group may be found in the Region-wide Section of this Chapter.

Past Significant Activities

CORE REGULATORY

The Los Angeles County Storm Water Permit (which the LA River Watershed falls within) permit was renewed in July 1996.

WATERSHED MANAGEMENT

Key regulatory staff are part of a LA River Watershed "team" for purposes of preparing a State of the Watershed Report/Water Quality Characterization Report (a draft of which was released April 13, 1998) and for coordinating permit renewals and regional monitoring program development.

Current Activities

The following is a summary of current Regional Board activities in the Los Angeles River Watershed which are expected to continue as part of the Watershed Management Initiative on a watershed basis. Activities which address the aforementioned pollutants or issues of concern are highlighted. Additionally, there are a large number of projects and activities currently underway by watershed stakeholders ranging from a wetlands assessment funded by the Coastal Conservancy and others to an NPDES Permit Public Education Program funded by the City of Alhambra.

CORE REGULATORY

Continuing core regulatory activities that have been integrated into the watershed management approach include (but are not limited to) renewal/revision of NPDES permits including those covered under Regional Board general permits. Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue. A draft watershed-wide regional monitoring program was created in 1998/99 and our modifications and improvements to discharger monitoring programs will target data gaps and eliminate duplicative and unnecessary monitoring. Coordination between major dischargers, environmental groups, volunteer monitors, and resource and regulatory agencies will be critical to the success of this task. Because of the large number of permits, renewal of permits in this watershed during its first cycle was spread over two years.

The Los Angeles River Watershed falls within Los Angeles County which was issued a renewed municipal storm water permit in 1996. There are 87 co-permittees covered under this permit including 85 cities, the County of Los Angeles, and the California Department of Transportation (Caltrans). Work on the permit will involve review of monitoring reports, evaluation of the storm water program's effectiveness, coordination with other watershed efforts, and modification of the permit as necessary. During 1997/98, discharger responsibilities under the permit concentrated on the evaluation of the five BMP model programs required in the 1996 permit: Illicit Connection/Illicit Discharges, Development Construction, Development Planning, Public Agency Activities, and Five-Year Public Education Strategy (including industrial/commercial site visits). The watershed also falls partly within the City of Long Beach which was issued a municipal storm water permit in 1999.

An important requirement of both storm water municipal permits is implementation of the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Numerical Design Standards for Best Management Practices (BMPs) which were adopted in 2000. The SUSMP is designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating BMPs in the design phase of new development and redevelopment. It provides for numerical design standards to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways.

The numerical design standard is that post-construction treatment BMPs be designed to mitigate (infiltrate or treat) storm water runoff from the first ¾ inch of rainfall, prior to its discharge to a storm water conveyance system. Other standards also apply; additional information on the SUSMP may be found on the Regional Board website http://www.swrcb.ca.gov/~rwqcb4.

Regulation of groundwater protection activities is intended to eventually become integrated into the watershed management approach while land disposal activities will likely remain separate. Accomplishment of core regulatory activities are a high priority that is currently funded; however, funds do not tend to go far enough to encompass extensive enforcement and response to complaints; however, enforcement is a high priority.

Due to limited resources, only the basic regulatory activities are performed: review of dischargers' monitoring reports, minimum necessary inspections and sampling, issuance/renewal of permits, levels 1 and 2 enforcement actions (noncompliance and violation notification), case handling, and answering inquiries from the public.

MONITORING AND ASSESSMENT

Work on a TMDL for nitrogen in the watershed is currently underway. A preliminary draft was released to the public on April 1, 1998; however, due to staff changes and resources, it was not completed. A public draft of this TMDL is expected to be available early in the summer of 2001.

A State of the Watershed/Water Quality Characterization Report was prepared during 1997/98 based on information obtained through the Board's ambient monitoring program, dischargers' receiving water monitoring data, and data available from other agencies. The first edition of the report focuses on the upper LA River Watershed. This document was released in April 1998.

NONPOINT SOURCE PROGRAM

The major nonpoint source-generated pollutants found throughout the watershed that have contributed to its impairments are lead, coliform, and oil, while chlorpyrifos is implicated in the upper watershed. These pollutants are common components of dry weather urban runoff and wet weather storm runoff. In many ways, the "point source" municipal stormwater permit for LA County will be a major tool in nonpoint source pollution elimination. Permitees are responsible for development and implementation of storm water management plans, for plans to eliminate non-storm water discharges (dry weather urban runoff), and must apply best management practices to prevent storm water pollution.

The Regional Board encourages pollution prevention and source control; the 205(j) and 319(h) grants are tools to provide funds for these types of projects. For FY00/01, we have listed as a priority for 319(h) grant funding activities (see Table 4) which demonstrate effective ways to reduce loadings of trash, nutrients, and coliform through pilot projects which implement trash reduction, management of horse corral runoff, golf course irrigation water runoff, urban runoff, or implementation of septic correction measures.

Staff will also be involved in stakeholder meetings and will assist in the development of watershed management plans which will be expected to address strategies to reduce point and nonpoint source pollutants as well as other issues other than strictly water quality concerns. A strong stakeholder group already exists and has been meeting regularly.

BASIN PLANNING

A priority basin planning issue is to implement the Basin Plan's ammonia objective. Some dischargers believe the objective may be too stringent for certain waters and that site-specific objectives may be justified while some resource agencies and many environmental groups support the current objective. The regional board objective for ammonia allows for studies to be performed to explore site-specific objectives, if appropriate. Dischargers which must meet this objective by June 2002, and should be well on their way to compliance by this point. This issue is especially relevant in the LA River since ammonia is already known to be a pollutant of concern.

Determination of appropriate nutrient (nitrate and phosphate) objectives for protection of aquatic life is also a remaining issue.

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

Review and comment on EIRs for the highest priority projects within the watershed will continue; however, there is currently no funding for this program.

WETLANDS PROTECTION AND MANAGEMENT

The San Gabriel and Lower Los Angeles Rivers and Mountains Conservancy is an independent State agency within the Resources Agency. State law established the Conservancy in 1999. Its jurisdiction includes the San Gabriel River and its tributaries, the Lower Los Angeles River and its tributaries, and the San Gabriel Mountains. Puente Hills, and San Jose Hills. It was established to preserve open space and habitats in order to provide for low-impact recreation and educational uses, wildlife and habitat restoration and protection, and watershed improvements within its jurisdiction. It is currently involved with beginning work on an open space plan for the area. Propositions 12 and 13 have directed funds to the Conservancy. The Santa Monica Mountains Conservancy is a state agency created by the Legislature in 1979 charged with primary responsibility for acquiring property with statewide and regional significance, and making those properties accessible to the general public. The Conservancy manages parkland in the Santa Monica Mountains, Santa Susana Mountains, the Simi Hills, the Santa Clarita Woodlands, the Whittier-Puente Hills, the Sierra Pelona, the Los Angeles River Greenway, the Rio Hondo, the Verdugo Mountains, the San Gabriel Mountains, and the San Rafael Hills. The agency's goals are to: 1) implement the Santa Monica Mountains Comprehensive Plan, 2) implement the Rim of the Valley Trails Corridor Master Plan, 3) implement the Los Angeles County River Master Plan, 4) further cooperation with local governments in the region to secure open space and parkland, and 5) expand education, public access, and resource stewardship components in a manner that best serves the public, protects habitat, and provides recreational opportunities.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

Following renewal of the watershed's permits, core regulatory activities will focus on permit compliance, monitoring report review, and enforcement as needed. Members of the watershed team will be involved with periodic updates of the State of the Watershed Report. Additionally, there will be on-going interaction with stakeholders and followup on goals established during the permit renewal phase. Pending completion of a final TMDL we will pursue agreement on pollutant loadings that can be implemented through future NPDES permits, the municipal stormwater permit, and through other nonpoint source control measures.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

We are making significant progress toward identifying and assessing problems in the upper watershed and involving stakeholders. Also by this time, we shall have completed intensive sampling and modeling of ammonia loads in the main channels in the Los Angeles River watershed for a TMDL which will give us a headstart on assessing and allocating pollutant loadings from both point and nonpoint sources.

Monitoring and special studies: Quarterly water quality assessment monitoring at a minimum of 14 stations along the LA River Watershed (particularly its tributaries) with sampling for general minerals, nutrients, metals, coliform, pesticides, radioactivity, volatile organics, and other organics, as well as gathering baseline information on trash, is proposed. **The annual cost of this monitoring is estimated at $113,400.** This monitoring will be in addition to monitoring of the main channel conducted by dischargers. **Additionally, a number of special studies will be needed which are expected to cost a total of $108,000.** TMDLs that need to be developed include:

1) Ammonia: The first phase of the TMDL was completed in FY97/98. Currently the model is at the calibration stages for dry weather simulations. Historical data as been gathered from the Regional Board and various other agencies to calibrate the model. Wet season calibration for the model will occur in the first quarter of 2001. Sampling efforts are currently underway to gather data for the wet season calibration effort. Investigation of nitrogen uptake by algae and algal growth rates and river nitrification rates are currently underway, and will be available for use in the model simulations.

2) Coliform: A first review indicates that the coliform contributions from POTWs is not significant. To give us a rough estimate of the sources of coliform, special studies are needed to determine the type of coliform present in the river: from human waste, horses, wildlife, or other. **These studies are estimated to cost $75,000.** Once the sources have been identified, a load allocation may be calculated, and BMPs or other solutions may be proposed to achieve such allocations.

R0026633

3) Metals: To develop a first phase TMDL for metals, more monitoring is needed. However, staff resources should be dedicated to data assessment and analysis, and to prepare an implementation strategy.

4) Trash: The municipal stormwater permit co-permittees in coordination with the Regional Board will be conducting a study to determine the threshold level for beneficial use impairment as part of this TMDL effort. A draft TMDL is out for review and is scheduled for adoption at a January 25, 2000, Board meeting.

5) Pesticides: A section of the river has been listed impaired due to pesticides found in fish or shellfish. POTWs are currently implementing effluent limitations to control pesticide loadings. Nonpoint source contributions need to be estimated. If toxicity money is available, **$100,000 would allow us to pinpoint specific areas and seasons where we have problems.**

6) Volatile organic compounds: A section of the river has been listed impaired due to VOCs from ground water. As efforts to clean up the ground water in the San Fernando Valley are implemented, staff expects that contamination from VOCs will decrease. Monitoring of VOCs is needed to determine if this assumption is correct.

Our efforts to involve stakeholders also shall include exploration of funding options (especially for implementation of nonpoint source measures) and continuation of other outreach activities, such as presentations, meetings, and participation in environmental events.

Also, efforts are underway to address problems with urban runoff (through the storm water municipal and industrial NPDES permits) and septic systems. Future activities should focus on horse corrals and golf courses, parks or other green areas. Activities proposed include outreach to implement BMPs. Tier I activities also should include monitoring and assessment to determine if Tier 2 or Tier 3 activities are needed to ensure successful implementation of BMPs and reduction of nitrogen and coliform loadings.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

Potential Long-term Activities

In the long-term, Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities (such as more refined regional procedures for conducting use attainability analyses and site-specific objective development) into the next update of the Basin Plan. More detailed analysis regarding certain beneficial uses needs to be done (species inhabiting/using the river, potential for aquatic life in the river, future water supply needs/diversions, ground water recharge areas). We will continue to pursue funding for Basin Planning programs. Comments on watershed issues in CEQA documents (for the highest priority projects) will continue to be prepared; however, there is currently no funding for this program.

Other issues include:

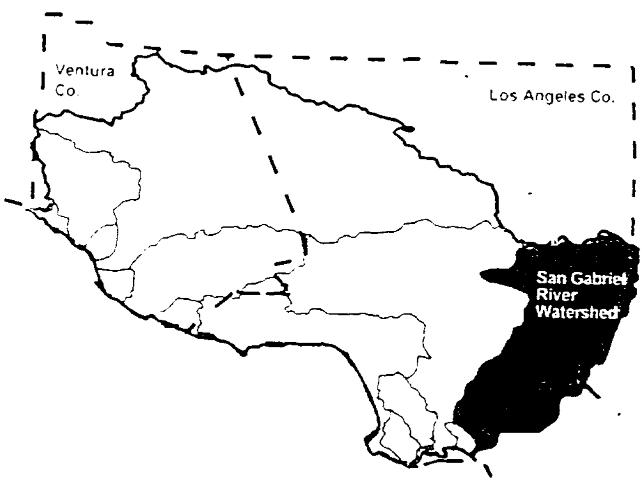
- Balancing maintenance of habitat in the river with flood control needs
- Evaluation of areas in the river for restoration purposes
- Evaluating critical habitat areas
- Evaluating the most protective (while providing flood control) long-term plans for vegetation/sediment removal under the 401 certification program
- Evaluate and implement low flow diversions where appropriate
- Assist in greenway developments along the river
- Evaluate estuarine habitats and water quality
- Implementing biological monitoring

THIS PAGE INTENTIONALLY LEFT BLANK

2.6 SAN GABRIEL RIVER WATERSHED

This watershed will be targeted for permit renewal purposes in FY05/06.

Overview of Watershed



Size of watershed: 689 sq. mi.

The San Gabriel River receives drainage from a large area of eastern Los Angeles County; its headwaters originate in the San Gabriel Mountains. The watershed consists of extensive areas of undisturbed riparian and woodland habitats in its upper reaches. Much of the watershed of the West Fork and East Fork of the river is set aside as a wilderness area; other areas in the upper watershed are subject to heavy recreational use. The upper watershed also contains a series of flood control dams. Further downstream, towards the middle of the watershed, are large spreading grounds utilized for groundwater recharge. The watershed is hydraulically connected to the Los Angeles River through the Whittier Narrows Reservoir (normally only during high storm flows). The lower part of the river flows through a concrete-lined channel in a heavily urbanized portion of the county before becoming an soft bottom channel once again near the ocean in the city of Long Beach. Large electrical power poles line the river along the channelized portion and nurseries, small stable areas, and a large poultry farm are located in these areas.

Beneficial Uses designated in the watershed:

Estuary	Above Estuary
Contact & noncontact water recreation	Contact & noncontact water recreation
Industrial service supply	Industrial service supply
Protection of rare & endangered species	Protection of rare & endangered species
Wildlife habitat	Wildlife habitat
Spawning	Spawning
Marine habitat	Warm- & coldwater habitat
Estuarine habitat	Municipal water supply
Navigation	Groundwater recharge
Commercial & sportfishing	Industrial process supply
Migratory	Agricultural supply

Water Quality Problems and Issues

Pollutants from dense clusters of residential and commercial activities have impaired water quality in the middle and lower watershed. Tertiary effluent from several sewage treatment plants enters the river in its middle reaches (which is partially channelized) while two power generating stations discharge cooling water into the river's estuary. The watershed is also covered under two municipal storm water NPDES permits. Several landfills are also located in the watershed.

Several reservoirs, which exist primarily for flood control purposes, occur in the upper part of the watershed. Frequent removal of accumulated sediments is necessary to maintain the flood control capacity of these reservoirs. Some of the removal methods previously used have had water quality impacts. Continued need for such maintenance could cause longer-term impacts. A study is currently underway to better assess impacts associated with the sluicing projects.

Significant Issues:

- Sluicing of reservoirs
- Protection of groundwater recharge areas
- Trash in upper watershed
- Mining/stream, modifications
- Ambient toxicity
- Urban and storm water runoff quality

Permitted discharges:

- Nine major NPDES dischargers (five POTWs)
- 23 minor permits
- 2 municipal storm water permits
- 65 discharges covered under general permits
- 549 dischargers covered under an industrial storm water permit
- 175 dischargers covered under a construction storm water permit

Types of permitted wastes discharged into the San Gabriel River Watershed:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	3	General
Nonhazardous (designated) contact cooling water	1 2	Major Minor
Nonhazardous (designated) domestic sewage & industrial waste	5	Major
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	4 37	Minor General
Nonhazardous (designated) noncontact cooling water	1 1	Minor General
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	1 2	Major Minor
Nonhazardous (designated) stormwater runoff	1 9 1	Major Minor General
Nonhazardous (designated) washwater waste (photo reuse washwater, vegetable washwater)	1	Minor
Hazardous contaminated groundwater	3 7	Minor General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage)	1 16	Minor General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

A majority of the 99 NPDES permittees in the watershed discharge directly to the San Gabriel River (38). Nineteen discharge to Coyote Creek and twelve discharge to San Jose Creek.

Of the 549 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Fabricated Metal Products, Except Machinery and Transportation Equipment*; *Chemicals and Allied Products*; *Motor Freight Transportation and Warehousing*; and *Motor Vehicle Parts, Used* categories.

There are 175 construction sites enrolled under the construction storm water permit. The sites are fairly evenly divided between residential and commercial and a similar number of sites are found in both the upper and lower watershed.

IMPAIRMENTS: The upper reaches of the river (in the Angeles National Forest) are heavily used for recreational purposes and have been impacted from trash, debris, and habitat destruction. Various reaches of the river are on the 1998 303(d) list due to nitrogen and its effects, trash, PCBs and pesticides, metals, and coliform. The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3-28.0 mg/l to protect against acute toxicity	ND - 21.1 mg/l (mean of 10.1±4.1)	San Gabriel River Reach 2 (Firestone to Whittier Narrows Dam) San Gabriel River Reach 1 (Estuary to Firestone) San Jose Creek Reach 2 (Temple to I-10 at White Ave) San Jose Creek Reach 1 (SG confluence to Temple St.) Coyote Creek Legg Lake El Dorado Lakes
toxicity	Basin Plan narrative objective	0 – 100% survival	San Gabriel River Reach 3 (Whittier Narrows to Ramona) San Gabriel River Reach 1 (Estuary to Firestone) Coyote Creek Walnut Creek
algae	Basin Plan narrative objective		San Gabriel River Reach 1 (Estuary to Firestone) San Jose Creek Reach 1 (SG confluence to Temple St.) San Jose Creek Reach 2 (Temple to I-10 at White Ave) Coyote Creek El Dorado Lakes
Eutrophication	Basin Plan narrative objective		El Dorado Lakes
pH	Basin Plan numeric objective: 6.5 - 8.5 pH units	6.9 - 9.4 pH units (mean of 8.5±0.6)	Walnut Creek El Dorado Lakes Legg Lake Santa Fe Dam Park Lake
odors	Basin Plan narrative objective		Legg Lake
low DO, organic enrichment	Basin Plan narrative objective Basin Plan numeric objective: annual mean greater than 7.0 mg/l no single sample less than 5.0 mg/l	0.1 - 14.9 mg/l (mean of 4.3±3.5)	Puddingstone Reservoir Crystal Lake
trash	Basin Plan narrative objective		San Gabriel River East Fork Legg Lake
Lead	USEPA water quality criteria: varies based on hardness but typically 3.2 - 25 ug/l	100 ug/l (maximum)	San Gabriel River Reach 2 (Firestone to Whittier Narrows Dam) Santa Fe Dam Park Lake El Dorado Lakes Legg Lake
Arsenic (tissue)	State Board numeric objective (tissue): Max. Tissue Residue Level 200 ng/g	240 - 300 ng/g (tissue)	San Gabriel River Estuary
Copper	USEPA water quality criteria varies based on hardness but typically 12 - 47 ug/l	90 ug/l (maximum)	Legg Lake El Dorado Lakes Santa Fe Dam Park Lake
Silver	USEPA water quality criteria varies based on hardness but typically 4.1 - 65 ug/l	30 ug/l (maximum)	Coyote Creek
Mercury (tissue)	NAS guidelines (tissue): 500 ng/g	510 ng/g (tissue)	Puddingstone Reservoir El Dorado Lakes

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
coliform	Basin Plan numeric objective: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml	ND - 240000 MPN/100ml	San Jose Creek Reach 2 (Temple to I-10 at White Ave) San Jose Creek Reach 1 (SG confluence to Temple St) San Gabriel River Reach 2 (Firestone to Whittier Narrows Dam) San Gabriel River Reach 1 (Estuary to Firestone) Coyote Creek
DDT	State Board numeric objective (tissue): Max. Tissue Residue Level 32.0 ng/g	25 - 36 ng/g (tissue)	Puddingstone Reservoir
PCBs	State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g	54 - 65 ng/g (tissue)	Puddingstone Reservoir
chlordane	State Board numeric objective (tissue): Max. Tissue Residue Level 1.1 ng/g	16.1 - 31.7 ng/g (tissue)	Puddingstone Reservoir
abnormal fish histology	Basin Plan narrative objective		Coyote Creek San Gabriel River Reach 1 (Estuary to Firestone) San Gabriel River Estuary

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled For Completion (FY)
nitrogen and its effects	San Gabriel River Reaches 1, 2, 3 San Jose Creek Reaches 1 and 2 Coyote Creek Walnut Creek	02/03
Nitrogen and its effects	El Dorado Lakes Puddingstone Reservoir Legg Lake Santa Fe Dam Lake Crystal Lake	03/04
coliform	San Gabriel River Reaches 1 and 2 San Jose Creek Reaches 1 and 2 Coyote Creek	02/03
metals	San Gabriel River Reach 2 San Gabriel River Estuary Coyote Creek	04/05

We see a need for an additional 1.4 PYs as well as $200,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Stakeholder Groups

Los Angeles/San Gabriel Rivers Watershed Council: This group was formed in 1995 following a large watershed conference held in the area which served as a springboard for other efforts. The Council has a board of directors and became incorporated as a nonprofit organization in 1996. The group is tracking watershed activities, but has primarily focused on flood control issues in the Los Angeles River as well as opportunities to create greenbelts and restore habitat. The Council's goal is to help facilitate a process to preserve, restore, and enhance all aspects of the two watersheds. There has been interest recently to convene a subcommittee to address water quality issues in more detail. More information on this group may be found on their website http://www.lasgriverswatershed.org.

Friends of the San Gabriel River

The Friends of the San Gabriel River is a non-profit organization founded in 1999 that advocates water quality improvements, restoration of habitat, and increased access to the river for the public. More information on this group may be found on their website at http://www.sangabrielriver.org/.

Past Significant Activities

CORE REGULATORY

The Los Angeles County Storm Water Permit (which the San Gabriel River Watershed falls within) permit was renewed in July 1996. Individual NPDES permits in this watershed were renewed in FY99/00.

WATERSHED MANAGEMENT

An in-house team of staff completed a "State of the Watershed Report" for the San Gabriel River. This report is available by request as hardcopy or electronic files.

MONITORING AND ASSESSMENT

As part of a larger-scale investigation which concluded in 1996, ambient toxicity (as well as fish histopathology) was evaluated at a number of locations in the river which lead to additional 303(d) listings for impairments. The East Fork Trash TMDL (1999) documented the main sources of trash in the upper watershed.

Current Activities

The following is a summary of current regional board activities in the San Gabriel River Watershed which are expected to continue as part of the Watershed Management Initiative on a watershed basis.

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits. There are nine major dischargers, 25 significant or minor dischargers under individual permits, as well as 39 dischargers currently covered under general permits. Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue. All of the County Sanitation Districts' permits for their inland POTWs (which comprise most of the flow in the middle to lower river) are being renewed this year.

The San Gabriel River Watershed falls within Los Angeles County which was issued a renewed municipal storm water permit in 1996. There are 87 co-permittees covered under this permit including 85 cities, the County of Los Angeles, and the California Department of Transportation (Caltrans). Work on the permit will involve review of monitoring reports, evaluation of the storm water program's effectiveness, coordination with other watershed efforts, and modification of the permit as necessary. During 1997/98, discharger responsibilities under the permit concentrated on the evaluation of the five BMP model programs required in the 1996 permit: Illicit Connection/Illicit Discharges, Development Construction, Development Planning, Public Agency Activities, and Five-Year Public Education Strategy (including industrial/commercial site

visits). The watershed also falls partly within the City of Long Beach which was issued a municipal storm water permit in 1999.
An important requirement of both storm water municipal permits is implementation of the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Numerical Design Standards for Best Management Practices (BMPs) which were adopted in 2000. The SUSMP is designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating BMPs in the design phase of new development and redevelopment. It provides for numerical design standards to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways.

The numerical design standard is that post-construction treatment BMPs be designed to mitigate (infiltrate or treat) storm water runoff from the first ¾ inch of rainfall, prior to its discharge to a storm water conveyance system. Other standards also apply; additional information on the SUSMP may be found on the Regional Board website http://www.swrcb.ca.gov/~rwqcb4.

Due to limited resources, only the basic regulatory activities are performed: review of dischargers' monitoring reports, minimum necessary inspections and sampling, issuance/ renewal of permits, levels 1 and 2 enforcement actions (noncompliance and violation notification), case handling, and answering inquiries from the public.

NONPOINT SOURCE PROGRAM

The Regional Board encourages pollution prevention and source control; the 205(j), Prop 13, SRF, and 319(h) grants are tools to provide funds for these types of projects. For FY00/01, we have listed as a priority for 319(h) grant funding activities (see Table 3) which demonstrate effective ways to reduce loadings of trash, nutrients, and coliform through pilot projects which implement trash reduction, management of horse corral runoff, golf course irrigation water runoff, urban runoff, or implementation of septic correction measures. High priority projects also include those involving restoration of aquatic and riparian habitats, as well as, enhancement of recreational uses.

MONITORING AND ASSESSMENT

In support of TMDL work, as well to obtain other needed information, we are requesting funding in order to start nitrogen, coliform, and metals TMDLs which are currently scheduled. We also plan on conducting ambient toxicity monitoring work and noted the need for a tidal prism mixing study to resolve issues concerning the fate of freshwater effluent in the estuary.

BASIN PLANNING

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

WETLANDS PROTECTION AND MANAGEMENT

The Southern California Wetlands Recovery Project considers the El Dorado Wetlands Restoration Plan a high priority for FY00/01 or future funding.

The San Gabriel and Lower Los Angeles Rivers and Mountains Conservancy is an independent State agency within the Resources Agency. State law established the Conservancy in 1999. Its jurisdiction includes the San Gabriel River and its tributaries, the Lower Los Angeles River and its tributaries, and the San Gabriel Mountains. Puente Hills, and San Jose Hills. It was established to preserve open space and habitats in order to provide for low-impact recreation and educational uses, wildlife and habitat restoration and protection, and watershed improvements within its jurisdiction. It is currently involved with beginning work on an open space plan for the area. Propositions 12 and 13 have directed funds to the Conservancy.

The Santa Monica Mountains Conservancy is a state agency created by the Legislature in 1979 charged with primary responsibility for acquiring property with statewide and regional significance, and making those properties accessible to the general public. The Conservancy manages parkland in the Santa Monica Mountains, Santa Susana Mountains, the Simi Hills, the Santa Clarita Woodlands, the Whittier-Puente Hills, the Sierra Pelona, the Los Angeles River Greenway, the Rio Hondo, the Verdugo Mountains, the San Gabriel Mountains, and the San Rafael Hills. The agency's goals are to: 1) implement the Santa Monica Mountains Comprehensive Plan, 2) implement the Rim of the Valley Trails Corridor Master Plan, 3) implement the Los Angeles County River Master Plan, 4) further cooperation with local governments in the region to secure open space and parkland, and 5) expand education, public access, and resource stewardship components in a manner that best serves the public, protects habitat, and provides recreational opportunities.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j), Prop. 13, SRF, and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

Potential Long-term Activities

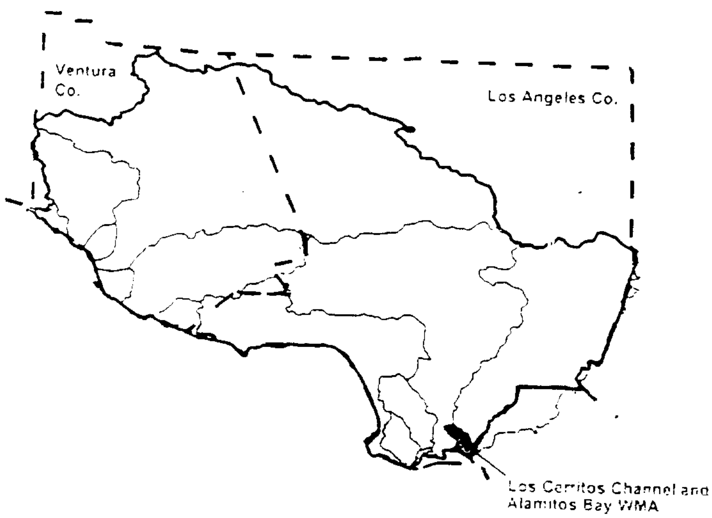
- Development of coordinated watershed monitoring program
- Hydrologic study of the estuary to evaluate mixing dynamics and effects on water quality and beneficial uses
- Evaluation of fish tissue from fish in the lower river and estuary
- Evaluation of toxicity impacts in the estuary
- Evaluation of habitats in the middle/lower river
- Evaluation of impacts from reservoir cleaning on water quality, particularly fisheries-related

- Evaluation of mining on instream beneficial uses
- Evaluation of impacts of reclaimed water on river/groundwater
- Evaluation of success of trash TMDL efforts in upper river
- Evaluation of impacts from industrial stormwater in the watershed
- Consideration of TMDL-related issues
- Implementation of biological monitoring

2.7 LOS CERRITOS CHANNEL AND ALAMITOS BAY WMA

This watershed will be targeted for permit renewal purposes in FY05/06.

Overview of WMA



Los Cerritos Channel, Tidal Prism, and Wetlands: The Los Cerritos Channel is concrete-lined above the tidal prism and drains a relatively small area of east Long Beach, albeit a densely urbanized one. The channel's tidal prism starts at Anaheim Road and connects with Alamitos Bay through the Marine Stadium; the wetlands connects to the Channel a short distance from the lower end of the Channel. The wetlands, and portion of the channel near the wetlands, is an overwintering site for a great diversity of birds (up to 50 species) despite its small size. An endangered bird species, the Belding's Savannah Sparrow, may nest there and an area adjacent to the wetlands is a historic least tern colony site. One small marina is located in the channel which is also used by rowing teams and is a popular fishing area.

Alamitos Bay: Alamitos Bay is composed of the Marine Stadium, a recreation facility built in 1932 and used for boating, water skiing, and jet skiing; Long Beach Marina, which contains five smaller basins for recreational craft and a boatyard; a variety of public and private berths; and the Bay proper which includes several small canals, a bathing beach, and several popular clamming areas. A small bathing lagoon, Colorado Lagoon in Long Beach, has a tidal connection with the Bay and a small wildlife pond, Sims Pond, also has a tidal connection. The latter is heavily used by overwintering migratory birds.

Beneficial uses designated in the watershed:

Estuary (marina, wetlands, bay)	*Above Estuary*
Contact & noncontact water recreation	Wildlife habitat
Industrial service supply	
Navigation	*Intermittent uses:*
Commercial & sportfishing	Noncontact water recreation
Estuarine habitat	Warmwater habitat
Marine habitat	
Wildlife habitat	
Preservation of rare & endangered species	
Migration of aquatic organisms	
Spawning habitat	
Shellfish harvesting	
Wetlands habitat	

Significant Issues:

- Loss of wetlands habitat in Los Cerritos area
- Impacts from antifouling paint in marinas
- Urban and storm water runoff

R0026645

Water Quality Problems and Issues

A considerable amount of leaching of boat paint likely occurs in the Bay, particularly in the marina. Nonpoint source runoff from storm drains are is also a likely source of problems.

Types of permitted wastes discharged into the Los Cerritos Channel WMA:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) filter backwash brine waters	1	Minor
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	2	General
Nonhazardous (designated) stormwater runoff	2 1	Minor General
Hazardous contaminated groundwater	1 1	Minor General
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	3	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

IMPAIRMENTS: Beneficial uses in the wetlands area are considered fully supported while those in the channel are not. Beneficial uses in the Bay are, for the most part, considered fully supported although Long Beach Marina is considered a site of concern due to elevated sediment concentrations of metals. The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Ammonia	Basin Plan narrative objective Basin Plan numeric objective: varies depending on pH and temperature but the general range is 0.53 - 2.7 mg/l of total ammonia (at average pH and temp.) in waters designated as WARM to protect against chronic toxicity and 2.3-28.0 mg/l to protect against acute toxicity	ND - 2.19 mg/l (mean of 0.34 ± 0.41)	Los Cerritos Channel
Copper (in tissue)	Basin Plan narrative objective		Los Cerritos Channel
Lead (in sediment)	Basin Plan narrative objective	510 ug/g (sediment)	Colorado Lagoon Los Cerritos Channel

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Zinc (in sediment)	Basin Plan narrative objective	690 ug/g (sediment)	Colorado Lagoon Los Cerritos Channel
chlordane (in tissue)	State Board numeric objective (tissue): Max. Tissue Residue Level 1.1 ng/g	64.9 ng/g (tissue)	Colorado Lagoon
DDT	State Board numeric objective (tissue): Max. Tissue Residue Level 32.0 ng/g	59.9 ng/g (tissue)	Colorado Lagoon
PCBs	State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g	42.0 ng/g (tissue)	Colorado Lagoon
dieldrin	State Board numeric objective (tissue): Max. Tissue Residue Level 0.65 ng/g	18.2 ng/g (tissue)	Colorado Lagoon
sediment toxicity	Basin Plan narrative objective		Colorado Lagoon
coliform	Basin Plan numeric objective Inland: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml Beaches: total coliform not to exceed 1,000 MPN/100ml in more than 20% of samples in 30 days and not more than 10,000 MPN/100ml at any time	2 - 170000 MPN/100ml	Los Cerritos Channel
PAHs	Basin Plan narrative objective	10,000 ng/g (sediment)	Colorado Lagoon

CURRENTLY SCHEDULED TMDLS:

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled For Completion (FY)
coliform	Los Cerritos Channel	04/05
ammonia	Los Cerritos Channel	04/05
metals	Los Cerritos Channel Colorado Lagoon	04/05
PAHs	Colorado Lagoon	04/05
Historic pesticides	Colorado Lagoon	04/05

Stakeholder Group

It is anticipated the Los Angeles/San Gabriel Watershed Council and the Friends of the San Gabriel River will function, at least initially, as this WMA's stakeholder groups. The Los Cerritos WMA is located between the Los Angeles and San Gabriel Rivers and drains to the same general area as the San Gabriel River. There is also a minor hydraulic connection between the lower San Gabriel River and Los Cerritos Channel due to the location of a power plant intake with the Long Beach Marina; the discharge from this facility is into the San Gabriel River estuary. Another potential stakeholder group is the Los Cerritos Wetlands Task Force http://www.loscerritos.org/.

Current Activities

The following is a summary of current regional board activities in the Los Cerritos Channel and Alamitos Bay Watershed which are expected to continue as part of the Watershed Management Initiative on a watershed basis. Please see the San Gabriel River Watershed Section for combined information on existing and needed resources for these two watersheds.

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits. There eight significant or minor dischargers under individual permits as well as seven dischargers currently covered under general permits. Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue.

The Los Cerritos Channel and Alamitos Bay WMA falls partly within Los Angeles County which was issued a renewed municipal storm water permit in 1996. There are 87 co-permittees covered under this permit including 85 cities, the County of Los Angeles, and the California Department of Transportation (Caltrans). Work on the permit will involve review of monitoring reports, evaluation of the storm water program's effectiveness, coordination with other watershed efforts, and modification of the permit as necessary. During 1997/98, discharger responsibilities under the permit concentrated on the evaluation of the five BMP model programs required in the 1996 permit: Illicit Connection/Illicit Discharges, Development Construction, Development Planning, Public Agency Activities, and Five-Year Public Education Strategy (including industrial/commercial site visits). The watershed falls mostly within the City of Long Beach which was issued a municipal storm water permit in 1999.

An important requirement of both storm water municipal permits is implementation of the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Numerical Design Standards for Best Management Practices (BMPs) which were adopted in 2000. The SUSMP is designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating BMPs in the design phase of new development and redevelopment. It provides for numerical design standards to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways.

The numerical design standard is that post-construction treatment BMPs be designed to mitigate (infiltrates or treat) storm water runoff from the first ¾ inch of rainfall, prior to its discharge to a storm water conveyance system. Other standards also apply; additional information on the SUSMP may be found on the Regional Board website http://www.swrcb.ca.gov/~rwqcb4.

NONPOINT SOURCE PROGRAM

The Regional Board encourages pollution prevention and source control; the 205(j) and 319(h) grants are tools to provide funds for these types of projects. For FY00/01, we have listed as a priority for 319(h) grant funding activities (see Table 3) which restore aquatic and riparian habitats and those that enhance recreational uses.

BASIN PLANNING

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

WETLANDS PROTECTION AND MANAGEMENT

The Southern California Wetlands Recovery Project has identified acquisition of an option on the 185-acre Bixby and100-acre Hellman Ranch parcels (which are in the area of the wetlands) priority projects for FY00/01 or future funding.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities and TMDLs in this area.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

Potential Long-term Activities

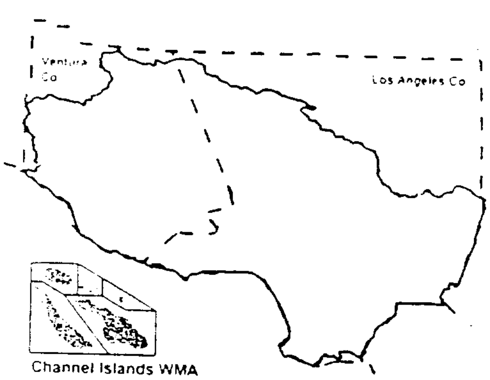
- Evaluation of existing conditions/beneficial uses
- Consideration of TMDL-related issues
- Implementation of biological monitoring

THIS PAGE INTENTIONALLY LEFT BLANK

2.8 *THE CHANNEL ISLANDS WMA*

This watershed will be targeted for permit renewal purposes in FY05/06.

Overview of WMA



Channel Islands WMA

The Channel Islands within the Region's boundaries are: Anacapa, San Nicolas, Santa Barbara, Santa Catalina, and San Clemente Islands. Anacapa and Santa Barbara Islands are part of the Channel Islands National Park. The waters within six nautical miles of Anacapa and Santa Barbara Islands are designated a national marine sanctuary. The ocean waters adjacent to the islands (not the entire circumference of Santa Catalina however) were designated Areas of Special Biological Significance by the state of California. The west side of San Nicolas supports a large gull rookery and elephant seal breeding area. The U.S. Navy has facilities on San Nicolas (and a desalination plant) and San Clemente Islands with a small package treatment plant on the latter. The city of Avalon is located on Santa Catalina Island and also has a small treatment plant.

Beneficial Uses of Island Watercourses

Municipal supply
Groundwater recharge
Contact & noncontact water recreation
Warmwater habitat
Wildlife habitat
Preservation of rare & endangered species

Water Quality Problems and Issues

Water quality in the vicinity of the islands is uniformly good. There are some potential threats from naval facilities and small treatment plants; however, no part of this watershed management area is on the 303(d) list.

Types of permitted wastes discharged into the Channel Islands WMA:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) filter backwash brine waters	2	Minor
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	1	Minor
Nonhazardous (designated) domestic sewage	1 1	Major Minor

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain non**hazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

Stakeholder Group

There is currently no stakeholder group organized for the islands.

Current Activities

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits. There is one major discharger (sewage treatment plant on Santa Catalina Island) and four significant or minor dischargers under individual permits. Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue.

The Channel Islands WMA

- Five islands
- One major discharger, four minor dischargers
- Areas offshore of islands designated as Areas of Special Biological Significance
- High quality marine and rocky intertidal habitat
- Heavy use by marine mammals and endangered species

Due to limited resources, only the basic regulatory activities are performed: review of dischargers' monitoring reports, minimum necessary inspections and sampling, issuance/renewal of permits, levels 1 and 2 enforcement actions (noncompliance and violation notification), case handling, and answering inquiries from the public.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

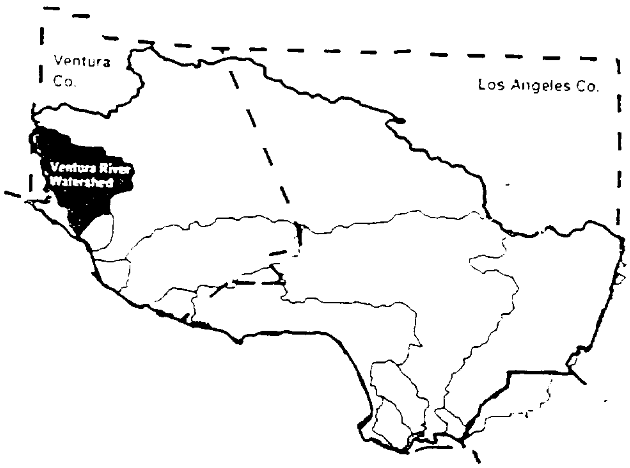
The Channel Islands WMA is being proposed for inclusion in a partial update of the Water Quality Assessment report due in 2002. Some staff resources will be needed in 2001/02 to gather and analyze existing data.

We will maintain involvement with island activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. As resources permit, we will also work with stakeholders to implement provisions of the Coastal Zone Act Reauthorization Amendments.

2.9 *VENTURA RIVER WATERSHED*

This was a targeted watershed for permitting purposes in FY95/96 and FY00/01.

Overview of Watershed



The Ventura River and its tributaries drain a coastal watershed in western Ventura County. The watershed covers a fan-shaped area of 235 square miles, which is situated within the western Transverse Ranges (the only major east-west mountain ranges in the continental U.S.). From the upper slopes of the Transverse Ranges, the surface water system in the Ventura River watershed generally flows in a southerly direction to an estuary, located at the mouth of the Ventura River. Groundwater basins composed of alluvial aquifers deposited along the surface water system, are highly interconnected with the surface water system and are quickly recharged or depleted, according to surface flow conditions. Topography in the watershed is rugged and as a result, the surface waters that drain the watershed have very steep gradients, ranging from 40 feet per mile at the mouth to 150 feet per mile at the headwaters.

Beneficial Uses in Watershed:

Estuary	*Above Estuary*
Navigation	Municipal supply
Commercial & sportfishing	Industrial service supply
Estuarine habitat	Industrial process supply
Marine habitat	Agricultural supply
Contact & noncontact water recreation	Contact & noncontact water recreation
Warmwater habitat	Warmwater habitat
Wildlife habitat	Wildlife habitat
Preservation of rare & endangered species	Preservation of rare & endangered species
Migratory & spawning habitat	Migratory & spawning habitat
Wetlands habitat	Wetlands habitat
Shellfish harvesting	Coldwater habitat
	Groundwater recharge
	Freshwater replenishment

Precipitation varies widely in the watershed. Most occurs as rainfall during just a few storms, between November and March. Summer and fall months are typically dry. Although snow occurs at higher elevations, melting snowpack does not sustain significant runoff in warmer months. The erratic weather pattern, coupled with the steep gradients throughout most of the watershed, result in high flow velocities with most runoff reaching the ocean.

Water Quality Problems and Issues

The majority of water quality problems involve eutrophication (excessive nutrients and effects), especially in the estuary/lagoon although some DDT and metals have been found in mussel and fish tissue (on the 303(d) list for these). A large storm drain enters the river near the estuary and homeless persons live in and frequent the river bed. Sediment in the estuary, however, appears relatively uncontaminated and in laboratory tests conducted through the Bay Protection and Toxic Cleanup Program, little sediment toxicity was found. In some sub- watersheds, high TDS concentrations impair the use of water for agriculture. The watershed's water quality problems are, for the most part, nonpoint source-related. There have also been incidents of releases of toxic materials into storm drains entering the lower river.

The Ventura River Watershed

- One major discharger (POTW)
- 27 dischargers covered under industrial stormwater permit
- Eutrophication concerns, especially in lagoon
- Some bioaccumulation of DDT and metals
- TDS concerns in some subwatersheds
- Impediments to steelhead trout migration (but much high quality habitat)

There is only one major discharger, a small POTW (3.0 MGD) in the middle reach of the Ventura River which has recently upgraded (end of 1997) to tertiary treatment The treatment plant effluent had been implicated in nuisance growth of aquatic plants and low dissolved oxygen found at times downstream of the discharge. For much of the year, the facility's effluent can make up two-thirds of the total river flow. The major concern was the facility's inability to meet the nutrients and suspended solids discharge limitations in its NPDES permit. Additionally, high biochemical oxygen demand (BOD) in the effluent resulted in dissolved oxygen concentrations in the river that could not support cold water aquatic habitat. The facility was required to upgrade under a Regional Board Cease and Desist Order. The most recent monitoring has shown the quality of the effluent has significantly improved including a reduction of nitrate-nitrogen from 20 mg/l to 4 mg/l, a reduction of suspended solids from 12 mg/l to 2 mg/l, and a reduction of BOD from 10 mg/l to 2 mg/l. DO levels in the river have improved dramatically to about 11 mg/l and algal growth is greatly reduced below the plant; however, nonpoint sources (agriculture and horse stables) still appear to be contributing to algal growth above the plant.

Types of permitted wastes discharged into the Ventura River Watershed:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) domestic sewage & industrial waste	1	Major
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	4	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

Of the 27 dischargers enrolled under the general industrial storm water permit in the watershed, the largest numbers fall in the *Motor Freight Transportation and Warehousing*; *Food and Kindred Products*; and *Oil and Gas Extraction* categories.

Water diversions, dams, and groundwater pumping also are thought to limit surface water resources needed to support a high quality fishery. Reduced water supplies affect water quality and thus beneficial uses, particularly with regards to the endangered steelhead trout (steelhead trout are known to utilize the River and some of its tributaries historically supported annual steelhead runs of 5000 – 6000 adults). Removal of the Matilija Dam (upper river) has recently been identified as a high priority.

The table below gives examples of typical data ranges which led to the 1998 303(d) listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

IMPAIRMENTS:

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
DDT	Basin Plan narrative objective	23.0 ng/g (tissue)	Ventura River Estuary
Algae	Basin Plan narrative objective		Ventura River Reach 2 (Main St. to Weldon Canyon) Ventura River Reach 1 (estuary to Main St.) Ventura River Estuary
Pumping, Water diversions	Basin Plan narrative objective		Ventura River Reach 4 (Coyote Creek to Camino Cielo Rd.) Ventura River Reach 3 (Weldon Canyon to confl. w/ Coyote Cr.)
Copper	Basin Plan narrative objective	4.1 ug/g (tissue)	Ventura River Reach 2 (Main St. to Weldon Canyon) Ventura River Reach 1 (estuary to Main St.)
Silver	Basin Plan narrative objective	0.03 ug/g (tissue)	Ventura River Reach 2 (Main St. to Weldon Canyon) Ventura River Reach 1 (estuary to Main St.)
Zinc	Basin Plan narrative objective	40.0 ug/g (tissue)	Ventura River Reach 2 (Main St. to Weldon Canyon) Ventura River Reach 1 (estuary to Main St.)
Trash	Basin Plan narrative objective		Ventura River Estuary
Se	Basin Plan narrative objective	2.2 ug/g (tissue)	Ventura River Reach 2 (Main St. to Weldon Canyon)

CURRENTLY SCHEDULED TMDLS

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
eutrophication	Ventura River Reaches 1 and 2 Ventura River Estuary	04/05

We see a need for an additional 1.3 PYs as well as $50,000 in contract dollars for FY00/01 TMDL work conducted in this watershed.

Stakeholder Group

Ventura River Steelhead Restoration and Recovery Plan Group A Plan was developed in response to the listing of steelhead trout as an endangered species by the National Marine

R0026655

Fisheries Service (NMFS) in August 1997. The plan was developed 1) to identify measures to mitigate impacts of ongoing operations and maintenance activities, 2) to identify future projects and, 3) identify and evaluate opportunities to promote recovery and restoration of the steelhead trout in the watershed. One staff person will continue to remain involved with the group, as needed.

Preliminary State of the Watershed Report Staff completed a Preliminary State of the Watershed Report for the Ventura River in 1995.

Significant Past Activities

In August 1997, the National Marine Fisheries Service (NMFS) listed the steelhead trout in Southern California as endangered under the Federal Endangered Species Act (ESA). The listing means that any project or action that may affect steelhead trout or their habitats will require consultation with NMFS to obtain an incidental take permit. In order to prepare for the listing and deal with possible regulatory requirements as a result of the listing, the Casitas Municipal Water District, City of Ventura, Ventura County Flood Control District, and seven other local public and private agencies collaborated and developed the **Ventura River Steelhead Restoration and Recovery Plan** in December 1997 (see above). The plan also contains large amount of background information on the watershed such as hydrology, biology, steelhead habitat conditions, and the operations and maintenance of water wastewater, solid waste, transportation and flood control facilities of the sponsoring agencies. The regulatory activities by the Regional Water Quality Control Board in the watershed were briefly reviewed in the plan.

Current Activities

The following is a summary of current regional board activities in the Ventura River Watershed which are expected to continue as part of the Watershed Management Initiative on a watershed basis.

CORE REGULATORY

Permits in this watershed were renewed together in June 1996; this watershed will be targeted again in FY2000-01. The Ventura County Municipal Stormwater Permit is scheduled for reissuance in spring 2000. Continuing core regulatory activities include compliance inspections, reviewing of monitoring reports, response to complaints, and enforcement actions as needed. Key regulatory staff will continue to remain involved in the Ventura River Watershed Team for purposes of coordinating watershed activities in-house and working on any needed State of the Watershed Report updates.

Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Municipal Storm Water Permit (adopted in 2000). Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Ventura County Municipal Storm Water Program. The "Discharger" consists of the co-permittees Ventura County Flood Control District, the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks. The Discharger is required to implement the approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) by January 27, 2001. The SQUIMP shall address conditions and requirements for new development and significant redevelopment.

The Ventura River receives municipal storm drain discharges from the City of Ojai, City of San Buenaventura (part), and unincorporated Ventura County (part).

To date, the storm water monitoring program has consisted of land-use based monitoring combined with receiving water monitoring and modeling. The Discharger intends to sign an agreement to participate in the Regional Monitoring Program established for Southern California municipal programs under the guidance of the Southern California Coastal Water Research Project.

Currently under consideration are agreements with sister agencies in regulatory-based encouragement of Best Management Practices. Most notably is the use of a GIS layer for pesticides application available from the Department of Pesticide Regulation (DPR). Reduction of pesticides identified as contaminants of concern for a watershed might be addressed through a Management Agency Agreement (MAA) with the DPR, or through waiving adoption of waste discharge requirements on an individual basis using information gathered in databases provided by the Ventura County Agricultural Commission office.

MONITORING AND ASSESSMENT

A receiving water monitoring program is implemented by the Ojai Valley Sanitary District, supplemented by ambient or special monitoring conducted by Regional Board staff. The monitoring supports compliance evaluation, nonpoint source identification, and potential TMDL development. Ventura River Watershed TMDL-type activities investigated sources of low dissolved oxygen in the river in the area of the treatment plant. In conjunction with the receiving water monitoring, land-use based monitoring is done as part of the Ventura County Municipal Storm Water Program. We would also like to begin early monitoring for 303(d) parameters in 2001, with a potential de-listing of some of the current 303(d) parameters.

WETLANDS PROTECTION AND MANAGEMENT

The Southern California Wetlands Recovery Project considers the removal of Matilija Dam on Matilija Creek, a tributary to the Ventura River northwest of Ojai a strong contender for funding in FY00/01 and future years. According to the US Fish & Wildlife Service, the removal would accomplish 1) restoration of the Ventura River ecosystem and contribute to recovery of endangered steelhead trout, 2) provide needed sediment for beach nourishment and coastal erosion control, and 3) facilitate recreational access to Matilija Wilderness Area in the Los Padres National Forest. Other projects under discussion involve land acquisitions at the mouth of the river. This habitat is primarily riparian.

NONPOINT SOURCE PROGRAM

A priority issue is continued work to determine the scope of water quality impacts from agricultural runoff in the Region. Some agricultural activities occur in the Ventura River Watershed. Development of solutions to any impacts is also a high priority and will be a major concern of the nonpoint source program and, by extension, watershed groups which will be addressing this as well as other problems.

Staff will pursue re-initiating stakeholder meetings in the watershed and assist in development of a watershed management plan which will be expected to address strategies to reduce point and nonpoint source pollutants as well as issues other than strictly water quality concerns. In the meantime, staff will remain involved with the agencies that collaborated to develop a plan for restoration and recovery of anadramous steelhead trout in the watershed. An example of regulatory-based encouragement can be found in this plan development. Equestrian stables in the San Antonio Creek tributary of the river were identified by Regional Board and U.S. Army Corps of Engineers staff as existing and potential sources of problems in the watershed. Facility owners are working to improve their operations from a water quality standpoint in an effort to avoid implementation of management practices under Waste Discharge Requirements.

BASIN PLANNING

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

Review of and comment for the highest priority EIRs in the watershed will continue although this is currently an unfunded program.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

Near-term **Basin Planning** issues include addressing impacts from hydromodification and pumping, particularly in steelhead trout restoration and dam removal efforts, and developing nutrient standards for the lagoon.

Potential Long-term Activities

Baseline watershed-wide bioassessment monitoring in this largely natural watershed will be an important component of any long-term planning and assessment. There are currently no funds for this type of activity.

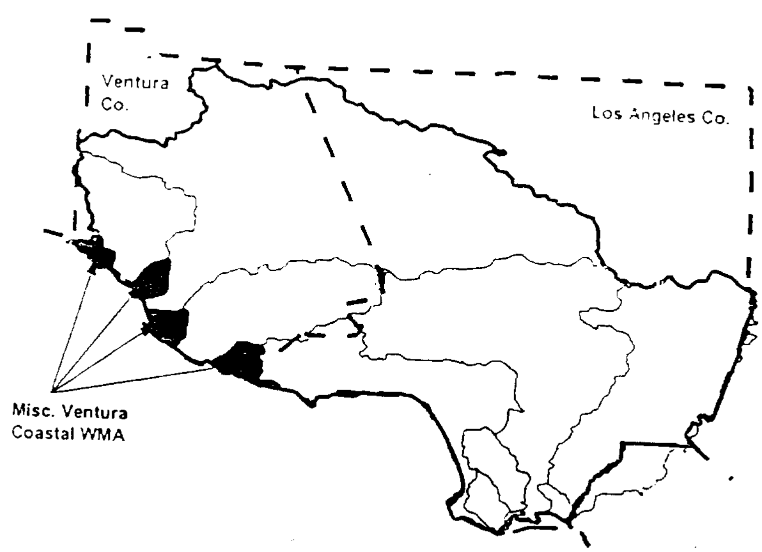
We will be involved to some extent with discussions concerning the proposal to decommission and remove the Matilija Dam. The Ventura County Board of Supervisors voted to request legislation be introduced to fund a Reconnaissance Study by the U.S. Army Corps of Engineers on that matter.

2.10 *MISCELLANEOUS VENTURA COASTAL WMA*

This Watershed Management Area was targeted for permitting purposes in FY00/01.

Overview of WMA

Channel Islands Harbor: Channels Islands Harbor is located south of the Santa Clara River and is in the immediate vicinity of considerable residential development and some agricultural land. The Southern California Edison inlet canal to the Ormond Beach Generating Station is located at the north end of the harbor. The harbor is home to many recreational boats and two boatyards.



Port Hueneme Harbor: Port Hueneme is a medium-sized deepwater harbor located in Ventura County, north of Mugu Lagoon. Part of it was operated by a U.S. Navy Construction Battalion until very recently while the rest of the harbor serves as a commercial port operated by the Oxnard Harbor District. The construction of a majority of the harbor was completed in 1975. The commercial side generally serves ocean-going cargo vessels and oil supply boats; the latter serve the oil platforms in the Santa Barbara Channel. Two endangered bird species may use the harbor, the California Brown Pelican and the California Least Tern.

Ventura Marina: Ventura Marina is a small craft harbor located between the mouths of the Ventura and Santa Clara Rivers. It is home to numerous small boats and two boatyards. The "Ventura Keys" area of the marina is a residential area situated along three canals. The marina is surrounded by agricultural land and a large unlined ditch drains into the Keys area. Since the marina is between the mouths of two rivers which discharge large sediment loads from their relatively undeveloped watersheds, the marina has a constant problem with keeping the entrance channel open.

McGrath Lake: McGrath Lake is a small brackish waterbody located just south of the Santa Clara River. The lake is located partially on State Parks land and partially on privately-owned oilfields in current production. A number of agricultural ditches drain into the lake. A state beach is located off the coastal side of the lake. The habitat around the lake is considered to be quite unique and it is utilized by a large number of overwintering migratory birds.

Beneficial Uses in WMA

Channel Islands Harbor
Industrial service supply
Contact & noncontact water recreation
Navigation
Commercial & sportfishing
Marine habitat
Wildlife habitat

Port Hueneme Harbor
Process water supply
Contact & noncontact water recreation
Navigation
Commercial & sportfishing
Marine Habitat
Wildlife habitat

Ventura Marina
Industrial service supply
Contact & noncontact water recreation
Navigation
Commercial & sportfishing
Marine habitat
Wildlife habitat
Shellfish harvesting

Ormond Beach
Industrial water supply
Contact & noncontact water recreation
Wildlife habitat
Wetlands habitat
Protection of rare & endangered species
Navigation
Power generation
Commercial & sportfishing
Marine habitat
Shellfish harvesting

Ormond Beach Wetlands and McGrath Lake
Estuarine habitat
Contact & noncontact water recreation
Wildlife habitat
Wetlands habitat
Protection of rare & endangered species

Open Coastline: A major feature of the coastline north of Mugu Lagoon is Ormond Beach and Ormond Beach Wetlands. There are a number of scenarios under consideration for restoration of this degraded yet valuable wetlands.

Water Quality Problems and Issues

Channel Islands Harbor: The harbor is on the 1998 303(d) list for lead and zinc. During the early to mid-1980s, the SMWP found low to intermediate levels of metals and organics except for one especially high accumulation of DDT. Sediment sampling for metals conducted by Regional Board staff in 1988 revealed slightly to moderately elevated levels. Copper at one site was nearly 50 ppm and zinc was as high as 76 ppm. Arsenic was slightly elevated (4 ppm) at a sampling site located next to a drain possibly connected to a nearby agricultural field. Under the BPTCP, the harbor is listed as site of concern due to DDT and silver sediment concentrations and sediment toxicity (but not recurrent toxicity); further monitoring is needed here.

The harbors
- One deepwater harbor and two small-craft marinas
- Accumulation of metals, PCBs, and historic pesticides in sediment and tissue
- Support considerable marine life

The wetlands and coast
- Historic pesticide contamination
- Loss of quality habitat
- Impacts from oil spills
- Use by endangered species

Port Hueneme Harbor: The harbor is on the 1998 303(d) list for PAHs, DDT, PCBs, TBT, and zinc. The SMWP has found elevated levels of Cu, Zn, PAHs, and PCBs. Zinc was at elevated levels on the commercial side while PCBs were very high on the Navy side. The Navy side is suspected of using large amounts of pentachlorophenol (PCP) for treatment of wood pilings. An Army Corps DEIR released in 1985 covering extension of one channel stated that water quality was good. The document also briefly discussed the port's biota which CDFG found to be "fairly healthy" and typical of southern California harbors. Sediment core samples were collected in 1985 as part of a proposed dredge project. Relatively low levels of metals were found and no pesticides were detected. It may well be that flushing is good in the harbor and only locating a station directly next to a source will result in bioaccumulation. The BPTCP found fairly minimal levels of sediment toxicity in recent testing but the harbor is considered a site of concern under the program due to accumulation of DDT, PCBs, TBT, PAHs, and zinc in mussel tissue. Further monitoring is needed here.

Ventura Marina: The marina (the Keys area) is on the 1998 303(d) list for coliform problems. The City of Ventura monitors six stations within the Keys and the nearby Arundell Barranca (open drain carrying mostly agricultural runoff) for coliform on a regular basis. There are currently ongoing discussions concerning the possibility of re-rerouting the barranca away from the marina. The SMWP has found moderately elevated levels of metals, DDT, and chlordane in the marina from sampling conducted in the late 1980s; however, it is not listed as a site of concern under the BPTCP.

McGrath Lake: The lake is on the 1998 303(d) list for pesticides. The BPTCP found varying amounts of sediment toxicity and sediment levels of many pesticides were very high; the lake is listed as a toxic hot spot due to sediment concentrations of DDT, chlordane, dieldrin, toxaphene and endosulfan above sediment quality guidelines. A characterization study is ongoing and restoration work is being planned. A major crude oil spill into the lake occurred in late 1993 and runoff from nearby agricultural fields is ongoing.

Open Coastline: Little is known of water quality in the Ormond Beach area. The Oxnard Treatment Plant discharges secondary effluent to the ocean off of Oxnard. The facility is currently investigating approaches to remove upstream brine dischargers in order to move toward water reclamation. Part of the reclaimed water is proposed for use in a seawater intrusion barrier project to protect the Oxnard Plain ground water basin. The ocean immediately off of the coast was part of Bight'98 and the 1994 Southern California Bight Pilot Project.

Types of permitted wastes discharged into the Misc. Ventura Coastal WMA:

Nature of Waste *Prior* to Treatment or Disposal	# of Permits	Types of Permits
Nonhazardous (designated) contaminated groundwater	1	Minor
Nonhazardous (designated) domestic sewage & industrial waste	1	Major
Nonhazardous (designated) wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage	5 4	Minor General
Nonhazardous (designated) noncontact cooling water	1	Major
Nonhazardous (designated) process waste (produced as part of industrial/manufacturing process)	1 1	Major Minor
Nonhazardous (designated) stormwater runoff	1	Minor
Nonhazardous (designated) filter backwash brine waters	1	Minor
Nonhazardous (designated) washwater waste (photo reuse washwater, vegetable washwater)	1	Minor
Inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage)	2	General

Hazardous wastes are those influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated wastes are those influent or solid wastes that contain **nonhazardous** wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Nonhazardous wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Inert wastes are those influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

Major discharges are POTWs with a yearly average flow of over 0.5 MGD or an industrial source with a yearly average flow of over 0.1 MGD and those with lesser flows but with acute or potential adverse environmental impacts.

Minor discharges are all other discharges that are not categorized as a Major. Minor discharges may be covered by a general permit, which are issued administratively, for those that meet the conditions specified by the particular general permit.

The table below gives examples of typical data ranges which led to the listings. See Table 7 in the Appendix for additional details on currently scheduled TMDLs as well as specific pollutants included in the TMDLs.

IMPAIRMENTS:

Impairments	Applicable Objective/Criteria	Typical Data Ranges Resulting in Impairment	303(d) Listed Waters/Reaches
Beach closures	Basin Plan narrative objective	10 - 37 days/year closed	McGrath Beach Mandalay Beach
Coliform	Basin Plan numeric objective. Inland: fecal coliform not to exceed log mean of 200 mpn/100ml in 30-day period and not more than 10% of samples exceed 400 MPN/100ml Beaches: total coliform not to exceed 1,000 MPN/100ml in more than 20% of samples in 30 days and not more than 10,000 MPN/100ml at any time	Objective was exceeded from 32 - 75% of time	Santa Clara River Estuary Beach/Surfers Knoll McGrath Beach Ventura Harbor: Ventura Keys
Sediment toxicity	Basin Plan narrative objective		
Chlordane (sediment)	Basin Plan narrative objective		McGrath Lake
DDT (sediment & Tissue)	Basin Plan narrative objective	160 ng/g	McGrath Lake
	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 32.0 ng/g	3,000 ng/g (sediment) 700 ng/g (tissue)	McGrath Lake Port Hueneme Harbor
PCBs (tissue)	Basin Plan narrative objective State Board numeric objective (tissue): Max. Tissue Residue Level 2.2 ng/g	2,000 ng/g	Port Hueneme Harbor
PAHs (sediment)	Basin Plan narrative objective	10,000 ng/g	Port Hueneme Harbor
Zinc (sediment & tissue)	Basin Plan narrative objective	320 - 400 ng/g (tissue) 380 ng/g (sediment)	Port Hueneme Harbor
Lead (sediment)	Basin Plan narrative objective	180 ng/g	Channel Islands Harbor
Tributyl tin (tissue)	Basin Plan narrative objective	7,000 ng/g	Channel Islands Harbor Port Hueneme Harbor

CURRENTLY SCHEDULED TMDLS

Type of TMDL	Listed Waters/Reaches in TMDL	Year Scheduled for Completion (FY)
coliform	McGrath Beach Mandalay Beach	01/02
zinc	Port Hueneme Harbor	04/05

We see a need for an additional 0.7 PY for FY00/01 TMDL work conducted in this watershed.

Stakeholder Group

Ormond Beach Task Force Ormond Beach is part of the Miscellaneous Ventura Coastal WMA; the area includes a somewhat degraded wetlands which has considerable restoration potential. The Task Force was formed in 1993 and meets on an infrequent basis to address issues and projects which may affect the beach and wetlands.

Current Activities

Both existing and needed resources are presented in a table in the "Near-term Activities" subsection.

CORE REGULATORY

Continuing core regulatory activities that will be integrated into the watershed management approach include (but are not limited to) necessary renewal/revision of NPDES permits. This will be a targeted watershed for the bulk of permit renewal purposes in FY 2000-01. There are three major dischargers, 13 significant or minor dischargers under individual permits, as well as one discharger currently covered under a general permit (additional information on permits may be found in the Appendix). Compliance inspections, review of monitoring reports, response to complaints, and enforcement actions relative to the watershed's NPDES permits will continue.

Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Municipal Storm Water Permit (adopted in 2000). Additionally, most urban areas in Ventura County, including this watershed, are implementing Best Management Practices under the Ventura County Municipal Storm Water Program. The "Discharger" consists of the co-permittees Ventura County Flood Control District, the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks. The Discharger is required to implement the approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) by January 27, 2001. The SQUIMP shall address conditions and requirements for new development and significant redevelopment.

The Miscellaneous Ventura Coastal WMA receives municipal storm drain discharges from the City of Oxnard (part), City of Port Hueneme, and City of San Buenaventura (part).

To date, the storm water monitoring program has consisted of land-use based monitoring combined with receiving water monitoring and modeling. The Discharger intends to sign an agreement to participate in the Regional Monitoring Program established for Southern California municipal programs under the guidance of the Southern California Coastal Water Research Project.

MONITORING AND ASSESSMENT

The Ventura Coastal drainages are being proposed for inclusion in a partial update of the Water Quality Assessment report due in 2002. Staff resources will be needed in 2000/01 to prepare the update. The monitoring needs in this WMA include staff to evaluate coastal receiving water data, sediment data analysis and interpretation, resources to integrate surface and ground water data, and resources to evaluate other information (e.g., pesticide and fertilizer use databases as well as those for grower/crop and crop timing).

McGrath Lake: A Consent Decree established a settlement with the responsible party in a 1993 crude oil spill. The settlement created a Trustee Council (California Department of Fish and Game, U.S. Fish and Wildlife Service, and California Department of Parks and Recreation) to determine how to spend $1.315 million targeted for natural resource restoration.

The Trustee Council formally requested assistance from the Regional Board to perform a study to characterize the water quality and sediments within the lake, as well as sources of contaminant inputs to the lake. The main objectives of the study were to determine whether it would be necessary or beneficial to dredge the lake to remove contaminated sediments, and whether it would be beneficial to spend funds on habitat improvement projects in and around the lake, given the ongoing potential contaminant inputs and uncontrolled water management activities. The Regional Board funded the characterization study (contributing $100,000) using some of the money the Board received from the oil spill settlement.

A preliminary study was conducted in August 1998 to aid in selection of sampling sites for the characterization study. The characterization study was conducted in October 1998 and included:

1) water quality measurements at several locations in the lake (temperature, dissolved oxygen, pH, and nutrient data)

2) surficial sediment samples at 10 stations in the lake will be analyzed for grain size, sediment chemistry (pesticides, petroleum hydrocarbons, metals) and sediment toxicity

3) deep sediment cores at 7 stations in the lake will be subsampled for sediment chemistry analyses

4) water column measurements at one station in an agricultural drain entering the lake (pesticides, metals, and nutrients)

5) sediment chemistry (pesticides and metals) at 2 stations in agricultural drains

The characterization study demonstrated widespread sediment contamination throughout most of the lake, including high concentrations of several trace metals and pesticides. Prior to undertaking a sediment cleanup and habitat restoration program, it would be useful to eliminate or reduce on-going sources of contamination, e.g., agricultural runoff. The Trustee Council plans to release a restoration plan in 2001 and work with local stakeholders to develop solutions to these problems.

Shoreline: Beginning in 1999, a new law requires public health officials in coastal counties to conduct weekly testing, between April 1 and October 31, at beaches visited annually by more than 50,000 people and at adjacent storm drains (including natural creeks, streams, and rivers, that flow during the summer. Due to the popularity of Ventura County beaches for year-round activities, the Ventura County Board of Supervisors authorized the implementation of a program that expanded the monitoring program to all 12 months of the year. Ventura County Environmental Health Department will conduct routine surf zone sampling at 52 beach locations. Data will be reviewed by the Regional Board and used to assess current conditions of Ventura County beaches for future 305(b) reports.

Open Coastline: Our source of data for the coastal areas comes chiefly from the one POTW and two generating stations which discharge offshore as well as regional data from Bight'98 and the 1994 SCBPP. These data support compliance evaluation.

WETLANDS PROTECTION AND MANAGEMENT

The Southern California Wetlands Recovery Project has listed Ormond Beach Wetlands acquisition and preparation of a restoration plan as a priority project for FY00/01 or future funding. The project involves acquisition of 600 acres of wetlands and dunes parcels privately-owned and implementation of an existing restoration plan for these parcels. Acquisition of land in the McGrath Lake area is also a high priority.

BASIN PLANNING

Basin Planning activities will include continued participation in both internal and external watershed planning efforts and further incorporation of watershed management and principles and watershed-specific priorities into future updates of the Basin Plan, where appropriate.

NONPOINT SOURCE PROGRAM

We are encouraging application for Proposition 13 funding for use in preparation of a watershed management plan for this watershed management area.

Groundwater

The Oxnard Forebay is a prime groundwater recharge area that is impacted by nitrogen discharges, mainly from densely populated communities using septic systems, and agricultural areas. The Regional Board undertook a study of septic systems in the area during FY98/99; in August 1999 the Board adopted a Basin Plan amendment to prohibit septic systems in the Oxnard Forebay. The amendment immediately prohibits the installation of new septic systems or the expansion of existing septic systems on lot sizes of less than five acres. Discharges from septic systems on lot sizes of less than five acres must cease by January 1, 2008. This prohibition will affect up to 3,000 septic systems and ten to fifteen thousand people. The County of Ventura has applied for Small Community Grant funding to provide adequate sewage treatment on behalf of the Saticoy and El Rio communities.

Another **319(h)** project is underway which also involves septic tanks. The Scope of Work for this project is still being developed but will involve the evaluation of several systems for nutrient removal.

A well head protection and demonstration project in the Fox Canyon Groundwater Management Area is being funded with **319(h)** monies. This project is destroying disused drinking water wells which may serve as a conduit for contamination to reach the deep water aquifer.

Currently under consideration are agreements with sister agencies in regulatory-based encouragement of Best Management Practices. Most notably is the use of a GIS layer for pesticides application available from the Department of Pesticide Regulation (DPR). Reduction of pesticides identified as contaminants of concern for a watershed might be addressed through a Management Agency Agreement (MAA) with the DPR, or through waiving adoption of waste discharge requirements on an individual basis using information gathered in databases provided by the Ventura County Agricultural Commission office.

Marinas

There are a number of marinas in this WMA, all with well-documented levels and types of pollution consistent with nonpoint sources. We have initiated enforcement actions on several commercial fishing operations to ensure compliance with state discharge requirements. We will be focusing our 319(h) priorities for the upcoming application period on a number of areas of concern in the Region including development of education and outreach programs and implementation of management measures which are intended to reduce pollution from these nonpoint sources in marinas. A particular area of concern in Port Hueneme has been management of squid wastes from fishing vessels.

Near-term Activities

Specific resource needs are described in the Region-wide Section of this document.

A preliminary review of resources for core regulatory activities against cost factors has determined that our region is seriously underfunded for our baseline program. We will be seeking more funding for our core program activities.

The Ventura Coastal drainages are being proposed for inclusion in a partial update of the Water Quality Assessment report due in 2002. Staff resources will be needed in 2000/01 to prepare the update. The monitoring needs in this WMA include staff to evaluate coastal receiving water data, sediment data analysis and interpretation, resources to integrate surface and ground water data, and resources to evaluate other information (e.g., pesticide and fertilizer use databases as well as those for grower/crop and crop timing).

Most watershed programs look to the Regional Board as the information management agency for the collected data. To meet that need, we require additional resources related to data management and interpretation. Some of the expenditures under NPDES support the monitoring that will ultimately be used to identify and quantify nonpoint source inputs.

We will maintain involvement with stakeholder activities and pursue funding options, especially those involving implementation of nonpoint source measures (coordinate 205(j) and 319(h) activities) as well as other outreach activities such as speeches, meetings, and participation in environmental events. With additional resources we propose conducting a number of education and outreach activities including holding regional workshops and conferences with other Regional Boards as well as experts in the field, contacting marina operators individually, and offering an incentives program.

Potential Long-term Activities

Arrundell Barranca: The Regional Board staff have been approached by the City of San Buenaventura for input on a potential project to re-route the Arrundell Barranca from Ventura Harbor to the Santa Clara River estuary. The proposal calls for a constructed wetlands near the estuary to treat the Barranca's water before entering the Santa Clara River. The project is proposed as a method of dealing with periodic coliform exceedances in areas of the Ventura Harbor/Ventura Keys.

Seawater Intrusion into the Oxnard Plain: The City of Oxnard is attempting to remove high TDS inputs to their treatment plant with the ultimate goal of reuse of the wastewater for a seawater intrusion barrier project in the Oxnard Plain.

Implementation of watershed-wide biological monitoring: This is a long-term goal for all of our watersheds.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 3. Regionwide Activities

There are many activities conducted at the Region which do not apply to a specific watershed; instead they represent ongoing regionwide strategies and policies, or programs which are not directly linked to the rotating watershed cycle. Also, statutory, regulatory, or funding requirements may dictate completion of some activities at odd intervals throughout the five-year watershed cycle (such as increased emphasis on pretreatment inspections). We expect that some of these activities, which include triennial reviews, water quality assessment (305(b)) reports, updating lists of impaired waterbodies (e.g. the federal 303(d) list), can be negotiated into a watershed schedule (see Monitoring and Assessment discussion under each Watershed section for proposed water quality assessment scheduling). See Table 2 below for more examples of watershed versus non-watershed related activities.

Table 2. Example Work Activities and Their Fit (or not) Into Watershed

Watershed Tasks	*Non-Watershed Tasks*
Renew permits	Issue new permits
	Develop new general permits
Integrate municipal storm water program	Issue individual industrial and storm water permits
Conduct inspections for watershed permits	Conduct inspections on new permits
Enforcement (in-cycle compliance)	Enforcement (spills, out of cycle compliance)
Implement NPS controls	Develop regional strategies to address NPS problems
TMDL/WLAs	
Develop, coordinate and implement watershed monitoring	Coordinate monitoring on a regional scale
Water Quality Assessments (State of the Watershed Reports, partial updates to 305(b) by watershed)	Biennial 305(b) Reports to USEPA
Develop watershed policies	Develop regional policies
Watershed-specific Basin Plan Updates	Regional Basin Plan Updates, Triennial Reviews (as Currently required)
Data management (input and use by watershed)	Regional Database management (development and
GIS (input of watershed-specific layers and information)	GIS (development and input of regional layers and Maintenance of system)
Watershed-specific outreach/education	General outreach education
Incorporation of CEQA and 401 Decisions into watershed planning (as groups are formed, and as timing permits)	Timely review of CEQA documents, 401 certifications per statutory deadlines

And, while the Watershed Management Initiative strives to integrate and coordinate the various Regional and State Board programs and address the highest priority funding needs for those programs, there is also need to respond to and accommodate priorities established by the individual Regional and State Boards' members, priorities established prior to the WMI which run on their own timelines, or other new mandates which may affect the way the WMI is implemented in a Region. It is important to re-state here that the WMI is not a new program but rather a way to describe our approach to integrating existing and newly evolving programs and mandates. The following describes our overall approach to implementing a number of programs (some statewide mandates) and other Board priorities.

Core Regulatory

During FY01/02, we shall be carrying out regularly scheduled permit renewals in the Santa Clara River and Calleguas Creek Watersheds. The other activities we will be conducting for this one year are on a regionwide rather than watershed scale due to a number of factors.

One activity involves renewing both officially and unofficially backlogged permits. Many backlogs were created unofficially through utilizing our original seven- rather than five-year cycle for permit renewals. These should decrease greatly as we phase into a five-year cycle but, in the meantime, there will likely continue to be some backlog for FY01/02. We also plan to renew our general permits (see below) to incorporate Basin Plan amendments and fine-tune other requirements.

Another activity which has taken up considerable time, and contributed to backlogged permits, is responding to appeals and lawsuits. At issue for a number of permits is a lack of regional nutrient objectives which has translated into a lack of permit limitations and subsequent petitions and/or lawsuits. Ideally, TMDLs would be adopted in the year proceeding permit renewals for a particular watershed . Permit limitations could then be based on allocations from the TMDLs. Also ideally, we would have state-adopted water quality objectives (or an implementation plan for federal numbers) or ecologically-relevant regional objectives for parameters such as nitrogen and phosphorus to use for development of permit limitations. These "official" numbers will likely be available in the near future but, in the meantime, we continue to experience challenges to our permit limitations (or lack thereof).

Recently enacted legislation which does not allow Board discretion to issue Time Schedule Orders without penalties has added to the difficulty of adopting permits per original schedules.

One of the final tasks of the Bay Protection and Toxic Cleanup Program was adoption of a statewide Consolidated Plan for cleanup of toxic hot spots. Water Code Section 13395 states that the Regional Board is required to reevaluate WDRs including (1) an assessment of the WDRs that may influence the creation or further pollution of the known toxic hot spot; (2) an assessment of which WDRs need to be modified to improve environmental conditions at the known toxic hot spot; and (3) a schedule for completion of any WDR modifications deemed appropriate. We were required to begin the reevaluation of WDRs associated with high priority known toxic hot spots within 120 days after final approval of the Consolidated Plan (by March 15, 2000). As part of our reevaluation, we were required to submit a list of WDRs associated with each high priority toxic hot spot within six months after final approval of the Consolidated Plan (by May 15, 2000). The priority list for moderate and low priority known toxic hot spots must be submitted within one year of final approval of the Consolidated Plan (by November 15, 2000). While we do not have to actually revise any WDRs within these timeframes, if we find that we will need to make revisions, we will need to supply a schedule. And as we renew or modify WDRs, we need to include a finding that the discharge may contribute to the pollution present at the toxic hot spot.

Core Regulatory – General Permits

There are many dischargers in this Region covered by general permits for discharges to surface water through a letter issued by the Executive Officer. This activity occurs as often

R0026670

outside as within the watershed cycle. 40 CFR §122.28 provides for issuance of general permits to regulate a category of point sources if the sources:

a) Involve the same or substantially similar types of operations;

b) Discharge the same type of waste;

c) Require the same type of effluent limitations or operating conditions;

d) Require similar monitoring; and

e) Are more appropriately regulated under a general permit rather than individual permits.

General permits currently in effect include:

- NPDES Permit No. CAG914001 – for discharges of volatile organic compound contaminated groundwater to surface waters (threat/complexity rating 2B)
- NPDES Permit No. CAG994002 – for discharges of treated groundwater from construction and project dewatering to surface waters (threat/complexity rating 3B)
- NPDES Permit No. CAG994001 – for groundwater discharges from construction and project dewatering to surface waters (threat/complexity rating 3C)
- NPDES Permit No. CAG674001 – for discharges of hydrostatic test water to surface waters (threat/complexity rating 3C)
- NPDES Permit No. CAG834001 – for treated groundwater and other wastewaters from investigation and/or cleanup of petroleum fuel pollution to surface waters (threat/complexity rating 2B)
- NPDES Permit No. CAG994003 – for discharges of nonprocess wastewaters not requiring treatment systems to surface waters (threat/complexity rating 3C)

As a point of comparison, the highest threat/complexity rating is 1A and the lowest 3C.

Core Regulatory – Storm Water

Storm water activities include those involving the three municipal permits in the Region, facilities regulated under the State's general industrial permit, and construction sites regulated under the State's general construction permit.

Municipal permits

Municipal permits currently in effect include:

NPDES Permit No. CAS004003 – adopted in 1999 this is the permit for municipal storm water and urban runoff discharges within the city of Long Beach

NPDES Permit No. CAS004002 – adopted in 2000 this is the permit for municipal storm water and urban runoff discharges within the Ventura County Flood Control District, County of Ventura, and cities of Ventura County

NPDES Permit No. CAS614001 – adopted in 1996 this is the permit for municipal storm water and urban runoff discharges with the county of Los Angeles

An important part of the urban municipal permits (Los Angeles County and City of Long Beach) are the Standard Urban Storm Water Mitigation Plans (SUSMPs) and Numerical Design Standards for Best Management Practices (BMPs) which were adopted in 2000. The SUSMPs are designed to ensure that storm water pollution is addressed in one of the most effective ways possible, i.e., by incorporating BMPs in the design phase of new development and redevelopment. It provides for numerical design standards to ensure that storm water runoff is managed for water quality concerns in addition to flood protection and that pollutants carried by storm water are retained and not delivered to waterways.

Monitoring has indicated that mass emissions of pollutants to the ocean are significant from the urban watersheds such as the Los Angeles River, Ballona Creek, and Coyote Creek. Studies have found chemical concentrations of pollutants that exceed state and federal water quality criteria in storm drains flowing to the ocean and that there are adverse health impacts from swimming near them.

Municipal storm water regulations at 40CFR 122.26 require that pollutants in storm water be reduced to the maximum extent practicable (MEP). The definition of MEP has generally been applied to mean implementation of economically achievable management practices. Because storm water runoff rates can vary from storm to storm, the statistical probabilities of rainfall or runoff events become economically significant and are central to the control of pollutants through cost-effective BMPs.

The numerical design standard is that post-construction treatment BMPs be designed to mitigate (infiltrate or treat) storm water runoff from the first ¾ inch of rainfall, prior to its discharge to a storm water conveyance system. Other standards also apply; additional information on the SUSMP may be found on the Regional Board website http://www.swrcb.ca.gov/~rwqcb4. **Effective implementation of the SUSMP would be aided by 1 PY for review of city approvals of projects.**

Retail gasoline outlets (RGOs) were given a categorical exemption by State Board to the SUSMP requirements, partly because the threshold to mitigate developed by the Regional Board which was based on size and RGOs were deemed too small. **A needed special project (0.5 PY) is to develop a new threshold to mitigate for RGOs.**

The Ventura County Municipal Storm Water Permit co-permittees must implement an approved Ventura Countywide Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) by 2001. The SQUIMP similarly addresses conditions and requirements for new development and significant redevelopment.

Industrial permit

The 1987 amendments to the Clean Water Act established a framework for regulating municipal and industrial storm water discharges under the NPDES Program. In 1990, the USEPA published final regulations that established application requirements for storm water permits. The regulations require that storm water associated with industrial activity that discharges either directly to surface waters or indirectly through municipal storm drains must be regulated by an NPDES permit.

State Board adopted the Industrial Activities Storm Water General Permit in 1997. The permit requires facility operators to (1) eliminate unauthorized nonstorm water discharges, (2) develop and implement a Storm Water Pollution Prevention Plan (SWPPP), and (3) perform monitoring of storm water discharges and authorized nonstorm water discharges. Facilities that discharge storm water associated with industrial activity requiring a General Permit are listed by category in the Code of Federal Regulations. These categories include manufacturing, mining/oil, recycling, steam electric generating, and light industry, among others. There are approximately 2,600 facilities in this Region covered by the general industrial permit. Most of these sites are in the Los Angeles River Watershed with the San Gabriel River Watershed and the Domiguez Channel and LA/LB Harbor WMA also containing a considerable number. **Five to ten additional PYs would be needed to fully address all aspects of industrial storm water permitting including compliance inspections of all facilities once every five years, review of SWPPPs, and followup work.**

Construction permit

In 1990, USEPA published final regulations that establish storm water permit application requirements for specified categories of industries. The regulations provide that discharges of storm water to waters of the United States from construction projects that encompass five or more acres of soil disturbance are effectively prohibited unless the discharge is in compliance with an NPDES permit.

State Board adopted a general permit for storm water discharges associated with construction activity in 1999. It contains narrative effluent limitations and requirements to implement appropriate Best Management Practices (BMPs) which emphasize source controls.

Elimination or reduction of nonstorm water discharges is a major goal of the general permit. It prohibits the discharge of materials other than storm water and authorized nonstorm water discharges. It also requires development of a Storm Water Pollution Prevention Plan (SWPPP) and monitoring program.

There is a total of 948 sites covered under the construction storm water permit as of November 2000. The majority of sites are in Ventura and western Los Angeles Counties with 310 in the Santa Clara River Watershed and 100 in the Calleguas Creek Watershed. There are a total of 307 residential sites of 10 acres or more in the Region compared to 112 sites of less than 10 acres. There are a total of 142 commercial sites of 10 acres or more while there are 104 sites of less than 10 acres.

Monitoring and Assessment

California Water Code Section 13192 required the SWRCB to assess and report on the State monitoring programs and to prepare a proposal for a comprehensive surface water quality monitoring program. As currently envisioned, the Surface Water Ambient Monitoring Program (SWAMP) will be implemented using a scientifically sound monitoring design with meaningful indicators of the environment and the results will be readily available to the public. Ambient monitoring serves as a measure of the overall quality of water resources and the overall effectiveness of Regional Boards prevention, regulatory, and remedial actions.

The SWAMP is intended to meet four goals:

1) Identify specific problems preventing the SWRCB, RWQCBs, and the public from realizing beneficial uses in targeted watersheds.

2) Create an ambient monitoring program that addresses all hydrologic units of the State using consistent and objective monitoring, sampling and analysis methods; consistent data quality assurance protocols; and centralized data management.

3) Document ambient water quality conditions in potentially clean and polluted areas.

4) Provide the data to evaluate the effectiveness of water quality regulatory programs in protecting beneficial uses of waters of the State.

Eventually, each of the SWRCB and RWQCBs existing monitoring programs (e.g., the State Mussel Watch Program, Toxic Substances Monitoring Program, toxicity studies, and fish/shellfish contamination studies) will be incorporated into SWAMP to ensure a coordinated approach without duplication.

Two general approaches are outlined in the current proposal for implementing SWAMP. One focuses on identifying specific problems in targeted watersheds (directed monitoring) through sampling in areas suspected to be contaminated or sampling to evaluate the status of the most sensitive beneficial use (e.g., sample frequently-consumed fish). The overall goal is to establish site-specific information in sites known or suspected to have water quality problems. Collecting information on locations which may need listing or delisting of waters under CWA Section 303(d) is a focus. The other approach involves documenting ambient water quality conditions in potentially clean and polluted areas (ambient monitoring). The overall goals is to develop a Statewide picture of the status and trends of the quality of California's water resources. It is intended that this portion of SWAMP will be implemented in each hydrologic unit of the State at least one time every five years. This portion of SWAMP is focused on collecting information on waters for which the State presently has little information and to determine the effects of diffuse sources of pollution.

Our general approach to implementing the SWAMP will be to sample in the preceding year those waters targeted under the WMI in the following year. For example, in FY00-01 we would sample in the Calleguas Creek and Santa Clara River Watersheds which are targeted under the WMI the following year. That way, each hydrologic unit in the Region would be sampled every five years. A possible exception to this approach is that we may investigate reference sites in non-targeted as well as targeted watersheds.

In general, we would utilize a stratified random approach to select sample sites (stratified to include areas around major confluences) except for our investigation into eutrophication which would utilize a uniform sampling approach and our followup work at previously identified problem sites. Depending on the number of samples deemed necessary (by the scientific review panel) in each stratum to give reliable results (and the associated costs), a more uniform sampling approach may be utilized instead, such as uniform sampling or sampling at confluences.

There is $360,000 available in FY00/01 for sampling and analysis. The majority (~60%) of those resources are anticipated to be dedicated toward biological monitoring as opposed to chemical analyses. Biological monitoring may include freshwater toxicity tests, habitat assessments, analysis of benthic invertebrates, fish bioassessments, or sediment toxicity tests. Much of this work will be conducted through a master contract with the Department of Fish & Game.

Basin Planning

Water Quality Legislation

The Porter-Cologne Water Quality Control Act (California Water Code) was enacted by the State in 1969 and became effective January 1, 1970. This legislation authorizes the State Board to adopt, review, and revise policies for all waters of the state and directs the Regional Boards to develop regional Basin Plans.

The Clean Water Act (CWA), enacted by the federal government in 1972, was designed to restore and maintain the chemical, physical, and biological integrity of the Nation's waters. One of the national goals states that wherever attainable, water quality should provide for the protection and propagation of fish, shellfish, and wildlife, and provide for recreation in and on the water (i.e., fishable, swimmable). The CWA directs states to establish water quality standards for all "waters of the United States" and review and update such standards on a triennial basis.

The USEPA has delegated responsibility for implementation of portions of the CWA to the State and Regional Boards, including water quality planning and control programs such as the National Pollutant Discharge Elimination System (NPDES).

Besides state and federal laws, several court decisions provide guidance for basin planning. One decision reaffirmed the public trust doctrine, holding that the public trust is "an affirmation of the duty of the state to protect the people's common heritage in streams, lakes, marshlands, and tidelands, surrendering that right of protection only in rare cases when the abandonment of that right is consistent with the purposes of the trust." Public trust encompasses uses of water for commerce, navigation, fisheries, and recreation.

Basin Plans

Regional Board Basin Plans are designed to preserve and enhance water quality and protect the beneficial uses of all regional waters by providing consistent long-term standards and program guidance for the Region. Specifically, Basin Plans (i) designate beneficial uses for surface and ground waters, (ii) set narrative and numerical objectives that must be attained or maintained to protect the designated beneficial uses and conform to the state's antidegradation policy, and (iii) describe implementation programs to protect all waters in the Region. In addition, Basin Plan incorporate (by reference) all applicable State and Regional Board plans and policies and other pertinent water quality policies and regulations.

As part of the State's Continuing Planning Process, components of Basin Plans are reviewed as new data and information become available or as specific needs arise. Comprehensive updates of Basin Plans occur in response to state and federal legislative requirements and as funding becomes available. State Board and other governmental entities' (federal, state and local) plans, that can affect water quality, are incorporated into the planning process. Following adoption by Regional Boards, the Basin Plans and subsequent amendments are subject to approval by the State Board, the State Office of Administrative Law (OAL), and the United States Environmental Protection Agency (USEPA).

Recent Basin Plan Amendments

Basin Plan amendments will be completed periodically as new standards, policies, and other information are developed. TMDLs will also be adopted as Basin Plan amendments. This will generate a significant workload for Standards/TMDL staff over the next 13 years. We also anticipate that watershed efforts utilized, in part, to accomplish TMDLs will identify other possibilities for Basin Plan studies and amendments (e.g., new or revised standards, new policies).

The first TMDL was adopted by the Regional Board in 1999 (amended in 2000) to reduce trash on the East Fork of the San Gabriel River. This Basin Plan amendment has since been approved by the State Board, OAL and USEPA.

A Basin Plan amendment updating municipal and domestic water supply designations was brought to the Board for consideration in late 1998. In November 1998, the Regional Board voted to amend the Water Quality Control Plan for the Los Angeles Region (Basin Plan), by adopting a resolution to "Incorporate Changes in Beneficial Use Designations for Selected Waters." This amendment removed the beneficial use designation for "Municipal and Domestic Supply" (MUN) from eight surface waters and two ground water areas along the coast. The State Board voted to approve this amendment at the February 1999 Board hearing, however, in July 1999, the State Office of Administrative Law (OAL) issued a Notification of Disapproval due to a number of details including our responses to comments. The Regional Board resubmitted groundwater portion of the amendment, which was approved by OAL in 2000.

In 1990, the Regional Board adopted Resolution No. 90-004 (Drought Policy) which had a term of three years and provided interim relief to dischargers who experienced difficulty meeting chloride objectives because of a state-wide drought. The policy adjusted effluent limits to the lesser of 1) 250 mg/l or 2) the chloride concentration in the water supply plus 85 mg/l. In 1995, the Regional Board extended the interim limits for three years and directed staff to develop a long-term solution to deal with the impact of changing water supply, especially during droughts. In 1997, the Regional Board adopted Resolution No. 97-002 (Chloride Policy) which amended the Basin Plan by setting the chloride objective at 190 mg/l except in the Calleguas Creek and Santa Clara River Watersheds where, due to the great concern for protection of agriculture, staff were directed to determine the chloride concentrations sufficient to protect agricultural beneficial uses. The Chloride Policy has since been approved by the State Board and Office of Administrative Law (OAL).

Water Quality Objectives

The CWA (§303) requires states to develop water quality standards for all waters and to submit to the USEPA for approval all new or revised water quality standards are established for inland surface and ocean waters. Water quality standards consist of a combination of beneficial uses and water quality objectives, as well as an antidegradation policy. Water quality objectives may be expressed as either numeric limits or a narrative statement.

In addition to the federal mandate, the California Water Code (§13241) specifies that each Regional Board shall establish water quality objectives. The Water Code defines water quality objectives as "the allowable limits or levels of water quality constituents or characteristics which are established for the reasonable protection of beneficial uses of water or the prevention of nuisance within a specific area." Thus, water quality objectives are intended (i) to protect the public health and welfare and (ii) to maintain or enhance water quality in relation to the designated existing and potential beneficial uses of the water. Water quality objectives are achieved through Waste Discharge Requirements and other programs. These objectives, when compared with future water quality data, also provide the basis for identifying trends toward degradation or enhancement of regional waters.

Triennial Review Process

The California Water Code, (§13240), directs the State and Regional Boards to periodically review and update Basin Plans. Furthermore, the CWA (§303 [c]) directs states to review water quality standards every three years (triennial review) and, as appropriate, modify and adopt new standards.

In the Triennial Review Process, basin planning issues are formally identified and ranked during the public hearing process. These and other modifications to the Basin Plan are implemented through Basin Plan amendments as described below. In addition, the Regional Board can amend the Basin Plan as needed. Such amendments need not coincide with the Triennial Review Process.

The year 2000 triennial review is currently underway with the public hearing process scheduled for January or February 2001. While basin planning priorities have not yet been identified through the process, there are clearly some issues that will need time and resources in the upcoming years. Many of these issues have been raised due to EPA recommendations, new legislation and court orders. For example, in EPA's letter approving the Basin Plan, EPA identified 14 issues that should be included in the triennial review. These include: updating beneficial uses to better identify waterbodies supporting rare, threatened and endangered species, in particular; updating water quality objectives (e.g., ammonia and bacteria); and updating implementation policies and procedures (e.g., for acute and chronic toxicity objectives).

Another issue, driven by recent legislation, involves the Regional Board waiver policy. Regional Boards may issue both categorical and individual waivers. In the case of categorical waivers, the Regional Board must approve and issue categorical waiver criteria either through adopting a specific resolution or Basin Plan amendment. Once a categorical waiver is approved by the Regional Board, Regional Board staff may be delegated the responsibility to review and approve categorical waivers. Four categorical waivers have been approved in the Region, as set forth in Resolution No. 53-5 (adopted in 1953). These are: septic tanks, swimming pool discharges, on-site drilling mud discharges from single oil wells, and discharges from private impoundments or lakes. Individual waivers are typically for construction or development projects that are short-term or one-time events.

Section 13269, Paragraph (a), of the Water Code states that certain Water Code provisions "may be waived" by a Regional Board for a specific discharge or a specific type of discharge "if the waiver is not against the public interest." However, recent legislation (Senate Bill 390, amending Section 13269) requires that all waivers or waiver categories be evaluated and renewed every 5 years. Initially, Regional Boards must evaluate and renew all waivers and waiver categories by January 1, 2003, otherwise they will automatically terminate. After this initial evaluation and renewal, Regional Boards must conduct on-going compliance monitoring and renew, every 5 years, all waivers and waiver categories. The evaluation of waivers requires an initial review of all waivers and waiver categories, as well as validation of the adequacy of waiver conditions through field sampling at a representative number of discharges granted waivers. Depending on the data generated from this exercise, the Regional Board may decide to renew the waiver category (based on the adequacy of waiver conditions and their observance), amend the conditions (based on their inadequacy as documented through field tests), or allow the waiver category to automatically terminate on 1/1/2003 (based on the documented impact on water quality). If the last option is chosen, the Regional Board will then have to determine how those discharges should be regulated—either through general WDRs or individual WDRs.

Another issue of importance is the anticipated workload associated with adopting TMDLs as Basin Plan amendments on a very short time schedule, as required by the Consent Decree.

There are a number of triennial review issues from 1995 that have not been addressed. In addition, future triennial review issues may include:

- Development of biomonitoring/biocriteria efforts
- Further work on ensuring compliance with ammonia objectives by June 2002
- Implementation issues associated with the California Toxics Rule and State Implementation Policy
- Specific refinements to certain beneficial uses; conducting regular beneficial use assessments to provide more detail – particularly for aquatic life
- Development of regional and watershed-specific policies for nonpoint sources

Proposed (Needed) Near-term (FY 2001/02) and Long-term (beyond FY 2002/03) Resource Allocation for Standards and Planning Activities

Task	Product	Near-term (H,M, or L priority)	Long-term (H,M, or L priority)	PYs	Contract ($)
Implement triennial review tasks	various	H	M	3.0	
Amend Basin Plan for adopted TMDLs	Updated Basin Plan	H		2.0

We will remain committed to involvement with the 205(j) grant program for planning and assessment activities. Table 3, which follows lists our priority projects under that grant program.

Table 3. Targeted Watersheds and Projects for 2001/02 Section 205(j) Grants in the Los Angeles Region

Watershed/ Waterbody	Project Description	Outcomes/ Products
Los Angeles River Watershed	Fund one component (bioassessment) of an overall watershed monitoring program; evaluate its usefulness in future watershed assessments and as an element in a watershed-wide monitoring program; establish baseline that can be used for comparison after implementation of control measures at pollutant sources (both point and nonpoint)	Additional assessment information for Year 2002 WQA; baseline beneficial use support information
Los Angeles River Watershed	Fund collection and assembly of <u>all</u> monitoring data for watershed including utilizing sources such as monitoring pledged in CEQA or 401 certification documents	Historic database (mapped sampling sites) as starting point for future work
Santa Monica Bay WMA	Prioritize storm drains needing diversion; focus efforts on major problem drains for coliform TMDL implementation	Ability to focus efforts on the major problem drains
Santa Monica Bay WMA	Fund portion of watershed-wide monitoring program in Malibu, with emphasis on nutrients and coliform or bioassessment concerns in the upper portion of the watershed as part of an integrated monitoring effort jointly undertaken by local stakeholders	Produce data for TMDLs; find sources of impairments; evaluate any BMPs being implemented; assess areas of watershed not previously studied
Calleguas Creek Watershed	Hydrologic model of watershed, including the lagoon	Hydrologic model (including Mugu Lagoon)
San Gabriel River Watershed	Fund collection and assembly of <u>all</u> monitoring data for watershed including utilizing sources such as monitoring pledged in CEQA or 401 certification documents	Historic database (mapped sampling sites) as starting point for future work
San Gabriel River Watershed	Fund collection of bioassessment data for watershed; evaluate its usefulness in future watershed assessments and as an element in a watershed-wide monitoring program; establish baseline that can be used for comparison after implementation of control measures at pollutant sources (both point and nonpoint)	Additional assessment information for Year 2002 WQA; baseline beneficial use support information
San Gabriel River Watershed	Hydrologic model of estuary (emphasis on establishing characteristics of fresh- and saltwater mixing zone)	Hydrologic model of estuary
San Gabriel River Watershed	Develop plan for maintenance of watershed's flood control dams.	Most effective method to clean out reservoirs without beneficial use impairments
Regionwide	Regional planning to remove septic tanks in densely populated areas and hook up to sewers	A plan to remove septics in densely populated areas and reduce inputs (coliforms and nutrients) to ground water and surface water from faulty septics and congested leachfields (a plan to implement coliform and nutrient TMDLs)

R0026680

Wetlands Protection and Management

Wetlands acres in the Region have diminished greatly over the past several decades as coastal development, in particular, has increased. Wetlands provide habitat, serve to slow down water flow, decrease total volume through infiltration, and filter out a number of pollutants through active uptake by plants as well as deposition in sediments. Wetlands such as coastal estuaries are a buffer zone between ocean and inland water resources and are heavily utilized by aquatic organisms. Continuous stretches of riparian habitat function as wildlife corridors to allow animal movement between increasingly isolated populations. They also serve as popular recreational destinations for residents and visitors. Unfortunately, many of our Region's wetlands are impacted by varying kinds and amounts of pollutants and alterations.

Over the past 7 years, we have embarked on a number of efforts to inventory and evaluate our Region's wetlands. These efforts have included the following:

- We funded a 1993 study, entitled *Waterbodies, Wetlands, and their Beneficial Uses in the Los Angeles Region* which provides descriptions, maps, photos, and functional values of wetlands throughout the region.

- Our Santa Monica Bay Restoration Project funded a wetlands inventory in 1993 which outlines historical changes in wetlands in the Santa Monica watershed, an inventory of current wetlands in the watershed, and potential restoration and creation projects in the watershed.

- The Regional Board continues the work of inventorying through participation in the Southern California Wetlands Recovery Project, which for the first phase effort, conducted an inventory of coastal wetlands from Santa Barbara to the U.S.-Mexico border. This inventory included information on twelve wetlands in seven watersheds for our region. When compared to estimated historical acreages, Los Angeles County has lost 93% of its wetlands while Ventura County has lost 58% of its wetlands.

  A 20-year regional wetland plan and strategy for prioritizing and restoring sites is being developed. Currently, the Project funds wetlands projects which involve planning, restoration, or acquisition. Some of the this region's wetlands given a high priority for funding include Los Cerritos Wetlands, Malibu Lagoon, Ormond Beach Wetlands, and the Ventura River estuary. More information about the Project may be found on its webpage at http:www.coastalconservancy.ca.gov/scwrp/index.html.

Water Quality Certification (401) Program

A key wetlands regulatory tool for the Regional Board is the CWA Section 401 Water Quality Certification Program which regulates discharges of dredge and fill materials to waters. The 401 certification program is one of the most effective tools the state has for regulating hydrologic modification projects, especially those which directly impact the region's diminishing acres of wetlands and riparian habitat. Program work is conducted in conjunction with U.S. Army Corps of Engineers and the California Department of Fish & Game.

Key program activities should include CEQA documents review/response (possibly involvement as lead agency), pre-construction meetings with applicants, site visits, application processing, follow-up monitoring and inspections, and enforcement. Unfortunately, the program is currently severely underfunded with only application processing being undertaken. **The program is currently funded at 2.1 PYs; the FY 00/01 statewide needs analysis for the 401 certification program indicated a needed augmentation of 13.9 PYs.** Any incremental increases in the baseline PYs would go first toward follow-up work and enforcement, then toward increased support of application processing, then coordination meetings, site visits, and CEQA documents review/response. Follow-up work is especially critical since mitigation wetlands often do not function as well as projected during the planning phase. Another very important activity that could be funded is the development of policies regarding in-stream gravel mining and use of in-stream sediment basins.

Furthermore, beginning in FY 00/01, the program began requiring in-house certification rather than sign-off by State Board. This has resulted in more detailed review of all projects, even those which would previously have been given less attention (those with little likelihood of producing impacts) with less time then being available for large projects likely to produce impacts. Another program change which occurred in the past fiscal year was allowing third-party petitions of certification decisions; previously, only the applicant was allowed to do this. This leads to potentially needing to divert scarce resources from application processing to litigation work.

Approximately 150-200 applications are processed each year. Information about projects and the program in general is available on the Regional Board website at http://www.swrcb.ca.gov/~rwqcb4/.

Recently, the Regional Board applied for USEPA wetlands protection grant funding under CWA Section 104(b)(3) for federal fiscal year 2001. The pre-proposal was competitive and the Board was asked to submit a full, detailed application. We are requesting $309,500 from USEPA to conduct a two-year study to access the effectiveness of wetlands mitigation conducted through the 401 certification program. Funds will be awarded during summer 2001.

Management of Nonpoint Source Pollution

Background

The Porter-Cologne Water Quality Control Act (Porter-Cologne), Division 7 of the California Water Code, establishes a comprehensive program for the protection of water quality and the beneficial uses of State waters. Porter-Cologne applies to both surface and ground waters, and to both point and nonpoint sources. The implementation portion of this comprehensive program should provide for the attainment of water quality standards.

The two primary federal statutes that establish a framework for addressing nonpoint source pollution in this Region are **Clean Water Act (CWA) Section 319** and the **Coastal Zone Act Reauthorization Amendments (CZARA) of 1990 Section 6217**. Together these statutes encourage states to assess water quality problems associated with nonpoint sources of pollution and to develop programs to control these sources.

- CWA Section 319 requires that, in order to be eligible for federal funding, states develop an assessment report detailing the extent of nonpoint source pollution, and a management program specifying nonpoint source controls.

- CZARA Section 6217(a) requires the state to develop and implement management measures for nonpoint source pollution to restore and protect coastal waters; establish coastal nonpoint source programs.

These programs will be implemented through changes to the state's current nonpoint source control program approved by USEPA under CWA Section 319 and through changes to the state's coastal zone management program (implemented in this state by the California Coastal Commission) approved by NOAA under Coastal Zone Management Act Section 306.

Under CZARA, California must (1) provide for the implementation of management measures that are in conformity with the USEPA *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* (1993) and (2) provide a process for developing and revising management measures to be applied in critical coastal areas and in areas where necessary to attain and maintain water quality standards.

Management measures are defined in CZARA as: "economically achievable measures to control the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollution reduction achievable through application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other available alternatives." Mechanisms for implementation of these management measures may include, for example, permit programs, zoning, enforceable water quality standards, and general environmental laws and prohibitions by which a state exerts control over private and public lands and water uses and natural resources in the coastal zone (including those which may be implemented by agencies other than the State Water Resources Control Board and the California Coastal Commission). States may also use voluntary approaches like economic incentives if they are backed by appropriate regulations.

The State recently adopted an updated nonpoint source management plan which includes a 5-year implementation plan as well as a longer-term 15-year implementation strategy. The plan by USEPA and NOAA in July 2000. Implementation of the plan will entail the use of considerable resources at the Regional Board level. Documents relating to this plan may be found at http://www.swrcb.ca.gov/nps/html/protecting.html.

While it is clear nonpoint sources of pollution are difficult to manage, the state's current nonpoint source management plan (developed in 1988 pursuant to Clean Water Act Section 319) does present a three-tiered management approach which can be implemented sequentially or a focus may be put on one tier if deemed effective in a particular situation:

- **Tier 1**, self-determined implementation of best management practices (BMPs), acknowledges the advantages of property and business owners pursuing creation of site-specific or business-specific programs of waste management tailored to their budget.

- **Tier 2**, regulatory-based encouragement of BMPs, may occur when voluntary implementation is lacking. Encouragement may be effected through Regional Board waiving of waste discharge requirements if compliance with BMPs occurs. Or, BMPs may be enforced indirectly by entering into management agency agreements (MAAs) with agencies which have the authority to enforce. These MAAs would reference the specific BMPs to be used and the means of implementation.

- The Regional Board can adopt and enforce requirements on any waste discharge including those from nonpoint sources. **Tier 3** in the nonpoint source management hierarchy involves prescribing effluent limitations which would in turn require implementation of BMPs in order to insure compliance.

The State's Nonpoint Source Management Plan supports Regional Boards actively promoting voluntary implementation of BMPs but also supports that, when necessary, the Regional Boards exercise their regulatory authority over nonpoint sources in order to achieve water quality objectives. This Regional Board utilizes the full range of nonpoint source management options. A discussion of the overall approach to management of nonpoint source pollution used in this Region follows while specific nonpoint source issues and implementation activities relative to individual watersheds are described in the appropriate watershed section.

Proposition 13 Funding

The passage of the Costa-Machado Water Act of 2000 (Proposition 13) provided for the availability of water quality grants under three subaccounts: (1) Chapter 6, Article 2, Watershed Protection Program, (2) Chapter 7, Article 2, Nonpoint Source Pollution Control Program, and (3) Chapter 7, Article 5, Coastal Nonpoint Source Control Program.

The Watershed Protection Program provides funding for development of local watershed management plans as a priority and, additionally, funding for implementation of nonpoint source control projects that are consistent with local watershed plans and Regional Board water quality control plans. The Nonpoint Source Control and Coastal Nonpoint Source Control Programs provide funding for implementation of nonpoint source control projects that are consistent with local watershed plans and Regional Board water quality control plans.

There are more specific requirements for funding under each subaccount but all three include the a number of criteria be used in the project ranking and selection process. Criteria include (but are not limited to) that the project: consider the entire ecosystem for protection or restoration; address the root causes of degradation, rather than the symptoms, has definable targets and desired future conditions; and that the project helps protect intact or nearly intact ecosystems and watersheds.

Sixty percent of the funding is required to go to the six southern California counties. Funding levels are considerably higher than that available through CWA Section 319(h) and will be a critical component of nonpoint source work in this Region.

Our Approach

The State's Nonpoint Source Management Plan puts an emphasis on prioritization of nonpoint source categories as well as those waters impacted by nonpoint source pollution. It also states that management activities and implementation schedules needs are to be identified (e.g. monitoring for source identification, education, training, regulation, interagency agreements, and employment of BMPs). As is discussed elsewhere, many of these activities are severely underfunded. However, with that in mind, the following presents this Region's goals and objectives for the implementation of the State's Nonpoint Source Management Plan. Program objectives which apply most specifically to particular watersheds are highlighted and enlarged upon in the appropriate watershed section, as appropriate. The following program objectives will serve as a basis for workplan development; the final list of tasks will be dependent on the level of funding. The current funding level of these objectives are also included below and further described in Table 8.

Nonpoint Source Program Goals

Long-term Program Goal: improve water quality by implementing the management measures identified in the California Management Measures for Polluted Runoff Report (CAMMPR) by 2013

- Facilitate implementation of watershed management plans for prevention and control of nonpoint source pollution throughout the Region
- Expand our nonpoint source pollution control efforts in the Region
- Encourage more implementation of management measures in targeted watersheds
- Track implementation of management practices

Nonpoint Source Program Objectives

1) Program management – We shall oversee implementation of the Nonpoint Source Program in this Region through a variety of activities including fulfilling reporting requirements for the program, attending nonpoint source program roundtable meetings, and preparing and tracking annual workplan tasks. *Funded*

2) Contract management - In order to encourage planning and implementation of appropriate management measures, we shall explore funding opportunities and assume responsibility for administering and tracking contracts through which federal and state funds can be directed toward finding solutions to nonpoint source problems. Table 4 identifies our high priority projects for funding through the Section 319(h) grant program. Table 5 identifies our high priority projects for funding through Proposition 13 funding. (Note: high priority projects for funding through the 205(j) grant program are listed in Appendix 4.8). *Partially Funded*

3) Establishment of regional and/or watershed strategies – We intend to focus on developing regional (and where appropriate, watershed-specific) strategies to address nonpoint source pollution from agriculture (including investigation of use of nutrients, pesticides, and irrigation return water at large farming operations, nurseries and horse stables), urban (specifically new and existing development, golf courses and septic tanks, the latter will be focused on densely populated communities and areas where ground water is a source of drinking water), marinas and hydromodifications. *Partially funded*

4) Increase coordination of nonpoint source program with TMDLs through identification and reporting on the primary sources of nonpoint source pollutants with associated loadings; increase coordination of the nonpoint source program with the WMI. *Partially funded*

5) Identify and prioritize management measures to control NPS activities and promote implementation of these specific management measures to reduce or eliminate nonpoint source pollution problems throughout the Region (see Table 6 for summary of Regional NPS Problems by Management Measure Category). *Partially funded*

- For **agriculture**, high priority NPS/CZARA Management Measures include: a) for **traditional agriculture**, erosion and sediment control, nutrient management, pesticide management, irrigation water management, and education/outreach; for **horse stables**, management of wastewater and runoff from confined animal facilities, grazing management, and education/outreach; for **nurseries**, nutrient management, pesticide management, irrigation water management, and education/outreach.

- For **urban**, high priority NPS/CZARA Management Measures include: a) watershed protection and runoff from new and existing development, b) for **septic systems** new and operating onsite disposal systems, and c) for **golf courses** pollution prevention/education.

- For **marinas**, medium priority NPS/CZARA Management Measures include: control of solid wastes, fish wastes, liquid material, and petroleum; boat cleaning and maintenance; maintenance of sewage facilities; and public education.

- For **hydromodification management**, low-medium priority NPS/CZARA Management Measures include: channelization and channel modification; streambank and shoreline erosion control; and education/outreach.

- For **wetlands, riparian areas & vegetated treatment systems,** low-medium priority NPS/CZARA Management Measures include protection of wetlands and riparian areas, restoration of wetlands and riparian areas, and education/outreach.

6) Increase participation in public outreach and education activities through technology transfer, public presentations and preparation of education packages. We will participate on technical advisory committees, regional workshops, and agency meetings to promote implementation of nonpoint source management measures through. *Partially funded*

Table 7 describes our short-term program objectives as they relate to our long-term goals. Table 8 summarizes our proposed FY2001/02 activities (potential workplan activities), describes the current level of funding, and defines where and at what level additional funding is needed. **We anticipate needing an additional 14.0 PYs to accomplish these tasks which are necessary to implement the State's upgraded NPS Plan.** Any incremental increase in staff levels would go toward: 1) greater identification, education, and promotion of stakeholder involvement, 2) increased determination of the effectiveness of BMPs and Management Measures implemented, 3) establishment of a more effective policy to address pollutants from septic systems, confined animal facilities, mobile businesses, in-stream gravel mining, and agricultural runoff, and 4) quantification of the effectiveness of mitigation used to replace wetlands and riparian areas impacted by development.

Table 4. High Priority Projects for FY 2001/02 319(h) Funding

Project Number	Project Description	Geographic Area/Watershed (* denotes Category 1 Priority Watersheds)	NPS Management Measures (as listed in State's Nonpoint Source Management Plan)	Watershed Restoration Action Strategy
R4 - 1	Pilot projects: trash reduction, management of horse corral runoff, golf course irrigation water runoff, urban runoff, or implementation of septic correction measures (NOT related to a NPDES permit). Leads to demonstration of effective ways to reduce loadings from these constituents, mainly, trash, nutrients, and coliform, all of which are causing impairments.	Los Angeles River Watershed*	3.4.B. 3.6.A. 1.B.	Los Angeles-San Gabriel Rivers Watershed Council. *The Los Angeles-San Gabriel Watershed, an Integrated Vision of the Future*, 1997
R4 - 2	Restore aquatic and riparian habitats; enhance recreational uses. Leads to protection and enhancement of beneficial uses	Los Angeles River Watershed*	6.B.	Los Angeles-San Gabriel Rivers Watershed Council. *The Los Angeles-San Gabriel Watershed, an Integrated Vision of the Future*, 1997
R4 - 3	Restore wetlands (Malibu, Topanga, and Trancas Lagoons). Leads to protection and restoration of beneficial uses	Santa Monica Bay WMA*	6.B.	Santa Monica Bay Restoration Project. *Santa Monica Bay Restoration Plan*, 1995.
R4 - 4	Pilot projects: trash reduction, management of horse corral runoff, golf course irrigation water runoff, urban runoff, or implementation of septic correction measures (NOT related to a NPDES permit). Leads to demonstration of effective ways to reduce loadings from these constituents, mainly, trash, nutrients, and coliform, all of which are causing impairments	Santa Monica Bay WMA*	3.4.B. 3.6.A. 1.B.	Santa Monica Bay Restoration Project. *Santa Monica Bay Restoration Plan*, 1995.
R4 – 5	Implement comprehensive erosion control projects, with expected demonstrable improvements, in previously identified top three problem subwatersheds in terms of sediment production. Leads to significant reduction in sediment and pesticide loads to Mugu Lagoon.	Calleguas Creek Watershed*	1.A. 1.G. 5.3.A.	Natural Resources Conservation Service. *Calleguas Creek Watershed Erosion and Sediment Control Plan for Mugu Lagoon*, 1995.
R4 – 6	Habitat enhancement/ riparian restoration. Leads to restoration and protection of beneficial uses	Calleguas Creek Watershed*	6.B.	Natural Resources Conservation Service. *Calleguas Creek Watershed Erosion and Sediment Control Plan for Mugu Lagoon*, 1995.
R4 – 7	Reduce nutrients, pesticides, and sediments in irrigation water that flows to surface water or infiltrates to ground water. Leads to implementation of measures needed to comply with TMDLs and de-list impairments.	Calleguas Creek Watershed*	1.C. 1.D. 1.F. 1.G.	Natural Resources Conservation Service. *Calleguas Creek Watershed Erosion and Sediment Control Plan for Mugu Lagoon*, 1995.

TABLE 7 – SHORT TERM OBJECTIVES

This table lists our specific short-term (1-5 years) objectives and the long-term goals to which they are linked

Objectives	Program Goal that the Objective Fulfills	2000	2001	2002	2003	2004	Management Measures
NPS Program management	Goals 2 and 4	X	X	X	X	X	
319(h)/205(j) contract management	Goals 1, 2 and 3	X	X	X	X	X	
Identify Primary sources of NPS impacts to water quality	Goals 1 and 2	X					
Identify and Prioritize Management Measures for NPS activities	Goals 1 and 2	X					
Increase coordination of NPS program with TMDLs and WMI	Goals 1 and 2	X	X	X	X	X	
Establishment of regional/watershed strategies	Goals 1 and 2	X	X	X	X	X	3.1A
Coordinate with other regulatory agencies and stakeholders to control NPS	Goals 1, 2 and 3	X	X	X	X	X	
Increase participation in outreach, education, workshops, TACs	Goals 2 and 3	X	X	X	X	X	1G,3.6A,4.3A
Promote implementation of high priority Management Measures for Agriculture and Urban Areas	Goals 2 and 3	X	X	X	X	X	1A,1C,1D,1E,1F,1G, 3.4A,3.4B,3.6A
Promote implementation of medium and low priority Management Measures for Marina's, Hydromodifications and Wetland and Riparian Area	Goals 2, 3 and 4	X		X	X	X	4.2A,4.2B,4.2C,4.2D, 4.2E,4.2F,4.3A 5.1.A,5.1.B,5.3.A, 5.4A, 6.0A, 6.0B, 6.0C

Long-Term Goal: Improve water quality by implementing Management Measures by 2013

- Program Goal 1: Facilitate implementation of watershed management plans for prevention and control of nonpoint source pollution throughout the Region
- Program Goal 2: Expand our nonpoint source pollution control efforts in the Region
- Program Goal 3: Encourage more implementation of Management Measures in targeted watersheds
- Program Goal 4: Track implementation of management practices

TABLE 8: PROPOSED SFY 2001/02 RESOURCE ALLOCATION

Task	Product	Management Measure(s)	Staff or Contract	Cost
NPS Program management	Annual Reports, Identify primary NPS impacts and prioritize management measures to control NPS activities		0.7	70,000
319(h)/205(j) contract management	Database to track projects & develop report summary, Contract QA/QC, Contract outreach		**0.7** 1.0	**70,000** 100,000
Increase coordination of NPS program with TMDLs and WMI	Better coordination of projects and increased participation in TMDL development and implementation		**0.1** 0.5	**10,000** 50,000
Establishment of regional/watershed strategies	Coordinated planning		0.2	20,000
Coordinate with other regulatory agencies and stakeholders to control NPS	Increase participation in outreach, education, workshops, TACs	1G,3.6A,4.3A, 5.4A, 6D	0.2 0.5	**20,000** 50,000
Promote implementation of high priority Management Measures for Agriculture And Urban Areas	Reduction of NPS impacts, summary of BMP's implemented, Enforcement of Non-compliance	1A, 1B,1C,1D,1E, 1F,1G,3.1A, 3.1B, 3.1C, 3.2A, 3.2B, 3.3A, 3.4A, 3.4B, 3.6A,	**0.9** 7.5	**90,000** 750,000
Promote implementation of medium and low priority Management Measures for Marina's, hydromodifi-cations, and wetland and riparian areas	Develop database to track projects and expand GIS system to confirmation project & mitigation locations	4.1A,4.2A,4.2B, 4.2C,4.2D,4.2E, 4.2F,4.3A,5.1A, 5.1.B,5.3.A, 5.4A, 6A, 6B, 6D	**0.1** 3.0	**10,000** 300,000
Coordinated planning	CEQA Review for watershed Management & large or regional projects	3.1A, 3.1B, 5.1B, 6A	1.5	150,000
Total funded staff Total unfunded staff			**2.9PYs** 14	**290,000** 1,400,000

STAFF COST ≥ 1 PY $100,000 (costs in **bold** are those with anticipated resources; costs not in bold are those currently without resources). Contract costs are for the entire contract even if multi-year.

Regional Board Enforcement Strategy

The statewide Water Quality Enforcement Policy adopted by State Board in 1996 is intended to make all enforcement consistent, predictable, and fair throughout the state. On March 3, 1997, the Regional Board adopted Resolution No. 97-005 which confirmed the Board's desire to carry out enforcement in a manner consistent with State Board's enforcement policy and that Regional Board staff prepare a regional enforcement strategy consistent with State Board's enforcement policy. The Resolution directed staff to implement the Regional Enforcement Strategy. The statewide enforcement policy is currently in the process of being revised.

The statewide Water Quality Enforcement Policy upon which the Region Board Enforcement Strategy is based states that "(v)iolations of Waste Discharge Requirements (WDRs) or applicable statutory or regulatory requirements should result in a prompt enforcement response against the discharger. At a minimum, the Regional Board staff must bring the following to the attention of their Regional Board for possible enforcement action:" effluent limit violations/other permit violations - major dischargers; effluent limit violations/other permit violations - other NPDES/WDR dischargers; toxicity violations - all NPDES dischargers; violations of compliance schedules and enforcement orders - all dischargers; failure to submit reports/deficient reports (excluding stormwater); violations of POTW pretreatment programs; stormwater permit violations/deficiencies/failure to submit reports; other violations and enforcement actions; and spills (generally, non-permittees).

Board staff are also involved in a number of interagency environmental task/strike forces including the U.S.E.P.A. Environmental Strike Force, Los Angeles County Strike Force, Ventura County Strike Force, and Santa Monica Mountains Task Force.

Data Management And GIS

The State Water Information Management system (SWIM) is an organizational-wide database that was designed to facilitate electronic reporting, tracking, and analysis of regional data and information. The two modules that have been developed so far have incorporated the core structure of the Waste Discharger System (WDS) and information for the Underground Investigations (UGI). The modular structure of the database allows inclusion of new programs without redesigning the data model. WDS has now been shut down and converted statewide to SWIM. We continue to develop and pilot new models and tools. Currently under development is a query by address tool, expanded ad-hoc query tool, and environmental data entry and retrieval tools.

SWIM now tracks information on permits, both NPDES and non-NPDES. This module expands the old database in several ways. We can now record the permit limits and can perform compliance checking of electronic data against these limits. Data submitted electronically are also available for evaluation by region or watershed or through a number of other filters. Data is also available for historic permits. Previously only data from the current fiscal year was online.

The Underground Investigations (UGI) module is a replacement for Region 4's Well Investigation Program (WIP) database. This module tracks the progress of WIP facilities, and provides reports to USEPA. This module could be expanded to track the progress of facilities in other programs such as Above Ground Tanks, Department of Defense, or Spills, Leaks, Investigation, and Cleanup should the need arise. This module could also be expanded to evaluate groundwater treatment methods, to track contaminants spatially, and to tie into Region 4's geographic information system (GIS).

The new database is Windows-based and uses pull-down menus to ensure consistency of data.

This past year we took the first steps to move our GIS from a limited "special project" oriented tool to a region- and program-wide standard tool. These steps include making Arcview available to all staff, having all coverages converted to standard projection and "served" from a central location, and developing custom interfaces for the UGT, WIP, and TMDL programs.

Over time, we expect to expand the capabilities of the system, by 1) adding new components to the system, 2) linking the data to geographic layers, 3) linking our system with others such as USEPA and 4) providing access by the public to certain information.

Specific needs include:

- A tool to search the entire database by address (currently under development)
- GIS connectivity with our database, to allow analysis of data using our GIS. This would facilitate watershed management
- Update coordinate fields in SWIM (to develop coverages, such as facility and sampling locations)
- Obtain additional GIS coverages, such as elevation contours, hydrogeologic basins, wetlands, land use
- Develop coverages to be available on the internet
- Develop a catalog of available maps
- Add a module to track 401 Certification application tracking and compliance
- Add a module to track CEQA documents
- Develop tools to perform TMDL analysis
- Internet connectivity, to allow the dischargers, other agencies, and the public to query the database
- A module to facilitate the input and storage of volunteer monitoring data
- Ability to scan in permits and reports and make them available electronically over the LAN and the internet
- Input information from other programs, such as SLIC, DOD and Underground Tanks
- Insure data compatibility with Southern California Coastal Water Research Project (SCCWRP) data

An estimate of minimum staff needs to coordinate this increased effort is 2 PYs/year. This would increase in future years as more demands are placed on our system. Significant contract dollars would also be needed. Exact costs are not available at this time.

Other Region-wide Activities

Other activities may be undertaken at odd intervals during the watershed cycle. These include, among others, processing applications for new permits, reviewing CEQA and NEPA documents, reviewing and commenting on requests for Section 401 water quality certification, landfill regulation, site (including DOD/DOE) cleanups, well investigation program activities, leaking underground storage tank cleanups, routine public outreach, and responding to spills, complaints (unrelated to permits), and special requests from the Regional Board (Table 2). Some of the other region-wide strategies and programs the Regional Board implements are described in more detail below.

BEACHES/COASTAL WATERSHED ACTIVITIES

This Region's coastal resources support many of our most valuable beneficial uses. Our beaches, from Ventura through Zuma, Malibu, Venice and Long Beach are world-renowned. The Region's coastal estuaries, dunes, and wetlands are nearly gone and what is left are highly degraded. These resources, while inherently valuable as natural resources, also have a high economic value to the State with many vacationers naming beaches and lakes as their prime vacation destination. These beaches and coastal resources are a huge tourist dollar generator.

Concurrently, our Region's ports and marinas are support valuable beneficial uses providing important avenues of trade as well as recreational boating opportunities and marine habitat. They too are impacted by the need to dredge and dispose of sediments often contaminated by upstream watershed sources.

It is clear the impacts to beaches, bays, coastal wetlands and estuaries, and near shore waters is especially critical to address from both an economic and ecological perspective. The Regional Board is focussing on protecting these resources through a combination of integrated coastal planning with an aggressive effort to assess and control watershed loadings of key pollutants - pathogens, trash and sediment (particularly contaminated) - which continue to degrade coastal areas and increase the costs of dredging. Also part of this effort will be a WEBsite which will provide access to "realtime" pathogen data for our beaches. These efforts are described in greater detail under individual watersheds. As funding is located for these issues, they will be coordinated Beaches/Coastal Watersheds activities. Specific elements that have funding are described below.

Contaminated Sediment Long-term Management Strategy

The Los Angeles County's coastline includes two of the nation's largest commercial ports and several major marina complexes and small-vessel harbors. Maintenance of authorized depths in existing channels and berthing areas and expansion and modernization of ports, harbors, and marinas, requires periodic dredging in virtually all of these facilities. Some of the sediments dredged from these harbors contain elevated levels of heavy metals, pesticides, and other contaminants. In most cases, the concentrations of these contaminants do not approach hazardous levels. However, the sediments contain enough contaminants that they are not suitable for unconfined ocean disposal. Additionally, the State's Bay Protection and Toxic Cleanup Program has identified bays and estuaries containing areas with contaminated sediments. Remediation of these sites may require dredging and disposal of this material. Disposal of any contaminated dredged materials requires special management, such as placement in a confined aquatic disposal site, capping, or disposal in an upland site. Additionally, some ports and harbors have considered other management techniques, such as treatment and beneficial re-use.

Recently, the ports and harbors have delayed or canceled several dredging projects because of contaminated sediment issues. The regulatory agencies evaluated disposal options for these projects on a case-by-case basis without the benefit of a regional perspective on management alternatives, cumulative impacts, and long-term solutions to prevent re-contamination of sediment. This approach has led to public concern over the ecological and human health implications of contaminated dredged material disposal. To resolve these issues, the regulatory and resource agencies, ports and harbors, environmental groups, and other interested parties agreed to establish a task force. The mission of the Contaminated Sediment Task Force (CSTF) is to prepare a Contaminated Sediment Long-Term Management Strategy (Strategy) for the Los Angeles region (limited to Los Angeles County). Past projects suggest that the major sources of contaminated dredge material will continue to be Marina del Rey Harbor, the ports of Los Angeles and Long Beach, and the mouth of the Los Angeles River.

The members of the CSTF agreed that the Strategy will consider confined aquatic and upland disposal, sediment treatment, beneficial re-use, other management techniques, and contamination source control. The CSTF agreed on a number of goals including identifying the scope of the contaminated sediment problem, an analysis of management and disposal alternatives, development of a unified regulatory approach, and identify inputs of contaminants to coastal waters and ongoing regional efforts to reduce such inputs with a view towards promoting efforts that would reduce the inflow of contaminants. Initially, the CSTF will work with existing watershed management programs.

The CSTF was established through a Memorandum of Understanding (MOU) among the state and federal agencies with regulatory jurisdiction over dredging and disposal activities, as identified by SB 673, and other agencies representing ports, harbors, and marinas. The following agencies are signatory to that MOU: U.S. Army Corps of Engineers; U.S. Environmental Protection Agency; California Coastal Commission; Regional Water Quality Control Board, Los Angeles Region; County of Los Angeles Department of Beaches and Harbors; City of Long Beach; Port of Long Beach; and Port of Los Angeles.

The CSTF will carry out its operation by two main committees (Executive and Management Committees), and five strategy development committees (Watershed Management and Source Reduction, Aquatic Disposal and Dredging Operations, Upland and Beneficial Re-use, Sediment Screening Thresholds, and Implementation Committees). The membership of the Management Committee includes those parties that signed the MOU and one organization selected to represent the environmental community (Heal the Bay). This committee is the main decision-making group with the CSTF. The Executive Committee consists of the chief executives of the four major agencies that regulate and manage dredging and disposal in Southern California. This committee will facilitate final agency concurrence, adoption, and implementation of the completed strategy. The strategy development committees will develop specific elements of the long-term management plan.

The CSTF has developed and is implementing an Interim Dredge Material Management Plan , and is required to complete the Contaminated Sediment Long-Term Management Strategy by January 1, 2003. The program is funded at the Regional Board and the Coastal Commission at 1 PY each per year over a five-year time period. The CSTF received $2,033,000 from the legislature to conduct studies to answer specific questions and fill data gaps necessary to allow completion of the long-term management plan.

The CSTF has a web site which may be consulted for additional information: http://www.ceres.ca.gov/coastalcomm/sediment/sdindex.html.

Regional Monitoring of Ocean Waters

The Southern California Bight Pilot Project conducted a survey in 1994 to assess the spatial extent and magnitude of ecological disturbances on the mainland shelf between Point Conception in Central California to the California-Mexico border. The survey was a cooperative effort between four large discharger agencies (City of Los Angeles, County Sanitation Districts of Los Angeles County, Orange County Sanitation District, and City of San Diego), regulators (U.S. Environmental Protection Agency, State Water Resources Control Board, and Los Angeles, Santa Ana, and San Diego Regional Water Quality Control Boards), as well as the Southern California Coastal Water Research Project, and the Santa Monica Bay Restoration Project. Monitoring focused on benthic infauna, sediment chemistry, sediment toxicity, demersal fish/invertebrate populations (trawling), water quality (CTD measurements), and bioaccumulation (fish tissue with species not consumed by humans). Final reports were published in 1998.

The Santa Monica Bay Restoration Project has developed a conceptual framework for ecosystem monitoring within Santa Monica Bay. Some components of this framework are being utilized. In1995, a regional sampling program was implemented for bacteriological monitoring at shoreline and inshore stations with high recreational use within the bay (a cooperative effort by City of Los Angeles, County Sanitation Districts of Los Angeles County, and Los Angeles County Department of Health Services).

Work on a regional sampling program to assess the loadings of contaminants entering the bay is also continuing. In the meantime, the Southern California Coastal Water Research Project (SCWRP) is working on a model POTW monitoring program for the four largest southern California dischargers (City of Los Angeles, Los Angeles County Sanitation Districts, Orange County Sanitation District, and City of San Diego) which will be available in 2000.

A second regional survey of the Southern California Bight was conducted in 1998. Rather than simply repeating the 1994 survey, the participants in the 1998 survey agreed to expand the monitoring program to include a larger geographic scope (including enclosed bays, harbors and estuaries, the Mexican coastline south of California, and offshore channel islands), new monitoring components (microbiology, greater emphasis on stormwater runoff impacts) and additional participants (small point source dischargers, stormwater groups and other interested parties, including volunteer monitoring programs being implemented by environmental organizations). Most of the sampling occurred over a six-week period from late July to early September, although certain components (water quality, microbiology) were performed during different time periods. Sampling of benthic infauna and sediment chemistry took place at approximately 250 stations, sediment toxicity at approximately 200 stations, and demersal fish/invertebrate populations and bioaccumulation at approximately 175 stations. The microbiology sampling was conducted at approximately 250 stations once per week over a 5-week period in August-September 1998 (dry season) and February-March 1999 (wet season). The water quality component included sampling once during dry weather (September-October) and twice during wet weather along several transect lines throughout the Bight.

As the monitoring data becomes available, it will be analyzed and discussed by the subcommittees and Steering Committee of the Bight'98 project, which include representatives from the participating agencies. Final reports are published as the data analysis is completed. The final reports for the microbiology studies have been released; other reports should come out in 2001 (e.g., toxicity, demersal fish/macroinvertebrate abundance, sediment chemistry, benthic infaunal communities and bioaccumulation) due to the longer time period required to analyze these types of samples. More information about the Bight and other related projects may be found on the SCWRP webpage http://www.sccwrp.org/.

USEPA's Environmental Monitoring and Assessment Program (EMAP) first visited the Bight to conduct regional monitoring in 1994, contributing to the funding of the Southern California Bight Pilot Project. However, EMAP was unable to provide funding for the Bight'98 survey. Planning is underway to conduct another bight-wide regional survey in 2002 and EMAP is planning to participate in this effort.

Coastal Ambient Monitoring Program (CAMP)/Seafood Monitoring

Governor Wilson's Executive Order W-162-97 (issued October 8, 1997) required Cal/EPA to inventory existing ocean and coastal water quality monitoring programs and make recommendations for a comprehensive program for monitoring water quality and reducing pollution within coastal watersheds, bays, estuaries, lagoons and nearshore ocean waters. The State Water Resources Control Board was assigned the responsibility to implement this mandate (funded by AB 1581 and AB 1429). SB 753 required the SWRCB to establish a statewide monitoring program to assess human health risks associated with recreational fishing and seafood consumption (Coastal Fish Contamination Study). A screening study was initiated during 1999 to assess approximately ten sites and supplement the information already available for Santa Monica Bay. However, oceanic conditions associated with an El Nino event precluded adequate collection of fish samples during 1999, so the screening study was extended into 2000 The goal is to develop a regional (Region 4 coastline, not just Santa Monica Bay) sampling program during 2001, which will probably keep most of the original framework created by the Bay Restoration Project, but expand it throughout the region. An inventory of coastal water quality monitoring programs has been prepared for Southern California with the assistance of SCCWRP; it can be accessed at: http://www.sfei.org/camp.

Other Regional Monitoring Programs (SMW/TSMP and BPCTP)

State Mussel Watch/Toxic Substances Monitoring Programs (SMW/TSMP): Water column monitoring for toxic substances can be unreliable since toxic substances are often transported intermittently and can be missed with standard "grab" sampling of water. In addition, harmful levels of toxicants are often present in such low concentrations that detecting them can be difficult and expensive. In some cases, a more realistic and cost-effective approach is to test the flesh of fish and other aquatic organisms that bioaccumulate these compounds in their tissues and concentrate toxicants through the food web.

In 1977, two biomonitoring programs were initiated by State Board: the Toxic Substances Monitoring and State Mussel Watch Programs. The Los Angeles Region is active in both programs which are implemented jointly by the State Board and the California Department of Fish and Game. Tissue samples collected under the TSMP are usually fish but can also include benthic invertebrates. The tissue is analyzed for trace metals and synthetic organic chemicals. The fish are generally collected from inland fresh waters but are occasionally collected from estuaries. The SMWP provides similar documentation of the quality of coastal marine and estuarine waters. Mussels, which are sessile (attached) bivalve invertebrates, serve as indicator organisms and provide a localized measurement of water quality, as they accumulate trace metals and synthetic organic chemicals in their tissues. Mussels are generally transplanted into the test site from "clean" areas of the state (generally Bodega Bay) although occasionally local, "resident" mussels are collected. Other types of shellfish can be used at times and sediments have, at times, been collected. The focus of TSMP sampling in the region has tended to be trend monitoring while the SMWP has been used more for "hot spot" identification although with lesser resources available in recent years, the SMWP has moved away from hot spot identification in favor of long-term trend monitoring at fewer sites in recent years. Data from these two programs have been critical in determining beneficial use impairments in coastal waters.

For FY00/01, the SWMP will seek to maintain a number of "long-term" sites in the LA/LB Harbor area as well as along the open coast in Santa Monica Bay . The TSMP will look toward evaluating targeted watersheds for this fiscal year, namely, the San Gabriel River (mostly in the estuary) and the Los Cerritos Channel Watershed.

Bay Protection and Toxic Cleanup Program (BPTCP): In 1989, state legislation added Sections 13390 through 13396 to the California Water Code which established the BPTCP. The program has four main goals: 1) to provide protection of existing and future beneficial uses of bays and estuarine waters, 2) to identify and characterize toxic hot spots, 3) to plan for cleanup or other mitigating actions of toxic hot spots, and 4) to develop effective strategies to control toxic pollutants, abate existing sources of toxicity, and prevent new sources of toxicity.

While in its identification and characterization phase, the program implemented regional monitoring at each of the coastal Regions. Sediment toxicity tests, chemical analyses, and benthic community surveys were used to classify each bay or estuarine waterbody. Waters were generally "pre-screened" for contamination using toxicity tests; if enough was found, more intensive monitoring followed to confirm the existence and spatial extent of monitoring. Using this approach, the Santa Monica Bay/Palos Verdes Shelf, parts of, Consolidated Slip/Dominguez Channel, Cabrillo Pier, Mugu Lagoon/Calleguas Creek, McGrath Lake, Los Angeles River Estuary, Marina Del Rey, and Marina Del Rey Entrance Channel were identified as candidate toxic hot spots. A number of other waters were identified as sites of concern.

State Board adopted a statewide, consolidated cleanup plan in June 1999 with Office of Administrative approval following in November 1999. Regional cleanup plans deal specifically with high priority candidate toxic hot spots; detailed cleanup plans were not required for moderate priority candidate toxic hot spots or sites of concern although listed in the document. Identified remediation/cleanup alternatives for toxic hot spots range from specific actions such as in-site capping, issuing waste discharge requirements, or dredging to more regional/watershed activities such as long-term management of contaminated sediments or proactive application of the watershed management approach as a preventive measure. At this point, no specific funding source has been identified to pay for remediation activities although potential funding mechanisms are addressed in the statewide consolidated cleanup plan. The best chance for obtaining funds for cleanup appears to be through the use of Supplemental Environmental Projects (SEPs) from enforcement actions or by partnering with other groups within the context of the watershed management approach to take advantage of local efforts. Funding for staff resources ended in June 1999.

Now that the Consolidated Plan has been approved, the Regional Board is required to reevaluate WDRs in compliance with Water Code Section 13395. The reevaluation shall consist of (1) an assessment of the WDRs that may influence the creation or further pollution of the known toxic hot spot; (2) an assessment of which WDRs need to be modified to improve environmental conditions at the known toxic hot spot; and (3) a schedule for completion of any WDR modifications deemed appropriate. We were required to begin the reevaluation of WDRs associated with high priority known toxic hot spots (i.e., Palos Verdes Shelf, Consolidated Slip, Cabrillo Beach, Mugu Lagoon, McGrath Lake) within 120 days after final approval of the Consolidated Plan (i.e., by March 15, 2000). As part of this reevaluation, we were required to develop a list of the WDRs associated with each high priority toxic hot spot (within six months after final approval of the Consolidated Plan (i.e., by May 15, 2000). The priority list for moderate and low priority known toxic hot spots (i.e., Ballona Creek Entrance Channel, Marina del Rey, Los Angeles River Estuary) must be developed within one year of final approval of the Consolidated Plan (i.e., by November 15, 2000). We do not have to actually revise any WDRs within these timeframes, but if we find that we will need to make revisions, we will need to supply a schedule. And as we renew or modify WDRs, we need to include a finding that the discharge may contribute to the pollution present at the toxic hot spot.

The program also has a website which may be consulted for additional information: http://www.swrcb.ca.gov/bptcp.

Funding Needs For Non-TMDL Programs (Watershed and Regionwide Activities)

This table presents resource needs (FY01/02) which are non-TMDL-related for watershed and regionwide activities. TMDL resource needs are described later in this section of the document.

Water-shed	Monitoring/ Special studies/ data handling	WQA	Standards/ planning	NPDES	Storm-water	Non-Chapter 15	NPS strategy imple-mentation	Wet-lands	TOTAL (PYs)	Con-tracts ($)
Santa Clara River	0.2	0.3	0.7	1.2	1.0	0.75	1.8	1.8	7.75	45,000

Region-wide	—	—	0.4	--	—	0.5	1.2	0.9	3.0	200,000

TMDL Scheduling And Development

Table 7 (in Appendix 4.7) shows 303(d) listed waterbodies/reaches by watershed. Clearly, there are a large number of waters in the Region which are impaired by a number of constituents (764 individual impairments were listed in the submittal to State Board). The overriding problem associated with TMDL development needs to be reiterated here, namely, staff resources at the Regional Board to either directly conduct or be involved in stakeholder-

R0026704

led TMDL investigations and in general stay dedicated to nonpoint source activities are still minimal. Specific TMDL resource needs for the next three fiscal years are defined in the resource planning matrix in the next section of this document. **In general, depending on the watershed, it is anticipated that 0.5 -2.0 PYs/watershed more will be needed** at a minimum to make additional headway on TMDLs and implementation of our nonpoint source strategy (as well as augment point source regulation, where needed); this need will increase as we add more TMDLs in the next two years to fully accomplish our TMDL mandate. Additionally, AB1740 (Ducheny) was enacted in 2000 and requires that to the extent interest is expressed by the public, and resources are available, each regional Board shall establish for each watershed where a water body is listed as impaired, an Advisory Committee consisting of the public and interested stakeholders who wish to be involved in the process of adoption and implementation of the corrective actions necessary to eliminate the impairment.

However, with a seemingly impossible workload before us, there is a reasonable and logical way to collapse or group TMDLs to make the most effective use of resources we currently have and any which we may obtain in the future. This is largely due to the fact that some of the "pollutants" for which a water may be listed are actually "effects" of pollutants. Table 7 reflects this collapsed approach. For example, many reaches of the Los Angeles River are listed for ammonia. Some of the same reaches are listed for pH problems while other reaches are listed for algae, scum, and odors. It is very likely the presence of these "pollutants" are interrelated. Excessive nitrogen (reflected here as high levels of ammonia) may lead to a condition of eutrophication (excessive nutrient loading) which can influence pH levels as well as promote increased algal growth. Scum may be evident due to floating algal material and odors may result when excessive algae starts to die off. Thus, it is reasonable to group together these TMDLs (calling it a "nitrogen and related effects" TMDL) and approach the problem by determining the sources of nitrogen loading into the watershed and the appropriate allocations in order to reduce loadings.

Another example relates to the Malibu Creek Watershed. Many of its reaches are listed as impaired due to coliform. Other reaches are listed for swimming restrictions or shellfish harvesting advisories (an effect of elevated coliform levels). It is reasonable to group together these various reaches and "pollutants" together when performing a TMDL. USEPA has produced a number of documents relating to TMDL development; these may be found on the Internet at http://www.epa.gov/owow/tmdl/.

Table 7A lists all of the TMDLs in the Region as well as a schedule for completion. All TMDLs must be completed by 2011 (as requested by U.S. EPA and State Board and per a consent decree). Table 7B lists all TMDLs that we will have started in the next five years (although some will be completed after that time period). It also gives more detail about the scheduling of activities such as actual TMDL development, formation of implementation strategies, and Basin Plan amendments for the next three fiscal years. Table 7C is a resource planning and project management tool detailing resource needs and intermediate milestones for all TMDLs that we will have started in the next three years. More information on TMDLs scheduled for each watershed may be found in the appropriate watershed section.

The following three tables summarize our near-term annual TMDL watershed resource needs (PYs and contract dollars) for the next three fiscal years, beyond what we expect to receive with current funding levels. These needs are also reflected in our resource allocation matrices (for the out-years). **It should be emphasized that we see need for an additional 14.8 PYs during the current fiscal year (FY00/01).**

Near-term Annual (FY00/01) TMDL Watershed Resource Needs (PYs and Contract Dollars)

Watershed	Pollutants	Monitoring/ Assessment	TMDL Develop -ment	Implement-ation Plan Develop-ment	Basin Plan Amendment	TOTAL (PYs)	Contracts ($)
Calleguas Creek	nitrogen, salts, chloride	0.3	1.6	0.2	0.4	2.5	$50,000
Santa Monica Bay	Coliform, nutrients, trash, metals	0.2	3.4	0.2	0.4	4.2	$230,000
LA River	Coliform, nitrogen, trash	0.4	0.7	0.4	0.4	1.9	$100,000
Dominguez Channel/LA -LB Harbors	Coliforms	0.2	0.3	0.2	0.4	1.1	$50,000
Ventura Coastal WMA	Coliform,	0.2	0.3	0.2	—	0.7	—
Los Cerritos WMA	none scheduled for FY00/01	0.2	—	—	—	0.2	—
Santa Clara River	Coliform, nitrogen,	0.2	1.1	0.4	0.4	2.2	$100,000
San Gabriel River	Nitrogen, metals,	0.4	0.9	0.1	—	1.4	$200,000
Ventura River	Eutroph.	0.2	0.9	0.2	—	1.3	$50,000
Channel Islands	no 303(d) waters	0.2	—	—	—	0.2	—
TOTALS		**2.5**	**9.2**	**1.9**	**2.0**	**15.6**	**$780,000**

Additionally, 1 PY each is needed for a region-wide data compiler/interpreter/report-writer and a public outreach person to coordinate workshops and meetings regarding 303(d) list topics.

As has been mentioned many times previously, a major impediment to completing these TMDLs per a 13-year schedule is the less than adequate resources for this program.

Near-term Annual (FY01/02) TMDL Watershed Resource Needs (PYs and Contract Dollars)

Watershed	Pollutants	Monitoring/ Assessment	TMDL Develop -ment	Implement-ation Plan Develop-ment	Basin Plan Amendment	TOTAL (PYs)	Contracts ($)
Calleguas Creek	Salts, pesticides, nutrients	0.8	1.9	0.6	0.4	2.8	$125,000
Santa Monica Bay	Coliform, nutrients, trash, PCBs, Metals	0.6	4.9	0.8	0.6	6.9	$225,000
LA River	Coliform, nitrogen, trash, metals	1.2	0.9	---	---	2.1	$50,000
Dominguez Channel/LA -LB Harbors	coliform	0.4	---	---	0.2	0.6	---
Ventura Coastal WMA	Coliforms	0.4	---	---	0.2	0.6	—
Los Cerritos WMA	NH_3	—	0.5	---	---	0.5	—
Santa Clara River	Eutroph., coliform, nitrogen	0.8	1.2	—	0.4	2.4	$40,000
San Gabriel River	Nitrogen, metals, coliform	1.0	1.2	0.2	0.4	2.8	$50,000
Ventura River	Eutroph.	—	0.3	0.2	—	0.5	$50,000
Channel Islands	no 303(d) waters	—	—	—	—	—	
TOTALS		**5.2**	**10.0**	**108**	**2.2**	**19.2**	**$530,000**

Additionally, 1 PY each is needed for a region-wide data compiler/interpreter/report-writer and a public outreach person to coordinate workshops and meetings regarding 303(d) list topics.

As has been mentioned many times previously, a major impediment to completing these TMDLs per a 13-year schedule is the less than adequate resources for this program.

Near-term Annual (FY02/03) TMDL Watershed Resource Needs (PYs and Contract Dollars)

Watershed	Pollutants	Monitoring/ Assessment	TMDL Develop -ment	Implement-ation Plan Develop-ment	Basin Plan Amendment	TOTAL (PYs)	Contracts ($)
Calleguas Creek	Salts, pesticides, PCBs	0.8	2.4	0.4	0.4	4.0	$125,000
Santa Monica Bay	Coliform, nutrients, PCBs, Metals	1.2	2.8	0.8	0.4	5.2	$225,000
LA River	Metals	---	0.3	0.2	---	0.5	$50,000
Dominguez Channel/LA -LB Harbors	none scheduled for FY02/03 (startup work)	---	---	---	---	---	---
Ventura Coastal WMA	PAHs, zinc	---	1.7	0.2	---	1.9	$60,000
Los Cerritos WMA	Pesticides, metals, PAHs, NH_3	0.2	3.4	0.2	---	3.8	$125,000
Santa Clara River	Chloride, eutroph., trash	0.4	1.2	0.2	---	1.8	$50,000
San Gabriel River	Nitrogen, Coliform	0.4	0.7	0.4	0.2	1.7	$40,000
Ventura River	Eutroph.	0.4	---	---	0.2	0.6	---
Channel Islands	no 303(d) waters	---	---	---	---	---	
TOTALS		**3.4**	**12.5**	**2.4**	**1.2**	**19.5**	**$675,000**

Additionally, 1 PY each is needed for a region-wide data compiler/interpreter/report-writer and a public outreach person to coordinate workshops and meetings regarding 303(d) list topics.

As has been mentioned many times previously, a major impediment to completing these TMDLs per a 13-year schedule is the less than adequate resources for this program.

With an anticipated near-term augmentation need of 14-19 PYs/year, we are actively seeking funds for this effort.

If we were required to redirect other resources (assuming we had the flexibility, which for the most part we don't), it would have a disastrous impact on our other programs. This magnitude of redirection would require almost a 50% reduction in our NPDES program which is already severely underfunded based on the number of facilities we regulate. Alternatively, we could cease all enforcement efforts and about one-third of our surface water regulatory program. None of these are acceptable alternatives.

Waste Types Categories (prior to treatment or disposal)
DCNWTRS – nonhazardous contaminated groundwater
DNONCON – nonhazardous noncontact cooling water
DPROCES – nonhazardous process waste (produced as part of industrial/manufacturing process)
DSTORMS – nonhazardous stormwater runoff
HCNWTRS – hazardous contaminated groundwater
DFILBRI – nonhazardous filter backwash brine waters
DDOMIND – nonhazardous domestic sewage & industrial waste
DWSHWTR – nonhazardous washwater waste (photo reuse washwater, vegetable washwater)
IMISCEL – inert wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage
DMISCEL – nonhazardous wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage
HCNWTRS – hazardous contaminated groundwater
DCONTAC – nonhazardous contact cooling water
DDOMEST – nonhazardous domestic sewage
NMISCEL – nonhazardous wastes from dewatering, rec. lake overflow, swimming pool wastes, water ride wastewater, or groundwater seepage
ICNWTRS – inert contaminated groundwater

Hazardous – influent or solid wastes that contain toxic, corrosive, ignitable, or reactive substances (prior to treatment or disposal) managed according to applicable Department of Health Services standards
Designated – influent or solid wastes that contain nonhazardous wastes (prior to treatment or disposal) that pose a significant threat to water quality because of their high concentrations
Inert – influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality
Nonhazardous – influent or solid wastes that do not contain soluble pollutants or organic wastes (prior to treatment or disposal) and have little adverse impact on water quality

R0026739

Appendix 4.2 NPDES Storm Water Wastewater Permit Reissuance

There are three Municipal Storm Water Permits in Region 4:

The Ventura County Municipal Storm Water Permit is scheduled for renewal in 2005.

The Los Angeles County Municipal Storm Water Permit is scheduled for renewal in 2002.

The City of Long Beach Municipal Storm Water Permit is scheduled for renewal in 2004.

Appendix 4.3 NPDES Pretreatment Wastewater Permit Reissuance

R0026742

The following are the Pretreatment Programs in Region 4 and their schedule for audit. The pretreatment compliance inspections are scheduled annually in years than an audit is not performed:

PROGRAM	AUDIT
Burbank	2002
Camarillo SD	2003
Las Virgenes MWD	2002
Los Angeles CSD	2004
City of Los Angeles	2004
Ojai Valley SD	2002
Oxnard	2001
San Buenaventura	2005
Simi Valley CSD	2001
Thousand Oaks	2001
Moorpark WTP	2005
Santa Paula	2001

Appendix 4.4 NPDES Compliance

All major NPDES dischargers will be inspected at least once per year. All minors will be inspected at least once during the life of the permit.

Appendix 4.5 Chapter 15 Permit Reissuance

Landfill Waste Discharge Requirements
Status and Proposed Reissuance for Priority Watersheds

Groundwater programs (including landfills) have not been officially integrated into the watershed approach. We expect to integrate these programs increasingly over the next several years. In the meantime, to the extent practicable, landfill issues will be considered when completing "State of the Watershed Reports" and designing watershed monitoring programs.

Our current priority (for the next two years) are the Santa Clara River Watershed, Calleguas Creek Watershed, and Dominguez Channel WMA. We are providing the current status and projected revision dates for landfills in these watersheds:

<u>Santa Clara River Watershed</u>

Wayside Landfill	Current WDR: Adopted in 1975 Landfill is closed WDR will be revised in 2001 to reflect closure/postclosure requirements
Chiquita Canyon Landfill	Current WDR: Adopted in 1998
Bailard Coastal Landfills	Current WDR: Adopted in 1988 Landfill is closed WDR will be rescinded in 2000
Bailard Landfill	Current WDR: Adopted in 1993* Landfill is closed WDR was updated in 2000
Coastal Landfill	Current WDR: Adopted in 1988 Landfill is closed WDR was updated in 2000
Santa Clara Disposal Site	Current WDR: Adopted in 1983* Landfill is closed WDR was updated in 2000
Toland Road Disposal Site	Current WDR: Adopted in 1996

<u>Calleguas Creek Watershed</u>

Simi Valley Landfill	Current WDR: Adopted in 1990 WDR will be updated in 2000

<u>Dominguez Channel WMA</u>

City of Los Angeles, Gaffey St Site	Current WDR: Adopted in 1955 Landfill is closed WDR will be rescinded in 2002

* Indicates that WDRs were revised in 1993 to reflect 40 CFR, Part 258 (Subtitle D) requirements)

R0026747

Appendix 4.6 Non-Chapter 15 Waste Discharge Requirements (WDRs)

Non-Chapter 15 Waste Discharge Requirements (WDRs)
DRAFT Review and Update Strategy
Los Angeles Region
FY 2001/2002 and 2002/2003

The Groundwater Regulatory Unit Programs (WDRs and landfills) have not yet been officially integrated into the watershed approach. We expect to integrate (stepwise) these programs in the next several years. The workplans for the next two years will focus on reducing the review backlog, and to the extent practicable, reviewing and renewing (if appropriate) permits in the targeted watersheds. These facilities will also be considered when designing watershed monitoring programs.

The following tables list all WDRs in the Santa Clara River and Calleguas Creek Watersheds (targeted watersheds in FY01/02), the Dominguez Channel WMA, (targeted watershed for FY02/03), and all WDRs due for review in FY01/02 and 02/03.

TABLE 7A. SUMMARY SCHEDULE FOR TMDL DEVELOPMENT
Assumes these activities are funded to adhere to this schedule

Los Angeles River Watershed

303(d) Listed Waterbody (Reach)	Pollutant	Type of TMDL	TMDL Start Date - FY (start of monitoring)	TMDL Completion Date - FY (Basin Plan amendment)	Comments
Los Angeles River Reach 5 (within Sepulveda Basin)	ChemA	historic pest.	2002/03	2005/06	
Echo Park Lake Peck Rd Lake	PCBs DDT, chlordane	PCBs and historic pest.	2007/08	2010/11	
Peck Rd Lake Lincoln Park Lake Echo Park Lake	Pb Pb Cu, Pb	metals	2007/08	2010/11	
Los Angeles River Reach 5 (within Sepulveda Basin) Los Angeles River Reach 2 (Figueroa St. to u/s Carson St.)	oil oil	oil	2007/08	2010/11	Further assessment needed
Los Angeles River Reach 6 (u/s of Sepulveda Basin)	Volatile organics	VOCs	2007/08	2010/11	

San Gabriel River Watershed

303(d) Listed Waterbody(Reach)	Pollutant	Type of TMDL	TMDL Start Date - FY (start of monitoring)	TMDL Completion Date - FY (Basin Plan Amendment)	Comments
San Gabriel River Reach 3 (Whittier Narrows to Ramona)	toxicity	nitrogen and its effects	1999/00	2002/03	
San Gabriel River Reach 2 (Firestone to Whittier Narrows Dam)	NH3				
San Gabriel River Reach 1 (Estuary to Firestone)	NH3				
San Gabriel River Reach 1 (Estuary to Firestone)	algae				
San Gabriel River Reach 1 (Estuary to Firestone)	toxicity				
San Jose Creek Reach 2 (Temple to I-10 at White Ave.)	NH3				
San Jose Creek Reach 2 (Temple to I-10 at White Ave.)	algae				
San Jose Creek Reach 1 (SG confluence to Temple St.)	NH3				
San Jose Creek Reach 1 (SG confluence to Temple St.)	algae				
Coyote Creek	NH3				
Coyote Creek	algae				
Coyote Creek	toxicity				
Walnut Creek	toxicity				
Walnut Creek	pH				
San Gabriel River East Fork	trash	trash	1998/99	1999/00	Completed
Legg Lake	trash	trash	2000/01	2008/09	
Puddingstone Reservoir	DDT, PCBs, chlordane	PCBs & pest.	2000/01	2005/06	
El Dorado Lakes	Hg	metals	2000/01	2005/06	
El Dorado Lakes	Cu, Pb				
Puddingstone Reservoir	Hg				
Legg Lake	Cu, Pb				
Santa Fe Dam Park Lake	Pb, Cu				
Coyote Creek	abnormal fish histology	Dependent on cause	2000/01	2005/06	Further Assessment needed - cause of abnormalities unknown
San Gabriel River Reach 1 (Estuary to Firestone)	abnormal fish histology				
San Gabriel River Estuary	abnormal fish histology				
El Dorado Lakes	algae, NH3, eutroph.	nitrogen and its effects	2001/02	2003/04	
El Dorado Lakes	pH				
Crystal Lake	algae, nutrients				
Legg Lake	NH3				
Legg Lake	pH				
Legg Lake	odors				
Puddingstone Reservoir	low DO, org. enrichment				
Santa Fe Dam Park Lake	pH				
San Gabriel River Reach 2 (Firestone to Whittier Narrows Dam)	Pb	metals	2000/01	2004/05	
San Gabriel River Estuary	As				
Coyote Creek	Ag

Table 7C. Detailed TMDL Tasks Schedule (next three years)

Santa Monica Bay WMA – Marina del Rey – Coliform and Effects
Consent Decree: March 2003

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	00/01	(1/10 py)		Problems statement write-up	1/01
Numeric Target	00/01	(2/5 py)		Rationale for numeric targets	3/01
Source Analysis	01/02	(2/5 py)	$20,000	Write-up of source analysis	9/01
Allocations	01/02	(3/10 py)	$30,000	Numeric allocations and rationale	4/02
Implementation Planning					
Implementation Plan	01/02	(1/5 py)		Report	5/02
Basin Plan Amendment	02/03	(1/5 py)		Draft Basin Plan Amendment	12/02
Implementation					
Monitoring	03/04	(1/5 py)		Monitoring data and QA/QC	11/03
Reevaluation	04/05	(1/5 py)		Report of reevaluation findings	12/04

Santa Monica Bay WMA – Marina del Rey –Historic PCBs, Pesticides and Effects
Consent Decree: March 2005

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	01/02	(1/10 py)		Problems statement write-up	1/03
Numeric Target	02/03	(2/5 py)		Rationale for numeric targets	3/03
Source Analysis	02/03	(2/5 py)	$50,000	Write-up of source analysis	5/03
Allocations	02/03	(3/10 py)	$50,000	Numeric allocations and rationale	9/03
Implementation Planning					
Implementation Plan	03/04	(1/5 py)		Report	11/03
Basin Plan Amendment	03/04	(1/5 py)		Draft Basin Plan Amendment	06/04
Implementation					
Monitoring	05/06	(1/5 py)		Monitoring data and QA/QC	9/05
Reevaluation	06/07	(1/5 py)		Report of reevaluation findings	11/06

Santa Monica Bay WMA – Marina del Rey –Metals
Consent Decree: March 2005

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	02/03	(1/10 py)		Problems statement write-up	12/02
Numeric Target	02/03	(2/5 py)		Rationale for numeric targets	2/03
Source Analysis	03/04	(2/5 py)	$25,000	Write-up of source analysis	7/03
Allocations	03/04	(3/10 py)	$25,000	Numeric allocations and rationale	4/04
Implementation Planning					
Implementation Plan	03/04	(1/5 py)		Report	5/04
Basin Plan Amendment	04/05	(1/5 py)		Draft Basin Plan Amendment	12/04
Implementation					
Monitoring	05/06	(1/5 py)		Monitoring data and QA/QC	2/06
Reevaluation	06/07	(1/5 py)		Report of reevaluation findings	4/07

Santa Monica Bay WMA – Beaches – Coliform and Effects
Consent Decree: March 2002

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	99/00	(1/10 py)		Problems statement write-up	12/99
Numeric Target	99/00	(2/5 py)	$100,000	Rationale for numeric targets	1/00
Source Analysis	00/01	(2/5 py)	$130,000	Write-up of source analysis	7/00
Allocations	00/01	(3/10 py)		Numeric allocations and rationale	11/00
Implementation Planning					
Implementation Plan	00/01	(1/5 py)		Report	5/01
Basin Plan Amendment	01/02	(1/5 py)		Draft Basin Plan Amendment	11/01
Implementation					
Monitoring	02/03	(1/5 py)		Monitoring data and QA/QC	11/02
Reevaluation	03/04	(1/5 py)		Report of reevaluation findings	12/03

Santa Monica Bay WMA – Nearshore & Offshore – Metals
Consent Decree: March 2004

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	01/02	(1/10 py)		Problems statement write-up	12/01
Numeric Target	01/02	(2/5 py)		Rationale for numeric targets	2/02
Source Analysis	01/02	(2/5 py)	$50,000	Write-up of source analysis	6/02
Allocations	02/03	(3/10 py)	$50,000	Numeric allocations and rationale	10/02
Implementation Planning					
Implementation Plan	02/03	(1/5 py)		Report	2/03
Basin Plan Amendment	03/04	(1/5 py)		Draft Basin Plan Amendment	9/03
Implementation					
Monitoring	04/05	(1/5 py)		Monitoring data and QA/QC	10/04
Reevaluation	05/06	(1/5 py)		Report of reevaluation findings	12/05

Santa Monica Bay WMA – Ballona Creek – Trash
Consent Decree: March 2001

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	98/99	(1/10 py)		Problems statement write-up	4/99
Numeric Target	99/00	(2/5 py)		Rationale for numeric targets	11/99
Source Analysis	99/00	(2/5 py)		Write-up of source analysis	12/99
Allocations	99/00	(3/10 py)		Numeric allocations and rationale	12/99
Implementation Planning					
Basin Plan Amendment	00/01	(1/5 py)		Report	3/01
Implementation					
Monitoring	02/03	(1/5 py)		Monitoring data and QA/QC	3/03
Reevaluation	02/03	(1/5 py)		Report of reevaluation findings	4/03

Table 7C. Detailed TMDL Tasks Schedule (next three years)

Santa Monica Bay WMA – Ballona Creek – Coliform and Effects
Consent Decree: March 2006

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	00/01	(1/10 py)		Problems statement write-up	7/00
Numeric Target	00/01	(2/5 py)		Rationale for numeric targets	9/00
Source Analysis	00/01	(2/5 py)	$20,000	Write-up of source analysis	2/01
Allocations	01/02	(3/10 py)	$20,000	Numeric allocations and rationale	11/01
Implementation Planning					
Implementation Plan	01/02	(1/5 py)		Report	12/01
Basin Plan Amendment	02/03	(1/5 py)		Draft Basin Plan Amendment	7/02
Implementation					
Monitoring	03/04	(1/5 py)		Monitoring data and QA/QC	12/03
Reevaluation	03/04	(1/5 py)		Report of reevaluation findings	3/04

Santa Monica Bay WMA – Ballona Creek –Metals and Effects
Consent Decree: March 2004

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	01/02	(1/10 py)		Problems statement write-up	7/01
Numeric Target	01/02	(2/5 py)		Rationale for numeric targets	9/01
Source Analysis	01/02	(2/5 py)	$25,000	Write-up of source analysis	2/02
Allocations	02/03	(3/10 py)	$25,000	Numeric allocations and rationale	11/02
Implementation Planning					
Implementation Plan	02/03	(1/5 py)		Report	12/02
Basin Plan Amendment	03/04	(1/5 py)		Draft Basin Plan Amendment	7/03
Implementation					
Monitoring	04/05	(1/5 py)		Monitoring data and QA/QC	4/05
Reevaluation	05/06	(1/5 py)		Report of reevaluation findings	5/06

Santa Monica Bay WMA – Ballona Creek – Historic PCBs, Pesticides and Effects
Consent Decree: March 2004

Tasks	FY	Staff Resources	Contracts	Products	Completion Dates
TMDL Development					
Problem Statement	02/03	(1/10 py)		Problems statement write-up	7/02
Numeric Target	02/03	(2/5 py)		Rationale for numeric targets	9/02
Source Analysis	02/03	(2/5 py)	$25,000	Write-up of source analysis	11/02
Allocations	03/04	(3/10 py)	$25,000	Numeric allocations and rationale	11/03
Implementation Planning					
Implementation Plan	03/04	(1/5 py)		Report	12/03
Basin Plan Amendment	04/05	(1/5 py)		Draft Basin Plan Amendment	7/04
Implementation					
Monitoring	05/06	(1/5 py)		Monitoring data and QA/QC	9/06
Reevaluation	06/07	(1/5 py)		Report of reevaluation findings	12/07
