Attachments:	LA_MS4_Land_Development_91311ed.pdf; Copy of wqo_2009_0009_app_21, with L.A. example.xls; Ventura Land Development excerpt.pdf; CA LID Ordinance summaries_8-24-11[1].pdf

Hello everyone:

Attached is the revised draft memorandum with recommendations for the Planning and Land Development Program (Part 4.E) of the draft Los Angeles County MS4 permit. This version of the memo reflects comments from the smaller Working Group, consisting of John Kemmerer, Ivar Ridgeway, and Melinda Becker. The major changes between this version and the August 25 version are as follows:

- Added design requirements for bio-treatment based on the Natural Resources Defense Council's May 8, 2009, letter to the Santa Ana Regional Water Board.
- Agreed to retain the treatment requirements in subpart 4.E.III.4. These requirements are in addition to requirements to provide off-site mitigation when technical infeasibility prevents the on-site retention of the storm water quality design volume (SWQDv) or biofiltration of 1.5 times the SWQDv. There is a placeholder for defining the pollutant-specific performance levels, which may be interpreted as technology-based effluent limitations. Performance levels may be described by referencing the draft SWRCB Phase II MS4 permit or the American Society of Civil Engineers (ASCE) BMP performance levels.
- Provided an alternative to Horner's equation for calculating infiltration rates by making conservative assumptions that the soil is wet and the infiltration rates are always at the low end of the reported range.
- Recommended that we not require, or rely upon the Permittees, to develop a Technical Guidance Manual.
- Recommended that we develop a spreadsheet calculator that credits or incentivizes reductions in impervious area, the preservation of trees and riparian buffers, and LID design. A copy of a similar spreadsheet from the California Construction General Permit is attached to this e-mail for your information.

Also attached for your information is a copy of part 4.E of the Ventura MS4 permit and a comparative summary of LID Ordinances.

Best regards,

Melinda Becker

TECHNICAL MEMORANDUM

PG Environmental, LLC
Permitting & Compliance Specialists

TO: U.S. EPA Region 9
State Water Resources Control Board
Los Angeles Regional Water Quality Control Board

FROM: PG Environmental, LLC

DATE: September 13, 2011

SUBJECT: L.A. MS4, Planning and Land Development Program

I. Introduction

This memorandum summarizes recommendations for the Planning and Land Development Program (Part 4.E) of the draft Los Angeles County Municipal Separate Storm Sewer System (MS4) permit (L.A. MS4 permit). These recommendations reflect discussions with staff from the Los Angeles Regional Water Quality Control Board (Regional Water Board), the State Water Resources Control Board (SWRCB), and the U.S. Environmental Protection Agency, Region 9 (EPA), collectively referred to hereinafter as the "Working Group." The larger Working Group discussed these issues during conference calls July 11 and August 25. The smaller Working Group discussed them separately August 8 and September 1. The notes from the two meetings were distributed to the Working Group members. This version of the memo reflects comments from the smaller Working Group, consisting of John Kemmerer (EPA), Ivar Ridgeway (Regional Water Board), and Melinda Becker (PG Environmental, LLC, referred to hereinafter as PG), during a conference call September 1. The major changes between this version and the August 25 version are as follows:

- Added design requirements for bio-treatment based on the Natural Resources Defense Council's May 8, 2009, letter to the Santa Ana Regional Water Board.
- Agreed to retain the treatment requirements in subpart 4.E.III.4. These requirements are in addition to requirements to provide off-site mitigation when technical infeasibility prevents the on-site retention of the storm water quality design volume (SWQDv) or biofiltration of 1.5 times the SWQDv. There is a placeholder for defining the pollutant-specific performance levels, which may be interpreted as technology-based effluent limitations. Performance levels may be described by referencing the draft SWRCB Phase II MS4 permit or the American Society of Civil Engineers (ASCE) BMP performance levels.
- Provided an alternative to Horner's equation for calculating infiltration rates by making conservative assumptions that the soil is wet and the infiltration rates are always at the low end of the reported range.
- Recommended that we not require, or rely upon the Permittees to develop, a Technical Guidance Manual.
- Recommended that we develop a spreadsheet calculator that credits or incentivizes reductions in impervious area, the preservation of trees and riparian buffers, and LID design. A copy of a

similar spreadsheet from the California Construction General Permit is provided under separate cover as an example.

PG is using the Ventura County MS4 permit (Order No. R4-2010-0108) as a template for the draft L.A. County MS4 permit. The recommended language changes to subpart 4.E. of the Ventura County permit, Planning and Land Development Program, are provided in this memo. Significant changes or additions to the recommended language in the August 25 memorandum are highlighted. A copy of the relevant parts of the Ventura County MS4 permit is provided as a separate attachment for ease of reference; the table of contents for this subpart is reproduced below for the reader's orientation.

II. Recommendations and Suggested Permit Language

The recommended changes in the requirements for the Land Development Program, as presented in the Ventura County MS4 permit, are described in this section.

Recommended Changes to Subpart 4.E.I.—Purpose:

All references to effective impervious area (EIA) are to be deleted. Instead, the permit will implement design criteria based on a volume capture approach. The permit should promote designs that minimize soil compaction during construction, as well as the construction of new impervious areas (IAs). The language is to remain consistent with the Ventura County MS4 permit except as follows:

(c) Minimize the percentage of ~~effective~~ impervious surfaces on land developments <u>by minimizing soil compaction during construction, designing projects to minimize the impervious area footprint, and</u>

employing Low-Impact Development (LID) design principles to mimic predevelopment water balance through infiltration, evapotranspiration and reuse.

(e) *Properly select, design and maintain ~~Treatment Control BMPs~~ LID and Hydromodification Control BMPs to address pollutants that likely will be generated, reduce changes to pre-development hydrology, ensure long-term function, and avoid the breeding of vectors.*

Recommended Changes to Subpart 4.E.II.—Applicability

Language is to remain consistent with the Ventura County MS4 permit.

Recommended Changes to Subpart 4.E III.—New Development/Redevelopment Performance Criteria

1. Delete all references to EIA and ineffective impervious surfaces.
2. New language: Subpart 4. E. III.1.(a):

Except as provided in subpart 4.E.III.1.(b), 4.E.III.2, or 4.E.III.3, the Permittees shall require the project to infiltrate and/or evapotranspire stormwater runoff and/or harvest rainwater for reuse. The total volume of storm water runoff retained on-site must equal or exceed the Storm Water Quality Design Volume (SWQDv) defined as the runoff from:

- *The 0.75-inch 24-hour rain event or*
- *The 85th percentile, 24-hour rain event, as determined from the Los Angeles County 85th percentile precipitation isohyetal map, whichever is greater.*

When calculating the capacity of the infiltration system, the Permittees shall account for the 24-hour infiltration loss considering the impact of increasing soil moisture content using Horton's Equation or other means approved by the Executive Officer of the Los Angeles Regional Water Quality Control Board. Horton's Equation is as follows:

(Eq. 1) $$Ft = fmin + (fmax - fmin)\, e^{-kt}$$

where:
Ft = infiltration rate at time t (in/hr),
fmin = minimum or saturated infiltration rate (in/hr),
fmax = maximum or initial infiltration rate (in/hr),
k = infiltration rate decay factor (/hr), and
t = time (hr) measured from time runoff first discharged into infiltration area.

Or

When calculating the capacity of the infiltration system, the designer shall assume that the soil is wet and the minimum infiltration rate applies. The infiltration rates presented by Hydrologic Soil Group in Table X will apply, absent more site-specific information:

Table X

Hydrologic Soil Group	*Description*	*Assumed Infiltration Rate (inches/hour)*
A	*Sand, loamy sand, or sandy loam*	*0.30*
B	*Silt loam or loam*	*0.15*
C	*Sandy clay loam*	*0.05*
D	*Clay loam, silty clay loam, sandy clay, silty clay, or clay*	*0.00*

If rainwater harvested for use in irrigation is to be credited toward the total volume of stormwater runoff retained on-site, the Permittees must require that the project proponent conduct a conservative (assuming reasonable worst-case scenarios) assessment of water demand during the wet season. This volume will be referred to as the "reliable" estimate of irrigation demand. The portion of water to be credited as retained on-site for reuse in irrigation may not exceed the reliable estimated irrigation demand during the wet season.

Harvested rainwater must be stored in a manner that precludes the breeding of mosquitoes or other vectors or with a draw down not to exceed 72 hours.

When evaluating the potential for on-site retention, the Permittees must consider the maximum potential for evapotranspiration from green roofs and harvest and reuse. ~~*The permittees shall develop minimum criteria for enhanced storm water reuse for non-potable and/or potable water supplies specific to the following land use categories:*~~

- ~~*Residential Development (4 Units and less)*~~
- ~~*Residential Development (5 Units or more)*~~
- ~~*Commercial*~~
- ~~*Industrial*~~
- ~~*Other*~~

The requirements shall address at a minimum the use of harvested rainwater for non-potable uses including toilet flushing, laundry, and cooling water makeup water. If the municipal or county plumbing code does not specifically address requirements for harvested rainwater, the Permittees shall develop a model ordinance and submit it to the city council or County Supervisors for consideration within X months of the effective date of this permit. The model ordinances shall be based on the International Association of Plumbing and Mechanical Officials' (IAPMO's) Green Plumbing and Mechanical Code Supplement to the

2012 National Standard Plumbing Code, or similar guidance to ensure the safe and effective use of harvested rainwater, separate from the existing provisions, if any, for reclaimed wastewater.

Recommended Changes to Subpart 4.E.III.1.(b)—Biofiltration

Except as provided in subpart 4.E.III.2 or 4.E.III.3, if the Permittee determines that the project cannot reliably retain 100 percent of the SWQDv on-site, even with the maximum application of green roofs and rainwater harvest and reuse, the project will be required to biofiltrate 1.5 times the volume of storm water runoff that cannot reliably be retained on-site, in accordance with the following equation.

(Eq. 2) $Bv= 1.5 * [Dv* (Dv-Rv/DV)]$

where :
Bv = *biofiltration volume,*
Dv = *SWQDv, and*
Rv= *volume reliably retained on-site.*

Bio-filtration systems discharging to a receiving water that is included on the Clean Water Act section 303(d) list of water-quality-limited water bodies due to nitrogen shall be designed and maintained to achieve enhanced nitrogen removal capability.

Bio-filtration BMPs shall be designed to accommodate the design flow at a surface loading rate no greater than 5 inches per hour and shall have a total volume, including pore spaces and prefilter detention volume, no less than the runoff volume generated by the design storm depth times 0.75.

Recommended Changes to Subpart 4.E.III.2.—Alternative Compliance for Technical Infeasibility

Subparts 4.E.III.2.(a) and (b) regarding smart growth and infill and technical infeasibility are to remain consistent with the text in the Ventura County MS4 permit, except that subpart 4.E.III.2.(b)(1) is to be changed as follows to make it consistent with City of Santa Monica Urban Runoff Reduction Requirements.

(1) Locations where seasonal high groundwater is within ~~5~~ 10 feet of the surface.

Subparts 4.E.III.2.(c)(1), (2), and (3) are to be replaced by the following text.

When a Permittee finds that the project applicant has demonstrated technical infeasibility, after confirming that the project design minimizes the impervious area to the extent allowed by local zoning regulations and considering recommended protective riparian buffers and protection of *environmentally sensitive areas, and the use of all available LID controls including green roofs and rainfall harvest and use, and biofiltration ~~geotechnical site constraints~~, the Permittee shall require the applicant to provide off-site mitigation.*

The required off-site mitigation volume will be equal to:

(Eq .3) $Mv = 1.5 * [Dv * (Dv - Ov/DV)]$

where
Mv = mitigation volume,
Dv = SWQDv, and
Ov = on-site volume = Rv (volume retained on-site) + Bv (on-site biofiltration volume).

The project applicant must perform off-site mitigation or provide sufficient funding for public or private off-site mitigation to achieve equivalent mitigation storm water volume through infiltration, reuse, evapotranspiration, and/or biofiltration.

The Permittees must develop a prioritized list of off-site mitigation projects, and when feasible, the mitigation must be directed to the highest priority mitigation project within the same drainage area as, or the nearest downstream drainage from, the proposed development or re-development. ~~*mitigation must be directed to the highest priority mitigation project within the affected drainage system (defined as draining the same hydrologic area) as identified in the Watershed Plan.*~~

Subpart 4.E.III.2.(c)(4) is to remain consistent with the Ventura County MS4 permit.
Subpart 4.E.III.2.(c)(5) is to be deleted.
Subpart 4.E.III.2.(d) is to remain essentially the same as that in the Ventura County MS4 permit except that the reference to the "5 percent EIA requirement" is to be replaced with "by retaining the SWQDv."

Recommended Changes to Subpart 4.E.III.3.—Hydromodification (Flow/Volume/Duration) Control Criteria

The Working Group expressed consensus that the L.A. MS4 permit should include a "placeholder" requirement to address hydromodification pending more detailed or site-specific requirements to be developed by the Permittees based on the pending SWRCB-funded studies. The placeholder should be stringent to be protective of the most sensitive or vulnerable water bodies and to incentivize the Permittees to conduct further analysis. A second goal is to identify a simple but protective approach for projects disturbing less than 50 acres. The following are recommended Interim Hydromodification Control Criteria.

4.E.III.3.(a)(3) Interim Hydromodification Control Criteria

RB-AR32601

(A) The Interim Hydromodification Control Criteria to protect natural drainage systems (to be defined) until Permittees complete Hydromodification Control Plans (HCPs), described in subpart (4) below, are as follows:

(i) ***<u>Projects disturbing land area less than 50 acres within natural drainage systems</u>*** *will be presumed to meet pre-development hydrology if one of the following demonstrations is made:*

(I) The project is designed to retain on-site, through infiltration, evapotranspiration, and/or harvest and reuse, the stormwater volume from the runoff of the 95th percentile storm, or

(II) The runoff flow rate, volume, velocity, and duration for the post-development condition do not exceed the pre-development ~~(i.e., naturally occurring)~~ condition for the 2-year, 24-hour rainfall event. This condition may be substantiated by simple screening models, including those described in Hydromodification Effects on Flow Peaks and Durations in Southern California Urbanizing Watersheds *(Hawley et al., 2011) or other models acceptable to the Permittee, or*

(III) The Erosion Potential (Ep) in the receiving water channel will approximate 1, as determined by a Hydromodification Analysis Study and the equation presented in Attachment X.

(ii) ***Projects disturbing land area greater than 50 acres within natural drainage systems (to be defined)*** *will be presumed to meet pre-development hydrology based on the successful demonstration of one of the following conditions:*

(I) The site infiltrates on-site at least the runoff from a 2-year, 24-hour storm event, or

(II) The runoff flow rate, volume, velocity, and duration for the post-development condition does not exceed the pre-development ~~(i.e., naturally occurring)~~ condition for the 2-year, 24-hour ~~or the 10-year, 24-hour~~ rainfall events. These conditions must be substantiated by hydrologic modeling acceptable to the Permittee, or

(III) The Erosion Potential (Ep) in the receiving water channel will approximate 1, as determined by a Hydromodification Analysis Study and the equation presented in Attachment X.

Recommended Changes to Subpart 4.E.III.4.—Water Quality Mitigation Criteria

~~This section is largely obsolete because the permit language as drafted no longer allows for treatment of the runoff from the EIA. Suggest replacing the existing text with the following:~~

The smaller Working Group decided that this section should retain provisions for treatment and recommended the following language change:

<u>(a) Each Permittee shall require all New Development and Redevelopment projects</u> ~~identified in subpart 4.E.II~~ <u>that have demonstrated that it is technically infeasible to retain 100 percent of the SWQDv on-site, per the criteria defined in subpart 4.E.III.2.(a) and (b), to provide treatment of the excess storm water</u>

runoff from the site. This requirement is in addition to the Alternative Compliance Measures described in subpart 4.E.III.2(c). The Permittee shall require these projects to implement post-construction storm water treatment BMPs and control measures to reduce pollutant loading as necessary (1) to meet the technology-based performance levels listed in Table X or (2) to ensure that the discharge does not cause or contribute to an exceedance of water quality standards in the receiving water, whichever is more stringent.

Table X—Technology-Based Treatment [Note: This table to be completed after agreement on language and approach]

Pollutant	**Effluent Concentration**	**References**
		SWRCB draft Phase II MS4 Permit. American Society of Civil Engineers, Storm Water BMPs

In addition to the requirements for controlling pollutant discharges as described in subpart 4.E.III.1 and the treatment requirements described above, the Permittees will ensure that the New Development and Redevelopment project will not cause the Permittee to exceed applicable wasteload allocations (WLAs) or fail to comply with Total Maximum Daily Load (TMDL) implementation plan requirements as described in part 5 of this permit.

Recommended Changes to Subpart 4.E.IV.—Implementation

In the Ventura County MS4 permit, the specifics of the implementation measures are to be developed in the *Ventura County Technical Guidance Manual*. PG recommends that the L.A. MS4 permit provide more prescriptive minimum standards to prevent soil compaction during construction and to provide enhanced protection of riparian buffers, habitat for endangered or threatened species, and preservation of native vegetation.

Recommended Changes to Subpart 4.E.IV.3.—Alternative Post-Construction Storm Water Mitigation

The recommended change deletes the reference to EIA and holds the RPAMP to meeting the on-site retention requirement. As written, this provision would not allow biofiltration or mitigation outside the Master Plan area.

(b)(3) ~~Reduce the percentage of Effective Impervious Area (EIA) to a target of 5 percent or less of the Redevelopment Project Area,~~ Captures or intercepts the SWQDv as defined in subpart 4.E.III.1(a).

Recommended Changes to Subpart 4.E.IV.4.—Developer Technical Guidance and Information:

The smaller Working Group agreed that Permittees should not be required to develop a Technical Guidance Manual. The Permittees are free to develop such manuals for internal guidance or guidance to their community. However, the manuals will not be subject to review or approval by the Regional Water Board Executive Officer, nor will they serve as a defense for failure to meet the terms of the MS4 permit. Therefore, it might be necessary to provide more detailed requirements in the MS4 permit. The following are examples of model requirements that could be included in subpart 4.E.IV.4.

- *Locate structures on less pervious soils where possible so as to preserve areas with permeable soils (Hydrologic Soil Group Classes A and B, as defined by the National Cooperative Soil Survey), to the extent possible, for use in storm water infiltration and groundwater recharge. Minimize the need to grade the site by concentrating development in areas with minimal non-engineered slopes and existing infrastructure, and mitigate any construction disturbance.*
- *The total disturbed area shall be no greater than 110 percent of the final project footprint plus the area of the construction storm water detention basins, if any, and as required to meet applicable Fire Department regulations for brush clearance.*
- *Construction vehicles shall be confined at all times to the area specifically permitted to be disturbed by construction as depicted in the approved construction documents. Physical barriers shall be used to designate and protect the boundary between disturbed and undisturbed areas.*
- *Materials staging shall be confined to the area permitted to be disturbed by construction or may be temporarily stored off-site at an approved location at the Contractor's option.*
- *Construction vehicles shall not traverse areas within the drip lines of those trees and other landscaping to be preserved. Approved visible physical barriers, such as continuous fencing, shall be provided to completely surround all trees and other landscaping to be preserved. Barriers shall be placed not less than 5 feet outside the drip lines of trees.*
- *Preserve or restore continuous riparian buffers widths along all natural drainages to a minimum width of 100 feet from each bank top, for a total of 200 feet plus the width of the stream, unless the Watershed Plan demonstrates that a smaller riparian buffer width is protective of water quality, hydrology, and aquatic life beneficial uses within a specific drainage.*
- *Identify and avoid development of areas containing habitat with threatened or endangered plant and animal species.*[1]

In addition, the Regional Water Board may consider including a spreadsheet for calculating the SWQDv and storm water runoff from the design storm, giving credit (and incentives) for maintaining trees, maintaining riparian buffers, and using various LID elements, including green roofs, pervious pavement, and rainfall harvesting. An example copy of the spreadsheet from the California Construction General Permit, Appendix 2.1, is provided as a separate attachment. It applies to post-construction development outside an MS4 jurisdiction. It could be modified, however, for use in the L.A. MS4, and it might be especially useful for smaller projects.

Appendix A

Excerpt from the *Technical Guidance on Implementing the Stormwater Runoff Requirements for Federal Projects under Section 438 of the Energy Independence and Security Act.*

United State Environmental Protection Agency, Office of Water (4503T), EPA 841-B-09-001. Washington, D.C. December 2009.

Pp. 12–16

Establishing Section 438 Performance Design Objectives
Described below are options site designers can use to comply with Section 438. There may be situations where Option 1 (retaining the 95th percentile rainfall event) is not protective enough to maintain or restore the predevelopment hydrology of the project (for example, in some headwater streams). In these cases, Option 2 (site-specific hydrologic analysis) could be used to determine the types of stormwater practices necessary to preserve predevelopment runoff conditions. Option 2 could also be used if predevelopment runoff conditions can be maintained by retaining less than the 95th percentile rainfall event. Because a performance based approach was selected in lieu of a prescriptive requirement in order to provide site designers maximum flexibility in selecting control practices appropriate for the site, Option 2 was provided in recognition that there are established methodologies that can be utilized to estimate the volume of infiltration and evapotranspiration based on site-specific hydrology and thus establish the predevelopment hydrology performance design objectives.

Option 1: Retain the 95th Percentile Rainfall Event

One approach to establishing the performance design objectives is to design, construct, and maintain stormwater management practices that manage rainfall onsite, and prevent the off-site discharge of the precipitation from all rainfall events less than or equal to the 95th percentile rainfall event to the maximum extent technically feasible (METF). This objective should be accomplished by the use of practices that infiltrate, evapotranspire and/or harvest and use rainwater. The 95th percentile rainfall event is the event whose precipitation total is greater than or equal to 95 percent of all storm events over a given period of record. For example, to determine what the 95th percentile storm event is in a specific location, all 24 hour storms that have recorded values over a 30 year period would be tabulated and a 95th percentile storm would be determined from this record, i.e., 5% of the storms would be greater than the number determined to be the 95th percentile storm. Thus the 95th percentile storm would be represented by a number such as 1.5 inches, and this would be the design storm (example 95th percentile storm events for selected cities are presented in Table 1). The designer would then select a system of practices, to the METF, that infiltrate, evapotranspire or harvest and use this volume multiplied by the total area of the facility/project footprint. Methods and data used to estimate the 95th percentile event are discussed in Part II of this document.

For the purposes of this guidance, retaining all storms up to and including the 95th percentile storm event is analogous to maintaining or restoring the pre-development hydrology with respect to the volume, flow rate, duration and temperature of the runoff for most sites. This 95th percentile approach was identified and recommended because this storm size represents the volume that appears to best represent the volume that is fully infiltrated in a natural condition and thus should be managed onsite to restore and maintain this pre-development hydrology for duration, rate and volume of stormwater flows. In general, only large storms generate significant runoff. In addition, this approach was identified because it employs natural treatment and flow attenuation methods that are presumed to have existed on the site before construction of infrastructure (e.g., building, roads, parking lots, driveways,) and is intended to infiltrate or evapotranspirate the full volume of the 95th percentile storm. Because this approach necessitates the use of practices that generally preclude extended detention, it will also typically address the issue of maintaining predevelopment temperatures. However, in cases where there are discharges to cool water streams or other sensitive receiving waters, additional strategies may be needed to ensure that stormwater discharges do not result in greater thermal impacts than would occur in pre-development conditions (Schueler and Helfrich, 1988).

Where technically feasible, the goal of Option 1 is that one hundred percent (100%) of the volume of water from storms less than or equal to the 95th percentile event over the footprint of the project should not be discharged to surface waters. In some cases, runoff can be harvested and used and ultimately may be discharged to surface waters or a sanitary treatment system; such direct or indirect discharges must be authorized or allowed by the regulatory authority. For example, if runoff is captured for nonpotable uses such as toilet flushing or other uses that are not irrigation related, these waters potentially could be discharged into the sanitary sewer system. Preferred mechanisms for retaining discharges from storms greater than the 95th percentile event are through overflow or diversion for the volume that exceeds the 95th percentile amount. Because standard underdrains typically discharge from smaller storms as well, underdrain designs, if employed, should ensure adequate retention capacity for the 95th percentile event volume. For structures such as roofs and paved surfaces that can increase the temperature of stormwater runoff, materials that minimize temperature increases (e.g., concrete vs. asphalt; vegetated roofs) should be considered and used as appropriate.

Retaining 100 percent of all rainfall events equal to or less than the 95th percentile rainfall event was identified as Option 1 because small, frequently-occurring storms account for a large proportion of the annual precipitation volume, and the runoff from those storm events also significantly alters the discharge frequency, rate and temperature of the runoff.

The runoff produced by these small storms and the initial portion of larger storms has a strong negative cumulative impact on receiving water hydrology and water quality. In areas that have been developed, runoff is generated from almost all storms, both small and large, due to the impervious surfaces associated with development and the loss of soils and vegetation. In contrast, natural or undeveloped areas discharge little or no runoff from small storms because the rain is absorbed by the landscape and vegetation. Studies have shown that increases in runoff event frequency, volume and rate can be diminished or eliminated through the use of GI/LID designs and practices, which infiltrate, evapotranspire and capture and use stormwater.

Option 1 was identified because it is a simplified approach to meet the intent of Section 438 in contrast to Option 2 which requires the designer to conduct a hydrologic analysis of the site based on site-specific conditions.

Option 2: Site-Specific Hydrologic Analysis

Another approach to establishing the performance design objective is to design, construct, and maintain stormwater management practices that preserve the pre-development runoff conditions following construction. Option 2 allows the designer to conduct a site-specific hydrologic analysis to determine the pre-development runoff conditions instead of using the estimated volume approach of Option 1. Under Option 2, the pre-development hydrology would be determined based on site-specific conditions and local meteorology by using continuous simulation modeling techniques, published data, studies, or other established tools. If the designer elects to use Option 2, the designer would then identify the pre-development condition of the site and quantify the post-development runoff volume and peak flow discharges that are equivalent to pre-development conditions.

The post-construction rate, volume, duration and temperature of runoff should not exceed the pre-development rates and the predevelopment hydrology should be replicated through site design and other appropriate practices to the maximum extent technically feasible. These goals should be accomplished through the use of infiltration, evapotranspiration, and/or rainwater harvesting and use. Defensible and consistent hydrological assessment tools should be used and documented. Additional discussions of appropriate methodologies to use in assessing site hydrology have been included in the technical sections of this document. See, for example, the discussion of spreadsheet versions or curve numbers based on the Natural Resource Conservation Service Technical Release 55 (TR-55) Method in Appendix A of this document.

RB-AR32607

(c) **Investigation of Complaints Regarding Facilities – Transmitted by the Regional Water Board Staff:** Each Permittee shall initiate, within one business day,[1] investigation of complaints (other than non-storm water discharges) to the MS4 from facilities within its jurisdiction. The initial investigation shall include, at a minimum, a limited inspection of the facility to confirm the complaint to determine if the facility is effectively complying with the municipal storm water urban runoff ordinances and, if necessary, to oversee corrective action.

(d) **Assistance of Regional Water Board Enforcement Actions:** As directed by the Regional Water Board Executive Officer, Permittees shall assist Regional Water Board enforcement actions by: helping in identification of current owners, operators, and lessees of facilities; providing staff, when available, for joint inspections with Regional Water Board inspectors; appearing as witnesses in Regional Water Board enforcement hearings; and providing copies of inspection reports and other progressive enforcement documentation.

(e) **Participation in a Task Force:** The Permittees shall participate with the Regional Water Board, and other public agencies on an enforcement task force such as the Storm Water Task Force, to communicate concerns regarding special cases of storm water violations by industrial and commercial facilities and to develop a coordinated approach to enforcement action.

E. Planning and Land Development Program

I. Purpose

1. The Permittees shall implement a Planning and Land Development Program pursuant to part 4.E. for all New Development and Redevelopment projects subject to this Order to:
   (a) Lessen the water quality impacts of development by using smart growth practices such as compact development, directing development towards existing communities via infill or redevelopment, safeguarding of environmentally sensitive areas, mixing of land uses (e.g., homes, offices, and shops), transit accessibility, and better pedestrian and bicycle amenities.
   (b) Minimize the adverse impacts from storm water runoff on the biological integrity of Natural Drainage Systems and the beneficial uses of waterbodies in accordance with requirements under CEQA (Cal. Pub. Resources Code § 21100).
   (c) Minimize the percentage of effective impervious surfaces on land developments to mimic predevelopment water balance through infiltration, evapotranspiration and reuse.

[1] Permittees may comply with the Permit by taking initial steps (such as logging, prioritizing, and tasking) to "initiate" the investigation within that one business day. However, the Regional Water Board would expect that the initial investigation, including a site visit, to occur within four business days.

RB-AR32608

(d) Minimize pollutant loadings from impervious surfaces such as roof-tops, parking lots, and roadways through the use of properly designed, technically appropriate BMPs (including Source Control BMPs such as good housekeeping practices), Low Impact Development Strategies, and Treatment Control BMPs.
(e) Properly select, design and maintain Treatment Control BMPs and Hydromodification Control BMPs to address pollutants that are likely to be generated, assure long-term function, and to avoid the breeding of vectors.[1]
(f) Prioritize the selection of BMPs suites to remove storm water pollutants, reduce storm water runoff volume, and beneficially reuse storm water to support an integrated approach to protecting water quality and managing water resources in the following order of preference:
  (1) Infiltration BMPs
  (2) BMPs that store and reuse storm water runoff.
  (3) BMPs that incorporate vegetation to promote pollutant removal and runoff volume reduction and integrate multiple uses
  (4) BMPs which percolate runoff through engineered soil and allow it to discharge downstream slowly
  (5) Approved modular/ proprietary treatment control BMPs that are based on LID concepts and that meet pollution removal goals

II. Applicability

1. New Development Projects.
(a) Development projects subject to Permittee conditioning and approval for the design and implementation of post-construction controls to mitigate storm water pollution, prior to completion of the project(s), are:
  (1) All development projects equal to 1 acre or greater of disturbed area and adding more than 10,000 square feet of impervious surface area
  (2) Industrial park 10,000 square feet or more of surface area
  (3) Commercial strip mall 10,000 square feet or more of impervious surface area
  (4) Retail gasoline outlet 5,000 square feet or more of surface area
  (5) Restaurant (SIC 5812) 5,000 square feet or more of surface area
  (6) Parking lot 5,000 square feet or more of impervious surface area, <u>or</u> with 25 or more parking spaces
  (7) Streets, roads, highways, and freeway construction of 10,000 square feet or more of impervious surface area shall incorporate USEPA guidance regarding Managing Wet Weather with Green Infrastructure: Green Streets to the maximum extent practicable.
  (8) Automotive service facilities (SIC 5013, 5014, 5511, 5541, 7532-7534 and 7536-7539) [5,000 square feet or more of surface area]

[1] Treatment BMPs when designed to drain within 72 hours of the end of rainfall minimize the potential for the breeding of vectors.

RB-AR32609

(9) Redevelopment projects in subject categories that meet Redevelopment thresholds (identified in subpart E.II.2 below)

(10) Projects located in or directly adjacent to, or discharging directly to an Environmentally Sensitive Area (ESA), where the development will:
  (A) Discharge storm water runoff that is likely to impact a sensitive biological species or habitat; and
  (B) Create 2,500 square feet or more of impervious surface area

(11) Single-family hillside homes. To the extent that a Permittee may lawfully impose conditions, mitigation measures or other requirements on the development or construction of a single-family home in a hillside area as defined in the applicable Permittee's Code and Ordinances, each Permittee shall require that during the construction of a single-family hillside home, the following measures to be implemented:
  (A) Conserve natural areas
  (B) Protect slopes and channels
  (C) Provide storm drain system stenciling and signage
  (D) Divert roof runoff to vegetated areas before discharge unless the diversion would result in slope instability
  (E) Direct surface flow to vegetated areas before discharge unless the diversion would result in slope instability

2. Redevelopment Projects

(a) Redevelopment projects subject to Permittee conditioning and approval for the design and implementation of post-construction controls to mitigate storm water pollution, prior to completion of the project(s), are:
  (1) Land-disturbing activity that results in the creation or addition or replacement of 5,000 square feet or more of impervious surface area on an already developed site on development categories identified in subpart 4.E.III.1.
  (2) Where Redevelopment results in an alteration to more than fifty percent of impervious surfaces of a previously existing development, and the existing development was not subject to post development storm water quality control requirements, the entire project must be mitigated.
  (3) Where Redevelopment results in an alteration to less than fifty percent of impervious surfaces of a previously existing development, and the existing development was not subject to post development storm water quality control requirements, only the alteration must be mitigated, and not the entire development.

(b) Redevelopment does not include routine maintenance activities that are conducted to maintain original line and grade, hydraulic capacity, original purpose of facility or emergency redevelopment activity required to protect public health and safety. Impervious surface replacement, such as the reconstruction of parking lots and roadways which does not disturb additional area and maintains the original grade and alignment, is considered a routine maintenance activity. Redevelopment does not include the repaving of existing roads to maintain original line and grade.

RB-AR32610

(c) Existing single-family dwelling and accessory structures are exempt from the Redevelopment requirements unless such projects create, add, or replace 10,000 square feet of impervious surface area.

3. Effective Date –The New Development and Redevelopment requirements contained in Section E of the Order shall begin (90 calendar days) after Regional Water Board Executive Officer approval of the changes to the Technical Guidance Manual needed to comply with this permit. After that date all discretionary permit projects or project phases that have not been deemed complete for processing, or discretionary permit projects without vesting tentative maps that have not requested and received an extension of previously granted approvals must comply with the requirements in Section E. Projects that have been deemed complete prior to the update of the technical design manual are not subject to this section. For Permittee's projects the effective date shall be the date the governing body or their designee approves initiation of the project design.

III. New Development/ Redevelopment Performance Criteria

1. Integrated Water Quality/ Flow Reduction/Resources Management Criteria
   (a) Except as provided in subpart 4.E.III.1.(c) below, Permittees shall require all New Development and Redevelopment projects identified in subpart 4.E.II to control pollutants, pollutant loads, and runoff volume emanating from impervious surfaces through infiltration, storage for reuse, evapotranspiration, or bioretention/ biofiltration by reducing the percentage of Effective Impervious Area (EIA) to 5 percent or less of the total project area.
   (b) Impervious surfaces may be rendered "ineffective", and thus not count toward the 5 percent EIA limitation, if the stormwater runoff from those surfaces is fully retained on-site for the design storm event specified in provision (c), below. To satisfy the EIA limitation and low-impact development requirements, the permittees must require stormwater runoff to be infiltrated, reused, or evapotranspired on-site through a stormwater management technique allowed under the terms of this permit and implementing documents. If on-site retention is determined to be technically infeasible pursuant to 4.E.III.2(b), an on-site biofiltration system that achieves equivalent stormwater volume and pollutant load reduction as would have been achieved by on-site retention shall satisfy the EIA limitation. An on-site biofiltration system that releases above the design volume shall achieve 1.5 times the amount of stormwater volume and pollutant load reduction as would have been achieved by on-site retention and, thereby, shall satisfy the EIA limitation.
   (c) The permittees shall require all features constructed or otherwise utilized to render impervious surfaces "ineffective", as described in provision (b), above, to be properly sized to infiltrate, store for reuse, or evapotranspire, without any runoff at least the volume of water, or in the case of biofiltration with release above the design volume, 1.5 times the volume of water, that results from:

RB-AR32611

(1) The 85th percentile 24-hour runoff event determined as the maximized capture stormwater volume for the area using a 48 to 72-hour draw down time, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998);
(2) The volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in the Ventura County Technical Guidance Manual for Storm Water Quality Control Measures (July 2002 and its revisions); or
(3) The volume of runoff produced from a 0.75 inch storm event.

(d) To address any impervious surfaces that may not be rendered "ineffective", surface discharge of stormwater runoff if any, that results from New Development and Redevelopment projects identified in subpart 4.E.II which have complied with subparts 4.E.III.1.(a)-(c), above, shall be mitigated in accordance with subpart 4.E.III.4.

2. Alternative Compliance for Technical Infeasibility

(a) To encourage smart growth and infill development of existing urban centers where on-site compliance with post-construction requirements may be technically infeasible, the permittees may allow projects that are unable to meet the Integrated Water Quality/Flow Reduction/Resources Management Criteria in subpart 4.E.III.1, above, to comply with this permit through the alternative compliance measures described in subpart 4.E.III.2.(c), below.

(b) To utilize alternative compliance measures, the project applicant must demonstrate that compliance with the applicable post-construction requirements would be technically infeasible by submitting a site-specific hydrologic and/or design analysis conducted and endorsed by a registered professional engineer, geologist, architect, and/or landscape architect. Technical infeasibility may result from conditions including the following:
(1) Locations where seasonal high groundwater is within 5 feet of the surface
(2) Locations within 100 feet of a groundwater well used for drinking water
(3) Brownfield development sites or other locations where pollutant mobilization is a documented concern
(4) Locations with potential geotechnical hazards
(5) Smart growth and infill or redevelopment locations where the density and/ or nature of the project would create significant difficulty for compliance with the on-site volume retention requirement
(6) Other site or implementation constraints identified in the LID Technical Guidance document required by subpart 4.E.IV.4.

(c) Alternative Compliance Measures. When a permittee finds that a project applicant has demonstrated technical infeasibility, the permittee shall identify alternative compliance measures that the project will need to comply with as a substitute for the otherwise applicable post-construction requirements listed in subparts 4.E.III.1.(a)-(c) of this permit. The Ventura County Technical Guidance Manual shall be revised to identify the alternative compliance measures and shall include the following requirement:

RB-AR32612

(1) Minimum on-site requirement. The project must take all feasible measures to reduce the percentage of Effective Impervious Area to no more than 30 percent of the total project area and treat all remaining runoff pursuant to the design and sizing requirements of subparts 4.E.III.1.(b)-(d).

(2) Offsite mitigation volume. The difference in volume between the amount of stormwater infiltrated, reused, and/ or evapotranspired and/or biofiltered by the project on-site and the otherwise applicable requirements of subparts 4.E.III.1.(a)-(c) (the "offsite mitigation volume'), above, must be mitigated by the project applicant either by performing offsite mitigation that is approved by the permittee or by providing sufficient funding for public or private offsite mitigation to achieve equivalent stormwater volume and pollutant load reduction through infiltration, reuse, evapotranspiration and/ or biofiltration.
   - For projects with demonstrable technical infeasibility that cannot reduce the Effective Impervious Area to 5% or less of the total project, but are able to reduce the Effective Impervious Area to no more than 30 percent of the total project, mitigation or payment in lieu must be equivalent to the amount of stormwater not managed on site.
   - For projects with demonstrable technical infeasibility that cannot reduce the Effective Impervious Area to 30% of the total project or less, mitigation or payment in lieu must be for 1.5 times the amount of stormwater not managed on site

(3) Location of off site mitigation. Offsite mitigation projects must be located in the same sub-watershed (defined as draining to the same hydrologic area in the Basin Plan) as the new development or redevelopment project. A list of eligible public and private offsite mitigation projects available for funding shall be identified by the Permittees and provided to the project applicant. Off site mitigation projects include green streets projects, parking lot retrofits, other site specific LID BMPs, and regional BMPs. Project applicants seeking to utilize these alternative compliance provisions may propose other offsite mitigation projects, which the Permittees may approve if they meet the requirements of this subpart.

(4) Timing and Reporting Requirements for Offsite Mitigation Projects. The Permittee(s) shall develop a schedule for the completion of offsite mitigation projects, including milestone dates to identify fund, design, and construct the projects. Offsite mitigation projects shall be completed as soon as possible, and at the latest, within 4 years of the certificate of occupancy for the first project that contributed funds toward the construction of the offsite mitigation project, unless a longer period is otherwise authorized by the Executive Officer. For public offsite mitigation projects, the permittees must provide in their annual reports a summary of total offsite mitigation funds raised to date and a description (including location, general design concept, volume of water expected to be retained, and total estimated budget) of all pending public offsite mitigation projects. Funding sufficient to address the offsite mitigation volume must be

RB-AR32613

transferred to the permittee (for public offsite mitigation projects) or to an escrow account (for private offsite mitigation projects) within one year of the initiation of construction.

(5) The project applicant must demonstrate that the EIA achieved on-site is as close to 5 percent EIA as technically feasible, given the site's constraints.

(d) Watershed equivalence. Regardless of the methods through which permittees allow project applicants to implement alternative compliance measures, the sub-watershed -wide (defined as draining to the same hydrologic area in the Basin Plan) result of all development must be at least the same level of water quality protection as would have been achieved if all projects utilizing these alternative compliance provisions had complied with subparts 4.E.III.1.(a)-(d) of the permit. The permittees shall provide in their annual report to the Regional Board a list of mitigation project descriptions and pollutant and flow reduction analyses (compiled from design specifications submitted by project applicants and approved by the permittee(s)) comparing the expected aggregate results of alternative compliance projects to the results that would otherwise have been achieved by meeting the 5 percent EIA requirement on-site.

3. Hydromodification (Flow/ Volume/ Duration) Control Criteria

(a) Each Permittee shall require all New Development and Redevelopment projects identified in subpart 4.E.II to implement hydrologic control measures, to prevent accelerated downstream erosion and to protect stream habitat in natural drainage systems. The purpose of the hydrologic controls is to minimize changes in post-development hydrologic storm water runoff discharge rates, velocities, and duration. This shall be achieved by maintaining the project's pre-project storm water runoff flow rates and durations.

(1) Description

(A) Hydromodification control in natural drainage systems shall be achieved by maintaining the Erosion Potential (E_p) in streams at a value of 1, unless an alternative value can be shown to be protective of the natural drainage systems from erosion, incision, and sedimentation that can occur as a result of flow increases from impervious surfaces and damage stream habitat (see Attachment "E" - Determination of Erosion Potential)

(B) Hydromodification control may include one, or a combination of on-site, regional subregional hydromodification control BMPs, LID strategies, or stream restoration measures, with preference given to LID strategies and hydromodification control BMPs. Any in-stream restoration measure shall not adversely affect the beneficial uses of the natural drainage systems

(C) Natural drainage systems, which include unlined or unimproved (not engineered) creeks, streams, rivers and their tributaries, are located in the following watersheds:

(i) Ventura River

(ii) Santa Clara River

RB-AR32614

(iii) Calleguas Creek
(iv) Malibu Creek
(v) Miscellaneous Ventura Coastal

(D) The Southern California Storm Water Monitoring Coalition (SMC) is developing a regional methodology to eliminate or mitigate the adverse impacts of hydromodification as a result of urbanization, including hydromodification assessment and management tools.

(i) The SMC has identified the following objectives for the Hydromodification Control Study (HCS):

(I) Establishment of a stream classification for Southern California streams

(II) Development of a deterministic or predictive relationship between changes in watershed impervious cover and stream-bed/ stream bank enlargement

(III) Development of a numeric model to predict stream-bed/ stream bank enlargement and evaluate the effectiveness of mitigation strategies

(E) The Permittees shall participate in the SMC HCS to develop:

(i) A regional stream classification system
(ii) A numerical model to predict the hydrological changes resulting from new development
(iii) A numerical model to identify effective mitigation strategies

(F) Until the completion of the SMC HCS, Permittees shall implement the Interim Hydromodification Control Criteria, described in subpart 4.E.III.3(a)(3)(A) below, to control the potential adverse impacts of changes in hydrology that may result from new development and redevelopment projects identified in subpart 4.E.II

(G) Existing single-family structures are exempt from the Hydromodification control requirements unless such projects disturb one acre or more of land or create, add, or replace 10,000 square feet or more of impervious surface area

(2) Exemptions to Hydromodification Controls. Permittees may exempt the following New Development and Redevelopment projects from implementation of Hydromodification controls where assessments of downstream channel conditions and proposed discharge hydrology indicate that adverse Hydromodification effects to present and future beneficial uses of Natural Drainage Systems are unlikely:

(A) All projects that disturb less than one acre.

(B) Projects that are replacement, maintenance or repair of a Permittee's existing flood control facility, storm drain, or transportation network.

(C) Redevelopment Projects in the Urban Core that do not increase the effective impervious area or decrease the infiltration capacity of pervious areas compared to the pre-project conditions.

RB-AR32615

(D) Projects that have any increased discharge go directly or via a storm drain to a sump, lake, area under tidal influence, into a waterway that has a 100-year peak flow (Q100) of 25,000 cfs or more, or other receiving water that is not susceptible to Hydromodification impacts;

(E) Projects that discharge directly or via a storm drain into concrete or improved (not natural) channels (e.g., rip rap, sackcrete, etc.), which, in turn, discharge into receiving water that is not susceptible to Hydromodification impacts (as in D above).

(3) Interim Hydromodification Control Criteria

(A) The Interim Hydromodification Control Criteria to protect natural drainage systems until Permittees complete Hydromodification Control Plans (HCPs), described in subpart 4.E.III.3(a)(4) below, are as follows:

(i) **Projects disturbing land area of less than fifty acres** will be subject to LID and/or source or treatment BMPs as addressed in this permit. The combined effects of LID and the treatment BMPs are considered adequate for Hydromodification control for projects that disturb less than 50 acres.

(ii) **Projects disturbing land areas of fifty acres or greater** Projects in this category shall develop and implement a Hydromodification Analysis Study (HAS) that demonstrates that post development conditions are expected to approximate the pre-project erosive effect of sediment transporting flows in receiving waters. The HAS must lead to the incorporation into the project design features intended to approximate, to the extent feasible, an Erosion Potential value of 1 or any alternative value that can be shown to be protective of the natural drainage systems from erosion, incision, and sedimentation that can occur as a result of flow increases from impervious surfaces and damage stream habitat in natural drainage systems, or

(I) Alternatively, project proponents in this category may elect to develop, in partnership with Permittees, an equivalent implementation method based on flow duration control in the form of nomographs relating planned impervious area and local soil type (infiltration rates) to determine hydromodification control BMP volume and land area requirements for the proposed project. The nomographs shall be derived from continuous simulation modeling using Ventura County specific rain gauge records and soil types, and calibrated using data from a local undeveloped watershed with similar conditions; or

(II) Alternatively, the Co-Permittees may revise the Ventura County Technical Guidance Manual for Stormwater

Quality Control Measures to address projects that disturb more than 50 acres.

(4) Final Criteria

(A) The Permittees shall develop and implement watershed specific HCPs no later than (180 days) after the completion of the SMC HCS.

(i) The HCP shall identify:

(I) Stream classifications

(II) Flow rate and duration control methods

(III) Sub-watershed mitigation strategies

(IV) Stream restoration measures, which will maintain the stream and tributary Erosion Potential at 1 unless an alternative value can be shown to be protective of the natural drainage systems from erosion, incision, and sedimentation that can occur as a result of flow increases from impervious surfaces and damage stream habitat in natural drainage system tributaries

(B) The HCP shall contain the following elements:

(i) Hydromodification Management Standards

(ii) Natural Drainage Areas and Hydromodification Management Control Areas

(iii) New Development and Redevelopment Projects subject to the HCP

(iv) Description of authorized Hydromodification Management Control BMPs

(v) Hydromodification Management Control BMP Design Criteria.

(vi) For flow duration control methods, the range of flows to control for, and goodness of fit criteria

(vii) Allowable low critical flow, Q_c, which initiates sediment transport

(viii) Description of the approved Hydromodification Model.

(ix) Any alternate Hydromodification Management Model and Design

(x) Stream Restoration Measures Design Criteria

(xi) Monitoring and Effectiveness Assessment

(xii) Record Keeping

(C) The HCP shall be deemed in effect upon Executive Officer approval.

4. Water Quality Mitigation Criteria

(a) Each Permittee shall require all New Development and Redevelopment projects identified in subpart 4.E.II to implement post-construction storm water treatment BMPs and control measures to mitigate storm water pollution as follows:

(1) Projects disturbing land areas less than 50 acres

(A) Volumetric Treatment Control BMP

(i) The 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area using a 48 to

RB-AR32617

72-hour draw down time, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998)*; or

(ii) The volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in the Ventura County Technical Guidance Manual for Storm Water Quality Control Measures (July 2002 and its revisions); or

(iii) The volume of runoff produced from a 0.75 inch storm event, prior to its discharge to a storm water conveyance system;[1] and/ or

(B) Flow Based Treatment Control BMP

(i) The flow of runoff produced from a rain event equal to at least 0.2 inches per hour intensity; or

(ii) The flow of runoff produced from a rain event equal to at least 2 times the 85th percentile hourly rainfall intensity as determined from local rainfall records; or

(iii) Eight percent of the 50-year storm design flow rate as determined from the method recommended in the Ventura County Technical Guidance Manual for Storm Water Quality Control Measures (July 2002 and its revisions)

(2) Projects disturbing land area of 50 acres or greater

(A) Eighty percent of the average runoff volume using an appropriate public domain continuous flow model (such as Storm Water Management Model (SWMM) or Hydrologic Engineering Center – Hydrologic Simulation Program – Fortran (HEC-HSPF), using the local rainfall record and relevant BMP Performance data.

IV. Implementation

1. Maintenance Agreement and Transfer

(a) Prior to issuing approval for final occupancy each Permittee shall require that all new development and redevelopment projects subject to post-construction BMP requirements provide an operation and maintenance plan and verification of ongoing maintenance provisions for LID practices, Treatment Control BMPs, and Hydromodification Control BMPs including but not limited to: final map conditions, legal agreements, covenants, conditions or restrictions, CEQA mitigation requirements, conditional use permits, and/ or other legally binding maintenance agreements.

(1) Verification at a minimum shall include the developer's signed statement accepting responsibility for maintenance until the responsibility is legally transferred; and either

[1] This option is available only for construction projects that disturb land area less than 5 acres.

RB-AR32618

(A) A signed statement from the public entity assuming responsibility for BMP maintenance; or

(B) Written conditions in the sales or lease agreement, which require the property owner or tenant to assume responsibility for BMP maintenance and conduct a maintenance inspection at least once a year; or

(C) Written text in project covenants, conditions, and restrictions (CCRs) for residential properties assigning BMP maintenance responsibilities to the Home Owners Association (HOA); or

(D) Any other legally enforceable agreement or mechanism that assigns responsibility for the maintenance of BMPs.

(b) Each Permittee shall require all development projects subject to post-construction BMP requirements to provide a plan for the operation and maintenance of all structural and treatment controls. The Operation and Maintenance plan shall follow the Technical Guidance Manual Appendix D "Maintenance Plan Guidance" (or subsequent guidance manual) for each BMP component. The plan shall be submitted for examination of relevance to keeping the BMPs in proper working order. Where BMPs are transferred to Permittee for ownership and maintenance, the plan shall also include all relevant costs for upkeep of BMPs in the transfer. Operation and Maintenance plans for private BMPs shall be kept on-site for periodic review by Permittee inspectors.

2. Tracking, Inspection, and Enforcement of Post-Construction BMPs

(a) Each Permittee shall implement a tracking system and an inspection and enforcement program for new development and redevelopment post-construction storm water BMPs as set forth in part 4.E. no later than (one year after Order adoption date).

(1) Implement a GIS or other electronic system for tracking projects that have been conditioned for post-construction BMPs. The electronic system, at a minimum, should contain the following information:

(A) Municipal Project ID
(B) State WDID No
(C) Project Acreage
(D) BMP Type and Description
(E) BMP Location (coordinates)
(F) Date of Acceptance
(G) Date of Maintenance Agreement
(H) Maintenance Records
(I) Inspection Date and Summary
(J) Corrective Action
(K) Date Certificate of Occupancy Issued
(L) Replacement or Repair Date

(b) Inspect all development sites upon completion of construction and prior to the issuance of occupancy certificates to ensure proper installation of LID measures, structural BMPs, treatment control BMPs and Hydromodification control BMPs. The inspection may be combined with other inspections provided it is conducted by trained personnel.

(c) Verify proper maintenance and operation of post-construction BMPs previously approved for new development and redevelopment and operated by the Permittees. The post construction BMP maintenance inspection program shall incorporate the following elements:
   (1) Post-construction BMP Maintenance Inspection checklist.
   (2) Inspection at least once every 2 years, beginning (Order adoption date), of post-construction BMPs to assess operation conditions with particular attention to:
   (3) Criteria and procedures for post construction Treatment Control and Hydromodification Control BMP repair, replacement, or re-vegetation.

(d) For post construction BMPs operated and maintained by parties other than the Permittees, the Permittees shall require annual reports by the other parties demonstrating proper maintenance and operations.

(e) Undertake enforcement as appropriate based on the results of the inspection.

3. Alternative Post Construction Storm Water Mitigation Programs

(a) A Permittee or a coalition of Permittees may apply to the Regional Water Board for approval of a Redevelopment Project Area Master Plan (RPAMP) for redevelopment projects within the Redevelopment Project Areas, in consideration of exceptional site constraints that inhibit site-by-site or project-by-project implementation of post-construction requirements.

(b) Upon review and a determination by the Regional Water Board Executive Officer that the proposal is technically valid and appropriate, the Regional Water Board may consider for approval such a program if its implementation will:
   (1) Result in equivalent or superior reduction of storm water pollutant loads in comparison to individual projects regulated by this permit.
   (2) Satisfy, on a Redevelopment Project Area-wide basis, the hydromodification criteria of this section.
   (3) Reduce the percentage of Effective Impervious Area (EIA) to a target of 5 percent or less of the Redevelopment Project Area, using properly sized storm water treatment/ collection features, as described in this Section.
   (4) Be fiscally sustainable and have secure funding; and
   (5) Be completed in four years of the adoption date of this permit.

(c) The RPAMP should prioritize the implementation of LID storm water mitigation measures, as described in this section.

(d) A Permittee or a coalition of Permittees may apply to the Regional Water Board for approval of a Redevelopment Project Area Master Plan (RPAMP) that takes into consideration the balancing of water quality protection with the needs for adequate housing, population growth, public transportation and management, land recycling, and urban revitalization.

(e) For the RPAMP to be considered, a technical panel of the Local Government Commission or an equivalent state or regional planning agency must have

RB-AR32620

reviewed and approved the proposed RPAMP, prior to its submittal to the Regional Water Board. The Regional Water Board Executive Officer may then consider the RPAMP for approval, or elect to submit it to the Regional Water Board for consideration.

(f) The RPAMP, on approval, may substitute in part or wholly for post-construction requirements.

(g) Redevelopment Project Areas include the following:
  (1) City Center areas
  (2) Historic District areas
  (3) Brownfield areas
  (4) Infill Development areas
  (5) Urban Transit Villages
  (6) Any other redevelopment area so designated by the Regional Water Board

(h) Nothing in these provisions shall be construed as to delay the implementation of post-construction control requirements, as approved in this Order.

4. Developer Technical Guidance and Information

(a) The Permittees shall update the Ventura County Technical Guidance Manual for Storm Water Quality Control Measures to include, at a minimum, the following:
  (1) Hydromodification Control criteria described in this Order, including numerical criteria.
  (2) Expected BMP pollutant removal performance including effluent quality (ASCE/ U.S. EPA International BMP Database, CASQA New Development BMP Handbook, technical reports, local data on BMP performance, and the scientific literature appropriate for southern California geography and climate).
  (3) Selection of appropriate BMPs for storm water pollutants of concern.
  (4) Data on Observed Local Effectiveness and performance of implemented BMPs.
  (5) BMP Maintenance and Cost Considerations.
  (6) Guiding principles to facilitate integrated water resources planning and management in the selection of BMPs, including water conservation, groundwater recharge, public recreation, multipurpose parks, open space preservation, and redevelopment retrofits.
  (7) LID principles and specifications, including the objectives and specifications for integration of LID strategies in the areas of:
    (A) Site Assessment.
    (B) Site Planning and Layout.
    (C) Vegetative Protection, Revegetation, and Maintenance.
    (D) Techniques to Minimize Land Disturbance.
    (E) Techniques to Implement LID Measures at Various Scales
    (F) Integrated Water Resources Management Practices.
    (G) LID Design and Flow Modeling Guidance.
    (H) Hydrologic Analysis.
    (I) LID Credits.

RB-AR32621

(b) Permittees shall update the Technical Guidance Manual within (120 days after Order adoption date).
(c) The Permittees shall facilitate implementation of LID by providing key industry, regulatory, and other stakeholders with information regarding LID objectives and specifications contained in the LID Technical Guidance Section through a training program. The LID training program will include the following:
(1) LID targeted sessions and materials for builders, design professionals, regulators, resource agencies, and stakeholders
(2) A combination of awareness on national efforts and local experience gained through LID pilot projects and demonstration projects
(3) Materials and data from LID pilot projects and demonstration projects including case studies
(4) Guidance on how to integrate LID requirements into the local regulatory program(s) and requirements
(5) Availability of the LID Technical Guidance regarding integration of LID measures at various project scales
(6) Guidance on the relationship among LID strategies, Source Control BMPs, Treatment Control BMPs, and Hydromodification Control requirements
(d) The Permittees shall submit revisions to the Ventura County Technical Guidance Manual to the Regional Water Board for Executive Officer approval.

5. Project Coordination
(a) Each Permittee shall facilitate a process for effective approval of post-construction storm water control measures. The process shall include:
(1) Detailed BMP review including BMP sizing calculations, BMP pollutant removal performance, and municipal approval; and
(2) An established structure for communication and delineated authority between and among municipal departments that have jurisdiction over project review, plan approval, and project construction through memoranda of understanding (MOU) or an equivalent agreement.

V. State Statute Conformity

1. California Environmental Quality Act (CEQA) Document Update
(a) Each Permittee shall incorporate into its CEQA process no later than (365 days after Order adoption date) those additional procedures necessary for considering potential storm water quality impacts and providing for appropriate mitigation when preparing and reviewing CEQA documents.
(1) The procedures shall require consideration of the following:
(A) Potential impact of project construction on storm water runoff.
(B) Potential impact of project post-construction activity on storm water runoff.
(C) Potential for discharge of storm water from areas from material storage, vehicle or equipment fueling, vehicle or equipment

Checklist for Minimizing Vector Production in Stormwater Management Structures

Management of mosquitoes and other vectors in stormwater management structures, such as flood control basins and Best Management Practices, is critical for protecting public health. With careful planning, such structures can be designed, built, operated, and maintained in a manner that minimizes opportunities for the proliferation of vectors. This publication provides checklists of action items intended to lessen the short and long-term potential for vector production in stormwater management structures while reducing dependence on pesticides to the maximum extent possible. With the wide variety of structures and build locations, it is anticipated that not all action items will apply to every project. Answers to frequently asked questions follow the checklist.

For simplicity, stormwater management structures have been divided into three categories, each with specific considerations. Certain structures may require reference to more than one checklist.

Dry Systems. Any structure designed to drain completely following capture and/or treatment of runoff. Examples include flood control basins, extended detention basins, infiltration basins and trenches, Austin sand filters, swales and strips, drain inlet inserts, linear-radial gross solids removal devices. Permanent-water features sometimes included as part of dry system design, such as micropools, should be considered separately using the checklist for “wetlands”.

Wet Systems. Any structure designed with features such as sumps, vaults, and/or basins that hold water permanently, or longer than 4 days. Examples include open catch basins, concrete retention basins, Delaware sand filters, and a variety of belowground proprietary devices.

Wetlands. Any structure constructed as a naturalistic system with permanent surface waters, regardless of the formal given name (e.g., stormwater pond, retention basin, wet basin, constructed wetlands, treatment wetlands, etc.). This section also applies to permanent-water features sometimes included as part of dry system design such as micropools.

Additional information is available from the California Department of Public Health

and from the University of California, Division of Agriculture and Natural Resources (UCANR)
http://www.ipm.ucdavis.edu/PDF/MOSQ/mosquitostormwater.pdf

To facilitate public health mosquito control, it is strongly recommended that project locations be provided to the local vector control agency. To locate your local mosquito and vector control agency, go to http://westnile.ca.gov and search by zip code.

DRY SYSTEMS

Recommended strategy: Complete discharge of all captured water in 4 days or less.

- ☐ Is the structure designed to discharge all captured water in 4 days or less?
- ☐ Has every effort been made to trace and eliminate persistent non-stormwater flows (e.g. irrigation runoff) that may enter the system and jeopardize non-chemical vector control efforts?
- ☐ Has groundwater depth been carefully evaluated to ensure that the structure will not be permanently or seasonally flooded (i.e. is the base of the basin higher than the local groundwater table)?
- ☐ Does the design provide an adequate slope between the inlets and outlets, with special attention given to ensure corners are above grade?
- ☐ Has soil been compacted adequately during grading to minimize subsidence, which can result in pools of standing water?
- ☐ Does the design slope take into consideration the inevitable accumulation of sediment and debris between maintenance periods that can result in standing water, especially in and around the inlet?
- ☐ Does the design minimize the use of features that increase the potential for standing water, such as loose riprap and concrete curbs?
- ☐ Does the structure include a concrete or earthen low-flow channel to concentrate (i.e. minimize available surface area) and direct non-stormwater flows to the outlet?
- ☐ Is the distribution piping sloped adequately and smooth (not corrugated) on the inside to prevent standing water?
- ☐ Are the inlet structures and energy dissipaters designed and sloped sufficiently to prevent scour depressions?
- ☐ Are the outlets designed with debris screens or other features that reduce the potential for clogging?
- ☐ Is the structure designed with safe and sufficient access for inspection, maintenance, and/or vector control activities when needed?
- ☐ Does the operation and maintenance plan include a minimum of quarterly inspections to ensure that vegetation overgrowth, sediment accumulation, or other factors have not created areas of standing water?
- ☐ Does the operation and maintenance plan include a minimum annual maintenance to remove vegetation overgrowth, remove sediment and debris accumulation, and otherwise return the structure to “as-designed” conditions?
- ☐ Is signage provided and clearly visible with minimum information indicating the type of structure (e.g. extended detention basin), ownership, and contact information?

WET SYSTEMS

Recommended strategy: Deny mosquito access to standing water by using covers, screens, and/or other barriers.

- ☐ Have sumps, vaults, or basins that hold water permanently, or longer than 4 days, been completely or partially sealed against adult mosquito entry?
- ☐ If used, are covers tight fitting, with gaps or holes of no greater than 1/16" (2 mm)?
- ☐ If used, are aluminum or nylon screens for sealing small openings secured with gaps or holes of no greater than 1/16" (2 mm)?
- ☐ If cast iron manhole covers are used, are pick holes sealed or is a mosquito-proof insert provided below?
- ☐ Where feasible, are the inlet and/or outlet conveyance pipes submerged to prevent adult mosquito entry into the main water storage area?
- ☐ Where feasible, are conveyance pipes fitted with flapper valves, collapsible fabric tubes, or other barriers to prevent adult mosquito entry into the main water storage area?
- ☐ Is the structure designed with safe and sufficient access to permanent water areas for inspection, maintenance, and/or vector control activities when needed?
- ☐ Does the operation and maintenance plan include a minimum of quarterly inspections to ensure that barriers to mosquito entry are intact and in place as designed?
- ☐ Where possible, is signage provided with minimum information indicating type of structure (e.g. CDS™), ownership, and contact information?

WETLANDS

Recommended strategy: Create and maintain habitat least-suitable for mosquito breeding.

- ☐ Is the system designed with features that minimize the areas suitable for mosquito production?
- ☐ Does the design discourage emergent vegetation in shallow water zones where vegetation is not needed or desired, for example by using concrete liners in sediment forebays?
- ☐ Are slopes designed as steep and uniform as possible to discourage invasive, emergent vegetation?
- ☐ Does the system include deep water zones, in excess of 4 ft, to reduce available area for emergent vegetation and provide refuge for natural mosquito predators such as mosquitofish and certain invertebrates?
- ☐ Where permitted, have mosquitofish been introduced to help control mosquitoes?
- ☐ Does the system include provisions for rapid dewatering if needed for emergency control of mosquitoes?
- ☐ Is the structure designed with safe and sufficient access for inspection, maintenance, and/or vector control activities when needed?
- ☐ Are access roads built close to the shoreline and around the perimeter of the wetland to the extent feasible?
- ☐ Are access points incorporated at regular intervals along the perimeter to allow for vector monitoring and control when necessary.
- ☐ Does the operation and maintenance plan include a minimum of quarterly inspections to ensure that vegetation overgrowth, sediment accumulation, or other factors have not created areas suitable for mosquito production?
- ☐ Does the operation and maintenance plan include a minimum annual maintenance to remove vegetation overgrowth, remove sediment and debris accumulation, and otherwise return the structure to “as-designed” conditions?
- ☐ Is signage provided and clearly visible with minimum information indicating type of structure (e.g. stormwater treatment pond), ownership, and contact information?

Frequently Asked Questions

DRY SYSTEMS

1. Why is it important to drain all captured water in 4 days or less?
Most mosquito species important to public health require at least 6 days to develop from egg to adult. Designing dry systems to drain completely in 4 days ensures that no mosquitoes will be produced with a built-in margin of safety of several days.

2. Our stormwater treatment BMPs were designed to dewater in 4 days, but persistent non-stormwater flows result in areas of standing water that routinely produce mosquitoes. How do we address this problem?
Dry-weather urban runoff is a major contributor to mosquito production in urban areas everywhere. If the source(s) cannot be traced and eliminated, the best alternate solution is to minimize the surface area available to mosquitoes by cutting a low-flow channel through the BMP to direct the water to the outlet as efficiently as possible.

3. Will very shallow areas of standing water that remain in our detention basins after a storm event provide a potential source of mosquito production?
Certain species of mosquitoes important to public health are very adaptable. Water as shallow as 1/16", and sometimes less, can be sufficient to allow mosquito larvae to develop.

WET SYSTEMS

1. Our stormwater treatment BMPs are installed belowground and covered. Why should we be concerned about mosquitoes?
Unfortunately, certain species of mosquitoes capable of transmitting disease are well-adapted for finding and breeding in belowground habitats. These mosquitoes can access belowground sources through openings as small as 1/16" (2mm) and they can fly great distances through pipes.

2. We wish to install a belowground proprietary BMP in a new housing development. If we seal the access covers against mosquitoes, how far away should we design the inlet grates to keep mosquitoes from accessing the permanent-water sump?
The absolute flight limits of mosquitoes that can breed belowground are unknown; however, recent studies found that females could fly at least 80 feet through 4" diameter pipe to reach a source of standing water and were unaffected by changes in pipe course. It is unlikely that mosquitoes can be excluded from underground sources using conveyance pipe length alone.

3. We are considering the addition of weep holes to our belowground sumps to allow them to dewater between storms so they do not produce mosquitoes. Will this work?
Weep holes are typically not a reliable choice for preventing mosquito production due to their high probability of failure due to clogging.

4. I was told that mosquitoes can not breed in water with a visible oil sheen on the water surface. Is this true or false?
With some exceptions, this is false. In most cases, the oil sheen visible on the water surface is not uniform, but is broken. Certain species of mosquitoes capable of transmitting disease can exploit these habitats by using the oil-free areas for egg laying and larval development. In addition, surface oils are broken down over time, disappearing altogether if not regularly replenished by oily runoff.

5. We are considering a provision to dewater our belowground sumps after every storm event to prevent mosquito production. Will this be effective?
It has the potential to be effective, but there are several complicating factors to consider: 1) dry-weather urban runoff frequently replenishes belowground sumps making pumping efforts futile, and 2) pumps often leave a small amount of residual water in the bottom of the sumps, and water as shallow as 1/16" or less can be sufficient to allow mosquito larvae to develop.

6. Our stormwater sumps contain very deep water. Will this prevent mosquito production?
Unlike deep water zones in ponds and wetlands where mosquitoes generally do not develop due to predators, wind, and wave action, mosquitoes are unaffected by water depth and/or surface area in belowground systems.

7. *Will flowing water prevent mosquito production?*
Flowing water will discourage females from laying eggs and can kill larvae. For example, a vortex separator receiving year-round flow from an urban stream should not produce mosquitoes due to constant movement of the entire water surface area. However, water flow through systems with square sumps (or sumps of other geometrical shapes) may not completely eliminate mosquito production due to the stagnant zones created in the corners where water movement is minimal.

8. *Will surface agitators prevent mosquito production?*
Agitators, sprinklers, or other means of disturbing the water surface will discourage females from laying eggs and can kill larvae, however, in order to be effective the *entire* surface must be disturbed.

9. *It seems that controlling mosquitoes in belowground stormwater systems without resorting to chemical treatment is rarely successful. How do we deal with this problem?* Field research has documented the difficulty in controlling mosquitoes in belowground stormwater systems without chemicals (i.e. exclusion of mosquitoes was successful in a few systems studied, but the vast majority of attempts resulted in only marginal reductions). However, for reasons that are not entirely understood, not all belowground systems produce mosquitoes equally; some are sporadic and some are year-round producers. It is strongly recommended that the local vector control agency be consulted to determine site-specific monitoring and control needs.

WETLANDS

1. Why are mosquitoes still being detected in well designed and maintained wetlands?
Mosquitoes are difficult to eliminate completely from wetlands due to the complexity of the created environment. The goal should be to minimize mosquito production by making the habitat less desirable for them.

2. Will the deep areas of stormwater ponds where no emergent vegetation can grow produce mosquitoes?
Deep, open areas of water are typically unsuitable for mosquito production due to surface disturbance caused by wind and exposure to predators. However, if the deep zones become colonized by floating vegetation such as water hyacinth or by clumps of floating filamentous algae, mosquitoes may breed in the shelters created among these plants.

3. Why is it important to keep emergent vegetation such as cattails and bulrush from getting overly dense?
Dense emergent vegetation, especially along perimeter margins, will prevent predators such as mosquitofish from accessing these areas, creating ideal habitats for mosquitoes.

4. Why is it important to eliminate floating vegetation such as water hyacinth and maintain water quality to discourage clumps of floating filamentous algae?
Not only are certain floating plants such as water hyacinth considered exotic invasive species harmful to North American ecosystems, but these plants provide excellent habitats for mosquitoes sheltered from predators.

5. How do I determine if mosquitofish are permissible for use in my area?
As a general rule, if the stormwater wetland is self contained, and does not empty into a natural waterway, mosquitofish can be used to control mosquitoes. If in doubt, it is best to consult with the local office of the Department of Fish and Game before stocking fish.

6. How often should mosquitofish be restocked to reduce mosquito numbers?
In general, mosquitofish are very hardy and will rapidly increase in numbers to form a stable population. Large game fish such as bluegill and bass may negatively impact or eradicate mosquitofish populations, as can large numbers of fishing birds; however, low temperatures are the leading cause of population failures. In cold climates, mosquitofish may need to be restocked each spring following the last frost.

7. Do we need to be concerned with mosquito production during "cold snaps" or winter periods?
Most mosquitoes important to public health can develop successfully in water ranging from approximately 45 to 100 °F, with the ability to survive short periods outside this spectrum. Short cold snaps may not be lethal to larvae if the habitat provides a buffer area, however, extended periods of cold below 45 °F will halt mosquito production.

8. Will encouraging nesting and roosting habitat for certain birds and bats around our stormwater wetland reduce the population of adult mosquitoes appreciatively?
Although certain birds (e.g. swallows, martins) and bats have been reported to consume large numbers of adult mosquitoes, these animals do not preferentially feed on mosquitoes and there is no evidence to show that they substantially reduce mosquito populations.

BEST MANAGEMENT PRACTICES
FOR MOSQUITO CONTROL IN CALIFORNIA

An electronic version of this manual and the companion document “Best Management Practices for Mosquito Control on California State Properties” are available from the California West Nile virus website at http://www.westnile.ca.gov/resources.php. Please see Table 1, page 22, for a list of California mosquito control agencies or visit http://mvcac.org.

For more information, please contact:
Vector-Borne Disease Section
California Department of Public Health
vbds@cdph.ca.gov
(916) 552-9730
http://www.cdph.ca.gov
http://www.westnile.ca.gov

Purpose of this Manual

This manual provides landowners with Best Management Practices (BMPs) for mosquito control. The term BMP is used to describe actions landowners can take to reduce mosquito production from permanent water sources, reduce or eliminate mosquito production from temporary water sources, and reduce the potential for disease transmission to humans on their property.

General Recommendations

- **Implement universal BMPs**
  - Use personal protective measures
  - Eliminate unnecessary standing water

- **Identify and implement applicable mosquito control BMPs**
  - Reduce stagnation by providing water flow and manage vegetation in ponds or other water bodies.
  - Collaborate with local vector control agencies to develop and implement appropriate Integrated Pest Management (IPM) strategies that are most suitable for specific land-use type(s).

Use personal protective measures when potentially exposed to adult mosquitoes.

Eliminate unnecessary standing water, reduce stagnation by providing water flow, and manage vegetation in ponds or other water bodies.

Collaborate with local vector control agencies to coordinate activities on your property within a larger Integrated Pest Management mosquito control program.

Table of Contents

Executive Summary

The California Department of Public Health (CDPH) in collaboration with the Mosquito and Vector Control Association of California (MVCAC) developed this Best Management Practices (BMPs) plan to promote mosquito control on California properties, and enhance early detection of West Nile virus (WNV).

This plan describes mosquito control BMPs to be implemented by property owners and managers. These recommended practices, when properly implemented, can reduce mosquito populations through a variety of means including: 1) reducing or eliminating breeding sites, 2) increasing the efficacy of biological control, and 3) decrease the amount of pesticides applied while increasing the efficacy of chemical control measures. It is critical that property owners and managers communicate regularly with local vector control agencies regarding control practices on lands that are located within or near a local agency's jurisdiction. Local vector control agencies may have more specific policies regarding the implementation of BMPs and other control operations, which may include use of enforcement powers authorized by the California Health and Safety Code.

There are many different BMPs included in this document and they are intended to provide overall guidance to reduce mosquito production on properties throughout California, though not all mosquito sources and land uses will be addressed in this document. If it is deemed necessary, site-specific BMP plans may be developed in collaboration with CDPH and the respective local mosquito and vector control agency.

Effective mosquito-borne disease surveillance and mosquito control to protect public health are dependent upon factors that may fluctuate temporally and regionally. Such factors include mosquito and pathogen biology, environmental factors, land-use patterns, resource availability; strategies that incorporate BMPs are the most effective means by which mosquito control can be conducted and individualized to specific situations. Best management practices included in this plan emphasize the fundamentals of integrated pest management (IPM) which include:

1. Knowledge of mosquito species composition and corresponding mosquito behavior and habitat, for both immature and adult stages.

2. Detecting and monitoring WNV activity by testing mosquitoes, birds, sentinel chickens, horses, and humans. Identifying the mosquito species present, locations, densities, and disease potential.

3. Managing mosquito populations by source reduction, habitat modification, and biological control (e.g., introduced predators and parasites). Pesticides are used to target immature and, when indicated, adult stages of the mosquito. Mosquito control products are selected and applied in a manner that minimizes risks to human health, beneficial and non-target organisms, and the environment.

4. Educating the general public about reducing mosquito production and minimizing their risk of exposure to WNV.

RECOMMENDATIONS FOR PROPERTY OWNERS AND MANAGERS

- Use this plan to identify and implement appropriate Best Management Practices to control mosquitoes.
- Eliminate unnecessary standing water, reduce stagnation by providing water flow, and manage vegetation in ponds or other water bodies.
- Collaborate with local vector control agencies to develop and implement appropriate integrated pest management strategies that are most suitable for specific land-use type(s).
- Ensure individuals use personal protective measures when potentially exposed to adult mosquitoes.

Introduction

Controlling mosquitoes is critical to maintaining both a high quality of life and protecting people from mosquito-transmitted (vectored) diseases such as West Nile virus (WNV). In many parts of California, residents have voted to form local mosquito control programs or agencies. As a result, approximately half the land area and 85% of the population of California are within the boundaries of a mosquito control program. Landowners and land managers have a responsibility to minimize mosquito production on their lands and play a key role in reducing mosquito populations throughout the State, regardless whether their property is inside or outside the jurisdiction of a mosquito control program. Information about mosquito surveillance, mosquito-borne diseases, and mosquito control is available in Appendices A and B.

Best Management Practices (BMPs) are defined as actions landowners can take to reduce or eliminate mosquito production from water sources on their property in an environmentally and fiscally responsible manner, and to reduce the potential for transmission of disease from mosquitoes to humans.

Each property is unique, and the BMPs listed in this manual will apply to some properties, but not others. Landowners should implement universally applicable BMPs and after evaluating their own property, also employ the mosquito control BMPs that are applicable to their situation.

Landowner Responsibility

According to the California Health and Safety Code, landowners in California are legally responsible to abate (eliminate the source of) a public nuisance arising from their property, including mosquitoes [H&S Code Sections 2001 - 4(d); 2002; 2060 (b)]. In areas that are within the jurisdictional boundaries of a mosquito control program, landowners should work with staff to address mosquito problems, particularly in areas where irrigation is used for agricultural purposes. Landowners that are not within the jurisdictional boundary of an established mosquito control program should seek advice from the nearest mosquito control agency or health department. Landowners may also contact the California Department of Public Health (CDPH) or consult the CDPH West Nile virus website for additional information about mosquitoes and mosquito control. http://www.westnile.ca.gov/resources.php.

Mosquito control programs have substantial authority to access private property, inspect known or suspected sources of mosquitoes, abate the source of a mosquito problem, and charge the landowner for work performed and/or charge fees if a landowner is unwilling or unable to address a mosquito problem arising from their property [H&S Code sections 2060-2067, 100170, and 100175]. Applicable sections of the California Health and Safety Code are summarized in Appendix C.

Mosquito Biology

The more than 50 species of mosquitoes in California share one common life history trait: the mosquito life cycle requires standing water. Management of standing water is the key to most of the mosquito control BMPs presented in this manual and is one of the oldest and most cost effective forms of mosquito control.

Mosquito species are broadly separated into two groups according to where they lay eggs, floodwater mosquitoes and standing water mosquitoes. Adult female floodwater mosquitoes lay eggs on mud or previously submerged vegetation. The eggs may remain dormant for days, months, or even years until they are flooded, at which time larvae hatch. Standing water mosquitoes lay eggs on the water surface. The eggs float on the surface for a few hours to a few days until the larvae hatch into the water.

Floodwater mosquito larval development (breeding) sites include irrigated pastures, rice fields, seasonally flooded duck clubs and other managed wetlands, tidal wetlands, riparian corridors, and snowmelt pools. These intermittent or seasonally flooded habitats can be among the most productive sources of mosquitoes because they are often free of natural predators.

Standing water mosquito breeding sites include artificial containers, treeholes, catch basins, open ditches, retention/detention ponds, natural or constructed ponds and wetlands, stormwater management devices, and along the edges of flowing streams. Sources are found everywhere from highly urban areas to natural wetlands and often produce multiple generations of mosquitoes each season. In southern California, urban sources can produce some species of mosquitoes year round.

Landowners or land managers can identify the presence of immature mosquitoes in water on their property. Mosquito larvae breathe air from above the water surface and most hang at an angle from or lay parallel with the surface of the water while consuming small bits of organic matter. When disturbed, larvae swim down into the water column in a serpentine motion. Mosquitoes may live as larvae from a couple of days to more than a month depending on the species, water temperature, and the amount of food available.

Mosquitoes then go through a non-feeding stage called a pupa. During this stage the mosquito changes into the winged adult form. The easily identified comma-shaped pupae hang from the water surface and move down through the water column in a rolling or tumbling motion when disturbed. This life stage typically lasts about a day, with the mosquito emerging from the back of the pupal case (above the water) as a flying adult. (See Figure 1: Mosquito Life Cycle).

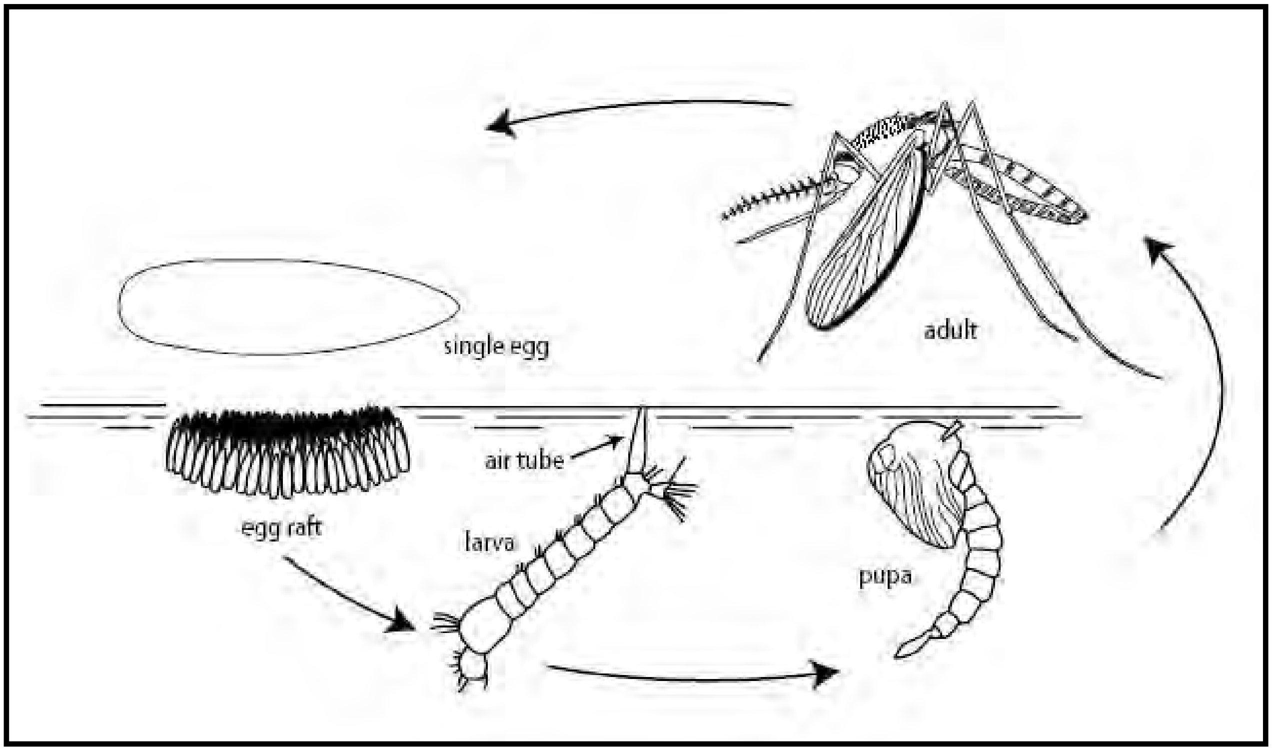

Figure 1. The life cycle of all mosquito species consists of four stages: egg, larva, pupa, and adult.

All adult mosquitoes feed on plant nectar; however blood is essential for female mosquitoes to produce eggs. To take a blood meal, the female's mouth parts pierce the skin, inject saliva, and suck blood out. It is through the injection of saliva that a mosquito causes the typical itchy bump and can infect a person or domestic animal with a disease causing organism. Depending on an individual's immune response, even a single bite can be a significant nuisance.

For more information on mosquito biology and key mosquito species found in California, please see Appendix D.

For additional information on the larval habitats of California mosquitoes, please see Appendix E.

Best Management Practices (BMPs)

Mosquito Control Best Management Practices At-A-Glance

- Eliminate artificial mosquito sources.
- Ensure man-made temporary sources of surface water drain within four days 96 hours) to prevent development of adult mosquitoes.
- Control plant growth in ponds, ditches, and shallow wetlands.
- Design facilities and water conveyance and/or holding structures to minimize the potential for producing mosquitoes.
- Use appropriate bio-rational products to control mosquito larvae.
- Use personal protective measures to prevent mosquito bites.

Each property is unique. Landowners should implement universally applicable mosquito control BMPs, and after evaluating their own property, also employ the mosquito control BMPs that are applicable to their property and circumstances. Using appropriate BMPs is an efficient and effective way to help prevent a mosquito problem.

Universally Applicable Mosquito Control BMPs

Eliminate Artificial Mosquito Breeding Sites and Harborage

- Examine outdoor areas and drain temporary and unnecessary water that may stand longer than 96 hours.
- Dispose of unwanted or unused artificial containers.
- Properly dispose of old tires.
- If possible, drill drainage holes, cover, or invert any container or object that holds standing water that must remain outdoors. Be sure to check for containers or trash in places that may be hard to see, such as under bushes or buildings.
- Clean clogged rain gutters and storm drains. Keep outdoor drains flowing freely and clear of leaves, vegetation, and other debris.
- Aerate ornamental ponds to avoid letting water stagnate.
- Change water in birdbaths, fountains, and animal troughs at least once per week.
- Ensure rain and/or irrigation water does not stand in plant containers, trash cans, boats, or other containers on commercial or residential properties.
- Regularly chlorinate swimming pools and keep pumps and filters operating. Unused or unwanted pools should be kept empty and dry, or buried.
- Maintain irrigation systems to avoid excess water use and runoff into storm drains.
- Minimize sites mosquitoes can use for refuge (harborage) by thinning branches, trimming and pruning ornamental shrubs and bushes, and keeping grass mowed short.

Use Personal Protective Measures

- Apply an EPA-registered mosquito repellent when outdoors; especially around dusk and dawn when mosquitoes are most active (see Appendix F for additional information on insect repellents).
- Wearing loose-fitting protective clothing including long sleeves and pant legs.
- Install and properly maintain fine mesh screens on windows and doors to prevent mosquito entry into homes.

Provide Mosquito Management Related Information to Property Managers

- Off-site landowners should provide property managers with basic information about mosquitoes and appropriate measures to minimize mosquito habitats.

Contact Local Mosquito Control Program

- Contact the local mosquito control program to evaluate your property for mosquito breeding sites and work cooperatively to prevent a mosquito problem on your property. A contact list for mosquito control programs is provided in Table 1.

Where local mosquito control programs do not exist, landowners may contact CDPH for assistance or consult the California West Nile virus website for additional information about mosquito control: http://www.westnile.ca.gov/resources.php

Mosquito Control BMPs for Residential and Landscaped Properties

Many residential and commercial properties have potential mosquito sources around buildings and grounds associated with excess or poorly managed irrigation, poor drainage, and miscellaneous landscape features. Mosquitoes can develop in the standing water associated with over-irrigation, irrigation breaks and/or runoff, clogged gutters, stormwater management structures, ornamental ponds, swimming pools, trash cans and flower pots, low areas or holes in turf where water collects and stands and low areas underneath pier and beam homes or buildings.

Mosquito sources can be minimized by taking precautions such as regular inspection and proper maintenance of irrigation systems and other water features, and elimination of unwanted standing water.

- Avoid over-irrigating to prevent excess pooling and runoff.
- Routinely inspect, maintain, and repair irrigation system components.

- All underground drain pipes should be laid to grade to avoid low areas that may hold water for longer than 96 hours.
- Back-fill tire ruts or other low areas that hold water for more than 96 hours.
- Improve drainage channels and grading to minimize potential for standing water.
- Keep drainage ditches free of excessive vegetation and debris to provide rapid drainage.
- Check and repair leaky outdoor faucets.
- Report any evidence of standing water to responsible maintenance personnel.
- Use waterfalls, fountains, aerators and/or mosquitofish in ponds and ornamental water features. Land owners must consult with the local mosquito control agencies or California Fish and Game regarding proper use of mosquitofish.
- Prevent mosquito breeding in rain barrels by properly screening all openings, preventing mosquito access to the stored water.
- For ponds and ornamental water features where mosquitofish cannot be used, landowners should use one of several readily available larval mosquito control products to treat water when they see immature mosquitoes.

Landowners should also review the stormwater runoff section of this manual because building rooftops, parking lots, etc. may have associated stormwater management features that produce mosquitoes.

Mosquito Control BMPs for Rural Properties

Mosquito breeding on rural properties is highly variable due to differences in location, terrain, and land use. This list is intended to provide general guidance, not site-specific requirements. BMPs that are most applicable and relevant to a specific mosquito source may be selected from the list and incorporated into the overall property management plan. Ideally, activities should be coordinated with those of a local mosquito control program.

Flood irrigation is a common practice in rural areas throughout California and always poses the potential for creating mosquito breeding sites. Mosquitoes commonly develop within irrigation infrastructure including in ditches clogged with vegetation, irrigation tail water areas and return sumps, blocked ditches or culverts, vegetated ditches; and leaking irrigation pipes, head gates, pumps, stand pipes, etc. The fields, orchards, and pastures being irrigated may also produce mosquitoes, particularly where natural undulation or poor grading create low lying areas where water collects and stands.

Recommendations for rural properties are based on “Mosquito Control Best Management Practices” produced by the Sacramento-Yolo Mosquito and Vector Control District, and from Lawler and Lanzaro (2005).

Mosquito Control BMPs for Ditches and Drains

- Construct or improve large ditches to a slope of at least 2:1 (vertical: horizontal) and a minimum 4 foot wide bottom. Consider a 3:1 slope or greater to discourage burrowing animal damage, potential seepage problems, and prevent unwanted vegetation growth.
- Keep ditches clean and well-maintained. Periodically remove accumulated sediment and vegetation. Maintain ditch grade and prevent areas of standing water.
- Design irrigation systems to use water efficiently and drain completely to avoid standing water.
- Prevent wet areas associated with seepage by repairing leaks in dams, ditches, and drains.

Mosquito Control BMPs for Irrigated Pastures and Cropland

- Grade to eliminate standing water from pastures and fields. Use Natural Resource Conservation Service (NRCS) guidelines: Laser leveling and periodic maintenance may be needed to allow proper drainage, efficient water flow, and reduce low-lying areas where standing water may accumulate.
- Reuse wastewater through return flow systems to effectively minimize mosquito production and conserve water. Eliminate and reuse excess water that may typically stagnate and collect at lower levels of irrigated fields.
- Irrigate only as frequently as is needed to maintain proper soil moisture. Check soil moisture regularly.
- Drain water as quickly as possible following irrigation. Check slopes may be used to direct water movement and drainage. Drainage ditches may be used to remove water from the lower end of the field.
- Install surface drains to remove excess water that collects at lower levels of irrigated fields.
- Inspect fields for drainage and broken checks to see whether re-leveling or reconstruction of levees is needed. Broken checks create cross-leakage that may provide habitat for mosquitoes.
- If possible, use closed conduits instead of open canals for water conveyance.
- Do not over fertilize. Over-fertilization can leach into irrigation run-off making mosquito production more likely in ditches or further downstream.
- When possible, use sprinklers or drip systems rather than flood irrigation.
- Keep animals off the pasture while the soil is soft. Mosquito habitat is created in irrigated pastures when water collects in hoof prints.

Mosquito Control BMPs for Rice Fields

Flooded rice fields can always support the development of mosquitoes. As the rice stand develops and grows denser, the production of mosquitoes tends to increase while the ability for chemical control agents to penetrate the canopy decreases. The BMPs presented in this section attempt to balance the needs of the grower with the need to control mosquitoes.

In California there is a long-standing cooperative effort among the Rice Commission, individual growers, and mosquito control agencies to manage mosquitoes on rice lands. Close cooperation between growers and vector control is particularly important with organic rice producers. With severe limits on chemical control options and greater expense for organic-compatible larvicides, organic rice growers should implement as many mosquito control BMPs as possible.

- Wherever feasible, maintain stable water levels during mosquito season by ensuring constant flow of water into ponds or rice fields to reduce water fluctuation due to evaporation, transpiration, outflow, and seepage.
- Inspect and repair levees to minimize seepage.
- Drain and fill in borrow pits and seepage areas external to the fields.
- Wherever feasible, maintain at least 4" – 6" (10-15 cm) of water in the rice field after rice seedlings have begun to stand upright. Any drainage should be coordinated with local vector control (where possible). Restocking of mosquitofish or use of alternative mosquito control measures should be instituted as soon as possible when fields are re-flooded.
- Whenever feasible, remove vegetation on the outer-most portions of field levees and checks, specifically where they interface with standing water.
- Control algae and weed growth as effectively as possible.
- Communicate frequently with your local mosquito control program regarding your crop management activities.
- Wherever feasible, maintain borrow pits (12" – 18" deep) (30-45 cm) on both sides of each check throughout rice fields to provide refuge for mosquitofish during low water periods.
- If a pyrethroid pesticide is to be applied to the fields stocked with mosquitofish, contact your local mosquito control program for advice on minimizing fish mortality.
- If a pesticide is applied, fields should be inspected for mosquitofish afterward and if needed, fish should be restocked as soon as feasible.

Mosquito Control BMPs for Dairies and Animal Holding Operations

Frequently infrastructure associated with dairies, feedlots, or other animal holding facilities can produce mosquitoes. Watering troughs and irrigated fields associated with the operation can create mosquito problems. Animal washing areas may also create mosquito problems, particularly drains and ditches, sumps, ponds, and wastewater lagoons.

The following activities can reduce mosquito production and simplify control activities around dairies and animal holding operations:

- All holding ponds should be surrounded by lanes of adequate width to allow safe passage of mosquito control equipment. This includes keeping the lanes clear of any materials or equipment (e.g. trees, calf pens, hay stacks, silage, tires, equipment, etc.).
- If fencing is used around the holding ponds, it should be placed on the outside of the lanes with gates provided for vehicle access.
- Large ponds should be divided into a series of smaller ponds that can be drained for removal of solid waste material.
- Ponds and lagoons should be narrow enough to allow solid waste removal after drying.
- All interior banks of the holding ponds should have a grade of at least 2:1.
- If possible, an effective solids separation system should be utilized such as a mechanical separator or two or more solids separator ponds. If ponds are used, they should not exceed 60' (18m) in surface width.
- Drainage lines should never by-pass the separator ponds, except those that provide for normal corral run-off and do not contain solids.
- When possible, floating debris should be removed from ponds prior to crust formation.
- If a thick crust exists (grass growing on crust), it should be left intact until the pond can be drained and the solid material removed.
- Vegetation should be controlled regularly to prevent emergent vegetation and barriers to access. This includes access lanes, interior pond embankments, and any weed growth that might become established within the pond surface.
- Dairy wastewater discharge for irrigation purposes should be managed so it does not stand for more than 4 days.
- Tire sidewalls or other objects that will not hold water should be used to hold down tarps (e.g. on silage piles). Whole tires or other water-holding objects should be replaced.

Mosquito Control BMPs for Wetlands

Wetlands are an important source of mosquito production on public and privately owned lands. Under the California Wildlife Protection Act, the term "wetlands" is defined as any lands which may be covered periodically or permanently with shallow water, which

include freshwater and saltwater marshes, open or closed brackish water marshes, swamps, mudflats, fens, and vernal pools (Fish & Game Code Section 2785). Many wetlands are protected by federal and state laws.

By definition, "natural" wetlands are not intensely managed and options for implementing mosquito control BMPs in these areas are very limited. Even in managed wetlands, not all BMPs listed below may be suitable for use in all wetlands. It is the responsibility of the landowner to become informed on timing and extent of acceptable activities in a given wetland habitat. Intermittently or seasonally flooded wetlands can produce formidable numbers of mosquitoes, whereas well-managed semi-permanent and permanent wetlands usually produce fewer mosquitoes because of their limited acreage, stable water levels, and abundance of natural predators of mosquito larvae.

Information within this section has been partially adapted from Kwasny et al. (2004). Based on the site activities and potential for mosquito production, the existing BMPs may need to be modified or supplemented to address public health risk, goals and management strategy issues, and requirements of California Department of Fish and Game (DFG), the local mosquito and vector control program, and CDPH.

Due to the delicate and sometimes protected wetlands ecosystems, landowners, biologists, managers, and staff from mosquito control programs should collaborate to control mosquitoes. Source reduction and source maintenance can be combined with the judicious use of specific larvicides to minimize mosquito production from these wetlands.

General Mosquito Control BMPs for Wetlands

- Manage vegetation routinely; activities such as annual thinning of rushes and cattails and removing excess vegetative debris enables natural predators to hunt mosquito larvae more effectively in permanent wetlands. Vegetation in shallow, temporary wetlands can be mowed when dry.
- Time flooding of seasonal wetlands to reduce overlap with peak mosquito activity.
- Flood wetlands from permanent-water sources containing mosquito predators (e.g., mosquito-eating fish or invertebrate predators) to passively introduce mosquito predators. Permanent wetlands and brood ponds can be stocked with mosquitofish or native predatory species.
- Maintain permanent or semi-permanent water within the wetland to maintain populations of larval mosquito predators. Discourage the use of broad spectrum pesticides.
- Use fertilizers conservatively and manage irrigation drainage to prevent or minimize fertilizer and/or manure flowing into wetlands. Buffers between agriculture fields and wetlands should be established.
- Comply with all Federal and State Environmental Laws and the California Health and Safety Code to prevent environmental harm while reducing or eliminating mosquito production.

Mosquito Control BMPs for Design and Maintenance of Wetlands

- Provide reasonable access on existing roads and levees to allow for monitoring, abatement, and implementation of BMPs. Make shorelines of natural, agricultural, and constructed water bodies accessible for periodic maintenance, mosquito monitoring and abatement procedures, and removal of emergent vegetation.
- Construct, improve, or maintain ditches with 2:1 slopes and a minimum 4 foot (1.2 m) width at the bottom. Consider a 3:1 slope or greater to discourage burrowing animal damage, potential seepage problems, and prevent unwanted vegetation growth.
- Construct, improve, or maintain levees to quality standards that ensure stability and prevent unwanted seepage. Ideally build levees with >3:1 slopes and > 80% compaction; consider 5:1 slope or greater in areas prone to overland flooding and levee erosion.
- Provide adequate water control structures for complete draw-down and rapid flooding.
- When possible, include independent inlets and outlets in the design of each wetland unit.
- Construct or enhance swales so they are sloped from inlet to outlet and allow maximum draw-down.
- Excavate deep channels or basins to maintain permanent water areas (>2.5 feet deep) within a portion of seasonal managed wetlands. This provides year-round habitat for mosquito predators that can inoculate seasonal wetlands when they are irrigated or flooded.

Wetland Infrastructure Maintenance Mosquito Control BMPs

- Inspect levees at least annually and repair as needed.
- Periodically inspect, repair, and clean water control structures.
    - Remove all debris, including silt and vegetation, which can impede drainage and water flow.
    - Ensure water control structures are watertight to prevent unnecessary water flow or seepage.
- Regularly remove trash, silt and vegetation from water delivery ditches to allow efficient water delivery and drainage.
    - Remove problem vegetation that inhibits water flow using herbicides or periodic dredging.
    - If possible, use closed conduits instead of open canals for water conveyance.
- Periodically test and repair pumps used for wetland flooding to maximize pump output.

Water Management Mosquito Control BMPs for Seasonal Wetlands

- Timing of flooding
  - Delay or "phase" fall flooding of wetlands as long as possible in consultation with local vector control agencies. Fall flooding is known to produce large numbers of mosquitoes and/or those in close proximity to urban areas to minimize late season mosquito production.
  - Strategically locate wetlands identified for early flooding. Wetlands that are flooded in early fall should not be close to urban areas or historically produce great numbers of mosquitoes.
  - When possible, water in managed wetlands should be drawn-down in late March or early April.
  - Use a flood-drain-flood regime to control floodwater mosquitoes; flood to trigger hatching of dormant mosquito eggs, drain water and larvae into an area where they can be easily treated, drowned in moving water, or consumed by predators, and immediately re-flood wetland. This water management regime should be used only when it does not conflict with water quality regulations.
- Speed of flooding
  - Flood wetlands as quickly as possible to reduce the potential for large numbers of mosquitoes. Coordinate flooding with neighbors and/or the water district to maximize flood-up rate.
- Water source
  - Flood wetlands with water from permanent water sources containing mosquito predators (i.e., mosquito-eating fish or invertebrate predators) to passively introduce mosquito predators. Permanent wetlands and brood ponds used as flooding sources can be stocked with mosquito-eating fish or maintained to encourage natural predator populations.
  - Maintain a separate permanent water reservoir that conveys water to seasonal wetlands that provides year-round habitat for mosquito predators that can inoculate seasonal wetlands when they are irrigated or flooded.
- Frequency and duration of irrigation
  - When possible, reduce the number and duration of irrigations to minimize standing water. The need to irrigate should be evaluated based on spring habitat conditions and plant growth. If extended duration irrigation

(generally 14-21 days) is considered for weed control (e.g., cocklebur),
    - additional measures to offset the potential for increased mosquito production may be needed.
    - Irrigate managed wetlands before soil completely dries after spring draw-down to discourage floodwater mosquitoes from laying eggs in the dry, cracked substrate.
    - Drain irrigation water into ditches or other water sources with mosquito predators instead of nearby dry fields.
    - Maintain high ground water levels by keeping channels or deep swales permanently flooded for subsurface irrigation to reduce the amount of irrigation water needed during the mosquito season.
- Communicate with your local mosquito control agency (if there is one)
    - Advise your local mosquito control agency when you intend to flood so that they can make timely applications of larvicide if necessary.
- Emergency preparedness
    - Whenever feasible, have an emergency plan that provides for immediate drainage into acceptable areas if a mosquito-borne disease related public health emergency occurs.

Vegetation Management Mosquito Control BMPs

- Control floating vegetation conducive to mosquito production (i.e., water hyacinth, water primrose, parrot feather, duckweed, and filamentous algae mats).
- Perform routine maintenance to reduce problematic emergent plant densities to facilitate the ability of mosquito-eating fish to move through vegetated areas and allow good penetration of chemical control agents.
- Manage vegetation based on local land management objectives and associated habitat uses to minimize mosquito production. Methods of vegetation control for managed wetlands include mowing, burning, disking, and grazing.
- Manage the spread and density of invasive, non-native emergent wetland vegetation to increase native plant diversity, increase the mobility of larval mosquito predators, and allow for more efficient penetration of chemical control agents.

Additional Water Management BMPs for Permanent Wetlands

- Maintain stable water levels in wetlands that are flooded during summer and early spring to prevent intermittent flooding of shoreline areas favorable to mosquito production. Water level fluctuation can be minimized by continuing a constant flow of water into the wetland.
- Circulate water to avoid stagnation (e.g., provide a constant influx of water equal to the net loss or discharge of water).
- Maintain water depths as deep as possible (18” – 24” [45-60 cm] or more) during the initial flood-up to minimize shallow habitats preferred by mosquito larvae. Shallow water levels can be maintained outside of the mosquito breeding season.

Additional Mosquito Control BMPs for Saltwater Marsh

- Improving water flow through the wetland system minimizes stagnant water and facilitates movement of fish and other natural predators. For example, mosquitoes in coastal tidal wetlands can be managed by constructing and maintaining ditches that drain off the water when the tide falls.

Mosquito Control BMPs for Stormwater Management and Associated Infrastructure

Federal and state environmental regulations require mitigation of the harmful effects of runoff water from storms, irrigation or other sources prior to entering natural waterways from point and non-point sources. Mitigation may include water capture, slowing flow velocity, reducing volume, and removal of pollutants. The term “stormwater” is used as a generic term for runoff water, regardless of source.

Stormwater infrastructure typically includes conveyance systems (e.g. drain inlets, catch basins, pipes, and channels), storage and infiltration systems (e.g. flood control basins, percolation basins), and more recently, structural treatment devices designed and installed specifically to remove suspended and dissolved pollutants from runoff (e.g., vegetated swales, dry detention basins, ponds and constructed wetlands, media filtration devices, and trash capturing devices). The size and variability of stormwater infrastructure, inconsistent quantity and timing of water flows, and propensity to carry and accumulate sediment, trash, and debris, makes these systems highly conducive to holding areas of standing water ideal for production of mosquitoes. Identification of the potential mosquito sources (often belowground) found within stormwater infrastructure is often more difficult than the solutions needed to minimize mosquitoes. Some of the information within this section has been adapted from Metzger (2004).

General Stormwater Management Mosquito Control BMPs

- Manage sprinkler and irrigation systems to minimize runoff entering stormwater infrastructure.
- Avoid intentionally running water into stormwater systems by not washing sidewalks and driveways, washing cars on streets or driveways, etc.
- Inspect facilities weekly during warm weather for the presence of standing water or immature mosquitoes.
- Remove emergent vegetation and debris from gutters and channels that accumulate water.
- Consider mosquito production during the design, construction, and maintenance of stormwater infrastructure.
- Design and maintain systems to fully discharge captured water in 96 hours or less.
- Include access for maintenance in system design.

- Design systems with permanent water sources such as wetlands, ponds, sumps, and basins to minimize mosquito habitat and plan for routine larval mosquito inspection and control activities with the assistance of a local mosquito control program.

Stormwater Conveyance

- Provide proper grades along conveyance structures to ensure that water flows freely.
- Inspect on a routine basis to ensure the grade remains as designed and to remove accumulations of sediment, trash, and debris.
- Keep inlets free of accumulations of sediment, trash, and debris to prevent standing water from backing up on roadways and gutters.
- Design outfalls to prevent scour depressions that can hold standing water.

Stormwater Storage and Infiltration Systems (Aboveground)

- Design structures so that they do not hold standing water for more than 96 hours to prevent mosquito development. Features to prevent or reduce the possibility of clogged discharge orifices (e.g., debris screens) should be incorporated into the design. The use of weep holes is not recommended due to rapid clogging.
- Provide a uniform grade between the inlets and outlets to ensure that all water is discharged in 96 hours or less. Routine inspection and maintenance are crucial to ensuring the grade remains as designed.
- Avoid the use of electric pumps. They are subject to failure and often require permanent-water sumps. Structures that do not require pumping should be favored over those that have this requirement.
- Avoid the use of loose rock rip-rap that may hold standing water.
- Design distribution pumping and containment basins with adequate slopes to drain fully. The design slope should take into consideration buildup of sediment between maintenance periods.

Stormwater Structures with Permanent-Water Sumps or Basins (Belowground)

- Where possible, seal access holes (e.g., pickholes in manhole covers) to belowground structures designed to retain water in sumps or basins to minimize

entry of adult mosquitoes. If using covers or screens, maximum allowable gaps of 1/16 inch (2 mm) will exclude entry of adult mosquitoes. Inspect barriers frequently and replace when needed.

- If the sump or basin is completely sealed against mosquitoes, with the exception of the inlet and outlet, the inlet and outlet should be completely submerged to reduce the available surface area of water for mosquitoes to lay eggs (female mosquitoes can fly through pipes).
- Where possible, design belowground sumps with the equipment necessary to allow for easy dewatering of the unit.
- Contact the local mosquito control program for advice with problem systems.

Stormwater Treatment Ponds and Constructed Treatment Wetlands

- Whenever possible, stock stormwater ponds and constructed wetlands with mosquito-eating fish available from local mosquito control programs.
- Design and maintain accessible shorelines to allow for periodic maintenance and/or control of emergent and shoreline vegetation, and routine monitoring and control of mosquitoes. Emergent plant density should be routinely managed so mosquito predators can move throughout the vegetated areas and are not excluded from pond edges.
- Whenever possible, design and maintain deep zones in excess of four feet (1.2 m) to limit the spread of invasive emergent vegetation such as cattails. The edges below the water surface should be as steep as practicable and uniform to discourage dense plant growth that may provide immature mosquitoes with refuge from predators and increased nutrient availability.
- Use concrete or liners in shallow areas to discourage plant growth where vegetation is not necessary.
- Whenever possible, provide a means for easy dewatering if needed.
- Manage the spread and density of floating and submerged vegetation that encourages mosquito production (i.e., water hyacinth, water primrose, parrot's feather, duckweed, and filamentous algal mats).
- If possible, compartmentalize managed treatment wetlands so the maximum width of ponds does not exceed two times the effective distance (40 feet [12 m]) of land-based application technologies for mosquito control agents.

General Access Requirements for Stormwater Treatment Structures

- All structures should be easily and safely accessible, without the need for special requirements (e.g., Occupational Safety and Health Administration - OSHA - requirements for "confined space"). This will allow for monitoring and, if necessary, abatement of mosquitoes.
- If utilizing covers, the design should include spring-loaded or lightweight access hatches that can be easily opened.
- Provide all-weather road access (with provisions for turning a full-size work vehicle) along at least one side of large aboveground structures that are less

than seven meters wide, or both sides if shore-to-shore distance is greater than seven meters. *Note:* Mosquito larvicides are applied with hand held equipment at small sites and with backpack or truck mounted high-pressure sprayers at large sites. The effective swath width of most backpack or truck-mounted larvicide sprayers is approximately 20-25 feet (6-7meters) on a windless day.

- Build access roads as close to the shoreline as possible to allow for maintenance and vector control crews to periodically maintain, control and remove emergent vegetation and conduct routine mosquito monitoring and abatement. Remove vegetation and/or other obstacles between the access road and the structure that might obstruct the path of larvicides to the water.
- Control vegetation (by removal, thinning, or mowing) periodically to prevent barriers to access.

Mosquito Control BMPs for Right of Ways and Easements

Right of ways and easements for a variety of infrastructure exist throughout California. Roadways, power lines, pipelines, canals, bike paths, utility access, railroads, etc. have lands associated with them that may produce mosquitoes. It is the responsibility of the company or individual associated with the infrastructure to prevent a public nuisance arising from the property, including a mosquito problem. The lands are as varied as the terrain in California, but the mosquito breeding sites found on these properties will be similar to those found in other sections of this manual.

Inspection of Property and Identification of Mosquito Sources

- Inspect property for standing water or evidence of standing water that may become mosquito sources.

Review and Implement Mosquito Control BMPs as Appropriate

Some rights of way and easements are very long and may have multiple types of mosquito breeding sites that fall within every category listed below, others will have none. After inspecting the property, implement mosquito control BMPs found in the sections below.

- If the property is in an urban area and is managed as commercial property, please refer to the following section:
  - *Residential and landscaped properties*, see page 5.

- If the property is associated with an irrigation canal or similar rural water conveyance, please refer to the following sections:
  - *Rural properties*, see page 6.
  - *Wetlands*, see page 9.

- If the property is associated with a variety of habitats like a railroad or pipeline

right of way, please refer to the following sections:
- o *Rural* properties, see page 6.
- o *Wetlands*, see page 9.

- If the property is associated with a roadway or other structure that would require management of runoff water, please refer to the following section:
  - o *Stormwater management* (associated BMPs), see page 14.

In many instances, right of ways and easements will simply fall to the local mosquito and vector control program or go completely unmanaged because they are very large and it is not possible to determine the responsible party.

Mosquito Control BMPs for Wastewater Treatment Facilities

Wastewater treatment facilities are designed to collect, treat, and release nutrient rich highly organic water. These facilities implement practices appropriate to removing contaminants from wastewater, but which may be in direct conflict with BMPs intended to prevent development of mosquito larvae. Further, managers are under intense pressure to meet water quality standards in effluent water and are frequently concerned that mosquito control BMPs will jeopardize compliance with effluent standards.

Wastewater facilities often include features that can produce mosquitoes. Examples include 1) a series of treatment or evaporation ponds, 2) the use of tules or other emergent vegetation to remove contaminants, 3) aerated and non-aerated ponds with emergent vegetation around the edges or throughout, 4) cracks and openings in crusted waste matter on the surface of treatment ponds, and 5) abandoned or unused pond basins that frequently hold shallow water. Certain activities may also create or enhance mosquito habitat including 1) allowing evaporation of wastewater from treatment ponds for maintenance or as a standard treatment method, 2) release of wastewater into marshes or floodplains for evaporation or infiltration, and 3) distribution of sludge onto irrigated agricultural lands.

For mosquito control around buildings and grounds, consult the *residential and landscape* section of this document. Similarly, many BMPs included in the *wetlands and dairy* sections of this document are pertinent to wastewater management facilities, particularly those sections related to construction and management of treatment ponds and wetlands and the use and distribution of wastewater or sludge onto agricultural lands. For mosquito control related to wastewater collection, conveyance, and distribution consult the *stormwater management* section of this manual.

- Monitor all treatment ponds for mosquito larvae – particularly in areas of emergent vegetation.
- Remove emergent vegetation from edges of aerated ponds.
- Immediately incorporate sludge into soil through plowing or disking.
- Insure all water distributed onto evaporation ponds dries completely in less than 96 hours.

- Check abandoned ponds or tanks weekly to ensure they are completely dry.
- Use mechanical agitation to prevent the formation of any crust on treatment ponds or tanks.
- Work closely with a local vector control program. If there is no local vector control agency, consult the closest vector control program, the local public health officer, or CDPH to prevent or abate a mosquito problem from the facility.

Mosquito Control BMPs for Wildlands – Undeveloped Areas

California encompasses about 100 million acres (40 million hectares) of land. Approximately 75 million acres (30 million hectares) are classified as wildlands, which include all undeveloped and non-cultivated property in the state. In many cases the properties are remote and mosquito control is neither feasible nor warranted. However, if you own a property that is near a town or are aware of a mosquito problem at the property, you may wish to contact the closest vector control program or CDPH to determine what if anything can be done to alleviate the problem.

Mosquito Control BMPs that May be Applicable to Wildlands

- Conduct routine mosquito surveillance by looking for immature mosquitoes in the water. Apply EPA-registered products (typically containing Bti, Bs, or methoprene) to control mosquito larvae.
- Evaluate reports of mosquito annoyance from visitors or the public, and if possible work with a local mosquito control program to be notified if there is an adult mosquito problem on or near your property.
- After a rainfall, pay particular attention to temporary water sources and ponds that rise. Treat sources with mosquito control products if needed.
- Stock ornamental ponds and other water features with mosquitofish available from local mosquito control programs. However, their use is restricted in natural bodies of water or in water features that drain into natural bodies of water. Land managers must consult with the local mosquito control agencies regarding proper use of mosquitofish or other available biological control agents.
  Work closely with a local mosquito control program to accurately identify, map, and monitor areas that may produce mosquitoes; and tailor control measures for each site, contingent on the species of mosquitoes that are present.
- Implement personal protective measures
  - Provide visitors and guests with information regarding the risk of mosquito-borne disease transmission and personal protective measures.
  - Install and maintain tight-fitting window and door screens on buildings.
  - If possible, minimize outdoor activities at dawn and dusk when mosquitoes are the most active.
  - Wear protective clothing such as long-sleeved shirts and long pants when going into mosquito-infested areas.
  - Use mosquito repellent when necessary, carefully following the directions on the label.

Evaluation of the Efficacy of BMPs

Landowners can easily evaluate the efficacy of the mosquito control BMPs they have implemented. You can do a simple evaluation as follows:

- Immature mosquitoes: Look for immature mosquitoes in standing water on your property – if the number is decreasing noticeably or immature mosquitoes can not be found, the BMPs you have implemented are working.
- Adult mosquitoes: Simply be aware of the level of mosquito annoyance you experience and ask guests or employees about their experience with regard to mosquitoes. People become accustomed to a certain level of mosquito activity and commonly notice increases or decreases in that level. If the annoyance level is increasing, you have more work to do; if the number is decreasing or mosquitoes are not noticeable – good job! The BMPs you have implemented are working.

The best way to evaluate the effectiveness of BMPs is through a comprehensive surveillance program of larval dipping and adult mosquito trapping, including species identification. Some important strengths of local mosquito control programs are their ability to evaluate treatment options, estimate treatment costs, recommend and implement those BMPs most appropriate for a property. Local mosquito abatement programs also are familiar with indigenous mosquito species and therefore know the type of habitat those mosquitoes come from, often monitor adult populations, and can identify if there is a mosquito problem in a particular area. Landowners can make substantial progress in solving mosquito problems on their own, but if possible, they should work closely with a local mosquito control program to implement and evaluate mosquito control BMPs.

CDPH disclaims any warranty or warranty for fitness of use for a particular purpose, expressed or implied, with respect to this data.CDPH disclaims any responsibility for the accuracy or completeness of this data. The mapped data does not constitute a legal survey.

Appendix A

Mosquito Control and Arbovirus Surveillance

Mosquito Control Practices

Mosquito control agencies and private landowners in California work cooperatively to implement an integrated pest management (IPM) approach to mosquito control. Source reduction (eliminating the places where mosquito larvae hatch and develop) is the most effective way of preventing adult mosquitoes; however, it may be possible to eliminate mosquito production from a source through other modifications of habitat and/or water management. Biological control agents, including native or introduced predators, are often utilized in combination with water management practices. Pesticides are an important part of an IPM program and mosquito specific larval control pesticides are often used to supplement other source reduction activities. When source reduction and larval control have not adequately reduced the mosquito population, the application of pesticides to control adult mosquitoes may be necessary. Personnel working for vector control agencies who apply pesticides in California are certified by California Department of Public Health (CDPH) after demonstrating the knowledge necessary to control mosquitoes safely and effectively using IPM techniques.

Larval Control

Larval control is the foundation of most mosquito control programs in California. Whereas adult mosquitoes are widespread in the environment, larvae must have water to develop; control efforts therefore can be focused on aquatic habitats. Minimizing the number of adults that emerge is crucial to reducing the incidence and risk of disease. The three key components of larval control are environmental management, biological control, and chemical control.

Environmental Management

Manipulating or eliminating potential mosquito breeding sources can provide dramatic reductions in mosquito populations. There are three levels of environmental management.

1. Source elimination: This approach completely eliminates potential habitats for mosquitoes. This strategy is generally limited to artificial habitats created by urbanization. Examples of source elimination include emptying or turning over containers holding water, filling in holes containing water with sand or gravel, cleaning drainage ditches of debris, and covering or inverting structures and vessels that could hold water.

2. Source reduction: This strategy aims to alter and sometimes eliminate available habitat for larvae which substantially reduces mosquito breeding and the need for

repeatedly applying pesticides. Unlike source elimination, standing water may exist but the total amount of water, or the time the water is left standing, is greatly reduced. Source reduction may require some maintenance (see below) to prevent further mosquito breeding. Examples of source reduction include limiting the growth of emergent vegetation in wetlands and ponds, constructing drainage ditches to remove water from areas prone to flooding, and clearing stormwater channels of silt and debris. Routine larval monitoring can indicate whether these efforts are effective or need further action.

3. Source maintenance: When eliminating or significantly altering mosquito breeding sources is prohibited and/or inappropriate, reducing the number of sheltered, predator-free habitats while having minimal impact on the surrounding environment can make an area unsuitable for mosquitoes. Source maintenance can include water management, vegetation management, wetland infrastructure maintenance, and wetland restoration. Strategic, focused plans must be developed for each site.

Biological Control

Biological control uses predators, parasites, or pathogens to reduce populations of mosquito larvae and is often combined with environmental management to enhance results. The mosquitofish (*Gambusia affinis)* has been used to control mosquitoes in California since 1921 and is the most widely used biological control agent in the world. These small fish are effective against mosquito larvae because they grow and reproduce rapidly, feed at the water surface where mosquito larvae are found, and tolerate a wide range of temperature and water quality.

Other fish are occasionally used with mixed success. Fish are most effective in permanent ponds and wetlands, but are also used in rice fields and stormwater canals with permanent water. Many local mosquito control agencies propagate mosquito-eating fish.

Although many other animals have been tested for mosquito control, and in natural wetlands predation is an important factor in reducing mosquito production, biological control by the intentional addition of mosquito predators other than mosquitofish is largely experimental rather than operational.

Chemical Control

Pesticides that control mosquito larvae are called larvicides. Four types of larvicides (bio-rational, surface films, growth regulators, and chemical products) encompassing seven active ingredients are registered for use in California. Larvicides are applied by hand, from hand-held or vehicle-mounted engine-driven blowers, or by aircraft, depending on the product, the formulation, and the target habitat. Applicators of any of these products must be certified by the CDPH or an appropriate regulatory authority.

1. Bio-rational products

Bio-rational products exploit insecticidal toxins found in certain naturally occurring bacteria. These bacteria are cultured in mass and packaged in various formulations. The bacteria must be ingested by mosquito larvae so the toxin is released. Therefore bio-rational products are only effective against larvae since pupae do not feed. The bacteria used to control mosquito larvae have no significant effects on non-target organisms when applied for mosquito control in accordance with product labels.

Two products that are used against mosquito larvae singly or in combination are *Bacillus thuringiensis israelensis* (Bti) and *Bacillus sphaericus* (Bs). Manufactured Bti contains dead bacteria and remains effective in the water for 24 to 48 hours; some slow release formulations provide longer control. In contrast, Bs products contain spores that in favorable conditions remain effective for more than 30 days. Both products are safe enough to be used in water that is consumed by humans.

Another bio-rational product available for mosquito control is derived from the soil bacterium *Saccharopolyspora spinosa,* which produces natural metabolites called spinosyns during fermentation. These metabolites are lethal to mosquito larvae when ingested or by contact. The most active metabolites are formulated into a product called “spinosad”. The product affects the central nervous system of the mosquito causing uncontrolled nervous impulses, ultimately killing the larvae.

2. Surface agents

Mosquito larvae and pupae breathe through tubes called “siphons” that extend above the water surface. Surface agents such as highly refined mineral oils or monomolecular films (alcohol derivatives) can spread across the surface of the water to prevent mosquitoes from breathing. Depending on the product, the film may remain on the water’s surface from a few hours to a few days. Surface films are the only available products that are effective against very late stage larvae and pupae.

3. Insect growth regulators

Insect growth regulators (IGRs) disrupt the physiological development of larvae thus preventing adults from emerging. The two products currently used for controlling mosquito larvae are methoprene and diflubenzuron.

The effective life of these products varies with the formulation. Methoprene can be applied in granular, liquid, pellet, or briquette formulation. Methoprene has minimal non-target effects and no use restrictions. Diflubenzuron is rarely used in California because it may affect growth of non-target aquatic invertebrates. IGRs for mosquito control can be used in sources of water that are consumed by humans.

4. Chemical larvicides

Chemical pesticides are rarely used to control mosquito larvae. Organophosphate larvicides are used infrequently because of their potential non-target effects and label restrictions. The organophosphate pesticides temephos and malathion are registered for use as larvicides in California. However, malathion is currently used exclusively for adult mosquito control in the state. Temephos can be safely and effectively used to treat temporary water or highly polluted water where there are few non-target organisms and/or livestock are not allowed access. The efficacy of temephos may be up to 30 days depending on the formulation.

Adult Control

IPM mosquito control programs initiate adult mosquito control when action levels or thresholds are reached or exceeded. Thresholds are based on local sampling of the adult mosquito population and/or when the risk of mosquito-borne disease increases above levels established by a local agency, often following guidelines established in the California Mosquito-borne Virus Surveillance and Response Plan. Thresholds are an integral component of mosquito control because they provide a range of predetermined actions based on quantified data. Thresholds also establish expectations and boundaries for responses that ensure appropriate mosquito control activities are implemented at the appropriate time. The threshold for adult mosquito control depends on several factors including:

- How local citizens tolerate nuisance mosquitoes by evaluating public service requests.
- Overall mosquito abundance.
- Presence of mosquito-borne disease in the region.
- Abundance of mosquito species that are vectors of disease.
- Local acceptance of adult mosquito control activities.
- Climate data.

Adult mosquitoes can only be controlled with adulticides. Many mosquito control programs in California include adulticiding as an integral component of their IPM program. Adulticiding falls into two categories – barrier applications and ultra-low volume (ULV) applications. Barrier applications target resting mosquitoes by applying pesticides to vegetation and structures. Barrier applications typically cover relatively small areas and are applied to alleviate specific problems rather than an area wide adult mosquito problem.

ULV applications are used to control adult mosquitoes over large areas. An “ultra-low volume” (typically less than 2 oz / acre [140 ml / ha] total volume) of tiny oil or water droplets carrying an insecticide are emitted from specialized equipment mounted to trucks or aircraft. The droplets kill adult mosquitoes on contact. ULV applications are made after sunset or before sunrise to coincide with the time that mosquitoes are most active, when non-target insects are least active, and when temperature inversions are most likely to occur. These applications are employed when mosquito populations must be reduced immediately to halt disease transmission. Multiple applications in a particular area may be utilized when the objective is to kill a high enough proportion of older adult mosquitoes to break a disease transmission cycle.

Adverse effects from ULV applications are rare; however, people with health problems should be aware when and where the applications are being conducted. This information can be obtained by contacting the local vector control agency. Chemicals currently registered for ULV applications against mosquitoes in California (as of June, 2010) include organophosphates (e.g., malathion and naled), pyrethrins, (e.g., pyrethrum) and pyrethroids (e.g., resmethrin, sumithrin, permethrin, and etofenprox). With the exception of the active ingredient etofenprox, formulations of both pyrethrins and pyrethroids include the synergist piperonyl butoxide (PBO), which increases their activity against mosquitoes.

1. Organophosphates

   Malathion and naled are neurotoxins that act by blocking the enzyme cholinesterase, inhibiting neurologic transmission. Malathion or naled may be used as rotational products with pyrethroid insecticides to help prevent development of pesticide resistance.

2. Pyrethrins

   Pyrethrins and pyrethroids are neurotoxins that act by causing uncontrolled firing of neurons. Pyrethrum is a natural insecticide derived from chrysanthemum flowers. Adult mosquitoes are rapidly paralyzed and killed on contact. Pyrethrins are degraded rapidly by sunlight and chemical processes. Residual pyrethrins from ULV applications typically remain less than one day on plants, soil, and water.

3. Pyrethroids

   Pyrethroids are manufactured pyrethrins. They have very low toxicity to birds and mammals but are toxic to fish if misapplied.

Compounds currently approved for larval and adult mosquito control in California are listed in Appendix B.

Mosquito Surveillance

Mosquito and Mosquito-Borne Disease Monitoring

Monitoring mosquito populations and mosquito-borne disease levels provides the necessary data to make informed management decisions.

The application of any pesticide to control mosquitoes in an IPM program is done after establishing the need to do so through mosquito population monitoring (surveillance).

Larval mosquito surveillance is the process of identifying and checking likely larval developmental sites for immature mosquitoes and treating the water to kill the mosquitoes prior to them emerging as flying, biting adults.

Adult mosquito surveillance is accomplished through a network of traps and through mosquito annoyance reports. Adult mosquito surveillance is a critical component of determining where mosquitoes are coming from, the potential for disease transmission in an area, and the need for adult mosquito control. Districts also use adult surveillance as a feedback or quality control mechanism to determine how effective the overall program is in reducing mosquito populations. Trapping adult mosquitoes and submitting those mosquitoes to test for diseases is often one component of a mosquito-vectored disease surveillance program. Collecting baseline data on mosquito populations and mosquito-borne disease also helps target educational efforts.

Mosquito Surveillance Techniques

1. Larval surveillance

   Larval surveillance is the routine sampling of aquatic habitats for developing mosquitoes. The primary tool is the "dip count" which indicates whether a habitat is producing mosquitoes and estimates larval density. A one-pint cup attached to a long handle is used to collect a standard volume of water ("dip sample"). The "dip count" may be expressed as the number of immature (larvae and pupae) mosquitoes per dip, per unit volume, or per unit surface area of the site.

2. Adult surveillance

   Several types of traps are used for adult surveillance, because mosquitoes are attracted to different traps depending on their species, sex, and physiological condition. The most common traps use light, carbon dioxide, water for egg laying, and a resting area. Trapped adults provide information about local distribution, density, and identity. The size of an adult mosquito population can also be assessed by the number and distribution of service requests from the public. Data are used to help locate new sources of mosquitoes or known sources with a recurrent problem

Annoyance Biting

Many species of mosquitoes are not important as vectors of disease, but can cause serious injury and discomfort to humans and animals. Each time a female mosquito pierces the skin to take blood, she contaminates the wound with her saliva, creating the potential for a mild allergic reaction. The common symptom of mosquito bites is irritated and swollen skin surrounding the bite with persistent itching for several days. Scratching these bites to alleviate the itching can result in secondary bacterial infections. In addition, when mosquito populations explode, the sheer number of mosquitoes attempting to bite can make life miserable.

Mosquitoes as Disease Vectors

Mosquitoes are the most important insect vectors of disease worldwide, causing millions of human deaths every year. Mosquito-borne pathogens are typically transmitted or "vectored" when a mosquito ingests a disease causing organism, the organism reproduces inside the mosquito, and is subsequently injected along with saliva into another animal or human host. The potential or "competence" to vector any particular disease causing organism varies greatly among mosquito species.

California has a long history of mosquito-borne disease. Mosquito control programs were first developed in the early 1900s to combat malaria and other diseases, and to reduce populations of nuisance mosquitoes. Currently, there are 12 mosquito-borne viruses recognized in California; however, only West Nile virus (WNV), western equine encephalomyelitis (WEE), and Saint Louis encephalitis (SLE) are significant threats to public health. Global trade and travel will continue to provide an avenue for introducing or re-introducing other mosquito-borne pathogens and their vectors into California and the United States. The diseases of greatest concern include Japanese encephalitis, dengue, yellow fever, Rift Valley fever, chikungunya, Venezuelan encephalitis, and malaria.

Virus Surveillance

In 2000, CDPH collaborated with the University of California, Davis, the California Department of Food and Agriculture, local mosquito and vector control agencies, and other state and local agencies to develop a comprehensive statewide surveillance program to detect and monitor WNV activity. More than 70 local mosquito and vector control districts and agencies, environmental health agencies, and county public health departments throughout California routinely contribute to the program. Surveillance includes testing for WNV infections in humans, horses, mosquitoes, wild birds, and "sentinel" chicken flocks located throughout California. The program also includes testing dead birds reported by the public for infections with WNV. A special website (http://www.westnile.ca.gov/) and toll-free hotline (877-WNV-BIRD) were created and are maintained by CDPH to support this surveillance program. The information from the program allows CDPH and local agencies to identify conditions conducive to WNV transmission and areas with elevated risk. This information is used by local mosquito control agencies to reduce the threat of WNV transmission to humans.

Mosquito Transmitted Diseases

Landowners throughout California, mosquito and vector control agencies, health departments, and CDPH work together to protect Californians from mosquito-borne diseases. Work to minimize the risk of disease transmission includes 1) comprehensive mosquito surveillance and control efforts on private and public lands, 2) agencies providing technical guidance and information to the medical and veterinary communities, and 3) educating the public about mosquitoes, the diseases they carry, and personal protective measures.

Encephalitis

Several mosquito-borne viruses that occur in California can cause encephalitis. The majority of human infections with these viruses have no symptoms. Those with so-called mild symptoms can still have significant illness and face prolonged recovery, and severe cases can be fatal or cause permanent neurological damage. There are several species of mosquitoes in California that can transmit WNV, SLE, and WEE viruses to people and animals. The most important species belong to the genus *Culex*. Specifically *Cx. tarsalis*, *Cx. pipiens*, and *Cx. quinquefasciatus* are significant public health concerns because of their widespread distribution throughout the state, their proximity to humans, and their capacity as very efficient vectors.

West Nile Virus

West Nile virus has become an endemic disease in California and like other encephalitic viruses, can cause serious illness. Many people who are infected do not get sick or may have a variety of symptoms that can include fever, head and body aches, nausea, vomiting, swollen lymph glands, and skin rash. Only about one in 150 infected people will develop a serious illness that may require hospitalization. Elderly people are at highest risk of developing the severe form of WNV and are at an increased risk of long-lasting physical and mental disorders. The severe form of the disease can be fatal.

Malaria

Malaria is caused by four species of protozoa. The parasites destroy red blood cells causing severe fever and anemia. Left untreated, malaria can cause kidney failure, coma, and death. Malaria was once a common public health threat in California and much of the southern United States, but it was eradicated by intensive mosquito control efforts and the discovery of anti-malarial drugs. However, the disease still occurs in many other countries worldwide, creating a perpetual risk of re-introduction, especially from infected travelers and immigrants. The *Anopheles* mosquitoes capable of transmitting malaria still occur in many areas of California.

Canine Heartworm

Canine heartworm occurs worldwide. It is caused by a filarial nematode transmitted by *Aedes* and some *Culex* mosquitoes that can infect domestic dogs, wild canines (e.g., foxes, coyotes, wolves), and cats. The tiny worms migrate through the body to the heart and cause thickening and inflammation of the heart, which can lead to difficulty in breathing, chronic cough, vomiting, and can sometimes be fatal.

Appendix B
Compounds Approved for Mosquito Control in California

Pesticides used for mosquito control have been evaluated for this purpose by the U.S. Environmental Protection Agency (EPA) and found to pose minimal risks to human health and the environment when used according to label directions. For updated information on specific products approved for use in California, please refer to the California Department of Pesticide Regulation website: http://www.cdpr.ca.gov/docs/label/labelque.htm.

Mosquito and vector control programs that apply pesticides to a water of the United States for the purpose of controlling any vector are required to obtain a National Pollution Discharge Elimination System (NPDES) Permit for Biological and Residual Pesticide Discharges to Waters of the United States. More information on the permit, issued by the State Water Resources Control Board, can be found at: http://www.waterboards.ca.gov/water_issues/programs/npdes/aquatic.shtml#davcp.

The components of this appendix have been adapted from the California Mosquito-Borne Virus Surveillance and Response Plan; please refer to the following website for more information: http://www.westnile.ca.gov.

The use of pesticides to control mosquitoes should be the last resort after BMPs outlined in this manual have been implemented. Individuals considering applying a pesticide must be adequately trained and always apply pesticides according to label directions. In California, local mosquito control agency employees must pass a testing and certification process through CDPH before they can apply pesticides to control mosquitoes. Similarly, commercial pesticide applicators must be appropriately certified by the California Department of Pesticide Regulation. Private landowners applying general use pesticides to control mosquitoes solely on their own property are not required to be certified; however, landowners have the same legal responsibility with regard to pesticide and environment related laws. Private citizens considering using pesticides should consult their County Agricultural Commissioner and the California Department of Fish and Game before application.

Examples of products containing specific active ingredients are provided below, but this is not an inclusive list nor constitutes product endorsement. For more information on pesticides and mosquito control, please refer to the U.S. EPA website: http://www.epa.gov/pesticides/health/mosquitoes/mosquito.htm.

Larvicides

1. *Bacillus thuringiensis*, subspecies *israelensis* (Bti: e.g., Aquabac 200G, VectoBac® 12AS, Teknar HP-D)
   Use: Approved for most permanent and temporary bodies of water.

Limitations: Only works on actively feeding stages. Does not persist well in the water column.

2. *Bacillus sphaericus* (Bs: e.g., VectoLex® CG)
   Use: Approved for most permanent and temporary bodies of water.
   Limitations: Only works on actively feeding stages. Does not work well on all species. May persist and have residual activity in some sites.

3. Spinosad (bacteria derived natural insecticide: e.g., Natular G)
   Use: Approved for most permanent and temporary bodies of water.
   Limitations: Only works on mosquito larvae.

4. IGRs (Insect Growth Regulators)
   a. (S)-Methoprene (e.g., Altosid® Pellets)
   Use: Approved for most permanent and temporary bodies of water.
   Limitations: Works best on older instars. Some populations of mosquitoes may show some resistance.
   b. Diflurobenzuron (e.g., Dimilin®25W)
   Use: Impounded tail water, sewage effluent, urban drains and catch basins.
   Limitations: Cannot be applied to wetlands, crops, or near estuaries.

5. Larviciding oils (e.g., GB-1111, BVA 2 Mosquito Larvicide Oil)
   Use: Ditches, dairy lagoons, floodwater. Effective against all stages, including pupae.
   Limitations: Consult with the California Department of Fish and Game for local restrictions.

6. Monomolecular films (e.g., Agnique® MMF)
   Use: Most standing water including certain crops.
   Limitations: Does not work well in areas with unidirectional winds in excess of 10 mph.

7. Organophosphate compounds
   Temephos (e.g., Abate® 2-BG)
   Use: Non-potable water; marshes; polluted water sites
   Limitations: Cannot be applied to crops for food, forage, or pasture. This material may not be effective on some *Culex tarsalis* populations in the Central Valley.

Adulticides

1. Organophosphate compounds
   Note: Many *Culex tarsalis* populations in the Central Valley have shown resistance to OP pesticides at approved label rates.
   a. Malathion (e.g., Fyfanon® ULV)
      Use: May be applied by air or ground equipment over urban areas, some

crops including rice, wetlands.
Limitations: Paint damage to cars; toxic to fish, wildlife and bees; crop residue limitations restrict application before harvest.

b. Naled (e.g., Dibrom® Concentrate, Trumpet® EC)
Use: Air or ground application on fodder crops, swamps, floodwater, residential areas.
Limitations: Similar to malathion.

c. Chlorpyrifos (e.g., Mosquitomaster 412)
Use: Air or ground application in urban or recreational areas
Limitations: Not registered for use over agricultural commodities or grazing lands and may be toxic to bees, fish, and some wildlife.

2. Pyrethrins (natural pyrethrin products: e.g., Pyrenone® Crop Spray, Pyrenone® 25-5, Evergreen®)
Use: Wetlands, floodwater, residential areas, some crops.
Limitations: Do not apply to drinking water, milking areas; may be toxic to bees, fish, and some wildlife. Some formulations with synergists have greater limitations.

3. Pyrethroids (synthetic pyrethrin products containing deltamethrin, cyfluthrin, permethrin, resmethrin, sumithrin, or etofenprox: e.g., Suspend® SC, Tempo Ultra SC, Aqua-Reslin®, Scourge® Insecticide, Anvil® 10+10 ULV, and Duet, which also contains the mosquito exciter prallethrin)
Use: All non-crop areas including wetlands and floodwater.
Limitations: May be toxic to bees, fish, and some wildlife; avoid treating food crops, drinking water or milk production.

PESTICIDES USED FOR LARVAL MOSQUITO CONTROL IN CALIFORNIA
LARVICIDES

Appendix C
Health and Safety Codes Pertinent to Mosquito Control

In California, mosquito and vector control agencies are regulated by sections of the California Health and Safety (H&S) Code, Food and Agriculture Code, California Code of Regulations, and others. The following components of this appendix have been adapted from the Overview of Mosquito Control Practices in California, California Department of Public Health: http://www.westnile.ca.gov/resources.php

Governing laws and regulations

Many federal and state laws govern the activities of vector control agencies, including the Clean Water Act (CWA), the Endangered Species Act (ESA), and the Federal Insecticide Fungicide and Rodenticide Act (FIFRA). Pesticide application by vector control agencies in California is regulated under FIFRA. FIFRA is administered through the U.S. Environmental Protection Agency, and regulates the registration, labeling, and sales of pesticides in the United States.

The California H&S Code encourages the formation of local mosquito control programs to protect the public health, safety, and welfare (H&S Code Section 2001-b) Website link: http://leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=01001-02000&file=2000-2007. The legal responsibility of landowners in California to avoid causing a public nuisance, including mosquitoes is implied in the section. The potential consequences of failing to prevent a public nuisance are described in the Code sections listed below.

Under the H&S Code, local vector control agencies have the authority to conduct surveillance for vectors, prevent the occurrence of vectors, and legally abate production of vectors or public nuisance defined as “Any water that is a breeding place for vectors” and “Any activity that supports the development, attraction, or harborage of vectors, or that facilitates the introduction or spread of vectors.”(H&S Code Section 2002(j) and 2040). Vector control agencies also have authority to participate in review, comment, and make recommendations regarding local, state, or federal land use planning and environmental quality processes, documents, permits, licenses, and entitlements for projects and their potential effects with respect to vector production. (H&S Code Section 2041) Website link: http://caselaw.lp.findlaw.com/cacodes/hsc/2040-2055.html

Additionally, agencies have broad authority to influence landowners to reduce or “abate” the source of a vector problem. Actions may include imposing civil penalties of up to $1000 per day plus costs associated with controlling the vector. Agencies have authority to “abate” vector sources on private and publicly owned properties. (H&S Code Sections 2060-2065). Website link: http://caselaw.lp.findlaw.com/cacodes/hsc/2060-2067.html

Mosquito and vector control programs that enter into a cooperative agreement with the California Department of Public Health are exempted from some pesticide related laws under Title 3 of the California Code of Regulations Section 6620. Specifically, these agencies are exempted from "Consent to Apply" (Title 3, California Code of Regulations, Section 6616), "Notice" (Title 3, California Code of Regulations, Section 6618), and the "Protection of Persons, Animals, and Property" (Title 3, California Code of Regulations, Section 6614). Essentially, these provisions obviate the vector control agency from having to notify or get permission from landowners prior to applying a pesticide to their property in the interest of preserving the public health. Website link: http://www.cdpr.ca.gov/docs/legbills/calcode/030201.htm#a6620

A vector control technician working at a vector control agency must be a "certified technician" or work under the direct supervision of a "certified technician" to apply pesticides. Vector control technicians achieve certification through an examination process administered by the California Department of Public Health.

Vector control agencies cannot use any pesticide not registered for use in California, and are required to keep detailed records of each pesticide application, including date, location, and amount applied. All pesticides must be applied in accordance with the labeling of the product as registered with the U.S. EPA.

Appendix D
Mosquitoes of California

The biology and key characteristics of the four major mosquito genera in California are described below.

Aedes

There are about 80 species of *Aedes* mosquitoes in the continental United States; 24 species occur in California. Certain species are widespread, may occur in very large numbers, and are among the worst biting pests. *Aedes* mosquitoes do not lay their eggs directly on the surface of standing water. Instead, they lay single eggs on intermittently flooded surfaces such as the damp soil around irrigated pastures and fields, along the edges of coastal tidal marshes, and inside dry treeholes and containers. Eggs are extremely resistant to drying and will lie dormant on dry surfaces until flooding occurs (eggs of *Ae. vexans* have been documented to lie dormant for up to three years). This can lead to many generations of eggs in a given habitat if female mosquitoes lay successive batches of eggs before the area is flooded. When flooding occurs, large numbers of eggs hatch spontaneously and develop rapidly to adults. Although larval developmental sites vary greatly, the most productive include transient ground pools, flooded areas along overflowing streams, flood and stormwater control basins, intermittently flooded agricultural lands, and container habitats such as tree holes, wheel ruts, and discarded tires.

Aedes are primarily summer-breeding mosquitoes. Because of their rapid larval development in newly-flooded habitats, adults often emerge before predators can colonize the water source. Most *Aedes* complete two to several generations per year depending on the frequency of habitat flooding from natural and artificial events. Adults cannot survive in colder weather. Therefore the majority of *Aedes* overwinter as eggs.

Typically, *Aedes* mosquitoes found in California will not enter buildings and homes; however, they are strong fliers and are known to travel many miles from their aquatic developmental sites to search for hosts. *Aedes* mosquitoes are diurnal (i.e., active during the day) during mild weather, especially around shaded areas, but will also bite at dusk. Most *Aedes* females feed on large mammals like cattle and horses, but will readily feed on humans. *Aedes* mosquitoes are aggressive and persistent biters causing people and animals to avoid areas where their numbers are great. One example is the species *Ae. nigromaculis*, which are currently not known to vector disease, but are considered a serious pest because they will seek out human hosts and bite during the day when people are most likely to be outdoors and active.

Anopheles

Approximately 22 species of *Anopheles* are found in the continental United States and of these, 5 occur in California. When feeding, *Anopheles* adults rest with their abdomens positioned at a distinct angle to the surface of the skin, whereas other species orient their bodies parallel. Females lay single floating eggs directly on the surface of permanent or semi-permanent standing water. A female can lay successive batches of up to 300 eggs during the breeding season. Eggs are not resistant to drying and typically hatch within two-three days, although hatching may take up to two-three weeks in colder climates. Larvae develop in 12 to 20 days, but can take longer in cooler weather. Preferred larval habitats include clear, fresh seepage water in sunlit or partly shaded pools, wetlands, roadside ditches, rice fields, and poorly maintained water troughs.

Adult females bite at dusk and dawn and prefer to feed on mammals. Many *Anopheles* mosquitoes prefer to feed on rabbits, but will also feed on large mammals such as livestock and humans. In California, *Anopheles* species may undergo two or more generations per year. Most species over-winter in protected areas as mated females, resuming activity the following spring. These are among the first mosquitoes to emerge and bite humans each year.

Historically, *Anopheles freeborni*, the western malaria mosquito, was a vector of malaria in California. Currently, with the disease eradicated from California and the United States, it is considered a nuisance mosquito. This species is widespread throughout California and females will lay their eggs in any standing fresh water, although it is abundant in rice fields or other wetlands during late summer. While most adult mosquitoes stay within a few miles of their breeding source, they will migrate further when seeking hibernation sites in fall. This can lead to a large influx of mosquitoes from uncontrolled areas to residential areas during September and October.

Culex

Culex, with 11 species found throughout the state is the second largest genus of mosquitoes in California, second only to *Aedes*. Females can lay up to seven rafts of eggs over a two-month life span; each raft contains from 100-300 eggs which are laid on the surface of standing water. *Culex* larvae occur in a broad range of aquatic sites ranging from containers such as discarded tires, water barrels, and flower pots to clogged gutters, catch basins, and water for irrigation and urban wastewater. During summer and periods of drought, areas without regularly flowing water, street drainage systems, and contaminated streams, ponds and pools become productive larval habitats. *Culex* larvae are known for thriving in polluted sources of water with a high organic content.

Culex mosquitoes prefer to take blood meals at dusk or after dark and can be painful and persistent biters. *Culex* preferably feed on birds but also feed on mammals including humans and horses. They readily enter houses and buildings in search of a suitable host. Two or more generations of *Culex* can occur per year. Females that emerge in late summer will mate and overwinter until the following spring or mid-summer.

Several species of *Culex* can transmit viruses that can cause encephalitis (i.e., inflammation of the brain), including WNV, SLE, and WEE. These mosquitoes are efficient and effective vectors of these diseases among birds, humans, horses and many other wild and domestic animals.

Culex tarsalis

Culex tarsalis, the Western encephalitis mosquito, is one of California's most important and efficient vectors of WNV, SLE, and WEE. This species is widespread in California. *Cx. tarsalis* prefer to lay their eggs on fresh or lightly polluted standing water such as rice fields, ditches, pastures, waste water ponds, and seasonal wetlands. Other more urban freshwater sources include ornamental ponds, storm drains, and flood control channels. Larvae usually develop into adults in approximately 8-14 days; warmer water can shorten the developmental period. *Cx. tarsalis* are active from spring through fall; however the population in the Central Valley peaks in June to July with a secondary, smaller peak in September coinciding with flooding of seasonal wetlands. *Cx. tarsalis* survive through the winter as adults in barns, culverts, caves, and similar dark, protected places.

Adult *Cx. tarsalis* can disperse a great distance up to 10-15 miles (16-24 km) in search of blood meals, generally traveling along riparian corridors, but most stay close to the site where they emerged. Adults rest by day in shaded areas such as animal burrows and treeholes. Females prefer feeding between dusk and dawn but may bite during the day in deep shade. Females obtain blood meals from birds or mammals and can transmit diseases between these groups.

Culex pipiens* and *Culex quinquefasciatus

Culex pipiens (the northern house mosquito) and *Culex quinquefasciatus* (the southern house mosquito) appear to be identical. *Cx. quinquefasciatus* occurs in Southern California, whereas *Cx. pipiens* is found along the coastal regions and in Northern California and is the most widely distributed mosquito species in the world. Both species can transmit encephalitis viruses. They are common in and around households and prefer to lay eggs in polluted water that is high in organic content such as dairy runoff, wastewater catchment basins, stormwater ponds, dirty flower pots, bird baths, or any drainage systems where standing water exists.

In California, *Cx. pipiens* and *Cx. quinquefasciatus* typically do not disperse from where they emerged. Females feed at dusk or after dark, readily enter homes and prefer avian hosts but will also feed on large mammals including humans. *Cx. pipiens* and *Cx. quinquefasciatus* are vectors of WNV and SLE virus, and have also been implicated in transmitting canine heartworm.

Other *Culex* mosquitoes.

Culex stigmatosoma, the foul water mosquito, *Cx restuans* and *Cx. erythrothorax* can also be infected with WNV, but their distributions are limited (e.g., *Cx. erythrothorax* is mainly found close to bodies of water with tules).

Culiseta

Only eight species of *Culiseta* mosquitoes occur in the continental United States, of which four are found in California. Females lay clusters of floating eggs (rafts) on the surface of standing water. *Culiseta* mosquitoes are moderately aggressive biters, attacking in the evening hours or in shade during the day. Peak populations occur during the cooler months. These mosquitoes prefer to feed on larger domestic animals, such as cattle and horses, but will also feed on humans. The distribution of *Cs. inornata*, an unusually large mosquito, is widespread and can be found at elevations of up to 10,000 feet. Larvae of *Cs. inornata* develop in permanent water habitats, including shallow marshes, peat bogs, roadside ditches, abandoned gravel pits, and in standing water in soil cavities left by fallen trees. The common name of this mosquito—the Large Winter mosquito—reflects that it is most active in cool weather habitats.

Anopheles species | *Aedes* species | *Culex* & *Culiseta* species

Appendix E

Appendix F
Insect Repellents

A number of products have been developed and registered by the Environmental Protection Agency for human use that repel adult mosquitoes and thus reduce the chances of mosquito bites. The most commonly used mosquito repellents contain the active ingredient DEET (N,N-diethyl-meta-toluamide), which has been formulated and sold under a variety of trade names. Repellents are available in a variety of concentrations and are formulated as aerosol sprays (most commonly at 15%), lotions, and solids (up to 100%). Spray repellents can be used on outer clothing as well as sparingly on the skin to ensure complete coverage. Repellents should not be used under clothing. The percentage of DEET in the repellent reflects the approximate length of time the product will repel mosquitoes (e.g., 23.8% DEET = about five hours of protection, 20% = about four hours, and 6.6% DEET = about two hours).

Topical repellents that contain picaridin, IR-3535, and oil of lemon eucalyptus are similar in efficacy to those with DEET, but often require more frequent application. Clothing and other materials impregnated with permethrin during manufacture are also available. It is important to always carefully read and understand the benefits and limitations of repellents listed on the product label before use. By law, all repellent products must be used according to their labels.

Appendix G
Additional Resources and Information

Mosquito Biology

Additional information on mosquitoes and mosquito-borne diseases is easily obtainable from a variety of reputable sources. More information on mosquito biology and ecology is available on the American Mosquito Control Association (AMCA) and the Mosquito and Vector Control Association of California (MVCAC) websites. Local mosquito and vector control agencies and their respective websites can provide detailed information about local mosquito species. Information on mosquito-borne diseases is available from the Centers for Disease Control and Prevention (CDC) and the CDPH websites. Contact information for local mosquito and vector control agencies in California can be found through the CDPH website by entering the zip code of the location of interest under "**Locate Your Local Mosquito and Vector Control Agency**" at http://www.westnile.ca.gov/; more information is available on the MVCAC website.

Monitoring Mosquitoes and Diseases

More information about reporting dead birds and WNV surveillance in California can be found at http://www.westnile.ca.gov/.
Methods for sampling adult mosquitoes and guidelines for designing, operating, and processing of traps are discussed in Guidelines for Integrated Mosquito Surveillance (Meyer et al. 2003) and are summarized in Appendix B of the California Mosquito-Borne Virus Surveillance and Response Plan which can be found at: http://www.westnile.ca.gov/resources.php

WNV	West Nile virus

ORDINANCE NO. 181899

An ordinance amending Sections 64.70.01 and 64.72 of Article 4.4 of Chapter VI of the Los Angeles Municipal Code to expand the applicability of the existing Standard Urban Stormwater Mitigation Plan (SUSMP) requirements by imposing rainwater Low Impact Development (LID) strategies on projects that require building permits; and amending Section 64.72.05 of Article 1 of Chapter IX of the Los Angeles Municipal Code to collect fees to recover Bureau of Sanitation costs of administering the provisions of this Ordinance.

WHEREAS, the City of Los Angeles is authorized by Article XI, §5 and §7 of the State Constitution to exercise the police power of the State by adopting regulations to promote public health, public safety and general prosperity;

WHEREAS, the City of Los Angeles has authority under the California Water Code to adopt and enforce ordinances imposing conditions, restrictions and limitations with respect to any activity that might degrade the quality of waters of the State;

WHEREAS, the City of Los Angeles has applied an integrated approach to incorporate wastewater, stormwater and runoff, and recycled water management into a single strategy through its Integrated Resources Plan;

WHEREAS, the City of Los Angeles is committed to a stormwater management program that protects water quality and water supply by employing watershed-based approaches that balance environmental and economic considerations;

WHEREAS, the purpose of this Ordinance includes, but is not limited to, rainwater harvesting and stormwater runoff management, water conservation, and recycled water reuse and gray water use, which are all key elements of the City of Los Angeles "Water Supply Action Plan" and are essential to ensuring responsible and sustainable development;

WHEREAS, urbanization has led to increased impervious surface areas resulting in increased water runoff and less percolation to groundwater aquifers causing the transport of pollutants to downstream receiving waters;

WHEREAS, the City of Los Angeles needs to take a new approach to managing rainwater and urban runoff while mitigating the negative impacts of development and urbanization;

WHEREAS, the City of Los Angeles' Los Angeles River Revitalization Plan has identified reduction in peak stormwater runoff in the Los Angeles River as necessary to implement many of the Los Angeles River revitalization projects;

WHEREAS, LID is widely recognized as a sensible approach to managing the quantity and quality of stormwater runoff by setting standards and practices to maintain or restore the natural hydrologic character of a development site, reduce off-site runoff, improve water quality, and provide groundwater recharge; and

WHEREAS, it is the intent of the City of Los Angeles to expand the applicability of the existing Standard Urban Stormwater Mitigation Plan requirements by providing stormwater and rainwater LID strategies for all projects that require building permits.

NOW THEREFORE,

THE PEOPLE OF THE CITY OF LOS ANGELES DO ORDAIN AS FOLLOWS:

Section 1. Section 64.70.01 of Article 4.4 of Chapter VI of the Los Angeles Municipal Code is amended in its entirety to read as follows:

SEC. 64.70.01. DEFINITIONS AND ABBREVIATIONS.

A. Definitions. For the purpose of this Article, the following words and phrases are defined and shall be construed as set out here, unless it is apparent from the context that they have a different meaning:

1. "**Basin Plan**" means a Water Quality Control Plan adopted by the California Regional Water Quality Control Board for a specific watershed or designated area.

2. "**Best Management Practice (BMP)**" means activities, practices, facilities, and/or procedures that when implemented will reduce or prevent pollutants in discharges.

3. "**Board**" means the Board of Public Works of the City of Los Angeles or its duly authorized representative.

4. "**Bureau**" means the Bureau of Sanitation of the City of Los Angeles or its duly authorized representative.

5. "**City**" means the City of Los Angeles or its duly authorized representatives.

6. "**Clean Water Act (CWA)**" means the Federal Water Pollution Control Act enacted in 1972, by Public Law 92-500, and amended by the Water Quality Act of 1987. The Clean Water Act prohibits the discharge of pollutants to Waters of the United States unless the discharge is in accordance with an NPDES permit.

7. "**Commercial Activity**" means any public or private activity involved in the storage, transportation, distribution, exchange or sale of goods and/or commodities or providing professional and/or non-professional services.

8. "**Construction Activity**" means clearing, grading, or excavating that results in soil disturbance. Construction activity does not include routine maintenance to maintain original line and grade, hydraulic capacity, or the original purpose of the facility, nor does it include emergency construction activities required to immediately protect public health and/or safety.

9. "**Control**" means to minimize, reduce or eliminate by technological, legal, contractual or other means, the discharge of pollutants from an activity or activities.

10. **"Development"** means the construction, rehabilitation, redevelopment or reconstruction of any public or private residential project (whether single-family, multi-unit or planned unit development); industrial, commercial, retail and any other non-residential projects, including public agency projects; or mass grading for future construction.

11. **"Development Best Management Practices Handbook"** means such handbook, as may be amended from time to time, adopted by the Board of Public Works.

12. "**Director**" means the Director of the Bureau of Sanitation of the Department of Public Works of the City of Los Angeles or the duly authorized representatives designated to administer, implement and enforce the provisions of this Article.

13. "**Discharge**" means any release, spill, leak, pump, flow, escape, dumping, or disposal of any liquid, semi-solid or solid substance.

14. **"Environmentally Sensitive Areas (ESAs)"** means an area in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which would be easily disturbed or degraded by human activities and developments (See California Public Resources Code § 30107.5). ESAs include, but are not limited to, areas designated as Significant Ecological Areas by the County of Los Angeles (Los Angeles County Significant Areas Study, Los Angeles County Department of Regional Planning (1976) and amendments); areas designated as Significant Natural Areas by the California Department of Fish and Game's Significant Natural Areas Program and field verified by the Department of Fish and Game; and areas listed in the Basin Plan as supporting the "Rare, Threatened, or Endangered Species (RARE)" beneficial use.

15. "**Hazardous Material(s)**" means any material(s) defined as hazardous by Division 20, Chapter 6.95 of the California Health and Safety Code.

16. "**Illicit Connection**" means any man-made conveyance that is connected directly to the storm drain system, excluding roof-drains, and any other similar connection that serves as a pathway for any illicit discharge.

17. "**Illicit Discharge**" means any discharge to the storm drain system that is prohibited under local, state or federal statutes, ordinances, codes or regulations. Illicit discharges include all non-stormwater discharges except discharges pursuant to an NPDES permit or discharges that are exempted or conditionally exempted by the NPDES permit or granted as a special waiver or exemption by the Regional Board.

18. "**Impervious Surface**" means any man-made or modified surface that prevents or significantly reduces the entry of water into the underlying soil, resulting in runoff from the surface in greater quantities and/or at an increased rate, when compared to natural conditions prior to development. Examples of places that commonly exhibit impervious surfaces include parking lots, driveways, roadways, storage areas, and rooftops. The imperviousness of these areas commonly results from paving, compacted gravel, compacted earth, and oiled earth.

19. "**Industrial Activity**" means any public or private activity that is associated with any of the 11 categories of activities defined in 40 CFR 122.26(b)(14) and required to obtain a NPDES permit.

20. "**Industrial/Commercial Facility**" means any facility involved and/or used in either the production, manufacture, storage, transportation, distribution, exchange or sale of goods and/or commodities, and any facility involved and/or used in providing professional and non-professional services. This category of facility includes, but is not limited to, any facility defined by the Standard Industrial Classifications (SIC). Facility ownership (federal, state, municipal, private) and profit motive of the facility are not factors in this Definition.

21. **"LID"** means Low Impact Development.

22. "**Maximum Extent Practicable (MEP)**" means the standard for implementation of stormwater management programs to reduce pollutants in stormwater. MEP refers to stormwater management programs taken as a whole. It is the maximum extent possible taking into account equitable considerations and competing facts, including but not limited to, the gravity of the problem, public health risk, societal concern, environmental benefits, pollutant removal effectiveness, regulatory compliance, public acceptance, ability to implement, cost, and technical feasibility. Section 402(p) of the Clean Water Act requires that municipal permits shall require controls to reduce the discharge of

pollutants to the maximum extent practicable, including management practices, control techniques and systems, design and engineering methods, and other provisions as the Administrator or the State determines appropriate for the control of these pollutants.

23. "**National Pollutant Discharge Elimination System (NPDES)**" means a permit issued by the U.S. EPA, State Water Resources Control Board, or the California Regional Water Quality Control Board pursuant to the Clean Water Act that authorizes discharges to Waters of the United States and requires the reduction of pollutants in the discharge.

24. "**Non-Stormwater Discharge**" means any discharge to a municipal storm drain system that is not composed entirely of stormwater.

25. "**Person**" means any individual, partnership, co-partnership, firm, company, corporation, association, joint stock company, trust, estate, governmental entity or any other legal entity, or their legal representatives, agents or assigns. The masculine gender shall include the feminine and the singular shall include the plural where indicated by the context.

26. "**Pollutant**" means any "pollutant" defined in Section 502(6) of the Federal Clean Water Act or incorporated into the California Water Code Sec. 13373. Pollutants may include, but are not limited to the following:

(a) Commercial and industrial waste (such as fuels, solvents, detergents, plastic pellets, hazardous substances, fertilizers, pesticides, slag, ash, and sludge);

(b) Metals (such as cadmium, lead, zinc, copper, silver, nickel, chromium, and non- metals such as phosphorus and arsenic);

(c) Petroleum hydrocarbons (such as fuels, lubricants, surfactants, waste oils, solvents, coolants, and grease);

(d) Excessive eroded soil, sediment, and particulate materials in amounts that may adversely affect the beneficial use of the receiving waters, flora or fauna of the State;

(e) Animal wastes (such as discharge from confinement facilities, kennels, pens, recreational facilities, stables, and show facilities); and

(f) Substances having characteristics such as pH less than 6 or greater than 9, or unusual coloration or turbidity, or excessive levels of fecal coliform, or fecal streptococcus, or enterococcus.

27. "**Receiving Waters**" means all surface water bodies within Los Angeles County that are identified by the Regional Board in a Basin Plan.

28. **"Redevelopment"** means land-disturbing activity that results in the creation, addition, or replacement of 500 square feet or more of impervious surface area on an already developed Site. Redevelopment includes, but is not limited to: the expansion of a building footprint; addition or replacement of a structure; replacement of impervious surface area that is not part of routine maintenance activity; and land disturbing activity related to structural or impervious surfaces. It does not include routine maintenance to maintain original line and grade, hydraulic capacity, or original purpose of facility, nor does it include emergency construction activities required to immediately protect public health and safety.

29. "**Regional Board**" means the California Regional Water Quality Control Board, Los Angeles Region.

30. "**Rules and Regulations**" shall mean Rules and Regulations adopted by the Board of Public Works Governing Pollution Control of Discharges into the Storm Drain System.

31. **"Site"** means land or water area where any "facility or activity" is physically located or conducted, including adjacent land used in connection with the facility or activity.

32. "**Storm Drain System**" means any facilities or any part of those facilities, including streets, gutters, conduits, natural or artificial drains, channels and watercourses that are used for the purpose of collecting, storing, transporting or disposing of stormwater and are located within the City of Los Angeles.

33. "**Storm Water or Stormwater**" means water that originates from atmospheric moisture (rainfall or snow melt) and that falls onto land, water, or other surfaces. Without any change in its meaning, this term may be spelled or written as one word or two separate words.

34. "**Stormwater Pollution Prevention Plan (SWPPP)**" means a plan required by and for which contents are specified in the State of California General Permit for Storm Water Discharges Associated with Industrial Activities or for Stormwater Discharges Associated with Construction Activities.

35. "**Stormwater Runoff**" means that part of precipitation (rainfall or snowmelt) which travels across a surface to the storm drain system or receiving waters.

36. "**Toxic Materials**" For purposes of compliance with the Los Angeles County Municipal Stormwater Permit, the term "toxic materials" means

any material(s) or combination of materials that directly or indirectly cause either acute or chronic toxicity in the water column.

37. "**Untreated**" means non stormwater runoff, wastewater or wash waters that have not been subjected to any applicable Treatment Control, Best Management Practices or are not in compliance with conditions of a separate or general NPDES permit.

38. "**Urban Runoff**" means surface water flow produced by storm and non-storm events. Non-storm events include flow from residential, commercial or industrial activities involving the use of potable and non-potable water.

Sec. 2. Section 64.72 of Article 4.4 of Chapter VI is amended to read as follows:

SEC. 64.72. STORMWATER POLLUTION CONTROL MEASURES FOR DEVELOPMENT PLANNING AND CONSTRUCTION ACTIVITIES

(A) Objective. The provisions of this Section contain requirements for construction activities and facility operations of Development and Redevelopment projects to comply with the requirements of the Standard Urban Stormwater Mitigation Plan, integrate LID practices and standards for stormwater pollution mitigation, and maximize open, green and pervious space on all Developments and Redevelopments consistent with the City's landscape ordinance and other related requirements in the Development Best Management Practices Handbook. LID shall be inclusive of SUSMP requirements.

(B) Scope. This Section contains requirements for stormwater pollution control measures in Development and Redevelopment projects and authorizes the Board to further define and adopt stormwater pollution control measures, develop LID principles and requirements, including but not limited to the objectives and specifications for integration of LID strategies, collect Best Management Practices compliance plan check fees, grant waivers from the requirements of the Standard Urban Stormwater Mitigation Plan, collect funds for projects that are granted waivers, conduct inspections, cite violators for infractions, and impose fines. Except as otherwise provided herein, the Board shall administer, implement and enforce the provisions of this Section.

(C) LID Requirements. All Developments and Redevelopments shall comply with the following:

1. Development or Redevelopment Involving four or Fewer Units Intended for Residential Use.

a. Development or Redevelopment less than one acre shall implement LID BMP alternatives identified in the Development Best Management Practices Handbook; and

b. Development or Redevelopment one acre or greater shall comply with the standards and requirements of this Article and with the Development Best Management Practices Handbook.

2. Development or Redevelopment Involving Nonresidential Use or five or More Units Intended for Residential Use.

a. Development or Redevelopment resulting in an alteration of at least fifty percent (50%) or more of the impervious surfaces on an existing developed Site, the entire Site must comply with the standards and requirements of this Article and with the Development Best Management Practices Handbook; and

b. Development or Redevelopment resulting in an alteration of less than fifty percent (50%) of the impervious surfaces of an existing developed Site, only such incremental Development shall comply with the standards and requirements of this Article and with the Development Best Management Practices Handbook.

3. A Development or Redevelopment of any size that would create 2,500 square feet or more of impervious surface area and is located partly or wholly within an ESA shall comply with the standards and requirements of this Article and with the Development Best Management Practices Handbook.

4. The Site for every Development or Redevelopment shall be designed to manage and capture stormwater runoff, to the maximum extent feasible, in priority order: infiltration, evapotranspiration, capture and use, treated through high removal efficiency biofiltration/biotreatment system of all of the runoff on site. High removal efficiency biofiltration/biotreatment systems shall comply with the standards and requirements of the Development Best Management Practices Handbook. A LID Plan shall be prepared to comply with the following:

a. Stormwater runoff will be infiltrated, evapotranspired, captured and used, treated through high removal efficiency Best Management Practices, onsite, through stormwater management techniques that comply with the provisions of the Development Best Management Practices Handbook. To the maximum extent feasible, onsite stormwater management techniques must be properly sized, at a minimum, to infiltrate, evapotranspire, store for use, treat through high removal efficiency biofiltration/biotreatment system, without any storm water runoff leaving the Site for at least the volume of water produced by the quality design storm event that results from:

(i) The 85th percentile 24-hour runoff event determined as the maximized capture stormwater volume for the area using a 48 to 72-hour draw down time, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998); or

(ii) The volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in the California Stormwater Best Management Practices Handbook – Industrial/Commercial, (2003); or

(iii) The volume of runoff produced from a 0.75 inch storm event.

For purposes of compliance with the LID requirements, and without changing the priority order of design preferences identified in this Section, all runoff from the water quality design storm event, as identified in Paragraph (a) of this Subdivision, that has been treated through an onsite high removal efficiency biofiltration/biotreatment system shall be deemed to have achieved 100% infiltration regardless of the runoff leaving the Site from an onsite high removal efficiency biofiltration/biotreatment system, and thus any runoff volume shall not be subject to the offsite mitigation requirement of this Article.

b. Pollutants shall be prevented from leaving the Site for a water quality design storm event as defined in Paragraph (a) of this Subdivision unless it has been treated through an onsite high removal efficiency biofiltration/biotreatment system.

c. Hydromodification impacts shall be minimized to natural drainage systems as defined in the MS4 Permit.

5. When, as determined by the Director, the onsite LID requirements are technically infeasible, partially or fully, as defined in the Development Best Management Handbook, the infeasibility shall be demonstrated in the submitted LID Plan, shall be consistent with other City requirements, and shall be reviewed in consultation with the Department of Building and Safety. The technical infeasibility may result from conditions that may include, but are not limited to:

a. Locations where seasonal high groundwater is within ten feet of surface grade;

b. Locations within 100 feet of a groundwater well used for drinking water;

c. Brownfield Development sites or other locations where pollutant mobilization is a documented concern;

d. Locations with potential geotechnical hazards;

e. Locations with impermeable soil type as indicated in applicable soils and geotechnical reports; and

f. Other site or implementation constraints identified in the Development Best Management Practices Handbook.

6. If partial or complete onsite compliance of any type is technically infeasible, the project Site and LID Plan shall be required to comply with all applicable Standard Urban Stormwater Mitigation Plan (SUSMP) requirements in order to maximize onsite compliance. For the remaining runoff that cannot feasibly be managed onsite, the project shall implement offsite mitigation on public and/or private land within the same sub-watershed out of the following five sub-watersheds: Upper Los Angeles River, Lower Los Angeles River, Ballona Creek, Santa Monica Bay, and Dominguez Channel. This shall include construction and perpetual maintenance of projects that will achieve at least the same level of runoff retention, infiltration and/or use, and water quality. All City Departments will assist the developer, when and where feasible, in the design, permitting and implementation of LID BMP projects within the public right of way, with a preference for utilizing the public right of way immediately adjacent to the subject development.

7. A Multi-Phased Project may comply with the standards and requirements of this Section for all of its phases by: (a) designing a system acceptable to the Bureau of Sanitation to satisfy these standards and requirements for the entire Site during the first phase, and (b) implementing these standards and requirements for each phase of Development or Redevelopment of the Site during the first phase or prior to commencement of construction of a later phase, to the extent necessary to treat the stormwater from such later phase. For purposes of this Section, "Multi-Phased Project" shall mean any Development or Redevelopment implemented over more than one phase and the Site of a Multi-Phased Project shall include any land and water area designed and used to store, treat or manage stormwater runoff in connection with the Development or Redevelopment, including any tracts, lots, or parcels of real property, whether Developed or not, associated with, functionally connected to, or under common ownership or control with such Development or Redevelopment.

8. The Director shall prepare, maintain, and update, as deemed necessary and appropriate, the Development Best Management Practices Handbook to set LID standards and practices and standards for stormwater pollution mitigation, including urban and stormwater runoff quantity and quality control development principles and technologies for achieving the LID standards. The Development Best Management Practices Handbook shall also include technical feasibility and implementation parameters, alternative compliance for

technical infeasibility, as well as other rules, requirements and procedures as the Director deems necessary for implementing the provisions of this Section of the Los Angeles Municipal Code. The Board of Public Works shall adopt the Development Best Management Practices Handbook no later than 90 days after the adoption of this Ordinance by the City Council and the Mayor.

9. The Director of the Bureau of Sanitation shall develop as deemed necessary and appropriate, in cooperation with other City departments and stakeholders, informational bulletins, training manuals and educational materials to assist in the implementation of the LID requirements.

10. The applicant can appeal the Director's determination of compliance with the provisions of this Article to the Board of Public Works within 30 days of the date of the determination.

11. Any Development or Redevelopment that is exempted from LID requirements under section D has the option to voluntarily opt in and incorporate into the project the LID requirements set forth herein. In such case, the Best Management Practices plan check fee associated with the project shall be waived and all LID related plan check processes shall be expedited.

12. Any Development or Redevelopment exempted from this Ordinance under section D shall comply with all applicable SUSMP requirements.

(D) Exceptions to LID Requirements. The provisions of this Section do not apply to any of the following:

1. A Development or Redevelopment that only creates, adds or replaces less than 500 square feet of impervious area;

2. A Development or Redevelopment involving only emergency construction activity required to immediately protect public health and safety;

3. Infrastructure projects within the public right-of-way;

4. A Development or Redevelopment involving only activity related to gas, water, cable, or electricity services on private property;

5. A Development or Redevelopment involving only re-striping of permitted parking lots;

6. A project involving only exterior movie or television production sets, or facades on an existing developed site.

(E) Other Agencies of the City of Los Angeles. All City of Los Angeles departments, offices, entities and agencies, shall establish administrative procedures necessary to implement the provisions of this Article on their Development and Redevelopment projects and report their activities annually to the Board of Public Works.

Sec. 3. Section 64.72.05 of Article 4.4 of Chapter VI of the Los Angeles Municipal Code is amended to read:

SEC. 64.72.05. LID PLAN CHECK FEES.

(A) Before review and approval of a set of plans and specifications for checking, the applicant shall pay a Best Management Practices plan check fee.

(B) The fee schedule for providing Best Management Practices plan check services for LID Implementation Plan, Standard Urban Stormwater Mitigation Plan (SUSMP), or Site Specific Mitigation Plan (SSMP) is as follows:

DEVELOPMENT CATEGORY	FEES
Development or Redevelopment less than 500 square feet	Exempt
Residential, 4 Units or Less:	
For Development or Redevelopment greater than or equal to 500 square feet and less than 2,500 square feet	$20 / Project
For Development or Redevelopment greater than or equal to 2,500 square feet	$200 / Project
Development or Redevelopment of any size that would create 2,500 square feet or more of impervious surface area and is located partly or wholly within an ESA*	$700 / Project
Nonresidential Use or 5 or More Units Intended for Residential Use:	
For Redevelopment that results in an alteration of less than fifty (50) percent of the impervious surfaces of an existing developed Site	$800 / Project
For new Development or where Redevelopment that results in an alteration of at least fifty (50) percent or more of the impervious surfaces of an existing developed Site	$1,000 / Project

* Projects located in, adjacent to, or discharging directly to a designated Environmentally Sensitive Area (ESA)

(C) At the discretion of the Bureau of Sanitation, a large scale project may be categorized as a Special Project and billed on actual cost incurred by the City.

(D) Off-hour Plan Check Fee. An applicant may apply to have the Bureau of Sanitation provide plan check services at other than normal working hours. If the Bureau approves an expedited application, the applicant must pay to the Bureau, in addition to the fees identified in Subsection B of this Section, an additional fifty percent of the fees owed.

(E) All entities, including City Departments and other public agencies, are required to pay the fees identified in Subsection B of this Section.

(F) All monies collected pursuant to the provisions of this Section shall be placed and deposited into the Stormwater Pollution Abatement Fund, under a separate account for each sub-watershed, established by Section 64.51.11 of this Code.

Sec. 4. The provisions of this Ordinance shall be operative 180 days after the effective date of the Ordinance, except that the provisions shall not apply to any of the following:

1. Any Development or Redevelopment for which the Department of Building and Safety accepted a permit application before the effective date of this Ordinance, and for which the permit applicant paid, before the effective date of this Ordinance, to the Department of Building and Safety all fees required by the Department to process the permit application; or

2. Any Development or Redevelopment for which a required entitlement application was filed with the Department of City Planning, and for which Department review of the application, with the exception of CEQA review, was deemed complete by the Department before the operative date of this Ordinance.

Sec. 5. If any provision of this Ordinance is found to be unconstitutional or otherwise invalid by any court of competent jurisdiction, such invalidity shall not affect the validity or enforceability of the remaining provisions of this Ordinance, and the provisions of this Ordinance are declared to be severable.

Sec. 6. The City Clerk shall certify to the passage of this ordinance and have it published in accordance with Council policy, either in a daily newspaper circulated in the City of Los Angeles or by posting for ten days in three public places in the City of Los Angeles: one copy on the bulletin board located at the Main Street entrance to the Los Angeles City Hall; one copy on the bulletin board located at the Main Street entrance to the Los Angeles City Hall East; and one copy on the bulletin board located at the Temple Street entrance to the Los Angeles County Hall of Records.

I hereby certify that this ordinance was passed by the Council of the City of Los Angeles, at its meeting of SEP 27 2011.

For conformance with the National Pollutant Discharge Elimination System (NPDES) Permit for Municipal Stormwater and Urban Runoff Discharges – Development Planning Program requirements, a significant portion of this handbook's information has been copied verbatim from documents issued by the State of California Regional Water Quality Control Board - Los Angeles Region (Regional Board) and the Los Angeles County Department of Public Works (LACDPW), and modified to suit the needs of the City of Los Angeles. These documents include the National Pollutant Discharge Elimination System Permit (NPDES No. CAS004001, Board Order No. 01-182), the Standard Urban Stormwater Mitigation Plan (SUSMP) (Board Resolution No. R-00-02) issued by the Regional Board to the County of Los Angeles and its co-permittees, and the LACDPW Development Planning Manual for Stormwater Management (Manual for the Standard Urban Stormwater Mitigation Plan).

This 4th edition is a revision to the 3rd edition to reflect the newly adopted Low Impact Development (LID) requirements that take effect [Date XX, XXXX]. The handbook was created under the direction of the City of Los Angeles, who is fully responsible for the content within.

This Development Best Management Practices Handbook, Part B Planning Activities, 4th edition was adopted by the City of Los Angeles, Board of Public Works on Date XX, XXXX] as authorized by Section 64.72 of the Los Angeles Municipal Code approved by Ordinance No. XXXXX.

SECTION 1: INTRODUCTION

1.1 BACKGROUND

Urban runoff discharged from municipal storm drain systems has been identified by local, regional, and national research programs as one of the principal causes of water quality impacts in most urban areas. Non-point source pollution, the diffuse pollution not traceable to a specific source, causes public health risks and safety concerns. Urban runoff potentially contains a host of pollutants such as trash and debris, bacteria and viruses, oil and grease, sediments, nutrients, metals, and toxic chemicals. These contaminants can adversely affect receiving and coastal waters, associated biota, and public health. While the impact of urban runoff pollution may not be immediately realized, the eventual effects can be dramatic. Urban runoff pollution is not only a problem during rainy seasons, but throughout the entire year due to all types of urban water use.

Stormwater pollution affects human life and aquatic plant and animal life. Potentially harmful viruses and bacteria are now found in our coastal waters along with soil particles, solids/ debris, litter, oil, grease, and chemical compounds. An epidemiological study (Haile, 1999) by the Santa Monica Bay Restoration Project, a project approved by Governor Pete Wilson and the United States Environmental Protection Agency (EPA), was conducted to investigate possible health effects of swimming in Santa Monica Bay. Study results indicated that individuals swimming near flowing storm drain outlets have a greater risk of developing various symptoms of illnesses compared to those swimming 400 yards away from the same drains (Haile, 1999). These pollutants also impact the natural aquatic habitat.

Oil and grease from parking lots, leaking petroleum or other hydrocarbon products, leachate from storage tanks, pesticides, cleaning solvents, and other toxic chemicals can contaminate stormwater and be transported downstream into water bodies and receiving waters. Fertilizer constituents from lawns and golf courses or leaking septic tanks can cause algal blooms. Disturbances of the soil from construction can allow silt to wash into storm channels and receiving waters, making them muddy, cloudy, and inhospitable to natural aquatic organisms. Heavy metals are toxic to aquatic organisms and many artificial surfaces of the urban environment such as galvanized metal, paint, or preserved wood containing metals contribute to stormwater pollution as the surfaces corrode, flake, dissolve, or decay.

Land development and construction activities significantly alter drainage patterns and contribute pollutants to urban runoff primarily through erosion and removal or change of existing natural vegetation. When homes, work places, recreational areas, roads, parking lots, and structures are built, and as other land disturbances occur, waterways can become altered. Water, potentially loaded with pollutants, flows preferentially through the new pathways. As the amount of impervious surface increases, water that once percolated into the soil now flows over the land surface. Accordingly, increases in impervious surfaces can increase the frequency and intensity of stormwater flows through a watershed. Flow from rainstorms and other water uses wash rapidly across the impervious landscape, scouring the surface of various kinds of urban pollutants such as automotive fluids, cleaning solvents, toxic or hazardous chemicals, detergents, sediment, metals, pesticides, oil and grease, and food wastes. These pollutants, unfiltered and unfettered, flow through stormwater infrastructure and ultimately contaminate receiving waters.

1.2 USERS OF THE HANDBOOK

This handbook provides guidance for individuals involved in new development and redevelopment projects. The target audience for this handbook includes developers, designers, contractors, homeowners, and other City of Los Angeles departments who are involved in site development, as well as the general public that may have an interest in stormwater pollution control.

1.3 HANDBOOK PURPOSE AND SCOPE

The purpose of this handbook is to assist developers in complying with the requirements of the Development Planning Program regulations of the City's Stormwater Program. This handbook summarizes the City's project review and permitting process, identifies stormwater mitigation measures, and references source and treatment control BMP information. This handbook also contains the necessary forms and worksheets required to be completed by the developer for approval.

1.4 LEGAL FRAMEWORK

With public concern growing over urban runoff and stormwater pollution, local, state, and federal agencies have devised plans to control and/or treat stormwater-related pollution before it reaches receiving waters.

The Federal Clean Water Act is the principal vehicle for control of stormwater pollution. Other programs dealing with stormwater pollution include the State of California General Plan Law (CGPL) for Municipalities and the California Environmental Quality Act (CEQA). Under the Federal Clean Water Act, each municipality throughout the nation is issued a stormwater permit through the National Pollutant Discharge Elimination System (NPDES) program. The primary goal of each permit is to stop polluted discharges from entering the storm drain system and local receiving and coastal waters. In California, the NPDES stormwater permitting program is administered by the State Water Resources Control Board (SWRCB) through its nine Regional Boards.

On July 5, 1996, the Los Angeles Regional Water Quality Control Board (Regional Board or RWQCB) adopted Order No. 96-054- the NPDES Stormwater Permit (Permit) for the County of Los Angeles and cities within (NPDES No. CAS614001). The Permit was issued to Los Angeles County and 84 permittee cities to reduce pollutants discharged from their Municipal Separate Storm Sewer Systems (MS4) to the Maximum Extent Practicable (MEP) statutory standard. The Permit is issued every five years. On December 13, 2001, the Regional Board adopted a new Permit (Order No. 01-182, NPDES Permit No. CAS004001) and amended it in 2007. Under this new Permit, the County of Los Angeles is designated as the Principal Permittee and the 84 cities, including the City of Los Angeles, as Permittees.

The requirement to implement the Permit is based on federal and state statutes, including Section 402(p) of the Federal Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990, and the California Water Code. The Federal Clean Water Act amendments of 1987 established a framework for regulating stormwater discharges from municipal, industrial, and construction activities under the NPDES program. The primary objectives of the stormwater program requirements are to:

- Effectively prohibit non-stormwater discharges, and
- Reduce the discharge of pollutants from stormwater conveyance systems to the MEP statutory standard.

Based on the Permit issued by the Regional Board, the County and its co-permittees are required to develop and implement a number of stormwater management programs designed to reduce pollutants in stormwater and urban runoff. These programs are the Public Information and Participation Program, Industrial/Commercial Facilities Program, Illicit Connections and Illicit Discharges Elimination Program, Development Planning Program, Development Construction Program, Public Agency Activities Program, and the Monitoring and Reporting Program.

One of these programs, the Development Planning Program, focuses on preventing pollutants that could be generated from new development and redevelopment projects from reaching stormwater conveyance systems and receiving waters.

A relatively recent stormwater management approach aimed at achieving this goal is the use of Low Impact Development (LID). Over the past 10 years, LID practices have received increased attention and implementation, becoming a leading practice for stormwater pollution prevention. In recognition of this, recent actions by the RWQCB, SWRCB, and US EPA have prioritized the use of LID as the preferred approach to stormwater management, including for the purpose of water quality compliance.

RB-AR32716

Low Impact Development is a stormwater management strategy that seeks to mitigate the impacts of increases in runoff and stormwater pollution as close to its source as possible. LID comprises a set of site design approaches and Best Management Practices (BMPs) that promote the use of natural systems for infiltration, evapotranspiration, and use of stormwater. These LID practices can effectively remove nutrients, bacteria, and metals from stormwater while reducing the volume and intensity of stormwater flows. With respect to urban development and redevelopment projects, it can be applied onsite to mimic the site's predevelopment drainage characteristics. Through the use of various infiltration techniques, LID is geared towards minimizing surface area that produces large amounts of runoff and does not allow water to infiltrate into the ground. Where infiltration is infeasible, the use of bioretention, rain gardens, vegetated rooftops, and rain barrels that will store, evaporate, detain, and/or treat runoff can be used.

The City of Los Angeles is adopting LID standards and practices for the purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff;
- Reducing stormwater/urban runoff while improving water quality;
- Promoting rainwater harvesting;
- Reducing offsite runoff and providing increased groundwater recharge;
- Reducing erosion and hydrologic impacts downstream; and
- Enhancing the recreational and aesthetic values in our communities.

In addition to LID requirements, the City must also comply with the Los Angeles Regional Water Quality Board requirements for Standard Urban Stormwater Mitigation Plan (SUSMP) which requires specific development and redevelopment categories to mitigate (either infiltrate or treat) stormwater runoff. The City of Los Angeles institutionalized the use of LID techniques for development and redevelopment projects by the adoption of Stormwater LID Ordinance XXXXXX. With the adoption of Stormwater LID Ordinance XXXXXX, this handbook has been amended to require stormwater mitigation for a much larger number of development projects.

Also, the California CGPL and CEQA provide a basis for municipalities to review and comment on all projects within their jurisdiction. Under the CGPL, municipalities are required to develop policies and regulations that guide development within the municipality. Each development project is reviewed for conformance with these policies. Under CEQA, projects are also subject to review and comment for potential adverse environmental impacts, including impacts from stormwater discharges.

1.5 DEVELOPMENT PLANNING PROGRAM

The Development Planning Program is, in order of priority, comprised of a LID Plan, and/or a Standard Urban Stormwater Mitigation Plan (SUSMP), and/or a Site Specific Mitigation Plan. This handbook provides guidance for compliance with the LID, SUSMP, and Site Specific Mitigation Plan requirements. Project applicants will be required to incorporate stormwater mitigation measures into their design plans and submit the plans to the City for review and approval as described in Section 2.

1.5.1 Low Impact Development Plan

Adopted by the City of Los Angeles on [DATE], the Stormwater LID Ordinance XXXXX requires stormwater mitigation for a much larger number of development and redevelopment projects than was previously required under SUSMP. Prior to the implementation of the LID Ordinance, the City's SUSMP program required only specific development and redevelopment categories to incorporate stormwater BMPs. The Stormwater LID Ordinance has expanded these categories to include all development and redevelopment projects that create, add, or replace 500 square feet or more of impervious area.

The Stormwater LID Ordinance applies to all development and redevelopment in the City of Los Angeles that requires building permits within the City after the ordinance effective date except for the following:

- Any development and redevelopment that creates, adds, or replaces less than 500 square feet of impervious area;
- Any development or redevelopment not requiring a building permit;
- Any building alteration or addition that does not expand the building footprint;
- Use of Land Permits that require no addition to or alteration of existing impervious surfaces;
- Re-striping of permitted parking lots;
- Any development and redevelopment involving emergency construction activities required to immediately protect public health and safety;
- Infrastructure projects within the public right-of-way, and utilities on private property (gas, water, cable, telephone, electric, etc.);
- Exterior movie and television production sets and/or facades on existing developed sites;
- Any development or redevelopment for which plans and complete application are accepted by the Department of Building and Safety for plan check and the appropriate fee is paid prior the effective date of the stormwater LID ordinance; and

RB-AR32718

- Any entitlement application for a Development or Redevelopment filed with the Department of City Planning and deemed complete with the exception of CEQA review prior to the effective date of this Stormwater LID ordinance.

1.5.2 Standard Urban Stormwater Mitigation Plan (SUSMP)

The SUSMP was adopted by the Regional Board on March 8, 2000 under Resolution No. R-00-02, and was further amended by the SWRCB on October 5, 2000 under State Water Board Order WQ 2000-11. The SUSMP was developed as part of the municipal stormwater program to address stormwater pollution from new development and redevelopment projects.

The NPDES Permit cites the categories of new development and redevelopment projects that require stormwater mitigation measures and outlines the necessary BMPs applicable to each category. The following project categories require a SUSMP:

1. Single-family hillside residential developments[1]
2. Housing developments (including single-family homes, multi-family homes, condominiums, and apartments) of ten or more units
3. Industrial/Commercial[2] developments of one acre or more of impervious surface area
4. Automotive service facilities (SIC 5013, 5014, 5541, 7532-7534, and 7536-7539)
5. Retail gasoline outlets
6. Restaurants (SIC 5812)
7. Parking lots with 5,000 square feet or more of surface area, including accessory driveways, or with 25 or more parking spaces
8. Projects located in, adjacent to, or discharging directly to a designated Environmentally Sensitive Area (ESA)

1Single-family hillside developments less than one are excluded from the numerical Structural and Treatment Control BMP design standard requirements.

2 Commercial Development: any development that is not heavy industrial or residential. The category includes, but is not limited to: hospitals, laboratories and other medical facilities, educational institutions, recreational facilities, plant nurseries, car wash facilities, mini-malls and other business complexes, shopping malls, hotels, office buildings, public warehouses and other light industrial complexes.

Industrial/Commercial Facility: any facility involved and/or used in the production, manufacturing, storage, transportation, distribution, exchange or sale of goods and/or commodities, and any facility involved and/or used in providing professional and non-professional services. This category of facilities includes, but is not limited to, any facility defined by the Standard Industrial Classifications (SIC).

RB-AR32719

1.5.3 Site Specific Mitigation Plan

New development and/or redevelopment projects not requiring a LID or SUSMP but which may potentially have adverse impacts on stormwater quality must incorporate a Site Specific Mitigation plan to mitigate stormwater pollution. Such projects may have, but are not limited to, one or more of the following characteristics:

1. Vehicle or equipment fueling areas
2. Vehicle or equipment maintenance areas, including washing and repair
3. Commercial or industrial waste handling or storage
4. Outdoor handling or storage of hazardous materials
5. Outdoor manufacturing areas
6. Outdoor food handling or processing
7. Outdoor animal care, confinement, or slaughter
8. Outdoor horticulture activities
9. Major transportation projects

Projects with one or more of the above characteristics or any project that is subject to the Site Specific Mitigation requirement will be required to incorporate appropriate stormwater mitigation measures or apply either LID or SUSMP to satisfy stormwater requirements.

RB-AR32720

SECTION 2: PROJECT REVIEW AND PERMITTING PROCESS

2.1 PLAN APPROVAL PROCESS

The requirement to incorporate stormwater pollution control measures into the design plans of new development and redevelopment projects in order to mitigate stormwater quality impacts is implemented through the City's plan review and approval process. During the review process, the plans will be reviewed for compliance with the City's General Plans, zoning ordinances, and other applicable local ordinances and codes, including stormwater requirements. Plans and specifications will be reviewed to ensure that the appropriate BMPs are incorporated to address stormwater pollution prevention goals. The reviewer will also determine if project designs need to be modified to address stormwater pollution prevention objectives.

New development and redevelopment projects are mainly processed through the Department of City Planning (DCP) and the Department of Building and Safety (LADBS). Entitlement approvals are processed by DCP and these projects require discretionary action. Building/Grading Permit approvals are processed by LADBS.

2.1.1 Department of City Planning Process

The Permit requirements are incorporated into the CEQA process for discretionary projects. As outlined in Section 1.5 of this handbook, certain project categories are considered to be potentially harmful to stormwater quality.

The CGPL and CEQA provide a basis for municipalities to review and comment on all projects within their jurisdiction. Under the CGPL, municipalities are required to develop policies and regulations that guide developments within their municipalities. Each development project is then reviewed for conformance with these policies. Under CEQA, projects are also subject to review for any adverse impacts the projects may have on the environment, including those impacts from stormwater discharges. These project types (e.g., zone variances, conditional use permits, plan amendments, site plan reviews, etc.) are considered discretionary review projects requiring review by an elected or appointed decision-making body. Mitigation measures for stormwater quality impacts (such as stormwater BMPs) will be incorporated into the project during environmental and project reviews. The project will be reviewed to ensure that required stormwater BMPs are included. Planning approvals for discretionary projects will not be granted until stormwater mitigation measures are incorporated into the project plans.

All applications for DCP's discretionary decisions are required to be accompanied by an environmental clearance (e.g., Categorical Exemption, Negative Declaration, Mitigated Negative

RB-AR32721

Declaration, or Environmental Impact Report). When an applicant files an application for a discretionary project, DCP staff at the public counter will determine whether the project qualifies for an exemption from CEQA. If the project is not exempt and could possibly have a significant impact, the applicant files an Environmental Assessment Form (EAF).

The DCP Environmental Review Section prepares the Initial Study and Checklist. DCP will indicate if the project will impact water absorption rates, drainage patterns, urban runoff or other water quality issues. If no significant effect upon the environment is found, a Negative Declaration will be issued for the project. If mitigation measures are needed, a Mitigated Negative Declaration (MND) is issued for the project, or an Environmental Impact Report (EIR) is required. Stormwater mitigation measures (as shown in Appendix B) will be added to the MND or the EIR for the decision-maker to impose as conditions.

The project applicant must incorporate stormwater pollution control measures into the design plans and submit these plans to the Department of Public Works, Bureau of Sanitation, Watershed Protection Division (WPD) for review and approval. See Appendix Cfor contact information. Upon satisfaction that all stormwater requirements have been met, WPD staff will stamp the plan approved. Following approval by DCP, building/grading permits are obtained from LADBS.

2.1.2 Department of Building and Safety Process

Applicants must submit design plans to LADBS personnel for review and approval prior to issuance of building/grading permits. LADBS personnel determine if the project requires stormwater mitigation measures and refer applicable projects to WPD for review and approval. LADBS issues the applicant a “Clearance Worksheet” that identifies all of the outstanding approvals from City agencies (see Appendix D). A building/grading permit will be issued once all corrections have been completed and clearances are obtained, including for stormwater requirements.

Outlined below are some guidelines for project applicants to follow in submitting design plans for review and approval.

Step One- Submit design plans

The project applicant submits the design plans to LADBS. During the plan review process, LADBS will refer projects needing discretionary action to DCP for additional processing.

Step Two - Define the project category

The plan check engineer will review the design plans and determine if the project falls under any of the SUSMP categories or meets any of the characteristics identified under Site Specific

Mitigation or LID requirements. If the project falls into any one of the SUSMP categories or characteristics cited under Site Specific Mitigation or LID, the plan check engineer will refer the applicant to WPD.

2.1.3 Department of Public Works / Bureau of Sanitation Process

To ensure compliance with all City Codes, it is recommended that the architect, civil engineer, plumbing engineer, and/ or landscape engineer coordinate at the early stage of the project design.

Step One - Identify appropriate BMPs

Identify, evaluate, and incorporate into the plan documents the appropriate BMP(s) for the project categories listed in Section 3.1 (LID), Section 3.2 (SUSMP), or Section 3.3 (Site Specific Mitigation) of this handbook, whichever is applicable.

To assist the residents in small scale residential development / redevelopment projects (4 units or less) Appendix E contains prescriptive methods detailing BMPs to be incorporated into the design plans. The advantage of the prescriptive methods is they are designed as pre-approved “boiler plates.” Use of prescriptive methods for these types of project categories will dramatically reduce plan preparation and review time.

Approval for development projects and building/grading permits will not be granted/issued until appropriate and applicable stormwater BMPs are incorporated into the project design plans. Also, a plumbing permit from LADBS will be required for certain treatment control BMPs such as grease traps, sump pumps, and clarifiers. For all projects other than small scale residential developments (4 units or less), if an infiltration BMP is chosen for treatment control, a soils report to address the feasibility of infiltration will be required to be submitted with the plan for review and approval.

Step Two– Submit LID, SUSMP, and/or Site Specific Mitigation plans to WPD

The following is a list of the minimum submittal requirements for Small Scale Residential Developments (4 units or less):

- Three sets of full plans (plot, elevation, utility, mechanical, plumbing, architectural, and landscape plans). WPD keeps one set of plans.
- Plans must include at least the following:
    - Location, size, and capacity of all BMPs on plans
    - Landscaping areas

RB-AR32723

The following is a list of the minimum submittal requirement for all other projects:

- Three sets of grading and/or site plans (may need plumbing, architectural, and landscape plans). WPD keeps one set of plans.
- Plans must be wet-stamped and signed by an engineer or architect.
- Plans must include at least the following:
    - Location of all BMPs on plans, including elevations and drainage patterns.
    - Detailed drawings of all BMPs, including model, size, and capacity
    - Stenciling note and/or detail
    - Trash enclosure location and details
    - Landscaping areas
- Flow calculations identifying flow rate or volume of stormwater runoff that must be treated (see Appendix F). Submit the manufacturer's product specifications to verify that the selected BMP model can adequately handle the design flow rate.
- Covenant & Agreement Form with an Operation & Maintenance Plan (see Appendix D)

Step Three – WPD Approval

Once all LID/SUSMP/Site Specific Mitigation requirements have been met, WPD staff will stamp the plans approved, sign the applicant's clearance worksheet, and clear the project in the LADBS plan check tracking system, known as the Plan Check and Inspection System (PCIS).

2.2 INSPECTION PROCESS

To ensure that all stormwater related BMPs are constructed and/or installed in accordance with the approved SUSMP, Site Specific Mitigation Plan, or LID plan. The City may require a Stormwater Observation Report (SOR) be submitted to the City prior to the issuance of the Certificate of Occupancy (see Appendix D). This is particularly true for complex projects. The SOR shall be prepared, signed, and stamped by the engineer of record (for example, a California-licensed civil engineer or qualified professional) responsible for the approved LID/SUSMP/Site Specific Mitigation Plan, certifying that:

1. He/she is the engineer or architect responsible for the approved LID/SUSMP/Site Specific Mitigation Plan and
2. He/she or the designated staff under his/her responsible charge has performed the required site visits at each significant construction stage and at completion to verify that

RB-AR32724

the BMPs shown on the approved plan have been constructed and installed in accordance with the approved LID/SUSMP/Site Specific Mitigation Plan.

The Certificate of Occupancy will be issued after all required clearances are obtained; the project has been determined, through the normal inspection process, to be built in accordance with the approved plan, including the construction and/or installation of appropriate stormwater-related BMPs; and the project has been determined to comply with all applicable codes, ordinances, and other laws.

2.3 BMP MAINTENANCE COVENANT AND AGREEMENT

A Covenant and Agreement (C&A) document shall be submitted, along with the design plans showing the project's stormwater measures, during the plan review and approval process, and must be signed by the legal owner or authorized agent of the property. The C&A shall also be recorded with the County Recorder. The City will withhold the grading and/or building permit for the development application until this requirement is satisfied. A sample form of the C&A is provided in Appendix D.

Maintenance is crucial for proper and continuous operation, effectiveness, and efficiency of a structural or treatment control BMP. The cost of long-term maintenance should be evaluated during the BMP selection process. By signing a maintenance C&A, the legal property owner affirms he/she will perform regular and long-term maintenance of all BMPs installed onsite. For residential properties where the structural or treatment control BMPs are located within a common area and will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the project's conditions, covenants and restrictions (CC&Rs). The C&A is bound to the property and transfers to the new owner with any subsequent sale of the property. Attached to the C&A will be an Operation and Maintenance (O&M) Plan (see Appendix D for a sample) describing the BMP operation and maintenance procedures, employee training program and duties, operating schedule, maintenance frequency, routine service schedule, and other activities. A Maintenance Log shall be maintained at the facility to document all of the activities mentioned above. These documents may be inspected by the City of Los Angeles at any time and shall be made available to the City upon request.

2.4 MUNICIPAL PROJECTS

Stormwater mitigation measures are required for all projects subject to the LID, SUSMP, or Site Specific Mitigation Plan. City projects that will be processed through DCP and/or LADBS will be subject to the review and approval process described in Section 2.1. For other City projects that do not undergo the plan review and approval process with DCP and/or LADBS, the public agency may use this handbook to incorporate the required stormwater mitigation measures into their projects.

RB-AR32725

2.5 OTHER PUBLIC AGENCY PROJECTS

Public agency projects other than from the City of Los Angeles, such as from Caltrans, the Metropolitan Transit Authority, etc., that are subject to the SUSMP or Site Specific Mitigation and require a permit from the City of Los Angeles are required to implement stormwater mitigation measures. Examples of such projects include the Alameda Corridor, Metro Rail stations, airport runways, and busways. Such projects must incorporate stormwater BMPs into their design plans and specifications, which must be submitted to WPD for review and approval.

RB-AR32726

SECTION 3: STORMWATER MANAGEMENT MEASURES

3.1 LOW IMPACT DEVELOPMENT (LID) PLAN

Project applicants for all developments and redevelopments will be required to incorporate stormwater mitigation measures into their design plans and submit the plans to the City for review and approval. The design plans will be subjected to a review process as indicated in Section 2, prior to the issuance of approvals for building and/or grading permits.

Projects that are part of a larger common plan of development involving five units or more will be subject to the requirements for "All Other Development", as set forth in Section 3.1.2. This includes projects that are subject to one common grading permit and projects that have phased schedules or are intended to be sectioned-off for sale to individual homeowners.

Project applicants for all developments and redevelopments will also be required incorporate the following performance measures and practices into their design plans.

Conserve Natural Areas

Each project site possesses unique topographic, hydrologic and vegetative features, some of which are more suitable for development than others. Locating development on the least sensitive portion of a site and conserving naturally vegetated areas can minimize environmental impacts in general and stormwater runoff impacts in particular.

If applicable and feasible for the given site conditions, the following measures are required and should be included in the project site layout:

1. Concentrate or cluster improvements on the least-sensitive portions of the site, while leaving the remaining land in a natural undisturbed state;
2. Limit clearing and grading of native vegetation at the site to the minimum area needed to build the home, allow access, and provide fire protection;
3. Maximize trees and other vegetation at the site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought-tolerant plants; and
4. Preserve riparian areas and wetlands.

Protect Slopes and Channels

Erosion of slopes and channels can be a major source of sediment and associated pollutants, such as nutrients, if not properly protected and stabilized.

RB-AR32727

Slope Protection
Slope protection practices must conform to design requirements or standards set forth by local permitting agency erosion and sediment control standards and design standards. The post-construction design criteria described below are intended to enhance and be consistent with these local standards.

1. Slopes must be protected from erosion by safely conveying runoff from the tops of slopes.
2. Slopes must be vegetated with first consideration given to native or drought-tolerant species.

Channel Protection
The following measures should be implemented to provide erosion protection to unlined receiving streams on the project site. Activities and structures must conform to applicable permitting requirements, standards and specifications of agencies with jurisdiction (e.g., U.S. Army Corps of Engineers, California Department of Fish and Game, or Regional Water Quality Control Board).

1. Utilize natural drainage systems to the maximum extent practicable, but minimize runoff discharge to the maximum extent practicable.
2. Stabilize permanent channel crossings.
3. Install energy dissipaters, such as rock riprap, at the outlets of storm drains, culverts, conduits or channels that discharge into unlined channels.

Provide Storm Drain System Stenciling and Signage
Storm drain message markers or placards are required at all storm drain inlets within the boundary of the project. The marker should be placed in clear sight facing toward anyone approaching the inlet from either side. All storm drain inlet locations must be identified on the development site map.

Some local agencies within the City have approved storm drain message placards for use. Consult local permitting agency stormwater staff to determine specific requirements for placard types and methods of application.

3.1.1 SMALL SCALE RESIDENTIAL DEVELOPMENTPROJECTS (4 UNITS AND LESS)

Small scale residential projects include all projects that increase impervious area by more than 500 square feet (i.e., residential development of 4 units or less and all other developments that are not subject to Section 1.5.2). These projects are not required to complete formal hydrologic analysis or to get approval from the Upper Los Angeles River Water Master (ULARWM). The

RB-AR32728

basic objectives for these projects include reducing a site's impervious surfaces, improving a site's ability to infiltrate stormwater, conserving stormwater runoff for other on-site water demand uses, and reducing negative impacts downstream.

REQUIREMENTS:

i. For new development less than 1 acre (including hillside development and redevelopment), the development shall implement adequately sized LID BMP alternatives as defined and listed in Appendix E; or

ii. For new developments that are one acre or larger, the development shall comply with the standards and requirements of Section 3.1.2 - All Other Developments; or

iii. For all new development and redevelopment projects ≥2,500 square feet that lie within an ESA, the development shall comply with the standards and requirements of Section 3.1.2 - All Other Developments.

BEST MANAGEMENT PRACTICES (BMPS):

Upon filing an application for a Building Permit with LADBS, a separate plot plan identifying the LID BMPs that are used (including size) and drainage area tributary to each BMP shall be shown in accordance with the prescriptive methods.

The following LID BMPs have been established as prescriptive LID improvement features to be employed on a qualifying small scale project. These BMPs are presented in the form of Fact Sheets in Appendix E with the intent of providing self-contained BMP background context and sizing requirements to facilitate a permit applicant to follow and comply with the City of Los Angeles' Stormwater LID Ordinance. Applicants may choose from one or more of the prescriptive BMPs to comply with the ordinance.

The specific small scale BMPs include the following:

1. Rain Barrels & Small Cisterns
2. Permeable Pavements (or Porous Pavement Systems)
3. Planter Boxes
4. Rain Gardens
5. Dry Wells

Figure 3.1 demonstrates the use of all five of these small scale residential BMPs at a residence.

Figure 3.1- Small Scale Residential BMP Schematic

3.1.2 ALL OTHER DEVELOPMENTS

Any new development or redevelopment project that does not meet the requirements of Section 3.1.1 – Small Scale Residential Development Projects shall comply with this section.

A LID Plan shall be prepared to comply with the following:

1. Stormwater runoff will be infiltrated, evapotranspired, captured and used, and/or treated through high removal efficiency Best Management Practices onsite, through stormwater management techniques as identified in Section 4.1. The onsite stormwater management techniques must be properly sized, at a minimum, to infiltrate, evapotranspire, store for use, and/or treat through a high removal efficiency biofiltration/biotreatment system, without any stormwater runoff leaving the site to the maximum extent feasible, for at least the volume of water produced by the water quality design storm event that results from:

    i. The 85th percentile 24-hour runoff event determined as the maximized capture stormwater volume for the area using a 48 to 72-hour drawdown time, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998); or

    ii. The volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in the California Stormwater Best Management Practices Handbook – Industrial/Commercial, (2003); or

    iii. The volume of runoff produced from a 0.75 inch storm event.

2. Pollutants shall be prevented from leaving the development site for a water quality design storm event as defined above unless it has been treated through an onsite high removal efficiency biofiltration/biotreatment system.

3. Hydromodification impacts shall be minimized to natural drainage systems.

REQUIREMENTS:

All other developments (residential developments of 5 units or more and nonresidential developments) shall adhere to the following requirements:

i. For new development or where redevelopment results in an alteration of at least fifty percent or more of the impervious surfaces of an existing developed site, the entire site shall comply with the standards and requirements of Section 3.1.2; or

RB-AR32731

ii. Where the redevelopment results in an alteration of less than fifty percent of the impervious surfaces of an existing developed site, only such incremental development shall comply with the standards and requirements of Section 3.1.2.

If partial or complete onsite compliance of any type is technically infeasible, the project Site and LID Plan shall be required to comply with, at a minimum, all applicable SUSMP requirements (Appendix G) in order to maximize onsite compliance. Any remaining runoff that cannot feasibly be managed onsite must be mitigated under the Offsite Mitigation Option. Figure 3.2 is a schematic which depicts the design requirements for small scale residential projects, while Figure 3.3 depicts the design requirements for all other developments.

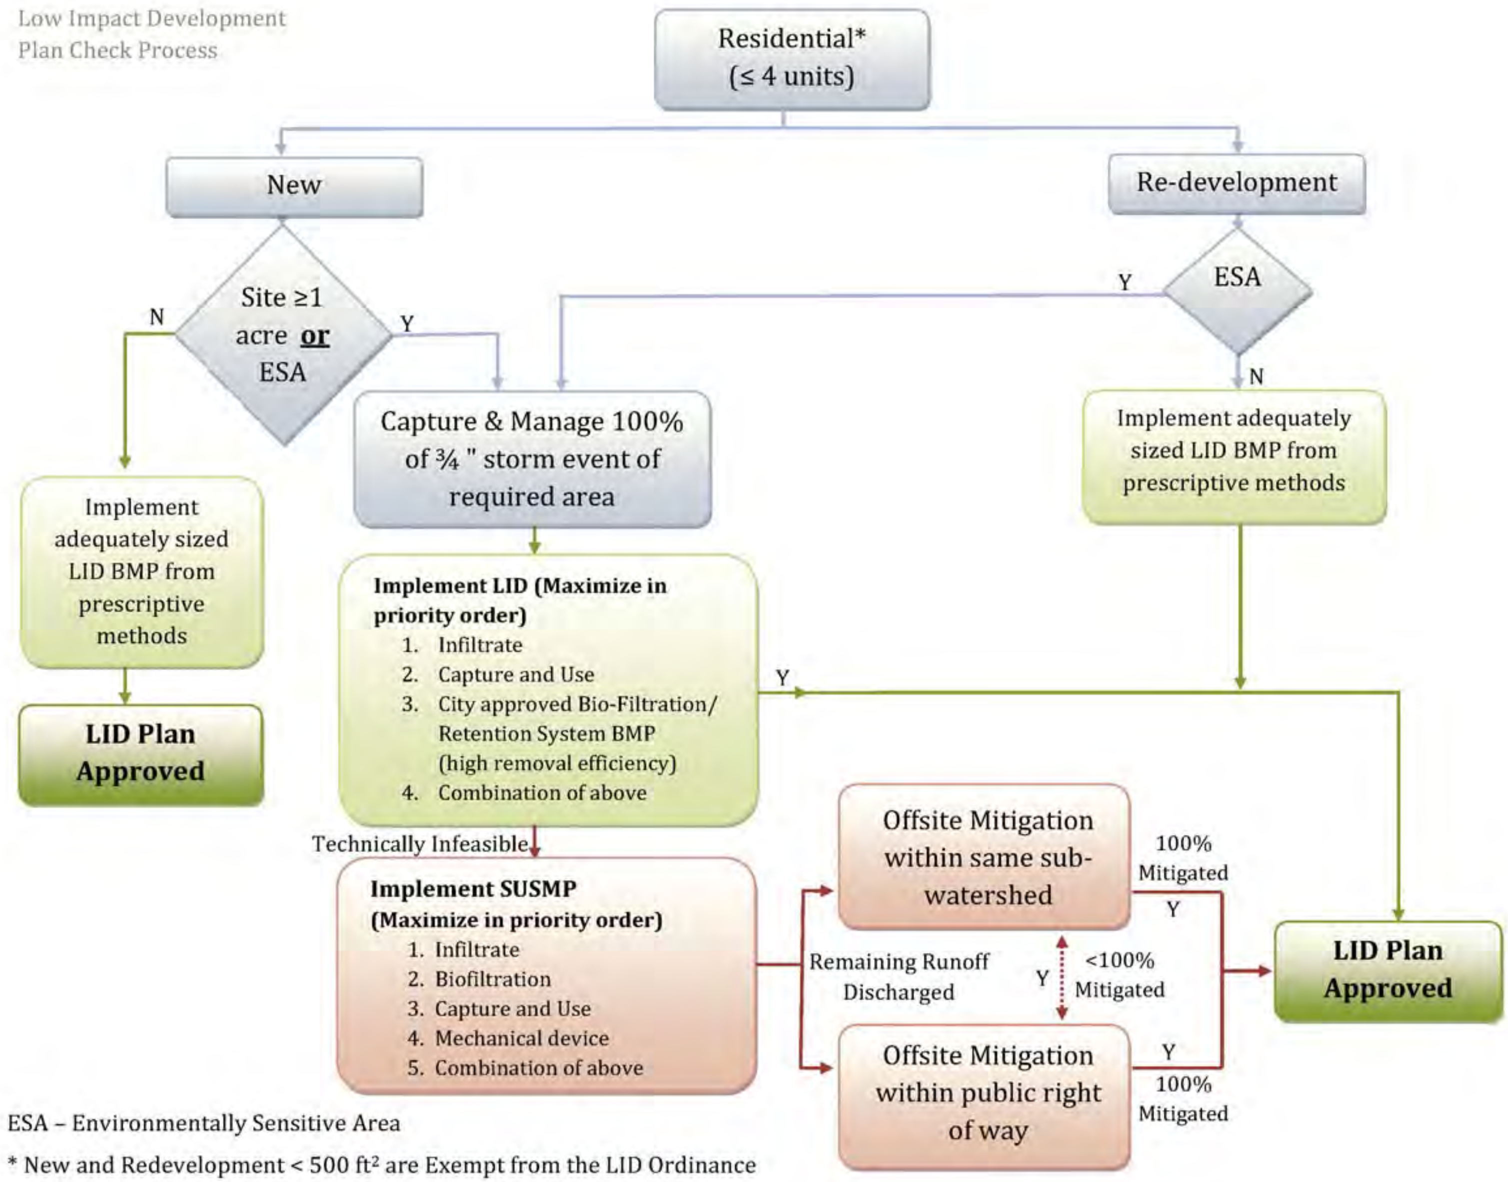

Figure3.2- Requirements for Residential Development of 4 Units or Less

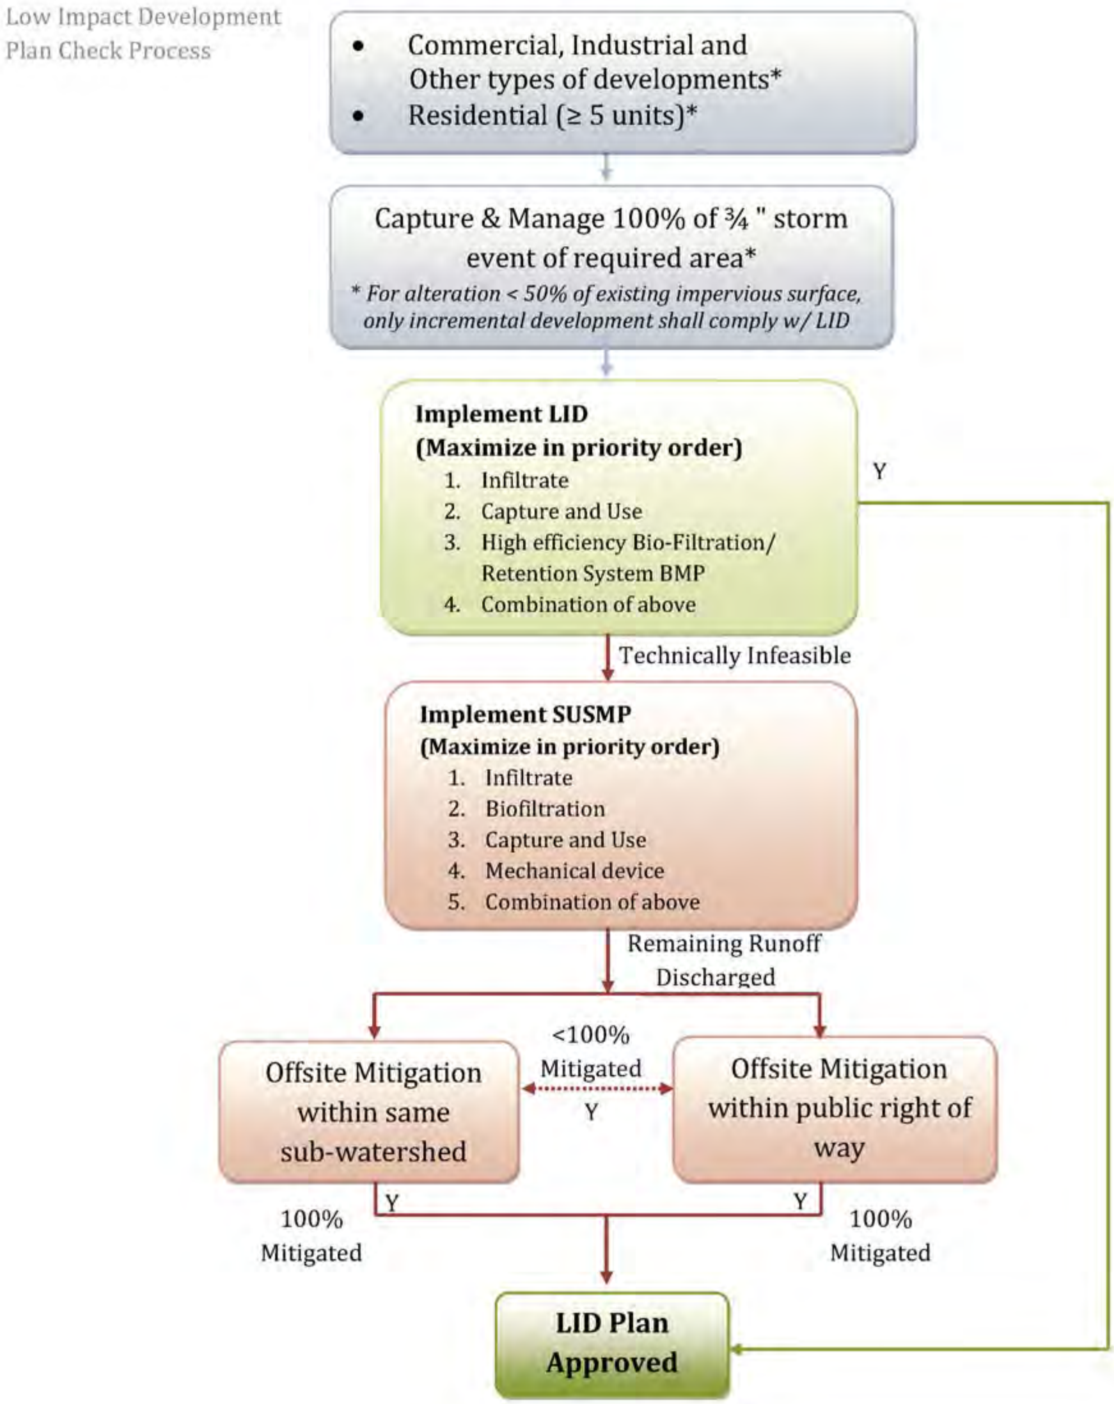
RB-AR32733



* New and Re-development < 500 ft^2 are exempt from the LID Ordinance

Figure 3.3 – Requirements for Residential Developments of 5 Units or More and All Other Development

3.2 STANDARD URBAN STORMWATER MITIGATION PLAN (SUSMP)

Any project that cannot comply with the LID requirements in Section 3.1.2 shall be required to comply with, at a minimum, all applicable SUSMP requirements (Appendix G) in order to maximize onsite compliance.

Project applicants will be required to incorporate stormwater mitigation measures into their design plans and submit the plans to the City for review and approval. The design plans will be subjected to a review process as indicated in Section 2, prior to the issuance of approvals for building and/or grading permits.

3.3 SITE SPECIFIC MITIGATION

Site Specific Project applicants will be required to submit to the City a design plan that incorporates appropriate stormwater mitigation measures and details the source and treatment control BMP(s), and must also submit the O&M plan for the treatment control BMPs. All maintenance agreements should refer the Covenant and Agreement forms in Appendix D. The design plans will be subject to the review and approval process described in Section 2, prior to the issuance of building or grading permits.

3.4 SOURCE CONTROL MEASURES

Source Control Measures are low-technology practices designed to prevent pollutants from contacting stormwater runoff or to prevent discharge of contaminated runoff to the storm drainage system. This section addresses site-specific, structural type Source Control Measures consisting of specific design features or elements. Non-structural type Source Control Measures, such as good housekeeping and employee training, are not included in the LID Handbook. The California Industrial Best Management Practice Manual may be consulted for this type of practice (SWQTF, 1993). The governing stormwater agency may require additional Source Control Measures not included in the LID Handbook for specific pollutants, activities or land uses.

This section describes control measures for specific types of sites or activities that have been identified as potential significant sources of pollutants in stormwater. Each of the measures specified in this section should be implemented in conjunction with appropriate non-structural Source Control Measures to optimize pollution prevention.

The measures addressed in this section apply to both stormwater and non-stormwater discharges. Non-stormwater discharges are the discharge of any substance, such as process wastewater, to the storm drainage system or water body that is not composed entirely of stormwater. Stormwater that is mixed or commingled with other non-stormwater flows is considered non-stormwater. Discharges of stormwater and non-stormwater to the storm drainage system or a water body may be subject to local, state, or federal permitting prior to

RB-AR32735

discharge. The appropriate agency should be contacted prior to any discharge. Discuss the matter with the stormwater staff if you are uncertain as to which agency should be contacted.

Some of the measures presented in this section require connection to the sanitary sewer system. Connection and discharge to the sanitary sewer system without prior approval or obtaining the required permits is prohibited. Contact the stormwater staff of the governing agency to obtain information regarding obtaining sanitary sewer permits from the various agencies within the City of Los Angeles. Discharges of certain types of flows to the sanitary sewer system may be cost prohibitive. The designer is urged to contact the appropriate agency prior to completing site and equipment design of the facility.

3.4.1 Source Control Measure Descriptions

Site-specific Source Control Measures and associated design features specified for various sites and activities are summarized in Table 3.1. Fact Sheets are presented in Appendix H for each source control measure. These sheets include design criteria established by the Approval Agencies to ensure effective implementation of the required Source Control Measures:

RB-AR32736

Table 3.1: Summary of Site-Specific Source Control Measure Design Features

Site-Specific Source Control Measure [(a)]	**DESIGN FEATURE OR ELEMENT**						
	Signs, placards, stencils	Surfacing (compatible, impervious)	Covers, screens	Grading/berming to prevent run-on	Grading/berming to provide secondary containment	Sanitary sewer connection	Emergency Storm Drain Seal

RB-AR32737

SECTION 4: BMP PRIORITIZATION AND SELECTION

4.1 PRIORITIZATION OF BMP SELECTION

BMPs shall be designed to manage and capture stormwater runoff. Infiltration systems are the first priority type of BMP improvements as they provide for percolation and infiltration of the stormwater into the ground, which not only reduces the volume of stormwater runoff entering the MS4, but in some cases, can contribute to groundwater recharge. If stormwater infiltration is not possible based on one or more of the project site conditions listed below, the developer shall utilize the next priority BMP.

The order of priority specified below shall apply to all projects categorized as"all other developments" in accordance with Section 3.1.2. Each type of BMP shall be implemented to the maximum extent feasible when determining the appropriate BMPs for a project.

1. Infiltration Systems
2. Stormwater Capture and Use
3. High Efficiency Biofiltration/Bioretention Systems
4. Combination of Any of the Above

For purposes of compliance with the LID requirements, and without changing the priority order of design preferences as mentioned in this section, all runoff from the water quality design storm event, as determined in Section 3.1.2 above, that has been treated through an onsite high removal efficiency biofiltration system shall be credited as equivalent to 100% infiltration regardless of the runoff leaving the site from the onsite high removal efficiency biofiltration system and that runoff volume shall not be subject to the offsite mitigation requirements.

If partial or complete onsite compliance of any type is technically infeasible, the project Site and LID Plan shall be required to comply with, at a minimum, all applicable SUSMP requirements in order to maximize onsite compliance. Under this option a mechanical / hydrodynamic unit may be used. Any remaining runoff that cannot feasibly be managed onsite must bemitigated under the offsite mitigation option. In order to mitigate the remaining volume using the offsite mitigation option a LID BMP waiver must be obtained by the Department of Public Works, and if necessary, a SUSMP waiver must be obtained from the Department of Public Works and the Los Angeles Regional Water Quality Control Board and/or Regional Board Executive Officer.

Existing conditions of a project site may prevent the proposed development from implementing onsite stormwater pollution reduction or flow control to the standards specified. To utilize alternative compliance measures, the project applicant must demonstrate that compliance with the LID requirements would be technically infeasible by submitting a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional civil engineer, geotechnical engineer or geologist.

RB-AR32738

4.2 INFILTRATION FEASIBILITY SCREENING

The implementation of infiltration BMPs may be deemed infeasible at a project site due to existing site conditions. To assist in the determination of compliance feasibility, a categorical screening of specific site information shall be carried out to assess site conditions.

The first category of screening shall consist of specific site conditions which, if present at the site, would deem the specified BMP-type “feasible”.The second category of screening shall consist of specific site conditions which, if present at the site,would deem the BMP-type “potentially feasible”. Project locations passing this screening category may still be able to utilize the screened compliance measure, though the implementation of such a measure may require supplementary actions (for example, an infiltration trench with a building set-back of only 7 feet may be approved if an impermeable membrane is installed at the foot of the building and extended vertically to prevent seepage). The third category of screening shall consist of site conditions which, if present at the site, would deem a specified BMP-type “infeasible”. This type of screening can generally be carried out in the pre-planning stage of a project. These categorical screenings must be verified by a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer or geologist.

To assist in the determination of site feasibility for infiltration BMPs, Table 4.1 has been created.

RB-AR32739

	Category 1 Screening (Feasible)	Category 2 Screening (Potentially Feasible)	Category 3 Screening (Infeasible)
Description	1. Underlying Groundwater ☐ Depth of bottom of infiltration facility to seasonal high groundwater is > 10 ft 2. Site Soils ☐ Infiltration rate is > 0.5 in/hr ☐ Geotechnical hazards are not a potential near the site 3. Site Surroundings ☐ Buildings or structures are at least 10 ft away from the potential infiltration BMP ☐ Site is not located on or within 50 feet upgradient of a steep slope (15% or greater) ☐ No continuous presence of dry weather flows	1. Underlying Groundwater ☐ Depth from bottom of infiltration facility to seasonal high groundwater is ≤ 10 ft ☐ Unconfined aquifer is present with beneficial uses that may be impaired by infiltration. Full treatment required if this is the case ☐ Groundwater is known to be polluted. Infiltration must be determined to be beneficial 2. Site Soils ☐ Infiltration rate is ≤ 0.5 in/hr but potential connectivity to higher K_{sat} soils is feasible ☐ Geotechnical hazards such as liquefaction are a potential near the site 3. Site Surroundings ☐ Buildings or structures are within 10 ft of the potential infiltration BMP ☐ High-risk areas such as service/gas stations, truck stops, and heavy industrial sites. Full treatment is required if this is the case, or high-risk areas must be separate from stormwater runoff mingling	1. Underlying Groundwater ☐ Depth from bottom of infiltration facility to seasonal high groundwater is ≤ 5 ft ☐ Sites with soil and/or groundwater contamination** 2. Site Soils ☐ Infiltration rate (K_{sat}) is ≤ 0.3 in/hr and connectivity to higher K_{sat} soils is infeasible ☐ Building sites designated “Landslide” or “Hillside Grading” areas as specified by the Department of City Planning’s Zone Information and Map Access System (ZIMAS) ☐ Geotechnical hazards such as liquefaction, collapsible soils, or expansive soils exist 3. Site Surroundings ☐ Site is located on a fill site (10 ft min) ☐ Site is located on or within 50 feet upgradient of a steep slope (20% or greater) and has not been approved by a professional geotechnical engineer or geologist
Instructions	If all of the above boxes are checked, they shall be confirmed by a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer or geologist, verifying that infiltration BMPs are feasible at the site*. Otherwise, proceed to Category 2 screening.	If all of the above boxes are checked,or if corresponding boxes in Category 1 are checked in combination with the above boxes, a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer or geologist shall be carried out to approve infiltration measures*. Otherwise, proceed to Category 3 screening.	If any of the above boxes are checked, a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer or geologist shall be submitted to prove infiltration practices are not feasible. *

Table 4.1: Infiltration Feasibility Screening

* See Geotechnical Report Requirements herein.

** The presence of soil and/or groundwater contamination and/or the presence of existing or removed underground storage tanks shall be documented by CEQA or NEPA environmental reports, approved geotechnical reports, permits on file with the City, or a review of the State of California’s Geotracker website.

RB-AR32740

Assessing Site Infiltration Feasibility

Assessing a site's potential for implementation of Low Impact Development best management practices (LID BMPs) and infiltration BMPs requires both the review of existing information and the collection of site-specific measurements. Available information regarding site layout and slope, soil type, geotechnical conditions, and local groundwater conditions should be reviewed as discussed below. In addition, soil and infiltration testing is required to be conducted to determine if stormwater infiltration is feasible and to determine the appropriate design parameters for the infiltration BMP.

Geotechnical Considerations and Report Requirements:

As determined by the City of Los Angeles, Department of Building and Safety, Grading Division, a geotechnical report will be required for projects that will incorporate infiltration as part of the drainage system. Geotechnical reports shall be signed by a professional Geotechnical or Civil Engineer licensed in the State of California and/or a Certified Engineering Geologist.

Refer to Building & Safety information bulletin, "Guidelines for Stormwater Infiltration" for additional information, Appendix I.

http://ladbs.org/LADBSWeb/LADBS_Forms/InformationBulletins/IB-P-BC2008-118StormwaterInfiltn.pdf

Site Conditions

Slope:

The site's topography should be assessed to evaluate surface drainage, topographic high and low points, and to identify the presence of steep slopes that qualify as hillside locations, all of which have an impact on what type of infiltration BMPs will be most beneficial for a given project site. Stormwater infiltration is more effective on level or gently sloping sites. On hillsides, infiltrated runoff may seep a short distance downslope, which could cause slope instability depending on the soil or geologic conditions, or result in nuisance seepage. Figure E-1 in Appendix E provides general guidance of the City with slopes greater than 20%.

Soil Type and Geology:

The site's soil types and geologic conditions should be determined to evaluate the site's ability to infiltrate stormwater and to identify suitable, as well as unsuitable locations for locating infiltration-based BMPs.

In addition, available geologic or geotechnical reports on local geology should be reviewed to identify relevant features such as depth to bedrock, rock type, lithology, faults, and hydrostratigraphic or confining units. These geologic investigations may also identify shallow water tables and past groundwater issues that are important for BMP design (see below). Figure E-5 in Appendix E provides general guidance identifying parts of the City that have well-draining soil conditions.

Groundwater Considerations:

The depth to groundwater beneath the project during the wet season may preclude infiltration. A minimum of five feet of separation to the seasonal (December through April) high ground water level and mounded groundwater level is required. For projects located in the Upper Los Angeles River Area, ten feet of separation is required.

Infiltration on sites with contaminated soils or groundwater that could be mobilized or exacerbated by infiltration is not allowed, unless a site-specific analysis determines the infiltration would be beneficial. A site-specific analysis may be conducted where groundwater pollutant mobilization is a concern to allow for infiltration-based BMPs. Areas with known groundwater impacts include sites listed by the Los Angeles Regional Water Quality Control Board's Leaking Underground Storage Tanks (LUST) program and Site Cleanup Program (SCP). The California State Water Resources Control Board maintains a database of registered contaminated sites through their 'Geotracker' Program. Registered contaminated sites can be identified in the project vicinity when the site address is typed into the "map cleanup sites" field. Mobilization of groundwater contaminants may also be of concern where contamination from natural sources is prevalent (e.g., marine sediments, selenium rich groundwater, to the extent that data is available). Figure E-3 in Appendix E provides general guidance identifying parts of the City that may be in areas of concern.

<u>Upper Los Angeles River Watermaster Requirements</u>

Infiltration projects located in the San Fernando Valley Watershed must comply with the requirements of the Upper Los Angeles River Watermaster. See Appendix J for requirements and approval process.

<u>Managing Offsite Drainage</u>

Locations and sources of offsite run-on to the site must be identified early in the design process. Offsite drainage must be considered when determining appropriate BMPs for the site so that the drainage can be managed. By identifying the locations and sources of offsite drainage, the volume of water running onto the site may be estimated and factored into the siting and sizing of onsite BMPs. Vegetated swales or storm drains may be used to intercept, divert, and convey offsite drainage through or around a site to prevent flooding or erosion that might otherwise occur.

4.3 CAPTURE AND USE FEASIBILITY SCREENING

Capture and use, commonly referred to as rainwater harvesting, collects and stores stormwater for later use, thereby reducing the quantity of stormwater runoff. Partial capture and use can also be achieved as part of a treatment train by directing the overflow to a bioretention system to provide additional volume reduction and water quality treatment in instances where the quantity of runoff from a storm event exceeds the volume of the collection tank.

In the City of Los Angeles, the use of collected stormwater will primarily be limited to subsurface drip irrigation of landscaped surfaces. However, as new guidelines and guidance becomes available the potential for other uses of collected stormwater will be considered. Capture and use BMPs that are designed with the intent to use captured stormwater for indoor or consumptive purposes will be reviewed on a case-by-case basis to ensure that all treatment, plumbing, and Building and Safety codes are met.

At a minimum, capture and use BMPs must be designed and maintained to ensure adequate capacity is available to capture the stormwater quality design volume within 3 days of a storm event. BMPs sized to capture only the runoff produced from the 0.75 inch storm event, or BMPs designed to capture less than this volume if being used in conjunction with other BMPs, must therefore drawdown their entire captured volume within 3 days of a storm event. Capture and use BMPs designed for storm events larger than 0.75 inches are not required to disperse their entire captured volume within 3 days of capture; rather, the requirement mandates that enough water be dispersed from the BMP to ensure that adequate capacity is available to capture the next storm event up to 0.75 inches. This drawdown time requirement must be fulfilled without dispersing water to surrounding landscaped areas within the first 24 hours following a storm event.

The implementation of capture and use BMPs may be deemed infeasible at a project site due to existing site conditions. To assist in the determination of compliance feasibility, a categorical screening of specific site information shall be carried out to assess site conditions. This screening approach follows the same general guidelines as those designed for the infiltration feasibility screening. Table 4.2 has been created to help determine site feasibility for capture and use BMPs.

	Category 1 Screening (Feasible)	Category 2 Screening (Potentially Feasible)	Category 3 Screening (Infeasible)
Description	1. Landscaped Area ☐ Landscaped area categorization of 3 exists in accordance with Table 4.3 2. Site Soils ☐ Geotechnical hazards are not a potential near the site 3. Drawdown Time ☐ Demands and conditions indicate the site is capable of meeting the 72-hour maximum drawdown requirement 4. Vector Control ☐ Approved vector control measures will be implemented	1. Landscaped Area ☐ Landscaped area categorization of 2 exists in accordance with Table 4.3 2. Site Soils ☐ Geotechnical hazards such as liquefaction are a potential near the site ☐ Soil hydraulic conductivities are sufficient for the designed water application rate; if not, soil amendments will be implemented 3. Drawdown Time ☐ Demands and conditions indicate the site is capable of meeting the 72-hour maximum drawdown requirement, though this may require water application that is not immediately used (e.g. overwatering)	1. Landscaped Area ☐ Landscaped area categorization of 1 exists in accordance with Table 4.3 2. Site Soils ☐ Geotechnical hazards such as landsliding, collapsible soils, or expansive soils exist 3. Site Surroundings ☐ Site is located on or within 50 feet of a steep slope (20% or greater) as determined by the Department of Building and Safety; irrigation within 3 days of a rain event could cause geotechnical instability 4. Drawdown Time ☐ Demands and conditions indicate the site is incapable of meeting the 72-hour maximum drawdown requirement
Instructions	If all of the above boxes are checked, they shall be confirmed by a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional civil engineer, geotechnical engineer, geologist, or landscape architect, verifying that capture and use BMPs are feasible at the site.* Otherwise, proceed to Category 2 screening.	If all of the above boxes are checked,or if corresponding boxes in Category 1 are checked in combination with the above boxes, a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional civil engineer, geotechnical engineer, geologist, or landscape architect, shall be carried out to approve capture and use measures.*Otherwise, proceed to Category 3 screening.	If any of the above boxes are checked, a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer, geologist, or landscape architect shall be submitted to prove capture & use practices are not feasible. *

Table 4.2: Capture and Use Feasibility Screening

* See Geotechnical Report Requirements contained in the Infiltration Feasibility section.

Table 4.3 has been created to help determine site feasibility for capture and use BMPs based on the local infiltration rate as well and the percent of the project that is landscaped. The table is to be used in conjunction with Table 4.2 to determine site feasibility.

Table 4.3: Landscaped Area Categorization

	Percent of Project that is Landscaped					
Local Infiltration Rate	0-5%	5-10%	10-20%	20-30%	30-50%	>50%
0.3 - 0.5 in/hr	2	2	2	1	1	1
0.2 - 0.3 in/hr	3	2	2	2	1	1
0.1 - 0.2 in/hr	3	3	2	2	2	1
0 - 0.1 in/hr	3	3	3	2	2	2

Assessing Site Capture and Use Feasibility

As with infiltration BMPs, assessing a site's potential for implementation of capture and use BMPs requires both the review of existing information and the collection of site-specific measurements. Available information regarding the site's landscaped area should be reviewed as discussed below. In addition, human health concerns should be prioritized, particularly with regards to vector control issues arising from the addition of standing water on site.

<u>Landscaped Area Assessment</u>

For capture and use BMPS, captured rainfall is stored during rain events and used for irrigation purposes at a later time, thereby offsetting potable water demand and reducing pollutant loading to the storm drain system. Therefore, sufficient landscaped area with appropriate water demand is needed for the captured runoff to be directed to. A properly sized cistern should be able to contain the runoff generated from the design storm event and discharge that water for irrigation use within a specified drawdown time.

In the City of Los Angeles, cisterns will primarily be sized to capture the runoff generated from the 0.75" storm while meeting the drawdown time requirement (72 hours in most cases). A site's landscaped area must therefore be able to retain this volume of water within the appropriate drawdown time. Depending on the type of irrigation application that is desirable at a site, two different methods exist to determine if a site has adequate landscaped cover for capture and use feasibility:

1. For sites with sufficient agronomic demand to meet or exceed the captured supply of stormwater within the drawdown time, Category 1 Feasibility may apply. Agronomic demand must be calculated and reported by a professional landscape architect or qualified professional.
2. For sites with sufficient landscaped area and dispersal capacity (i.e. ability to receive irrigation water without generating runoff) to meet or exceed the captured supply of

RB-AR32745

stormwater within the drawdown time, Category 2 Feasibility may apply. The dispersal capacity can be assumed to be equal to the infiltration capacity of the site soil for simplicity. The infiltration rate must be calculated and reported by a professional landscape architect, civil engineer, geotechnical engineer, or geologist.

The above criteria must be assessed assuming that no irrigation occurs within the first 24 hours immediately following a storm. This means that a drawdown time of 72 hours must consider only 48 hours of active application. Agronomic demands and infiltration rates must be assessed within 3 days of a storm event to account for resulting diminished demands.

BMPs designed for extended holding times shall be reviewed on a case-by-case basis for feasibility. A site not meeting the minimum landscaped area criteria is not feasible for capture and use BMPs (See Table 4.3 in conjunction with Table 4.2).

Los Angeles County Department of Public Health Requirements

Projects that are implementing rainfall or urban runoff capture and distribution systems must obtain approval from the County of Los Angeles, Department of Public Health. See Appendix K for the Policy and Operation Manual.

Vector Control Considerations

A vector is any insect, arthropod, rodent, or other animal that is capable of harboring or transmitting a causative agent of human disease. In the City of Los Angeles, the most significant vector population related to stormwater is mosquitoes.

Vector sources occur where conditions provide habitat suitable for breeding, particularly any source of standing water. This means that stormwater BMPs, especially those of the capture and use type, can be breeding grounds for mosquitoes and other vectors resulting in adverse public health effects related to vectors and disease transmission. Because of this, efforts shall be made to design capture and use BMPs that do not facilitate the breeding of vectors. Vectors should be considered during the preparation of stormwater management and maintenance plans and during preconstruction planning to avoid creating possible public health hazards.

Minimizing mosquito production potential requires that standing water not be available for sufficient time to permit eggs to develop to adult mosquitoes. For stormwater BMP's, this can be achieved in one of three ways: 1) discharge of all captured water within 72 hours, 2) deny mosquitoes access to standing water (this is known as "exclusion"), or 3) make the habitat less suitable for mosquito breeding. The most effective design strategy to exclude vectors from LID practices is to design the system to ensure that water is discharged within 72 hours, thereby eliminating the potential vector breeding source. The capture and use feasibility screening shall

RB-AR32746

consider the site’s ability to disperse of the captured storage volume within this recommended drawdown time.

Oversized capture and use BMPs designed to hold captured stormwater for periods longer than 72 hours will require additional treatment such as filtration or disinfection to protect the collection tanks from fouling, to prevent the breeding of vectors, and/or to improve the quality of water for reuse applications.These BMPs must have appropriate vector control measures incorporated into the design of the system to exclude vector access and breeding (i.e., observation access for vector inspection and treatment).They should be approved by the County of Los Angeles Department of Public Health. These scenarios will be reviewed on a case-by-case basis.

If vector breeding is taking place at a site as a result of contained stormwater or inadequately maintained BMPs, the Greater Los Angeles County Vector Control District has the ability to fine site owners for violating the California Health and Safety Code (Section 2060 – 2067).

RB-AR32747

4.4 INFILTRATION BMPS

Infiltration refers to the physcial process of percolation, or downward seepage, of water through a soil's pore space. As water infiltrates, the natural filtration, adsorption, and biological decomposition properties of soils, plant roots, and micro-organisms work to remove pollutants prior to the water recharging the underlying groundwater. Infiltration BMPs include infiltration basins, infiltration trenches, infiltration galleries, bioretention without an underdrain, dry wells, and permeable pavement. Infiltration can provide multiple benefits, including pollutant removal, peak flow control, groundwater recharge, and flood control. However, conditions that can limit the use of infiltration include soil properties, proximity to building foundations and other infrastructure, geotechnical hazards (e.g., liquefaction, landslides), and potential adverse impacts on groundwater quality (e.g industrial pollutant source areas, contaminated soils, groundwater plumes)[3]. To ensure that infiltration would be physcially feasible and desireable (i.e., not have adverse impacts), a categorical screening of site feasibility criteria must be completed prior to the use of infiltration BMPs following the guidelines presented in Section 4.2.

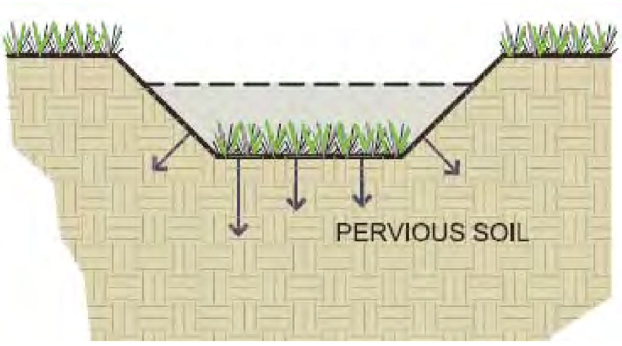
4.4.1 Infiltration BMP Types

<u>**Surface Infiltration BMPs**</u>

These BMPs rely on infiltration in a predominantly vertical (downward) direction and depend primarily on soil characteristics in the upper soil layers. These infiltration BMPs include:

Infiltration Basins

An infiltration basin consists of an earthen basin constructed in naturally pervious soils with a flat bottom typically vegetated with dry-land grasses or irrigated turf grass. An infiltration basin functions by retaining the design runoff volume in the basin and allowing the retained runoff to percolate into the underlying native soils over a specified period of time.



Infiltration Trenches

Infiltration trenches, which are similar to basins, are long, narrow, gravel-filled trenches, often vegetated, that infiltrate stormwater runoff from small drainage areas. Infiltration trenches may include a shallow depression at the surface, but the majority of runoff

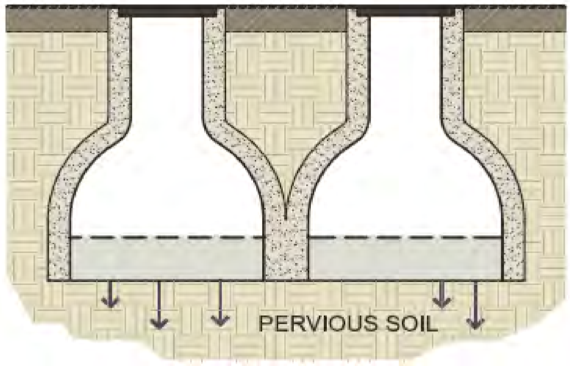
3 Depending on the design of the infiltration practice, Federal Underground Injection Control (UIC) Rules (40 CFR 144) may apply, which may further restrict the use of infiltration facilities in some locations.

RB-AR32748

is stored in the void space within the gravel and infiltrates through the sides and bottom of the trench.

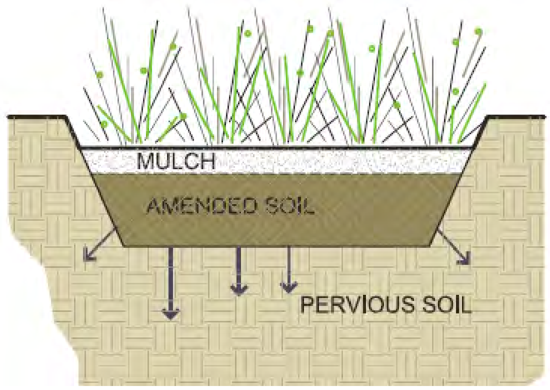
Infiltration Galleries

Infiltration galleries are open-bottom, subsurface vaults that store and infiltrate stormwater. A number of vendors offer prefabricated, modular infiltration galleries that provide subsurface storage and allow for infiltration. Infiltration galleries come in a variety of material types, shapes and sizes.



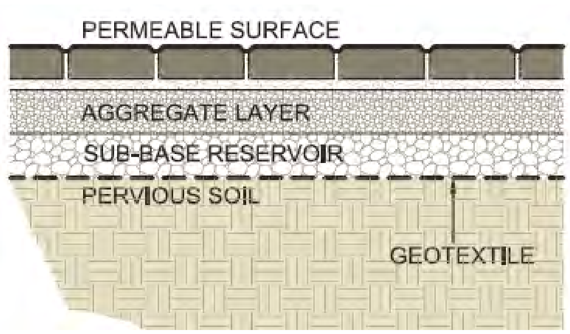
Bioretention

Bioretention stormwater treatment facilities are landscaped shallow depressions that capture and filter stormwater runoff. These facilities function as a soil and plant-based filtration device that removes pollutants through a variety of physical, biological, and chemical treatment processes. The facilities normally consist of a ponding area, mulch layer, planting soils, plantings, and, optionally, a subsurface gravel reservoir layer.



Permeable Pavements

Permeable (or pervious) pavements contain small voids that allow water to pass through to a stone base. They come in a variety of forms; they may be a modular paving system (concrete pavers, modular grass or gravel grids) or poured-in-place pavement (porous concrete, permeable asphalt). All permeable pavements with a stone reservoir base treat stormwater and remove sediments and metals to some degree by allowing stormwater to percolate through the pavement and enter the soil below.



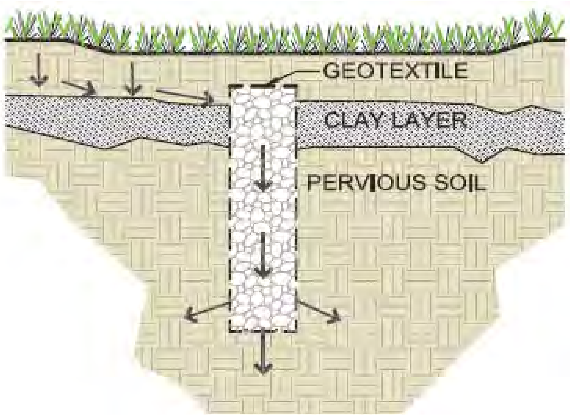
RB-AR32749

Multi-Directional Infiltration BMPs

These BMPs take advantage of the hydraulic conductivities (K_{sat}) of multiple soil strata and infiltration in multiple directions. They may be especially useful at locations where low K_{sat} values are present near the surface and soils with higher permeabilities exist beneath. A Multi-Directional Infiltration BMP may be implemented to infiltrate water at these lower soil layers, thus allowing infiltration to occur at sites that otherwise would be infeasible. These infiltration BMPs typically have smaller footprints and include, but are not limited to:

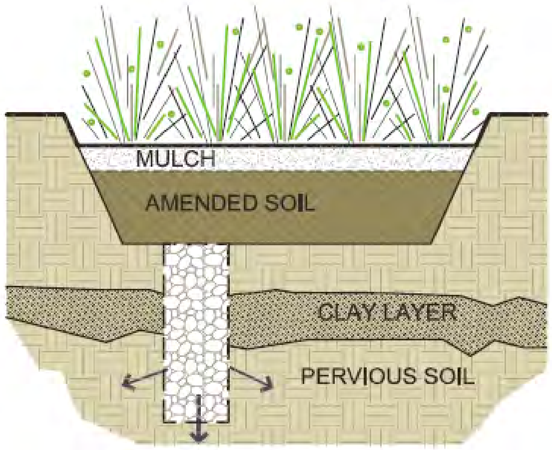
Dry Wells

A dry well is defined as an excavated, bored, drilled, or driven shaft or hole whose depth is greater than its width. Drywells are similar to infiltration trenches in their design and function, as they are designed to temporarily store and infiltrate runoff, primarily from rooftops or other impervious areas with low pollutant loading. A dry well may be either a drilled borehole filled with aggregate or a prefabricated storage chamber or pipe segment.



Hybrid Bioretention/Dry Wells

A bioretention facility with dry wells is useful in areas with low surface-level hydraulic conductivities that would normally deem a bioretention BMP infeasible but have higher levels of permeability in deeper strata. By incorporating drywells underneath the bioretention facility, water is able to be infiltrated at deeper soil layers that are suitable for infiltration, if present. This hybrid BMP combines the aesthetic and filtration qualities of a bioretention facility with the enhanced infiltration capabilities of a dry well.



4.4.2 Siting Requirements and Opportunity Criteria

Drainage areas implementing infiltration BMPs must pass the Category 1 or Category 2 Screening in accordance with the siting requirements set forth in Table 4.1. This screening process must be approved by a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional geotechnical engineer or geologist.

RB-AR32750

Additionally, drainage areas that will result in high sediment loading rates to the infiltration facility shall require pretreatment to reduce sediment loads and avoid system clogging. Examples of appropriate pretreatment may include: sedimentation/settling basins, baffle boxes, hydrodynamic separators, media filters, vegetated swales, or filter strips.

4.4.3 Calculating Size Requirements for Infiltration BMPs

The main challenge associated with infiltration BMPs is preventing system clogging and subsequent infiltration inhibition. In addition, infiltration BMPs must be designed to drain in a reasonable period of time so that storage capacity is available for subsequent storms and so that standing water does not result in vector risks or plant mortality. Infiltration BMPs should be designed according to the requirements listed in Table 4.4 and outlined in the text following.

Infiltration facilities must be sized to completely infiltrate the design capture volume within 48 hours. Steps for the simple sizing method are provided below.

Step 1: Calculate the Design Volume

Infiltration facilities shall be sized to capture and infiltrate the design capture volume (V_{design}) based on the runoff produced from a 0.75-inch (0.0625 ft) storm event.

$$V_{design} \text{ (cu ft)} = 0.0625 \times \textit{Catchment Area} \text{ (sq ft)}$$

Where:

Catchment Area = (Impervious Area x 0.9) + [(Pervious Area + Undeveloped Area) x 0.1]

For catchment areas given in acres, multiply the above equation by 43,560 sq. ft./acre.

Table 4.4: Infiltration BMP Design Criteria

Design Parameter	Unit	Basins and Trenches	Galleries	Bioretention	Permeable Pavement	Dry Well	Hybrid Bioretention/ Dry Well
Design Capture Volume, $V_{capture}$	cubic feet	0.0625 x Catchment Area (sq. ft.)[a]					
Design Surface Drawdown Time	hr	48					
Setbacks and Elevations	feet	In accordance with the Infiltration Feasibility Criteria, Section 4.2					
Pretreatment	-	Appropriate Treatment Control Measure shall be provided as pretreatment for all tributary surfaces other than roofs					
Hydraulic Conductivity, $K_{sat,measured}$	in/hr	Measured hydraulic conductivity at the location of the proposed BMP at the depth of the proposed infiltrating surface (or effective infiltration rate when multi directional infiltration is occurring					
Factor of Safety, FS[b]	-	3					
Facility geometry	-	Bottom slope ≤ 3% (basins); side slope shall not exceed 3:1 (H:V)	Flat bottom slope	Bottom slope ≤ 3%; side slope shall not exceed 3:1 (H:V)	Pavement slope ≤ 5%; If ≥ 2%, area shall be terraced	Typical 18 – 36 inch diameter; flat bottom slope	Bioretention: Bottom slope ≤ 3%; side slope shall not exceed 3:1 Drywell: flat bottom
Ponding Depth	inch	18 (maximum)[c]					
Media Depth	feet	2 (min) 8 (max)	-	2 (min) 8 (max)	2 (min) 8 (max)	-	2 (min) 8 (max)
Gravel media diameter	inch	1 – 3	-	-	1 - 2	3/8 – 1	3/8 - 1
Inlet erosion control	-	Energy dissipater to reduce velocity					
Overflow device	-	Required if system is on-line and does not have an upstream bypass structure.Shall be designed to handle the peak storm flow in accordance with the Building and Safety code and requirements					

a: Catchment area = (impervious area x 0.9) + [(pervious area + undeveloped area) x 0.1]

b:Listed FS values to be used only if soil infiltration / percolation test was performed and a detailed geotechnical report from a professional geotechnical engineer or engineering geologist is provided. A FS of 6 will be assigned if only a boring was done.

c: Ponding depth may vary for galleries (which have a storage depth) and may be different from one vendor to another. Ponding depth is not necessarily applicable to permeable pavement.

Step 2: Determine the Design Infiltration Rate

The infiltration rate will decline between maintenance cycles as the surface becomes clogged with particulates and debris. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the sizing of facilities depending on a site's infiltration rate and expected surface loading. Where applicable, the measured infiltration rate discussed here is the infiltration rate of the underlying soils and not the infiltration rate of the filter media bed or engineered surface soils.Facility maintenance is required to maintain the infiltration rate for the life of the project.Infiltration rates used for design must be divided by the appropriate factors of safety.

$$K_{sat,design} = K_{sat,measured}/FS$$

Where:

FS = Infiltration factor of safety, in accordance with Table 4.4

Measured infiltration rates shall be determined by in-ground, site specific infiltration tests or can be based on laboratory tests conducted on soil samples collected during the exploratory work for a site-specific geotechnical report.

Step 3: Calculate the BMP Surface Area

Determine the size of the required infiltrating surface by assuming the design capture volume will fill the available ponding depth plus the void spaces based on the porosity of the gravel fill (normally about 30 - 40%[4]) or amended soil (normally about 20 – 30%).

Determine the maximum depth of runoff that can be infiltrated within 48 hours as follows:

$$D_{eff} = (T \times K_{sat,design}) / (12 \times n)$$

Where:

D_{eff} = Effective trench depth (ft)

T = Drawdown time (hours), which is assumed to be 48 hours

n = Void ratio (use 0.40 for gap graded gravel; 0.3 for amended soil)

Determine the minimum infiltrating surface area necessary to infiltrate the design volume:

$$A_{min} = V_{design} / D_{eff}$$

Where:

A_{min} = Minimum infiltrating surface area (ft^2)

The calculated minimum BMP surface area only considers the surface area of the BMP where infiltration can occur. For dry wells, the calculated surface area is the total surface area of the well lying in soils with $K_{sat,measured}$ values > 0.3 in/hr. In other words, the portion of the dry well

4Terzaghi and Peck stated that in the densest possible arrangement of cohesionless spheres, the porosity is equivalent to 26%; in the loosest possible arrangement, the porosity is equal to 47% (Terzaghi K. and Peck R. Soil Mechanics in Engineering Practice. 2cnd ed. New York: John Wiley and Sons; 1967).

that extends through impermeable layers should not be considered part of the infiltrating area. For the hybrid bioretention/dry well BMP design, the calculated BMP surface area applies to the combined surface area of the bioretention facility and the infiltrating portion of the underlying dry well(s).

For infiltration trenches and basins, the surface area should be calculated as the surface area at mid-ponding depth.

Note that A_{min} represents the minimum calculated surface area. It is up to the discretion of the developer if A_{min} will be exceeded to allow for less media storage.

Step 4: Calculate the Media Storage Depth

Determine the depth of the infiltration unit to be filled with media for capturing the design capture volume. The depth shall not exceed 8 feet.

$$D_{media} = [V_{design} - (K_{sat,design} \times T \times A_{min} / 12)] / (A_{min} \times n) \leq 8$$

Where:

D_{media} = Minimum media storage depth of the infiltration facility (ft)

If D_{media} is calculated as greater than 8 feet, the design infiltration area (A_{design}) shall be increased and the depth of media shall be recalculated until it is less than 8 feet.

Many project developers may elect to in increase the design infiltration area such that $A_{design}>A_{min}$. This is especially feasible where infiltration rates are relatively high (leading to a low A_{min} value). The depth of media (D_{media}) should be calculated using the actual design area in Step 4 above. For projects with designed infiltration areas significantly higher than A_{min}, it may be feasible to have no media storage (i.e. D_{media} = 0 ft). For this to apply, the following condition must be met:

$$A_{design} \geq (V_{design} \times 12) / (K_{sat,design} \times T)$$

Infiltration Sizing Example

Given: 30,000 ft^2 apartment complex (including parking) with 10,000 ft^2 of landscaped area. An infiltration test has resulted in a $K_{sat,measured}$value of 0.5 in/hr; Factor of Safety = 4. Design an infiltration trench meeting the sizing requirements. Assume the trench is full of gap-graded gravel with a porosity of 0.3.

1) Determine V_{design}
   Catchment Area = (30,000ft^2 x 0.9) + [(10,000 ft^2) x 0.1] = 28,000 ft^2
   $\boldsymbol{V_{design}}$ = 0.0625 * 28,000 ft^2 = **1,750 ft^3**

2) Determine $K_{sat,design}$
   $\boldsymbol{K_{sat,design}}$ = (0.5 in/hr) /4 = **0.125 in/hr**

3) Determine A_{min}
   D_{eff} = (48 hrs x 0.125 in/hr) / (12 x 0.3) = 1.67 ft
   $\boldsymbol{A_{min}}$ = 1,750ft^3 / 1.67 ft = **1,050ft^2**

4) Determine D_{media}
   $\boldsymbol{D_{media}}$= [1,750 ft^3 – (0.125 in/hr x 48 hrs x 1,050 ft^2)/(12)] / (1,050 ft^2 x 0.3) = **3.9 ft**

RB-AR32755

The trench should therefore be designed with a minimum of 1,050 ft^2 of infiltrating surface area. At this minimum surface area, the gravel media depth should be at least 3.9 feet.

4.4.4 Design Criteria and Requirements

Unless specifically stated, the following criteria and requirements listed below are required for the implementation of all infiltration BMPs. Provisions not met must be approved by the City of Los Angeles.

Permeable Pavement Application
Los Angeles World Airports Parking

- Infiltration BMPs have been designed and constructed to promote uniform ponding and infiltration.
- Where necessary, a sediment forebay or separate pretreatment unit (e.g. vegetated swale, filter strip, hydrodynamic device, etc.) is located between the inlet and infiltration BMP. The sediment forebay has a volume greater than or equal to 25% of the total design volume.
- Sediment forebay has a minimum length to width ratio of 2:1 and is designed to conduct flow to the infiltration BMP.
- Any embankment slopes (interior and exterior) are not steeper than 3:1 (H:V) unless approved by the City of Los Angeles.
- The bottom of the infiltration bed is native soil and has been over-excavated to at least one foot in depth. It is recommended that the excavated soil be amended with 2 – 4 inches of coarse sand (e.g., 2 – 5 mm sand) before being replaced uniformly without compaction.
- The hydraulic conductivity (Ksat) of the subsurface layers is sufficient to ensure the maximum drawdown time of 48 hours.
- Where Ksat values are greater than 2.4 in/hr, pretreatment is provided to address pollutants of concern prior to infiltration to protect groundwater quality; pretreatment may be considered to be addressed in the amended media or sand layers within the BMP if provided.
- Provided overflow safely conveys flows to the downstream stormwater conveyance system, an additional BMP, or an alternatively acceptable discharge point.
- Where the infiltration system is placed underground, an observation well is provided for inspection/mainteance purposes.
- Porous pavement facilities consist of various layers of material. The top layer consists of either asphalt or concrete with a percentage of voids of at least 15%. This layer is

followed by a stone reservoir layer or a thick layer of aggregate with 25-35% voids. Two transition layers are also present. The depth of each layer and the specific materials used shall be determined by a licensed civil engineer.

- Dry wells shall be filled with washed 3/4 – 1 inch crushed rock, recycled concrete aggregate, or open-graded gravel (i.e. gravel with a small percentage of small particles). If a perforated pipe has been installed in the well, perforations are 3/8" and are smaller than the fill gravel. A woven geotextile shall be placed over the top of the drywell to prevent sediment clogging.

4.4.5 Soil and Vegetation Requirements

Soil and vegetation to be incorporated in infiltration facilities shall be selected by a licensed landscape architect. In general, drought and flood resistant plant species native to California should be selected when possible. Soil media should be selected to not restrict performance requirements. Selected soils shall therefore have a higher hydraulic conductivity than the underlying soil, shall be able to support the selected plant palette, and shall be graded to provide adequate filtration as to not clog underlying soils.

4.4.6 Construction Requirements

To preserve and avoid the loss of infiltration capacity, the following construction guidelines shall be adhered to:

Underground Infiltration Units
Lowe's, Pacoima

- The entire area draining to the infiltration facility is stabilized before construction of the infiltration facility begins, or a diversion berm is placed around the perimeter of the infiltration site to prevent sediment entrance during construction.
- Infiltration BMPs shall not be used as sediment control facilities during construction.
- Compaction of the subgrade with vehicles and/or equipment is minimized. If the use of heavy equipment on the base of the facility cannot be avoided, the infiltrative capacity shall be restored by tilling or aerating prior to placing the infiltrative bed.
- Where pervious pavement is to be installed, installation of the pavement shall be scheduled as the the last installation at a development site. Vehicular traffic is prohibited for at least 2 days following installation. Site materials shall not stored on pervious pavement.

RB-AR32758

4.4.7 Operations and Maintenance

- Frequent inspections of the infiltration facilities shall occur to ensure that surface ponding infiltrates into the subsurface completely within the design drawdown time following storms. If vector breeding is taking place at a site as a result of contained stormwater or inadequately maintained BMPs, the Greater Los Angeles County Vector Control District has the ability to fine site owners for violating the California Health and Safety Code (Section 2060 – 2067).
- Regular inspections shall take place to ensure that the pretreatment sediment removal BMP/forebay is working efficiently. Sediment buildup exceeding 50% of the forebay sediment storage capacity shall be removed.
- The infiltration facility shall be maintained to prevent clogging. Maintenance activities include checking for debris/sediment accumulation and removal of such debris.
- Facility soil (if applicable) shall be maintained. Flow entrances, ponding areas, and surface overflow areas will be inspected for erosion periodically. Soil and/or mulch will be replaced as necessary to maintain the long-term design infiltration rate for the life of the project.
- Site vegetation shall be maintained as frequently as necessary to maintain the aesthetic apperance of the site as well as the filtration capabilities (where applicable). This includes the removal of fallen, dead, and/or invasive plants, watering as necessary, and the replanting and/or reseeding of vegetation for reestablishment as necessary.
- Pervious pavement areas that are damaged or clogged shall be replaced/repaired per manufacture’s recommendation as needed.

4.5 CAPTURE AND USE BMPS

Capture and Use refers to a specific type of BMP that operates by capturing stormwater runoff and holding it for efficient use at a later time. On a commercial or industrial scale, capture and use BMPs are typically synonomous with cisterns, which can be implemented both above and below ground. Cisterns are sized to store a specified volume of water with no surface discharge until this volume is exceeded. The primary use of captured runoff is for subsurface drip irrigation purposes. The temporary storage of roof runoff reduces the runoff volume from a property and may reduce the peak runoff velocity for small, frequently occurring storms. In addition, by reducing the amount of stormwater runoff that flows overland into a stormwater conveyance system, less pollutants are transported through the conveyance system into local streams and the ocean. The onsite use of the harvested water for non-potable domestic purposes conserves City-supplied potable water and, where directed to unpaved surfaces, can recharge groundwater in local aquifers.

4.5.1 Siting Requirements and Opportunity Criteria

Drainage areas implementing capture and use BMPs must pass the Category 1 or Category 2 Screening in accordance with the siting requirements set forth in Section 4.3. This screening process must be approved by a site-specific geotechnical investigation report and/or hydrologic analysis conducted and certified by a State of California registered professional civil engineer, geotechnical engineer, geologist, or other qualified professional.

4.5.2 Calculating Size Requirements for Capture and Use BMPs

At a minimum, capture and use BMPs must be designed and maintained to ensure adequate capacity is available to capture the stormwater quality design volume within 3 days of a storm event. BMPs sized to capture the runoff produced from the 0.75 inch storm event, or BMPs designed to capture less than this volume if being used in conjunction with other BMPs, must therefore drawdown their entire captured volume within 3 days of a storm event. Capture and use BMPs designed for storm events larger than 0.75 inches are required to disperse enough water from the BMP within 3 days of a storm to ensure that adequate capacity is available to capture the next storm event up to 0.75 inches.Capture and use BMPs designed for these extended holding times will require additional treatment such as filtration or disinfection to protect the collection tanks from fouling, to prevent the breeding of vectors, and/or to improve the quality of water for reuse applications.These scenarios will be reviewed on a case-by-case basis.

Calculate the Minimum Capture Volume for a 72-hour Holding Time

Assuming that demands and conditions at a site indicate that the 72-hour drawdown time requirement will be met, all cisterns shall be sized to capture the runoff generated from the 0.75-inch storm event at a minimum[5]:

$$V_{design} \text{ (gallons)} = 0.4675 * \textit{Catchment Area} \text{ (sq. ft.)}$$

Where:

Catchment Area = (Impervious Area x 0.9) + [(Pervious Area + Undeveloped Area) x 0.1]

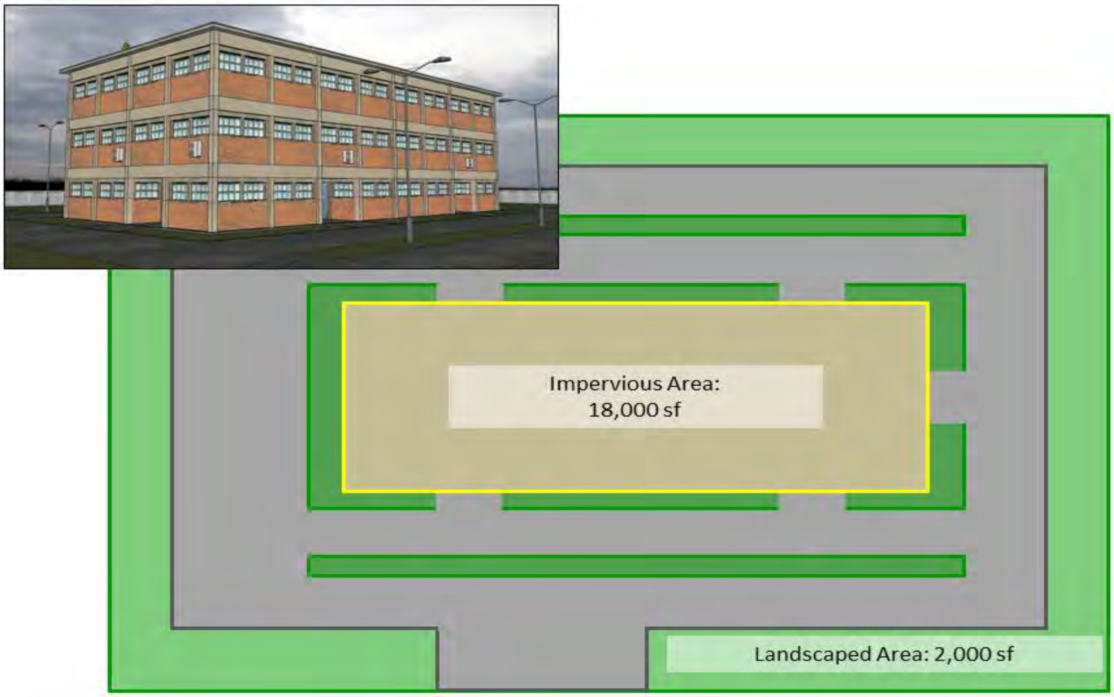
For catchment areas given in acres, multiply the above equation by 43,560 sq. ft./acre.

The capture volume V_{design} represents not only the minimum volume a cistern must be sized to to fully satisfy the requirements of Section 3.1.2, but alsorepresents the cistern capacity that must be available within 72 hours following a storm event. BMPs sized to capture the 0.75-inch storm event or less must therefore drawdown their entire captured volume within 72 hours of a storm event. Calculations must be provided with the project submittal to demonstrate that V_{design}canbe discharged within 72 hours following a 0.75-inch (and larger) storm event without causing or contributing to dry weather runoff or additional wet weather runoff.

5Capture and use BMPs used in combination with other BMP types to collectively meet the water quality design storm standard set forth in Section 3.1.2 may be sized to capture less than V_{design}. The entire capture capacity of these BMPs must be emptied within 72 hours of a storm event to allow for the capture of the next storm event.

Capture and Use Sizing Example

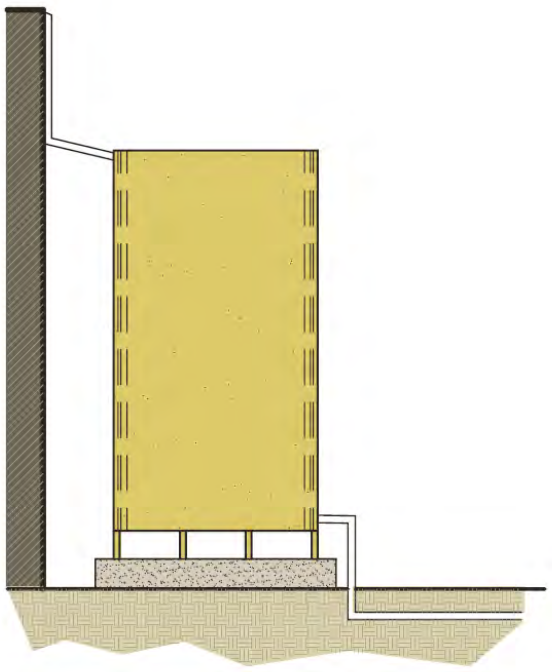
Given: 20,000 ft^2 warehouse building with parking lot, 90% impervious, 10% landscaped. Design a cistern meeting the minimum sizing requirements to capture the entire 0.75-inch storm event.



1) Determine V_{design}
   Catchment Area = (18,000ft^2 x 0.9) + [(2,000 ft^2) x 0.1] = 16,400ft^2
   $\boldsymbol{V_{design}}$ = 0.4675 * 16,400ft^2 = **7,670 gallons**

For a full capture system, the cistern should be designed with a minimum storage capacity of 7,670 gallons. If a larger cistern is desired, the facility must be maintained to ensure that a capacity of 7,670 gallons is available within 3 days of the most recent storm event.

4.5.3 Design Criteria and Requirements



- Unless specifically stated, the following criteria and requirements listed below are required for the implementation of all capture and use BMPs. Provisions not met must be approved by the City of Los Angeles.
- Fertilizers, pesticides, or herbicides on landscaped areas shall be minmized.
- Above-ground cisterns are secured in place and designed to meet seismic requiremnts for tanks.
- Overflow outlet is provided upstream of the tank inlet and is designed to disperse overflow onsite and through stable vegetated areas where erosion or suspension of sediment is minimized. Dispersion will take place at least 3 feet from public sidewalks, at least 5 feet from property lines and foundations, and at least 6 feet away from basement walls. Overflow from the tank into the storm drain system is not allowed.
- For landscape applications, a subsurface drip irrigation system has been aproved and installed to adequately discharge the captured water[6].
- If a pumping system is used, a reliable pump capable of delivering 100% of the design capacity is provided. Pump is accessible for maintenance. Pump has been selected to operate within 20% of its best operating efficiency. A high/low-pressure pump shut off system is installed in the pump discharge piping in case of line clogging or breaking.
- If an automated harvesting control system is used, it is complete with a rainfall or soil moisture sensor. The automated system has been programmed to not allow for continuous application on any area for more than 2-hours.
- Dispersion is directed so as not to knowingly cause geotechnical hazards related to slope stability or triggering expansive (clayey) soil movement.
- Cisterns do not allow UV light penetration to prevent algae growth.

6If alternative distribution systems (such as spray irrigation) are approved, the City will establish guidelines to implement these new systems.

RB-AR32763

- Cistern placement allows easy access for regular maintenance. If cistern is undergrond, manhole shall be accessible, operational, and secure.
- Refer to County of Los Angeles , Department of Health Services for additional guidelines and requiremnets.
- Provide observation access for vector inspection and treatment.

4.5.4 Operations and Maintenance

- Cistern components, including spigots, downspouts, and inlets will be inspected 4 times annually to ensure proper functionality. Parts will be repaired or replaced as needed.
- Cisterns and their components will be cleaned as necessary to prevent algae growth and the breeding of vectors.
- Dispersion areas will be maintained to remove trash and debris, loose vegetation, and rehabilitate any areas of bare soil.
- Effective energy dissipation and uniform flow spreading methods will be employed to prevent erosion and facilitate dispersion.
- Cisterns will be emptied as necessary to prevent standing water from remaining for more than 72 hours following the conclusion of a storm event, unless exclusion devices are implemented to prevent vector access. If vector breeding is taking place at a site as a result of contained stormwater or inadequately maintained BMPs, the Greater Los Angeles County Vector Control District has the ability to fine site owners for violating the California Health and Safety Code (Section 2060 – 2067).

RB-AR32764

4.6 BIOFILTRATION BMPS

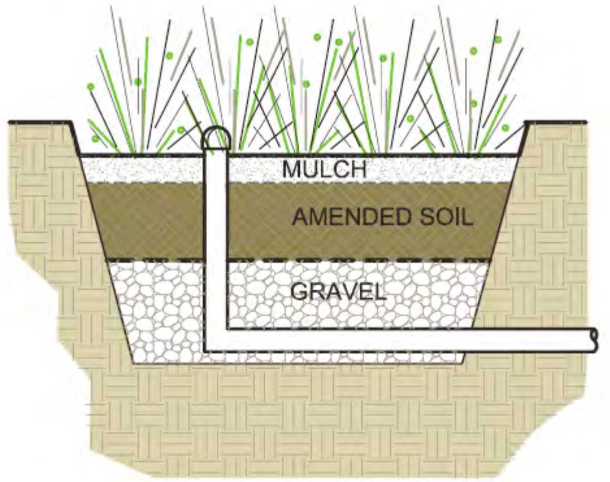
Projects that have demonstrated they cannot manage 100% of the water quality design volume onsite through infiltration and/or capture and use BMPs may manage the remaining volume through the use of a high removal efficiency biofiltration/biotreatment BMP. A high removal efficiency biofiltration/biotreatment BMP shall be sized to adequately capture 1.5 times the volume not managed through infiltration and/or captureanduse.

Biofiltration BMPs are landscaped facilities that capture and treat stormwater runoff through a variety of physical and biological treatment processes. Facilities normally consist of a ponding area, mulch layer, planting soils, plants, and in some cases, an underdrain. Runoff that passes through a biofiltration system is treated by the natural adsorption and filtration characteristics of the plants, soils, and microbes with which the water contacts. Biofiltration BMPs include vegetated swales, filter strips, planter boxes, high flow biotreatment units, bioinfiltration facilities, and bioretention facilities with underdrains. Biofiltration can provide multiple benefits, including pollutant removal, peak flow control, and low amounts of volume reduction through infiltration and evapotranspiration.

4.6.1 Biofiltration BMP Types

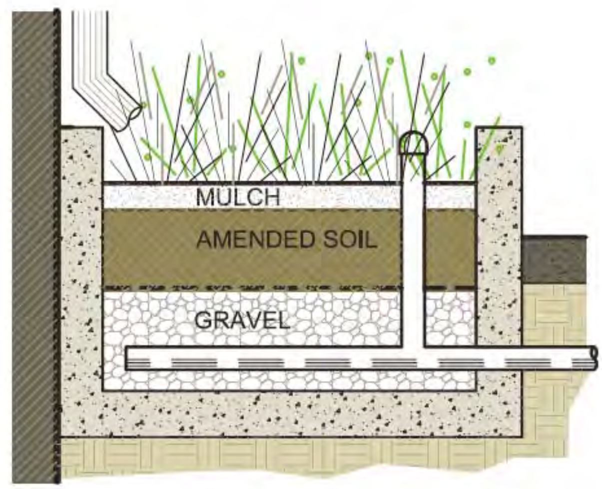
Biofiltration BMPs rely on various hydraulic residence times and flow-through rates for effective treatment. As a result, a variety of BMPs are available.

Bioretention with Underdrain



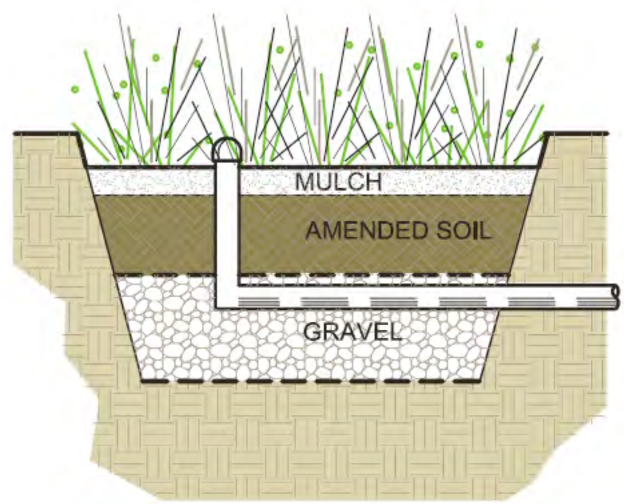
Bioretention facilities are landscaped shallow depressions that capture and filter stormwater runoff. As stormwater passes down through the planting soil, pollutants are filtered, adsorbed, and biodegraded by the soil and plants. Because they are not contained within an impermeable structure, they may allow for infiltration. For sites not passing the infiltration feasibility screening for reasons other than low infiltration rates (such as soil contamination, expansive soils, etc.), an impermable liner may be needed to prevent incidental infiltration.

Planter Boxes



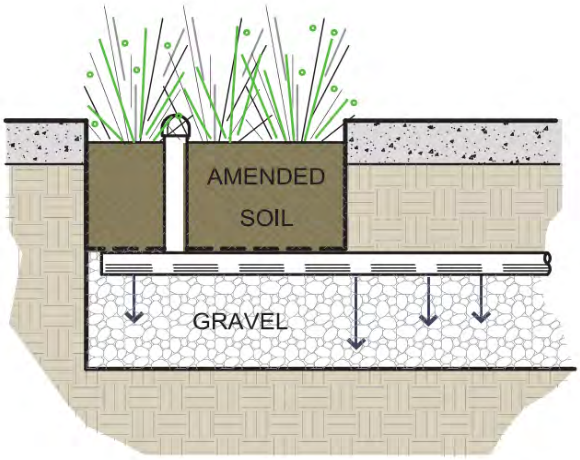
Planter boxes are bioretention treatment control measures that are completely contained within an impermeable structure with an underdrain (they do not infiltrate). They are similar to bioretention facilities with underdrains except they are situated at or above ground and are bound by impermeable walls. Planter boxes may be placed adjacent to or near buildings, other structures, or sidewalks.

Bioinfiltration



Bioinfiltration facilities are designed for partial infiltration of runoff and partial biotreatment. These facilities are similar to bioretention devices with underdrains but they include a raised underdrain above a gravel sump designed to facilitate infiltration and nitrification/denitrification. These facilities can be used in areas where there are little to no hazards associated with infiltration, but infiltration screening does not allow for infiltration BMPs due to low infiltration rates or high depths of fill.

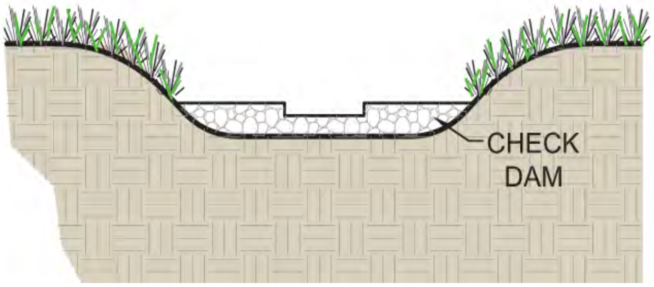
High-Flow Biotreatment with Raised Underdrain



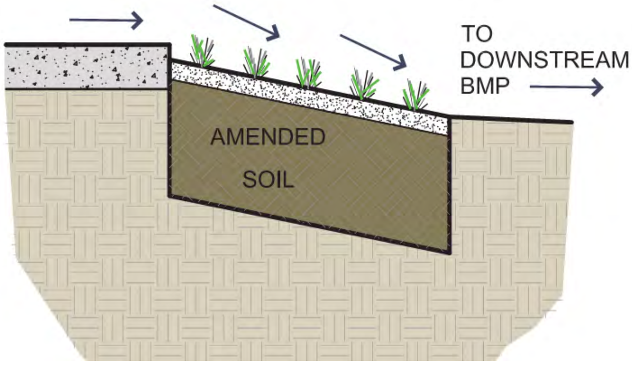
High-flow biotreatment devices are proprietary treatment BMPs that incorporate plants, soil, and microbes engineered to provide treatment at higher flow rates and with smaller footprints than their non-proprietary counterparts. Like bioinfiltration devices, they should incorporate a raised underdrain above a gravel sump to facilitate incidental infiltration where feasible.They must be shown to have pollutant removal efficiencies equal to or greater than the removal efficiencies of their non-proprietary counterparts. Proof of this performance must be provided by adequate third party field testing.

Vegetated Swales

Vegetated swales are open, shallow channels with dense, low-lying vegetation covering the side slopes and bottom that collect and slowly convey runoff to downstream discharge points. An effective vegetated swale achieves uniform sheet flow through the densely vegetated area for a period of several minutes. The vegetation in the swale can vary depending on its location and is the choice of the designer. Most swales are grass-lined.



Filter Strips (to be used as part of a treatment train)



Filter strips are vegetated areas designed to treat sheet flow runoff from adjacent impervious surfaces such as parking lots and roadways, or intensive landscaped areas such as golf courses. While some assimilation of dissolved constituents may occur, filter strips are generally more effective in trapping sediment and particulate-bound metals, nutrients, and pesticides. Filter strips are more effective when the runoff passes through the vegetation and thatch layer in the form of shallow, uniform flow. Filter strips are primarily used to pretreat runoff before it flows to an infiltration BMP or another biofiltration BMP.

4.6.2 Siting Requirements and Opportunity Criteria

Sites with plans to implement high removal efficiency biofiltration/biotreatment systems for the management of stormwater must first be screened for infiltration and capture and use BMP feasibility. Biofiltration should be implemented to treat all runoff onsite to the maximum extent feasible at sites incapable of implementing infiltration and/or capture and use BMPs as a result of the feasibility screening process set forth in this handbook.

Sites implementing biofiltration BMPs must have sufficient area available to ensure that BMPs produce adequate contact time for filtration to occur. For biofiltration BMPs with underdrains, sufficient vertical relief must exist to permit vertical percolation through the soil media to the underdrain below. For biofiltration BMPs with incidental infiltration, it must be demonstrated that there are no hazards associated with infiltration (i.e. infiltration screening does not allow for infiltration BMPs due to low infiltration rates or high depths of fill).

4.6.3 Calculating Size Requirementsfor Biofiltration BMPs

Biofiltration BMPs should be designed according to the requirements listed in Table 4.5 and outlined in the section below.

Table 4.5: Biofiltration BMP Design Criteria

Design Parameter	Unit	Bioretention with Underdrain	Planter Box	Bioinfiltration	High Flow Biotreatment[a]	Vegetated Swale	Filter Strip
Design Capture Volume, $V_{capture}$	cubic feet	1.5 x 0.0625 * Catchment Area (sq. ft.)[b]					-
Design Drawdown Time	hr	48 (surface); 96 (total)				-	-
Factor of Safety[c]	-	2				-	
Soil Media Infiltration Rate	in/hr	5 (max)			Per manufacturer's standards	-	
Design Contact Time	min	-				≥ 7	
Slope in Flow Direction	%	-				1% (min) 6% (max)	2% (min) 33% (max)
Design Flow Velocity	ft/sec	-				≤ 1	
Max Ponding/Flow Depth	inch	18	12	18	-	5	1
Soil Depth	ft	2 (3 preferred)	2 (3 preferred)	2 (3 preferred)	-	2	-
Underdrain	-	Slotted PVC pipe within 6" of bottom of facility	Slotted PVC pipe within 6" of bottom of facility	Slotted PVC pipe at least 2' above bottom of facility	Per manufacturer's standards	N/A	Not required
Inlet erosion control	-	Energy dissipater to reduce velocity					
Overflow device	-	Required if system is on-line and does not have an upstream bypass structure. Shall be designed to handle the peak storm flow in accordance with the Building and Safety code and requirements					Not Required

a: High flow biotreatment BMP design criteria displayed in Table 4.5 are general guidelines. Specific designs will vary depending on the vendor, design type, size, etc. High flow biotreatment BMPs must be sized to treat the design capture volume specified. They must be shown (by third party field testing) to have a pollutant removal efficiency equal to or greater than their non-proprietary counterparts.

b: Catchment area = (impervious area x 0.9) + [(pervious area + undeveloped area) x 0.1]

c: Listed FS values to be used only if soil infiltration / percolation test was performed and a detailed geotechnical report from a professional geotechnical engineer or engineering geologist is provided A FS of 6 will be assigned if only a boring was done.

Bioretention, Planter Box, Bioinfiltration, and High-Flow Biotreatment Sizing

With the exception of swales and filter strips, biofiltration facilities can be sized using one of two methods: a simple sizing method or a hydrologic routing modeling method. With either method the design capture volume must be completely infiltrated within the drawdown time shown in Table 4.5. Steps for the simple sizing method are provided below.

Step 1: Calculate the Design Volume

Biofiltration facilities shall be sized to capture and treat 150% of the design capture volume (V_{design}) based on the runoff produced from a 0.75-inch (0.0625 ft) storm event.

$$V_{design} \text{ (cu ft)} = 1.5 * 0.0625 \text{ ft} * \textit{Catchment Area} \text{ (sq. ft.)}$$

Where

Catchment area = (Impervious Area x 0.9) + [(Pervious Area + Undeveloped Area) x 0.1]

Step 2: Determine the Design Infiltration Rate

The infiltration rate will decline between maintenance cycles as the surface and underlying soil matrix becomes clogged with particulates and debris. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the sizing of facilities depending on a site's infiltration rate and expected surface loading. Unlike infiltration BMPs, the measured infiltration rate discussed here is the infiltration rate of the filter media bed or engineered surface soils in the biofilter. A target long-term$K_{sat,media}$of 5 in/hr is recommended for non-proprietary amended soil media. Facility maintenance is required to maintain the infiltration rate for the life of the project. Infiltration rates used for design must be divided by the appropriate factors of safety.

$$K_{sat,design} = K_{sat,media}/FS$$

Step 3: Calculate the BMP Ponding Depth

Select a ponding depth (d_p) that satisfies geometric criteria and is congruent with the constraints of the site. The ponding depth must satisfy the maximum ponding depth constraint shown in Table 4.5 as well as the following:

$$d_p \text{ (ft)} = (K_{sat,design} \times T) / 12$$

Where:

d_p = Ponding depth (ft)

$K_{sat,design}$= Design infiltration rate of filter media (in/hr)

T = Required surface drain time (hrs), from Table 4.5

Step 4: Calculate the BMP Surface Area

Calculate infiltrating surface area (filter bottom area) required:

RB-AR32770

$$A_{min} = \frac{V_{design}}{[(T_{fill}K_{sat,design}/12) + d_p]}$$

Where:

A_{min} = Design infiltrating area (ft^2)

T_{fill}= Time to fill to max ponding depth with water (hrs) [unless a hydrologic routing model is used, assume a maximum of 3 hours]

The calculated BMP surface area only considers the surface area of the BMP where infiltration through amended media can occur. The total footprint of the BMP should include a buffer for side slopes and freeboard.

Bioinfiltration BMPs and high-flow biotreatment devices should incorporate a raised underdrain above the gravel sump to facilitate incidental infiltration where feasible. For these instances, infiltration screening in accordance with Section 4.2 must be carried out to show thatinfiltration BMPs are not allowed due to low infiltration rates or high depths of fill (i.e. there are not hazards associated with infiltration). These BMPs are not suitable for project sites that do not pass infiltration feasibility screening due to associated hazards of infiltration (e.g. high groundwater table, contaminated soil or groundwater, landslide zones, etc.)

Swale Sizing

Swales shall be designed with a trapezoidal channel shape with side slopes of 3:1 (H:V). They shall incorporate at least two feet of soil beneath the vegetated surface. The following steps shall be followed for swale sizing. As is the case with other biofiltration BMPs, the sizing criteria presented in Table 4.5 must be met.

Step 1: Determine the Swale Base Width and Corresponding Unit Length

The base width of a swale must be between 2 and 10 feet. The designer may select the base width that is most appropriate for the site, but the swale length (per unit catchment area) must meet the minimum requirements as shown in Table 4.6 below.

Table 4.6: Swale Base Length (Per Unit Catchment Area)

Base of Swale	ft	2	3	4	5	6	7	8	9	10
Minimum Swale Length per Acre of Catchment Area	ft/acre	770	635	535	470	415	370	335	305	285

Step 2: Determine the Distance Between Check Dams

For volume storage, swales must incorporate check dams at specified intervals depending on the longitudinal slope of the swale, which must be between one and six percent. The check dams must be 12 inches in height and include a 6 inch deep notch in the middle of the check dam that is between one and two feet wide. All check dam structures shall extend across the entire base of the swale. They may be designed using a number of different materials including concrete blocks, gabions, gravel bags, rip rap, or earthen berms. The distance between successive check dams shall be determined from the longitudinal slope of the swale in the flow direction. Table 4.7 summarizes the design distances between check dams based on slope.

Table 4.7: Check Dam Spacing Requirements for Swales

Slope	%	1	2	3	4	5	6
Distance Between Checkdams	ft	100	50	33	25	20	17

For intermediary slopes not shown in Table 4.7, linear interpolation may be used to calculate the distance between check dam structures.

Step 3: Determine the Total Swale Length

The total length of the swale (L_{swale}) is a function of the catchment area and unit swale length from Table 4.6. Total swale length is calculated as follows:

L_{swale} (ft) = *Catchment Area* (ft^2) x (1 acre/43,560 ft^2) x
Swale Length per Acre of Catchment Area (ft/acre)

Where

Catchment area = (Impervious Area x 0.9) + [(Pervious Area + Undeveloped Area) x 0.1]

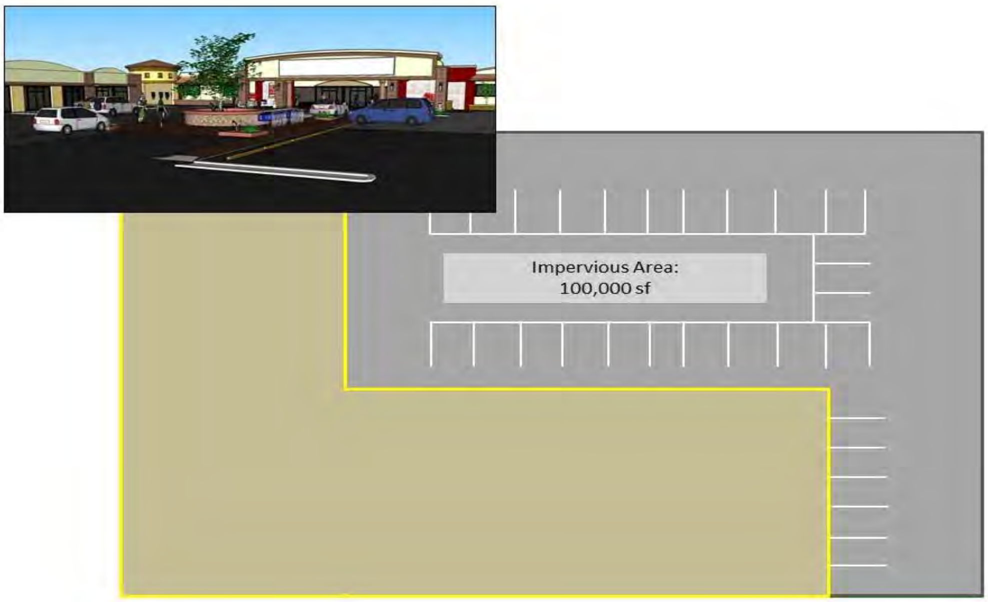
If there is adequate space on the site to accommodate a larger swale, consider using a greater length to increase the hydraulic residence time and improve the swale's pollutant removal capability. If the calculated length is too long for the site, the layout may be modified by meandering the swale or increasing the base width of the swale up to 10 feet. The total swale length shall never be less than 100 feet.

Filter Strip Sizing

Because filter strips are most often used for pretreatment purposes, their design will depend on the desired flow-rate to be treated and the type of BMP downstream, among other factors. As a result, filter strip sizing is not covered in this handbook, but will be determined on a case-by-case basis by the City of Los Angeles.

Bioinfiltration Sizing Example

Given: 100,000 ft^2 commercial development, 100% impervious (negligible landscaping). Design a bioinfiltration BMP to treat runoff from the entire development ($K_{sat,media}$= 5 in/hr; Factor of Safety = 2.).



1) Determine V_{design}
   Catchment Area = (100,000ft^2 x 0.9) = 90,000ft^2
   $\boldsymbol{V_{design}}$ = 1.5 x 0.0625 x 90,000ft^2 = **8,500 ft^3**

2) Determine $K_{sat,design}$
   $\boldsymbol{K_{sat,design}}$ = (5 in/hr) /2 = **2.5 in/hr**

3) Determine d_p
   d_p = (2.5 in/hr * 48 hrs)/12 = 10.0 ft

   Adhering to the max ponding depth requirements of Table 4.5, $\boldsymbol{d_p}$ **= 1.50 ft**

4) Calculate the infiltrating surface area, A_{min}

$$\mathbf{A_{min}} = \frac{8{,}500\, cuft}{[(3hr * 2.5\, in/hr\ /12) + 1.5\ ft]} = \mathbf{4{,}000\ ft^2}$$

For a full capture system, bioinfiltration units must be designed with a combined surface area of 4,000 ft^2.

4.6.4 Design Criteria and Requirements

Unless specifically stated, all criteria and requirements listed below are required for the implementation of all biofiltration BMPs. Provisions not met must be approved by the City of Los Angeles.

- Where applicable, biofiltration BMPs shall be constructed with a minimum planting soil depth of 2 feet (3 feet preferred).
- Where applicable, biofiltration BMPs shall be designed to drain below the planting soil in less than 48 hours and completely drain from the underdrains in 96 hours.
- Underdrains shall be constructed of slotted PVC pipe, sloped at a minimum of 0.5%, placed on a 6-inch minimum bed of washed aggregate, and covered with 6 inches of the same aggregate. Underdrain drains freely to a downstream stormwater conveyance system, an additional BMP, or an alternatively acceptable discharge point.
- If system is online, an overflow is present. The overflow safely conveys flows to the downstream stormwater conveyance system, an additional BMP, or an alternatively acceptable discharge point.
- Inflow to swales shall be directed towards the upstream end of the swale.
- Bioinfiltration BMPs and high-flow biotreatment BMPs designed for secondary infiltration shall pass the infiltration feasibility screening for all hazardous criteria. If necessary, weep holes shall be used to increase infiltration.
- Swales shall be constructed with a bottom width between 2 and 10 feet. Check dams shall be incorporated at the appropriate distances as specified in Table 4.7. Check dams are 12 inches in height and include a 6 inch deep notch in the middle of the check dam that is 1-2 feet wide. Each check dam extends across the entire width of the swale's base.
- Filter strips shall be constructed to extend across the full width of the tributary area. They shall be designed with sufficient slope in the flow direction to prevent ponding. They shall have a minimum length of 4 ft in the flow direction when sized for pretreatment purposes.

RB-AR32774

4.6.5 Soil and Vegetation Requirements

Soil and vegetation to be incorporated in biofiltration facilities shall be selected by a licensed landscape architect. In general, drought and flood resistant plant species native to Southern California should be selected when possible. Soil media should be selected to facilitate vigorous plant growth and not restrict performance requirements. Where the project receiving waters are impaired for nutrients or a nutrient-related TMDL is in place, media should be selected to minimize the potential for leaching of nutrients from biofiltration systems.

4.6.6 Operations and Maintenance

Biofiltration areas require annual plant, soil, and mulch layer maintenance to ensure optimum infiltration, storage, and pollutant removal capabilities. In general, biofiltration maintenance requirements are typical landscape care procedures. The following operations and maintenance practices will be adhered to:

- Facility soil will be maintained. Flow entrances, ponding areas, and surface overflow areas will be inspected for erosion periodically. Soil and/or mulch will be replaced as necessary to maintain an infiltration rate at or near the initial $K_{sat,design}$value for the duration of the project.
- Site vegetation will be maintained as frequently as necessary to maintain fire protection, public safety, and the aesthetic appearance of the site as well as the filtration capabilities. This includes the removal of fallen, dead, and/or invasive plants, watering as necessary, and the replanting and/or reseeding of vegetation for reestablishment as necessary. Swales and filters will be mowed as necessary.
- BMP inlets will be inspected and maintained to ensure even flow enters the facility. Sediment collecting at the inlet will be removed as necessary.
- Proprietary devices will be inspected and maintained in accordance with the requirements of the manufacturer.

SECTION 5: OFFSITE MITIGATION MEASURES

5.1 OFFSITE MITGATION MEASURES

The option for offsite mitigation shall only be exercised after the following conditions have been met:

1. All the stormwater management techniques allowed (i.e., in priority order of infiltration, capture and use, treated through high removal efficiency biofiltration system) have been exhausted (i.e. are deemed technically infeasible), and;

2. All applicable Standard Urban Stormwater Mitigation Plan (SUSMP) requirements are implemented in order to maximize onsite compliance, and;

3. A LID, and if necessary, SUSMP BMP waiver is obtained from the Department of Public Works, Bureau of Sanitation.

Offsite project BMPs should be located as close as possible to the project site, on private and/or public land, and should address a mix of land uses similar to thoseincluded in the proposed project. The offsite project shall not be located within waters of the US and it shall be demonstrated that equivalent pollutant removal is accomplished prior to discharge to waters of the US.

For the remaining runoff that cannot feasibly be managed onsite, the project shallimplement offsite mitigation in either:

(1) The public right of way immediately adjacent to the subject development and/or;

(2) Within the same sub-watershed (as defined as draining to the same hydrologic area as defined in the Basin Plan) as the proposed project

Construction of an offsite mitigation project(s) shall achieve at least the same level of water quality protection as if all of the runoff were retained onsite and also be sized to mitigate the volume from the onsite and the tributary area from the adjacent street (from the crown of the street to the curb face for the entire length of the development site). All City Departments will assist the developer, when and where feasible, permitting and implementation of LID BMP projects within the public right of way.

Construction work in the public right-of-way will be the responsibility of the developer, and requires a "Revocable Permit"from the Department of Public Works, Bureau of Engineering (BOE). The developer will also be required to file a covenant and agreement with the county

RB-AR32776

recorder's office to insure the owner assumes full responsibility for perpetual maintenance of the onsite and offsite BMP(s) executed by a covenant and agreement. The type of BOE permitrequired depends on the scope of construction work. Additional permit information and detailed flowcharts can be found at: http://eng.lacity.org/techdocs/permits/index.htm

Green Infrastructure Projects

In an effort to assist developers the City has recently approved and adopted a series of green street standard plans. The plans provide a series of standards that developers can implement utilizing the public right of way immediately adjacent to the development. These standard plans provide general requirements for green streets, parkway swales in major/secondary highways, parkway swales in local/collector streets, parkway swales with no street parking, vegetated stormwater curb extensions, and interlocking pavers for vehicular and pedestrian alleys. The green street standard plans can be obtained from the Bureau of Engineering's Website at:

http://eng.lacity.org/techdocs/stdplans/s-400.htm

http://eng.lacity.org/techdocs/stdplans/Pdfs/Green%20Street%20Standard%20Plans%20FAQ%20Sheet_091010.pdf

Executive Summary

Green Solution Projects *improve water quality by using soil, plants, and natural processes to capture, filter and clean polluted urban and stormwater runoff, while creating new parks, natural habitat, recreation and other open space lands.*

This Executive Summary presents a synopsis of Community Conservancy International's (CCI) **Green Solution Project** study and presents CCI's findings, conclusions and recommendations on the potential of using existing public lands to help improve water quality while creating a network of new, green open space lands throughout Los Angeles County. As part of CCI's on-going efforts to develop practical solutions to difficult environmental problems that affect both people and nature, we are pleased to present this compilation of our research results on innovative and effective methods for addressing polluted urban and stormwater runoff that plagues the rivers, streams, lakes, beaches, bays and coastal waters of L.A. County (*see Polluted Waters Map of Los Angeles County at end of this section*). CCI's Executive Summary is based on the methodology and data described in the Technical Report prepared by Geosyntec Consultants, with Geographic Information System (GIS) data analysis provided by GreenInfo Network. For a copy of the complete report, go to www.ccint.org/greensolution.html.

Nearly all of the county's waters are in violation of federal and state water quality standards. CCI's **Green Solution Project** study presents a creative, practical and fresh approach to these problems by focusing on unpaving concrete and impervious areas and retrofitting pervious areas on existing public lands throughout Los Angeles County, so that these lands can act as natural filters while also providing important and badly-needed park, habitat and recreation opportunities.

The results of this study are quite exciting, as they show that there is indeed a substantial amount of land throughout every watershed in the county – up to 20,000 acres - suitable for Green Solution projects. These findings are particularly important as the need for innovative solutions to both water quality problems and the lack of park, habitat and open space in urban areas continue to grow.

As part of Community Conservancy International's focus on critical problems affecting people and the environment, CCI identified polluted urban and stormwater runoff as an increasingly serious and pressing need in California, and especially in Los Angeles County, where extensive urbanization has resulted in vast areas of paved surfaces and daily high volumes of contaminated runoff. These same urbanized areas are among the most park-poor in the United States, lack natural open space that serve as a healthy respite to city dwellers from urban congestion, and have lost nearly all of their native habitat lands.

The long-term, damaging impacts of polluted urban and stormwater runoff on beaches, aquatic life, and human health and on the health of oceans, birds and marine mammals worldwide have been well documented. This **Green Solution** approach is essential to effectively address water pollution produced throughout the nation, and particularly in areas where the natural functions of watersheds, rivers and the soil itself have been dramatically altered. CCI initiated, designed and directed the **Green Solution Project** study, provided the initial funding, and secured the public and private grants to fund this work. This study focused on the water pollution clean-up needs within the watersheds of the L.A. County Flood Control District[i]. (*See Watersheds and Drain Outlets map at end of this section.)*

Green Solution projects focus on combining land conservation with water quality improvements to:

- **Create** new habitat and open space to naturally clean up polluted runoff
- **Re-green** urban areas
- **Restore** native habitat to cultivated landscapes
- **Develop** new recreation opportunities
- **Protect** threatened creeks and rivers, as well as the ocean and coastal waters

To be considered a **Green Solution**, projects must:

- **Convert** paved, impervious areas to pervious lands that allow water to filter into soil and plants
- **Retrofit** existing pervious areas to effectively catch, filter, clean, store, and, reduce runoff
- **Create multiple benefits, such as** parks, recreation, habitat, and other open space opportunities

Green Solution Projects are essential to help Los Angeles County cities within the county meet water quality improvement goals and increasingly strict legal requirements to clean up polluted urban and stormwater runoff. CCI's **Green Solution Project** study provides quantified data necessary to guide project selection to effectively address urgent water quality problems due to runoff. The project provided the research and technical analysis necessary to quantify the amount of acreage needed in each watershed for retrofitting or for conversion from concrete to pervious Green Solution, multi-benefit projects to help meet the water quality improvement requirements established by the Regional Water Quality Control Board.

Until CCI's **Green Solution Project** study, the conventional assumption made in examining how to improve water quality using natural Green Solutions in L.A. County was that this approach was not really feasible, as very little land was believed available for these types of solutions. Part of this perception was due to the assumption that only existing open space or vacant lands were suitable for conversion to Green Solutions.

The CCI study found that there is a wide range of existing public lands, in a variety of land uses, that are in fact potentially suitable for creative multiple-benefit, Green Solution projects.

A Fresh and Practical Approach: Green Solutions on Existing Public Lands

The **Green Solution** approach can be implemented in any area that needs to address urban runoff pollution problems. Conventional thought has often been that, in heavily urbanized areas, very little land is available or suitable for conversion to green, multiple-benefit projects that can naturally filter and clean urban runoff. This study shows that many types of land uses can be utilized for these multiple-benefit projects, and that the benefits – including variations by land use - can be quantified. Community Conservancy International's fresh approach focused on how to make best use of lands already in public ownership that are potentially suitable for both water quality improvement and "green" multiple-benefit projects. We found that a significant amount of land does exist that is suitable for Green Solutions – and that there are also a surprising number of large (greater than 10 acres) parcels that could be effectively utilized.

The CCI Team's analysis found that nearly 40% of the polluted runoff clean-up needs in the county could be met by implementing Green Solution projects on existing public lands (based on average need and acres of suitable land). The CCI Team's analysis showed 10,027 parcels of public lands with some portion suitable for Green Solution projects. The team's analysis found that an average of 39,000 acres are needed county-wide for Green Solution projects, and that a net average of 15,000 acres of existing public lands in the county are in fact suitable for Green Solution Projects. By implementing Green Solution projects on these public lands, an average 360,000 acres of drainage area could be treated. We found a maximum of 20,000 suitable public acres with Green Solution project potential. (*See maps of Opportunity Public Parcels by size, owner and land use at end of this section.*)

While **Green Solution Projects** can be implemented on both public and private lands, focusing on existing public lands offers a cost-effective and readily available solution not only to the increasingly serious water quality problems in Los Angeles County, but also to the demand to make communities healthier and more livable by creating a green network of park, native habitat, recreation and other open space lands, as well as to the growing need to address drought and global warming issues by capturing, conserving and recycling our increasingly precious water resources.

The Problem: Polluted Urban Runoff Impacts L.A. County's Rivers, Bays and Beaches & Ocean Waters Worldwide

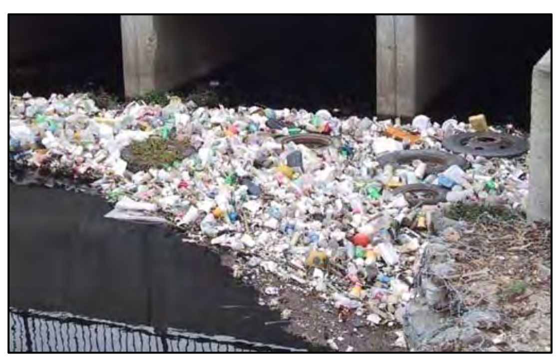
There is an urgent and growing need to clean up polluted runoff to improve water quality throughout Los Angeles County (*see Polluted Waters map at end of this section*). Serious water pollution from stormwater and daily urban runoff plagues all of the rivers, streams, lakes, coastal waters, bays and beaches in the county, endangering the health of people, animals and the aquatic and marine life dependent on these waters for survival, closing beaches, causing grave economic impacts, and polluting ocean waters around the world.

Pollution associated with stormwater and daily urban (dry weather) runoff can only be solved by addressing the generation of pollutants, and the flow and treatment of runoff throughout each watershed, and by taking full advantage of all opportunities for conversion of paved, impervious surfaces to pervious surfaces that allow soil and plants to naturally infiltrate and clean water.

Almost 100 different pollutants are found in L.A. County's waters in amounts significantly above federal and state public health standards. Nearly all water bodies in Los Angeles County - rivers, streams, lakes, bays, ocean - are in violation of the U.S. Clean Water Act, which sets water quality standards intended to protect human health and marine and aquatic life. These pollutants have contaminated over 300 miles of rivers and streams, 160,000 acres of lakes, both Santa Monica and San Pedro Bays and the entire county coastline.[ii] UCLA and Stanford University scientists found that up to 1.5 million people get sick each year from infections and gastrointestinal illnesses caused by bacteria at L.A. County beaches.[iii] L.A. County had the worst beach water quality record in California in 2005, as well as the five most polluted beaches in the state[iv].

The pollution impacts from urban runoff is endangering oceans and marine life around the world[v]. **Sixteen million tons of trash end up on L.A. County's beaches every year**[vi] – and this does not count the additional millions of tons that are carried by ocean currents and which accumulate in huge floating "rafts" of plastic trash in the Pacific Ocean between California and Japan. The largest of these is twice the size of Texas. Trash chokes one million seabirds worldwide every year; plastic is found in the stomachs of seabirds, turtles and marine mammals around the worlds, and toxic pollutants and bacteria from runoff can be fatal to marine mammals. Low oxygen "dead zones" are spreading due to increasing fertilizer use and growing coastal populations.[vii]

Urban runoff is polluted water from sprinklers, yards and landscaping, from hosing down driveways, sidewalks, cars and parking lots, from washing equipment outside businesses, and from other daily home and business uses that flows - untreated in any way - through county and city drains every day, even in dry weather. All property in every community throughout the county produces runoff, and in dry weather generates a total of 330 million gallons of water every day[viii] – **enough to fill the Rose Bowl four times over**. **This daily runoff carries pollutants** from homes, landscaped areas, businesses and parking lots directly into our creeks, rivers, lakes, beaches, bays and ocean – in most cases without treatment of any kind.



When it rains, the problem is far worse, as the high volumes of stormwater carry huge amounts of trash and pollutants through the county's drainage system very quickly. On rainy days, the flow can increase to 6.5 billion gallons per day.[ix] In an average rainfall year, over 150 billion gallons of stormwater flow through the county's drainage system, without treatment of any kind.[x]

Pollutants in L.A. County's stormwater and daily urban runoff include infection-causing bacteria, toxic metals, pesticides, household and industrial chemicals, trash, oil, oxygen-choking fertilizers and other toxins. High bacteria counts cause serious illnesses and thousands of beach closures in L.A. County every year.[xi] Summer beach closures cost local cities millions of dollars in lost revenue, and these ongoing ocean and beach pollution problems hurt L.A. County's worldwide image as a desirable tourist destination.

The Importance of The Green Solution

Many water quality experts and scientists believe that much of the toxins, bacteria and other contaminants carried by daily urban and stormwater runoff can be permanently addressed by directing these polluted waters to a network of new and well-designed "green" areas: new and restored natural habitat, parks, and recreation lands that allow soil and plants to naturally filter and uptake water and pollutants as well as providing a wide range of open space and other benefits. This would also provide desperately-needed park, recreation and habitat in areas throughout urbanized L.A. County that are starved for these amenities.

As a result of decades of intensive growth and development, much of the county is now heavily urbanized; this extensive development has resulted in a majority of the county's urban areas being paved with concrete, asphalt and other non-porous or impervious substances that do not allow water to penetrate into the soil. This wide-spread imperviousness is one of the biggest causes of L.A. County's polluted runoff problems. Green Solution projects provide one of the most viable and effective means of permanently cleaning up polluted runoff because they restore the natural functions of soil and plants to capture, filter and clean contaminants from runoff before it reaches rivers, bays, beaches and the coast.

Green Solution projects include regional scale projects on large parcels that can clean runoff from surrounding areas and serve a large drainage area, as well as local or on-site projects, which typically clean runoff just from that site, and serve small drainage areas.

These **Green Solution** projects can make urgently-needed and lasting water quality improvements in the county's polluted waters, and can provide many multiple benefits, including:

- reduce infection-causing bacteria
- remove other pollutants
- reduce runoff volumes
- store and recycle water for later use as irrigation
- improve water quality in rivers, at beaches, and in Santa Monica and San Pedro Bays

RB-AR32787

Green Solution Projects are proving to be one of the most effective and cost-efficient ways to make lasting water quality improvements consistent with the requirements of the Regional Water Quality Control Board. While providing park and recreation opportunities in heavily urbanized and park-poor areas and restoring important natural habitat, Green Solution Projects can also be effective "water recyclers", and can reduce the effects of drought caused by global warming by catching, storing and re-using stormwater to water parks and landscaping or to sustain natural areas.

Green Solutions effectively utilize natural treatment processes which take advantage of the natural functions of soils and plants. These include biofiltration (filtration of pollutants through vegetation and soil), bio-uptake (biological processes such as the assimilation of pollutants such as nitrogen and phosphorous, which soil and plants can convert for their beneficial use), infiltration, runoff volume reduction through evapotranspiration, and other biological, physical, and biochemical processes that significantly improve water quality. In many cases, natural treatment processes are more effective than other types of more structural and conventional Best Management Practices because they are passive systems, requiring little energy, operations and maintenance – often similar to conventional landscaping maintenance.

The CCI Team's New Methodology & Preliminary Findings

The CCI Team developed a unique methodology to quantify the amount of land potentially necessary for conversion or retrofit to Green Solution projects in order to address polluted runoff and the amount and locations of existing public lands suitable for these projects. The overall approach and analysis posed and responded to the following research questions:

- How much of L.A. County's land actually contributes runoff?
- What pollutants can be cleaned up by Green Solution projects?
- How much land is needed for Green Solutions to clean runoff from contributing areas?
- Which public lands are suitable for Green Solution projects?
- What percent of the Green Solutions need in L.A. County can be met by converting or retrofitting portions of existing publicly-owned lands?

The watersheds evaluated in this study are: Ballona Creek; Dominquez Channel; Upper Los Angeles River; Lower Los Angeles River; Upper San Gabriel River; Lower San Gabriel River; Santa Clara River; Central Santa Monica Bay Coast; North Santa Monica Bay Coast; and South Santa Monica Bay Coast (*see Map of Watersheds following this section*).

The CCI Team evaluated how stormwater and urban runoff moves through each watershed in the county, including both natural flow of water and directed flow within the constructed (man-made) storm drain system. The constructed system drains stormwater and daily urban (dry weather) runoff into over 143,000 individual entry points in gutters and curbs (catch basins) all over the county; these catch basins then empty into an underground network of nearly 5,000 miles of pipes (the storm drains) that flow into the county's streams and river channels, and then out to the beaches, coast and ocean.

The amount of runoff produced in Los Angeles County depends on the extent of imperviousness of lands in each watershed. The team analyzed watersheds within the study area, and determined that there are the equivalent of over 517,000 net acres effectively contributing runoff. This was determined by calculating the percent imperviousness by land use, based on the L.A. County Hydrology Manual and on industry standards for determining runoff. Runoff produced by both impervious and pervious areas was accounted for (90% and 10%, respectively). Figure 1, below, shows each watershed's relative contribution of runoff.

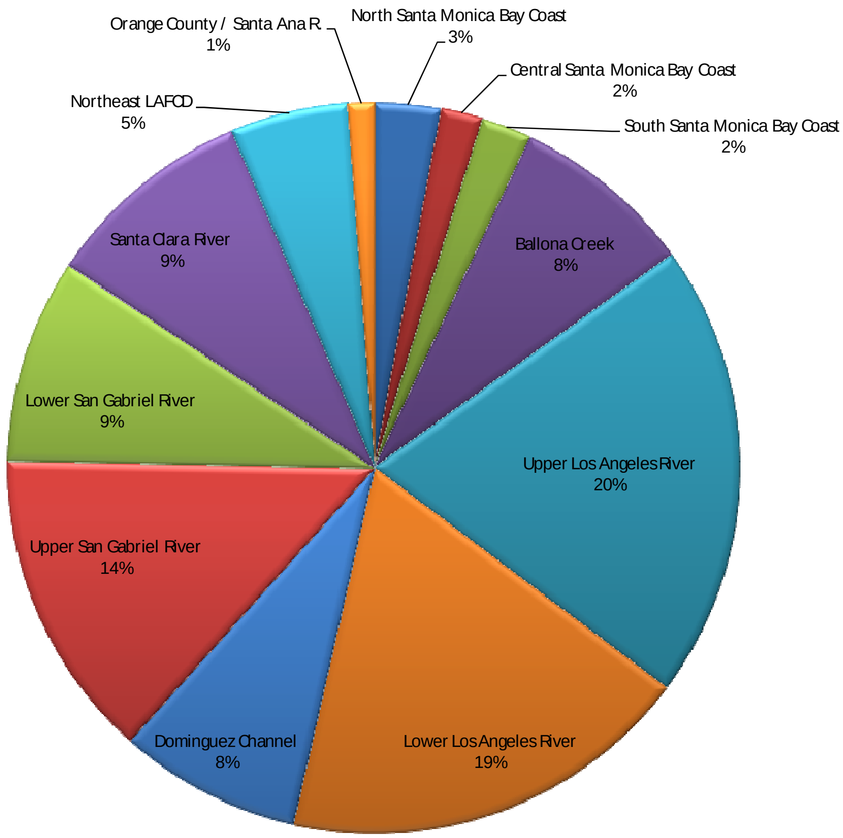


Figure 1. Relative Contribution of Runoff from Los Angeles County Watersheds

Pollutants of concern that were identified as able to be addressed by Green Solution projects are:

- Bacteria
- Excessive nutrients, i.e.; nitrates and other fertilizer-based chemicals
- Heavy metals, including lead and copper
- Oil & grease
- Oxygen-demanding substances
- Sediment
- Trash & debris

Determining which public lands could be suitable for Green Solution projects included an evaluation of location, land use, size, slope, and portion of parcels suitable for either conversion or retrofit. Large parcels (> 100 acres) were evaluated individually; parcels less than ¼ acre were not included. Parcels that had a 20% slope over greater than 50% of their area were excluded. Parcels without significant upstream contributing pollutant loads (e.g., in upper reaches of a natural watershed) were also excluded. Ranges (low to high) were determined in each land use type of the percent of a parcel's area that could be suitable for either conversion of paved, impervious surface to pervious, porous surface or for retrofit of existing pervious

RB-AR32789

to more effective catchment, filtration or storage. Depending on the specific land use, percentages of area deemed suitable ranged between 3% to 55%.

The following land uses were identified as being potentially suitable:

- Developed Open Space
- Undeveloped Open Space
- Regional Parks
- Vacant
- Commercial Recreation
- Public Facilities
- Public Office Buildings
- Schools and Colleges
- Residential
- Rights-of-Way
- Powerlines
- Transportation
- Airports
- Waterways

To capture, filter, clean, and reduce pollutants carried by runoff from watersheds throughout the county, the analysis showed that a total of 26,000 to 52,000 acres are needed for conversion or retrofit into Green Solution projects, with an average need of 39,000 acres. Figure 2 shows the acreage needed by watershed.

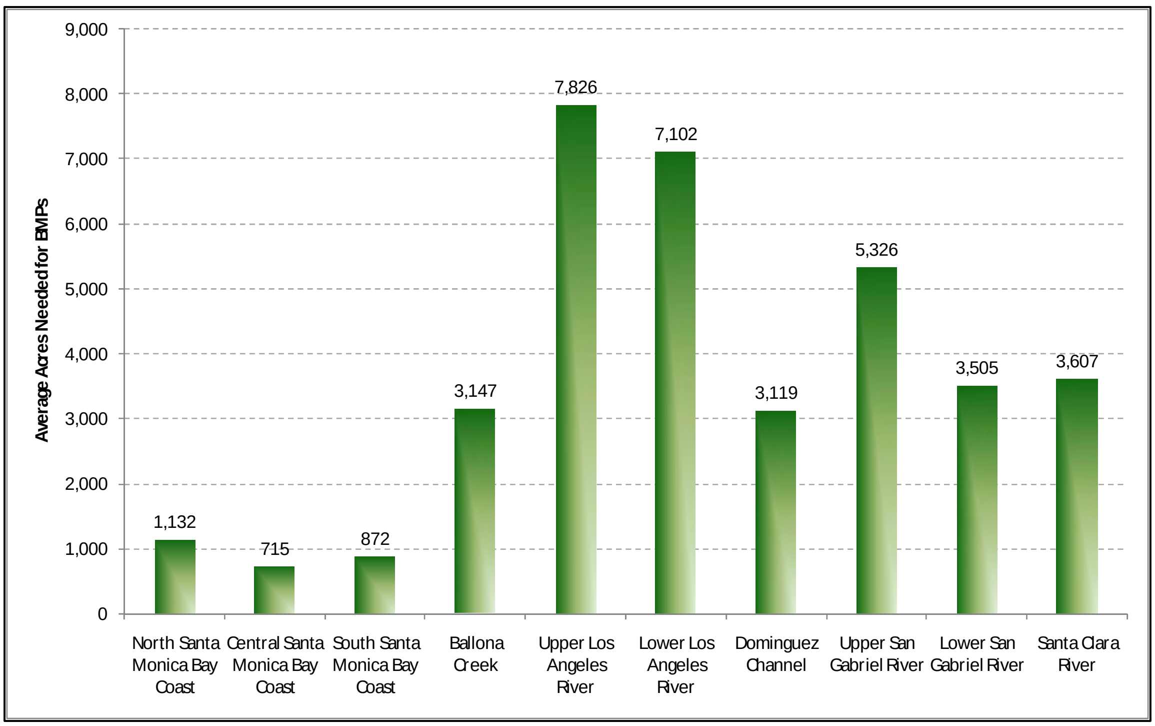

Figure 2. Acres of Land Needed for Green Solution Runoff Treatment, Average by Watershed

There are 10,027 opportunity public parcels – those that passed the rigorous screening and evaluation for suitability – comprising a total land mass of over 71,000 acres. Based on the analysis, which took into account variability within land uses and other factors, these parcels contain a net range of between 9,500 and 20,200 acres of public land that are potentially suitable as Green Solution Projects, with a total average of 15,000 acres in the study area. Figure 3 shows the number of opportunity public parcels, total land acres of those parcels, and both average and total (maximum) acres of public lands suitable for Green Solution Projects by watershed.

Watershed	Total Parcels	Total Acres	Average Suitable Acres	Maximum Suitable Acres
North Santa Monica Bay	120	992	262	351
Central Santa Monica Bay	233	1,037	153	211
South Santa Monica Bay	253	3,862	680	897
Ballona Creek	991	3,831	739	1,009
Upper Los Angeles River	1,893	13,663	2,592	3,490
Lower Los Angeles River	2,812	15,656	3,524	4,948
Dominguez Channel	1,029	6,504	1,356	1,815
Upper San Gabriel River	1,144	11,442	2,017	2,755
Lower San Gabriel River	912	9,202	2,054	2,821
Santa Clara River	264	2,559	586	766
Totals	**9,651**	**68,748**	**13,963**	**19,063**

Figure 3. Opportunity Public Parcels, Total Parcel Acres and Acres Suitable for Green Solution Projects

If Green Solution projects were implemented on the average acres of those public lands deemed suitable, nearly 40% of the Green Solution project need county-wide could be met. Depending on the watershed, between 16% and 78% of each individual watersheds' average runoff clean-up needs that can be addressed through Green Solutions could be met. Figure 4 shows the average need met, by watershed. If these projects were implemented, runoff from approximately 360,000 acres of drainage area could be effectively treated with Green Solution projects.

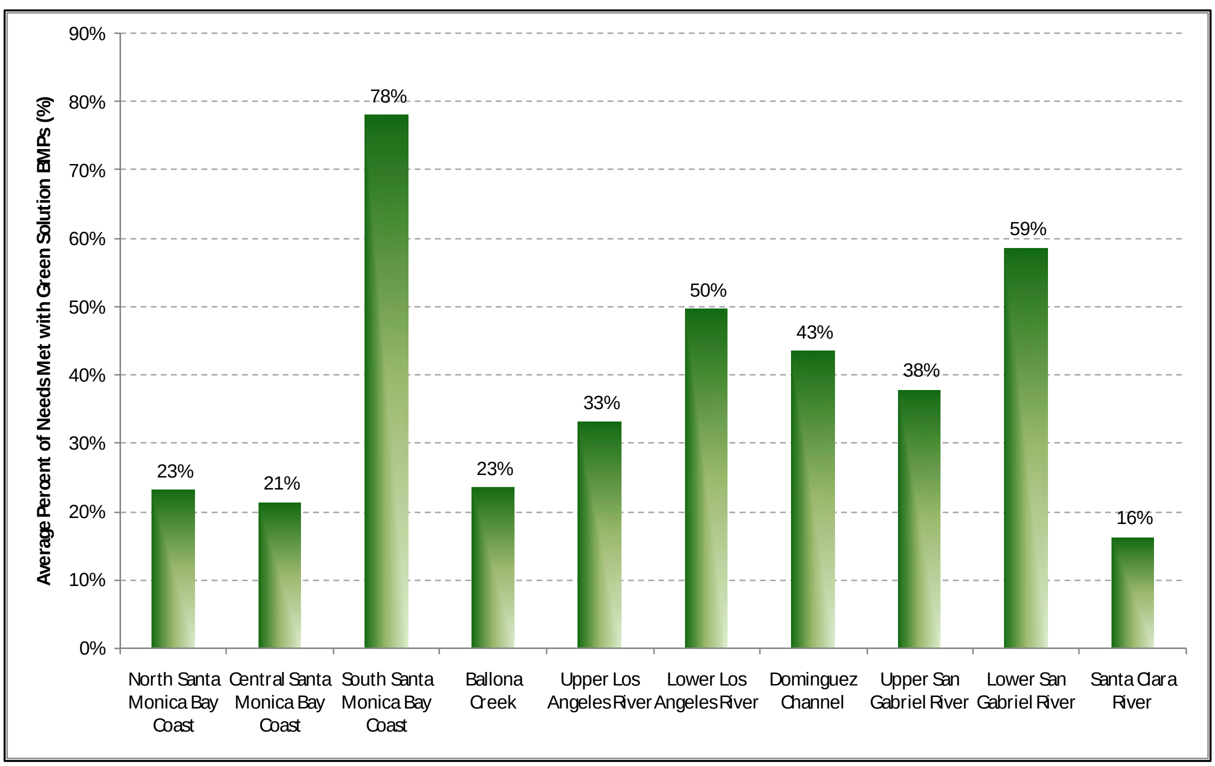

Figure 4. Average percent of Green Solution Project Need Met, per Watershed

Recommendations and Next Steps

This study evaluated an enormous area, encompassing almost 3,000 square miles, multiple watersheds, and tens of thousands of acres of opportunity public lands. The scope and magnitude of the area studied necessitated certain assumptions and summarizing of data.

Next steps should focus on public lands within specific watersheds that are most suitable for **Green Solution projects**. Further studies should develop site-specific concept designs for Green Solution Projects that combine park, habitat and recreation with water quality improvements aimed at naturally cleaning polluted runoff on the highest priority sites that meet strict water quality, land conservation and community needs criteria. Water quality, hydrologic, land conservation, open space and community demographic data must be integrated to carefully analyze, prioritize and rank for project implementation those lands selected as most appropriate for Green Solution projects in each watershed. Top-ranked, specific sites should then be selected for development of Green Solution Project concept designs; these sites should be representative of sites throughout the watershed and should be chosen for maximum replicability to produce the greatest possible benefits to both water quality, natural and human communities.

Water quality, land, conservation and community need and demographic information that should be researched and quantified include the following:

Water Quality Improvement Factors

- Pollutant loading and runoff quantity
- Potential water quality benefit
- Area-specific hydrology
- Proximity to storm drains
- Size of drainage area to be treated
- Other site-specific opportunities

Land Conservation/ Multiple Benefit Factors

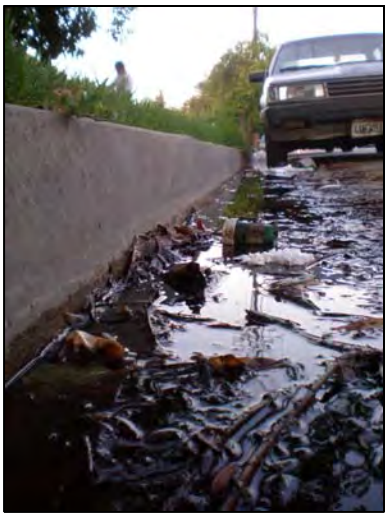
- Nexus with other park & open space uses
- Trail and river connectivity potential
- Potential for trail creation
- Habitat connectivity & need
- Habitat sensitivity
- Habitat restoration potential

Community Need Factors

- Park & open space deficit
- Public access need & potential
- Youth density
- Population density
- Income
- Other demographics

Conclusion

Community Conservancy International's **Green Solution Project Study** demonstrated that significant and wide-spread opportunities exist on public lands in Los Angeles County to address serious polluted runoff problems that harm human health and the environment, while re-greening the heavily-urbanized landscape in the county by creating new networks of park, recreation, habitat and other open space lands. This is the first time that this type of quantitative analysis has been done. Until CCI's Green Solution Project study, the conventional assumption made about the viability of improving water quality using natural "Green Solutions" in L.A. County was that this approach was not really feasible, as very little land was believed available for these types of solutions.



The CCI Team found that there are between 9,500 and 20,200 acres on 10,000 parcels of public lands currently suitable for **Green Solution Projects** in all of the watersheds in L.A. County, and that conversion or retrofit of these publicly-owned lands would address nearly 40% of the polluted runoff problem in the watershed that can be dealt with by Green Solutions – while also creating badly-needed park, habitat and other green open space amenities for surrounding communities.

This new and innovative **Green Solution Project** approach presents a practical way to move forward quickly to protect and improve water quality throughout Los Angeles County and to establish a network of green open space, park, recreation and habitat lands. In addition, the Green Solution Project approach has ramifications throughout the United States. The Green Solution approach can be applied in any area which needs to address pressing water quality problems due to runoff, and which wishes to emphasize the multiple benefits that can be achieved by Green Solution Projects through restoring and creating habitat, park, recreation and other open space lands.

Funders

The Green Solution Project study was funded by the State Coastal Conservancy, Santa Monica Bay Restoration Foundation, Santa Monica Mountains Conservancy, Rivers and Mountains Conservancy, the Trust for Public Land and Community Conservancy International.

About The Community Conservancy International Team

The Green Solution Project Team consisted of Community Conservancy International, Geosyntec Consultants and GreenInfo Network. CCI initiated the project and provided the vision, direction and overall project management, evaluation of all research, data and technical analyses, and production of all project materials. Geosyntec Consultants, a leader in water resources engineering and water quality, and in developing technically sound and innovative green approaches to water quality problems throughout the United States, conducted the technical research and analysis and prepared the attached Technical Report. Geosyntec served as a technical advisor and did not participate in the development of findings or conclusions described in the Executive Summary. GreenInfo Network specializes in complex data analysis and use of integrated Geographic Information Systems mapping technology; GreenInfo Network analyzed and developed all data and prepared all maps.

To quantify the acreage needed and the amount of existing public lands suitable for Green Solution Projects to make effective and lasting water quality improvements in Santa Monica Bay, San Pedro Bay, and the county's numerous watersheds, CCI worked with staff from the State Coastal Conservancy, the Santa Monica Mountains Conservancy, the Rivers and Mountains Conservancy, and the Santa Monica Bay Restoration Commission.

Community Conservancy International

Community Conservancy International (CCI) specializes in tackling complex and challenging problems created by the interaction of people and nature. CCI develops innovative solutions by combining long-range vision with the focused planning needed to transform ideas into reality. By bringing a broad diversity of skills, experience and expertise to each project, CCI is able to implement strategic and practical programs to realize far-reaching visions.

CCI seeks solutions that combine the protection and restoration of natural lands and waters with compatible community uses and permanent public benefits, including cultural, educational, and economic opportunities. CCI works on diverse projects in urban and rural areas that help both natural habitats and people. CCI's projects range from parks and beaches to wilderness and watersheds, and from recreational sites to mixed-use developments. CCI is dedicated to working in areas with exceptional unmet needs: where natural habitats have been degraded; where communities have been neglected; and where recreation, education, cultural and economic opportunities are significantly lacking. For more information, go to www.ccint.org.

Geosyntec Consultants

Geosyntec is a leading national provider of consulting, engineering design and construction management services throughout the U.S. and selectively in other parts of the world. Geosyntec specializes in the earth and environmental sciences and the engineering and construction management disciplines, and is an independent, employee-owned corporation with more than 500 personnel located in 34 offices in the U.S., Canada, Malaysia, and the U.K.

Geosyntec is a leader in the design and development of constructed wetlands for treatment of urban runoff, and is known for its innovative work in stormwater and surface water management, permitting, Best Management Practice (BMP) design, NPDES compliance program management, and monitoring. Geosyntec's business and reputation in stormwater was built on experience in all aspects of water quality science, planning, implementation, infrastructure design, and construction phases. Geosyntec has developed innovative monitoring and planning studies to help public agencies meet water quality objectives, and has implemented the design, construction and monitoring of treatment and source-control BMPs. Geosyntec's projects have been recognized for Outstanding BMP Implementation and Outstanding Research by CASQA, and Geosyntec staff have been recognized locally and nationally by ASCE.

GreenInfo Network

Over the past 10 years, GreenInfo Network (www.greeninfo.org) has provided Geographic Information System (GIS) and related technology support to a wide range of water, land conservation and many other types of projects throughout California and the U.S. A non-profit, GreenInfo Network assists other public interest groups and agencies working at local, regional and national scales, providing them with services including data creation and acquisition, geospatial analyses, geographic modeling, conservation and land use planning, watershed-based planning and modeling, database development, and high quality communications design and cartography. GreenInfo Network's staff is highly skilled in effective, efficient and creative use of information technology to help clients more effectively understand and communicate the relationships between issues, people and places.

For a complete copy of the Green Solution Project report, go to www.ccint.org/greensolution.html

[i] This report deals only with waters within the Los Angeles County Flood Control District, consistent with boundaries established by the Regional Water Quality Control Board for purposes of enforcing the U.S. Clean Water Act. This excludes Palmdale, Lancaster, the high desert, parts of the Angeles National Forest and Avalon.

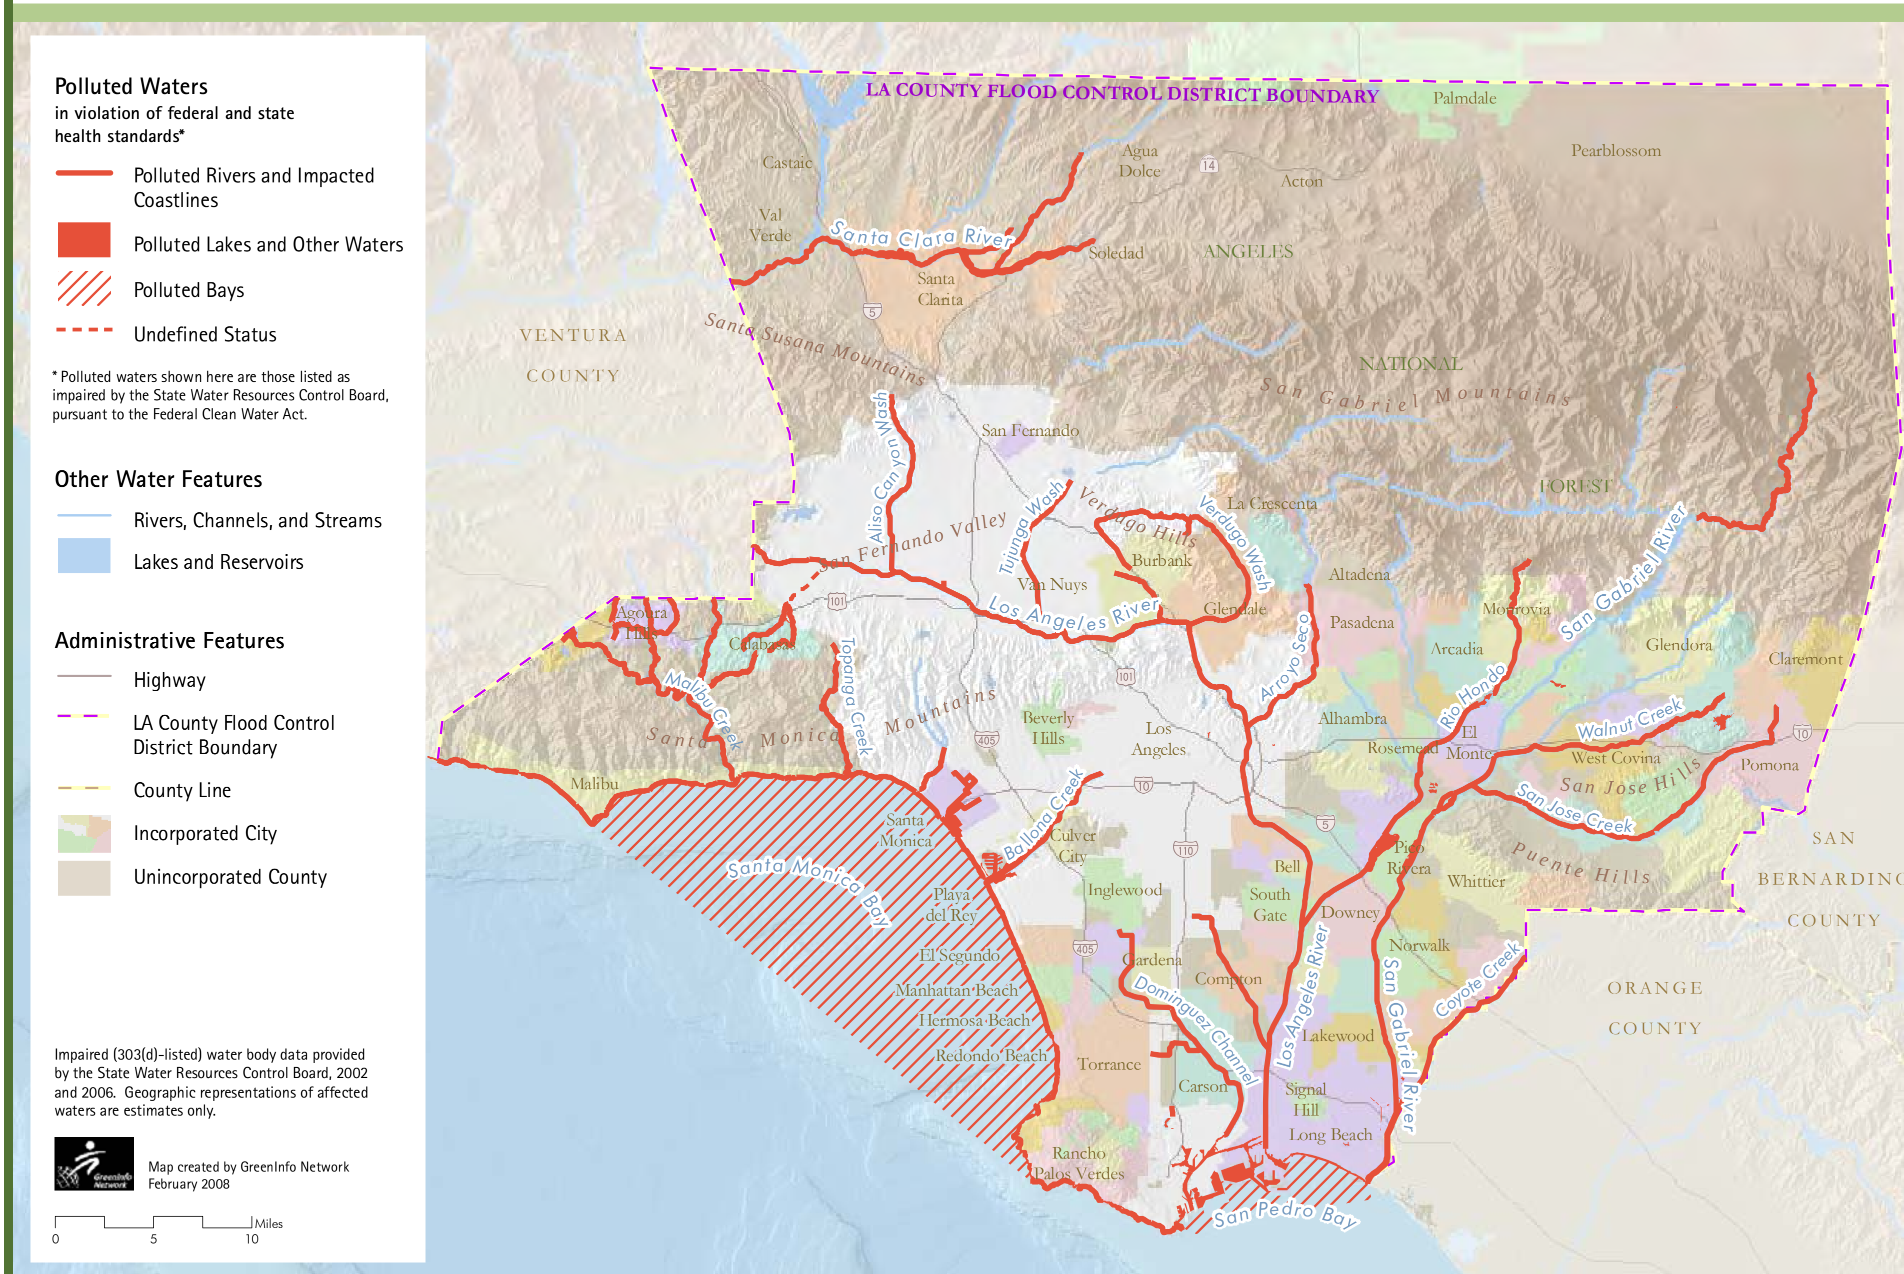
Polluted Waters of Cities in Los Angeles County



Community Conservancy International

Green Solution Project

Watersheds and Drain Outlets of Los Angeles County

L.A. County Watershed Summary

- Almost 3,000 square miles
- 85 cities
- 33 distinct watersheds draining to ocean
- 34 urban coastal drainage areas emptying into bays and ocean
- 580 miles of rivers and streams

Urban and Stormwater Runoff Flows

All property in every community throughout the county produces runoff that flows - untreated in any way - to L.A. County's rivers, beaches, bays, and ocean.

Daily Urban Runoff	330 million gallons per day in dry weather
Annual Urban Runoff	over 110 billion gallons
Stormwater Runoff	6.5 billion gallons per day for every half inch of rain
Annual Stormwater Runoff	over 150 billion gallons in an average year

Watershed

A watershed is the entire area that captures all waters that drain into a river and its tributaries.

Urban Runoff

Urban (dry weather) runoff is polluted water from sprinklers, yards and landscaping, hosing down driveways, sidewalks, cars and parking lots, washing equipment outside businesses, and other daily uses that flows through county and city drains every day.

Stormwater Runoff

When it rains, the volume of runoff increases dramatically. High volumes of stormwater carry huge amounts of trash and pollutants through the county drainage system.

Stormwater Glossary

Best Management Practice (BMP)	Any procedure or device designed to minimize the quantity of pollutants that enter the storm drain system or to control stormwater flow. See Chapter Two.
C.3	Provision in the Municipal Regional Permit. Requires the Permittees to use their planning authorities to include appropriate source control, site design, and stormwater treatment measures in new development and redevelopment projects to address pollutant discharges and prevent increases in runoff flows. Updates C.3 Provisions added to a preceding permit issued by the San Francisco Bay Water Board in February 2003.
C.3 Web Page	http://www.cccleanwater.org/c3.html
California Stormwater Quality Association (CASQA)	Publisher of the California Stormwater Best Management Practices Handbooks, available at www.cabmphandbooks.com.
California BMP Method	A method for determining the required volume of stormwater treatment facilities. Described in Section 5.5.1 of the California Stormwater Best Management Practice Manual (New Development) (CASQA, 2003).
Condition of Approval (COA)	Requirements a municipality may adopt for a project in connection with a discretionary action (e.g., adoption of an EIR or negative declaration or issuance of a use permit). COAs may specify features required to be incorporated into the final plans for the project and may also specify uses, activities, and operational measures that must be observed over the life of the project.
Contra Costa Clean Water Program (CCCWP)	CCCWP is a collaboration established by an agreement among 19 Contra Costa cities and towns, Contra Costa County, and the Contra Costa County Flood and Water Conservation District. CCCWP implements common tasks and assists the member agencies to implement their local stormwater pollution prevention programs.
Design Storm	A hypothetical rainstorm defined by rainfall intensities and durations.
Detention	The practice of holding stormwater runoff in ponds, vaults, within berms, or in depressed areas and letting it discharge slowly to the storm drain system. See definitions of infiltration and retention.
Directly Connected Impervious Area	Any impervious surface which drains into a catch basin, area drain, or other conveyance structure without first allowing flow across pervious areas (e.g. lawns).
Direct Infiltration	Infiltration via methods or devices, such as dry wells or infiltration trenches, designed to bypass unsaturated surface soils and transmit runoff directly to groundwater.

Drawdown time	The time required for a stormwater detention or infiltration facility to drain and return to the dry-weather condition. For detention facilities, drawdown time is a function of basin volume and outlet orifice size. For infiltration facilities, drawdown time is a function of basin volume and infiltration rate.
Flow Control	Control of runoff rates and durations as required by Provision C.3.g. of the Municipal Regional Permit.
Head	In hydraulics, energy represented as a difference in elevation. In slow-flowing open systems, the difference in water surface elevation, e.g., between an inlet and outlet.
Hydrograph	Runoff flow rate plotted as a function of time.
Hydrograph Modification Management Plan (HMP)	A Plan implemented so that post-project runoff from projects creating or replacing an acre or more of impervious area shall not exceed estimated pre-project rates and/or durations, where increased runoff would result in increased potential for erosion or other adverse impacts to beneficial uses. The HMP is available on the CCCWP's C.3 web page. Also see definition for flow control.
Hydrologic Soil Group	Classification of soils by the Natural Resources Conservation Service (NRCS) into A, B, C, and D groups according to infiltration capacity.
Impervious surface	Any material that prevents or substantially reduces infiltration of water into the soil. See discussion of imperviousness in Chapter Two.
Indirect Infiltration	Infiltration via facilities, such as bioretention areas, expressly designed to treat runoff and then allow infiltration to surface soils.
Infiltration	Seepage of runoff through soil to mix with groundwater. See definition of retention.
Infiltration Device	Any structure that is designed to infiltrate stormwater into the subsurface and, as designed, bypasses the natural groundwater protection afforded by surface or near-surface soil. See definition for direct infiltration.
Infiltration Rate	Rate at which water can be added to a soil without creating runoff.
Integrated Management Practice (IMP)	A facility (BMP) that provides small-scale treatment, retention, and/or detention and is integrated into site layout, landscaping and drainage design. See Low Impact Development.
Integrated Pest Management (IPM)	An approach to pest management that relies on information about the life cycles of pests and their interaction with the environment. Pest control methods are applied with the most economical means and with the least possible hazard to people, property, and the environment.

RB-AR32811

Lead Agency	The public agency that has the principal responsibility for carrying out or approving a project. (California Environmental Quality Act Guidelines §15367).
Low Impact Development (LID)	A stormwater management strategy aimed at maintaining or restoring the natural hydrologic functions of a site. LID design detains, treats, and infiltrates runoff by minimizing impervious area, using pervious pavements and green roofs, dispersing runoff to landscaped areas, and routing runoff to rain gardens, cisterns, swales, and other small-scale facilities distributed throughout a site.
Maximum Extent Practicable (MEP)	Standard, established by the 1987 amendments to the Clean Water Act, for the reduction of pollutant discharges from municipal storm drains. Also see Chapter Two.
Municipal Regional Permit	A stormwater NPDES permit and Waste Discharge Requirements issued by the San Francisco Bay Regional Water Quality Control Board to 76 cities, towns, and Flood Control Districts on October 14, 2009. Similar requirements are in an permit issued by the Central Valley Water Board to eastern Contra Costa municipalities on September 23, 2010.
Municipal Separate Storm Sewer System (MS4)	A conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, diteches, manmade channels, or storm drains) as defined in 40 CFR 122.26(b)(8).
National Pollutant Discharge Elimination System (NPDES)	As part of the 1972 Clean Water Act, Congress established the NPDES permitting system to regulate the discharge of pollutants from municipal sanitary sewers and industries. The NPDES was expanded in 1987 to incorporate permits for stormwater discharges as well.
Numeric Criteria	Sizing requirements for stormwater treatment facilities established in Provision C.3.d. of the Municipal Regional Permit.
Operation and Maintenance (O&M)	Refers to requirements in the Municipal Regional Permit to inspect treatment BMPs and implement preventative and corrective maintenance in perpetuity. See Chapter Six.
Percolation Rate	The rate at which water flows through a soil.
Permeable or Pervious or Porous Pavements	Pavements for roadways, sidewalks, or plazas that are designed to infiltrate runoff, including pervious concrete, pervious asphalt, porous pavers, and granular materials. See the Design Sheet for Pervious Pavements.
Percentile Rainfall Intensity	A method of determining design rainfall intensity. Storms occurring over a long period are ranked by rainfall intensity. The storm corresponding to a given percentile yields the design rainfall intensity.
Permeability	The rate at which water flows through a saturated soil under steady state conditions.

Pre-Project	Conditions that exist on a development site immediately before the project to which municipal approvals apply.
Proprietary Stormwater Treatment Facilities	Products designed and marketed by private businesses for treatment of stormwater. Many of these products do not meet requirements of the Municipal Regional Permit.
Rational Method	A method of calculating runoff flows based on rainfall intensity, tributary area, and a factor representing the proportion of rainfall that runs off.
Regional Water Quality Control Board (Regional Water Board or RWQCB)	California RWQCBs are responsible for implementing pollution control provisions of the Clean Water Act and California Water Code within their jurisdiction. There are nine California RWQCBs. Western and central Contra Costa County are under the jurisdiction of the RWQCB for the San Francisco Bay Region; eastern Contra Costa County is under the jurisdiction of the RWQCB for the Central Valley Region.
Self-retaining area	An area designed to retain runoff. Self-retaining areas may include graded depressions with landscaping or pervious pavements.
Self-treating area	Natural, landscaped, or turf areas that drain overland off-site or to the storm drain system.
Source Control	A facility or procedure to prevent pollutants from entering runoff.
Stormwater Control Plan	A plan specifying and documenting permanent features and facilities to control pollutants and stormwater flows for the life of the project.
Stormwater Control Operation & Maintenance Plan	A plan detailing operation and maintenance requirements for stormwater treatment and flow-control facilities incorporated into a project.
Storm Water Pollution Prevention Plan (SWPPP)	A plan providing for temporary measures to control sediment and other pollutants during construction.
Treatment	Removal of pollutants from runoff, typically by filtration or settling.
WEF Method	A method for determining the minimum design volume of stormwater treatment facilities, recommended by the Water Environment Federation and American Society of Civil Engineers. Described in *Urban Runoff Quality Management* (WEF/ASCE, 1998).
Water Board	See Regional Water Quality Control Board.
Water Quality Volume (WQV)	For stormwater treatment facilities that depend on detention to work, the volume of water that must be detained for a minimum specified drawdown time to achieve pollutant removal.

RB-AR32813

Start

How to Use this Guidebook

Read the Overview to get a general understanding of the requirements. Then follow the step-by-step instructions to prepare your Stormwater Control Plan.

THIS *Guidebook* will help you ensure that your project complies with the C.3 requirements in the California Regional Water Quality Control Boards' Municipal Regional Permit. The requirements are complex and technical. Most applicants will require the assistance of a qualified civil engineer, architect, or landscape architect. Because every project is different, you should begin by scheduling a pre-application meeting with municipal planning staff.

ICON KEY
Helpful Tip
Submittal Requirement
Terms to Look Up
References & Resources

To use the *Guidebook,* start by reviewing Chapter One to find out whether and how Provision C.3 applies to your project. Chapter One also provides an overview of the entire process of planning, design, construction, operation, and maintenance leading to compliance.

If there are terms and issues you find puzzling, look for answers in the glossary or in Chapter Two. Chapter Two provides background on key stormwater concepts and water quality regulations, including design criteria.

Then proceed to Chapter Three and follow the step-by-step guidance to prepare a Stormwater Control Plan for your site. The Stormwater Control Plan is submitted with your application for entitlements and development approvals.

Chapter Four, the Low Impact Development Design Guide, includes instructions for preparing and presenting your design and calculations. The calculations must be included in your Stormwater Control Plan to show compliance with permit requirements.

RB-AR32814

As you proceed with design and construction of your project, consult Chapter Five for guidance on preparing construction documents and overseeing construction of Low Impact Development features and facilities.

In Chapter Six you'll find a detailed description of the process for ensuring operation and maintenance of your stormwater facilities over the life of the project. The chapter includes step-by-step instructions for preparing a Stormwater Facilities Operation and Maintenance Plan.

Local Requirements
Cities, towns, or the County may have requirements that differ from, or are in addition to, this county-wide Guidebook. See Appendix A for local requirements.

Throughout each Chapter, you'll find references and resources to help you understand the regulations, complete your Stormwater Control Plan, and design stormwater control measures for your project.

The most recent version of the *Guidebook,* including updates and errata, is on the Contra Costa Clean Water Program website. The on-line *Guidebook* is in Adobe Acrobat format. If you are reading the *Guidebook* on a computer with an internet connection, you can use hyperlinks to navigate the document and to access various references. The hyperlinks are throughout the text, as well as in "References and Resources" sections (marked by the 🕮 icon) and in the Bibliography. Some of these links (URLs) may be outdated. In that case, try entering portions of the title or other keywords into a web search.

Construction-Phase Controls
Your Stormwater Control Plan is a separate document from the Storm Water Pollution Prevention Plan (SWPPP). A SWPPP provides for temporary measures to control sediment and other pollutants during construction at sites that disturb one acre or more. See the CCCWP website for information on requirements for construction-phase controls.

► PLAN AHEAD TO AVOID THE THREE MOST COMMON MISTAKES

The most common (and costly) errors made by applicants for development approvals with respect to C.3 compliance are:

1. Not planning for C.3 compliance early enough. You should think about your strategy for C.3 compliance before completing a conceptual site design or sketching a layout of subdivision lots (Chapter 3).

2. Assuming proprietary stormwater treatment facilities will be adequate for compliance. A complete Low Impact Development design, including reuse, infiltration, evapotranspiration, or bioretention facilities, is now required for nearly all projects (Chapter 2).

3. Not planning for periodic inspections and maintenance of treatment and flow-control facilities. Consider who will own and who will maintain the facilities in perpetuity and how they will obtain access, and identify which arrangements are acceptable to your municipality (Chapter 6).

Chapter 1

Policies and Procedures

Determine if your development project must comply with the Municipal Regional Permit C.3 requirements, and review the steps to compliance.

Thresholds, Effective Dates, and Requirements

Table 1-1 (on following page) summarizes requirements for development projects. Thresholds are based on impervious area created or replaced in connection with a project. Interior remodels and routine maintenance or repair such as roof or exterior surface replacement and pavement resurfacing are excluded.

The 2010-2012 effective dates refer to the date on which a planning application has received final discretionary approval. At the discretion of local municipal staff, projects with applications that are deemed complete and diligently pursued prior to these dates may not have to meet all requirements (requirements in previous *Guidebook* editions may apply).

► THE "50% RULE" FOR PROJECTS ON PREVIOUSLY DEVELOPED SITES

Projects on previously developed sites may also need to retrofit drainage to provide treatment of runoff from all impervious areas of the entire site. For sites creating or replacing a total amount of impervious area greater than the applicable threshold (Table 1-1):

- If the new project results in an alteration of more than 50% of the impervious surface of a previously existing development, and the existing development was not subject to stormwater treatment measures, then the entire project must be included in the treatment measure design.

- If the new project results in an alteration of less than 50% of the impervious surface of a previously existing development, and the existing development was not subject to stormwater treatment

RB-AR32816

ICON KEY

- ☞ Helpful Tip
- Submittal Requirement
- Terms to Look Up
- References & Resources

measures, then only the new and replaced impervious surface must be included in the treatment system design.

In contrast to the 50% rule for treatment requirements, flow-control requirements use the developed condition of a previously developed site as a baseline when determining if runoff rates or durations will increase as a result of the project.

TABLE 1-1. THRESHOLDS, EFFECTIVE DATES, and Requirements summarized.*

Impervious Area Threshold	Effective Date	Requirement
All projects requiring municipal approvals or permits	May 1, 2010	As encouraged or directed by local staff, preserve or restore open space, riparian areas, and wetlands as project amenities, minimize land disturbance and impervious surfaces (especially parking lots) cluster structures and pavements, include micro-detention in landscaped and other areas, and direct runoff to vegetated areas. Use Bay-friendly landscaping features and techniques. Include Source Controls specified in Appendix D.
Projects between 2,500 and 10,000 square feet requiring approvals or permits	December 1, 2012	Install one or more of the following: Direct roof runoff into cisterns or rain barrels for reuse; direct roof runoff onto vegetated areas; direct runoff from sidewalks, walkways, and/or patios on to vegetated areas; direct runoff from driveways and/or uncovered parking lots on to vegetated areas; construct sidewalks, walkways, and/or patios with permeable surfaces; construct bike lanes, driveways, and uncovered parking lots with permeable surfaces.
Auto service facilities, gas stations, restaurants, and uncovered parking lots over 5,000 square feet	December 1, 2011	Prepare and submit a Stormwater Control Plan as described in Chapter 3, including features and facilities to ensure runoff is treated before leaving the site. Evaluate feasibility of storage for later use. Use the LID Design Guide in Chapter 4, including sizing factors and criteria for "treatment only."
All projects between 10,000 square feet and one acre†	August 15, 2006	
Projects an acre and larger†	October 14, 2006	Select one of four flow-control compliance options in Appendix C. Where required, design project features and facilities for hydrograph modification management (flow-control) as well as stormwater treatment. Prepare and submit a Stormwater Control Plan as described in Chapter 3 and use the LID Design Guide in Chapter 4, including the sizing factors and criteria for "treatment and flow control."

*Summary only. Requirements for any particular project are determined by your municipality.
†Detached single-family homes that are not part of a larger plan of development are specifically excluded.
For road widening projects, count only the impervious area associated with new traffic lanes.

RB-AR32817

Compliance Process at a Glance

For the applicant for development project approval, compliance follows these general steps:

1. Discuss C.3 requirements during a pre-application meeting with municipal staff.

2. Review the instructions in this *Guidebook* before you prepare your tentative map, preliminary site plan, drainage plan, and landscaping plan.

3. Prepare a Stormwater Control Plan and submit it with your application for development approvals (entitlements).

4. Following development approval, create your detailed project design, incorporating the features described in your Stormwater Control Plan.

5. In a table on your construction plans, list each stormwater control feature and facility and the plan sheet where it appears.

6. Prepare a draft Stormwater Facility Operation and Maintenance Plan and submit it with your application for building permits. Execute legal documents assigning responsibility for operation and maintenance of stormwater facilities. Some municipalities require legal agreements and financial commitments for operation and maintenance be recorded prior to recordation of a final parcel map.

7. Maintain stormwater facilities during construction and following construction in accordance with required warranties.

8. Following construction, submit a final Stormwater Facility Operation and Maintenance Plan and formally transfer responsibility for maintenance to the owner or permanent occupant.

9. The occupant or owner must periodically verify stormwater facilities are properly maintained.

Local Requirements

Cities, towns, or the County may have requirements that differ from, or are in addition to, this county-wide Guidebook. See Appendix A for local requirements.

Preparation of a complete and detailed Stormwater Control Plan is the key to cost-effective C.3 compliance and expeditious review of your project. Instructions for preparing a Stormwater Control Plan are in Chapter 3.

RB-AR32818

Implementing C.3 on Phased Projects

When determining whether Provision C.3 requirements apply, a "project" should be defined consistent with CEQA definitions of "project." That is, the "project" is the whole of an action which has the potential for adding or replacing or resulting in the addition or replacement of roofs, pavement, or other impervious surfaces and thereby resulting in increased flows and stormwater pollutants. "Whole of an action" means the project may not be segmented or piecemealed into small parts if the effect is to reduce the quantity of impervious area for any part to below the C.3 threshold.

Grandfathering. Municipalities may, at their discretion, exempt projects for which applications received final discretionary approval prior to the dates in Table 1-1. However, this "grandfathering" applies only to the specific discretionary approval that was the subject of the original application. Subsequent applications for further approvals constitute a "project" for the purposes of C.3. If those subsequent approvals or entitlements cover specific locations, modes, or designs for addition or replacement of roofs, pavement, or other impervious surfaces, and if the impervious area created or replaced is in excess of the applicable thresholds, then the C.3 requirements will apply to those areas of the project covered by the subsequent approval or entitlement.

CEQA
See the CCCWP's New Development web page for guidance on how to document stormwater impacts and mitigations in Initial Studies and Environmental Impact Reports.

Consider for example an application for a subdivision tentative map which receives final discretionary approval prior to the C.3 start dates. The project may be exempt from Provision C.3; however, if the project proponent later applies for discretionary approval of specific locations, modes, or designs of paving and structures, then C.3 requirements would apply to those improvements.

Applying the "50% rule." Municipal staff will determine case-by-case when and how the "50% rule" applies; in doing so staff may use the original entitlement (discretionary approval) as a guide when calculating the impervious area of the "previously existing development".

Stormwater Control Plan requirements for phased projects. Municipal staff may require, as part of an application for approval of a phased development project, a conceptual or master Stormwater Control Plan which describes and illustrates, in broad outline, how the drainage for the project will comply with the Provision C.3 requirements. The level of detail in the conceptual or master Stormwater Control Plan should be consistent with the scope and level of detail of the development approval being considered. The conceptual or master Stormwater Control Plan should

Local Requirements
Cities, towns, or the County may have requirements that differ from, or are in addition to, this countywide Guidebook. See Appendix A and check with local planning and community development staff.

RB-AR32819

specify that a more detailed Stormwater Control Plan for each later phase or portion of the project will be submitted with subsequent applications for discretionary approvals.

Applying C.3 to New Subdivisions

If a tentative map approval would potentially entitle future owners of individual parcels to construct new or replaced impervious area which, in aggregate, could exceed the thresholds in Table 1-1, then the applicant must take steps to ensure C.3 requirements can and will be implemented as the subdivision is built out.

If the tentative map application does not include plans for site improvements, the applicant should nevertheless identify the type, size, location, and final ownership of stormwater treatment and flow-control facilities adequate to serve new roadways and any common areas, and to also manage runoff from an expected reasonable estimate of the square footage of future roofs, driveways, and other impervious surfaces on each individual lot. The municipality may condition approval of the map on implementation of stormwater treatment measures in compliance with Provision C.3 when construction occurs on the individual lots. This condition may be enforced by a grant deed of development rights or by a development agreement.

If a municipality deems it necessary, the future impervious area of one or more lots may be limited by a deed restriction. This might be necessary when a project is exempted from one or all C.3 provisions because the total impervious area is below a threshold, or to ensure runoff from impervious areas added after the project is approved does not overload a stormwater treatment and flow-control facility.

Subdivision maps should dedicate an "open space easement, as defined by Government Code Section 51075," to suitably restrict the future building of structures at each stormwater facility location.

In general, it is recommended **stormwater treatment facilities not be located on individual single-family residential lots**, particularly when those facilities manage runoff from other lots, from streets, or from common areas. However, local requirements vary. A better alternative may be to locate stormwater facilities on one or more separate, jointly owned parcels.

See the *Policy for C.3 Compliance for Subdivisions* on the Contra Costa Clean Water Program's C.3 web page.

After consulting with local planning staff, applicants for subdivision approvals will propose one of the following four options, depending on project characteristics and local policies:

RB-AR32820

1. Show the sum of future impervious areas to be created or replaced on all parcels could not exceed the applicable C.3 thresholds shown in Table 1-1.

2. Show that, for each and every lot, the intended use can be achieved with a design which disperses runoff from roofs, driveways, streets, and other impervious areas to self-retaining pervious areas, using the criteria in Chapter 4 of this *Guidebook*.

3. Prepare improvement plans showing drainage to treatment and/or flow-control facilities designed in accordance with this *Guidebook,* and commit to constructing the facilities prior to transferring the lots.

4. Prepare improvement plans showing drainage to treatment and/or flow-control facilities designed in accordance with this *Guidebook*, and provide appropriate legal instruments to ensure the proposed facilities will be constructed and maintained by subsequent owners.

For the option selected, municipal staff will determine the appropriate conditions of approval, easements, deed restrictions, or other legal instruments necessary to assure future compliance. In general, when new streets and common areas are constructed, facilities to treat runoff from those new impervious areas must be constructed concurrently, and agreements for the operation and maintenance of those facilities must be executed timely.

Compliance with Flow-Control Requirements

As shown in Table 1-1, in addition to incorporating treatment controls, projects creating or replacing an acre or more of impervious area must also provide flow control so post-project runoff does not exceed estimated pre-project rates and durations. Projects subject to flow-control requirements have four options for demonstrating compliance. The options are summarized in Table 1-2. Detailed requirements are in Appendix C.

Depending on location and existing site conditions, a project proponent may wish to consider the feasibility of these options in the following order:

- For projects on previously developed sites, it may be possible to show the project will not increase the existing quantity of impervious area and will not facilitate the efficiency of drainage collection and conveyance (Option 1).

- Depending on project location, the project proponent may be able show all downstream channels between the project site and the Bay/Delta are enclosed pipes, are engineered hardened channels, are subject to tidal action, or are aggrading (Option 4a).

RB-AR32821

- Proponents may use the LID Design Guide in Chapter 4 to meet both treatment and flow-control requirements (Option 2).
- Proponents of larger developments, particularly those with complex or extensive drainage, might consider creating a continuous hydrologic simulation model, using the criteria in Appendix C, to demonstrate that, after incorporation of flow-control measures, post-project runoff will not exceed pre-project rates or durations (Option 3).

TABLE 1-2. Options for compliance with flow-control requirements*

What must be demonstrated	*How applicants can comply*	*Stormwater Control Plan submittal requirements*
Option 1: No increase in impervious area	Compare the project design to the pre-project condition and show the project will not increase impervious area and also will not increase efficiency of drainage collection and conveyance.	Inventory and accounting of existing and proposed impervious areas, measures used to reduce imperviousness, and a qualitiative comparison of pre- and post-project drainage efficiency.
Option 2: Integrated Management Practices	Use the design procedure and design criteria in this *Guidebook*, and the Program's sizing tool, to select and size IMPs for flow control (also meets treatment requirements).	Stormwater Control Plan and sizing tool output (Chapter 3).
Option 3: Post-project runoff does not exceed pre-project rates and durations	Use a continuous-simulation model and 30 years or more of hourly rainfall data to simulate pre-project and post-project runoff, including the effect of proposed control facilities.	Model parameters and modeling techniques are specified in Appendix C.
Option 4a: All downstream reaches are at "low risk" of erosion	Show all downstream channels between the project site and the Bay/Delta are enclosed pipes, are engineered hardened channels, are subject to tidal action, or are aggrading.	Report or letter report by an engineer or qualified environmental professional documenting drainage between the project site and the Bay or Delta.
Options 4b and 4c: Erosion risks are mitigated by in-stream restoration projects	Propose and implement appropriate in-stream restoration projects to fully mitigate potential risk.	Requires additional regulatory approvals. See Appendix C.

*Summary only. Applicability to and requirements for any particular project are determined by your municipality.

RB-AR32822

- Under Options 4b and 4c, proponents may propose and implement an appropriate in-stream restoration project to fully mitigate the potential risk of increased downstream erosion created by their proposed development.

Runoff treatment is required regardless of the flow-control compliance option chosen.

Alternative Compliance Options

In lieu of incorporating facilities to treat runoff from impervious areas at the development project site, an applicant may propose a secondary project that will treat runoff from an equivalent amount of impervious area at another location within the same watershed.

To be considered, the secondary project must include construction, operation, and maintenance of facilities meeting the criteria in Chapter 4. Those facilities must treat runoff from an amount of impervious surface equivalent to, or greater than, the impervious surface that would be subject to requirements at the project location.

An applicant may propose to combine on-site and off-site facilities to add up to the equivalent amount of impervious area as would be required for only on-site treatment. An applicant may also propose to share in a larger project and be credited for a proportional amount of the impervious area for which runoff is treated by that project.

Consideration or acceptance of such proposals is at the discretion of the local municipality.

Experience has shown implementation of LID facilities, as described in Chapter 4, is feasible on nearly all development sites with sufficient advance planning.

Chapter

2

Concepts and Criteria

Technical background and explanations of policies and design requirements

The Regional Water Board first issued a municipal stormwater NPDES permit to Contra Costa County, its cities and towns, and the Contra Costa Flood Control and Water Conservation District in 1993. The permit mandates a comprehensive program to prevent stormwater pollution. That program now includes measures to prevent pollution from municipal facilities and operations, identification and elimination of illicit discharges to storm drains, business inspections, public outreach, construction site inspections, monitoring and studies of stream health, and control of runoff pollutants from new developments and redevelopments.

The Regional Water Board added Provision C.3 in 2003, and the permittees began implementing the provision in 2005. The Regional Water Board added hydrograph modification management (flow control) requirements in 2006.

In October 2009, the Regional Water Board included Contra Costa municipalities in its first Municipal Regional Permit (MRP). The MRP applies to 77 municipal Bay Area permittees and supersedes the countywide stormwater NPDES permits.

The MRP mandates a Low Impact Development (LID) approach similar to that developed by the CCCWP from 2003 through 2009. This chapter explains the technical background of the LID approach and how it was derived.

Water-Quality Regulations

MRP Provision C.3 requires municipalities to condition development approvals with incorporation of specified stormwater controls. The municipalities' annual report to the Regional Water Board includes a list of development projects approved during the year and the specific stormwater controls required for each project. In the annual report, the municipalities also document their program to verify stormwater treatment and flow-control facilities are being adequately

RB-AR32824

maintained. The municipalities—not the Regional Board or its staff—are charged with ensuring development projects comply with the C.3 requirements. (Regional Water Board staff sometimes reviews stormwater controls in connection with applications for Clean Water Act Section 401 water-quality certification, which is required for projects that involve work in streams, including dredging and filling.)

In a nutshell, MRP Provision C.3 requires that applicable new developments and redevelopments:

- Design the site to minimize imperviousness, detain runoff, and infiltrate, reuse or evapotranspirate runoff where feasible
- Cover or control sources of stormwater pollutants
- Treat runoff prior to discharge from the site
- Ensure runoff does not exceed pre-project peaks and durations
- Maintain treatment and flow-control facilities

► MAXIMUM EXTENT PRACTICABLE

Clean Water Act Section 402(p)(3)(iii) sets the standard for control of stormwater pollutants as "maximum extent practicable," but doesn't define that term. As implemented, "maximum extent practicable" is ever-changing and varies with conditions.

Many stormwater controls, including LID, have proven to be practicable in most development projects. To achieve fair and effective implementation, criteria and guidance for those controls must be detailed and specific—while also offering the right amount of flexibility or exceptions for special cases. The MRP includes various standards, including hydrologic criteria, which have been found to provide "maximum extent practicable" control. CCCWP's C.3 guidance is continuously improved and refined based on the experience of municipal planners and engineers, with input from land developers and development professionals.

► BEST MANAGEMENT PRACTICES

Clean Water Act Section 402(p) and USEPA regulations (40 CFR 122.26) specify a municipal program of "management practices" to control stormwater pollutants. Best Management Practice (BMP) refers to any kind of procedure or device designed to minimize the quantity of pollutants that enter the Municipal Separate Storm Sewer System (MS4).

To minimize confusion, this guidebook refers to "facilities," "features," "controls," and Integrated Management Practices (IMPs) to be incorporated into development projects. All of these are BMPs.

RB-AR32825

Hydrology for NPDES Compliance

► IMPERVIOUSNESS

Schueler (1995) proposed imperviousness as a "unifying theme" for the efforts of planners, engineers, landscape architects, scientists, and local officials concerned with urban watershed protection. Schueler argued (1) that imperviousness is a useful indicator linking urban land development to the degradation of aquatic ecosystems, and (2) imperviousness can be quantified, managed, and controlled during land development.

Imperviousness has long been understood as the key variable in urban hydrology. Peak runoff flow and total runoff volume from small urban catchments is usually calculated as a function of the ratio of impervious area to total area (rational method). The ratio correlates to the composite runoff factor, usually designated "C". Increased flows resulting from urban development tend to increase the frequency of small-scale flooding downstream.

Imperviousness links urban land development to degradation of aquatic ecosystems in two ways.

First, the combination of paved surfaces and piped runoff efficiently collects urban pollutants and transports them, in suspended or dissolved form, to surface waters. These pollutants may originate as airborne dust, be washed from the atmosphere during rains, or may be generated by automobiles and outdoor work activities.

Second, increased peak flows and runoff durations can cause erosion of stream banks and beds, transport of fine sediments, and disruption of aquatic habitat. Measures taken to control stream erosion, such as hardening banks with riprap or concrete, may permanently eliminate habitat. By reducing infiltration to groundwater, imperviousness may also reduce dry-weather stream flows.

Imperviousness has two major components: rooftops and transportation (including streets, highways, and parking areas). The transportation component is usually larger and is more likely to be directly connected to the storm drain system.

The effects of imperviousness can be mitigated by disconnecting impervious areas from the drainage system and by making drainage less efficient—that is, by encouraging detention and retention of runoff near the point where it is generated. Detention and retention reduce peak flows and volumes and allow pollutants to settle out or adhere to soils before they can be transported downstream.

RB-AR32826

► SIZING REQUIREMENTS FOR STORMWATER TREATMENT FACILITIES

MRP permit criteria for sizing stormwater treatment facilities and flow-control facilities are based on simulation of runoff from a long-term (30-year or more) rainfall record. This is different from the "event-based" or "design storm" hydrology typically used to size drainage and flood-control facilities.

The CCCWP's LID design guidance (Chapter 4) was crafted to ensure LID facilities comply with the NPDES permit's hydraulic sizing requirements for stormwater treatment facilities and flow-control facilities, as well as meeting the LID mandate in MRP Provision C.3.c. The technical background follows.

Most runoff is produced by frequent storms of small or moderate intensity and duration. Treatment facilities are designed to treat smaller storms and the first flush of larger storms—approximately 80% of average annual runoff.

MRP Provision C.3.d. identifies two sets of criteria for sizing stormwater treatment facilities—volume-based and flow-based.

For **volume-based** treatment facilities, MRP Provision C.3.d. references two alternative methods, the **WEF method** and the **California BMP method**. As described in Chapter 4, local rainfall data and the California BMP method are used for sizing detention basins in Contra Costa County. Both the WEF and California BMP methods are based on continuous simulation of runoff from a hypothetical one-acre area entering a basin designed to draw down in 48 hours. The simulation is iterated to find the unit basin size that detains about 80% of the total runoff during the simulation period. The unit basin storage size is expressed as a depth which varies from about 0.45" to 0.85" in Contra Costa County.

ICON KEY
Helpful Tip
Submittal Requirement
Terms to Look Up
References & Resources

For **flow-based** facilities, the NPDES permit specifies the rational method be used to determine flow. The rational method uses the equation

$Q = CiA$, where

Q = flow

C = weighted runoff factor between 0 and 1

i = rainfall intensity

A = area

The permit identifies three alternatives for calculating rainfall intensity:

1. the intensity-duration-frequency method, with a hydrograph corresponding to a 50-year storm,

2. the 85th percentile rainfall intensity times two, and

3. 0.2 inches per hour.

An analysis conducted for the CCCWP determined all three methods yielded similar results. The 0.2 inches per hour rainfall intensity is used for sizing flow-based treatment facilities in Contra Costa County. This intensity corresponds to storms producing approximately 0.6 inches precipitation.

The CCCWP used the 0.2 inches per hour criterion to develop a consistent countywide sizing factor for bioretention facilities when used for stormwater treatment only (i.e., not for flow control). The factor is based on a design maximum surface loading rate of 5 inches per hour (now mandated by MRP Provision C.3.c.i.(2)(b)(iv)). The sizing factor is the ratio of the design intensity of rainfall on tributary impervious surfaces (0.2 inches/hour) to the design percolation rate in the facility (5 inches/hour), or 0.04 (dimensionless).

► FLOW-CONTROL (HYDROGRAPH MODIFICATION MANAGEMENT)

MRP Provision C.3.g. specifies for applicable projects:

> "Increases in runoff flow and volume shall be managed so that post-project runoff shall not exceed estimated post-project runoff peaks and durations, where such increased flow and/or volume is likely to cause increased potential for erosion of creek beds and banks, silt pollutant generation, or other adverse impacts on beneficial uses due to increased erosive force."

Contra Costa applicants for development approvals may select among four options for compliance. See Table 1-2. The first three options allow an applicant to demonstrate—by showing there will be no net increase in impervious area, by using Integrated Management Practice designs and sizing factors developed by the CCCWP, or by constructing a site-specific hydrologic model—that runoff will not exceed pre-project rates and durations.* Applicants may use the fourth option to demonstrate that, even though runoff will increase, it will not cause erosion or other significant effects on beneficial uses. This may be done by showing downstream channels are not susceptible to erosion (Option 4a) or that a

* For sites that are already partially developed, see the Technical Memorandum, "Guidance on Flow Control For Development Projects on Sites that are Already Partially Developed," on the CCCWP's C.3 web pages.

restoration project will mitigate any impacts from increased flows (Options 4b and 4c).

Details on compliance requirements are in Appendix C. Technical background is in the Hydrograph Modification Management Plan, which is available on the CCCWP's website.

Selection of Stormwater Treatment Facilities

The MRP mandates an LID approach similar to the approach developed by Contra Costa municipalities and incorporated in earlier editions of this *Stormwater C.3 Guidebook*.

► HARVESTING, USE, INFILTRATION, AND EVAPOTRANSPIRATION

MRP Provision C.3.c.i.(2)(b) requires applicable projects to treat 100% of the amount of runoff identified in Provision C.3.d. using LID facilities, which are defined as follows:

- LID treatment measures are harvesting and re-use, infiltration, evapotranspiration, or biotreatment.
- A properly engineered and maintained biotreatment system may be considered only if it is infeasible to implement harvesting and re-use, infiltration, or evapotranspiration at a project site.
- Infeasibility to implement harvesting and re-use, infiltration, or evapotranspiration at a project site may result from conditions including the following:
    - Locations where seasonal high groundwater would be within 10 feet of the LID treatment measure.
    - Locations within 100 feet of a groundwater well used for drinking water.
    - Development sites where pollutant mobilization in the soil or groundwater is a documented concern.
    - Locations with potential geotechnical hazards.
    - Smart growth and infill or development sites where the density and nature of the project would create significant difficulty for compliance with the onsite volume retention requirement.

RB-AR32829

- Locations with tight clay soils that significantly limit the infiltration of stormwater.

Here is how these requirements are implemented in Contra Costa municipalities:

The LID Design Guide directs the applicant to first consider incorporating into the proposed project design LID features that minimize runoff. These features include:

- Minimized disturbance of natural drainage
- Minimized amount of roofs and paving
- Permeable pavements and green roofs
- Dispersing runoff to landscape

Remaining runoff from impervious surfaces must be directed to LID facilities designed to the hydraulic sizing criteria in Provision C.3.d.

The LID Design Guide then directs the applicant to assess the feasibility of meeting the permit's treatment and flow-control requirements—for each specific sub-drainage area within the site—by storing runoff for later use.

There are two options identified.

The first option is to store runoff for two days or less, which requires a consistent, reliable demand for a non-potable use other than irrigation. For this option, the applicant is directed to calculate the required storage and 48-hour drawdown rate for 80% capture. This calculation uses the methodology specified in CASQA Handbook and local rainfall data as specified in MRP Provision C.3.d.i.(1)(b). It is presumed storage of this quantity of runoff is feasible, and the applicant is directed to evaluate whether a reliable, accessible, implementable non-potable demand exists for this supply during the rainy season.

The second option is to accumulate runoff throughout the rainy season for use during the irrigation season. The required storage volume is calculated using the mean annual precipitation falling on the impervious surface times a factor of 0.6, which accounts for estimated losses to evaporation (less than 10%), the 80% capture of runoff, and runoff produced and used during the irrigation season (May – October). The applicant is directed to evaluate whether (1) there is sufficient landscape within or near the project to ensure demand for this quantity of water each year, and (2) whether annual storage of this quantity of water is feasible.

For projects located at sites with Hydrologic Soil Group "A" or "B" soils, the LID Design Guide requires remaining runoff be routed to one of the following types of facilities:

- Dry well
- Bioretention
- Cistern + Bioretention
- Bioretention + Vault

All of these facilities are designed to infiltrate at least the flow of runoff specified in Provision C.3.d. when sized and configured for "treatment only" and a greater volume when sized and configured for "treatment and flow control."

For projects located at sites with "tight clay soils that significantly limit the infiltration of stormwater" (Hydrologic Soil Group "C" and "D" soils), the LID Design Guide requires remaining runoff be routed to one of the following facilities:

- Bioretention
- Cistern + Bioretention
- Bioretention + Vault

In these soil conditions, the amount of infiltration and evapotranspiration achieved by a bioretention facility is subject to unpredictable variation based on location-specific soil, slopes, and subsurface drainage patterns. Bioretention facilities are designed to facilitate infiltration and evapotranspiration to the extent feasible given conditions at the location.

Flow-through planters may be used where facilities are located on upper-story plazas, adjacent to building foundations, where mobilization of pollutants in soil or groundwater is a concern, and where potential geotechnical hazards are associated with infiltration. Flow-through planters facilitate evapotranspiration and, like bioretention facilities, reuse runoff to promote growth of plants within the facility.

Pending Actions

MRP Provision C.3.c.iii.(1) requires the municipal permitees to submit proposed feasibility and infeasibility criteria for runoff storage/reuse and infiltration to the Water Board by May 1, 2011.

RB-AR32831

► NON-LID TREATMENT FACILITIES

MRP Provision C.3.e.ii.(1) states:

> When considered at the watershed scale, certain types of smart growth, high density and transit-oriented development can either reduce existing impervious surfaces, or create less "accessory" impervious areas and automobile-related pollutant impacts. Incentive LID treatment reduction credits approved by the Water Board may be applied to these types of Special Projects.

Pending Actions
MRP Provision C.3.e.ii.(2) requires the municipal permitees to submit types of projects proposed for consideration of "LID treatment reduction credits" to the Water Board by December 1, 2010.

Through experience, Contra Costa municipalities have determined the LID facilities in Chapter 4 can be implemented on most "smart growth, high-density, and transit-oriented development," and have decided LID facilities should be incorporated on those projects. Contra Costa municipalities have set an overall goal of incorporating LID treatment for runoff from at least 95% of impervious area created or replaced, and incorporating non-LID treatment for runoff from the remaining 5% of impervious area created or replaced.

Projects where LID may not always be feasible generally fall into one of the following two categories:

- Portions of sites which are not being developed or redeveloped, but which must be retrofit to meet treatment requirements in accordance with the "50% rule."
- Sites smaller than one acre approved for lot-line to lot-line development or redevelopment as part of a municipality's stated objective to preserve or enhance a pedestrian-oriented "smart-growth" type of urban design.

In these special situations, municipal staff may—based on evidence that 100% LID treatment is infeasible—allow non-LID treatment to be used to treat runoff from some or all impervious surfaces. The non-LID treatment must include media filtration.

Regional Water Board staff has found oil/water separators ("water quality inlets") and storm drain inlet filters do not meet the "maximum extent practicable" standard.* When used as a sole method of stormwater treatment, hydrodynamic separators, including vortex separators and continuous deflection separators ("CDS units"), do not meet the "maximum extent practicable" requirement, although they may be used in series with other facilities.†

Criteria for Infiltration Devices

MRP Provision C.3.d.iv. restricts the design and location of "infiltration devices" that, as designed, may bypass filtration through surface soils before reaching groundwater. These devices include dry wells, infiltration basins, and infiltration trenches, but do not include bioretention facilities or other facilities that treat runoff before allowing it to infiltrate.

Infiltration devices may not be used in areas of industrial or light industrial activity; areas subject to high vehicular traffic (25,000 or greater average daily traffic on main roadway or 15,000 or more average daily traffic on any intersecting roadway); automotive repair shops; car washes; fleet storage areas (bus, truck, etc.); nurseries, or other areas with pollutant sources that could pose a high threat to water quality, as determined by municipal staff.

The vertical distance from the base of any infiltration device to the seasonal high groundwater mark shall be at least 10 feet. Infiltration devices shall be located a minimum of 100 feet horizontally from any known water supply wells.

In addition, infiltration devices are not recommended where:

- The infiltration device would receive drainage from areas where chemicals are used or stored, where vehicles or equipment are washed, or where refuse or wastes are handled.
- Surface soils or groundwater are polluted.
- The facility could receive sediment-laden runoff from disturbed areas or unstable slopes.
- Increased soil moisture could affect the stability of slopes of foundations.

---

† *Policy on the Use of Hydrodynamic Separators to Achieve Compliance with NPDES Provision C.3*, November 16, 2005

RB-AR32833

- Soils are insufficiently permeable to allow the device to drain within 72 hours.

► MOST LID FEATURES AND FACILITIES ARE NOT INFILTRATION DEVICES

Self-treating and self-retaining areas, pervious pavements, bioretention facilities, and flow-through planters are not considered to be infiltration devices because they do not bypass filtration through surface soils before reaching groundwater.

Bioretention facilities work by percolating runoff through 18 inches or more of engineered soil. This removes most pollutants before the runoff is allowed to seep into native soils below or discharge through the outlet. Further pollutant removal typically occurs in the unsaturated (vadose) zone before moisture reaches groundwater. Self-treating and self-retaining areas allow removal of pollutants in surface soils before runoff mixes with groundwater.

Where there is concern about the effects of increased soil moisture on slopes or foundations, an impermeable barrier may be added so the facility is "flow through" and all treated runoff is underdrained away from the facility. See the design sheets for Bioretention Facilities and Flow-Through Planters in Chapter 4.

Environmental Benefit Perspective

The diverse natural geography of Contra Costa County includes tidal and freshwater wetlands, alluvial plains, and mountain slopes. Average annual rainfall varies from 12.5 inches in Brentwood to 30 inches in Orinda.

The climate, soils, slope, and vegetation give each Contra Costa stream a characteristic structure of riffles, pools, terraces, floodplains, and wetlands. In relatively undisturbed stream reaches, this geomorphic structure supports trees and other riparian vegetation. Trees provide shade (cooling stream temperatures), create root wads and undercut banks (refuge for fish) and produce falling leaves and detritus (the bottom of a food web). Fish, frogs, and other animals have evolved to thrive in riparian habitats. Because Contra Costa habitats are diverse and complex, some species are specialized, have limited ranges, and may be rare.

Contra Costa's landscape, like that of all the San Francisco Bay Area, has been repeatedly transformed since the Spanish arrived in the 1770s. Even before the area was developed, European grasses, weeds, and other plants replaced much of the native vegetation. Creek flows were diverted to irrigate farms, and wetlands were diked or filled for farmland.

Suburbs and former farm towns developed rapidly during and after the Second World War. In many places, to make flood-prone land suitable for development, creeks were channelized or confined within levees. Buildings, streets, and pavement now cover much of the land, and storm drains pipe runoff from urban

RB-AR32834

neighborhoods directly into the creeks. Urbanization has changed the timing and intensity of stream flows and has set off a chain of unanticipated consequences. These consequences include more frequent flooding, destabilized stream banks, armoring of streambanks with riprap and concrete, loss of streamside trees and vegetation, and the destruction of stream habitat.

The remaining habitat, even where it has been disturbed and reduced to remnants, is an important refuge for various species. The U.S. and California have listed some of these species, including steelhead (*Oncorhyncus mykiss),* as endangered. Other species are listed as threatened, rare, or having other special status.

Once altered, natural streams and their ecosystems cannot be fully restored. However, it is possible to stop, and partially reverse, the trend of declining habitat and preserve and enhance some ecosystem values for the benefit of future generations.

This is an enormous, long-term effort. Managing runoff from a single development site may seem inconsequential, but by changing the way most sites are developed (and redeveloped), we may be able to preserve and enhance existing stream ecosystems in urban and urbanizing areas.

Preparing Your Stormwater Control Plan

Step-by-step assistance to document compliance.

Your Stormwater Control Plan will demonstrate your project complies with all applicable requirements in the stormwater NPDES permit—to minimize imperviousness, retain or detain stormwater, slow runoff rates, incorporate required source controls, treat stormwater prior to discharge from the site, control runoff rates and durations if required, and provide for operation and maintenance of treatment and flow-control facilities.

ICON KEY
Helpful Tip
Submittal Requirement
Terms to Look Up
References & Resources

The Plan must be submitted with your application for discretionary approvals and must have sufficient detail to ensure the stormwater design, site plan, and landscaping plan are congruent.

A complete and thorough Stormwater Control Plan will facilitate quicker review and fewer cycles of review. Every Contra Costa municipality requires a Stormwater Control Plan for every applicable project.

Your Stormwater Control Plan will consist of a report and an exhibit.

Municipal staff will use the checklist on the following page to evaluate your Plan:

STORMWATER CONTROL PLAN CHECKLIST

CONTENTS OF EXHIBIT

Show all of the following on drawings:

- ❒ Existing natural hydrologic features (depressions, watercourses, relatively undisturbed areas) and significant natural resources. (Step 1 in the following step-by-step instructions)
- ❒ Existing and proposed site drainage network and connections to drainage off-site. (Step 3)
- ❒ Layout of buildings, pavement, and landscaped areas. (Step 3)
- ❒ Impervious areas proposed (roof, plaza/sidewalk, and streets/parking) and area of each. (Step 3)
- ❒ Entire site divided into separate Drainage Management Areas, with each DMA identified as self-treating, self-retaining (zero-discharge), draining to a self-retaining area, or draining to an IMP. Each DMA has one surface type (roof, paving, or landscape), is labeled, and square footage noted. (Step 3)
- ❒ Locations and sizes of proposed treatment and flow-control facilities. (Step 3)
- ❒ Potential pollutant source areas, including refuse areas, outdoor work and storage areas, etc. listed in Appendix D and corresponding required source controls. (Step 4)

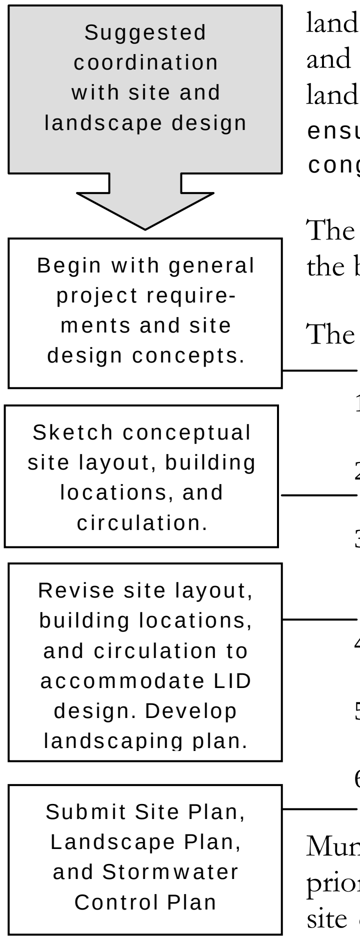
CONTENTS OF REPORT

Include all of the following in a report:

- ❒ Narrative analysis or description of site features and conditions that constrain, or provide opportunities for, stormwater control. Include soil types (including Hydrologic Soil Group), slopes, and depth to groundwater (Step 2)
- ❒ Narrative description of site design characteristics that protect natural resources. (Step 3)
- ❒ Narrative description and/or tabulation of site design characteristics, building features, and pavement selections that minimize imperviousness of the site. (Step 3)
- ❒ Evaluation of the feasibility of storage and use, infiltration, and evapotranspiration (Step 3).
- ❒ Tabulation of DMAs, including self-treating areas, self-retaining areas, areas draining to self-retaining areas, and areas tributary to Integrated Management Practices (IMPs), in the format shown in Chapter 4. Output from the IMP Sizing Calculator may be used. (Step 3)
- ❒ Sketches and/or descriptions showing there is sufficient hydraulic head to route runoff into, through, and from each IMP to an approved discharge point. (Step 3)
- ❒ A table of identified pollutant sources and for each source, the source control measure(s) used to reduce pollutants to the maximum extent practicable. See worksheet in Appendix D. (Step 4)
- ❒ General maintenance requirements for infiltration, treatment, and flow-control facilities. (Step 5)
- ❒ Means by which facility maintenance will be financed and implemented in perpetuity. (Step 5)
- ❒ Statement accepting responsibility for interim operation & maintenance of facilities. (Step 5)
- ❒ Identification of any conflicts with codes or requirements or other anticipated obstacles to implementing the Stormwater Control Plan. (Step 6)
- ❒ Construction Plan C.3 Checklist. (Step 6)
- ❒ Certification by a civil engineer, architect, and landscape architect. (Step 6)
- ❒ Appendix: Compliance with flow-control requirements (if using an HMP compliance option other than Option 2, Integrated Management Practices).

RB-AR32837

Step by Step



Plan and design your stormwater controls integrally with the site planning and landscaping for your project. It's best to start with general project requirements and preliminary site design concepts; then prepare the detailed site design, landscape design, and Stormwater Control Plan simultaneously. This will help ensure that your site plan, landscape plan, and Stormwater Control Plan are congruent.

The following step-by-step procedure should optimize your design by identifying the best opportunities for stormwater controls early in the design process.

The recommended steps are:

1. Assemble needed information.
2. Identify site opportunities and constraints.
3. Follow the LID design guidance in Chapter 4 to analyze your project for LID and to develop and document your drainage design.
4. Specify source controls using the table in Appendix D.
5. Plan for ongoing maintenance of treatment and flow-control facilities.
6. Complete the Stormwater Control Plan.

Municipal staff may recommend you prepare and submit a preliminary site design prior to formally applying for planning and zoning approvals. Your preliminary site design should incorporate a conceptual plan for site drainage, including self-treating and self-retaining areas and the location and approximate sizes of any treatment and flow-control facilities. This additional up-front design effort will save time and avoid potential delays later in the review process.

Step 1: Assemble Needed Information

To select types and locations of treatment and flow-control facilities, the designer needs to know the following site characteristics:

- Existing natural hydrologic features and natural resources, including any contiguous natural areas, wetlands, watercourses, seeps, or springs.
- Existing site topography, including contours of any slopes of 4% or steeper, general direction of surface drainage, local high or low points or depressions, any outcrops or other significant geologic features.

RB-AR32838

- Zoning, including requirements for setbacks and open space.
- Soil types (including hydrologic soil groups) and depth to groundwater, which may determine whether infiltration is a feasible option for managing site runoff. Depending on site location and characteristics, and on the selection of treatment and flow-control facilities, site-specific information (e.g. from boring logs or geotechnical studies) may be required.
- Existing site drainage. For undeveloped sites, this should be obtained by inspecting the site and examining topographic maps and survey data. For previously developed sites, site drainage and connection to the municipal storm drain system can be located from site inspection, municipal storm drain maps, and plans for previous development.
- Existing vegetative cover and impervious areas, if any.

Step 2: Identify Constraints & Opportunities

Review the information collected in Step 1. Identify the principal constraints on site design and selection of treatment and flow-control facilities as well as opportunities to reduce imperviousness and incorporate facilities into the site and landscape design. For example, constraints might include impermeable soils, high groundwater, groundwater pollution or contaminated soils, steep slopes, geotechnical instability, high-intensity land use, heavy pedestrian or vehicular traffic, utility locations, or safety concerns. Opportunities might include existing natural areas, low areas, oddly configured or otherwise unbuildable parcels, easements and landscape amenities including open space and buffers (which can double as locations for bioretention facilities), and differences in elevation (which can provide hydraulic head).

Prepare a brief narrative describing site opportunities and constraints. This narrative will help you as you proceed with LID design and explain your design decisions to others.

Step 3: Prepare and Document Your LID Design

Use the Low Impact Development Design Guide (Chapter 4) to analyze your project for LID, design and document drainage, and specify preliminary design details for integrated management practices.

Chapter 4 includes calculation procedures and formats for presenting your calculations.

As shown in the checklist (page 24), your Exhibit must show:

RB-AR32839

- The entire site divided into separate Drainage Management Areas (DMAs), with each area identified as self-treating, self-retaining, draining to a self-retaining area, or draining to an IMP. Each area should be clearly marked with a unique identifier.
- For each drainage area, the types of impervious area proposed, and the area of each.
- Proposed locations and sizes of treatment and flow-control facilities. Each facility should be clearly marked with a unique identifier.

Your Stormwater Control Plan report must include:

- An assessment of the feasibility of storing runoff and using it for irrigation or other non-potable use as a means of achieving criteria for treatment or treatment-and-flow-control. Use the equations and questions in Chapter 4.
- Tabulation of proposed self-treating areas, self-retaining areas, areas draining to self-retaining areas, and areas draining to IMPs, and the corresponding IMPs identified on the Exhibit.
- Calculations, in the format shown in Chapter 4, showing the minimum square footage required and proposed square footage for each IMP. If flow-control requirements apply, the required storage volume or volumes must also be shown.
- Preliminary designs for each IMP. The design sheets and accompanying drawings in Chapter 4 may be used or adapted for this purpose.

Also include in your Stormwater Control Plan report:

- A narrative overview of your design and how your design decisions optimize the site layout, use pervious surfaces, disperse runoff from impervious surfaces, and drain impervious surfaces to engineered IMPs. See Chapter 4.
- A narrative briefly describing each DMA, its drainage, and where drainage will be directed.
- A narrative briefly describing each IMP. Include any special characteristics or features distinct from the design sheets in Chapter 4.

Group and consolidate descriptions, or provide additional detail, as necessary to help the reviewer understand your drainage design.

RB-AR32840

Step 4. Specify Source Control BMPs

Some everyday activities – such as trash recycling/disposal and washing vehicles and equipment – generate pollutants that tend to find their way into storm drains. These pollutants can be minimized by applying **source control BMPs.**

Source control BMPs include **permanent**, structural features that may be required in your project plans—such as roofs over and berms around trash and recycling areas—and **operational** BMPs, such as regular sweeping and "housekeeping," that must be implemented by the site's occupant or user. The maximum extent practicable standard typically requires both types of BMPs. In general, operational BMPs cannot be substituted for a feasible and effective permanent BMP.

Use the following procedure to specify source control BMPs for your site:

► IDENTIFY POLLUTANT SOURCES

Review the first column in the **Pollutant Sources/Source Control Checklist** (Appendix D). Check off the potential sources of pollutants that apply to your site.

► NOTE LOCATIONS ON STORMWATER CONTROL PLAN EXHIBIT

Note the corresponding requirements listed in Column 2 of the Pollutant Sources/Source Control Checklist (Appendix D). Show the location of each pollutant source and each permanent source control BMP in your Stormwater Control Plan Exhibit.

► PREPARE A TABLE AND NARRATIVE

Check off the corresponding requirements listed in Column 3 in the Pollutant Sources/Source Control Checklist (Appendix D). Now, create a table using the format in Table 3-1. In the left column, list each potential source on your site (from Appendix E, Column 1). In the middle column, list the corresponding permanent, structural BMPs (from Columns 2 and 3, Appendix D) used to prevent pollutants from entering runoff. Accompany this table with a narrative that explains any special features, materials, or methods of construction that will be used to implement these permanent, structural BMPs.

RB-AR32841

TABLE 3-1. Format for table of permanent and operational source control measures.

Potential source of runoff pollutants	*Permanent source control BMPs*	*Operational source control BMPs*

► IDENTIFY OPERATIONAL SOURCE CONTROL BMPS

To complete your table, refer once again to the Pollutant Sources/Source Control Checklist (Appendix D, Column 4). List in the right column of your table the operational BMPs that should be implemented as long as the anticipated activities continue at the site. The local stormwater ordinance requires that these BMPs be implemented; the same BMPs may also be required as a condition of a use permit or other revocable discretionary approval for use of the site.

Step 5: Stormwater Facility Maintenance

As required by MRP Provision C.3.h, your local municipality will periodically verify that treatment and flow-control facilities on your site are maintained and continue to operate as designed.

To make this possible, your municipality will require that you include in your Stormwater Control Plan:

1. A means to finance and implement facility maintenance in perpetuity.

2. Acceptance of responsibility for maintenance from the time the facilities are constructed until responsibility for operation and maintenance is legally transferred. A warranty covering a period following construction may also be required.

3. An outline of general maintenance requirements for the treatment and flow-control facilities you have selected.

Your local municipality will also require that you prepare and submit a detailed Stormwater Facilities Operation and Maintenance Plan that sets forth a maintenance schedule for each of the treatment and flow-control facilities built on your site. An agreement assigning responsibility for maintenance and providing for inspections and certification may also be required.

Details of these requirements, and instructions for preparing a Stormwater Facilities Operation and Maintenance Plan, are in Chapter 6.

References and Resources

- *Chapter 6*
- *Model Stormwater Ordinance (CCCWP, 2005)*
- Operation, Maintenance, and Management of Stormwater Management Systems (Watershed Management Institute, 1997)

Step 6: Stormwater Control Plan Exhibit & Report

Your Stormwater Control Plan should document the information gathered and decisions made in Steps 1-5. A clear, complete, well-organized Plan will make it possible to confirm your design meets the minimum requirements of the Municipal Regional Permit, the municipal stormwater pollution prevention ordinance, and this *Guidebook*.

► COORDINATION WITH SITE, ARCHITECTURAL, AND LANDSCAPING PLANS

Before completing your Stormwater Control Plan exhibit and report, ensure your stormwater control design is fully coordinated with the site plan, grading plan, and landscaping plan being proposed for the site.

Information submitted and presentations to design review committees, planning commissions, and other decision-making bodies must incorporate relevant aspects of the stormwater design. In particular, ensure:

- Curb elevations, elevations, grade breaks, and other features of the drainage design are consistent with the delineation of DMAs.
- The top edge (overflow) of each bioretention facility is level all around its perimeter—this is particularly important in parking lot medians.
- The resulting grading and drainage design is consistent with the design for parking and circulation.
- Bioretention facilities and other IMPs do not create conflicts with pedestrian access between parking and building entrances.

RB-AR32843

- Vaults and utility boxes will be accommodated outside bioretention facilities and will not be placed within bioretention facilities.

- The visual impact of stormwater facilities, including planter boxes at building foundations and any terracing or retaining walls required for the stormwater control design, is shown in renderings and other architectural drawings.

- Landscaping plans, including planting plans, show locations of bioretention facilities, and the plant requirements are consistent with the engineered soils and conditions in the bioretention facilities.

- Renderings and representation of street views incorporate any stormwater facilities located in street-side buffers and setbacks.

- Any potential conflicts with local development standards have been identified and resolved.

Review Chapter 5, IMP Construction, to anticipate additional requirements for construction of IMPs.

► CONSTRUCTION PLAN C.3 CHECKLIST

When you submit construction plans for City review and approval, the plan checker will compare that submittal with your Stormwater Control Plan. By creating a Construction Plan C.3 Checklist for your project, you will facilitate the plan checker's comparison and speed review of your project.

TABLE 3-2. Format for Construction Plan C.3 Checklist.

Stormwater Control Plan Page #	*BMP Description*	*See Plan Sheet #s*

Here's how:

1. Create a table similar to Table 3-2. Number and list each measure or BMP you have specified in your Stormwater Control Plan in Columns 1 and 2 of the table. Leave Column 3 blank. Incorporate the table into your Stormwater Control Plan.

RB-AR32844

2. When you submit construction plans, **duplicate the table** (by photocopy or electronically). Now fill in Column 3, identifying the plan sheets where the BMPs are shown. List all plan sheets on which the BMP appears. Submit the updated table with your construction plans.

Note that the updated table—or Construction Plan C.3 Checklist—is **only a reference tool** to facilitate comparison of the construction plans to your Stormwater Control Plan. Local municipal staff can advise you regarding the process required to propose changes to the approved Stormwater Control Plan.

See Chapter 5 for details of IMP construction to be included in construction plans.

► CERTIFICATION

Your local municipality may require that your Stormwater Control Plan be certified by an architect, landscape architect, or civil engineer. See Appendix A.

Your certification should state: "The selection, sizing, and preliminary design of stormwater treatment and other control measures in this plan meet the requirements of Regional Water Quality Control Board Order R2-2009-0074 and subsequent amendments."

► STORMWATER CONTROL PLAN REPORT SAMPLE OUTLINE AND CONTENTS

I. Project Setting

   A. Project Name, Location, Description

   B. Existing site features and conditions

   C. Opportunities and constraints for stormwater control

II. Low Impact Development Design Strategies

   A. Optimization of site layout

      (1) Limitation of development envelope

      (2) Preservation of natural drainage features

      (3) Setbacks from creeks, wetlands, and riparian habitats

      (4) Minimization of imperviousness

      (5) Using drainage as a design element

RB-AR32845

B. Use of permeable pavements

C. Dispersal of runoff to pervious areas

D. Assessment of the feasibility of short-term and seasonal storage and reuse to meet treatment and flow-control requirements.

(1) Identification of impervious areas where runoff might be feasibly captured and stored.

(2) Calculation of minimum required storage and use rates for non-irrigation and irrigation uses for each such area.

(3) Storage for non-irrigation uses –Is there within the project site a reliable, accessible, implementable on-site non-potable demand to fully and reliably use the calculated supply during the rainy season?

(4) Storage for irrigation uses – Is there sufficient landscape within or near the project to ensure demand to the calculated quantity of water each year, and if so, is annual storage of this quantity of water feasible?

E. Use of Integrated Management Practices

III. Documentation of Drainage Design

A. Drainage Management Areas

(1) Tabulation

(2) Descriptions

B. Integrated Management Practices

(1) Tabulation and Sizing Calculations

(2) Descriptions

IV. Source Control Measures

A. Description of site activities and potential sources of pollutants

B. Table showing sources, permanent source controls, and operational source controls

V. Facility Maintenance Requirements

RB-AR32846

A. Ownership and responsibility for maintenance in perpetuity.

(1) Commitment to execute any necessary agreements and/or annex into a fee mechanism, per local requirements.

(2) Statement accepting responsibility for operation and maintenance of facilities until that responsibility is formally transferred.

B. Summary of maintenance requirements for each stormwater facility.

VI. Construction Plan C.3 Checklist

VII. Certifications

Attachment: Stormwater Control Plan Exhibit

Appendix: Compliance with Flow-Control (Hydrograph Modification Management) requirements (if IMPs are not used).

► STORMWATER CONTROL PLAN TEMPLATE

A template with the above format and headings is available on the CCCWP website.

► EXAMPLE STORMWATER CONTROL PLANS

Example Stormwater Control Plans can be accessed via the CCCWP's website. Because of the pace at which the Regional Water Board has issued new requirements, some of these plans may have been prepared under requirements that have now been superseded. Your Stormwater Control Plan will reflect the unique character of your own project and should meet the requirements identified in this *Guidebook*. Municipal staff can assist you to determine how specific requirements apply to your project.

Low Impact Development Design Guide

Guidance for designing and documenting your LID site drainage, stormwater treatment facilities, and flow-control facilities, including feasibility of storage for later use

Your Stormwater Control Plan—to be submitted with your application for planning and zoning approvals (entitlements)—must show how your project will comply with the applicable Low Impact Development, stormwater treatment, and flow-control (hydrograph modification management) standards in the Municipal Regional Permit (MRP).

This will require careful documentation of:

- Pervious and impervious areas in the planned project.
- Drainage from each of these areas.
- Locations, sizes, and types of proposed LID, stormwater treatment, and flow-control facilities.

Your Stormwater Control Plan must include calculations showing the site drainage and proposed treatment and flow-control facilities meet the criteria in this Guidebook.

This Low Impact Development Design Guide will help you:

- Analyze your project and identify and select options for meeting LID requirements and runoff treatment requirements—and flow-control requirements, if they apply.

RB-AR32848

- **Design and document drainage** for the whole site and document how that design meets this Guidebook's stormwater treatment and flow-control criteria.

- **Specify preliminary design details** and integrate your LID drainage design with your paving and landscaping design.

For most projects, you will need to iterate these three steps to converge on a workable design that complements site conditions and project objectives. Non-LID facilities are discussed in the final section of this chapter.

ICON KEY
Helpful Tip
Submittal Requirement
Terms to Look Up
References & Resources

Before beginning your LID design, determine whether flow-control requirements apply to your site. See Table 1.1 in Chapter 1. If flow-control requirements apply, review Appendix C to understand your options for meeting those requirements. The calculation procedures in this Design Guide enable you to comply with flow-control requirements using "Option 2" in Appendix C. If flow-control requirements do not apply, or if you are using another option to meet flow-control requirements, then you may use the treatment-only factors to size your facilities.

Analyze Your Project for LID

Conceptually, there are five LID strategies for managing runoff from buildings and paving:

1. **Optimize the site layout** by preserving natural drainage features and designing buildings and circulation to minimize the amount of roofs and paving.

2. **Use pervious surfaces** such as turf, gravel, or pervious pavement—or use surfaces that retain rainfall, such as "green roofs."

3. **Disperse runoff** from impervious surfaces on to adjacent pervious surfaces (e.g., direct a roof downspout to disperse runoff onto a lawn).

4. **Store runoff and use it later** for irrigation or other non-potable use.

5. Drain impervious surfaces to engineered **Integrated Management Practices** (IMPs), such as bioretention facilities, flow-through planters, or dry wells. IMPs evapotranspirate some runoff, infiltrate

RB-AR32849

runoff to groundwater, and/or percolate runoff through engineered soil and allow it to drain away slowly.

A combination of two or more strategies may work best for your project. Table 4-1 includes ideas for applying LID strategies to site conditions and types of development. It may be useful as a starting point for thinking through application of the five strategies.

With forethought in design, the five LID strategies can provide multiple, complementary benefits to your development. Pervious surfaces reduce heat island effects and temperature extremes. Landscaping improves air quality, creates a better place to live or work, and upgrades value for rental or sale. Retaining natural hydrology helps preserve and enhance the natural character of the area. LID drainage design can also conserve water and reduce the need for drainage infrastructure.

RB-AR32850

► OPTIMIZE THE SITE LAYOUT

To minimize stormwater-related impacts, apply the following design principles to the layout of newly developed and redeveloped sites:

- Define the development envelope and protected areas, identifying areas that are most suitable for development and areas that should be left undisturbed.
- Set back development from creeks, wetlands, and riparian habitats.
- Preserve significant trees.

Where possible, conform the site layout along natural landforms, avoid excessive grading and disturbance of vegetation and soils, and replicate the site's natural drainage patterns.

Concentrate development on portions of the site with less permeable soils, and preserve areas that can promote infiltration.

Coordination
Chapter One includes a presentation of how review of your project's site design and landscape design is coordinated with review for compliance with Provision C.3.

For all types of development, **limit overall coverage** of paving and roofs. This can be accomplished by designing compact, taller structures, narrower and shorter streets and sidewalks, smaller parking lots (fewer stalls, smaller stalls, and more efficient lanes), and indoor or underground parking. Examine site layout and circulation patterns and identify areas where landscaping can be substituted for pavement.

Detain and retain runoff throughout the site. On flatter sites, it typically works best to intersperse landscaped areas and IMPs among the buildings and paving. On hillside sites, drainage from upper areas may be collected in conventional catch basins and piped to landscaped areas and IMPs in lower areas. Or use low retaining walls to create terraces that can accommodate IMPs. Wherever possible, direct drainage from landscaped slopes offsite and not to IMPs.

Use drainage as a design element. Use depressed landscape areas, vegetated buffers, and bioretention areas as amenities and focal points within the site and landscape design. Bioretention areas can be almost any shape and should be located at low points.

► USE PERVIOUS SURFACES

Consider a green roof. Green roofs are growing (in popularity), and many have been built in the Bay Area in the last few years. Benefits include longer roof life, lower heating and cooling costs, and better sound insulation, in addition to air quality and water quality benefits.

RB-AR32851

However, initial costs are higher than for conventional roofs, and green roofs may add to the complexity of permitting, financing, and insuring new buildings. For C.3 compliance purposes, green roofs are considered not to produce increased runoff or runoff pollutants (i.e., any runoff from a green roof requires no further treatment or detention).

Pending Actions
MRP Provision C.3.c.i.(2)(b)(vii) requires the municipal permitees to submit proposed minimum specifications for green roofs to the Water Board by December 1, 2010.

Green roof designs with growing media 4 inches or deeper are encouraged but not required. Where possible, drainage from green roofs should be routed to landscaping rather than being tied directly into storm drains. This is because drain water may be high in organics due to extended contact with soils and plant roots.

Consider permeable pavements and surface treatments. Inventory paved areas on your preliminary site plan. Identify where permeable pavements, such as crushed aggregate, turf block, unit pavers, pervious concrete, or pervious asphalt could be substituted for impervious concrete or asphalt paving.

► DISPERSE RUNOFF TO ADJACENT PERVIOUS AREAS

Look for opportunities to direct runoff from impervious areas to adjacent landscaping. The design, including slopes and soils, must reflect a reasonable expectation that an inch of rainfall will soak into the soil and produce no runoff. For example, a lawn or garden depressed 3-4" below surrounding walkways or driveways provides a simple but functional landscape design element.

For sites subject to stormwater treatment requirements only, a 2:1 maximum ratio of impervious to pervious area is acceptable. If flow-control requirements apply, the impervious-to-pervious ratio must be limited to 1:1. Be sure soils will drain adequately.

Under some circumstances, it may be allowable to direct runoff from impervious areas to pervious pavement (for example, from roof downspouts to a parking lot paved with crushed aggregate or turf block). The pore volume of pavement and base course must be enough to retain an inch of rainfall, including runoff from the tributary area. The slopes and soils must be compatible with infiltrating that volume without producing runoff. This solution is most practical on flat sites with permeable soils.

► STORE RUNOFF FOR LATER USE

Use the following instructions and equations for a preliminary screening of the potential for storing runoff for later use on the site. As noted in Chapter 3, this determination of feasibility must be included in your Stormwater Control Plan.

RB-AR32852

First, identify all specific impervious areas (for example, a roof or portion of a roof) from which runoff might be feasibly captured and stored. Consider direction of drainage and potential locations for runoff storage. Calculate the square footage of each area.

Pending Actions
MRP Provision C.3.c.iii.(1) requires the municipal permittees to submit proposed feasibility and infeasibility criteria for runoff storage/reuse and infiltration to the Water Board by May 1, 2011.

Then use the isohyetal diagram (County Public Works Drawing B-166) to estimate the Mean Annual Precipitation (MAP) at the project location.

Apply the following analysis for each specific impervious area identified. You will need to identify the Hydrologic Soil Group (A, B, C, or D) of the native soil underlying each specific impervious area.

Storing for a later use other than irrigation. If treatment-only requirements apply to your project (Table 1-1), use the following regression equation to estimate the storage volume for 80% capture:

Required volume (ft^3) = Impervious area (ft^2) × (0.0032 × MAP (in) + 0.0058)
(Eq 4-1)

This volume must be used (i.e., storage must be fully drained) each 48 hours.

If flow-control requirements also apply, use Equation 4-5, p. 51, to calculate the required storage volume. Referring to Table 4-8, use the factor for the upstream volume V of a "cistern + bioretention" facility. Then use the appropriate equation for the site soil group (Equation 4-17, 4-12, 4-10, or 4-11 from Table 4-9 on p. 51) to calculate the required use rate.

Given the calculated use rate, answer the following question and include the answer in your Stormwater Control Plan:

Is there within or near the project site a reliable, accessible, implementable on-site non-potable demand to fully use this supply during the rainy season?

Consider opportunities to use stored runoff for:

- Toilet flushing.
- Industrial use.
- Washing.
- Other uses.

RB-AR32853

Storing for irrigation use. To be sure of diverting 80% of runoff for irrigation, it is necessary to store runoff during periods when there is little to no irrigation demand (approximately November through April) so that it may be used during the dry season. If treatment-only requirements apply, use the following equation to estimate the required storage:

Required volume (ft^3) = Impervious area (ft^2) × MAP (in)/12 × 0.6) *(Eq 4-2)*

Answer the following questions and include the answers in your Stormwater Control Plan: (1) Is there sufficient landscape within or near the project to ensure demand for this quantity of water each year? (2) If yes, is annual storage of this quantity of water feasible?

If flow-control requirements also apply, seasonal storage is not likely to be a feasible solution and need not be evaluated. Flow-control facilities are designed to store and release runoff flows which occur more rarely than once per year, and the facilities must be drained between storms.

If short-term or seasonal use of runoff from a specific impervious area is feasible, identify that area as a self-retaining drainage management area (DMA), as described on page 45.

Storage of a smaller volume of runoff for later use. Runoff storage that is less than the minimum calculated by Equations 4-1 and 4-2 is encouraged for water conservation. However, facilities for treatment and flow control must be sized independently of and in addition to storage for later use.

► DIRECT RUNOFF TO INTEGRATED MANAGEMENT PRACTICES

The CCCWP has developed design criteria for the following IMPs:

- Bioretention facilities, which can be configured as swales, free-form areas, or planters to integrate with your landscape design.
- Flow-through planters, which can be used near building foundations and other locations where infiltration to native soils is not desired.

RB-AR32854

- Cistern + bioretention facilities, which use an upstream storage volume and metered flow to reduce the required square footage of a bioretention facility or flow-through planter.

- Bioretention + vault facilities, which capture a volume downstream of bioretention and meter outflows.

- Dry wells and other infiltration facilities, which can be used only where soils are permeable. See restrictions on page 20.

See the design sheets at the end of this chapter.

Finding the right location for treatment and flow-control facilities on your site involves a careful and creative integration of several factors:

- To make the most efficient use of the site and to maximize aesthetic value, integrate IMPs with site landscaping. Many local zoning codes may require landscape setbacks or buffers, or may specify that a minimum portion of the site be landscaped. It may be possible to locate some or all of your site's treatment and flow-control facilities within this same area, or within utility easements or other non-buildable areas.

- Planter boxes and bioretention facilities must be level or nearly level all the way around. Linear bioretention facilities (swales) may be gently sloped end to end, but opposite sides must be at the same elevation. Facilities on steeper slopes must be terraced or provided with check dams.

- For effective, low-maintenance operation, locate facilities so drainage into and out of the device is by gravity flow. Pumped systems are feasible, but are expensive, require more maintenance, are prone to untimely failure, and can cause mosquito control problems. Most IMPs require 3 feet or more of head.

- Bioretention facilities and other IMPs require excavations three or more feet deep, which can conflict with underground utilities.

- If the property is being subdivided now or in the future, the facility should be in a common, accessible area. In particular, avoid locating facilities on private residential lots. Even if the facility will serve only one site owner or operator, make sure the facility is located for ready access by inspectors from the local municipality and the Contra Costa Mosquito and Vector Control District.

- The facility must be accessible to equipment needed for its maintenance. Access requirements for maintenance will vary with

RB-AR32855

the type of facility selected. Bioretention facilities will typically need access for the same types of equipment used for landscape maintenance.

To complete your analysis, include in your Stormwater Control Plan a brief narrative documenting the site layout and site design decisions you made. This will provide background and context for how your design meets the quantitative LID design criteria.

Develop and Document Your Drainage Design

The CCCWP's design documentation procedure begins with careful delineation of pervious areas and impervious areas (including roofs) throughout the site. The procedure accounts for how runoff from each delineated area is managed. For areas draining to IMPs, the procedure ensures each IMP is appropriately sized.

The procedure results in a space-efficient, cost-efficient LID design for meeting C.3 requirements on most residential and commercial/industrial developments. The procedure arranges documentation of drainage design and IMP sizing in a consistent format for presentation and review.

This procedure is intended to facilitate, not substitute for, creative interplay among site design, landscape design, and drainage design. Several iterations may be needed to optimize your drainage design as well as aesthetics, circulation, and use of available area for your site.

You should be able to complete the needed calculations using only the project's site development plan, hydrologic soil group (A, B, C, or D) and mean annual precipitation. Mean annual precipitation at locations in Contra Costa County can be determined using isohyetal maps accessible from the CCCWP's C.3 web page.

The CCCWP has created an IMP Sizing Calculator to facilitate the iterative calculations needed to create an optimal site design. The calculator is a stand-alone application and is available, along with instructions for its use, on the CCCWP's C.3 web pages. In addition to performing calculations, the IMP Sizing Calculator formats calculation results into a summary report. The summary report can be attached to your Stormwater Control Plan submittal.

Should you decide to use the calculator, be sure to read through the following instructions, as they include key information you will need for design.

The following formulas and procedures can be used without the sizing calculator to complete calculations and prepare a report suitable for submittal with your Stormwater Control Plan. The same formulas and procedures should be used to check and verify calculations made with the IMP Sizing Calculator.

RB-AR32856

► STEP 1: DELINEATE DRAINAGE MANAGEMENT AREAS

This is the key first step. You must divide the entire project area into individual, discrete Drainage Management Areas (DMAs). Typically, lines delineating DMAs follow grade breaks and roof ridge lines. The Exhibit, tables, text, and calculations in your Stormwater Control Plan will illustrate, describe, and account for runoff from each of these areas.

Use separate DMAs for each surface type (e.g., landscaping, pervious paving, or roofs). Each DMA must be assigned a single hydrologic soil group. Assign each DMA an identification number and determine its size in square feet.

► STEP 2: CLASSIFY DMAS AND DETERMINE RUNOFF FACTORS

Next, determine how drainage from each DMA will be handled. Each DMA will be one of the following four types:

1. Self-treating areas.
2. Self-retaining areas (also called "zero-discharge" areas).
3. Areas that drain to self-retaining areas.
4. Areas that drain to IMPs.

Self-treating areas are landscaped or turf areas that do not drain to IMPs, but rather drain directly off site or to the storm drain system. Examples include upslope undeveloped areas which are ditched and drained around a development and grassed slopes that drain off-site to an existing public street or storm drain. In general, self-treating areas include no impervious areas, unless the impervious area is very small (5% or less) in relationship to the receiving pervious area and slopes are gentle enough to ensure runoff from impervious areas will be absorbed into the vegetation and soil.

Rationale

Pollutants in rainfall and windblown dust will tend to become entrained in the vegetation and soils of landscaped areas, so no additional treatment is needed. It is assumed the self-treating landscaped areas will produce runoff less than or equal to the pre-project site condition.

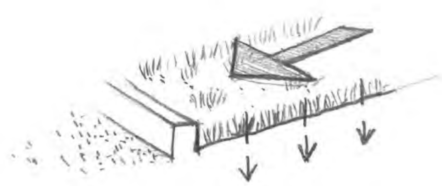

FIGURE 4-1. SELF-TREATING AREAS are entirely pervious and drain directly off-site or to the storm drain system.

Self-retaining areas are designed to retain the first one inch of rainfall without producing any runoff. The technique works best on flat, heavily landscaped sites. It may be used on mild slopes if there is a reasonable expectation that a one-inch rainfall event would produce no runoff.

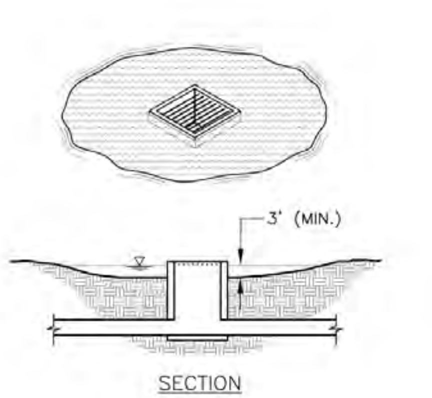

FIGURE 4-2. SELF-RETAINING AREAS. Berm or depress the grade to retain at least an inch of rainfall and set inlets of any area drains at least 3 inches above low point to allow ponding.

To create self-retaining turf and landscape areas in flat areas or on terraced slopes, berm the area or depress the grade into a concave cross-section so that these areas will retain the first inch of rainfall. Grade slopes, if any, toward the center of the pervious area. Inlets of area drains, if any, should be set 3 inches above the low point to allow ponding.

Under some circumstances, pervious pavement (e.g., crushed stone, pervious asphalt, or pervious concrete) can be self-retaining. Adjacent roofs or impervious pavement may drain on to the pervious pavement in the same maximum ratios as described below. A gravel base course four or more inches deep will ensure an adequate proportion of rainfall is infiltrated into native soils (including clay soils) rather than producing runoff. Consult with a qualified engineer regarding infiltration rates, pavement stability, and suitability for the intended traffic.

Drainage from green roofs is considered to be self-retained. An emergency overflow should be provided for extreme events. Areas draining to storage for later use may be considered "self-retained" if facilities with the required storage volumes and release rates are provided and reliable demand is documented in the Stormwater Control Plan.

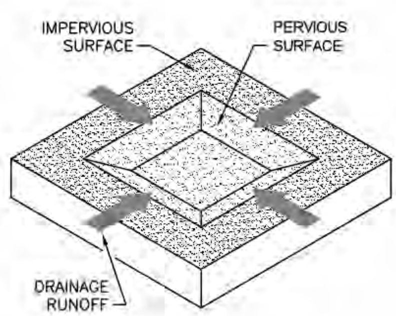

FIGURE 4-3. RELATIONSHIP OF IMPERVIOUS TO PERVIOUS area for self-retaining areas.
Where flow-control requirements apply: ***pervious ≥ impervious***
Where only treatment requirements apply : ***pervious ≥ ½ impervious***

Areas draining to self-retaining areas. Runoff from impervious or partially pervious areas can be managed by routing it to self-retaining pervious areas. For example, roof downspouts can be directed to lawns, and driveways can be sloped toward landscaped areas. The maximum ratio is 2 parts impervious area for every 1 part pervious area if only treatment requirements apply to the development project. If flow-control requirements also apply, the maximum ratio is 1 part impervious area for every 1 part pervious area.

RB-AR32858

The drainage from the impervious area must be directed to and dispersed within the pervious area, and the entire area must be designed to retain an inch of rainfall without flowing off-site. For example, if the maximum ratio of 2 parts impervious area into 1 part pervious area is used, then the pervious area must absorb 3 inches of water over its surface before overflowing to an off-site drain.

A partially pervious area may be drained to a self-retaining area. For example, a driveway composed of unit pavers may drain to an adjacent lawn. In this case, the maximum ratios are, for treatment-only sites:

Derivation of Criteria

A computer model was used to continuously simulate rainfall, infiltration, and runoff at an hourly time-step over 30 years. Results indicate drainage areas using the 1:1 ratio will not exceed pre-project peaks and durations.

(Runoff factor) x (tributary area) $\leq$ 2 x (self-retaining area) *Equation 4-3*

For sites subject to flow-control requirements:

(Runoff factor) x (tributary area) $\leq$ 1 x (self-retaining area) *Equation 4-4*

Use the runoff factors in Table 4-2.

TABLE 4-2. RUNOFF FACTORS for evaluating drainage to self-retaining areas and for sizing IMPs.

Surface	Treatment and Flow Control	Treatment only
Roofs	1.0	1.0
Concrete or Asphalt	1.0	1.0
Pervious Concrete	0.1	0.1
Porous Asphalt	0.1	0.1
Grouted Unit Pavers	1.0	1.0
Solid Unit Pavers Set in Sand	0.5	0.2
Open and Porous Pavers	0.1	0.1
Crushed Aggregate	0.1	0.1
Turfblock	0.1	0.1
Landscape, Group A Soil	0.1	0.1
Landscape, Group B Soil	0.3	0.1
Landscape, Group C Soil	0.5	0.1
Landscape, Group D Soil	0.7	0.1

Prolonged ponding is a potential problem at higher impervious/pervious ratios. In your design, ensure that the pervious area soils can handle the additional run-on and are sufficiently well-drained.

RB-AR32859

Runoff from self-treating and self-retaining areas does not require any further treatment or flow control. Further, there is no requirement for operation and maintenance inspections (see Chapter 6).

Areas draining to IMPs are used to calculate the required size of the IMP. On most densely developed sites—such as commercial and mixed-use developments and small-lot residential subdivisions—most DMAs will drain to IMPs.

The CCCWP has developed sizing factors (ratios of IMP area to impervious DMA area). For each IMP design, factors are provided for:

- Treatment-only.
- Treatment-plus-flow-control.

Treatment-only IMPs are smaller and in some cases are simpler in design.

More than one drainage management area can drain to the same IMP. However, because the minimum IMP sizes are determined by ratio to drainage area size, one drainage area may not drain to more than one IMP. See Figures 4-4 and 4-5.

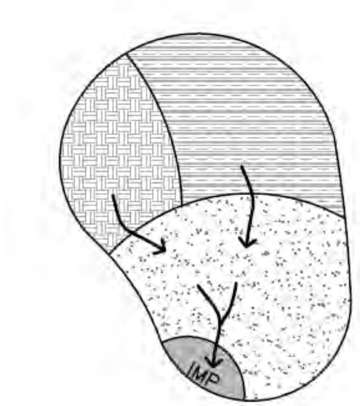

FIGURE 4-4. MORE THAN ONE
Drainage Management Area can drain to a single IMP.

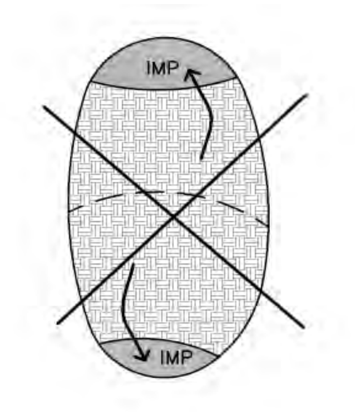

FIGURE 4-5. ONE DRAINAGE
Management Area cannot rain to more than one IMP. Use a grade break to divide the DMA.

Where possible, design site drainage so only impervious roofs and pavement drain to IMPs. This yields a simpler, more efficient design and also helps protect IMPs from becoming clogged by sediment.

If it is necessary to include turf, landscaping, or pervious pavements within the area draining to an IMP, list each surface as a separate DMA. A runoff factor (similar to a "C" factor used in the rational method) is applied to account for the reduction in the quantity of runoff. For example, when a turf or landscaped drainage management area drains to an IMP, the resulting increment in IMP size is:

(pervious area) × (runoff factor) × (sizing factor).

Use the runoff factors in Table 4-2.

► STEP 3: TABULATE DRAINAGE MANAGEMENT AREAS

- Tabulate self-treating areas in the format shown in Table 4-3.
- Tabulate self-retaining areas in the format shown in Table 4-4.
- Tabulate areas draining to self-retaining areas in the format shown in Table 4-5. Check to be sure the total amount of (square feet of tributary area × runoff factor) for all DMAs draining to a receiving self-retaining area is no greater than a 1:1 ratio to the square footage of the receiving self-retaining area itself. A 2:1 ratio may be used on sites not subject to flow-control requirements.

Compile a list of DMAs draining to IMPs. Proceed to Step 4 to check the sizing of the IMPs.

TABLE 4-3. FORMAT FOR TABULATING Self-Treating Areas

DMA Name	*Area (square feet)*

TABLE 4-4. FORMAT FOR TABULATING Self-Retaining Areas

DMA Name	*Area (square feet)*

TABLE 4-5. FORMAT FOR TABULATING Areas Draining to Self-Retaining Areas

DMA Name	*Area (square feet)*	*Post-project surface type*	*Runoff factor*	*Product (Area × runoff factor)[A]*	*Receiving self-retaining DMA*	*Receiving self-retaining DMA Area (square feet) [B]*	*Ratio [A]/[B]*

► STEP 4: SELECT AND LAY OUT IMPS ON SITE PLAN

Select from the IMPs in Table 4-6.

TABLE 4-6. IMP SELECTION

	Treatment Only				Treatment + Flow Control			
Hydrologic Soil Group	A	B	C	D	A	B	C	D
Bioretention	✓	✓	✓	✓	✓	✓	✓	✓
Flow-through Planter	✓	✓	✓	✓			✓	✓
Dry Well	✓	✓			✓	✓		
Cistern + Bioretention					✓	✓	✓	✓
Bioretention + Vault					✓	✓	✓	✓

Descriptions, illustrations, designs, and design criteria for the IMPs are in the design sheets at the end of this chapter. Once you have laid out the IMPs, calculate the square footage you have set aside on your site plan for each IMP.

► STEP 5: CALCULATE MINIMUM IMP AREA AND VOLUMES

For **treatment only**, the minimum IMP areas and volumes are determined by summing up the contributions of each tributary DMA and multiplying times the factors shown in Table 4-7. Criteria for IMPs, including surface reservoir depths, underdrain bedding requirements, and depths and characteristics of planting soils, are in design sheets in this chapter.

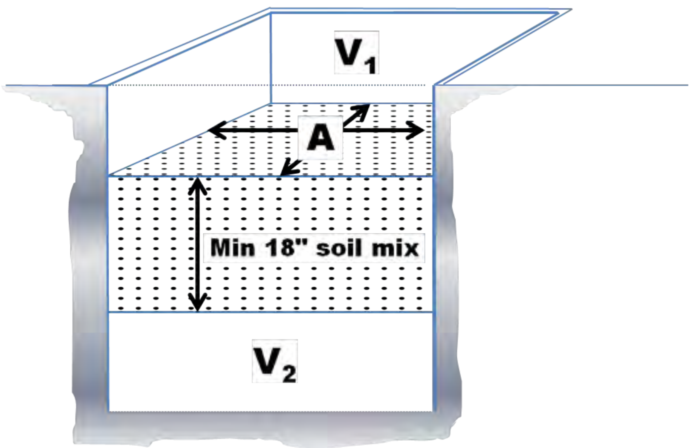
TABLE 4-7. MINIMUM IMP AREAS AND VOLUMES for treatment only

Hydrologic Soil Group	A	B	C	D
Bioretention Facility A	0.04	0.04	0.04	0.04
Flow-through Planter A	0.04	0.04	0.04	0.04
Dry Well (treatment only) A V	0.02 0.068	0.04 0.136	N/A N/A	N/A N/A
A = ft^2 of IMP footprint per ft^2 of tributary area (unitless) V = ft^3 per ft^2 of tributary area (ft.) Apply runoff factors from Table 4-2 for landscape or other pervious surfaces.				

RB-AR32862

For treatment-and-flow-control, the minimum area and minimum storage volumes are found by summing up the contributions of each tributary DMA and applying sizing factors and equations. The configuration of area (A), surface reservoir volume (V_1) and subsurface reservoir volume (V_2) for bioretention facilities and flow-through planters is shown in Figure 4-6.

FIGURE 4-6. A, V_1, and V_2.



Note: V_2 is the free volume. For gravel, multiply by an assumed porosity of 0.4.

V_1 is the floodable volume above the soil layer (that is, the total volume of surface storage when the facility just begins to overflow). V_2 is the storage volume below the soil layer. If gravel fill is used to provide subsurface volume, only the free pore volume is considered and is calculated by multiplying the volume of gravel by an assumed porosity of 0.4.

Sizing factors for treatment-only IMPs do not require any adjustment for differing rainfall patterns. Both area (A) and volume (V_1, V_2) sizing factors for treatment-plus-flow-control IMPs, however, must be adjusted to account for the effects of differing rainfall patterns on pre-project and post-project runoff. Cisterns and dry wells have a single storage volume.

Note these volumes can be configured in a variety of practical combinations of depth and area to best fit into your landscape design. For example, if a bioretention facility were designed with double the minimum value of A, then the depth of the surface reservoir and the depth of the subsurface reservoir could both be halved. Some other strategies to achieve the required minimum values of V1 and V2 are described in the design sheets in this chapter.

The minimum values of A, V_1, and V_2 are calculated by Equation 4-5.

Equation 4-5

$$Min.IMP\ Area\ or\ Volume = \sum \begin{pmatrix} DMA & & DMA \\ Square & \times & Runoff \\ Footage & & Factor \end{pmatrix} \times \begin{pmatrix} IMP \\ Sizing \\ Factor \end{pmatrix} \times \begin{pmatrix} Rain \\ Adjustment \\ Factor \end{pmatrix}$$

IMP Sizing Factors and equations for calculating Rain Adjustment Factors are in Tables 4-8 and 4-9.

TABLE 4-8. FACTORS FOR CALCULATING IMP Area and Storage Volumes (Treatment-and-flow-control)

Facility Design	Soil Group	Area (ft^2/ft^2)	Volume V_1 (ft^3/ft^2)	Volume V_2 (ft^3/ft^2)	Rainfall Adjustment for Surface Area	Rainfall Adjustment for Storage Volume	Maximum Release Rate
Bioretention Facility	A	0.07	0.058	No min.	Eq. 4-6	Eq. 4-6	No orifice
	B	0.11	0.092	No min.	Eq. 4-7	Eq. 4-7	No orifice
	C	0.06	0.050	0.066	Eq. 4-8	Eq. 4-8	Eq. 4-10
	D	0.05	0.042	0.055	Eq. 4-9*	Eq. 4-9	Eq. 4-11
Flow-through Planter	A	Not permitted in "A" soils					
	B	Not permitted in "B" soils					
	C	0.06	0.050	0.066	Eq. 4-8	Eq. 4-8	Eq. 4-10
	D	0.05	0.042	0.055	Eq. 4-9*	Eq. 4-9	Eq. 4-11
Dry Well	A	0.05	0.130	N/A	Eq. 4-6	Eq. 4-6	No release
	B	0.06	0.204	N/A	Eq. 4-7	Eq. 4-7	No release
	C	Not permitted in "C" soils					
	D	Not permitted in "D" soils					
Cistern + Bioretention	A	0.020	0.193	N/A	Eq. 4-13	Eq. 4-6	Eq. 4-17
	B	0.009	0.210	N/A	Eq. 4-14	Eq. 4-7	Eq. 4-12
	C	0.013	0.105	N/A	Eq. 4-15	Eq. 4-8	Eq. 4-10
	D	0.017	0.063	N/A	Eq. 4-16	Eq. 4-9	Eq. 4-11
Bioretention + Vault	A	0.04	N/A	0.096	N/A	Eq. 4-6	No release
	B	0.04	N/A	0.220	N/A	Eq. 4-7	Eq. 4-12
	C	0.04	N/A	0.152	N/A	Eq. 4-8	Eq. 4-10
	D	0.04	N/A	0.064	N/A	Eq. 4-9	Eq. 4-11

A = ft^2 of IMP footprint per ft^2 of tributary impervious area (unitless)
V_1, V_2 = ft^3 per ft^2 of equivalent tributary impervious area (ft.) Cisterns, dry wells, and vaults have only one volume.
*If MAP is 25 inches or greater, this equation will yield a rainfall adjustment less than 0.8 and a bioretention facility area less than 0.04 times the tributary area. In that case, use 0.04 times the tributary area to calculate the minimum allowable bioretention facility area. Equation 4-9 may still be used to adjust minimum required storage volumes.

TABLE 4-9. EQUATIONS TO BE USED in calculating IMP sizes and outflow rates.

Eq. 4-6	$Rain\ Adjustment = \frac{0.0009 \times (MAP_{project\ site} - 20.2) + 0.07}{0.07}$
Eq. 4-7	$Rain\ Adjustment = \frac{-0.0005 \times (MAP_{project\ site} - 20.2) + 0.11}{0.11}$
Eq. 4-8	$Rain\ Adjustment = \frac{-0.0022 \times (MAP_{project\ site} - 20.2) + 0.06}{0.06}$
Eq. 4-9	$Rain\ Adjustment = \frac{-0.0022 \times (MAP_{project\ site} - 20.2) + 0.05}{0.05}$
Eq. 4-10	$Flow\ (cfs\ per\ ft^2) = \frac{0.093 \times (MAP_{project\ site} - 20.2) + 1.42}{10^6}$
Eq. 4-11	$Flow\ (cfs\ per\ ft^2) = \frac{0.122 \times (MAP_{project\ site} - 20.2) + 1.85}{10^6}$
Eq. 4-12	$Flow\ (cfs\ per\ ft^2) = \frac{0.071 \times (MAP_{project\ site} - 20.2) + 0.91}{10^6}$
Eq. 4-13	$Area\ Ratio = \frac{0.151 \times (MAP_{project\ site} - 20.2) + 2.30}{2.30}$
Eq. 4-14	$Area\ Ratio = \frac{0.071 \times (MAP_{project\ site} - 20.2) + 0.91}{0.91}$
Eq. 4-15	$Area\ Ratio = \frac{0.093 \times (MAP_{project\ site} - 20.2) + 1.42}{1.42}$
Eq. 4-16	$Area\ Ratio = \frac{0.122 \times (MAP_{project\ site} - 20.2) + 1.85}{1.85}$
Eq. 4-17	$Flow\ (cfs\ per\ ft^2) = \frac{0.151 \times (MAP_{project\ site} - 20.2) + 2.30}{10^6}$

MAP = Mean Annual Precipitations, determined from Contra Costa County Public Works Figure B-166.

Use the format of Table 4-10 to present the calculations of the required minimum area and volumes of the receiving IMP.

RB-AR32865

TABLE 4-10. FORMAT FOR PRESENTING CALCULATIONS of minimum IMP Areas and Volumes

				IMP Area
				V or V1
				V2
			Orifice Size:	

► STEP 6: DETERMINE IF IMP AREA AND VOLUME ARE ADEQUATE

Sizing and configuring IMPs may be an iterative process. After computing the minimum IMP area using Steps 1–6, review the site plan to determine if the reserved IMP area is sufficient.

If so, the planned IMPs will meet the Provision C.3 sizing requirements. If not, revise the plan accordingly. Revisions may include:

- Reducing the overall imperviousness of the project site.
- Changing the grading and drainage to redirect some runoff toward other IMPs which may have excess capacity.
- Making tributary landscaped DMAs self-treating or self-retaining (may require changes to grading).
- Expanding IMP surface area.

RB-AR32866

- Using a different IMP—the cistern + bioretention and bioretention + vault options were created to achieve flow control in a smaller footprint than bioretention alone. Note these options are more costly and complex to build and operate.

Note revisions to square footage of an IMP typically require a corresponding revision to the square footage of the surrounding or adjacent DMA area.

Once a design with adequate area is achieved, review the IMP configuration to confirm the required minimum volumes are met. If not, revisions to V_1 may include adjusting depth or side slopes and extending the floodable storage area to include adjacent paved or landscaped areas. Revisions to V_2 may include adjusting width or depth, or incorporating buried pipes or arches in the gravel layer.

► STEP 7: COMPUTE MAXIMUM ORIFICE FLOW RATE

This step applies only to treatment-and-flow-control bioretention facilities and flow-through planters built on native Group C and Group D soils, cistern + bioretention-facilities built in all soils, and bioretention + vault facilities built on Group B, Group C, and Group D native soils. See Table 4-6.

Treatment-only bioretention facilities and flow-through planters in Group C and Group D soils are equipped with underdrains, but there is no restriction on the rate of outflow.

For treatment-and-flow-control IMPs, the underdrain has a flow control orifice sized to ensure rates and durations of flows do not exceed pre-project conditions.

For a cistern + bioretention-facility, the flow-control orifice is placed on the outlet from the cistern where it discharges to the bioretention facility. The bioretention facility must have an underdrain in B, C, and D soils, but no flow-control orifice is required on the underdrain.

For a bioretention + vault facility, the flow-control orifice is placed on the discharge from the vault.

Find the appropriate equation in Tables 4-8 and 4-9 to determine the maximum underdrain flow. Sum the total area draining to an IMP (including all tributary DMAs; do not use runoff factors. Compute the maximum orifice release rate, and then apply the orifice equation (Eq. 4-18) to determine the required orifice area. Then use Eq. 4-19 to determine the diameter of the flow control orifice.

Equation 4-18

$$Orifice\ Area\ (in\ \ feet) = \frac{UnderdrainMaxFlow}{c \times \sqrt{64.4 \times H}}$$

RB-AR32867

where c is the orifice coefficient, which may be approximated as 0.6. H is the height of the storage above the orifice.

Equation 4-19

$$Orifice\ Diameter\ (in\ inches) = 12 \times \sqrt{\frac{4 \times Orifice\ Area}{\pi}}$$

STEP 8: COMPLETE YOUR SUMMARY REPORT

Present your IMP sizing calculations in tabular form. Adapt the following format as appropriate to your project. (Note: the IMP Sizing Calculator produces this output for you.) Coordinate your presentation of DMAs and calculation of minimum IMP sizes with the Stormwater Control Plan exhibit (labeled to show delineation of DMAs and locations of IMPs) and with your Stormwater Control Plan report, which should incorporate a brief description of each DMA and each IMP.

Tabulate and sum the total area of all DMAs and IMPs listed and show it is equal to the total project area. This step may include adjusting the square footage of some DMAs to account for area used for IMPs.

Format:

Project Name:

RB-AR32869

Specify Preliminary Design Details

In your Stormwater Control Plan, describe your features and facilities in sufficient detail to demonstrate the area, volume, and other criteria of each can be met within the constraints of the site.

Ensure these details are consistent with preliminary site plans, landscaping plans, and architectural plans submitted with your application for planning and zoning approvals.

Following are design sheets for:

- Self-treating and self-retaining areas
- Pervious pavements
- Bioretention
- Flow-through planter
- Dry well
- Cistern + bioretention
- Bioretention + vault

These design sheets include recommended configurations and details, and example applications, for these features and facilities. **The information in these design sheets must be adapted and applied to the conditions specific to the development project**. Local planning, building, and public works officials have final review and approval authority over the project design.

Keep in mind that proper and functional design of features and facilities is the responsibility of the applicant. Effective operation of facilities throughout the project's lifetime will be the responsibility of the property owner.

Alternatives to LID Design

LID has been found to be feasible for nearly all development sites. If you believe LID design may be infeasible for your development site, review the criteria for the selection of stormwater treatment facilities on page 16. If flow-control requirements apply, also review the options for compliance in Appendix C. Then consult with municipal staff before preparing an alternative design for stormwater treatment or flow-control.

RB-AR32870

Pending Actions
MRP Provision C.3.e.ii.(2) requires the municipal permitees to submit types of projects proposed for consideration of "LID treatment reduction credits" to the Water Board by December

For all alternative designs, the applicant must submit a complete Stormwater Control Plan, including an exhibit showing the entire site divided into discrete Drainage Management Areas, text and tables showing how drainage is routed from each DMA to a treatment facility, and calculations demonstrating the design achieves the applicable design criteria for each facility.

► TREATMENT CONTROL ALTERNATIVES

Here are criteria and design considerations for alternatives that may be used under the conditions allowed by the permit and by the municipality:

Sand Filters. To ensure effectiveness is not compromised by compacting or clogging of the filter surface, sand filters must be maintained frequently.

The following criteria apply to sand filters:

- Calculate the design flow using the rational method with an intensity of 0.2"/hour and the runoff factors for treatment only from Table 4-2.
- To determine the required filter surface area, divide the design flow by an allowable maximum design surface loading rate of 5"/hour.
- The minimum depth of filter media is 18". The media should be washed sand, with gradation similar to that specified for fine aggregate in ASTM C-33.
- The entire filter area must be accessible for easy maintenance without the need to enter a confined space.

A typical filter design includes a gravel drain layer and a perforated pipe underdrain. Filter fabric may be used to prevent the filter media from entering the gravel layer.

The design should not include any permanent pool or other standing water. Instead of including a pretreatment basin, consider the following features in the area tributary to the filter to reduce the potential for filter clogging:

- Limit the size of the Drainage Management Area.
- Include only impervious areas in the DMA.
- Stabilize slopes and eliminate sources of sediment in the DMA.
- Provide screens for trash and leaves at storm drain inlets.

For additional design considerations and details, see *Design of Stormwater Filtering Systems* by Richard A. Claytor and Thomas R. Schueler, The Center for Watershed Protection, 1996, and *California Stormwater BMP Handbooks* Fact Sheet TC-40, Media Filter.

"Wet" Detention Ponds and Constructed Wetlands. The required detention volume is determined using the "Unit Basin Storage Size for 80% Capture" chart available on the CCCWP's website and the mean annual precipitation determined from Contra Costa County Public Works Drawing B-166. . Before proceeding with design, contact the Contra Costa Mosquito and Vector Control District to coordinate the design and plan ongoing inspection and maintenance of the facility for mosquito control. For design considerations and details, see the *California Stormwater Best Management Practices Handbooks*, Fact Sheet TC-20, "Wet Ponds," and Fact Sheet TC-21, "Constructed Wetlands."

Higher-rate surface filters and vault-based filters. As described on page 16, these facilities may be used only in specific types of projects where other alternatives have proven infeasible. For surface filters, the grading and drainage design should minimize the area draining to each unit and maximize the number of discrete drainage areas and units. Proprietary facilities should be installed and maintained consistent with the manufacturer's instructions.

► TREATMENT AND FLOW CONTROL ALTERNATIVES

By using the CCCWP's design procedure, including LID IMPs, your project will meet requirements to minimize imperviousness, treat runoff, and control runoff peaks and durations. If the use of LID IMPs is not feasible, compliance with each of these requirements must be demonstrated individually. Separate facilities may be needed for treatment and for flow control.

If flow-control compliance is achieved by Options #1 or #4 in Appendix C, treatment compliance may be achieved by use of LID IMPs sized using treatment-only criteria.

Cistern with sand filter. Treatment and flow-control requirements can be met by using the cistern, including the volume calculated using Equation 4-5 and the discharge rate calculated using Equation 4-5 and Equation 4-17, 4-12, 4-10 or 4-11, and a sand filter sized to achieve a maximum surface loading rate of 5"/hour based on the calculated maximum discharge of the cistern orifice.*

* This option would not occur under the Program's current policy. All development projects subject to HMP requirements are also subject to LID requirements. It is retained here for information pending further Water Board action.

RB-AR32872

Treatment-and-flow-control detention basin, wet pond, or wetland. A detention basin may be sized and configured to achieve treatment and flow control:

- The facility must contain a volume calculated using the "Unit Basin Storage Size for 80% capture" chart which has a drawdown time of 48 hours. To achieve maximum treatment effectiveness, this volume and discharge rate should be as close to the criteria as possible, neither oversized nor undersized.

- The facility must also match pre-project peak flows and durations as must be shown using the modeling procedure described under Option #3 in Appendix C.

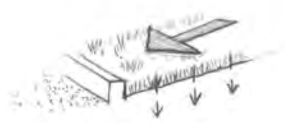
Applicants considering this option should consult with municipal staff and with the Contra Costa Mosquito and Vector Control District before proceeding with design.*

* This option would not occur under current policy. Detention basins and wetlands are suitable for drainage management areas larger than an acre; projects creating or replacing an acre or more of impervious area are always subject to LID requirements.

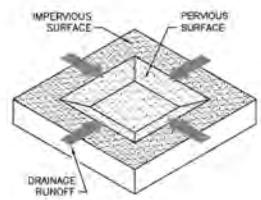
RB-AR32873

Self-Treating and Self-Retaining Areas

► CRITERIA



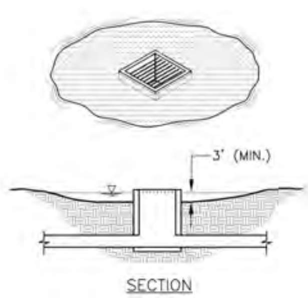
Rainfall on self-treating areas infiltrates or—during intense storms— drains directly off-site or to the storm drain system.



Self-retaining areas are designed to retain the first one inch of rainfall without producing any runoff. During intense storms, runoff may drain off-site, to the storm drain system, or to IMPs.

LID design seeks to manage runoff from roofs and paving so effects on water quality and hydrology are minimized. Runoff from landscaping, however, does not need to be managed the same way. Runoff from landscaping can be managed by creating self-treating and self-retaining areas.

Self-treating areas are natural, landscaped, or turf areas that drain directly off site or to the storm drain system. Examples include upslope undeveloped areas from which runoff is piped or ditched and drained around a development and grassed slopes that drain offsite to a street or storm drain. Self-treating areas may not drain on to adjacent paved areas within the project.



Set overflows and area drain inlets (if any) high enough to ensure ponding (3" deep) over the surface of the self-retaining area.

Where a landscaped area is upslope from or surrounded by paved areas, a self-retaining area (also called a zero-discharge area) may be created. Self-retaining areas are designed to retain the first one inch of rainfall without producing any runoff. The technique works best on flat, heavily landscaped sites. It may be used on mild slopes if there is a reasonable expectation that the first inch of rainfall would produce no runoff.

Best Uses

- Sites with extensive landscaping

Advantages

- No maintenance verification requirement
- Complements site landscaping

Limitations

- Requires substantial square footage
- Grading requirements must be coordinated with landscape design

CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

Areas draining to self retaining areas. Drainage from roofs and paving can be directed to self-retaining areas and allowed to infiltrate into the soil. The maximum ratios are:

Site requirement	Maximum allowable ratio
Treatment only	2 parts impervious: 1 pervious
Treatment and flow-control	1 part impervious: 1 pervious

The self-retaining area must be bermed or depressed to retain an inch of rainfall including the flow from the tributary impervious area.

► DETAILS

Drainage from self-treating areas must flow to off-site streets or storm drains without flowing on to paved areas within the project.

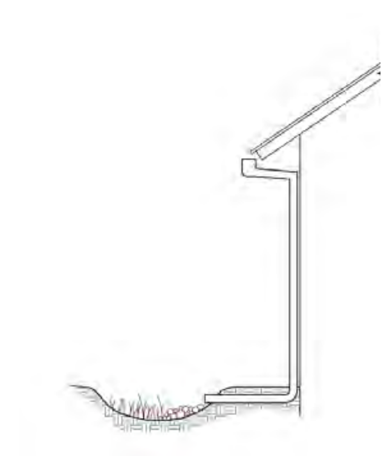
To create self-retaining turf and landscape areas in flat areas or on terraced slopes, berm the area or depress the grade into a concave cross-section so that these areas will retain the first inch of rainfall. Inlets of area drains, if any, should be set 3 inches above the low point to allow ponding.

Pavement within a self-treating area cannot exceed 5% of the total area.

In self-retaining areas, overflows and area drain inlets should be set high enough to ensure ponding over the entire surface of the self-retaining area.

Self-retaining areas should be designed to promote even distribution of ponded runoff over the area.

Leave enough reveal (elevation difference) to accommodate buildup of turf or mulch.



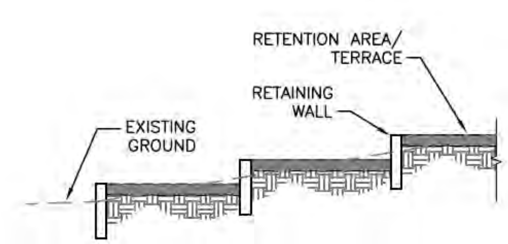
Connecting a roof leader to a self-retaining area. The head from the eave height makes it possible to route roof drainage some distance away from the building.

► APPLICATIONS

Lawn or landscaped areas adjacent to streets can be considered self-treating areas.

Self-retaining areas can be created by depressing lawn and landscape below surrounding sidewalks and plazas.

Runoff from walkways or driveways in parks and park-like areas can sheet-flow to self-retaining areas.



Mild slopes can be terraced to create self-retaining areas.

Roof leaders can be connected to self-retaining areas by piping beneath plazas and walkways. If necessary, a "bubble-up" can be used.

Self-retaining areas can be created by terracing mild slopes. The elevation difference promotes subsurface drainage.

► DESIGN CHECKLIST FOR SELF-TREATING AREAS

- ❒ The self-treating area is at least 95% lawn or landscaping (not more than 5% impervious).
- ❒ Re-graded or re-landscaped areas have amended soils, vegetation, and irrigation as may be required to maintain soil stability and permeability.
- ❒ Runoff from the self-treating area does not enter an IMP or another drainage management area, but goes directly offsite or to the storm drain system.

► DESIGN CHECKLIST FOR SELF-RETAINING AREAS

- ❒ Area is bermed all the way around or graded concave.
- ❒ Slopes do not exceed 4%.
- ❒ Entire area is lawn, landscaping, or pervious pavement (see criteria in Chapter 4).
- ❒ Area has amended soils, vegetation, and irrigation as may be required to maintain soil stability and permeability.
- ❒ Any area drain inlets are at least 3 inches above surrounding grade.

► DESIGN CHECKLIST FOR AREAS DRAINING TO SELF-RETAINING AREAS

- ❒ Ratio of tributary impervious area to self-retaining area is not greater than 2:1 (1:1 if flow-control requirements apply).
- ❒ Roof leaders collect runoff and route it to the self-retaining area.
- ❒ Paved areas are sloped so drainage is routed to the self-retaining area.
- ❒ Inlets are designed to protect against erosion and distribute runoff across the area.

This page intentionally left blank.

Pervious Pavements

► CRITERIA

Impervious roadways, driveways, and parking lots account for much of the hydrologic impact of land development. In contrast, pervious pavements allow rainfall to collect in a gravel or sand base course and infiltrate into native soil.

Pervious pavements are designed to transmit rainfall through the surface to storage in a base course. For example, a 4-inch-deep base course provides approximately 1.6 inches of storage. Runoff stored in the base course infiltrates to native soils over time. Except in the case of solid pavers, the surface course provides additional storage.

When configured to drain directly off-site, areas with the following pervious pavements may be regarded as "self-treating" and require no additional treatment or flow control.

- Pervious concrete
- Porous asphalt
- Porous pavers
- Crushed aggregate (gravel)
- Open pavers with grass or plantings
- Open pavers with gravel
- Artificial turf

Areas with pervious pavements can be self-retaining areas receiving runoff from impervious areas if they are bermed or

Best Uses

- Flat areas
- Areas with permeable native soils
- Low-traffic areas
- Where aesthetic quality can justify higher cost

Advantages

- No maintenance verification requirement
- Variety of surface treatments can complement landscape design

Limitations

- Initial cost
- Placement requires specially trained crews
- Geotechnical concerns, especially in clay soils
- Concerns about pavement strength and surface integrity

CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

depressed to retain the first one inch of rainfall, including runoff from any tributary impervious areas.

Solid unit pavers—such as bricks, stone blocks, or precast concrete shapes—are considered to reduce runoff compared to impervious pavement, when the unit pavers are set in sand or gravel with $\frac{3}{8}$" gaps between the pavers. Joints must be filled with an open-graded aggregate free of fines.

Use the runoff factors in Table 4-2.

► DETAILS

Permeable pavements can be used in clay soils; however, special design considerations, including an increased depth of base course, typically apply and will increase the cost of this option. Geotechnical fabric between the base course and underlying clay soil is recommended.

Permeable pavements are best used on grades from flat to approximately 2%. Installations on steeper grades, particularly on clay soils, require cut-off trenches lateral to the slope to intercept, store, and infiltrate drainage from the base course.

Pavement strength and durability typically determines the required depth of base course. If underdrains are used, the outlet elevation must be a minimum of 3 inches above the bottom elevation of the base course.

Pervious concrete and porous asphalt must be installed by crews with special training and tools. Industry associations maintain lists of qualified contractors.

Parking lots with crushed aggregate or unit pavers may require signs or bollards to organize parking.

▶ DESIGN CHECKLIST FOR PERVIOUS PAVEMENTS

- ❒ No erodible areas drain on to pavement.
- ❒ Subgrade is uniform. Compaction is minimal.
- ❒ Reservoir base course is of open-graded crushed stone. Base depth is adequate to retain rainfall and support design loads.
- ❒ If a subdrain is provided, outlet elevation is a minimum of 3 inches above bottom of base course.
- ❒ Subgrade is uniform and slopes are not so steep that subgrade is prone to erosion.
- ❒ Rigid edge is provided to retain granular pavements and unit pavers.
- ❒ Solid unit pavers are set in sand or gravel with minimum $\frac{3}{8}$" gaps between the pavers. Joints are filled with an open-graded aggregate free of fines.
- ❒ Permeable pavements are installed by industry-certified professionals according to vendor's recommendations.
- ❒ Selection and location of pavements incorporates Americans with Disabilities Act requirements, site aesthetics, and uses.

Bioretention Facilities

Bioretention facilities can rectangular, linear, or nearly any shape.
Photo by Scott Wikstrom

Bioretention detains runoff in a surface reservoir, filters it through plant roots and a biologically active soil mix, and then infiltrates it into the ground. Where native soils are less permeable, an underdrain conveys treated runoff that does not infiltrate to a storm drain or to surface drainage.

Bioretention facilities can be configured as in-ground or above-ground planter boxes, with the bottom open to allow infiltration to native soils underneath. *If infiltration cannot be allowed, use the sizing factors and criteria for the Flow-Through Planter.*

▶ CRITERIA

For development projects subject only to runoff treatment requirements, the following criteria apply:

Parameter	Criterion
Soil mix depth	18 inches minimum
Soil mix requirements	See Appendix B
Soil mix surface area	0.04 times tributary impervious area (or equivalent)
Surface reservoir depth	6 inches minimum; may be sloped to 4 inches where adjoining walkways.
Underdrain	Required in Group "C" and "D" soils. Perforated pipe (PVC SDR 35 or approved equivalent) embedded in gravel ("Class 2 permeable" recommended), connected to storm drain or other accepted discharge point.

Best Uses

- Commercial areas
- Residential subdivisions
- Industrial developments
- Roadways
- Parking lots
- Fit in setbacks, medians, and other landscaped areas

Advantages

- Can be any shape
- Low maintenance
- Can be landscaped

Limitations

- Require 4%-15% of tributary impervious square footage
- Require 3-4 feet of head
- Irrigation may be required

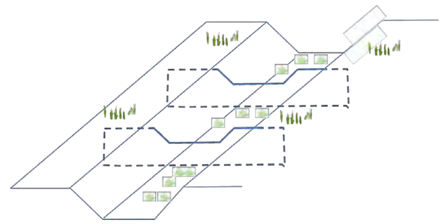
CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

RB-AR32882

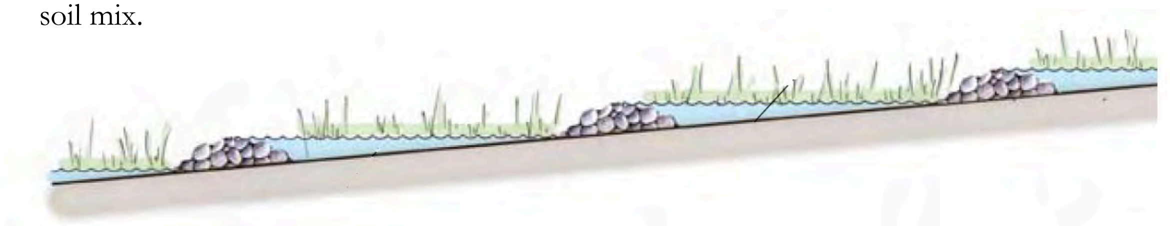
Where flow-control requirements also apply, the bioretention facility mutt be designed to meet the minimum surface area (A), surface volume (V_1), and subsurface volume (V_2) using the sizing factors and equations in Tables 4-8 and 4-9.



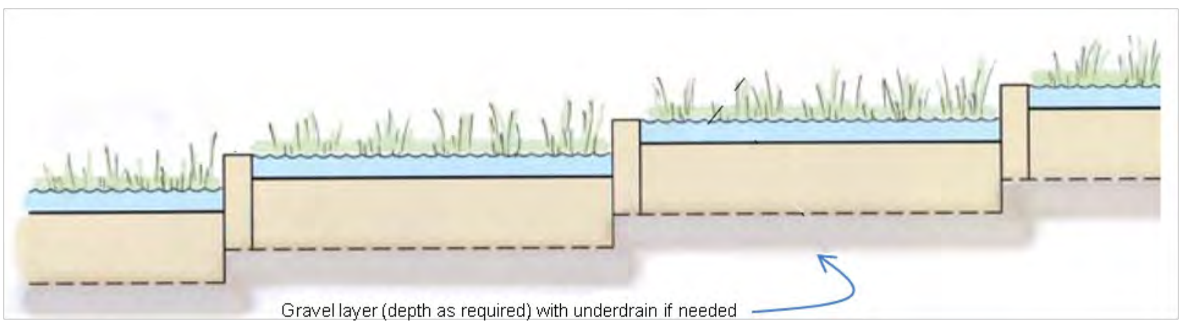
Key check dams into bottom and side slopes.

▶ DETAILS

Plan and Profile. On the surface, a bioretention facility should be one level, shallow basin—or a series of basins. As runoff enters each basin, it should flood and fill throughout before runoff overflows to the outlet or to the next downstream basin. This will help prevent movement of surface mulch and soil mix.

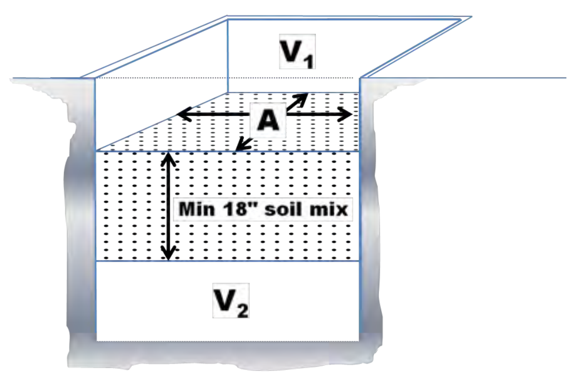


Swale with check dams. Provides limited storage; not suitable for slopes 6% and greater.



Planter on slope provides more storage. Check dams should be keyed into planter sides. (USEPA 2009b)

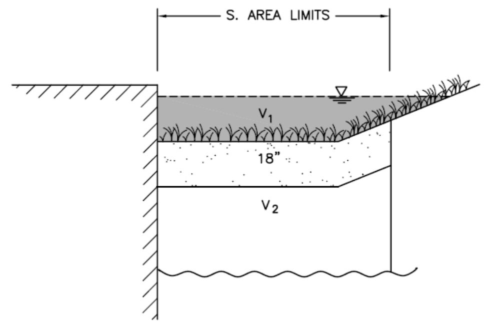
In a linear swale, check dams should be placed for every 4 to 6 inches of elevation change and so that the lip of each dam is at least as high as the toe of the next upstream dam. A similar principle applies to bioretention facilities built as terraced roadway shoulders.



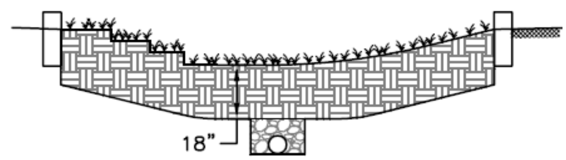
(a) A, V_1 and V_2

Minimum Surface Volume. For a treatment-and-flow-control facility, the sizing factor V_1 is equivalent to the sizing factor A flooded to a 12" depth (10" overflow plus 2" freeboard). Surrounding the facility with a 12" vertical wall minimizes the required surface area as shown in (a). However, alternatives include:

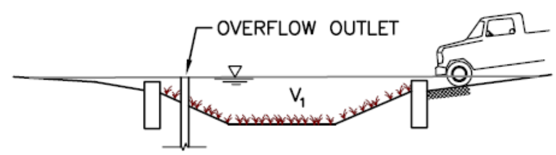
- Increasing the facility area and reducing the surface depth accordingly.
- Sloping the soil mix surface to be deeper than 12" at the middle, but less deep at the edges, so the average 12" depth is achieved (works best on larger facilities).
- Sloping or stepping back the wall as shown in (b) and (c) (requires additional area).
- Allowing shallow flooding on a portion of adjacent landscape or paving when the facility is at peak capacity as shown in (d) (rare and relatively brief events).



(b) Sloped side wall



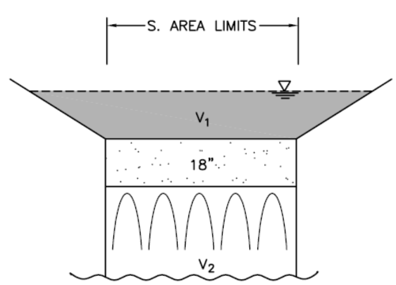
(c) Stepped back side wall



(d) allowing occasional flooding of adjacent landscaping and pavement.

Soil mix. The required soil mix is similar to a loamy sand. It must maintain a minimum percolation rate of 5" per hour throughout the life of the facility, and it must be suitable for maintaining plant life with a minimum of fertilizer use. Typically, on-site soils will not be suitable due to clay content. See Appendix B and check with local staff for further guidance.

Storage and drainage layer. "Class 2 permeable," Caltrans specification 68-1.025, is preferred. Open-graded crushed rock, washed, may be used, but requires 4"-6" washed pea gravel be substituted at the top of the crushed rock gravel layers. Do not use filter fabric to separate the soil mix from the gravel drainage layer or the gravel drainage layer from the native soil.

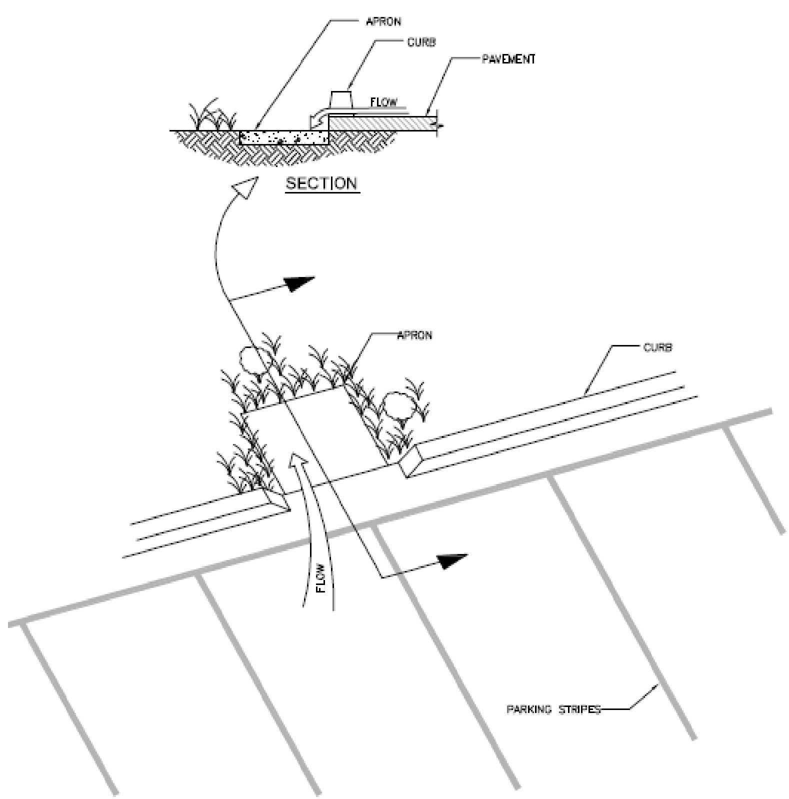


Buried pipes or arches may be used to achieve the required subsurface volume V_2

Minimum subsurface volume. No minimum subsurface volume is required for treatment-only facilities. The gravel layer must be extensive enough and deep enough to ensure the soil mix is well-drained. For treatment-a nd-flow-control facilities where the native soils are Hydrologic Soil Group C or D, the minimum subsurface volume V_2 specified in Table 4-8 is equivalent to the minimum area times a 30" deep layer of gravel of 40% porosity (V_2 is the void space, not the entire volume of gravel.) Note that if the facility area is increased, the required depth is correspondingly decreased. If desired, voids created by buried structures such as pipes or arches may be substituted, as long as the voids are hydraulically interconnected and the minimum subsurface volume calculated by Equation 4-5 is achieved.

Inlets. Paved areas draining to the facility should be graded, and inlets should be placed, so that runoff remains as sheet flow or as dispersed as possible. Curb cuts should be wide (12" is recommended) to avoid clogging with leaves or debris. Allow for a minimum reveal of 4"-6" between the inlet and soil mix elevations to ensure turf or mulch buildup does not block the inlet. In addition, place an apron of stone or concrete, a foot square or larger, inside each inlet to prevent vegetation from growing up and blocking the inlet.

Where runoff is collected in pipes or gutters and conveyed to the facility, protect the landscaping from high-velocity flows with energy-dissipating rocks. In larger installations, provide cobble-lined channels to better distribute flows throughout the facility.



Recommended design details for bioretention facility inlets (see text).

"Bubble ups" can be used to dissipate energy when runoff is piped from roofs and upgradient paved areas.

Underdrains. In locations where native soils beneath the facility are Hydrologic Soil Group A or B, underdrains are optional but municipal reviewers may require them as a preventative against poor drainage. For treatment-only facilities where native soils are Group C or D, a perforated pipe must be bedded in the gravel layer and must terminate at a storm drain or other approved discharge point. Underdrains must be constructed of rigid pipe and provided with a cleanout.

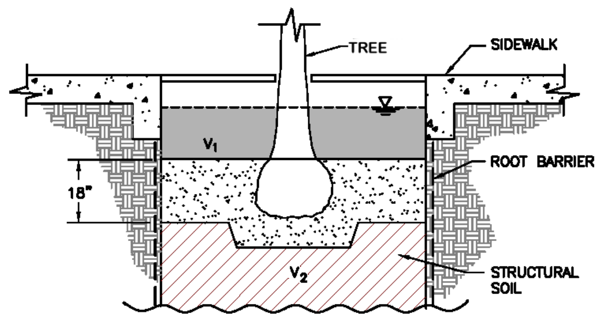
Flow-control orifice. For treatment-and-flow-control facilities, the underdrain must be routed through a device designed to limit flows to that specified in Equation 4-10 or 4-11. Details of combined outlet-and-underdrain facilities are shown on page 76.

Overflow outlets. In treatment-only facilities, overflow outlets must be set high enough to ensure the surface reservoir fills and the entire surface area of soil mix is flooded before the outlet elevation is reached. In swales, this can be achieved with appropriately placed check dams.

In treatment-and-flow-control facilities, the outlet elevation must be set to achieve the minimum surface storage volume calculated using Equation 4-5 and the V_1 sizing factor.

The outlet should be designed to exclude floating mulch and debris.

Vaults, utility boxes and light standards. It is best to locate utilities outside the bioretention facility—in adjacent walkways or in a separate area set aside for this purpose. If utility structures are to be placed within the facility, the locations should be anticipated and adjustments made to ensure the minimum bioretention surface area and volumes are achieved. Leaving the final locations to each individual utility can produce a haphazard, unaesthetic appearance and make the bioretention facility more difficult to maintain.

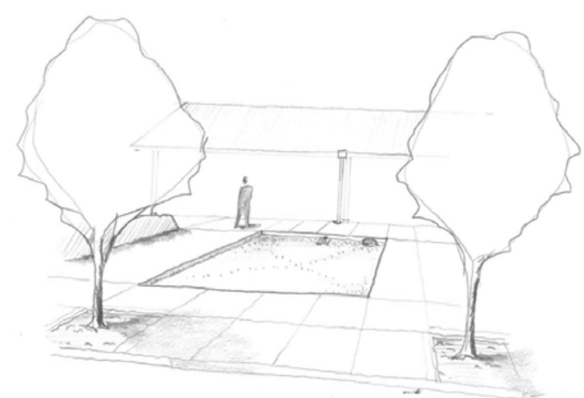


Bioretention facility configured as a tree well.
The root barrier is optional.

Emergency overflow. The site grading plan should anticipate extreme events and potential clogging of the overflow and route emergency overflows safely.

Trees. Bioretention areas can accommodate small or large trees within the minimum areas and volumes calculated by Equation 4-5. Tree canopies intercept rain, and extensive tree roots maintain soil permeability and help retain runoff. Normal maintenance of a bioretention facility should not affect tree lifespan.

The bioretention facility can be integrated with a tree pit of the required depth and filled with structural soil. If a root barrier is used, it can be located to allow tree roots to spread throughout the bioretention facility while protecting adjacent pavement. Locations and planting elevations should be selected to avoid blocking the facility's inlets and outlets as trees mature.



Bioretention facility configured as a recessed decorative lawn with hardscaped edge.

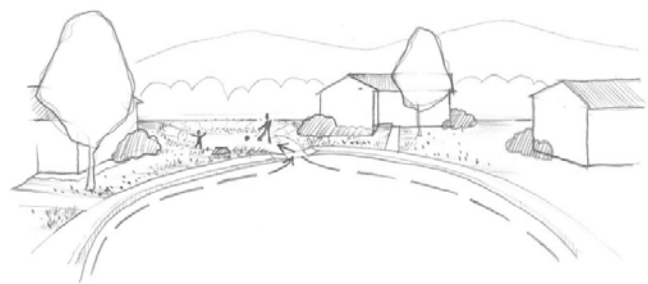
► APPLICATIONS

Multi-purpose landscaped areas. Bioretention facilities are easily adapted to serve multiple purposes. The loamy sand soil mix will support turf or a plant palette suitable to the location and a well-drained soil. See Appendix B for additional guidance on soil, plant selection, and irrigation.

Example landscape treatments:

- Lawn with sloped transition to adjacent landscaping.
- Swale in setback area
- Swale in parking median
- Lawn with hardscaped edge treatment
- Decorative garden with formal or informal plantings
- Traffic island with low-maintenance landscaping
- Raised planter with seating
- Bioretention on a terraced slope

Residential subdivisions. In the design of many subdivisions, it has proven easiest and most effective to drain roofs and driveways to the streets (in the conventional manner) and then drain the streets to bioretention areas, with one bioretention area for each 1 to 6 lots, depending on subdivision layout and topography.



Bioretention facility configured and planted as a lawn/ play area.

Bioretention areas can be placed on one or more separate, dedicated parcels with joint ownership.

Sloped sites. Bioretention facilities must be constructed as a basin or series of basins, with the circumference of each basin level. It may be necessary to add curbs or low retaining walls during final grading if elevations have not been determined with sufficient precision during design.

Design Checklist for Bioretention

- ❒ Volume or depth of surface reservoir meets or exceeds minimum.
- ❒ 18" depth "loamy sand" soil mix with minimum long-term percolation rate of 5"/hour. See Appendix B.
- ❒ Area of soil mix meets or exceeds minimum.
- ❒ Perforated pipe (PVC SDR 35 or approved equivalent) underdrain bedded in "Class 2 perm" with holes facing downward. Connection and sufficient head to storm drain or approved discharge point (except in "A" or "B" soils).
- ❒ No filter fabric.
- ❒ Underdrain has a clean-out port consisting of a vertical, rigid, non-perforated PVC pipe, with a minimum diameter of 4 inches and a watertight cap.
- ❒ Location and footprint of facility are shown on site plan, landscaping plan, and grading plan.
- ❒ Bioretention area is designed as a basin (level edges) or a series of basins, and grading plan is consistent with these elevations. If facility is designed as a swale, check dams are set so the lip or weir of each dam is at least as high as the toe of the next upstream dam.
- ❒ Curb inlets are 12" wide, have 4"-6" reveal and an apron or other provision to prevent blockage when vegetation grows in, and energy dissipation as needed.
- ❒ Overflow connected to a downstream storm drain or approved discharge point.
- ❒ Emergency spillage will be safely conveyed overland.
- ❒ Plantings are suitable to the climate, exposure, and a well-drained soil, and occasional inundation during large storm events.
- ❒ Irrigation system with connection to water supply, on a separate zone.
- ❒ Vaults, utility boxes, and light standards are located outside the minimum soil mix surface area.
- ❒ When excavating, avoid smearing of the soils on bottom and side slopes. Minimize compaction of native soils and "rip" soils if clayey and/or compacted. Protect the area from construction site runoff.

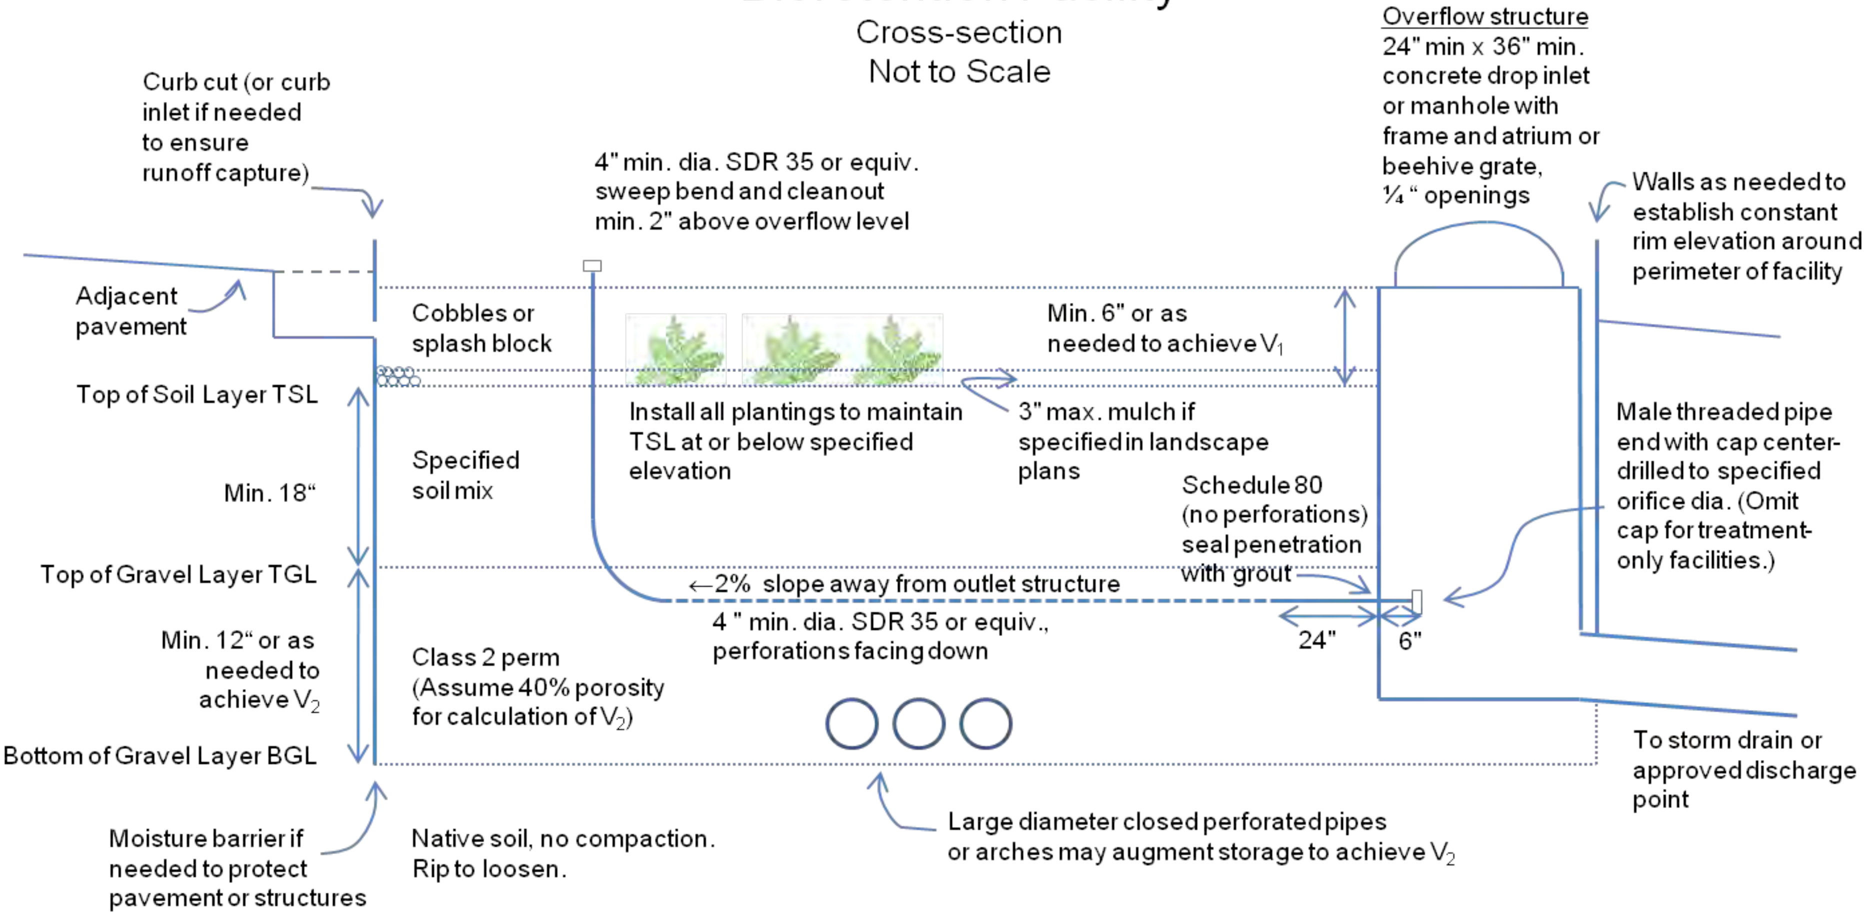
For treatment-and-flow-control facilities only

- ❒ Volume of subsurface storage meets or exceeds minimum.
- ❒ In "C" and "D" native soils, underdrain is connected to discharge through an appropriately sized orifice or other flow-limiting device.

RB-AR32888

Bioretention Facility

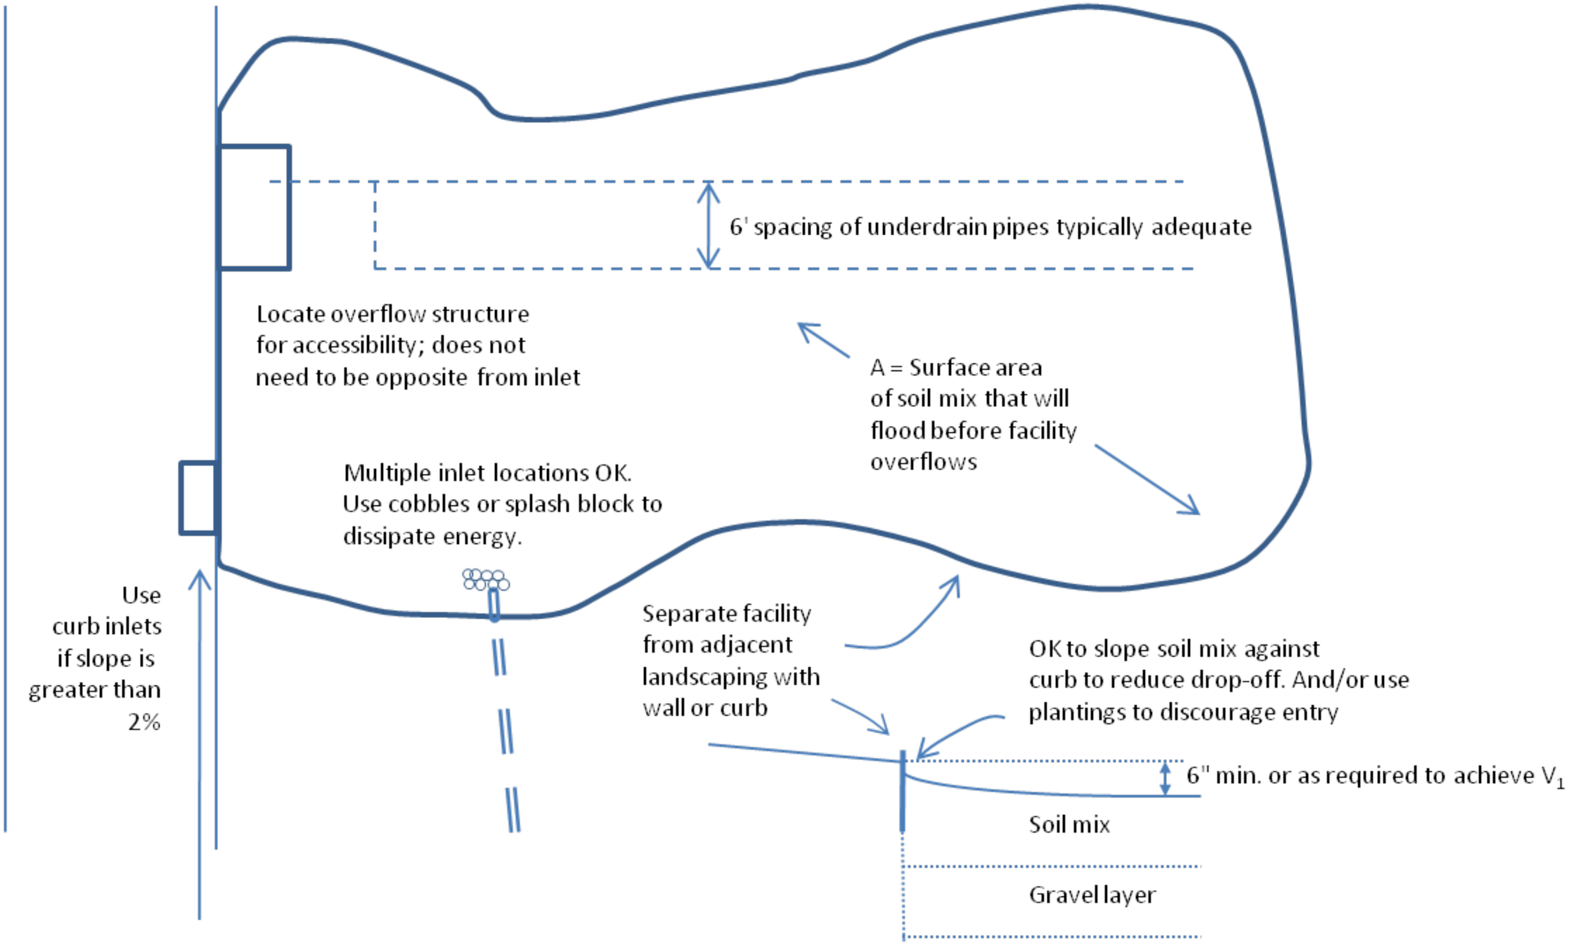
Cross-section
Not to Scale



Notes:
- No liner, no filter fabric, no landscape cloth.
- Maintain BGL. TGL, TSL throughout facility area at elevations to be specified in plan.
- Class 2 perm layer may extend below and underneath drop inlet.
- Preferred elevation of perforated pipe underdrain is near top of gravel layer.
- See Appendix B for soil mix specification, planting and irrigation guidance.
- See Chapter 4 for factors and equations used to calculate V_1, V_2 and orifice diameter.

Bioretention Facility

Plan (Not to Scale)



Note: Call out elevations of curb, pavement, inlet, top of soil layer (TSL), bottom of soil layer (BSL), and bottom of gravel layer (BGL) at all inlets and outlets and at key points along edge of facility.

This page intentionally left blank.

Flow-through Planter

Planter prior to planting

Flow-through planters treat and detain runoff without allowing seepage into the underlying soil. They can be used next to buildings and on slopes where stability might be affected by adding soil moisture.

Flow-through planters typically receive runoff via downspouts leading from the roofs of adjacent buildings. However, they can also be set in-ground or fit into terraces and receive sheet flow from adjacent paved areas.

Flow-through planters may be used where facilities are located on upper-story plazas, adjacent to building foundations, where seasonal high groundwater would be within 10 feet of the facility, where mobilization of pollutants in soil or groundwater is a concern, and where potential geotechnical hazards are associated with infiltration.

5th Edition

The restriction on where flow-through planters may be used applies to sites subject to treatment-only requirements as well as those subject to treatment-plus-flow-control requirements.

Pollutants are removed as runoff passes through the soil layer and is collected in an underlying layer of gravel or drain rock. A perforated-pipe underdrain must be connected to a storm drain or other discharge point. An overflow outlet conveys flows which exceed the capacity of the planter.

► CRITERIA

Treatment only. For development projects subject only to runoff treatment requirements, the following criteria apply:

Best Uses

- Management of roof runoff
- Next to buildings or on building plazas
- Dense urban areas
- Where infiltration is not desired

Advantages

- Can be used on or next to structures and on slopes
- Versatile
- Can be any shape
- Low maintenance

Limitations

- Can be used only on sites with "C" and "D" soils
- Requires underdrain
- Requires 3-4 feet of head

CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

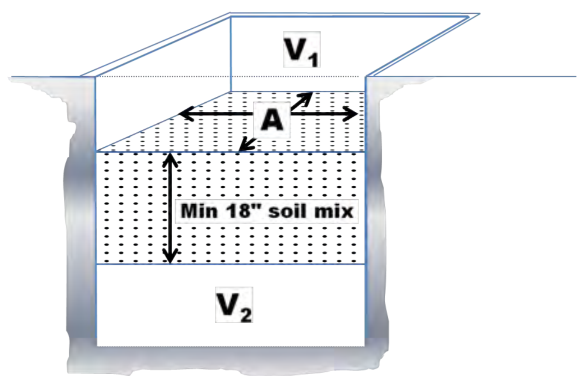
www.cccleanwater.org

Parameter	**Criterion**
Soil mix depth	18 inches minimum
Soil mix	See Appendix B
Soil mix surface area	0.04 times tributary impervious area (or equivalent)
Surface reservoir depth	6" minimum; may be sloped to 4" where adjoining walkways.
Underdrain	Required. Perforated pipe (PVC SDR 35 or approved equivalent) embedded in gravel ("Class 2 permeable" recommended), connected to storm drain or other accepted discharge point.

Treatment and flow control. In addition to the treatment requirements above, the flow-through planter must be designed to meet the minimum surface area (A), surface volume (V_1), and subsurface volume (V_2) calculated using the sizing factors and Equation 4-5. In addition, the planter underdrain must be equipped with an orifice or other device to limit flow to that calculated by Equation 4-10 or 4-11. A suggested outlet design is on page 83.

► DETAILS

Configuration. In a vertical-sided box-like planter for treatment-and-flow-control with the minimum surface area A, the minimum surface volume V_1 can be achieved with an overflow height of 10" (12" total height of walls with 2" of freeboard). The minimum subsurface volume V_2 can be achieved with a gravel (Class 2 permeable) depth of 30". This combination results in a planter approximately 5' high. The planter height can be reduced by incorporating void-creating structures into a shallower Class 2 permeable layer or by increasing the planter area so that the minimum V_2 is achieved.



Parameters for flow-through planters for treatment and flow-control: A, V1, and V2.

The planter must be level. To avoid standing water in the subsurface layer, set the perforated pipe underdrain and orifice as nearly flush with the planter bottom as possible.

Inlets. Protect plantings from high-velocity flows by adding rocks or other energy-dissipating structures at downspouts and other inlets.

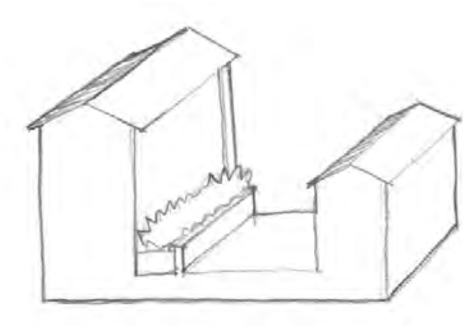
Soil mix. The required soil mix is similar to a loamy sand. It must maintain a minimum percolation rate of 5" per hour throughout the life of the facility, and it must be suitable for maintaining plant life. Typically, on-site soils will not be suitable due to clay content. Various local suppliers have identified mixes which meet these criteria. Check with local staff regarding acceptable soil mixes. See Appendix B for further guidance.

Gravel storage and drainage layer. "Class 2 permeable," Caltrans specification 68-1.025, is recommended. Open-graded crushed rock, washed, may be used, but requires 4"-6" of washed pea gravel be substituted at the top of the crushed rock layer. Do not use filter fabric to separate the soil mix from the gravel drainage layer.

Emergency overflow. The planter design and installation should anticipate extreme events and potential clogging of the overflow and route emergency overflows safely.

► APPLICATIONS

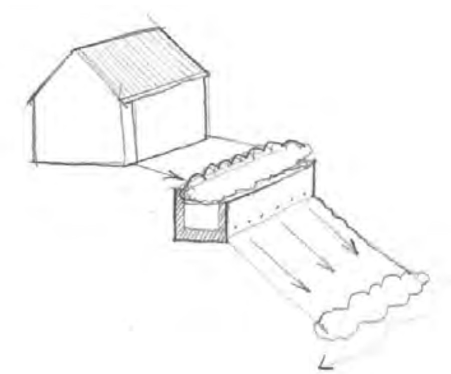
Adjacent to buildings. Flow-through planters may be located adjacent to buildings, where the planter vegetation can soften the visual effect of the building wall. A setback with a raised planter box may be appropriate even in some neo-traditional pedestrian-oriented urban streetscapes.



Flow-through planter on the plaza level of a podium-style development.

At plaza level. Flow-through planters have been successfully incorporated into podium-style developments, with the planters placed on the plaza level and receiving runoff from the tower roofs above. Runoff from the plaza level is typically managed separately by additional flow-through planters or bioretention facilities located at street level.

Steep slopes. Flow-through planters provide a means to detain and treat runoff on slopes that cannot accept infiltration from a bioretention facility. The planter can be built into the slope similar to a retaining wall. The design should consider the need to access the planter for periodic maintenance. Flows from the planter underdrain and overflow must be directed in accordance with local requirements. It is sometimes possible to disperse these flows to the downgradient hillside.



Flow-through planter built into a hillside. Flows from the underdrain and overflow must be directed in accordance with local requirements.

Design Checklist for Flow-through Planter

- ❐ Location is on an upper-story plaza, adjacent to a building foundation, where seasonal high groundwater would be within 10 feet of the facility, where mobilization of pollutants in soil or groundwater is a concern, or where potential geotechnical hazards are associated with infiltration
- ❐ Reservoir depth is 4"-6" minimum.
- ❐ 18" depth "loamy sand" soil mix with minimum long-term infiltration rate of 5"/hour.
- ❐ Surface area of soil mix meets or exceeds minimum.
- ❐ "Class 2 perm" drainage layer.
- ❐ No filter fabric.
- ❐ Perforated pipe (PVC SDR 35 or approved equivalent) underdrain with outlet located flush or nearly flush with planter bottom.
- ❐ Connection with sufficient head to storm drain or discharge point.
- ❐ Underdrain has a clean-out port consisting of a vertical, rigid, non-perforated PVC pipe, with a minimum diameter of 4" and a watertight cap.
- ❐ Overflow outlet connected to a downstream storm drain or approved discharge point.
- ❐ Location and footprint of facility are shown on site plan and landscaping plan.
- ❐ Planter is set level.
- ❐ Emergency spillage will be safely conveyed overland.
- ❐ Plantings are suitable to the climate, exposure, and a well-drained soil.
- ❐ Irrigation system with connection to water supply, on a separate zone.

For treatment-and-flow-control flow-through planters only

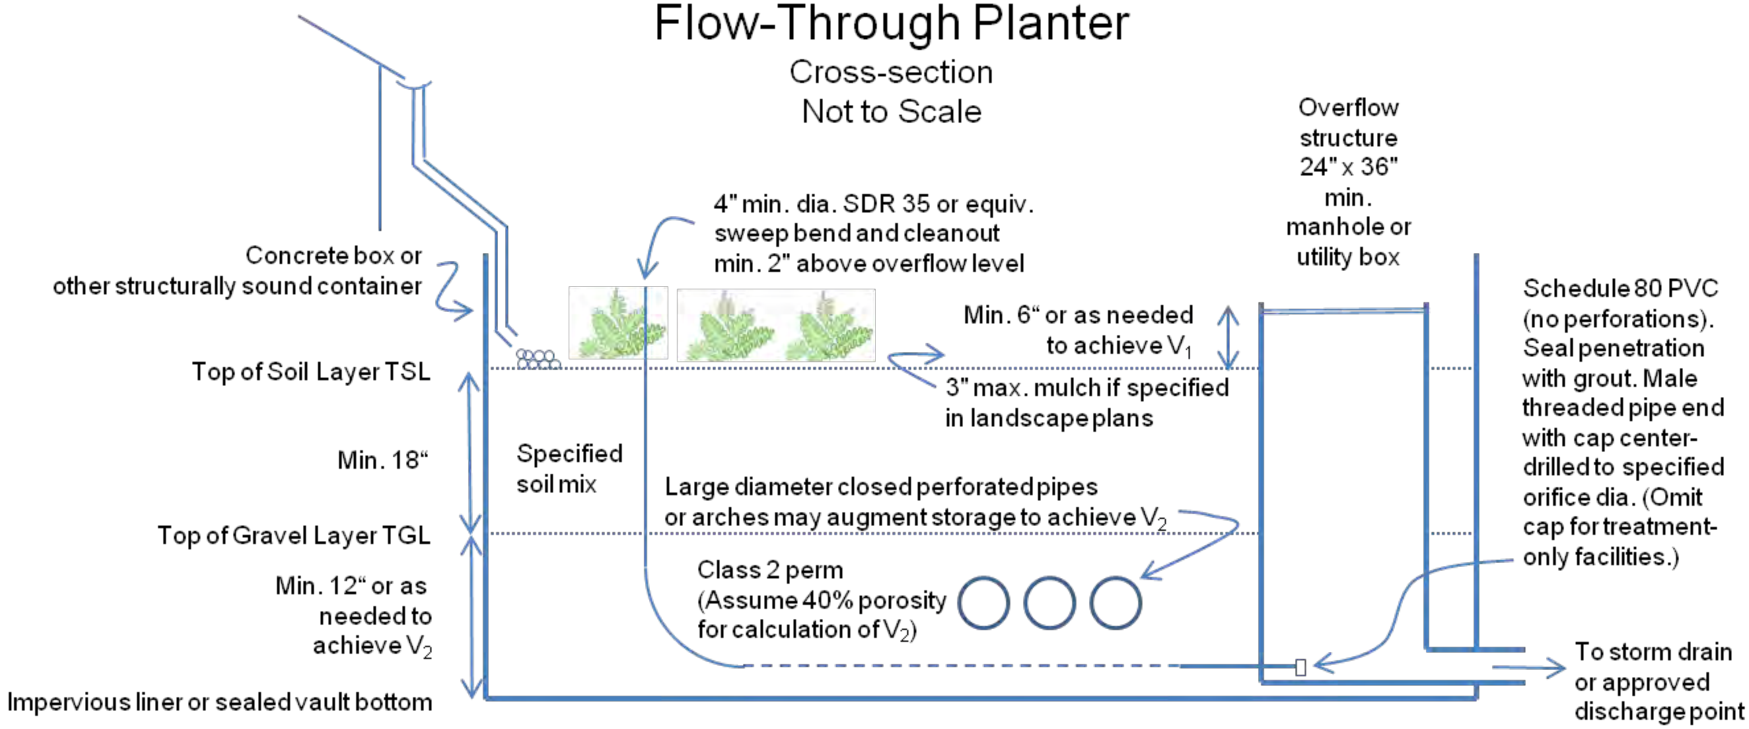
- ❐ Volume of surface storage meets or exceeds minimum.
- ❐ Volume of subsurface storage meets or exceeds minimum.
- ❐ Underdrain is connected via an appropriately sized orifice or other flow-limiting device.

RB-AR32895

Flow-Through Planter

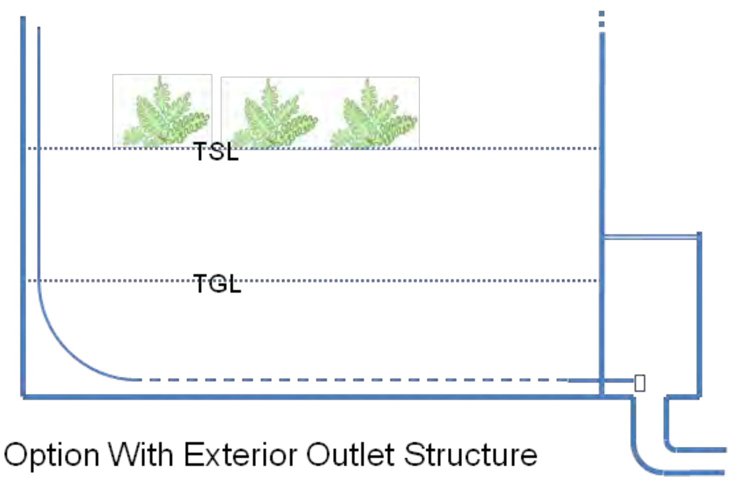
Cross-section

Not to Scale

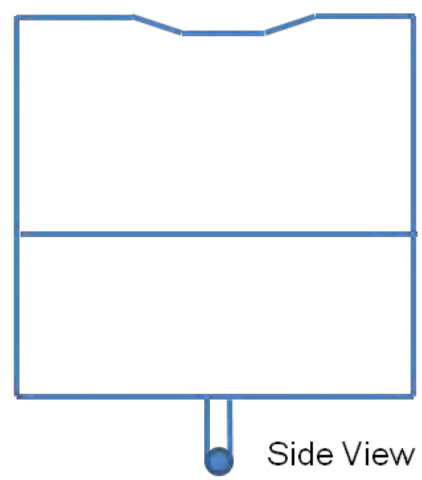


Notes:

- Underdrain to be min. 4" PVC SDR 35 or equiv. with holes facing down.
- Locate underdrain as close as possible to bottom.
- No filter fabric, no landscape cloth.
- See Appendix B for soil specification and planting guidance.
- See Chapter 4 for factors and equations used to calculate V_1, V_2 and orifice diameter



Option With Exterior Outlet Structure suitable for smaller planters



Side View

This page intentionally left blank.

Dry Wells and Infiltration Basins

The typical dry well is a prefabricated structure, such as an open-bottomed vault or box, placed in an excavation or boring. The vault may be empty, which provides maximum space efficiency, or may be filled with rock.

An infiltration basin has the same functional components—a volume to store runoff and sufficient area to infiltrate that volume into the native soil—but is open rather than covered.

► CRITERIA

Dry wells and infiltration basins must be designed with the minimum volume and infiltrative area calculated by Equation 4-5 using the sizing factors in Table 4-8.

Consult with the local municipal engineer regarding the need to verify soil permeability and other site conditions are suitable for dry wells and infiltration basins. Some proposed criteria are on Page 5-12 of Caltrans' 2004 *BMP Retrofit Pilot Study Final Report* (CTSW-RT-01-050).

► DETAILS

Dry wells should be sited to facilitate maintenance and allow for the potential future need for removal and replacement.

In locations where native soils are coarser than a medium sand, the area directly beneath the facility should be over-excavated by two feet and backfilled with sand as a groundwater protection measure.

Best Uses

- Projects on sites with permeable soils

Advantages

- Compact footprint
- Can be installed in paved areas

Limitations

- Can be used only on sites with Group "A" or Group "B" soils
- Requires minimum of 10' from bottom of facility to seasonal high groundwater
- Not suitable for drainage from some industrial areas or arterial roads
- Must be maintained to prevent clogging.
- Typically not as aesthetically pleasing as bioretention facilities

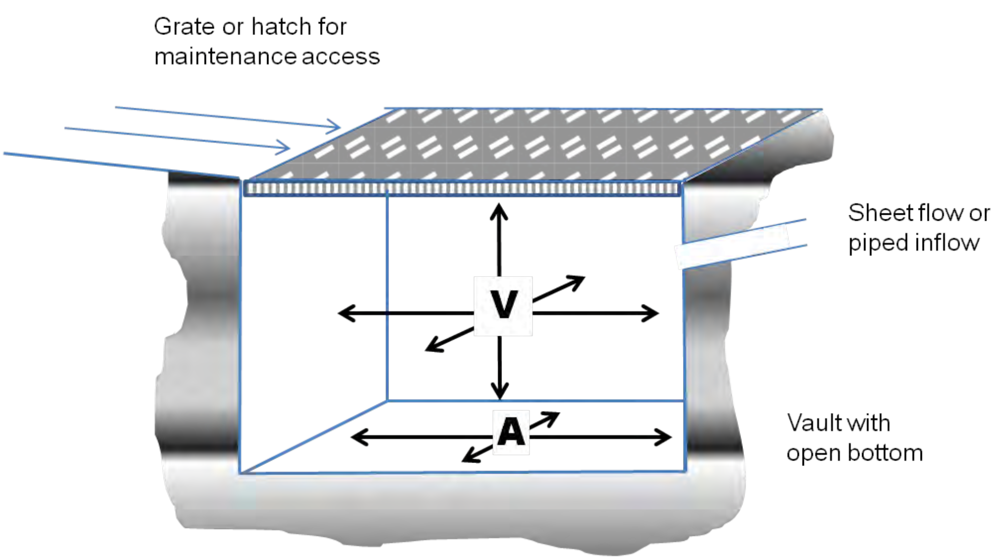
CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

Design Checklist for Dry Wells and Infiltration Basins

- ❐ Volume (V) and infiltrative area (A) meet or exceed minimum.
- ❐ Overflow connected to a downstream storm drain or approved discharge point.
- ❐ Emergency spillage will be safely conveyed overland.
- ❐ Depth from bottom of the facility to seasonally high groundwater elevation is ≥10'.
- ❐ Areas tributary to the facility do not include automotive repair shops; areas subject to high vehicular traffic (25,000 or greater average daily traffic on main roadway or 15,000 or more average daily traffic on intersecting roadway), car washes; fleet storage areas (bus, truck, etc.); nurseries, or other uses that may present an exceptional threat to groundwater quality.
- ❐ Underlying soils are in Hydrologic Soil Group A or B. Infiltration rate is sufficient to ensure a full basin will drain completely within 72 hours. Soil infiltration rate has been confirmed.
- ❐ 10' setback from structures or as recommended by structural or geotechnical engineer



Cistern + Bioretention Facility

In this functional sculpture, a cistern captures roof runoff and drains it slowly to a landscaped area. Photo courtesy of the City of Seattle.

A cistern in series with a bioretention facility or flow-through planter can meet treatment and flow-control requirements where space is limited. The cistern includes an orifice for flow control. The downstream bioretention facility or flow-through planter is sized to accommodate the maximum flow from the cistern orifice.

► CRITERIA

Cistern. Size the cistern using Equation 4-5 and the factors and rainfall adjustment equations in Tables 4-8 and 4-9. The cistern must also include an orifice or other device to limit outflow to the calculated maximum release rate.

Bioretention facility. Size the bioretention facility or flow-through planter using Equation 4-5 and the factors and rainfall adjustment equations in Tables 4-8 and 4-9.

► DETAILS

Preventing mosquito harborage. Cisterns should be designed to drain completely, leaving no standing water. Drains should be located flush with the bottom of the cistern. Alternatively—or in addition—all entry and exit points should be provided with traps or sealed or screened to prevent mosquito entry. Note mosquitoes can enter through

Best Uses

- To meet flow-control requirements in limited space.
- Management of roof runoff
- Dense urban areas

Advantages

- Storage volume can be in any configuration
- Small footprint

Limitations

- Somewhat complex to design, build, and operate
- Requires head for both cistern and bioretention facility

CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

openings $\frac{1}{16}$" or larger and will fly for many feet through pipes as small as ¼".

Exclude debris. Provide leaf guards and/or screens to prevent debris from accumulating in the cistern.

Ensure access for maintenance. Design the cistern to allow for cleanout. Avoid creating the need for maintenance workers to enter a confined space. Ensure the outlet orifice can be easily accessed for cleaning and maintenance.

► APPLICATIONS

Shallow ponding on a flat roof. The "cistern" storage volume can be designed in any configuration, including simply storing rainfall on the roof where it falls and draining it away slowly. In sites with Group "D" soils, the required average depth amounts to about ¾".

Cistern attached to a building and draining to a planter. This arrangement allows the flow-through planter to be constructed at a height as low as 30".

Design Checklist for Cistern + Bioretention

- ❒ Cistern volume meets or exceeds calculated minimum V_1.
- ❒ Cistern outlet with orifice or other flow-control device restricts flow to calculated maximum. A center-drilled threaded cap is suggested for easy maintenance.
- ❒ Cistern outlet is piped to bioretention area or flow-through planter.
- ❒ Bioretention surface area meets or exceeds the calculated minimum.
- ❒ Except for surface area, bioretention facility is designed to the criteria for "treatment only" in the "Bioretention Facility" design sheet (p. 69) or "Flow-through Planter" design sheet (p. 79).
- ❒ Cistern is designed to drain completely and/or sealed to prevent mosquito harborage.
- ❒ Design provides for exclusion of debris and accessibility for maintenance.
- ❒ Overflow connected to a downstream storm drain or approved discharge point.
- ❒ Emergency spillage will be safely conveyed overland.

.

Bioretention + Vault

A bioretention facility in series with a vault can meet treatment and flow-control requirements where space is limited. In this configuration, the bioretention facility is sized to a minimum of 4% of the tributary impervious area. The underdrain and overflow from the bioretention facility are routed to a storage vault, which can be located beneath a plaza, sidewalk, or parking area. An orifice limits the rate of discharge from the vault to the storm drain system.

▶ CRITERIA

Bioretention facility. Size and design the bioretention facility to the treatment-only criteria (see Bioretention Facility design sheet, p. 69.)

Vault. Size the vault using Equation 4-5 and the factors and rainfall adjustment equations in Tables 4-8 and 4-9. The vault must include an orifice or other device to limit outflow.

▶ DETAILS

Preventing mosquito harborage. Vaults should be designed to drain completely, leaving no standing water. Where possible, vaults should have an open bottom to allow infiltration into the native soil. If the vault is sealed, then drains should be located flush with the bottom of the vault. Alternatively—or in addition—all entry and exit points, should be provided with traps or sealed or screened to prevent mosquito entry. Note mosquitoes can enter through openings $\frac{1}{16}$" or larger and will fly for many feet through pipes as small as ¼".

Ensure access for maintenance. Design the vault to allow for cleanout. Avoid creating the need for maintenance workers to enter a confined space. Ensure the outlet orifice can be easily accessed for cleaning and maintenance.

▶ APPLICATIONS

Parking lot. Because the required landscaped bioretention facilities is only 4% of the tributary impervious area, the bioretention component can in many cases be integrated into parking lot medians and islands. The vault component can be located beneath aisles or driveways.

Best Uses

- To meet flow-control requirements in limited space
- Parking lots
- Dense urban areas

Advantages

- Smaller footprint than bioretention facility sized for flow control

Limitations

- Somewhat complex to design, build, and operate
- Requires head for both bioretention facility and vault

CONTRA COSTA CLEAN WATER PROGRAM

Stormwater C.3 Guidebook

www.cccleanwater.org

Multiple bioretention facilities draining to a single vault. Two or more bioretention areas can be connected to a single vault. The vault minimum volume and outlet maximum flow rate are the sum of those calculated for each individual bioretention facility.

Vault with pumped discharge. Where insufficient head exists, vaults may be equipped with pumps to discharge (at a rate no greater than the calculated maximum) to a storm drain or approved discharge point.

Design Checklist for Bioretention + Vault

- ❒ Bioretention facility is designed to the treatment-only criteria in the "Bioretention Facility" design sheet (pp. 69-78).
- ❒ Vault volume meets or exceeds calculated minimum.
- ❒ Vault outlet with orifice or other flow-control device restricts flow to calculated maximum.
- ❒ Bioretention facility underdrain is routed to the vault.
- ❒ Bioretention facility overflow is routed to the vault.
- ❒ Sufficient head exists to convey flow from the underdrain to the vault and from the vault to the discharge point.
- ❒ Vault is designed to drain completely and/or sealed to prevent mosquito harborage.
- ❒ Vault design provides for exclusion of debris and accessibility for maintenance.
- ❒ Vault outlet and overflow are connected to a downstream storm drain or approved discharge point.
- ❒ Emergency spillage will be safely conveyed overland.

Bioretention + Vault

Chapter 5

Construction of Integrated Management Practices

Guidance for preparing construction documents and overseeing construction of Integrated Management Practices

Details of construction are critical to ensuring stormwater facilities work properly. A misplaced inlet, an overflow at the wrong elevation, or the wrong soil mix can make a bioretention facility useless or ineffective even before it comes on-line, and could result in delays to project approvals and additional expense.

Your Stormwater Control Plan must contain enough detail to demonstrate your planned LID features and facilities are feasible and are coordinated with the project site plan, architectural renderings, landscape design, and other information submitted with your application for development approvals. Additional detail must be shown on plans submitted with applications for building and grading permits. During construction, municipal inspectors will check the work against the approved plans.

The Design Sheets in Chapter 4 include details, many of which are critical to proper functioning of the IMP. This chapter describes specific items to be checked during review of construction documents and during construction.

ICON KEY
☞ Helpful Tip
Submittal Requirement
Terms to Look Up
🕮 References & Resources

LID features and facilities have been routinely incorporated into development projects for only a few years. The community of land development professionals and municipal staff continue to compile and analyze "lessons learned" from their experience. The following guidance is based on those lessons.

RB-AR32906

What to Show on Construction Plans

With few exceptions, the plan set should include separate sheets specifically incorporating the features and facilities described in the Stormwater Control Plan. The information on these sheets must be carefully coordinated and made consistent with grading plans, utility plans, landscaping plans, and (in many cases) architectural plans. Consider including the grading plan (screened) as background for the stormwater sheets. It may also be appropriate to show portions of the roofing plan wherever roof ridges define Drainage Management Areas (DMAs).

Design Note

Avoid creating bioretention areas that are deeper than necessary, and avoid having landscaped slopes draining on to the top of bioretention soil. Use surface drainage, such as valley gutters or trench drains, to keep drainage within a few inches below top of pavement. Or use a "bubble up" to bring drainage back up closer to the surface.

► GRADING IS KEY

Municipal staff will typically require plans showing the outline of each bioretention facility or other IMP, along with the delineation of DMAs. Call out elevations, including the following:

- At curb cut inlets, show elevations for top of paving, top of curb, and top of the bioretention soil layer.
- At overflow grates, show the grate elevation and the adjacent top of soil elevation.
- Call out elevations of piped inlets.

Show how DMAs follow grade breaks, consistent with the grading plan and the Stormwater Control Plan.

For treatment-and-flow-control IMPs, demonstrate how the minimum surface volume V_1 is attained by the design.

► SHOW HOW RUNOFF MOVES

As needed for clarity, show the direction of runoff flow across roofs and pavement and into IMPs. For runoff conveyed via pipes or channels, show locations, slopes, and elevations at the beginning and end of each run.

For roof drainage, show the routing of roof leaders. Use drawings or notes to make clear how drainage from leaders is routed under walkways, across pavement, through drainage pipes, or by other means to reach the IMP.

Show pipes or channels connecting the IMP underdrain and overflow to the site drainage system, municipal storm drain system, or other approved discharge point. Call out slopes and key elevations.

► SHOW IMPS IN CROSS-SECTION

Use one or more cross-section drawings to illustrate details and key IMP elevations, including bottom of excavation, top of gravel layer, top of soil layer, edge treatments, inlet elevations, overflow grate elevations, rim elevations, locations of rock for energy dissipation, moisture barriers, and other information. Call out specifications or refer to specifications elsewhere for gravel (Class 2 perm) and soil mix.

Show the arrangement and details of outlet structures, particularly for treatment-plus-flow-control IMPs. The details in the Chapter 4 design sheets for bioretention and flow-through planters may be used as a general guide.

Items to Be Inspected During Construction

Successful construction of IMPs requires attention to detail during every stage of the construction process, from initial layout to rough grading, installation of utilities, construction of buildings, paving, landscaping, and final clean-up and inspection.

Construction project managers need to understand the purpose and function of IMPs and know how to avoid common missteps that can occur during construction. For bioretention facilities, the following operating principles should be noted at a pre-construction meeting.

- Runoff flow from the intended tributary drainage management area must flow into the facility.
- The surface reservoir must fill to its intended volume during high inflows.
- Runoff must filter rapidly through the layer of imported soil mix.
- Filtered runoff must infiltrate into the native soil to the extent possible (or allowable).
- Remaining runoff must be captured and drained to a storm drain or other approved location.

See the model construction inspection checklist on the following pages.

RB-AR32908

IMP CONSTRUCTION CHECKLIST

LAYOUT (to be confirmed prior to beginning excavation)

- ❒ Square footage of the facility meets or exceeds minimum shown in Stormwater Control Plan
- ❒ Site grading and grade breaks are consistent with the boundaries of the tributary Drainage Management Area(s) (DMAs) shown in the Stormwater Control Plan
- ❒ Inlet elevation of the facility is low enough to receive drainage from the entire tributary DMA
- ❒ Locations and elevations of overland flow or piping, including roof leaders, from impervious areas to the facility have been laid out and any conflicts resolved
- ❒ Rim elevation of the facility is laid out to be level all the way around, or elevations are consistent with a detailed cross-section showing location and height of interior dams
- ❒ Locations for vaults, utility boxes, and light standards have been identified so that they will not conflict with the facility
- ❒ Facility is protected as needed from construction-phase runoff and sediment

EXCAVATION (to be confirmed prior to backfilling or pipe installation)

- ❒ Excavation conducted with materials and techniques to minimize compaction of soils within the facility area
- ❒ Excavation is to accurate area and depth
- ❒ Slopes or side walls protect from sloughing of native soils into the facility
- ❒ Moisture barrier, if specified, has been added to protect adjacent pavement or structures.
- ❒ Native soils at bottom of excavation are ripped or loosened to promote infiltration

OVERFLOW OR SURFACE CONNECTION TO STORM DRAINAGE
(to be confirmed prior to backfilling with any materials)

- ❒ Overflow is at specified elevation (typically no lower than two inches below facility rim)
- ❒ No knockouts or side inlets are in overflow riser
- ❒ Overflow location selected to minimize surface flow velocity (near, but offset from, inlet recommended)
- ❒ Grating excludes mulch and litter (beehive or atrium-style grates with ¼" openings recommended)
- ❒ Overflow is connected to storm drain via appropriately sized piping

UNDERGROUND CONNECTION TO STORM DRAIN/OUTLET ORIFICE
(to be confirmed prior to backfilling IMP with any materials)

- ❒ Perforated pipe undedrain (PVC SDR 35 or approved equivalent) is installed with holes facing down
- ❒ Perforated pipe is connected to storm drain (treatment only) or orifice (treatment-and-flow-control)
- ❒ Underdrain pipe is at elevation shown in plans. In facilities allowing infiltration, preferred elevation is above native soil but low enough to be covered by at least 2 inches of Class 2 perm; in sealed planter boxes or bioretention facilities with liners, preferred elevation is as near bottom as possible
- ❒ Cleanouts are in accessible locations and connected via sweeps
- ❒ Structures (arches or large diameter pipes) for additional surface storage are installed as shown in plans and specifications and have the specified volume

(continued)

IMP CONSTRUCTION CHECKLIST (CONTINUED)

DRAIN ROCK/SUBDRAIN (to be confirmed prior to installation of soil mix)

- ❒ Rock is installed as specified. Class 2 permeable, Caltrans specification 68-1.025 recommended, or 4"-6" pea gravel is installed at the top of the crushed rock layer
- ❒ Rock is smoothed to a consistent top elevation. Depth and top elevation are as shown in plans
- ❒ Slopes or side walls protect from sloughing of native soils into the facility
- ❒ No filter fabric is placed between the subdrain and soil mix layers

SOIL MIX

- ❒ Soil mix is as specified. Quality of mix is confirmed by delivery ticket or on-site testing as appropriate to the size and complexity of the facility
- ❒ Mix installed in lifts not exceeding 12"
- ❒ Mix is not compacted during installation but may be thoroughly wetted to encourage consolidation
- ❒ Mix is smoothed to a consistent top elevation. Depth of mix (18" min.) and top elevation are as shown in plans, accounting for depth of mulch to follow and required reservoir depth

IRRIGATION

- ❒ Irrigation system is installed so it can be controlled separately from other landscaped areas. Smart irrigation controllers and drip emitters are recommended
- ❒ Spray heads, if any, are positioned to avoid direct spray into outlet structures

PLANTING

- ❒ Plants are installed consistent with approved planting plan
- ❒ Any trees and large shrubs are staked securely
- ❒ No fertilizer is added; compost tea may be used
- ❒ No native soil or clayey material are imported into the facility with plantings
- ❒ 1"-2" mulch may be applied following planting; mulch selected to avoid floating
- ❒ Final elevation of soil mix maintained following planting
- ❒ Curb openings are free of obstructions

FINAL ENGINEERING INSPECTION

- ❒ Drainage Management Area(s) are free of construction sediment and landscaped areas are stabilized
- ❒ Inlets are installed to provide smooth entry of runoff from adjoining pavement, have sufficient reveal (drop from the adjoining pavement to the top of the mulch or soil mix, and are not blocked
- ❒ Inflows from roof leaders and pipes are connected and operable
- ❒ Temporary flow diversions are removed
- ❒ Rock or other energy dissipation at piped or surface inlets is adequate
- ❒ Overflow outlets are configured to allow the facility to flood and fill to near rim before overflow
- ❒ Plantings are healthy and becoming established
- ❒ Irrigation is operable
- ❒ Facility drains rapidly; no surface ponding is evident
- ❒ Any accumulated construction debris, trash, or sediment is removed from facility

Chapter

6

Operation & Maintenance of Stormwater Facilities

How to prepare a customized Stormwater Facilities Operation & Maintenance Plan for the treatment BMPs on your site.

Stormwater NPDES Permit Provision C.3.e requires each municipality verify stormwater treatment and flow-control facilities are adequately maintained. Municipalities must report the results of inspections to the Water Boards annually.

Facilities you install as part of your project will be incorporated into the local municipality's verification program. This is a six-stage process:

1. Determine who will own the facility and be responsible for its maintenance in perpetuity and document this in your Stormwater Control Plan. The Stormwater Control Plan must also identify the means by which ongoing maintenance will be assured (for example, a maintenance agreement that runs with the land).

2. Identify typical maintenance requirements, allow for these requirements in your project planning and preliminary design, and document the typical maintenance requirements in your Stormwater Control Plan.

3. Prepare an Operation and Maintenance Plan (O&M Plan) for the site incorporating detailed requirements for each treatment and flow-control facility. Typically, a draft O&M Plan must be submitted with the building permit application, and a final O&M Plan must be submitted for review and approved by the municipality prior to building permit final and issuance of a certificate of occupancy. Local requirements vary as to schedule. Check with municipal staff.

RB-AR32912

4. Maintain the facilities from the time they are constructed until ownership and maintenance responsibility is formally transferred.

5. Formally transfer operation and maintenance responsibility to the site owner or occupant. A warranty, secured by a bond, or other financial instrument, may be required to secure against lack of performance due to flaws in design or construction. A typical warranty period will cover two rainy seasons.

6. Maintain the facilities in perpetuity and comply with your municipality's self-inspection, reporting, and verification requirements.

See the schedule for these stages in Table 6-1. Again, local requirements will vary.

TABLE 6-1. SCHEDULE FOR PLANNING operation and maintenance of stormwater treatment and flow-control faciliites

Stage	*Description*	*Where documented*	*Schedule*
1	Determine facility ownership and maintenance responsibility	Stormwater Control Plan	Discuss with planning staff at pre-application meeting
2	Identify typical maintenance requirements	Stormwater Control Plan	Submit with planning & zoning application
3	Develop detailed operation and maintenance plan	O&M Plan	Submit draft with Building Permit application; final due before building permit final and applying for a Certificate of Occupancy
4	Interim operation and maintenance of facilities	As required by municipal O&M verification program	During and following construction including warranty period
5	Formal transfer of operation & maintenance responsibility	As required by municipal O&M verification program	On sale and transfer of property or permanent occupancy
6	Ongoing maintenance and compliance with inspection & reporting requirements	As required by municipal O&M verification program	In perpetuity

RB-AR32913

Stage 1: Ownership and Responsibility

Your Stormwater Control Plan must specify a means to finance and implement maintenance of treatment and flow-control facilities in perpetuity.

Depending on the intended use of your site and the policies of the local municipality, this may require one or more of the following:

- Execution of a maintenance agreement that "runs with the land."
- Creation of a homeowners association (HOA) and execution of an agreement by the HOA to maintain the facilities as well as an annual inspection fee.
- Formation of a new community facilities district or other special district, or addition of the properties to an existing special district.
- Dedication of fee title or easement transferring ownership of the facility (and the land under it) to the municipality.

Ownership and maintenance responsibility for treatment and flow-control facilities should be discussed at the beginning of project planning, typically at the pre-application meeting for planning and zoning review. Experience has shown provisions to finance and implement maintenance of treatment and flow-control facilities can be a major stumbling block to project approval, particularly for small residential subdivisions. (See "Applying C.3 to New Subdivisions" in Chapter 1.)

► PRIVATE OWNERSHIP AND MAINTENANCE

The municipality may require—as a condition of project approval—that a maintenance agreement be executed.

The CCCWP has prepared the following model agreements:

- Operation and Maintenance Agreement for a Single Parcel with a Stormwater Management Facility
- Operation and Maintenance Agreement for Subdivisions with Stormwater Management Facilities
- Operation and Maintenance Agreement for Subdivisions with Stormwater Management Facilities and a Homeowners Association
- CC&R and Subdivision Map Provisions for Subdivisions with Stormwater Management Facilities

RB-AR32914

- CC&R Provisions for Subdivisions with Stormwater Management Facilities and a Homeowners Association

The model agreements "run with the land," so the agreement executed by a developer is binding on the owners of the subdivided lots. The agreement must be recorded prior to conveyance of the subdivided property.

ICON KEY
☞ Helpful Tip
Submittal Requirement
Terms to Look Up
🕮 References & Resources

The model agreements provide the municipality may collect a management and/or inspection fee established by the standard fee schedule. In addition, the agreements provide that, if the property owner fails to maintain the stormwater facility, the municipality may enter the property, restore the stormwater facility to good working order and obtain reimbursement, including administrative costs, from the property owner.

To augment and enforce maintenance requirements, the County established a two-tiered Community Facilities District (Mello-Roos) throughout the unincorporated area to cover the costs of inspections, reporting to the Water Board and, if necessary, code enforcement and maintenance and repair of individual facilities. Some cities and towns may have similar districts.

► TRANSFER TO PUBLIC OWNERSHIP

Municipalities may sometimes choose to have a treatment and flow-control facility deeded to the public in fee or as an easement and maintain the facility as part of the municipal storm drain system. The municipality may recoup the costs of maintenance through a special tax, assessment district, or similar mechanism.

Locating an IMP in a public right-of-way or easement creates an additional design constraint—along with hydraulic grade, aesthetics, landscaping, and circulation. However, because sites typically drain to the street, it may be possible to locate a bioretention swale parallel with the edge of the parcel. The facility may complement, or substitute for, an underground storm drain system.

Local Requirements

Cities, towns, or the County may have requirements that differ from, or are in addition to, this countywide Guidebook. See Appendix A and check with local planning and community development staff.

Even if the facility is to be deeded or transferred to the municipality after construction is complete, it is still the responsibility of the builder to identify general operation and maintenance requirements, prepare a detailed operation and maintenance plan, and to maintain the facility until that responsibility is formally transferred.

RB-AR32915

Stage 2: General Maintenance Requirements

Include in your Stormwater Control Plan a general description of anticipated facility maintenance requirements. This will help ensure that:

- Ongoing costs of maintenance have been considered in your facility selection and design.
- Site and landscaping plans provide for access for inspections and by maintenance equipment.
- Landscaping plans incorporate irrigation requirements for facility plantings.
- Initial maintenance and replacement of facility plantings is incorporated into landscaping contracts and guarantees.

Fact sheets available on the CCCWP C.3 web page describe general maintenance requirements for the types of stormwater facilities featured in the LID Design Guide (Chapter 4). You can use this information to specify general maintenance requirements in your Stormwater Control Plan.

Maintenance fact sheets for conventional stormwater facilities are available in the California Stormwater BMP Handbooks.

Stage 3: Stormwater Facilities O&M Plan

Submit a draft O&M Plan with construction documents when you apply for permits to begin grading or construction on the site. Revise your draft O&M plan in response to any comments from your municipality, and incorporate new information and changes developed during project construction. Submit a revised, final O&M plan before construction is complete.

Your Final Stormwater Control O&M Plan must be submitted to and approved by your municipality before your building permit can be made final and a certificate of occupancy issued.

Your O&M Plan must be kept on-site for use by maintenance personnel and during site inspections. It is also recommended that a copy of the Stormwater Control Plan be kept onsite as a reference.

Municipal Regional Permit Provision C.3.h requires Contra Costa municipalities periodically verify operation and maintenance (O&M) of facilities installed in their jurisdiction. Each year, they must report to the Water Board the facilities inspected that year and the status of each.

RB-AR32916

The final O&M plan should incorporate solutions to any problems noted or changes that occurred during construction. For this reason, the final O&M plan may be submitted at the end of the construction period, before the application for final building permit and Certificate of Occupancy.

► TOOLS AND ASSISTANCE

The following step-by-step instructions—and forms available on the CCCWP website—will help you prepare your Stormwater Control Operation and Maintenance Plan. You may use, adapt, and assemble these documents to prepare your own Plan, which will be customized to the specific needs of your site.

These include:

- A form for stating or updating key contact information.
- An example Inspection and Maintenance Log.
- A format for an independent inspector's annual inspection report.
- An example maintenance matrix including necessary maintenance activities, recommended frequency of inspections of maintenance, and indications that maintenance is necessary.

Additional useful references, including links to additional documents, are available in "References and Resources" at the end of this chapter.

► YOUR O&M PLAN: STEP BY STEP

The following step-by-step guidance will help you prepare each required section of your Stormwater Control Operation and Maintenance Plan.

Preparation of the plan will require familiarity with your stormwater facilities as they have been constructed and a fair amount of "thinking through" plans for their operation and maintenance. The text and forms provided here will assist you, but are no substitute for thoughtful planning.

► STEP 1: DESIGNATE RESPONSIBLE INDIVIDUALS

To begin creating your O&M Plan, your organization must designate and identify:

- The individual who will have direct responsibility for the maintenance of stormwater controls. This individual should be the designated contact with municipal inspectors and should sign self-inspection reports and any correspondence with the municipality regarding verification inspections.

RB-AR32917

- Employees or contractors who will report to the designated contact and are responsible for carrying out BMP operation and maintenance.

- The corporate officer authorized to negotiate and execute any contracts that might be necessary for future changes to operation and maintenance or to implement remedial measures if problems occur.

- Your designated respondent to problems, such as clogged drains or broken irrigation mains, that would require immediate response should they occur during off-hours.

It is recommended to use the form available on the CCCWP website to list this information. Updated contact information must be provided to the municipality immediately whenever a property is sold and whenever designated individuals or contractors change. Complete a new form—and mail or fax a copy to the municipality—whenever this occurs.

Draw or sketch an organization chart to show the relationships of authority and responsibility between the individuals responsible for O&M. This need not be elaborate, particularly for smaller organizations.

Describe how funding for BMP operation and maintenance will be assured, including sources of funds, budget category for expenditures, process for establishing the annual maintenance budget, and process for obtaining authority should unexpected expenditures for major corrective maintenance be required.

Describe how your organization will accommodate initial training of staff or contractors regarding the purpose, mode of operation, and maintenance requirements for the stormwater facilities on your site. Also, describe how your organization will ensure ongoing training as needed and in response to staff changes.

► STEP 2: SUMMARIZE DRAINAGE AND BMPS

Incorporate the following information from your Stormwater Control Plan into your O&M Plan:

- Figures delineating and designating pervious and impervious areas.

- Figures showing locations of stormwater facilities on the site.

- Tables of pervious and impervious areas served by each facility.

Review the Stormwater Control Plan narrative that describes each facility and its tributary drainage area and update the text to incorporate any changes that may have occurred during planning and zoning review, building permit review, or construction. Incorporate the updated text into your O&M Plan.

RB-AR32918

► STEP 3: DOCUMENT FACILITIES "AS BUILT"

Include the following information from final construction drawings:

- Plans, elevations, and details of all facilities. Annotate if necessary with designations used in the Stormwater Control Plan.
- Design information or calculations submitted in the detailed design phase (i.e., not included in the Stormwater Control Plan)
- Specifications of construction for facilities, including sand or soil, compaction, pipe materials and bedding.

In the final O&M Plan, incorporate field changes to design drawings, including changes to any of the following:

- Location and layouts of inflow piping, flow splitter boxes, and piping to off-site discharge
- Depths and layering of soil, sand, or gravel
- Placement of filter fabric or geotextiles (not recommended between soil and gravel layers of bioretention facilities)
- Changes or substitutions in soil or other materials.
- Natural soils encountered (e.g. sand or clay lenses)

► STEP 4: PREPARE CUSTOMIZED MAINTENANCE PLANS

Prepare a maintenance plan, schedule, and inspection checklists (routine, annual, and after major storms) for each facility. Plans and schedules for two or more similar facilities on the same site may be combined.

Use the following resources to prepare your customized maintenance plan, schedule, and checklists.

- Specific information noted in Steps 2 and 3, above.
- Other input from the facility designer, municipal staff, or other sources.
- BMP Operation and Maintenance Fact Sheets (available on the CCCWP C.3 web page).

Note any particular characteristics or circumstances that could require attention in the future, and include any troubleshooting advice.

RB-AR32919

Also include manufacturer's data, operating manuals, and maintenance requirements for any:

- Pumps or other mechanical equipment.
- Proprietary devices used as or in conjunction with BMPs.

Manufacturers' publications should be referenced in the text (including models and serial numbers where available). Copies of the manufacturers' publications should be included as an attachment in the back of your O&M Plan or as a separate document.

To better organize your maintenance plan, consider using the "O&M Maintenance Matrix" available on the Program's C.3 web page to present inspection frequencies, observations, and appropriate maintenance response.

► STEP 5: COMPILE O&M PLAN

Your O&M Plan should follow this general outline:

I. Inspection and Maintenance Log

II. Updates, Revisions and Errata

III. Introduction

  A. Narrative overview describing the site; drainage areas, routing, and discharge points; and treatment and flow control facilities

IV. Responsibility for Maintenance

  A. General

    (1) Name and contact information for responsible individual(s).

    (2) Organization chart or charts showing organization of the maintenance function and location within the overall organization.

    (3) Reference to Operation and Maintenance Agreement (if any). A copy of the agreement should be attached.

    (4) Maintenance Funding

      (a) Sources of funds for maintenance

      (b) Budget category or line item

RB-AR32920

(c) Description of procedure and process for ensuring adequate funding for maintenance

B. Staff Training Program

C. Records

D. Safety

V. Summary of Drainage Areas and Stormwater Facilities

A. Drainage Areas

(1) Drawings showing pervious and impervious areas (copied or adapted from Stormwater Control Plan)

(2) Designation and description of each drainage area and how flow is routed to the corresponding facility.

B. Treatment and Flow Control Facilities

(1) Drawings showing location and type of each facility

(2) General description of each facility (Consider a table if more than two facilities)

(a) Area drained and routing of discharge.

(b) Facility type and size

VI. BMP Design Documentation

A. "As-built" drawings of each facility (design drawings in the draft Plan)

B. Manufacturer's data, manuals, and maintenance requirements for pumps, mechanical or electrical equipment, and proprietary facilities (include a "placeholder" in the draft plan for information not yet available).

C. Specific operation and maintenance concerns and troubleshooting

VII. Maintenance Schedule or Matrix

A. Maintenance Schedule for each facility with specific requirements for:

(1) Routine inspection and maintenance

(2) Annual inspection and maintenance

(3) Inspection and maintenance after major storms

B. Service Agreement Information

Assemble and make copies of your O&M Plan. One or more copies must be submitted to the municipality, and at least one copy kept on-site. Here are some suggestions for formatting the O&M Plan:

- Format plans to 8½" x 11" to facilitate duplication, filing, and handling.
- Include the revision date in the footer on each page.
- Scan graphics and incorporate with text into a single electronic file. Keep the electronic file backed-up so that copies of the O&M Plan can be made if the hard copy is lost or damaged.

► STEP 6: UPDATES

Your Stormwater Control Operation and Maintenance Plan will be a living document.

Operation and maintenance personnel may change; mechanical equipment may be replaced, and additional maintenance procedures may be needed. Throughout these changes, the O&M Plan must be kept up-to-date.

Updates may be transmitted to your municipality at any time. However, at a minimum, updates to the O&M Plan must accompany the annual inspection report. These updates should reference the sections of the Plan being changed and should be placed in reverse chronological order (most recent at the top) in Section II of the binder. If the entire O&M Plan is updated, as it should be from time to time, these updates should be removed from the first section, but may be filed (perhaps in the back of the binder) for possible future reference.

Stage 4: Interim Operation & Maintenance

In accordance with NPDES Permit Provision C.3.e.ii, include the following statement in your Stormwater Control Plan:

> The property owner accepts responsibility for interim operation and maintenance of stormwater treatment and flow-control facilities until such time as this responsibility is formally transferred to a subsequent owner.

RB-AR32922

Applicants will typically be required to warranty stormwater facilities against lack of performance due to flaws in design or construction for a minimum of two rainy seasons following completion of construction. The warranty may need to be secured by a bond or other financial instrument.

Stage 5: Transfer Responsibility

As part of the final O&M plan, note the expected date when responsibility for operation and maintenance will be transferred. Notify your municipality when this transfer of responsibility takes place.

Stage 6: Operation & Maintenance Verification

Each Contra Costa municipality will implement a Stormwater Treatment Measures Operation and Maintenance Verification Program, including periodic site inspections.

Local stormwater ordinances state municipalities may require an annual certificate of compliance certifying operation and maintenance of treatment and flow-control facilities. To obtain a certificate of compliance, the responsible party must request and pay for an inspection from the municipality each year. Alternatively, owners or lessees may arrange for inspection by a private company authorized by the municipality. Based on the results of the inspection, the municipality may issue a certificate, issue a conditional certificate requiring correction of noted deficiencies by a specific date, or deny the certificate.

Some municipalities have established alternative procedures. Check with local staff for requirements.

Appendix B

Soils, Plantings, and Irrigation for Bioretention Facilities

Additional guidance for design and construction of bioretention facilities and flow-through planters

Bioretention facility owners are responsible for ensuring the following standards of performance are achieved throughout the life of the facility:

- Runoff must percolate through the imported bioretention soil mix at a minimum rate of 5" per hour.
- Plantings must be maintained in a healthy condition without use of conventional fertilizers or pesticides.
- Irrigation systems must minimize water use and be controlled to prevent overwatering and underdrain flow during dry weather.

As described in Chapter 5, municipalities will periodically verify these standards continue to be achieved. Operation and maintenance verification is required by the municipalities' stormwater NPDES permit issued by the Regional Water Quality Control Board.

The design criteria and checklists and other guidance in Chapter 4—including the design sheets—aim to ensure new bioretention facilities and planter boxes can reliably meet these standards of performance.

The additional guidance in this Appendix will assist applicants and their designers as they proceed from

Appendix B Contents

RB-AR32928

initial planning through design and construction.

Responsibility for design, construction, maintenance, and performance of stormwater treatment and flow-control facilities and their components rests with the applicant or property owner.

Soils

Soils for bioretention areas must meet two objectives:

- Be sufficiently permeable to infiltrate runoff at a minimum rate of 5" per hour during the life of the facility, and
- Have sufficient moisture retention to support healthy vegetation.

Some native loamy sands may be suitable for both objectives; however, such soils are rare in Contra Costa and are not generally available from suppliers.

ICON KEY
Helpful Tip
Submittal Requirement
Terms to Look Up
References & Resources

Achieving both objectives with an engineered soil mix requires careful specification of soil gradations and a substantial component of organic material (typically compost).

The Contra Costa Clean Water Program has developed specifications for two bioretention soil mixes. Local soil products suppliers have expressed interest in developing "brand-name" mixes that meet these specifications. At their sole discretion, municipal construction inspectors may choose to accept test results and certification for a "brand-name" mix from a soil supplier. A list of suppliers who have submitted test results and certification to the Program is on the Program website. Updated soil and compost test results may be required; tests must be within 120 days prior to the delivery date of the bioretention soil to the project site.

Credit
This Appendix was prepared based on recommendations by WRA Environmental Consultants, Inc.
www.wra-ca.com

Typically, batch-specific test results and certification will be required for projects installing more that 100 cubic yards of bioretention soil.

► SOIL SPECIFICATION

Bioretention soils should meet the following criteria.

1. General Requirements
   Bioretention soil shall achieve a long-term, in-place infiltration rate of at least 5 inches per hour. Bioretention soil shall also support vigorous plant growth.

Bioretention Soil shall be a mixture of topsoil or fine sand, and compost, measured on a volume basis.

Mix A – Topsoil Blend
10%-20% Topsoil
50%-60% Fine Sand
30%-40% Compost

Mix B – Fine Sand Blend
60%-70% Fine Sand
30%-40% Compost

1.1. Submittals
The applicant must submit to the municipality for approval:

A. A sample of mixed bioretention soil.

B. Certification from the soil supplier or an accredited laboratory that the Bioretention Soil meets the requirements of this guideline specification.

C. Grain size analysis results of the fine sand component performed in accordance with ASTM D 422, Standard Test Method for Particle Size Analysis of Soils.

D. Quality analysis results for compost performed in accordance with Seal of Testing Assurance (STA) standards, as specified in Section 1.4.

E. Organic content test results of mixed Bioretention Soil. Organic content test shall be performed in accordance with by Testing Methods for the Examination of Compost and Composting (TMECC) 05.07A, "Loss-On-Ignition Organic Matter Method".

F. A description of the equipment and methods used to mix the sand and compost to produce Bioretention Soil.

G. Provide the following information about the testing laboratory(ies) name of laboratory(ies) including

1) contact person(s)

2) address(es)

3) phone contact(s)

4) e-mail address(es)

5) qualifications of laboratory(ies), and personnel including date of current certification by STA, ASTM, or approved equal

1.2. Sand for Bioretention Soil

A. General
Sand shall be free of wood, waste, coating such as clay, stone dust, carbonate, etc., or any other deleterious material. All aggregate passing the No. 200 sieve size shall be non-plastic.

B. Sand for Bioretention Soil Texture
Sand for Bioretention Soils shall be analyzed by an accredited lab using #200, #100, #40, #30, #16. #8, #4, and 3/8 inch sieves (ASTM D 422 or as approved by municipality), and meet the following gradation:

Sieve Size	Percent Passing (by weight)	
	Min	*Max*
3/8 inch	100	100
No. 4	90	100
No. 8	70	100
No. 16	40	95
No. 30	15	70
No. 40	5	55
No. 100	0	15
No. 200	0	5

Note all sands complying with ASTM C33 for fine aggregate comply with the above gradation requirements.

1.3. Topsoil for Bioretention Soil

A. General
Topsoil shall be free of wood, waste, or any other deleterious material.

B. Topsoil for Bioretention Soil Texture
The overall topsoil texture shall be loamy sand as analyzed by an accredited laboratory. The overall dry weight percentages shall be 60-90% sand, with less than 20% passing than the #200 sieve and less than 5% clay of the total weight with no gravel.

1.4. Composted Material

Compost shall be a well decomposed, stable, weed free organic matter source meeting the standards developed by the US Composting Council (USCC). The product shall be certified through the USCC Seal of Testing Assurance (STA) Program (a compost testing and information disclosure program).

A. Compost Quality Analysis

Before delivery of the soil, the supplier shall submit a copy of lab analysis performed by a laboratory that is enrolled in the US Composting Council's Compost Analysis Proficiency (CAP) program and using approved Test Methods for the Evaluation of Composting and Compost (TMECC). The lab report shall verify:

1) Feedstock Materials shall be specified and include one or more of the following: landscape/yard trimmings, grass clippings, food scraps, and agricultural crop residues.

2) Organic Matter Content: 35% - 75% by dry wt.

3) Carbon and Nitrogen Ratio: C:N < 25:1.

4) Maturity/Stability: shall have a dark brown color and a soil-like odor. Compost exhibiting a sour or putrid smell, containing recognizable grass or leaves, or is hot (120F) upon delivery or rewetting is not acceptable. In addition any one of the following is required to indicate stability:

a. Oxygen Test < 1.3 O2 /unit TS /hr

b. Specific oxy. Test < 1.5 O2 / unit BVS /

c. Respiration test < 8 C / unit VS / day

d. Dewar test < 20 Temp. rise (°C)

e. e. Solvita® > 5 Index value

5) Toxicity: any one of the following measures is sufficient to indicate non-toxicity.

a. NH4- : NO3-N < 3

b. Ammonium < 500 ppm, dry basis

c. Seed Germination > 80 % of control

d. Plant Trials > 80% of control

e. e. Solvita® > 5 Index value

6) Nutrient Content: provide analysis detailing nutrient content including N-P-K, Ca, Na, Mg, S, and B.

a. Total Nitrogen content 0.9% or above preferred.

b. Boron: Total shall be <80 ppm; Soluble shall be <2.5 ppm

7) Salinity: Must be reported; < 6.0 mmhos/cm

8) pH shall be between 6.5 and 8. May vary with plant species.

B. Particle size: 95% passing a 1/2" screen.

C. Bulk density: shall be between 500 and 1100 dry lbs/cubic yard

D. Moisture Content shall be between 30% - 55% of dry solids.

E. Inerts: compost shall be relatively free of inert ingredients, including glass, plastic and paper, < 1 % by weight or volume.

F. Weed seed/pathogen destruction: provide proof of process to further reduce pathogens (PFRP). For example, turned windrows must reach min. 55C for 15 days with at least 5 turnings during that period.

G. Select Pathogens: Salmonella <3 MPN/4grams of TS, or Coliform Bacteria <10000 MPN/gram.

H. Trace Contaminants Metals (Lead, Mercury, Etc.) Product must meet US EPA, 40 CFR 503 regulations.

I. Compost Testing
The compost supplier will test all compost products within 120 calendar days prior to application. Samples will be taken using the STA sample collection protocol. (The sample collection protocol can be obtained from the U.S. Composting Council, 4250 Veterans Memorial Highway, Suite 275, Holbrook, NY 11741 Phone: 631-737-4931, www.compostingcouncil.org). The sample shall be sent to an independent STA Program approved lab. The compost supplier will pay for the test.

► PLACEMENT AND COMPACTION OF BIORETENTION SOILS

Place the bioretention soil in 8" to 12" lifts. Lifts are not to be compacted but are placed to reduce the possibility of excessive settlement. Allow time for natural compaction and settlement prior to planting. Bioretention soil may be watered to encourage compaction.

Plantings

► PLANT SELECTION GUIDELINES

The plants tabulated in Attachment B-1 were selected for the following characteristics:

- Adaptation to Contra Costa's climate
- Drought tolerance
- Adaptation to well-drained soils
- Adaptation to low soil fertility
- Allow infiltration
- Are not invasive weeds
- Do not have aggressive roots

Characteristics noted in the table, including irrigation preferences and ability to tolerate heat, coastal conditions, flooding, and wind should be considered when selecting plants.

This list is not comprehensive, nor will all these species succeed at every site. Selection for a particular site should be done by experienced professionals familiar with the plants and site conditions. Avoid planting species on the California Invasive Plant Council's invasive plant inventory list.

► PLANT INSTALLATION

Trees and large shrubs installed in bioretention facilities are susceptible to blowing over before roots are established. They should be staked securely. Three stakes per tree are recommended at windy sites. Straps should be inspected once or twice a year and removed once trees are established to prevent girdling.

► FERTILIZATION

Due to the potential for conveying nutrients to storm drains, no fertilizer should be added to bioretention facilities or planter boxes. Compost tea, available from various nurseries and garden supply retailers, may be applied at a recommended rate of 5 gallons mixed with 15 gallons of water per acre.

Compost tea can be applied up to two weeks prior to planting and once per year between March and June. Application is not recommended when temperatures are

RB-AR32934

below 50°F or above 90°F or when rain is forecast in the next 48 hours. Additional applications may be made as needed to correct nutrient deficiencies.

► MULCH

Mulch is not required but is recommended for the purpose of retaining moisture, preventing erosion and minimizing weed growth. Aged mulch, also called compost mulch, reduces the ability of weeds to establish, keeps soil moist, and replenishes soil nutrients. Aged mulch can be obtained through soil suppliers or directly from commercial recycling yards. Apply 1" to 2" of composted mulch, once a year, preferably in June following weeding.

Compared to bark mulch, aged mulch has somewhat less of a tendency to float into overflow inlets during intense storms. To reduce mulch entering overflow inlets, it is recommended to use atrium or beehive grates with ¼" openings over overflow inlets.

► WEED CONTROL

Weeds should be controlled primarily by manual methods and soil amendment. In response to problem areas or threatening invasions, corn gluten, white vinegar, vinegar-based products such as Burn-out, or non-selective natural herbicides such as Safer's Sharpshooter may be used.

► PEST AND DISEASE CONTROL

Synthetic pesticides should not be used on bioretention facilities. Beneficial nematodes and non-toxic controls may be used. Acceptable natural pesticides include Safer® Aphid, Whitefly, and Mealybug Killer, Safer® Tree and Shrub Insect Attach, Safer® for Evergreens, and Neem oil.

Irrigation

Bioretention soils have a high infiltration rate and require a different irrigation system design than what is typically used for heavy clay soils in Contra Costa County. Irrigation systems must be designed to minimize water use, avoid overwatering, and prevent the underdrain discharges during dry weather.

Bioretention facilities and planter boxes may need to be irrigated more than once a day. Irrigation controls should allow separate control of times and durations of irrigation for bioretention facilities and planter boxes vs. other landscape areas.

Smart irrigation controllers are strongly encouraged. Available controllers may access weather stations, use sensors to measure soil temperature and moisture, and allow input of soil types, plant types, root depth, light conditions, slope, and usable rainfall.

Drip emitters are strongly recommended over spray irrigation. Use multiple, lower-flow (one-half to two gallons per hour) emitters in fast-draining bioretention soils. Use two or more emitters for perennials, ground covers, and bunchgrasses. Four to six emitters may be needed for larger shrubs and trees. Some types of emitters encourage horizontal distribution of water.

Spray heads must be positioned to avoid direct spray into bioretention facility or planter box outlet structures.

Plant Recommendations for Bioretention Facilities and Planter Boxes

Key

Water Preference-Low/Moderate/High	We have provided recommendations for irrigation. All plants should be watered with more frequency during the first two years after planting. After this establishment period, Low water use plants will only need supplemental irrigation at the hottest and driest sites. Plants with Moderate irrigation needs will be best with occasional supplemental water (once per week to once per month) and plants with High irrigation needs will be best with more frequent watering especially during periods of drought in the cooler seasons.
Water Preference-Summer Irrigation	Plants with a check in this column will not withstand a long period of summer drought without irrigation. Plants with an 'ok' in this column are tolerant of, but do not require, frequent summer irrigation. Plants with nothing in this column may not tolerate summer irrigation.
Tolerates Heat	A check in the heat column indicates that the plant will tolerate hot sites. It should not be confused with a plants preference for sun. Absence of the check indicates it should only be used in areas close to the Bay or other cool sites.
Tolerates Coast	The coast column indicates plants that perform well within 1,000 feet of the ocean or bay. Most of these plants tolerate some amount of salt air, fog, and wind.
Tolerates Flooding	
Tolerates Wind	A check in the wind column means that the plant will tolerate winds of ten miles per hour or more.
CA Native - c	Cultivar of California native. Cultivars offer habitat benefits to native wildlife and are adapted to the local climate but have reduced genetic diversity.
Other Notes - Sunset Climate Zones	Under the Other Notes category, we have indicated appropriate Sunset Climate Zones only for plants that will not do well across all of Contra Costa County. Please refer to the *Sunset Western Garden Book* which defines climate zones in the Bay Area based on elevation, influence of the Pacific Ocean, presence of hills and other factors.

RB-AR32946

Appendix C

Flow Control

Instructions and tools for meeting flow-control (hydrograph modification management) requirements.

Provision C.3.g in the MRP states:

> Stormwater discharges from [applicable] projects shall not cause an increase in the erosion potential of the receiving stream over the pre-projct (existing) condition. Increases in runoff flow and volume shall be managed so that post-proejct runoff shall not exceed pre-project rates and durations, where such increased flow and/or volume is likely to cause increased potential for erosion of creek beds and banks, silt pollutant generation, or other adverse impacts on beneficial uses due to increased erosive force.

As required by a 2003 amendment to the previous NPDES permit, the CCCWP submitted a **Hydrograph Modification Management Plan (HMP)**, including a proposed **flow-control** standard, in July 2005. The flow-control standard was retained in the MRP issued in October 2009. See Attachment C-1.

The flow-control standard applies to projects which create or replace one acre or more of impervious area and for which applications for development approvals are deemed complete after October 14, 2006. See Chapter 1, including Table 1-1.

Appendix C Contents

RB-AR32948

The flow-control standard is preventative: project proponents are encouraged to design their projects so there will be no increase in runoff as compared to the pre-project condition of the development site. The CCCWP has created designs and design aids for Low Impact Development Integrated Management Practices (IMPs) which may be used to achieve this criterion.

However, increased runoff is allowed if it can be demonstrated the increases are unlikely to cause downstream erosion or other impacts on beneficial uses of streams. This may be the case either because the drainage downstream between the project site and the Bay/Delta is in pipes or in channels that are tidally influenced or aggrading. Or the applicant may propose a stream restoration project or projects which fully mitigate the erosion risk.

References & Resources

Comparison of post-project to pre-project flows is based on continuous simulation of runoff over a period of 30 years or more, using local hourly rainfall data, and statistical analysis of peak flow recurrence and of the cumulative duration of flows. See the discussion in Chapter 2.

To demonstrate compliance with the standard, select one of the following four options:

Option 1. Demonstrate the project produces no net increase in impervious area. A simple inventory and accounting of existing and proposed impervious area is required. You will also need to show, qualitatively, that changes to drainage facilities will not increase the efficiency of drainage collection and conveyance.

Option 2. Implement IMPs such as planters, swales, and bioretention areas using the Program's low-impact development site design procedure and facility sizing tool. Applicable criteria, including runoff factors and IMP sizing ratios, have been selected to meet the flow-control standard and are incorporated into the tool.

Option 3. Use a continuous-simulation hydrologic computer model such as USEPA's Hydrologic Simulation Program—Fortran (HSPF) to simulate pre-project and post-project runoff, including the effect of proposed IMPs, detention basins, or other storwmater management facilities. An hourly rainfall record of at least 30 years must be used. Compile flow statistics and produce summary peak flow and flow duration graphics to demonstrate the following criteria are met:

> For flow rates from 10% of the pre-project 2-year runoff event (0.1Q2) to the pre-project 10-year runoff event (Q10), the post-project discharge rates and durations shall not deviate above the pre-project rates and durations by more than 10% over more than 10% of the length of the flow duration curve.

For flow rates from 0.5Q2 to Q2, the post project peak flows shall not exceed pre-project peak flows. For flow rates from Q2 to Q10, post-project peak flows may exceed pre-project flows by up to 10% for a 1-year frequency interval. For example, post-project flows could exceed pre-project flows by up to 10% for the interval from Q9 to Q10 or from Q5.5 to Q6.5, but not from Q8 to Q10.

Option 4. Show that, because of the specific characteristics of the stream receiving runoff from the project site, or because of proposed channel restoration projects, or both, there is little likelihood the cumulative impacts from new development could increase the net rate of stream erosion significantly.

Option 4a. Low Risk. Show all downstream reaches, from the project site to the Bay/Delta, are enclosed pipes, hardened channels, subject to tidal action, or aggrading.

Option 4b. Medium Risk. Use the methods and criteria in this Appendix to confirm each reach downstream from the project to the Bay/Delta meets criteria for the "medium risk" (or "low-risk") classification. Implement an in-stream mitigation project to stabilize stream beds or banks, improve natural stream functions, and/or improve habitat values. The expected environmental benefits of the mitigation project must substantially outweigh the potential impacts of an increase in runoff from the development project.

Option 4c. High Risk. Implement a comprehensive program of in-stream measures to improve stream channel hydrological and ecological functions while accommodating increased flows.

Whichever option is used to demonstrate flow control compliance, projects must also meet the C.3 treatment requirements. Under Option 2, projects can meet both the treatment and flow control requirements by using the low-impact development site design procedure and facility sizing tool. The following sections contain instructions and references to assist you.

Option 1: No increase in impervious area

This option applies to sites which have been previously developed. To use Option 1, simply compare existing to proposed impervious area. You will also need to show, qualitatively, that changes to drainage facilities will not increase the efficiency of drainage collection and conveyance.

► RATIONALE

In many cases, redevelopment of a previously built site will result in decreases in total impervious area—because of setback and landscaping requirements and use

RB-AR32950

of IMPs to treat runoff. Even when sized for stormwater treatment only, IMPs also reduce runoff peaks and durations considerably. The combination of decreased impervious area and IMPs practically assures that post-project runoff will not exceed pre-project peaks and durations.

► MEETING THE REQUIREMENTS

Use a base map or aerial photo.

- Identify existing roofs, paved areas, and other impervious surfaces.
- Delineate the impervious areas, dividing them to facilitate identification of each area and estimation of its square footage.
- Mark each delineated area with a unique identifier and calculated square footage.
- Prepare a table listing each delineated area and its square footage and show a total for the project site.

Refer to the table of areas you prepared for the design of treatment facilities (Chapter 3, Step 3). Sum the impervious areas. Do not include pervious pavements or other pervious surfaces in this sum.

► PREPARING YOUR SUBMITTAL

See the instructions in Chapter 3, Step 2, regarding assessment of site opportunities and constraints to reduce imperviousness and retain or detain site drainage and in Chapter 3, Step 3, regarding design features and surface treatments used to minimize imperviousness. Make sure this information is included in your Stormwater Control Plan.

Include in your Stormwater Control Plan, as an attachment, figure, or exhibit, the marked-up base map or aerial photo showing existing impervious surfaces.

Include in your Stormwater Control Plan the tabulation and sum of existing impervious areas and a comparison to the total proposed impervious area.

If you used the recommended Low Impact Development design procedure (Chapter 4), including sizing IMPs for stormwater treatment only, no further documentation of reduced drainage efficiency is required. If you used a different design procedure to design stormwater treatment facilities, describe the existing and proposed drainage systems and explain, qualitatively or quantitatively:

- Why the time of concentration is increased as a result of the proposed development, and
- Why the total volume of runoff is reduced as a result of the proposed development.

RB-AR32951

Option 2: Integrated Management Practices

Most applicants will find it easiest and most cost-effective to use this option. Use the Program's Design and Documentation Procedure for Low Impact Development (Chapter 4) to select and size swales, planter boxes, bioretention areas, or other IMPs to meet both treatment and flow-control requirements for your project.

► RATIONALE

The Program developed designs and sizing factors for a variety of IMPs. The sizing factor applicable to a particular IMP is dependent on the soil type and rainfall pattern at the development site. The sizing factors were calculated to ensure runoff discharged from the IMP does not exceed the pre-project peaks and durations of runoff from the area tributary to the IMP. See Chapter Two, Chapter Four, and the Program's Hydrograph Modification Management Plan for more background on calculation of the IMP sizing factors.

► MEETING THE REQUIREMENTS

Follow the instructions in Chapter Four to size IMPs. The Program's IMP sizing tool, which is available on the Program's C.3 web page, may be used to facilitate calculations. Select the "Treatment and Flow Control" option to size IMPs to provide both treatment and flow control for site runoff.

► PREPARING YOUR SUBMITTAL

Show calculations as described in Chapter 4. Or incorporate the output from the Program's IMP sizing tool into your Stormwater Control Plan.

Option 3: Model Pre- and Post-Project Runoff

This option is for applicants who wish to design their own flow-control facilities customized to the needs and character of their development projects. It requires the development of a continuous simulation hydrologic model of the project under pre-project and post-project conditions, including the effect of proposed IMPs, detention basins, or other storwmater management facilities

Building a continuous-simulation hydrologic model for a project, and analyzing its output to compare post-project to pre-project hydrology, may be a better option than the Program's IMP designs and sizing factors:

- When it is proposed to use facilities such as detention basins, constructed wetlands, or other facilities for which the Program has not developed sizing factors.
- For large drainage areas with complex drainage, steep slopes, dense vegetation, thin top soil, or other hydrological conditions where a site-

RB-AR32952

specific model can provide a better representation of post-project and pre-project hydrology.

Because of the time and resources required to implement this option, it is typically applicable to larger developments (sites greater than 20 acres).

Projects that select Option 3 to meet the flow control requirements (Table 1-1) must also meet stormwater treatment requirements and LID requirements. Treatment requirements and flow-control requirements can be met via separate facilities in series, or a single facility may be designed for both treatment and flow-control. For example, a pond or wetland can serve as a treatment facility if it detains the required water quality volume for 48 hours and contains suitable design elements. To show the same pond or wetland also meets flow-control requirements, the applicant would need to construct a computer model to compare post-project to pre-project hydrology on the development site, including the hydrologic effects of the proposed pond or wetland.

Development of continuous simulation hydrologic model for a specific development site requires specialized expertise and substantial resources. Municipal staff may require the applicant to establish a force account or similar financial mechanism to provide for independent, third-party review of model documentation and output. Engineering and other design considerations related to flow-control may need to be coordinated with considerations related to flood protection and controlling other potential environmental impacts of the development.

Consult with municipal staff before beginning work on a computer model, and coordinate implementation with environmental agencies from which project approvals must be obtained.

► RATIONALE

Conventionally, drainage facilities have been designed to accommodate peak flows or volumes generated by a specific hypothetical rainfall event (design storm). The design storm is typically characterized by its recurrence interval (e.g., a 10-year or 100-year storm). Conventional drainage facilities, including flood-control basins, are designed for protection from flooding, not to protect streams from erosion.

As regulatory agencies began to develop criteria to protect streams from accelerated erosion caused by urbanization and increased imperviousness, many agencies limited the allowable increase in peak discharge associated with a specific design storm. The science of fluvial geomorphology showed that, for stable streams in undeveloped watersheds, the "channel forming flow"—the event with the most capability to move sediment—recurred approximately every 1-2 years. Initial criteria for stream protection focused on designing facilities to control peak flows from runoff events at and near this magnitude.

Further analysis of urbanizing streams indicated increases in the frequency and duration of lower flows can also contribute to accelerated stream erosion. Rainfall

RB-AR32953

events which would produce little or no runoff in a pre-development watershed produce significant runoff from impervious surfaces—and that runoff is typically piped directly to streams. To fully protect streams in urbanizing watersheds from accelerated erosion, it may be necessary to control the entire regime of large and small flows.

Continuous simulation models, which typically use as input hourly rainfall data over 30 years or more, can simulate the entire runoff flow regime under existing and post-project conditions. Two sets of criteria are generally used to compare modeled pre-project and post-project flows over the long term: peak flows for each event contained in the simulation, and duration of flows at the full range of simulated flow rates.

Regardless of the hydrologic calculation method used, estimation of runoff from a particular development site requires selection of appropriate parameters to represent the quantity of rainfall that runs off versus that which puddles, infiltrates into the ground, or is absorbed by vegetation. The rational method uses "C" factors and the SCS methodology uses curve numbers to represent these relationships. Continuous simulation models, such as USEPA's Hydrologic Simulation Program—Fortran (HSPF), use a more complex suite of parameters to characterize soils and vegetation. Values for these parameters can be calibrated to stream flow data for whole watersheds. For individual development sites, or where stream flow data is not available, appropriate values for each parameter must be estimated.

► MEETING THE REQUIREMENTS

After discussing the process for technical review with municipal staff, build and run a continuous-simulation hydrologic model of the existing site and the proposed development including detention/retention facilities. Procedures and parameters must be consistent with the instructions in the Attachment 3 to the CCCWP's HMP. Prepare a statistical analysis of the results as described in that guidance.

► PREPARING YOUR SUBMITTAL

Provide a detailed report on the hydrologic modeling that includes, at a minimum:

- An **introduction** that provides a description of existing site conditions, land uses and land cover and a description of the proposed project.

- Separate **site maps** for pre-project and post-project conditions. The site maps should delineate the sub-basins used to characterize the site within the model under pre-project and post-project conditions and show a basin number or other identifier for each sub-basin. Show on your maps: hydraulic structures, roadways, drainageways, stormwater management facilities, and topography; the post-project map should also include proposed grading and site layout.

- An estimate of the Mean Seasonal Precipitation at the project site and identification of the long-term rainfall data set used in the simulation. The data should be from the Contra Costa gauge site with the most similar mean seasonal precipitation to the project site, as indicated by the Contra Costa County Public Works Department Mean Seasonal Isohyets Map (rainfall data and Isohyetal map available on the Program's web site).

- A table of model parameters used to characterize each sub-basin shown on the pre-project and post-project site maps. The table should include the sub-basin identifier, total basin area, pervious area, impervious area, NRCS soil type, and other model parameters used to define infiltration and runoff characteristics of the sub-basin. Applicants submitting an HSPF hydrologic analysis should include PWATER parameter values for each pervious land segment. (Common HSPF parameter values are provided in Appendix A of the CCCWP modeling guidance.)

- A detailed description of proposed facilities for stormwater treatment and flow control. Describe the type of facility, design dimensions, overflow capacity, underdrain sizing parameters (control device), emergency overflow route, and any other hydraulic controls. Describe how the facilities were characterized in the model and methods used for facility sizing; if IMPs are modeled, include a detailed discussion of the assumed water movement hydraulics describing infiltration, soil water storage, and soil water movement. Provide a sketch of each facility showing key hydraulic design elements such as orifice sizing and placement.

- A table of model parameters used to characterize proposed stormwater management facilities, such as FTABLEs (HSPF), rating curves etc.

- A description of runoff routing that explains how runoff from each sub-basin is routed through the project site. For sub-basins which drain to a single stormwater management facility, a discussion of the basin routing is sufficient. For more complex sub-basins or series of sub-basins, with explicit routing, provide a table describing the reach parameters and transform methods in addition to the detailed routing description. (Routing parameters will vary depending on hydrologic model and routing method selected.)

- Modeling results, summarized as partial duration statistics and flow duration tables. To compute partial duration statistics and separate the long-term HSPF output time series into discrete storm events, use a 24 hour period with flows less than 0.02 cfs per acre to signify the end of an event. The partial duration statistics table should list for each flow event: start date, event duration, peak flow, flow volume and recurrence

RB-AR32955

interval. Show peak flow frequency and flow duration curves that illustrate the proposed project meets the peak flow control and flow duration control standard (as outlined in HMP Attachment 3).

Option 4a: Low Risk of Accelerated Erosion

This option may be applicable if your project is in low-elevation areas near the Bay/Delta or an adjacent urbanized area drained by underground pipes or hardened channels. It is the responsibility of the applicant to demonstrate all downstream channels between the project site and the Bay/Delta meet the "low risk" criteria.

► RATIONALE

Flow control is not necessary if it can be demonstrated that increased flow peaks and durations would have no effect on downstream channels. "No effect" can be stipulated if it is demonstrated that the entire drainage route from the site to the Bay/Delta is in pipes, engineered hardened channels, channels subject to tidal action, or channels subject to accumulation of sediments.

For some projects, this demonstration can be a simple reference to municipal storm drain maps (for example). However, drainage channels, particularly small channels, are not always well documented. Even where drainage is documented, the boundaries of areas tributary to the drainage may be difficult to discern. For this reason, Contra Costa has not prepared a comprehensive map showing where Option 4a applies. Where necessary, applicants may need to provide field notes, photographs, or other documentation to verify the characteristics of specific reaches along the route between their project site and the Bay/Delta.

Many reaches of Contra Costa's major creeks are natural or unhardened; Option 4a cannot be used to establish compliance with flow-control requirements for projects upstream of these reaches.

► MEETING THE REQUIREMENTS

Trace the drainage route from the project site down to the Bay/Delta. Divide the route into reaches based on the type and characteristics of drainage structures (pipe, engineered channel, natural channel). Assemble documentation and confirm each reach is in one of the following categories:

1. Enclosed pipe.

2. Channel with continuous hardened beds and banks engineered to withstand erosive forces and composed of concrete, engineered riprap, sackcrete, gabions, mats, etc. (Channel hardening must be an engineered continuous installation and not piecemealed in response to localized bank failure and erosion.)

3. Channel subject to tidal action.

RB-AR32956

4.

TABLE C-1. Suggested format for presentation of reach-by-reach information for "low risk" (Option 4a).

Reach ID	*Description*	*"Low Risk" Category*	*Reference or documentation*

h
i
ch is aggrading, i.e. consistently subject to accumulation over decades and with no indicators on erosion on the channel banks.

► PREPARING YOUR SUBMITTAL

Your report, signed by an engineer or qualified environmental professional, should include as necessary a map or diagram showing each reach, a narrative briefly describing the reaches in order from site to Bay/Delta, and a tabulated presentation of the documentation used to confirm the status of each reach. The format illustrated in Table C-1 can be used.

You can facilitate review of your submittal by attaching photocopies of, or providing links to, the key source materials used to establish each "low risk" classification. Examples of sources are in Table C-2.

TABLE C-2. Examples of source materials which could document "low risk" (Option 4a).

	"Low Risk" Category	*Examples of Source Materials*
1	Enclosed pipes	Municipal storm drain map or personal communication with municipal staff
2	Channel with continuous hardened beds and banks	Project name or number for original construction of the channel, or personal communication with staff of the agency responsible for channel maintenance, or field reconnaissance.
3	Tidally influenced channel	Elevation of outfall to channel (from construction drawings or field reconnaissance), or personal communication with Flood Control District staff.
4	Aggrading channel	Visual survey by a qualified geomorphologist or personal communication with Flood Control District staff confirming the history of sediment accumulation and removal.

RB-AR32957

Option 4b: Medium Risk of Accelerated Erosion

This option allows an applicant, in certain cases, to mitigate potential effects of increased runoff on a stream reach by sponsoring a bed or bank restoration project of limited scope.

The option is only available to projects smaller than 20 acres total area.

The applicant must first confirm downstream reaches have characteristics indicating channel beds and banks are, in the main, relatively resistant to accelerated erosion from increased runoff.

The applicant must then have a qualified geomorphologist confirm this finding and develop a proposal for a mitigation project, the benefits of which must substantially outweigh potential impacts of an increase in runoff from the proposed development project.

The applicant must also obtain concurrence from staff of regulatory agencies having jurisdiction—including Regional Water Board staff—that the mitigation project is feasible and desirable.

► RATIONALE

In a "medium risk" stream reach, the channel is stable under current conditions and may be able to absorb a slight increase in watershed imperviousness, but accelerated erosion cannot be ruled out. For some development projects upstream of these reaches, flow-control facilities may be costly or difficult to build, and the resulting benefit may be uncertain and small.

Detailed studies of the potential effects of a development on a stream can be costly, time consuming, and (in the case of a "medium risk" stream reach) could simply reiterate that increased erosion is not likely, but is possible.

As an alternative to extensive study of the stream, applicants have the option of proposing a mitigation project. Contra Costa streams have a substantial backlog of needed (but unfunded) maintenance to prevent or repair localized bank failures. Properly designed and executed, localized restoration projects can have substantial environmental benefits. Mitigation projects should seek to attenuate or reduce excessive erosive stresses (for example, by increasing channel cross section or reducing gradient), rather than just increasing shear resistance by stabilizing banks.

The benefits of the mitigation project must substantially outweigh the incremental increase in the risk of erosion due to the increased runoff represented by the project. This balance is established by the opinion of a qualified geomorphologist and then confirmed by consensus among staff of the agencies having jurisdiction.

Program consultants outlined a process and created technical tools applicants may use to implement this option. To begin the process, an engineer or qualified environmental professional can use the Program's Basic Geomorphic Assessment

RB-AR32958

procedure to evaluate downstream reaches and show each reach is either "low risk" (see Option 4a) or "medium risk."

► MEETING THE REQUIREMENTS

Implementation of Option 4b proceeds in two phases. In the first phase, an engineer or qualified environmental professional makes a preliminary determination whether all reaches of drainage downstream from the project site to the Bay/Delta are either "low risk" or "medium risk" according to the Program's criteria. If this determination is affirmative, the applicant may proceed to the second phase, in which a qualified stream geomorphologist confirms the preliminary determination and proposes an appropriate mitigation project.

Applicants are strongly encourage to coordinate with municipal staff, staff of the Contra Costa Flood Control and Water Conservation District, property owners of stream reaches and adjacent parcels, and regulatory agencies having jurisdiction (including the Regional Water Board and the California Department of Fish and Game) during the first phase and/or before proceeding the second phase.

First phase (conducted by an engineer, stream geomorphologist, or other qualified environmental professional): As in Option 4a, trace the drainage route from the project site down to the Bay/Delta. Divide the route into reaches based on the type and characteristics of drainage structures. Identify and assemble documentation for any "low risk" reaches as in Option 4a.

Conduct the field site review and collect the field data described in the Basic Geomorphic Assessment procedure to each of the remaining reaches downstream to the point where:

- all further downstream reaches are "low risk," or
- the channel enters a publicly managed reservoir.

For each of these reaches, complete a Geomorphic Assessment Form, including field notes and photographs, to calculate the channel vulnerability indicators and evaluate the appropriate risk class. Write a narrative risk justification to accompany each assessment form.

Second phase (conducted by a qualified stream geomorphologist): Confirm the findings of the preliminary report using the information in the assessment forms, additional field data, and other available information.

Identify and describe a suitable mitigation project to stabilize stream beds or banks, improve natural stream functions, and/or improve habitat values. If a suitable project exists in the same stream reach or watershed, that project should be proposed; otherwise, a project in another watershed may be acceptable.

► PREPARING YOUR SUBMITTAL

Prepare a preliminary plan and proposal for the mitigation project including milestones, schedule, cost estimates, and funding. Include a written commitment from the developer or project proponent to implement the mitigation project timely in connection with the proposed development project.

Provide an opinion and supporting analysis by one or more qualified environmental professionals that the expected environmental benefits of the mitigation project substantially outweigh the potential impacts of an increase in runoff from the development project.

To complete documentation of compliance with flow-control requirements under Option 4b, obtain letters or meeting notes in which staff representatives of regulatory agencies having jurisdiction state the project is feasible and desirable. This must include a letter signed by the Regional Water Board Executive Officer or designee referencing this requirement.

Option 4c: High Risk of Accelerated Erosion

As noted at the beginning of this appendix, the Program's flow-control standard is preventative: project proponents are encouraged to design their projects so that there will be no increase in runoff as compared to the pre-project condition of the development site. This policy aims to ensure watershed-wide increases in runoff and the attendant impacts are minimized, while obviating the need for extensive analysis to characterize the complex and unpredictable relationship between increased runoff and accelerated stream erosion in a particular watershed.

However, where it is very difficult or infeasible to achieve no increase in runoff—or in cases where a stream channel is to be restored as mitigation for other environmental impacts—an applicant may propose to alter the receiving stream channel to accommodate the predicted post-project flow regime.

The analysis required to determine design objectives for in-stream measures will typically involve watershed-scale continuous hydrologic modeling of pre-project and post-project runoff flows, sediment transport modeling, collection and/or analysis of field data to characterize channel morphology including analysis of bed and bank materials and bank vegetation, selection and design of in-stream structures, and project environmental permitting.

► RATIONALE

Stream channels which do not meet the criteria for "low-risk" (Option 4a) or "medium-risk" (Option 4b) are considered at "high-risk" of accelerated erosion due to increased watershed imperviousness. High risk channels are geomorphically unstable under existing conditions, and therefore vulnerable to any increase in impervious area.. It is presumed that increases in runoff flows to these channels will accelerate bed and bank erosion.

If downstream drainage includes high-risk channels, the applicant must either control runoff flows to pre-project peaks and durations or propose a comprehensive program of in-stream measures to improve channel functions while accommodating increased flows.

► MEETING THE REQUIREMENTS

To obtain approval for a project which discharges increased runoff peaks and durations to a high-risk channel, the project proponent must perform a comprehensive analysis to determine the design objectives for channel restoration and must propose a comprehensive program of in-stream measures to improve channel functions while accommodating increased flows. Specific requirements are developed case-by-case in consultation with regulatory agencies having jurisdiction.

Different project types, channels, and locations will demand different investigative approaches; however, the following framework can be tailored to most situations:

- Evaluation of watershed historic conditions.
- Evaluation of channel geomorphic conditions.
- Evaluation of project impacts on hydrology and sediment yield.
- Prediction of impacts on receiving channels.
- Design of avoidance or mitigation.
- Monitoring and adaptive management.

HMP Attachment 4 includes additional detail regarding this framework and recommended evaluation method and design methods.

► PREPARING YOUR SUBMITTAL

The analysis for compliance with flow-control requirements may, and in many cases should be, integrated with analyses conducted pursuant to obtaining Clean Water Act Section 401 or Section 404 certification, CEQA, California Department of Fish and Game Stream Alteration Permits, and other regulatory approvals which may be required for the development project or implementation of in-stream measures, or both.

Discuss the contents of required submittals with the staff of agencies having jurisdiction prior to the start of the analytical work.

- Municipal Regional Permit Provision C.3.g. and Attachment C.
- *Contra Costa Clean Water Program Final Hydrograph Modification Management Plan*, revised April 19, 2006.

I. Demonstrating Compliance with the Standard

Contra Costa Permittees shall ensure project proponents shall demonstrate compliance with the HM standard by demonstrating that any one of the following four options is met:

1. **No increase in impervious area.** The project proponent may compare the project design to the pre-project condition and show the project will not increase impervious area and also will not facilitate the efficiency of drainage collection and conveyance.

2. **Implementation of hydrograph modification IMPs.** The project proponent may select and size IMPs to manage hydrograph modification impacts, using the design procedure, criteria, and sizing factors specified in the Contra Costa Clean Water Program's *Stormwater C.3 Guidebook*. The use of flow-through planters shall be limited to upper-story plazas, adjacent to building foundations, on slopes where infiltration could impair geotechnical stability, or in similar situations where geotechnical issues prevent use of IMPs that allow infiltration to native soils. Limited soil infiltration capacity in itself does not make use of other IMPs infeasible.

3. **Estimated post-project runoff durations and peak flows do not exceed pre-project durations and peak flows.** The project proponent may use a continuous simulation hydrologic computer model such as USEPA's Hydrograph Simulation Program—Fortran (HSPF) to simulate pre-project and post-project runoff, including the effect of proposed IMPs, detention basins, or other stormwater management facilities. To use this method, the project proponent shall compare the pre-project and post-project model output for a rainfall record of at least 30 years, using limitations and instructions provided in the Program's *Stormwater C.3 Guidebook*, and shall show the following criteria are met:

   a. For flow rates from 10% of the pre-project 2-year runoff event (0.1Q2) to the pre-project 10-year runoff event (Q10), the post-project discharge rates and durations shall not deviate above the pre-project rates and durations by more than 10% over more than 10% of the length of the flow duration curve.

   b. For flow rates from 0.5Q2 to Q2, the post-project *peak flows* shall not exceed pre-project peak flows. For flow rates from Q2 to Q10, post-project peak flows may exceed pre-project flows by up to 10% for a 1-year frequency interval. For example, post-project flows could exceed pre-project flows by up to 10% for the interval from Q9 to Q10 or from Q5.5 to Q6.5, but not from Q8 to Q10.

4. **Projected increases in runoff peaks and durations will not accelerate erosion of receiving stream reaches.** The project proponent may show that, because of the specific characteristics of the stream receiving runoff from the project site, or because of proposed stream restoration projects, or both, there is little likelihood that the cumulative impacts from new development could increase the net rate of stream erosion to the extent that beneficial uses would be significantly impacted. To use this option, the project proponent shall evaluate the receiving stream to determine the relative risk of erosion impacts and take the appropriate actions as described below and in Table A-1. Projects 20 acres or larger in total area shall not use the medium risk methodology in "b" below.

   a. **"Low Risk."** In a report or letter report, signed by an engineer or qualified environmental professional, the project proponent shall show that all downstream channels between the project site and the Bay/Delta fall into one of the following "low-risk" categories.

i. Enclosed pipes.

ii. Channels with continuous hardened beds and banks engineered to withstand erosive forces and composed of concrete, engineered riprap, sackcrete, gabions, mats, etc. This category excludes channels where hardened beds and banks are not engineered continuous installations (i.e., have been installed in response to localized bank failure or erosion).

iii. Channels subject to tidal action.

iv. Channels shown to be aggrading, i.e., consistently subject to accumulation of sediments over decades, and to have no indications of erosion on the channel banks.

b. **"Medium Risk."** Medium risk channels are those where the boundary shear stress could exceed critical shear stress as a result of hydrograph modification, but where either the sensitivity of the boundary shear stress to flow is low (e.g., an oversized channel with high width to depth ratios) or where the resistance of the channel materials is relatively high (e.g., cobble or boulder beds and vegetated banks). In "medium-risk" channels, accelerated erosion due to increased watershed imperviousness is not likely but is possible, and the uncertainties can be more easily and effectively addressed by mitigation than by additional study.

In a preliminary report, the project proponent's engineer or qualified environmental professional will apply the Program's "Basic Geomorphic Assessment"[1] methods and criteria to show each downstream reach between the project site and the Bay/Delta is either at "low-risk" or "medium-risk" of accelerated erosion due to watershed development. In a following, detailed report, a qualified stream geomorphologist[2] will use the Program's Basic Geomorphic Assessment methods and criteria, available information, and current field data to evaluate each "medium-risk" reach. For *each* "medium-risk" reach, the detailed report shall show one of the following:

i. A detailed analysis, using the Program's criteria, showing the particular reach may be reclassified as "low-risk."

ii. A detailed analysis, using the Program's criteria, confirming the "medium-risk" classification, and:

1. A preliminary plan for a mitigation project for that reach to stabilize stream beds or banks, improve natural stream functions, and/or improve habitat values, and
2. A commitment to implement the mitigation project timely in connection with the proposed development project (including milestones, schedule, cost estimates, and funding), and
3. An opinion and supporting analysis by one or more qualified environmental professionals that the expected environmental benefits of the mitigation project

---

[1] Contra Costa Clean Water Program *Hydrograph Modification Management Plan*, May 15, 2005, Attachment 4, pp. 6-13. This method must be made available in the Program's *Stormwater C.3 Guidebook*.

[2] Typically, detailed studies will be conducted by a stream geomorphologist retained by the lead agency (or, on the lead agency's request, another public agency such as the Contra Costa County Flood Control and Water Conservation District) and paid for by the project proponent.

substantially outweigh the potential impacts of an increase in runoff from the development project, and

4. Communication, in the form of letters or meeting notes, indicating consensus among staff representatives of regulatory agencies having jurisdiction that the mitigation project is feasible and desirable. In the case of the Regional Water Board, this must be a letter, signed by the Executive Officer or designee, specifically referencing this requirement. (This is a preliminary indication of feasibility required as part of the development project's Stormwater Control Plan. All applicable permits must be obtained before the mitigation project can be implemented.)

c. **"High Risk."** High-risk channels are those where the sensitivity of boundary shear stress to flow is high (e.g., incised or entrenched channels, channels with low width-to-depth ratios, and narrow channels with levees) or where channel resistance is low (e.g., channels with fine-grained, erodible beds and banks, or with little bed or bank vegetation). In a "high-risk" channel, it is presumed that increases in runoff flows will accelerate bed and bank erosion.

To implement this option (i.e., to allow increased runoff peaks and durations to a high-risk channel), the project proponent must perform a comprehensive analysis to determine the design objectives for channel restoration and must propose a comprehensive program of in-stream measures to improve channel functions while accommodating increased flows. Specific requirements are developed case-by-case in consultation with regulatory agencies having jurisdiction. The analysis will typically involve watershed-scale continuous hydrologic modeling (including calibration with stream gauge data where possible) of pre-project and post-project runoff flows, sediment transport modeling, collection and/or analysis of field data to characterize channel morphology including analysis of bed and bank materials and bank vegetation, selection and design of in-stream structures, and project environmental permitting.

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

How to use this worksheet (also see instructions on page 28 of the *Stormwater C.3 Guidebook*):

1. Review Column 1 and identify which of these potential sources of stormwater pollutants apply to your site. Check each box that applies.

2. Review Column 2 and incorporate all of the corresponding applicable BMPs in your Stormwater Control Plan drawings.

3. Review Columns 3 and 4 and incorporate all of the corresponding applicable permanent controls and operational BMPs in a table in your Stormwater Control Plan. Use the format shown in Table 3-1 on page 27 of the *Guidebook*. Describe your specific BMPs in an accompanying narrative, and explain any special conditions or situations that required omitting BMPs or substituting alternative BMPs for those shown here.

IF THESE SOURCES WILL BE ON THE PROJECT SITE …	… THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ A. **On-site storm drain inlets**	❑ **Locations of inlets.**	❑ **Mark all inlets with the words "No Dumping! Flows to Bay" or similar.**	❑ **Maintain and periodically repaint or replace inlet markings.** ❑ **Provide stormwater pollution prevention information to new site owners, lessees, or operators.** ❑ **See applicable operational BMPs in Fact Sheet SC-44, "Drainage System Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com** ❑ **Include the following in lease agreements: "Tenant shall not allow anyone to discharge anything to storm drains or to store or deposit materials so as to create a potential discharge to storm drains."**
❑ B. **Interior floor drains and elevator shaft sump pumps**		❑ **State that interior floor drains and elevator shaft sump pumps will be plumbed to sanitary sewer.**	❑ **Inspect and maintain drains to prevent blockages and overflow.**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ C. **Interior parking garages**		❑ **State that parking garage floor drains will be plumbed to the sanitary sewer.**	❑ **Inspect and maintain drains to prevent blockages and overflow.**
❑ D1. **Need for future indoor & structural pest control**		❑ **Note building design features that discourage entry of pests.**	❑ **Provide Integrated Pest Management information to owners, lessees, and operators.**
❑ D2. **Landscape/ Outdoor Pesticide Use**	❑ **Show locations of native trees or areas of shrubs and ground cover to be undisturbed and retained.** ❑ **Show self-retaining landscape areas, if any.** ❑ **Show stormwater treatment and hydrograph modification management BMPs. (See instructions in Chapter 3, Step 5 and guidance in Chapter 5.)**	**State that final landscape plans will accomplish all of the following.** ❑ **Preserve existing native trees, shrubs, and ground cover to the maximum extent possible.** ❑ **Design landscaping to minimize irrigation and runoff, to promote surface infiltration where appropriate, and to minimize the use of fertilizers and pesticides that can contribute to stormwater pollution.** ❑ **Where landscaped areas are used to retain or detain stormwater, specify plants that are tolerant of saturated soil conditions.** ❑ **Consider using pest-resistant plants, especially adjacent to hardscape.** ❑ **To insure successful establishment, select plants appropriate to site soils, slopes, climate, sun, wind, rain, land use, air movement, ecological consistency, and plant interactions.**	❑ **Maintain landscaping using minimum or no pesticides.** ❑ **See applicable operational BMPs in Fact Sheet SC-41, "Building and Grounds Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com** ❑ **Provide IPM information to new owners, lessees and operators.**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE …	… THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ E. **Pools, spas, ponds, decorative fountains, and other water features.**	❑ **Show location of water feature and a sanitary sewer cleanout in an accessible area within 10 feet. (Exception: Public pools must be plumbed according to County Department of Environmental Health Guidelines.)**	**If the local municipality requires pools to be plumbed to the sanitary sewer, place a note on the plans and state in the narrative that this connection will be made according to local requirements.**	❑ **See applicable operational BMPs in Fact Sheet SC-72, "Fountain and Pool Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**
❑ F. **Food service**	❑ **For restaurants, grocery stores, and other food service operations, show location (indoors or in a covered area outdoors) of a floor sink or other area for cleaning floor mats, containers, and equipment.** ❑ **On the drawing, show a note that this drain will be connected to a grease interceptor before discharging to the sanitary sewer.**	❑ **Describe the location and features of the designated cleaning area.** ❑ **Describe the items to be cleaned in this facility and how it has been sized to insure that the largest items can be accommodated.**	❑ **See the brochure, "Water Pollution Prevention Tips to Protect Water Quality and Keep Your Food Service Facility Clean." Provide this brochure to new site owners, lessees, and operators.**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ G. **Refuse areas**	❑ **Show where site refuse and recycled materials will be handled and stored for pickup. See local municipal requirements for sizes and other details of refuse areas.** ❑ **If dumpsters or other receptacles are outdoors, show how the designated area will be covered, graded, and paved to prevent run-on and show locations of berms to prevent runoff from the area.** ❑ **Any drains from dumpsters, compactors, and tallow bin areas shall be connected to a grease removal device before discharge to sanitary sewer.**	❑ **State how site refuse will be handled and provide supporting detail to what is shown on plans.** ❑ **State that signs will be posted on or near dumpsters with the words "Do not dump hazardous materials here" or similar.**	❑ **State how the following will be implemented:** **Provide adequate number of receptacles. Inspect receptacles regularly; repair or replace leaky receptacles. Keep receptacles covered. Prohibit/prevent dumping of liquid or hazardous wastes. Post "no hazardous materials" signs. Inspect and pick up litter daily and clean up spills immediately. Keep spill control materials available on-site. See Fact Sheet SC-34, "Waste Handling and Disposal" in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**
❑ H. **Industrial processes.**	❑ **Show process area.**	❑ **If industrial processes are to be located on site, state: "All process activities to be performed indoors. No processes to drain to exterior or to storm drain system."**	❑ **See Fact Sheet SC-10, "Non-Stormwater Discharges" in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE …	… THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ I. **Outdoor storage of equipment or materials. (See rows J and K for source control measures for vehicle cleaning, repair, and maintenance.)**	❑ **Show any outdoor storage areas, including how materials will be covered. Show how areas will be graded and bermed to prevent run-on or run-off from area.** ❑ **Storage of non-hazardous liquids shall be covered by a roof and/or drain to the sanitary sewer system, and be contained by berms, dikes, liners, or vaults.** ❑ **Storage of hazardous materials and wastes must be in compliance with the local hazardous materials ordinance and a Hazardous Materials Management Plan for the site.**	**Include a detailed description of materials to be stored, storage areas, and structural features to prevent pollutants from entering storm drains.** **Where appropriate, reference documentation of compliance with the requirements of Contra Costa Hazardous Materials Programs for:** ▪ **Hazardous Waste Generation** ▪ **Hazardous Materials Release Response and Inventory** ▪ **California Accidental Release (CalARP)** ▪ **Aboveground Storage Tank** ▪ **Uniform Fire Code Article 80 Section 103(b) & (c) 1991** ▪ **Underground Storage Tank** **www.cchealth.org/groups/hazmat/**	❑ **See the Fact Sheets SC-31, "Outdoor Liquid Container Storage" and SC-33, "Outdoor Storage of Raw Materials " in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ J. **Vehicle and Equipment Cleaning**	❑ **Show on drawings as appropriate:** **(1) Commercial/industrial facilities having vehicle/equipment cleaning needs shall either provide a covered, bermed area for washing activities or discourage vehicle/equipment washing by removing hose bibs and installing signs prohibiting such uses.** **(2) Multi-dwelling complexes shall have a paved, bermed, and covered car wash area (unless car washing is prohibited on-site and hoses are provided with an automatic shut-off to discourage such use).** **(3) Washing areas for cars, vehicles, and equipment shall be paved, designed to prevent run-on to or runoff from the area, and plumbed to drain to the sanitary sewer.** **(4) Commercial car wash facilities shall be designed such that no runoff from the facility is discharged to the storm drain system. Wastewater from the facility shall discharge to the sanitary sewer, or a wastewater reclamation system shall be installed.**	❑ **If a car wash area is not provided, describe measures taken to discourage on-site car washing and explain how these will be enforced.**	**Describe operational measures to implement the following (if applicable):** ❑ **Washwater from vehicle and equipment washing operations shall not be discharged to the storm drain system.** ❑ **Car dealerships and similar may rinse cars with water only.** **See Fact Sheet SC-21, "Vehicle and Equipment Cleaning," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ K. **Vehicle/Equipment Repair and Maintenance**	❑ **Accommodate all vehicle equipment repair and maintenance indoors. Or designate an outdoor work area and design the area to prevent run-on and runoff of stormwater.** ❑ **Show secondary containment for exterior work areas where motor oil, brake fluid, gasoline, diesel fuel, radiator fluid, acid-containing batteries or other hazardous materials or hazardous wastes are used or stored. Drains shall not be installed within the secondary containment areas.** ❑ **Add a note on the plans that states either (1) there are no floor drains, or (2) floor drains are connected to wastewater pretreatment systems prior to discharge to the sanitary sewer and an industrial waste discharge permit will be obtained.**	❑ **State that no vehicle repair or maintenance will be done outdoors, or else describe the required features of the outdoor work area.** ❑ **State that there are no floor drains or if there are floor drains, note the agency from which an industrial waste discharge permit will be obtained and that the design meets that agency's requirements.** ❑ **State that there are no tanks, containers or sinks to be used for parts cleaning or rinsing or, if there are, note the agency from which an industrial waste discharge permit will be obtained and that the design meets that agency's requirements.**	**In the Stormwater Control Plan, note that all of the following restrictions apply to use the site:** ❑ **No person shall dispose of, nor permit the disposal, directly or indirectly of vehicle fluids, hazardous materials, or rinsewater from parts cleaning into storm drains.** ❑ **No vehicle fluid removal shall be performed outside a building, nor on asphalt or ground surfaces, whether inside or outside a building, except in such a manner as to ensure that any spilled fluid will be in an area of secondary containment. Leaking vehicle fluids shall be contained or drained from the vehicle immediately.** ❑ **No person shall leave unattended drip parts or other open containers containing vehicle fluid, unless such containers are in use or in an area of secondary containment.**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ L. **Fuel Dispensing Areas**	❑ **Fueling areas[1] shall have impermeable floors (i.e., portland cement concrete or equivalent smooth impervious surface) that are: a) graded at the minimum slope necessary to prevent ponding; and b) separated from the rest of the site by a grade break that prevents run-on of stormwater to the maximum extent practicable.** ❑ **Fueling areas shall be covered by a canopy that extends a minimum of ten feet in each direction from each pump. [Alternative: The fueling area must be covered and the cover's minimum dimensions must be equal to or greater than the area within the grade break or fuel dispensing area[1].] The canopy [or cover] shall not drain onto the fueling area.**		❑ **The property owner shall dry sweep the fueling area routinely.** ❑ **See the Business Guide Sheet, "Automotive Service—Service Stations" in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**

[1] **The fueling area shall be defined as the area extending a minimum of 6.5 feet from the corner of each fuel dispenser or the length at which the hose and nozzle assembly may be operated plus a minimum of one foot, whichever is greater.**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
❑ M. **Loading Docks**	❑ **Show a preliminary design for the loading dock area, including roofing and drainage. Loading docks shall be covered and/or graded to minimize run-on to and runoff from the loading area. Roof downspouts shall be positioned to direct stormwater away from the loading area. Water from loading dock areas shall be drained to the sanitary sewer, or diverted and collected for ultimate discharge to the sanitary sewer.** ❑ **Loading dock areas draining directly to the sanitary sewer shall be equipped with a spill control valve or equivalent device, which shall be kept closed during periods of operation.** ❑ **Provide a roof overhang over the loading area or install door skirts (cowling) at each bay that enclose the end of the trailer.**		❑ **Move loaded and unloaded items indoors as soon as possible.** ❑ **See Fact Sheet SC-30, "Outdoor Loading and Unloading," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**
❑ N. **Fire Sprinkler Test Water**		❑ **Provide a means to drain fire sprinkler test water to the sanitary sewer.**	❑ **See the note in Fact Sheet SC-41, "Building and Grounds Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com**

APPENDIX D—STORMWATER POLLUTANT SOURCES/SOURCE CONTROL CHECKLIST

IF THESE SOURCES WILL BE ON THE PROJECT SITE ...	... THEN YOUR STORMWATER CONTROL PLAN SHOULD INCLUDE THESE SOURCE CONTROL BMPs		
1 Potential Sources of Runoff Pollutants	2 Permanent Controls—Show on Stormwater Control Plan Drawings	3 Permanent Controls—List in Stormwater Control Plan Table and Narrative	4 Operational BMPs—Include in Stormwater Control Plan Table and Narrative
O. **Miscellaneous Drain or Wash Water or Other Sources** ❑ **Boiler drain lines** ❑ **Condensate drain lines** ❑ **Rooftop equipment** ❑ **Drainage sumps** ❑ **Roofing, gutters, and trim.** ❑ **Other sources**		❑ **Boiler drain lines shall be directly or indirectly connected to the sanitary sewer system and may not discharge to the storm drain system.** ❑ **Condensate drain lines may discharge to landscaped areas if the flow is small enough that runoff will not occur. Condensate drain lines may not discharge to the storm drain system.** ❑ **Rooftop equipment with potential to produce pollutants shall be roofed and/or have secondary containment.** ❑ **Any drainage sumps on-site shall feature a sediment sump to reduce the quantity of sediment in pumped water.** ❑ **Avoid roofing, gutters, and trim made of copper or other unprotected metals that may leach into runoff.** ❑ **Include controls for other sources as specified by local reviewer.**	
❑ P. **Plazas, sidewalks, and parking lots.**			❑ **Sweep plazas, sidewalks, and parking lots regularly to prevent accumulation of litter and debris. Collect debris from pressure washing to prevent entry into the storm drain system. Collect washwater containing any cleaning agent or degreaser and discharge to the sanitary sewer not to a storm drain.**

Introduction

Rainfall within the County of Los Angeles varies spatially. The Los Angeles Regional Water Quality Control Board (RWQCB) agreed to use a spatially distributed statistical rainfall distribution for water quality studies. The RWQCB allows the use of 85th percentile 24-hour rainfall event or the 0.75-inch event for Standard Urban Storm Water Mitigation Plan (SUSMP) and Best Management Practices (BMP) design hydrologic studies.

The 85th percentile 24-hour rainfall depths vary from 0.30 to 1.50 inches within the County of Los Angeles. This report provides the analysis used to determine the spatial distribution of the 85th percentile 24-hour rainfall within the County of Los Angeles.

Analysis

The County of Los Angeles Department of Public Works maintains an extensive network of rain gages throughout the county. The 85th percentile 24-hour rainfall spatial distribution analysis required selection of gages to represent rainfall throughout the county. The analysis began with the selection of ninety-nine rain gages. Rain gage selection was based on spatial distribution and rainfall record length. Historic precipitation data includes 40 to 80 years of rainfall at most of the selected gages. Most rain gages in the Antelope Valley had approximately 15 years of historic record available for analysis.

Percentile Analysis

Percentile analysis determines a data value for a specified percentage. For example, if the 85th percentile rainfall depth is analyzed and a value of 1.00 inches is determined, 85 percent of all rainfall events produce 1.00 inch or less of precipitation. The analysis includes 24-hour periods with measurable rainfall and excludes all other 24-hour periods. The analysis provided the average 24-hour rainfall, the 50th, 75th, 85th, 90th, 95th, and 99th percentile 24-hour rainfall depth at each rain gage. The average rainfall represents the sum of all 24-hour rainfall depths divided by the number of records. Appendix A provides the percentile analysis for each rain gage.

Statistical Analysis

A statistical analysis of the data sample confirmed the validity of the percentile analysis. Each data sample was broken into groups of 0.50-inch depths and plotted as a histogram. The probability of occurrence for each 0.50-inch group was determined. Plotting the cumulative probability for the groups resulted in values very similar to the percentile analysis values. The 85th percentile 24-hour rainfall depths ranged from 0.50 to 1.5 inches for the various gages distributed throughout the County. Appendix B shows the histogram, the probability distribution tables, and cumulative distribution chart for the ninety-nine gages analyzed.

Mapping 85th Percentile 24-hour Isohyets

A Geographic Information System (GIS) shape file was created using latitude and longitude coordinates for each rain gage. The GIS shape file also contained the data associated with the 24-hour rainfall analysis. The Spatial Analyst program extension was used with ArcView to create a rainfall grid based on the 85th percentile data for each gage. Contours were created from the grid file to represent the 85th percentile rainfall depth throughout the County of Los Angeles. These isohyets were compared to the NOAA 2-year 24-hour isohyets. The NOAA 2-year 24-hour isohyets reflect topographic influences on spatial rainfall patterns within the County of Los Angeles. The isohyets were also compared to county topography. Rain gages that caused anomalies in the isohyets were discarded. The final isohyetal map used ninety rain gages. The nine discarded gages had small data sets.

A new grid and isohyetal contours were produced after discarding the nine gages. The contours were again compared to the NOAA contours and topographic features in the county. In the County of Los Angeles, areas of higher elevation generally receive more rainfall due to changes in pressure and temperature. The isohyetal map of the 85th percentile 24-hour storm shows this orographic affect. Higher rainfall occurs over the mountains and hills.

Two dummy rain gages added near the county border keep the isohyetal distribution consistent with topography. Accurate portrayal of the isohyets along the Malibu Coast and in the Antelope Valley requires the dummy gages.

Appendix C contains the 85th percentile 24-hour isohyetal map, a map of the rain gage locations, and a description of the settings and process used to create the rainfall grid and contour lines in ArcView. This report also contains an electronic copy of all the data used for the 85th percentile 24-hour rainfall depth analysis.

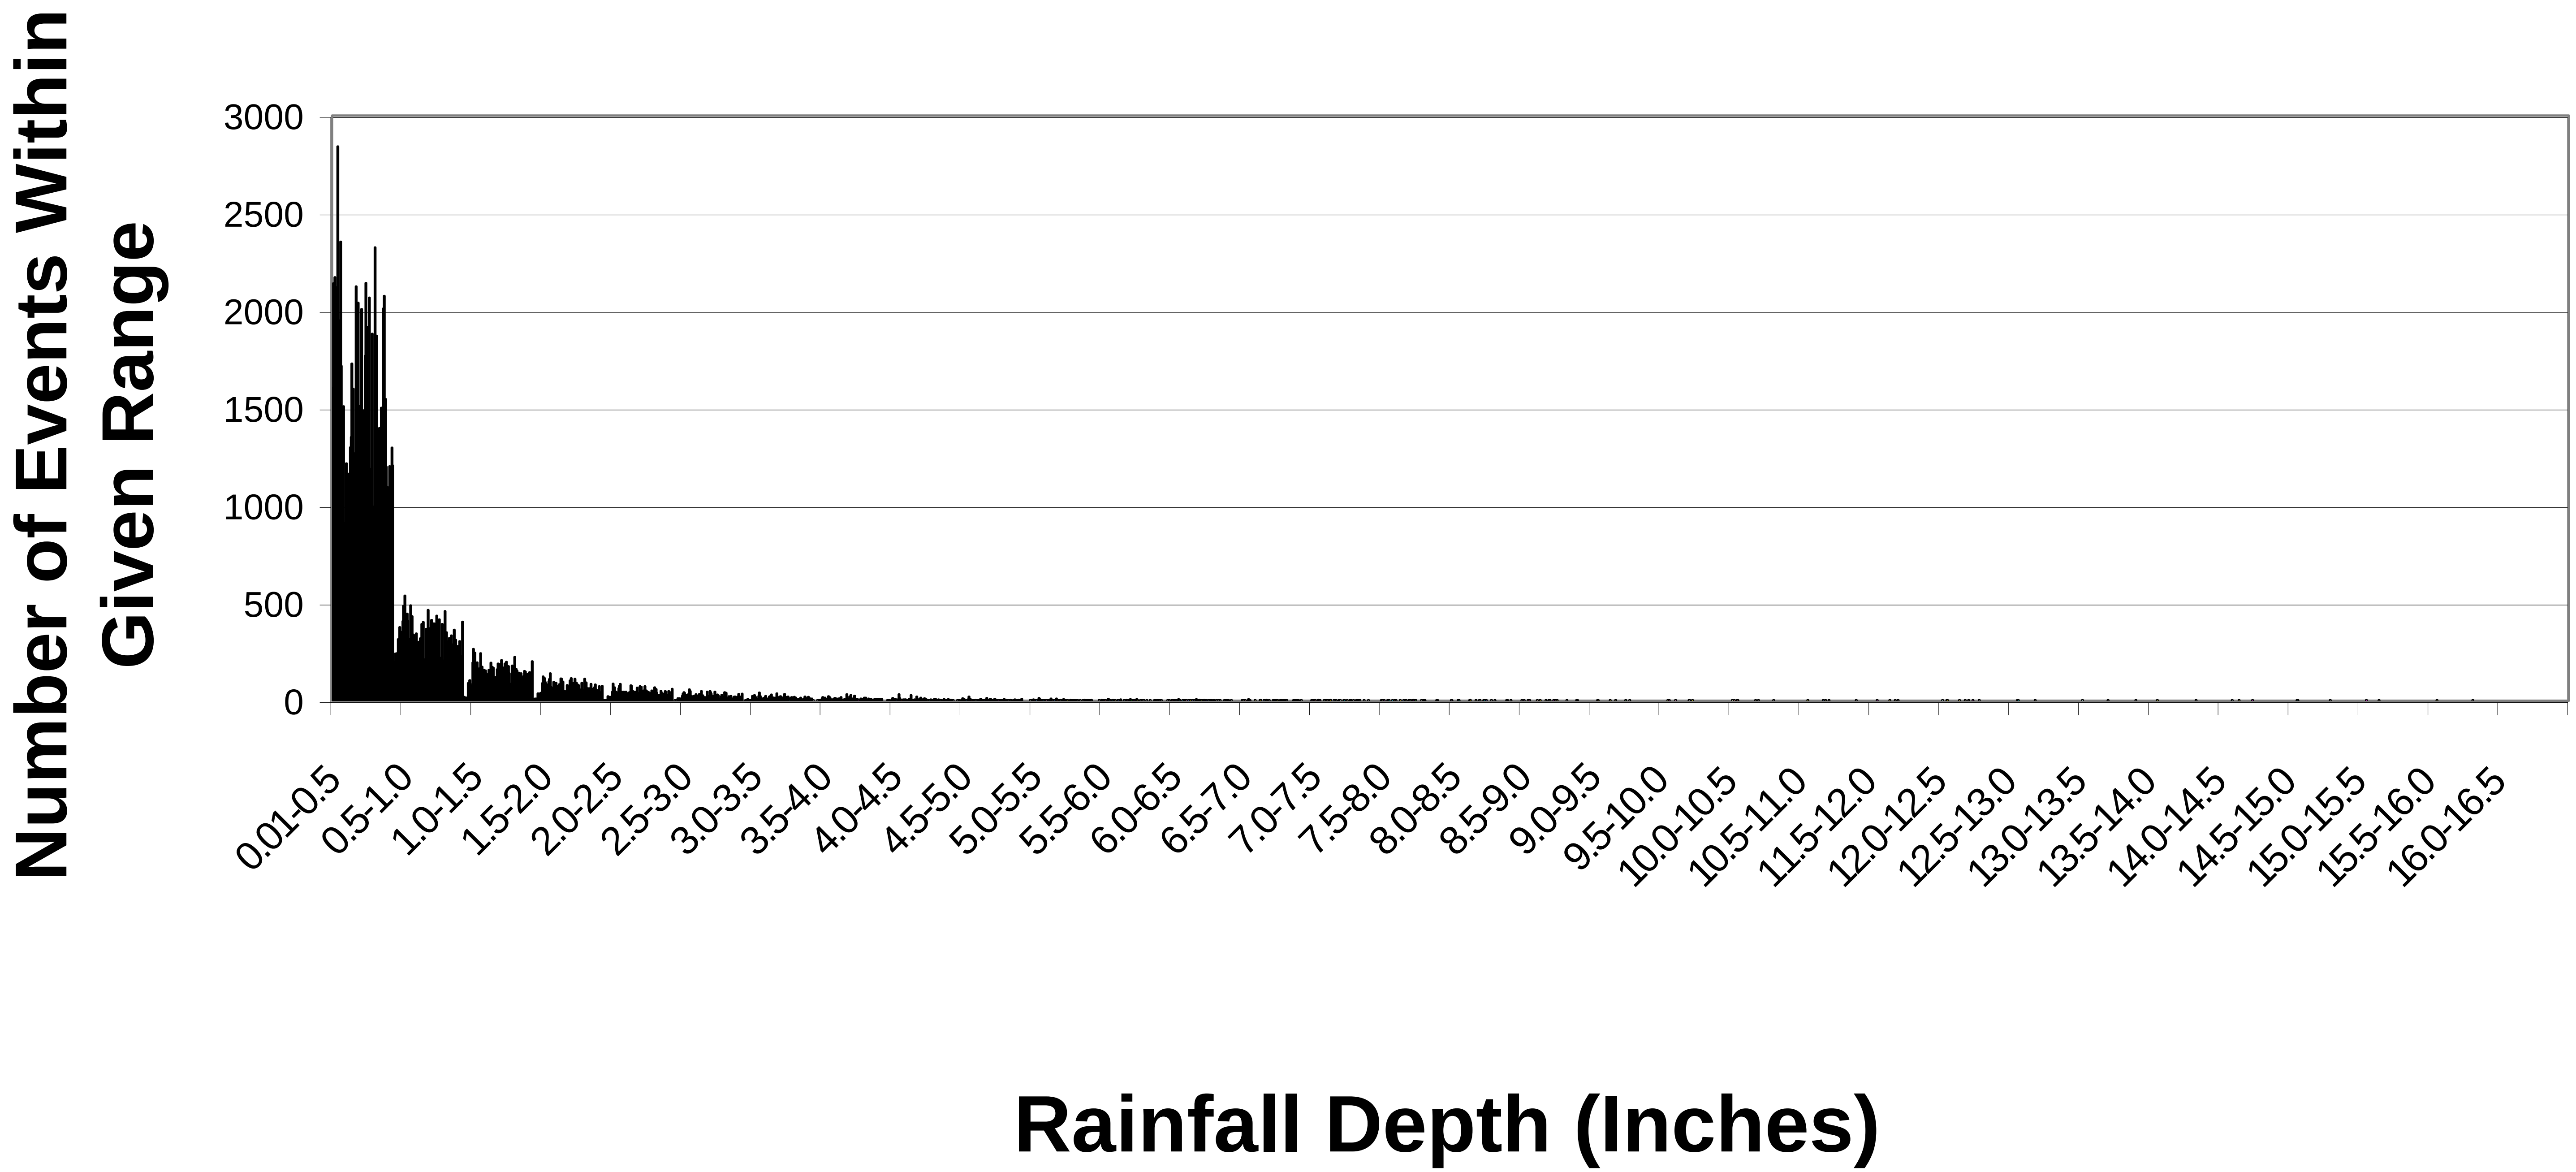
24-hr Rainfall Depth Histogram



File: Probability Analysis of 85th Percentile 24-hr Rainfall.xls
Worksheet: Histogram
Date: 03/16/2004

Probability that Rainfall Depth will Occur in a Given Range

Rainfall Depth Inches / Gage #	5	6	10	13	17	23	25	43	44	53	57	63	82	107	120	125	128	156	172	176	201	223	225	227	237	238	277	283	291	293	298	299	304	306	322	334	352	356	372	373	379	390	391	405	406	409	425	434	435	438	443	446

Procedure for Creating an Isohyetal Map

1. Create a shape file with rainfall depth data at given points throughout the county (rain gages).

2. Import shape file into ArcView and activate the Spatial Analyst extension.

3. Select the shape file with the rainfall data and then zoom to the extents of the shape file.

4. Choose the Interpolate Grid option from the Surface pull down menu.

5. Set the following levels for the input parameters:

    a. Output Extent – select the Same as Display option.
    b. Set the grid size at 1000.
    c. Leave the other settings alone and select the OK button.

6. Choose the spline method from the next pop-up menu.

7. Choose the data values corresponding to the contours desired (i.e., 85th percentile values).

8. Leave the weight value at 0.1.

9. Set the number of points to 50.

10. Select Tension as the type for the interpolation surface and select the OK button.

11. ArcView will create a grid file. If the grid file appears to be what was expected, select the grid file.

12. Select Create Contours from the Surface pull down menu.

13. Set the contour interval and the base (beginning) contour and select the OK button.

14. ArcView will create contours. Select Convert to Shape file from the Theme pull down menu.

15. Auto-label the contours and create a layout for the map.

agricultural commodities (60 FR 47487, September 13, 1995) (FRL–4973–3).

The Agency will take separate actions to propose revocation of any affected tolerances that are not supported for import purposes only.

B. Docket Content

1. *Review docket*. The registration review docket contains information that the Agency may consider in the course of the registration review. The Agency may include information from its files including, but not limited to, the following information:

- An overview of the registration review case status.
- A list of current product registrations and registrants.
- **Federal Register** notices regarding any pending registration actions.
- **Federal Register** notices regarding current or pending tolerances.
- Risk assessments.
- Bibliographies concerning current registrations.
- Summaries of incident data.
- Any other pertinent data or information.

The docket contains a document summarizing what the Agency currently knows about the ethylene case and a preliminary work plan for anticipated data and assessment needs. Additional documents provide more detailed information. During this public comment period, the Agency is asking that interested persons identify any additional information they believe the Agency should consider during the registration review of the pesticide ethylene. The Agency identifies in the docket the areas where public comment is specifically requested, though comment in any area is welcome.

2. *Other related information*. More information on the ethylene case, including the active ingredients for the case, may be located in the registration review schedule on the Agency's website at *http://www.epa.gov/oppsrrd1/registration_review/schedule.htm*. Information on the Agency's registration review program and its implementing regulation may be seen at *http://www.epa.gov/oppsrrd1/registration_review*.

3. *Information submission requirements*. Anyone may submit data or information in response to this document. To be considered during a pesticide's registration review, the submitted data or information must meet the following requirements:

- To ensure that EPA will consider data or information submitted, interested persons must submit the data or information during the comment period. The Agency may, at its discretion, consider data or information submitted at a later date.
- The data or information submitted must be presented in a legible and useable form. For example, an English translation must accompany any material that is not in English and a written transcript must accompany any information submitted as an audiographic or videographic record. Written material may be submitted in paper or electronic form.
- Submitters must clearly identify the source of any submitted data or information.
- Submitters may request the Agency to reconsider data or information that the Agency rejected in a previous review. However, submitters must explain why they believe the Agency should reconsider the data or information in the pesticide's registration review.

As provided in 40 CFR 155.58, the registration review docket for the ethylene case will remain publicly accessible through the duration of the registration review process; that is, until all actions required in the final decision on the registration review case have been completed.

BILLING CODE 6560–50–S

ENVIRONMENTAL PROTECTION AGENCY

[EPA–HQ–OW–2009–0817; FRL–9095–3]

Stakeholder Input; Stormwater Management Including Discharges From New Development and Redevelopment

AGENCY: Environmental Protection Agency.

ACTION: Notice.

SUMMARY: The Environmental Protection Agency (EPA) is announcing its plans to initiate national rulemaking to establish a comprehensive program to reduce stormwater discharges from new development and redevelopment and make other regulatory improvements to strengthen its stormwater program. The purpose of this notice is to request input from the public to help EPA shape such a comprehensive program and to announce EPA's intent to hold several public ''listening sessions'' in January 2010. EPA seeks input on this undertaking regarding performance, effectiveness and cost of stormwater control measures; ecological data, including ecological benefits from stormwater controls; technical information on design, implementation and operation and maintenance of stormwater control measures; suggestions for how the existing program may be modified to better meet the goals of the Clean Water Act; and any other information that may help EPA develop improvements to the existing program, including better control of pollutants in stormwater from the built environment created by development and redevelopment.

DATES: Written comments must be submitted on or before February 26, 2010.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–HQ–OW–2009–0817, by one of the following methods:

- *http://www.regulations.gov:* Follow the online instructions for submitting comments.
- *E-mail: OW-Docket@epa.gov,* Attention Docket ID No. EPA–HQ–OW–2009–0817.
- *Fax:* 202–566–9744.
- *Mail:* Water Docket, U.S. Environmental Protection Agency, Mail code: 4203M, 1200 Pennsylvania Ave., NW., Washington, DC 20460. Attention Docket ID No. EPA–HQ–OW–2009–0817.
- *Hand Delivery:* Water Docket, EPA Docket Center, EPA West Building Room 3334, 1301 Constitution Ave., NW., Washington, DC, Attention Docket ID No. EPA–HQ–OW–2009–0817. Such deliveries are only accepted during the Docket's normal hours of operation, and special arrangements should be made for deliveries of boxed information.

Instructions: Direct your comments to Docket ID No. EPA–HQ–OW–2009–0817. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *http://www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *http://www.regulations.gov* or e-mail. The *http://www.regulations.gov* Web site is an ''anonymous access'' system, which

RB-AR32998

means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an e-mail comment directly to EPA without going through *http://www.regulations.gov* your e-mail address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. For additional information about EPA's public docket, visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm*.

FOR FURTHER INFORMATION CONTACT: For further information on the notice, contact Jonathan Angier, EPA Headquarters, Office of Water, Office of Wastewater Management at tel.: 202–564–0729 or e-mail: *angier.jonathan@epa.gov*.

Public Listening Sessions: EPA will hold several informal public listening sessions in January 2010 to gather input on possible regulatory changes to the stormwater program. The public listening sessions will provide a review of EPA's current regulatory approach to permitting stormwater discharges, a summary of the recommendations from the National Research Council report *Urban Stormwater Management in the United States* (The National Academies Press, 2009), and potential considerations for regulatory changes to strengthen the program. The public listening sessions will afford an opportunity for the public to provide input on regulatory actions that EPA is considering. Brief oral comments (three minutes or less) will be accepted at the sessions, and written statements will be accepted. The dates and locations of the listening sessions are as follows:

- January 19, 2010, 10 a.m. to 3 p.m. at EPA Region 5 Office, 77 W. Jackson Blvd., Chicago, IL 60604
- January 20, 2010, 10 a.m. to 3 p.m. at EPA Region 9 Office, 75 Hawthorne Street, San Francisco, CA 94105
- January 25, 2010, 10 a.m. to 3 p.m. at EPA Region 8 Office, 1595 Wynkoop Street, Denver, CO 80202–1129
- January 26, 2010, 10 a.m. to 3 p.m. at EPA Region 6 Office, 1445 Ross Avenue, Suite 1200, Dallas, Texas 75202
- January 28, 2010, 10 a.m. to 3 p.m. at EPA HQ Office, Ariel Rios Building, 1200 Pennsylvania Ave. NW., Washington, DC 20004

In order to provide adequate seating for those wishing to attend EPA's public listening sessions, interested individuals must register to attend by January 15, 2010 on the Internet at *http://www.epa.gov/npdes/stormwater/rulemaking.*

SUPPLEMENTARY INFORMATION:

I. General Information

A. How Can I Get Copies of This Document and Other Related Information?

1. Docket. EPA has established an official public docket for this action under Docket ID No. EPA–HQ–OW–2009–0817. The official public docket is the collection of materials that is available for public viewing at the Water Docket in the EPA Docket Center, (EPA/DC) EPA West, Room 3334, 1301 Constitution Ave., NW., Washington, DC. Although all documents in the docket are listed in an index, some information is not publicly available, i.e., CBI or other information whose disclosure is restricted by statute. Publicly available docket materials are available in hard copy at the EPA Docket Center Public Reading Room, open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Water Docket is (202) 566–2426.

2. Electronic Access. You may access this **Federal Register** document electronically through the EPA Internet under the ''Federal Register'' listings at *http://www.epa.gov/fedrgstr/.* Electronic versions of this notice and other stormwater documents are available at EPA's stormwater Web site *http://www.epa.gov/npdes/stormwater/rulemaking.*

An electronic version of the public docket is available through EPA's electronic public docket and comment system, EPA Dockets. You may use EPA Dockets at *http://www.epa.gov/edocket/* to submit or view public comments, access the index listing of the contents of the official public docket, and to access those documents in the public docket that are available electronically. Once in the system, select ''search'', then key in the appropriate docket identification number.

Certain types of information will not be placed in the EPA Dockets. Information claimed as CBI and other information whose disclosure is restricted by statute, which is not included in the official public docket, will not be available for public viewing in EPA's electronic public docket. EPA policy is that copyrighted material will not be placed in EPA's electronic public docket but will be available only in printed, paper form in the official public docket. Although not all docket materials may be available electronically, you may still access any of the publicly available docket materials through the docket facility identified in Section I.A.1.

Submitting CBI. Do not submit this information to EPA through regulations.gov or e-mail. Clearly mark all of the information that you claim to be CBI. For CBI information on computer discs mailed to EPA, mark the surface of the disc as CBI. Also identify electronically the specific information contained in the disc or that you claim is CBI. In addition to one complete version of the specific information claimed as CBI, you must submit a copy that does not contain the information claimed as CBI for inclusion in the public document. Information so marked will not be disclosed except in accordance with procedures set forth in 40 CFR Part 2.

It is important to note that EPA's policy is that public input, whether submitted electronically or in paper, will be made available for public viewing in EPA's electronic public docket as EPA receives them and without change, unless the input contains copyrighted material, CBI, or other information whose disclosure is restricted by statute. When EPA identifies any input containing copyrighted material, EPA will provide a reference to that material in the version of the document that is placed in EPA's electronic public docket. The entire printed submittal, including the copyrighted material, will be available in the public docket.

Documents submitted on computer disks that are mailed or delivered to the docket will be transferred to EPA's electronic public docket. Input that is mailed or delivered to the Docket will be scanned and placed in EPA's electronic public docket. Where practical, physical objects will be photographed, and the photograph will be placed in EPA's electronic public docket along with a brief description written by the docket staff.

B. How and to Whom Do I Submit Input?

You may submit input electronically, by mail, through hand delivery/courier, or in person by attending one of the 5 listening sessions. To ensure proper receipt by EPA, identify the appropriate docket identification number in the subject line on the first page of your input. Please ensure that your input is submitted within the specified comment period.

1. Electronically. If you submit electronic input as prescribed below, EPA recommends that you include your name, mailing address, and an e-mail address or other contact information in the body of your comment. Also include this contact information on the outside of any disk or CD–ROM you submit, and in any cover letter accompanying the disk or CD–ROM. This ensures that you can be identified as the submitter of the comment and allows EPA to contact you in case EPA cannot read your submittal due to technical difficulties or needs further information on the substance of your input. EPA's policy is that EPA will not edit your input, and any identifying or contact information provided in the body of the text will be included as part of the input that is placed in the official public docket, and made available in EPA's electronic public docket. If EPA cannot read your submittal due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your input.

i. EPA Dockets. Your use of EPA's electronic public docket to provide input to EPA electronically is EPA's preferred method for receiving comments. Go directly to EPA Dockets at *http://www.epa.gov/edocket*, and follow the online instructions for submitting input. Once in the system, select ''search'', and then key in Docket ID No. EPA–HQ–OW–2009–0817. The system is an ''anonymous access'' system, which means EPA will not know your identity, e-mail address, or other contact information unless you provide it.

ii. E-mail. Input may be sent by electronic mail (e-mail) to *ow-docket@epa.gov*, Attention Docket ID No. EPA–HQ–OW–2009–0817. In contrast to EPA's electronic public docket, EPA's e-mail system is not an ''anonymous access'' system. If you send an e-mail directly to the Docket without going through EPA's electronic public docket, EPA's e-mail system automatically captures your e-mail address. E-mail addresses that are automatically captured by EPA's e-mail system are included as part of the submittal that is placed in the official public docket, and made available in EPA's electronic public docket.

iii. Disk or CD–ROM. You may submit input on a disk or CD–ROM that you mail to the mailing address identified in this section. These electronic submissions will be accepted in Microsoft Word or ASCII file format. Avoid the use of special characters and any form of encryption.

2. By Mail. Send the original and three copies of your input to: Water Docket, Environmental Protection Agency, Mailcode: 4101T, 1200 Pennsylvania Ave., NW., Washington, DC 20460, Attention Docket ID No. EPA–HQ–OW–2009–0817.

3. By Hand Delivery or Courier. Deliver your input to: Public Reading Room, Room B102, EPA West Building, 1301 Constitution Avenue, NW., Washington, DC 20004, Attention Docket ID No. EPA–HQ–OW–2009–0817. Such deliveries are only accepted during the Docket's normal hours of operation (8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays).

II. Background

Statutory and Regulatory Overview

Under section 402(p) of the Clean Water Act, the Environmental Protection Agency regulates stormwater discharges from municipal separate storm sewer systems (publicly owned conveyances or systems of conveyances that discharge to waters of the U.S. and are designed or used for collecting or conveying storm water, are not combined sewers, and are not part of a publicly owned treatment works), stormwater discharges associated with industrial activity, and stormwater discharges from construction sites of one acre or larger. See 40 CFR 122.26(a). Under EPA's regulations, these stormwater discharges are required to be covered by National Pollutant Discharge Elimination System (NPDES) permits.

EPA developed the stormwater regulations under section 402(p) in two phases, as directed by the statute. In the first phase, under section 402(p)(4), EPA promulgated regulations establishing application requirements for NPDES permits for stormwater discharges from medium and large municipal separate storm sewer systems (MS4s) (serving populations of 100,000 or more) and stormwater discharges associated with industrial activity. EPA published the final Phase I rule on November 16, 1990 (55 FR 47990). *See* 40 CFR 122.26. The Phase I rule, among other things, defined ''stormwater discharges associated with industrial activity'' to include construction sites of five acres or larger. 40 CFR 122.26(b)(14)(x). In the second phase, under section 402(p)(5) and (6), EPA was required to conduct a study to identify other stormwater discharges that needed further controls to protect water quality, report to Congress on the results of the study, and to designate for regulation additional categories of stormwater discharges not regulated in Phase I. EPA promulgated the Phase II rule on December 8, 1999, designating small MS4s and small construction sites (1–5 acres) and requiring NPDES permits for these discharges. 64 FR 68722.

With respect to MS4s, the Phase I regulations are primarily application requirements that identify components that must be addressed in permit applications from large and medium MS4s. The regulations require these MS4s to develop a stormwater management program (SWMP), track and oversee industrial facilities regulated under the NPDES stormwater program, conduct monitoring, and submit periodic reports.

Under the Phase II rule, regulated small MS4s are generally defined as any MS4 that is not already covered by the Phase I program and that are located within the urbanized area boundary as determined by the U.S. Decennial Census. Separate storm sewer systems such as those serving military bases, universities, large hospital or prison complexes, and highways are also included in the definition of ''small MS4.'' 40 CFR 122.26(b)(16). In addition, a small MS4 located outside of an urbanized area may be designated as a regulated small MS4 if the NPDES permitting authority determines that its discharges cause, or have the potential to cause, an adverse impact on water quality. *See* 40 CFR 122.32(a)(2), 123.35(b)(3).

Phase II stormwater regulations also require that the MS4, under the permit, implement stormwater management programs (SWMPs), and require that the SWMPs include six minimum control measures. The minimum control measures are: Public education and outreach, public participation and involvement, illicit discharge detection and elimination, construction site runoff control, post construction runoff control, pollution prevention and good housekeeping. Regulations applicable to Phase II MS4 permits are found in 40 CFR 122.30–122.37. In general, Phase II MS4 permits are general permits, although small MS4s may apply for individual permits under the Phase I rule's application provisions in 40 CFR 122.26(d).

Under section 402(p)(6), EPA is authorized to designate additional stormwater discharges to be regulated other than those already regulated, and to establish a comprehensive program to regulate them. In addition, under EPA's stormwater regulations, EPA (or States authorized to administer the NPDES program) may require NPDES permits

RB-AR33000

for currently unregulated stormwater discharges by designating discharges pursuant to 40 CFR 122.26(a)(9)(i)(C) or (D).

National Research Council Report

In 2006, EPA asked the National Research Council (NRC) to conduct a review of its stormwater program, considering all entities regulated under the program, i.e., municipal, industrial and construction. In October 2008, the National Research Council released the report *Urban Stormwater Management in the United States* (The National Academies Press, 2009) finding, among other things, that ''the rapid conversion of land to urban and suburban areas has profoundly altered how water flows during and following storm events, putting higher volumes of water and more pollutants into the nation's rivers, lakes, and estuaries. These changes have degraded water quality and habitat in virtually every urban stream system.''

This report recommends a number of actions, including conserving natural areas, reducing hard surface cover (e.g., roads and parking lots—impervious surface areas), and retrofitting urban areas with features that hold and treat stormwater (NRC, *Report in Brief,* 2008). EPA takes seriously the significant findings and recommendations included in the NRC Report, and continues to evaluate how the Agency's stormwater program can be strengthened in light of the report. The *Report in Brief* can be accessed at: *http://dels.nas.edu/dels/rpt_briefs/stormwater_discharge_final.pdf.* A full copy of the report can be obtained from The National Academies Press, *http://books.nap.edu/catalog.php?record_id=12465.* A prepublication copy is available at: *http://www.epa.gov/npdes/pubs/nrc_stormwaterreport.pdf.*

EPA shares the NRC Committee's perspective that it is imperative that the stormwater regulations be as effective as possible in protecting water quality. The NRC Report has provided EPA with the opportunity to reexamine the effectiveness of its stormwater programs, some of which are nearly 20 years old. For instance, EPA is interested in assessing the level of accountability that the regulations and the permits issued under the regulations provide to MS4s to minimize the discharge of pollutants in stormwater. The role of MS4s in reducing stormwater impacts from the built environment is crucial and growing, given that these sources of adverse water quality impacts are continually expanding. As the urban, suburban and exurban human environment expands, there is an increase in impervious land cover and therefore an increase in stormwater discharges. This increase in impervious land cover reduces or eliminates the natural infiltration of precipitation, which greatly increases the volume of stormwater discharges. This increased volume of stormwater discharges results in the scouring of rivers and streams; degrading the physical integrity of aquatic habitats, stream function and overall water quality. In addition, the increase in impervious land cover results in the increase of the pollutant load discharged from storm sewers. As precipitation moves across roads, rooftops, and other impervious surfaces, it picks up pollutants that are then discharged, either directly or through storm sewers, to our Nation's waters.

To address the degradation of water quality caused by stormwater discharges from impervious cover, EPA is exploring regulatory options that would strengthen the stormwater program, including establishing specific post construction requirements for stormwater discharges from, at a minimum, new development and redevelopment. EPA does not currently regulate stormwater discharges from new development and redevelopment directly. However, both Phase I MS4s and Phase II MS4s are required through the MS4 permit to address stormwater discharges from new development and redevelopment in their SWMPs, but the regulations do not include specific management practices or standards to be implemented. Among the Phase I requirements for a SWMP is a ''comprehensive master plan to develop, implement, and enforce controls to reduce the discharge of pollutants from municipal storm sewers, which receive discharges from areas of new development and significant redevelopment. Such plan shall address controls to reduce pollutants in discharges from municipal separate storm sewers after construction is completed.'' (40 CFR 122.26(d)(2)(iv)(A)(2)).

Phase II regulations include post construction requirements as one of the six minimum control measures to be addressed in the SWMP. Small MS4s must ''develop, implement, and enforce a program to address'' stormwater discharges from new development and redevelopment projects of one acre or greater to ''ensure that controls are in place that would prevent or minimize water quality impacts.'' 40 CFR 122.34(b)(5). The program must include strategies including structural and/or non-structural best management practices (BMPs) appropriate for the community; use of ordinances or other regulatory mechanisms to the extent allowable under State, Tribal or local law; and measures to ensure adequate long-term operation and maintenance of BMPs. The Phase II rule recommends (but does not require) that the program to address stormwater from new development and redevelopment should attempt to maintain pre-development runoff conditions by installing and implementing stormwater control measures.

As stated in the report, the NRC found that ''stormwater permits leave a great deal of discretion to the regulated community to set their own standards and to self-monitor.'' As a result, across the Nation there is inconsistency in the NPDES program and in stormwater management programs required by NPDES permit with respect to stormwater discharges from MS4s caused by stormwater discharges from development. Despite the lack of specificity in the current regulations, some permitting authorities have required controls for stormwater discharges from developed property that neutralize the impacts from stormwater by promoting practices that retain stormwater on-site through infiltration, evapotranspiration, or stormwater reuse. To help make permitting more consistent and robust nationally, EPA is considering ways to strengthen the MS4 permit regulations, including establishing specific requirements for stormwater discharges from, at a minimum, new development and redevelopment; expanding the area defined as MS4s to include rapidly developing areas; and devising a single set of consistent regulations for all MS4s. In addition, EPA is exploring regulatory options to directly address stormwater discharges from new development and redevelopment, including new and redeveloped sites outside the MS4 boundary, that may be contributing to waterbody impairment, through the designation of an additional category or categories of discharges under CWA section 402(p)(6).

Proposed Information Collection Request (ICR)

EPA has proposed an Information Collection Request (ICR) to collect data to support this effort to strengthen the stormwater regulations (published October 30, 2009, 74 FR 56191). The proposed ICR discusses the administration of three questionnaires: The first for the owners, operators, developers, and contractors of new development and redevelopment; the second for the owners and operators of MS4s (including those not federally regulated); and the third for the States and territories. The data collected through this ICR would support EPA's rulemaking activities by providing EPA with information to characterize the current level of stormwater controls and stormwater control measures; the area currently covered by federal and state stormwater requirements; the current burden and expenditures by States and MS4s associated with existing requirements; and technical, financial, and environmental data needed to quantify the incremental pollutant removals, compliance costs, and impacts for various regulatory options that EPA might consider. Under the proposed ICR, EPA seeks any available information concerning current stormwater control practices, including those referred to as green infrastructure or low-impact development. For further information, see: *http://www.epa.gov/npdes/stormwater/rulemaking*.

III. Input on Stormwater Practices and Considerations for Modifying Regulations

Today's notice is being issued to make the public aware of opportunities to provide input on current stormwater practices and to inform the public of and solicit comment on EPA's preliminary considerations for modifying or supplementing EPA's stormwater regulations. EPA is accepting information during the listening sessions and/or by submission of written comments in order to gain early public input on stormwater practices and regulations.

A. Solicitation for Additional Input Regarding Stormwater Control Practices

1. In addition to the information collection request described above, EPA is soliciting comment and input from the general public concerning current stormwater control practices, as well as information concerning innovative approaches to stormwater control. In particular, EPA is seeking information on the following aspects of structural approaches to stormwater control: design, performance, operation and maintenance, capital and lifetime cost, and environmental and economic benefit information on practices that retain stormwater on-site through infiltration, evapotranspiration, or stormwater reuse. EPA solicits comment and input on these retention practices that have been used for ''green field'' development, redevelopment (where there was some pre-existing infrastructure), and retrofitting existing development. While a significant amount of data has been collected and is available (see, EPA's Urban BMP Performance Tool (*http://www.epa.gov/npdes/stormwater/urbanbmp*) or the International Stormwater BMP Database (*http://www.bmpdatabase.org*)), EPA is accepting any more recent information that is not already available in these databases.

2. Cost comparisons of different stormwater management approaches for specific sites. EPA solicits comment and input on different stormwater management approaches, including comparison of stormwater management systems that rely primarily on conveyance and detention of excess discharge with stormwater management systems that relies primarily on on-site retention. Cost comparisons should preferably be between similar sized projects and/or between individual management methods of similar scope and capability.

3. Design, performance, operation and maintenance, capital and lifetime costs, and environmental and economic benefit information for communities and/or site owners or operators that have elected to modify or retrofit their stormwater management practices for existing development, as a separate effort that is not in conjunction with redevelopment. This may occur if the existing stormwater management practices were insufficient to reduce pollutants, restore habitat and stabilize stream morphology, or to correct past mistakes. This may also occur as part of a larger watershed restoration plan. EPA is also soliciting comments and input on: where retrofit practices have been installed, what the drivers were for the project, and information on the specific retrofit practices that were installed.

4. EPA is also soliciting comments and input on monitoring information that may have been collected to show the impacts of stormwater control measures on water quality and/or flow rates in the receiving waterbody. This includes information on the effects of retrofits for existing discharges (before and after installation, if possible), as well as any water monitoring information obtained before and after new development and redevelopment.

B. Preliminary Considerations for Modifying/Supplementing EPA's Stormwater Regulations

By today's notice, EPA is informing the public of its preliminary considerations for modifying or supplementing EPA's stormwater regulations and soliciting public input on these considerations. The following are ideas that EPA is considering for strengthening the stormwater requirements and for which EPA seeks input:

1. *Expand the area subject to federal stormwater regulations.* EPA currently requires MS4s within Census-designated urbanized areas to apply for permit coverage (see *http://www.epa.gov/npdes/stormwater/urbanmaps* for maps of all urbanized areas). Based on the 1990 Census, there are 405 urbanized areas in the United States that cover 2% of total U.S. land area and contain approximately 63 percent of the Nation's population. Under the present regulations, development that is occurring outside currently regulated MS4s may not be subject to federal controls to protect water quality notwithstanding the fact that the resulting stormwater discharges may be contributing to waterbody impairment. For example, for Phase II MS4s, only the portion of the municipal jurisdiction (i.e. township) that is within the Census-designated urbanized area is required to be regulated, which may leave stormwater discharges in parts of the jurisdiction unregulated.

EPA solicits comments and input from the public on the need for expanding the area subject to federal regulation, and, if needed, how to expand the coverage of the federal stormwater program beyond the Census urbanized area boundary. EPA would be interested in views on (1) How to identify the appropriate jurisdictional boundaries for permit coverage, including the township, county, sewer district, or others; (2) how to identify areas that should be covered based on development pressures and to protect water quality; and (3) whether EPA should consider regulating stormwater discharges from particular types or sizes of development that are not covered by an MS4 permit.

2. *Establish specific requirements to control stormwater discharges from new development and redevelopment.* EPA is considering establishing specific requirements, including standards, to control stormwater discharges from new development and redevelopment. EPA welcomes comments on what standard or standards could apply to new development and redevelopment that promote sustainable practices that mimic natural processes to (1) Infiltrate and recharge, (2) evapotranspire, and/or (3) harvest and reuse precipitation. For example, there could be a national requirement for on-site stormwater controls such that post development hydrology mimics predevelopment hydrology on a site-specific basis. EPA could establish a suite of specific options of standards for meeting such a requirement, for example, on-site retention of a specific size storm event in an area, limits on the amount of

RB-AR33002

effective impervious surfaces (defined as impervious surfaces with direct hydraulic connection to the downstream drainage (or stream) system, also referred to as directly connected impervious area), use of site-specific calculations to determine predevelopment hydrology, and/or use of regional specific standards to reflect local circumstances. EPA could require these standards as part of the MS4 permit on a site-specific basis. EPA is interested in input regarding the need for and the type of standards to set. Should the standard be different for discharges from new development versus redevelopment and, if so, how should it differ? Are there specific circumstances in which (for example) a requirement for new development and redevelopment to maintain pre-development hydrology would not be advisable or would cause other environmental impacts? Finally, EPA is interested in input regarding responsibility for maintaining stormwater control measures that infiltrate, evapotranspirate and/or reuse water.

The impacts from stormwater discharges from new and redevelopment occur not only within the MS4 but also from sources outside the MS4 regulated areas. EPA is interested in input regarding the appropriate framework for implementing standards for new and redevelopment outside of the MS4 regulations.

3. Develop a single set of consistent requirements for Phase I and Phase II MS4s. EPA's Phase I regulations primarily contain application requirements that identify components that must be addressed in permit applications. The Phase II regulations establish six ''minimum measures'' that must be included in an MS4 permit that were more specific than Phase I. Many Phase I and Phase II permits address issues that are virtually identical. EPA requests input on whether EPA should modify the regulations to develop a consistent set of requirements that would apply to all regulated MS4s. For example, should EPA apply the six minimum measures to all MS4s? Should EPA add other measures? For instance, Phase I MS4s are required to implement a program to control discharges for industrial facilities in their service area. Should this requirement be extended to all MS4s? EPA also requests input on any other modifications to improve the stormwater regulations.

4. Require MS4s to address stormwater discharges in areas of existing development through retrofitting of the sewer system, drainage area, or individual structures with improved stormwater control measures. Stormwater discharge from large areas of impervious cover in developed areas is a significant contributor to water quality impairments in the receiving waters of urban areas. Changes to the stormwater management practices in areas of existing development will reduce these impacts. In some states, MS4 permits now require the MS4 to install retrofit practices that infiltrate or otherwise retain stormwater in areas of existing development to reduce these impacts. EPA requests input on whether it should consider requirements for the retrofit of existing development to address stormwater. In particular, EPA requests comment on requiring MS4s to develop a long-term retrofit implementation plan that is targeted to addressing stormwater problems in urban waters.

5. Whether EPA should include additional changes to the stormwater regulations (for example, requiring permits to include buffer requirements) in sensitive areas. EPA is interested in views on whether it should consider making any other changes to the current regulatory program (e.g., specific structural or nonstructural stormwater control measures) in addition to the ones described above to protect waterbodies in sensitive areas.

Dated: December 17, 2009.

Peter Silva,

Assistant Administrator, Office of Water.

BILLING CODE 6560–50–P

FEDERAL DEPOSIT INSURANCE CORPORATION

Agency Information Collection Activities: Renewal of a Currently Approved Collection; Comment Request

AGENCY: Federal Deposit Insurance Corporation (FDIC).

ACTION: Notice and request for comment.

SUMMARY: In accordance with requirements of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.), the FDIC may not conduct or sponsor, and the respondent is not required to respond to, an information collection unless it displays a currently valid Office of Management and Budget (OMB) control number. The FDIC hereby gives notice that it is seeking public comment on renewal of its ''Foreign Banks'' information collection (OMB No. 3064–0114). At the end of the comment period, any comments and recommendations received will be analyzed to determine the extent to which the FDIC should modify the collection prior to submission to OMB for review and approval.

DATES: Comments must be submitted on or before February 26, 2010.

ADDRESSES: Interested parties are invited to submit written comments. All comments should refer to the name of the collection. Comments may be submitted by any of the following methods:

- *http://www.FDIC.gov/regulations/laws/federal/notices.html.*
- *E-mail: comments@fdic.gov.*
- *Mail:* Leneta G. Gregorie (202.898.3719), Counsel, Federal Deposit Insurance Corporation, 550 17th Street, NW., Washington, DC 20429.
- *Hand Delivery:* Comments may be hand-delivered to the guard station at the rear of the 550 17th Street Building (located on F Street), on business days between 7 a.m. and 5 p.m.

A copy of the comments may also be submitted to the FDIC Desk Officer, Office of Information and Regulatory Affairs, Office of Management and Budget, New Executive Office Building, Room 10235, Washington, DC 20503.

FOR FURTHER INFORMATION CONTACT: For further information about the information collection discussed in this notice, please contact Leneta G. Gregorie, by telephone at (202) 898–3719 or by mail at the address identified above.

SUPPLEMENTARY INFORMATION: The FDIC is proposing to renew, without change, the following information collection.

Title: Foreign Banks.

Estimated Number of Respondents and Burden Hours:

FDIC collection	Hours per response	Number of respondents	Times per year	Burden hours
Application to move a branch	8	1	1	8
Application for consent to operate a noninsured branch	8	1	1	8
Application to conduct activities	8	1	1	8

Renee Purdy - Items 4 and 5 from our Recap (To Do List) for 9/28/11 LA MS4 permit meeting

From:	Wesley Ganter <wes.ganter@pgenv.com>
To:	"kemmerer.john@epa.gov" <kemmerer.john@epa.gov>, Renee Purdy <rpurdy@wat...
Date:	10/6/2011 2:56 PM
Subject:	Items 4 and 5 from our Recap (To Do List) for 9/28/11 LA MS4 permit meeting
CC:	Wesley Ganter <wes.ganter@pgenv.com>, Jim Parker <jim.parker@pgenv.com>,...
Attachments:	Core Permit Requirements_SummaryTable and Draft Language_Industrial and Commercial_PG_100611.docx; Core Permit Requirements_SummaryTable and Draft Language_Illicit Connection IllicitDischarge_PG_100611.docx

Hi everyone:

Per the recap email from our 9/28 meeting (see below), PG has attached two templates for Item 4 - **Core Permit Requirements Objectives, Elements, and Issue Tables.** Individual files are provided for the Industrial & Commercial and Illicit Connection and Illicit Discharge Elimination MCMs. You will note that the tables include objectives, draft citations, requirements, issues, and opportunity for flexibility amongst dischargers columns. These tables should be considered preliminary drafts and will be more formally completed throughout October. Nonetheless, the tables are intended to serve as templates and to solicit your feedback. At the present time we envision creating 8 such tables (e.g., all 6 MCMs plus monitoring and reporting).

You will also note that we have also included our proposed draft permit language for the respective MCM. PG had previously prepared this language and had held several discussions with Ivar to refine it so we thought it best to attach it now for your consideration. PG has also completed draft language for the Public Information and Participation Program and made significant progress on the Public Agencies Activities Program. Therefore we will be able to rapidly move forward with those elements and then turn our focus to Construction, Planning and New Development, Reporting, and Monitoring.

We hope that these tables will provide significant benefit at the planned November 10th informational Board meeting and possibly for other planned workshops or meetings. Likewise, they will help our team to readily see and digest the requirements and then identify and resolve issues before substantial permit writing occurs.

Please let us know if you have any suggested improvements or modifications to the template as we will be moving forward with the remaining tables quickly.

Also, I provided Renee the Item 5 - **Microsoft Project File** – earlier in the week.

Thanks much and contact me directly if you have questions or comments.

RB-AR33004

Core Permit Requirements – Table of Objectives, Elements, and Issues

Minimum Control Measure – Industrial/Commercial Storm Water Sources

Primary Objectives:	• To identify and track industrial/commercial facilities which may be critical sources of storm water pollution to the MS4. • To educate and raise storm water awareness of industrial/commercial facility employees to ultimately change behaviors that will reduce pollutant discharges to the MS4. • To ensure the implementation of BMPs at from industrial/commercial facilities to reduce the contribution of pollutants to storm water from industrial/commercial activities and materials storage. • To increase the detection of illicit discharges and connections to the MS4 from industrial/commercial facilities. • To minimize the occurrence of illicit discharges and connections to the MS4 from industrial/commercial facilities.

Permit Citation[1]	Category	Description of Requirement	Issues to be Addressed by Regional Board	Opportunities for Flexibility amongst Dischargers
Part VI.C.8.a	General	Ensure implementation of pollutant reduction and control measures at industrial and commercial facilities, with the objective of reducing pollutants in storm water.		
Part VI.C.8.b.i	Track	Maintain an updated watershed-based inventory or database of all industrial and commercial facilities within the jurisdiction that are critical sources of storm water pollution. Incorporate this information into GIS.		
Part VI.C.8.b.ii	Track	This permit requirement lists the specific information which must be included in the inventory or database of critical sources.		
Part VI.C.8.b.iii	Track	Update the inventory or database of critical sources at least annually.		
Part VI.C.8.c.i	Inspect	Inspect all commercial facilities identified by the Permit twice during the 5-year term of the Order, with the first mandatory compliance inspection within 2 years after Order adoption date. This permit requirement includes subsections that detail inspection and BMP requirements for different types of facilities, such as, (1) restaurants, (2) automotive service facilities, (3) retail gasoline outlets and automobile dealerships,		

[1] Short-name permit citation from current Draft Los Angeles County MS4 Permit. Full permit citation includes suffix, "Part VII – Provisions, C - Special Provisions (Baseline) – 8 - Industrial/Commercial Business Program."

RB-AR33005

		and (4) commercial nurseries and nursery centers.		
Part VI.C.8.c.ii.1	Inspect	Conduct compliance inspections at industrial facilities identified by the Permit. Initial inspection must be within 2 years after Order adoption date. Conduct follow-up inspections at 20 percent of no-exposure facilities each year after the initial inspections are complete.		
Part VI.C.8.c.ii.2	Inspect	During each inspection, confirm that each operator has a current WDID number, has a No Exposure Certification, if applicable, and is effectively implementing BMPs for the reduction of pollutants in storm water discharges from the facility.		
Part VI.C.8.d.i	Ensure Compliance	Ensure BMP implementation of the source control BMPs identified in the *California Stormwater BMP Handbook, Industrial and Commercial*		
Part VI.C.8.d.ii	Ensure Compliance	Ensure implementation of additional pollutant-specific controls for critical sources that discharge to MS4s that directly discharge to ESAs or to CWA § 303(d) listed impaired waterbodies.		
Part VI.C.8.d.ii	Ensure Compliance	Implement a progressive enforcement policy to ensure that facilities are brought into compliance with all storm water requirements within a reasonable time period, as specified in the Permit.		
Part VI.C.8.e.i	Interagency Coordination	A Permittee may refer a violation(s) of its municipal storm water ordinances and California Water Code § 13260 by Industrial and Commercial facilities to the Regional Water Board provided that the Permittee has conducted and documented at least two follow-up inspections and two warning letters or notices of violation.		
Part VI.C.8.e.ii	Interagency Coordination	For facilities in violation of municipal storm water ordinances and subject to the Industrial Activities Storm Water General Permit (IASGP), Permittees may escalate referral of such violations to the Regional Water Board (promptly via telephone or electronically) after one inspection and one written notice of violation		
Part VI.C.8.e.iii	Interagency Coordination	Initiate, within one business day of complaint transmittal by the Regional Water Board, investigation of complaints (other than non-storm water discharges to the MS4) from facilities.		
Part VI.C.8.e.iv	Interagency Coordination	Provide assistance to the Regional Water Board for enforcement actions, as directed by the Regional Water Board		

RB-AR33006

		Executive Officer.		
Part VI.C.8.e.v	Interagency Coordination	Participate in an enforcement task force with the Regional Water Board and other public agencies.		

RB-AR33007

Draft Permit Language

Part VI.C.8 – Industrial/Commercial Facilities Program

a. General

i. Each Permittee shall require implementation of pollutant reduction and control measures at industrial and commercial facilities, with the objective of reducing pollutants in storm water. At a minimum, the Industrial/ Commercial Facilities Control Program shall be implemented in accordance with the requirements listed in this part, consisting of the following components:

(1) Track

(2) Inspect

(3) Ensure compliance with municipal ordinances at industrial and commercial facilities that are critical sources of pollutants in storm water

b. Track Critical Sources

i. Each Permittee shall maintain an updated watershed-based inventory or database of all industrial and commercial facilities within its jurisdiction that are critical sources of storm water pollution. The incorporation of facility information into a Geographical Information System (GIS) is required. Critical Sources to be tracked are summarized below, and specified in Attachment "B":

(1) Commercial Facilities

(A) Restaurants

(B) Automotive service facilities

(C) RGOs and automobile dealerships

(D) Nurseries and Nursery Centers (Merchant Wholesalers, Nondurable Goods, and Retail Trade)

(2) U.S. EPA Phase I, II Facilities

(3) Other federally-mandated facilities [as specified in 40 CFR 122.26(d)(2)(iv)(C)]

(A) Municipal landfills

(B) Hazardous waste treatment, disposal, and recovery facilities

(C) Facilities subject to SARA Title III (also known as the Emergency Planning and Community Right-to-Know Act (EPCRA))

(4) All other commercial or industrial facilities tributary to an impaired water body segment, where the facility generates pollutants for which the water body segment is impaired

Comment [A1]: Per Ivar (6/27/11), no need to add additional categories. Mobile sources s/b handled in PIPP. Plastics already captured as EPA Phase I facilities. SC

Comment [A2]: Per Ivar (6/27/11), keep tabs on State Board's IASGP as it may abandon this reference ... in which case this will need to be modified. SC

Comment [A3]: Confirmed the use of Phase II here with Ivar (6/27/11). Alternatively just replace with 40 CFR 122.26(b)(14).

Ivar (6/27/11) stated Phase I facilities captures preproduction plastics transfer and storage facilities.

Per Ivar, get away from tiers and prioritization. Only prioritization method he would consider is based on exposure. SC

Comment [A4]: Taken from State Board's Phase II general permit. SC

RB-AR33008

(5) All other commercial or industrial facilities that the Permittee determines may contribute a significant pollutant load to the MS4

ii. Each Permittee shall include the following minimum fields of information for each critical source industrial and commercial facility in its watershed-based inventory or database:

(1) Name of facility

(2) Name of owner/ operator and contact information

(3) Address of facility (physical and mailing)

(4) A narrative description including Standard Industrial Classification (SIC) System/ North American Industry Classification System (NAICS) codes that best describe the industrial activities performed and principal products used at each facility and status of exposure to storm water.

(5) Name of receiving water

(6) Identification of whether the facility is tributary to a CWA § 303(d) listed waterbody segment or waterbody segment subject to a TMDL, where the facility generates pollutants for which the waterbody segment is impaired

(7) Coverage under the IASGP or other individual or general NPDES permits or any applicable waiver issued by the Regional or State Board pertaining to storm water discharges

iii. Each Permittee shall update its inventory of critical sources at least annually. The update shall be accomplished through collection of new information obtained through field activities or through other readily available inter and intra-agency informational databases (e.g., business licenses, pretreatment permits, sanitary sewer connection permits, and similar information).

Comment [A5]: Implies waterbody information but specified below as well. SC

Comment [A6]: (5) Description of BMPs employed. MB

Couldn't they choose to do this as part of inspection records, or do you mean structural treatment controls? SC

c. Inspect Critical Sources

i. **Commercial Facilities**

Mandatory Compliance Inspections: Each Permittee shall inspect all commercial facilities identified in Parts 4.D.2(a)(1), 4.D.2(a)(4), and 4.D.2(a)(5) twice during the 5-year term of the Order, provided that the first mandatory compliance inspection occurs no later than (2 years after Order adoption date). A minimum interval of 6 months between the first and the second mandatory compliance inspection is required. In addition, each Permittee shall implement the activities outlined in the following subparts. At each facility, inspectors shall verify that the operator is implementing the source control BMPs for the corresponding facility type as specified in Parts 4.D.3(a)(1) - 4.D.3(a)(4). The Permittees shall require implementation of additional BMPs where storm water from the MS4 discharges to an environmentally sensitive area (ESA, see Part 6 for definition) or a CWA § 303(d) listed waterbody (see Part 4.D.4(b) below).

RB-AR33009

(1) Restaurants - *Scope of Inspection*: Each Permittee shall inspect all restaurants within its jurisdiction to confirm that storm water BMPs are being effectively implemented in compliance with state law, and county and municipal ordinances. The following BMPs shall be implemented, unless the pollutant generating activity does not occur: the Municipal Sidewalk and Street Washing BMPs listed in Attachment 2 of Regional Water Board Resolution 98-08, and the BMPs listed in Table 2 (BMPs at Restaurants).[2]

Comment [A7]: Confirmed with Ivar (6/27/11). There is no need to modify Order to address non-traditional flood control district and their reg mechanisms. SC

Table 2 - BMPs at Restaurants

Pollutant-Generating Activity	BMP Narrative Description	California Stormwater BMP Handbook Industrial and Commercial BMP Identification #
Waste/ Hazardous Materials Storage, Handling and Disposal	Implementation of effective storage, handling and disposal procedures for hazardous materials.	By Permittees
Unauthorized Non-Storm Water Discharges	Effective elimination of non-storm water discharges.	SC-10
Accidental Spills/ Leaks	Implementation of effective spills/ leaks prevention and response procedures.	SC-11
Outdoor Storage of Raw Materials	Implementation of effective source control practices and structural devices.	SC-33
Storage and Handling of Solid Waste	Implementation of effective solid waste storage/ handling practices and appropriate control measures	SC-34
Parking/ Storage Area Maintenance	Implementation of effective parking/ storage area designs and housekeeping/ maintenance practices	SC-43
Storm Water Conveyance System Maintenance	Implementation of proper conveyance system operation and maintenance protocols.	SC-44

Comment [A8]: Confirmed with Ivar (6/27/11): Reference most recent BMPs developed by CASQA throughout. He foresees that watershed based permit would lead to pooled resources and access to CASQA would not be cost prohibitive. SC

(2) Automotive Service Facilities – *Scope of Inspection*: Each Permittee shall inspect all automotive service facilities within its jurisdiction to confirm that storm water BMPs are being effectively implemented in compliance with state law, and county and municipal ordinances. The following BMPs shall be implemented, unless the pollutant generating activity does not occur: the Municipal Sidewalk and

[2] The BMPs refer to the current version of the California Stormwater BMP Handbook, Industrial and Commercial. The January 2003 version was current at the time of Order adoption. In accordance with Part 4.A.2, other BMPs may be substituted upon approval by the Executive Officer.

RB-AR33010

Street Washing BMPs listed in Attachment 2 of Regional Water Board Resolution 98-08, and the BMPs listed in Table 3 (BMPs at Automotive Service Facilities).[3]

Table 3 - BMPs at Automotive Service Facilities

RB-AR33011

(3) Retail Gasoline Outlets and Automobile Dealerships – *Scope of Inspection*: Each Permittee shall inspect all RGOs and automobile dealerships within its jurisdiction to confirm that storm water BMPs are being effectively implemented in compliance with state law, and county and municipal ordinances. The following BMPs shall be implemented, unless the pollutant generating activity does not occur: the Municipal Sidewalk and Street Washing BMPs listed in Attachment 2 of Regional Water Board Resolution 98-08, the Stormwater Quality Task Force Best Management Practice Guide for RGOs, and the BMPs listed in Table 4 (BMPs at Retail Gasoline Outlets and Automobile Dealerships).[4]

Table 4 - BMPs at Retail Gasoline Outlets and Automobile Dealerships

Pollutant-Generating Activity	BMP Narrative Description	California Stormwater BMP Handbook Industrial and Commercial BMP Identification #

Building and Grounds Maintenance	Implementation of effective facility maintenance practices.	SC-41
Parking/ Storage Area Maintenance	Implementation of effective parking/ storage area designs and housekeeping/ maintenance practices	SC-43

[4] The BMPs refer to the current version of the California Stormwater BMP Handbook, Industrial and Commercial. The January 2003 version was current at the time of Order adoption. In accordance with Part 4.A.2, other BMPs may be substituted upon approval by the Executive Officer.

RB-AR33012

(4) Commercial Nurseries and Nursery Centers (Merchant Wholesalers, Nondurable Goods, and Retail Trade) – *Scope of Inspection*: Each Permittee shall inspect all commercial nurseries and nursery centers within its jurisdiction to confirm that storm water BMPs are being effectively implemented in compliance with state law, and county and municipal ordinances. The BMPs listed in Table 5 (BMPs at Nurseries)[5] shall be implemented, unless the pollutant generating activity does not occur.

Table 5 - BMPs at Nurseries

Pollutant-Generating Activity	BMP Narrative Description	California Stormwater BMP Handbook Industrial and Commercial BMP Identification #
Unauthorized Non-Storm Water Discharges	Effective elimination of non-storm water discharges.	SC-10
Outdoor Loading/ Unloading	Implementation of effective outdoor loading/ unloading practices.	SC-30
Outdoor Liquid Storage	Implementation of effective outdoor liquid storage source controls and practices.	SC-31
Outdoor Equipment Operations	Implementation of effective outdoor equipment source control devices and practices.	SC-32
Outdoor Storage of Raw Materials	Implementation of effective source control practices and structural devices.	SC-33
Building and Grounds Maintenance	Implementation of effective facility maintenance practices.	SC-41

ii. **Industrial Facilities**

Each Permittee shall conduct compliance inspections as specified below.

(1) Frequency of Inspections

(A) *Mandatory Compliance Inspections*: Each Permittee shall perform an initial mandatory compliance inspection at all industrial facilities identified in Parts 4.D.2(a)(2) - 4.D.2(a)(5) no later than (2 years after Order adoption date). After the initial inspection, all facilities determined as having exposure of industrial activities to storm water are subject to a second mandatory compliance inspection. A minimum interval of 6

Comment [A9]: Question the RB on whether they want to abandon or modify the Tier 1 and 2 categorizations used in the current LA permit (See above). Ventura did not use this convention and it is included here instead.

Per Ivar, lets strike and build flexibility into option SQMP up front. SC

[5] The BMPs refer to the current version of the California Stormwater BMP Handbook, Industrial and Commercial. The January 2003 version was current at the time of Order adoption. In accordance with Part 4.A.2, other BMPs may be substituted upon approval by the Executive Officer.

RB-AR33013

months between the first and the second mandatory compliance inspection is required. A facility need not be inspected more than twice during the term of the Order unless subject to an enforcement action as specified in Part 4.D.4(c)(2) below.

(B) *No Exposure Verification*: Following the first mandatory compliance inspection, a Permittee shall also perform a second mandatory compliance inspection yearly at a minimum of 20% of the facilities determined not to have exposure of industrial activities to storm water at the time of the first mandatory compliance inspection. The purpose of this inspection is to verify the continuity of the no exposure status. Facilities determined as having exposure will be notified that they must obtain coverage under the IASGP. A minimum interval of 6 months between the first and the second mandatory compliance inspection is required.

(C) *Applicable to All Facilities*: A Permittee need not inspect facilities that have been inspected by the Regional Water Board within the previous 24 month interval. However, if the Regional Water Board performed only one inspection, the Permittee shall conduct the second required mandatory compliance inspection.

(2) Scope of Inspection:

Each Permittee shall confirm that each operator:

(A) Has a current Waste Discharge Identification (WDID) number for facilities discharging storm water associated with industrial activity, and that a Storm Water Pollution Prevention Plan (SWPPP) is available on-site; <u>or</u>

(B) Has applied and has a current No Exposure Certification (and WDID number) for facilities subject to this requirement;

(C) Is effectively implementing BMPs in compliance with state law, and county and municipal ordinances. Facilities must implement the source control BMPs identified in the *California Stormwater BMP Handbook, Industrial and Commercial*[6], unless the pollutant generating activity does not occur. The Permittees shall require implementation of additional BMPs where storm water from the MS4 discharges to an environmentally sensitive area (ESA, see

[6] The BMPs refer to the current version of the California Stormwater BMP Handbook, Industrial and Commercial. The January 2003 version was current at the time of Order adoption, and the source control BMPs can be found in Section 3 of that version. In accordance with Part 4.A.2, other BMPs may be substituted upon approval by the Executive Officer.

RB-AR33014

Part 6 for definition) or a CWA § 303(d) listed waterbody (see Part 4.D.4(b) below).

d. Ensure Compliance of Critical Sources

i. *BMP Implementation*:

Facilities must implement the source control BMPs identified in the *California Stormwater BMP Handbook, Industrial and Commercial*[7], unless the pollutant generating activity does not occur. In the event that a Permittee determines that a BMP is infeasible at any site, the Permittee shall require implementation of similar BMPs that will achieve the equivalent reduction of pollutants in the storm water discharges. Likewise, for those BMPs that are not protective of water quality standards, Permittees may require additional site-specific controls.

ii. *Environmentally Sensitive Areas (ESAs) and Impaired Waters*:

For critical sources that discharge to MS4s that directly discharge to ESAs or to CWA §303(d) listed impaired waterbodies, the Permittees shall require operators to implement additional pollutant-specific controls to reduce pollutants in storm water runoff that are causing or contributing to exceedances of water quality objectives. If the Regional Water Board has approved a TMDL Implementation Plan for the receiving water, the Permittees shall require operators to take all actions necessary to implement the applicable provisions of the TMDL Implementation Plan.

iii. *Progressive Enforcement*:

Each Permittee shall implement a progressive enforcement policy to ensure that facilities are brought into compliance with all storm water requirements within a reasonable time period as specified below.

(1) Follow-up inspections: In the event that a Permittee determines, based on an inspection conducted, that an operator has failed to adequately implement all necessary BMPs, that Permittee shall take progressive enforcement actions which, at a minimum, shall include a follow-up inspection within 4 weeks from the date of the initial inspection.

(2) Enforcement action: In the event that a Permittee determines that an operator has failed to adequately implement BMPs after a follow-up inspection, that Permittee shall take enforcement action as established through authority in its municipal code and ordinances or through the judicial system.

Comment [A10]: Consider referencing an ERP here SC

[7] The BMPs refer to the current version of the California Stormwater BMP Handbook, Industrial and Commercial. The January 2003 version was current at the time of Order adoption, and the source control BMPs can be found in Section 3 of that version. In accordance with Part 4.A.2, other BMPs may be substituted upon approval by the Executive Officer.

RB-AR33015

(3) Each Permittee shall maintain records and make them available on request to the Regional Water Board, including inspection reports, warning letters, notices of violations, and other enforcement records, demonstrating a good faith effort to bring facilities into compliance.

e. Interagency Coordination

i. *Referral of Violations of Municipal Ordinances and California Water Code § 13260:*

A Permittee may refer a violation(s) of its municipal storm water ordinances and California Water Code § 13260 by Industrial and Commercial facilities to the Regional Water Board provided that the Permittee has made a good faith effort of progressive enforcement to achieve compliance with its own ordinances. At a minimum, a Permittee's good faith effort must be documented with:

(1) Two follow-up inspections

(2) Two warning letters or notices of violation

ii. *Referral of Violations of the Industrial Activities Storm Water General Permit (IASGP), including Requirements to File a Notice of Intent or No Exposure Certification:*

For those facilities in violation of municipal storm water ordinances and subject to the IASGP, Permittees may escalate referral of such violations to the Regional Water Board (promptly via telephone or electronically) after one inspection and one written notice of violation (copied to the Regional Water Board) to the operator regarding the violation. In making such referrals, Permittees shall include, at a minimum, the following documentation:

(1) Name of the facility

(2) Operator of the facility

(3) Owner of the facility

(4) WDID Number (if applicable)

(5) Industrial activity being conducted at the facility that is subject to the IASGP

(6) Records of communication with the facility operator regarding the violation, which shall include at least one inspection report

(7) The written notice of violation copied to the Regional Water Board

iii. *Investigation of Complaints Transmitted by the Regional Water Board Staff:*

Comment [A11]: Confirmed with Ivar (6/27/11). Permittees don't all have actual storm water ordinances and we should generalize throughout. Global changes. SC

Comment [A12]: Strike the term good faith effort—vague and unenforceable, and complicates enforcement. Just say that the Permittee must have at a minimum, documented . . .

This term and logic is consistent with EPA's permit improvement guide. Likely copied directly from it. SC

Comment [A13]: 1.Why wait to the end of the quarter? Why do they only have to do one inspection and one followup letter here but two – for failure to file a ROWD? What is t the logic?

Confirmed with Ivar (6/27/11): Ordinance violations likely cover those with immediate threat. SC

RB-AR33016

Each Permittee shall initiate, within one business day,[8] investigation of complaints (other than non-storm water discharges to the MS4) from facilities within its jurisdiction. The initial investigation shall include, at a minimum, a limited inspection of the facility to confirm validity of the complaint and to determine if the facility is in compliance with municipal storm water ordinances and, if necessary, to oversee corrective action.

iv. *Assistance with Regional Water Board Enforcement Actions:*

As directed by the Regional Water Board Executive Officer, Permittees shall assist Regional Water Board enforcement actions by:

(1) Assisting in identification of current owners, operators, and lessees of properties and sites.
(2) Providing staff, when available, for joint inspections with Regional Water Board inspectors.
(3) Appearing to testify as witnesses in Regional Water Board enforcement hearings.
(4) Providing copies of inspection reports and other progressive enforcement documentation.

v. *Participation in a Task Force:*

The Permittees shall participate with the Regional Water Board, and other public agencies on an enforcement task force to communicate concerns regarding special cases of storm water violations by industrial and commercial facilities, and to develop a coordinated approach to enforcement action.

DRAFT

[8] Permittees may comply with the Permit by taking initial steps (such as logging, prioritizing, and tasking) to "initiate" the investigation within that one business day. However, the Regional Water Board would expect that the initial investigation, including a site visit, to occur within four business days.

ABSTRACT OF DISSERTATION

EFFECTS OF URBANIZATION ON THE HYDROLOGIC REGIMES AND GEOMORPHIC STABILITY OF SMALL STREAMS IN SOUTHERN CALIFORNIA

In southern California streams, altered hydrologic and sediment regimes associated with urbanization (hydromodification) have induced significant morphologic responses such as incision, widening, and planform shifts from single-thread to braided with far-reaching effects to adjacent land and throughout drainage networks. The overarching objective of this dissertation is to improve process-based understanding of these changes such that the risk of future degradation may be mitigated through improved management. Three chapters follow from this fundamental flow of logic: changes in land cover beget changes in flow regimes, leading to increased erosive energy and sediment-transport potential, which, dependent on the relative resistance of the setting, can culminate into substantial changes in channel form.

The purpose of Chapter 1 was to understand the first step in this sequence: how urbanization affects the flow regime. Duration Density Functions (DDFs) were developed as histogram-style cumulative duration curves that represent the full range of geomorphically-significant flows as simple power functions. Using long-term data from 52 U. S. Geological Survey (USGS) gauges, empirical models were fit to both peak flows and DDF parameters (i.e., magnitude and shape) as multivariate functions of statistically-significant spatial variables including total impervious area. With little flow control at the subdivision scale to date, total impervious area became an effective hydrologic

PREVIEW

RB-AR33021

surrogate for urbanization, demonstrating an exponential effect on peak flows, particularly the 1-, 1.5-, and 2-yr events, and increased durations of all sediment-transporting flows. For example, watersheds with ~10% imperviousness typically exhibit a ~5-fold increase in $Q_{1.5}$ and 2 to 3 times as many days of sediment-transporting flows relative to an undeveloped setting. The models developed in Chapter 1 directly informed the hydrologic components of the subsequent chapters, where impervious area was not found to be a significant predictor of geomorphic response when considered independent of setting or sediment transport.

The focus of Chapter 2 was to understand the relative susceptibilities of regional channel types to hydromodification in the context of a 'Screening Tool' that is being developed to help managers assess risk across geomorphic settings. Specifically, Chapter 2 is focused on 1) the general framework of a pre-final version of the susceptibility screening tool, and 2) the development of risk-based analyses of geomorphic thresholds, a central component of key decision nodes in the screening tool. Geomorphic thresholds are real and of great concern in stream management, such that any susceptibility-assessment scheme should account for the proximity to such threshold-based responses. Logistic-regression analyses of braiding, incision, and bank stability directly and probabilistically assess proximity to geomorphic thresholds, and offer a framework for assessing risk that goes beyond expert judgment. Calibrated with local data that were collected in an extensive field campaign, the logistic models were highly significant (i.e., $p < 0.005$ to $p < 0.0001$) and correctly classified unstable states in ~90% of the cases using simple but powerful predictor variables that can be measured at the screening/reconnaissance level. A screening tool that incorporates objective probabilistic-based components is novel relative to previous and more subjective classification

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

RB-AR33022

schemes, such that regionally-diverse agencies and staff can quantitatively assess channel susceptibility with less variable results.

With the objective of developing a process-based understanding of observed channel changes, Chapter 3 presents models that predict relative magnitudes, directions, and risks of channel responses as functions of cumulative sediment-transport capacity ratios (Lr) that contrast 25-yr DDF simulations of urbanized versus undeveloped conditions. Lr was a highly significant term in quantifying channel 'enlargement', whereas logistic regression of Lr in combination with d_{50} suggested that fine-grained systems (i.e., especially $d_{50} \leq 16$ mm) have little capacity to absorb any increases in sediment-transport potential. A regional Channel Evolution Model (CEM) that includes departures from the original CEM of Schumm *et al.* (1984) is also presented along with a modified dimensionless stability diagram (*sensu* Watson *et al.* (1988)) that provides a conceptual framework for assessing relative departure from equilibrium/reference form for both lateral and vertical channel responses.

The overarching conclusion of this dissertation is that urbanization markedly affects the flow regimes of streams in southern California and that the corresponding imbalances in sediment-transport capacity result in substantial geomorphic instabilities across most stream settings. Consequently, mitigation strategies should be tailored to specific stream types and incorporate process-based objectives such as maintaining sediment continuity via duration standards rather than traditional regulations focused exclusively on flow magnitude.

ACKNOWLEDGEMENTS

Throughout this journey I have been blessed with an invaluable support network of faculty, friends, and family. First to my advisor, Dr. Brian Bledsoe, who has been a perennial bulwark since my first bike ride out to the ERC. Through coursework and research, Skype calls from Chile, California budget crises, late registration, future plans, and family surprises, your genuine and steady guidance has been par excellence. Thank you for a first-rate project, uninterrupted funding, masterly reviews, and balanced conversations – I always leave our meetings feeling energized and could not envision a better advisor/student relationship. Cheers.

To my committee members, Drs. Eric Stein, Chester Watson, and Ellen Wohl, I cannot thank you enough for your time and care in steering this dissertation into clear waters. Eric, thank you for keeping me tied to stakeholder goals, for sharing your wealth of local knowledge, resources, and energy, and for flying out for one of our meetings. Chester, your course and pioneering research truly gave me the shoulders of a giant to stand on. Ellen, from our field trip to Pawnee Buttes to lectures, critical-thinking essays and seminars, I feel so much more complete, and at the same time completely humbled to have you on my committee.

Next to Gloria Garza, who is the eternal champion of graduate students. Despite crunched deadlines you morphed these chapters into a 'silver singing river' of a

RB-AR33024

manuscript. Through it all, your incredible assistance and cheerful e-mails kept the stress-meter down, and I'm still in awe of how quickly you churned out revisions. I am forever grateful. And to the staff in the CEE office, Laurie Alburn, Linda Hinshaw, and Kathy Stencel, your smiling faces and support from before I was even a student have made me feel so welcome at CSU.

To my CSU and SCCWRP colleagues, particularly Dave Dust, Becky Schaffner, Liesl Tiefenthaler, Greg Lyon, and Jeff Brown, thank you for your tireless work in the field, logistical support, GIS assistance, photography, and for making many weeks in the hot sun a quite enjoyable experience. This wouldn't have been possible without you or the detailed work of the Stillwater Science survey crew, chiefly Scott Dusterhoff and Alexander Wong. And to Dr. Derek Booth, I am very grateful to have had this indirect opportunity to collaborate with you.

In his latest book Outliers (2008), Malcolm Gladwell deduces success to the necessary combination of talent and opportunity. To advisors and mentors from my previous life, Drs. Jim Mihelcic, Kevin Hallinan, Joseph Saliba, Roddy Williams, and Art Parola, thank you for your tremendous support and collaboration that clearly helped to get me in the door.

Speaking of opportunities, I am forever indebted to my parents Jeff and Jeanie. My dad was my first role model and the man who introduced me to a love of rivers, nature, and the importance of methodically looking to the data. My mom was my first teacher, instilling in me a passion for learning, the value of hard work, and love of family. Her warm angelic presence brings tranquility to all that I do. To the rest of my family

Reproduced with permission of the copyright owner. Further reproduction prohibited without permission.

RB-AR33025

and friends, particularly, Dan, Tiffany, David, Diane, Eric, Em, Chanda, and Lynne, thank you for your love and support.

Finally, to my wife Dr. Laura Kissel Hawley, who is my inspiration, my solace, my Dulcinea. Knowing what you had to go through during residency makes this look easy. Your grace through both life's trials and blessings gives me composure. The care and dignity you afford your patients gives me hope. Your boundless love fills me up, and I spill over. May we follow every dream and always have our time in the hammock.

Technical Report 654

July 2011

Executive Summary

A critical first step to hydromodification management is quantifying the effects of watershed urbanization on both flow peaks and flow durations. This report provides an analysis of forty-three regional U. S. Geological Survey gauges with records greater than ~20 yrs located in watersheds ranging from 1.3 – 272 km^2. The goal was to quantify effects of hydromodification, and to develop regionally calibrated, empirically derived models that can be applied to ungauged streams throughout southern California. The study watersheds spanned a gradient of urban development and ranged from 0 to 23% total impervious area based on 2001 land use data. With little flow control at the subdivision scale to date, most of the region's impervious area is hydrologically effective, in that it is relatively well-connected to surface-drainage networks. Consequently, total impervious area was an effective hydrologic surrogate for urbanization.

Large increases were observed in instantaneous-peak flows of more frequent return periods (e.g., 1.5 and 2 year storms), with greater than a 5-fold increase in 2-year events (Q_2) observed in a watershed with 20% imperviousness relative to ≤ ~1% imperviousness (Table ES-1). Effects of urbanization decreased for larger, less frequent storms. For example, 20% impervious cover resulted in a 40% increase in 10-year peak flows. Such attenuating influence of urbanization with return period is generally consistent with both theory and previous studies (Bledsoe and Watson, 2001; Hollis, 1975; Sauer *et al.*, 1983). During very large, infrequent events (e.g., Q_{100}) soils become saturated and behave similar to impervious surfaces; therefore, urbanization effects can be difficult to detect.

Table ES-1. Influence of urbanization (as measured by total impervious area) on peak-flow rates.

Flow	Peak Factors[a] for Impervious Extent, Imp_{max}					Factor Range at 20% Impervious	
	1%	5%	10%	15%	20%	Minimum	Maximum
$Q_{1.5}$	x 1.1	1.8	3.2	5.7	9.8	6.3	13.6
Q_2	x 1.1	1.5	2.4	3.6	5.6	3.8	7.3
Q_5	x 1	1.2	1.4	1.6	1.9	1	2.2
Q_{10}	x 1	1	1	1	1	1	1.4
Q_{25}	x 1	1	1	1	1	1	1

[a] 'typical' factors (i.e., median influence factors of all five sets of Q_i equations)

Effects of hydromodification on flow duration were expressed as duration density functions (DDFs), which are genrally defined as the number of days that exceed a given flow. They are conceptually similar to probability density functions for logarithmically-binned mean daily discharges greater than some nominal value, for example 1 to 10 cubic feet per second (0.03 to 0.3 m^3/s), depending on watershed size.

The results of this study show that for a particular watershed size and climatic setting, urbanization resulted in proportionally-longer durations of all geomorphically-effective flows, with a more pronounced effect on the durations of low to moderate flows. For example, an average watershed from the study area with ~15% imperviousness could experience three to four times as many days of moderate flows (~100 cfs) and greater than 2-fold duration increases for even the largest flows (~1,000 cfs) relative to an undeveloped setting (i.e., ~1% imperviousness, Figure ES-1). These empirical findings of decreasing influence of urbanization on flow duration with increasing flow magnitude are consistent with the findings regarding peak flows: urbanization tends to show higher influence on more frequent events, with decreasing influence over the largest, rarest storms.

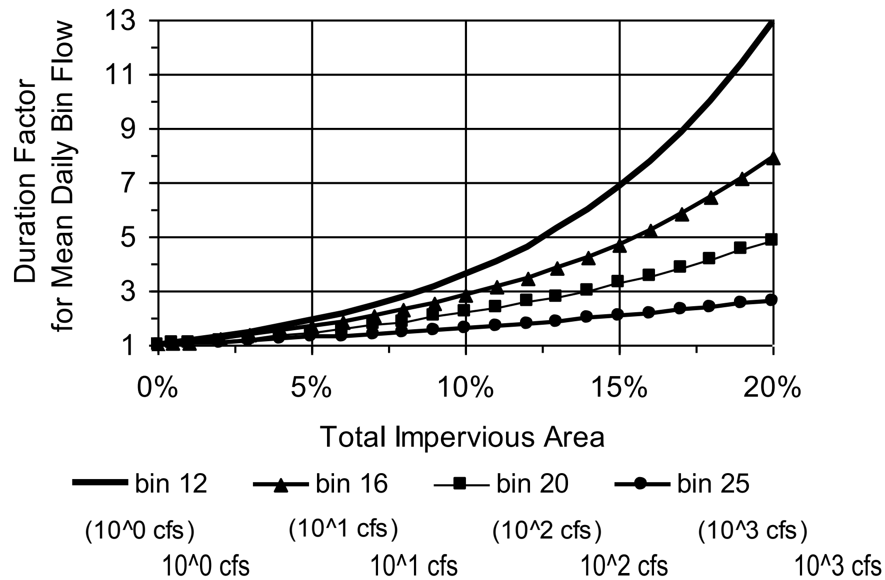

Figure ES-1: Duration factors of respective flow magnitudes across a gradient of Total Impervious Cover based on a 25-year DDF simulations of an average watershed; Average Watershed: A = 25 mi2 and P = 25 in.

The models presented in this report may be used to estimate the effects of unmitigated urbanization on flow peaks and flow durations as a part of regional hydromodification management programs. They could be incorporated into screening tools for hydromodification susceptibility (e.g., Bledsoe *et al.*, 2010). They could also serve as a relatively simple, first step in a modeling tool framework prior to employing more sophisticated modeling techniques such as continuous flow simulations based on different landuse and stormwater management scenarios.

The following report includes methodological background and justifications for the development of a suite of models that predict instantaneous peak flows (as an alternative to the existing USGS regional equations (Waananen and Crippen, 1977)), and duration density functions. The report also includes a summary of landuse and climatic histories, and regional geomorphic relationships such as drainage density vs. annual precipitation and main channel length vs. drainage area. The report concludes with a detailed case study of two gauged watersheds spanning relatively equal periods of pre-urban and post-urban periods, along with a cross-comparison to a proximate reference watershed that remained entirely undeveloped for an identical period of operation. The at-a-station case study, combined with the empirical models, presents a weight of evidence that urbanization has a pronounced and statistically-significant influence on flow magnitudes and durations of southern California stream networks.

Acknowledgements

We would like to thank organizations and individuals who contributed to this project in terms of funding, data collection, and analysis. This research was funded in part by a State of California research grant, for which we are very grateful. Becky Schaffner of SCCWRP was extremely helpful in providing GIS assistance and training. The USGS continues to deliver spatial and hydrologic data to the public domain that are unparalleled in terms of scale and quality. We would like to extend our gratitude to all staff (past and present), and particularly to Scott Patterson of the South Poway Field Office whose time and care in answering questions provided clarity regarding individual gauges. This document is much improved as a result.

Introduction

By decreasing infiltration and increasing direct runoff, impervious surfaces can create larger peaks, less groundwater recharge, and increased variability, especially if stormwater is routed directly to streams. These fundamental hydrologic interrelations, such as larger peaks and increased flashiness, have been demonstrated regionally (Galster *et al.*, 2006; Konrad and Booth, 2002) and on a national scale using United States Geological Survey (USGS) gauge data (Poff *et al.*, 2006; Sauer *et al.*, 1983). In California, increased peak flows in developed watersheds have been documented by the USGS as early as 1963 (Waananen, 1969). Durbin (1974) reported potential increases in the 2-yr flow (Q_2) of 3- to 6-fold in San Bernardino County, with little effect on higher return intervals such as the 50-yr flow. Rantz (1971) used development extent and percentage of channels sewered to estimate peak factors for the San Francisco Bay area ranging from 1 to 4 for Q_2, and decreasing with larger return intervals (e.g., 1 to 2.5 for Q_{50}).

Such changes in flow, broadly associated with urbanization, are documented as having profound effects on biologic and geomorphic processes, so much so that the U.S. Environmental Protection Agency (EPA) has recently begun to mandate 'hydromodification' regulations (EPA, 2006). Channel instability and complex responses have been associated with urbanization across hydroclimatic regimes (Bledsoe and Watson, 2001; Booth, 1990; Chin, 2006; Chin and Gregory, 2001; Simon and Downs, 1995; Trimble, 1997), while altered flow and sediment regimes affect aquatic life cycles, habitats, food webs, and facilitate colonization by invasive species, among other types of degradation (Poff *et al.*, 2006; Roesner and Bledsoe, 2002; Waters, 1995).

Our recent field investigations in southern California seem to indicate a relatively high geomorphic sensitivity to hydromodification (Hawley, 2009), consistent with previous studies (Coleman *et al.*, 2005) and the semiarid climate in general (Trimble, 1997). The hydrogeomorphic setting (i.e., steep topography, flashy regimes, high-sediment loads, and largely nonresistant bed material) generally compounds risk factors for far-reaching channel responses such as headcutting, extensive mass-wasting, and planform shifts.

An important first step in any hydromodification management program is to quantify the effects of hydromodification on both peak flows and durations (*sensu* Wolman and Miller, 1960). The challenges in quantifying effects are 1) how to determine the most effective flow magnitudes to manage (i.e., which flow magnitudes are most affected by hydromodification); and 2) how to integrate effects on flow duration (i.e., which flow magnitudes perform the most cumulative work on the channel boundary). This report addresses these issues via the following objectives:

1. offer an updated alternative to the USGS (Waananen and Crippen, 1977) regional equations for estimating peak flows of ungauged streams that is calibrated with more recent southern California gage data;
2. develop a physically-based empirical method for estimating long-term cumulative flow duration histograms for ungauged sites; and

3. determine how urbanization affects peak flows and cumulative durations for all geomorphically-important flows by including urban components (if statistically significant) in Objectives 1 and 2.

In filling these knowledge gaps, we offer the following hypotheses:

H_0: urban influence on the magnitudes of peak flows will be highest at the more frequent events and lowest at the longer recurrence intervals;

H_0: the lack of representation of southern California gauges used to develop the USGS national urban equation (Sauer *et al.*, 1983) should result in better performance by models calibrated directly to the region; and

H_0: cumulative durations can be modeled with reasonable accuracies and will be significantly influenced by urbanization.

Research Foundations and Justification

This paper principally builds on the work and ongoing data collection of the USGS. To this day, Waananen and Crippen's (1977) simple power functions of drainage area and mean annual precipitation serve as a primary method of peak-flow estimation in southern California. Limited by an overall lack of gauge data on "streams with drainage areas generally less than 25 mi^2, and particularly less than 10 mi^2," the models came with substantial standard errors and were deemed "generally applicable for streams with drainage areas greater than 10 mi^2" (Waananen and Crippen, 1977).

Given over 30 more years of data, and especially more data on smaller streams, it was prudent to revisit these equations. In this paper, we go beyond the Log-Pearson Type III distribution to a more regionally-appropriate statistical distribution. With several gauges in developed watersheds, urbanization was included in the models using direct measures of total impervious area (TIA). This approach is arguably less subjective and more parsimonious than the USGS national approach to urban flow augmentation (Sauer *et al.*, 1983), which can be time intensive and is subject to user interpretation of "basin development factors" that are typically immeasurable with available Geographic Information System (GIS) data. Moreover, of the 199 gauges used to develop the national equations, few gauges were from semiarid settings, with only one from southern California (San Diego Creek, gauge no. 11048500). Despite largely-different hydrologic behavior relative to much of the rest of the nation, the USGS national equations are currently being applied throughout the region.

Toward Cumulative Durations

Peak flows alone can be useful in understanding potential erosive energy at an individual recurrence interval; however, they have less meaning when considered independent of durations. Whether a large flow lasts for minutes or days, it has substantial implications for cumulative sediment transport.

Moreover, all flows capable of moving sediment have the potential to influence channel form, *sensu* the concept of geomorphic *effectiveness* (Wolman and Miller, 1960).

It follows that when evaluating the potential impacts of urbanization on channel stability, researchers have begun to favor cumulative sediment-transport models based on continuous or cumulative flows over extended periods (e.g., years/decades). In evaluating various flow-control schemes in the Pacific Northwest, Booth and Jackson (1997) touted the potential benefits of 'duration' standards in contrast to 'peak' standards, particularly at flows above the threshold of sediment entrainment. Consideration of all sediment-transporting flows would seem especially important in the semiarid environment known for sporadic sediment movements (Graf, 1981, 1988), extended periods of aggradation/degradation and lagged recovery times (Wolman and Gerson, 1978), and relatively infrequent periods of equilibrium (Bull, 1997). One of the only published approaches to addressing hydromodification in California to date uses flow-duration histograms produced from long-term rainfall-runoff simulations in Hydrologic Engineering Center - Hydrologic Modeling System (HEC-HMS) to compute an 'effective work index' by summing excess shear stress over cumulative flow durations of 50 yrs (Santa Clara, 2004). The corresponding mitigation goal is to design flow control such that cumulative post-developed sediment-transport capacity matches the pre-developed regime. The Sediment Impact Analysis Method (SIAM), publicly available via the U. S. Army Corps of Engineers (USACE) in the Hydrologic Engineering Center - River Analysis System (HEC-RAS) software package, is also designed to use a histogram-style flow-duration curve and can be used to model long-term sediment transport (Mooney, 2007; USACE, 2009).

An alternative to solely using rainfall-runoff models to develop flow-frequency curves is to base them on local gauge data. Using the nearest upstream/downstream gauge (Hey, 1975) or a gauge from a similar watershed, frequency curves have typically been scaled using a nondimensional index such as $Q/Q_{bankfull}$ (Emmett, 1975; Leopold, 1994) or Q/Q_2 (Watson *et al.*, 1997). The advantage of the latter is that the 2-yr flow may be estimated by a USGS regional equation, whereas the bankfull flow is often difficult to define and does not have a consistent return interval across different streams (Biedenharn *et al.*, 2000, 2001; Pickup and Warner, 1976; Williams, 1978). The disadvantage of scaling based on the 2-yr flow is that, at least in southern California, it comes with much poorer accuracies than higher recurrence intervals (Waananen and Crippen, 1977). It may also be difficult to define which gauge(s) is similar enough to the ungauged watershed for direct scaling (e.g., similar topography, basin size, precipitation).

We expand on the Watson *et al.* (1997) approach by developing a statistical model to estimate flow-duration curves for ungauged sites with all regional gauges meeting our selection criteria, such that a synthetic flow-duration histogram is predicted as a function of watershed-scale physical descriptors such as drainage area and precipitation. The resulting *conditional* probability density functions that predict cumulative durations of geomorphically-effective flows in a histogram format are henceforth referred to as Duration Density Functions (DDFs). The logarithmically-distributed histogram bins are represented by power functions (i.e., #days = coef * Q^{exp}) and scaled by the maximum daily flow of record. Given a way to predict the shape (exponent), magnitude (coefficient), and scale (Q_{max}) based on physical parameters, one could predict long-term durations of sediment-transporting flows for any ungauged watershed. More importantly regarding hydromodification, DDFs could simulate the increases in durations of sediment-transporting flows associated with unmitigated urbanization by including a statistically-significant surrogate measure (e.g., TIA) in the model. In this light, DDFs can become a central tool in understanding, modeling, and mitigating the effects of hydromodification in southern California.

Study Domain

Southern California is generally described in this study as the greater Los Angeles/San Diego area within about 100 mi of the Pacific coast, including portions of Ventura, Los Angeles, San Bernardino, Orange, Riverside, and San Diego Counties and ca. 20 to 25 million residents. Mountain ranges to the north (Transverse Ranges) and east (Peninsular Ranges) offer fairly well-defined geologic bounds, with a total relief of up to 11,500 ft (3,500 m) and short travel distances to the ocean on the order of 50 mi (~80 km). The steep slopes promote runoff and produce more hydrologically-efficient watersheds than low-relief settings.

The climate is broadly characterized as Mediterranean, but precipitation and vegetative influences tend to increase with elevation, although there are obvious differences between the west (wetter) and east (drier) slopes of the Peninsular Ranges due to an effective 'rain shadow'. Regional extremes of average annual precipitation range 8 to 40 in/yr (200 to 1,000 mm/yr), while vegetation changes from sparse grasses and chaparral to dense coniferous stands at higher elevations. When rains do fall, they can be intense; the 2-yr 24-hr rainfall ranges ~2 to 6 in. (50 to 160 mm) across the domain.

This leads to a flashy regime with short-lived instantaneous peak flows that are much larger than the corresponding daily means. For example, a 10-yr instantaneous event would typically attenuate to a daily-mean flow on the order of a 2- to 3-yr event, with the former likely ten to twenty times the latter. Systems are predominantly ephemeral and clearly dominated by overland flow with little groundwater storage relative to humid systems. The heterogeneous lithologies have variable infiltration capacities, but differences seem to be overwhelmed during high-intensity storms, although they probably play a role in seepage losses during transmission (Knighton, 1998).

Beyond seasonal patterns, large fluctuations in annual, decadal, and even multi-decadal precipitation result in an active fire regime. Regional fires are often newsworthy for both direct (e.g., property destruction and mass evacuations) and indirect damage (e.g., post-fire landslides and flooding), and the corresponding pulses in both sediment and runoff (Booker *et al.*, 1993; California Forest Service (CaFS), 1951; Gabet and Dunne, 2003; Los Angeles County Flood Control District (LACFCD), 1959; McPhee, 1989). As early as 1947, the CaFS had recorded post-fire peaks two to thirty times as large as pre-fire peak flows for equivalent storms in their experimental forest, with influence decreasing with storm magnitude.

Finally, during field investigations of recently-developed suburban neighborhoods, we saw little evidence of stormwater retention/detention. Developed watersheds often had lined channels (i.e., concrete or riprap) and energy dissipaters at outfalls were occasionally present. Large regional basins and dammed reservoirs do exist; however, flow controls in watersheds less than ~40 mi^2 (~100 km^2) were largely lacking. With the understanding that unmitigated urbanization largely increases flow variability, and that streams in southern California are inherently flashy, we hypothesize that the effects of urbanization may be especially pronounced.

Methods

Gauge data are made publicly available by the USGS, which adheres to strict quality assurance/quality control procedures prior to publishing flows as accepted/approved. To ensure comparable quality in processing and analysis, we developed the following methods. Some of the methods include a limited presentation and discussion of preliminary 'results' that informed model design and/or were less central to the overall conclusions of this research. For example, regarding peak flows, it was necessary to decide on a distribution prior to the building of statistical models. Gauge-selection criteria, below, describes how we tested several distributions and which was selected to use in model design.

The following sub-sections summarize the methodological process by which we arrived at final models and conclusions. First, we systematically-selected regional gauges and processed their peak-flow data. Next, we developed a method for processing and representing all daily-mean flows via cumulative histogram-based functions. Methods were then considered for objectively representing urbanization extent. Next, informed by literature and a theoretical understanding of surface-drainage network hydrology, an expansive array of spatially-based variables was populated for inclusion in the analyses. Lastly, analytical methods are presented including a cross-validation procedure that guided final model design.

Unit Disclaimer

Acknowledging the general preference of International System (SI) units among the scientific community, we felt it was beneficial to develop these equations in U.S. Customary System (or English) units for more direct comparisons to the U. S. Geological Survey (Waananen and Crippen, 1977) equations. Without becoming overly cumbersome, we try to offer SI units in parentheses and some figures are expressed in SI units.

Gauge-Selection Criteria

Our first step was the systematic selection of regional gauges for model development. The focus was on watersheds less than ~100 mi^2 (250 km^2), primarily due to the fact that most of the region's larger streams have been affected by dams and diversions. We excluded gauges that were artificially influenced by flow diversions to isolate only the effects of urbanization relative to the undeveloped, free-flowing setting.

We strove for a balance between a large representation of sites and gauges with sufficiently long records. Short records increase the likelihood of misrepresenting the true flow regime, while overly-conservative record-length requirements would eliminate the bulk of gauges. For example, only nineteen of the gauges within the study domain had records of 50 yrs or more; however, there were forty-nine gauges with records greater than 20 yrs. There was a natural break in the record lengths of the candidate gauges at ca. 15 yrs (two gauges at 18 yrs with one gauge at 14 yrs and the balance less than ca. 8 yrs). With limited urban/semi-urban gauges (i.e., only eight gauges > 2.5% imperviousness), the fact that the 14-yr record was in a partially urban watershed (imperviousness = 2.7% in 2001) supported its inclusion. This totaled fifty-two gauges with a spatial distribution depicted in Figure 1. A summary of selected gradients such as drainage area and record length is provided in Table 1 (a comprehensive dataset may be obtained by contacting the corresponding author). These gradients also serve as bounds to the applicable ranges of our models.

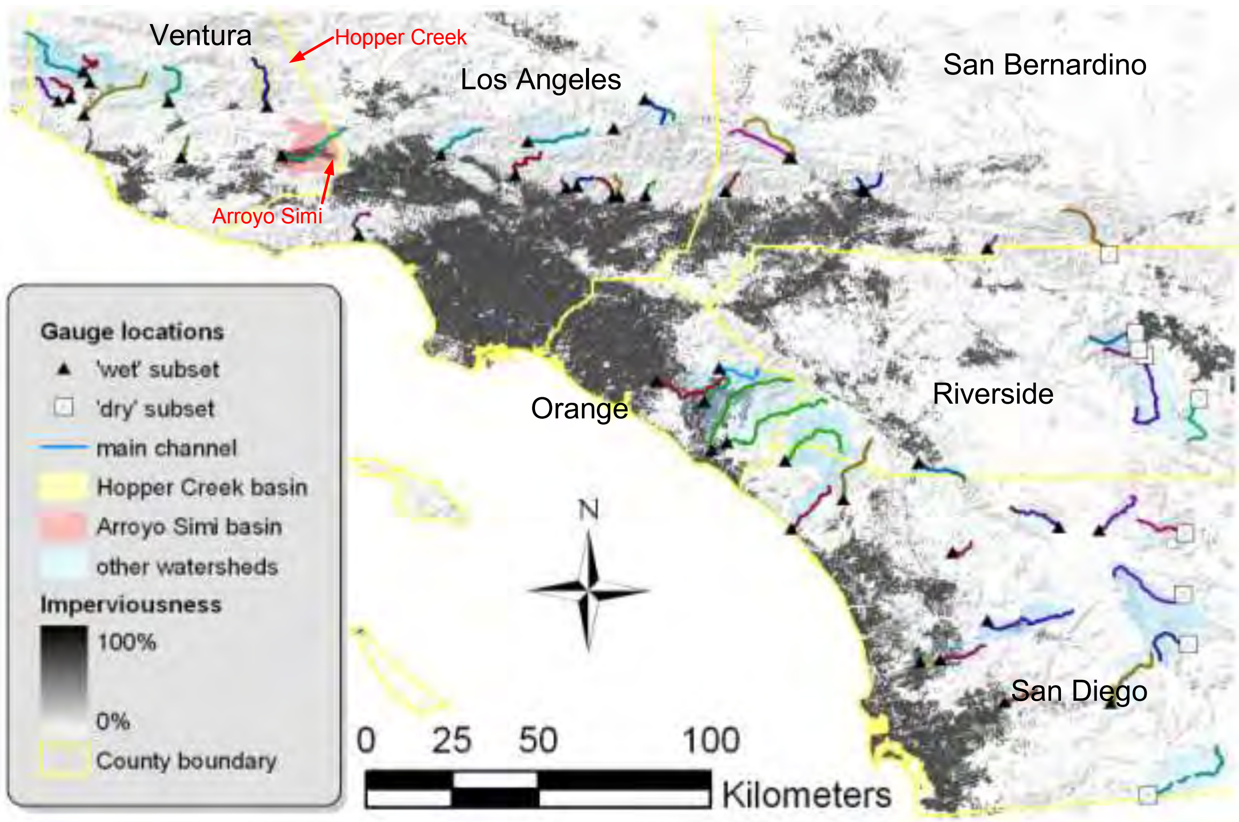

Figure 1. Locations of gauges used in equation development ('wet' subset) with corresponding watershed and main channel, overlaid by a gradient of imperviousness and county boundaries, with rural (Hopper) and urban (Arroyo Simi) case study gauges.

Table 1. Selected[a,b] gradients of the forty-three USGS gauged watersheds used to develop models (i.e., model-application bounds), and the nine hydrogeomorphically-distinct gauges[c] that were withheld from models.

[a] Table includes all USGS gauges in the study domain with watersheds less than ~250 km², flow records greater than ~15 yrs, and no upstream dams/diversions.

[b] Gaps in U.S. Department of Agriculture (USDA) geospatial soil coverages precluded the inclusion of soil characteristics in the analysis; however, a representative sample of regional watersheds ranged from 100% Natural Resources Conservation Service (NRCS) Type D to 100% NRCS Type B and up to 10% Type A soils with undeveloped NRCS Curve Numbers that ranged 77 to 88 with a mean of 83.4.

[c] The nine gauges in Hydrologic Unit Code (HUC) 18100200 and 18070305 were excluded from model development due to their significantly ($p < 0.05$) different hydrogeomorphic setting on the east slope of the Peninsular Range.

[d] Total years of annual maximum instantaneous peak records as recorded and made available by the USGS (i.e., not necessarily equal to "End" minus "Begin" due to intermittent records at several gauges).

[e] Average and maximum road density and impervious values based on integration of spatial extent over the gauge records using three to four measures of spatial extent in time, delineated from historical USGS quadrangle maps and contemporary geospatial coverages from USGS and CalAtlas in a GIS.

[f] Mean annual precipitation integrated over the watershed using USGS shapefile developed using regional precipitation data from 1900 to 1960.

[g] Total precipitation volume over 24-hr duration with a probability of occurrence once every 2 yrs, spatially integrated over the watershed using NRCS shapefile developed using regional precipitation data from 1961 to 1990.

[h] Contributing watershed area delineated in a GIS using the USGS HUC boundaries and a 10-m National Elevation Dataset (NED).

[i] Drainage density developed using total stream length in basin as delineated in a GIS using the USGS National Hydrography Dataset (NHD) developed at a 1:24,000 scale.

[j] Average basin elevation and channel slope measured after USGS protocol using points at 10 and 85% of the main-channel distance from gauge to basin divide.

[k] Average surface slope of the entire watershed using clipped NED model from USGS.

[l] Representative valley slope over reach at gauge l

The gauges had relatively-normal distributions of variables such as record length, precipitation, and surface slope, although drainage area and density showed a small positive skew. Imperviousness, however, had a highly-positive skew of 2.2. As of 2001, only fifteen gauges had watersheds with more than 1% TIA, while only six were greater than 10% imperviousness.

Another notable spatial trend was that eight gauges located in the eastern-most portion of the domain and one gauge in the far southeast at the Mexican border ('dry' subset Figure 1) lie in what is effectively a rain shadow. Stratified by USGS 8-digit Hydrologic Unit Codes (HUCs) of 18100200 or 18070305, the so-called 'dry' gauges were subject to less mean-annual precipitation as well as different types of events (i.e., local convective thunderstorms in addition to winter frontal storms). Hawley (2009) demonstrated significantly-different hydrologic behavior in the 'dry' subset, so much so that models were developed by using a discontinuous 'dummy' variable. In order to develop more targeted models for the balance of the gauges, we excluded the 'dry' subset in this study, making the final sample size forty-three and our models not applicable for watersheds east of the Peninsular Ranges (i.e., HUCs 18100200 and 18070305).

Instantaneous Peak Flows

Procedures were developed to populate recurrence-interval flows for the 1-, 1.5-, 2-, 5-, 10-, 25-, 50-, and 100-yr events from peak-flow data as recorded by the USGS. Their method seemed to be a hybrid of an annual-maximum and partial-duration approach, with an average of one record per calendar/water year, but cases of same-year peaks and occasional gaps during dry years. If a gauge was online during a no-flow year and a corresponding peak of 0 was not already recorded, the record was augmented to standardize the sample size at all gauges, populating an annual-maximum series. This was required on seven gauges and had clear implications on Q_1; however, it had little effect on higher recurrence intervals. For example, recurrence probabilities such as $Q_{1.5}$ and Q_2 generally had several similar flows near those rankings such that a shift would still result in a flow from the same range (e.g., 349 versus 331 cubic feet per second (cfs) for $Q_{1.5}$ and 570.5 versus 571 cfs for Q_2 at Arroyo Seco). Even less effect would be seen at the higher flows (i.e., p = 1:25 versus 1:24 is effectively equivalent as representative of the 25-yr flow).

Other cases of record gaps included years with the date and/or stage of the peak but no flow. Interpolations based on USGS-rating relationships were used to estimate a reasonable flow for that date based on equivalent gauge heights and/or daily-mean flows. This was performed at eight gauges, representing less than 20% of the total. The interpolated flows were not used to determine a flow for a specific return interval; rather, they were simply used as placeholders in the plotting-position rankings.

Next, flows were proportionally ranked to determine recurrence probabilities via the Weibull plotting position (Chow, 1964; Yevjevich, 1972). Several commonly-used probability distributions were then tested to represent the flow-frequency relationship at each gauge, including the normal, lognormal (LN), exponential, and gamma. Because a central component of this paper is an updated alternative to the USGS 1977 regional equations, we also considered the Log-Pearson Type III (LP3), a log-transformed three-parameter gamma distribution that has been the standard USGS flow-frequency method since 1967 (U. S. Water Resources Council, 1967). Distributions were fit by minimizing residual squares between recorded and modeled flows (i.e., method of moments) giving proportional weight to the larger flows; whereas, the reverse procedure would dampen the significance of larger flows by minimizing residuals among recurrence probabilities. With easily-invertible distributions (e.g., normal, LN, and gamma) we fit flows directly to recurrence probabilities, whereas distributions that could not be solved analytically when inverted required alternative solutions (e.g., weighted skew factor (G) for the LP3 method).

Despite application in previous studies, the LP3 performed relatively poorly due to the flashy regimes and the corresponding effect on the skew factor. Even by following the recommended weighting scheme (U. S. Water Resources Council, 1981), the large number of gauges with years of very low or no flow typically converted a highly-positive skew in arithmetic space to a negative skew after the log-transformation. As discussed by Chow *et al.* (1988), this imposes an artificial upper bound on the data. Attempts to account for the low/zero flows within the confines of the LP3 method via the addition of correction factors both large (log (Q + 100 cfs)) and small (log (Q + 0.1 cfs)) were regularly outperformed by a simple regression of flow (Q_i) as a function of log-transformed recurrence interval {ln(i)} (Figure 2).

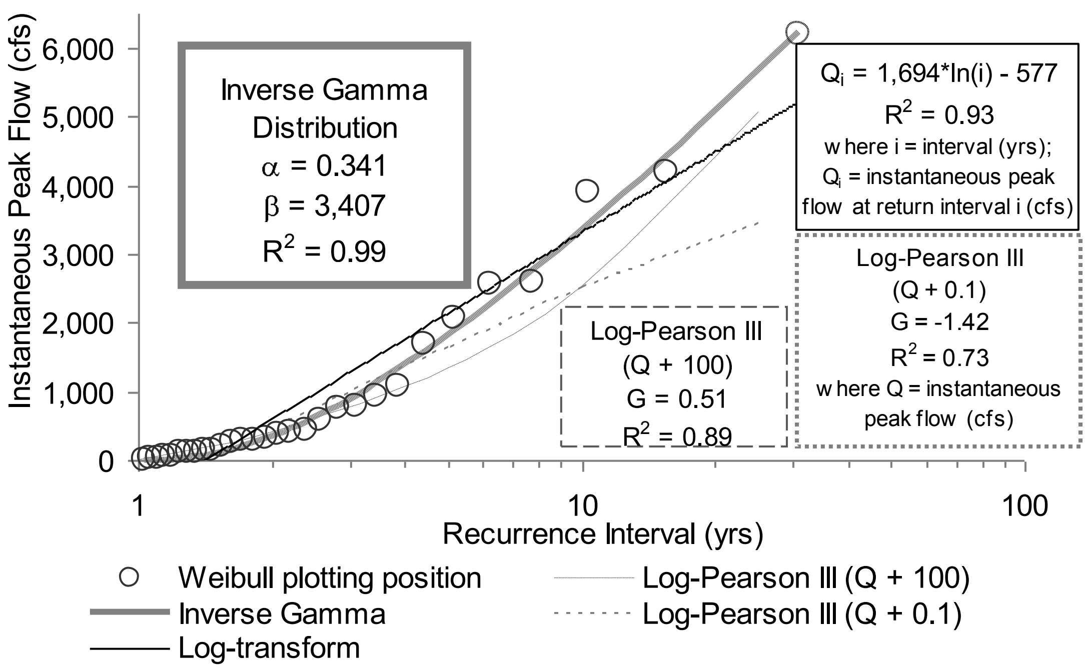

Figure 2. Flow versus recurrence interval of 30-yr record at USGS gauge no. 11033000, West Fork San Luis Rey River near Warner Springs, California, with Log-Pearson Type III adjusted (Q + 0.1) and (Q + 100) and inverse gamma distributions, and log-transform function.

Among all tested distributions, the inverse gamma with parameters α and β was superior in every case in terms of homoscedasticity of residuals and R^2 (e.g., mean and median R^2 0.95 and 0.97, respectively, with only three cases < 0.90). Bounded by zero by definition, the gamma function is ideal for modeling skewed distributions without the need for a log transformation (Chow *et al.*, 1988) – befitting for the flashy ephemeral regimes of southern California. Gamma-distribution flows were used to develop models for flows greater than or equal to the 5-yr interval, while the Weibull plotting position was used for the 1-, 1.5-, and 2-yr events due to nominal interpolation gaps over the smaller ranges given the relatively-large record lengths.

Long-Term Cumulative Durations

Although peak flows are important in understanding erosive energy at a given return interval, flow durations offer a much more complete understanding of the cumulative sediment-transport potential. Accordingly, we developed procedures to mathematically represent all daily-mean flows on record with cumulative duration curves. First, daily-mean flows were binned via a histogram procedure analogous to the initial steps of an effective-discharge calculation after Biedenharn *et al.* (2000, 2001). Histogram bins were scaled by the maximum daily-mean flow on record (Q_{max}) rather than an instantaneous peak flow (e.g., Q_2 after Watson *et al.* (1997)) for two reasons. First, as described in detail later, Q_{max} values could be predicted with much greater accuracies than the highly variable Q_2. Second, scaling with Q_{max} ensured consistent temporal scales for the duration analyses because daily-mean discharges were the only long-term records widely available (i.e., opposed to shorter intervals such as 1 hr or 15 min) and the two time scales were not transferable or even scalable. That is, the ratio of peak to daily mean was not consistent across return periods, sites, or even equivalent flows at the same site. For example, two equivalent 10-yr peak flows recorded at the same gauge could have corresponding daily-mean flows that differed by a factor of two in rural settings, and up to three in urban settings, potentially attributable to the spatial extent, intensity, or even timing of the event.

Regarding the selection of the type and number of bins for our models, the truly limiting factor in sediment-distribution curves – the ultimate application of our models – is ensuring a relatively-continuous flow-frequency distribution such that no bins are populated by 0 days of occurrence (Biedenharn *et al.*, 2000, 2001). Although arithmetic bins are statistically more prudent, the extreme flashiness of ephemeral streams in southern California made logarithmic bins the only practical way to represent flow frequency without discontinuities. The following equation was used to size logarithmically-equivalent bins after Raff *et al.* (2004):

$$H_{B\text{-}log} = \{\ln(Q_{max}) - \ln(Q_{min})\} / (N_B - 1) \qquad \textbf{Eq. (1)}$$

where:

$H_{B\text{-}log}$ = bin size of logarithmically-spaced histogram bins;
Q_{max} = maximum flow of record;
Q_{min} = minimum flow of record; and

N_B = number of bins.

For consistency across all gauges toward development of a regional equation, we set Q_{min} equal to 0.01 cfs at all sites, the lowest non-zero daily-mean flow reported by any gauge. Bins 1 through N_B were then populated by the total number of days of occurrence at flow rates within the respective bins. Lower and upper bounds of each logarithmically-spaced bin were determined using the following equations after Raff *et al.* (2004):

$$B_{lwr-log} = e^{\{\ln(Q_{min}) + (B-2)*H_{B-log}\}}$$ **Eq. (2)**

$$B_{upr-log} = e^{\{\ln(Q_{min}) + (B-1)*H_{B-log}\}}$$ **Eq. (3)**

where:

$B_{lwr-log}$ = lower logarithmically-spaced bound of bin number (B);
$B_{upr-log}$ = upper logarithmically-spaced bound of bin number (B); and
B = bin number (i.e., 1 to N_B, where N_B = total number of bins).

Setting N_B equal to 25 provided a reasonable balance of resolution (small bin sizes) and continuous frequency distributions. All but three gauges, Buckhorn (6 yrs), Honda Barranca (9 yrs), and Keys C (14 yrs), had daily-flow records long enough to sufficiently populate 25 bins. Little San Gorgonio, despite having a long enough record (37 yrs), was skewed by an extreme flow resulting in 3 of the top 6 bins being empty with the remaining three only having 1 day of occurrence. An additional three gauges (Cucamonga, Pechanga, and Waterman) each had 1 bin populated with 0 days of occurrence, but because the adjacent bins were amply populated, we could 'borrow' 0.5 days from each adjacent bin to convert the 0-day bin into a 1-day bin. Of the original forty-three gauges, this resulted in thirty-nine that could be included in the DDF models.

In order to represent the histograms in a concise, transferable format, the next step was to convert them into *conditional* Probability Density Functions (PDFs) by fitting power functions to the centroids of the bins representing the geomorphically-effective range of flows. Again looking toward application, with a high likelihood of under-predicting sediment transport due to data intervals of days rather than minutes (Watson *et al.*, 1997), further bias was avoided by fitting the DDFs to the arithmetic-bin centroids, as opposed to the logarithmic centroids. This positioned each centroid on a slightly higher flow than the otherwise geometric centroid (e.g., 806 cfs versus 774 cfs for bin 21 at San Antonio, or 8,119 cfs versus 7,793 cfs for bin 25). Given that sediment transport increases non-linearly with flow, such a scheme would better approximate the composite transport of the individual flows within the bin.

The next consideration was which bins would be important to represent for sediment transport. Their distributions were relatively continuous over bins 12-25, and particularly continuous over bins 16-25, such that they could be well-represented with simple power functions. Fortuitously, those bins that could be well-fit coincided with the same ranges that would be important for sediment transport. From preliminary analyses it was apparent that streams characterized by threshold behavior (i.e., bankfull dimensionless shear stress (τ_{*BF}) ~0.03 to 0.06) would be sufficiently represented with a 16-25 scheme, while live-bed channels (i.e., τ_{*BF} ~1 to 10+) would require the broader range. As demonstrated by Hawley (2009), cumulative sediment transport became relatively insignificant below bin 12, despite cases of entrainment at lower flows.

Figure 3 offers an example of a typical DDF fit of bins 16-25 at the San Antonio gauge. Overlaid in Figure 3 is the De Luz gauge as an example of one of the poorer fits (i.e., eight gauges with $R^2 < 0.95$, three gauges < 0.90). By depicting two gauges with relatively similar watersheds, Figure 3 also alludes to the significance of the gauge-record length. DDFs scaled nonlinearly with years of duration, primarily attributable to the extreme flashiness and inter-year variability in precipitation. Longer gauge records have higher probabilities of experiencing an extreme precipitation event, corresponding to nonlinear increases in flows and durations.

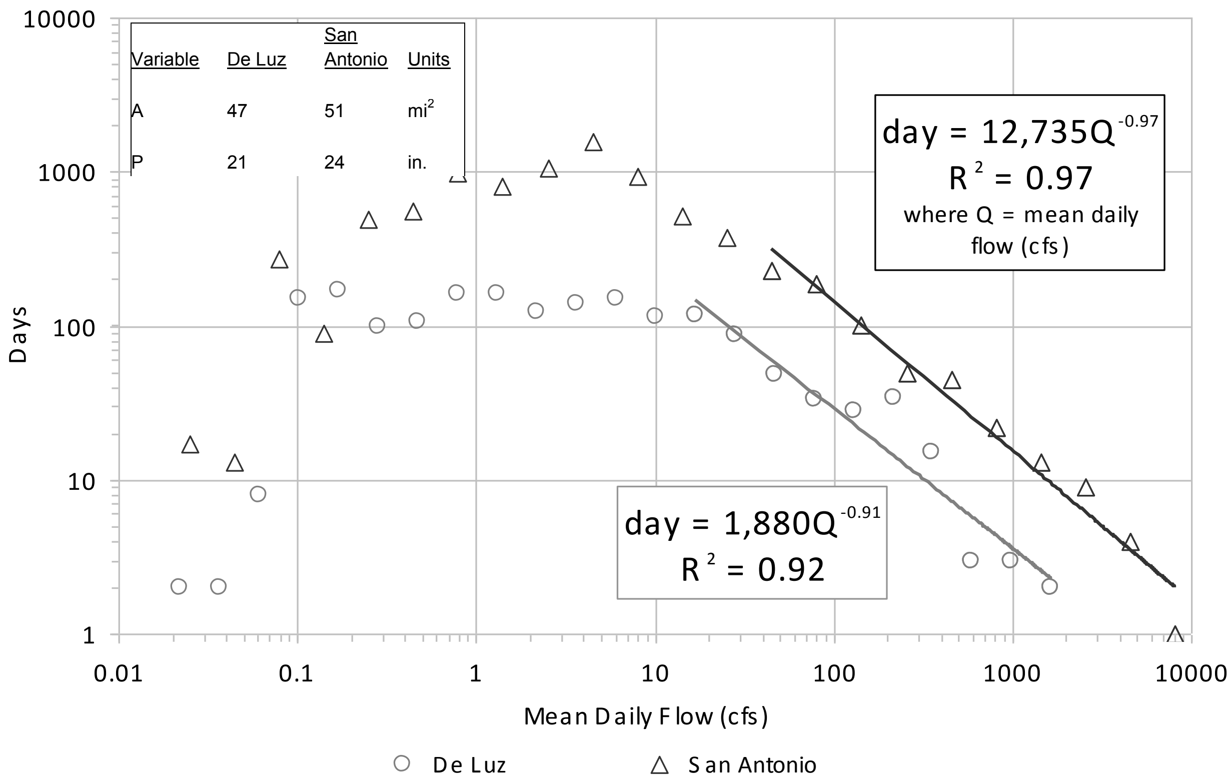

Figure 3. DDFs of gauges De Luz and San Antonio fitted to centroids of logarithmically distributed histogram bins 16-25 with selected variables of drainage area (A), average annual precipitation (P), and record length (Yr).

The 16-25 scheme with the coefficient and exponent parameters termed d1 and d2, respectively, showed largely-homoscedastic residuals (Figure 3) at the risk of not capturing all sediment-transporting bins in live-bed channels (bin 16 of San Antonio = 45 cfs). The second scheme, termed day1 and day2, regressed bins 12-25 to more conservatively include all significant sediment-transporting flows (e.g., bin 12 at San Antonio = 4.5 cfs). However, as one could envision with De Luz (Figure 3), the disadvantage in including bins 12-15 is that it resulted in more heteroscedastic residuals at some gauges. R^2 values were also slightly worse, with eleven gauges less than 0.95 and five gauges less than 0.90. The general form of the power functions used in the respective schemes is:

$days_{@Q} = d1 * Q^{d2}$ (bins 16-25, i.e., τ_{*BF} ~0.03 to 0.06) **Eq. (4)**

$days_{@Q} = day1 * Q^{day2}$ (bins 12-25, i.e., τ_{*BF} ~1 to 10+) **Eq. (5)**

where:

$days_{@Q}$	=	number of days of occurrence at flow rate (Q);
Q	=	arithmetic average of daily-mean flows corresponding to the lower- and upper-bin boundaries defined by Eqs. (2) and (3), respectively (cfs);
d1	=	coefficient for power function fit to bins 16-25;
d2	=	exponent for power function fit to bins 16-25;
day1	=	coefficient for power function fit to bins 12-25;
day2	=	exponent for power function fit to bins 12-25; and
τ_{*BF}	=	dimensionless shear-stress ranges at approximate 'bankfull' flow range (i.e., on the order of Q_{10}) corresponding to threshold (0.03 to 0.06), and live-bed (1 to 10+) behavior.

With the outlined methods for processing daily-mean flows, DDFs were fit to all gauges to populate a matrix of their respective components (i.e., Q_{max}, d1/day1, d2/day2). The dataset was used to develop models of each DDF component as multivariate functions of statistically-significant watershed descriptors, offering an objective method for estimating flows and cumulative durations at ungauged locations.

Measures of Urbanization

An investigation focused on understanding the influence of urbanization on flow regimes should dedicate great care to measuring its extent. With the goal of objectively representing urbanization in both space and time, we first looked to what other researchers have used to characterize it, including but not limited to:

- % impervious area (Booth, 1991, 2000; Espey and Winslow, 1974; Galster *et al.*, 2006; Leopold, 1968; Sauer *et al.*, 1983),
- % developed (Galster *et al.*, 2006; Rantz, 1971),
- % served by storm sewers (Leopold, 1968; Rantz, 1971),
- % paved (Hollis, 1975),

- road density (Konrad and Booth, 2002),
- population density (Konrad and Booth, 2002; Sauer *et al.*, 1983), and
- numerical indices, e.g., function of channel conditions, stormwater connectivity, etc. (Espey and Winslow, 1974; Sauer *et al.*, 1983).

Measures have ranged from qualitative groupings (e.g., rural versus urban) to fully-continuous variables (e.g., % impervious). One of the more widely used approaches is to employ the USGS National Urban Equations developed by Sauer *et al.* (1983). The second most significant variable in the seven-parameter approach is the Basin Development Factor (BDF), which is a somewhat subjectively-assigned composite index (0 to 12) of channel improvements, channel linings, storm drains/sewers, and curb and guttered streets.

We had several goals regarding the quantification of urbanization in our equations. First, despite being an empirical approach, assurance of fidelity to hydrologic processes was desired. Next, measures should be readily quantifiable via publically-available GIS data (i.e., no subjectivity or field investigations necessary). Third, the variable should be a continuous metric wherever possible (e.g., % impervious) rather than taking the form of a categorical variable such as high, medium, and low. Finally, because urbanization is not constant through time, we needed to be able to measure changes in spatial extent over the gauge records.

Arguably, the measure of urbanization that is most rooted in theory and most important hydrologically is imperviousness (Novotny, 2003). Impervious surfaces diminish infiltration potential, eliminate interception storage of plant surfaces, and decrease surface roughness relative to soil/vegetated surfaces, all of which acts to increase direct surface runoff and and the rate at which it flows. However, it is whether an impervious surface is *connected* to the drainage network that determines if the potential effects are transferred downstream. Effective Impervious Area (EIA) is defined as impervious surfaces that are directly connected to the downstream drainage system, consequently excluding any areas draining to pervious surfaces (Booth and Jackson, 1997). Although it is more representative of process than TIA, EIA can be arduous to measure. The two metrics have been correlated on regional scales such as for Denver, Colorado (Alley and Veenhuis, 1983), and western Washington (Dinicola, 1989); however, large differences in stormwater regulations throughout the country both in space and time suggest that the application of such relations to other regions would be imprudent. Fortunately for this research (although unfortunately for receiving streams), stormwater at the subdivision scale in southern California has largely gone unmitigated to date. This makes TIA generally much more representative of EIA than in other regions. Additionally, TIA is readily quantifiable in GIS via the USGS national impervious raster from 2001, meeting both criteria of being objectively quantifiable and largely representative of process.

Other important physical descriptors of urbanization are alterations of the hydrologic network via storm sewers, channelization/lining, or artificial surface storage. The latter has a diminishing effect on peak flows, while the other network adjustments can amplify peaks via decreased roughness and often shorter/steeper flow paths. Unfortunately, no public domain GIS layers were available to quantify storm sewers; therefore, it was decided to measure both road density and impervious area as potential surrogates. The USGS National Hydrography Dataset (NHD) offered measures of known artificial-channel adjustments in existing stream networks (e.g., 'artificial path', 'canalditch', 'connector', or 'pipeline'). Quantifications of such artificial stream-network links were included, although they did not prove to be statistically significant in preliminary models.

As such, impervious area and road density were used as the primary measures of urbanization. State of California (Cal-Atlas) road vectors from 2000 and 2007, along with a USGS impervious raster (2001), provided contemporary measures. The 2000 vector file was clipped to match georeferenced historical USGS topographic quadrangle maps, providing two additional snapshots of road density in time (typically ranging between the 1950s to 1980s). An example at one of the most urban gauges, Arroyo Trabuco (gauge no. 11047300), is presented in Figure 4, along with 2001 impervious levels. Knowing which roads were not constructed at respective points in time provided the basis for clipping-out associated impervious areas from the 2001 raster file such that changes in imperviousness through time could also be estimated. This procedure was performed for each watershed greater than 1% impervious area in 2001 (15 gauges), with the expectation that watersheds with less than 1% impervious area in 2001 would show little change in development through time. As a check to see how urban measures changed in a rural setting, the historical procedure was performed on one gauge with 0.4% impervious area in 2001 (Lone Pine, gauge no. 11063500).

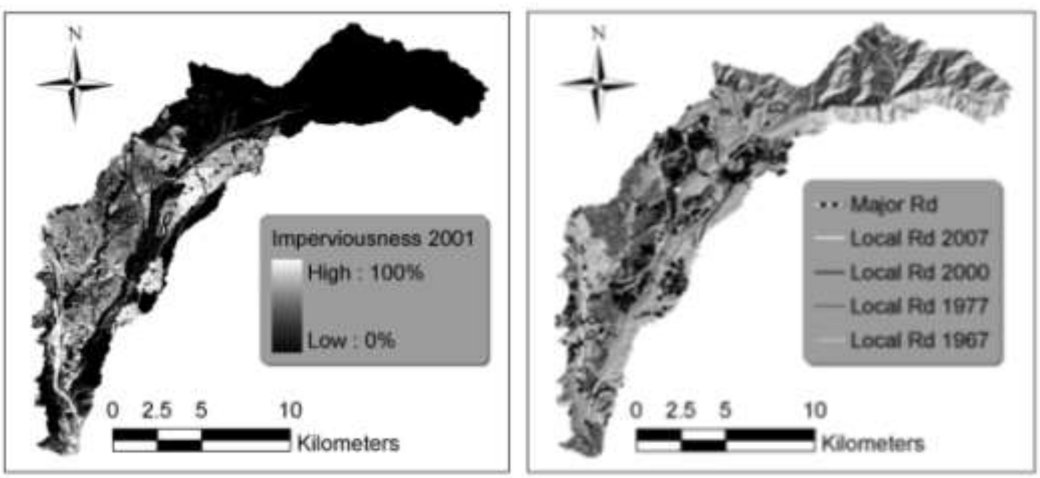

Figure 4. 2001 imperviousness and road vectors tracked through time per USGS historic quadrangle maps and current Cal-Atlas shapefiles at Arroyo Trabuco (Orange County, California, near intersection of Interstates 5 and 405).

It was apparent from the historical analysis that both road density and imperviousness tended to progress relatively linearly during development phases (Figure 5) such that the trapezoidal rule was sufficient to integrate mean values over the record. The gauges with the five highest integrated road densities (i.e., > 4 mi/mi^2) were covered by measured values of road density over their entire flow record. However, it was necessary to develop procedures to estimate measures of urbanization at gauges with records extending beyond the earliest measured values (e.g., pre-1950s). Given that the earliest measured values indicated relatively undeveloped/rural settings, Hawley (2009) was able to co

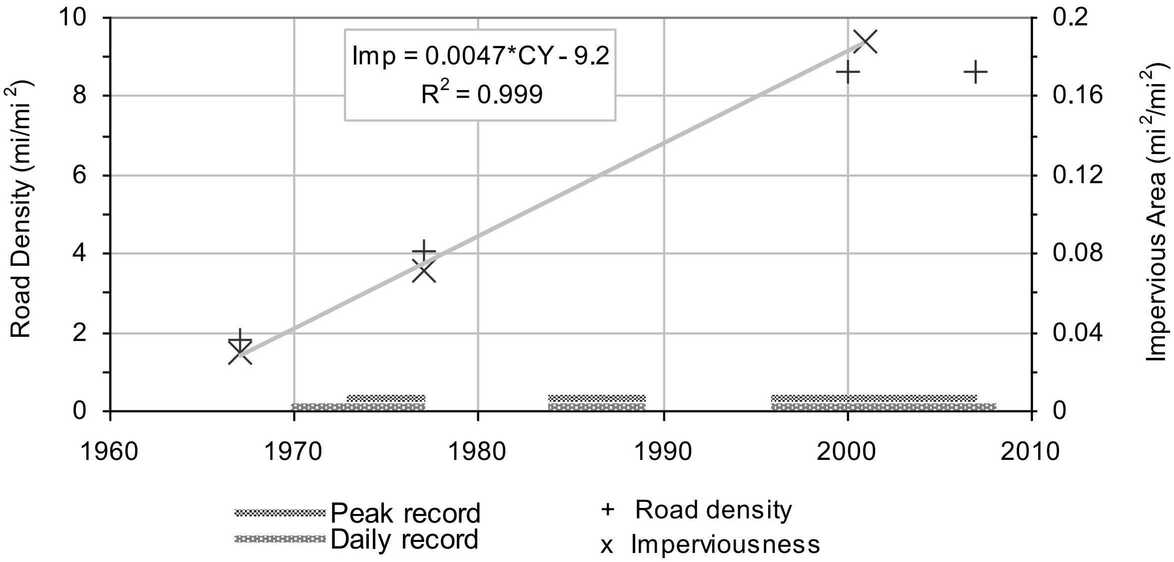

Figure 5. Imperviousness and road density through time at Arroyo Trabuco, overlaid by active gauge years and linear regression of imperviousness (Imp) as a function of calendar year (CY) from 1967 to 2001.

After tracking the progression of urbanization in great detail, several time-integrated measures were quantified of both road density and impervious area for testing in the models. Those that proved to be most consistently significant (i.e., $p < 0.05$) in preliminary models are indicated in **bold**:

- Imperviousness (TIA)
  - **Average spatial extent** (i.e., aerial extent of total imperviousness tracked through time and integrated over gauge record)
  - **Maximum spatial extent** (i.e., aerial extent of total imperviousness during last year of gauge record)
  - Fraction of record > (i.e., amount of time out of total years of record greater than xx% impervious area)
    - 1.5%
    - **5%**

- **7.5%**
- 10%
- 15%

- Road Density
    - Average spatial extent
    - Maximum spatial extent
    - Fraction of record >
        - 2 mi/mi^2
        - 4 mi/mi^2
        - 5 mi/mi^2
        - 6 mi/mi^2
        - 8 mi/mi^2

One potential explanation for the discrepancy in statistical significance between impervious area and road density is that TIA is a better surrogate for EIA than road density given such little stormwater mitigation to date. Furthermore, although the road density and imperviousness tend to be linearly correlated (e.g., Figure 5) at individual sites, they are *exponentially* correlated across all sites. As evident in Figure 6, a relatively-undeveloped gauge in a rural setting could have road densities up to 4 mi/mi^{2}and still have minimal amounts of impervious area (i.e., ~1.5%), while a gauge in a developing watershed with just 50% higher road density could have over seven times as much impervious area (i.e., 6 mi/mi^{2}relative to 10% imperviousness). This exponential relation masks potentially-critical differences in imperviousness in the early phases of development when ~2 mi/mi^{2}could represent less than 0.1% TIA in a rural basin or greater than 2% in a developing basin. The correlation is also misrepresentative in highly urbanized basins, as the relationship seems more linear than exponential above ~6 mi/mi^2. Such a complex, discontinuous relationship between road density and TIA would make it difficult for a continuous model to use one measure as a surrogate for the other.

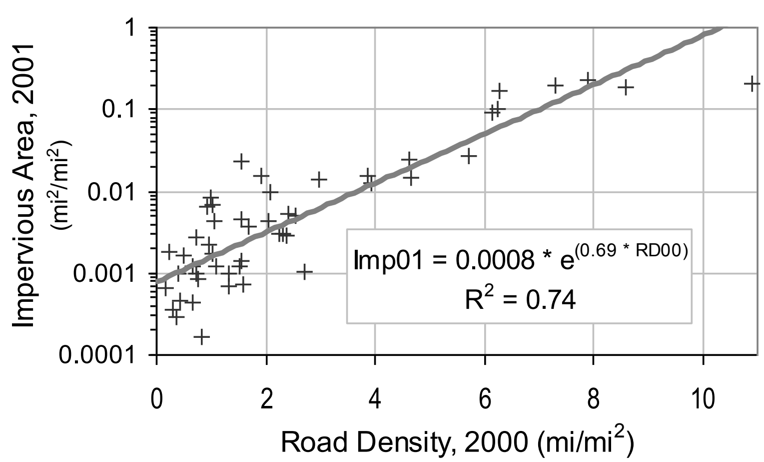

Figure 6. Exponential correlation between impervious area in 2001 (Imp01) and road density in 2000 (RD00) across all sites.

Other Physically-Based Metrics

One way to avoid specious conclusions in empirical studies is to develop multiple competing hypotheses (Schumm, 1991). It is not enough to infer causation by observing higher flows in urban settings. To be truly exhaustive, alternatives should be offered such as: were the urban gauges set in steeper watersheds, were they active during exceptional precipitation years, etc.? A matrix of readily-quantifiable hydrogeomorphic metrics was populated across varying temporal and spatial scales (Table 2) to test the influence of a multitude of potentially competing factors. GIS data (see Reference section) were acquired from public-domain sources such as the USGS, U.S. Department of Agriculture (USDA), National Oceanic and Atmospheric Administration (NOAA), and State of California geospatial clearinghouse (Cal-Atlas). Empty fields in some USDA polygons precluded a complete analysis of Natural Resources Conservation Service (NRCS) soil types; however, most source data were complete. Two sources of average annual precipitation were available. The USGS layer (1900 - 1960) was of slightly coarser spatial grain than the NRCS (1961 - 1990) shapefile, but because the 1977 USGS equations for southern California were developed with the former, both precipitation coverages were tested in the models. General resolution of these data was such that their precision was typically on the order of 1% of the measurement (e.g., 10-m National Elevation Dataset (NED) over 1 km of channel).

Table 1. Summary of variables tested in models with corresponding significance.

	Variable [(a)]	Units	Definition (equation)	GIS Source/Scale
spatial (x and y)	**A**	mi^2	drainage area	HUC and NED/10m
	Stm	mi	total stream length	NHD/ 1:24,000
	DD	mi/mi^2	drainage density (DD = Stm/A)	
	L	mi	length of main channel from gauge to basin divide	
	Shp	mi/mi^2	main-channel length divided by drainage area, i.e., shape (Shp = L/A)	
	W_{vly}	ft	valley width, measured from base of hillslope at gauge location	
	Ord	-	order – Strahler (1952) stream order	
	Arf_{Stm}	-	artificial fraction of total stream length, i.e., code ≠ 460	NHD
	Arf_{Mn}	-	artificial fraction of main channel	
topographic (x, y, and z)	Rlf	ft	total relief along main channel (elevation at divide minus elevation at gauge)	
	Elev	ft	average basin elevation, i.e., average of elevations at 10% and 85% of main-channel length measured from gauge to divide	
	Gage	ft	elevation at gauge	
	S_{chn}	ft/mi	average slope of main channel via elevations at 10% and 85% points	
	Vly	ft/mi	valley slope at gauge measured across geomorphically-continuous valley ~10% of main-channel length or ~1,500 ft (500 m)	
	Srf	ft/ft	average surface slope of watershed	

	Variable [a]	Units	Definition (equation)	GIS Source/Scale
precipitation	**P**	in.	average annual precipitation (area-weighted)	USGS (1900 - 1960)
	Pnrcs	in.	average annual precipitation (area-weighted)	NRCS (1961 - 1990)
	P224	in.	2-yr 24-hr precipitation volume (area-weighted)	NRCS
	IP	-	precipitation intensity relative to annual average (IP = P224/Pnrcs)	
	LAhst	-	relative difference from long-term precipitation average of 15.07 in. recorded at LA during gauged years	(1878 - 2006)
	$LAwt_{yr}$	-	number of exceptionally 'wet' precipitation years (50% > LA average, i.e., > 22.6 in.) during gauge record	
	$LAwt_{rt}$	-	relative number of exceptionally 'wet' precipitation years (50% > LA average) during gauge record divided by gauge record	
	SDhst	-	relative difference from long-term precipitation average of 9.96 in. recorded at SD during gauged years	(1850 - 2005)
	$SDwt_{yr}$	-	number of exceptionally 'wet' precipitation years (50% > SD average, i.e., > 14.9 in.) during gauge record	
	$SDwt_{rt}$	-	relative number of exceptionally 'wet' precipitation years (50% > SD average) during gauge record divided by gauge record	

[a] Variables: primary in **bold**, secondary in *italics*, and no statistical signficance is plain text

ArcMap software by Environmental Systems Research Institute (ESRI), including extensions such as 'spatial analyst', was used to optimize GIS measurements such as delineating watersheds and flow paths. Automated results from NED processing were cross-checked with existing shapefiles such as USGS HUC boundaries and NHD flowlines to verify estimates of drainage area, drainage density, etc.

Figure 7 depicts the inter-annual, decadal, and multi-decadal trends in regional precipitation as recorded at the two long-term precipitation gauges in Los Angeles (LA) and San Diego (SD). It includes the number of active gauges as well as number of gauges above specified levels of road density, suggesting that the more urban period of record (post ~1970) potentially had larger volumes of precipitation than the pre-urban period. By looking at records of individual gauges, Figure 8 shows some of the more urban records were active during wetter years; however, the most urban gauge (Arroyo Trabuco) was active during one of the driest composite climates on record. As such, we included the relative difference between mean-annual precipitation during flow records, along with the number of exceptionally wet years (50% > mean), in the models.

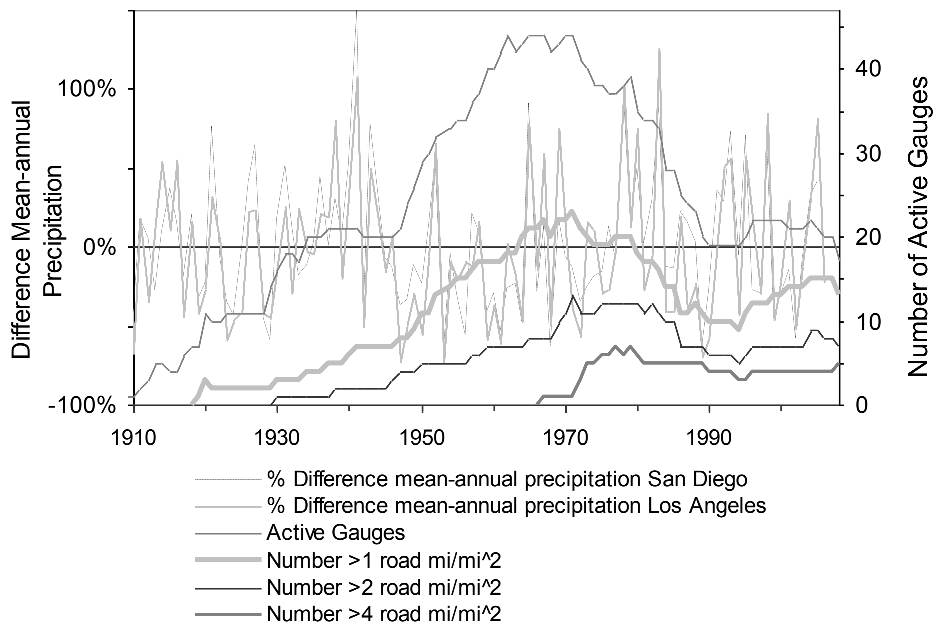

Figure 7. Inter-annual precipitation variability recorded at Los Angeles and San Diego overlaid with number of active gauges and number of gauged watersheds exceeding specified road-density levels (indicating increasing urbanization).

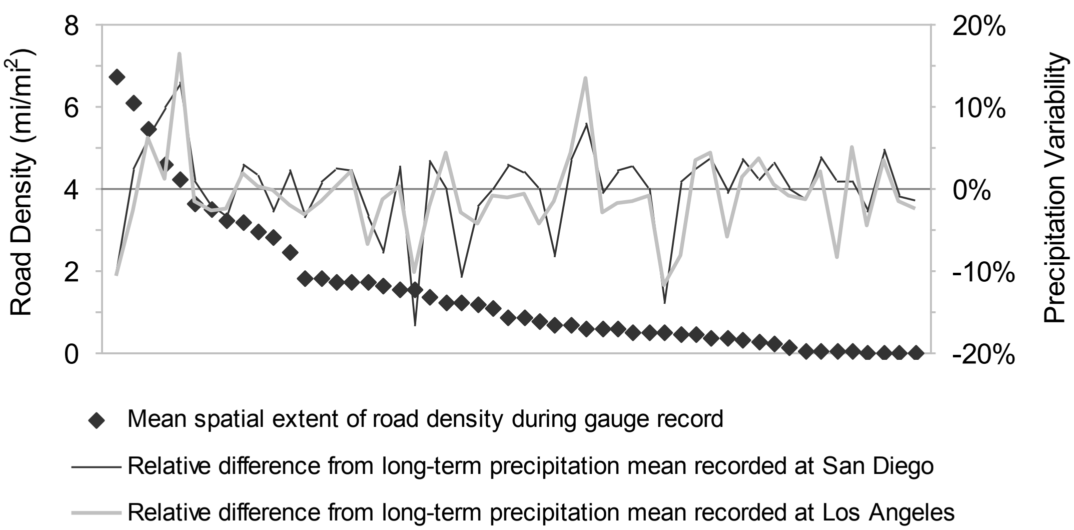

Figure 8. Mean spatial extent of road density overlaid by relative difference from long-term mean-annual precipitation recorded at Los Angeles and San Diego during gauge records.

Watershed configurations and drainage patterns varied throughout the study domain from linear to circular and parallel to dendritic, respectively. The slight departure in the overall trend of main-channel length (length of longest stem from gauge traced to drainage divide) as a function of drainage area from Hack's (1957) relationship is less notable than the variance within the sample (Figure 9), particularly important because one of the most exceptionally-linear watersheds (Arroyo Trabuco, 37 km to 140 km^2) was also one of the most urbanized. To represent these potentially-significant differences, the parameter 'Shp' was added as an alternative independent variable, defined as main-channel length/area.

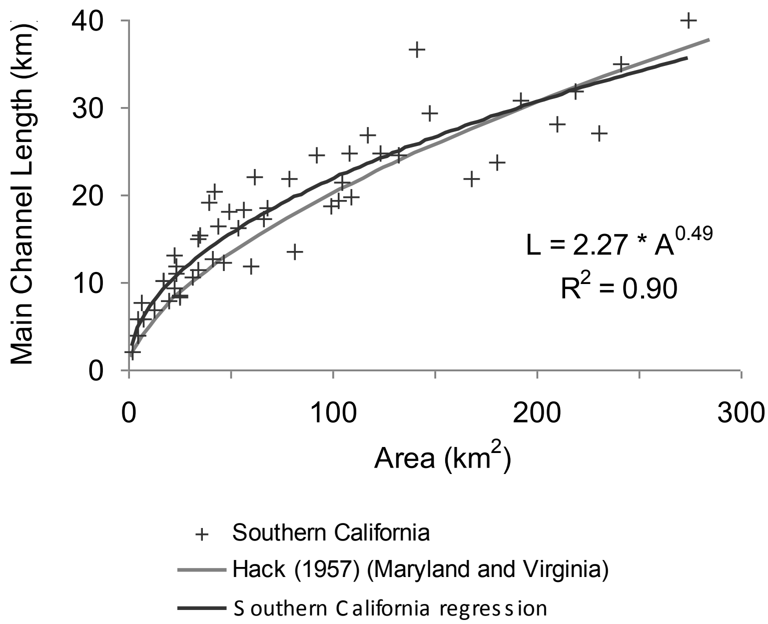

Figure 9. Main-channel length to basin divide (L) versus drainage area (A): southern California and the Hack (1957) relationship from Maryland and Virginia.

Consistent with Gregory (1976), drainage density was positively correlated to mean-annual precipitation in the semiarid regime and negatively correlated in the more humid setting (Figure 10). Additional parameters not explicitly accounted for in the models were vegetative cover, soil type/depth, and bedrock permeability due to incomplete spatial data; however, vegetation density may be implicitly captured in a discontinuous/threshold manner via mean-annual precipitation – one of the process-based explanations to the pattern in Figure 10. Other potentially contributing, but admittedly inter-correlated, factors which exhibited similarly-shaped patterns with drainage density included the 2-yr 24-hr precipitation, average surface slope, and average basin elevation. Two additional variables that showed scattered, slightly-positive correlations with drainage density were total basin relief and the 2-yr 24-hr precipitation volume standardized by the mean-annual precipitation.

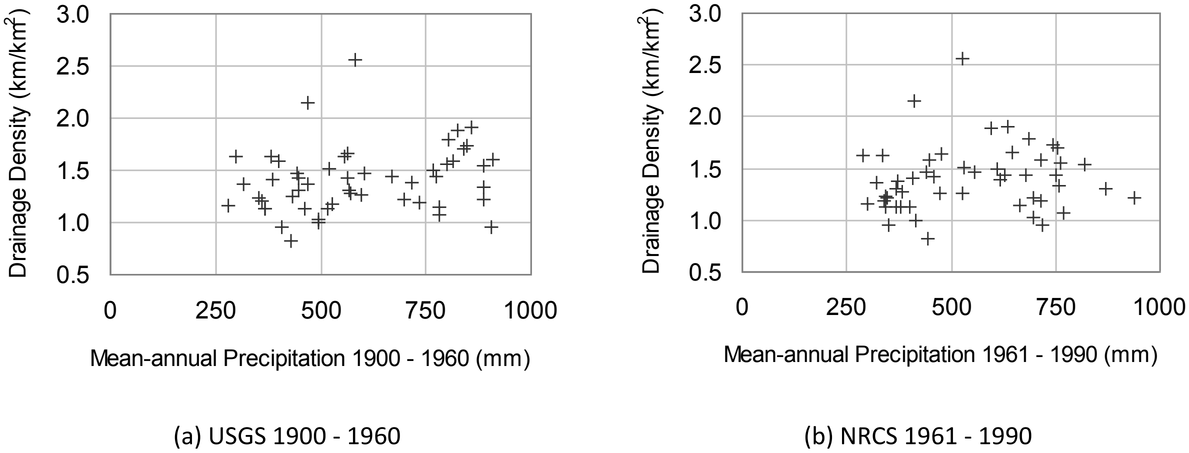

Figure 10. Drainage density versus area-averaged mean-annual precipitation.

Analytical Methods and Model Design

Beyond representing physical processes with appropriate quantitative variables, it was also important to guide their combination in model design to obviate potential collinearity issues. The objectives of the modeling were 2-fold: 1) to represent process by determining which variables were most significant in predicting flow magnitudes and durations, and 2) to determine which combinations and forms of these critical variables resulted in the most optimally-fit models for application. To guide the selection process, a cross-validation step was performed prior to final model design in which every fourth gauge (sorted alphabetically) was withheld resulting in a 33/10 calibration/validation split.

Multivariate power functions via regression analysis have been widely used by the USGS in developing regional equations for recurrence-interval flows (Jennings *et al.*, 1994). Logarithmic transformations of primary variables (e.g., Q, A, and P) in the southern California dataset created relatively constant residual variance, such that our analyses continue in this tradition. We used Statistical Analysis Software (SAS) to perform ordinary least squares regression. Hundreds of iterations of models were run with various withholding schemes using forward, backward, and best subset selection to determine the most consistently-significant parameters and candidate models for final testing. Due to sample variance, some variables were tested in multiple forms (e.g., exponential and power) and varied units (e.g., slope in ft/ft or ft/mi), expanding the range of variables from which the models could select.

Because unguided model selection often resulted in collinear variables and/or multiple forms of the same variable, our basic model framework was to test combinations of up to one variable from distinct process-based categories to preclude collinear variables from competing to represent the same process within the same model. Regarding peak-flow equations, the models selected from the following categories:

- watershed/network size: drainage area (A) or total stream length (Stm);
- spatial efficiency: shape (Shp) or drainage density (DD);
- precipitation: mean annual (P), 2-yr 24-hr volume (P_{224}), or 2-yr 24-hr relative to mean annual (IP);
- topographic efficiency: average slope of watershed surface (Srf), average channel slope (S_{chn}), valley slope at site (Vly), and total relief along main channel (Rlf);
- imperviousness (TIA): average imperviousness over record (Imp_{av}), maximum imperviousness of record (Imp_{max}), fraction of record length greater than 5% impervious (Imp_5), and fraction of record length greater than 7.5% impervious (Imp_7).

Identical steps were taken in designing equations for the component variables of DDFs (i.e., Q_{max}, d1/day1, and d2/day2). Beyond the process-based categories discussed above, a probabilistic category was added with candidate variables that increased the likelihood of having an extremely large/long event. This included the number of years of gauge record (Yr), the relative difference from long-term precipitation average recorded at LA during gauged years (LA_{hst}), and the number of active gauge years that were exceptionally 'wet', that is, 50% greater than the long-term mean recorded at LA ($LAwt_{yr}$ and $LAwt_{rt}$).

Finally, due to the fact that DDFs essentially pivot around Q_{max}, it was clear that their shape (i.e., d2 or day2) would best be explained by direct measures of their magnitude (d1 or day1) and scale (Q_{max}). All else being equal, a larger DDF magnitude would correspond to a steeper (more negative) slope, while a larger scale (Q_{max}) would tend to correspond to a flatter (less negative) curve. As such, d1/day1 and Q_{max} were included in some of the d2/day2 models to evaluate the performance benefits relative to the risk of compounding prediction errors on the application side. Instantaneous peak flows were also tested as a substitute for daily Q_{max}, with Q_{10} being the best candidate for final models due to performance in predicting d2/day2, as well as regularly having the best prediction accuracies among all instantaneous Q_i in preliminary models.

Model forms that were congruent with hydrologic theory and had high performance in the cross-validation phase were selected for final model calibration. Model performance was measured via several indicators such as a high significance of individual variables (typically $p < 0.05$), high Adjusted R^2 (Adj. R^2) and/or minimum corrected Akaike Information Criterion (AIC_c), and homoscedastic residuals across both calibration and validation data. We assessed model performance, including standard diagnostics, in both logarithmic and arithmetic space. Outliers were identified using standard diagnostics (e.g., Cook'D, Rstudent residual, etc.); however, to be withheld from the model there needs to be supporting *a priori* evidence and/or compelling physically-based justification (e.g., the hydrogeomorphically-distinct 'dry' subset of gauges east of the Penninsular Range discussed above). In general, we attempted to follow the guideline of ca. 10 observations per predictor variable, such that models from the cross-validation phase typically had only three to four independent variables (i.e., per thirty-three samples) allowing for exceptions in cases of high performance/statistical significance.

Results

The presentation of results is divided into three subsections: 1) cross-validation summary, 2) peak-flow equations, and 3) DDF models. Because competing models often performed similarly, we include five to six models for each dependent variable. This reduces the risk of giving too much weight to one model/variable as they are all physically based, and there is generally no clear basis for choosing one model over a similarly performing alternative. It also better represents the range of influence of urbanization in that different proportions of the variance are explained depending on what other statistically-significant variables are included.

Cross-Validation Summaries and Individual Variable Performance

Cross-validation models of Q_i and DDF components are summarized in Tables 3(a) and 3(b), respectively. Measures of watershed size (Stm, A) and precipitation (P, P_{224}) accounted for the most variance across all return-interval flows. Measures of imperviousness accounted for up to one quarter of the variance of the 1-yr flow, with decreasing significance for higher flows (e.g., partial R^2 ~0.10, 0.06, 0.02 for 1.5-, 2-, and 5-yr flows, respectively). At higher return intervals (i.e., $\geq Q_{10}$), the size of the watershed accounted for so much of the variance that few additional terms were statistically significant (i.e., $p < 0.05$), resulting in high performance using relatively-simple models. For example, for return intervals 10, 25, 50, and 100, R^2 in arithmetic space ranged from 0.7 to 0.9 for both calibration and validation subsamples using the following equations:

$Q_i = f(A, P)$

$Q_i = f(Stm, P)$

$Q_i = f(Stm, P_{224})$ (see Figure 11 for cross-validation performance at Q_{25})

Table 2. Summary of cross-validated models.

(a) For instantaneous peak flows ($n_{calibration} = 33$, $n_{validation} = 10$)

Dependent Variable	Urbanization Significant ($p < 0.05$) in Validated Model?	Best Predictor Variables [(a)]	Average Calibration Standard Error[(b)]	Average Validation Standard Error[(b)]
Q1.5	✓	A, Strm (0.2); P, P_{224}, IP, (0.2); Imp_{max} (0.1)	80%	100%

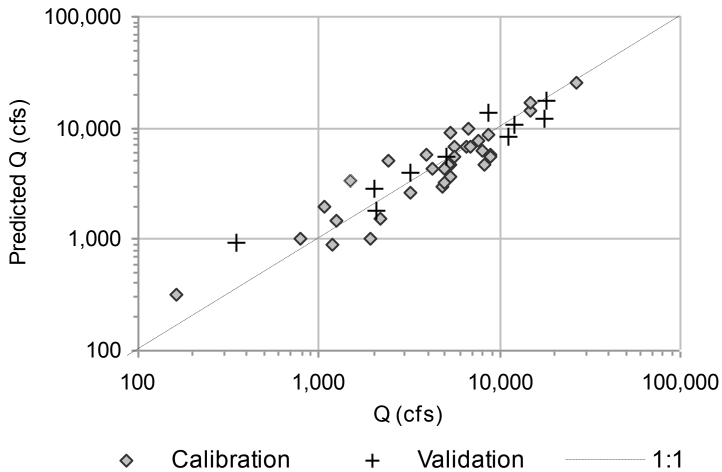

Figure 11. Cross-validation performance of $Q_i = f$(Stm, P_{224}) for 25-yr return interval (predicted Q_{25} versus actual) with 1:1 'perfect-fit' line overlaid.

However, the diminishing predictive power of watershed scale (i.e., A and Stm) with storm frequency (e.g., partial R^2 for A ~0.7 at Q_5 versus ~0.2 at $Q_{1.5}$) explained why equations with more classes of hydrologic variables generally performed better than simpler models for return intervals less than 5 yrs. That is, with decreasing volumes of precipitation, the efficiency with which a drainage network concentrated and conveyed runoff became increasingly significant in predicting peak flow. Although hundreds of models were tested, the form that performed best during cross validation in terms of arithmetic space R^2, AIC, SE, and least patterned residuals for $Q_{1.5}$ and Q_2 was:

$Q_i = f(\text{Stm, Shp, IP, Vly, Imp}_{max})$

Imperviousness could account for up to 25% of variability in the 1-yr flow, but other terms had little predictive power. Largely attributable to the fact that fifteen of the forty-three gauges had entire years of no flow (i.e., $Q_1 = 0$), models showed poor overall performance and unacceptably-patterned residuals. Consequently, no Q_1 equations were advanced to final calibration.

Based on performance across all remaining return intervals (i.e., 1.5, 2, 5, 10, 25, 50, and 100), five base-models were selected for final calibration. A summary of the cross-validated models is presented in Table 3(a).

Recall that DDFs have three components: Q_{max} (scale), d1 or day1 (magnitude), and d2 or day2 (shape). Process-based categories such as scale and precipitation explained most of the variance of Q_{max} (partial R^2 of 0.6 and 0.2, respectively). Record length (Yr) was the next most significant variable in forward selection, explaining 3 to 4% of the variance. The most significant measure of network spatial efficiency was DD (2 to 3% of the variance) when used in combination with A, P or P_{224}, and Yr. Other measures of spatial and topographical efficiency were insignificant ($p >> 0.05$) except in models where precipitation was intentionally withheld, which resulted in poorer overall performance. This suggested that the measures were acting more as a surrogate for precipitation. Finally, urbanization was insignificant in predicting the maximum daily-mean flow on record, consistent with the models of the rarest and largest peak flows (i.e., $\geq Q_{25}$).

Forward selection of DDF magnitude parameters typically identified the following form, with corresponding partial R^2 in parentheses:

d1: Yrs (0.52), A (0.05 - 0.06), P (0.14), Imp_x (0.04 - 0.06)

day1: Yrs (0.46), A (0.07 - 0.09), P (0.18), Imp_x (0.10 - 0.11), S_{chn} (0.02 - 0.03)

One of three similarly performing impervious descriptors (i.e., Imp_x representing Imp_{av}, Imp_5, or Imp_7) was typically the third variable added during forward selection for 'day1', while it was generally the fourth best explanatory variable for 'd1'. Exponential forms of the impervious terms consistently explained more variance than the power form.

Models of day1 with S_{chn} had improved calibration accuracy but reduced validation performance compared to the base model (i.e., A, P, Yrs, and Imp_x). Adding both Srf (0.03 - 0.04) and DD (0.02 - 0.03) to the base model improved both calibration and validation performance. Despite reservations about including six independent variables with only thirty calibration observations, the fact that all variables were significant ($p < 0.05$) supported their inclusion. One model of d1 had modest performance with no urban term (A, DD, Srf, Yrs) during calibration, but had substandard performance with the valiadation data across all measures (i.e., R^2, Adj. R^2, SE, AIC, and AIC_c). It was selected for final model calibration in order to compare performance of urban models against the best non-urban model.

A substantial outlier was identified during the calibration/validation phase of d1. In this case, there was significant *a priori* rationale to consider excluding the Ventura River gauge near Meiners Oaks, California (gauge no. 11116550), because the DDF itself was poorly fit (worst R^2 at 0.79) with unacceptably-patterned residuals. Withholding the outlier resulted in substantial changes to the parameter values, increased the significance of urbanization and drainage area (partial R^2 of 0.04 to 0.07 and 0.12, respectively), and improved overall model performance. Similar to the expanded day1 models, d1 as a function of A, P, DD, Srf, Yrs, and Imp_x resulted in improved performance in the validation data and less heteroscedastic residuals.

The shape of the DDFs (d2 or day2) was highly influenced by its magnitude (Q_{max}) and scale (d1 or day1). Models that intentionally withheld such measures were not only poorly fit (best Adj. R^2 0.57 for d2), but had severely patterned residuals. Conversely, models that included d1 (partial R^2 0.54) and Q_{max} (partial R^2 0.28), or Q_{10} (partial R^2 0.32) as an alternative to Q_{max}, accounted for up to 90% of the total variance. Inclusion of these variables was necessary to achieve high model performance ($R^2 > 0.6$).

Another significant outlier (Little Dalton near Glendora, California) was identified during d2 cross validation; however, there was no concurring *a priori* evidence to withhold the gauge from the models. Two similarly performing models were identified during calibration in the following forms:

$$d2 = f(Q_{10}, d1, Yrs, Imp_x)$$

$$d2 = f(Q_{10}, d1, Yrs, P_x)$$

The model with P or P_{224} in place of Imp_x performed slightly better during calibration (Adj. R^2 0.90 versus 0.88); however, had larger errors and more patterned residuals in validation (R^2 0.83 versus 0.93, Standard Error (SE) 14% versus 9%). Both were selected for final calibration, along with a three-term equation that substituted Slp_{chn} for Yrs and P, which performed slightly worse in both calibration and validation, but all terms were significant at the $p < 0.05$ level.

Likewise with the calibration of day2, Q_{10} and day1 explained most of the variance (0.31 and 0.51, respectively), with Q_{max} explaining 26% of the variance in the place of Q_{10}. Models that intentionally excluded those variables could barely explain the total variance that 'day1' could explain individually. Standard diagnositics revealed unacceptably-patterned residuals when plotted against Q_{10}. The shape, which slightly resembled the trend of drainage density versus precipitation (Figure 10), became less pronounced when Imp_x was included in the model. They were most evenly distributed by including P_{224}, Yr, and Elev in place of imperviousness, but the five-variable model for day2 performed the poorest with the validation data (R^2 0.56 versus 0.86 for day2 = f(day1, Q_{10}, Yrs, Imp_{av})). This was despite the fact that each variable in the five-variable model was significant at the 0.05 level during calibration and the model on the whole accounted for more variance (i.e., 91% versus 85%). As such, both models were selected for final calibration.

In summary, for each dependent variable, cross validation produced five to twelve reasonably performing candidate models that were advanced to final calibration; the best performing models are presented herein. A central finding was that measures of imperviousness were highy significant ($p < 0.05$) in predicting instantaneous peak flows at return intervals less than or equal to 5 yrs. Additionally, urbanization was highly significant in predicting the magnitude of DDFs ($p < 0.05$ in nineteen of twenty models, $p < 0.001$ in nine of twenty models). This was particularly true for the day1 (partial R^2 ~0.10) scheme that includes more bins with low/moderate flows (bins 12-25) as opposed to the d1 (partial R^2 ~0.05) scheme which is more skewed toward the highest flows (bins 16-25). DDF shape (d2 or day2) was less explained by urbanization ($p < 0.10$ in four of fourteen models), other than through the indirect influence of DDF magnitude, which explained greater than 50% of the variance of its shape.

Peak-Flow Equations

Five equations are presented for each return-interval flows. By using the same equation formats for all recurrence intervals, it is apparent how the most influential variables change with return period. In general, there seems to be a behavior change around the 2- and 5-yr events, transitioning from a high influence of drainage efficiency, rainfall intensity, and imperviousness to a greater dependency on watershed size such as area and total stream length.

The equations have varied forms; however, the final equation (Eq. (10)) is intentionally presented as a revision to the USGS 1977 equations that were functions of only A and P. We added an exponential term for Imp_{max} because it models the effects of urbanization in a simple continuous form (i.e., $Imp_{max} \rightarrow 0$, urban term $\rightarrow 1$, equation $\rightarrow$ rural equation). We present each equation with the corresponding variable definitions (in Table 2); and parameters, units, and performance measures (in Tables 4(a) through 4(j)) for each return interval. ***In these equations, uppercase terms indicate variables and lowercase nomenclature indicates the corresponding β parameter from the regression. Bold font draws attention to terms with varied units.***

Equation (6) is presented with corresponding parameters, units, and performance measures in Table 4(a):

$$Q_i = e^{(Incpt)} * Stm^{stm} * e^{(shp*Shp)} * IP^{ip} * Vly^{vly} * e^{(impmax*Impmax)} \qquad \textbf{Eq. (6)}$$

where:

- Q_i = instantaneous peak flow at return interval i yrs (cfs);
- Stm = total stream length in basin (mi);
- Shp = length of main channel (traced to basin divide) divided by total drainage area (mi/mi^2);
- IP = P_{224}/P_{nrcs}, i.e., 2-yr 24-hr volume/average annual volume: NRCS 1961 - 1990 (in/in);
- Vly = valley slope at gauge as measured across a geomorphically-continuous valley setting (i.e., relatively continuous valley width lacking major tributary confluences) up to a length of ~10% of main-channel length or ~1,500 ft (ft/mi);

and

Imp$_{max}$ impervious area as **fraction** of total drainage area **(mi^2/mi^2)**.

(a) Adjusted R^2 reported from geometric space
(b) Standard Error of estimate expressed as percentage of sample mean in arithmetic space
(c) Corrected AIC reported from arithmetic space
(d) Adjusted R^2 reported from arithmetic space (for linear models)

Equation (7) is presented with corresponding parameters, units, and performance measures in Table 4(b):

$$Q_i = e^{(Incpt)} * A^a * DD^{dd} * P_{224}^{p224} * Imp_{max}^{impmax} \qquad \textbf{Eq. (7)}$$

where:

A = total contributing drainage area (mi^2);

DD = drainage density computed by total stream length divided by drainage area (mi/mi^2);

P_{224} = 2-yr 24-hr precipitation volume: NRCS (in.);

Imp_{max} expressed as **percentage** of total drainage area **(mi^2/mi^2) * 100%**; and

$Imp_{max} \geq 1\%$ or else term is dropped.

Equation (8) is presented with corresponding parameters, units, and performance measures in Table 4(c):

$$Q_i = e^{(Incpt)} * Stm^{stm} * P_{224}^{p224} * e^{(impmax*Impmax)} \qquad \textbf{Eq. (8)}$$

where:

Imp_{max} expressed as **fraction** of total drainage area **(mi^2/mi^2)**.

Equation (9) is presented with corresponding parameters, units, and performance measures in Table 4(d):

$$Q_i = e^{(Incpt)} * A^a * P_{224}^{p224} * Elv_{bsn}^{elv} * e^{(impmax*Impmax)} \qquad \textbf{Eq. (9)}$$

where:

Elv_{bsn} = average elevation between the 10 and 85% points along the main channel from outlet to divide (feet above mean sea level); and

Imp_{max} expressed as **fraction** of total drainage area **(mi^2/mi^2)**.

Equation (10) is presented with corresponding parameters, units, and performance measures in Table 4(e):

$$Q_i = e^{(Incpt)} * A^a * P^p * e^{(impmax*Impmax)} \quad \textbf{Eq. (10)}$$

where:

P = average annual precipitation, USGS: 1900 - 1960 (in.); and

Imp_{max} impervious area as **fraction** of total drainage area **(mi^2/mi^2)**.

Model performance generally increases up to Q_{10}, with relatively consistent precision at higher return intervals. Performance of Eq. (9) relative to the USGS rural (1977) and urban (1983) equations is depicted in Figures 12 and 13, respectively. The disparity between our models and the USGS models decreases with increasing return period (Table 5).

100	45%	32%	33%	37%	38%	40%	60%

Given the longer records and a focus on smaller watersheds, our models generally outperform the USGS equations (Table 5). It should be noted that the SE for the USGS urban equation is substantially influenced (perhaps unduly) by the large number of predictor variables (seven) relative to the sample size. However, direct comparisons of unadjusted metrics such as R^2 or Sum of Squared Errors (SSE) demonstrated better performance by our equations in every case relative to the USGS urban equations. The single case where our equations were outperformed by the USGS rural equations was Eq. (6) at the 100-yr flow, which is included because it was one of the best performing equations at $Q_{1.5}$ through Q_{10}.

Duration Density Functions

Power functions (Eqs. (4) and (5)) are used to predict durations of bin flows as scaled by Q_{max} using Eq. (1). Two forms of the power function cover different ranges of bins (i.e., bins 16-25 with d1 and d2 or bins 12-25 using day1 and day2). Models for each are presented with Q_{max} followed by d1 and d2, followed in turn by day1 and day2.

Models of Q_{max} (cfs) that were advanced from cross validation performed comparatively well during final calibration in both geometric and arithmetic space. The only notable change was that DD and Yr became less significant, with p-values greater than 0.05 in some cases. Final models are presented with corresponding parameters, units, and performance measures in Table 4(f):

$$Q_{max} = e^{Incpt} * A^{a} * P_x^{px} * Yr^{yr} \quad \textbf{Eq. (11)}$$

$$Q_{max} = e^{Incpt} * A^{a} * P_x^{px} * Yr^{yr} * DD^{dd} \quad \textbf{Eq. (12)}$$

$$Q_{max} = e^{Incpt} * Stm^{stm} * P_x^{px} * Yr^{yr} \quad \textbf{Eq. (13)}$$

where:

Q_{max} = maximum mean 24-hr flow (cfs);

Yr = length of mean-daily flow record (yrs);

P_x = P or P_{224} (as specified in Table 4(f)), where:

P = mean annual precipitation 1900 - 1960 (USGS) (in.); and

P_{224} = 2-yr 24-hr precipitation volume (NRCS) (in.).

A substantial outlier was identified during the cross-validation phase of d1, and confirmed during final calibration *across all model forms.* Consistently outside of the 95% confidence interval for model predictions, studentized residuals ranged from -2.5 to -4, while other points generally fell within -2 to 2. The 'best' case for its inclusion was model d1 = f(A, DD, Srf, Yrs, Imp_{av}), with a Cook's D of 0.39 and an RStudent residual of -3.0, corresponding to a two-sided p-value of 0.005. Because the coefficient of the DDF was suspected to be atypically low *a priori*, a one-sided p-value could be justified (i.e., 0.0026). However, Cook's D and the Rstudent residual were usually far worse, ranging up to 1.0 and -5.1, respectively, in model d1 = f(A, P, Yrs, Imp_7), corresponding to a two-sided p-value of 0.00001, which clearly justified its removal during final calibration.

The base model d1 = f(A, P, Yr, Imp_x), performed relatively well in geometric space; however, arithmetic space performance was significantly improved by adding Srf and DD. Given that the expanded model offered slightly more homoscedastic residuals and all variables were significant ($p < 0.05$) during both cross validation and final calibration, we include it as an alternative to the four-term model. Equations are presented with corresponding parameters, units, and performance measures in Table 4(g). The relatively-large standard errors in arithmetic space are somewhat misleading because the appropriate scales are geometric, varying over three orders of magnitude (300 - 360,000).

$$d_1 = e^{(incpt)} * A^{a} * P^{p} * Yr^{yr} * e^{(impx * Impx)}$$ **Eq. (14)**

$$d_1 = e^{(incpt)} * A^{a} * P^{p} * Yr^{yr} * DD^{dd} * e^{(srf * Srf)} * e^{(impx * Impx)}$$ **Eq. (15)**

where:

Srf = average surface slope of watershed (m/m); and

Imp_x = Imp_{av}, Imp_5, or Imp_7 (as specified in Table 4(g)), where:

Imp_{av} =average impervious extent over record as a fraction of total drainage area **(mi^2/mi^2)**;

Imp_5 =fraction of record greater than 5% TIA **(yr/yr)**; and

Imp_7 =fraction of record greater than 7.5% TIA **(yr/yr)**.

As during the cross-validation phase, the majority of the variance in d2 was explained by d1, Q_{10}, and Yr (in that order). In the fourth position, both impervious and precipitation terms accounted for similar proportions of the variance, while no additional variables were significant. Performance measures such as R^2 and SE slightly favored the models that included precipitation in the place of imperviousness. In contrast, however, residuals relative to predicted values were more equitably distributed by including imperviousness.

With similar performance across several measures, alternatives of the linear base model (d2 = f(Q10, d1, Yr)) developed in arithmetic space are presented, with corresponding parameter values and performance measures in Table 4(h).

$$d_2 = Incpt + \beta_{Q10} * \ln(Q_{10}) + \beta_{d1} * \ln(d1) + \beta_{yr} * \ln(Yr) + \beta_{impx} * Imp_x \quad \textbf{Eq. (16)}$$

$$d_2 = Incpt + \beta_{Q10} * \ln(Q_{10}) + \beta_{d1} * \ln(d1) + \beta_{yr} * \ln(Yr) + \beta_{Px} * \ln(P_x) \quad \textbf{Eq. (17)}$$

where:

Q_{10} = 10-yr instantaneous peak flow (cfs); and

d1 = coefficient of DDF calibrated in ‘days’ and ‘cfs’.

As with d1, models of day1 explained the most variance and had greatest homoscedasticity using the exponential forms of imperviousness as opposed to power forms. Standard diagnostics showed similar performance with each impervious measure (i.e., Imp_{av}, Imp_7, and Imp_5), justifying the inclusion of all three forms. The six-term model performed the best in both cross validation and final calibration, with all terms significant ($p < 0.05$) and the greatest homoscedasticity. Furthermore, the case could be made that this form of model offers a more complete representation of the effect of urbanization. That is, imperviousness is still predicted to have an exponential effect on days of occurrence even after accounting for the wide range of other theoretically-important, relatively-significant variables. As such, we include them as alternatives to the more heuristic four-term models. Day1 equations are presented with corresponding parameters, units, and performance measures in Table 4(i). The smaller (arithmetic space) standard errors in comparison to d1 are more attributable to the smaller day1 range (100 to 60,000) than substantial improvements in performance:

$$day_1 = e^{(incpt)} * A^{a} * P^{p} * Yr^{yr} * e^{(impx * Impx)}$$ **Eq. (18)**

$$day_1 = e^{(incpt)} * A^{a} * P^{p} * Yr^{yr} * DD^{dd} * e^{(srf * Srf)} * e^{(impx * Impx)}$$ **Eq. (19)**

Day2 had three consistently significant predictor variables: Q_{10}, day1, and Yr. The placeholder for the fourth variable was tested with all remaining independent variables; however, similar to the d2 models, the best performance was achieved with measures of imperviousness or precipitation. Residual patterns relative to Q_{10} were less pronounced than during cross validation, with impervious models slightly more patterned than those that included precipitation measures. Equation formats are presented with corresponding parameters, units, and performance measures in Table 4(j):

$$day_2 = Incpt + \beta_{Q10} * \ln(Q_{10}) + \beta_{day1} * \ln(day1) + \beta_{yr} * \ln(Yr) + \beta_{impx} * Imp_x$$ **Eq. (20)**

$$day_2 = Incpt + \beta_{Q10} * \ln(Q_{10}) + \beta_{day1} * \ln(day1) + \beta_{yr} * \ln(Yr) + \beta_{Px} * \ln(P_x)$$ **Eq. (21)**

where:

Q_{10} = 10-yr instantaneous peak flow (cfs); and

day1 = coefficient of DDF calibrated in ‘days’ and ‘cfs’.

Implications and Discussion

The models predict higher peak flows (especially for ≤ Q_5), and longer durations across all sediment-transporting flows in urban watersheds. As an example, we applied them to a hypothetical watershed with average conditions, controlling for everything but imperviousness. Beyond model application, case studies are presented of two gauges whose records spanned periods of relatively undeveloped and developed periods, offering support to the broader statistical models. Finally, recall that the models were developed using gauges ranging in drainage area from 0.5 to 105 mi^2 with 0 to 26% TIA (Table 1); therefore, the equations should not be applied to watersheds outside of those bounds. Regarding DDFs, models were calibrated with gauges that had a positively-skewed range of ~20 to 95 yrs with a mean of ~45 and standard deviation of ~20. In application, we recommend simulations within one standard deviation of the mean (i.e., ~25 to 65 yrs, convenient for the typical engineering time frame of ~50 yrs).

Effects of Urbanization Predicted by Models

Large increases were found in instantaneous-peak flows of more frequent return periods relative to a rural setting of ≤ ~1% imperviousness. The effects of urbanization decreased with larger, less frequent storms. For example, median peak factors for a watershed with 20% imperviousness were ~10x, ~6x, and ~2x for the 1.5-, 2-, and 5-yr flows, respectively (Figure 14). Such attenuating influence of urbanization with return period is generally consistent with both theory and previous studies (Bledsoe and Watson, 2001; Hollis, 1975; Sauer *et al.*, 1983), including studies specific to California (Rantz, 1971) and southern California (Durbin, 1974). Fundamental hydrology suggests that during very large, infrequent events (e.g., Q_{100}) soils have become saturated and behave similar to impervious surfaces.

The peak factors presented here are generally larger than those from previous studies. For example, Hammer (1972) and Hollis (1975) suggested that the 1.5- to 2-yr flows could double or triple at 10 to 20% imperviousness, and Bledsoe and Watson (2001) found peak factors ranging 1.5 to 4 dependent on regional setting. At those same impervious ranges and flow intervals, median-peak factors from the models ranged 3 to 10, with the maximum projected increase of 7x at Q_2 and 14x at $Q_{1.5}$ with 20% imperviousness. Though such increases may seem extreme, they are not the largest that have been reported (e.g., Urbonas and Roesner (1993)). The flashiness of the setting combined with limited flow-control practices suggest that peak factors of southern California could be larger than in other regions, although the relatively small basin sizes from this study may also play a factor in the higher peak factors.

Models of 1-yr flows performed poorly overall and are not reported, but the influence of urbanization was nevertheless unequivocal. Despite fifteen of the forty-three gauges having a Q_1 of 0 cfs (range 0 to 236, median 1.8, and mean of 14 cfs) the four most urban gauges (Imp_{av} 9 to 14%) accounted for the four largest 1-yr flows (i.e., 236, 102, 49, and 26 cfs) over records of 23 to 43 yrs.

Model Key: 1 = f(A, P, Imp_{max}) 2 = f(A, P_{224}, Elv, Imp_{max}) 3 = f(A, P_{224}, DD, Imp_{max}) 4 = f(Stm, P_{224}, Imp_{max}) 5 = f(Stm, IP, Shp, Vly, Imp_{max})

Figure 14. Peak factors for instantaneous peak flows as a function of TIA for all five calibrated peak flow models: (a) at Q1.5, (b) at Q2, (c) at Q5, (d) at Q10.

Finally, regarding peak-flow models, the fact that Imp_{max} accounted for more variance than other impervious measures such as Imp_{av}, Imp_5, or Imp_7, shows the ease at which the most developed portion of a gauge record can overwhelm the undeveloped peak flows, especially for the more frequent return intervals. It may suggest the potential for a statistically-significant influence at higher return intervals (e.g., Q_{10}) in the future as gauges have more time to record large precipitiation events at those impervious levels.

Regarding the DDF curves, gauge data to date did not show urbanization as statistically significant in explaining their scale (Q_{max}), but it had an exponential effect on the magnitude (d1 and day1, i.e., number of days), with a linear effect on d2 and day2 (shape). The combined effect tends to magnify durations of the moderate flows slightly more than durations of the largest flows. Figure 15 presents a 25-yr simulation of an average watershed across rural and urban scenarios using both models (i.e., d1/d2, bins 16-25 and day1/day2, bins 12-25) demonstrating relatively good agreement. Differing only by levels of imperviousness (i.e., Imp_{av} 12% versus 0.5%), the urban setting showed a 3-fold increase in the number of expected days at 50 cfs, with a 2- to 2.4-fold increase at 850 cfs (Table 7).

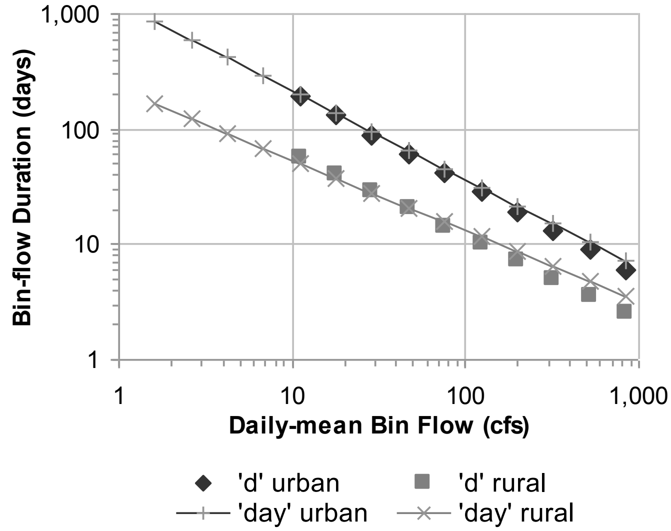

Figure 14 – DDFs of 25-yr simulations of equivalent watersheds in rural and urban settings

Table 5 – Summary of 25-yr DDF simulation for 'dry', rural, and urban scenarios in an average[(a)] watershed

	Variable	Rural	Urban	Ratio (Urban/Rural)
key values for DDF model input	Imp_{av}	0.5%	12%	
	Q_{max} (cfs)	1,040	1,040	1
	Q_{10} (cfs)	2,470	2,730	1.1
d1/d2 model	d1	326	1,330	4.1
	d2	-0.72	-0.80	1.1
	days @ ~10 cfs (bin 16)	57	194	3.4
	days @ ~50 cfs (bin 19)	20	61	3.0
	days @ ~125 cfs (bin 21)	10	28	2.8
	days @ ~320 cfs (bin 23)	5.0	13	2.6
	days @ ~850 cfs (bin 25)	2.5	6.1	2.4

	day2	-0.61	-0.77	1.3
	days @ ~10 cfs (bin 16)	51	199	3.9
	days @ ~50 cfs (bin 19)	21	66	3.1
	days @ ~125 cfs (bin 21)	12	31	2.7

days @ ~320 cfs (bin 23)	6.4	15	2.3
days @ ~850 cfs (bin 25)	3.6	7.2	2.0

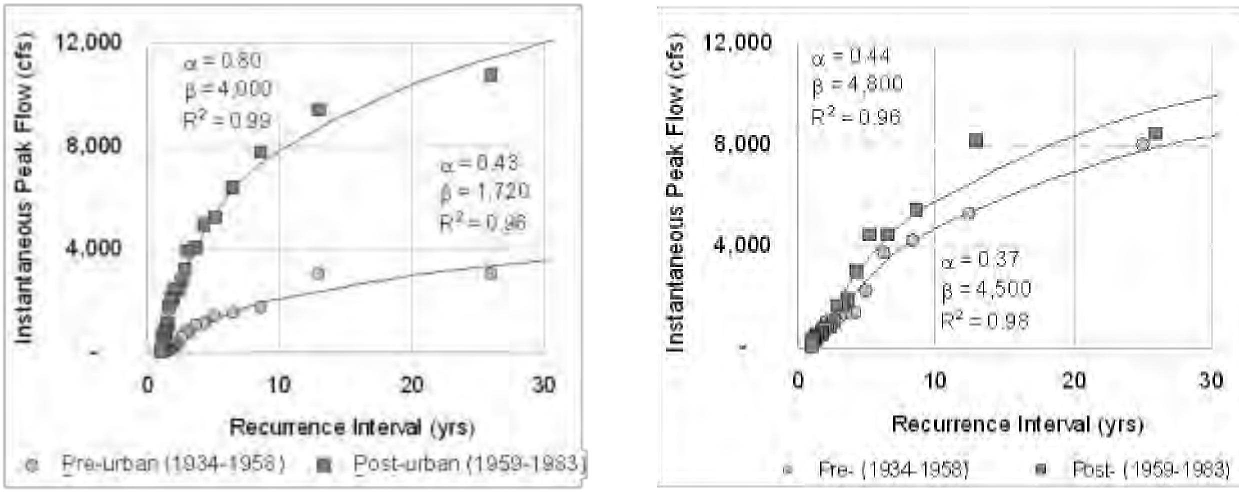
[(a)] 'average' watershed (A ~30 mi^2, P ~14 in., DD ~1.9 mi/mi^2, Srf ~18%)

Alternative urban scenarios predict similarly disproportionate increases in durations. For example, 5% imperviousness would increase durations of bin 16 by ~1.5 and bin 25 by ~1.3, while 15% imperviousness would result in ~4.1 and ~2.4-fold increases, respectively. These empirical findings of decreasing influence of urbanization on flow duration with increasing flow magnitude are consistent with the findings regarding peak flows: urbanization tends to show higher influence on more frequent events, with decreasing influence over the largest, rarest storms.

In conclusion, the fact that Imp_{av}, Imp_7, and Imp_5 outperformed Imp_{max} in DDF models suggests that it may take longer for urbanization to show an effect on the cumulative durations of all flows than to appreciably affect instantaneous peaks at small return intervals. Relatively low measures of imperviousness (i.e., < ~5%) did not show as strong of a statistically-significant influence on durations as on peak flows; however, above 5% and especially above 7.5% there was an unmistakable influence. From this, we are not suggesting that above 5 or 7.5% imperviousness all watersheds behave identically, but rather that it is more difficult for the models to discern differences in durations below those thresholds with current data.

1.1.1 At-a-station effects of urbanization

Two gauges (Arroyo Simi in Ventura County and San Diego Creek in Orange County) spanned equal periods of relatively undeveloped and developing/developed states such that they could be divided into 'pre-urban' and 'post-urban' samples. The paired data showed a marked influence across all peaks and durations of record. For example, Arroyo Simi, depicted in Figure 16(a), had more than a 10-fold difference in the 2-yr flow (2,040 cfs versus 174 cfs), while the 25-yr flow was over three times as large at 10,700 cfs relative to 3,000 cfs. Figure 15(b) summarizes the record at the rural gauge of Hopper Creek spanning the same time frame. By comparison, peak flows differed by an average of only 20% across the two periods in the rural setting, and are likely attributable to the variability in the inter-period precipitation.



1934-1958: Imp_{av} = 2.6%, Imp_{max} = 4.7%
1959-1983: Imp_{av} = 7.3%, Imp_{max} = 8.6%

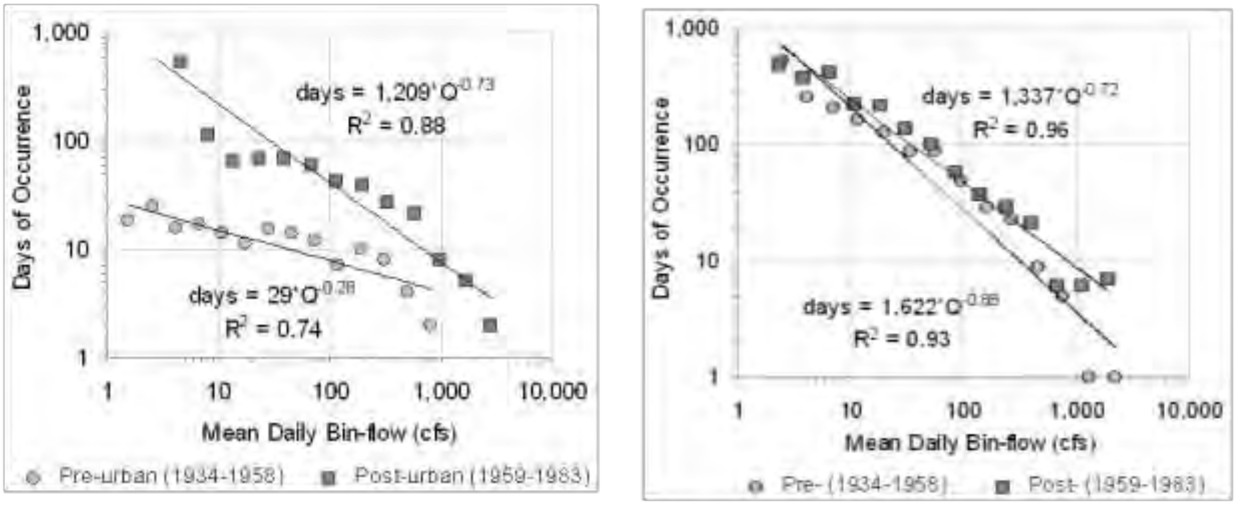
1934-1958: Imp_{av} and Imp_{max} = 0.0%
1959-1983: Imp_{av} and Imp_{max} = 0.0%

(a) recorded at Arroyo Simi during the pre-urban and post-urban periods

(b) recorded at Hopper Creek covering the same periods with no urbanization

Figure 16 – Instantaneous-peak flow relative to recurrence interval, with fitted gamma distributions

The long-term durations of daily-mean flows were also clearly affected by the change in land use at Arroyo Simi and San Diego. Figure 17(a) presents the respective DDFs of Arroyo Simi, recording both higher flows and longer durations for the urban regime. The maximum daily discharges over the 24.5-yr periods were 1,000 and 3,610 cfs, respectively, with the undeveloped regime incurring only 4 days at 500 cfs and 2 days at 800 cfs, while the post-developed regime had 21 days at 600 cfs and 8 days at 1,000 cfs. Additionally, 5 days at 1,700 cfs and 2 days at 2,900 cfs were recorded during the post-urban period, with no days of comparable flows in the pre-urban period. Presuming sediment is entrained by these higher flows, the post-developed regime had on average four to five times as many days of sediment-transporting flows as the pre-developed case, with an additional 7 days of flows that far exceeded the maximum flow in the undeveloped setting.



(a) at Arroyo Simi during the pre-urban and post-urban periods

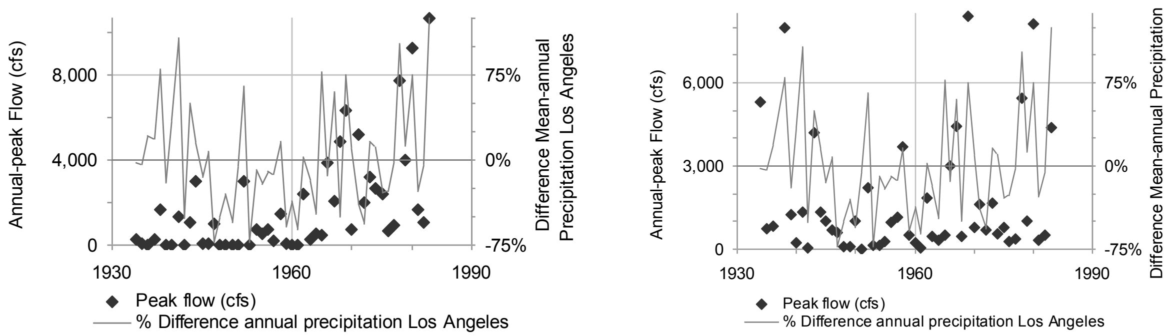
(b) at Hopper Creek covering the same periods with no urbanization

Figure 15 – Cumulative-duration histogram centroids, with fitted DDFs

In contrast, bin flows and durations during the same two periods at the undeveloped gauge were relatively similar. Figure 17(b) presents the nearly overlaid DDFs of Hopper Creek, with all but the two largest bins differing by an average of only 50%. The latter period experienced 6 days at 1,100 cfs and 7 days at 1,900 cfs, while the earlier period only had 1 day at each of the corresponding bins of 1,300 and 2,200 cfs. Even so, the maximum-daily flow was actually largest in the 'pre-' period (2,770 cfs versus 2,400 cfs).

In summary, the rural gauge had a small vertical shift in the DDF between the two periods with slightly more days of similar flows. However, the urban gauge showed dramatic shifts in the DDF both vertically and laterally. At both San Diego and Arroyo Simi, Q_{max} increased by a factor of 3 to 4, while durations of corresponding bin flows increased by factors of 3 to 6 from the undeveloped to urban portions of the records.

We considered potential differences in climate as a competing hypothesis as opposed to urbanization as the primary cause of increased flows and durations between the two periods. As seen in Figure 18(a), the pre-urban period of Arroyo Simi (1934 - 1958) begins with relatively wet years and trends downward, while the post-urban period (1959 - 1983) begins in a relative drought and trends upward. Although the higher peak flows in the respective periods generally correspond with exceptionally wetter years, precipitation alone clearly can not explain the somewhat flat trend in peak flows during the pre-urban period and the largely upward trend during the post-urban period. In contrast, the relative similarity among the highest peaks between the same two periods at the rural gauge of Hopper Creek (Figure 17(b)) and better correlation with the higher precipitation years adds support for causation between urbanization and the latter-period extreme flows recorded at Arroyo Simi.



(a) recorded at Arroyo Simi (urban during second half of record)

(b) recorded at Hopper Creek (rural)

Figure 16 – Annual peak flows overlaid with relative difference in mean-annual precipitation at the Los Angeles weather station

By tracking urbanization through time via impervious cover, the positive trend in peak flows at Arroyo Simi is much better explained (Figure 19). Indeed, multivariate at-a-station regression can explain up to 60% of the variance in annual-peak flows at Arroyo Simi by including imperviousness and annual precipitation as recorded at Los Angeles, with imperviousness highly significant ($p < 0.0001$) and accounting for 30 to 40% of the total variance.

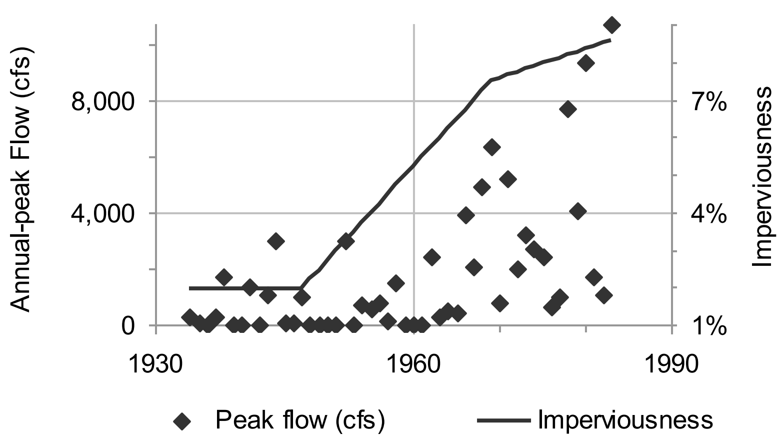


Figure 17 – Annual peak flows recorded at Arroyo Simi overlaid with interpolated percentage of impervious cover in the watershed as tracked via historic USGS quadrangle maps

As indicated in Table 8, the urban records did correspond to periods of slightly higher precipitation in terms of the annual precipitation at the Los Angeles weather station and number of exceptionally wet and dry years. However, these climatic differences alone cannot explain the dramatic differences in flows and durations. The post-urban period of Arroyo Simi has nine flows larger than the largest instantaneous-peak flow from the pre-urban period. In the case of San Diego, there were five flows higher than the maximum from the pre-urban regime. By comparison, the rural gauge at Hopper Creek had only two flows during the latter period that were higher than the highest peak from the first half of the record and they differed by only 5% (i.e., 8,400 and 8,120 cfs versus 8,000 cfs). Also recall that the rural gauge recorded a higher Q_{max} and only slightly less (50%) days of equivalent flows during the earlier period, compared with 3- to 5-fold duration increases at the urban gauges with substantially larger values of Q_{max}.

Table 6 – Comparison of flows, durations, climate, and imperviousness over the pre-urban and post-urban periods of Arroyo Simi (Ventura County) and San Diego Creek (Orange County)

	Variable/ Value	Arroyo Simi (Ventura County)			San Diego Creek (Orange County)

	'wet' years (#)	3	6	2	3	4	1.3
	'high' peaks (#)	2	10	5	1	6	6.0
	'dry' years (#)	4	3	0.75	4	1	0.25
	'low' peaks (#)	18	8	0.44	11	5	0.45
impervious-ness	Spatial Extent During Period	TIA Pre (%)	TIA Post (%)	Ratio	TIA Pre (%)	TIA Post (%)	Ratio
	maximum	4.7	8.6	1.8	3.2	14.9	4.5
	mean	2.6	7.2	2.8	3.2	9.7	2.9

[(a)] 'wet' and 'high' correspond to years/events 50% greater than the respective means, while 'dry' and 'low' indicate years/events 50% lower than the mean

The differences in flows and durations between undeveloped and developed periods at the same gauges and the relative similarity during the same periods at the rural gauge add to the weight of evidence that such changes are largely attributable to urbanization. In fact, these differences observed at individual gauges were larger than what is predicted in the models, particularly in terms of Q_{max}. The effects of urbanization captured in the models may have been dampened by the widespread variability across all sites, most of which were still relatively undeveloped. As more years of data are gathered at urban gauges, the models could be further refined to account for urbanization with a more equitable sampling of urban data.

Summary and Conclusions

The overarching objective of this paper was to understand the effects of urbanization on the magnitude and duration elements of flow regimes (i.e., 'hydromodification') in southern California. In doing so, updated alternatives to the USGS regional equations were developed for peak flows, which outperformed both rural (Waananen and Crippen, 1977) and urban (Sauer *et al.*, 1983) models in twenty-nine out of thirty cases in terms of Standard Error, Adj. R^2, etc. The difference was particularly substantial for more frequent return periods (e.g., Adj. R^2 in arithmetic space ~ 0.7 to 0.8 versus < 0.4 at Q_{10}).

Additionally, our models documented changes in the significance of individual variables with return period, reflecting shifts in physical processes. For example, at more frequent events, the efficiency with which a drainage network concentrated and conveyed runoff became increasingly significant in predicting peak flow, while the predominant variables at less frequent events were measures of watershed size and precipitation volume. This may point to different model forms for different return intervals, for example using Eq. (6) to estimate flows less than or equal to Q_5, and Eq. (8) or (10) for Q_{10} and higher.

Beyond peak flows, we developed a method for estimating long-term cumulative durations at ungauged sites. DDFs expand on previous approaches to histogram-style duration curves in that their magnitude, shape, and scale are based on watershed physical properties rather than scaling based on a nearby gauge and a single flow. Most importantly regarding hydromodification, both the peak flow and DDF models account for urbanization using measures of total impervious area, which were statistically significant ($p < 0.05$), particularly for peak flows $\leq Q_2$ and the magnitude (coefficient) component of DDFs, resulting in longer durations across all flows greater than some nominal value (e.g., 1 to 10 cfs).

Multivariate regression controlling for other potentially-significant hydro-climatic variables (e.g., drainage area, mean annual rainfall, surface slope, etc.) correlated urbanization to higher peaks and longer durations of all geomorphically-significant flows. These effects were also documented at individual gauges whose records spanned both pre-urban and post-urban periods. Moreover, these effects were not linear. Although several metrics, units, and equation forms were tested for modeling the effects of urbanization, the form that was most powerful was typically the exponential of total imperviousness as a fraction of the drainage area. That is, flow magnitudes and durations associated with identical watersheds differing only by measures of imperviousness (e.g., ~1% and ~10%) would be disproportionately larger. In terms of peaks, differences would be most substantial at the more frequent events (e.g., ~3.2 x $Q_{1.5}$, ~2.4 x Q_2, and ~1.4 x Q_5). Regarding durations of daily-mean flows, ~2 to 4 times as many days of *all* sediment-transporting flows would be predicted, with the largest increases occurring at more frequent events and smaller but significant increases at the most infrequent events.

Such changes in the hydrologic regime can have far-reaching effects on receiving channels in terms of cumulative erosive energy and channel stability. Particularly for channels considered highly susceptible to hydromodification (e.g., live-bed unconfined systems), significant changes in channel form such as incision, widening, or planform shifts are anticipated if land-cover conversions from pervious to impervious go unmitigated. The relatively-dramatic responses in channel form that have been observed throughout the region are better explained in the context of such equally compelling changes in flow rates and durations of sediment-transporting events. The physically-based, empirically-calibrated hydrologic models presented here may become important tools in developing a process-based understanding of hydromodification effects on fluvial systems in southern California.

Future Work

The logical next step is to apply these hydrologic models to sites where geomorphic data have been collected to evaluate whether changes in flows correspond to sediment discontinuities that in turn correlate to channel degradation. For example, can risk-based models of channel stability be developed using these hydrologic models as a starting point?

Future work could also focus on the refinement of the DDF models developed in this paper. For example, we were limited to daily-mean flow data for these analyses, but one could follow up with the USGS in a subsequent study to see if any of the gauges have 15-min or hourly data over their entire record (i.e., twenty of the fifty-two gauges were 'real-time' sites offering 15-min data for the last 60 days but only daily data over extended records). If one could acquire the finer resolution data for enough sites, they could repeat the histogram procedure in the hope of developing a scaling factor for the DDFs in this paper.

International Stormwater Best Management Practices (BMP) Database Pollutant Category Summary Statistical Addendum:

TSS, Bacteria, Nutrients, and Metals

Prepared by
Geosyntec Consultants, Inc.
Wright Water Engineers, Inc.

Under Support From
Water Environment Research Foundation
Federal Highway Administration
Environment and Water Resources Institute of the
American Society of Civil Engineers

July 2012

Disclaimer

The BMP Database ("Database") was developed as an account of work sponsored by the Water Environment Research Foundation (WERF), the American Society of Civil Engineers (ASCE)/Environmental and Water Resources Institute (EWRI), the American Public Works Association (APWA), the Federal Highway Administration (FHWA), and U.S. Environmental Protection Agency (USEPA) (collectively, the "Sponsors"). The Database is intended to provide a consistent and scientifically defensible set of data on Best Management Practice ("BMP") designs and related performance. Although the individuals who completed the work on behalf of the Sponsors ("Project Team") made an extensive effort to assess the quality of the data entered for consistency and accuracy, the Database information and/or any analysis results are provided on an "AS-IS" basis and use of the Database, the data information, or any apparatus, method, or process disclosed in the Database is at the user's sole risk. The Sponsors and the Project Team disclaim all warranties and/or conditions of any kind, express or implied, including, but not limited to any warranties or conditions of title, non-infringement of a third party's intellectual property, merchantability, satisfactory quality, or fitness for a particular purpose. The Project Team does not warrant that the functions contained in the Database will meet the user's requirements or that the operation of the Database will be uninterrupted or error free, or that any defects in the Database will be corrected.

UNDER NO CIRCUMSTANCES, INCLUDING CLAIMS OF NEGLIGENCE, SHALL THE SPONSORS OR THE PROJECT TEAM MEMBERS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES INCLUDING LOST REVENUE, PROFIT OR DATA, WHETHER IN AN ACTION IN CONTRACT OR TORT ARISING OUT OF OR RELATING TO THE USE OF OR INABILITY TO USE THE DATABASE, EVEN IF THE SPONSORS OR THE PROJECT TEAM HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The Project Team's tasks have not included, and will not include in the future, recommendations of one BMP type over another. However, the Project Team's tasks have included reporting on the performance characteristics of BMPs based upon the entered data and information in the Database, including peer reviewed performance assessment techniques. Use of this information by the public or private sector is beyond the Project Team's influence or control. The intended purpose of the Database is to provide a data exchange tool that permits characterization of BMPs solely upon their measured performance using consistent protocols for measurements and reporting information.

The Project Team does not endorse any BMP over another and any assessments of performance by others should not be interpreted or reported as the recommendations of the Project Team or the Sponsors.

INTERNATIONAL STORMWATER BMP DATABASE
www.bmpdatabase.org

1 INTRODUCTION

In 2010, the Water Environment Research Foundation (WERF), Federal Highway Administration (FHWA), and the American Society of Civil Engineers' Environmental and Water Resources Institute (EWRI) co-sponsored a comprehensive stormwater best management practice (BMP) performance analysis technical paper series relying on data contained in the International Stormwater BMP Database (BMPDB).[2] This series, published in 2011, included papers for solids, bacteria, nutrients, and metals, with each paper summarizing the regulatory context of the constituent category, primary sources, fate and transport processes, removal mechanisms, and statistical summaries of BMP performance for data contained in the BMPDB. This report is an update of the statistical summaries provided in that series to include the data from over 50 new studies added to the database in late 2011 after the publication of the series. This report is not intended to replace the discussion of the previous technical papers because only the statistical summaries are included here. Constituents summarized in this report are listed in Table 1.

Table 1. Constituents Summarized by Pollutant Category

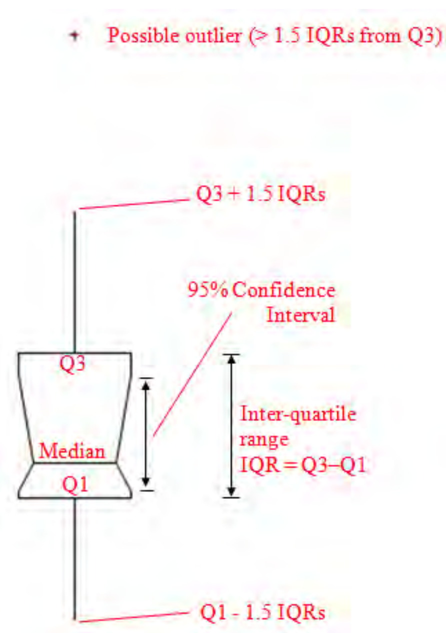
Pollutant Category	Summarized Constituent
Solids	Total suspended solids (TSS)
Bacteria	Fecal coliform *Escherichia coli* (*E. coli*) Enterococcus
Metals	Arsenic (total and dissolved) Cadmium (total and dissolved) Chromium (total and dissolved) Copper (total and dissolved) Iron (total and dissolved) Lead (total and dissolved) Nickel (total and dissolved) Zinc (total and dissolved)
Nutrients	Total phosphorus Orthophosphate Dissolved phosphorus Total nitrogen Total Kjeldahl nitrogen (TKN) Nitrate plus nitrite (NOx)

[2] The BMP Database is a long-term project that began in 1994 through the vision of members active in the Urban Water Resources Research Council of ASCE and the leadership of EPA. Funded for many years by EPA, the project is now supported by a coalition of partners including WERF, FHWA, EWRI and the American Public Works Association (APWA). The technical reports can be downloaded from www.bmpdatabase.org/BMPPerformance.htm.

2 CATEGORY-LEVEL BMP ANALYSIS

An overview of BMP performance for the analyzed constituents is provided in the subsections 2.1 to 2.4 below. The analyses were based upon the distributions of effluent water quality for individual events by BMP category, thereby providing greater weight to those BMPs for which there are a larger number of data points reported. In other words, the performance analysis presented in this technical summary is "storm-weighted," as opposed to "BMP weighted."[3] This update does not include BMP weighted analyses (i.e., analyses of individual study site central tendencies).

Figure 1. Box Plot Key



The BMP categories included in this analysis are grass strips, bioretention, bioswales, composite/treatment train BMPs, detention basins (surface/grass-lined), green roofs, manufactured devices, media filters, porous pavement, retention ponds (surface pond with a permanent pool), wetland basins (basins with open water surface), and wetland channels (swales and channels with wetland vegetation). Note that for bacteria, manufactured devices are broken down into three subcategories: disinfection devices (Manufactured Device – D), inlet insert/filtration (Manufactured Device – F), and physical settling/straining devices (Manufactured Device – P).[4] The effectiveness and range of unit treatment processes present in a particular BMP may vary depending on the BMP design. Several other BMP categories and sub-classes are included in the database, but these have been excluded from this analysis due to limited data sets available for meaningful categorical comparisons. To be included in this category-level summary, at least three BMPs must be included in the BMP category, with each BMP having effluent data for at least three storms. A variety of additional screening criteria are applied for purposes of category-level analysis to make sure that the data sets and BMP designs are reasonably representative, as documented in the "Monitoring Station" table of the BMP Database, which can be downloaded from www.bmpdatabase.org. Poor performance of a BMP is not a reason for data exclusion.

In the subsections below, side-by-side box plots for the various BMPs measurements have been generated using the influent and effluent concentrations from the studies. For each BMP

[3] There are several viable approaches to evaluating data in the BMP Database. Two general approaches that have been presented in the past (Geosyntec Consultants and Wright Water Engineers, 2008) are the "BMP-weighted" and "storm-weighted" approaches. The BMP-weighted approach represents each BMP with one value representing the central tendency and variability of each individual BMP study, whereas the storm-weighted approach combines all of the storm events for the BMPs in each category and analyzes the overall storm-based data set. The storm-weighted approach has been selected for this memorandum as it provides a much larger data set for analysis.

[4] A separate technical summary for manufactured devices (Geosyntec and Wright Water Engineers, 2012) was also released in July 2012 providing a more detailed analysis of manufactured device subcategories based on unit treatment processes. See www.bmpdatabase.org to download this analysis.

category, the influent box plots are provided on the left and the effluent box plots are provided on the right. A key to the box plots is provided in Figure 4.

In addition to the box plots, tables of influent/effluent medians, 25th and 75th percentiles, and number of studies and data points are provided, along with 95% confidence intervals about the medians. The median and interquartile ranges were selected as descriptive statistics for BMP performance because they are non-parametric (do not require distributional assumptions for the underlying data set) and are less affected by extreme values than means and standard deviations. Additionally, the median is less affected by assumptions regarding values below detection limits and varying detection limits for studies conducted by independent parties over many years. However, confidence intervals about the median can still be affected by outliers if simple substitution is used. Therefore, a robust regression-on-order statistics (ROS) method as described by Helsel and Cohn (1988) was utilized to provide probabilistic estimates of non-detects before computing descriptive statistics. Despite use of this robust method, conclusions regarding BMP performance should carefully consider the influence of large percentages of non-detects. The number of influent and effluent non-detects should be reviewed before making conclusions, particularly for dissolved metals where non-detects are most prevalent. For more information on the influence of non-detects on dissolved metals data in the BMP Database, see the discussion in the Metals Technical Summary (Wright Water Engineers and Geosyntec, 2011), accessible at www.bmpdatabase.org).

Confidence intervals in the figures and tables were generated using the bias corrected and accelerated (BCa) bootstrap method described by Efron and Tibishirani (1993). This method is a robust approach for computing confidence intervals that is resistant to outliers and does not require any restrictive distributional assumptions. Due to random sampling that is conducted as part of this method, insignificant variations in the results may occur and is the cause of any inconsistencies between the values in the attachments and the tables presented below. Comparison of the confidence intervals about the influent and effluent medians can be used to roughly identify statistically significant differences between the central tendencies of the data. However, non-parametric hypothesis tests, such as the Mann-Whitney rank sum test or the Wilcoxon signed-rank test, can provide additional and more robust results for evaluating significant differences between medians. The Mann-Whitney test applies to independent data sets, whereas the Wilcoxon test applies to paired data sets (Helsel and Hirsch, 1992). Results of these tests are provided in the attached statistical summary reports for TSS, bacteria, metals, and nutrients. In some cases, the Mann-Whitney and Wilcoxon hypothesis test results produce conflicting conclusions regarding statistically significant differences. Such cases are more likely to occur where there are imbalances in the number of influent and effluent samples for a particular data set since the Mann-Whitney test operates on the entire data set, whereas the Wilcoxon test only operates on data pairs.

In the summary tables which follow, effluent values in **bold green** indicate the upper 95% confidence interval of the effluent median is less than the lower 95% confidence interval of the influent median. Effluent values in ***red bold italics*** indicate the lower 95% confidence interval of the effluent median is greater than the upper 95% confidence interval of the influent median. BMP categories with summary statistics in grey indicate that there are less than three studies with either influent or effluent data available – these statistics should be used with caution due to

RB-AR33117

the limited data available. In some cases, the retention ponds and wetland basin categories have been combined into a single category to provide more than three studies. Values with no color italic emphasis indicate the influent and effluent intervals overlap.

Be aware that for some BMP types, a statistically significant difference between influent and effluent concentrations may not be present, but the effluent concentrations achieved by the BMP are relatively low and may be comparable to the performance of other BMPs that have statistically significant differences between inflow and outflow. For example, data sets that have low influent concentrations and similarly low effluent concentration (i.e., clean water in = clean water out) may not show statistically significant differences. However this does not necessarily imply that the BMP would not have been effective at higher influent concentrations.

Disclaimer

The BMP Database ("Database") was developed as an account of work sponsored by the Water Environment Research Foundation (WERF), the American Society of Civil Engineers (ASCE)/Environmental and Water Resources Institute (EWRI), the American Public Works Association (APWA), the Federal Highway Administration (FHWA), and U.S. Environmental Protection Agency (USEPA) (collectively, the "Sponsors"). The Database is intended to provide a consistent and scientifically defensible set of data on Best Management Practice ("BMP") designs and related performance. Although the individuals who completed the work on behalf of the Sponsors ("Project Team") made an extensive effort to assess the quality of the data entered for consistency and accuracy, the Database information and/or any analysis results are provided on an "AS-IS" basis and use of the Database, the data information, or any apparatus, method, or process disclosed in the Database is at the user's sole risk. The Sponsors and the Project Team disclaim all warranties and/or conditions of any kind, express or implied, including, but not limited to any warranties or conditions of title, non-infringement of a third party's intellectual property, merchantability, satisfactory quality, or fitness for a particular purpose. The Project Team does not warrant that the functions contained in the Database will meet the user's requirements or that the operation of the Database will be uninterrupted or error free, or that any defects in the Database will be corrected.

UNDER NO CIRCUMSTANCES, INCLUDING CLAIMS OF NEGLIGENCE, SHALL THE SPONSORS OR THE PROJECT TEAM MEMBERS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES INCLUDING LOST REVENUE, PROFIT OR DATA, WHETHER IN AN ACTION IN CONTRACT OR TORT ARISING OUT OF OR RELATING TO THE USE OF OR INABILITY TO USE THE DATABASE, EVEN IF THE SPONSORS OR THE PROJECT TEAM HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The Project Team's tasks have not included, and will not include in the future, recommendations of one BMP type over another. However, the Project Team's tasks have included reporting on the performance characteristics of BMPs based upon the entered data and information in the Database, including peer reviewed performance assessment techniques. Use of this information by the public or private sector is beyond the Project Team's influence or control. The intended purpose of the Database is to provide a data exchange tool that permits characterization of BMPs solely upon their measured performance using consistent protocols for measurements and reporting information.

The Project Team does not endorse any BMP over another and any assessments of performance by others should not be interpreted or reported as the recommendations of the Project Team or the Sponsors.

International Stormwater BMP Database Performance Data Summary Table

In 2010, the Water Environment Research Foundation (WERF), Federal Highway Administration (FHWA), and the American Society of Civil Engineers' Environmental and Water Resources Institute (EWRI) co-sponsored a comprehensive stormwater best management practice (BMP) performance analysis technical paper series relying on data contained in the International Stormwater BMP Database (BMP Database).[1] The BMP Database is a publically-available research database that contains results of stormwater BMP studies independently conducted and provided by researchers throughout the U.S. and several other countries. The BMP Database contains performance data for over 450 BMP studies, including over 265,000 water quality records, along with precipitation and flow data. The database is currently limited to post-construction, permanent stormwater BMPs in urban areas. The project is a long-term, multi-faceted effort that includes guidance on BMP monitoring, standardized database reporting information, and recommended performance analysis protocols.

During 2010-2011, a WERF Research Digest and performance analysis technical paper series were completed, providing information on BMP performance for these stormwater parameter categories:

- Nutrients
- Solids
- Metals
- Fecal indicator bacteria
- Runoff volume

This short paper provides a tabular summary of data used in these technical summaries. The WERF Research Digest (available through www.werf.org) or the underlying individual technical summaries should be obtained (www.bmpdatabase.org) for more detailed information.

For each pollutant category analyzed in the technical paper series, a variety of statistics have been completed. For a quick reference, Table 1 provides the median influent and effluent concentrations and associated 95% confidence limits for the median values. Important considerations for use of this table include:

[1] The BMP Database is a long-term project that began in 1994 through the vision of members active in the Urban Water Resources Research Council of ASCE and the leadership of EPA. Funded for many years by EPA, the project is now supported by a coalition of partners including WERF, FHWA, EWRI and the American Public Works Association (APWA).

- The median concentrations in this table are based on a “storm-weighted” approach. There are several viable approaches to evaluating data in the BMP Database, with the two approaches used in previous BMP Database summaries being the “BMP-weighted” and “storm-weighted” approaches. The BMP-weighted approach represents the influent and effluent for each BMP with one value representing the central tendency for each BMP, whereas the storm-weighted approach combines all of the storm events for the BMPs in each category and analyzes the overall storm-based data sets. (Each storm is weighted equally in the storm event based approach.) The storm-weighted approach has been selected for this summary because it provides a much larger number of values for statistical analysis, while retaining the overall variability of storm event concentrations. Some modifications to this approach were used for fecal indicator bacteria, as described in the fecal indicator bacteria technical paper.

- For simplicity, this table does not show number of samples or the number of BMP studies associated with each BMP-constituent concentration; however, this information is provided in the individual technical papers. Some BMP types such as wetland basins and channels, porous pavement and bioretention have much more limited data sets for a number of parameters. Assumptions related to data screening (i.e., excluded studies) are also provided in the individual pollutant summaries.

- Information regarding statistically significant differences between influent and effluent values is provided in the individual technical papers. Comparison of the confidence limits for the medians can provide an approximate measure of significance of differences between the values. Specifically, if the 95% confidence intervals for the inflow and outflow medians do not overlap, the medians are, roughly, significantly different at about a 95% confidence level. More robust hypothesis testing has also been provided in attachments to the solids, nutrients and metals summaries. Specifically, the Mann-Whitney test for independent data sets (unpaired samples) and the Wilcoxon signed rank test (using log-transformed data) for paired inflow-outflow data have been provided.

- Manufactured devices included in the BMP Database incorporate a broad range of unit treatment processes that may result in widely varying performance for individual devices within this broad category. For example, some manufactured devices rely on hydrodynamic gravitational separation only, some provide filtration, others provide peak attenuation, and some provide a treatment train of multiple unit processes. The “manufactured device” category summarized in Table 1 provides only a gross characterization of the range of performance provided by this broad category. More refined analysis based on finer segmentation by unit treatment processes is necessary to draw conclusions for a particular type of device. As a result, the primary use of the data summaries at the broad category level is only for general information related to ranges of effluent concentrations potentially achievable with this general category of BMPs. For example, none of the manufactured devices analyzed for fecal indicator bacteria would be capable of achieving an instream primary contact recreation standard; whereas, some types of manufactured devices can reduce total suspended solids concentrations below 30 mg/L. The on-line BMP Database search tool (www.bmpdatabase.org) could then be

RB-AR33149

used as a follow-up to refine such broad, general observations and further evaluate how individual manufactured devices performed.

- Rounding in this table may differ slightly from the underlying data summaries.
- Some analyses (e.g., dissolved metals) are affected by large numbers of non-detects, which may not be fully apparent in this condensed summary table, although some flagging has been provided, as described in the table footnotes. Methods used to address non-detects (censored data) are described in each technical memorandum.
- The BMP Database data set is continually growing; therefore, the statistics reported in this table will change as the data set grows. The analysis data set for Table 1 is based on the August 2010 version of the BMP Database for all parameters except metals, which is based on the December 2010 version of the BMP Database.
- A table key defining acronyms and describing how to interpret the reported data is provided following the two-page table.

Users of this storwater quality table should be aware that pollutant load reductions can be achieved by reducing pollutant concentrations, surface runoff volumes, and/or a combination of both. Using bioretention as an example, the existing BMP Database dataset does not show a statistically significant reduction in nitrate concentrations; however, nitrate loads are expected to be reduced at bioretention sites that effectively reduce volumes discharged to surface waters.

Table 1. Summary of Inflow and Outflow Data by BMP Category (Median Values with 95% Confidence Limits for the Median Values)

Table Notes

Explanation of Data Provided:

Table Entry			Explanation
Zn T	In	74	Median influent total zinc value
		(66-94)	95% confidence interval for median influent zinc value
	Ef	20	Median effluent total zinc value
		(10-26)	95% confidence interval for median effluent zinc value

* = Greater than 50% non-detects in the influent
NA = Not available for analysis
DL = Data set has greater than 80% non-detects; summary statistics have been excluded from this table

BMP Type:
BR = Bioretention (with underdrains)
BS = Biofilter - grass swale
DB = Detention basin (dry, grass-lined)
BI = Biofilter - grass strip
MD = Manufactured device (all categories)
MF = Media filter (all categories)
PP = Permeable pavement (all categories)
RP = Retention pond (wet pond)
WB = Wetland basin
WC = Wetland channel

Sample Type:
In = influent
Ef = effluent

Units:
mg/L = milligrams per liter
μg/L = micrograms per liter (for metals)
NTU = nephelometric turbidity units (for turbidity)
#/100 mL = colonies per 100 milliliters (for bacteria)

Parameter-related Acronyms:
TSS = Total suspended solids
TDS = Total dissolved solids
Ortho-P = Phosphorus, Orthophosphate as Phosphorus
TKN = Total Kjeldahl nitrogen
TOC = Total organic carbon
As = Arsenic
Cd = Cadmium
Cr = Chromium
Cu = Copper
Pb = Lead
Ni = Nickel
Zn = Zinc

Sample Fraction:

D = Dissolved
T = Total

International Stormwater BMP Database 2010 Bacteria Data Set
Prepared by Wright Water Engineers and Geosyntec Consultants, July 19, 2010.

Spreadsheets Included in this Workbook
All Data: Contains a basic statistical summary of event-based bacteria data reported in the BMP Database for inflows and outflows to BMPs. Summary in "horizontal format" with all inflow storm events on one row per BMP study and all outflow events on one row per BMP study. This format is not conducive to additional statistical analysis; it is provided as a simple summary.

E. coli: Contains analysis data set for E. coli, screened based on minimum sample size. Database-style "vertical" format conducive to import into statistical programs.

Fecal Coliform: Contains analysis data set for E. coli, screened based on minimum sample size. Database-style "vertical" format conducive to import into statistical programs.

Enterococcus: Contains analysis data set for E. coli, screened based on minimum sample size. Database-style "vertical" format conducive to import into statistical programs.

MD Unit Processes: Identifies the unit processes identified for manufactured devices in the data set.

Censored Data: Counts non-detects and values greater than the upper quantitation limit, for general information only.

Analysis Data Set
For a BMP study to be included, a minimum of 5 outflow events must have been sampled.
For BMP studies with 5 or more outflow events but fewer than 5 inflow events, the inflow data is excluded from analysis.
Total coliform and fecal strep data are not included in detailed statistical analysis.
Values reported at the upper or lower quantitation limits have been analyzed using the quantitation limit (simple substitution method).
For sampling events with multiple grab samples, the median has been calculated to represent the storm event.
A limitation of this data set is that many of the BMP studies are based on grab samples, as opposed to EMCs.
Hamilton Ecoroof green roof studies that are divided into separate studies for 2001 and 2002 in the master database but have been joined into one data set for purposed of this analysis.

BMP Category Level Analysis
Composite BMP types are not included. (Only one of these has 5 or more samples.)
Only Fecal Coliform had adequate numbers of studies to conduct comparisons among BMP categories.
BMP category comparisons include only these BMP categories: DB (11), GS (9), MD (9), MF (14), RP (6). Be aware that unit treatment processes in the manufactured device category may vary substantially within this category.

Values Used for Threshold Comparisons

	EPA Primary Contact Std
Enterococcus	33/100 mL freshwater and 35/100 mL marine
Escherichia coli	126/100 mL
Fecal Coliform	200/100 mL (old EPA-recommended indicator)

INVESTIGATION OF THE FEASIBILITY AND BENEFITS OF LOW-IMPACT SITE DESIGN PRACTICES ("LID") FOR VENTURA COUNTY

Richard R. Horner†

ABSTRACT

The Clean Water Act NPDES permit that regulates municipal separate storm sewer systems (MS4s) in Ventura County, California will be reissued in 2007. The draft permit includes provisions for requiring the use of low impact development practices (LID) for certain kinds of development and redevelopment projects. Using six representative development project case studies, the author investigated the practicability and relative benefits of the permit's LID requirements. The results showed that (1) LID site design and source control techniques are more effective than conventional best management practices (BMPs) in reducing runoff rates; (2) Effective Impervious Area (EIA) can practicably be capped at three percent, a standard more protective than that proposed in the draft permit; and (3) in five out of six case studies, LID methods would reduce site runoff volume and pollutant loading to zero in typical rainfall scenarios.

† Richard R. Horner, Ph.D., Research Associate Professor, University of Washington Departments of Civil and Environmental Engineering and Landscape Architecture; Adjunct Associate Professor, University of Washington Center for Urban Horticulture

INTRODUCTION

The Assessment in Relation to Municipal Permit Conditions

This purpose of this study is to investigate the relative water quality and water reuse benefits of three levels of storm water treatment best management practices (BMPs): (1) basic "treat-and-release" BMPs (e.g., drain inlet filters, CDS units), (2) commonly used BMPs that expose runoff to soils and vegetation (extended-detention basins and biofiltration swales and filter strips), and (3) low-impact development (LID) practices. The factors considered in the investigation are runoff volume, pollutant loading, and the availability of water for infiltration or other reuse. In order to assess the differential impact of storm water reduction approaches on these factors, this study examines six case studies typical of development covered by the Ventura County Municipal Separate Storm Sewer System Permit.

Low-impact development methods reduce storm runoff and its contaminants by decreasing their generation at sources, infiltrating into the soil or evaporating storm flows before they can enter surface receiving waters, and treating flow remaining on the surface through contact with vegetation and soil, or a combination of these strategies. Soil-based LID practices often use soil enhancements such as compost, and thus improve upon the performance of more traditional basins and biofilters. For the study's purposes, verification of the practicability and utility of LID practices was based on a modified version of the Planning and Land Development Program (Part 4, section E) in the Draft Ventura County Municipal Separate Storm Sewer System Permit ("Draft Permit"). The Draft Permit requires that Effective Impervious Area (EIA) of certain types of new development and redevelopment projects be limited to five percent of total development project area. EIA is defined as hardened surface hydrologically connected via sheet flow or a discrete hardened conveyance to a drainage system or receiving water body. (Draft Permit p. 50) The study modified this requirement to three percent, as a way to test both the feasibility of meeting the higher, five percent standard in the draft permit and because as the lower, three percent EIA is essential to protect the Ventura County aquatic environment (see Attachment A).

The Draft Permit further requires minimizing the overall percentage of impervious surfaces in new development and redevelopment projects to support storm water infiltration. The Draft Permit also directs an integrated approach to minimizing and mitigating storm water pollution, using a suite of strategies including source control, LID, and treatment control BMPs. (Draft Permit p. 50) It is noted in this section of the document that impervious surfaces can be rendered "ineffective" if runoff is dispersed through properly designed vegetated swales. In testing the practicability of the draft permit's requirements and a three percent EIA standard, this study broadened this approach to encompass not only vegetated swales (channels for conveyance at some depth and velocity) but also vegetated filter strips (surfaces for conveyance in thin sheet flow) and bioretention areas (shallow basins with a range of vegetation types in which runoff infiltrates through soil either to groundwater or a subdrain for eventual surface discharge). The Draft Permit's stipulation of "properly designed" facilities was interpreted to entail, among other requirements, either determination that existing site soils can support runoff reduction through infiltration or that soils will be amended using accepted LID techniques to attain this objective. Finally, the study further broadened implementation options to include water harvesting (collection and storage for use in, for example, irrigation or gray water systems), roof downspout infiltration trenches, and porous pavements.

The Draft permit was interpreted to require management of EIA, other impervious area (what might be termed Not-Connected Impervious Area, NCIA), and pervious areas as follows:

- Runoff from EIA is subject to treatment control and the Draft Permit's Hydromodification Mitigation Control requirements before discharge.

- NCIA must be drained onto a properly designed vegetated surface or its runoff managed by one of the other options discussed in the preceding paragraph. To the extent NCIA runoff is not eliminated prior to discharge from the site in one of these ways, it is subject to treatment control and the Draft Permit's Hydromodification Mitigation Control requirements before discharge.

- Runoff from pervious areas is subject to treatment control and the Draft Permit's Hydromodification Mitigation Control requirements before discharge. This provision applies to pervious areas that both do and do not receive drainage from NCIA.

Where treatment control BMPs are required to manage runoff from the site, the Draft Permit's Volumetric or Hydrodynamic (Flow Based) Treatment Control design bases were assumed to apply. The former basis applies to storage-type BMPs, like ponds, and requires capturing and treating either the runoff volume from the 85th percentile 24-hour rainfall event for the location, the volume of annual runoff to achieve 80 percent or more volume treatment, or the volume of runoff produced from a 0.75 inch storm event. The calculations in this analysis used the 0.75-inch quantity. The Hydrodynamic basis applies to flow-through BMPs, like swales, and requires treating the runoff flow rate produced from a rain event equal to at least 0.2 inches per hour intensity (or one of two other approximately equivalent options).

Scope of the Assessment

With respect to each of the six development case studies, three assessments were undertaken: a baseline scenario incorporating no storm water management controls; a second scenario employing conventional BMPs; and a third development scenario employing LID storm water management strategies.

To establish a baseline for each case study, annual storm water runoff volumes were estimated, as well as concentrations and mass loadings of four pollutants: (1) total suspended solids (TSS), (2) total recoverable copper (TCu), (3) total recoverable zinc (TZn), and (4) total phosphorus (TP). These baseline estimates were based on the anticipated land use and cover with no storm water management efforts.

Two sets of calculations were then conducted using the parameters defined for the six case studies.

The first group of calculations estimated the extent to which basic BMPs reduce runoff volumes and pollutant concentrations and loadings, and what impact, if any, such BMPs have on recharge rates or water retention on-site.

The second group of calculations estimated the extent to which commonly used soil-based BMPs and LID site design strategies ameliorate runoff volumes and pollutant concentrations and loadings, and the effect such techniques have on recharge rates. When evaluating LID strategies, it was presumed that EIA would be limited to three percent and runoff from EIA, NCIA, and pervious areas would be managed as indicated above. The assessment of basins, biofiltration, and low-impact design practices analyzed the expected infiltration capacity of the case study sites. It also considered related LID techniques and practices, such as source reduction strategies, that could work in concert with infiltration to serve the goals of: (1) preventing increase in annual runoff volume from the pre- to the post-developed state, (2) preventing increase in annual pollutant mass loadings between the two development states, and (3) avoiding exceedances of California Toxics Rule (CTR) acute saltwater criteria for copper and zinc.

The results of this analysis show that:

- Developments implementing no post-construction BMPs result in storm water runoff volume and pollutant loading that are substantially increased, and recharge rates that are substantially decreased, compared to pre-development conditions.

- Developments implementing basic post-construction treatment BMPs achieve reduced pollutant loading compared to developments with no BMPs, but storm water runoff volume and recharge rates are similar to developments with no BMPs.

- Developments implementing traditional basins and biofilters, and even more so low-impact post-construction BMPs, achieve significant reduction of pollutant loading and runoff volume as well as greatly enhanced recharge rates compared to both developments with no BMPs and developments with basic treatment BMPs.

- Typical development categories, ranging from single family residential to large commercial, can feasibly implement low-impact post-construction BMPs designed in compliance with the draft permit's requirements, as modified to include a lower, three percent EIA requirement.

This report covers the methods employed in the investigation, data sources, and references for both. It then presents the results, discusses their consequences, draws conclusions, and makes recommendations relative to the feasibility of utilizing low-impact development practices in Ventura County developments.

CASE STUDIES

Six case studies were selected to represent a range of urban development types considered to be representative of coastal Southern California, including Ventura County. These case studies involved: a multi-family residential complex (MFR), a relatively small-scale (23 homes) single-family residential development (Sm-SFR), a restaurant (REST), an office building (OFF), a relatively large (1000 homes) single-family residential development (Lg-SFR) and a sizeable commercial retail installation (COMM).[1]

Parking spaces were estimated to be 176 sq ft in area, which corresponds to 8 ft width by 22 ft length dimensions. Code requirements vary by jurisdiction, with the tendency now to drop below the traditional 200 sq ft average. About 180 sq ft is common, but various standards for full- and compact-car spaces, and for the mix of the two, can raise or lower the average.[2] The 176 sq ft size is considered to be a reasonable value for conventional practice.

Roadways and walkways assume a wide variety of patterns. Exclusive of the two SFR cases, simple, square parking lots with roadways around the four sides and square buildings with walkways also around the four sides were assumed. Roadways and walkways were taken to be 20 ft and 6 ft wide, respectively.

Single-family residences were assumed each to have a driveway 20 ft wide and 30 ft long. It was further assumed that each would have a sidewalk along the front of the lot, which was calculated to be 5749 sq ft in area. Assuming a square lot, the front dimension would be 76 ft. A 40-ft walkway was included within the property. Sidewalks and walkways were taken to be 4 ft wide.

Exclusive of the COMM case, the total area for all of these impervious features was subtracted from the total site area to estimate the pervious area, which was assumed to have conventional landscaping cover (grass, small herbaceous decorative plants, bushes, and a few trees). For the COMM scenario, the hypothetical total impervious cover was enlarged by 10 percent to represent the landscaping, on the belief that a typical retail commercial establishment would typically be mostly impervious.

Table 1 (page 5) summarizes the characteristics of the six case studies. The table also provides the recorded or estimated areas in each land use and cover type.

---

[1] Building permit records from the City of San Marcos in San Diego County provided data on total site areas for the first four case studies, including numbers of buildings, building footprint areas (including porch and garage for Sm-SFR), and numbers of parking spaces associated with the development projects. While the building permit records made no reference to features such as roadways, walkways, and landscaping normally associated with development projects, these features were taken into account in the case studies using assumptions described herein. Larger developments were not represented in the sampling of building permits from the San Marcos database. To take larger development projects into account in the subsequent analysis, the two larger scale case studies were hypothesized. The Lg-SFR scenario scaled up all land use estimates from the Sm-SFR case in the ratio of 1000:23. The hypothetical COMM scenario consisted of a building with a 2-acre footprint and 500 parking spaces. As with the smaller-scale cases, these hypothetical developments were assumed to have roadways, walkways, and landscaping, as described herein.

METHODS OF ANALYSIS

Annual Storm Water Runoff Volumes

Annual surface runoff volumes produced were estimated for both pre- and post-development conditions for each case study site. Runoff volume was computed as the product of annual precipitation, contributing drainage area, and a runoff coefficient (ratio of runoff produced to rainfall received). For impervious areas the following equation was used:

$$C = (0.009)\, I + 0.05$$

where I is the impervious percentage. This equation was derived by Schueler (1987) from Nationwide Urban Runoff Program data (U.S. Environmental Protection Agency 1983). With I = 100 percent for fully impervious surfaces, C is 0.95.

The basis for pervious area runoff coefficients was the Natural Resource Conservation Service's (NRCS) Urban Hydrology for Small Watersheds (NRCS 1986, as revised from the original 1975 edition). This model estimates storm event runoff as a function of precipitation and a variable representing land cover and soil, termed the curve number (CN). Larger events are forecast to produce a greater amount of runoff in relation to amount of rainfall because they more fully saturate the soil. Therefore, use of the model to estimate annual runoff requires selecting some event or group of events to represent the year. A 0.75-inch rainfall event was used in the analysis here for the relative comparison between pre- and post-development and applied to deriving a runoff coefficient for annual estimates, recognizing that smaller storms would produce less and larger storms more runoff.

To select CN for the pre-development case, an analysis performed in the area of the Cedar Fire in San Diego County was used in which CN was determined before and after the 2003 fire.[3] In the San Diego analysis, CN = 83 was estimated for the pre-existing land cover, which was generally chaparral, a vegetative cover also typical of Ventura County. As indicated below, soils are also similar in Ventura and San Diego Counties, making the parameter selection reasonable for use in both locations. For post-development landscaping, CN = 86 was selected based on tabulated data in NRCS (1986) and professional judgment.

Pre- and post-development runoff quantities were computed with these CN values and the 0.75-inch rainfall, and then divided by the rainfall to obtain runoff coefficients. The results were 0.07

[3] American Forests, *San Diego Urban Ecosystem Analysis After the Cedar Fire* (Feb. 3, 2006) (http://www.ufei.org/files/pubs/SanDiegoUrbanEcosystemAnalysis-PostCedarFire.pdf).

and 0.12, respectively. Finally, total annual runoff volumes were estimated based on an average annual precipitation in the City of Ventura of 14.71 inches.[4]

Storm Water Runoff Pollutant Discharges

Annual pollutant mass discharges were estimated as the product of annual runoff volumes produced by the various land use and cover types and pollutant concentrations typical of those areas. Again, the 0.75-inch precipitation event was used as a basis for volumes. Storm water pollutant data have typically been measured and reported for general land use types (e.g., single-family residential, commercial). However, an investigation of low-impact development practices of the type this study sought to conduct demands data on specific land coverages. The literature offers few data on this basis. Those available and used herein were assembled by a consultant to the City of Seattle for a project in which the author participated. They appear in Attachment B (Herrera Environmental Consultants, Inc. undated).

Pollutant concentrations expected to occur typically in the mixed runoff from the several land use and cover types making up a development were estimated by mass balance; i.e., the concentrations from the different areas of the sites were combined in proportion to their contribution to the total runoff.

The Effect of Conventional Treatment BMPs on Runoff Volume, Pollutant Discharges, and Recharge Rates

The first question in analyzing how BMPs reduce runoff volumes and pollutant discharges was, What BMPs are being employed in Ventura County developments under the permit now in force? This permit is open-ended and provides regulated entities with a large number of choices and few fixed requirements. These options presumably include manufactured BMPs, such as drain inlet inserts (DIIs) and continuous deflective separation (CDS) units. Developments may also select such non-proprietary devices as extended-detention basins (EDBs) and biofiltration swales and filter strips. EDBs hold water for two to three days for solids settlement before releasing whatever does not infiltrate or evaporate. Biofiltration treats runoff through various processes mediated by vegetation and soil. In a swale, runoff flows at some depth in a channel, whereas a filter strip is a broad surface over which water sheet flows. Each of these BMP types was applied to each case study, although it is not clear that these BMPs, in actuality, have been implemented consistently within Ventura County to date.

The principal basis for the analysis of BMP performance was the California Department of Transportation's (CalTrans, 2004) BMP Retrofit Pilot Program, performed in San Diego and Los Angeles Counties. One important result of the program was that BMPs with a natural surface infiltrate and evaporate (probably, mostly infiltrate) a substantial amount of runoff, even if conditions do not appear to be favorable for an infiltration basin. On average, the EDBs, swales, and filter strips lost 40, 50 and 30 percent, respectively, of the entering flow before the discharge point. DIIs and CDS units do not contact runoff with a natural surface, and therefore do not reduce runoff volume.

The CalTrans program further determined that BMP effluent concentrations were usually a function of the influent concentrations, and equations were developed for the functional

[4] Ventura County Watershed Protection District (http://www.vcwatershed.org/fws/specialmedia.htm). The City of Ventura is considered to be representative of most of the developed and developing areas in Ventura County. However, there is some variation around the county, with the maximum precipitation registered at Ojai (annual average 21.32 inches). Ojai is about 15 miles inland and lies at elevation 745 ft at the foot of the Topatopa Mountains, the orographic effect of which influences its meteorology. Ojai's higher rainfall was taken into account in the calculations, and the report notes the few instances where it affected the conclusions.

relationships in these cases. BMPs generally reduced influent concentrations proportionately more when they were high. In relatively few situations influent concentrations were constant at an "irreducible minimum" level regardless of inflow concentrations.

In analyzing the effects of BMPs on the case study runoff, the first step was to reduce the runoff volumes estimated with no BMPs by the fractions observed to be lost in the pilot study. The next task was estimating the effluent concentrations from the relationships in the CalTrans report. The final step was calculating discharge pollutant loadings as the product of the reduced volumes and predicted effluent concentrations. As before, typical pollutant concentrations in the mixed runoff were established by mass balance.

Estimating Infiltration Capacity of the Case Study Sites

Infiltrating sufficient runoff to maintain pre-development hydrologic characteristics and prevent pollutant transport is the most effective way to protect surface receiving waters. Successfully applying infiltration requires soils and hydrogeological conditions that will pass water sufficiently rapidly to avoid overly-lengthy ponding, while not allowing percolating water to reach ground-water before the soil column captures pollutants.

The study assumed that infiltration would occur in surface facilities and not in below-ground trenches. The use of trenches is certainly possible, and was judged to be an approved BMP by CalTrans after the pilot study. However, the intent of this investigation was to determine the ability of pervious areas to manage the site runoff. This was accomplished by determining the infiltration capability of the pervious areas in their original condition for each development case study, and further assessing the pervious areas' infiltration capabilities if soils were modified according to low impact development practices.

The chief basis for this aspect of the work was an assessment of infiltration capacity and benefits for Los Angeles' San Fernando Valley (Chralowicz et al. 2001). The Chralowicz study posited providing 0.1-0.5 acre for infiltration basins to serve each 5 acres of contributing drainage area. At 2-3 ft deep, it was estimated that such basins could infiltrate 0.90-1.87 acre-ft/year of runoff in San Fernando Valley conditions. Soils there are generally various loam textures with infiltration rates of approximately 0.5-2.0 inches/hour. The most prominent soils in Ventura County, at least relatively near the coast, are loams, sandy loams, loamy sands, and silty clay loams, thus making the conclusions of the San Fernando Valley study applicable for these purposes.[5] This information was used to estimate how much of each case study site's annual runoff would be infiltratable, and if the pervious portion would provide sufficient area for infiltration. For instance, if sufficient area were available, the infiltration configuration would not have to be in basin form but could be shallower and larger in surface area. This study's analyses assumed the use of bioretention areas rather than traditional infiltration basins.

Volume and Pollutant Source Reduction Strategies

As mentioned above, the essence of low-impact development is reducing runoff problems before they can develop, at their sources, or exploiting the infiltration and treatment abilities of soils and vegetation. If a site's existing infiltration and treatment capabilities are inadequate to preserve pre-development hydrology and prevent runoff from causing or contributing to violations of water quality standards, then LID-based source reduction strategies can be implemented, infiltration and treatment capabilities can be upgraded, or both.

---

[5] Cabrillo Port Liquefied Natural Gas Deepwater Port Draft EIS/EIR (Oct. 2004) (http://www.cabrilloport.ene.com/files/eiseir/4.05%20%20-Agriculture%20and%20Soils.pdf).

Source reduction can be accomplished through various LID techniques. Soil can be upgraded to store runoff until it can infiltrate, evaporate, or transpire from plants through compost addition. Soil amendment, as this practice is known, is a standard LID technique.

Upgraded soils are used in bioretention cells that hold runoff and effect its transfer to the subsurface zone. This standard LID tool can be used where sufficient space is available. This study analyzed whether the six development case study sites would have sufficient space to effectively reduce runoff using bioretention cells, assuming the soils and vegetation could be amended and enhanced where necessary.

Conventional pavements can be converted to porous asphalt or concrete or replaced with concrete or plastic unit pavers or grid systems. For such approaches to be most effective, the soils must be capable of infiltrating the runoff passing through, and may require renovation.

Source reduction can be enhanced by the LID practice of water harvesting, in which water from impervious surfaces is captured and stored for reuse in irrigation or gray water systems. For example, runoff from roofs and parking lots can be harvested, with the former being somewhat easier because of the possibility of avoiding pumping to use the water and fewer pollutants. Harvesting is a standard technique for Leadership in Energy and Environmental Design (LEED) buildings.[6] Many successful systems of this type are in operation, such as the Natural Resources Defense Council offices (Santa Monica, CA), the King County Administration Building (Seattle, WA), and two buildings on the Portland State University campus (Portland, OR). This investigation examined how water harvesting could contribute to storm water management for case study sites where infiltration capacity, available space, or both appeared to be limited.

RESULTS OF THE ANALYSIS

1. "Base Case" Analysis: Development without Storm Water Controls

Comparison of Pre- and Post-Development Runoff Volumes

Table 2 (page 9) presents a comparison between the estimated runoff volumes generated by the respective case study sites in the pre- and post-development conditions, assuming implementation of no storm water controls on the developed sites. On sites dominated by impervious land cover, most of the infiltration that would recharge groundwater in the undeveloped state is expected to be lost to surface runoff after development. This greatly increased surface flow would raise peak flow rates and volumes in receiving water courses, raise flooding risk, and transport pollutants. Only the office building, the plan for which retained substantial pervious area, would lose less than half of the site's pre-development recharge.

[d] Quantity of water infiltrating the soil; the difference between precipitation and runoff

Pollutant Concentrations and Loadings

Table 3 presents the pollutant concentrations from the literature and loadings calculated as described for the various land use and cover types represented by the case studies. Landscaped areas are expected to release the highest TSS concentration, although relatively low TSS mass loading because of the low runoff coefficient. The highest copper concentrations and loadings are expected from parking lots. Roofs, especially commercial roofs, top the list for both zinc concentrations and loadings. Landscaping would issue by far the highest phosphorus, although access roads and driveways would contribute the highest mass loadings.

Table 3. Pollutant Concentrations and Loadings for Case Study Land Use and Cover Types

Land Use	Concentrations				Loadings			
	TSS (mg/L)	TCu (mg/L)	TZn (mg/L)	TP (mg/L)	Lbs. TSS/ acre-year	Lbs. TCu/ acre-year	Lbs. TZn/ acre-year	Lbs. TP/ acre-year
Residential roof	25	0.013	0.159	0.11	79	0.041	0.503	0.348
Commercial roof	18	0.014	0.281	0.14	57	0.044	0.889	0.443
Access road/driveway	120	0.022	0.118	0.66	380	0.070	0.373	2.088
Parking	75	0.036	0.097	0.14	237	0.114	0.307	0.443
Walkway	25	0.013	0.059	0.11	79	0.041	0.187	0.348
Landscaping	213	0.013	0.059	2.04	85	0.005	0.024	0.815

The CTR acute criteria for copper and zinc are 0.0048 mg/L and 0.090 mg/L, respectively. Table 3 shows that all developed land uses are expected to discharge copper above the criterion, based on the mass balance calculations using concentrations from Table 3. Any surface release from the case study sites would violate the criterion at the point of discharge, although dilution by the receiving water would lower the concentration below the criterion at some point. Even if copper mass loadings are reduced by BMPs, any surface discharge would exceed the criterion initially, but it would be easier to dilute below that level. In contrast, runoff from some land covers would not violate the acute zinc criterion. Because of this difference, the evaluation considered whether or not the zinc criterion would be exceeded in each analysis, whereas there was no point in this analysis for copper. There are no equivalent water quality criteria for TSS and TP; hence, their concentrations were not further analyzed in the different scenarios.

Table 4 shows the overall loadings, as well as zinc concentrations, expected to be delivered from the case study developments should they not be fitted with any BMPs. As Table 4 shows, all cases are forecast to exceed the 0.090 mg/L acute zinc criterion, and the retail commercial development does so by a wide margin. Because of its size, the large residential development dominates the mass loading emissions.

Table 4. Case Study Pollutant Concentration and Loading Estimates without BMPs

	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]

2. *"Conventional BMP" Analysis: Effect of Basic Treatment BMPs*

Effect of Basic Treatment BMPs on Post-Development Runoff Volumes

The current permit allows regulated parties to select from a range of BMPs in order to treat or infiltrate a given quantity of annual rainfall. The range includes drain inlet inserts, CDS units, and other manufactured BMPs, detention vaults, and sand filters, all of which isolate runoff from the soil; as well as basins and biofiltration BMPs built in soil and generally having vegetation. Treatment BMPs that do not permit any runoff contact with soils discharge as much storm water runoff as equivalent sites with no BMPs, and hence yield zero savings in recharge. As mentioned above, the CalTrans (2004) study found that BMPs with a natural surface can reduce runoff by substantial margins (30-50 percent for extended-detention basins and biofiltration).

With such a wide range of BMPs in use, runoff reduction ranging from 0 to 50 percent, and a lack of clearly ascertainable requirements, it is not possible to make a single estimate of how much recharge savings are afforded by maximal implementation of the current permit. We made the following assumptions regarding implementation of BMPs. Assuming natural-surface BMPs perform at the average of the three types tested by CalTrans (2004), i.e., 40 percent runoff reduction, the estimate can be bounded as shown in Table 5 (page 11). The table demonstrates that allowing free choice of BMPs without regard to their ability to direct water into the ground forfeits substantial groundwater recharge benefits when hardened-surface BMPs are selected. Use of soil-based conventional BMPs could cut recharge losses from half or e more of the full potential to about one-quarter to one-third or less, except with the highly impervious commercial development. This analysis shows the wisdom of draining impervious to pervious surfaces, even if those surfaces are not prepared in any special way. But as subsequent analyses showed, soil amendment can gain considerably greater benefits.

Table 5. Pre- and Post-Development with Conventional BMPs: Distribution of Surface Runoff Versus Recharge to Groundwater

Annual Volume (acre-ft)	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]
Precipitation[b]	13.4	3.72	0.95	2.60	162	6.37
Pre-development runoff[c]	0.94	0.26	0.07	0.18	11	0.45

[d] Ranging from the quantity with hardened bed BMPs to the quantity with soil-based BMPs
[e] Quantity of water infiltrating the soil; the difference between precipitation and runoff

Effect of Basic Treatment BMPs on Pollutant Discharges

Table 6 (page 12) presents estimates of zinc effluent concentrations and mass loadings of the various pollutants discharged from four types of conventional treatment BMPs. The manufactured CDS BMPs in this table, which do not expose runoff to soil or vegetation, are not expected to drop any of the concentrations sufficiently to meet the acute zinc criterion at the discharge point. The loading reduction results show the CDS units always performing below 50 percent reduction for all pollutants analyzed, and most often in the vicinity of 20 percent, with zero copper reduction.

When treated with swales or filter strips, effluents from each development case study site are expected to fall below the CTR acute zinc criterion. All but the large commercial site would meet the criterion with EDB treatment. These natural-surface BMPs, if fully implemented and well maintained, are predicted to prevent the majority of the pollutant masses generated on most of the development sites from reaching a receiving water. Only total phosphorus reduction falls below 50 percent for two case studies. Otherwise, mass loading reductions range from about 60 to above 80 percent for the EDB, swale, and filter strip. This data indicates that draining impervious to pervious surfaces, even if those surfaces are not prepared in any special way, pays water quality as well as hydrologic dividends.

Table 6. Pollutant Concentration and Loading Reduction Estimates with Conventional BMPs

3. *LID Analysis: Development According to Modified Draft Permit Provisions*

(a) Hydrologic Analysis

The LID analysis was first performed according to the Draft Permit provisions under the Planning and Land Development Program (Part 4, section E). In this analysis, however, EIA was limited to three instead of five percent, under the reasoning presented in Attachment A. All runoff from NCIA was assumed to drain to vegetated surfaces, as provided in the Draft Permit.

One goal of this exercise was to identify methods that reduce runoff production in the first place. It was hypothesized that implementation of source reduction techniques could allow all of the case study sites to infiltrate substantial proportions of the developed site runoff, advancing the hydromodification mitigation objective of the Draft Permit. When runoff is dispersed into the soil instead of being rapidly collected and conveyed away, it recharges groundwater, supplementing a resource that maintains dry season stream flow and wetlands. An increased water balance can be tapped by humans for potable, irrigation, and process water supply. Additionally, runoff volume reduction would commensurately decrease pollutant mass loadings.

Accordingly, the analysis considered the practicability of more than one scenario by which the draft permit's terms could be met, as modified to reflect three percent EIA. In one option, all roof runoff is harvested and stored for some beneficial use. A second option disperses runoff into the soil via roof downspout infiltration trenches. The former option is probably best suited to cases like the large commercial and office buildings, while distribution in the soil would fit best with residences and relatively small commercial developments. The analysis was repeated with the assumptions of harvesting OFF and COMM roof runoff for some beneficial use and dispersing roof runoff from the remaining four cases in roof downspout infiltration systems.

Expected Infiltration Capacities of the Case Study Sites

The first inquiry on this subject sought to determine how much of the total annual runoff each property is expected to infiltrate. This assessment tested the feasibility of draining all but three percent of impervious area to pervious land on the sites. Based on the findings of Chralowicz et al. (2001), it was assumed that an infiltration zone of 0.1-0.5 acres in area and 2-3 ft deep would serve a drainage catchment area in the size range 0-5 acres and infiltrate 0.9-1.9 acre-ft/year. The conclusions of Chralowicz et al. (2001) were extrapolated to conservatively assume that 0.5 acre would be required to serve each additional five acres of catchment, and would infiltrate an incremental 1.4 acre-ft/year (the midpoint of the 0.9-1.9 acre-ft/year range). According to these assumptions, the following schedule of estimates applies:

Pervious Area Available for Infiltration	Catchment Served acres	Infiltration Capacity
0.5 acres	0-5 acres	1.4 acre-ft/year
1.0 acres	5-10 acres	2.8 acre-ft/year
1.5 acres	10-15 acres	4.2 acre-ft/year
(Etc.)	...	...

As a formula, infiltration capacity ≈ 2.8 x available pervious area. To apply the formula conservatively, the available area was reduced to the next lower 0.5-acre increment before multiplying by 2.8.

As shown in Table 7, five of the six sites have adequate or greater capacity to infiltrate the full annual runoff volume from NCIA and pervious areas where EIA is limited to three percent of the total site area (four at the higher Ojai rainfall). Indeed, five of the six development types have sufficient pervious area to infiltrate *all* runoff, including runoff from EIA areas. With the most representative rainfall, only the large commercial development, with little available pervious area, falls short of the needed capacity to infiltrate all rainfall, but it still has the capacity to meet the terms of the draft permit, as modified for this analysis. These results are based on infiltrating in the native soils with no soil amendment. For any development project at which infiltration-oriented BMPs are considered, it is important that infiltration potential be carefully assessed using site-specific soils and hydrogeologic data. In the event such an investigation reveals a marginal condition (e.g., hydraulic conductivity, spacing to groundwater) for infiltration basins, soils could be enhanced to produce bioretention zones to assist infiltration. Notably, the four case studies with far greater than necessary infiltration capacity would offer substantial flexibility in designing infiltration, allowing ponding at less than 2-3 ft depth.

Table 7. Infiltration and Runoff Volume With 3 Percent EIA and All NCIA Draining to Pervious Areas

	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]
EIA runoff (acre-ft/year)	0.38	0.11	0.03	0.07	4.6	0.18
NCIA + pervious area runoff (acre-ft/year)	**8.63**	**1.73**	**0.47**	**0.76**	**75.0**	**5.39**
Total runoff (acre-ft/year)	9.01	1.84	0.50	0.83	79.6	5.57
Pervious area available for infiltration (acres)	3.66	1.67	0.39	1.61	72.7	0.47
Estimated infiltration capacity (acre-ft/year)[b]	**9.8**	**4.2**	**1.4**	**4.2**	**203**	**1.4**
Infiltration capacity [c]	> 100%[d]	> 100%	> 100%	> 100%	> 100%	~26% [d]

[b] Based on Chralowicz et al. (2001) according to the schedule described above
[c] Compare runoff production from NCIA + pervious area (**row 3**) with estimated infiltration capacity (**row 6**)
[d] At Ojai rainfall levels, capacity would be ~78 percent at the MFR site and ~18 percent at the COMM site.

As Table 7 shows, five of the six case study sites have the capacity to infiltrate *all* runoff produced onsite by draining impervious surfaces to pervious areas. Even runoff from the area assumed to be EIA could be infiltrated in most cases based on the amount of pervious area available in typical development projects. By showing that it is possible under normal site conditions and using native soils to retain *all* runoff in typical developments, these results demonstrate that a three percent EIA requirement, which would not demand that all runoff be retained, is feasible and practicable.

Additional Source Reduction Capabilities of the Case Study Sites: Water Harvesting Example

Infiltration is one of a wide variety of LID-based source reduction techniques. Where site conditions such as soil quality or available area limit a site's infiltration capacity, other source LID measures can enhance a site's runoff retention capability. For example, soil amendment, which improves infiltration, is a standard LID technique. Water harvesting is another. Such practices can also be used where infiltration capacity is adequate, but the developer desires greater flexibility for land use on-site. Table 8 shows the added implementation flexibility created by subtracting roof runoff by harvesting it or efficiently directing it into the soil through downspout dispersion systems, further demonstrating the feasibility of meeting the draft permit's proposed requirements, as modified to include a three percent EIA standard.

Table 8. Infiltration and Runoff Volume Reduction Analysis Including Roof Runoff Harvesting or Disposal in Infiltration Trenches (Assuming 3 Percent EIA and All NCIA Draining to Pervious Areas)

	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]
EIA runoff (acre-ft/year)	0.38	0.11	0.03	0.07	4.6	0.18
Roof runoff (acre-ft/year)	4.92	0.93	0.09	0.20	41	2.33
Other NCIA + pervious area runoff (acre-ft/year)	**3.71**	**0.79**	**0.39**	**0.56**	**35**	**3.06**
Total runoff (acre-ft/year)	9.01	1.84	0.50	0.83	79.6	5.57
Pervious area available for infiltration (acres)	3.66	1.67	0.39	1.61	72.7	0.47
Estimated infiltration capacity (acre-ft/year)[b]	**9.8**	**4.2**	**1.4**	**4.2**	**203**	**1.4**

[a] MFR—multi-family residential; Sm-SFR—small-scale single-family residential; REST—restaurant; OFF—office building; Lg-SFR—large-scale single-family residential; COMM—retail commercial;
[b] Based on Chralowicz et al. (2001) according to the schedule described above
[c] Comparison of runoff production from NCIA + pervious area **(row 3)** with estimated infiltration capacity **(row 6)**
[d] If the higher rainfall at Ojai is assumed, capacity would be ~32 percent of the amount needed for the COMM case.

Effect of Full LID Approach on Recharge

Table 9 (page 15) shows the recharge benefits of preventing roofs from generating runoff and infiltrating as much as possible of the runoff from the remainder of the case study sites. The data show that LID methods offer significant benefits relative to the baseline (no storm water controls) in all cases. These benefits are particularly impressive in developments with relatively high site imperviousness, such as in the MFR and COMM cases. In the latter case the full LID approach (excluding the common and effective practice of soil amendment) would cut loss of the potential water resource represented by recharge and harvesting from 86 to 37 percent.

Table 9. Comparison of Water Captured Annually (in acre-ft) from Development Sites for Beneficial Use With a Full LID Approach Compared to Development With No BMPs

	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]
Pre-development recharge[b] (acre-ft)	12.5	3.46	0.88	2.42	150	5.92
No BMPs:						
post-development recharge [b] (acre-ft)	4.39	1.88	0.45	1.76	82	0.80
post-development runoff (acre-ft)	8.08	1.57	0.43	0.66	68	5.12
post-development % recharge lost	65%	46%	49%	27%	45%	86%
Full LID approach:						
post-development runoff capture (acre-ft)[c]	12.5	3.46	0.88	2.42	150	3.73
post-development runoff (acre-ft)	0	0	0	0	0	2.19
post-development % recharge lost	0%	0%	0%	0%	0%	37%

[a] MFR—multi-family residential; Sm-SFR—small-scale single-family residential; REST—restaurant; OFF—office building; Lg-SFR—large-scale single-family residential; COMM—retail commercial
[b] Quantity of water infiltrating the soil; the difference between precipitation and runoff
[c] Water either entirely infiltrated in BMPs and recharged to groundwater or partially harvested from roofs and partially infiltrated in BMPs. For the first five case studies, EIA was not distinguished from the remainder of the development, because these sites have the potential to capture all runoff.

(b) Water Quality Analysis

As outlined above, it was assumed that EIA discharges, as well as runoff from all pervious surfaces, are subject to treatment control. For purposes of the analysis, treatment control was assumed to be provided by conventional sand filtration. This choice is appropriate for study purposes for two reasons. First, sand filters can be installed below grade, and land above can be put to other uses. Under the Draft Permit's approach, pervious area should be reserved for receiving NCIA drainage, and using sand filters would not draw land away from that service or other site uses. A second reason for the choice is that sand filter performance data equivalent to the data used in analyzing other conventional BMPs are available from the CalTrans (2004) work. Sand filters may or may not expose water to soil, depending on whether or not they have a hard bed. This analysis assumed a hard bed, meaning that no infiltration would occur and thus there would be no additional recharge in sand filters. Performance would be even better than shown in the analytical results if sand filters were built in earth.

Pollutant Discharge Reduction Through LID Techniques

The preceding analyses demonstrated that each of the six case studies could feasibly comply with the draft permit's requirements, as modified to include a more protective three percent EIA standard. Moreover, for five of the six case studies, *all* storm water discharges could be eliminated at least under most meteorological conditions by dispersing runoff from impervious surfaces to pervious areas. Therefore, pollutant additions to receiving waters would also be eliminated. This demonstrates not only that a lower EIA (three percent) is a feasible and practicable approach to maintaining the natural hydrology of land being developed, as discussed above, but that a lower EIA is a feasible and practicable way to eliminate the discharge of pollutants that could cause or contribute to violations of water quality standards.

While the high proportion of impervious area present on the large commercial site relative to pervious area would not allow eliminating all discharge, harvesting roof water and draining NCIA to properly-prepared pervious area would substantially decrease the volume discharged. Deployment of treatment control BMPs (e.g. sand filter treatment) could cut contaminant discharges from pollutants in the remaining volume of runoff to low levels.

Table 10 presents the pollutant reductions from the untreated case achievable through the complete LID approach described above in comparison to conventional treatments (from Table 6). Assuming EIA still discharges through sand filters, pollutant loadings from the untreated condition are expected to decrease by more than 96 percent for all but the COMM case. In that challenging case loadings would still fall by at least 89 percent for TSS and the metals and by 83 percent for total phosphorus, assuming City of Ventura rainfall levels, and slightly less assuming the higher Ojai rainfall levels. Thus, the Draft Permit's basic premise of disconnecting most impervious area, supplemented by specially managing roof water, is shown by both water quality and hydrologic results to be feasible and to afford broad and significant environmental benefits.

Table 10. Pollutant Loading Reduction Estimates With a Full LID Approach Relative to Conventional BMPs

	MFR[a]	Sm-SFR[a]	REST[a]	OFF[a]	Lg-SFR[a]	COMM[a]
Conventional TSS loading reduction[b]	15.7-69.9%	19.9-75.4%	22.0-80.6%	24.0-82.6%	19.9-75.4%	16.9-72.3%

Conventional TZn loading reduction[b]	22.7-78.4%	22.4-78.1%	22.9-84.3%	23.1-78.8%	22.4-78.1%	25.1-80.9%
Conventional TP loading reduction[b]	30.6-66.3%	41.5-70.7%	40.7-69.1%	45.9-76.2%	41.5-70.7%	20.3-55.0%
LID TSS loading reduction[c]	99.4%	99.3%	99.5%	99.4%	99.3%	89.0%[d]
LID TCu loading reduction[c]	98.1%	96.7%	98.0%	96.2%	96.7%	90.6%[d]
LID TZn loading reduction[c]	99.1%	98.8%	98.9%	98.3%	98.8%	94.8%[d]
LID TP loading reduction[c]	98.1%	98.6%	98.8%	98.7%	98.6%	83.1%[d]

[a] MFR—multi-family residential; Sm-SFR—small-scale single-family residential; REST—restaurant; OFF—office building; Lg-SFR—large-scale single-family residential; COMM—retail commercial; CDS—continuous deflective separation unit; EDB—extended-detention basin; NCIA—not connected impervious area; EIA—effective (connected) impervious area
[b] Range from Table 6 represented by treatment by CDS unit, EDB, biofiltration swale, or biofiltration strip
[c] Based on directing roof runoff to downspout infiltration trenches (MFR, Sm-SFR, REST, and Lg-SFR) or harvesting it (OFF and COMM), draining other NCIA to pervious areas, and treating EIA with sand filters
[d] If the higher rainfall at Ojai is assumed, reduction estimates for TSS, TCu, TZn, and TP would be 84.0, 86.3, 92.5, and 75.5 percent, respectively.

SUMMARY AND CONCLUSIONS

This paper demonstrated that common Ventura County area residential and commercial development types subject to the Municipal NPDES Permit are likely, without storm water management, to reduce groundwater recharge from the predevelopment state by approximately half in most cases to a much higher fraction with a large ratio of impervious to pervious area. With no treatment, runoff from these developments is expected to exceed CTR acute copper and zinc criteria at the point of discharge and to deliver large pollutant mass loadings to receiving waters.

Conventional soil-based BMP solutions that promote and are component parts of low-impact development approaches, by contrast, regain about 30-50 percent of the recharge lost in development without storm water management, although commercially-manufactured filtration and hydrodynamic BMPs for storm water management give no benefits in this area. It is expected the soil-based BMPs generally would release effluent that meets the acute zinc criterion at the point of discharge, although it would still exceed the copper limit. Excepting phosphorus, it was found that these BMPs would capture and prevent the movement to receiving waters of the majority of the pollutant loadings considered in the analysis.

It was found that a three percent Effective Impervious Area standard can be met in typical developments, and that by draining all site runoff to pervious areas, runoff can be eliminated entirely in most development types. This result was reached assuming the use of native soils. Soil enhancement (typically, with compost) can further advance infiltration. Draining impervious surfaces onto the loam soils typical of Ventura County, in connection with limiting directly connected impervious area to three percent of the site total area, should eliminate storm runoff from some development types and greatly reduce it from more highly impervious types. Adding roof runoff elimination to the LID approach (by harvesting or directing it to downspout infiltration trenches) should eliminate runoff from all but mostly impervious developments. Even in the development scenario involving the highest relative proportion of impervious surface, losses of rainfall capture for beneficial uses could be reduced from more than 85 to less than 40 percent, and pollutant mass loadings would fall by 83-95 percent from the untreated scenario when draining to pervious areas was supplemented with water harvesting. These results demonstrate the basic soundness of the Draft Permit's concept to limit directly connected impervious area and drain the remainder over pervious surfaces.

ATTACHMENT A

JUSTIFICATION OF PROPOSED EFFECTIVE IMPERVIOUS AREA LIMITATION

Summary

The literature shows that adverse impacts to the physical habitat and biological integrity of receiving waters occur as a result of the conversion of natural areas to impervious cover. These effects are observed at the lowest levels of impervious cover in associated catchments (two to three percent) and are pronounced by the point that impervious cover reaches five percent. To protect biological productivity, physical habitat, and other beneficial uses, effective impervious area should be capped at no more than three percent.

I. Impacts to physical habitat of California receiving waters observed at three percent impervious cover

Stein *et al.*[7] note that while studies from parts of the country with climates more humid than California's indicate that physical degradation of stream channels can initially be detected when watershed impervious cover approaches 10%, biological effects, which may be more difficult to detect, may occur at lower levels (CWP 2003).[8] Recent studies from both northern and southern California indicate that intermittent and ephemeral streams in California are more susceptible to the effects of hydromodification than streams from other regions of the US, with stream degradation being recognized when the associated catchment's impervious cover is as little as 3-5% (Coleman *et al.* 2005).[9] Furthermore, supplemental landscape irrigation in semi-arid regions, like California, can substantially increase the frequency of erosive flows (AQUA TERRA Consultants 2004).[10]

Coleman, *et al.*[3] report that the ephemeral/intermittent streams in southern California (northwestern Los Angeles County through southern Ventura County to central Orange County) appear to be more sensitive to changes in percent impervious cover than streams in other areas. Stream channel response can be represented using an *enlargement curve*, which relates the percent of impervious cover to a change in cross-sectional area. The data for southern California streams forms a relationship very similar in shape to the enlargement curves developed for other North American streams. However, the curve for southern California streams is above the general curve for streams in other climates. This suggests that a specific enlargement ratio is produced at a lower value of impervious surface area in southern California than in other parts of North America. Specifically, the estimated threshold of response is approximately 2-3% impervious cover, as compared to 7-10% for other portions of the U.S. It is important to note that this conclusion applies specifically to streams with a catchment drainage area less than 5 square miles.

[10] AQUA TERRA Consultants, (2004) *Urbanization and Channel Stability Assessment in the Arroyo Simi Watershed of Ventura County CA*. FINAL REPORT. Prepared for Ventura County Watershed Protection Division, Ventura CA.

This study concludes that disconnecting impervious areas from the drainage network and adjacent impervious areas is a key approach to protecting channel stability. Utilizing this strategy can make it practical to keep the effective impervious cover (*i.e.* the amount hydrologically connected to the stream) equal to or less than the identified threshold of 2-3%.

II. Impacts to biological integrity of receiving waters observed with any conversion from natural to impervious surface

Two separate studies conducted by Horner *et al.*[11,12] in the Puget Sound region (Washington State), Montgomery County, Maryland, and Austin, Texas built a database totaling more than 650 reaches on low-order streams in watersheds ranging from no urbanization and relatively little human influence (the reference state, representing "best attainable" conditions) to highly urban (>60 percent total impervious area, "TIA"). Biological health was assessed according to the benthic index of biotic integrity (B-IBI) and, in Puget Sound, the ratio of young-of-the-year coho salmon (*Oncorhynchus kisutch*), a relatively stress-intolerant fish, to cutthroat trout (*Oncorhynchus clarki*), a more stress-tolerant species. The following discussion summarizes the results and conclusions of these two studies.

There is no single cause for the decline of water resource conditions in urbanizing watersheds. Instead, it is the cumulative effects of multiple stressors that are responsible for degraded aquatic habitat and water quality. Imperviousness, while not a perfect yardstick, appears to be a useful predictor of ecological condition. However, a range of stream conditions can be associated with any given level of imperviousness. In general, only streams that retain a significant proportion of their natural vegetative land-cover <u>and</u> have very low levels of watershed imperviousness appear to retain their natural ecological integrity. It is this change in watershed land-cover that is largely responsible for the shift in hydrologic regime from a sub-surface flow dominated system to one dominated by surface runoff.

While the decline in ecological integrity is relatively continuous and is consistent for all parameters, the impact on physical conditions appears to be more pronounced earlier in the urbanization process than chemical degradation. It is generally acknowledged, based on field research and hydrologic modeling, that it is the shift in hydrologic conditions that is the driving force behind physical changes in urban stream-wetland ecosystems.

Multiple scales of impact operate within urbanizing watersheds: landscape-level impacts, including the loss of natural forest cover and the increase in impervious surface area throughout the watershed; riparian corridor-specific impacts such as encroachment, fragmentation, and loss of native vegetation; and local impacts such as water diversions, exotic vegetation, stream channelization, streambank hardening, culvert installation, and pollution from the widespread use of pesticides and herbicides. All of these stressors contribute to the overall cumulative impact.

The researchers found that there is no clear threshold of urbanization below which there exists a "no-effect" condition. Instead, there appears to be a relatively continuous decline in almost all measures of water quality or ecological integrity. Losses of integrity occur from the lowest levels of TIA and are already pronounced by the point that TIA reaches 5 percent.

Similarly, the Alliance for the Chesapeake Bay[13] reports that small-watershed studies by the Maryland Department of Natural Resources Biological Stream Survey have shown that some sensitive species are affected by even low amounts of impervious cover. In one study, no brook trout were observed in any stream whose watershed had more than 2 percent impervious cover, and brook trout were rare in any watershed with more than 0.5 percent impervious cover.

III. Ventura County's watersheds include biologically-significant water bodies

The literature discussed above is relevant to the watersheds of Ventura County, which contain rivers and streams that currently or historically support a variety of beneficial uses that may be impaired by water quality degradation and stream hydromodification as a result of storm water runoff from impervious land cover. Unlike some Southern California watersheds, Ventura County still has many natural stream systems with a high degree of natural functionality.

For instance, the Ventura River watershed in northwestern Ventura County "supports a large number of sensitive aquatic species,"[14] including steelhead trout, a federally-listed endangered species. Although "local populations of steelhead and rainbow trout have nearly been eliminated along the Ventura River" itself, the California Department of Fish and Game has "recognized the potential for the restoration of the estuary and enhancement of steelhead populations in the Ventura River."[15] Steelhead may also be present in tributaries such as San Antonio Creek.[16] Thriving rainbow trout populations exist in tributaries of the Ventura River including Matilija Creek and Coyote Creek.[17] The Ventura River either does or is projected to support the following beneficial uses: warm freshwater habitat; cold freshwater habitat; wildlife habitat; rare, threatened, or endangered species; migration of aquatic organisms; and spawning and reproduction.[18] Furthermore, the Ventura River Estuary also supports commercial fishing, shellfish harvesting, and wetland habitat.[19] The Ventura River receives municipal storm drain discharges from Ojai, San Buenaventura, and unincorporated areas of Ventura County.[20]

The Santa Clara River watershed in northern Ventura County "is the largest river system in southern California that remains in a relatively natural state."[21] Sespe Creek is one of the Santa Clara's largest tributaries, and "supports significant steelhead spawning and rearing habitat."[22] Other creeks in the Santa Clara River watershed that support steelhead are Piru Creek and Santa Paula Creek. Sespe Creek and the Santa Clara River also provide spawning habitat for the Pacific lamprey. Rainbow trout populations exist in tributaries of the Santa Clara River including Sespe Creek.[23] The creeks and the Santa Clara river do or are projected to support the following beneficial uses: warm freshwater habitat; cold freshwater habitat; wildlife habitat; preservation of biological habitats rare, threatened, or endangered species; migration of aquatic organisms; and spawning and reproduction.[24] Los Padres National Forest covers much of the Santa Clara River watershed, but increasing development in floodplain areas has been

identified as a threat to the river system's water quality.[25] Furthermore, the Santa Clara estuary supports the additional beneficial uses of shellfish harvesting and wetlands habitat.[26] The Santa Clara River receives municipal storm drain discharges from Fillmore, Oxnard, San Buenaventura, Santa Paula, and unincorporated areas of Ventura County.[27]

The Calleguas Creek watershed "empties into Mugu Lagoon, one of southern California's few remaining large wetlands."[28] It supports or is projected to support the following beneficial uses: estuarine habitat; marine habitat; wildlife habitat; preservation of biological habitats; rare, threatened, or endangered species; migration of aquatic organisms; spawning and reproduction; shellfish harvesting; and wetlands habitat.[29] Historically, Calleguas Creek drained largely agricultural areas. But this watershed has been under increasing pressure from sedimentation due to increased surface flow from municipal discharges and urban wastewaters, among other sources.[30] Increasing residential developments on steep slopes has been identified as a substantial contributing factor to the problem of accelerated erosion in the watershed (and sedimentation in the Lagoon). Calleguas Creek receives municipal storm drain discharges from Camarillo, Moorpark, Simi Valley, Thousand Oaks, and unincorporated areas of Ventura County.[31]

Ventura County's coastal streams also support a variety of beneficial uses:[32]

- Little Sycamore Canyon Creek in southern Ventura County (warm freshwater habitat; wildlife habitat; rare, threatened or endangered species; and spawning and reproduction);
- Lake Casitas tributaries (warm freshwater habitat; cold freshwater habitat; wildlife habitat; rare, threatened or endangered species; spawning and reproduction; and wetland habitat);
- Javon Canyon and Padre Juan Canyon (warm freshwater habitat; cold freshwater habitat; wildlife habitat; and spawning and reproduction); and
- Los Sauces Creek in northern Ventura County (warm freshwater habitat; cold freshwater habitat; wildlife habitat; migration of aquatic species; and spawning and reproduction).

IV. Conclusion

In order to protect the biological habitat, physical integrity, and other beneficial uses of the water bodies in Ventura County, effective impervious area should be capped at no more than three percent.

INITIAL INVESTIGATION OF THE FEASIBILITY AND BENEFITS OF LOW-IMPACT SITE DESIGN PRACTICES ("LID") FOR THE SAN FRANCISCO BAY AREA

Richard R. Horner[†]

ABSTRACT

The Clean Water Act NPDES permit that regulates municipal separate storm sewer systems (MS4s) in the San Francisco Bay Area, California will be reissued in 2007. The draft permit includes general provisions related to low impact development practices (LID) for certain kinds of development and redevelopment projects. Using six representative development project case studies, based on California building records, the author investigated the practicability and relative benefits of LID options for the majority of the region having soils potentially suitable for infiltration either in their natural state or after amendment using well recognized LID techniques. The results showed that (1) LID site design and source control techniques are more effective than conventional best management practices (BMPs) in reducing runoff rates; and (2) in each of the case studies, LID methods would reduce site runoff volume and pollutant loading to zero in typical rainfall scenarios.

[†] Richard R. Horner, Ph.D., Research Associate Professor, University of Washington Departments of Civil and Environmental Engineering and Landscape Architecture; Adjunct Associate Professor, University of Washington Center for Urban Horticulture

INTRODUCTION

The Assessment in Relation to Municipal Permit Conditions

This purpose of this study is to investigate the relative water quality and water reuse benefits of three levels of storm water treatment best management practices (BMPs): (1) basic "treat-and-release" BMPs (e.g., drain inlet filters, CDS units), (2) commonly used BMPs that expose runoff to soils and vegetation (extended-detention basins and biofiltration swales and filter strips), and (3) low impact development (LID) practices. The factors considered in the investigation are runoff volume, pollutant loading, and the availability of water for infiltration or other reuse. In order to assess the differential impact of storm water reduction approaches on these factors, this study examines six case studies typical of development covered by the proposed Municipal Regional Urban Runoff Phase I NPDES Stormwater Permit (MRP).

This report covers locations in the Bay Area most amenable to soil infiltration of stormwater runoff, those areas having soils in Natural Resources Conservation Service (NRCS) Hydrologic Soil Groups A, B, or C as classified by the Natural Resources Conservation Service (http://websoilsurvey.nrcs.usda.gov/app/WebSoilSurvey.aspx). Depending on site-specific conditions, A and B soils would generally effectively infiltrate water without modification, whereas C soils could require organic amendments according to now standard LID methods. This report does not cover locations with group D soils, which are generally not amenable to infiltration, again depending on the specific conditions on-site. A subsequent report will examine options in these locations, which include other LID techniques (e.g., roof runoff harvesting for irrigation or gray water supply) and state-of-the-art conventional stormwater management practices. A minority but still substantial fraction of the Bay Area has group D soils (39.3, 68.0, 18.3, and 50.1 percent of the mapped areas of Alameda, Contra Costa, San Mateo, and Santa Clara Counties, respectively). Regarding any mapped soil type, it is important to keep in mind that soils vary considerably within small distances. Characteristics at specific locations can deviate greatly from those of the major mapped unit, making infiltration potential either more or less than may be expected from the mapping.

Low impact development methods reduce storm runoff and its contaminants by decreasing their generation at sources, infiltrating into the soil or evaporating storm flows before they can enter surface receiving waters, and treating flow remaining on the surface through contact with vegetation and soil, or a combination of these strategies. Soil-based LID practices often use soil enhancements such as compost, and thus improve upon the performance of more traditional basins and biofilters. The study encompassed vegetated swales (channels for conveyance at some depth and velocity), vegetated filter strips (surfaces for conveyance in thin sheet flow), and bioretention areas (shallow basins with a range of vegetation types in which runoff infiltrates through soil either to groundwater or a subdrain for eventual surface discharge). Application of these practices in a low impact site design mode requires either determination that existing site soils can support runoff reduction through infiltration or that soils will be amended using accepted LID techniques to attain this objective. Finally, the study further broadened implementation options to include water harvesting (collection and storage for use in, for example, irrigation or gray water systems), roof downspout infiltration trenches, and porous pavements.

The investigation also considered whether typical development patterns and local conditions in the Bay Area would enable LID implementation as required by a new standard proposed for the 2007 Ventura County Municipal Storm Water Permit. This standard requires management of effective impervious area (EIA), limiting it to 5%, as well as other impervious area (what might be termed Not-Connected Impervious Area, NCIA), and pervious areas.

Where treatment control BMPs are required to manage runoff from a site, Volume or Flow Hydraulic Design Bases commonly used in California were assumed to apply. The former basis applies to storage-type BMPs, like ponds, and requires capturing and treating either the runoff volume from the 85th percentile, 24-hour rainfall event for the location or the volume of annual runoff to achieve 80 percent or more volume treatment. The calculations in this analysis used the 85th percentile 24-hour rainfall event basis. The Flow basis applies to flow-through BMPs, like swales, and requires treating the runoff flow rate produced from a rain event equal to at least 0.2 inches per hour intensity (or one of two other approximately equivalent options).

Scope of the Assessment

With respect to each of the six development case studies, three assessments were undertaken: a baseline scenario incorporating no stormwater management controls; a second scenario employing conventional BMPs; and a third development scenario employing LID stormwater management strategies.

To establish a baseline for each case study, annual stormwater runoff volumes were estimated, as well as concentrations and mass loadings of four pollutants: (1) total suspended solids (TSS), (2) total recoverable copper (TCu), (3) total recoverable zinc (TZn), and (4) total phosphorus (TP). These baseline estimates were based on the anticipated land use and cover with no stormwater management efforts.

Two sets of calculations were then conducted using the parameters defined for the six case studies. The first group of calculations estimated the extent to which basic BMPs reduce runoff volumes and pollutant concentrations and loadings, and what impact, if any, such BMPs have on recharge rates or water retention on-site.

The second group of calculations estimated the extent to which commonly used soil-based BMPs and LID site design strategies ameliorate runoff volumes and pollutant concentrations and loadings, and the effect such techniques have on recharge rates. When evaluating LID strategies in the context of the EIA concept employed in the draft Ventura County MS4 permit, it was presumed that EIA would be limited to three percent. It was also assumed that pervious surfaces on a site receiving runoff from other areas on the site would be sized and prepared to manage (through infiltration or storage) the volume directed there in addition to precipitation falling directly on those areas. The assessment of basins, biofiltration, and low impact design practices analyzed the expected infiltration capacity of the case study sites. It also considered related LID techniques and practices, such as source reduction strategies, that could work in concert with infiltration to serve the goals of: (1) preventing increase in annual runoff volume from the pre- to the post-developed state, (2) preventing increase in annual pollutant mass loadings between the two development states, and (3) avoiding exceedances of the Water Quality Control Plan for the San Francisco Bay Basin (Basin Plan) criteria for copper and zinc.

The results of this analysis show that:

- A full-range of typical development categories common in the Bay Area, from single family residential to restaurants, housing developments, and commercial uses like office buildings, can feasibly implement standard LID techniques to achieve no stormwater discharge during rain events equal to, and in some cases greater than, design storm conditions. This conclusion is based on an analysis that used actual building records in California and annual rainfall records in two rainfall zones in the Bay Area to show that site conditions support this level of performance. In addition, site conditions typical at a wide range of development projects are more than sufficient to attain compliance with a three percent EIA limit, as is being contemplated in other MS4 re-issuance proceedings in California presently.

- Developments implementing no post-construction BMPs result in storm water runoff volume and pollutant loading that are substantially increased, and recharge rates that are substantially decreased, compared to pre-development conditions.

- Developments implementing basic post-construction treatment BMPs achieve reduced pollutant loading compared to developments with no BMPs, but stormwater runoff volume and recharge rates are similar to developments with no BMPs.

- Developments implementing traditional basins and biofilters, and even more so low impact post-construction BMPs, achieve significant reduction of pollutant loading and runoff volume as well as greatly enhanced recharge rates compared to both developments with no BMPs and developments with basic treatment BMPs.

This report covers the methods employed in the investigation, data sources, and references for both. It then presents the results, discusses their consequences, draws conclusions, and makes recommendations relative to the feasibility of utilizing low-impact development practices in Bay Area developments.

CASE STUDIES

Six case studies were selected to represent a range of urban development types considered to be representative of the Bay Area. These case studies involved: a multi-family residential complex (MFR), a relatively small-scale (23 homes) single-family residential development (Sm-SFR), a restaurant (REST), an office building (OFF), a relatively large (1000 homes) single-family residential development (Lg-SFR), and a single home (SINGLE).[1]

Parking spaces were estimated to be 176 sq ft in area, which corresponds to 8 ft width by 22 ft length dimensions. Code requirements vary by jurisdiction, with the tendency now to drop below the traditional 200 sq ft average. About 180 sq ft is common, but various standards for full- and compact-car spaces, and for the mix of the two, can raise or lower the average.[2] The 176 sq ft size is considered to be a reasonable value for conventional practice.

Roadways and walkways assume a wide variety of patterns. Exclusive of the two SFR cases, simple, square parking lots with roadways around the four sides and square buildings with walkways also around the four sides were assumed. Roadways and walkways were taken to be 20 ft and 6 ft wide, respectively.

Single-family residences were assumed each to have a driveway 20 ft wide and 30 ft long. It was further assumed that each would have a sidewalk along the front of the lot, which was calculated to be 5749 sq ft in area. Assuming a square lot, the front dimension would be 76 ft. A 40-ft walkway was included within the property. Sidewalks and walkways were taken to be 4 ft wide. For each case study the total area for all of these impervious features was subtracted from the total site area to estimate the pervious area, which was assumed to have conventional landscaping cover (grass, small herbaceous decorative plants, bushes, and a few trees).

---

[1] Building permit records from the City of San Marcos in San Diego County provided data on total site areas for the first four case studies, including numbers of buildings, building footprint areas (including porch and garage for Sm-SFR), and numbers of parking spaces associated with the development projects. While the building permit records made no reference to features such as roadways, walkways, and landscaping normally associated with development projects, these features were taken into account in the case studies using assumptions described herein. Larger developments and redevelopment were not represented in the sampling of building permits from the San Marcos database. To take these types of projects into account in the subsequent analysis, the Lg-SFR scenario scaled up all land use estimates from the Sm-SFR case in the ratio of 1000:23. The single home case (SINGLE) was derived from Bay Area records obtained at http://www.ppic.org/content/other/706EHEP_web_only_appendix.pdf, which showed 8000 ft^2 as a rough average for a single home lot in the region. As with the other cases, these hypothetical developments were assumed to have roadways, walkways, and landscaping, as described herein.

METHODS OF ANALYSIS

Annual Stormwater Runoff Volumes

Annual surface runoff volumes produced were estimated for both pre- and post-development conditions for each case study site. Runoff volume was computed as the product of annual precipitation, contributing drainage area, and a runoff coefficient (ratio of runoff produced to rainfall received). For impervious areas the following equation was used:

$$C = (0.009)\,I + 0.05$$

where I is the impervious percentage. This equation was derived by Schueler (1987) from Nationwide Urban Runoff Program data (U.S. Environmental Protection Agency 1983). With I = 100 percent for fully impervious surfaces, C is 0.95.

The basis for pervious area runoff coefficients was the Natural Resource Conservation Service's (NRCS) Urban Hydrology for Small Watersheds (NRCS 1986, as revised from the original 1975 edition). This model estimates storm event runoff as a function of precipitation and a variable representing land cover and soil, termed the curve number (CN). Larger events are forecast to produce a greater amount of runoff in relation to amount of rainfall because they more fully saturate the soil. Therefore, use of the model to estimate annual runoff requires selecting some event or group of events to represent the year. The 85th percentile, 24-hour rainfall event was used in the analysis here for the relative comparison between pre- and post-development and applied to deriving a runoff coefficient for annual estimates, recognizing that smaller storms would produce less and larger storms more runoff.

A memorandum titled Rainfall Data Analysis and Guidance for Sizing Treatment BMPs (http://www.cccleanwater.org/construction/Publications/CCCWPBasinSizingMemoFINAL_4-20-05.pdf) prepared for the Contra Costa Clean Water Program demonstrated a linear relationship between unit basin storage volume for 80 percent capture (which is related to the 85th percentile event) and mean annual precipitation. Rainfall for Bay Area 85th percentile, 24-hour events could thus be determined from locations where events have been established in direct proportion to mean annual rainfall.

In order to obtain appropriate regional estimates of annual precipitation, rainfall records were obtained from a number of sites in the four counties, plus the city of Vallejo, covered by the permit.[3] The mean annual range is from 13.73 to 24.30 inches, with quantities close to either 14 or 20 inches predominating. The study was performed for both of these rainfall totals. These figures were used in conjunction with 85th percentile, 24-hour event amounts of 0.75 for Los Angeles and 0.92 for Santa Rosa (http://ci.santa-rosa.ca.us/pworks/other/SW/SRSWManualFinalDraft.pdf), respectively, and mean annual totals of 12 and 31 inches for the respective cities to estimate 85 percentile, 24-hour event quantities of 0.77 and 0.82 inch for the 14 and 20-inch Bay Area rainfall zones, respectively.

Pre- and post-development runoff quantities were computed with selected CN values and the 0.77- and 0.82-inch rainfalls. The CN choices based on tabulated data in NRCS (1986) and professional judgment were 83 before development and 86 after land modification. Estimate runoff amounts were then divided by the rainfall totals to obtain runoff coefficients. The results were about the same for the two rainfall zones at 0.07 and 0.12 before and after development, respectively. Finally, total annual runoff volumes were estimated based on the two average annual precipitation figures.

Stormwater Runoff Pollutant Discharges

Annual pollutant mass discharges were estimated as the product of annual runoff volumes produced by the various land use and cover types and pollutant concentrations typical of those areas. Again, the 0.75-inch precipitation event was used as a basis for volumes. Stormwater pollutant data have typically been measured and reported for general land use types (e.g., single-family residential, commercial). However, an investigation of low impact development practices of the type this study sought to conduct demands data on specific land coverages. The literature offers few data on this basis. Those available and used herein were assembled by a consultant to the City of Seattle for a project in which the author participated. They appear in Attachment A (Herrera Environmental Consultants, Inc. undated).

Pollutant concentrations expected to occur typically in the mixed runoff from the several land use and cover types making up a development were estimated by mass balance; i.e., the concentrations from the different areas of the sites were combined in proportion to their contribution to the total runoff.

The Effect of Conventional Treatment BMPs on Runoff Volume, Pollutant Discharges, and Recharge Rates

The first question in analyzing how BMPs reduce runoff volumes and pollutant discharges was, What BMPs are being employed in Bay Area developments under the permit now in force? These county permits provide regulated entities with a large number of choices and few fixed requirements regarding the selection of stormwater BMPs. (See Contra Costa County NPDES Municipal Stormwater Permit, Order No. 99-058; see also Santa Clara County NPDES Municipal Stormwater Permit, Order No. 01-024, at C.3.a.). Clean Water Program Available options presumably include manufactured BMPs, such as drain inlet inserts (DIIs) and continuous deflective separation (CDS) units. Developments may also select such non-

3 http://www.census.gov/stab/ccdb/cit7140a.txt, http://www.acwd.org/dms_docs/76d0b026b60d97830492079a48b1cb88.pdf, http://www.ci.berkeley.ca.us/aboutberkeley/weather.html, http://www.usbr.gov/dataweb/dams/ca10168.htm, http://www.redwoodcity.org/about/weather.html.

proprietary devices as extended-detention basins (EDBs) and biofiltration swales and filter strips. EDBs hold water for two to three days for solids settlement before releasing whatever does not infiltrate or evaporate. Biofiltration treats runoff through various processes mediated by vegetation and soil. In a swale, runoff flows at some depth in a channel, whereas a filter strip is a broad surface over which water sheet flows. Each of these BMP types was applied to each case study, although it is not clear that these BMPs, in actuality, have been implemented consistently within the Bay Area to date.

The principal basis for the analysis of BMP performance was the California Department of Transportation's (CalTrans, 2004) BMP Retrofit Pilot Program, performed in San Diego and Los Angeles Counties. One important result of the program was that BMPs with a natural surface infiltrate and evaporate (probably, mostly infiltrate) a substantial amount of runoff, even if conditions do not appear to be favorable for an infiltration basin. On average, the EDBs, swales, and filter strips lost 40, 50 and 30 percent, respectively, of the entering flow before the discharge point. DIIs and CDS units do not contact runoff with a natural surface, and therefore do not reduce runoff volume.

The CalTrans program further determined that BMP effluent concentrations were usually a function of the influent concentrations, and equations were developed for the functional relationships in these cases. BMPs generally reduced influent concentrations proportionately more when they were high. In relatively few situations influent concentrations were constant at an "irreducible minimum" level regardless of inflow concentrations.

In analyzing the effects of BMPs on the case study runoff, the first step was to reduce the runoff volumes estimated with no BMPs by the fractions observed to be lost in the pilot study. The next task was estimating the effluent concentrations from the relationships in the CalTrans report. The final step was calculating discharge pollutant loadings as the product of the reduced volumes and predicted effluent concentrations. As before, typical pollutant concentrations in the mixed runoff were established by mass balance.

Estimating Infiltration Capacity of the Case Study Sites

Infiltrating sufficient runoff to maintain pre-development hydrologic characteristics and prevent pollutant transport is the most effective way to protect surface receiving waters. Successfully applying infiltration requires soils and hydrogeological conditions that will pass water sufficiently rapidly to avoid overly-lengthy ponding, while not allowing percolating water to reach ground-water before the soil column captures pollutants.

The study assumed that infiltration would occur in surface facilities and not in below-ground trenches. The use of trenches is certainly possible, and was judged to be an approved BMP by CalTrans after the pilot study. However, the intent of this investigation was to determine the ability of pervious areas to manage the site runoff. This was accomplished by determining the infiltration capability of the pervious areas in their original condition for each development case study, and further assessing the pervious areas' infiltration capabilities if soils were modified according to low impact development practices.

The chief basis for this aspect of the work was an assessment of infiltration capacity and benefits for Los Angeles' San Fernando Valley (Chralowicz et al. 2001). The Chralowicz study posited providing 0.1-0.5 acre for infiltration basins to serve each 5 acres of contributing drainage area. At 2-3 ft deep, it was estimated that such basins could infiltrate 0.90-1.87 acre-ft/year of runoff in San Fernando Valley conditions. Soils there are generally various loam textures with infiltration rates of approximately 0.5-2.0 inches/hour. Loams are also common formations in the portion of the Bay Area covered by this report, those areas with Hydrologic

Soil Groups A, B, and C,[4] thus making the conclusions of the San Fernando Valley study applicable for these purposes. This information was used to estimate how much of each case study site's annual runoff would be infiltratable, and if the pervious portion would provide sufficient area for infiltration. For instance, if sufficient area were available, the infiltration configuration would not have to be in basin form but could be shallower and larger in surface area. This study's analyses assumed the use of bioretention areas rather than traditional infiltration basins.

Volume and Pollutant Source Reduction Strategies

As mentioned above, the essence of low impact development is reducing runoff problems before they can develop, at their sources, or exploiting the infiltration and treatment abilities of soils and vegetation. If a site's existing infiltration and treatment capabilities are inadequate to preserve pre-development hydrology and prevent runoff from causing or contributing to violations of water quality standards, then LID-based source reduction strategies can be implemented, infiltration and treatment capabilities can be upgraded, or both.

Source reduction can be accomplished through various LID techniques. Soil can be upgraded to store runoff until it can infiltrate, evaporate, or transpire from plants through compost addition. Soil amendment, as this practice is known, is a standard LID technique.

Upgraded soils are used in bioretention cells that hold runoff and effect its transfer to the subsurface zone. This standard LID tool can be used where sufficient space is available. This study analyzed whether the six development case study sites would have sufficient space to effectively reduce runoff using bioretention cells, assuming the soils and vegetation could be amended and enhanced where necessary.

Conventional pavements can be converted to porous asphalt or concrete or replaced with concrete or plastic unit pavers or grid systems. For such approaches to be most effective, the soils must be capable of infiltrating the runoff passing through, and may require renovation.

Source reduction can be enhanced by the LID practice of water harvesting, in which water from impervious surfaces is captured and stored for reuse in irrigation or gray water systems. For example, runoff from roofs and parking lots can be harvested, with the former being somewhat easier because of the possibility of avoiding pumping to use the water and fewer pollutants. Harvesting is a standard technique for Leadership in Energy and Environmental Design (LEED) buildings.[5] Many successful systems of this type are in operation, such as the Natural Resources Defense Council office (Santa Monica, CA), the King County Administration Building (Seattle, WA), and two buildings on the Portland State University campus (Portland, OR). This investigation examined how water harvesting could contribute to stormwater management for case study sites where infiltration capacity, available space, or both appeared to be limited.

RESULTS OF THE ANALYSIS

1. *"Base Case" Analysis: Development without Stormwater Controls*

Comparison of Pre- and Post-Development Runoff Volumes

Table 2 presents a comparison between the estimated runoff volumes generated by the respective case study sites in the pre- and post-development conditions, assuming implementation of no stormwater controls on the developed sites. On sites dominated by impervious land cover, most of the infiltration that would recharge groundwater in the undeveloped state is expected to be lost to surface runoff after development. This greatly increased surface flow would raise peak flow rates and volumes in receiving water courses, raise flooding risk, and transport pollutants. Only the office building, the plan for which retained substantial pervious area, would lose less than 40 percent of the site's pre-development recharge.

Table 2. Pre- and Post-Development without BMPs: Distribution of Surface Runoff Versus Recharge to Groundwater (annual volume in acre-ft)

Pollutant Concentrations and Loadings

Table 3 presents the pollutant concentrations from the literature and loadings calculated as described for the various land use and cover types represented by the case studies. Landscaped areas are expected to release the highest TSS concentration, although relatively low TSS mass loading because of the low runoff coefficient. The highest copper concentrations and loadings are expected from parking lots. Roofs, especially commercial roofs, top the list for both zinc concentrations and loadings. Landscaping would issue by far the highest phosphorus, although access roads and driveways would contribute the highest mass loadings. With expected concentrations being equal in the two rainfall zones, mass loadings in the 20 inches/year zone would be higher than those in the 14 inches/year zone in the same proportion as the ratio of rainfall quantities.

Table 3. Pollutant Concentrations and Loadings for Case Study Land Use and Cover Types

The Basin Plan freshwater acute criteria for copper and zinc are 0.013 mg/L and 0.120 mg/L, respectively (http://www.swrcb.ca.gov/rwqcb2/basinplan/web/BP_CH3.html). All developed land uses are expected to discharge copper at or above the criterion, based on the mass balance calculations using concentrations from Table 3. Any surface release from the case study sites would just meet or violate the criterion at the point of discharge, although dilution by the receiving water would lower the concentration below the criterion at some point. Even if copper mass loadings are reduced by BMPs, any surface discharge would equal or exceed the criterion initially, but it would be easier to dilute below that level. In contrast, runoff from land covers other than roofs would not violate the acute zinc criterion. Because of this difference, the evaluation considered whether or not the zinc criterion would be exceeded in each analysis, whereas there was no point in this analysis for copper. There are no equivalent water quality criteria for TSS and TP; hence, their concentrations were not further analyzed in the different scenarios.

Table 4 shows the overall loadings, as well as zinc concentrations, expected to be delivered from the case study developments should they not be fitted with any BMPs. As Table 4 shows, all cases are forecast to exceed the 0.120 mg/L acute zinc criterion. Because of its size, the large residential development dominates the mass loading emissions.

Table 4. Case Study Pollutant Concentration and Loading Estimates without BMPs

2. *"Conventional BMP" Analysis: Effect of Basic Treatment BMPs*

Effect of Basic Treatment BMPs on Post-Development Runoff Volumes

The current set of regional permits allows regulated parties to select from a range of BMPs in order to treat or infiltrate a given quantity of annual rainfall. The administrative draft of the proposed MRP is also non-specific regarding the role of LID in satisfying permit conditions. The range of BMPs includes drain inlet inserts, CDS units, and other manufactured BMPs, detention vaults, and sand filters, all of which isolate runoff from the soil; as well as basins and biofiltration BMPs built in soil and generally having vegetation. Treatment BMPs that do not permit any runoff contact with soils discharge as much stormwater runoff as equivalent sites with no BMPs, and hence yield zero savings in recharge. As mentioned above, the CalTrans (2004) study found that BMPs with a natural surface can reduce runoff by substantial margins (30-50 percent for extended-detention basins and biofiltration).

With such a wide range of BMPs in use, runoff reduction ranging from 0 to 50 percent, and a lack of clearly ascertainable requirements, it is not possible to make a single estimate of how much recharge savings are afforded by maximal implementation of the current permits or the Municipal Regional Permit (MRP), if issued as now proposed. We made the following assumptions regarding implementation of BMPs. Assuming natural-surface BMPs perform at the average of the three types tested by CalTrans (2004), i.e., 40 percent runoff reduction, the estimate can be bounded as shown in Table 5. The table demonstrates that allowing free choice of BMPs without regard to their ability to direct water into the ground forfeits substantial groundwater recharge benefits when hardened-surface BMPs are selected. Use of soil-based conventional BMPs could cut recharge losses from half or more of the full potential to about one-quarter to one-third or less, except with the highly impervious commercial development. This analysis shows the wisdom of draining impervious to pervious surfaces, even if those surfaces are not prepared in any special way. But as subsequent analyses showed, soil amendment can gain considerably greater benefits.

Table 5. Pre- and Post-Development with Conventional BMPs: Distribution of Surface Runoff Versus Recharge to Groundwater (annual volume in acre-ft)

[a] MFR—multi-family residential; Sm-SFR—small-scale single-family residential; REST—restaurant; OFF—office building; Lg-SFR—large-scale single-family residential; SINGLE—single family home; CDS— continuous deflective separation unit; EDB—extended-detention basin

When treated with extended-detention basins, swales, or filter strips, effluents from each development case study site are expected to fall below the Basin Plan acute zinc criterion. These natural-surface BMPs, if fully implemented and well maintained, are predicted to prevent the pollutant masses generated on the six case study development sites from reaching a receiving water in both rainfall zones, which do not differ appreciably. Only total phosphorus reduction falls below 50 percent for three case studies. Otherwise, mass loading reductions range from about 60 to above 80 percent for the EDB, swale, and filter strip. These data indicate that draining impervious to pervious surfaces, even if those surfaces are not prepared in any special way, pays water quality as well as hydrologic dividends.

3. *LID Analysis*

(a) Hydrologic Analysis

The LID analysis repeats the analysis above, focusing here on the performance of LID techniques in reducing or eliminating runoff from the six development case studies. In addition to assessing the total runoff that would be expected, the analysis also considered whether LID techniques would be sufficient to attain compliance with a performance standard being considered by the Los Angeles Regional Water Quality Control Board for Ventura County, California. This standard limits EIA (Effective Impervious Area) to five percent (but our analysis further assumed EIA would be ultimately reduced to three percent). All runoff from NCIA (Not-Connected Impervious Area) was assumed to drain to vegetated surfaces.

One goal of this exercise was to identify methods that reduce runoff production in the first place. It was hypothesized that implementation of source reduction techniques could allow all of the case study sites to infiltrate substantial proportions, or all, of the developed site runoff, advancing the hydromodification mitigation objective of the Draft Permit. When runoff is dispersed into the soil instead of being rapidly collected and conveyed away, it recharges groundwater, supplementing a resource that maintains dry season stream flow and wetlands. An increased water balance can be tapped by humans for potable, irrigation, and process water supply. Additionally, runoff volume reduction would commensurately decrease pollutant mass loadings.

Accordingly, the analysis considered the practicability of more than one scenario. In one option, all roof runoff is harvested and stored for some beneficial use. A second option disperses runoff into the soil via roof downspout infiltration trenches. The former option is probably best suited to cases like large commercial and office buildings, while distribution in the soil would fit best with residences and relatively small commercial developments. The analysis was repeated with the assumptions of harvesting OFF roof runoff for some beneficial use and dispersing roof runoff from the remaining four cases in roof downspout infiltration systems.

Expected Infiltration Capacities of the Case Study Sites

The first inquiry on this subject sought to determine how much of the total annual runoff each property is expected to infiltrate, since infiltration is a basic (although not exclusive) LID technique. Based on the findings of Chralowicz et al. (2001), it was assumed that an infiltration zone of 0.1-0.5 acres in area and 2-3 ft deep would serve a drainage catchment area in the size range 0-5 acres and infiltrate 0.9-1.9 acre-ft/year. The conclusions of Chralowicz et al. (2001) were extrapolated to conservatively assume that 0.5 acre would be required to serve each additional five acres of catchment, and would infiltrate an incremental 1.4 acre-ft/year (the midpoint of the 0.9-1.9 acre-ft/year range). According to these assumptions, the following schedule of estimates applies:

Pervious Area Available for Infiltration	Catchment Served acres	Infiltration Capacity
0.5 acres	0-5 acres	1.4 acre-ft/year
1.0 acres	5-10 acres	2.8 acre-ft/year
1.5 acres	10-15 acres	4.2 acre-ft/year
(Etc.)	...	...

As a formula, infiltration capacity ≈ 2.8 x available pervious area. To apply the formula conservatively, the available area was reduced to the next lower 0.5-acre increment before multiplying by 2.8.

As shown in Table 7, in both rainfall zones all six of the sites have adequate or greater capacity to infiltrate the full annual runoff volume expected from NCIA and pervious areas where EIA is limited to three percent of the total site area. Indeed, five of the six development types have sufficient pervious area to infiltrate *all* runoff, including runoff from EIA areas. These results are based on infiltrating in the native soils with no soil amendment. For any development project at which infiltration-oriented BMPs are considered, it is important that infiltration potential be carefully assessed using site-specific soils and hydrogeologic data. In the event such an investigation reveals a marginal condition (e.g., hydraulic conductivity, spacing to groundwater) for infiltration basins, soils could be enhanced to produce bioretention zones to assist infiltration. Notably, the five case studies with far greater than necessary infiltration capacity would offer substantial flexibility in designing infiltration, allowing ponding at less than 2-3 ft depth.

[b] Based on Chralowicz et al. (2001) according to the schedule described above
[c] Compare runoff production from NCIA + pervious area (row 3) with estimated infiltration capacity (row 6)

As Table 7 shows, each of the six case study sites have the capacity to infiltrate *all* or substantially all of the runoff produced onsite annually by draining impervious surfaces to pervious areas on native soils or, in some soil regimes, soils amended with organic matter. If these sites were designed as envisioned in this analysis, no runoff discharge is expected in storms as large as, and probably larger than, the design storm event—using infiltration only. Discharge would be anticipated only with exceptionally intense, large, or prolonged rainfall that saturates the ground at a faster rate than water can infiltrate or evaporate. Even runoff from the area assumed to be EIA could be infiltrated in most cases based on the amount of pervious area available in typical development projects. Therefore, this analysis shows that the EIA performance standard being considered for Ventura County, California, or one more stringent, can be met readily in development projects occurring on A, B, and C soils in the San Francisco Bay Area.

Additional Source Reduction Capabilities of the Case Study Sites: Water Harvesting Example

As noted, infiltration is one of a wide variety of LID-based source reduction techniques. Where site conditions such as soil quality or available area limit a site's infiltration capacity, other source LID measures can enhance a site's runoff retention capability. For example, soil amendment, which improves infiltration, is a standard LID technique. Water harvesting is another. Such practices can also be used where infiltration capacity is adequate, but the developer desires greater flexibility for land use on-site. Table 8 shows the added LID implementation flexibility created by subtracting roof runoff by harvesting it or efficiently directing it into the soil through downspout dispersion systems, further demonstrating the feasibility and robust performance of LID options for reducing or eliminating runoff in most expected conditions. Specifically, all development types studied could readily infiltrate and/or retain all expected annual precipitation.

Effect of Full LID Approach on Recharge

Table 9 shows the recharge benefits of preventing roofs from generating runoff and infiltrating as much as possible of the runoff from the remainder of the case study sites. The data show that LID methods offer significant benefits relative to the baseline (no stormwater controls) in all cases. These benefits are particularly impressive in developments with relatively high site imperviousness, such as in the MFR case.

[b] Quantity of water infiltrating the soil; the difference between precipitation and runoff

[c] Water either entirely infiltrated in BMPs and recharged to groundwater or partially harvested from roofs and partially infiltrated in BMPs. EIA was not distinguished from the remainder of the development, because these sites have the potential to capture all runoff.

(b) Water Quality Analysis

It was assumed that any site discharges would be subject to treatment control. For purposes of the analysis, treatment control was assumed to be provided by conventional sand filtration. This choice is appropriate for study purposes for two reasons. First, sand filters can be installed below grade, and land above can be put to other uses. Pervious area should be reserved for receiving NCIA drainage, and using sand filters would not draw land away from that service or other site uses. A second reason for the choice is that sand filter performance data equivalent to the data used in analyzing other conventional BMPs are available from the CalTrans (2004) work. Sand filters may or may not expose water to soil, depending on whether or not they have a hard bed. This analysis assumed a hard bed, meaning that no infiltration would occur and thus there would be no additional recharge in sand filters. Performance would be even better than shown in the analytical results if sand filters were built in earth.

Pollutant Discharge Reduction Through LID Techniques

The preceding analyses demonstrated that in each of the six case studies, *all* stormwater discharges could be eliminated at least under most meteorological conditions by dispersing runoff from impervious surfaces to pervious areas. Therefore, pollutant additions to receiving waters would also be eliminated.

SUMMARY AND CONCLUSIONS

This paper demonstrated that common Bay Area residential and commercial development types subject to the Municipal NPDES Permit are likely, without stormwater management, to reduce groundwater recharge from the pre-development state by approximately half in most cases to a much higher fraction with a large ratio of impervious to pervious area. With no treatment, runoff from these developments is expected to exceed Basin Plan acute copper and zinc criteria at the point of discharge and to deliver large pollutant mass loadings to receiving waters.

Conventional soil-based BMP solutions that promote and are component parts of low impact development approaches, by contrast, regain about 30-50 percent of the recharge lost in development without stormwater management in Bay Area locations having NRCS Hydrologic Soil Groups A, B, and C. It is expected the soil-based BMPs generally would release effluent that meets the acute zinc criterion at the point of discharge, although it would still exceed or just barely meet the copper limit. Excepting phosphorus, it was found that these BMPs would capture and prevent the movement to receiving waters of the majority of the pollutant loadings considered in the analysis.

It was found that by draining all site runoff to pervious areas with A, B, or C soil types, runoff can be eliminated entirely in most development categories. It follows that a three percent Effective Impervious Area standard can be met in typical developments, as well. This result was reached assuming the use of native soils or well recognized soil enhancement techniques (typically, with compost). Draining impervious surfaces onto these soils, in connection with limiting directly connected impervious area to three percent of the site total area, should eliminate storm runoff from some development types and greatly reduce it from more highly impervious types. Adding roof runoff elimination to the LID approach (by harvesting or directing it to downspout infiltration trenches) provides an additional tool, increasing flexibility and confidence that no discharge in most meteorological conditions is a feasible performance expectation. Even in the development scenarios involving the highest relative proportion of impervious surface, losses of rainfall capture for beneficial uses could be reduced from the untreated scenario when draining to pervious areas was supplemented with water harvesting. These results demonstrate the basic soundness of the concept of using LID techniques to reduce stormwater pollution in the Bay Area, and further show that limiting directly connected impervious area and draining the remainder over pervious surfaces, as contemplated by some Regional Water Boards in California, is also feasible.

SUPPLEMENTARY INVESTIGATION OF THE FEASIBILITY AND BENEFITS OF LOW-IMPACT SITE DESIGN PRACTICES ("LID") FOR THE SAN FRANCISCO BAY AREA

Richard R. Horner†

ABSTRACT

The Clean Water Act NPDES permit that regulates municipal separate storm sewer systems (MS4s) in the San Francisco Bay Area, California will be reissued in 2007. The draft permit includes general provisions related to low impact development practices (LID) for certain kinds of development and redevelopment projects. Using eight representative development project case studies, based on California building records, the author investigated the practicability and relative benefits of LID options for the portion of the region having soils potentially limiting to infiltration. The principal LID option applicable in this situation is roof runoff harvesting, supplement by dispersion of the roof water in single-home sites. Other site runoff would be treated by conventional stormwater best management practices (BMPs), as specified in the permit. The results showed that effectively managing roof runoff and treating the remainder with conventional BMPS can: (1) reduce annual runoff volumes by almost half to more than 3/4, depending on land use characteristics, with much of the water saved available for a beneficial use; and (2) decrease mass loadings of pollutants to receiving waters by 63 to over 90 percent, depending on pollutant and land use.

† Richard R. Horner, Ph.D., Research Associate Professor, University of Washington Departments of Civil and Environmental Engineering and Landscape Architecture; Adjunct Associate Professor, University of Washington Center for Urban Horticulture

INTRODUCTION

Background

A report titled Initial Investigation of the Feasibility and Benefits of Low-Impact Development Practices ("LID") for the San Francisco Bay Area used six representative development project case studies, based on California building records, to investigate the practicability and relative benefits of LID options for the majority of the region having soils potentially suitable for infiltration either in their natural state or after amendment using well recognized LID techniques. The results demonstrated that: (1) LID site design and source control techniques are more effective than conventional best management practices (BMPs) in reducing runoff rates; and (2) in each of the case studies, LID methods would reduce site runoff volume and pollutant loading to zero in typical rainfall scenarios.

For a broad regional assessment of relatively large scale use of soil-based, infiltrative LID practices, the initial report covered areas having soils in Natural Resources Conservation Service (NRCS) Hydrologic Soil Groups A, B, or C as classified by the Natural Resources Conservation Service (http://websoilsurvey.nrcs.usda.gov/app/WebSoilSurvey.aspx). Depending on site-specific conditions, A and B soils would generally effectively infiltrate water without modification, whereas C soils could require organic amendments according to now standard LID methods. This supplementary report covers locations with group D soils, which are generally not amenable to infiltration, again depending on the specific conditions on-site. A minority but still substantial fraction of the Bay Area has group D soils (39.3, 68.0, 18.3, and 50.1 percent of the mapped areas of Alameda, Contra Costa, San Mateo, and Santa Clara Counties, respectively). Regarding any mapped soil type, it is important to keep in mind that soils vary considerably within small distances. Characteristics at specific locations can deviate greatly from those of the major mapped unit, making infiltration potential either more or less than may be expected from the mapping. The soil survey data are regarded as appropriate for use in broad-scale assessments such as underlie this and the initial report, but once site-specific implementation begins, it is important to verify site conditions.

General Assessment Methods

The assessment for group D soils reported herein emphasizes the use of LID practices appropriate in areas with relatively restrictive soils to the greatest possible extent, supplemented by conventional stormwater management practices implemented at fully practicable, high levels of effectiveness. The assessment was performed in a manner analogous to the analysis for the other soil groups and as described in the initial report. To recap briefly, with respect to each of several development case studies, three assessments were undertaken: a baseline scenario incorporating no stormwater management controls; a second scenario employing conventional BMPs; and a third development scenario employing LID stormwater management strategies. In each assessment, annual stormwater runoff volumes were estimated, as well as concentrations and mass loadings (the products of concentrations times flow volumes) of four pollutants: (1) total suspended solids (TSS), (2) total recoverable copper (TCu), (3) total recoverable zinc (TZn), and (4) total phosphorus (TP). The results of the second and third assessments were expressed in terms of the extent to which the management practices would reduce pollutant concentrations and loadings and runoff volumes, converting stormwater discharge a potential beneficial use (direct consumption or, in the case of group A, B, C soil areas, groundwater recharge).

Six case studies were selected to represent a range of urban development types considered to be representative of the Bay Area. These case studies involved: a multi-family residential complex (MFR), a relatively small-scale (23 homes) single-family residential development (Sm-SFR), a restaurant (REST), an office building (OFF), a relatively large (1000 homes) single-family residential development (Lg-SFR), and a single home (SINGLE). The land cover types for these various land uses were derived from building permit and other public records from the Bay Area or elsewhere in California.

Adaptation of Methods for Areas with Group D Soils

A key LID technique in a setting with soils relatively restrictive to infiltration is water harvesting, which can be applied at larger scales in commercial and light industrial developments and at smaller residential scales using cisterns or rain barrels. Harvesting has been successful in reducing runoff discharged to the storm drain system and conserving water in applications at all scales. For example, in downtown Seattle the King County Government Center collects enough roof runoff to supply over 60 percent of the toilet flushing and plant irrigation water requirements, saving approximately 1.4 million gallons of potable water per year (http://www.psat.wa.gov/Publications/LID_studies/rooftop_rainwater.htm; http://dnr.metrokc.gov/dnrp/ksc_tour/features/features.htm). A much smaller public building in Seattle, the Carkeek Environmental Learning Center, drains roof runoff into a 3500-gallon cistern to supply toilets (http://www.harvesth2o.com/seattle.shtml). Collecting drainage from individual dwellings for household use is a standard technique around the world, particularly in areas deficient in rainfall and without affordable alternative sources.

An additional general category of LID practices for poorly infiltrating locations, applicable especially at single homes and other relatively small-scale developments, is runoff dispersion for storage in vegetation and soil until evapotranspiration and some infiltration occurs. Section C.3.c of the California Regional Water Quality Control Board San Francisco Bay Region "Administrative Draft" NPDES Municipal Regional Stormwater Permit ("the Permit") requires all single-family home projects that create and/or replace 5,000 square feet or more of impervious surface to implement one or more stormwater lot-scale BMPs from a selection of: (1) diverting roof runoff to vegetated areas; (2) directing paved surface runoff flow to vegetated areas; and/or (3) installing driveways, patios, and walkways with pervious material such as pervious concrete or pavers. Another way of distributing and dissipating roof runoff used successfully in varied soils in the state of Washington is the downspout dispersion system, consisting of a splash block or gravel-filled trench serving to spread roof runoff over a vegetated area (Washington Department of Ecology 2005 [Volume III, Section 3.1.2]).

The basis of the group D soils assessment was harvesting roof runoff to the maximum possible degree, supplemented in smaller-scale developments by runoff dispersion methods. The report asserts that, through these LID BMPs, it is practicable to prevent the entrance of any roof runoff into the municipal storm drain system in any soils setting in the Bay Area. In group D soils, infiltration likely cannot be relied upon to reduce runoff from other portions of developments, such as walkways, driveways, parking lots, access roads, and landscaping. Some water loss would undoubtedly occur, especially through evapotranspiration and at least some infiltration of runoff generated on or directed to landscaping. The analysis presented in this report does not take account of these losses and hence is somewhat conservative in estimating benefits.

As required by the Permit, any runoff not attenuated by harvest, evapotranspiration, or infiltration would be subject to quantity and quality controls. The analysis assumes that extended-detention basins (EDBs) with water residence times up to 72 hours would provide this control. EDBs are one of several general-purpose, conventional stormwater BMPs available for this service, others being wet ponds, constructed wetlands, sand or other media filters, and biofiltration swales and filter strips. The California Department of Transportation (Caltrans, 2004) tested the performance of all of these practices in its BMP Retrofit Pilot Program, conducted in San Diego and Los Angeles Counties. The initial report investigating LID for A, B, and C soils presented estimates of benefits for EDBs, swales, and filter strips, along with continuous deflective separation (CDS) units, a practice that effectively captures only large particulate pollutants. For brevity, this follow-up report focuses on just EDBs as the supplement to LID. In performance, EDBs tend to fall between swales and filter strips for total suspended solids, slightly lower than the other two BMP types for metals, and either between the two or comparable to swales for total phosphorus.

These practices were applied to the same six case studies used in the initial analysis and described in Table 1 of the first report. Two additional case studies were defined for the assessment reported here: a sizeable commercial retail installation (COMM) and an urban redevelopment (REDEV). The hypothetical COMM scenario consists of a building with a 2-acre footprint and 500 parking spaces. Parking spaces were estimated to be 176 sq ft in area, which corresponds to 8 ft width by 22 ft length dimensions. A simple, square parking lot with roadways around the four sides and a square building with walkways also around the four sides were assumed. Roadways and walkways were taken to be 20 ft and 6 ft wide, respectively. The REDEV case was taken from an actual project in Berkeley involving a remodel of an existing structure, built originally as a corner grocery store with apartments above and a large side yard, and the addition of a new building on the same site to create a nine-unit, mixed-use, urban infill project. Table 1 summarizes the characteristics of these two case studies. The table also provides the recorded or estimated areas in each land use and cover type.

Table 1. Characteristics and Land Use and Land Cover Areas of Added Case Studies

	COMM[a]	REDEV[a]
No. buildings	1	1
Total area (ft^2)	226,529	5,451
Roof area (ft^2)	87,120	3,435
No. parking spaces	500	2 uncovered
Parking area (ft^2)	88,000	316 uncovered
Access road area (ft^2)	23,732	-
Walkway area (ft^2)	7,084	350
Driveway area (ft^2)	-	650
Landscape area (ft^2)	20,594	700

[a] COMM—retail commercial; REDEV—commercial/residential infill

The assessment for group D soils employed the same methods as the earlier analysis to estimate annual stormwater runoff volumes and pollutant discharges. Please refer to the initial report for details on those methods. The Natural Resource Conservation Service (NRCS, 1986) methodology cited in that report was applied to estimate that infiltration in group D soils would be roughly 60 percent of the amount through landscaping or the bed of a conventional BMP in C soils, which were the basis for establishing runoff coefficients in the first analysis. While that initial analysis was performed for both 14- and 20-inch average annual runoff zones, typical of different Bay Area locations, this supplementary work covered only the former condition. This simplification was made in the interest of brevity in this report, given that the first analysis showed almost no difference in conclusions between the two situations.

RESULTS OF THE ANALYSIS

Table 2 provides a comprehensive summary of the results. Rows shaded in gray compare runoff and pollutant discharges with and without treatment by CDS units, which can capture relatively large solids but have no mechanisms for dissolved substances and the finer particles. Having no soil contact and very limited residence time for evaporation, this BMP cannot reduce runoff volume at all. It can achieve some substantial reductions in TSS and TP for land uses relatively high in landscaped area but little removal of metals, especially copper.

The blue-shaded rows show the performance of conventional EDBs. In the group D soils considered in this analysis, they were estimated to reduce annual runoff volumes by 13-23 percent, the higher values for land uses with relatively small impervious footprints (OFF and REST). These BMPs can capture the majority of the long-term mass loading of most pollutants from most land uses in these soils, falling below 50 percent in reducing metals in stormwater flowing from residential developments.

Rows shaded in green present the results of applying LID BMPs appropriate for group D soils, roof runoff harvesting supplemented by dispersion in single-home land uses, plus treating the remaining runoff with EDBs. Comparing annual runoff volumes with and without LID, it can be seen that removing roof runoff from the storm drain system affords very significant benefits in reducing surface discharge and putting much of that water to productive use. Compared to directing all site runoff to EDBs, LID is expected to reduce volume by almost 10 times in the REDEV case, by about five times for the various residential land uses, 3.6 times for the large commercial development, and around twice for the OFF and REST cases. This management strategy can recover over 3/4 of the stormwater that would otherwise go down the drain in the intense redevelopment case, approximately 2/3 for the multi- and single-family residential cases, over half in the COMM development, and almost half in the office and restaurant cases with relatively small roof footprints.

Reduction of volume translates to decreases in pollutant loadings also. The combination of LID and EDB treatment is estimated to raise copper and zinc reductions to about 70 to over 90 percent in all except the developments with relatively low roof proportions (60-65 percent in these cases). TSS predictions come in at a quite consistent 75-82 percent across land uses. Total phosphorus estimates are a similarly consistent 63-71 percent, a bit higher in the highly impervious REDEV case.

Effectively managing roof runoff gives a way out of the dilemma posed by group D soils in the Bay Area. The analysis has demonstrated that harvesting this runoff stream, supplemented by ground dispersion techniques with sufficient space, shows strong promise to reduce the majority of flow inputs to municipal storm drain systems while conserving water. Moreover, this strategy can also stem the majority of solids, copper, zinc, and phosphorus transport to receiving waters.

Table 2. Runoff Volume and Pollutant Loading Reductions with Conventional and Low-Impact Development (LID) Best Management Practices (BMPs) for Eight Land Use Case Studies in Hydrologic Group D Soils

SECTION 4: DESIGN EXAMPLES FOR THE CITY OF LOS ANGELES

This section provide specific examples of Green Street applications in the City of Los Angeles. The purpose of this section is to provide a broad range of siting and varying scale applications that can be reproduced in other suitable locations throughout the City.

RB-AR33210

Section
4.1

The design scenarios presented in this section illustrate different ways that vegetated swales, planters, pervious paving, infiltration trenches, stormwater curb extensions, canopy trees, and curb inlets can be applied to diverse settings within the City of Los Angeles.

GREEN STREETS AND PARKING LOTS

The design scenarios presented in this section illustrate different ways that vegetated swales, planters, pervious paving, infiltration trenches, stormwater curb extensions, canopy trees, and curb inlets can be applied to diverse settings within the City of Los Angeles. Designers and developers are encouraged to review these examples for ideas. Several "before and after" illustrations show the potential for green streets and parking lot retrofit opportunities in Los Angeles. The goal of illustrating multiple site strategies is to give the user of this guidebook a broad range of siting and varying scale applications that can be similarly reproduced throughout the region. The examples shown include some developed projects and some conceptual projects for reference only. Whether a particular site is located in a low or high-density residential neighborhood, a commercial "main street" district, along an arterial or boulevard street, or within a small or large parking lot, there are multiple stormwater design options available.

Section
4.1.1

OROS STREET

The Oros Streetend Biofiltration Project was implemented in the Elysian Valley neighborhood of northeast Los Angeles, California, along Oros Street between Blake Avenue and the Los Angeles River. Oros Street was designed to capture stormwater runoff from private homes and the street and allow for infiltration into the soil via stormwater gardens and an infiltration basin. Other benefits include the beatification of the neighborhood with new infrastructure and ample greenscape.

The Oros Street Project was a joint project between the City of Los Angeles and North East Trees with assistance from numerous agencies and community stakeholders. This keystone project serves as a model project for the Los Angeles Stormwater Program, demonstrating that creative restoration initiatives can provide multiple benefits by improving water quality, involving stakeholders such as NET and showing the City of Los Angeles is leading the way among major United States cities in using cutting edge design to curb stormwater pollution.

Utilizing new technology, the City's Bureau of Sanitation and Bureau of Street Services constructed five Stormwater Gardens along the street's corridor. The gardens are bioretention areas in the parkway that capture and infiltrate stormwater runoff. The park also assists in the removal of pollutants, serving dual functions for the neighborhood community. Runoff from the street is collected via two newly constructed catch basins and filtered through catch basin inserts before discharging into an underground detention/infiltration basin located underneath Steelhead Park for subsequent infiltration into the ground. Ultimately, this project resulted in zero discharge of stormwater (up to the design storm capacity) and urban runoff to the adjacent Los Angeles River.

First "Green Street" in Los Angeles is Completed

A National Model of Sustainability That Cleans Water Before Entering the Los Angeles River LOS ANGELES, CA – North East Trees and Los Angeles City Council President Eric Garcetti, joined by project partners and the neighbors, officially dedicated the first "Green Street" in Los Angeles on Oros Street at the Los Angeles River in Elysian Valley.

The Oros Green Street Project was designed to capture stormwater runoff from private homes and a residential street and clean it through a series of soil filtration and vegetative bioretention treatments before it ever gets into the Los Angeles River, while simultaneously

"This project marks the first time that a neighborhood can say that it is contributing no pollutants to the Los Angeles River because the Oros Green Street Project will clean water from this neighborhood before it enters the River"
— Larry Smith, Executive Director of North East Trees.

"This project is the new gold standard for how North East Trees and our project partners can transform and complete the cycle of restoring nature's services in an urban environment." "We need green streets to have a clean river,"

"Today we're demonstrating that a major goal of the LA River Revitalization Master Plan is within our reach, thanks to the collaboration between our city and North East Trees."
— Council President Eric Garcetti.

RB-AR33212

improving and beautifying a neighborhood with new infrastructure and greenscape. It is an eco-friendly and innovative model of sustainability that manages and cleans storm and dry weather runoff and pollutants that traditionally went directly to the stormwater system (or the Los Angeles River). "This project marks the first time that a neighborhood can say that it is contributing no pollutants to the Los Angeles River because the Oros Green Street Project will clean water from this neighborhood before it enters the River" said Larry Smith, Executive Director of North East Trees. "This project is the new gold standard for how North East Trees and our project partners can transform and complete the cycle of restoring nature's services in an urban environment."

"We need green streets to have a clean river," said Council President Eric Garcetti. "Today we're demonstrating that a major goal of the LA River Revitalization Master Plan is within our reach, thanks to the collaboration between our city and North East Trees."

The Oros Green Street Project was a collaboration mobilized by North East Trees with the City of Los Angeles, county, state and federal agencies as well as neighborhood resident stakeholders. It was funded through grants and services from the California Water Quality Control Board (over $500,000) and the City of Los Angeles' Proposition O Bond Act ($385,000) with close coordination and services from the Los Angeles Department of Public Works, Bureau of Street Services and Bureau of Sanitation. This project also marks the first Proposition O-funded project to be completed. This project also marks the first Proposition O-funded project to be completed.

11TH STREET

A commercial street in downtown Los Angeles at Hope Street near 11th Street was recently designed to capture runoff and infiltrate it through landscaped areas using drought tolerant plants. The purpose of the project is to capture, clean, and temporarily detain stormwater. Every 10 feet or so, the curbs are notched, leading to below-grade, rock-strewn planters filled with grasses, trees and flowers. This green street is a great example of how urban infrastructure can be converted to green infrastructure.

All three City agencies had to approve the newest infiltration planters at the privately developed Luma building, which opened on Hope Street in downtown Los Angeles in 2008. The gold-certified Leadership in Energy and Environmental Design building was co-developed by Gerding Edlen Development, a Portland, Ore., firm that has been incorporating infiltration planters in its buildings for several years.

The purpose of the project is to capture, clean, and temporarily detain stormwater.

RB-AR33214

4.1.3

RIVERDALE AVENUE

The Riverdale Avenue Green Street project was proposed with the goal of establishing a City standard to promote infiltration of street runoff and to promote runoff management.

Rendering of Riverdale Avenue Green Street Project

In the past year, the Green Streets Committee developed a draft pilot project list and selection criteria, and obtained funding from the Coastal Conservancy for a pilot project on Riverdale Avenue in Elysian Park. The Riverdale Avenue Green Street project was proposed with the goal of establishing a City standard to promote infiltration of street runoff and to promote runoff management. This project will demonstrate the use of storm water planters to treat and infiltrate storm water runoff, thereby providing water quality and flood control benefits. A primary goal of this project is to create a model for a new standard of residential street design to reduce the amount of storm water and urban runoff from streets.

The project will reconstruct the existing parkways on both sides of Riversdale Avenue between Crystal Street and its terminus at the south side of the Los Angeles River. The proposed parkway swales will be able to capture and treat urban runoff from 14.6 acres of residential land with the dual benefit of irrigating the parkway plants and infiltrating the street runoff and thereby protecting the Los Angeles River from the pollutants in storm water and urban runoff. Additionally, the planters will improve the existing urban streetscape by replacing grass parking strips with drought tolerant, native landscaping. The project will include signage to explain the purpose of the infiltration swales and the need to protect the Los Angeles River from polluted urban and storm water runoff.

BIMINI SLOUGH

Section
4.1.4

In this part of Los Angeles, parks are in short supply, and there are 1,000 residents for every one-third of an acre of green space.

Project location

The Bimini “Slough” Ecology Park Project (pronounced "slew"), meaning that it is low land, i.e. a marsh area where runoff water from surrounding hills collects on a rainy day. The 20,000 square feet park covers what was previously Second Street between South Bimini Place and Juanita Avenue (near the intersection of Vermont Avenue and Third Street). In this part of Los Angeles, parks are in short supply, and there are 1,000 residents for every one-third of an acre of green space. This park is the Bresee Foundation's gift to the community.

Project Description

The Bimini Slough Ecology Park was completed in 2004 to be enjoyed by all those living in the neighborhood near the Bresee Community Center. This park, previously one city block, was restored to the natural Sacatella Creek that years ago flowed through here before the city grew and its waters were diverted. The Project addresses not only the need for green space, but also serves as a model for addressing key environmental issues.

The park was designed to highlight this characteristic and incorporate into it several features beneficial to the environment. The Project consists of three primary components:

- A state-of-the-art drip irrigation system, which will minimize water usage;
- A selection of plants and trees native to the area which will provide color and require little water; and;
- A bio-filtration vegetated 180-ft swale. Helped by its vegetation and trash interceptor, the swale will serve as a filter for storm water runoff and will eliminate pollutants from the water before it enters the ocean.

Targeted Pollutants

The Project will treat runoff from the surrounding community and targets the following pollutants:

- Bacteria - Trash
- Metals - Oil & Grease

GREEN PARKING LOTS

Section
4.1.5

Green parking lots reduce runoff that is discharged into local water bodies by using permeable paving and natural drainage landscapes.

Project Funding

The Project was a gift from the Breese Foundation with in-kind services from the Metropolitan Water District, City of Los Angeles, Department of Public Works, Bureau of Sanitation, and North East Trees.

Green parking refers to several techniques applied together to reduce the contribution of parking lots to the total impervious cover in a lot. Green parking lots reduce runoff that is discharged into local water bodies by using permeable paving and natural drainage landscapes. From a stormwater perspective, application of green parking techniques in the right combination can dramatically reduce impervious cover and consequently, the amount of stormwater runoff. Green parking lot techniques include setting maximums for the number of parking lots created, minimizing the dimensions of parking lot spaces, utilizing alternative pavers in overflow parking areas, using bioretention areas to treat stormwater, and encouraging shared parking.

Utilizing alternative pavers is an effective green parking technique. They can replace conventional asphalt or concrete in both new developments and redevelopment projects. Alternative pavers can range from medium to relatively high effectiveness in meeting stormwater quality goals. The different types of alternative pavers include gravel, cobbles, wood mulch, brick, grass pavers, turf blocks, natural stone, pervious concrete, and porous asphalt. In general, alternate pavers require proper installation and more maintenance than conventional asphalt or concrete. (Refer to permeable paving fact sheets in the guidelines).

Bioretention areas can effectively treat stormwater in a parking lot. Stormwater is directed into a shallow, landscape area and temporarily detained. The runoff then filters down through the bed of the facility and is infiltrated into the subsurface or collected into an underdrain pipe for discharge into a stream or another stormwater facility. Bioretention facilities can be attractively integrated into landscaped areas and can be maintained by commercial landscaping firms. (Refer to bioretention-related fact sheets in the guidelines).

5 Steps Toward A Green Parking Lot

1. Determine native soil infiltration rate.
2. Determine the direction of stormwater flow and where it needs to be collected.
3. Determine opportunities for incorporating permeable pavement and natural drainage landscapes.
4. Determine the required dimensions for natural drainage landscape areas and ensure that the receiving area is sufficient and practical.
5. Identify location of overflow structure and where the structure is to be connected to the storm drain system.

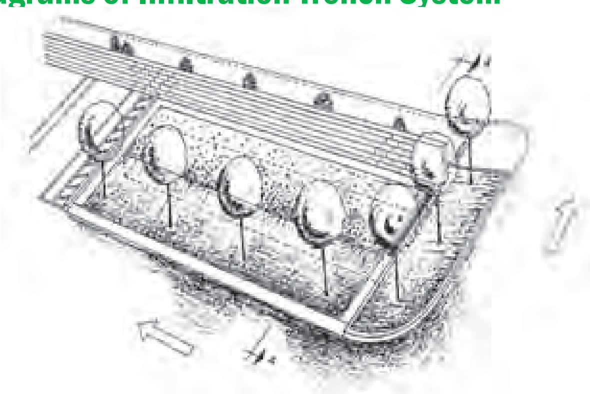
RB-AR33218

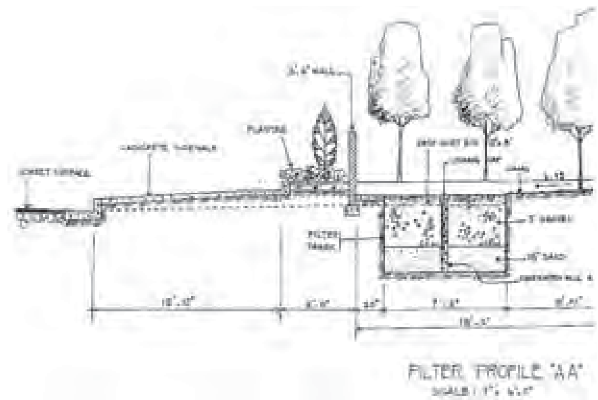
A green parking lot can prevent pollution at the source, remove pollutants before runoff is discharged, control discharge rates of stormwater runoff, and provide a pleasant parking experience. Green parking lots may save capital and maintenance costs and will enhance protection of downstream water bodies.

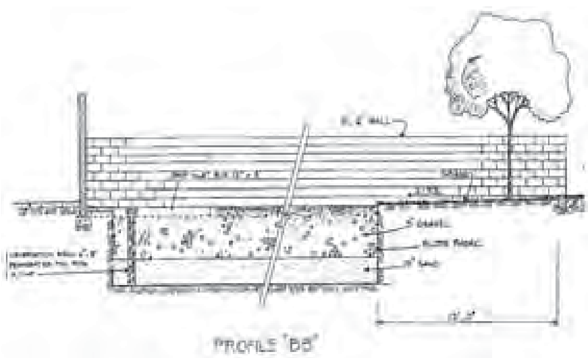
Venice Parking Lot

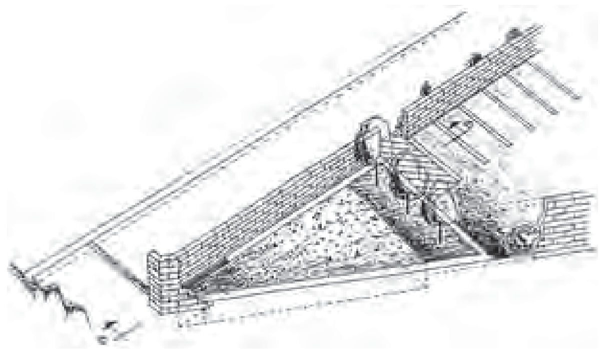
An infiltration trench system was implemented in a city parking lot at the intersection of Venice Blvd and Dell Ave in the Venice Beach Area. There were nine infiltration trenches constructed in this 1.5 acre parking lot. The system captures and infiltrates the beach parking lot runoff measuring 5,253 cubic feet or 39,295 gallons. The dimensions of the trench are: 15′ l X 5.3′ w X 4.5′ d; it includes a gravel bed as well as a sand filter.

Diagrams of Infiltration Trench System







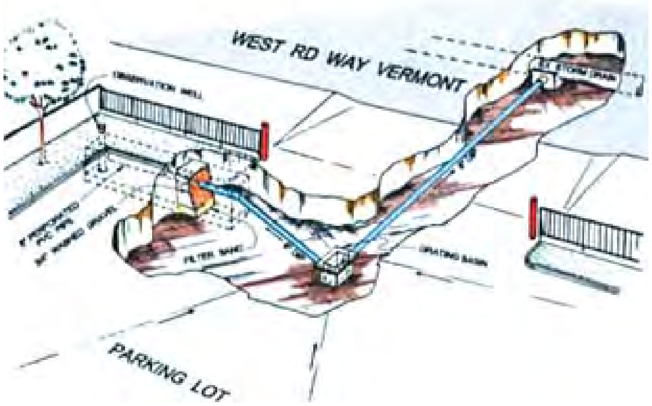


Construction of the Infiltration Trench

Finished Infiltration Trench

Constituent Parking Lot

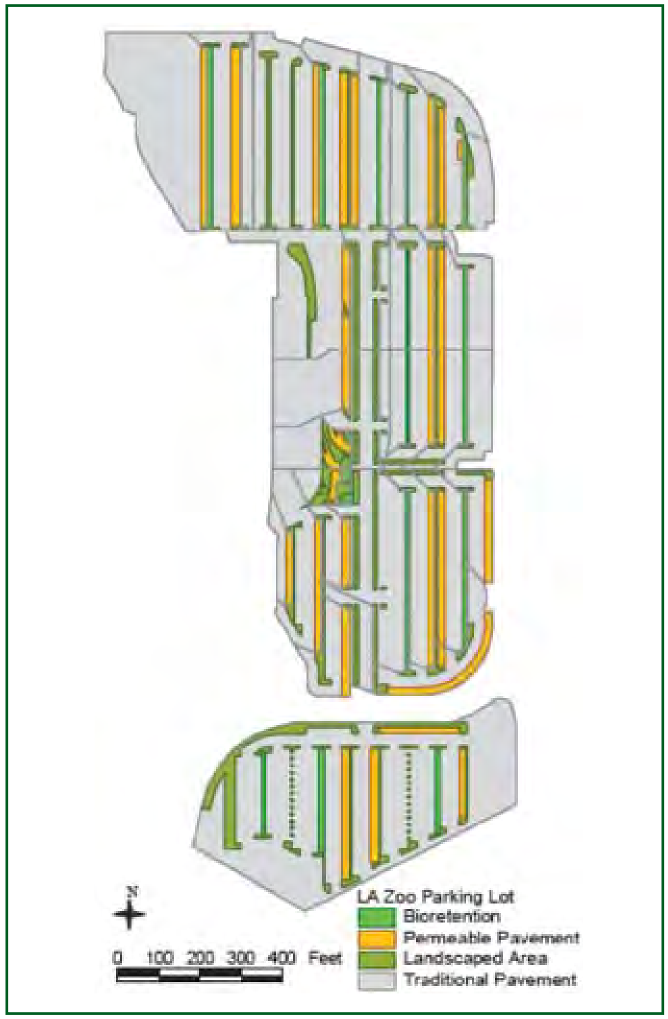
Another infiltration trench example can be found in the Constituency Center parking lot in Los Angeles City Council District 8.



LA Zoo Parking Lot

The Los Angeles Zoo Parking Lot Project is a Proposition O project that involves water quality improvement and sustainable design. The 134-acre Los Angeles Zoo, located in the northeast corner of Griffith Park, is owned and operated by the City of Los Angeles. The zoo's main parking lot consists of 33 acres of impervious, failing asphalt concrete pavement. Surface water from the parking lot and Zoo Drive flows to a storm drain that empties directly into the Los Angeles River. This water has the potential to contribute trash, heavy metals, pathogens, total suspended solids, oil and grease, and gasoline to the Los Angeles River Watershed.

The Zoo Parking Lot Project will renovate the Zoo's existing main parking lot to provide additional infiltration, runoff reduction, and pollutant loading control through implementation of Low Impact Development (LID) concepts and Best Management Practices (BMPs). Low impact development concepts and BMPs that will be incorporated into the project include permeable pavement and bioretention cells.



The permeable pavement will filter the storm water to remove pollutants before being discharged to the existing underground storm water system. The bioretention cells will provide the same filter removal process as the permeable pavement with underground storage, but will incorporate native plants above the surface that will aid in evapotranspiration of the stormwater. Landscaping will be provided to meet the City's goal of one tree per four parking stalls. Native and naturalized vegetation will be implemented so that the parking lot blends well with the Zoo and its surroundings. The Los Angeles Zoo Parking Lot Project can even assist in the revival of Griffith Park, which was affected by recent wildfires.

In addition, the project will provide a "first exhibit" educational experience, improve the parking lot circulation and repair the parking lot surfaces. The goal of the project is to become the Zoo's first exhibit achieving a "Demonstration on Environmental Sustainability." It will act as a model that can be

GRAND AVENUE TREE WELLS

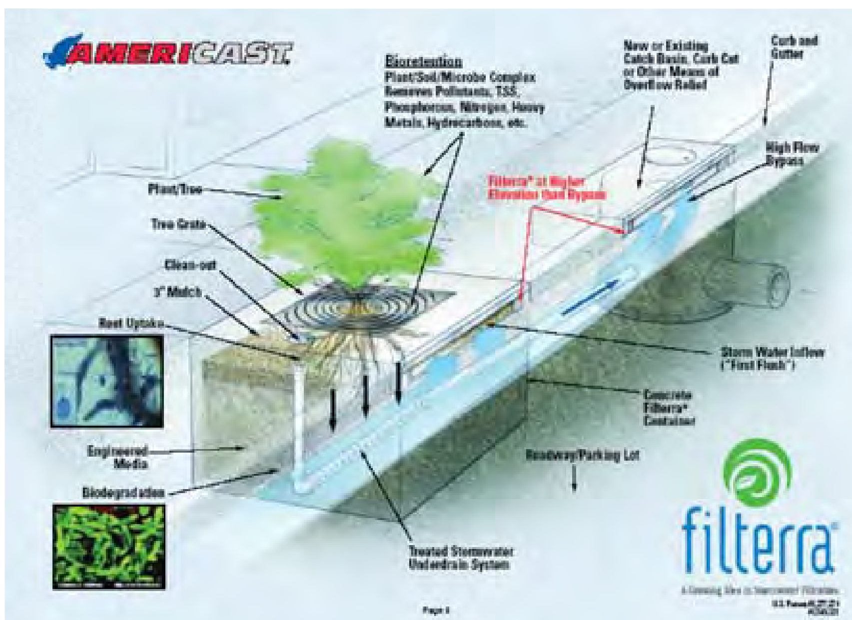
The Grand Avenue Tree Well project targets a 5-acre high-density residential and commercial corridor in the Venice area by installing seven stormwater bioretention filtration BMPs.

replicated throughout the City, multiplying the Los Angeles Zoo Parking Lot's water quality benefits many times over.

The Grand Avenue Tree Well project targets a 5-acre high-density residential and commercial corridor in the Venice area by installing seven stormwater bioretention filtration BMPs. The project site is considered a "hot spot" in Santa Monica Bay Watershed. Dry weather flow and a portion of the wet weather flow along Abbot Kinney Blvd and Grand Ave. will be diverted and treated using the Filterra Stormwater Bioretention Filtration System® before it enters the storm drain, thus eliminating trash, bacteria, metals, and TSS discharges to the Bay.

Goals

- Reduces the size and cost of downstream stormwater control facilities by infiltrating stormwater in upland areas.
- Reduce downstream flooding and protect stream bank integrity
- Reduce downstream pollutant loading
- Increases beneficial and recreational uses of receiving waterbodies
- Reduce potential for human safety and health risk



In general, Bioretention Systems can be described as shallow, landscaped depressions commonly located in parking lot islands or within small pockets in residential areas that receive stormwater runoff. Stormwater flows into the bioretention area, ponds on the surface, and gradually infiltrates into the soil bed. Pollutants are removed by a number of processes including adsorption, filtration, volatilization, ion exchange and decomposition (Prince George's County, MD, 1993). Filtered runoff can either be allowed to infiltrate into the surrounding soil (functioning as an infiltration basin or rainwater garden), or collected by an under-drain system and discharged to the storm sewer system or directly to receiving waters (functioning like a surface sand filter). Runoff from larger storms is generally diverted past the area to the storm drain system.

Incorporate the Concept of "Green" BMPs

- The project is consistent with the Low Impact Development (LID) concept by incorporating distributed small-scale green BMPs as opposed to a large conventional structural BMP.
- Consistent with the Mayor's million tree initiatives by incorporating trees/plans into the stormwater quality treatment system.
- Consistent with the "Green Street" initiative by providing landscape along street corridors and increasing the aesthetics values for the area.

RB-AR33222

SECTION 4.2: GREEN ALLEYS

Simple infrastructure changes such as using permeable pavement or adding bioswales in alleys will reduce urban runoff, recharge groundwater, and improve water quality in streams, rivers, and coastal waters.

Section
4.2.1

HATTERAS/EMELITA STREET RENDERING

Simple infrastructure changes such as using permeable pavement or adding bioswales in alleys will reduce urban runoff, recharge groundwater, and improve water quality in streams, rivers, and coastal waters. The following pictures illustrate the potential to transform an existing Los Angeles alley after green infrastructure principles are applied:

The Los Angeles Department of City Planning's Urban Design Studio recently prepared a report for green alleys entitled, "An Exploration of Green Alleys for Los Angeles for the Green Streets Committee." The case studies examined in this report explored the potential to green two alleys in the North Hollywood area of Los Angeles.

In the following scenario, permeable pavers and Grasscrete creates an inviting "Hollywood driveway." (Grasscrete is an interlocking concrete system with grass that grows between it, able to withstand the weight of garbage trucks as well as traffic from the residential parking areas.)

Existing conditions, alley east of Vineland Avenue between Hatteras and Emelita Streets in Los Angeles

Rendering of the greened alley, featuring a "Hollywood driveway" with Grasscrete and permeable pavement, as well as drought-resistant landscaping and energy efficient streetlights.

The alley is also planted with drought-resistant landscaping on the left, which further helps filter stormwater runoff. Additionally, to encourage non-automotive traffic down the alley, energy-efficient pedestrian scale streetlights have been added.

Simple infrastructure changes such as using permeable pavement or adding bioswales in alleys will reduce urban runoff, recharge groundwater, and improve water quality in streams, rivers, and coastal waters.

CANOPY TREES

In 2008, the Million Trees Los Angeles initiative engaged tens of thousands of individuals, businesses, and community groups in tree planting and maintenance — increasing L.A.'s annual tree planting tenfold and creating a legacy of environmental activism.

Million Trees Los Angeles: A City Of Los Angeles Green Initiative

In September 2006, Mayor Antonio Villaraigosa announced his plan to plant one million trees over several years. In 2008, the Million Trees Los Angeles initiative engaged tens of thousands of individuals, businesses, and community groups in tree planting and maintenance -- increasing L.A.'s annual tree planting tenfold and creating a legacy of environmental activism. Many of the trees have been planted in parkways, creating green streets across the City. In 2009, The City of Los Angeles received an Environmental Award from the U.S. EPA's Pacific Southwest office in recognition of this program.

Keystone Projects

Balboa Boulevard Signature Project - An MTLA signature planting project was completed, this time along Balboa Boulevard, a major San Fernando Valley transportation corridor. The area received 78 street trees of various species, such as crape myrtle, sweet shade, gingko and atlas cedar. The project will benefit area residents and students that go to Birmingham High School, Mulholland Middle School, the West Valley Special Education Center, and the Hi Tech High School. The Balboa Boulevard signature project was made possible by the collaborative effort of MTLA, the Air Quality Management District (AQMD), and the Los Angeles Conservation Corps.

Jefferson Boulevard Signature Project

As part of the Mayor's South Los Angeles Day of Service on September 20th, 47 more trees were planted in the South Los Angeles area, particularly along Jefferson Boulevard from Crenshaw Boulevard to Hillcrest Drive. The partnership of MTLA, AQMD and the Koreatown Youth and Community Center is responsible for the Jefferson Boulevard signature project.

SECTION 5: IMPLEMENTING GREEN STREETS AND PARKING LOT PROJECTS

This section provides practical guidance in the implementation of Green Street and parking lot projects in terms of reducing project costs, creating incentives, reaching the public, and understanding project scale.

RB-AR33226

SECTION 5 IMPLEMENTING GREEN STREETS AND PARKING LOT PROJECTS

It is anticipated that the Bureaus of Sanitation, Street Services and Engineering, as well as the Community Redevelopment Agency, will include green streets elements into all new and pending street capital improvement projects involving parkways, sidewalk or median construction or reconstruction.

Following implementation of the design guidelines, it is anticipated that the Bureaus of Sanitation, Street Services and Engineering, as well as the Community Redevelopment Agency, will include green streets elements into all new and pending street capital improvement projects involving parkways, sidewalk or median construction or reconstruction. The City Planning Department will incorporate Green Streets policy and concepts into the General/Community Plans. In this section of the Green Streets Guidelines, specific methods to implement green streets and parking lots into the City of Los Angeles are explored. Topics covered include reducing implementation costs, creating incentive programs, providing public education and outreach, and choosing demonstration projects.

RB-AR33227

Section
5.1

REDUCING PROJECT COSTS

The City of Los Angeles has numerous opportunities to retrofit the existing built environment, therefore, the overall goal should be to reduce costs as much as possible and to deliver additional stormwater related benefits when applying design solutions. In general, retrofitting green streets and parking projects is more costly than implementing new development projects simply because the former has site constraints that must be addressed. For example, there are often extra costs associated with removing existing concrete or asphalt in order to make way for new green space. In some cases, using a "green" approach might cost more, but the ancillary benefits (such as traffic calming, improved neighborhood aesthetics, and a safer pedestrian environment) often outweigh the costs. The following describes four ways to reduce costs when implementing green street and parking lot projects:

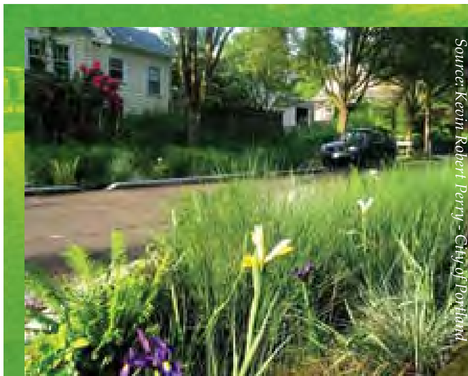

Figure 5.1: NE Siskiyou Green Street in Portland, Oregon avoided alterations to the existing storm pipe infrastructure and was therefore built cost-effectively.

Minimize Existing Impacts

One way to reduce construction costs is to minimize the impact to the existing storm drain infrastructure as much as possible and maintain existing storm drain inlet locations. Altering drain inlet locations and installing new storm drains at intersections can be very cost prohibitive in some projects. In many cases, stormwater facilities constructed up-gradient of existing storm drain inlets may require little, if any, alteration to infrastructure. Many green streets projects in Portland, Oregon were built inexpensively because they minimized impacts to the existing piped infrastructure. For example, the NE Siskiyou Green Street project installed two stormwater curb extensions just upstream of the existing stormwater drain inlets and never touched the existing storm infrastructure. By avoiding any such impact, the project's overall costs were reduced significantly.

Look for High-Opportunity Projects

When searching for cost effective green street projects, look for candidate sites that have minimal site constraints and maximum space for stormwater facilities. In some cases, available landscape space can be easily regraded and planted to provide stormwater management. In other cases, there are streets and parking lots that have excess asphalt area that can be converted into a stormwater facility at minimal cost. High-opportunity projects also include street and parking lot projects that have willing stakeholders, agencies, owners, or neighbors that can help provide advocacy or funding for a particular project.

Combine Green Streets with Other Street Improvements

Continual capital improvements are needed to maintain street longevity. Asphalt paving often needs to be replaced; curbs, sidewalks, and utility lines need to be repaired; and overall traffic/pedestrian improvements are constantly being planned. The most opportune time to incorporate a green street element is when a street is already planned and budgeted for improvement. Coordinating the efforts between regular street

RB-AR33228

improvements and green street improvements can help reduce the cost of green street implementation by achieving positive economies of scale. In many situations, green street projects can be integrated and budgeted as part of solutions for local traffic problems. For example, stormwater curb extensions can help narrow street widths, provide traffic calming benefits, and potentially be paid for by a non-green street-related budget.

Keep Design Solutions Simple

During the design phase of green street and parking lot projects, it is important to keep the design as simple as possible. Highly engineered design solutions can often increase project costs. Green streets should rely on a natural, landscape-approach to stormwater management. A component that is often over-designed in green street and parking lot construction is the means by which water gets in and out of landscape stormwater facilities. Overdesigned inlet structures not only increase project costs, but they often detract from the aesthetics of a project. Keeping the design simple and allowing water to surface flow in and out of stormwater facilities will help keep costs more manageable. Likewise, using only surface overflow to an existing downstream storm drain inlet, when possible, can simplify a project's design and greatly reduce costs. Another effective cost saving strategy is to limit the amount of imported hardscape materials. For example, it may seem advantageous to use deeper concrete walls to facilitate greater ponding depth, but the marginal benefit compared to shallower stormwater facilities, which require fewer resources, may not justify the additional expense. With larger construction projects, the designer should balance the total cut and fill on a project. It can be expensive to excavate, haul, and dispose of excess soil.

RB-AR33229

Section
5.2
CREATING INCENTIVES

There are several options for creating incentives for municipalities and property owners to retrofit green streets or parking lots.

There are several options for creating incentives for municipalities and property owners to retrofit green streets or parking lots. As described below, these incentives can be classified into three different categories: reward-based incentives, mandate-based incentives, and community-based incentives.

Reward-based Incentives

Reward-based incentives compensate a developer or property owner for incorporating green street and parking lot elements into their project. This type of incentive may include utility fee discounts, tax benefits, project grant funding, or even expedited review of development proposals. Reward-based incentives are particularly applicable to private development associated with parking lot projects. However, when private development occurs in conjunction with public streets, reward-based incentives can also apply. An example of a reward-based incentive is the City of Portland's Clean River Rewards Discount Program that allows up to a 35% reduction in residential or commercial stormwater utility fees for employing certain landscape-based stormwater management strategies on-site.

Mandate-based Incentives

This type of incentive require a developer or property owner to employ green street and/or parking lot strategies or their on-site stormwater management fee will be levied or increased. Mandate-based incentives can result in a more wide-spread application of green street and parking lot projects, but they can also set a more negative tone to a positive effort. Mandate-based incentives may also create a burden for municipal staff by creating a larger green street and parking lot program than originally anticipated.

Community-based Incentives

Many neighborhoods and business districts see the value of "greening" their environment in terms of improving quality of life, increasing property values, and increasing business profits. Local neighborhoods are often willing to combine resources and help pay for a green street project, or agree to undertake long-term maintenance, or simply provide advocacy for a municipality's green street efforts. One way to bring to bear full community resources is to form a community benefit district. Such an entity is comprised of a network of businesses and other property owners within a defined area who voluntarily agree to pay additional property tax in order to finance capital improvements and services that enhance, but do not replace, those provided by the city. Alternatively, parking benefit districts serve the same function, but derive their funding from on-street parking meters or non-resident parking passes. General problem-solving is another common form of community-based incentives. For example, green street and parking lot projects have the potential to reduce neighborhood flooding, provide traffic calming, and provide pedestrian safety benefits. Communities are more inclined to endorse and provide incentives toward green street projects when they are part of a more comprehensive solution to neighborhood problems.

5.3 PUBLIC EDUCATION AND OUTREACH

Source: Nevue Ngai Associates

Figure 5.2: A green street public workshop describes several options for retrofitting a boulevard

One of the best tools for successful stormwater management is educating the general public. There is a lot of confusion and misconceptions about using various stormwater management strategies. People sometimes think of stormwater facilities as "swamps" or "mosquito nests" and are unaware of well-designed stormwater facility examples. Likewise, people may not realize well-designed stormwater facilities can look just as good as conventional landscapes. Therefore, it is important to show the general public specific examples of successful demonstration projects (local or otherwise) in order to assure them that stormwater facilities can help protect the environment and can also provide a unique and attractive neighborhood amenity. There are several ways to promote stormwater education and outreach, such as:

- Conduct public tours of successful stormwater projects built in the local area, including field trip tours for school children who would like to learn more about environmental sustainability.
- Offer public meetings/workshops on the topic of sustainable stormwater management. Provide specific education materials that explain how well-designed stormwater facilities should not allow any prolonged periods of standing water that promote mosquito breeding.
- Send out brochures or provide fact sheets that describe different ways to manage stormwater runoff.
- Install interpretative signs for key stormwater demonstration projects. The signs should describe the particular elements of a project and where to find more information.

RB-AR33231

DEMONSTRATION PROJECT APPROACHES

Section
5.4

Green street and parking lot demonstration projects can be selected and designed using one or a combination of three approaches. Depending on the approach taken, demonstration projects can range from small to large, retrofit to new construction, and simple to complex.

Strategic Approach

This approach locates stormwater facilities intermittently, but strategically, to provide the most efficient level of stormwater management. Because this approach uses smaller facilities, it tends to be the least expensive to construct and maintain. This approach is widely used for retrofitting existing streets. One example of this approach is the SW 12th Avenue Green Street in Portland, Oregon (Figure 5-3).

Opportunity Approach

This approach locates stormwater facilities in areas where there are very few constraints and that offer high demonstration value. By using this approach, under-utilized landscape or impervious areas are converted into stormwater facilities of any size. One example of this approach is the five rain gardens located along NE Sandy Boulevard in Portland, Oregon (Figure 5-4).

Full-Integration Approach

This green street approach integrates the entire street frontage for stormwater management. A full-integration approach offers the most stormwater management benefits, but it is usually the most expensive to build and maintain. This approach is most compatible with new construction projects or if a street is planned to be completely rebuilt. An example of this approach is the Street Edge Alternatives in Seattle, Washington (Figure 5-5).

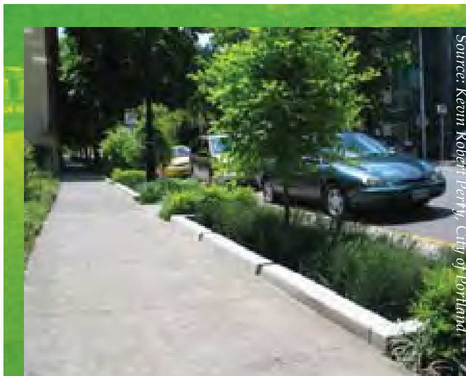

Figure 5-3: Portland's SW 12th Avenue Green Street project utilizes a strategic approach in placing smaller stormwater facilities intermittently along the streetscape

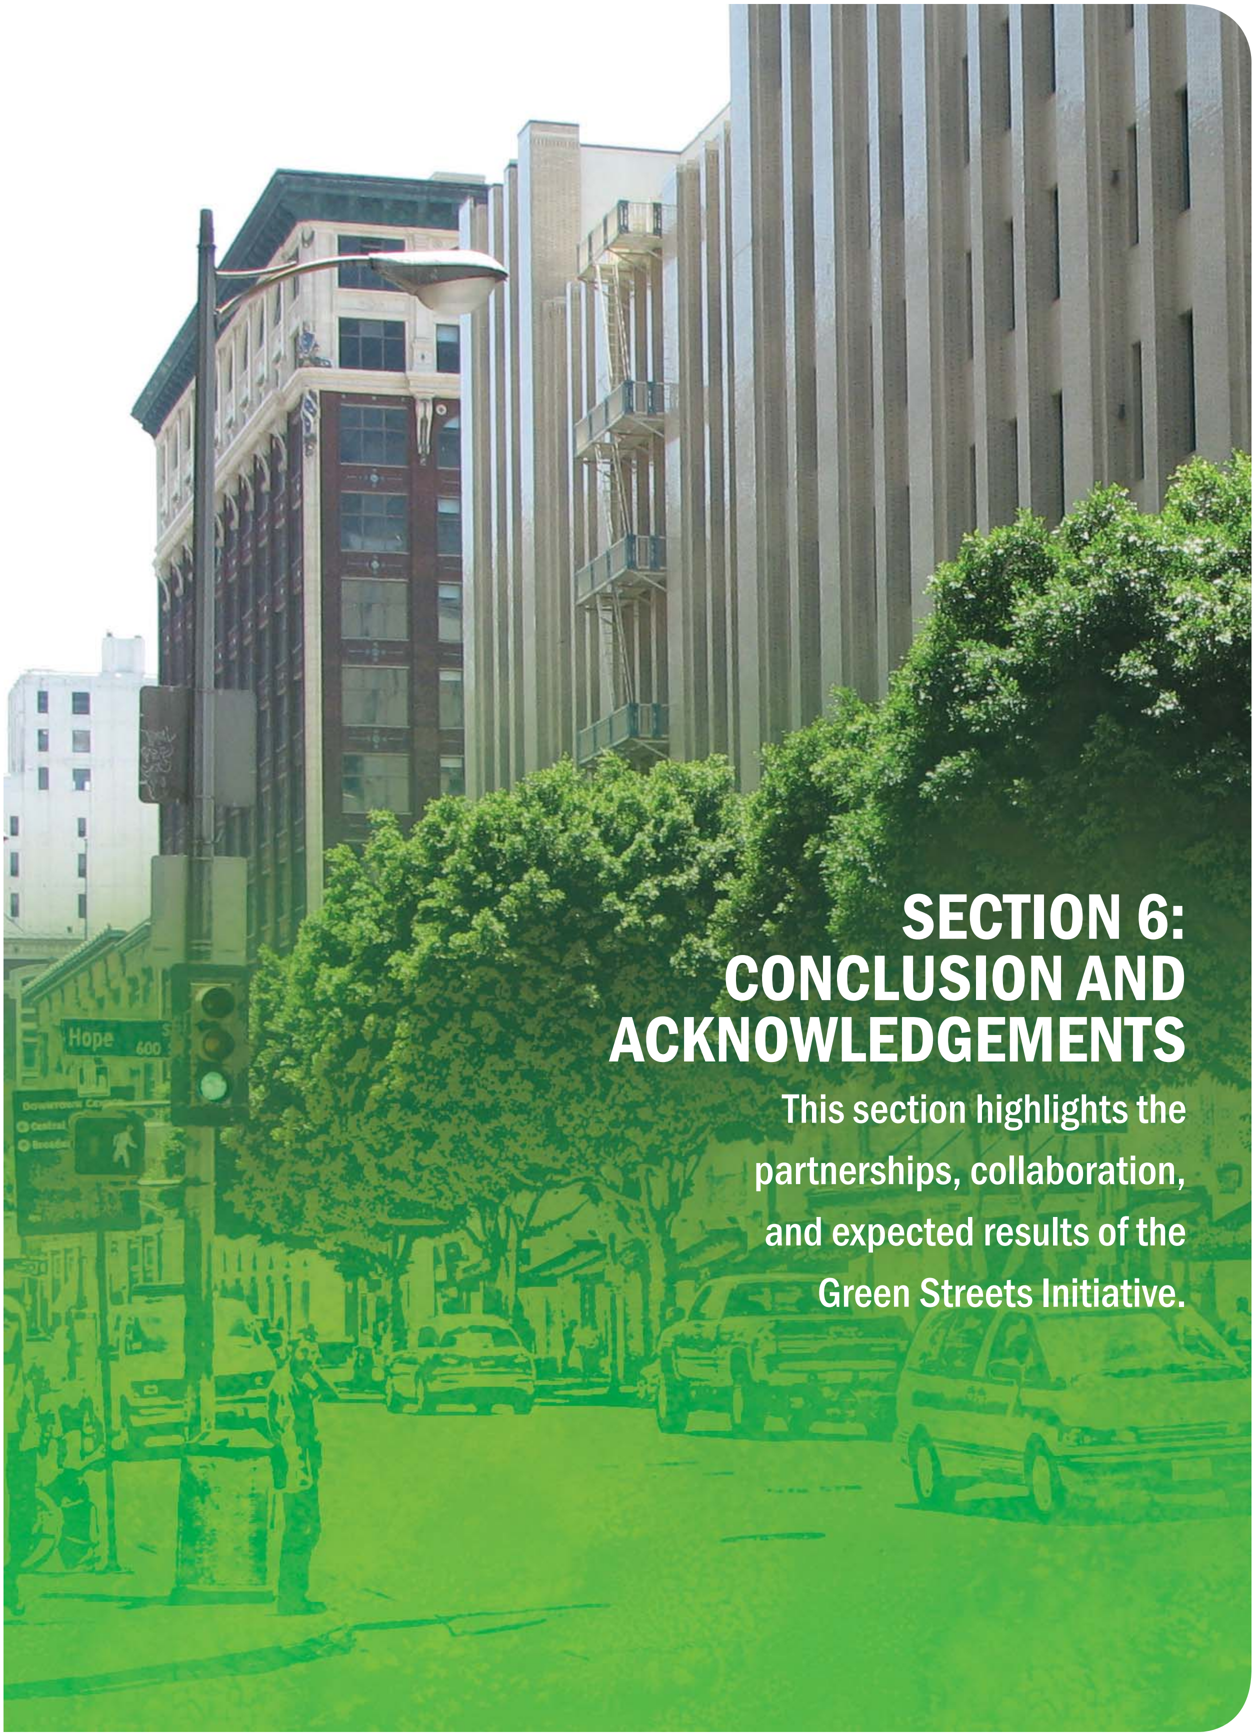
Figure 5-4: The five rain garden projects located along NE Sandy Boulevard in Portland are located where the site constraints were minimal

Figure 5-5: When a street is completely reconstructed, such as the Street Edge Alternatives (SEA) Streets in Seattle, Washington, the project uses a full-integration approach.

RB-AR33232

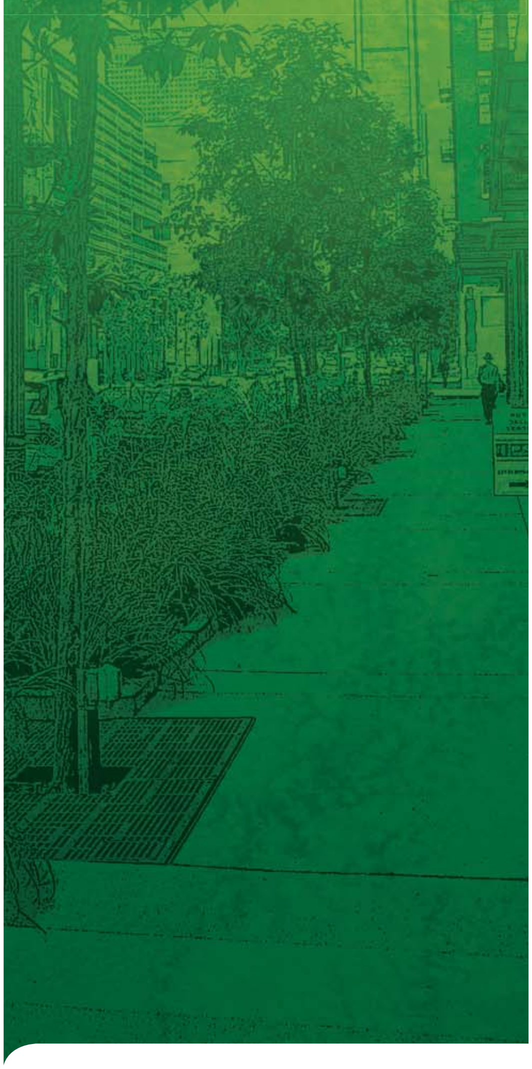


SECTION 6: CONCLUSION AND ACKNOWLEDGEMENTS

This section highlights the partnerships, collaboration, and expected results of the Green Streets Initiative.

SECTION 6: CONCLUSION AND ACKNOWLEDGEMENTS

The success of a Green Streets Initiative requires a partnership between all implementing departments, including Bureaus of Sanitation, Engineering, and Street Services.



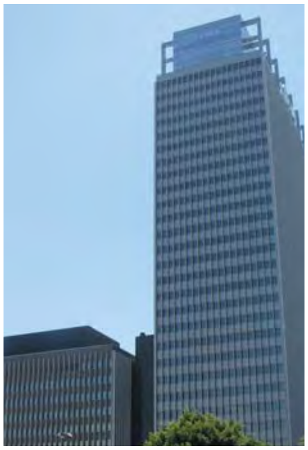
Conclusion

The success of the Green Streets Initiative requires a partnership between all implementing departments, including the Department of Public Works' Bureaus of Sanitation, Engineering, and Street Services; the Departments of City Planning, Environmental Affairs, Water and Power, and Transportation; and the Community Redevelopment Agency. Next steps in implementing a Green Streets Initiative in Los Angeles include completion of successful demonstration projects. The City's capital improvement program for new roadway construction projects would typically employ traditional end-of-line treatment systems which could require large amounts of land. The Green Streets Initiative takes an alternate approach to the traditional structural treatment systems by exploring public right-of-ways where infiltration swales or other types of pervious surfaces can be constructed to collect, retain, or detain storm water runoff. This "Green Streets" approach embraces a more regional, sustainable solution with multiple beneficial uses and is consistent with the Low Impact Development (LID) concepts, which looks at and identify opportunity sites within the upper watershed to implement small scale, low cost solutions. In addition, it is expected that the new Los Angeles County NPDES Permit will require storm water mitigation for roadway construction projects.

This initiative will also help conserve the City's limiting and ever-decreasing water supply. Water use in the City of Los Angeles in the 2007-2008 fiscal year exceeded 650,000 acre-feet. While demand continues to grow, recent drought years have put a tremendous strain on the City's water supply. To address this problem, the City's Department of Water & Power implemented a plan to enhance storm water capture and expand ground water storage. This Green Street initiative will help the City achieve water conservation goals identified in the plan.

The Green Street Initiative will address the new NPDES Permit requirements, reduce stormwater runoff, improve water quality, supplement the City's water supply via groundwater recharge (where applicable), improve air quality through reduction of heat island effects from street pavement, and provide a more aesthetically pleasing environment.

RB-AR33234



Acknowledgments

The Green Streets Initiative program appreciates all who contributed to this guidebook standard, which was developed by the City of Los Angeles Bureau of Sanitation with guidance from the Board of Public Works, the Green Streets Committee, and input from the Public Works and Energy and Environment Committees of the Los Angeles City Council. SECTION 1

INTRODUCTION

1.1 Introduction

The Construction Site Best Management Practices (BMP) Manual (BMP Manual) has been prepared by the Los Angeles County Department of Public Works (LACDPW) Construction Division to assist Contractors in the process of selection and implementation of construction site BMPs. This BMP Manual includes the LACDPW requirements for the implementation of construction site BMPs. As site conditions change or as deemed necessary, LACDPW may impose additional construction site BMPs for contractor activities. Additional BMPs may be included in the project's contract Special Provisions or may be required by the LACDPW Engineer (Engineer).

LACDPW has developed a program to control runoff from construction sites. The program requires Contractors to implement an effective combination of BMPs to protect water quality as identified in Table 1-1.

Table 1-1

Water Quality Protection Requirements

Category	Requirements	BMP Section of Manual
Soil Stabilization	Erosion from disturbed soil and concentrated flows shall be prevented by implementing appropriate BMPs, such as limiting grading and excavation during the wet season, diverting run-on, controlling runoff, slowing and spreading flows, breaking up disturbed areas with linear barriers and covering erosion susceptible areas.	Section 3
Sediment Control	Sediment shall not be discharged offsite, to the storm drain system or receiving waters. Sediments generated on the project shall be retained by implementing appropriate BMPs.	Section 4
Wind Erosion Control	Prevent wind erosion and dust by applying water or other dust palliatives or by covering as necessary.	Section 5
Tracking Control	Prevent or reduce tracking of sediment and prevent sediment from discharging to paved surfaces, offsite or entering storm drains or watercourses.	Section 6
Non-Storm Water	Non-storm water shall be retained on the construction site and shall be prevented from discharging to the	Section 7

Management	ground, offsite, or entering storm drains or watercourses. BMPs will be implemented to prevent non-storm water discharges.	
Waste Management & Material Pollution Control	Construction-related materials and waste shall be protected from contact with precipitation and run-on and runoff. Spills, leaks or residues shall be cleaned up immediately and all materials and waste shall be prevented from coming in contact with water or from being discharged to the ground, or discharged from the site or to the storm drain system.	Section 8

1.2 Organization of this BMP Manual

The organization of this BMP Manual is as follows:

- Section 1: Introduction – identifies the purpose and use of this BMP Manual, including a brief discussion of the regulatory framework and permits associated with the LACDPW storm water pollution prevention program.

- Section 2: Selecting and Implementing BMPs – provides the process for the selection and implementation of construction site BMPs.

- Section 3: Temporary Soil Stabilization – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Temporary Soil Stabilization BMPs and Concentrated Flow Conveyance BMPs.

- Section 4: Temporary Sediment Control – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Temporary Sediment Control BMPs.

- Section 5: Wind Erosion Control – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Wind Erosion Control BMPs.

- Section 6: Tracking Control – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Tracking Control BMPs.

- Section 7: Non-Storm Water Management – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Non-Storm Water Management BMPs.

- Section 8: Waste Management and Material Pollution Control – provides a list, appropriate application, limitations, standards and specifications, and inspection and maintenance of Waste Management and Material Pollution Control BMPs.

- Appendix A provides a list and definitions of frequently used abbreviations, acronyms, and terms used in this BMP Manual.

- Appendix B has the LACDPW BMP Checklist with instructions.

- Appendix C has the LACDPW Notice of BMP Noncompliance form with instructions.

The Contractor shall know and fully comply with the applicable provisions of the contract Special Provisions, Construction Site BMP Manual and SWPPP Preparation Manual (if a SWPPP is required by contract Special Provisions), Permits, and Federal, State, and local regulations that govern the Contractor's operations and storm water discharges from the construction site.

This BMP Manual refers to the Engineer repeatedly. The Engineer is the LACDPW authorized representative on site (Engineer, Inspector, or LACDPW consultant).

1.3 Regulations and Permits

In 1972, the Federal Water Pollution Control Act (also referred to as the Clean Water Act) (CWA) was amended to provide that the discharge of pollutants to waters of the United States from any point source is unlawful unless the discharge is in compliance with an NPDES permit. In 1987, the CWA was amended to establish a framework for regulating municipal and industrial storm water discharges under the NPDES Program. In 1990, the U.S. Environmental Protection Agency (USEPA) published final regulations that establish storm water permit application requirements for specified categories of industries. In 2003, the Phase II regulations became effective for small construction sites. The regulations provide that discharges of storm water to waters of the United States from construction projects that encompass one acre or more of soil disturbance are effectively prohibited unless the discharge is in compliance with an NPDES Permit.

The Regional Water Quality Control Board (RWQCB) regulates the discharge of storm water from municipalities and activities within their jurisdiction including construction. Part of the RWQCB Los Angeles Region regulations requires the County to have adequate enforcement capabilities for controlling storm water runoff. Los Angeles County Code Chapter 12.80.630 Storm Water and Pollution Runoff Control fulfills the requirement of the RWQCB for enforceable regulations.

The State Water Resources Control Board (SWRCB) issued the Small Municipal Separate Storm Sewer System (MS4) Permit (Small MS4 Permit) effective August 8, 2003 which will impact the County's unincorporated areas in the Antelope Valley. LACDPW requires the Antelope Valley portions of Los Angeles County to comply with the same requirements for Construction Site Storm Water Runoff Control as the rest of the County.

1.3.1 General Permit

The SWRCB has elected to adopt one statewide General Permit that will apply to all storm water discharges associated with construction activity.

In 2009, the SWRCB re-issued *National Pollutant Discharge Elimination System (NPDES) Permit No. CAS000002 under Order No. 2009-0009-DWQ, Waste Discharge Requirements for Discharges of Storm Water Runoff Associated with Construction and Land Disturbance Activities* (Construction General Permit) that requires all dischargers where construction activities disturb one or more acres to comply with the Construction General Permit and develop and implement a Storm Water Pollution Prevention Plan (SWPPP). For construction sites that disturb one or more acres, refer to the LACDPW "Storm Water Pollution Prevention Plan (SWPPP) Preparation Manual."

1.3.2 Municipal Permit

On December 13, 2001, the RWQCB, Los Angeles Region, adopted Order No. 01-182, NPDES Permit No. CAS004001, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles, and Incorporated Cities Therein (MS4 Permit). This Permit was issued to the Los Angeles County Flood Control District, the County of Los Angeles, and 84 cities within the county; and requires the preparation and implementation of a storm water pollution prevention program to control runoff from construction sites within its jurisdiction. The MS4 Permit jurisdiction includes all areas of Los Angeles County except the northern (Antelope Valley) area. This BMP Manual is part of the LACDPW program to control runoff from all construction sites within Los Angeles County including the Antelope Valley.

1.3.3 Los Angeles County Code

The Contractor is subject to enforcement action by Chapter 12.80 of the Los Angeles County Code (12.80.630) that states, *"Any person, firm, corporation, municipality or district or any officer or agent of any firm corporation, municipality or district violating any provision of this chapter shall be guilty of a misdemeanor. Such violation shall be punishable by a fine of not more than $1,000 or by imprisonment in the county jail for a period not to exceed six months, or by both fine and imprisonment. Each day during any portion of which such violation is committed, continued or permitted shall constitute a separate offense and shall be punishable as such (Ord. 98-0021§1(part), 1998)."* LACDPW applies this code to all their construction sites.

SECTION 2

SELECTING AND IMPLEMENTING BMPS

This Section provides instructions to assist Contractors in the selection and implementation of construction site BMPs. The requirements in this BMP Manual reflect the LACDPW minimum requirements. LACDPW may impose additional construction site BMPs as necessary to adequately protect water quality and comply with storm water pollution prevention regulations. Additional BMPs may be included in the project's contract Special Provisions or required in the field by the Engineer.

Construction site BMPs are required to be implemented on a year-round basis during construction activities, including during any temporary suspension of work.

2.1 Minimum BMP Requirements

Table 2-1 lists the Construction Site BMPs approved for use on LACDPW construction sites. The minimum BMPs identified on Table 2-1 shall be implemented on all LACDPW construction sites.

(1) This table indicates minimum required BMPs. Additional BMPs may be required as a result of actual field conditions, Contractor activities, or construction operations.
(2) The Contractor shall select and implement one or a combination of soil stabilization BMPs.

(3) The Contractor shall implement one or a combination of BMPs for prevention of sediment discharges along the perimeter of the Project site.

(4) One or a combination of BMPs is required to break up the sheet flow lengths (grade breaks for exposed soil).

(5) The Contractor shall implement effective wind erosion and dust control BMPs in conformance with the requirements of the jurisdictional air quality regulatory agency.

(6) Required for discharging accumulated precipitation. Separate permits are required for groundwater dewatering.

(7) Required for vehicles and equipment fueling, cleaning or maintenance, or other construction activities on the Construction site if waste is generated.

(8) Required for prevention of potential sewage spills as well as for inclusion in any plan for emergency spill cleanup and response.

Table 2-2, "Storm Water Pollution Controls for Construction Activities" is a guide for selection of storm water BMPs. The table is based on Construction activity categories. The Contractor shall use Table 2-2 to select additional BMPs based on the types of construction activities to be conducted on the construction site.

2.2 BMP Inspections and Checklist

To ensure the proper implementation and functioning of water pollution control practices, the Contractor shall regularly inspect and maintain the construction site for the water pollution control practices as follows:

- At a minimum once every week.
- Within 48 hours prior to a qualifying rain event (1/2 inch or more of precipitation with a 48 hour or greater period between rain events);
- Within 48 hours after a qualifying rain event
- At least every 24 hours during extended precipitation events.

Detailed instructions for conducting inspections and filling out the BMP Checklist are included in Appendix B.

2.3 BMP Noncompliance and Enforcement Actions

Corrective actions may be required to comply with the SWPPP or contract Special Provisions. The corrective actions identified on the BMP Checklist are required to be completed by the end of the day that the inspection was performed and documented. If the corrective actions identified on the BMP Checklist are not completed by the end of the day, enforcement actions of the contract Special Provisions will be triggered. One of the enforcement tools is the Notice of BMP Noncompliance Form (Appendix C).

When the Engineer identifies that one or more of the BMPs have not been properly implemented and maintained, the Notice of BMP Noncompliance form may be implemented:

1. Part 1 of the Notice of BMP Noncompliance Form will be completed to identify the date of noncompliance, (A) BMP Description, (B) Location, (C) Recommended corrective action(s), and (D) Date Corrective Action to be Completed (within 2 working days).
2. A copy of the form will be given to the Contractor.
3. When the corrective action is completed by the Contractor, the completion date will be entered in Column (E) "Date Corrective Action Completed."
4. If the corrective action is completed by the specified date, "Yes" will be checked in Column (F) Corrective action completed within 2 days.
5. If the corrective action is not completed by the specified date, the Engineer will check "No" in Column (F) indicating the corrective action was not completed within two days, and immediately notify the Environmental Compliance Unit (ECU).
6. Part 2 of the form will be completed if a corrective action was not completed within two days. Contractual Sanctions will be implemented on a daily basis until the recommended corrective action is completed to the satisfaction of the Engineer and the ECU. The date will be written in Column (E) once the corrective action is completed.

> Noncompliance for the same violation will result in immediate monetary penalty without allowing 2 days for compliance. It is noted that this form is only one tool and it is up to the Engineer whether additional enforcement is necessary including immediate fines. For example, discharge of concrete waste may result in immediate monetary penalty.

The LACDPW, as a permittee, is subject to enforcement action by the SWRCB, Environmental Protection Agency, private citizens, and citizen groups. The LACDPW will assess the Contractor a penalty of $1,000 for each calendar day that the Contractor does not fully implement or comply with the provisions set forth in Section 7-8.6 "Water Pollution Control," of the contract Special Provisions, including but not limited to, compliance with the applicable provisions of the Special Provisions, manuals, permits and Federal, State and local regulations. The Contractor shall be responsible for the costs and for liabilities imposed by law as a result of the Contractor's failure to comply with the provisions. Costs and liabilities include, but are not limited to: fines, penalties, and damages, whether assessed against the LACDPW or the Contractor, including those levied under the Federal Clean Water Act and the State Porter Cologne Water Quality Act. In addition the LACDPW will deduct from payments due the Contractor, the total amount of any legal fees, staff costs, and consultant fees as a result of the Contractor's noncompliance with these provisions.

SECTION 3

TEMPORARY SOIL STABILIZATION BMPs

3.1 Temporary Soil Stabilization

Temporary soil stabilization is erosion control that consists of protecting or covering exposed areas of soil or stockpiles to minimize erosion by implementing at least one, or any combination, of the BMPs shown on Table 3-1. Provide effective soil cover for inactive areas and all finished slopes, open space, utility backfill, and completed lots and inactive portions thereof. Implement appropriate erosion control BMPs (runoff control and soil stabilization) in conjunction with sediment control BMPs for areas under active construction.

3.2 Temporary Concentrated Flow Conveyance Controls

Temporary concentrated flow conveyance controls are erosion controls that consist of BMPs used to intercept, divert, convey and discharge concentrated flows to minimize erosion from within the construction site and downstream of the construction site. Temporary concentrated flow conveyance controls are required to effectively manage all run-on, all runoff within the site and all runoff that discharges from the site. Run-on from offsite shall be directed away from all disturbed areas.

Table 3-1

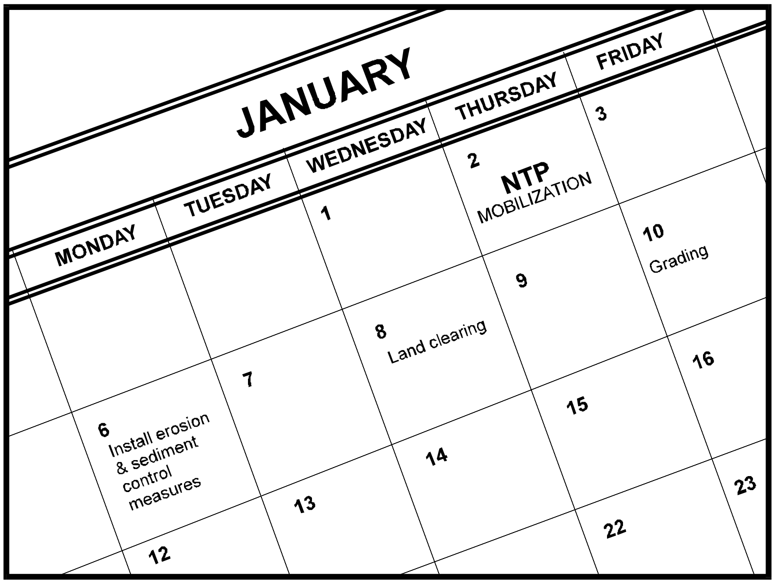
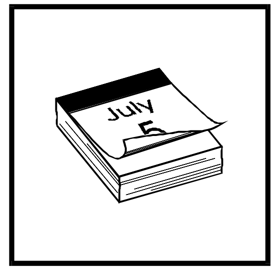
(This page left intentionally blank)

Scheduling

SS-1





Standard Symbol

BMP Objectives

- Soil Stabilization
- Sediment Control
- Tracking Control
- Wind Erosion Control
- Non-Storm Water Management
- Materials and Waste Management

Definition and Purpose

This best management practice (BMP) involves sequencing of construction activities with the implementation of construction site BMPs such as temporary soil stabilization (erosion control) and temporary sediment control measures. The purpose is to reduce the amount and duration of soil exposed to erosion by wind, rain, runoff and vehicle tracking, and to perform the construction activities and control practices in accordance with the planned schedule.

Appropriate Applications

Scheduling and planning the project are the very first steps in an effective storm water program and are required for every construction project.

Limitations

None identified.

Standards and Specifications

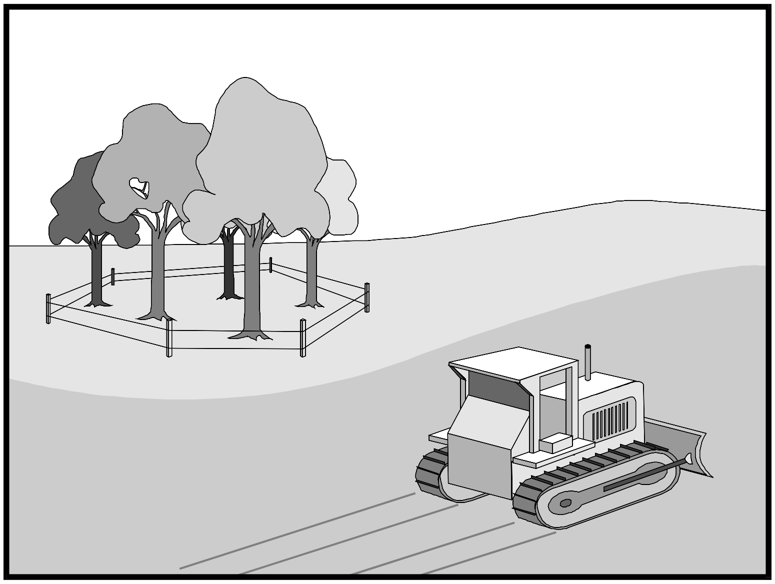
- Construction sequencing shall be scheduled to minimize land disturbance for all projects throughout the year. Appropriate BMPs shall be implemented on a year round basis. The construction schedule shall be reflected in the SWPPP implementation of BMPs.
- Schedule year around implementation and deployment of:
  - Temporary soil stabilization BMPs.
  - Temporary sediment control BMPs.
  - Tracking control BMPs.
  - Wind erosion control BMPs.
  - Non-storm water BMPs.
  - Waste management and materials pollution control BMPs.

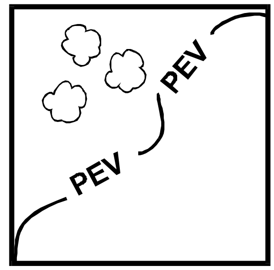
- Develop the sequencing and timetable for the start and completion of each item such as site clearing and grubbing, grading, excavation, paving, pouring foundations, installing utilities, etc., to minimize the soil disturbing activities during the rainy season.
- Schedule major grading operations for the non-rainy season when practical.
- Stabilize non-active areas within 14 days from the cessation of soil-disturbing activities or one day prior to the onset of precipitation, whichever occurs first.
- Monitor the weather forecast for rainfall.
- When rainfall is predicted, adjust the construction schedule to allow the implementation of soil stabilization and sediment controls and sediment treatment controls on all disturbed areas prior to the onset of rain.
- Be prepared year-round to deploy soil stabilization and sediment control practices. Erosion may be caused during the non-rainy season by unseasonal rainfall, wind, and vehicle tracking. Keep the site stabilized year-round, and retain and maintain sediment tapping devices in operational condition.
- Incorporate staged seeding and re-vegetation of graded slopes as work progresses according to the contract Special Provisions or as directed by the Engineer.
- Apply and maintain temporary erosion and sediment controls to all areas until permanent stabilization has been established.

Maintenance and Inspection

- Review and update project site weekly.
- Verify that work is progressing in accordance with the schedule. If progress deviates, take corrective actions.
- Amend the schedule when changes are warranted or when directed by the Engineer.

Preservation of Existing Vegetation SS-2





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Preservation of existing vegetation is the identification and protection of desirable vegetation that provides erosion and sediment control benefits.

Appropriate Applications

- Preserve existing vegetation at areas on a site where no construction activity is required by the contract Special Provisions.
- On a year-round basis, temporary fencing shall be installed at the limits clearing and grubbing operations and other soil-disturbing activities. The temporary fencing shall be installed prior to commencement of clearing and grubbing operations and other soil-disturbing activities
- Clearing and grubbing operations shall be staged to preserve existing vegetation.

Limitations

Protection of existing vegetation requires planning, and may limit the area available for construction activities.

Standards and Specifications

Do NOT drive over vegetation or store materials on vegetation or otherwise disturb vegetation outside construction project boundaries shown on the project plans.

Schedule

- The Contractor shall not prune or remove any trees for any reason during the nesting season (see contract Special Provisions) for migratory non-game native bird species, including raptors.
- If approved by the Engineer, the Contractor may prune or remove any trees during the nesting season. The Contractor will coordinate with the Agency to provide all required bird surveys to detect any protected native birds in the trees to be removed and other suitable nesting habitat.

- If a protected native bird is found, the Agency will delay all clearance/construction disturbance activities in suitable nesting habitat or continue the surveys in order to locate any nests. If an active nest is located, clearance/construction disturbance activities shall be delayed until the nest is vacated and juveniles have fledged and when there is no evidence of a second attempt at nesting. Limits of construction to avoid a nest shall be established in the field by the Agency.

- Refer to contract Special Provisions for any other provisions or requirements for the preservation vegetation.

Design and Layout

- Mark areas to be preserved with temporary fencing.

- Minimize the disturbed areas by locating temporary roadways, stockpiles and layouts areas to avoid stands of trees, shrubs, and grass. Follow existing contours to reduce cutting and filling.

Installation

- Construction materials, equipment storage, and parking areas shall be located where they will not cause root compaction.

- Keep equipment away from trees to prevent trunk and root damage.

- Maintain existing irrigation systems.

- Employees and subcontractors shall be trained to perverse protective devices. No heavy equipment, vehicular traffic, or storage piles of any construction materials shall be permitted within the drip line of any tree to be remain. Removed trees shall not be felled, pushed, or pulled into any retained trees. No toxic or construction materials (including paint, acid, nails, gypsum board, chemicals, fuels, and lubricants) shall be stored within 50 feet of the drip line of any retained trees, nor disposed of in any way which would impact vegetation.

Trenching and Tunneling

- Trenching shall be as far away from tree trunks as possible, usually outside of the tree drip line or canopy. Curve trenches around trees to avoid large roots or root concentrations. If roots are encountered, consider tunneling under them. When trenching and/or tunneling near or under trees to be retained, tunnels shall be at least 18 inches below the ground surface, and not below the tree center to minimize impact on the roots.

- Tree roots shall not be left exposed to air; they shall be covered with soil as soon as possible, protected, and kept moistened with wet burlap or peat moss until the tunnel and/or trench can be completed.

- The ends of damaged or cut roots shall be cut off smoothly.
- Trenches and tunnels shall be backfilled as soon as possible. Careful backfilling andcompacting will eliminate air spaces in the soil which can damage roots.
- After all other work is complete, fences and barriers shall be removed last. This is because protected trees may be destroyed by carelessness during the final cleanup and landscaping.

Maintenance and Inspection

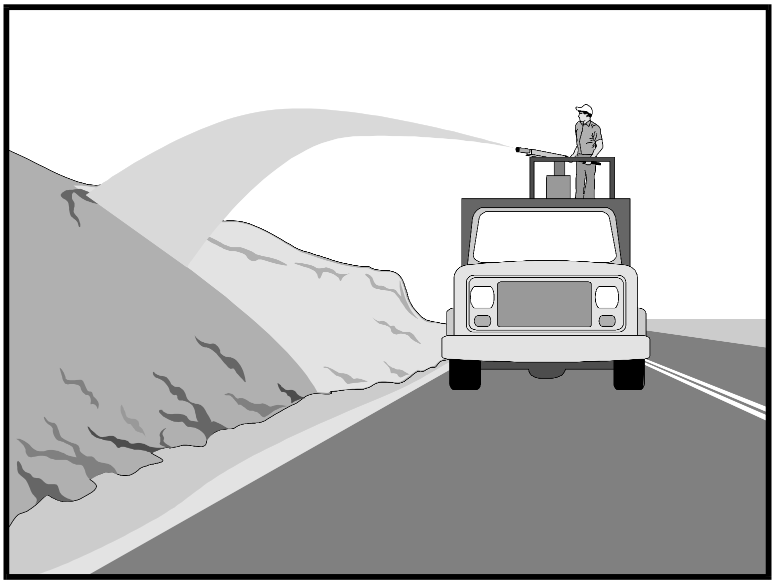
During construction, the limits of disturbance shall remain clearly marked at all times. Irrigation or maintenance of existing vegetation shall conform to the requirements in the landscaping plan. If damage to protected trees still occurs, maintenance guidelines described below shall be followed:

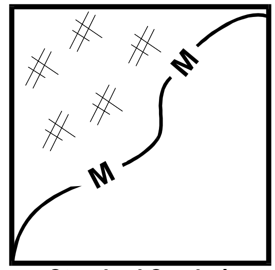
- Verify that protective measures remain in place. Restore damaged protection measures immediately
- Serious tree injuries shall be attended to by an arborist.
- Damage to the crown, trunk, or root system of a retained tree shall be repaired immediately.
- Trench as far from tree trunks as possible, usually outside of the tree drip line or canopy. Curve trenches around trees to avoid large roots or root concentrations. If roots are encountered, consider tunneling under them. When trenching or tunneling near or under trees to be retained, place tunnels at least 18 in. below the ground surface, and not below the tree center to minimize impact on the roots.
- Do not leave tree roots exposed to air. Cover exposed roots with soil as soon as possible. If soil covering is not practical, protect exposed roots with wet burlap or peat moss until the tunnel or trench is ready for backfill.
- Cleanly remove the ends of damaged roots with a smooth cut.
- Remove any trees intended for retention if those trees are damaged seriously enough to affect their survival, as determined by the Engineer. If replacement is required, the new tree shall be of similar species, as required by the contract special provisions or as directed by the Engineer.
- If bark damage occurs, cut back all loosened bark into the undamaged area, with the cut tapered at the top and bottom and drainage provided at the base of the wood. Limit cutting the undamaged area as much as possible.
- Aerate soil that has been compacted over a trees root zone by punching holes 12 in. deep with an iron bar, and moving the bar back and forth until the soil is loosened. Place holes 18 in. apart throughout the area of compacted soil under the tree crown.

- Fertilization
  - Fertilize stressed or damaged broadleaf trees to aid recovery.
  - Fertilize trees in the late fall or early spring.
  - Apply fertilizer to the soil over the feeder roots and in accordance with label instructions, but never closer than 3 ft to the trunk. Increase the fertilized area by one-fourth of the crown area for conifers that have extended root systems.
  - Discontinue the application of any erodible landscape material within 2 days before a forecasted rain event or during periods of precipitation.
  - Follow WM-1 for storage of fertilizers.
- Retain protective measures until all other construction activity is complete to avoid damage during site cleanup and stabilization.
- Inspect existing vegetation weekly and before and after every rainfall events. During extended rainfall events, inspect existing vegetation at least once every 24 hours.

Hydraulic Mulch

SS-3





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Hydraulic mulch consists of applying a mixture of shredded wood fiber or a hydraulic matrix and a stabilizing emulsion or tackifier with hydroseeding equipment, which temporarily protects exposed soil from erosion by raindrop impact or wind. This is one of five temporary soil stabilization alternatives to consider.

Appropriate Applications

- Hydraulic mulch is applied to disturbed areas requiring temporary protection until permanent vegetation is established or to disturbed areas that must be re-disturbed following a period of inactivity.

Limitations

- Wood fiber hydraulic mulches are generally short-lived (only last a part of a growing season) and need 24 hours to dry before rainfall occurs to be effective.
- Paper mulches alone are not permitted. Paper mulch is allowed if in combination with other mulch such as wood.
- Avoid use in areas where the mulch would be incompatible with immediate future earthwork activities and would have to be removed.

Standards and Specifications

- Prior to application, roughen embankment and fill areas by rolling with a crimping or punching type roller or by track walking. Track walking shall only be used where other methods are impractical.
- Avoid mulch over-spray onto the roadway, sidewalks, lined drainage channels, and existing vegetation.
- Selection of hydraulic mulches by the Contractor must be approved by the Engineer.

Hydraulic Mulch

- Wood fiber mulch can be applied alone or as a component of hydraulic matrices. Wood fiber mulch shall be applied per manufacture's recommendations typically at the rate of 2,000 to 4,000 lb/ac. This type of mulch is manufactured from wood or wood waste from lumber mills or from urban sources.

Hydraulic Matrices

- Hydraulic matrices include a mixture of wood fiber mulch and tackifier applied as slurry. It is typically applied at the rate of 2,000 to 4,000 lb/ac with 5-10% by weight of a stabilizing emulsion or tackifier (e.g., guar, psyllium, acrylic copolymer, polyacrylamide).

Bonded Fiber Matrix

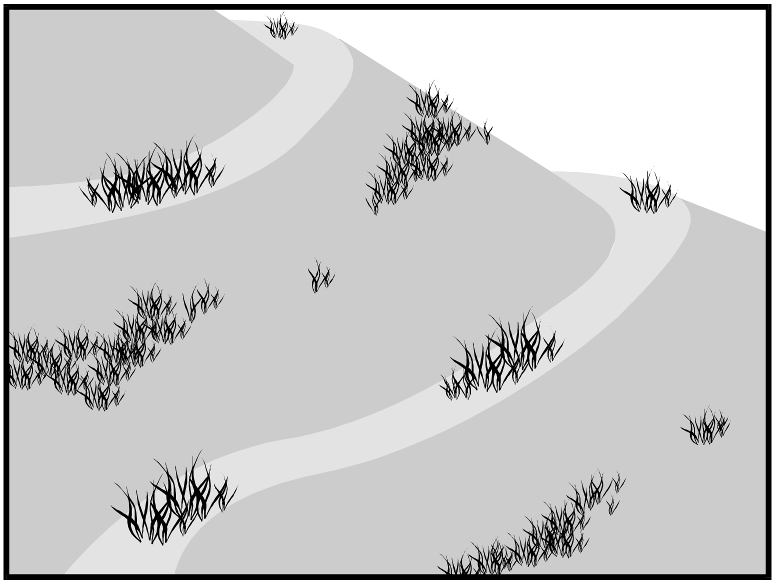
- Bonded fiber matrix (BFM) is a hydraulically-applied system of fibers and adhesives that upon drying forms an erosion-resistant blanket that promotes vegetation, and prevents soil erosion. BFMs are typically applied at rates from 3,000 to 4,500 lb/ac based on the manufacturer's recommendation. The biodegradable BFM is composed of materials that are 100% biodegradable. The binder in the BFM should also be biodegradable and should not dissolve or disperse upon re-wetting. Typically, biodegradable BFMs should not be applied immediately before, during or immediately after rainfall if the soil is saturated. Depending on the product, BFMs require 12 to 24 hours to dry to become effective.

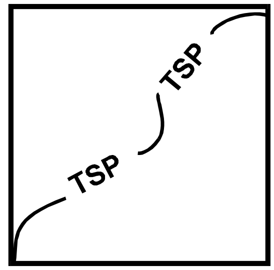
Maintenance and Inspections

- Inspect hydraulic mulched slopes and areas weekly and before and after every rainfall events. During extended rainfall events, inspect hydraulic mulched slopes and areas at least once every 24 hours.
- Maintain an unbroken, temporary mulched ground cover throughout the period of construction when the soils are not being reworked.
- The Contractor is responsible for maintaining all slopes to prevent erosion for the duration of the project or per the contract Special Provisions.

Hydroseeding

SS-4





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Hydroseeding typically consists of applying a mixture of wood fiber, seed, fertilizer, and stabilizing emulsion with hydro-seeding equipment, which temporarily protects exposed soils from erosion by water and wind.

Appropriate Applications

- Hydroseeding is applied on disturbed soil areas requiring temporary protection until permanent vegetation is established or disturbed soil areas that must be re-disturbed following an extended period of inactivity.
- Hydroseeding mix shall be per the contract Special Provisions or approved by the Engineer.

Limitations

- Hydroseeding may be used alone only when there is sufficient time in the season to ensure adequate vegetation establishment and erosion control. Otherwise, hydroseeding must be used in conjunction with a soil binder or mulching (i.e., straw mulch), refer to BMP SS-5, Table 1 for options.
- Steep slopes are difficult to protect with temporary seeding.
- Temporary seeding may not be appropriate in dry periods without supplemental irrigation.
- Temporary vegetation may have to be removed before permanent vegetation is applied.
- Temporary vegetation is not appropriate for short-term inactivity.

Standards and Specifications

To select appropriate hydroseeding mixtures, an evaluation of site conditions shall be performed with respect to:

- Soil conditions
- Site topography
- Season and climate
- Vegetation types
- Maintenance requirements
- Sensitive adjacent areas
- Water availability
- Plans for permanent vegetation

The following steps shall be followed for implementation:

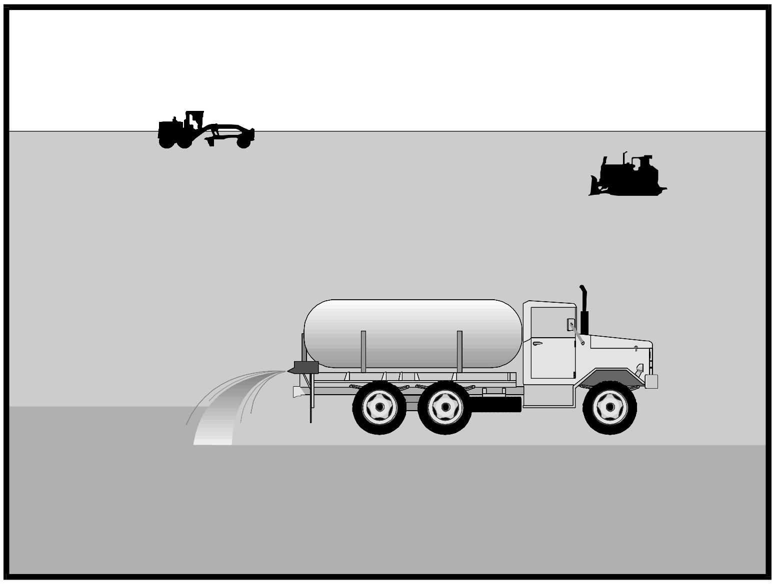
- Hydroseeding can be accomplished using a multiple-step or one-step process. The multiple-step process ensures maximum direct contact of the seeds to soil. When the one-step process is used to apply the mixture of fiber, seed, etc., the seed rate shall be increased to compensate for all seeds not having direct contact with the soil.
- Prior to application, roughen the slope, fill area, or area to be seeded with the furrows trending along the contours. Rolling with a crimping or punching type roller or track walking is required on all slopes prior to hydroseeding.
- Apply a straw mulch to keep seeds in place and to moderate soil moisture and temperature until the seeds germinate and grow.
- All seeds shall be in conformance with the California State Seed Law of the Department of Agriculture. Each seed bag shall be delivered to the site sealed and clearly marked as to species, purity, percent germination, dealer's guarantee, and dates of test; provide the Engineer with such documentation. The container shall be labeled to clearly reflect the amount of Pure Live Seed (PLS) contained.
- Commercial fertilizer shall conform to the requirements of the California Food and Agricultural Code. Fertilizer shall be in pellet or granular form.
- Follow-up applications shall be made as needed to cover bare spots, and to maintain adequate soil protection.
- Avoid over-spray onto the travel way, sidewalks, lined drainage channels, and existing vegetation.

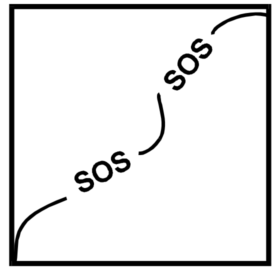
Maintenance and Inspection

- Inspect hydroseeded slopes and areas weekly and before and after every rainfall events. During extended rainfall events, inspect hydroseeded slopes and areas at least once every 24 hours.
- All seeded areas shall be inspected for failures and re-seeded, fertilized, and mulched within the planting season, using not less than half the original application rates. Any temporary revegetation efforts that do not provide adequate cover must be reapplied as required by the Engineer.
- The Contractor is responsible for maintaining all slopes to prevent erosionfor the duration of the project or per the contract Special Provisions.

Soil Binders

SS-5





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Soil binders consist of applying and maintaining a soil stabilizer to exposed soil surfaces. Soil binders are materials applied to the soil surface to temporarily prevent water-induced erosion of exposed soils on construction sites. Soil binders also provide temporary dust, wind, and soil stabilization (erosion control) benefits. This is one of five temporary soil stabilization alternatives to consider.

Appropriate Applications

Soil binders are typically applied to disturbed areas requiring short-term temporary protection. Because soil binders can often be incorporated into the work, they may be a good choice for areas where grading activities will soon resume. Application on stockpiles to prevent water and wind erosion is an additional appropriate use.

Limitations

- Soil binders are temporary in nature and may need reapplication.
- Soil binders require a minimum curing time until fully effective which may be 24 hours or longer. Soil binders may need reapplication after a storm event.
- Soil binders will generally experience spot failures during heavy rainfall events. If runoff penetrates the soil at the top of a slope treated with a soil binder, it is likely that the runoff will undercut the stabilized soil layer.
- Soil binders do not hold up to pedestrian or vehicular traffic across treated areas.
- Some soil binders are incompatible with existing vegetation.
- Soil binders may not penetrate soil surfaces made up primarily of silt and clay, particularly when compacted.
- Performance of soil binders depends on temperature, humidity, and traffic across treated areas.

Standards and Specifications

General Considerations

- Soil binder shall be approved by the Engineer prior to application.
- Site-specific soil types will dictate the appropriate soil binders to be used.
- A soil binder shall be environmentally benign (non-toxic to plant and animal life), easy to apply, easy to maintain, economical, and shall not stain paved or painted surfaces.
- Avoid over-spray onto the travel way, sidewalks, lined drainage channels, and existing vegetation.

Soil Binders Applications

After selecting an appropriate soil binder, the untreated soil surface must be prepared before applying the soil binder. The untreated soil surface must contain sufficient moisture to assist the agent in achieving uniform distribution. In general, the following steps shall be followed:

- Follow manufacturer's recommendations for application rates, pre-wetting of application area, and cleaning of equipment after use.
- Prior to application, roughen embankment and fill areas by rolling with a crimping or punching type roller or by track walking. Track walking shall only be used where rolling is impractical. Crown or slope ground to avoid ponding.
- Consider the drying time for the selected soil binder and apply with sufficient time before anticipated rainfall. Soil binders shall not be applied during or immediately before rainfall.
- Soil binders shall not be applied to frozen soil, areas with standing water, under freezing or rainy conditions, or when the air temperature is below 4oC (40^oF) during the curing period.
- More than one treatment is often necessary, although the second treatment may be diluted or have a lower application rate.
- Generally, soil binders require a minimum curing time before they are fully effective. Refer to manufacturer's recommendations for specific cure times.
- Uniformly pre-wet ground at a rate of 0.03 to 0.3 gal/yd^2 or according to manufacturer's recommendations. In low humidity, reactivate chemicals by re-wetting with water at a rate of 0.1 to 0.2 gal/yd^2.
- Apply soil binder solution under pressure. Overlap spry pattern by 6 to 12 inches.
- Allow treated area to cure for the time recommended by the manufacturer; typically, at least 24 hours.

Selecting a Soil Binder

Properties of common soil binders used for erosion control are provided in Table 1. Use Table 1 to select an appropriate soil binder.

Factors to consider when selecting a soil binder include the following:

- Suitability to situation - Consider where the soil binder will be applied; determine if it needs a high resistance to leaching or abrasion, and whether it needs to be compatible with any existing vegetation. Determine the length of time soil stabilization will be needed, and if the soil binder will be placed in an area where it will degrade rapidly. In general, slope steepness is not a discriminating factor for the listed soil binders.

- Soil types and surface materials - Fines and moisture content are key properties of surface materials. Consider a soil binder's ability to penetrate, leaching potential, and ability to form a surface crust on the surface materials.

- Frequency of application - The frequency of application can be affected by subgrade conditions, surface type, climate, and maintenance schedule. Frequent applications could lead to high costs. Application frequency may be minimized if the soil binder has good penetration, low evaporation, and good longevity. Consider also that frequent application will require frequent equipment clean-up.

After considering the above factors, the soil binders in Table 1 will be generally appropriate as follows:

Plant-Material Based (Short Lived)

-*Guar:* Guar is a non-toxic, biodegradable, natural galactomannan-based hydrocolloid treated with dispersent agents for easy field mixing. It shall be diluted at the rate of 1 to 5 lb per 100 gallons of water, depending on application machine capacity. Recommended minimum application rates are as follows:

Application Rates for Guar Soil Stabilizer

Slope (V:H):	Flat	1:4	1:3	1:2	1:1
lb/ac	40	45	50	60	70

-*Psyllium:* Psyllium is composed of the finely ground muciloid coating of plantago seeds that is applied as a dry powder or in a wet slurry to the surface of the soil. It dries to form a firm but rewettable membrane that binds soil particles together but permits germination and growth of seed. Psyllium requires 12 to 18 hours drying time. Psyllium shall be applied at a rate of 80 to 200 lb/ac, with enough water in solution to allow for a uniform slurry flow.

-*Starch:* Starch is non-ionic, cold-water soluble (pre-gelatinized) granular cornstarch. The material is mixed with water and applied at the rate of 150 lb/ac. Approximate drying time is 9 to 12 hours.

Plant-Material Based (Long Lived)

-*Pitch and Rosin Emulsion:* Generally, a non-ionic pitch and rosin emulsion has a minimum solids content of 48%. The rosin shall be a minimum of 26% of the total solids content. The soil stabilizer shall be non-corrosive, water-dilutable emulsion that upon application cures to a water insoluble binding and cementing agent. For soil erosion control applications, the emulsion is diluted and shall be applied as follows:

For clayey soil:	5 parts water to 1 part emulsion
For sandy soil:	10 parts water to 1 part emulsion

Application can be by water truck or hydraulic seeder with the emulsion/product mixture applied at the rate specified by the manufacturer. Approximate drying time is 19 to 24 hours.

Polymeric Emulsion Blends

-*Acrylic Copolymers and Polymers:* Polymeric soil stabilizers shall consist of a liquid or solid polymer or copolymer with an acrylic base that contains a minimum of 55% solids. The polymeric compound shall be handled and mixed in a manner that will not cause foaming or shall contain an anti-foaming agent. The polymeric emulsion shall not exceed its shelf life or expiration date; manufacturers shall provide the expiration date. Polymeric soil stabilizer shall be readily miscible in water, non-injurious to seed or animal life, non-flammable, shall provide surface soil stabilization for various soil types without totally inhibiting water infiltration, and shall not re-emulsify when cured. The applied compound shall air cure within a maximum of 36 to 48 hours. Liquid copolymer shall be diluted at a rate of 10 parts water to 1 part polymer and applied to soil at a rate of 1,175 gal/ac.

-*Liquid Polymers of Methacrylates and Acrylates:* This material consists of a tackifier/sealer that is a liquid polymer of methacrylates and acrylates. It is an aqueous 100% acrylic emulsion blend of 40% solids by volume that is free from styrene, acetate, vinyl, ethoxylated surfactants or silicates. For soil stabilization applications, it is diluted with water in accordance with manufacturer's recommendations, and applied with a hydraulic seeder at the rate of 20 gal/ac. Drying time is 12 to 18 hours after application.

-*Copolymers of Sodium Acrylates and Acrylamides:* These materials are non-toxic, dry powders that are copolymers of sodium acrylate and acrylamide. They are mixed with water and applied to the soil surface for erosion control at rates that are determined by slope gradient:

Slope Gradient (V:H)	lb/ac
Flat to 1:5	3-5
1:5 to 1:3	5-10
1:2 to 1:1	10-20

-*Poly-Acrylamide and Copolymer of Acrylamide:* Linear copolymer polyacrylamide is packaged as a dry-flowable solid. When used as a stand-alone stabilizer, it is diluted at a rate of 1 lb/100 gal of water and applied at the rate of 5 lb/ac.

-*Hydro-Colloid Polymers:* Hydro-Colloid Polymers are various combinations of dry-flowable poly-acrylamides, copolymers and hydro-colloid polymers that are mixed with water and applied to the soil surface at rates of 53 to 62 lb/ac. Drying times are 0 to 4 hours.

Maintenance and Inspection

- Inspect slopes stabilized with soil binders weekly and before and after every rainfall events. During extended rainfall events, inspect slopes stabilized with soil binders at least once every 24 hours.
- Reapplying the selected soil binder may be needed for proper maintenance. High traffic areas shall be inspected daily, and lower traffic areas shall be inspected weekly.
- The Contractor is responsible for maintaining all slopes to prevent erosion for the duration of the project or per the contract Special Provisions.
- Maintain an unbroken, temporary stabilized area while disturbed soil areas are nonactive. Repair any damaged stabilized area and re-apply soil binder to exposed areas.

Chemicals	Plant Material Based (Short Lived)	Plant Material Based (Long Lived)	Polymeric Emulsion Blends
Relative Cost	Low	Low	Low
Resistance to Leaching	High	High	Low to Moderate
Resistance to Abrasion	Moderate	Low	Moderate to High
Longevity	Short to Medium	Medium	Medium to Long
Minimum Curing Time before Rain	9 to 18 hours	19 to 24 hours	0 to 24 hours
Compatibility with Existing Vegetation	Good	Poor	Poor

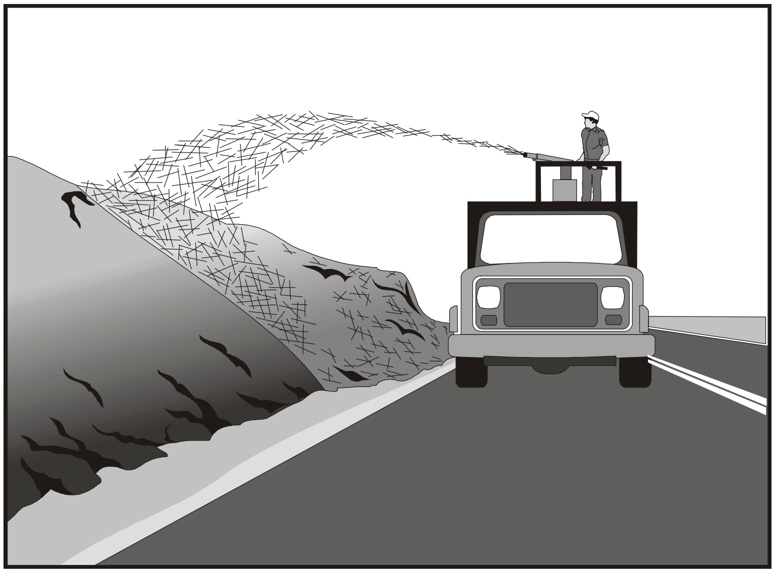
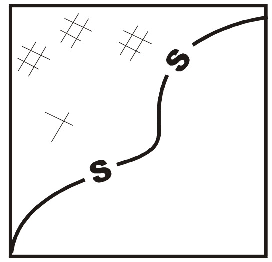
Straw Mulch

SS-6





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Straw mulch consists of placing a uniform layer of straw and incorporating it into the soil with a studded roller or anchoring it with a stabilizing emulsion. This is one of five temporary soil stabilization alternatives to consider.

Appropriate Applications

- Straw mulch is typically used for soil stabilization as a temporary surface cover on disturbed areas until soils can be prepared for revegetation and permanent vegetation is established.
- Also typically used in combination with temporary and/or permanent seeding strategies to enhance plant establishment.

Limitations

- Use of Straw Mulch shall be approved by Engineer
- There is a potential for introduction of weed-seed and unwanted plant material.
- When straw blowers are used to apply straw mulch, the treatment areas must be within 150 feet of a road or surface capable of supporting trucks.
- Mulch may have to be removed prior to permanent seeding or soil stabilization.
- "Punching" of straw does not work in loose sandy soils or very compact soils.

Standards and Specifications

- Straw shall be derived from wheat, rice, or barley.
- A tackifier is the preferred method for anchoring straw mulch to the soil on slopes.
- Crimping, punch roller-type rollers, or track-walking may also be used to incorporate straw mulch into the soil on slopes. Track walking shall only be used where other methods are impractical.
- Avoid placing straw onto the travel way, sidewalks, lined drainage channels, sound walls, and existing vegetation.
- Straw mulch with tackifier shall not be applied during or immediately before rainfall.

Application Procedures

- Apply loose straw per contract Special Provisions, or at a minimum rate of 4,000 lb/ac, either by machine or by hand distribution.
- If stabilizing emulsion will be used to anchor the straw mulch in lieu of incorporation, roughen embankment or fill areas by rolling with a crimping or punching-type roller or by track walking before placing the straw mulch. Track walking should only be used where rolling is impractical.
- The straw mulch must be evenly distributed on the soil surface.
- Anchor the mulch in place by using a tackifier or by “punching” it into the soil mechanically (incorporating).
- A tackifier acts to glue the straw fibers together and to the soil surface. The tackifier shall be selected based on longevity and ability to hold the fibers in place.A tackifier is typically applied at a rate of 125 lb/ac. In windy conditions, the rates are typically 178 lb/ac.
- Methods for holding the straw mulch in place depend upon the slope steepness, accessibility, soil conditions and longevity. Install straw mulch into the soil as follows:
  - On small areas, a spade or shovel can be used.
  - On slopes with soils, which are stable enough and of sufficient gradient to safely support construction equipment without contributing to compaction and instability problems, straw can be “punched” into the ground using a knife-blade roller or a straight bladed coulter, known commercially as a “crimper.”
  - On small areas and/or steep slopes, straw can also be held in place using plastic netting or jute. The netting shall be held in place using 11 gauge wire staples, geotextile pins or wooden stakes. Refer to BMP SS-7, “Geotextiles, Plastic Covers and Erosion Control Blankets/Mats.”

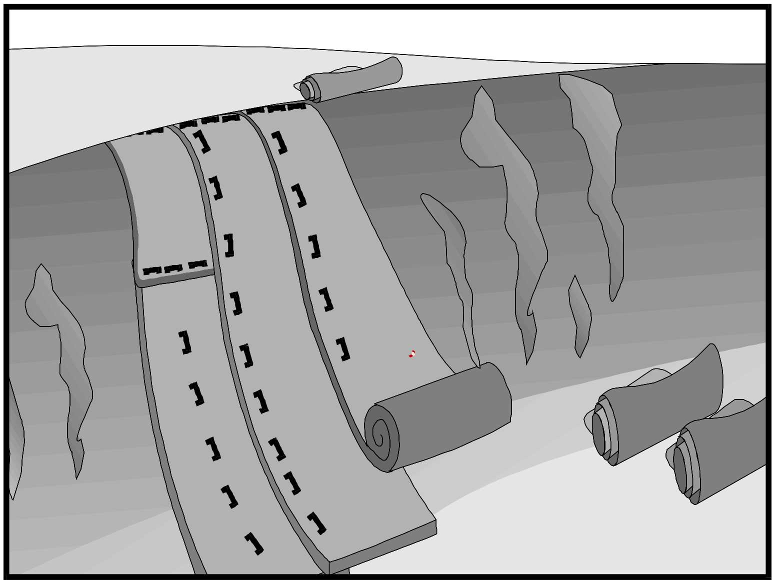
Maintenance and Inspections

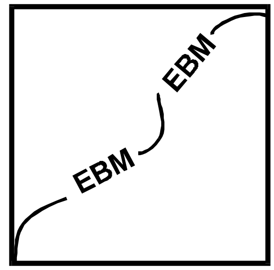
- The key consideration in maintenance and inspection is that the straw needs to last long enough to achieve erosion control objectives.
- Inspect areas stabilized with straw mulch weekly and before and after every rainfall events. During extended rainfall events, inspect areas stabilized with straw mulch at least once every 24 hours.
- Maintain an unbroken, temporary mulched ground cover while disturbed soil areas are non-active. Repair any damaged ground cover and re-mulch exposed areas.
- Reapplication of straw mulch and tackifier may be required by the Engineer to maintain effective soil stabilization over disturbed areas and slopes.
- The Contractor is responsible for maintaining all slopes to prevent erosionfor the duration of the project or per the contract Special Provisions.

(This page left intentionally blank)

Geotextiles, Mats, Plastic Covers and Erosion Control Blankets

SS-7





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

This Best Management Practice (BMP) involves the placement of geotextiles, mats, plastic covers, or erosion control blankets to stabilize disturbed soil areas and protect soils from erosion by wind or water. This is one of five temporary soil stabilization alternatives to consider.

Appropriate Applications

These measures are used when disturbed soils may be particularly difficult to stabilize, including the following situations:

- Steep slopes, generally steeper than 1:3 (V:H).
- Slopes where the erosion potential is high, adjacent to water bodies, or Environmentally Sensitive Areas (ESAs).
- Slopes and disturbed soils where mulch must be anchored.
- Disturbed areas where plants are slow to develop.
- Channels with high flow velocities.
- Stockpiles.

Limitations

- Blankets and mats are more expensive than other erosion control measures, due to labor and material costs. This usually limits their application to areas inaccessible to hydraulic equipment, or where other measures are not applicable, such as channels.
- Blankets and mats are generally not suitable for excessively rocky sites, or areas where the final vegetation will be mowed (since staples and netting can catch in mowers).
- Blankets and mats must be removed and disposed of prior to application of permanent soil stabilization measures.

- Plastic sheeting is easily vandalized, easily torn, photodegradable, and must be disposed of as solid waste.
- Plastic results in 100% runoff, which may cause serious erosion problems in the areas receiving the increased flow.
- The use of plastic shall be limited to covering stockpiles, or very small graded areas for short periods of time (such as through one imminent storm event), until alternative measures, such as seeding and mulching, may be installed.
- Geotextiles, mats, plastic covers, and erosion control covers have maximum flow rate limitations; consult the manufacturer for proper selection.

Standards and Specifications

Material Selection

There are many types of erosion control blankets and mats, and selection of the appropriate type shall be based on the specific type of application and site conditions.

Geotextiles

- Material shall be a woven polypropylene fabric with minimum thickness of 0.06 inch, minimum width of 12 ft and shall have minimum tensile strength of 150 lbs (warp), 80 lbs (fill) in conformance with the requirements in ASTM Designation: D 4632. The permittivity of the fabric shall be approximately 0.07 sec^{-1} in conformance with the requirements in ASTM Designation: D4491. The fabric shall have an ultraviolet (UV) stability of 70 percent in conformance with the requirements in ASTM designation: D4355. Geotextile blankets shall be secured in place with wire staples or sandbags and by keying into tops of slopes and edges to prevent infiltration of surface waters under the geotextile. Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.

Plastic Covers

- Plastic sheeting shall have a minimum thickness of 6 mils, and shall be keyed in at the top of the slope and firmly held in place with sandbags or other weights placed no more than 10 ft apart. Seams are typically taped or weighted down their entire length, and there shall be and overlap of at least 12 to 24 inches at all seams. Edges shall be embedded a minimum of 6 inches in soil.

Erosion Control Blankets/Mats

- Biodegradable rolled erosion control products (RECPs) are typically composed of jute fibers, curled wood fibers, straw, coconut fiber, or a combination of these materials. For an RECP to be considered 100% biodegradable, the netting, sewing or adhesive system that holds the biodegradable mulch fibers together must also be biodegradable.

– **Jute** is a natural fiber that is made into a yarn, which is loosely woven into a biodegradable mesh. It is designed to be used in conjunction with vegetation and has limited longevity. The material is supplied in rolled strips, which shall be secured to the soil with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Excelsior (curled wood fiber)** blanket material shall consist of machine produced mats of curled wood excelsior with 80 percent of the fiber 6 inches or longer. The excelsior blanket shall be of consistent thickness. The wood fiber shall be evenly distributed over the entire area of the blanket. The top surface of the blanket shall be covered with a photodegradable extruded plastic mesh. The blanket shall be smolder resistant without the use of chemical additives and shall be non-toxic and non-injurious to plant and animal life. Excelsior blanket shall be furnished in rolled strips, a minimum of 48 inches wide, and shall have an average weight of 0.8 lb/yd^2, ±10 percent, at the time of manufacture. Excelsior blankets shall be secured in place with wire staples. Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.

– **Straw blanket** shall be machine-produced mats of straw with a lightweight biodegradable netting top layer. The straw shall be attached to the netting with biodegradable thread or glue strips. The straw blanket shall be of consistent thickness. The straw shall be evenly distributed over the entire area of the blanket. Straw blanket shall be furnished in rolled strips a minimum of 6.5 ft wide, a minimum of 80 ft long and a minimum of 0.5 lb/yd^2. Straw blankets shall be secured in place with wire staples. Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.

– **Wood fiber blanket** is composed of biodegradable fiber mulch with extruded plastic netting held together with adhesives. The material is designed to enhance revegetation. The material is furnished in rolled strips, which shall be secured to the ground with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Coconut fiber blanket** shall be machine-produced mats of 100% coconut fiber with biodegradable netting on the top and bottom. The coconut fiber shall be attached to the netting with biodegradable thread or glue strips. The coconut fiber blanket shall be of consistent thickness. The coconut fiber shall be evenly distributed over the entire area of the blanket. Coconut fiber blanket shall be furnished in rolled strips with a minimum of 6.5 ft wide, a minimum of 80 ft long and a minimum of 0.5 lb/yd^2. Coconut fiber blankets shall be secured in place with wire staples. Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.

– **Coconut fiber mesh** is a thin permeable membrane made from coconut or corn fiber that is spun into a yarn and woven into a biodegradable mat. It is designed to be used in conjunction with vegetation and typically has longevity of several years. The material is supplied in rolled strips, which shall be secured to the soil with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Straw coconut fiber blanket** shall be machine-produced mats of 70% straw and 30% coconut fiber with a biodegradable netting top layer and a biodegradable bottom net. The straw and coconut fiber shall be attached to the netting with biodegradable thread or glue strips. The straw coconut fiber blanket shall be of consistent thickness. The straw and coconut fiber shall be evenly distributed over the entire area of the blanket. Straw coconut fiber blanket shall be furnished in rolled strips a minimum of 6.5 ft wide, a minimum of 80 ft long and a minimum of 0.5 lb/yd^2. Straw coconut fiber blankets shall be secured in place with wire staples. Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.

- Non-biodegradable RECPs are typically composed of polypropylene, polyethylene, nylon or other synthetic fibers. In some cases, a combination of biodegradable and synthetic fibers is used to construct the RECP. Netting used to hold these fibers together is typically non-biodegradable as well.

– **Plastic netting** is a lightweight biaxially-oriented netting designed for securing loose mulches like straw to soil surfaces to establish vegetation. The netting is photodegradable. The netting is supplied in rolled strips, which shall be secured with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Plastic mesh** is an open-weave geotextile that is composed of an extruded synthetic fiber woven into a mesh with an opening size of less than 0.2 inch. It is used with revegetation or may be used to secure loose fiber such as straw to the ground. The material is supplied in rolled strips, which shall be secured to the soil with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Synthetic fiber with netting** is a mat that is composed of durable synthetic fibers treated to resist chemicals and ultraviolet light. The mat is a dense, three-dimensional mesh of synthetic (typically polyolefin) fibers stitched between two polypropylene nets. The mats are designed to be revegetated and provide a permanent composite system of soil, roots, and geomatrix. The material is furnished in rolled strips, which shall be secured with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Bonded synthetic fibers** consist of a three-dimensional geomatrix nylon (or other synthetic) matting. Typically it has more than 90% open area, which facilitates root growth. Its tough root-reinforcing system anchors vegetation and protects against hydraulic lift and shear forces created by high volume discharges. It can be installed over prepared soil, followed by seeding into the mat. Once vegetated, it becomes an invisible composite system of soil, roots, and geomatrix. The material is furnished in rolled strips that shall be secured with U-shaped staples or stakes in accordance with manufacturers' recommendations.

– **Combination synthetic and biodegradable RECPs** consist of biodegradable fibers, such as wood fiber or coconut fiber, with a heavy polypropylene net stitched to the top and a high-strength continuous-filament geomatrix or net stitched to the bottom. The material is designed to enhance revegetation. The material is furnished in rolled strips, which shall be secured with U-shaped staples or stakes in accordance with manufacturers' recommendations.

Site Preparation

- Proper site preparation is essential to ensure complete contact of the blanket or matting with the soil.
- Grade and shape the area of installation.
- Remove all rocks, clods, vegetation or other obstructions so that the installed blankets or mats will have complete, direct contact with the soil.
- Prepare seedbed by loosening 2 in. to 3 in. of topsoil.

Seeding

Seed the area before blanket installation for erosion control and revegetation. Seeding after mat installation is often specified for turf reinforcement application. When seeding prior to blanket installation, all check slots and other areas disturbed during installation must be re-seeded. Where soil filling is specified, seed the matting and the entire disturbed area after installation and prior to filling the mat with soil.

Anchoring

- U-shaped wire staples, metal geotextile stake pins or triangular wooden stakes can be used to anchor mats and blankets to the ground surface.
- Staples shall be made of 11 gauge steel wire and shall be U-shaped with 8-inch legs and 2-inch crown.
- Metal stake pins shall be 0.188 in. diameter steel with a 1.5 in. steel washer at the head of the pin.
- Wire staples and metal stakes shall be driven flush to the soil surface.
- All anchors shall be 6 in. to 18 in. long and have sufficient ground penetration to resist pullout. Longer anchors may be required for loose soils.

Installation on Slopes

Installation shall be in accordance with the manufacturer's recommendations. In general, these will be as follows:

- Begin at the top of the slope and anchor the blanket in a 6 in. deep by 6 in. wide trench. Backfill the trench and tamp earth firmly.
- Unroll the blanket down slope in the direction of water flow.
- Overlap the edges of adjacent parallel rolls 2 in. to 3 in. and staple every 3 ft.
- When blankets must be spliced, place blankets end over end (shingle style) with 6 in. overlap. Staple through overlapped area, approximately 12 in. apart.
- Lay blankets loosely and maintain direct contact with the soil. Do not stretch.
- Staple blankets sufficiently to anchor blanket and maintain contact with the soil. Staples shall be placed down the center and staggered with the staples placed along the edges. Steep slopes, 1:1 (V:H) to 1:2 (V:H), require a minimum of 2 staples/yd^2. Moderate slopes, 1:2 (V:H) to 1:3 (V:H), require a minimum of 1½ staples/yd^2, placing 1 staple/yd on centers. Gentle slopes require a minimum of 1 staple/yd^2.

Installation in Channels

Installation shall be in accordance with the manufacturer's recommendations. In general, these will be as follows:

- Dig initial anchor trench 12 in. deep and 6 in. wide across the channel at the lower end of the project area.
- Excavate intermittent check slots, 6 in. deep and 6 in. wide across the channel at 25 ft to 30 ft intervals along the channels.
- Cut longitudinal channel anchor slots 4 in. deep and 4 in. wide along each side of the installation to bury edges of matting, whenever possible extend matting 2 in. to 3 in. above the crest of the channel side slopes.
- Beginning at the downstream end and in the center of the channel, place the initial end of the first roll in the anchor trench and secure with fastening devices at 12 in. intervals. Note: matting will initially be upside down in anchor trench.
- In the same manner, position adjacent rolls in anchor trench, overlapping the preceding roll a minimum of 3 in.
- Secure these initial ends of mats with anchors at 12 in. intervals, backfill and compact soil.

- Unroll center strip of matting upstream. Stop at next check slot or terminal anchor trench. Unroll adjacent mats upstream in similar fashion, maintaining a 3 in. overlap.

- Fold and secure all rolls of matting snugly into all transverse check slots. Lay mat in the bottom of the slot then fold back against it. Anchor through both layers of mat at 12 in. intervals, then backfill and compact soil. Continue rolling all mat widths upstream to the next check slot or terminal anchor trench.

- Alternate method for non-critical installations: Place two rows of anchors on 6 in. centers at 25 ft to 30 ft intervals in lieu of excavated check slots.

- Shingle-lap spliced ends by a minimum of 12 in. apart on 12 in. intervals.

- Place edges of outside mats in previously excavated longitudinal slots, anchor using prescribed staple pattern, backfill and compact soil.

- Anchor, fill and compact upstream end of mat in a 12 in. by 6 in. terminal trench.

- Secure mat to ground surface using U-shaped wire staples, geotextile pins, or wooden stakes.

- Seed and fill turf reinforcement matting with soil, if specified.

Soil Filling (if specified for turf reinforcement)

- Always consult the manufacturer's recommendations for installation.

- Do not drive tracked or heavy equipment over mat.

- Avoid any traffic over matting if loose or wet soil conditions exist.

- Use shovels, rakes or brooms for fine grading and touch up.

- Smooth out soil filling, just exposing top netting of mat.

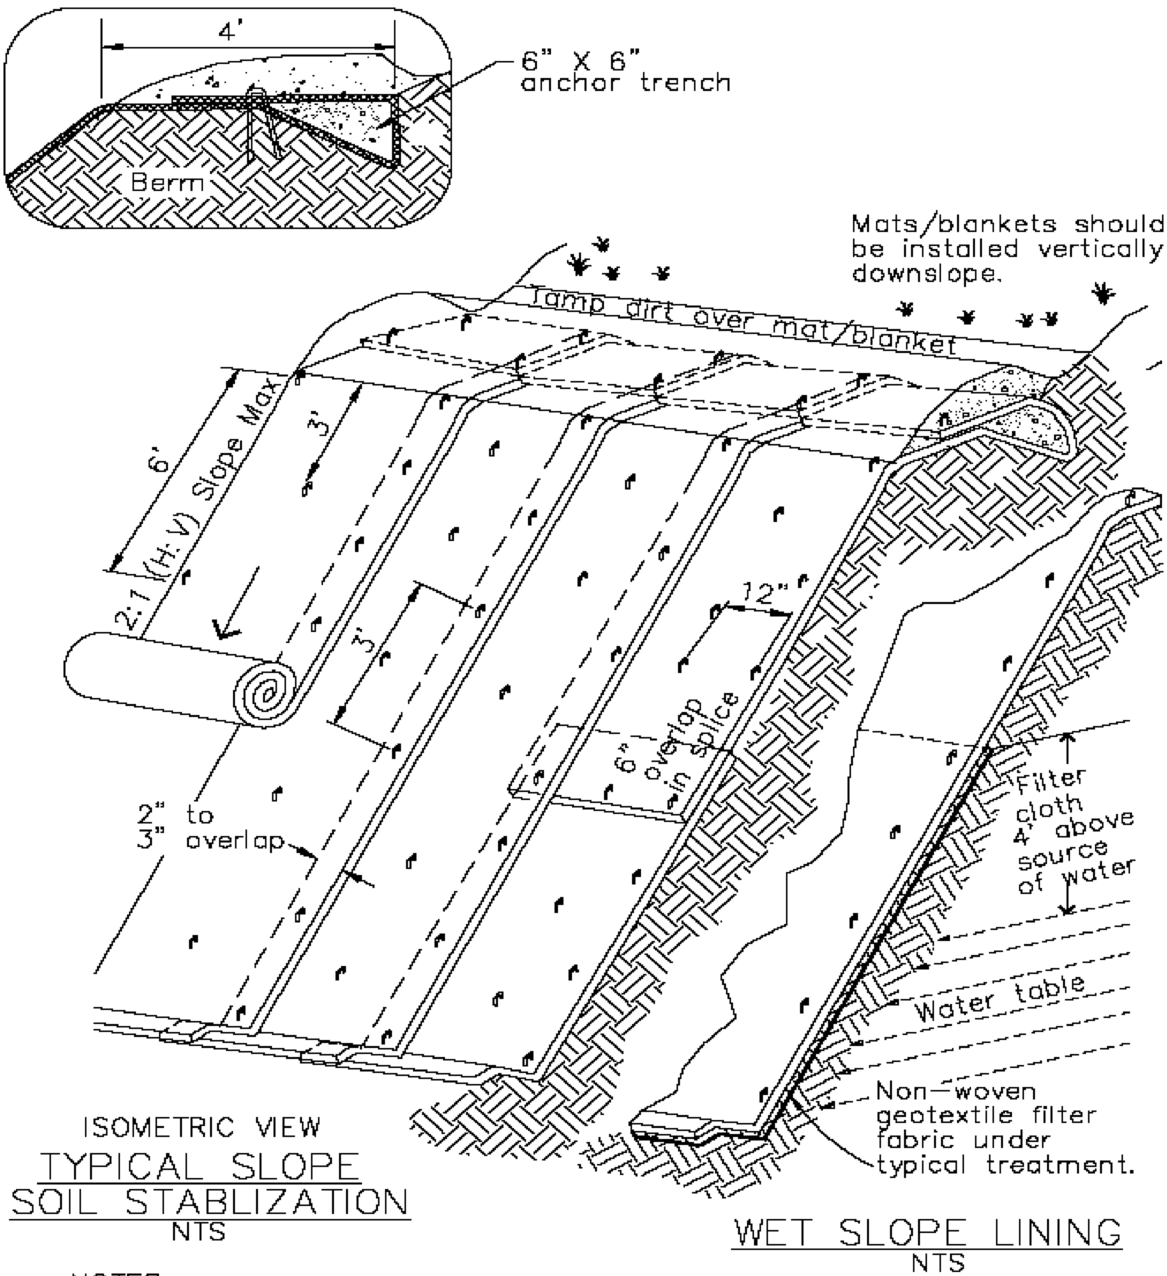
Temporary Soil Stabilization Removal

- When no longer required for the work, temporary soil stabilization shall become the property of the Contractor. Temporary soil stabilization removed from the project site shall be disposed of in conformance with all applicable laws and regulations. If approved by the Engineer, the contractor may leave the temporary soil stabilizer in place.

Maintenance and Inspection

Areas treated with temporary soil stabilization shall be maintained to provide adequate erosion control. Temporary soil stabilization shall be reapplied or replaced on exposed soils when area becomes exposed or exhibits visible erosion.

- Inspect all slopes and areas stabilized with geotextiles, mats, plastic covers, or erosion control blankets weekly and before and after every rainfall events. During extended rainfall events, inspect all slopes and areas stabilized with geotextiles, mats, plastic covers, or erosion control blankets at least once every 24 hours.
- Any failures shall be repaired immediately. If washout or breakage occurs, the material shall be re-installed after repairing the damage to the slope.



NOTES:

1. Slope surface shall be free of rocks, clods, sticks and grass. Mats/blankets shall have good soil contact.
2. Lay blankets loosely and stake or staple to maintain direct contact with the soil. Do not stretch.
3. Install per manufacturer's recommendations

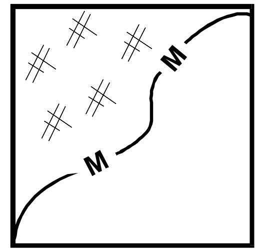
Wood Mulching

SS-8



Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Wood mulching consists of applying a mixture of shredded wood mulch, bark or compost. Wood mulch is mostly applicable to landscape projects.

The primary function of wood mulching is to reduce erosion by protecting bare soil from rainfall impact, increasing infiltration, and reducing runoff.

Appropriate Applications

Wood mulching is considered a temporary soil stabilization (erosion control) alternative in the following situations:

- As a stand-alone temporary surface cover on disturbed areas until soils can be prepared for revegetation and permanent vegetative cover can be established.
- As short term, non-vegetative ground cover on slopes to reduce rainfall impact, decrease the velocity of sheet flow, settle out sediment and reduce wind erosion.

Limitations

- Shredded wood does not withstand concentrated flows and is prone to sheet erosion.
- Green material has the potential for the presence of unwanted weeds and other plant materials. Delivery system is primarily by manual labor, although pneumatic application equipment is available.

Standards and Specifications

Mulch Selection

There are many types of mulches, and selection of the appropriate type shall be based on the type of application and site conditions. Prior to use of wood mulches, there shall be concurrence with the Engineer since some mulch use on construction projects may not be compatible with planned or future projects. Selection of wood mulches by the Contractor must be approved by the Engineer.

Application Procedures

Prior to application, after existing vegetation has been removed, roughen embankment and fill areas by rolling with a punching-type roller or by track walking. The construction-application procedures for mulches vary significantly depending upon the type of mulching method specified. Two (2) methods are highlighted here:

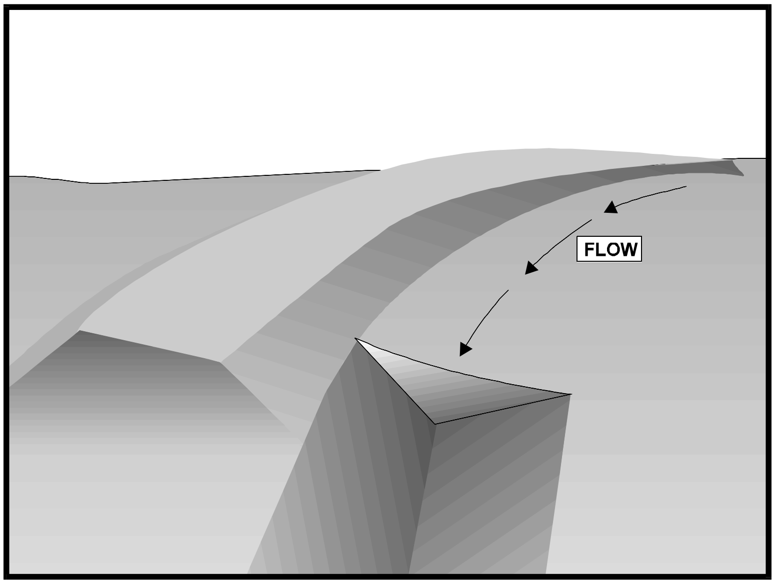
- Green Material: This type of mulch is produced by recycling vegetation trimmings such as grass, shredded shrubs and trees. Methods of application are generally by hand, although pneumatic methods are available. Mulch shall be composted to kill weed seeds.
  - It can be used as a temporary ground cover with or without seeding.
  - The green material shall be evenly distributed on site to a depth of not more than 2 in.
- Shredded Wood: Suitable for ground cover in ornamental or revegetated plantings.
  - Shredded wood/bark is conditionally suitable; see note under limitations.
  - Shall be distributed by hand (although pneumatic methods may be available).
  - The mulch shall be evenly distributed across the soil surface to a depth of 2 in. to 3 in.
- Avoid mulch placement onto the traveled way, sidewalks, lined drainage channels, sound walls, and existing vegetation.
- All material must be removed before re-starting work on the slopes.

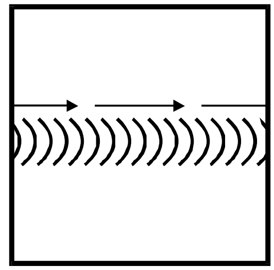
Maintenance and Inspection

- Inspect areas stabilized with wood mulch weekly and before and after every rainfall events. During extended rainfall events, inspect areas stabilized with wood mulch at least once every 24 hours.
- Wood mulch needs to last long enough to achieve erosion-control objectives. If the mulch is applied as a stand-alone erosion control method over disturbed areas (without seed), it shall last the length of time the site will remain barren or until final re-grading and revegetation.
- Where vegetation is not the ultimate cover, such as ornamental and landscape applications of bark or wood chips, inspection and maintenance shall focus on longevity and integrity of the mulch.

Earth Dikes/Drainage Swales and Lined Ditches

SS-9





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

These are structures that intercept, divert and convey surface run-on, generally sheet flow, to prevent erosion.

Appropriate Applications

- Earth dikes/drainage swales and lined ditches may be used to:
  - Convey surface runoff down sloping land.
  - Intercept and divert runoff to avoid sheet flow over sloped surfaces.
  - Divert and direct runoff towards a stabilized watercourse, drainage pipe or channel. Surface water diversion in streambeds or channels shall be in compliance with the contract Special Provisions and regulatory permits.
  - Intercept runoff from paved surfaces.
- Earth dikes/drainage swales and lined ditches also may be used:
  - Below steep grades where runoff begins to concentrate.
  - Along roadways and facility improvements subject to flood drainage.
  - At the top of slopes to divert run-on from adjacent or undisturbed slopes.
  - At bottom and mid-slope locations to intercept sheet flow and convey concentrated flows.
- This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Engineer.

Earth Dikes/Drainage Swales and Lined Ditches

Limitations

- Earth dikes/drainage swales and lined ditches are not suitable as sediment trapping devices.
- May be necessary to use other soil stabilization and sediment controls, such as check dams, plastics, and blankets, to prevent scour and erosion in newly graded dikes, swales and ditches.

Standards and Specifications

- Care must be applied to correctly size and locate earth dikes, drainage swales and lined ditches. Excessively steep, unlined dikes and swales are subject to erosion and gully formation.
- Conveyances shall be stabilized.
- Use a lined ditch for high flow velocities.
- Select flow velocity based on careful evaluation of the risks due to erosion of the measure, soil types, over topping, flow backups, washout, and drainage flow patterns for each project site.
- Compact any fills to prevent unequal settlement.
- Do not divert runoff from the construction project onto other property.
- When possible, install and utilize permanent dikes, swales and ditches early in the construction process.
- Provide stabilized outlets. Refer to SS-10, "Outlet Protection/Velocity/ Dissipation Devices."

Maintenance and Inspections

- Inspect earth dikes, drainage swales and lined ditches weekly and before and after every rainfall events. During extended rainfall events, inspect earth dikes, drainage swales and lined ditches at least once every 24 hours.
- Inspect ditches and berms for washouts. Replace lost riprap, damaged linings or soil stabilizers as needed.
- Inspect channel linings, embankments, and beds of ditches and berms for erosion and accumulation of debris and sediment. Remove debris and sediment, and repair linings and embankments as needed or as directed by the Engineer.
- Temporary conveyances shall be completely removed as soon as the surrounding drainage area has been stabilized, or at the completion of construction.

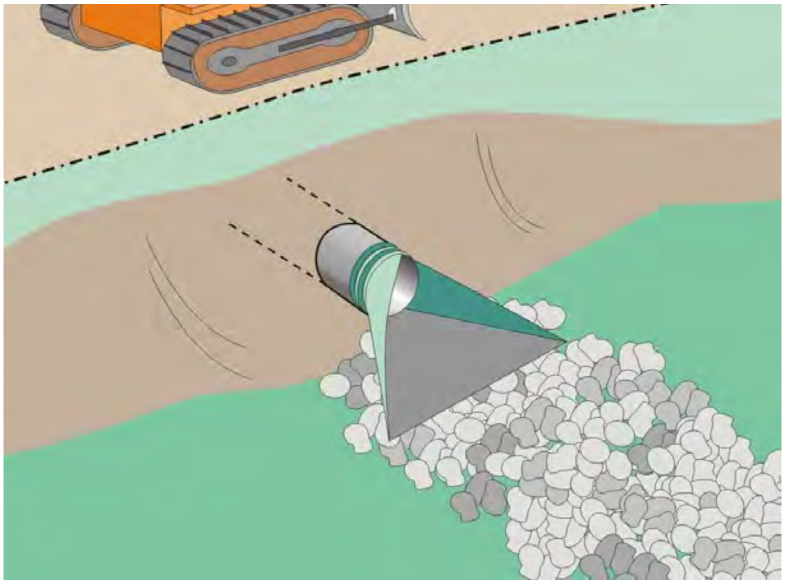
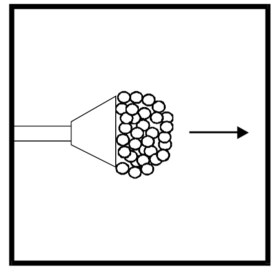
Outlet Protection/Velocity Dissipation Devices

SS-10





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Outlet protection and velocity dissipation devices are placed at pipe outlets to prevent scour and reduce the velocity and/or energy of storm water flows.

Appropriate Applications

- These devices may be used at the following locations:
  - Outlets of pipes, drains, culverts, slope drains, diversion ditches, swales, conduits or channels.
  - Outlets located at the bottom of mild to steep slopes.
  - Points where lined conveyances discharge to unlined conveyances.

Limitations

The use of outlet protection and velocity dissipation devices in streambeds shall be in compliance with the contract Special Provisions and approved by the Engineer.

Standards and Specifications

- There are many types of energy dissipaters, with rock being the one that is represented in the figure on Page 3. Please note that this is only one example and the Engineer may approve other types of devices proposed by the contractor.
- Install riprap, grouted riprap, or concrete apron at selected outlet. Riprap aprons are best suited for temporary use during construction.
- Grouted riprap shall be approved by the Engineer prior to installation.
- Carefully place riprap to avoid damaging the filter fabric.

- For proper operation of apron:
  - Align apron with receiving stream and keep straight throughout its length. If a curve is needed to fit site conditions, place it in upper section of apron.
  - If size of apron riprap is large, protect underlying filter fabric with a gravel blanket.
- Outlets on slopes steeper than 10% shall have additional protection.

Standards and Specifications

- There are many types of energy dissipaters, with rock being the one that is represented in the figure on Page 3. Please note that this is only one example and the Engineer may approve other types of devices proposed by the contractor.
- Install riprap, grouted riprap, or concrete apron at selected outlet. Riprap aprons are best suited for temporary use during construction.
- Carefully place riprap to avoid damaging the filter fabric.
- For proper operation of apron:
  - Align apron with receiving stream and keep straight throughout its length. If a curve is needed to fit site conditions, place it in upper section of apron.
  - If size of apron riprap is large, protect underlying filter fabric with a gravel blanket.
- Outlets on slopes steeper than 10% shall have additional protection.

Maintenance and Inspection

- Inspect all outlet protection and velocity dissipation devices weekly and before and after every rainfall events. During extended rainfall events, inspect outlet protection and velocity dissipation devices at least once every 24 hours.
- Inspect apron for displacement of the riprap and/or damage to the underlying fabric. Repair fabric and replace riprap that has washed away.
- Inspect for scour beneath the riprap and around the outlet. Repair damage to slopes or underlying filter fabric immediately.
- Temporary devices shall be completely removed as soon as the surrounding drainage area has been stabilized, or at the completion of construction.

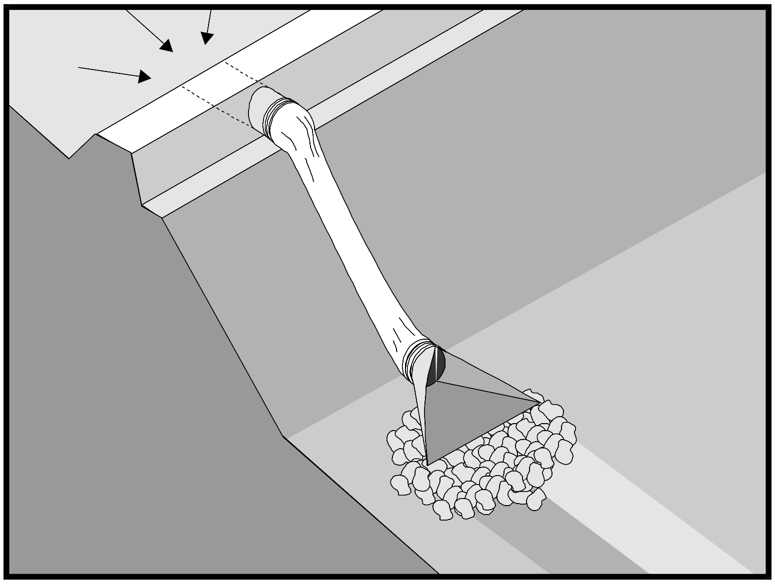
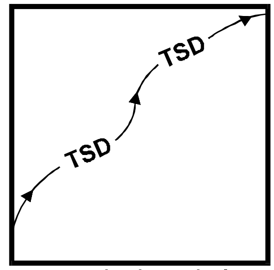
Slope Drains

SS-11





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A slope drain is a pipe used to intercept and direct surface runoff or groundwater into a stabilized watercourse, trapping device or stabilized area. Slope drains are used with lined ditches to intercept and direct surface flow away from slope areas to protect cut or fill slopes.

Appropriate Applications

- Slope drains may be used on construction sites where slopes may be eroded by surface runoff.
- Slope drains shall be implemented in conjunction with other BMPs. Slope drains result in concentrated flow that shall be dissipated at the outlet to prevent erosion.

Limitations

- None identified.

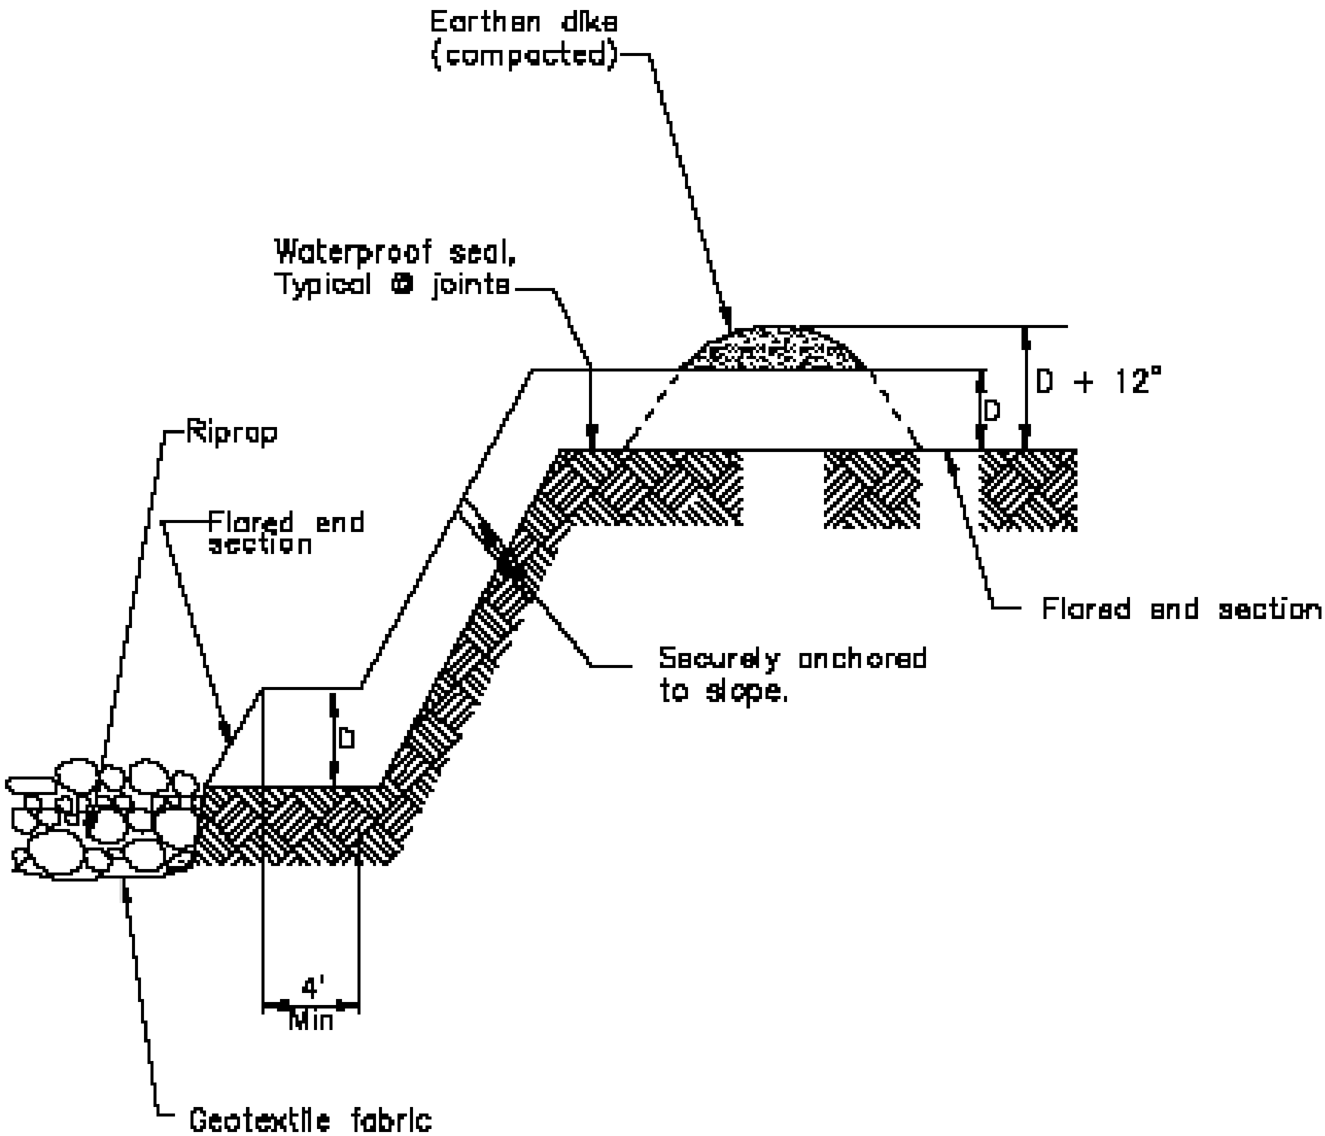
Standards and Specifications

- When using slope drains, limit drainage area to 10 ac per pipe. For larger areas, use a rock-lined channel or a series of pipes.
- Maximum slope should be generally limited to 1:2 (V:H), as energy dissipation below steeper slopes is difficult.
- Direct surface runoff to slope drains with interceptor dikes. See BMP SS-8, “Earth Dikes/Drainage Swales, and Lined Ditches.”
- Slope drains can be placed on or buried underneath the slope surface.
- Recommended materials are PVC, ABS, or comparable pipe.
- When installing slope drains:
  - Install slope drains perpendicular to slope contours.
  - Compact soil around and under entrance, outlet, and along length of pipe.

- Securely anchor and stabilize pipe and appurtenances into soil.
- Check to ensure that pipe connections are water tight.
- Protect area around inlet with filter cloth. Protect outlet with riprap or other energy dissipation device. For high energy discharges, reinforce riprap with concrete or use reinforced concrete device.
- Protect inlet and outlet of slope drains; use standard flared end section at entrance and exit for pipe slope drains 12in. and larger.

Maintenance and Inspection

- Inspect slope drains weekly and before and after every rainfall events. During extended rainfall events, inspect slope drains at least once every 24 hours.
- Inspect outlet for erosion and downstream scour. If eroded, repair damage and install additional energy dissipation measures. If downstream scour is occurring, it may be necessary to reduce flows being discharged into the channel unless other preventative measures are implemented.
- Inspect slope drainage for accumulations of debris and sediment.
- Remove built-up sediment from entrances, outlets, and within drains as required.
- Make sure water is not ponding onto inappropriate areas (e.g., active traffic lanes, material storage areas, etc.).



TYPICAL SLOPE DRAIN

NOT TO SCALE

SECTION 4

TEMPORARY SEDIMENT CONTROL BMPs

Temporary sediment control BMPs include practices that intercept, slow, or detain the flow of storm water to allow sediment to settle and be contained on the construction site. Temporary sediment control BMPs consist of installing temporary barriers or basins placed below the toe of slopes, down gradient of areas of exposed soil, around stockpiles, and other appropriate locations along the construction site perimeter. Fiber rolls and/or gravel bag berms are required to break up slope lengths. Effective perimeter controls (i.e., silt fence, fiber rolls, gravel bag berms, or sandbag berms) shall be established and maintained. Temporary sediment control practices include the BMPs shown on Table 4-1.

Table 4-1
Temporary Sediment Control BMPs

ID	BMP Name
SC-1	Silt Fence
SC-2	Sediment/Desilting Basin
SC-3	Sediment Trap
SC-4	Check Dam
SC-5	Fiber Rolls
SC-6	Gravel Bag Berm
SC-7	Street Sweeping and Vacuuming

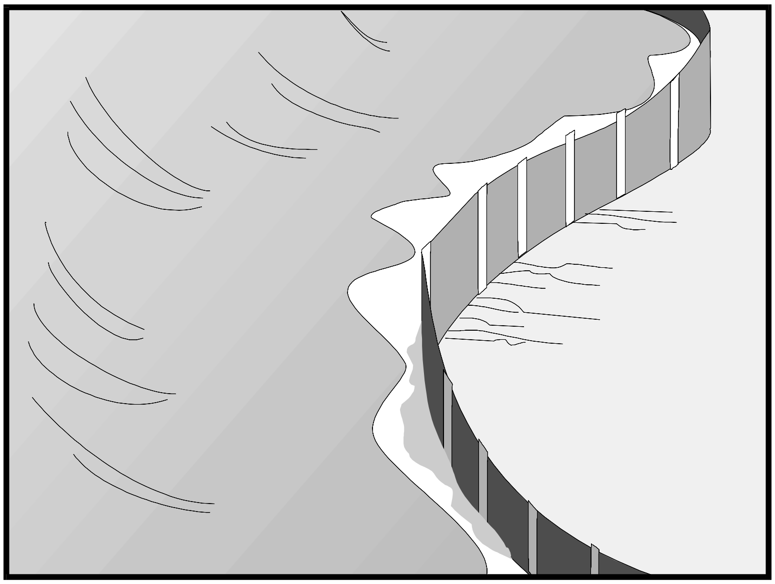
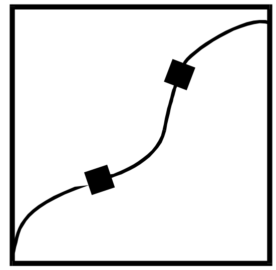
SC-9	Straw Bale Barrier
SC-10	Storm Drain Inlet Protection

(This page left intentionally blank)

Silt Fence





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A silt fence is a temporary linear sediment barrier of permeable fabric designed to intercept and slow the flow of sediment-laden sheet flow runoff. Silt fences allow sediment to settle from runoff before water leaves the construction site.

Appropriate Applications

Silt fences are placed:

- Below the toe of exposed and erodible slopes.
- Down-slope of exposed soil areas.
- Around temporary stockpiles.
- Along streams and channels.
- Along the perimeter of a project.

Limitations

- Shall not be used below slopes subject to creep, slumping, or landslides.
- Shall not be used in streams, channels, drain inlets, or anywhere flow is concentrated.
- Shall not be used to divert flow. Silt fences shall not be used in concentrated flow areas.

Standards and Specifications

Design and Layout

- The maximum length of slope draining to any point along the silt fence shall be 200 ft or less.
- The slope of area draining to silt fence shall be less than 1:1 (V:H).
- Shall not use as mid-slope protection on slopes greater than 1:4 (V:H).

- Limit silt fence installation to locations suitable for temporary ponding and deposition of sediment.
- Fabric life span is generally limited. Longer periods may require fabric replacement.
- Lay out shall be in accordance with Pages 5 and 6 of this BMP.
- For slopes steeper than 1:2 (V:H) and that contain a high number of rocks or large dirt clods that tend to dislodge, it may be necessary to install additional protection immediately adjacent to the bottom of the slope, prior to installing silt fence. Additional protection may be a chain link fence or a cable fence.
- For slopes adjacent to water bodies or Environmentally Sensitive Areas (ESAs), or as directed by the engineer, additional temporary soil stabilization BMPs shall be used.

Materials

- Silt fence fabric shall be woven polypropylene with a minimum width of 36 inches and a minimum tensile strength of 100 lb force. The fabric shall conform to the requirements in ASTM designation D4632 and shall have an integral reinforcement layer. The reinforcement layer shall be a polypropylene, or equivalent, net provided by the manufacturer. The permittivity of the fabric shall be between 0.1 sec-1 and 0.15 sec-1 in conformance with the requirements in ASTM designation D4491. Contractor shall submit certificate of compliance with these specifications.
- Wood stakes shall be commercial quality lumber of the size and shape shown on the plans. Each stake shall be free from decay, splits or cracks longer than the thickness of the stake or other defects that would weaken the stakes and cause the stakes to be structurally unsuitable.
- Bar reinforcement may be used in lieu of wood stakes. The bars shall be equal to a number four (4) or greater. End protection shall be provided for any exposed bar reinforcement.
- Staples used to fasten the fence fabric to the stakes shall be not less than 1.75 inches long and shall be fabricated from 15 gauge or heavier wire. The wire used to fasten the tops of the stakes together when joining two sections of fence shall be 9 gauge or heavier wire.

Installation

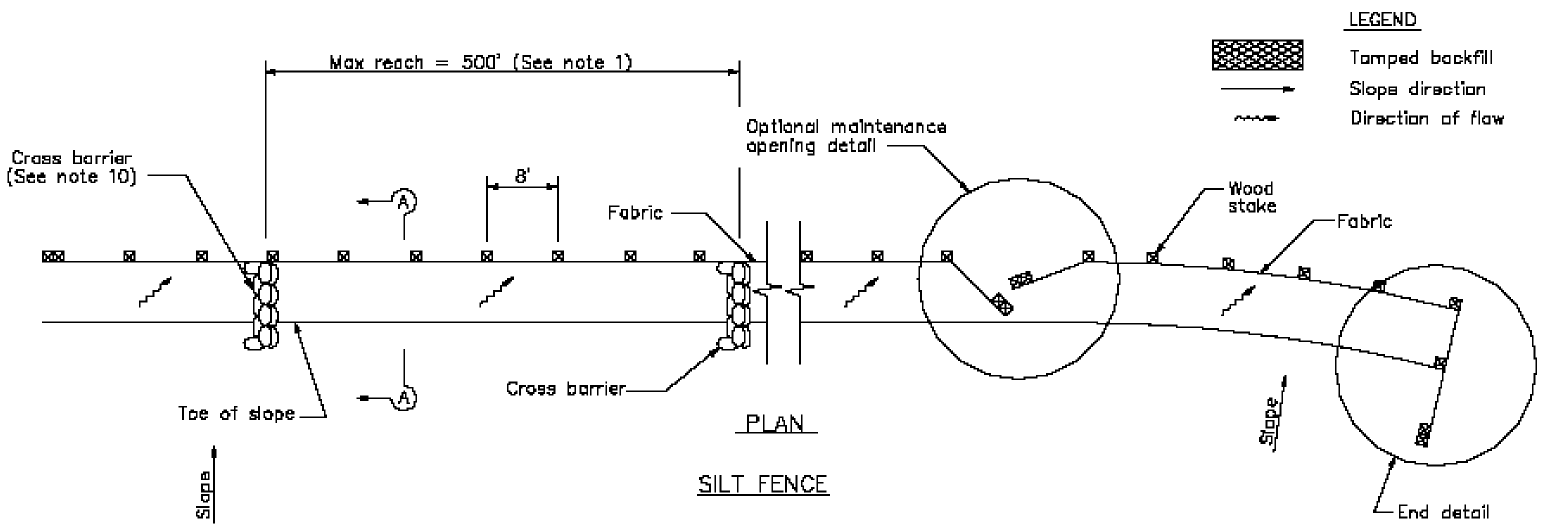
- Silt fences shall be used in conjunction with soil stabilization source controls up slope to provide effective erosion and sediment control.
- Bottom of the silt fence shall be keyed or trenched -in a minimum of 12 inches. Trenches shall not be excavated wider and deeper than necessary for proper installation of the temporary linear sediment barriers.

- Excavation of the trenches shall be performed immediately before installation of the temporary linear sediment barriers.
- Construct silt fences with a set-back of at least 3 feet from the toe of a slope. Where a silt fence is determined to be not practical due to specific site conditions, the silt fence may be constructed at the toe of the slope, but shall be constructed as far from the toe of the slope as practical.
- Construct the length of each reach so that the change in base elevation along the reach does not exceed 1/3 the height of the barrier.
- Cross barriers shall be a minimum of 1/3 and a maximum of 1/2 the height of the linear barrier.

Maintenance and Inspection

- Ensure that perimeter controls are maintained and protected from activities that reduce their effectiveness.
- Repair undercut silt fences. Repair or replace split, torn, slumping, or weathered fabric.
- Inspect all silt fences a minimum of weekly and before and after every rainfall events. During extended rainfall events, inspect inlet protection devices at least once every 24 hours. Perform necessary maintenance, or maintenance required by the Engineer.
- Maintain silt fences to provide an adequate sediment holding capacity. Sediment shall be removed when the sediment accumulation reaches one-third (1/3) of the barrier height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of outside the right-of-way in conformance with all applicable laws and regulations.
- Silt fences that are damaged and become unsuitable for the intended purpose, as determined by the Engineer, shall be removed from the site of work, disposed of outside the project right-of-way in conformance with all applicable laws and regulations, and replaced with new silt fence barriers.
- Remove silt fence when no longer needed or as required by the Engineer. Fill and compact post holes and anchorage trench, remove sediment accumulation, grade fence alignment to blend with adjacent ground and stabilized disturbed soil areas.

Silt Fence



PLAN

SILT FENCE

NOTES

1. Construct the length of each reach so that the change in base elevation along the reach does not exceed 1/3 the height of the linear barrier, in no case shall the reach length exceed 500'.
2. The last 8'-0" of fence shall be turned up slope.
3. Stake dimensions are nominal.
4. Dimension may vary to fit field condition.
5. Stakes shall be spaced at 8'-0" maximum and shall be positioned on downstream side of fence.
6. Stakes to overlap and fence fabric to fold around each stake one full turn. Secure fabric to stake with 4 staples.
7. Stakes shall be driven tightly together to prevent potential flow-through of sediment at joint. The tops of the stakes shall be secured with wire.
8. For end stake, fence fabric shall be folded around the stakes one full turn and secured with 4 staples.
9. Minimum 4 staples per stake. Dimensions shown are typical.
10. Cross barriers shall be a minimum of 1/3 and a maximum of 1/2 the height of the linear barrier.
11. Maintenance openings shall be constructed in a manner to ensure sediment remains behind silt fence.
12. Joining sections shall not be placed at sump locations.
13. Sandbag rows and layers shall be offset to eliminate gaps.

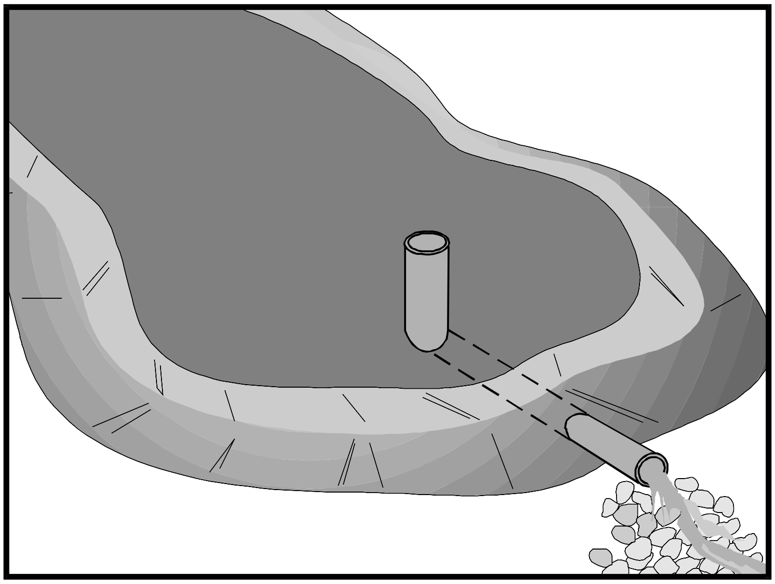
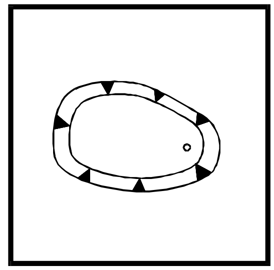
Sediment/Desilting Basin

SC-2





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A sediment/desilting basin is a temporary basin formed by excavating and/or constructing an embankment so that sediment-laden runoff is temporarily detained under still conditions, allowing sediment to settle out before the runoff is discharged (refer to Figures 1 and 2).

Appropriate Applications

As required by the Construction General Permit (NPDES No. CAS000002, Order 2009-0009-DWQ), sediment basins shall be designed at a minimum to the method provided in CASQA's Construction BMP Guidance Handbook. This BMP is consistent with the CASQA handbook. This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Engineer.

Sediment/Desilting Basins shall be used:

- Where sediment-laden water may enter the drainage system or watercourses.
- At outlets of disturbed soil areas with areas between 5 ac and 10 ac.

Limitations

- Alternative BMPs must be thoroughly investigated for erosion control before selecting temporary desilting basins.
- Requires large surface areas to permit settling of sediment. Size may be limited by availability of space on the construction site.
- Not appropriate for drainage areas greater than 75 ac.
- For safety reasons, basins shall have protective fencing.
- Not allowed for dewatering or groundwater.

Standards and Specifications

- Limit the contributing area to the sediment/desilting basin to only the runoff from the disturbed soil areas. Use temporary concentrated flow conveyance controls to divert runoff from undisturbed areas away from the sediment/desilting basin.

- Sediment/desilting basin shall be designed by a professional Engineer registered with the State of California. The Design details shall be included in the SWPPP or SWPPP amendment or approved by the Engineer prior to construction.

- The design shall include maintenance requirements, including sediment and vegetation removal, to ensure continuous function of the trap outlet and bypass structures.

Sediment Basin

- Sediment basins shall, at a minimum, be designed as follows:
  - Option 1: Sediment basin(s) shall be designed using the standard equation:

    $$As=1.2Q/Vs \qquad \text{(Eq. 1)}$$

    Where:

    As = Minimum surface area for trapping soil particles of a certain size.

    Vs = Settling velocity of the design particle size chosen(*Vs* = 0.00028 ft/s for a design particle size of 0.01 mm at 68 ºF)

    1.2 = Factor of safety recommended by USEPA to account for the reduction in basin efficiency caused due to turbulence and other non ideal conditions.

    $$Q = C\ I\ A \qquad \text{(Eq. 2)}$$

    Where:

    Q = Discharge rate measured in cubic feet per second

    C = Runoff coefficient (unit less)

    I = Precipitation intensity for the 10-year, 6-hour rain event (in/hr)

    A = Area draining into the sediment basin in acres.

    The design particle size shall be the smallest soil grain size determined by wet sieve analysis, or the fine silt sized (0.01mm [or 0.004 in.]) particle, and the *Vs* used shall be 100 percent of the calculated settling velocity.

The basin length is determined by measuring the distance between the inlet and the outlet. If the outlet structure will be used to control the flow, the length shall be more than twice the dimension as the width. If the topography does not allow for this configuration, baffles shall be used to meet the ratio. If the basin length will be used to control flow, the length shall be designed to capture 100% of the design particle size. The depth shall not be less than 3 ft nor greater than 5 ft for safety reasons and for maximum efficiency (2 ft of sediment storage, 2 ft of capacity). The basin(s) shall be located on the site where it can be maintained on a year-round basis and shall be maintained on a schedule to retain the 2 ft of capacity.

OR

– Option 2: Pursuant to local ordinance for sediment basin design and maintenance, provided that the design efficiency is as protective or more protective of water quality than Option 1.

OR

– Option 3: The use of an equivalent surface area design or equation, provided that the design efficiency is as protective or more protective of water quality than Option 1.

In order to design a sediment basin properly, the site constraints, soil particle size distribution, drainage area, and local hydrology shall be considered.

Typical Hydrologic *Design Methodology*

Evaluate the site constraints and assess the drainage area for the sediment basin. Consider on- and off-site flows as well as changes in drainage areas associated with construction. To minimize additional construction during the course of the project, identify and use the maximum drainage area when calculating the basin dimensions.

The Los Angeles County Department of Public Works, Hydrology Manual, January 2006 (http://dpw.lacounty.gov/wrd/publication/engineering/2006 Hydrology Manual shall be used to obtain the needed rainfall intensity.

Calculate the surface area required for the sediment basin using Equation 1. Discharge is estimated for a 10-year 6-hour event using the rational method procedure. Vs is estimated using Stokes Law (Eq. 3)

$V_s = 2.81\ d^2$ (Eq. 3)

Where:

Vs = Settling velocity in feet per second at 68 ºF.

d = diameter of sediment particle in millimeters (smallest soil grain particle size determined by wet sieve analysis or fine silt (0.01mm [or 00.0004 in.]).

- The basin outlet design requires an iterative trial and error approach that considers the maximum water surface elevation, elevation versus volume relationship, elevation versus discharge relationship, and the estimated inflow hydrograph. To adequately design the basin to settle sediment, the outlet configuration and associated outflow rates shall be estimated. There are numerous methodologies:

- Outlet design typically includes multiple horizontal rows of orifices (3 or more) with at least 2 orifices per row (see figures 1 and 2).
- Select the appropriate orifice diameter and number of perforations per row with the objective if minimizing the number of rows while maximizing the detention time. Each outlet should have more than one orifice
- The diameter of each orifice is typically a maximum of 3-4 inches and a minimum of 0.25 -0.5 inches.
- If a rectangular orifice is used, it is recommended to have a minimum height of 0.5 inches and a maximum height of 6 inches.
- Rows are typically spaced at three times the diameter center to center vertically with a minimum distance of 4 inches on center and a maximum distance of 1 foot on center.
- Each row is calculated separately for outflow rate using the flow through a single orifice and multiplying by the number of orifices in that row. Repeat this step for each row and sum the rows. The total outflow rate is then compared to the detention time within the basin.

  Flow through a single orifice can be estimated using the following equation (Eq. 4):

  $Q = BC' A(2gH)^{0.5}$ (Eq. 4)

  Where:

  Q = Discharge in ft^3/s

  C' = Orifice coefficient (unit less)

  A = area of the orifice (ft^2)

  g = acceleration due to gravity (ft^3/s)

  H = head above the orifice (ft)

  B = anticipated Blockage or clogging factor (unitless), dependent on anticipated sediment and debris load, trash rack configuration, etc., so the value is dependent on professional judgment and/or local requirements (B is never greater than 1 and a value of 0.5 is generally used).

- For the orifice coefficient (C') the value of 0.6 is most often recommended and used, or

  C' = 0.66 for thin materials- where the thickness of the material (used to form the orifice) is equal to or less than the diameter of the orifice, or

  C' = 0.8 when the material is thicker than the orifice diameter.

- If different sizes of orifices are used along the riser then they must be sized so that not more than 50 percent of the design storm event drains in one third of the draw down time. This will allow adequate settling time for events smaller than the design storm event. The entire volume of the basin shall be designed to drain within 72 hours or less if required by local vector control regulations. If the basin fails to empty within 72 hours, the basin shall be pumped dry in accordance with the APP (see NS-2 Dewatering Operations BMPs).

- Floating outlet skimmer: The floating outlet skimmer drains water from the upper portion of the water column in the basin. This prevents clogging from bottom sediments. Figure 4 shows the floating outlet skimmer.

- Hold and release valve: A valve system for releasing water from a detention basin is critical. The valve system may be manual, bladder devices or electronic. The valve shall be closed during the rain event and settling time and then released to drain within 72 hours or less if required by local vector regulations.

Evaluate the Capacity of the Sediment Basin

- Sediment basins cannot be expected to perform as designed if not properly maintained or the sediment yield is larger than expected. Sediment basin design must include maintenance requirements sediment yield and basin storage volume.

- Sediment yield can be estimated using the Modified Universal Soil Loss Equation (MUSLE, Eq. 5) and annual soil loss can be estimated using the Revised Universal Soil Loss Equation (RUSLE, Eq.6).

  $Y = 95 (Q \times q_p)^{0.56} \times K \times LS \times C \times P$ (Eq. 5)

  $A = R \times K \times LS \times C \times P$ (Eq. 6)

  Where:

  A = annual soil loss, tons per acre per year

  R = rainfall erosion index, in 110 ft. tons/acre in /hour

  K = soil erodibility factor, in tons/acre per unit of R

  LS = Slope length and steepness factor (unit less)

  C = vegetative cover factor (unit less)

  P = erosion control practice factor (unit less)

  Y – single storm sediment yield in tons

  Q = runoff volume in acre-feet

  q = peak flow in cfs.

- Determination of the appropriate equation shall consider construction duration and local environmental factors. For example, a year-long project should use RUSLE. Where a project that is less than a year should use the MUSLE. Both equations are used to estimate soil loss and evaluate the sediment storage volume required and maintenance frequency.

- Soil loss estimates are an essential step in the design and maintenance requirements must be understood by the implementers in the field. Providing maintenance methods, frequencies and specifications shall be included on the SWPPP Site map.
- Once the amount of soil entering the basin is estimated, the depth required for sediment storage shall be determined by dividing the estimated sediment loss by the surface area of the basin.

General Requirements

- The basin shall consist of the following 2 zones:
- A sediment storage zone of at least 1 foot deep
- A settling zone at least 2 feet deep
- The basin depth shall be no less than 3 feet deep (not including free board). Free board shall be 1 foot or more as required by local regulations.
- Proper hydraulic design of the outlet is critical to achieving the desired performance of the basin. The water quality outlet should be designed to drain the basin within 24 to 72 hours (also referred to as "drawdown time"). (The 24-hour limit is specified to provide adequate settling time; the 72-hour limit is specified to mitigate vector control concerns.)
- The length to settling depth ratio shall be less than 200.
- SS-10 shall be used to protect the basin inlet and slopes against erosion.
- Design and locate sediment/desilting basins so that they can be maintained. Construct desilting basins prior to construction activities.
- Sediment/desilting basins, regardless of size and storage volume, shall include features to accommodate overflow or bypass flows that exceed the design storm event. The calculated basin volume and proposed location shall be submitted to the Engineer for approval at least 3 days prior to the basin construction.
- Construct an emergency spillway to accommodate flows not carried by the principal spillway.
- Spillway shall consist of an open channel (earthen or vegetated) over undisturbed material (not fill) or constructed of a non-erodible riprap.
- Spillway control section, which is a level portion of the spillway channel at the highest elevation in the channel, shall be a minimum of 20 ft in length.
- A forebay, constructed upstream of the basin may be provided to remove debris and larger particles.

- Basin inlets shall be located to maximize travel distance to the basin outlet.
- If baffles are used, construct them of earthen berms that are stabilized to prevent erosion or other structural materials to divert flows and allow settling throughout the basin. Baffles shall be designed to diver the design flows and allow
- The outflow from the basins shall be provided with outlet protection to prevent erosion and scouring of the embankment and channel. See BMP SS-10, "Outlet Protection/Velocity Dissipation Devices."
- Basin shall be located: (1) by excavating a suitable area or where a low embankment can be constructed across a swale, (2) where post-construction (permanent) detention basins will be constructed, (3) where failure would not cause loss of life or property damage, (4) where the basins can be maintained on a year-round basins to provide access for maintenance, including sediment removal and sediment stockpiling in a protected area, and to maintain the basin to provide the required capacity.
- Areas under embankments, structural works, and sediment/desilting basin must be cleared, stripped of vegetation.
- Structure shall be placed on a firm, smooth foundation with the base securely anchored with concrete or other means to prevent floatation.
- Discharge from the basin shall be accomplished through a water quality outlet. An example is shown in Figure 3. The principal outlet shall consist of a corrugated metal, high density polyethylene (HDPE), or reinforced concrete riser pipe with dewatering holes and an anti-vortex device and trash rack attached to the top of the riser, to prevent floating debris from flowing out of the basin or obstructing the system. This principal structure shall be designed to accommodate the inflow design storm.
- A rock pile or rock-filled gabions can serve as alternatives to the debris screen, although the designer should be aware of the potential for extra maintenance involved should the pore spaces in the rock pile clog.
- The two most common outlet problems that occur are: (1) the capacity of the outlet is too great resulting in only partial filling of the basin and drawdown time less than designed for; and (2) the outlet clogs because it is not adequately protected against trash and debris. To avoid these problems, the following outlet types are recommended for use: (1) a single orifice outlet with or without the protection of a riser pipe, and (2) perforated riser. Design guidance for single orifice and perforated riser outlets are as follows:

Flow Control Using a Single Orifice At The Bottom Of The Basin (Figure 1):

The outlet control orifice should be sized using the following equation:

$$a = \frac{2A(H - Ho)^{0.5}}{3600CT(2g)^{0.5}} = \frac{(7x10^{-5})A(H - Ho)^{0.5}}{CT} \qquad \text{(Eq. 2)}$$

where:

a = area of orifice (ft^2)

A = surface area of the basin at mid elevation (ft^2)

C = orifice coefficient

T = drawdown time of full basin (hrs)

G = gravity (32.2 ft/s^2)

H = elevation when the basin is full (ft)

Ho = final elevation when basin is empty (ft)

With a drawdown time of 40 hours, the equation becomes:

$$a = \frac{(1.75x10^{-6})A(H - Ho)^{0.5}}{C} \qquad \text{(Eq. 3)}$$

Flow Control Using Multiple Orifices (see Figure 2):

$$a_t = \frac{2A(h_{\max})}{CT(2g[h_{\max} - h_{centroid\ of\ orifices}])^{0.5}} \qquad \text{(Eq. 4)}$$

With terms as described above except:

a_t = total area of orifices

h_{max} = maximum height from lowest orifice to the maximum water surface (ft)

$h_{centroid\ of\ orifices}$ = height from the lowest orifice to the centroid of the orifice configuration (ft)

Allocate the orifices evenly on two rows; separate the holes by 3x hole diameter vertically, and by 120 degrees horizontally (refer to Figure 3).

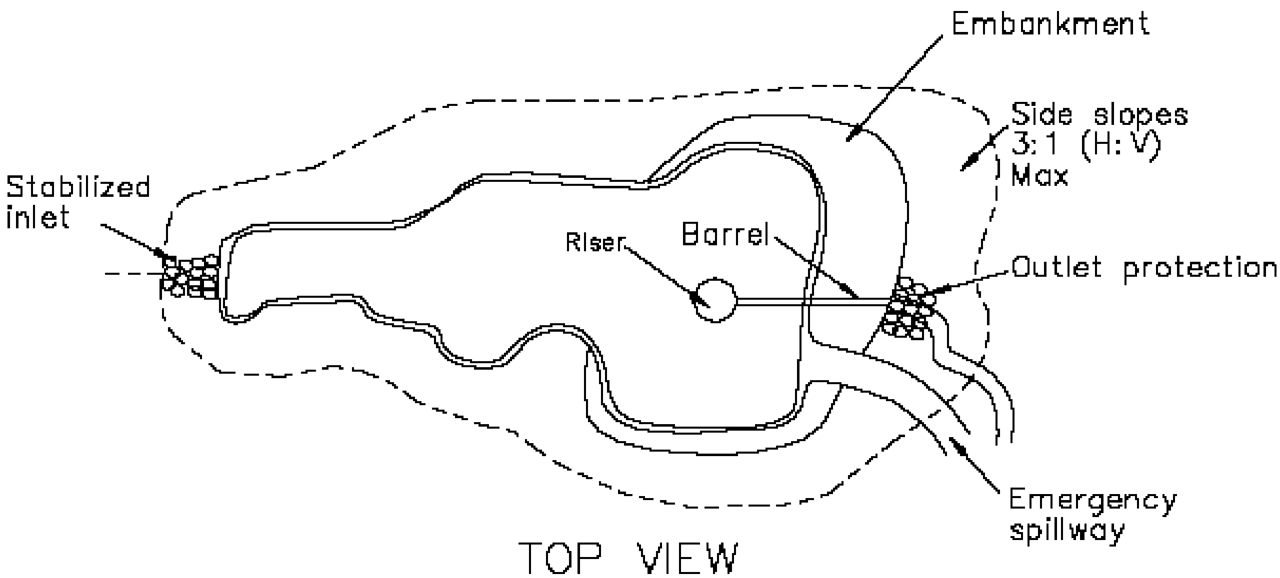
Because basins are not maintained for infiltration, water loss by infiltration should be disregarded when designing the hydraulic capacity of the outlet structure.

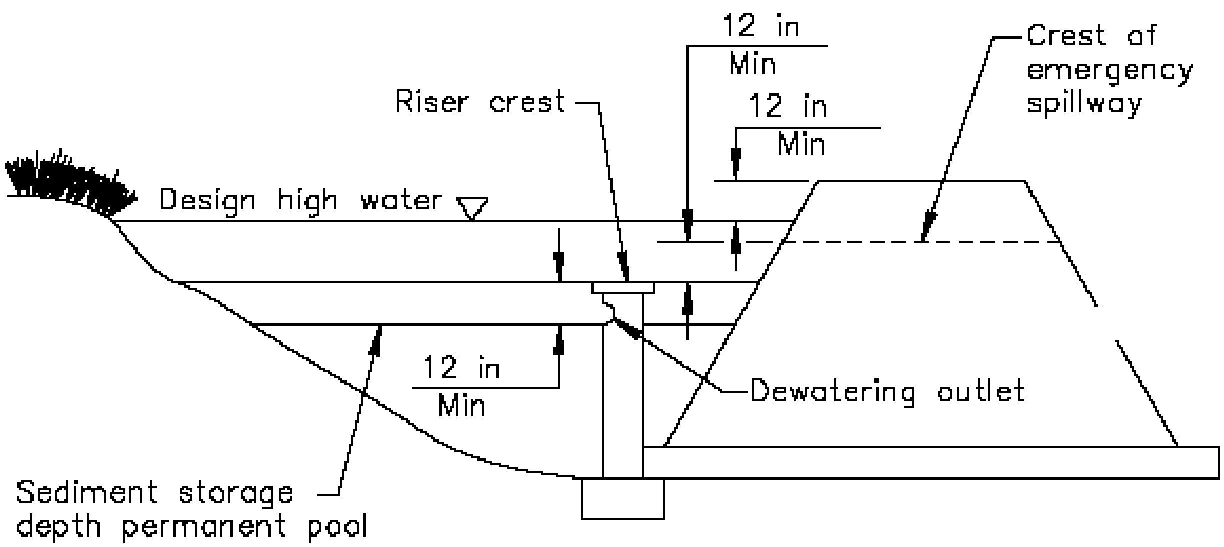
- The Contractor shall verify that the outlet is properly designed to handle the design and peak flows.
- Attach riser pipe (watertight connection) to a horizontal pipe (barrel), which extends through the embankment to toe of fill. Provide anti-seep collars on the barrel.
- Cleanout level shall be clearly marked on the riser pipe

Insignificant quantities of accumulated precipitation may be dewatered to the sediment/desilting basin unless precipitation is forecasted within 24 hours. Refer to NS-2 "Dewatering Operations" and the APP.

Inspection and Maintenance

- Inspect sediment basins weekly and before and after rainfall events. During extended rainfall events, inspect sediment basins at least every 24 hours.
- Examine basin banks for seepage and structural soundness.
- Check inlet and outlet structures and spillway for any damage or obstructions. Repair damage and remove obstructions as needed, or as directed by the Engineer.
- Remove standing water from the basin within 72 hours after accumulation.
- Check inlet and outlet area for erosion and stabilize if required, or if directed by the Engineer.
- Remove accumulated sediment when its volume reaches one-third the volume of the sediment storage. Properly dispose of sediment and debris removed from the basin.
- Check fencing for damage and repair as needed or as directed by the Engineer.





NOTE:
This outlet provides no drainage for permanent pool.

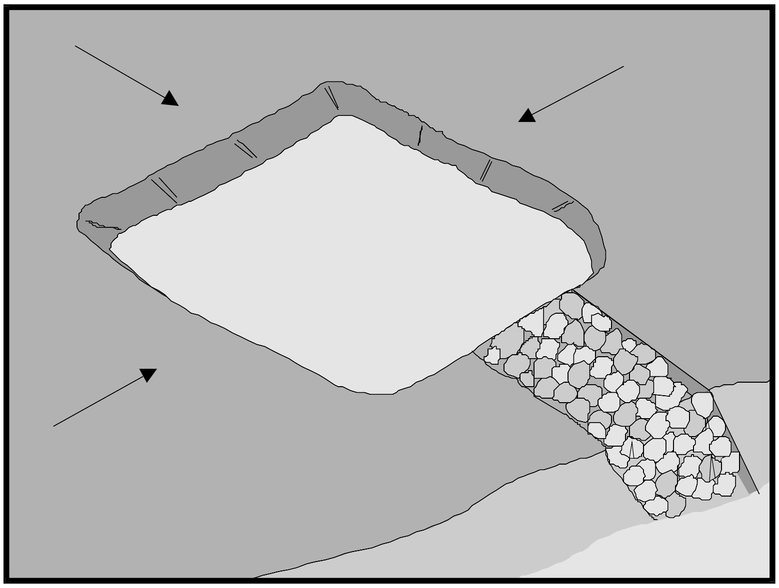
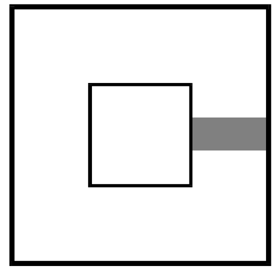
Sediment Trap

SC-3





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A sediment trap is a temporary containment area that allows sediment in collected storm water to settle out during infiltration or before the runoff is discharged through a stabilized spillway. Sediment traps are formed by excavating or constructing an earthen or other embankment across a waterway or low drainage area.

Appropriate Applications

- Sediment traps may be used on construction projects where the drainage area is less than 5 ac. Traps should be placed where sediment-laden storm water enters a storm drain or watercourse.
- This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Engineer.
- As a supplemental control, sediment traps provide additional protection for a water body or for reducing sediment before it enters a drainage system.

Limitations

- Requires large surface areas to permit infiltration and settling of sediment.
- Not appropriate for drainage areas greater than 5 ac.
- Only removes large and medium sized particles and requires upstream erosion control.
- Size may be limited by availability of area on construction site.

Standards and Specifications

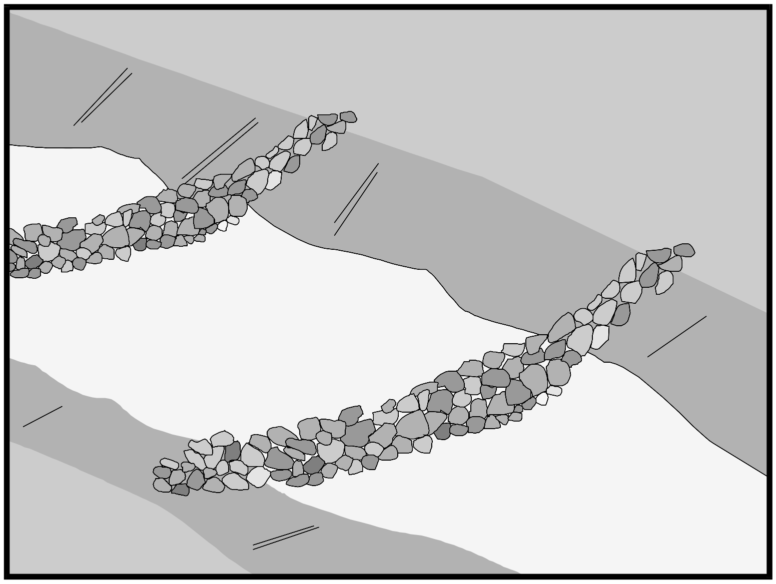
- Trap shall be situated according to the following criteria: (1) by excavating a suitable area or where a low embankment can be constructed across a swale, (2) where failure would not cause loss of life or property damage, and (3) to provide access for maintenance, including sediment removal and sediment stockpiling in a protected area.
- Trap shall be sized to accommodate a settling zone and sediment storage zone with recommended minimum volumes of 67 yd^3/ac and 33 yd^3/ac of contributing drainage area, respectively, based on 0.5 inches of runoff volume over a 24-hr period. Multiple traps and/or additional volume may be required to accommodate site specific rainfall and soil conditions.
- Sediment/desilting basin shall be designed by a professional Engineer registered with the State of California. The design details shall be included in the SWPPP or SWPPP amendment or approved by the Engineer prior to construction.
- The design shall include maintenance requirements, including sediment and vegetation removal, to ensure continuous function of the trap outlet and bypass structures.
- Areas under embankments, structural works, and sediment traps shall be cleared and stripped of vegetation and root material. The pool area shall be cleared.
- Use SS-10 to protect the trap outlets against erosion.
- Fencing shall be provided to prevent unauthorized entry.

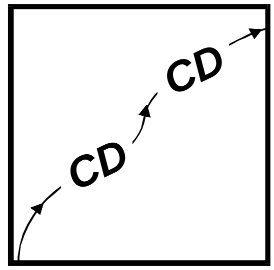
Maintenance and Inspection

- Inspect sediment traps a minimum of weekly, before and after rainfall events. During extended rainfall events, inspect sediment traps at least every 24 hours.
- If captured runoff has not completely infiltrated within 72 hours, the sediment trap must be dewatered per NS-2 requirements.
- Inspect trap banks for embankment seepage and structural soundness. Inspect outlet area for erosion and stabilize as required, or as directed by the Engineer.
- Inspect outlet structure and rock spillway for any damage or obstructions. Repair damage and remove obstructions as needed or as directed by the Engineer.
- Remove accumulated sediment when the volume has reached one-third the original trap volume. Properly dispose of sediment and debris removed from the trap.
- Inspect fencing for damage and repair as needed or as directed by the Engineer.

Check Dams

SC-4





BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Check dams reduce scour and channel erosion by reducing flow velocity and encouraging sediment settlement. A check dam is a small device constructed of rock, gravel bags, sandbags, fiber rolls, or other appropriate product placed across a natural or man-made channel or drainage ditch.

Appropriate Applications

- Check dams may be installed:
  - In small open channels that drain 10 ac or less.
  - In steep channels where storm water runoff velocities exceed 4.9 ft/sec.
  - During the establishment of grass linings in drainage ditches or channels.
  - In temporary ditches where the short length of service does not warrant establishment of erosion-resistant linings.
- This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Engineer.

Limitations

- Not to be used in live streams.
- Not appropriate in channels that drain areas greater than 10 ac.
- Not to be placed in channels that are already grass lined unless erosion is expected, as installation may damage vegetation.
- Require extensive maintenance following high velocity flows.
- Promotes sediment trapping, which can be re-suspended during subsequent storms or removal of the check dam.
- Not to be placed in lined ditches designed for concentrated flow. Sediment must be prevented prior to entering lined or paved drain facilities.
- Not to be constructed from straw bales or silt fence.

Standards and Specifications

- Check dams shall be placed at a distance and height to allow small pools to form behind them. Install the first check dam approximately 16 ft from the outfall device and at regular intervals based on slope gradient and soil type.

- For multiple check dam installation, backwater from downstream check dam shall reach the toe of the upstream dam.

- High flows (typically a 2-year storm or larger) shall safely flow over the check dam without an increase in upstream flooding or damage to the check dam.

- Where grass is used to line ditches, check dams shall be removed when grass has matured sufficiently to protect the ditch or swale.

- Rock shall be placed individually by hand or by mechanical methods (no dumping of rock) to achieve complete ditch or swale coverage.

- Fiber rolls may be used as check dams if approved by the Engineer. Refer to SC-5 "Fiber Rolls."

- Gravel bags may be used as check dams with the following specifications:

Materials

– ***Bag Material:*** Bags shall be either polypropylene, polyethylene or polyamide woven fabric, minimum unit weight (four ounces per square yard), mullen burst strength exceeding 300 psi in conformance with the requirements in ASTM designation D3786, and ultraviolet stability exceeding 70% in conformance with the requirements in ASTM designation D4355.

– ***Bag Size:*** Each gravel-filled bag shall have a length of 18 in., width of 12 in., thickness of 3 in., and mass of approximately 33 lb. Bag dimensions are nominal, and may vary based on locally available materials. Alternative bag sizes shall be submitted to the Engineer for approval prior to deployment.

– ***Fill Material:*** Fill material shall be between 0.4 and 0.8 inch in diameter, and shall be clean and free from clay balls, organic matter, and other deleterious materials. The opening of gravel-filled bags shall be secured such that gravel does not escape. Gravel-filled bags shall be between 28 and 48 lb in mass. Fill material is subject to approval by the Engineer.

Installation

– Install along a level contour.

– Tightly abut bags and stack gravel bags using a pyramid approach. Gravel bags shall not be stacked any higher than 3.2 ft.

– Upper rows of gravel bags shall overlap joints in lower rows.

Maintenance and Inspection

- Inspect all check dams weekly and before and after every rainfall events. During extended rainfall events, inspect check dams at least once every 24 hours.
- Remove sediment when depth reaches one-third of the check dam height.
- Remove accumulated sediment prior to permanent seeding or soil stabilization.
- Remove check dam and accumulated sediment when check dams are no longer needed or when required by the Engineer.
- Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of in conformance with all applicable laws and regulations. If removed sediment is stored on site, it shall be in accordance with WM-3 Stockpile Management.

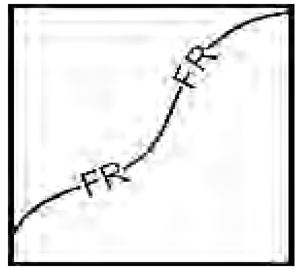
Fiber Rolls

SC-5



Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A fiber roll consists of wood excelsior, rice or wheat straw, or coconut fibers that is rolled or bound into a tight tubular roll and placed on the toe and face of slopes to intercept runoff, reduce its flow velocity, release the runoff as sheet flow and provide removal of sediment from the runoff. Fiber rolls may also be used for run-on diversion, inlet protection and check dams under certain situations.

Appropriate Applications

- This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Contractor or Engineer.
- Along the toe, top, face, and at grade breaks of exposed and erodible slopes to shorten slope length and spread runoff as sheet flow.
- Below the toe of exposed and erodible slopes.
- Fiber rolls may be used as check dams in unlined ditches if approved by the Engineer (refer to SC-4 "Check Dams").
- Fiber rolls may be used for drain inlet protection if they can be properly anchored and if approved by the Engineer (refer to SC-10 "Storm Drain Inlet Protection").
- Fiber rolls may be used for run-on diversion when properly anchored and approved by the Engineer.
- Down-slope of exposed soil areas.
- Around temporary stockpiles.
- Along the perimeter of a project.

Limitations

- Runoff and erosion may occur if the fiber roll is not adequately trenched in.
- Fiber rolls at the toe of slopes greater than 1:5 may require the use of 20" diameter rolls or installations achieving the same protection (i.e., stacked smaller diameter fiber rolls, etc.).
- Difficult to move once saturated.
- Fiber rolls could be transported by high flows if not properly staked and trenched in.
- Fiber rolls have limited sediment capture zone.
- Do not use fiber rolls on slopes subject to creep, slumping, or landslide.

Standards and Specifications

Fiber Roll Materials

- Fiber rolls shall be either:
  - Prefabricated rolls.
  - Rolled tubes of erosion control blanket.

Assembly of Field Rolled Fiber Roll

- Roll length of erosion control blanket into a tube of minimum 8 in. diameter.
- Bind roll at each end and every 4 ft. along length of roll with jute-type twine.

Installation

- Slope inclination of 1:4 or flatter: fiber rolls shall be placed on slopes 20 ft. (6m) apart.
- Slope inclination of 1:4 to 1:2: fiber rolls shall be placed on slopes 15 ft. (4.5 m) apart.
- Slope inclination 1:2 or greater: fiber rolls shall be placed on slopes 10 ft. (3 m) apart.
- Stake fiber rolls into a 2 to 4 in. trench.
- Use wood stakes with a nominal classification of 3/4 by 3/4 in, and minimum length of 24 in. Drive stakes at the end of each fiber roll and spaced 2 ft (600 mm) apart if Type 2 installation is used (refer to Page 4). Otherwise, space stakes 4 ft maximum on center if installed as shown on Pages 5 and 6.
- If more than one fiber roll is placed in a row, the rolls shall be overlapped; not abutted.

Removal

- Fiber rolls are typically left in place.
- If fiber rolls are removed, collect and dispose of sediment accumulation, and fill and compact holes, trenches, depressions or any other ground disturbance to blend with adjacent ground.

Maintenance and Inspection

- Ensure that all perimeter controls are maintained and protected from activities that reduce their effectiveness.
- Repair or replace split, torn, unraveling, or slumping fiber rolls.
- Inspect all fiber rolls weekly and before and after every rainfall events. During extended rainfall events, inspect fiber rolls at least once every 24 hours.
- Perform maintenance as needed or as required by the Engineer.
- Maintain fiber rolls to provide an adequate sediment holding capacity. Sediment shall be removed when the sediment accumulation reaches three quarters (3/4) of the barrier height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of outside the highway right-of-way in conformance with all applicable laws and regulations. If removed sediment is stored on site, it shall be in conformance with WM-3 Stockpile Management.

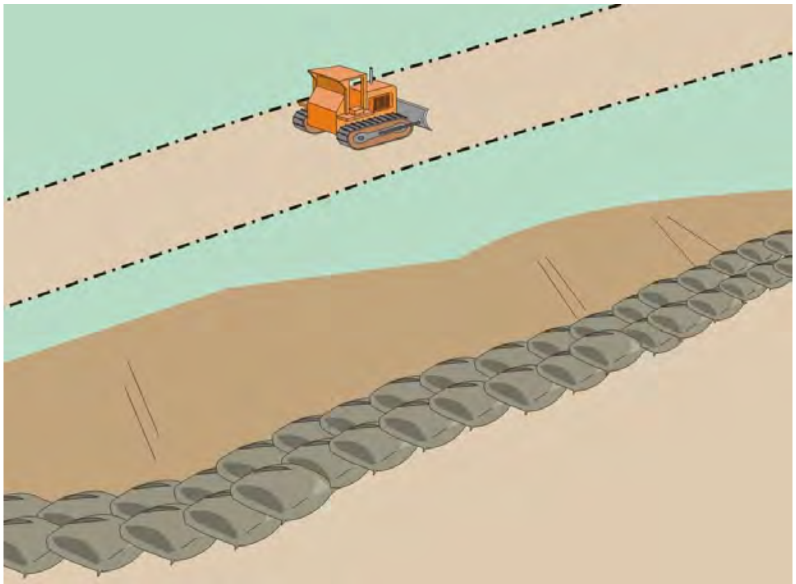
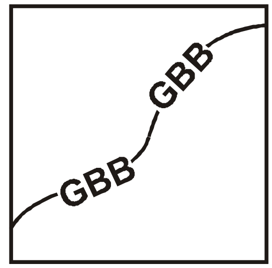
Gravel Bag Berm

SC-6





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A gravel bag berm consists of one or more rows of gravel bags that are installed end to end to form a barrier across a slope to intercept runoff, reduce its flow velocity, release the runoff as sheet flow and provide some sediment removal. Gravel bags can be used where flows are moderately concentrated, such as ditches, swales, and storm drain inlets (see BMP SC-10, Storm Drain Inlet Protection), and to divert and/or detain flows.

Appropriate Applications

- BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the Contractor or Engineer.
- Along streams and channels.
- Below the toe of exposed and erodible slopes.
- At grade breaks of exposed and erodible slopes to shorten slope length and spread runoff as sheet flow.
  - Slope inclination of 1:4 or flatter: fiber rolls shall be placed on slopes 20 ft. (6m) apart.
  - Slope inclination of 1:4 to 1:2: fiber rolls shall be placed on slopes 15 ft. (4.5 m) apart.
  - Slope inclination 1:2 or greater: fiber rolls shall be placed on slopes 10 ft. (3 m) apart.
- Around stockpiles.
- Across channels to serve as a barrier for utility trenches or provide a temporary channel crossing for construction equipment, to reduce stream impacts.
- Parallel to a roadway to keep sediment off paved areas.

- At the top of slopes to divert runoff away from disturbed slopes.
- Along the perimeter of a site.
- To divert or direct flow or create a temporary sediment basin.
- During construction activities in stream beds when the contributing drainage area is less than 5 ac.
- When site conditions or construction sequencing require adjustments or relocation of the barrier to meet changing field conditions and needs during construction.
- Gravel bag berms may be used as check dams in accordance with SC-4.

Limitations

- Degraded gravel bags may rupture, spilling contents.
- Installation can be labor intensive.
- Limited durability for long term projects.
- When used to detain concentrated flows, maintenance requirements increase.

Standards and Specifications

Materials

- Bag Material: Bags shall be woven polypropylene, polyethylene or polyamide fabric, minimum unit weight four ounces per square yard, mullen burst strength exceeding 300 psi in conformance with the requirements in ASTM designation D3786, and ultraviolet stability exceeding 70% in conformance with the requirements in ASTM designation D4355.
- Bag Size: Each gravel-filled bag shall have a length of 18 in., width of 12 in., thickness of 3 in., and mass of approximately 33 lb. Bag dimensions are nominal, and may vary based on locally available materials. Alternative bag sizes shall be submitted to the Engineer for approval prior to deployment.
- Fill Material: Gravel shall be between 0.4 and 0.8 inch in diameter, and shall be clean and free from clay balls, organic matter, and other deleterious materials. The opening of gravel-filled bags shall be secured such that gravel does not escape. Gravel-filled bags shall be between 28 and 48 lb in mass. Fill material is subject to approval by the Engineer.

Installation

- When used as a linear control for sediment removal:
  - Install along a level contour.
  - Turn ends of gravel bag row up slope to prevent flow around the ends.
  - Generally, gravel bag barriers shall be used in conjunction with temporary soil stabilization controls up slope to provide effective erosion and sediment control.

- When used for concentrated flows:
  - Stack gravel bags to required height using a pyramid approach.
  - Upper rows of gravel bags shall overlap joints in lower rows.
- Construct gravel bag barriers with a set-back of at least 3 ft from the toe of a slope to maximize sediment storage capacity. Where it is determined to be not practicable due to specific site conditions, the gravel bag barrier may be constructed at the toe of the slope, but shall be constructed as far from the toe of the slope as practicable.
- Contractor shall certify compliance with these specifications when installing gravel bag berms.

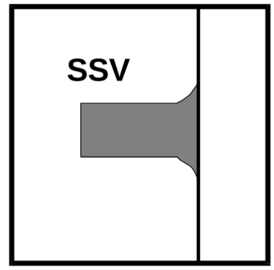
Maintenance and Inspection

- Ensure that all perimeter controls are maintained and protected from activities that reduce their effectiveness.
- Inspect all gravel bag berms weekly and before and after every rainfall events. During extended rainfall events, inspect gravel bag berms at least once every 24 hours.
- Reshape or replace gravel bags as needed, or as directed by the Engineer.
- Repair washouts or other damages as needed, or as directed by the Engineer.
- Inspect gravel bag berms for sediment accumulation and remove sediment when accumulation reaches one-third of the berm height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of outside the highway right-of-way in conformance with all applicable laws and regulations. If removed sediment is stored on site, it shall be stored in performance with WM-3 Stockpile Management.
- Remove gravel bag berms when no longer needed. Remove accumulated sediment and clean, re-grade, and stabilize the area.

(This page left intentionally blank)

Street Sweeping and Vacuuming

SC-7



Standard Symbol

BMP Objectives
- ● Soil Stabilization
- ● Sediment Control
- ● Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Practices to remove tracked sediment to prevent the sediment from entering a storm drain or watercourse.

Appropriate Applications

These practices are implemented anywhere sediment is tracked from the project site onto public or private paved roads, typically at points of ingress/egress.

Limitations

Sweeping and vacuuming may not be effective when soil is wet or muddy.

Standards and Specifications

- ■ Streets will be cleaned in such a manner as to prevent unauthorized non-storm water discharges from reaching surface water or MS4 drainage systems.
- ■ Manually sweep or shovel may be used or a sweeper/vacuum truck. The swept sediment and debris shall be vacuumed or contained and swept off site.
- ■ Kick brooms or sweeper attachments shall not be used.
- ■ Visible sediment tracking shall be swept and/or vacuumed daily.
- ■ If not mixed with debris or trash, consider incorporating the removed sediment back into the project.

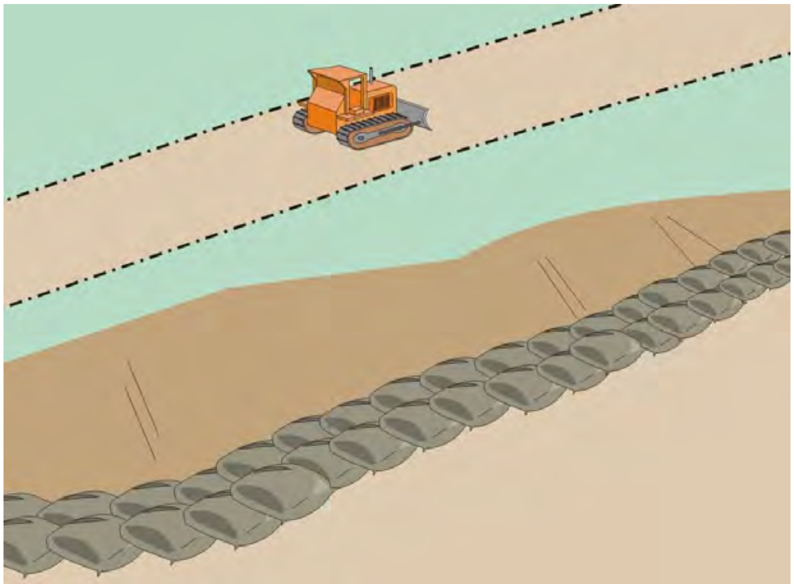
Maintenance and Inspection

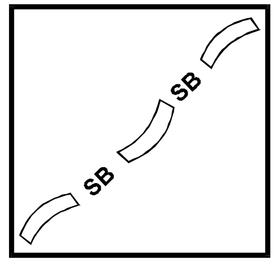
- ■ Inspect ingress/egress access points daily and sweep tracked sediment as needed, or as required by the Engineer.
- ■ Be careful not to sweep up any unknown substance or any object that may be potentially hazardous.
- ■ Adjust brooms frequently; maximize efficiency of sweeping operations.
- ■ After sweeping is finished, properly dispose of sweeper wastes at an approved dumpsite per WM-5 and WM-6 for proper disposal procedures.

(This page left intentionally blank)

Sandbag Barrier

SC-8





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A sandbag barrier is a temporary linear sediment barrier consisting of stacked sandbags, designed to intercept and slow the flow of sediment-laden sheet flow runoff. Sandbag barriers allow sediment to settle from runoff before water leaves the construction site.

Appropriate Applications

- This BMP may be implemented on a project-by-project basis in addition to other BMPs when determined necessary and feasible by the Contractor or Engineer.
- Along the perimeter of a site.
- Along streams and channels.
- Below the toe of exposed and erodible slopes.
- Down slope of exposed soil areas.
- Around stockpiles.
- Across channels to serve as a barrier for utility trenches or provide a temporary channel crossing for construction equipment, to reduce stream impacts.
- Parallel to a roadway to keep sediment off paved areas.
- At the top of slopes to divert roadway runoff away from disturbed slopes.
- To divert or direct flow or create a temporary sediment/desilting basin.
- During construction activities in stream beds when the contributing drainage area is less than 5 ac.

- With plastic cover along the perimeter of vehicle and equipment fueling and maintenance areas or chemical storage areas.
- To capture and detain non-storm water flows until proper cleaning operations occur.
- When site conditions or construction sequencing require adjustments or relocation of the barrier to meet changing field conditions and needs during construction.
- To temporarily close or continue broken, damaged or incomplete curbs.

Limitations

- Limit the drainage area upstream of the barrier to 5 ac.
- Degraded sandbags may rupture spilling sand.
- Installation can be labor intensive.
- Limited durability for long-term projects.
- When used to detain concentrated flows, maintenance requirements increase.

Standards and Specifications

Materials

- Sandbag Material: Sandbag shall be woven polypropylene, polyethylene or polyamide fabric, minimum unit weight four ounces per square yard, mullen burst strength exceeding 300 psi in conformance with the requirements in ASTM designation D3786, and ultraviolet stability exceeding 70% in conformance with the requirements in ASTM designation D4355. Use of burlap is not acceptable.
- Sandbag Size: Each sand-filled bag shall have a length of 18 in., width of 12 in., thickness of 3 in., and mass of approximately 33 lb. Bag dimensions are nominal, and may vary based on locally available materials. Alternative bag sizes shall be submitted to the Engineer for approval prior to deployment.
- Fill Material: All sandbag fill material shall be non-cohesive, Class 1 or Class 2 permeable material free from clay and deleterious material. Fill material is subject to approval by the Engineer.

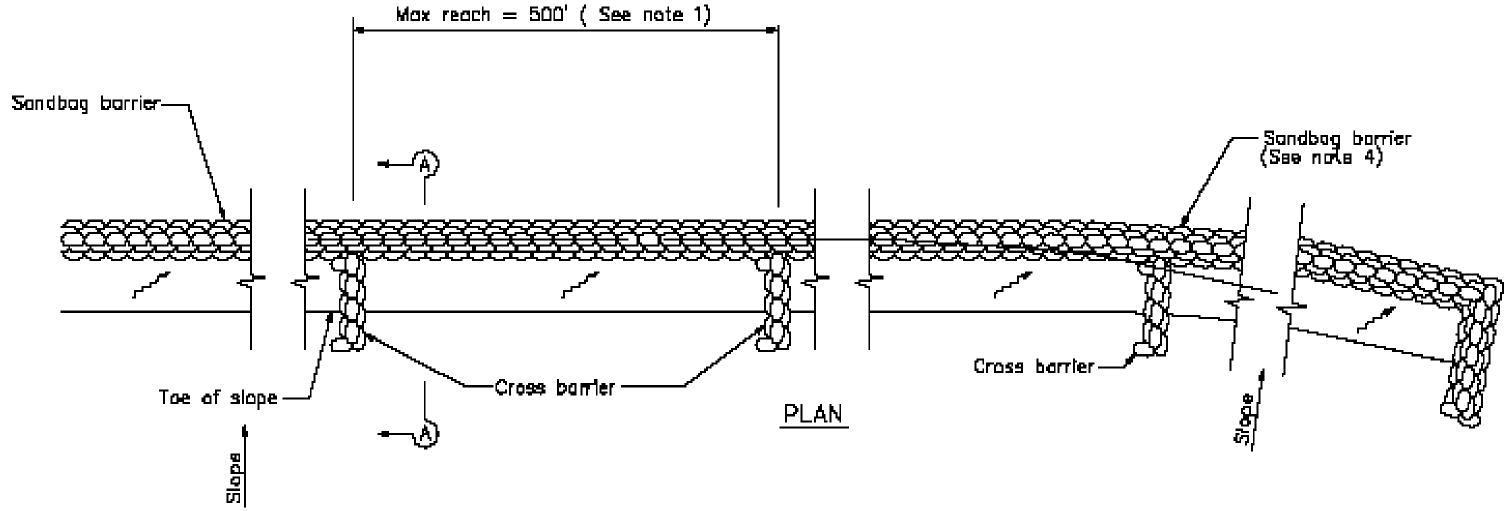
Installation

- When used as a linear sediment control:
  - Install along a level contour.
  - Turn ends of sandbag row up slope to prevent flow around the ends.
  - Generally, sandbag barriers shall be used in conjunction with temporary soil stabilization controls up slope to provide effective erosion and sediment control.
  - Install as shown in Pages 4 and 5 of this BMP.

- Construct sandbag barriers with a set-back of at least 3 ft from the toe of a slope. Where a setback is determined to be not practical due to specific site conditions, the sandbag barrier may be constructed at the toe of the slope, but shall be constructed as far from the toe of the slope as practicable.

Maintenance and Inspection

- Ensure that all perimeter controls are maintained and protected from activities that reduce their effectiveness.
- Inspect all sandbag barriers weekly and before and after every rainfall events. During extended rainfall events, inspect sandbag barriers at least once every 24 hours.
- Reshape or replace sandbags as needed, or as directed by the Engineer.
- Repair washouts or other damages as needed, or as directed by the Engineer.
- Inspect sandbag barriers for sediment accumulations and remove sediments when accumulation reaches one-third the barrier height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of off the construction site in conformance with all applicable laws and regulations. If accumulated sediment is stored on site, it shall be in accordance with WM-3 Stockpile Management.
- Remove sandbags when no longer needed. Remove sediment accumulation, and clean, re-grade, and stabilized the area.



SANDBAG BARRIER

NOTES

1. Construct the length of each reach so that the change in base elevation along the reach does not exceed 1/2 the height of the linear barrier. In no case shall the reach length exceed 500'.
2. Place sandbags tightly.
3. Dimension may vary to fit field condition.
4. Sandbag barrier shall be a minimum of 3 bags high.
5. The end of the barrier shall be turned up slope.
6. Cross barriers shall be a min of 1/2 and a max of 2/3 the height of the linear barrier.
7. Sandbag rows and layers shall be staggered to eliminate gaps.

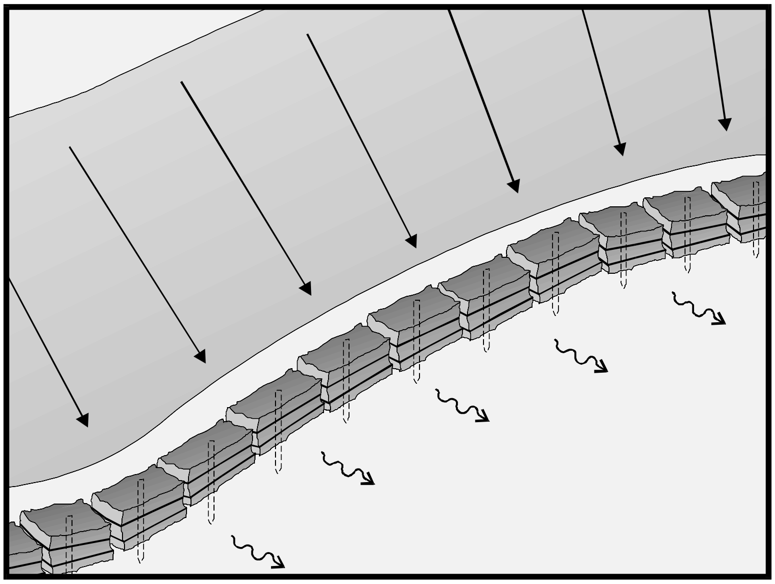
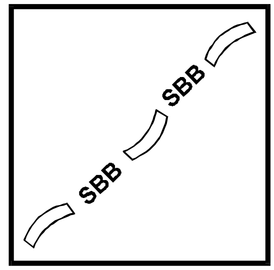
Straw Bale Barrier





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A straw bale barrier is a temporary linear sediment barrier consisting of straw bales, designed to intercept and slow sediment-laden sheet flow runoff. Straw bale barriers allow sediment to settle from runoff before water leaves the construction site.

Appropriate Applications

- This BMP may be implemented on a project-by-project basis in addition to other BMPs when determined necessary and feasible by the Contractor or Engineer.
- Along the perimeter of a site.
- Along streams and channels.
- Below the toe of exposed and erodible slopes.
- Down slope of exposed soil areas.
- Around stockpiles.
- Across minor swales or ditches with small catchments.
- Around above grade type temporary concrete washouts (See BMP WM-8, "Concrete Waste Management").
- Parallel to a roadway to keep sediment off paved areas.

Limitations

- Installation can be labor intensive.
- Straw bale barriers are maintenance intensive.
- Degraded straw bales may fall apart when removed or left in place for extended periods.
- Shall not be used on paved surfaces.
- Shall not to be used for drain inlet protection or in areas of concentrated flow.
- May introduce undesirable non-native plants to the area or be an attractive food source for some animals (see Permits in Section 7-5 of the contract Special Provisions).

Standards and Specifications

Materials

- **Straw Bale Size**: Each straw bale shall be a minimum of 14 in. wide, 18 in. in height, 36 in. in length and shall have a minimum mass of 51 lb. The straw bale shall be composed entirely of vegetative matter, except for the binding material.
- **Bale Bindings**: Bales shall be bound by either steel wire, nylon or polypropylene string placed horizontally. Jute and cotton binding shall not be used. Baling wire shall be a minimum diameter of 14 gauge. Nylon or polypropylene string shall be approximately 12 gauge in diameter with a breaking strength of 80 lbs. force.
- **Stakes**: Wood stakes shall be commercial quality lumber of the size and shape shown on the plans. Each stake shall be free from decay, splits or cracks longer than the thickness of the stake, or other defects that would weaken the stakes and cause the stakes to be structurally unsuitable. Steel bar reinforcement shall be equal to a number four designation or greater. End protection shall be provided for any exposed bar reinforcement.

Installation

- Limit the drainage area upstream of the barrier to 0.25 ac/100ft of barrier.
- Limit the slope length draining to the straw bale barrier to 100 ft.
- Slopes of 2:100 (V:H) (2%) or flatter are preferred. If the slope exceeds 1:10 (V:H) (10%), the length of slope upstream of the barrier must be less than 50 ft.
- Install straw bale barriers along a level contour, with the last straw bale turned up slope.

- Straw bales must be installed in a trench and tightly abut adjacent bales.
- Install straw bale barriers with a set-back of at least 3 ft from the toe of a slope. Where it is determined to be not practical due to specific site conditions, the straw bale barrier may be constructed at the toe of the slope, but shall be constructed as far from the toe of the slope as practical.
- Install straw bale barriers per pages 4 and 5 of this BMP for installation detail.

Maintenance and Inspection

- Ensure that all perimeter controls are maintained and protected from activities that reduce their effectiveness.
- Inspect all straw bale barriers weekly and before and after every rainfall events. During extended rainfall events, inspect straw bale barriers at least once every 24 hours.
- Inspect straw bale barriers for sediment accumulations and remove sediment when depth reaches one-third the barrier height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of outside the right-of-way in conformance with all applicable laws and regulations.
- Replace or repair damage bales as needed or as directed by the Engineer.
- Repair washouts or other damages as needed or as directed by the Engineer.
- Remove straw bales when no longer needed. Remove sediment accumulation, and clean, re-grade, and stabilized the area.

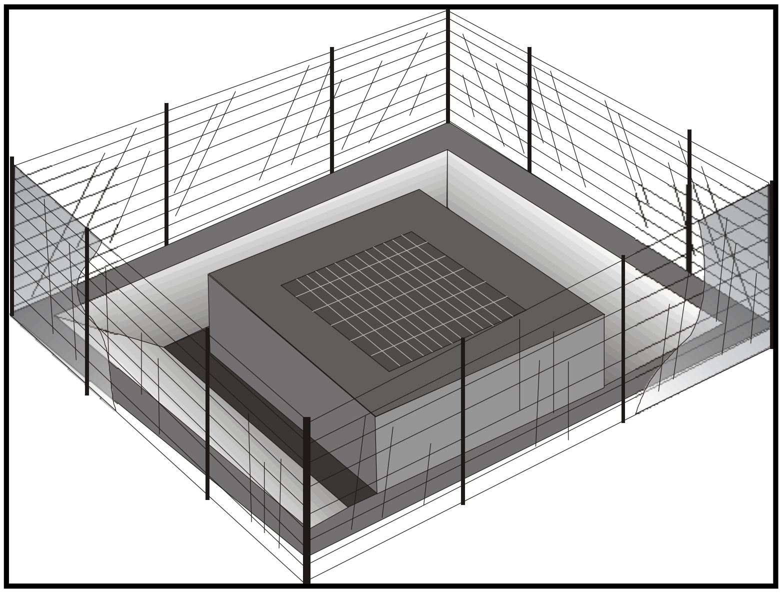
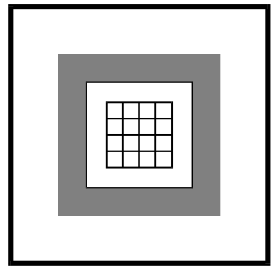
Storm Drain Inlet Protection

SC-10





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Storm drain inlet protection includes devices used at storm drain inlets that are subject to runoff from construction activities to detain and/or filter sediment-laden runoff to allow sediment to settle and/or to filter sediment prior to discharge into storm drainage systems or watercourses.

Appropriate Applications

- Where ponding will not encroach into roadway traffic.
- Where sediment laden surface runoff may enter an inlet.
- Where disturbed drainage areas have not yet been permanently stabilized.
- Required to be implemented on a year around basis.

Limitations

- Not a stand-alone BMP. Storm Drain Inlet Protection shall always be implemented with other erosion and sediment controls upgradient.
- Requires an adequate area for water to pond without encroaching upon traveled way and shall not be an obstacle to oncoming traffic.
- Other methods of temporary protection are required to prevent non-storm water discharges from entering the storm drain system.
- Sediment removal may be difficult in high flow conditions or if runoff is heavily sediment laden. If high flow conditions are expected, use other on-site sediment trapping techniques (e.g. check dams) in conjunction with inlet protection.
- For drainage areas larger than 1 ac, runoff shall be routed to a sediment trapping device designed for larger flows. See BMPs SC-2, “Sediment/Desilting Basin,” and SC-3 “Sediment Trap.”
- Filter fabric fence inlet protection is appropriate in open areas that are subject to sheet flow and for flows not exceeding 0.5 cfs.

- Gravel bag barriers for inlet protection are applicable when sheet flows or concentrated flows exceed 0.5 cfs, and it is necessary to allow for overtopping to prevent flooding.
- Fiber rolls and foam barriers are not appropriate for locations where they cannot be properly anchored to the surface.
- Excavated drop inlet sediment traps are appropriate where relatively heavy flows are expected and overflow capability is needed.

Standards and Specifications

Identify existing and/or planned storm drain inlets that have the potential to receive sediment-laden surface runoff. Determine which method to use.

Methods and Installation

- ***DI Protection Type 1 - Filter Fabric Fence -*** The filter fabric fence (Type 1) protection is illustrated on Page 5. It is similar to constructing a silt fence. See BMP SC-1, "Silt Fence." Do not place filter fabric underneath the inlet grate since the collected sediment may fall into the drain inlet when the fabric is removed or replaced.
- ***DI Protection Type 2 - Excavated Drop Inlet Sediment Trap -*** The excavated drop inlet sediment trap (Type 2) is illustrated in Page 6. It is similar to constructing a temporary silt fence, See BMP SC-1, "Silt Fence." Size excavated trap to provide a minimum storage capacity calculated at the rate of 67 yd^3/ac of drainage area.
- ***DI Protection Type 3 – Gravel bag -*** The gravel bag barrier (Type 3) is illustrated in Page 7. Flow from a severe storm shall not flow over the curb. In areas of high clay and silts, use filter fabric and gravel as additional filter media. Construct gravel bags in accordance with BMP SC-6, "Gravel Bag Berm." Gravel bags shall be used due to their high permeability.
- ***DI Protection Type 4 – Block and Gravel Filter – The block and gravel filter*** (Type 4) is placed around the inlet as illustrated in Page 8. Block and gravel filters are suitable for curb inlets commonly used in residential, commercial, and industrial construction. Engineer approval is required.
- ***DI Protection Type 5 – Foam Barriers and Fiber Rolls –*** Foam barrier or fiber roll (Type 5) is placed around the inlet and keyed and anchored to the surface. Foam barriers and fiber rolls are intended for use as inlet protection where the area around the inlet is unpaved and the foam barrier or fiber roll can be secured to the surface. Engineer approval is required.

Maintenance and Inspection

General

- Inspect all inlet protection devices weekly and before and after every rainfall events. During extended rainfall events, inspect inlet protection devices at least once every 24 hours.

- Ensure that all storm drain inlets are maintained and protected from activities that reduce their effectiveness.
- Remove all inlet protection devices within thirty days after the site is stabilized, or when the inlet protection is no longer needed.
  - Bring the disturbed area to final grade and smooth and compact it. Appropriately stabilize all bare areas around the inlet.
  - Clean and re-grade area around the inlet and clean the inside of the storm drain inlet as it must be free of sediment and debris.

Requirements by Method

- ***Type 1 - Filter Fabric Fence***

This method shall be used for drain inlets requiring protection in areas where finished grade is established and erosion control seeding has been applied or is pending.

  - Make sure the stakes are securely driven in the ground and are structurally sound (i.e., not bent, cracked, or splintered, and are reasonably perpendicular to the ground). Replace damaged stakes.
  - Replace or clean the fabric when the fabric becomes clogged with sediment. Make sure the fabric does not have any holes or tears. Repair or replace fabric as needed or as directed by the Engineer.
  - At a minimum, remove the sediment behind the fabric fence when accumulation reaches one-third the height of the fence or barrier height. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of outside the right-of-way in conformance with all applicable laws and regulations.

- ***Type 2 – Excavated Drop Inlet Sediment Trap***

This method may be used for drain inlets requiring protection in areas that have been cleared and grubbed, and where exposed soil areas are subject to grading.

  - Remove sediment from basin when the volume of the basin has been reduced by one-third.

- ***Type 3 - Gravel Bag Barrier***

This method may be used for drain inlets surrounded by AC or paved surfaces.

  - Inspect bags for holes, gashes, and snags.
  - Check gravel bags for proper arrangement and displacement. Remove the sediment behind the barrier when it reaches one-third the height of the barrier. Removed sediment shall be incorporated in the project at locations designated by the Engineer or disposed of in conformance with applicable laws and regulations.

■ ***Type 4 -Block and Gravel Filter***

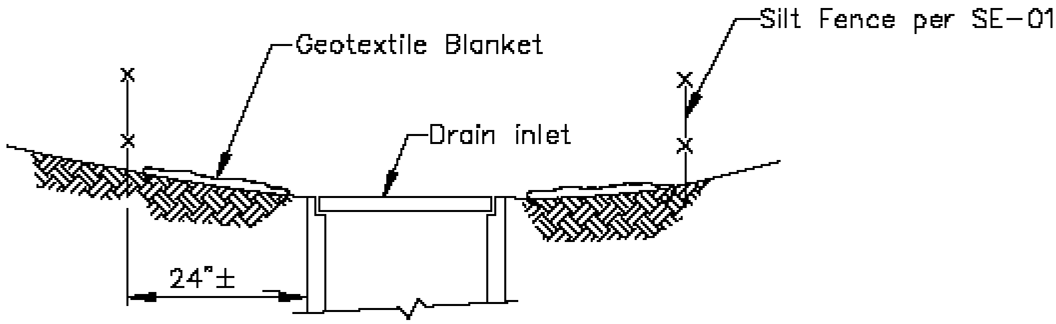
The block and gravel filter (Type 4) is shown in the figures. Block and gravel filters are suitable for curb inlets commonly used in residential, commercial, and industrial construction.

- Place hardware cloth or comparable wire mesh with 0.5 in. openings over the drop inlet so that the wire extends a minimum of 1 ft beyond each side of the inlet structure. If more than one strip is necessary, overlap the strips. Place filter fabric over the wire mesh.
- Place concrete blocks lengthwise on their sides in a single row around the perimeter of the inlet, so that the open ends face outward, not upward. The ends of adjacent blocks should abut. The height of the barrier can be varied, depending on design needs, by stacking combinations of blocks that are 4 in., 8 in., and 12 in. wide. The row of blocks should be at least 12 in. but no greater than 24 in. high.
- Place wire mesh over the outside vertical face (open end) of the concrete blocks to prevent stone from being washed through the blocks. Use hardware cloth or comparable wire mesh with 0.5 in. opening.
- Pile washed stone against the wire mesh to the top of the blocks. Use 0.75 to 3 in.

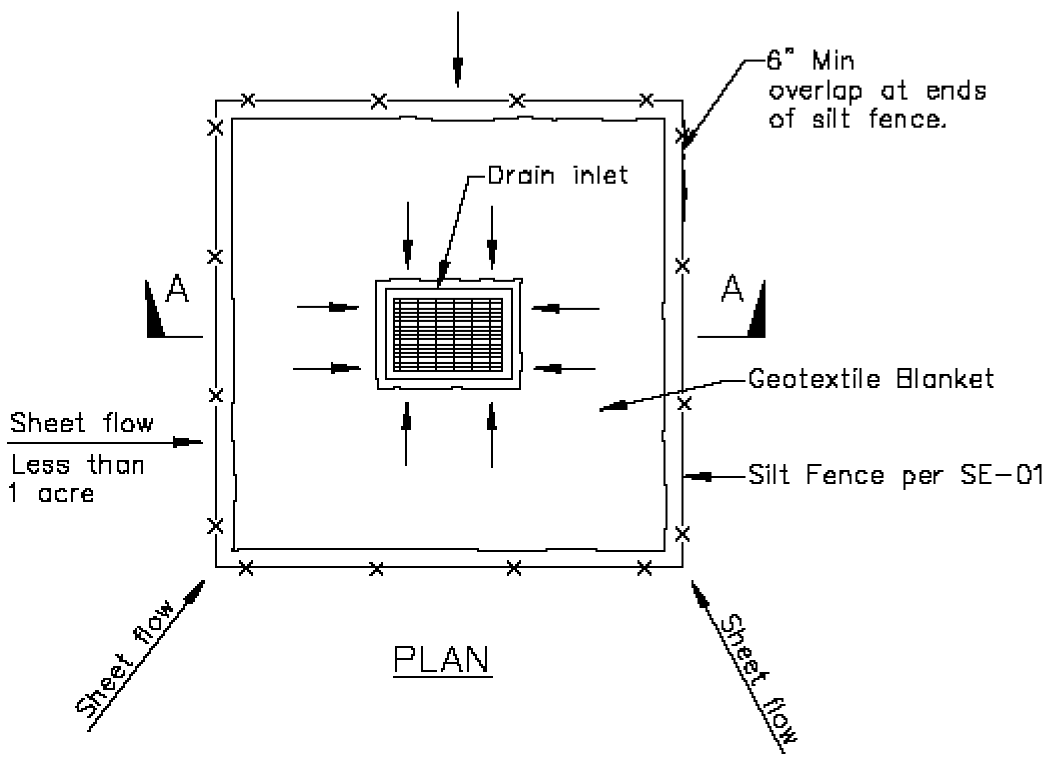
■ ***Type 5 Foam Barriers and Fiber Rolls***

This method may be used for drain inlets requiring protection in areas that have been cleared and grubbed, and where exposed soil areas subject to grading. Engineer approval is required.

- Check foam barrier or fiber roll for proper arrangement and displacement. Remove the sediment behind the barrier when it reaches one-third the height of the barrier. Removed sediment shall be incorporated in the construction site at locations designated by the Engineer or disposed of in conformance with all applicable laws and regulations.



SECTION A–A



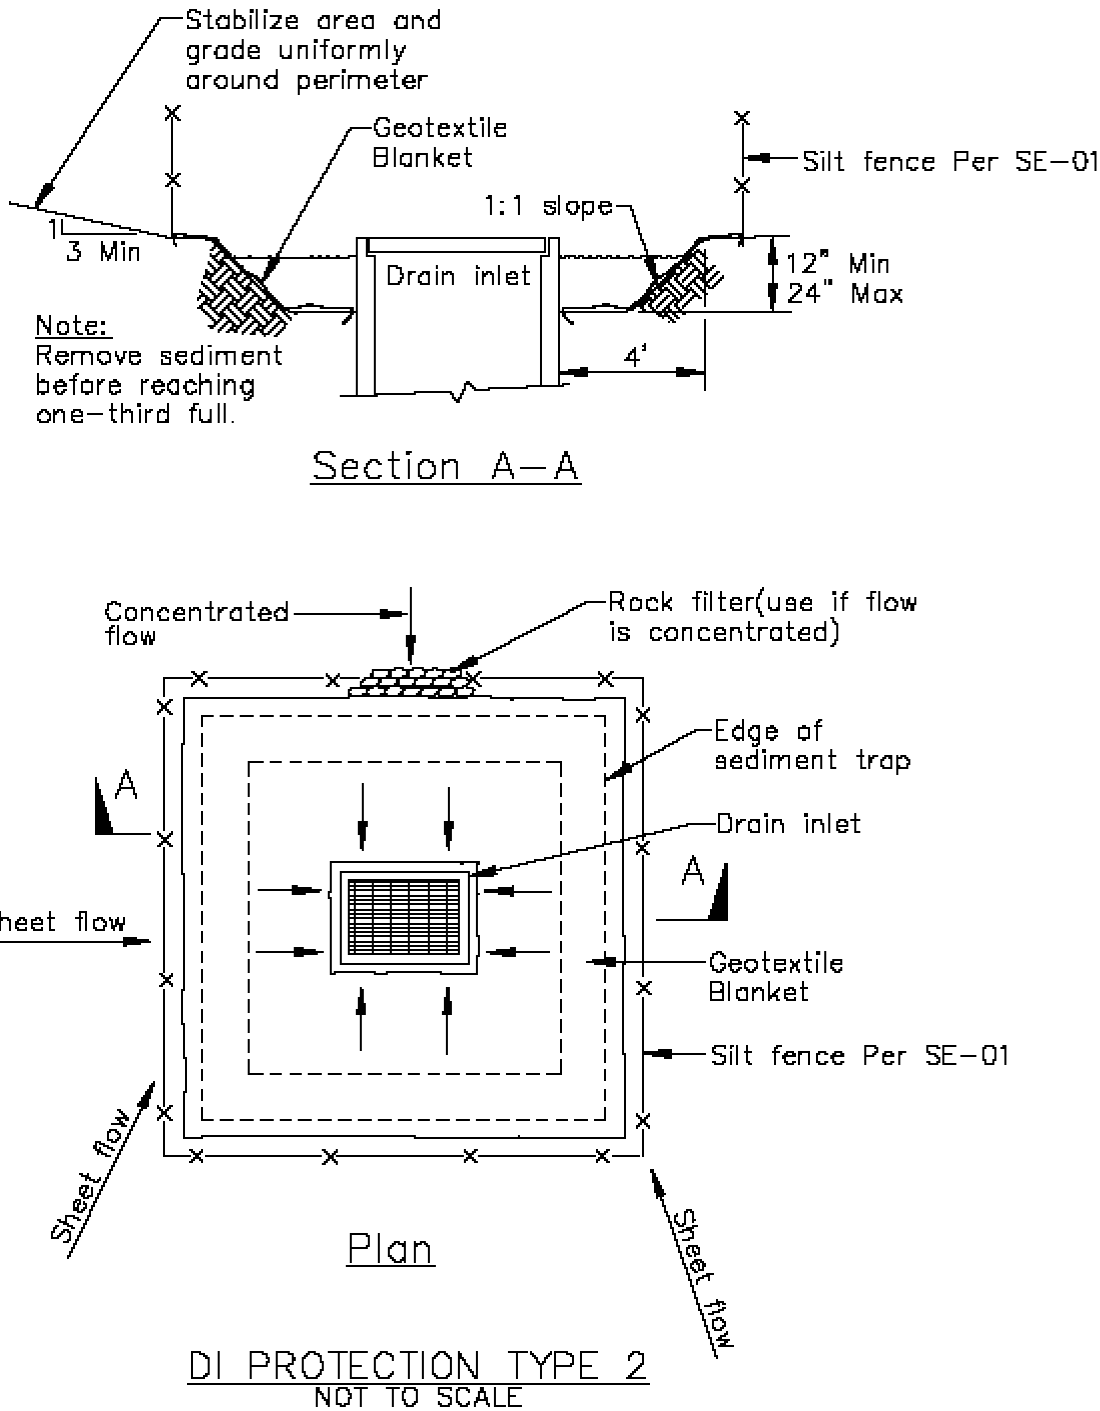
PLAN

DI PROTECTION TYPE 1
NOT TO SCALE

NOTES:

1. For use in areas where grading has been completed and final soil stabilization and seeding are pending.
2. Not applicable in paved areas.
3. Not applicable with concentrated flows.

Storm Drain Inlet Protection

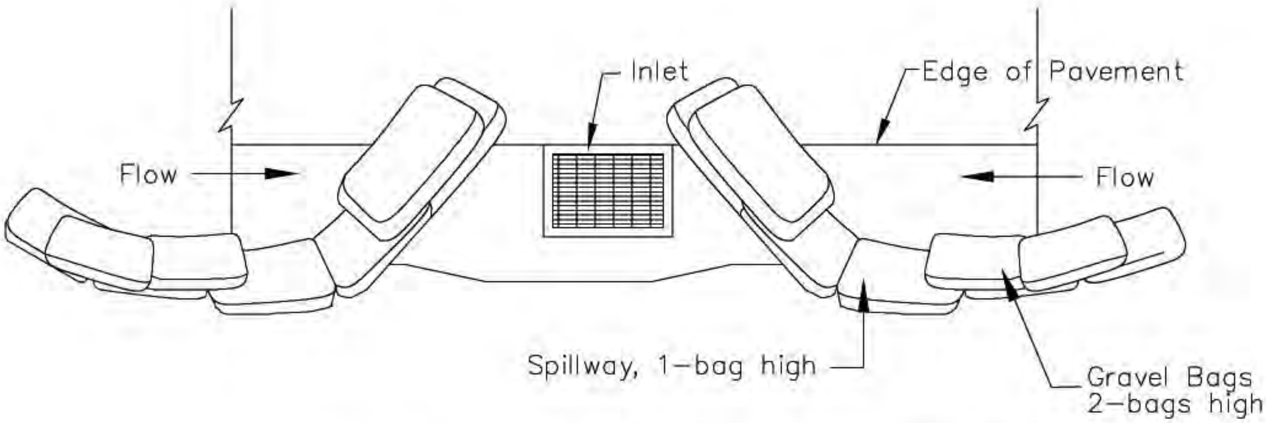


DI PROTECTION TYPE 2

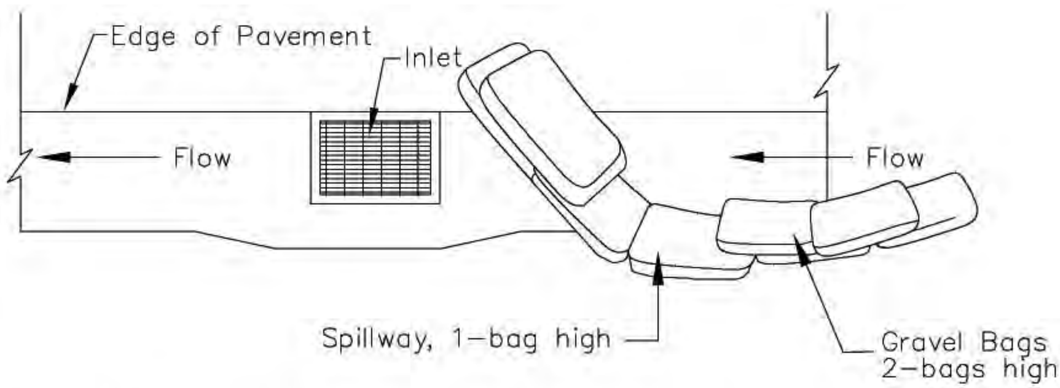
NOT TO SCALE

Notes

1. For use in cleared and grubbed and in graded areas.
2. Shape basin so that longest inflow area faces longest length of trap.
3. For concentrated flows, shape basin in 2:1 ratio with length oriented towards direction of flow.



TYPICAL PROTECTION FOR INLET WITH OPPOSING FLOW DIRECTIONS



TYPICAL PROTECTION FOR INLET WITH SINGLE FLOW DIRECTION

NOTES:

1. Intended for short-term use.
2. Use to inhibit non-storm water flow.
3. Allow for proper maintenance and cleanup.
4. Bags must be removed after adjacent operation is completed
5. Not applicable in areas with high silts and clays without filter fabric.

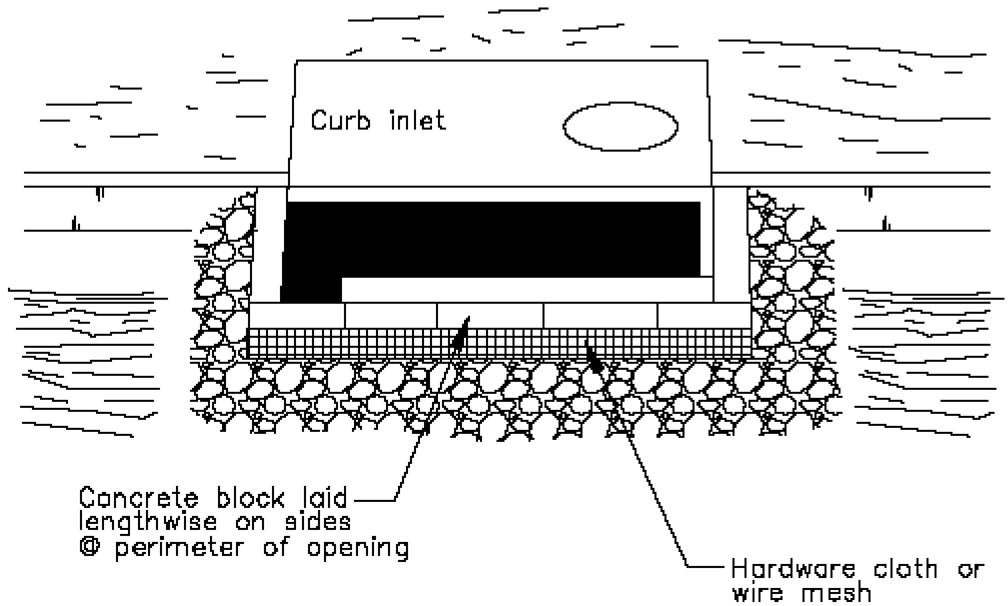
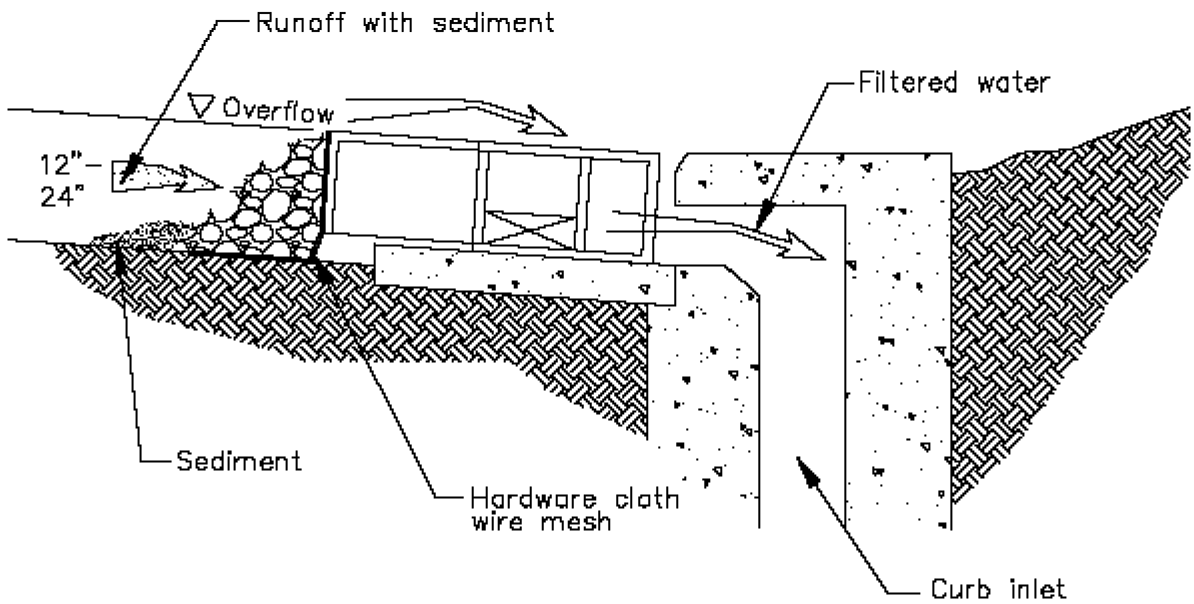
Not to scale





DI PROTECTION – TYPE 4

NOT TO SCALE

SECTION 5

WIND EROSION CONTROL BMPS

Wind erosion control consists of applying water or dust palliatives, covering or other control method approved by the Engineer to prevent or alleviate wind erosion, dust nuisance and prevent sediment from leaving the construction site. It is recognized that soil stabilization BMPs are also effective as wind erosion control (i.e., hydromulch, hydroseeding, soil binders, straw mulch, geotextiles, plastic covers, wind erosion control blankets/mats, wood mulch). Implementation of effective wind erosion controls is required. Wind erosion control BMPs are shown on Table5-1.

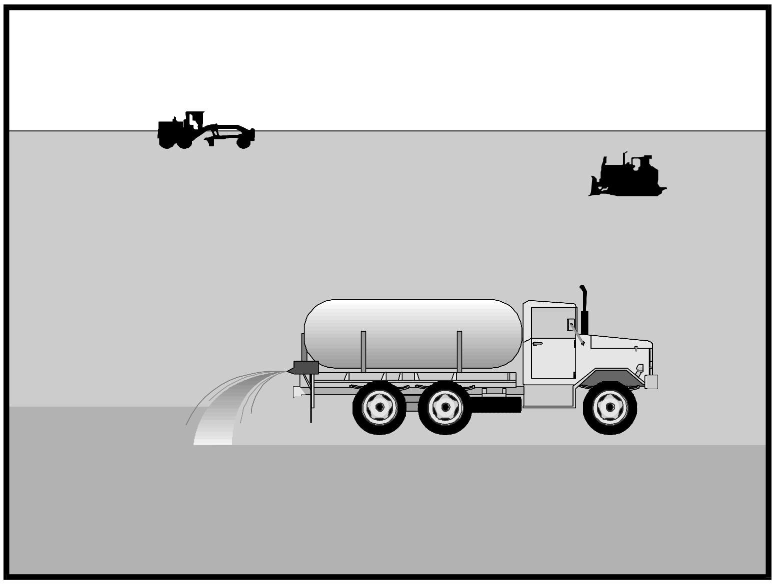
Table 5-1 Wind Erosion Control BMPs	
ID	**BMP Name**
WE-1	Wind Erosion Control

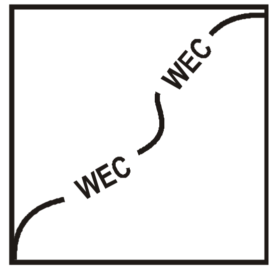
RB-AR33361

(This page left intentionally blank)

Wind Erosion Control

WE-1





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Wind erosion control consists of applying water and/or other dust palliatives as necessary to prevent or alleviate erosion by the forces of wind. Covering of all stockpiles is required year round.

Appropriate Applications

This practice is implemented on all exposed soils subject to wind erosion.

Standards and Specifications

- Effective wind erosion control shall be implemented.
- Implement good housekeeping measures on the construction site to control the air deposition of site materials and from site operations. Such particulates can include, but are not limited to, sediment, nutrients, trash, metals, bacteria, oil and grease and organics.
- Water shall be applied by means of pressure-type distributors or pipelines equipped with a spray system or hoses and nozzles that will ensure even distribution.
- All distribution equipment shall be equipped with a positive means of shutoff.
- Unless water is applied by means of pipelines, at least one mobile unit shall be available at all times to apply water or dust palliative to the project.
- If reclaimed water is used, the sources and discharge must meet California Department of Health Services water reclamation criteria and the Regional Water Quality Control Board requirements. Non-potable water shall not be conveyed in tanks or drain pipes that will be used to convey potable water and there shall be no connection between potable and non-potable supplies. Non-potable tanks, pipes and other conveyances shall be marked "NON-POTABLE WATER - DO NOT DRINK."
- Soil stabilization BMPs are also effective as wind erosion control (SS-3, SS-4, SS-5, SS-6, SS-7, and SS-8).

Maintenance and Inspection

- Inspect wind erosion control measures daily and document weekly.
- Check areas that have been protected to ensure coverage and effectiveness of Wind erosion controls. If wind erosion or dust are observed, Contractor shall immediately reapply or implement additional wind erosion control BMPs.

SECTION 6

TRACKING CONTROL BMPS

Tracking control consists of preventing or reducing vehicle and equipment tracking of sediment and other debris onto paved surfaces and preventing sediment from entering the storm drain system or watercourses. Sediment control for Street Sweeping and Vacuuming is also recognized as a tracking control BMP. However, street sweeping and vacuuming is not allowed as a stand-alone BMP for tracking control. Tracking control BMPs are shown on Table 6-1.

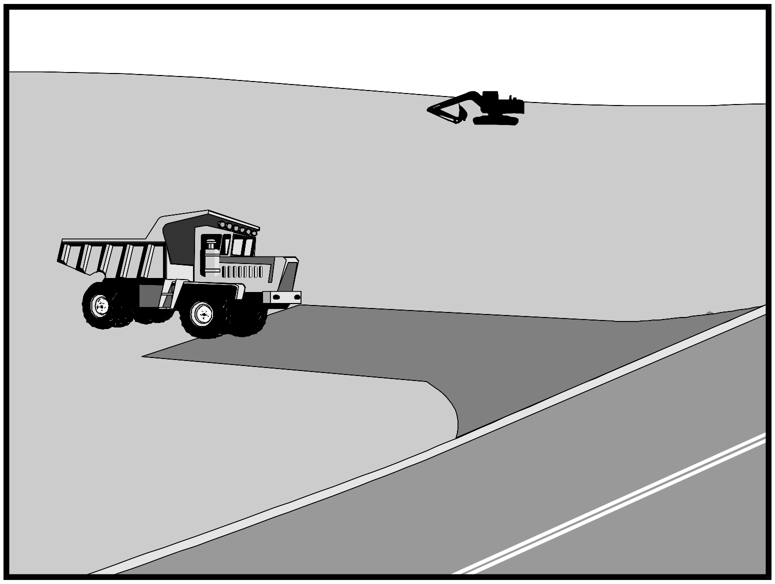
Table 6-1
Tracking Control BMPs

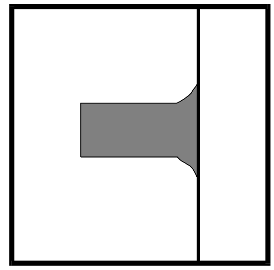
ID	BMP Name
TC-1	Stabilized Construction Entrance/Exit
TC-2	Stabilized Construction Roadway
TC-3	Entrance/Outlet Tire Wash

(This page left intentionally blank)

RB-AR33366

Stabilized Construction Entrance/Exit TC-1





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ● Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A stabilized construction access is defined by a point of entrance/exit to a construction site that is stabilized to reduce the tracking of mud and dirt onto all paved surfaces and paved private and public roads by construction vehicles.

Appropriate Applications

- Use at all construction sites:
  - Where dirt or mud can be tracked onto paved surfaces or paved private or public roads.
  - Adjacent to water bodies.
  - Where poor soils are encountered.
  - Where dust is a problem during dry weather conditions.
- This BMP shall be implemented on all construction sites.

Limitations

- None identified

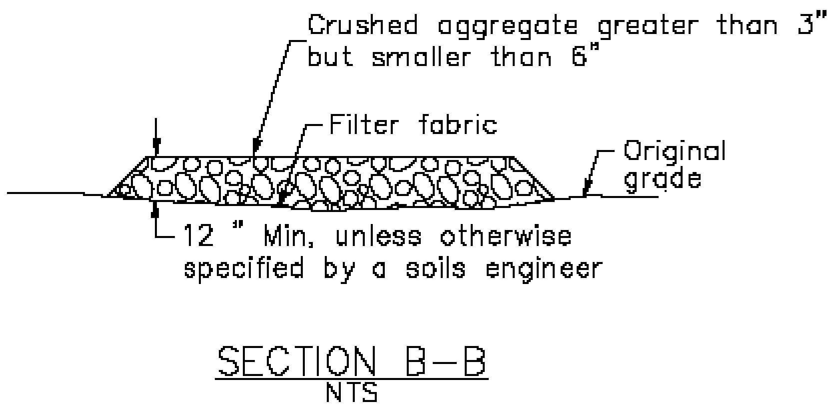
Standards and Specifications

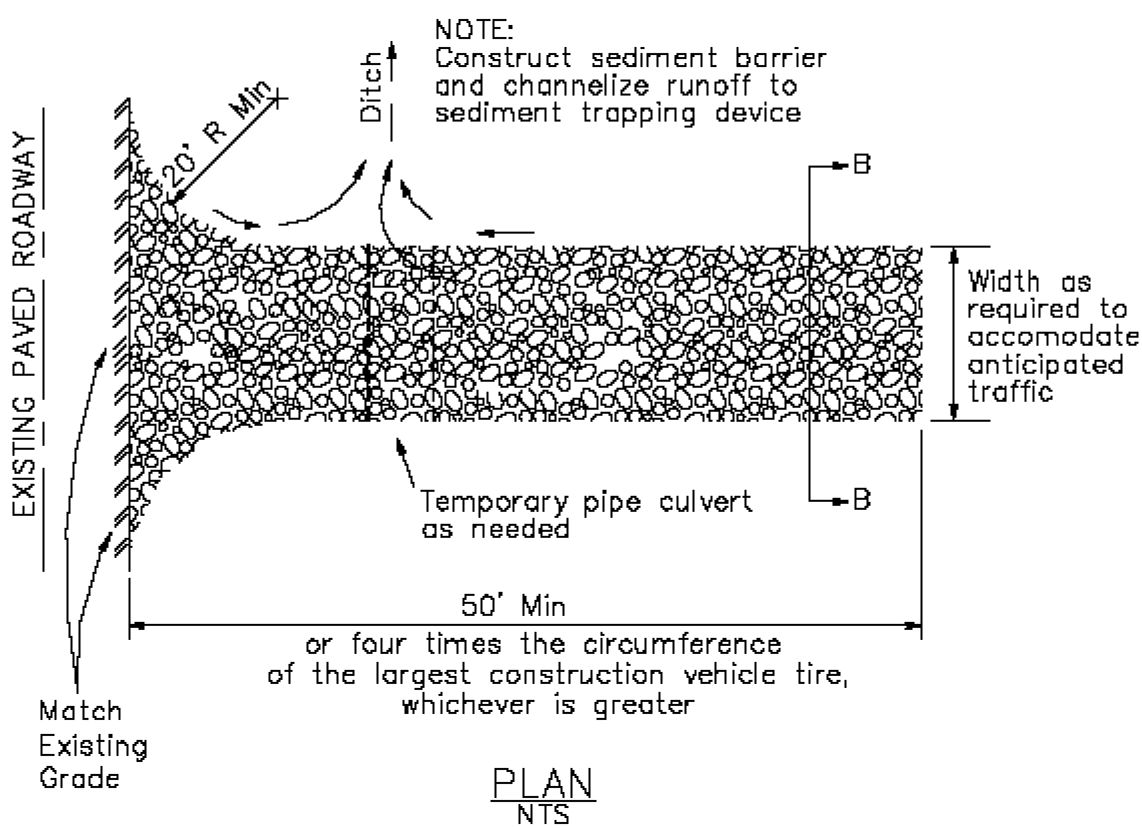
- Stabilize all construction entrances and exits to the construction site.
- Ensure that construction activity traffic to and from the project is limited to entrances and exits that employ effective controls to prevent offsite tracking of sediment.
- Prevent the off-site tracking of loose construction and landscape materials.
- Limit speed of vehicles to control dust.
- Properly grade each construction entrance/exit to prevent runoff from leaving the construction site.
- Route runoff from stabilized entrances/exits through a sediment-trapping device before discharge.

- Design stabilized entrance/exit to support the heaviest vehicles and equipment that will use it.
- Select construction access stabilization (aggregate, asphaltic concrete, concrete) based on longevity, required performance, and site conditions. The use of asphalt concrete (AC) grindings for stabilized construction access/roadway is not allowed.
- Use of constructed/manufactured steel plates with ribs for entrance/exit access is allowed with written approval from the Engineer.
- Place crushed aggregate over geotextile fabric to at least 12 in. depth, or place aggregate to a depth recommended by the Engineer. Crushed aggregate greater than 3 inches and smaller than 6 inches shall be used.
- Designate combination or single purpose entrances and exits to the construction site.
- Implement BMP SC-7, "Street Sweeping and Vacuuming" as needed and as required.
- Require all employees, subcontractors, and suppliers to utilize the stabilized construction access.

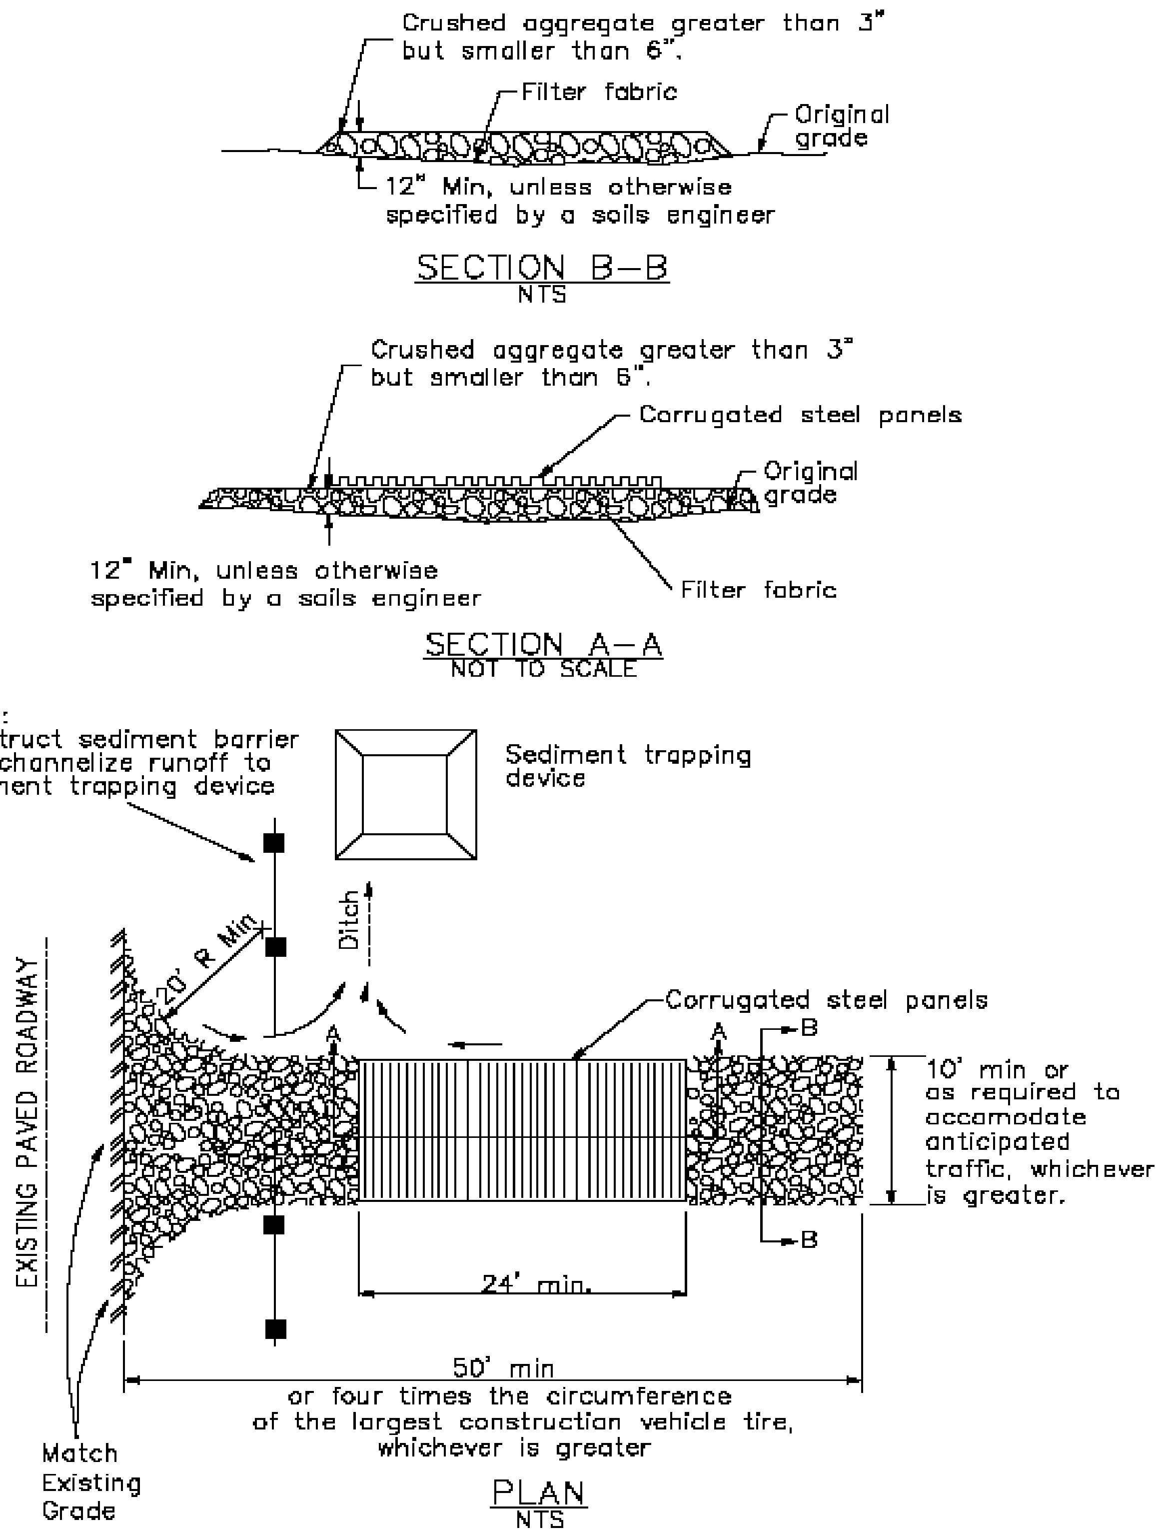
Maintenance and Inspection

- Ensure that all pollutant controls at entrances and exits are maintained and protected from activities that reduce their effectiveness.
- Inspect all entrances, exits, access roads daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect all entrances, exits, access roads at least once every 24 hours.
- Remove any sediment or other construction activity related materials that are deposited on the roads (by sweeping and vacuuming).
- Remove aggregate, separate and dispose of sediment if construction entrance/exit is clogged with sediment or as directed by the Engineer.





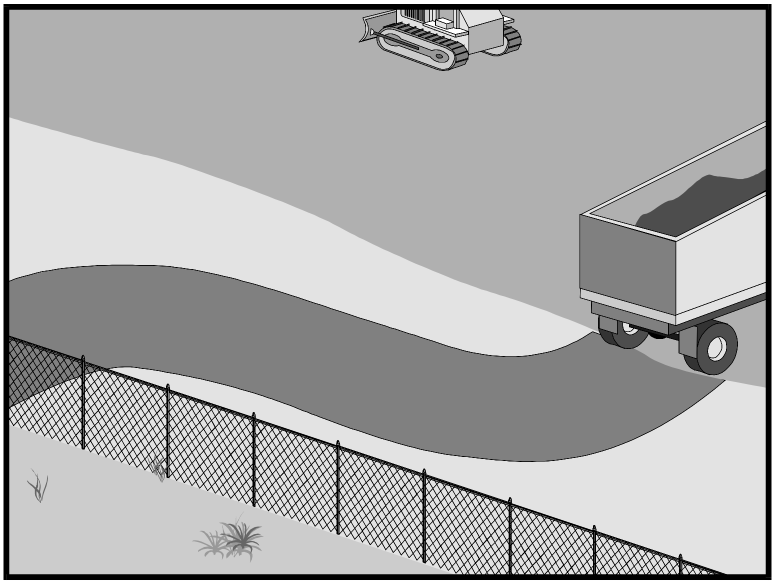
Stabilized Construction Entrance/Exit (Type 1)

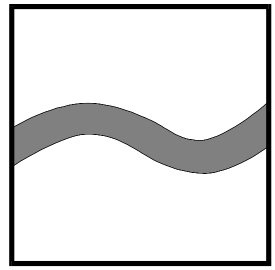


Stabilized Construction Entrance/Exit (Type 2)

Stabilized Construction Roadway

TC-2





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ● Tracking Control
- ● Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A stabilized construction roadway is a temporary access road. It is designed for the control of dust and erosion created by vehicular tracking.

Appropriate Applications

- Construction roadways and short-term detour roads:
  - Where tracking is a problem.
  - Where dust is a problem.
  - Adjacent to water bodies.
  - Where poor soils are encountered.
  - Where there are steep grades and additional traction is needed.

Limitations

None identified.

Standards and Specifications

- Properly grade roadway to prevent runoff from leaving the construction site.
- Install NS-4 Temporary Stream Crossing as directed by the Engineer.
- Design stabilized access to support the heaviest vehicles and equipment that will use it.
- Stabilize roadway using aggregate, asphalt concrete, or concrete based on longevity, required performance, and site conditions. The use of cold mix asphalt or asphalt concrete (AC) grindings for stabilized construction roadway is not allowed.
- If aggregate is selected, place crushed aggregate over geotextile fabric to at least 12 in. depth, or place aggregate to a depth recommended by the Engineer. Crushed aggregate greater than 3 inches and smaller than 6 inches shall be used.

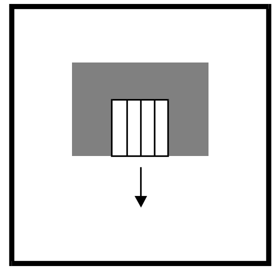
- Properly grade roadway to prevent runoff from leaving the construction site.
- Limit speed of vehicles to control dust or as directed by the Engineer.
- Coordinate materials with those used for stabilized construction entrance/exit points.

Maintenance and Inspection

- Inspect stabilized construction roadways weekly and before and after every rainfall events. During extended rainfall events, inspect stabilized construction roadways at least once every 24 hours.
- Keep all temporary roadway ditches clear.
- When no longer required, remove stabilized construction roadway and re-grade and repair slopes.

Entrance/Outlet Tire Wash

TC-3



Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ● Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A tire wash is an area located at stabilized construction access points to remove sediment tires and undercarriages, and to prevent sediment from being transported onto paved roadways.

Appropriate Applications

- Tire washes may be used on construction sites where dirt and mud tracking onto paved roads by construction vehicles may occur.
- This BMP may be implemented on a project-by-project basis with other BMPs when determined necessary and feasible by the contract special provisions or Engineer.

Limitations

- Requires a supply of wash water.
- The waste water shall not be disposed of onsite.

Standards and Specifications

- Incorporate with a stabilized construction entrance/exit. See BMP TC-1, “Stabilized Construction Entrance/Exit” and BMP SC-7, “Street Sweeping and Vacuuming”
- Pre-constructed tire wash systems are available for purchase or lease.
- Construct on level ground when possible, on a pad of coarse aggregate, greater than 3 inches and smaller than 6 inches. A geotextile fabric shall be placed below the aggregate.
- The tire wash shall be designed and constructed/manufactured for anticipated traffic loads.
- The tire wash shall be activated automatically upon vehicle’s approach.

- Tire Wash shall remove all dirt/mud and debris from the tires and tire-grooves, wheel wells and undercarriages of the vehicles.
- The water recycling system shall be capable of processing the water to sufficiently remove mud/silt and debris for re-use. The water shall be replaced as needed or as directed by the engineer.
- The tire wash shall perform so that no visible mud/silt or debris, dried or wet, is observed on the paved road after the tire wash.
- The tire was shall perform so that no visible mud/silt and debris is observed on the truck tires or the undercarriage of the trucks after the tire wash
- Require all employees, subcontractors, and others that leave the site to use the wash facility.
- Implement BMP SC-7, "Street Sweeping and Vacuuming".

Maintenance and Inspection

- Inspect tire wash weekly and before and after every rainfall events. During extended rainfall events, inspect tire wash at least once every 24 hours.
- Ensure that all pollutant controls at entrances and exits (e.g. tire wash off locations) are maintained and protected from activities that reduce their effectiveness.
- Remove accumulated sediment in wash rack and/or sediment trap to maintain system performance.

SECTION 7

NON-STORM WATER MANAGEMENT BMPS

The discharge of materials other than storm water and authorized non-storm water discharges are prohibited. Non-storm water management BMPs are source control BMPs that prevent pollution by limiting or preventing potential pollutants at the source, eliminating onsite and off-site discharge and discharge the ground. These non-storm water management BMPs are also referred to as “good housekeeping practices” which involve day-to-day operations of the construction site and contractor’s yard in order to maintain a clean, orderly, and safe construction site. Non-storm water management BMPs are shown on Table 7-1.

Table 7-1
Non-Storm Water Management BMPs

ID	BMP Name
NS-1	Water Conservation Practices
NS-2	Dewatering Operations (see Section 7.1 and 7.2)
NS-3	Paving and Grinding Operations
NS-4	Temporary Stream Crossing
NS-5	Clear Water Diversion
NS-6	Illicit Connection/Illegal Discharge Detection and Reporting
NS-7	Potable Water/Irrigation
NS-8	Vehicle and Equipment Cleaning
NS-9	Vehicle and Equipment Fueling
NS-10	Vehicle and Equipment Maintenance
NS-11	Pile Driving Operations
NS-12	Concrete Curing
NS-13	Material and Equipment Use Over Water
NS-14	Concrete Finishing
NS-15	Structure Demolition/Removal Over or Adjacent to Waters
NS-16	Temporary Batch Plant

7.1 Construction Dewatering

All construction groundwater dewatering shall be in full compliance with the Monitoring and Reporting Program and Waste Discharge Requirements (WDR) of the NPDES permit included in the contract Special Provisions, if applicable. All Contractor operations shall be in full compliance with all applicable laws and regulations that govern water quality.

If groundwater is encountered on the construction site and the contract Special Provisions do **not** include provisions for construction dewatering **and** an NPDES permit from the RWQCB, the Contractor shall immediately notify the Engineer for direction. No groundwater shall be discharged to the sanitary sewer system, street/gutter, ground or any other location, whether contaminated, treated, or not, until approved by the Engineer. A construction dewatering plan in accordance with contract Special Provisions and NPDES Permit issued by the RWQCB, must be submitted to the Engineer for approval, prior to any dewatering discharge.

7.2 Accumulated Precipitation

Accumulated precipitation can be water from rain or snow melt. Accumulated precipitation on the construction site shall be managed in order to minimize the discharge of pollutants (mainly sediment) from entering the storm drain system.

The Contractor shall submit an Accumulated Precipitation Procedure (APP) detailing methods and procedures for management and discharge of accumulated precipitation on the construction site (contract Special Provisions 7-8.6). The APP shall include a description of: treatment technologies/BMPs, equipment, and discharge locations. The APP shall describe other pertinent information including: areas expected to accumulate precipitation, BMPs to protect accumulated precipitation from becoming sediment laden, inspection of accumulated precipitation prior to discharge, notification to the Engineer before any discharge of precipitation, options for not discharging precipitation, inspection, maintenance and repair procedures, and APP amendments.

If a SWPPP is required for the project per the contract Special Provisions (7-8.6.3), the APP shall be included in Attachment K of the SWPPP. If a SWPPP is not required per the contract Special Provisions, the Contractor shall prepare an APP and submit it to the Engineer separately in accordance with contract Special Provision Section 7-8.6.2.

The Contractor shall follow the procedures identified in NS-2 Dewatering Operations BMPs for the treatment of accumulated precipitation. The controls identified in BMP NS-2 Dewatering Operations are for sediment only. If the accumulated precipitation is determined or suspected to have come into contact with any pollutants other than sediment, the Contactor shall not discharge or immediately terminate discharge, and notify the Engineer for direction.

Accumulated precipitation that has been mixed with groundwater shall be managed as groundwater (see Section 7.1 Construction Dewatering). Accumulated precipitation, that has been mixed with non-storm water, shall be managed the same as the non-storm water in accordance with WM-10 Liquid Waste Management BMPs.

See the following example for a SWPPP project. After the example, see the required text for preparation of an APP for all projects.

EXAMPLE: (for SWPPP Project)

Accumulated Precipitation Procedure (APP)

Project Name: ______________________________

Project ID/ID Number: ______________________________

☒SWPPP required for this project ☐SWPPP not required for this project

This project may accumulate precipitation due to low lying areas, planned excavations or other construction-related water trapping equipment or materials. No accumulated water will be discharged without implementing this accumulated precipitation procedure (APP).

Areas Expected to Trap Precipitation

The planned excavation areas for this project include the roadway areas, parking lots, alleys, sidewalks and roadway medians where the existing asphalt concrete will be removed and where the shoulder will be excavated for roadway widening. The project plans and water pollution control drawings (WPCDs) in the SWPPP show the areas that will be excavated. No other areas are expected to accumulate significant precipitation on the project when it rains. If other areas are observed to accumulate precipitation, they will be added by amending this APP.

BMPs Selected to Protect Accumulated Precipitation

To keep accumulated rainwater in the excavated areas from becoming laden with sediment, the excavated areas will be protected with erosion and sediment control BMPs as described in Section 500.4.1 and 500.4.2 of the SWPPP. A sand bag barrier will be placed along the edge of the shoulder where the shoulder meets the existing vegetation that will be preserved during construction. The excavated areas will be provided with compacted base in accordance with the contract plans and specifications as much as possible 24 hours before a 50% or more chance of rain. Plastic sheeting will be kept on hand to further protect areas where compacted base cannot be placed prior to a rain event. At no time will more than an acre of exposed soil be allowed when there is a 50% chance of rain. If it begins raining, the remaining exposed soil will be covered with plastic to prevent erosion. The potential flows along the length of the roadway will be checked using check dams. The combination of compacted base, plastic sheeting, check dams and sandbag barriers should provide and effective erosion and sediment control prior to rainwater entering the storm drain system. Drain inlets will also be protected during construction using the storm drain inlet BMPs described in Section 500.4.2 of the SWPPP. In addition, during the roadway paving and removal of existing materials, drain inlets will be covered when rain is not expected using filter fabric and sand bags as described in Section 500.4.6 of the SWPPP, BMP NS-3 and as shown in WPCD 14 of the SWPPP (drain inlet cover detail). Note: SC-10 drain inlet protection is not adequate for non-storm water discharges such as paving.

Option(s) for not Discharging Accumulated Precipitation

If less than 3,000 gallons of water is accumulated (standard size of water truck tank), the water may be pumped into the water truck on site and used for dust control in accordance with BMP WE-1 as described in Section 500.4.4 of the SWPPP. The accumulated precipitation may be pumped to a tank if it is determined to be feasible by the contractor. The stored water will be used for dust control or will be disposed of properly offsite.

Inspection Prior to Discharge

After a precipitation event, water that is trapped in the excavation may need to be discharged to continue construction. The water will be inspected to determine whether it has come into contact with any other pollutants (e.g., spilled fuel) prior to discharge. If other pollutants are suspected, the water will be handled in accordance with BMP WM-10 liquid waste management for disposal off site.

Discharge BMPs and Location(s)

If sediment is the only potential pollutant, the water will be discharged through a gravity bag filter (See attached typical construction drawing and specifications). The accumulated rainwater will be pumped through a non-woven geotextile fabric that collects sand, silt and fines as described in BMP NS-2. The pump will be selected to match the flow capacity of the gravity bag filter in accordance with the manufacturer's specifications. The sediment particle size, the available pore sizes of the filter material and the expected flow rates will be considered when selecting the proper pump and filter bag. The bag may need to be cleaned frequently if there is clogging. The bag material (pore size) or pump may need to be changed to address clogs, bursts or other problems. The manufacturer's specifications are attached to this APP. The actual size of the gravity bag filter, and pump will be determined after the rain event and will coincide with the amount of water trapped.

The gravity bag filter will be located on a paved area as shown on WPCD 4 of the SWPPP, where the additional water will not result in erosion. The flow path from the gravity bag filter to the storm drain inlet will be inspected and cleaned as necessary to prevent transfer of pollutants to the storm drain system. The gravity bag filter will be placed on a bed of clean gravel 0.4 to 0.8 inch in diameter that will extend outside the bag at least 6 inches on all sides.

Notification

The Engineer will be informed prior to each discharge of accumulated precipitation even though this procedure is followed.

Sampling and Analysis

The discharge of accumulated precipitation will be sampled and analyzed in accordance with the sampling and analysis plan in the SWPPP Section 600.2.

EXAMPLE

Inspection, Maintenance and Repair
The gravity bag filter will be monitored hourly during discharge events. The flow, bag condition, bag capacity and secondary gravel barrier will be inspected for adequate function. If the discharge treatment system is not functioning adequately, the discharge will be stopped immediately. The gravity bag filter will be maintained and repaired as necessary for adequate function. If necessary the treatment method will be modified and a revised APP will be submitted to the Engineer for Approval prior to discharge.

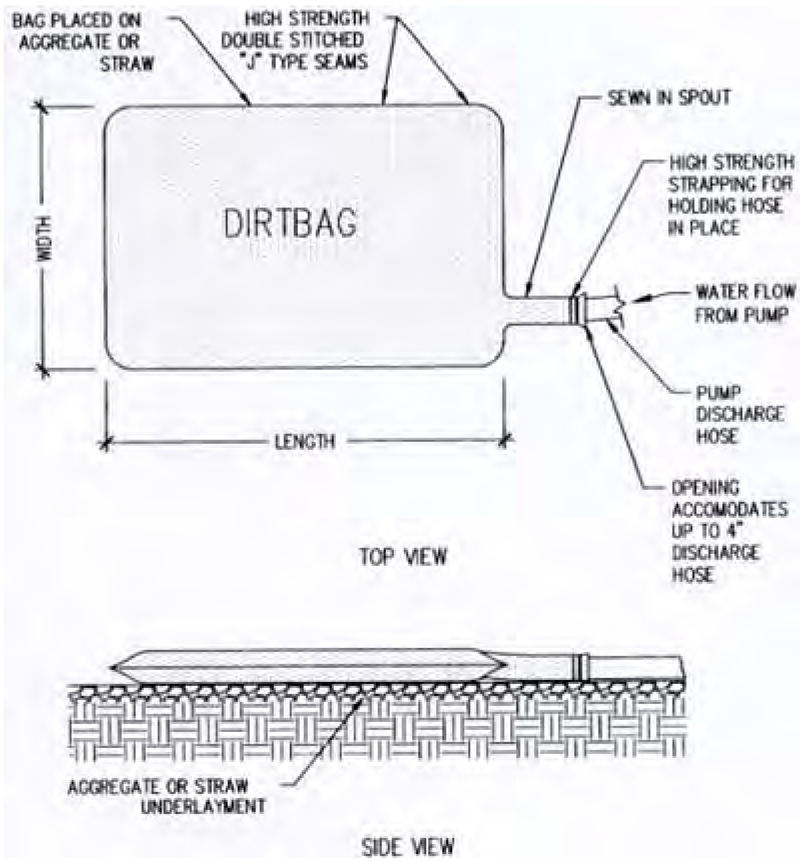
EXAMPLE

DIRTBAG®

Typical Construction:



Dirtbag® Specification:
Control of Sediment In Pumped Water

1.0 **Description**

1.1 This work shall consist of furnishing, placing and removing Dirtbag® pumped sediment control device as directed by the design enginer or as shown on the contract drawings. Dirtbag® pumped-silt control system is marketed by The BMP Store.

2.0 **Materials**

2.1 Dirtbag®

2.1.1 Dirtbag® shall be manufactured using a polypropylene nonwoven geotextile from SI Geosolutions, then sewn into a bag with a double needle matching using a high strength thread.

2.1.2 Each standard Dirtbag® has a fill spout large enough to accommodate a 4" discharge hose. Straps are attached to secure the hose and prevent pumped water from escaping without being filtered.

2.1.3 Dirtbag® seams shall have an average wide width strength per ASTM D-4884 as follows:

EXAMPLE

Dirtbag® Style	Test Method	Test Method
Dirtbag® 53	ASTM D-4884	60 lbs./in
Dirtbag® 55	ASTM D-4884	100 lbs./in

Property	Test Method	Units	Test Results Style 53	Style 55
Weight	ASTM D-3776	oz/yd	8	10
Grab Tensile	ASTM D-4632	lbs.	205	250
Puncture	ASTM D-4833	lbs.	110	150
Flow Rate	ASTM D-4491	gal/min/ft²	110	85
Permittivity	ASTM D-4491	sec.⁻¹	1.5	1.2
Mullen Burst	ASTM D-3786	lbs. in²	350	460
UV Resistant	ASTM D-4355	%	70	70
AOS % Retained	ASTM D-4751	US Sieve	80	100

All properties are Minimum Average Roll Value (MARV) except the weight of the fabric which is given for information only. Depending on soil conditions and filtration requirements, additional geotextile options are available. Please call our engineering staff for solutions.

3.0 **Construction Sequence**

3.1.1 To install Dirtbag® on a slope so incoming water flows downhill through Dirtbag® without creating more erosion. Strap the neck of Dirtbag® tightly to the discharge hose. To increase the efficiency of filtration, place the bag on an aggregate or haybale bed to maximize water flow through the surface area of the bag.

3.1.2 Dirtbag® is full when it no longer can efficiently filter sediment or allow water to pass at a reasonable rate. Flow rates will vary depending on the size of Dirtbag®, the type and amount of sediment discharged into Dirtbag®, the type of ground, rock or other substance under the bag and the degree of the slope on which the bag lies. Under most circumstances Dirtbag® will accommodate flow rates of 1100 gallons per minute. Use of excessive flow rates or overfilling Dirtbag® with sediment will cause the bag to rupture or failure of the hose attachment straps.

3.1.3 Dispose Dirtbag® as directed by the site engineer. If allowed, Dirtbag® may be cut open and the contents seeded after removing visible fabric. Dirtbag® is strong enough to be lifted with optional straps if it must be hauled away. Off-site disposal may be facilitated by placing Dirtbag® in the back of a dump truck or flatbed prior to use and allowing the water to drain from the bag while in place, thereby eliminating the need to lift Dirtbag®.

4.0 **Basis of Payment**

4.1 The payment for any Dirtbag® used during construction is to be included in the bid of overall erosion and sediment control plan unless a unit price is requested.

REQUIRED TEXT: To be completed by Contractor for all projects if APP is required.

Accumulated Precipitation Procedure (APP)

Project Name: ____

Project ID/ID Number: ____

[Check appropriate box below based on contract Special Provisions Section 7-8.6.]

☐SWPPP required for this project ☐SWPPP not required for this project

This project may accumulate precipitation due to: **[Insert brief description of how precipitation may be trapped on site such as in low lying areas, planned excavations or other means where it may be necessary to discharge water to the storm drain system or water body.]**. No accumulated water will be discharged without implementing this accumulated precipitation procedure (APP).

Areas Expected to Trap Precipitation
[Describe in detail the areas that are expected to trap rain water on the construction site.]

BMPs Selected to Protect Accumulated Precipitation
[Describe BMPs that are selected for the project that will minimize sediment in accumulated precipitation, if any.]

Option(s) for not Discharging Accumulated Precipitation
[Describe options for not discharging accumulated precipitation offsite such as storing the water on site, infiltration, using the water for dust control or other method approved by the Engineer.]

Inspection Prior to Discharge
After a precipitation event, water that is trapped in the excavation may need to be discharged to continue construction. The water will be inspected to determine whether it has come into contact with any other pollutants (e.g., spilled fuel) prior to discharge. If other pollutants are suspected, the water will be handled in accordance with BMP WM-10 liquid waste management for disposal off site.

Discharge BMPs and Location(s)
If sediment is the only potential pollutant, the water will be **[Describe how NS-2 Dewatering Operations BMPs will be implemented including a description of the selected BMPs and equipment for minimizing sediment in the discharge. Describe the location of the BMPs and equipment to be used.] [Describe location(s) of the discharge such as to the gutter, drain inlet,**

water body, etc. Include BMPs for erosion control and velocity dissipation at the discharge point where erosion could occur.]

Notification

The Engineer will be informed prior to each discharge of accumulated precipitation even though this procedure is followed.

Sampling and Analysis

The discharge of accumulated precipitation will be sampled and analyzed in accordance with the sampling and analysis plan in the SWPPP Section 600.2. **[If the construction project does not require a SWPPP, delete this sampling and analysis section.]**

Inspection, Maintenance and Repair

The accumulated precipitation discharge and associated BMPs and equipment will be monitored hourly during discharge events. The flow, BMP conditions and potential for sediment in the flow path will be inspected. In the event the BMPs, equipment or flow path are not functioning adequately, the discharge will be stopped until the treatment system is maintained or repaired to function adequately. This may require a revision to this APP which will need to be approved by the Engineer.

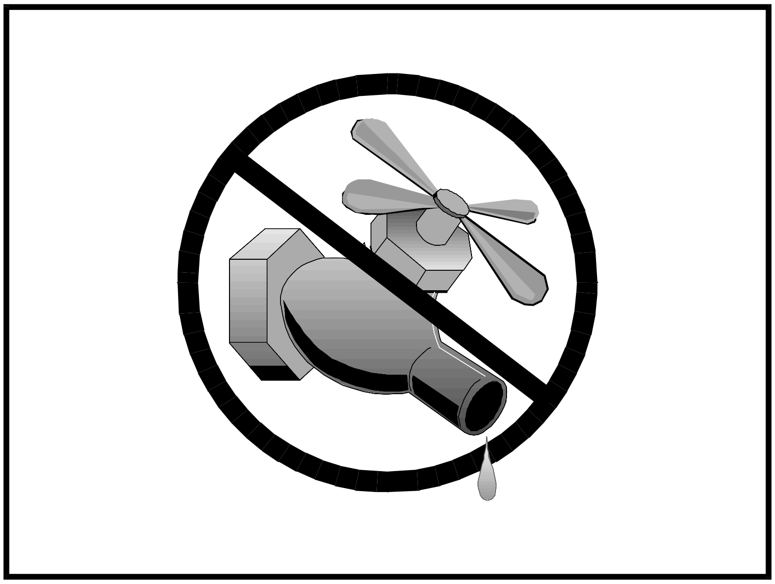
Water Conservation Practices

NS-1



Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Water conservation practices are activities that use water during the construction of a project in a manner that avoids discharge to the ground or discharge causing erosion and/or the transport of pollutants off site.

Appropriate Applications

- Water conservation practices are implemented on all construction sites and wherever water is used.
- Applies to all construction projects.

Limitations

- None identified.

Standards and Specifications

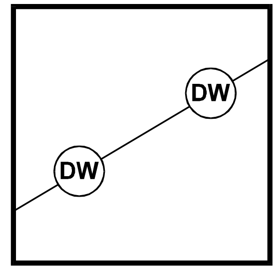
- Keep water equipment in good working condition.
- Stabilize water truck filling area.
- Repair water leaks immediately.
- Do not allow water to flow offsite or into storm drain system.
- Vehicles and equipment washing on the construction site is discouraged.
- Avoid using water to clean construction areas. Do not use water to clean pavement. Paved areas shall be swept and vacuumed.
- Direct construction water runoff to areas where it can infiltrate into the ground.
- Apply water for wind erosion control in accordance with WE-1 BMPs.
- Report discharges to Engineer immediately.

Maintenance and Inspection

- Inspect water conservation practices weekly and before and after every rainfall events. During extended rainfall events, inspect water conservation practices at least once every 24 hours.
- Repair water equipment as needed or as directed by the Engineer.

Dewatering Operations

NS-2



Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Dewatering Operations are practices that manage the discharge of pollutants when non-storm water and accumulated precipitation (storm water) must be removed from a work location so that construction work may be accomplished.

Appropriate Applications

- These practices are implemented for discharges of non-storm water and storm water (accumulated rain water) from construction sites. Non-storm water includes, but is not limited to, dewatering of piles, water from cofferdams, water diversions, and water used during construction activities that must be removed from a work area.

- Practices identified in this section are also appropriate for implementation when managing the removal of accumulated precipitation (storm water) from a construction site.

- Storm water mixed with non-storm water shall be managed as non-storm water.

Limitations

- All construction groundwater dewatering shall be in full compliance with the contract special provisions and Monitoring and Reporting Program and Waste Discharge Requirements (WDR) of the NPDES permit included in the contract Special Provisions. All Contractor operations shall be in full compliance with all applicable laws and regulations that govern water quality.

- If groundwater is encountered on the construction site and the contract Special Provisions do **not** include provisions for construction dewatering, the Contractor shall immediately notify the Engineer for direction. No groundwater shall be discharged to the sanitary sewer system, street/gutter, or any other location, whether contaminated, treated, or not, without prior approval by the Engineer.

Dewatering Operations

Standards and Specifications

- Dewatering for accumulated precipitation (storm water) shall follow this BMP in accordance with the approved Accumulated Precipitation Procedure (APP) and use treatment measures specified herein (See example in Section 7.2).
- The Contractor shall submit an APP as part of the SWPPP detailing methods and procedures for management and discharge of accumulated precipitation on the construction site, including treatment technologies/BMPs, equipment, discharge locations, and all other pertinent information. If a SWPPP is not required per the contract Special Provisions, the Contractor shall prepare an APP and submit it to the Engineer separately.
- Sediment control and other appropriate BMPs. Implement SS-10 "Outlet Protection/Velocity Dissipation Devices" to prevent erosion at the discharge point.
- Discharges must comply with regional and watershed-specific discharge requirements.
- The controls discussed in this BMP address sediment only. If the presence of other pollutants is identified in the contract Special Provisions, the Contractor shall implement dewatering pollution controls as required by the contract Special Provisions.
- If other pollutants are identified or suspected in the water to be removed by dewatering, and are not identified in the contract Special Provisions, the contractor shall not discharge the water and immediately notify the Engineer.
- Reuse water on-site (such as dust control, compaction, etc) if approved by the Engineer.
- Treatment system shall be fenced to prevent unauthorized entry
- Additional permits or permissions from other agencies may be required for dewatering cofferdams or diversions.

Maintenance and Inspection

- Inspect dewatering operations daily and document weekly and before and after every rainfall events. During extended rainfall events, inspect paving and grinding operations at least once every 24 hours.
- Inspect all BMPs implemented to comply with permit requirements frequently and repair or replace BMPs to ensure they function as designed.
- Conduct water quality monitoring pursuant to the permit requirements of the contract Special Provisions. Documentation must be included in the SWPPP.
- Accumulated sediment that is commingled with other pollutants must be disposed of in accordance with all applicable laws and regulations and as approved by the Engineer.

Sediment Treatment

A variety of methods can be used to treat water during dewatering operations from the construction site. Several devices are presented in this section that provide options to achieve sediment removal. The size of particles present in the sediment and Permit or receiving water limitations on sediment are key considerations for selecting sediment treatment option(s); in some cases, the use of multiple devices may be appropriate. If a selected method or device does not adequately remove sediment, a different or additional method shall be implemented.

Category 1: Constructed Settling Technologies

The devices discussed in this category are to be used exclusively for dewatering operations only.

Sediment/Desilting Basin (SC-2)

A sediment/desilting basin is a temporary basin with a controlled release structure that is formed by excavation and/or construction of an embankment to detain sediment-laden runoff and allow sediment to settle out before discharging.

Appropriate Applications:

- Effective for the removal of trash, gravel, sand, and silt and some metals that settle out with the sediment.

Maintenance:

- Maintenance is required for safety fencing, vegetation, embankment, inlet and outfall structures, as well as other features.
- Removal of sediment is required when the storage volume is reduced by one-third.

Sediment Trap (SC-3)

A sediment trap is a temporary basin formed by excavation and/or construction of an earthen embankment across a waterway or low drainage area to detain sediment-laden runoff and allow sediment to settle out before discharging.

Appropriate Applications:

- Effective for the removal of large and medium sized particles (sand and gravel) and some metals that settle out with the sediment.

Maintenance:

- Maintenance is required for vegetation, embankment, inlet and outfall structures, as well as other features.
- Removal of sediment is required when the storage volume is reduced by one-third.

Category 2: Mobile Settling Technologies

The devices discussed in this category are typical of tanks that can be used for sediment treatment of dewatering operations. A variety of vendors are available who supply these tanks.

Weir Tank

A weir tank separates water and waste by using weirs. The configuration of the weirs (over and under weirs) maximizes the residence time in the tank and determines the waste to be removed from the water, such as oil, grease, and sediments.

Appropriate Applications:

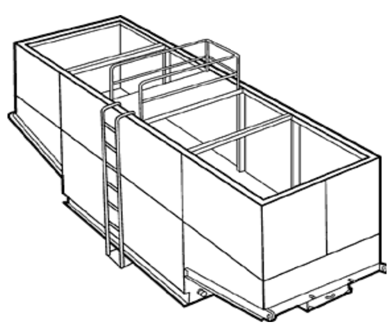
- The tank removes trash, some settleable solids (gravel, sand, and silt), some visible oil and grease, and some metals (removed with sediment). To achieve high levels of flow, multiple tanks can be used in parallel. If additional treatment is desired, the tanks can be placed in series or as pre-treatment for other methods.

Implementation:

- Tanks are delivered to the site by the vendor, who can provide assistance with set-up and operation.
- Tank size will depend on flow volume, constituents of concern, and residency period required. Vendors shall be consulted to appropriately size tank.

Maintenance:

- Periodic cleaning is required based on visual inspection or reduced flow.
- Oil and grease disposal must be by licensed waste disposal company in accordance with WM-6.



Weir Tank

Dewatering Tank

A dewatering tank removes debris and sediment. Flow enters the tank through the top, passes through a fabric filter, and is discharged through the bottom of the tank. The filter separates the solids from the liquids.

Appropriate Applications:

- The tank removes trash, gravel, sand, and silt, some visible oil and grease, and some metals (removed with sediment). To achieve high levels of flow, multiple tanks can be used in parallel. If additional treatment is desired, the tanks can be placed in series or as pre-treatment for other methods.

Implementation:

- Tanks are delivered to the site by the vendor, who can provide assistance with set-up and operation.
- Tank size will depend on flow volume, constituents of concern, and residency period required. Vendors shall be consulted to appropriately size tank.

Maintenance:

- Periodic cleaning is required based on visual inspection or reduced flow.
- Oil and grease disposal must be by licensed waste disposal company in accordance with WM-6..

Dewatering Tanks

Category 3: Basic Filtration Technologies

Gravity Bag Filter

A gravity bag filter, also referred to as a dewatering bag, is a square or rectangular bag made of non-woven geotextile fabric that collects sand, silt, and fines.

Appropriate Applications:

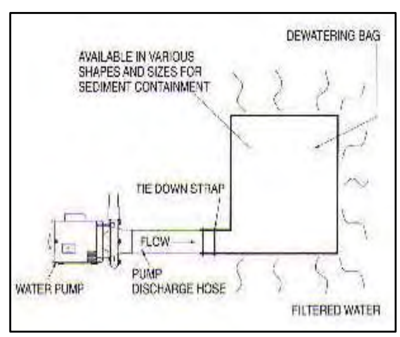
- Effective for the removal of sediments (gravel, sand, and silt). Some metals are removed with the sediment.

Implementation:

- Water is pumped into one side of the bag and seeps through the bottom and sides of the bag.
- A secondary barrier, such as a rock filter bed or gravel bag barrier, is placed beneath and beyond the edges of the bag to capture sediments that escape the bag.

Maintenance:

- Inspection of the flow conditions, bag condition, bag capacity, and the secondary barrier is required.
- Replace the bag when it no longer filters sediment or passes water at a reasonable rate.
- The bag is disposed off-site, or on-site as directed by the Engineer.



Gravity Bag Filter

Category 4: Advanced Filtration Technologies

Sand Media Particulate Filter

Water is treated by passing it through canisters filled with sand media. Generally, sand filters provide a final level of treatment. They are often used as a secondary or higher level of treatment after a significant amount of sediment and other pollutants have been removed.

Appropriate Applications:

- Effective for the removal of trash, gravel, sand, and silt and some metals, as well as the reduction of biochemical oxygen demand (BOD) and turbidity.
- Sand filters can be used for standalone treatment or in conjunction with bag and cartridge filtration if further treatment is required.
- Sand filters can also be used to provide additional treatment to water treated via settling or basic filtration.

Implementation:

- The filters require delivery to the site and initial set up. The vendor can provide assistance with installation and operation.

Maintenance:

- The filters require monthly service to monitor and maintain the sand media.

Sand Media Particulate Filters

Pressurized Bag Filter

A pressurized bag filter is a unit composed of single filter bags made from polyester felt material. The water filters through the unit and is discharged through a header, allowing for the discharge of flow in series to an additional treatment unit. Vendors provide pressurized bag filters in a variety of configurations. Some units include a combination of bag filters and cartridge filters for enhanced contaminant removal.

Appropriate Applications:

- Effective for the removal of sediment (sand and silt) and some metals, as well as the reduction of BOD, turbidity, and hydrocarbons. Oil absorbent bags are available for hydrocarbon removal.
- Filters can be used to provide secondary treatment to water treated via settling or basic filtration.

Implementation:

- The filters require delivery to the site and initial set up. The vendor can provide assistance with installation and operation.

Maintenance:

- The filter bags require replacement when the pressure differential exceeds the manufacturer's recommendation.

Pressurized Bag Filter

Cartridge Filter

Cartridge filters provide a high degree of pollutant removal by utilizing a number of individual cartridges as part of a larger filtering unit. They are often used as a secondary or higher (polishing) level of treatment after a significant amount of sediment and other pollutants are removed. Units come with various cartridge configurations (for use in series with pressurized bag filters) or with a larger single cartridge filtration unit (with multiple filters within).

Appropriate Applications:

- Effective for the removal of sediment (sand, silt, and some clays) and metals, as well as the reduction of BOD, turbidity, and hydrocarbons. Hydrocarbons can effectively be removed with special resin cartridges.
- Filters can be used to provide secondary treatment to water treated via settling or basic filtration.

Implementation:

- The filters require delivery to the site and initial set up. The vendor can provide assistance.

Maintenance:

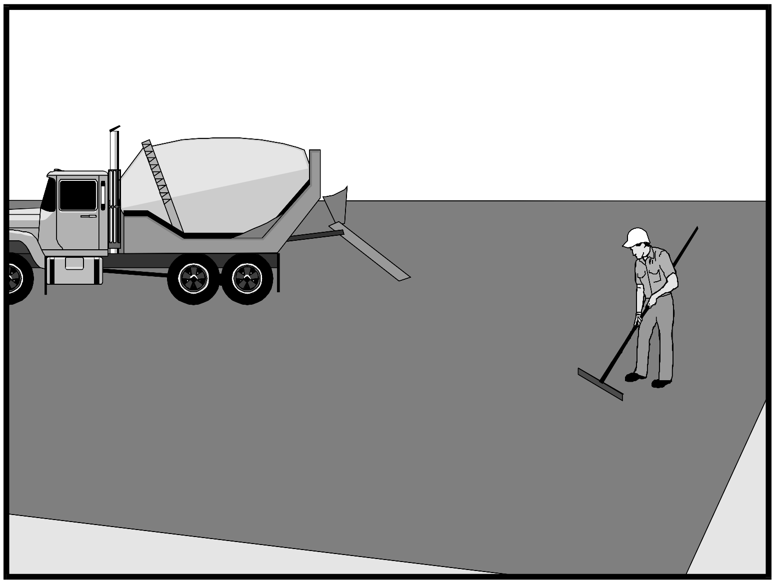
- The cartridges require replacement when the pressure differential exceeds the manufacturer's recommendation.

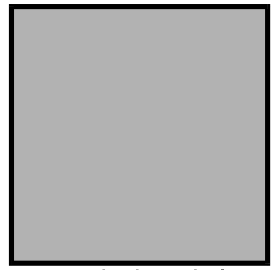
Cartridge Filter

(This page left intentionally blank)

Paving and Grinding Operations

NS-3





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Procedures and practices for conducting paving, concrete slurry, cement or masonry, saw cutting, and grinding operations to minimize the transport of pollutants to the storm drain system or receiving water body.

Appropriate Applications

These procedures are implemented where paving, surfacing, resurfacing, grinding, slurry, cement, mortar or sawcutting, may pollute storm water runoff or discharge to the storm drain system or watercourses.

Limitations

- ■ Finer solids are not effectively removed by sediment control BMPs (SC-1 through SC-10) settling or filtration systems. SC-10 is not adequate for drain inlet protection from paving/concrete pollutants.

Standards and Specifications

- ■ Substances used to coat asphalt transport trucks, asphalt trucks, and asphalt spreading equipment shall not contain soap and shall be non-foaming and non-toxic.
- ■ Place plastic materials under asphaltic concrete (AC) paving equipment while not in use, to catch and/or contain drips and leaks. See also BMP WM-4, “Spill Prevention and Control.”
- ■ When paving involves AC, the following steps shall be implemented to prevent the discharge of uncompacted or loose AC, tack coats, equipment cleaners, or other paving materials:
- – Minimize sand and gravel from new asphalt from getting into storm drains, streets, and creeks by sweeping.
- – Old, broken, or spilled asphalt shall be removed from the project site and recycled or disposed of as approved by the Engineer.
- – AC grindings, pieces, or chunks shall not be used in embankments or shoulder backing unless approved by the Engineer.

- Collect and remove all broken asphalt and recycle off-site or dispose of offsite in accordance with all applicable laws and regulations.
- During chip seal application and sweeping operations, petroleum or petroleum covered aggregate shall not be discharged to the ground surface, enter any storm drain or water courses. Filter fabrics or plastic must be used to cover inlets to prevent any discharge of sediment or water until installation is complete.
- Use only non-toxic substances to coat asphalt transport trucks and asphalt spreading equipment.

■ Drainage inlet structures and manholes shall be covered with plastic during application of seal coat, tack coat, slurry seal, and/or fog seal, or any other paving/concrete, cement, slurry or mortar related pollutant to prevent any discharge to the storm drain system.

■ Seal coat, tack coat, slurry seal, or fog seal shall not be applied if rainfall is predicted to occur during the application or curing period.

■ Paving equipment parked onsite shall be parked over plastic to prevent discharge to the ground surface.

■ No washing of asphalt equipment shall be conducted on-site. When cleaning dry, hardened asphalt from equipment, manage hardened asphalt debris as described in BMP WM-5, "Solid Waste Management." Any cleaning onsite shall follow BMP NS-8, "Vehicle and Equipment Cleaning."

■ Do not wash sweepings from exposed aggregate concrete into a storm drain system. Collect and return to stockpile (WM-3), or dispose of properly.

Sawcutting

■ Do not conduct sawcutting during rain or when there is a 50% percent chance of measurable precipitation (0.01 inches or more).

■ Use minimum sawcutting blade speed to reduce required amount of water needed.

■ Vacuum up sawcutting waste as it is generated. Do not wait to complete sawcutting operation.

■ After vacuuming, the fine slurry shall be swept up after it dries.

■ Do not allow sawcutting waste slurry to get to storm drain inlet. SC-10 Storm Drain Inlet Protection and other sediment BMPs are not adequate to prevent discharge. Drain inlets shall be protected by impervious materials such as plastic. The impervious drain inlet protection shall be removed after the sawcutting operation is completed and all waste is cleaned up. The waste slurry must be completely contained in a concrete washout (WM-8) and/or shall be disposed of offsite without discharging to permeable or impermeable surfaces.

Pavement Grinding or Removal

- Residue from PCC grinding operations shall be picked up by means of a vacuum attachment to the grinding machine, shall not be allowed to flow across the pavement, and shall not be left on the surface of the pavement. See also BMP WM-8, "Concrete Waste Management;" and BMP WM-10, "Liquid Waste Management."
- Collect pavement digout material by mechanical or manual methods. This material may be recycled if approved by the Engineer for use as shoulder backing or base material at locations approved by the Engineer.
- If digout material cannot be recycled, transport the material to a storage site approved by the Engineer or offsite in accordance with all applicable laws and regulations. Digout activities shall not be conducted in the rain.
- When approved by the Engineer, stockpile material removed from roadways away from drain inlets, drainage ditches, and watercourses and stored consistent with BMP WM-3, "Stockpile Management."
- Disposal or use of AC grindings shall be approved by the Engineer. See also BMP WM-8, "Concrete Waste Management."
- No "kick-brooms" shall be used.

Thermoplastic Striping

- All thermoplastic striper and pre-heater equipment shutoff valves shall be inspected to ensure that they are working properly to prevent leaking thermoplastic from entering drain inlets, the storm water drainage system, or watercourses.
- The pre-heater shall be filled carefully to prevent splashing or spilling of hot thermoplastic. Leave six inches of space at the top of the pre-heater container when filling thermoplastic to allow room for material to move when the vehicle is deadheaded.
- Contractor shall not pre-heat, transfer, or load thermoplastic near drain inlets or watercourses.
- Clean truck beds daily of loose debris and melted thermoplastic. When possible recycle thermoplastic material. Thermoplastic waste shall be disposed of in accordance with all applicable laws and regulations.

Raised/Recessed Pavement Marker Application and Removal

- Do not transfer or load bituminous material near drain inlets, the storm water drainage system or watercourses.

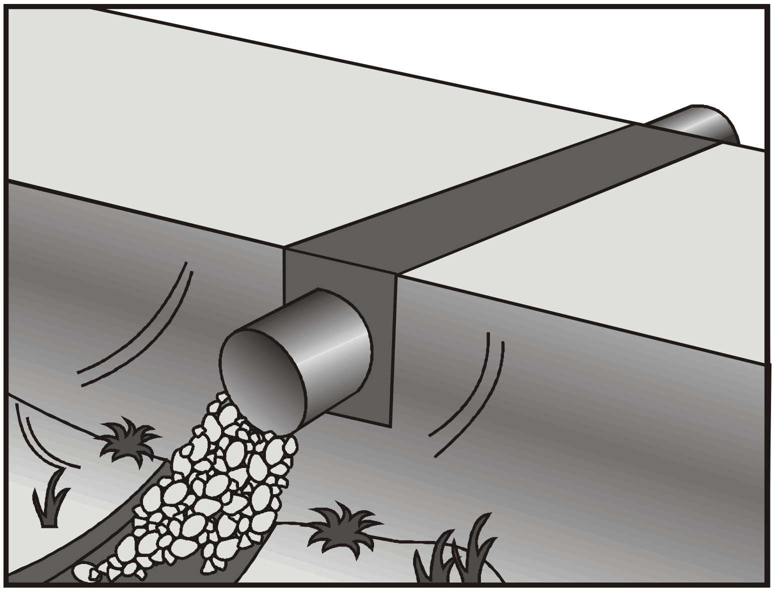
- Melting tanks shall be loaded with care and not filled to beyond six inches from the top to leave room for splashing when vehicle is deadheaded.
- When servicing or filling melting tanks, ensure all pressure is released before removing lids to avoid spills.
- On large scale construction sites, use mechanical or manual methods to collect excess bituminous material from the roadway after removal of markers.
- Waste shall be disposed of in accordance with all applicable laws and regulations.

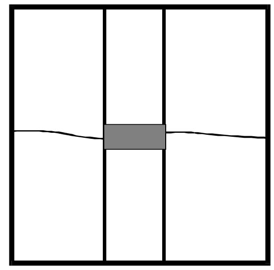
Maintenance and Inspection

- Inspect paving and grinding operations weekly and before and after every rainfall events. During extended rainfall events, inspect paving and grinding operations at least once every 24 hours.
- Inspect sawcutting operation and ensure that all waste slurry is vacuumed up. Any residual shall be swept or scraped up if necessary to remove it.
- Ensure that employees and subcontractors are implementing appropriate measures during paving operations.

Temporary Stream Crossing

NS-4





Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

A temporary stream crossing is a structure placed across a waterways, drainage swales or ditches that allows vehicles to cross the waterway during construction, minimizing, reducing, or managing erosion and downstream sedimentation caused by the vehicles.

Appropriate Applications

Temporary stream crossings are installed at sites:

- Where construction equipment or vehicles need to cross a waterways drainage swales or ditches.

Limitations

- Fully comply with the specific permit requirements or mitigation measures identified in the contract Special Provisions and all regulatory permits, such as Regional Water Quality Control Board (RWQCB) 401 Certification, U.S. Army Corps of Engineers 404 permit, California Department of Fish and Game Streambed Alteration Agreement, and US Forest Service Permits. Comply with all water quality monitoring and numerical-based water quality standards identified in the contract Special Provisions and all regulatory permits.
- Appropriate erosion and sediment control BMPs shall be installed during construction and removal of stream crossing.
- May become a constriction in the waterway, which can obstruct flood flow and cause flow backups or washouts. If improperly designed, flow backups can increase the pollutant load through washouts and scouring.
- Dry Ford shall only be used in the non-rainy season and when no flows are present. The use of the Ford is contingent on a 5-day clear weather forecast.
- CCS should not be used in excessively high or fast flows. Use of natural or other gravel in the stream for construction of Cellular Confinement System (CCS) crossing will be contingent upon approval by fisheries agencies.

■ Upon completion of construction activities, all stream crossing shall be removed and the area stabilized and restored to pre-construction conditions or as directed by the Engineer.

Standards and Specifications

General Considerations

■ No stream crossing is allowed without prior approval by the Engineer and compliance with the contract Special Provisions, applicable permits, laws and regulations.

■ Select site where erosion potential is low.

The following types of temporary stream crossings shall be considered:

■ Culverts - Used on perennial and intermittent streams.

■ Dry Fords - Appropriate during the dry season only. Used on dry washes, streams, and channels.

■ Cellular Confinement System (CCS) crossing structures consist of clean, washed gravel and cellular confinement system blocks. Used on dry washes and ephemeral streams, and low flow perennial streams.

■ Bridges - Appropriate for streams with high flow velocities, steep gradients and/or where temporary restrictions in the channel are not allowed.

Design and installation requires knowledge of stream flows and soil strength. Stream crossing shall be designed by a professional Engineer registered with the State of California. The Design details shall be included in the SWPPP or SWPPP amendment or approved by the Engineer prior to construction. Both hydraulic and construction loading requirements shall be considered with the following:

■ Comply with all applicable requirements for culvert and bridge crossings, particularly if the temporary stream crossing will remain through the rainy season.

■ Provide stability in the crossing and adjacent areas to withstand the design flow. The design flow and safety factor shall be selected based on careful evaluation of the risks due to over flowing, flow backups, or washout.

■ Shall not use oil or other potentially hazardous materials for surface treatment.

■ A Spill Prevention and Clean-up Plan shall be developed and included in the SWPPP, or submitted to the Engineer for approval prior to construction, for all potential spills from the crossing as a result of construction traffic or activities.

Construction Requirements:

- Stabilize construction roadways, adjacent work area and streambed against erosion.
- Construct during the non-rainy season and 5-day clear weather forecast to minimize stream disturbance and reduce costs.
- Construct at or near the natural elevation of the stream bed to prevent potential flooding upstream of the crossing.
- Install temporary sediment control BMPs to minimize erosion of embankment into flow lines. Install Sediment Controls along the perimeter (sides) of the crossing.
- Vehicles and equipment shall not be driven, operated, fueled, cleaned, maintained, or stored in the streambed.
- Temporary water body crossings and encroachments shall be constructed to minimize scour. Cobbles used for temporary water body crossings or encroachments shall be clean, rounded river cobble.
- The exterior of vehicles and equipment that will encroach on the water body within the project shall be maintained free of grease, oil, fuel, and residues.
- Any temporary artificial obstruction placed within flowing water shall only be built from material, such as clean gravel, that will cause little or no siltation.
- Drip pans shall be placed under all vehicles and equipment placed on docks, barges, or other structures over water bodies when the vehicle or equipment is planned to be idle for more than one hour.
- Conceptual temporary stream crossings are shown in figures at the end of this section.

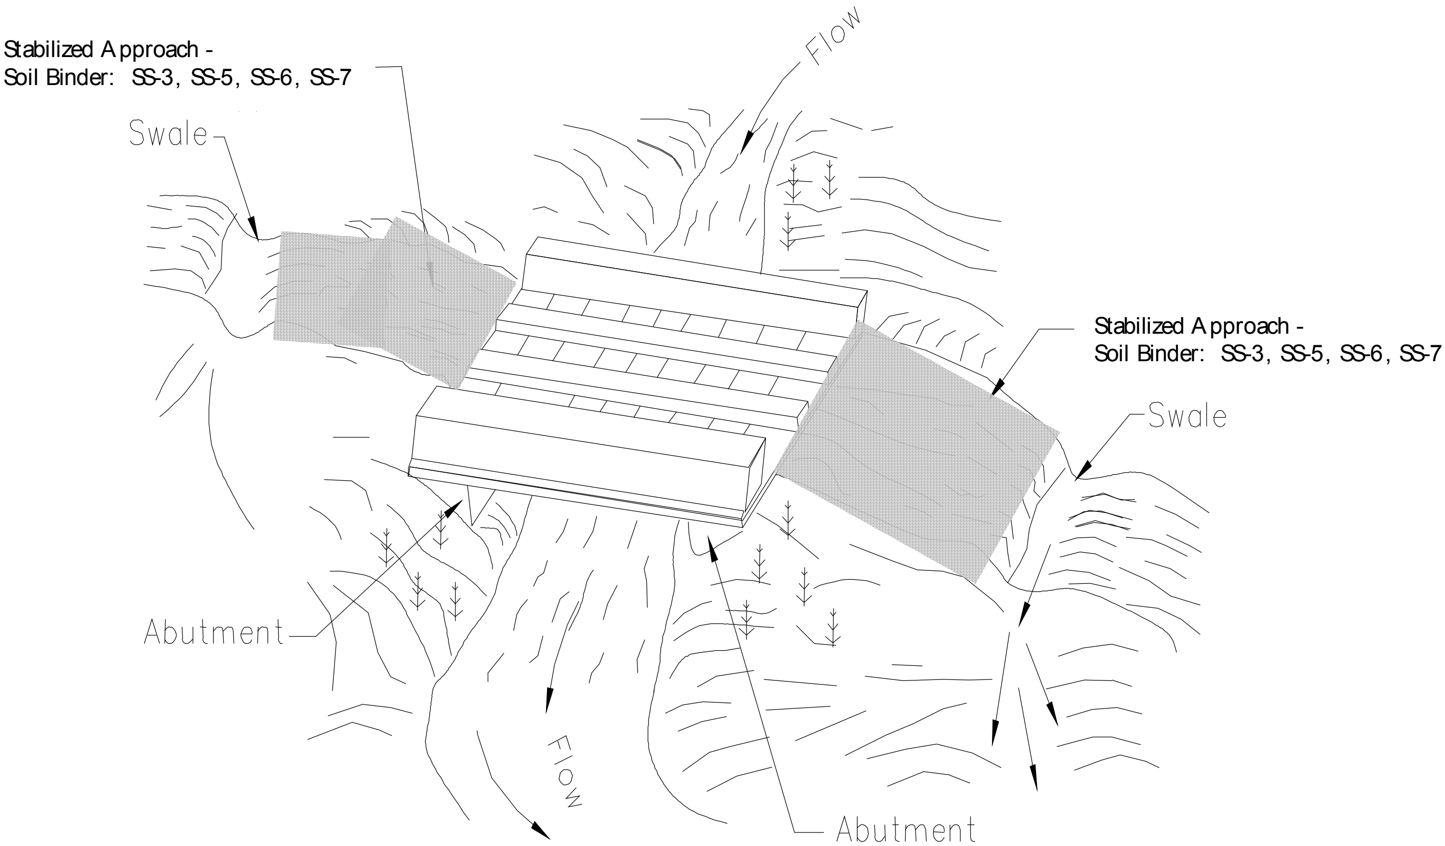
Specific Requirements:

- Culverts are relatively easy to construct and able to support heavy equipment loads.
- Dry Fords are the least expensive of the crossings, with maximum load limits.
- CCS allow designers to use either angular or naturally-occurring, rounded gravel, because the cells provide the necessary structure and stability. In fact, natural gravel is optimal for this technique, because of the habitat improvement it will provide after removal of the CCS.
- A gravel depth of 6 to 12 inches for a CCS structure is sufficient to support most construction equipment.
- An advantage of a CCS crossing structure is that relatively little rock or gravel is needed, because the CCS provides the stability.

- Bridges are generally more expensive to design and construct, but provides the least disturbance of the stream bed and constriction of the waterway flows.

Maintenance and Inspection

- Inspect streambed crossing weekly and before and after every rainfall events. During extended rainfall events, inspect streambed crossing at least once every 24 hours.
- Removal of debris behind fords, in culverts, and under bridges as directed by the Engineer.
- Replacement of lost protective aggregate from inlets and outlets of culverts.
- Checking for blockage in the channel, debris buildup in culverts or behind fords, and under bridges.
- Checking for erosion of abutments, channel scour, riprap displacement, or piping in the soil.
- Checking for structural weakening of the temporary crossing, such as cracks, and undermining of foundations and abutments.
- Removal of temporary crossing promptly when it is no longer needed or as directed by the Engineer.



NOTE:
Surface flow of road diverted by swale and/or dike.

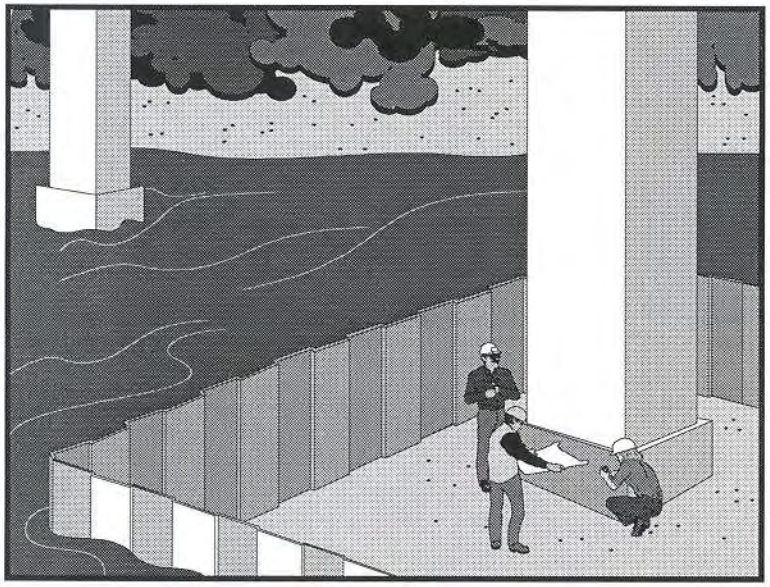
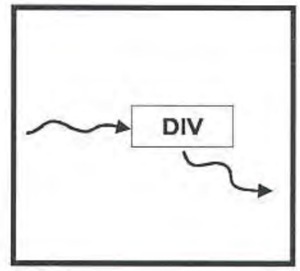
Clear Water Diversion

NS-5





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Clear water diversion consists of a system of structures and measures that intercept clear surface water runoff upstream of a project site, transport it around the work area, and discharge it downstream with minimal water quality degradation for either the project construction operations or the construction of the diversion. Clear water diversions are used in a waterway or storm drain system to enclose a construction area and reduce sediment pollution from construction work occurring in or adjacent to water. Isolation techniques are methods that isolate near shore work from a waterbody. Structures commonly used as part of this system include diversion ditches, berms, dikes, slope drains, rock, gravel bags, wood, sheet piles, aqua barriers, cofferdams, filter fabric or turbidity curtains, drainage and interceptor swales, pipes, or flumes.

Appropriate Applications

- Clear water diversions are appropriate for isolating construction activities occurring within or near a water body such as streambank stabilization, or channel, culvert, bridge, piers or abutment repair or construction. They may also be used in combination with other methods, such as clear water bypasses and/or pumps.

- Pumped diversions are suitable for intermittent and low flow streams. Excavation of a temporary bypass channel, or passing the flow through a pipe.

- Fully comply with the specific permit requirements or mitigation measures identified in the contract Special Provisions and all regulatory permits, such as Regional Water Quality Control Board (RWQCB) 401 Certification, U.S. Army Corps of Engineers 404 permit, California Department of Fish and Game Streambed Alteration Agreement, and US Forest Service Permits. Comply with all water quality monitoring and numerical-based water quality standards identified in the contract Special Provisions and all regulatory permits.

- The Contractor is cautioned that the Project involves work within and requires removal of portions of streambed or an active flood control channel which is subject to flows of high and uncontrolled magnitude. Although such flows would most likely occur during the storm season, from October 15 to April 15, there is the possibility that such occurrences can take place at other times of the year. The Contractor shall assume all risks associated with working in an active streambed channel.

- The Contractor shall consult with the National Weather Service to determine the possibility of storms.

- The Contractor shall be responsible for providing for the passage of all flows through the Work site, maintaining water quality as required by the permits by implementation of BMPs, and the safety personnel, equipment, and materials under its jurisdiction.

- The Contractor shall provide for the flow of water from all sources, including nuisance water, through Work site at all times.

Limitations

- Diversion/encroachment activities may constrict the waterway, which can obstruct flood flows and cause flooding or washouts. Diversion structures shall not be installed without identifying potential impacts to the stream channel.

- Between October 15th through April 15th the Contractor shall:
  - Maintain the capacity of the channel shall be maintained at 100% of design capacity.
  - Not conduct work, store materials/equipment, or operate equipment within the channel.
  - Completely remove all temporary surface water diversions structures from the channel.

- Diversion or isolation activities shall not completely dam stream flow.

- Dewatering and removal may require additional sediment control or water treatment (See NS-2, “Dewatering Operations”).

Standards and Specifications

- The Contractor shall submit a Surface Water Diversion Plan per the contract Special Provisions for all working within a streambed or channel.

- If the contract Special Provisions do not contain requirements for a Surface Water Diversion Plan, then the Contractor shall prepare a Surface Water Diversion Plan, per this BMP, and submit it to the Engineer for approval prior to conducting any work over a watercourse.

- The Surface Water Diversion Plan shall be designed by a professional Engineer registered with the State of California. The Surface Water Diversion Plan shall be included in the SWPPP.

- The Contractor shall design, construct, maintain, and remove a temporary surface water diversion system as specified herein. The Surface Water Diversion Plan shall contain at a minimum the following information:
  - A written description of the Surface Water Diversion System.
  - A site plan (drawn to scale) and diagrammatic representation of the diversion of water system, showing the location of all BMPs, equipment within the project limits (including check dams, pumps, piping details, discharge and sampling locations, power source, etc.).
  - The Plan will also include equipment specifications and all other information, as requested by the Agency, for the complete understanding and operation of the dewatering plan.
- The contractor shall demonstrate to the satisfaction of the Engineer that all components of the temporary surface water diversion system are fully functional prior to initiation of any work in associated portion of the channel.
- The temporary surface water diversion system shall be water-tight. If any nuisance water leaks occur within the work area, the Contractor shall immediately contain and re-direct/remove the nuisance water away from the work areas.
- The Contractor shall strictly confine all work and storage of materials and equipment with the boundaries of the temporary surface water diversion system.
- During storms, obstructions such as equipment and materials shall be removed from the channel.
- All temporary improvements installed by the Contractor for the diversion of water, not specified as a permanent improvement as part of the contract, shall be removed and the site restored.
- The system shall be routinely cleaned of silt/sediment as directed by the Engineer and any required repaired made immediately. If during the progress of work, the Agency determines that the Plan or implementation of the Plan is inadequate, the Contractor shall, at his expense, furnish any equipment, labor, materials, and outside services necessary to perform the work satisfactory to the Agency.
- Excavation equipment buckets may reach out into the water for the purpose of removing or placing fill materials. Only the bucket of the crane/ excavator/backhoe may operate in a water body. The main body of the crane/excavator/backhoe shall not enter the water body, except as necessary to cross the stream to access the work site.
- Implement guidelines presented in SS-12, Streambank Stabilization to minimize impacts to streambanks.

- All surrounding areas at the head wall and outfall structure shall be stabilized with SS-3, SS-4, SS-7, SS-12, or a combination of such if necessary.
- Stationary equipment such as motors and pumps, located within or adjacent to a water body, shall be positioned over drip pans.
- When any artificial obstruction is being constructed, maintained, or placed in operation, sufficient water shall, at all times, be allowed to pass downstream to maintain aquatic life downstream.
- The exterior of vehicles and equipment that will enter the streambed or channel shall be maintained free of grease, oil, fuel, and residues.
- Drip pans shall be placed under all vehicles and equipment, including vehicles or equipment will be idle for more than one hour.
- Where possible, avoid or minimize diversion/encroachment impacts by scheduling construction during periods of low flow or when the stream is dry. See also the contract Special Provisions for scheduling requirements. Scheduling shall also consider seasonal releases of water from dams, fish migration and spawning seasons, and water demands due to crop irrigation.
- Construct diversion structures with materials free of potential pollutants such as soil, silt, sand, clay, grease, or oil.

Temporary Diversions/Encroachments

- Construct diversion channels in accordance with BMP SS-9, "Earth Dikes/Drainage Swales, and Ditches."
- In high flow velocity areas, stabilize slopes of embankments and diversion ditches using an appropriate liner, in accordance with BMP SS-7, "Geotextiles, Plastic Covers & Erosion Control Blankets/Mats", or use rock slope protection.
- Where appropriate, use natural streambed materials such as large cobbles and boulders for temporary embankment/slope protection, or other temporary soil stabilization methods.
- Provide for velocity dissipation at transitions in the diversion, such as the point where the stream is diverted to the channel and the point where the diverted stream is returned to its natural channel. See also BMP SS-10, "Outlet Protection/Velocity Dissipation Devices."

Temporary Dry Construction Areas

- When dewatering behind temporary structures to create a temporary dry construction area (such as coffer dams), pass pumped water through a sediment settling device, tank or settling basin, before returning water to the water body; see also BMP NS-2, "Dewatering Operations."

- If pollutants (except sediment) are identified in the contract Special Provisions, the contractor shall fully comply with the contract Special Provisions. If pollutants (except sediment) are observed or identified, the contractor shall discharge any water and immediately notify the Engineer.

- Any substance used to assemble or maintain diversion structures, such as form oil, shall be non-toxic and non-hazardous.

- Any material used to minimize seepage underneath diversion structures, such as grout, shall be non-toxic, non-hazardous, and as close to a neutral pH as possible.

Isolation Techniques:

Isolation techniques are methods that isolate near shore work from a waterbody. Techniques include sheet pile enclosures, water-filled geotextile (Aqua Dam), gravel berm with impermeable membrane, gravel bags, coffer dams, and K-rail.

Filter Fabric Isolation Technique

A filter fabric isolation structure (See Figure 1D) is a temporary structure built into a waterway to enclose a construction area and reduce sediment pollution from construction work in or adjacent to water. This structure is composed of filter fabric, gravel bags, and steel t-posts.

Appropriate Applications:

- Filter fabric may be used for construction activities such as streambank stabilization, or culvert, bridge, pier or abutment installation. It may also be used in combination with other methods, such as clean water bypasses and/or pumps.

- This method involves placement of gravel bags or continuous berms to "key-in" the fabric, and subsequently staking the fabric in place.

- This is a method that should be used in relatively calm water, and can be used in smaller streams.

Limitations

- Do not use if the installation, maintenance and removal of the structures will disturb sensitive aquatic species of concern.

- Not appropriate for projects where dewatering is necessary.

- Not appropriate to completely dam streamflow.

Standards and Specifications:

- For the filter fabric isolation method, a non-woven or heavy-duty fabric is recommended over standard silt fence. Using rolled geotextiles allows non-standard widths to be used.

- Anchor filter fabric with gravel bags filled with clean, washed gravel. Do not use sand. If a bag should split open, the gravel can be left in the stream, where it can provide aquatic habitat benefits.

- Another anchor alternative is a continuous berm, made with the Continuous Berm Machine. This is a gravel-filled bag that can be made in very long segments. The length of the berms is usually limited to 20 ft for ease of handling.

Installation

- Place the fabric on the bottom of the stream, and place either a bag of clean, washed gravel or a continuous berm over the bottom of the fabric, such that a bag-width of fabric lies on the stream bottom. The bag should be placed on what will be the outside of the isolation area.

- Pull the fabric up, and place a metal t-post immediately behind the fabric, on the inside of the isolation area; attach the fabric to the post with three diagonal nylon ties.

- Continue placing fabric as described above until the entire work area has been isolated, staking the fabric at least every 6 ft.

Maintenance and Inspection:

- During construction and operation, inspect daily during the workweek.

- Schedule additional inspections during storm events.

- Immediately repair any gaps, holes or scour.

- Remove sediment buildup.

- Remove BMP upon completion of construction activity. Recycle or re-use if applicable.

Turbidity Curtain Isolation Technique

A turbidity curtain (refer to Figures 1A through 1D) is a fabric barrier used to isolate the near shore work area. The barriers are intended to confine the suspended sediment. The curtain is a floating barrier, and thus does not prevent water from entering the isolated area; rather, it prevents suspended sediment from getting out.

Appropriate applications:

Turbidity curtains should be used where sediment discharge to a stream is unavoidable. They are used when construction activities adjoin quiescent waters, such as lakes, ponds, lagoons, bays, and slow flowing rivers. The curtains are designed to deflect and contain sediment within a limited area and provide sufficient retention time so that the soil particles will fall out of suspension.

Limitations:

- Turbidity curtains shall not be used in flowing water; they are best suited for use in ponds, lakes, lagoons, bays, and very slow-moving rivers.
- Turbidity curtains should not be placed across the width of a channel.
- Removing sediment that has been deflected and settled out by the curtain may create a discharge problem through the re-suspension of particles and by accidental dumping by the removal equipment.

Standards and Specifications:

- Turbidity curtains should be oriented parallel to the direction of flow.
- The curtain should extend the entire depth of the watercourse in calm-water situations.
- In wave conditions, the curtain should extend to within 1 ft of the bottom of the watercourse, such that the curtain does not stir up sediment by hitting the bottom repeatedly. If it is desirable for the curtain to reach the bottom in an active-water situation, a pervious filter fabric may be used for the bottom 1 ft.
- The top of the curtain should consist of flexible flotation buoys, and the bottom shall be held down by a load line incorporated into the curtain fabric. The fabric shall be a brightly colored impervious mesh.
- The curtain shall be held in place by anchors placed at least every 100 ft.
- First place the anchors, then tow the fabric out in a furled condition, and connect to the anchors. The anchors should be connected to the flotation devices, and not to the bottom of the curtain. Once in place, cut the furling lines, and allow the bottom of the curtain to sink.
- Sediment that has been deflected and settled out by the curtain may be removed if so directed by the Engineer. Consideration must be given to the probable outcome of the removal procedure. It must be asked if it will create more of a sediment problem through re-suspension of the particles or by accidental dumping of material during removal. It is recommended that the soil particles trapped by the turbidity curtain only be removed if there has been a significant change in the original contours of the affected area in the watercourse.
- Particles should always be allowed to settle for a minimum of 6 to 12 hours prior to their removal or prior to removal of the turbidity curtain.

Maintenance and Inspection:

- The curtain shall be inspected daily for holes or other problems, and any repairs needed should be made promptly.

- Allow sediment to settle for 6 to 12 hours prior to removal of sediment or curtain. This means that after removing sediment, wait an additional 6 to 12 hours before removing the curtain.

- To remove, install furling lines along the curtain, detach from anchors, and tow out of the water.

K-rail River Isolation

This is temporary sediment control, or stream isolation method that uses K-rails (refer to Figure 2) to form the sediment deposition area, or to isolate the in-stream or near-bank construction area.

Barriers are placed end-to-end in a pre-designed configuration and gravel-filled bags are used at the toe of the barrier and also at their abutting ends to seal and prevent movement of sediment beneath or through the barrier walls.

Appropriate Applications:

- The K-rail isolation can be used in streams with higher water velocities than many other isolation techniques.

Limitations:

- The K-rail method does not allow for full dewatering.

Standards and Specifications:

- To create a floor for the K-rail, move large rocks and obstructions. Place washed gravel and gravel-filled bags to create a level surface for K-rail to sit.

- Place the bottom two K-rails adjacent to each other, and parallel to the direction of flow; fill the center portion with gravel bags. Then place the third K-rail on top of the bottom two; there should be sufficient gravel bags between the bottom K-rails such that the top one is supported by the gravel. Place plastic sheeting around the K-rails, and secure at the bottom with gravel bags.

- Further support can be added by pinning and cabling the K-rails together. Also, large riprap and boulders can be used to support either side of the K-rail, especially where there is strong current.

Maintenance and Inspection:

- The barrier shall be inspected at least once daily, and any damage, movement or other problems should be addressed immediately.

- Sediment should be allowed to settle for at least 6 to 12 hours prior to removal of sediment, and for 6 to 12 hours prior to removal of the barrier.

Stream Diversions

Stream diversions consist of a system of structures and measures that intercept an existing stream, upstream of the project, and transport it around the work area, and discharge it downstream (refer to Figure 3). The selection of which stream diversion technique to use depends upon the type of work involved, physical characteristics of the site, and the volume of water flowing through the project.

Appropriate Applications:

- Pumped diversions are appropriate in areas where de-watering is necessary.
- Dam-type diversions may serve as temporary access to the site.
- Where work areas require isolation from flows.

Limitations:

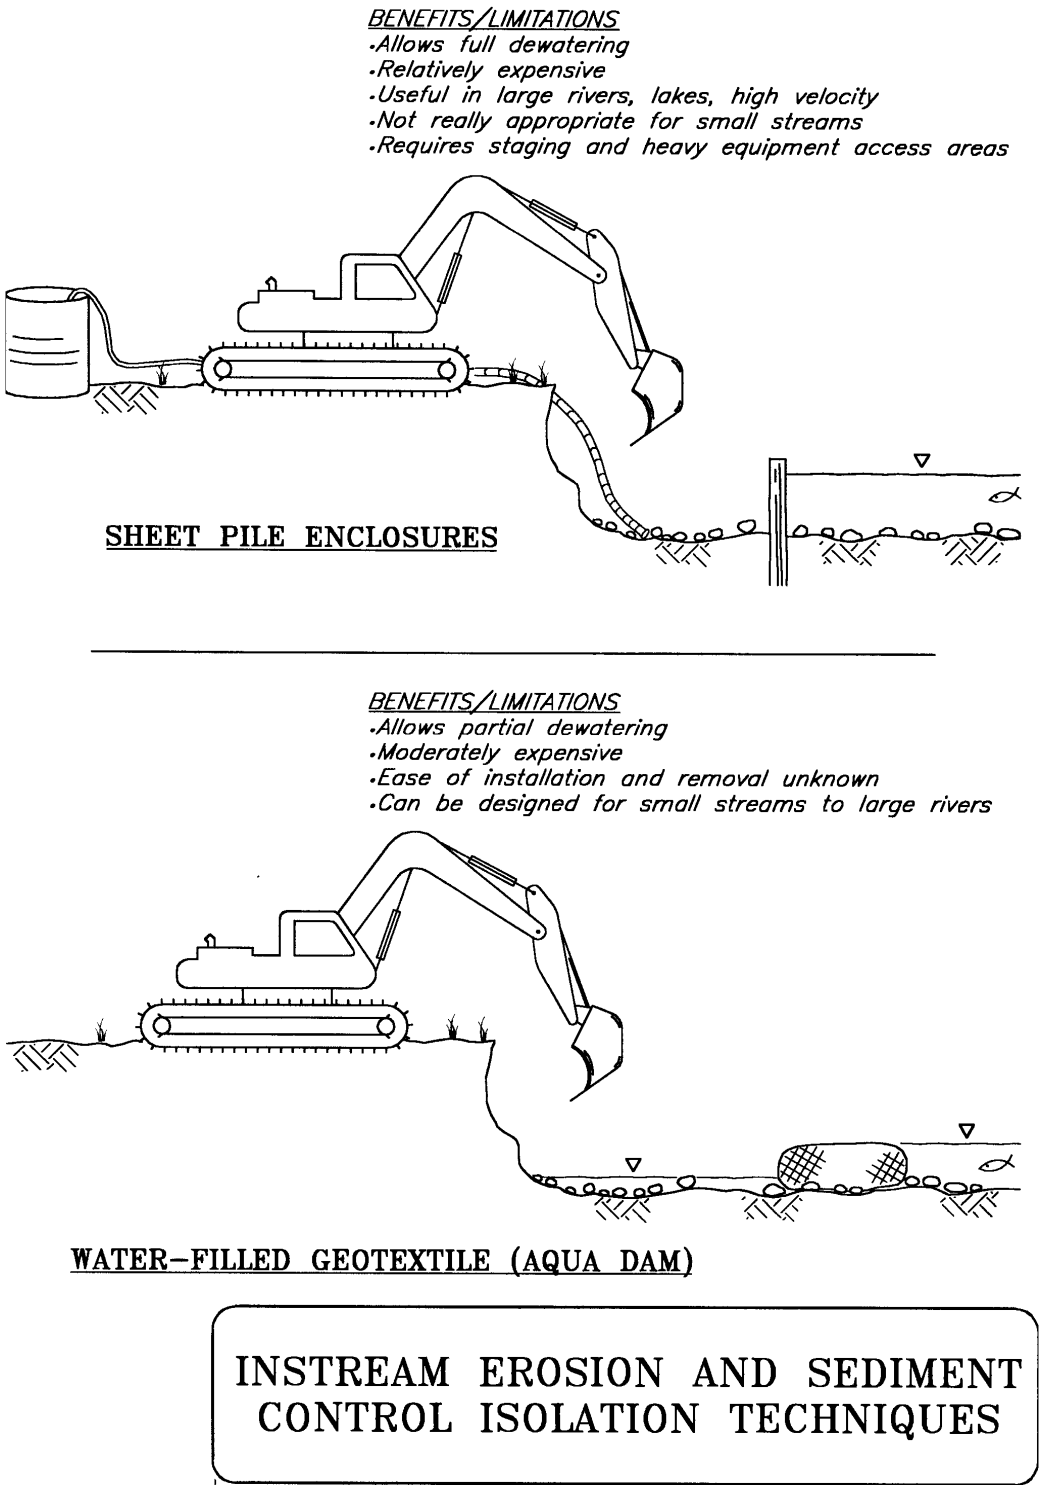
- Pumped diversions have limited flow capacity.
- Pumped diversions require frequent monitoring of pumps.
- Large flows during storm events can overtop dams.
- Flow diversion and re-direction with small dams involves in-stream disturbance and mobilization of sediment.

Standards and Specifications:

- Stream diversions shall be constructed only when there are no flowing or ponded water in the streambed.
- Installation guidelines will vary based on existing site conditions and type of diversion used.
- Diversions and pump capacity shall be sized to convey design flows rates.
- Adequate energy dissipation must be provided at the outlet to minimize erosion.
- Dam materials used to create dams upstream and downstream of diversion should be erosion resistant; materials such as steel plate, sheetpile, sandbags, continuous berms, inflatable water bladders, etc. would be acceptable.
- When constructing a diversion channel, begin excavation of the channel at the proposed downstream end, and work upstream. Once the watercourse to be diverted is reached, and the excavated channel is stable, breach the upstream end, and allow water to flow down the new channel. Once flow has been established in the diversion channel, install the diversion weir in the main channel; this will force all water to be diverted from the main channel.

Maintenance and Inspection:

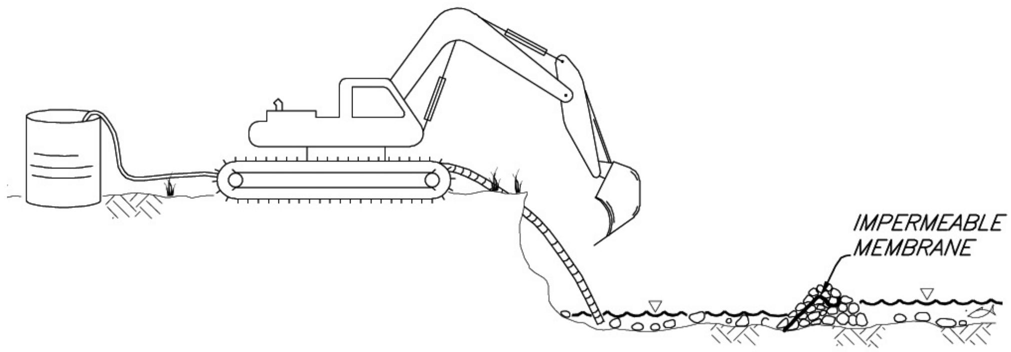
- Inspect diversion/encroachment structures before and after significant storms, and at least once per week while in service. Inspect daily during the construction.
- Pumped diversions require frequent monitoring of pumps.
- Inspect embankments and diversion channels before and after significant storms, and at least once per week while in service for damage to the linings, accumulating debris, sediment buildup, and adequacy of the slope protection. Remove debris and repair linings and slope protection as required. Repair holes, gaps, or scour.
- Upon completion of work, the diversion or isolation structure should be removed and flow should be re-directed through the new culvert or back into the original stream channel. Recycle or re-use if applicable.



BENEFITS/LIMITATIONS
•Allows full dewatering
•Relatively expensive
•Useful in large rivers, lakes, high velocity
•Not really appropriate for small streams
•Requires staging and heavy equipment access areas
SHEET PILE ENCLOSURES
BENEFITS/LIMITATIONS
•Allows partial dewatering
•Moderately expensive
•Ease of installation and removal unknown
•Can be designed for small streams to large rivers
WATER-FILLED GEOTEXTILE (AQUA DAM)
INSTREAM EROSION AND SEDIMENT CONTROL ISOLATION TECHNIQUES

Figure 1A

BENEFITS/LIMITATIONS
- Allows partial dewatering
- Relatively inexpensive
- Useful for small streams
- Minimal TSS when removed



NOTES:

Step 1. Install clean gravel with impermeable membrane

Step 2. Do work

Step 3. Decommission berm by removing impermeable membrane

Step 4. Pump work area. Head differential will cause water to flow into work area through gravel

Step 5. Remove or spread gravel

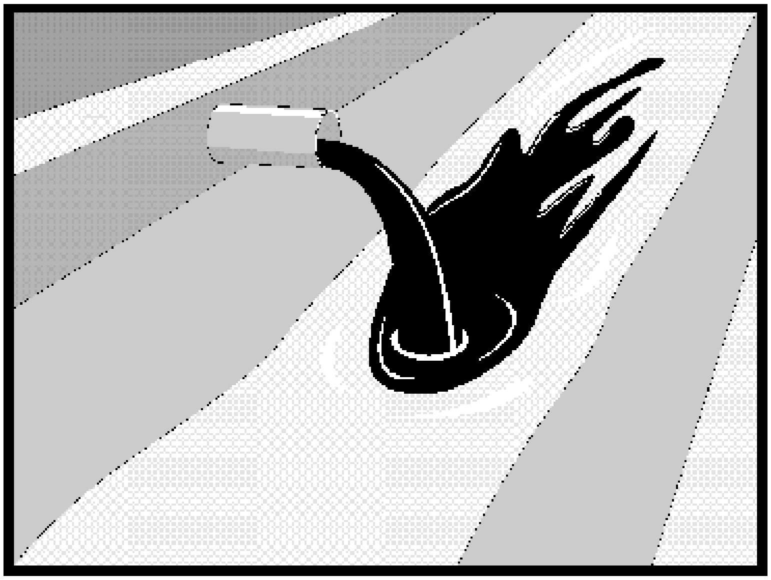
Illicit Connection/Illegal Discharge Detection and Reporting

NS-6



Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Procedures and practices designed for construction contractors to recognize illicit connections or illegally dumped or discharged materials on a construction site and report incidents to the Engineer.

Appropriate Applications

Illicit connection/illegal discharge detection and reporting is applicable for all project sites and anytime an illicit connection or discharge is discovered or illegally dumped material is found on the construction site.

Illicit connections and illegal discharges or dumping, for the purposes of this BMP, refer to discharges and dumping caused by parties other than the contractor.

Limitations

None identified.

Standards and Specifications

- Procedures and practices presented in this BMP are general. Contractor shall use extreme caution, immediately notify the Engineer when illicit connections or illegal dumping or discharges are discovered, and take no further action unless directed by the Engineer.
- If pre-existing hazardous materials or wastes are known to exist onsite, the contractor's responsibility will be detailed in the contract Special Provisions.
- Inspect construction site before beginning the job for evidence of illicit connections or illegal dumping or discharges.
- Secure the project site in order to prevent illicit connections or illegal dumping or discharges once construction begins.

- Inspect construction site weekly during project execution for evidence of illicit connections or illegal dumping or discharges.
- Observe construction site perimeter for evidence or potential of illicitly discharged or illegally dumped material, which may enter the construction site.

Identification of Illicit Connections and Illegal Dumping or Discharges

- Unlabeled or non-identifiable material shall be assumed to be hazardous.
- Solids - Look for debris, or rubbish piles. Solid waste dumping often occurs on roadways with light traffic loads or in areas not easily visible to the public.
- Liquids – signs of illegal liquid dumping or discharge can include:
  - Visible signs of staining or unusual colors to the pavement or surrounding adjacent soils.
  - Pungent odors coming from the drainage systems.
  - Discoloration or oily substances in the water or stains and residues detained within ditches, channels or drain boxes.
  - Abnormal water flow during the dry weather season.
- Urban Areas - Evidence of illicit connections or illegal discharges is typically detected at storm drain outfall locations or at manholes. Signs of an illicit connection or illegal discharge can include:
  - Abnormal water flow during the dry weather season.
  - Unusual flows in subdrain systems used for dewatering.
  - Pungent odors coming from the drainage systems.
  - Discoloration or oily substances in the water or stains and residues detained within ditches, channels or drain boxes.
  - Excessive sediment deposits, particularly adjacent to or near other active construction sites.
- Rural Areas - Illicit connections or illegal discharges involving irrigation drainage ditches are detected by visual inspections. Signs of an illicit discharge can include:
  - Abnormal water flow during the dry weather season.
  - Non-standard junction structures.
  - Broken concrete or other disturbances at or near junction structures.

Reporting

- Notify the Engineer of any illicit connections and illegal dumping or discharge incidents at the time of discovery.

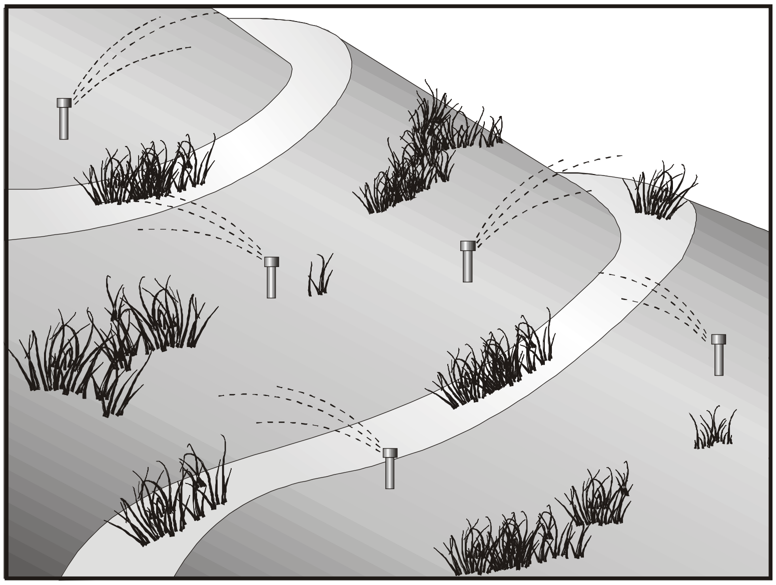
Cleanup and Removal

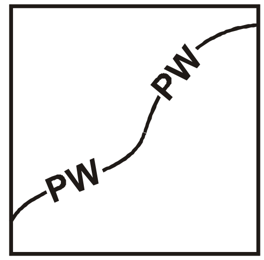
The Agency may direct contractor to clean up non-hazardous dumped or discharged material on the construction site.

(This page left intentionally blank)

Potable Water/Irrigation

NS-7





Standard Symbol

BMP Objectives
- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Potable Water/Irrigation management consists of practices and procedures to manage the discharge of potential pollutants generated during discharges from irrigation water lines, landscape irrigation, lawn or garden watering, planned and unplanned discharges from potable water sources, water line flushing, hydrant flushing and any other water.

Appropriate Applications

Implement this BMP whenever the above activities or discharges occur or could occur at or enter or run-on to a construction site.

Limitations

- None identified.

Standards and Specifications

- Do not allow potable water/irrigation activities to allow discharge to the storm drain system or receiving waters.
- Engineer approval is required prior to commencing any washing activities that could discharge to a permeable or impermeable surface, the storm drain or receiving waterbody.
- Shut off the water source to broken lines, sprinklers, or valves as soon as possible to prevent excess water flow.
- Install appropriate BMPs to protect downstream storm water drainage systems and watercourses from water pumped or bailed from trenches excavated to repair water lines or other reason.
- Dechlorinate all water lines with a by properly neutralizing chemical such as sulfur dioxide, see Appendix B of the American Water Works Association (AWWA) C651. Disposal of heavily chlorinated water shall comply with all applicable law and requirements of Federal, State, County, or other local agencies.

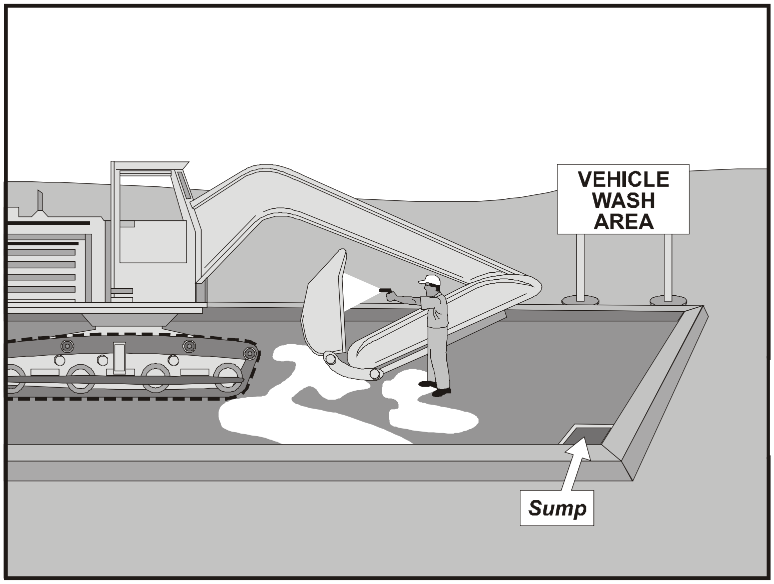
Potable Water/Irrigation

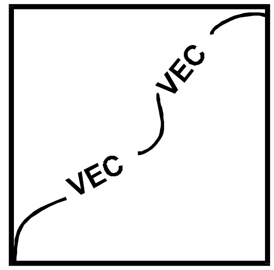
Maintenance and Inspection

- Inspect potable water and irrigation systems weekly, and before and after every rainfall events. During extended rainfall events, inspect all entrances, exits, access roads at least once every 24 hours.
- Repair broken water lines immediately or as directed by the Engineer.
- Inspect irrigated areas for signs of erosion and/or discharge. If erosion or discharge are observed, take corrective action to stop discharge and erosion immediately or as directed by the Engineer.
- Inspect irrigated areas within the construction limits for excess watering. Adjust watering times and schedules to ensure that the appropriate amount of water is being used and to minimize runoff. Consider factors such as soil structure, grade, time of year, and type of plant material in determining the proper amounts of water for a specific area.

Vehicle and Equipment Cleaning

NS-8





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Vehicle and equipment cleaning procedures and practices are used to minimize or eliminate the discharge of pollutants from vehicle and equipment cleaning operations to the ground, storm drain system or to watercourses.

Appropriate Applications

These procedures are applied on all construction sites where vehicle and equipment cleaning is performed.

Limitations

- Sediment control BMPs (SC-1 through SC-10) are not adequate to prevent the discharge of pollutants generated from vehicle and equipment cleaning.

Standards and Specifications

- On-site vehicle and equipment washing is discouraged.
- Prevent disposal of any rinse or wash waters or materials onto impervious or pervious site surfaces or into the storm drain system or watercourses.
- Cleaning of vehicles and equipment with soap, solvents or steam shall not occur on the project site unless the Engineer has been notified in advance and the resulting wastes are fully contained and disposed of offsite in conformance with all applicable laws and regulations. Resulting wastes and by-products shall not be discharged or buried and must be captured and recycled or disposed according to the requirements of WM-6, "Hazardous Waste Management," depending on the waste characteristics. Minimize use of solvents. The use of diesel for vehicle and equipment cleaning is prohibited.
- Vehicle and equipment wash water shall be contained to prevent it from entering the storm drain inlets or watercourses and shall not be discharged on site. Protect drain inlets (SC-10 is not adequate) by covering with plastic to completely block the inlet and do not allow any discharge. Remove plastic after cleaning operations are completed and the water has been disposed of properly.

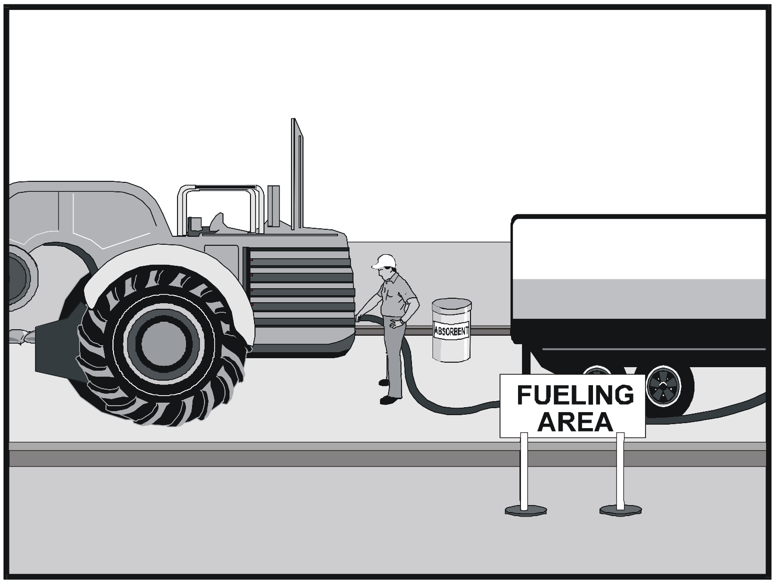
- All vehicles/equipment that regularly enter and leave the construction site shall be cleaned off-site.
- Prevent oil, grease or fuel from leaking onto the ground (impervious or pervious site surfaces) or into the storm drains or surface waters.
- Clean up leaks or spills immediately and dispose of properly in accordance with WM-4.
- When vehicle/equipment washing/cleaning must occur onsite, cleaning area shall have the following characteristics, and shall be approved by the Engineer:
  - Located away from storm drain inlets, drainage facilities, or watercourses.
  - Paved with concrete or asphalt and bermed to contain wash waters and to prevent run-on and runoff.
  - Configured with a sump to allow collection and disposal of wash water.
  - Wash waters shall not be discharged to storm drains or watercourses.
  - Used only when necessary.
- When cleaning vehicles/equipment with water:
  - Use as little water as possible. High pressure sprayers may use less water than a hose, and shall be considered.
  - Use positive shutoff valve to minimize water usage.

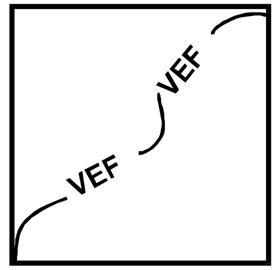
Maintenance and Inspection

- Inspect all entrances, exits, access roads daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect all entrances, exits, access roads at least once every 24 hours.
- Monitor employees and subcontractors throughout the duration of the construction project to ensure appropriate practices are being implemented.
- Remove liquids and sediment as needed or as directed by the Engineer.

Vehicle and Equipment Fueling

NS-9





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Vehicle and equipment fueling procedures and practices are designed to minimize or eliminate the discharge of fuel spills and leaks onto the ground (impervious or pervious site surfaces) or into storm drain systems or to watercourses.

Appropriate Applications

These procedures are applied on all construction sites where vehicle and equipment fueling takes place.

Limitations

- Onsite vehicle and equipment fueling shall only be used where it's impractical to send vehicles and equipment off-site for fueling.

Standards and Specifications

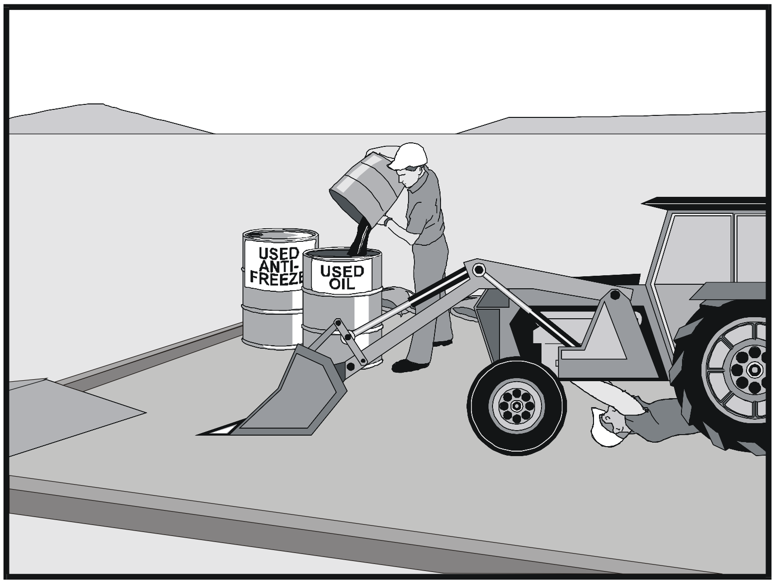
- The contractor shall select and designate an area to be used for fueling. The fueling area shall be identified in the SWPPP or approved by the Engineer for non-SWPPP projects.
- Prevent oil, grease, or fuel to leak in to the ground, offsite, storm drains, surface waters, or water courses.
- Absorbent spill clean-up materials and spill kits shall be available in fueling areas and on fueling trucks and shall be disposed of properly after use.
- Drip pans or absorbent pads shall be used during vehicle and equipment fueling.
- Dedicated fueling areas shall be protected with berms and/or dikes from storm water run-on and runoff, and shall be located at least 50 ft from downstream drainage facilities and watercourses. Fueling must be performed on level-grade areas.
- Nozzles used in vehicle and equipment fueling shall be equipped with an automatic shut-off to control drips and spills. Fueling operations shall not be left unattended.

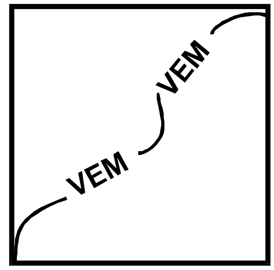
- Comply with applicable local Air Quality Management District regulations with berms and/or dikes District's (AQMD) regulations. Ensure nozzles are secured upright when not in use.
- Fuel tanks shall not be "topped-off."
- Vehicles and equipment shall be inspected on each day of use for leaks. Leaks shall be repaired immediately or problem vehicles or equipment shall be removed from the project site.
- Absorbent spill clean-up materials shall be available in fueling and maintenance areas and used on small spills instead of hosing down or burying techniques. The spent absorbent material shall be removed promptly and disposed of properly.
- Federal, state, and local requirements shall be observed for any stationary above ground storage tanks. Refer to WM-1, "Material Delivery and Storage."
- Mobile fueling of construction equipment throughout the site shall be minimized. Whenever practical, equipment shall be transported to the designated fueling area.

Maintenance and Inspection

- Inspect all fueling areas and operations daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect all entrances, exits, access roads at least once every 24 hours.
- Fueling areas and storage tanks shall be inspected regularly.
- Keep an ample supply of spill cleanup material on the site.
- Immediately cleanup spills and properly dispose of contaminated soil and cleanup materials in accordance with WM-4.

Vehicle and Equipment Maintenance NS-10





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ○ Materials and Waste Management

Definition and Purpose

Procedures and practices to minimize or eliminate the discharge of pollutants to the storm drain systems or to watercourses from vehicle and equipment operation, maintenance, and modification procedures.

Appropriate Applications

These procedures are applied on all construction projects for storage, operation, and maintenance of heavy equipment and vehicles.

Limitations

- None identified.

Standards and Specifications

- Place all vehicles or equipment to be maintained or stored in a designated and dedicated area.
- Use off-site maintenance facilities whenever practical.
- The vehicles or equipment maintenance and storage areas shall be identified in the SWPPP or approved by the Engineer for non-SWPPP projects.
- Dedicated maintenance areas shall be protected from storm water run-on and runoff, and shall be located at least 50 ft from downstream drainage facilities and watercourses.
- Prevent oil, grease, or fuel to leak in to ground (impervious or pervious site surfaces), storm drains, or watercourses.
- Clean spills and leaks immediately and dispose of leaked materials and cleanup waste properly in accordance with WM-4.
- Drip pans or absorbent pads shall be used during all vehicle and equipment maintenance work
- All maintenance areas are required to have spill kits (see WM-4) and/or use other spill protection devices.

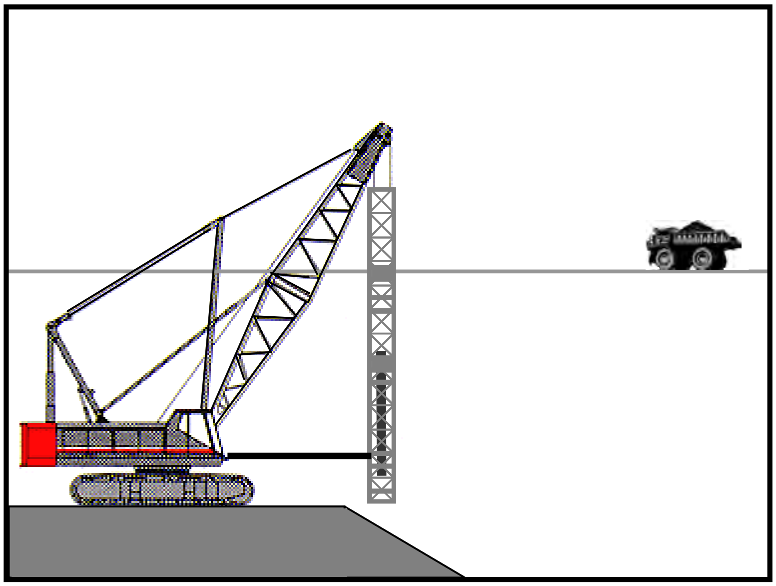
- Absorbent spill clean-up materials shall be available in maintenance areas and shall be disposed of properly after use.
- For long-term projects, consider constructing roofs or using portable tents over maintenance areas.
- Properly dispose of used oils, fluids, lubricants, and spill cleanup materials.
- Do not dump oil, fuels and lubricants onto the ground (impervious or pervious site surfaces), storm drain system, or watercourses.
- Properly dispose or recycle used batteries.
- Do not bury used tires.
- Repair fluid and oil leaks immediately.
- Provide spill containment dikes or secondary containment around stored oil and chemical drums per WM-1.

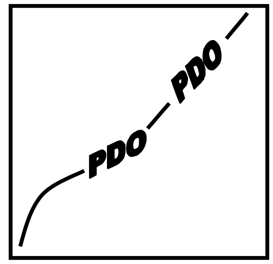
Maintenance and Inspection

- Inspect all vehicle and equipment maintenance areas weekly, and before and after every rainfall events. During extended rainfall events, inspect all vehicle and equipment maintenance areas at least once every 24 hours.
- Maintain waste fluid containers in leak proof condition.
- Vehicles and equipment shall be inspected on each day of use. Leaks shall be repaired immediately or the problem vehicle(s) or equipment shall be removed from the project site. Spills shall be cleaned up in accordance with BMP WM-04 Spill Prevention and Control.
- Inspect equipment for damaged hoses and leaky gaskets routinely. Repair or replace as needed and clean up any spills or leaks immediately.
- Wastes generated from cleanups shall be disposed of in accordance with BMP WM-04 Spill Prevention and Control in compliance with all applicable laws and regulations.

Pile Driving Operations

NS-11





Standard Symbol

BMP Objectives

○ Soil Stabilization
○ Sediment Control
○ Tracking Control
○ Wind Erosion Control
● Non-Storm Water Management
● Materials and Waste Management

Definition and Purpose

The construction and retrofit of bridges and retaining walls often include driving piles for foundation support and shoring operations. Driven piles are typically constructed of concrete, steel, or timber. Driven sheet piles are used for shoring and cofferdam construction. Proper control and use of equipment, materials, and waste products from pile driving operations will reduce the discharge of potential pollutants to the storm drain system or watercourses.

Appropriate Applications

These procedures apply to all construction sites where permanent and temporary pile driving operations (impact and vibratory), including operations using pile shells for construction of cast-in-steel-shell and cast-in-drilled-hole piles.

Limitations

- None identified.

Standards and Specifications

- Use drip pans or absorbent pads under all pile driving equipment during use or storage. Plastic sheeting is not a substitute for drip pans or absorbent pads. Refer to BMPs NS-9 “Vehicle and Equipment Fueling” and NS-10 “Vehicle and Equipment Maintenance.”

- All hydraulic hose connections shall be “capped and bagged” when disconnected.

- Have spill kits and cleanup materials available at all locations of pile driving. Refer to BMP WM-4 “Spill Prevention and Control.”

- Implement other BMPs as applicable, such as WM-5 “Solid Waste Management,” WM-6 “Hazardous Waste Management,” and WM-10 “Liquid Waste Management.”

- When not in use, store pile driving equipment away from concentrated flows of storm water, drainage courses, and inlets. Protect hammers and other hydraulic attachments from run-on by placing them on and covering them with plastic sheeting or a comparable material.

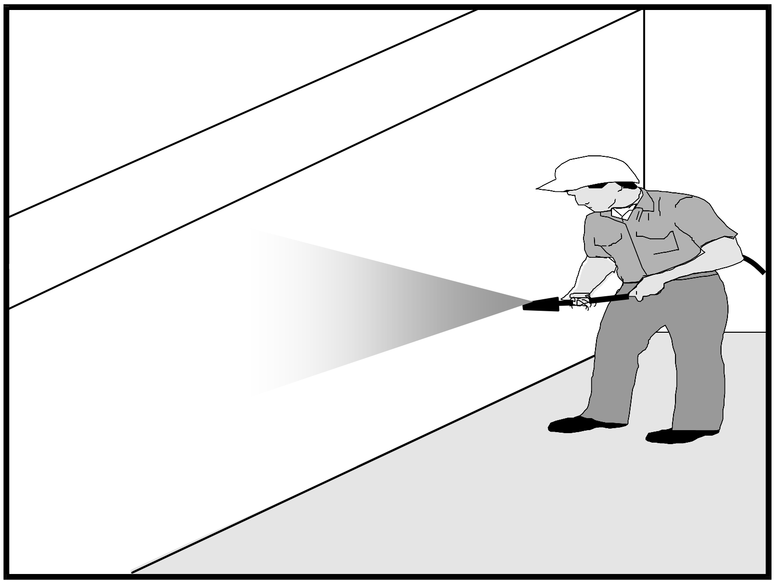
- Use less hazardous products, e.g. vegetable oil instead of hydraulic fluid, when practicable.

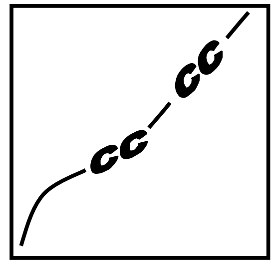
Maintenance and Inspection

- Inspect all pile driving equipment daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect all pile driving equipment areas at least once every 24 hours.

Concrete Curing

NS-12





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Concrete curing is used in the construction of structures such as bridges, retaining walls, and pump houses. Concrete curing includes the use of both chemical and water methods. Proper procedures minimize pollution of runoff during concrete curing.

Appropriate Applications

All concrete elements of a structure (e.g., footings, columns, abutments, stems, soffit, deck) are subject to curing requirements.

Limitations

- None identified.

Standards and Specifications

Chemical Curing

- Prevent over-spray or drift of curing compounds by applying the curing compound close to the concrete surface. Apply an amount of compound that covers the surface, but does not allow any runoff of the compound.
- Use proper storage and handling techniques for concrete curing compounds. Refer to BMP WM-1, "Material Delivery and Storage."
- Protect drain inlets prior to the application of curing compounds.
- Refer to WM-4, "Spill Prevention and Control."
- Apply cure water in a manner the does not produce runoff or result in a non-storm-water discharge.
- Prevent cure water from discharging to the ground, storm drain system and watercourses to collection areas for removal as approved by the Engineer and in accordance with all applicable permits, laws and regulations.
- Utilize wet blankets or a similar method that maintains moisture while minimizing the use and possible discharge of water.

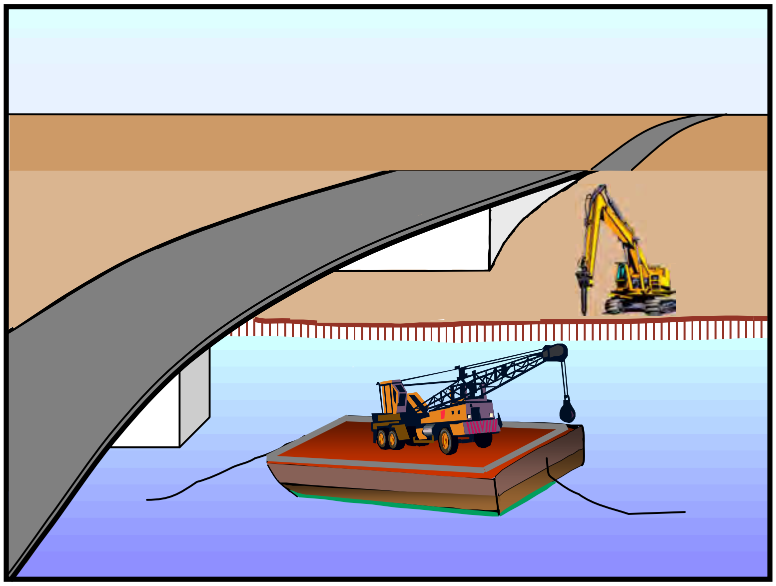
Concrete Curing

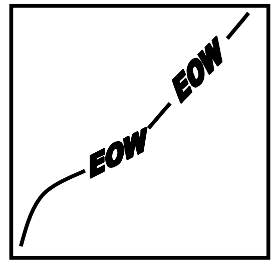
Maintenance and Inspection

- Inspect all concrete curing operations and equipment weekly, and before and after every rainfall events. During extended rainfall events, inspect all concrete curing operations and equipment at least once every 24 hours.
- Ensure that employees and subcontractors implement appropriate measures for storage, handling, and use of curing compounds.
- Inspect cure containers and spraying equipment for leaks. Repair leaks immediately.

Material and Equipment Use Over Water

NS-13





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Procedures for the proper use, storage, and disposal of materials and equipment on bridges, barges, boats, temporary construction pads, or similar locations that minimize or eliminate the discharge of potential pollutants to a watercourse.

Appropriate Applications

These procedures shall be implemented for construction materials and wastes (solid and liquid) and any other materials that may be detrimental if released. Applies where materials and equipment are used on bridges, barges, boats, docks, and other platforms over or adjacent to a watercourse.

Limitations

- Fully comply with the specific permit requirements or mitigation measures identified in the contract Special Provisions and all regulatory permits, such as Regional Water Quality Control Board (RWQCB) 401 Certification, U.S. Army Corps of Engineers 404 permit, California Department of Fish and Game Streambed Alteration Agreement, and US Forest Service Permits. Comply with all water quality monitoring and numerical-based water quality standards identified in the contract Special Provisions and all regulatory permits.

Standards and Specifications

- The Contractor shall submit to the Engineer a Debris Containment and Collection Plan per the contract Special Provisions for debris produced when working over or adjacent to watercourses.
- If the contract Special Provisions do not contain requirements for a Debris Containment and Collection Plan, then the Contractor shall prepare a Debris Containment and Collection Plan, per this BMP, and submit it to the Engineer for approval prior to conducting any work over a watercourse.
- The Debris Containment and Collection Plan shall be designed by a professional Engineer registered with the State of California. The Debris Containment and Collection Plan shall be included in the SWPPP.

- The Debris Containment and Collection Plan shall contain at a minimum the following information:
  - Debris containment method
  - Diagrammatic Plans showing locations of equipment, drums/bins, and any other containment apparatus
  - Emergency Response and Spill Response Plan
  - Working drawings of any containment system
  - Loads applied to the existing bridge structure by any containment structure
  - Provisions for ventilation and air movement for visibility and worker safety
  - Manufacturers' instructions on the proper use of equipment.
- The debris containment method shall fully contain all water, debris, and visible dust produced. Including all water, debris, and visible dust produced from abrasive blasting or any other blast cleaning methods.
- The containment structure shall be supported with either rigid or flexible supports. The rigid or flexible containment materials on the containment structure shall retain airborne particles, but may allow air flow through the containment materials. Flexible materials shall be supported and fastened to prevent escape of abrasive and blast materials due to whipping from traffic or wind and to maintain the clearances.
- All joints shall be sealed. Sealing may be by overlapping of seams when using flexible materials or by using tape, caulking, or other sealing measures.
- If at any time during the execution of the work, the containment system fails to contain all water, debris, or dust , the Contractor shall immediately suspend all operations except those intended to minimize adverse impact to the environment. Operations shall not resume until modifications have been made to correct the cause of the failure.
- Debris produced when cleaning shall not be temporarily stored on the ground or pavement. Debris accumulated inside the containment system shall be removed before the end of each work shift. Debris shall be stored in approved, leak proof containers and shall be handled in such a manner that no spillage will occur. Do not allow demolished material to enter waterway.
- Drip pans shall be placed under all vehicles and equipment placed on bridges, docks, barges, or other structures over water bodies when the vehicle or equipment is expected to be idle for more than one hour. Ensure that an adequate supply of spill cleanup materials is available.

- Refer to BMPs WM-1, "Material Delivery and Storage" and WM-4, "Spill Prevention and Control."
- Maintain equipment in accordance with BMP NS-10, "Vehicle and Equipment Maintenance." If a leaking line cannot be repaired, remove equipment from over the water and the construction site.
- Provide watertight curbs or toe boards to contain spills and prevent materials, tools, and debris from leaving the bridges, barge, platform, dock, etc.
- Secure all materials to prevent discharges to receiving waters via wind.
- Identify types of spill control measures to be employed, including the storage of such materials and equipment. Ensure that staff are trained regarding the deployment and access of control measures and that measures are being used.
- Comply with all necessary permits required for construction within or near the watercourse, such as RWQCB, U.S. Army Corps of Engineers, Department of Fish and Game and other local permitting agencies.
- Discharges to waterways shall be reported to the Engineer immediately upon discovery. A written discharge notification must follow within 5 days.
- Refer to BMP NS-15, "Structure Demolition/Removal Over or Adjacent to Water."

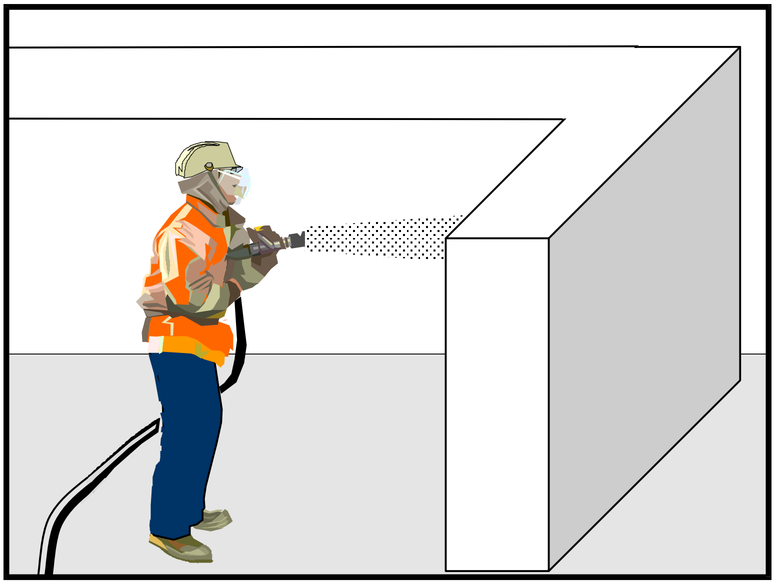
Maintenance and Inspection

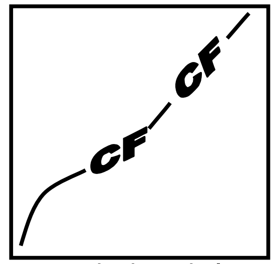
- Inspect materials and equipment and containment methods daily and document weekly and before and after rainfall events. During extended rainfall events, inspect materials and equipment and containment methods at least every 24 hours.
- Inspect equipment for leaks and spills on a daily basis. Repairs leaks and clean up spills immediately.
- Ensure that employees and subcontractors implement appropriate measures for storage and use of materials and equipment.
- Inspect and maintain all associated BMPs and perimeter controls to ensure continuous protection of the watercourse.

(This page left intentionally blank)

Concrete Finishing

NS-14





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Concrete finishing methods are used for bridge deck rehabilitation, paint removal, curing compound removal, final surface finish appearances, and other construction operations that remove or add to concrete surfaces. Methods include sand blasting, shot blasting, grinding, high pressure water blasting, or other method. Proper procedures minimize the impact that concrete finishing methods may have on runoff.

Appropriate Applications

These procedures apply to all construction sites where concrete finishing operations are performed.

Limitations

- None identified

Standards and Specifications

- If the contract Special Provisions do not contain requirements for a Debris Containment and Collection Plan, then the Contractor shall prepare a Debris Containment and Collection Plan, per this BMP, and submit it to the Engineer for approval prior to conducting any work over a watercourse.
- Submit MSDS of all shot blasting material not previously disclosed in submittals to the Engineer for approval 7 days prior to operation.
- Collect and properly dispose of water and solid waste from high-pressure water blasting operations in accordance with spill disposal procedures in WM-4.
- Do not allow slag or other shot blasting material to contact the soil or surrounding areas. Protect all areas with plastic sheeting to prevent discharge to soil or surrounding areas.
- Protect inlets during sandblasting operations by covering them with filter fabric during finishing operations.

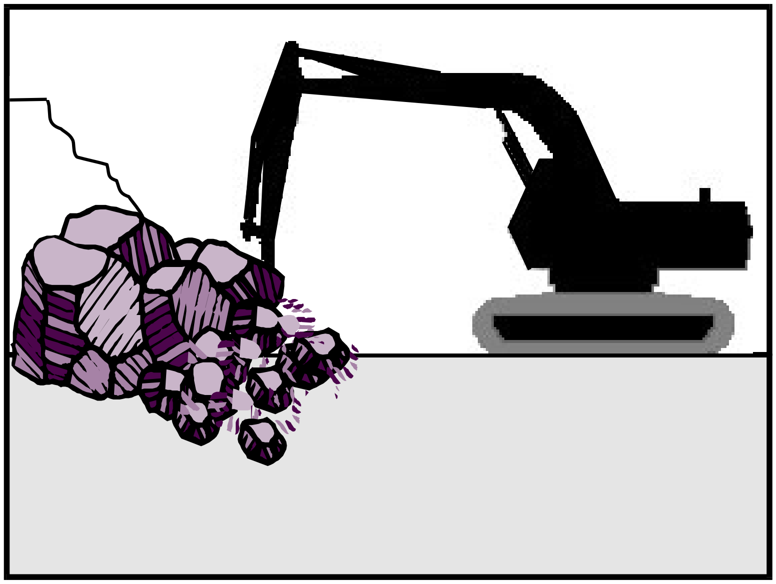
- Refer to BMP WM-8, "Concrete Waste Management."
- Minimize the drift of dust and blast material as much as possible by keeping the blasting nozzle close to the surface.
- When blast residue contains a potentially hazardous waste, refer to BMP WM-6, "Hazardous Waste Management."
- Debris produced when cleaning shall not be temporarily stored on the ground or pavement. Debris accumulated inside the containment system shall be removed before the end of each work shift. Debris shall be stored in approved, leak proof containers and shall be handled in such a manner that no spillage will occur.
- The Contractor shall disposed of the debris generated at a facility equipped to recycle the debris, is subject to the following requirements:
  - An exclusively recyclable material (ERM) such as Copper slag abrasive blended by the supplier with a calcium silicate compound shall be used for blast cleaning.
  - If cleaning or finishing metal surfaces, the debris produced shall be tested by using Title 22 of the California Code of Regulations CAM Metals Method, and 40 CFR Part 268 Method. The Contractor to confirm that the Soluble Threshold Limit Concentrations (STLC), the Total Threshold Limit Concentrations (TTLC), and the Toxicity Characteristic Leaching Procedure (TCLP) of the heavy metals are below regulatory limits and the debris may be transported to the recycling facility as a non-hazardous waste.
  - The Contractor shall make all arrangements with the recycling facility and perform any testing required by the recycling facility operator, or in compliance with regulations.
  - The Contractor shall specify to the Agency, the name, location and Statement of Qualifications (SOQs) of the recycling facility for review and approval by the Agency.

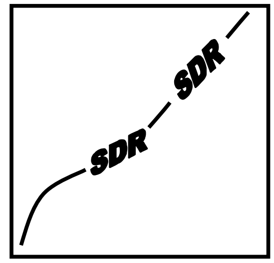
Maintenance and Inspection

- Inspect concrete finishing operations weekly and before and after rainfall events. During extended rainfall events, inspect concrete finishing operations at least every 24 hours.

Structure Demolition/Removal Over or Adjacent to Water

NS-15





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Procedures to protect water bodies from debris and wastes associated with structure demolition or removal over or adjacent to watercourses.

Appropriate Applications

Full bridge demolition and removal, partial bridge removal (e.g., barrier rail, edge of deck), concrete channel removal, outfall structure construction/repair, or any other structure removal that could potentially affect water quality.

Limitations

- Fully comply with the specific permit requirements or mitigation measures identified in the contract Special Provisions and all regulatory permits, such as Regional Water Quality Control Board (RWQCB) 401 Certification, U.S. Army Corps of Engineers 404 permit, California Department of Fish and Game Streambed Alteration Agreement, and US Forest Service Permits. Comply with all water quality monitoring and numerical-based water quality standards identified in the contract Special Provisions and all regulatory permits.

Standards and Specifications

- The Contractor shall submit to the Engineer a Debris Containment and Collection Plan per the contract Special Provisions for debris produced when working over or adjacent to watercourses.
- If the contract Special Provisions do not contain requirements for a Debris Containment and Collection Plan, then the Contractor shall prepare a Debris Containment and Collection Plan, per this BMP, and submit it to the Engineer for approval prior to conducting any work over a watercourse.
- The Debris Containment and Collection Plan shall be designed by a professional Engineer registered with the State of California. The Debris Containment and Collection Plan shall be included in the SWPPP.

- The Debris Containment and Collection Plan shall contain at a minimum the following information:
  - Debris containment method
  - Diagrammatic Plans showing locations of equipment, drums/bins, and any other containment apparatus
  - Emergency Response and Spill Response Plan
  - Working drawings of any containment system
  - Loads applied to the existing bridge structure by any containment structure
  - Provisions for ventilation and air movement for visibility and worker safety
  - Manufacturers' instructions on the proper use of equipment.
- The debris containment method shall fully contain all water, debris, and visible dust produced. Including all water, debris, and visible dust produced from abrasive blasting or any other blast cleaning methods.
- The containment structure shall be supported with either rigid or flexible supports. The rigid or flexible containment materials on the containment structure shall retain airborne particles, but may allow air flow through the containment materials. Flexible materials shall be supported and fastened to prevent escape of abrasive and blast materials due to whipping from traffic or wind and to maintain the clearances.
- All joints shall be sealed. Sealing may be by overlapping of seams when using flexible materials or by using tape, caulking, or other sealing measures.
- If at any time during the execution of the work, the containment system fails to contain all water, debris, or dust , the Contractor shall immediately suspend all operations except those intended to minimize adverse impact to the environment. Operations shall not resume until modifications have been made to correct the cause of the failure.
- Debris produced when cleaning shall not be temporarily stored on the ground or pavement. Debris accumulated inside the containment system shall be removed before the end of each work shift. Debris shall be stored in approved, leak proof containers and shall be handled in such a manner that no spillage will occur. Do not allow demolished material to enter waterway.
- Refer to BMPs WM-1, "Material Delivery and Storage" and WM-4, "Spill Prevention and Control."
- Drip pans shall be placed under all vehicles and equipment placed on bridges, docks, barges, or other structures over water bodies when the vehicle or equipment is expected to be idle for more than one hour. Ensure that an adequate supply of spill cleanup materials is available.

- Maintain equipment in accordance with BMP NS-10, "Vehicle and Equipment Maintenance." If a leaking line cannot be repaired, remove equipment from over the water and the construction site.
- Refer to BMP NS-5, "Clear Water Diversion" to direct water away from work areas.
- Use attachments on construction equipment such as backhoes to catch debris from small demolition operations.
- Stockpile accumulated debris and waste generated during demolition away from watercourses and in accordance with BMP WM-3, "Stockpile Management."
- Ensure safe passage of wildlife, as necessary.
- Discharges to waterways shall be reported to the Engineer immediately upon discovery. A written discharge notification must follow within 5 days.
- For structures containing hazardous materials (e.g., lead paint or asbestos) refer to BMP WM-6, "Hazardous Waste Management." For demolition work involving soil excavation around lead-painted structures, refer to BMP WM-7, "Contaminated Soil Management."

Ventilated Containment Structure

- Multiple flap overlapping door tarps shall be used at entry ways to the ventilated containment structure to prevent dust or debris from escaping.
- Baffles, louvers, flapper seals or ducts shall be used at make-up air entry points to the ventilated containment structure to prevent escape of abrasives and resulting surface preparation debris.
- The ventilation system in the ventilated containment structure shall be of the forced input air flow type with fans or blowers.
- Negative air pressure shall be employed within the ventilated containment structure and will be verified by visual methods by observing the concave nature of the containment materials while taking into account wind effects or by using non-hazardous smoke or other visible means to observe air flow. The input air flow shall be properly balanced with the exhaust capacity throughout the range of operations.
- The exhaust air flow of the ventilation system in the ventilated containment structure shall be forced into dust collectors (wet or dry) or bag houses with HEPA collection efficiency.

Maintenance and Inspection

- Inspect containment methods daily and document weekly and before and after rainfall events. During extended rainfall events, inspect containment methods at least every 24 hours.
- Any debris-catching devices shall be emptied regularly. Collected debris shall be removed and stored away from the watercourse and protected from run-on and runoff.

Temporary Batch Plant

NS-16

---TBP---

Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

A temporary batch plant is often needed during the construction of roads, bridges, and other large structures in remote areas. Their purpose is for the manufacture of Portland Cement Concrete (PCC), asphalt concrete (AC), slurries, and grouts. These temporary facilities generally consist of fly ash, lime, and cement; heated tanks of liquid asphalt; sand and gravel material storage areas; mixing equipment; above ground storage tanks for concrete additives and water; and designated areas for sand and gravel truck unloading, concrete truck loading, and concrete truck washout. Proper control and use of equipment, materials, and waste will reduce the discharge of potential pollutants to the underlying ground or surrounding areas, offsite, to the storm drain system or watercourses, reduce air emissions, and mitigate noise impacts.

Appropriate Applications

These controls are required on construction sites where temporary batch plant facilities are employed.

Limitations

■

Standards and Specifications

General Requirements

- ■ Temporary batch plants may be subject to the General Industrial NPDES Permit. Compliance with this permit requires the submittal of a Notice of Intent (NOI) to the State Water Resources Control Board (SWRCB).
- ■ Proper planning, design, and construction of the facilities shall be implemented to minimize potential water quality, air quality, and noise impacts associated with the use of temporary batch plants.
- ■ Temporary batch plant shall comply with all County or City ordinances, the Air Resources Board (ARB), Air Quality Management District (AQMD), and Regional Water Quality Control Board (RWQCB) may require alternative mitigation measures for temporary batch plants.
- ■ Temporary batch plants shall be managed to comply with AQMD Portable Equipment Registration requirements, South Coast AQMD Rule 403.

Location and Design

- Temporary batch plants and access roads shall be properly located and designed to reduce water quality impacts to receiving water bodies. Batch plants shall be located a minimum of 50 feet from watercourses, drainage courses, and drain inlets. Batch plants shall be located to minimize the potential for storm water to run onto the site.
- Construct continuous interior AC or PCC berms around the batch plant equipment to facilitate proper run-on, containment and cleanup of releases. Rollover or flip top curb or dikes shall be placed at entrance and exit points.
- Direct runoff from the paved portion of the batch plants into a sump and pipe to a lined washout area or dewatering tank.
- Direct storm water and non-storm water runoff from unpaved portions of the batch plant facility to catchment ponds or tanks.
- Construct and remove concrete washout facilities in accordance with WM-8, Concrete Waste Management.
- A recommended layout of a typical batch plant and associated BMPs is located at the end of this BMP description sheet. If the layout planned is different than attached layout, a complete drawing shall be submitted to the engineer for approval.

Operational Requirements

- Washout of concrete trucks shall be conducted in a designated area, in accordance with WM-8, Concrete Waste Management.
- Do not dispose of concrete offsite or into drain inlets, the storm water drainage system, or watercourses. There shall be no discharge, spills or leaks of concrete waste into the underlying soil or onto surrounding areas.
- Equipment washing shall occur in a designated area in accordance with WM-8. Washing equipment, tools, or vehicles for removal of PCC shall be conducted in accordance with non-storm water management BMPs, NS-7, Potable Water/Irrigation, an NS-8, Vehicle and Equipment Cleaning.
- All dry material transfer points shall be ducted through a fabric or cartridge type filter unless there are no visible emissions from the transfer plant.
- Equip all bulk storage silos, including auxiliary bulk trailers, with a fabric or cartridge type filters.
- Maintain silo vent filters in proper operating condition.
- Equip silos and auxiliary bulk storage trailers with dust-tight service hatches.
- Fabric dust collectors (except for vent filters) shall be equipped with an operational pressure differential gauge to measure the pressure drop across

the filters.

- All transfer points shall be equipped with a wet suppression system to control fugitive particulate emissions unless there are no visible emissions.

- There shall be no visible emissions beyond the property line, while the equipment is being operated.

- Collect dust emissions from the loading of open-bodied trucks at the drip point of dry batch plants, or dust emissions from the drum feed for central mix plants.

- Equip silos and auxiliary bulk storage trailers with a visible and/or audible warning mechanism to warn operators that the silo or trailer is full.

- All open-bodied vehicles transporting material shall be loaded with a final layer of wet sand and the truck shall be covered with a tarp to reduce emissions.

Tracking Controls

- Related roads (batch truck and material delivery truck roads) and areas between stockpiles and conveyor hoppers shall be stabilized (TC-2, Stabilized Construction Roadway), or paved with a cohesive hard surface that can be repeatedly swept, maintained intact, and cleaned as necessary to control dust emissions.

- Trucks shall not track PCC from plants onto public roads. Use appropriate practices from TC-1 Stabilized Construction Entrance/Exit and/or TC-3 Entrance/Outlet Tire Wash, to prevent tracking of sediment from the site.

Material Storage Controls

- BMP WM-1, Material Delivery and Storage, shall be implemented at all batch plants using concrete components or compounds. Cover and contain materials as required by the contract Special Provisions.

- BMP WM-2, Material Use shall be conducted in a way to prevent the discharge of materials to the storm drain system or watercourses.

- Prevent finer materials from being dispersed into the air during operations, such as unloading of cement delivery trucks.

- Stockpiles shall be covered and bermed with perimeter sediment barriers per WM-3, Stockpile Management. Provide secondary containment for all liquid materials (as per WM-1). Handle solid and liquid waste in accordance with WM-5, Solid Waste Management, WM-10, Liquid Waste Management, and WM-8, Concrete Waste Management.

- Maintain adequate supplies of spill cleanup materials and train staff to respond to spills per WM-4, Spill Prevention and Control.

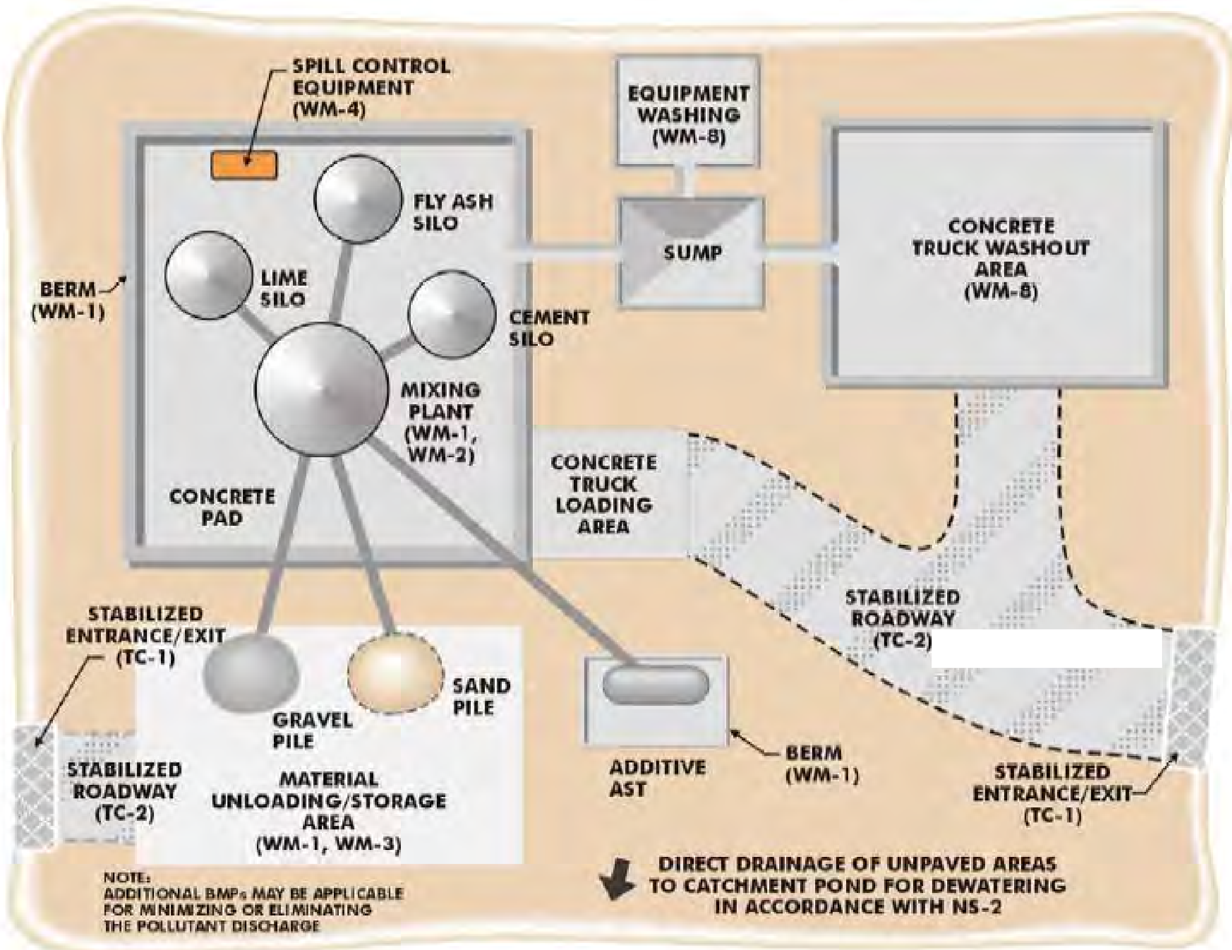
- Immediately clean up spilled cement and fly ash and contain or dampen so that dust or emissions from wind erosion or vehicle traffic are minimized.

Equipment Maintenance BMPs

- Equipment shall be maintained to prevent fluid leaks and spills per NS-9, Vehicle and Equipment Fueling, and NS-10, Vehicle and Equipment Maintenance.
- Incorporate other BMPs such as WM-5, Solid Waste Management, WM-6, Hazardous Waste Management, and WM-10, Liquid Waste Management.

Maintenance and Inspection

- Inspect all components of the temporary batch plant operations and equipment weekly, and before and after every rainfall events. During extended rainfall events, inspect all components of the temporary batch plant operations and equipment at least once every 24 hours.
- Inspect and verify that controls are in place prior to the commencement of associated activities.
- Inspect and repair equipment, including damaged hoses, fittings, and gaskets.



Typical Temporary Batch

(This page left intentionally blank)

SECTION 8

WASTE MANAGEMENT AND

MATERIAL POLLUTION CONTROL BMPS

Waste management and material pollution control BMPs consist of source control measures to prevent non-storm water pollution by limiting or preventing potential pollutants at the source before they come into contact with storm water. These waste management and material pollution control BMPs are also referred to as "good housekeeping practices" which involve day-to-day operations of the construction site and contractor's yard in order to maintain a clean, orderly, and safe construction site. Waste Management and Material Pollution Control BMPs are shown on Table 8-1.

Table 8-1
Waste Management and
Material Pollution Control BMPs

ID	BMP Name
Material Pollution Control	
WM-1	Material Delivery and Storage
WM-2	Material Use
WM-3	Stockpile Management
Waste Management	
WM-4	Spill Prevention and Control
WM-5	Solid Waste Management
WM-6	Hazardous Waste Management
WM-7	Contaminated Soil Management
WM-8	Concrete Waste Management
WM-9	Sanitary/Septic Waste Management
WM-10	Liquid Waste Management

8.1. Material Pollution Control BMPs

Material pollution control BMPs (also referred as materials handling) consist of implementing procedural and structural BMPs for the handling, storage, and use of construction material to prevent the discharge of those materials to the ground, paved surfaces, storm drain system or watercourses. The objective of material pollution control BMPs is to limit or prevent potential pollutants at the source before they come into contact with storm water and prevent contamination to the underlying soil.

8.2. Waste Management BMPs

Waste management BMPs consists of implementing procedural and structural BMPs for the handling, storage, and disposal of construction waste to prevent the release of those wastes to the storm drain system or watercourses. The objective of waste management BMPs is to limit or prevent potential pollutants at the source before they come into contact with storm water and prevent contamination to the underlying soil..

8.2.1 Hazardous Waste Management

The handling, storage, and disposal of all hazardous waste or other waste that requires special handling shall be in full compliance with the contract Special Provisions. All Contractor operations shall be in full compliance with the all applicable laws and regulations that govern the management of hazardous and other waste.

If suspected hazardous waste or other waste that requires special handling is encountered on the construction site and the contract Special Provisions do **not** include provisions for the management of such waste, the Contractor shall immediately notify the Engineer for direction.

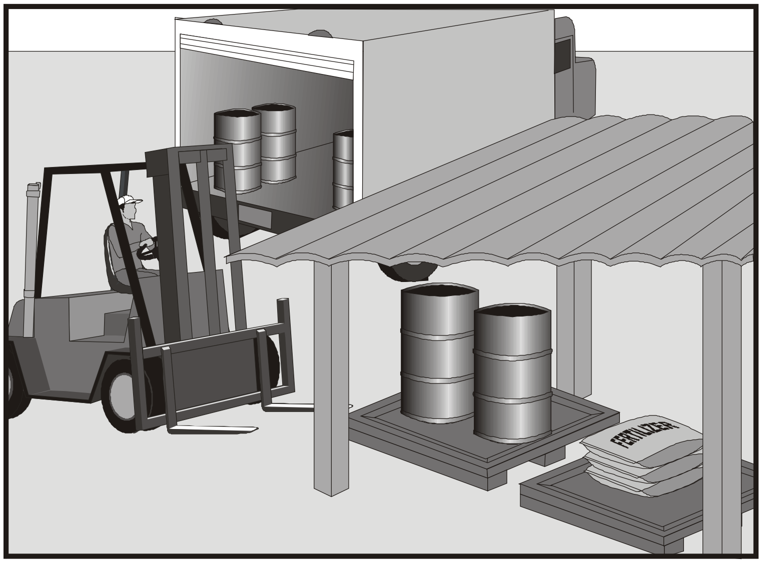
8.2.2 Contaminated Soil Management

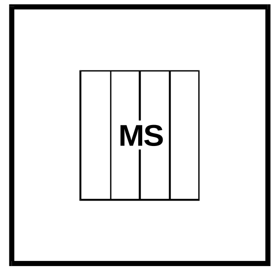
The handling, storage, and disposal of all contaminated soil shall be in full compliance with the contract Special Provisions. All Contractor operations shall be in full compliance with all applicable laws and regulations that govern the management of contaminated soil.

If suspected contaminated soil is encountered on the construction site and the contract Special Provisions do **not** include provisions for the management of contaminated soil, the Contractor shall immediately notify the Engineer for direction.

Material Delivery and Storage

WM-1





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Procedures and practices for the proper handling and storage of materials in a manner that minimizes or eliminates the discharge of these materials to the ground, storm drain system or to watercourses.

Appropriate Applications

These procedures are implemented at all construction sites with delivery and storage of but not limited to the following:

- Hazardous chemicals such as:
  - Acids/limes
  - glues,
  - adhesives,
  - paints/solvents, and
  - curing compounds.
- Soil stabilizers and binders.
- Fertilizers.
- Detergents.
- Plaster.
- Petroleum products such as fuel, oil, and grease.
- Asphalt and concrete components.
- Pesticides and herbicides.
- Other materials that may be detrimental if released to the environment.

Limitations

None identified.

Standards and Specifications

General

- Train employees and subcontractors on the proper material delivery and storage practices.
- Temporary storage areas shall be located away from vehicular traffic.
- Material Safety Data Sheets (MSDS) shall be supplied to the Engineer for all materials stored or used on the project.

Material Storage Areas and Practices

- Store chemicals in watertight containers (with appropriate secondary containment to prevent any spillage or leakage) or in a storage shed (completely enclosed).
- Minimize exposure of construction materials to precipitation.
- Liquids, petroleum products, and substances listed in 40 CFR Parts 110, 117, or 302 shall be stored in approved containers and drums and shall be placed in temporary containment facilities for storage.
- Each temporary containment facility shall have a permanent cover and side wind protection or be covered when not being used and prior to and during rain events.
- A temporary containment facility shall provide for a spill containment volume able to contain precipitation from a 24-hour, 25-year storm event, plus 110% of the capacity of the largest container within its boundary.
- A temporary containment facility shall be impervious to the materials stored therein for a minimum contact time of 72 hours.
- A temporary containment facility shall be maintained free of accumulated rainwater and spills. In the event of spills or leaks, accumulated rainwater and spills shall be collected and placed into drums. These liquids shall be handled as a hazardous waste unless testing determines them to be non-hazardous. All collected liquids or non-hazardous liquids shall be sent to an approved disposal site in accordance with WM-5 and WM-6.
- Sufficient separation shall be provided between stored containers to allow for spill cleanup and emergency response access.
- Incompatible materials, such as chlorine and ammonia, shall not be stored in the same temporary containment facility.
- Materials shall be stored in their original containers and the original product labels shall be maintained in place in a legible condition. Damaged or otherwise illegible labels shall be replaced immediately. Unlabeled containers

shall not be stored onsite and shall be disposed of immediately in accordance with WM-5 and WM-6.

- Bagged and boxed materials shall be stored on pallets and shall not be allowed on the ground. To provide protection from wind and rain, bagged and boxed materials shall be covered when not being actively used and prior to rain events. Broken boxes or bags shall be immediately contained or disposed of properly in accordance with WM-5 and WM-6.
- Stockpiles shall be protected in accordance with BMP WM-3, "Stockpile Management."
- Minimize the material inventory stored on-site (e.g., only a few days supply).
- Have proper storage instructions posted at all times in an open and conspicuous location.
- Do not store hazardous chemicals, drums, or bagged materials directly on the ground. Dry items shall be placed on a pallet and covered. Liquids shall be placed in secondary containment and covered.
- Contain all fertilizers and other landscape materials when they are not actively being used.
- Stack erodible landscape material on pallets and cover stored landscaped materials when not being used or applied.
- Keep ample supply of appropriate spill clean up material near storage areas.

Material Delivery Practices

- Keep an accurate, up-to-date inventory of material delivered and stored on-site.
- Employees trained in emergency spill clean-up procedures shall be present when dangerous materials or liquid chemicals are unloaded.

Spill Clean-up

- Contain and clean up all liquid or dry spills or leaked material immediately and dispose of properly in accordance with WM-5 or WM-6.
- If residual materials are on the ground after construction is complete, properly remove and dispose any hazardous materials or contaminated soil in accordance with WM-5 and WM-6.
- Use BMP WM-4, "Spill Prevention and Control," for cleanup procedures of spills of chemicals and/or hazardous materials.

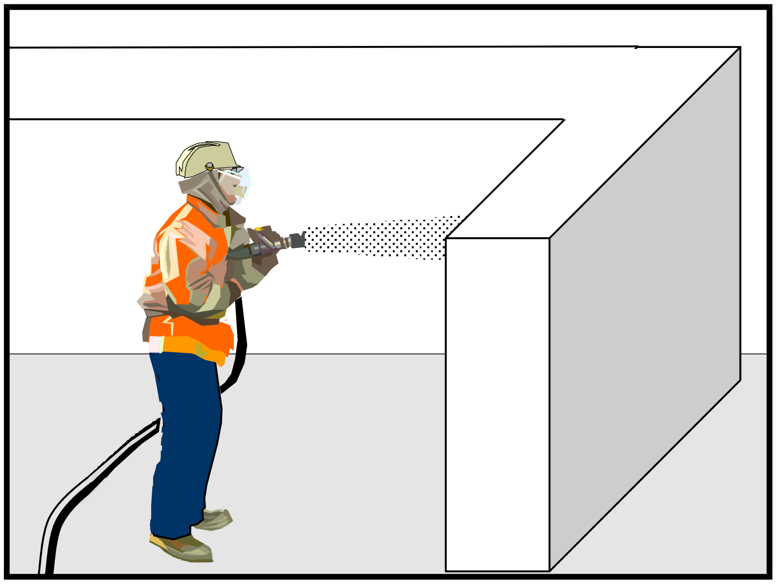
Maintenance and Inspection

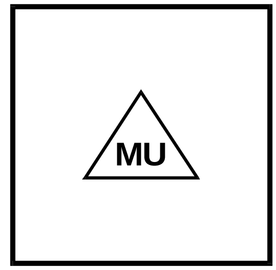
- Inspect all material delivery and storage areas weekly, and before and after every rainfall events. During extended rainfall events, inspect all material delivery and storage areas at least once every 24 hours.
- Storage areas shall be kept clean, well organized, and equipped with ample clean-up supplies as appropriate for the materials being stored.
- Perimeter controls, containment structures, covers, and liners shall be repaired or replaced as needed to maintain proper function.

RB-AR33464

Material Use

WM-2





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

These are procedures and practices for use of construction material in a manner that minimizes or eliminates the discharge of these materials to the ground, storm drain system or to watercourses.

Appropriate Applications

This BMP applies to all construction sites. These procedures apply but are not limited to when the following materials are used or prepared on site:

- Hazardous chemicals such as:
  - Acids/lime,
  - glues,
  - adhesives,
  - paints/solvents, and
  - curing compounds.
- Soil stabilizers and binders.
- Fertilizers.
- Detergents.
- Plaster.
- Petroleum products such as fuel, oil, and grease.
- Asphalt and concrete components.
- Pesticides and herbicides.
- Other materials that may be detrimental if released to the environment.

Limitations

- Safer alternative building and construction products may not be available or suitable in every instance.

Standards and Specifications

- Material Safety Data Sheets (MSDS) shall be supplied to the Engineer for all materials stored or used on the project.
- Latex paint and paint cans, used brushes, rags, absorbent materials, and drop cloths, when thoroughly dry and are no longer hazardous, may be disposed of with other construction debris.
- Do not remove the original product label, it contains important safety and disposal information. Use the entire product before disposing of the container.
- Mix paint indoors, or in a containment area. Never clean paintbrushes or rinse paint containers into a street, gutter, storm drain or watercourse. Dispose of any paint thinners, residue and sludge(s), that cannot be recycled, as hazardous waste.
- For water-based paint, clean brushes to the extent practical, and rinse to a drain leading to a sanitary sewer where permitted, or into a concrete washout pit. For oil-based paints, clean brushes to the extent practical and filter and reuse thinners and solvents.
- Use recycled and less hazardous products when practical. Recycle residual paints, solvents, non-treated lumber, and other materials.
- Use materials only where and when needed to complete the construction activity. Use safer alternative materials as much as possible. Reduce or eliminate use of hazardous materials on-site when practical.
- Do not over-apply fertilizers and pesticides. Prepare only the amount needed. Strictly follow the recommended usage instructions. Apply surface dressings in smaller applications, as opposed to large applications, to allow time for it to work in and to avoid excess materials being carried off-site by runoff.
- Discontinue the application of any erodible landscape material within 2 days before a forecasted rain event or during periods of precipitation.
- Apply erodible landscape material at quantities and application rates according to manufacture recommendations or based on written specifications by knowledgeable and experienced field personnel.
- Application of herbicides and pesticides shall be performed by a licensed applicator.
- Contractors are required to complete the “Report of Chemical Spray Forms” when spraying herbicides and pesticides.
- Keep an ample supply of spill clean up material near use areas. Train employees in spill clean up procedures.

- Avoid exposing applied materials to rainfall and runoff unless sufficient time has been allowed for them to dry.

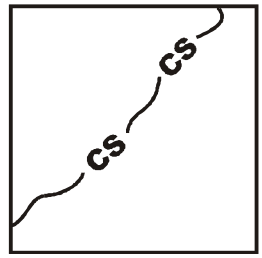
Maintenance and Inspections

- Inspect all material use areas weekly, and before and after every rainfall events. During extended rainfall events, inspect all material use areas at least once every 24 hours.

(This page left intentionally blank)

Stockpile Management

WM-3



Standard Symbol

BMP Objectives

- ● Soil Stabilization
- ● Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ○ Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Stockpile management procedures and practices are designed to reduce or eliminate air and storm water pollution from stockpiles of soil, and paving materials such as portland cement concrete (PCC) rubble, asphalt concrete (AC), asphalt concrete rubble, aggregate base, aggregate subbase or pre-mixed aggregate, asphalt binder (so called "cold mix" asphalt), green waste and other materials and wastes.

Appropriate Applications

Implemented in all projects that stockpile soil and other materials and wastes.

Limitations

- None identified

Standards and Specifications

- Protection of stockpiles is a year-round requirement.
- Locate stockpiles a minimum of 50 ft away from concentrated flows of storm water, drainage courses, and inlets.
- Implement wind erosion control practices as appropriate on all stockpiled material. For specific information see BMP WE-1, "Wind Erosion Control".
- All stockpiles shall comply with AQMD Rule 403 requirements.
- Contaminated soil shall not be stockpiled on the project site and be managed in accordance with BMP WM-7, "Contaminated Soil Management."
- Bagged materials should be placed on pallets and covered.
- Do not stockpile pressure treated wood. Pressure treated wood shall be managed in accordance with the contact Special Provisions.

Protection of Stockpiles not Actively Being Used

- Cover and contain loose stockpiled construction materials that are not actively being used (i.e. soil, aggregate, base materials, green waste, etc.) at all times.

Protection of Active Stockpiles

- ***Soil stockpiles and waste stockpiles:***
  - Soil stockpiles shall be covered and protected with a temporary perimeter sediment barrier.
- ***Stockpiles of portland cement concrete rubble, asphalt concrete, asphalt concrete rubble, aggregate base, or aggregate subbase:***
  - The stockpiles shall be covered and protected with a temporary perimeter sediment barrier.
- ***Stockpiles of "cold mix":***
  - Cold mix stockpiles shall be placed on and covered with plastic or comparable material.
- ***Stockpiles of green waste:***
  - Green waste shall be covered and protected with a temporary perimeter sediment barrier.

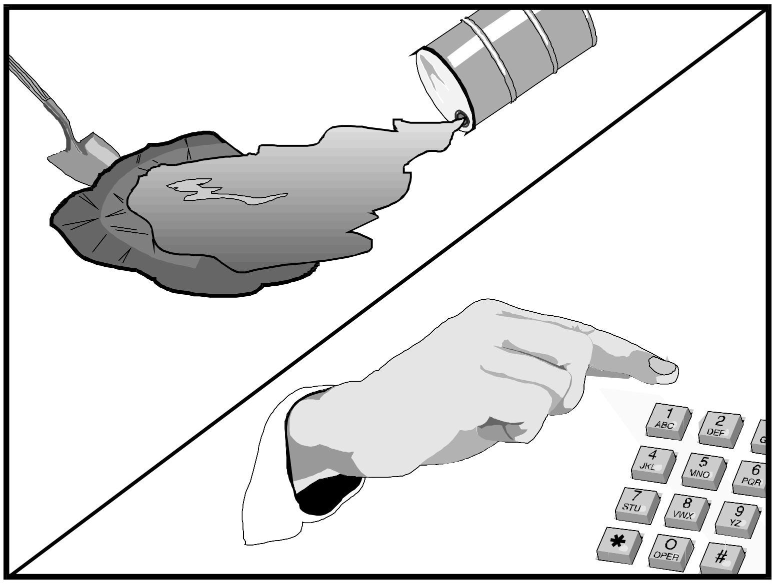
Plastic materials shall be limited when more sustainable products exist. If plastic is used, materials more resistant to photo degradation shall be considered.

Inspection and Maintenance

- Inspect all active and non-active stockpiles weekly, and before and after every rainfall events. During extended rainfall events, inspect all active and non-active stockpiles at least once every 24 hours.
- Repair and/or replace perimeter controls and covers as needed, or as directed by the Engineer, to keep them functioning properly. Sediment shall be removed when sediment accumulation reaches one-third (1/3) of the barrier height. Covers shall be repaired or replaced when they do not cover the entire stockpile or are no longer effective.

Spill Prevention and Control

WM-4



Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

These procedures and practices are implemented to prevent, control and clean-up spills in a manner that minimizes or prevents the discharge of spilled material to the permeable or impermeable ground surface, drainage system or watercourses.

Appropriate Application

This best management practice (BMP) applies to all construction projects. Spill control procedures are implemented anytime liquids or dry materials or wastes (including chemicals, hazardous or non-hazardous substances) are stored or used onsite. Substances may include, but are not limited to:

- Soil stabilization products/binders.
- Dust Palliatives.
- Herbicides/Pesticides, Fertilizers
- Deicing/anti-icing chemicals.
- Sanitary wastes
- Fuels, Lubricants, Other petroleum distillates
- Paint solvents and thinners
- Vehicle fluids
- Asphalt and Portland Cement products

Limitations

- Procedures and practices presented in this BMP are general. The Contractor shall identify appropriate practices for the specific materials or wastes used or stored on-site.

Standards and Specifications

- Spills of materials and wastes shall be contained and cleaned up immediately.
- Spills identified during a rain event shall be covered and protected from storm water run-until they can be cleaned up.
- Spills shall not be buried, or washed or cleaned up with water.
- Water shall not be used to clean up spills. Dry methods such as rags and absorbents shall be used. Water used for decontaminating sampling equipment shall not be allowed to enter storm drains or watercourses and shall be collected.
- All collected spill cleanup waste shall be disposed of in accordance with BMP WM-6, "Hazardous Waste Management."
- Water overflow or minor water spillage shall be contained and shall not be allowed to discharge into drainage facilities or watercourses.
- Proper storage, clean-up and spill reporting instruction for hazardous materials stored or used on the project site shall be posted at all times in an open, conspicuous and accessible location.
- Waste storage areas shall be kept clean, well organized and equipped with ample clean-up supplies as appropriate for the materials being stored. Perimeter controls, containment structures, covers and liners shall be repaired or replaced as needed to maintain proper function.

Education

- Educate employees and subcontractors on what a "significant spill" is for each material they use, and what is the appropriate response for "significant" and "insignificant" spills.
- Educate employees and subcontractors on potential dangers to humans and the environment from spills and leaks.
- Hold regular meetings to discuss and reinforce appropriate disposal procedures (incorporate into regular safety meetings).
- Establish a continuing education program to train new employees.
- The Contractor shall oversee and enforce proper spill prevention and control measures and shall ensure appropriate personnel are assigned and trained for spill cleanup.

Cleanup and Storage Procedures

- Equipment and materials for cleanup of spills shall be available on site and spills and leaks shall be cleaned up immediately and disposed of properly.
- Sewage pipeline breaks or spills shall be handled in accordance with the contract special provisions, if applicable. The required plan for sewage spills shall be referenced and described in Section 500.4.6 of the SWPPP, if applicable.
- Minor Spills
  - Minor spills typically involve small quantities of oil, gasoline, paint, etc., which can be controlled by the first responder at the discovery of the spill.
  - Use absorbent materials on small spills. Water shall not be used to clean up spills. Do not bury the spill or spilled materials.
  - Remove the absorbent materials promptly and dispose of properly.
  - The practice commonly followed for a minor spill is:
    - Contain the spread of the spill.
    - Recover spilled materials.
    - Clean the contaminated area and/or properly dispose of contaminated materials.
- Semi-Significant Spills
  - Semi-significant spills still can be controlled by the first responder along with the aid of other personnel such as laborers and the foreman, etc. This response may require the cessation of all other activities.
  - Clean up spills immediately:
    - Notify the project foreman immediately. The foreman shall notify the Engineer.
    - Contain spread of the spill.
    - If the spill occurs on paved or impermeable surfaces, clean up using "dry" methods (absorbent materials, cat litter and/or rags). Contain the spill by encircling with absorbent materials and do not let the spill spread widely.
    - If the spill occurs in dirt areas, immediately contain the spill by constructing an earthen dike. Dig up and properly dispose of contaminated soil.
    - If the spill occurs during rain, cover spill with tarps or other material to prevent contaminating runoff.

- Significant/Hazardous Spills
  - For significant or hazardous spills that cannot be controlled by personnel in the immediate vicinity, the following steps shall be taken:
  - Notify the Engineer immediately and follow up with a written report.
  - Notify the local emergency response by dialing 911. In addition to 911, the contractor will notify the proper county officials. It is the contractor's responsibility to have all emergency phone numbers at the construction site. The Los Angeles County Fire Department Health Hazardous Material Division should be called at (323)890-4317 or after hours Call: 911 or (323)881-2455 (Health Haz Mat).
  - For spills of federal reportable quantities, in conformance with the requirements in 40 CFR parts 117.3 and 302.4, the contractor shall notify the National Response Center at (800) 424-8802.
  - The services of a spills contractor or a Haz-Mat team shall be obtained immediately. Construction personnel shall not attempt to clean up the spill until the appropriate and qualified staff has arrived at the job site.
  - Other agencies which may need to be consulted include, but are not limited to, the Coast Guard, the Highway Patrol, the City/County Police Department, Department of Toxic Substances, California Division of Oil and Gas, Cal/OSHA, RWQCB, etc.

Disposal Procedures

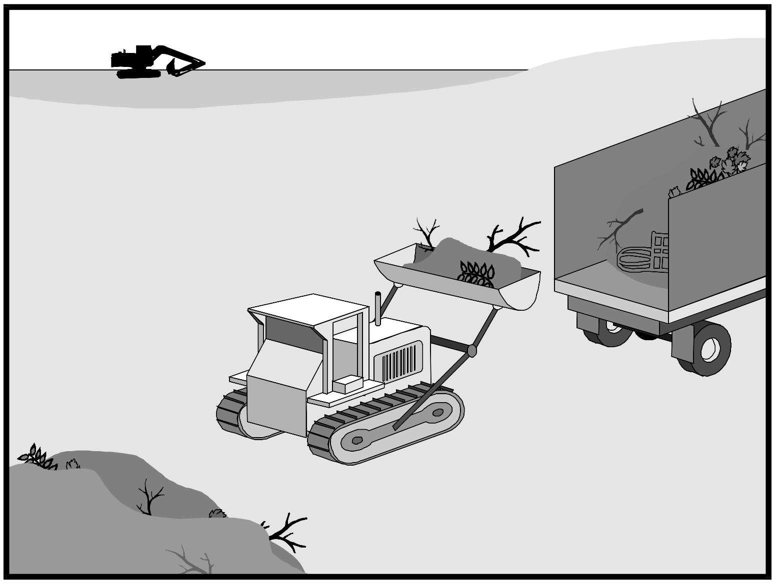
- Proper disposal is disposal offsite in accordance with all applicable laws and regulations.
- Used clean up materials, contaminated materials, and recovered spill material that is no longer suitable for the intended purpose shall be stored and disposed of in accordance with WM-6, "Hazardous Waste Management" BMPs.
- Waste that is not hazardous and is not defined as waste that requires special handling under California Code of Regulations, Title 22 Division 4.5, Title 23, Division 3, Chapter 3, and Title 27, Division 2, Subdivision 1 shall be disposed of in accordance WM-5 Solid Waste Management.

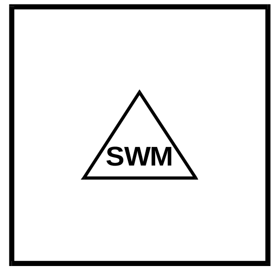
Maintenance and Inspection

- Inspect the project site for spills daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect project site for spills at least once every 24 hours.
- Verify that spill control clean-up materials are located near material storage, unloading, and use areas.
- Update spill prevention and control plan and stock appropriate clean-up materials whenever changes occur in the types of chemicals used or stored onsite.

Solid Waste Management

WM-5





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Solid waste management procedures and practices are designed to minimize or eliminate the discharge of pollutants offsite, to the ground, drainage systems or watercourses.

Appropriate Applications

Solid waste management procedures and practices are implemented on all construction sites that generate solid wastes.

Solid wastes include but are not limited to:

- Construction wastes including brick, dry mortar, timber, steel and metal scraps, sawdust, pipe and electrical cuttings, inert equipment parts, styrofoam and other materials used to transport and package construction materials.
- Planting wastes, including vegetative material, plant containers, and packaging materials.
- Litter and debris including food containers, beverage cans, coffee cups, paper bags, plastic wrappers, and smoking materials, including litter generated by the public and other contractors.

Limitations

- Solid waste that requires special handling and disposal because of a potential hazard to human health, the environment, or water quality shall be handled and disposed of in accordance with WM-6.

Standards and Specifications

Education

- The Contractor shall oversee and enforce proper solid waste procedures and practices.
- Educate employees and subcontractors on solid waste storage and disposal procedures. Hold regular meetings to discuss and reinforce disposal procedures (incorporate into regular safety meetings).

- Require that employees and subcontractors follow solid waste handling and storage procedures.

- Prohibit littering by employees, subcontractors, and visitors.

- Wherever possible, minimize production of solid waste materials.

Collection, Storage, and Disposal

- Prevent discharges from waste disposal containers to the ground, offsite or storm water drainage system or receiving water.

- Litter and debris shall be removed from drainage grates, trash racks, and ditch lines immediately.

- The contractor shall provide covered and watertight dumpsters of sufficient size and numbers to contain the solid waste generated on the construction site including waste generated by the public. Cover waste disposal containers at all times.

- Trash containers/dumpsters shall be provided in the Contractor's yard, field trailer areas, and at locations where workers congregate for lunch and break periods or where directed by the Engineer. Additional containers and more frequent pickup and removal are required during the demolition phase of construction.

- Trash containers/dumpsters shall be empty once every two weeks. Full trash containers/dumpsters shall be empty within two days of being full. The contents of the containers/dumpsters and all solid waste shall be disposed of outside the right-of-way in conformance with all applicable laws and regulations.

- Litter stored in containers shall be handled and disposed of by licensed disposal contractors.

- Solid waste disposal haulers and facilities shall be approved by the Engineer. The Contractor shall be responsible for signing any manifests for solid waste disposal.

- Solid waste containers shall be located at least 50 ft from drainage facilities and watercourses and shall not be located in areas susceptible to flooding or ponding.

- Waste container washout on the construction site is not allowed.

- Additional containers and more frequent pickup and removal are required during the demolition phase of construction.

- Segregate potentially hazardous waste from non-hazardous construction site waste.

- Liquid wastes (e.g., used oils, solvents, and paints) and chemicals (e.g., acids, pesticides, additives, curing compounds) and solid waste that is hazardous shall not be disposed of in containers designated for solid waste. See BMP WM-6, "Hazardous Waste Management" for proper disposal procedures.

- Salvage or recycle vegetation debris, packaging and/or surplus building materials when practical. Wood pallets, cardboard boxes, and construction scraps can be recycled.

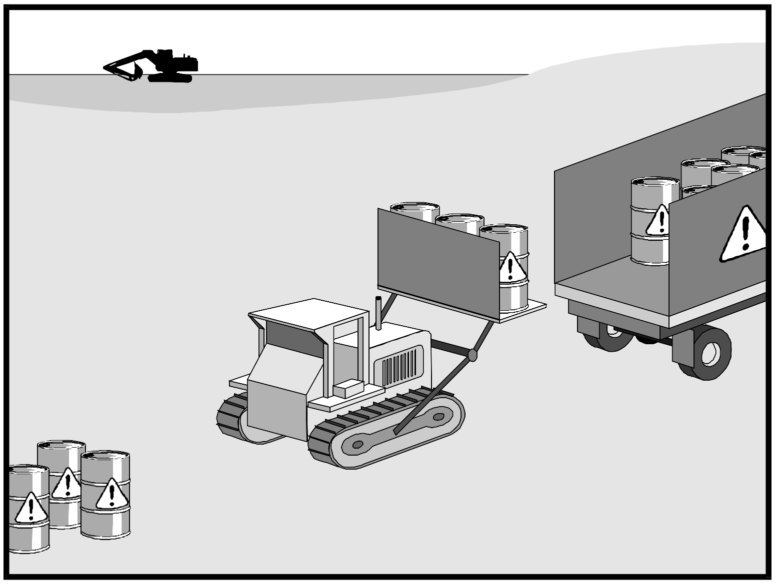
Maintenance and Inspection

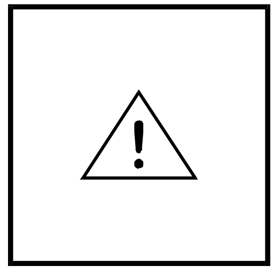
- Inspect the project site for solid waste management daily and document weekly, and before and after every rainfall events. During extended rainfall events, inspect project site for solid waste management at least once every 24 hours.

- Inspect solid waste disposal facilities to identify any waste that should be handled and disposed of under WM-6 Hazardous Waste Management. Typically, inspect for used oily rags, used absorbent, used oil containers, and other wastes that require special handling and disposal.

(This page left intentionally blank)

Hazardous Waste Management





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

These are procedures and practices to minimize or eliminate the discharge of pollutants from contractor generated waste or waste illegally dumped on site by others, that is hazardous waste, or waste that is otherwise not allowed to be disposed of as solid waste, to the ground, storm drain systems or to watercourses.

Appropriate Applications

- This best management practice (BMP) applies to all construction sites. This applies to hazardous waste, non-hazardous waste, designated waste and any other waste that requires special disposal practices due to a potential threat to human health, the environment, or water quality, or as identified by the Engineer. It can be solid, liquid or gaseous waste that is regulated and requires special handling and disposal.

- Hazardous waste management applies to median and shoulder soils of roadways that have been contaminated by aerially deposited lead (ADL). Refer to contract Special Provisions.

- Hazardous waste management practices are implemented on construction sites that generate waste from but not limited to:
  - Petroleum Products,
  - Asphalt Products,
  - Concrete Curing Compounds,
  - Herbicides/Pesticides,
  - Acids/bases,
  - Paints/Stains,
  - Solvents,
  - Wood Preservatives,

- Any materials deemed a hazardous waste in California Code of Regulations, Title 23, Division 3, Chapter 15, Title 22 Division 4.5, or listed in 40 CFR Parts 110, 117, 261, or 302, or
- Any materials deemed designated waste or non-hazardous waste in California Code of Regulations, Title 27 Division 2, Subdivision 1.

Limitations

- This BMP does not relieve the Contractor from responsibility for compliance with federal, state, and local laws regarding storage, handling, transportation, and disposal of hazardous wastes.
- This BMP does not cover waste addressed specifically by the contract Special Provisions.

Standards and Specifications

Education

- Educate employees and subcontractors on proper hazardous waste storage and disposal procedures.
- Educate employees and subcontractors on safety procedures and potential dangers to humans and the environment from hazardous wastes.
- Educate employees and subcontractors in identification of hazardous and solid waste.
- Hold regular meetings to discuss and reinforce hazardous waste management procedures (incorporate into regular safety meetings).
- The Contractor's Qualified SWPPP Practitioner (QSP) or BMP manager for projects without SWPPPs shall oversee and enforce proper hazardous waste management procedures and practices.
- Make sure that hazardous waste is collected, removed, and disposed of only at authorized disposal areas.

Storage Procedures

- All hazardous wastes shall be stored in a secured area and in approved, sealed, and leak-proof containers with sealed lids constructed of a suitable material and shall be labeled as required by Title 22 CCR, Division 4.5 and 49 CFR Parts 172,173, 178, and 179.
- All hazardous waste shall be stored, transported, and disposed as required in Title 22 CCR, Division 4.5 and 49 CFR 261-263.
- Waste containers shall be stored in temporary containment facilities that shall comply with the following requirements:
  - Temporary containment facility shall provide a spill containment volume able to contain precipitation from a 24-hour, 25 year storm event, plus the greater of 10% of the aggregate volume of all containers or 100% of the capacity of the largest container within its boundary, whichever is greater.

- Temporary containment facility shall be impervious to the materials stored there for a minimum contact time of 72 hours.
- Temporary containment facilities shall be covered and maintained free of accumulated rainwater and spills. In the event of spills or leaks accumulated rainwater and spills shall be immediately placed into drums after each rainfall. These liquids shall be handled as a hazardous waste unless testing determines them to be non-hazardous. Non-hazardous liquids shall be sent to an approved disposal site.
- Sufficient separation shall be provided between stored containers to allow for spill cleanup and emergency response access.
- Incompatible materials, such as chlorine and ammonia, shall not be stored in the same temporary containment facility.
- Temporary containment facilities shall be covered at all times. Covered facilities may include use of plastic tarps for small facilities or constructed roofs with overhangs. A storage facility having a solid cover and sides is preferred to a temporary tarp. Storage facilities shall be equipped with adequate ventilation.

■ Drums shall not be overfilled and wastes shall not be mixed.

■ Containers of dry waste shall be stored on pallets.

■ Paint brushes and equipment for water and oil based paints shall be cleaned within a contained area and shall not be allowed to contaminate site soils, watercourses or drainage systems. Waste paints, thinners, solvents, residues, and sludges that cannot be recycled or reused shall be disposed of as hazardous waste. When thoroughly dry, latex paint and paint cans, used brushes, rags, absorbent materials, and drop cloths shall be disposed of as solid waste.

■ Ensure that hazardous waste collection containers and spill kits are available at all hazardous waste storage areas.

■ Designate hazardous waste storage areas on site away from storm drains or watercourses and away from moving vehicles and equipment to prevent accidental spills. All hazardous wastes shall be protected from traffic and equipment.

■ Minimize production or generation of hazardous materials and hazardous waste on the construction site.

■ Use containment berms in fueling and maintenance areas and where the potential for spills is high.

■ Segregate potentially hazardous waste from non-hazardous construction site debris.

- Keep liquid or semi-liquid hazardous waste in appropriate containers (closed drums or similar) and under cover.
- Clearly label all hazardous waste containers with the waste being stored and the date of accumulation.
- Clean up spills of waste immediately.
- Do not mix different types wastes. For example, do not mix solids and liquids and do not mix hazardous and non-hazardous, nor designated and non-hazardous.

Disposal Procedures

- These disposal procedures apply to waste disposal unless specifically stated otherwise in the contract Special Provisions.
- If directed by the Engineer, the Contractor shall collect an appropriate number of samples of waste generated and shall have the sample analyzed by a Department of Health Services (DHS) certified laboratory in order to meet waste profiling requirements of the disposal facility.
- The Contractor shall complete all required waste profile forms. The "Generator" of the hazardous waste shall be identified by the Engineer. If the spill/leak of hazardous water is caused by the Contractor or Contractor's operations, the Contractor shall be identified as the "Generator" of the hazardous waste.
- A copy of a completed and typed draft Hazardous Waste Manifest for the transportation of hazardous waste, including the correct EPA ID Number, shall be submitted to the Engineer for approval prior to transporting the hazardous waste off-site. The Engineer shall provide the EPA ID Number. If the Contractor is identified as the Generator, then the Contractor shall obtain the EPA ID Number. Hazardous waste shall not be transported off-site unless the Hazardous Waste Manifest has been signed by the Generator.
- A copy of a completed and typed draft Non-Hazardous Waste Manifest for the transportation of non-hazardous waste shall be submitted to the Engineer for approval prior to transporting the non-hazardous waste off-site. Non-Hazardous waste shall not be transported off-site unless the Non-Hazardous Waste Manifest has been signed by the Generator.
- Waste shall be transported by a licensed hazardous waste transporter to an authorized and licensed disposal facility or recycling facility.
- Hazardous waste as defined by California Code of Regulations, Title 22 CCR, Division 4.5 and Title 23, Division 3, Chapter 15 or as determined by the Engineer shall not be stored on site unless covered by the contract Special Provisions.

- Hazardous waste, non-hazardous waste, designated waste and other waste that presents a potential threat to human health, the environment or water quality shall be disposed in accordance with all applicable laws and regulations including but not limited to California Code of Regulations, Title 22 Division 4.5, Title 23, Division 3, Chapter 3, and Title 27, Division 2, Subdivision 1.

- Make sure that toxic liquid wastes (e.g., used oils, solvents, and paints), chemicals (e.g., acids, pesticides, additives, curing compounds), and any other wastes that have special handling and disposal requirements under California Code of Regulations, Title 22 Division 4.5, Title 23, Division 3, Chapter 3, and Title 27, Division 2, Subdivision 1 are not disposed of in dumpsters designated for solid waste or construction debris.

- Dispose of rainwater accumulated in secondary containment as hazardous waste.

Maintenance and Inspection

- The Contractor's Site-Specific Health and Safety Officer (SHSO) or Safety Office (based on contract Special Provisions) shall monitor on-site hazardous waste storage and disposal procedures.

- Inspect the project site for non-hazardous and hazardous waste weekly, and before and after every rainfall events. During extended rainfall events, inspect project site for non-hazardous and hazardous waste at least once every 24 hours.

- Waste storage areas shall be kept clean, well organized, and equipped with ample clean-up supplies as appropriate for the materials being stored.

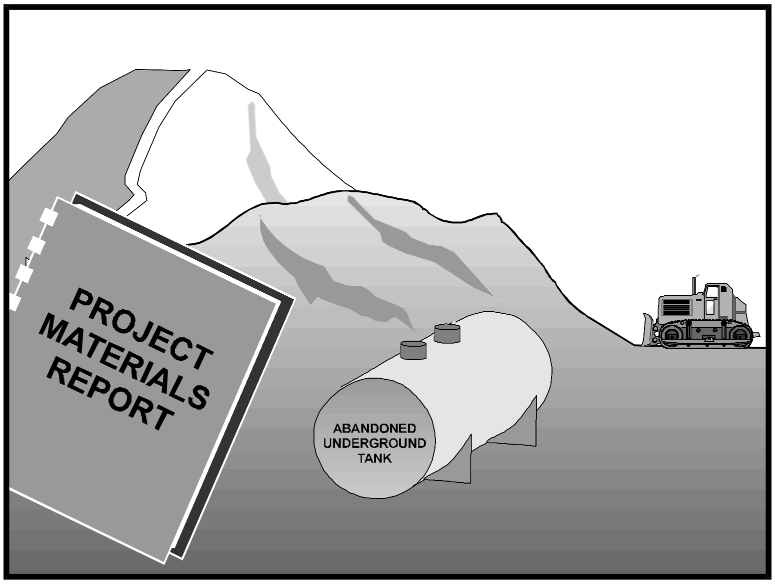
- Storage areas shall be inspected in conformance with the contract Special Provisions and the SWPPP.

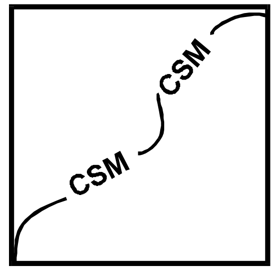
- Perimeter controls, containment structures, covers, and liners shall be repaired or replaced as needed to maintain proper function.

(This page left intentionally blank)

Contaminated Soil Management

WM-7





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

These are procedures and practices to minimize or eliminate the discharges of pollutants to the drainage system or to watercourses from contaminated soil.

Appropriate Applications

- Contaminated soil management is implemented on construction projects in highly urbanized or industrial areas where soil contamination may have occurred due to spills, illicit discharges, and leaks from underground oil pipelines and storage tanks.

Limitations

- The procedures and practices presented in this best management practice (BMP) are general. The contractor shall identify appropriate practices and procedures for the specific contaminants known to exist or discovered on site.

Standards and Specifications

- Contaminated soils are often identified during project planning and development with known locations identified in the contract Special Provisions.
- If contaminated soils are encountered on the project site and are not identified in the contract Special Provisions. The Engineer shall solely characterize the extent, volume, and type of contaminated soil.
- All soil sampling will be conducted by the Engineer.

Education

- The Contractor shall comply with the Agency-approved Site-Specific Health and Safety Plan (refer to contract Special Provisions).
- Prior to performing any excavation work at the locations containing material classified as hazardous, employees and subcontractors shall complete a safety training program which meets 29 CFR 1910.120 and 8 CCR 5192 covering the potential hazards as identified.

- Educate employees and subcontractors in identification of contaminated soil.
  - Detected or undetected spills and leaks.
  - Acid or alkaline solutions from exposed soil or rock formations high in acid or alkaline forming elements.
  - Look for contaminated soil as evidenced by discoloration, odors, differences in soil properties, abandoned underground tanks or pipes, or buried debris.

Handling Procedures for Contaminated Soils

- To minimize on-site storage, contaminated soil shall be disposed of properly in accordance with all applicable regulations. All hazardous waste storage will comply with the requirements in Title 22, CCR, Sections 6626.250 to 66265.260.
- Contaminated soils or hazardous material shall not be stockpiled on the project site.
- Contaminated material and hazardous material on exteriors of transport vehicles shall be removed and placed either into the current transport vehicle or the excavation prior to the vehicle leaving the exclusion zone.
- Procure all permits and licenses, pay all charges and fees, and give all notices necessary and incident to the due and lawful prosecution of the work, including registration for transporting vehicles carrying the contaminated material and the hazardous material.
- Collect water from decontamination procedures and treat and/or dispose of it at an appropriate disposal site.
- Collect non-reusable protective equipment, once used by any personnel, and dispose of at an appropriate disposal site.
- Install temporary security fence to surround and secure the exclusion zone. Remove fencing when no longer needed.
- Excavation, transport, and disposal of contaminated material and hazardous material/waste shall be in accordance with the rules and regulations of the following agencies (the specifications of these agencies supersede the procedures outlined in this BMP):
  - United States Department of Transportation (USDOT).
  - United States Environmental Protection Agency (USEPA).
  - California Environmental Protection Agency (CAL-EPA).
  - California Division of Occupation Safety and Health Administration (CAL-OSHA).
  - Local regulatory agencies.

Procedures for Underground Storage Tank Removals

- Prior to commencing tank removal operations, obtain the required underground storage tank removal permits and approval from the federal, state, and local agencies, which have jurisdiction over such work.
- Arrange to have tested, as directed by the Engineer, any liquid or sludge found in the underground tank prior to its removal to determine if it contains hazardous substances.
- Following the tank removal, take soil samples beneath the excavated tank and perform analysis as required by the local agency representative(s).
- The underground storage tank, any liquid and/or sludge found within the tank, and all contaminated substances and hazardous substances removed during the tank removal shall be transported to disposal facilities permitted to accept such waste.

Water Control

- Take all necessary precautions and preventive measures to prevent the flow of water, including ground water, from mixing with hazardous substances or underground storage tank excavations. Such preventative measures may consist of, but are not limited to: berms, cofferdams, grout curtains, freeze walls, and seal course concrete or any combination thereof.
- If water does enter an excavation and becomes contaminated, such water, when necessary to proceed with the work, shall be transported off-site and disposed at a recycling or disposal facility approved by the Engineer.

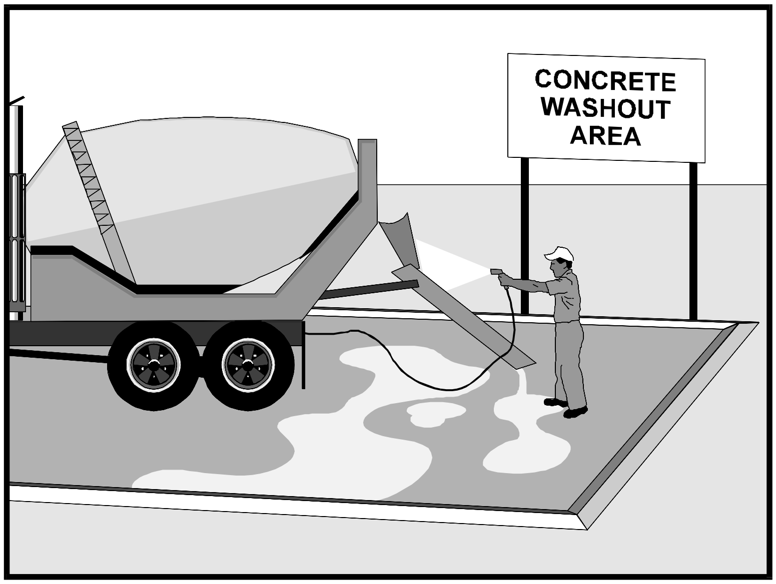
Maintenance and Inspection

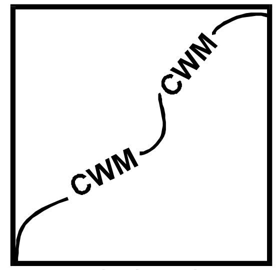
- The Contractor's Site-Specific Health and Safety Officer (SHSO) or Safety Office (based on contract Special Provisions) shall monitor contaminated soil excavation and disposal procedures.
- Inspect the areas of known contaminated soil weekly, and before and after every rainfall events. During extended rainfall events, inspect areas of known contaminated soil at least once every 24 hours.
- Confirm that areas of known contaminated soil are secure and not being tracked or impacting water quality.

(This page left intentionally blank)

Concrete Waste Management

WM-8





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

These are procedures and practices that are designed to minimize or eliminate the discharge of concrete waste and similar materials to the ground, storm drain systems or watercourses.

Appropriate Applications

- ■ Concrete waste management procedures and practices are implemented on construction projects where concrete is used as a construction material or where concrete dust and debris result from demolition activities.
- ■ Where slurries containing Portland cement concrete (PCC) or asphalt concrete (AC) are generated, such as from sawcutting, coring, grinding, grooving, and hydro-concrete demolition.
- ■ Where concrete trucks and equipment are washed on site, when approved by the Engineer. Refer to NS-8, “Vehicle and Equipment Cleaning."
- ■ Where grout and mortar-mixing stations are used.

Limitations

- ■ None identified.

Standards and Specifications

- ■ Concrete washout areas and other washout areas shall not discharge or leak onto the underlying soil or to the surrounding areas.
- ■ Watertight concrete washout bins are recommended.

Education

- ■ Educate all employees, subcontractors, and suppliers on the concrete waste management requirements described herein.
- ■ The Contractor’s Qualified SWPPP Practitioner (QSP) or BMP Manager (based on the contract Special Provisions) shall oversee and enforce concrete waste management procedures.

Concrete Demolition Wastes

- Stockpile concrete demolition wastes in accordance with BMP WM-3, "Stockpile Management."
- Disposal of hardened PCC and AC waste outside the site to an appropriate facility (in accordance with WM-5) or as directed by Engineer if allowed to incorporate onsite.

Concrete Slurry Waste Management and Disposal

- PCC and AC waste shall not be allowed to discharge to the ground or enter storm drainage systems or watercourses.
- A sign shall be installed adjacent to each temporary concrete washout facility to inform concrete equipment operators to utilize the proper facilities as shown on Page 6.
- Residue from saw cutting, coring and grinding operations shall be picked up by means of a vacuum device. Residue shall not be allowed to flow across the pavement and shall not be left on the surface of the pavement. See also BMP NS-3, "Paving and Grinding Operations."
- Vacuumed slurry residue shall be disposed of in accordance with BMP WM-5, "Solid Waste Management." Slurry residue shall be disposed of immediately offsite or temporarily stored in a facility as described in "Onsite Temporary Concrete Washout Facility, Concrete Transit Truck Washout Procedures" below), or within an impermeable containment vessel or bin approved by the Engineer.

Onsite Temporary Concrete Washout Facility, Concrete Transit Truck Washout Procedures

- Temporary concrete washout facilities shall be located a minimum of 50 ft from storm drain inlets, open drainage facilities, and watercourses, unless determined infeasible by the Engineer. Each facility shall be located away from construction traffic or access areas to prevent disturbance or tracking.
- A sign shall be installed adjacent to each washout facility to inform concrete equipment operators to utilize the proper facilities. The sign shall be installed as shown on page 6.
- Temporary concrete washout facilities shall be constructed above or below grade, or placed in watertight bins or containers. Temporary concrete washout facilities shall be constructed and maintained in sufficient quantity and size to contain all liquid and concrete waste generated.
- Wash concrete from mixer chutes into approved concrete washout facility. Perform washout of concrete mixers, delivery trucks, and other delivery systems in designated areas only.

- Pump excess concrete in concrete pump bin back into concrete mixer truck.

- Concrete washout from concrete pumper bins can be washed into concrete pumper trucks and discharged into designated washout area or properly disposed offsite.

- Once concrete wastes are washed into the designated area and allowed to harden, the concrete shall be broken up, removed, and disposed of in conformance with applicable federal, state and local regulations (WM-5).

- Washout facilities will be covered 24 hours prior to a 50% or more chance of rain. If not covered prior to rain, washouts shall be covered during rain event. No water will be allowed to overflow from washout and any accumulated rain water will be handled and disposed of as washout water.

Temporary Concrete Washout Facility Type "Above Grade"

- Temporary concrete washout facility Type "Above Grade" shall be constructed as shown on Page 6 or 7, with a minimum length and minimum width of 10 ft, but with sufficient quantity and volume to contain all liquid and concrete waste generated by washout operations. .

- Straw bales, wood stakes, and sandbag materials shall conform to the provisions in BMP SC-9, "Straw Bale Barrier" and BMP SC-8, "Sandbag Barrier."

- Plastic lining material shall be a minimum of 10-mil polyethylene sheeting and shall be free of holes, tears or other defects that compromise the impermeability of the material. Liner seams shall be installed in accordance with manufacturers' recommendations. No seams in the plastic are allowed at the bottom of the washout.

Temporary Concrete Washout Facility (Type Below Grade)

- Temporary concrete washout facility Type "Below Grade" shall be constructed as shown on page 7, with a recommended minimum length and minimum width of 10 ft. The quantity and volume shall be sufficient to contain all liquid and concrete waste generated by washout operations. The length and width of a facility may be increased, at the Contractor's expense, upon approval of the Engineer. Lath and flagging shall be commercial type.

- Plastic lining material shall be a minimum of 10-mil polyethylene sheeting and shall be free of holes, tears or other defects that compromise the impermeability of the material. Liner seams shall be installed in accordance with manufacturers' recommendations. No seams in the plastic material are allowed at the bottom of the washout.

- The soil base shall be prepared free of rocks or other debris that may cause tears or holes in the plastic lining material.

Removal of Temporary Concrete Washout Facilities

- When temporary concrete washout facilities are no longer required for the work and as washouts are filled, as determined by the Engineer, the hardened concrete shall be removed and disposed of in conformance with applicable federal, state and local regulations. Disposal of PCC dried residues, slurries or liquid waste shall be disposed of in conformance with all applicable laws and regulations. Materials used to construct temporary concrete washout facilities shall become the property of the Contractor, shall be removed from the site of the work, and shall be disposed of in conformance with all applicable laws and regulations.
- Holes, depressions or other ground disturbance caused by the removal of the temporary concrete washout facilities shall be backfilled and repaired.

Maintenance and Inspection

- Inspect temporary concrete washout facilities weekly, and before and after every rainfall events. During extended rainfall events, inspect temporary concrete washout facilities at least once every 24 hours.
- Temporary concrete washout facilities shall be maintained to provide adequate holding capacity with a minimum freeboard of 4 inches for above grade facilities and 12 inches for below grade facilities. Maintaining temporary concrete washout facilities shall include removing and disposing of hardened concrete and returning the facilities to a functional condition. Hardened concrete materials shall be removed and disposed of in conformance with applicable federal, state and local regulations.
- Existing facilities must be cleaned, or new facilities must be constructed and ready for use once the washout is 75% full.
- Temporary concrete washout facilities shall be inspected for damage (i.e. tears in polyethylene liner, missing sandbags, etc.). Damaged facilities shall be repaired immediately.

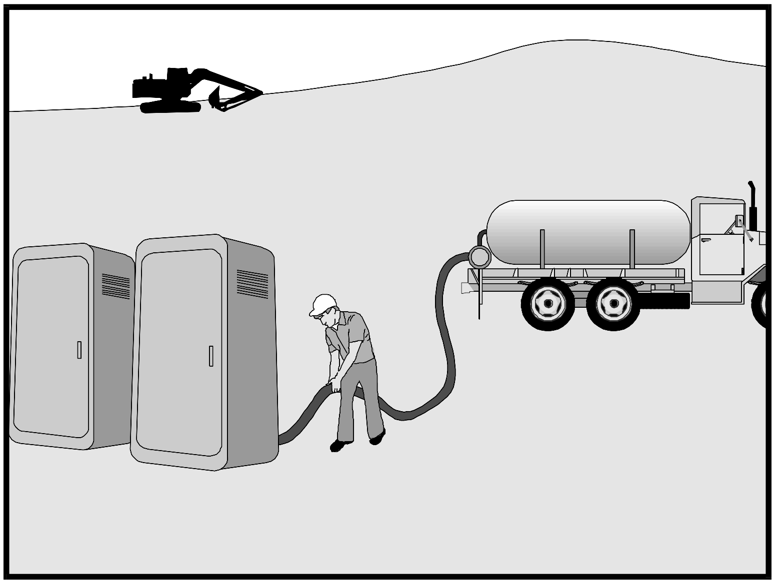
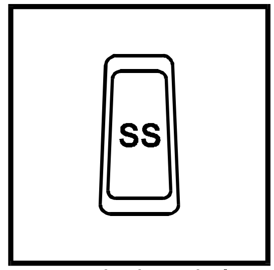
Sanitary/Septic Waste Management

WM-9





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Procedures and practices to minimize or eliminate the discharge of construction site sanitary/septic waste materials to the storm drain system or to watercourses.

Appropriate Applications

Sanitary/septic waste management practices are implemented on all construction sites that use temporary or portable sanitary/septic waste systems.

Limitations

- None identified.

Standards and Specifications

Education

- Educate employees, subcontractors, and suppliers on sanitary/septic waste storage and disposal procedures.
- Educate employees, subcontractors, and suppliers of potential dangers to humans and the environment from sanitary/septic wastes.
- Hold regular meetings to discuss and reinforce disposal procedures (incorporate into regular safety meetings).

Storage and Disposal Procedures

- Ensure the containment of sanitation facilities (e.g., portable toilets) to prevent discharges of pollutants to the ground surface, storm water drainage system or receiving water.
- Clean or replace sanitation facilities and inspect them regularly for leaks and spills.
- Temporary sanitary facilities shall be located away from drainage facilities, watercourses, and from traffic circulation. When subjected to high winds or risk, temporary sanitary facilities shall be secured to prevent overturning.

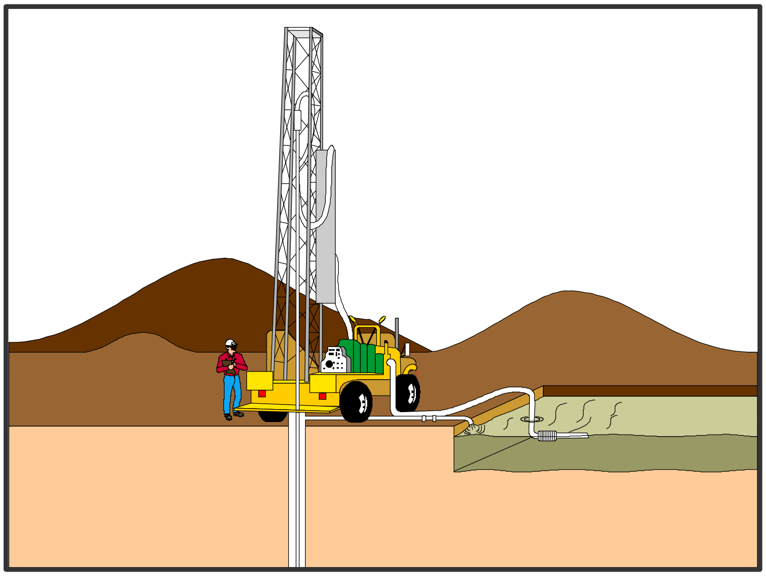
- Wastewater shall not be discharged or buried on the construction site.
- Sanitary and septic systems that discharge directly into sanitary sewer systems, where permissible, shall comply with the local health agency, city, county, and sewer district requirements.
- Properly connect temporary sanitary facilities that discharge to the sanitary sewer system to avoid illicit discharges.
- Ensure that sanitary/septic facilities are maintained in good working order by a licensed service.
- Use only reputable, licensed sanitary/septic waste haulers.
- Clean up spills and leaks immediately. Spills and leaks shall not be covered or buried onsite. Contaminated soil shall be disposed of properly in accordance with permits, laws and regulations.

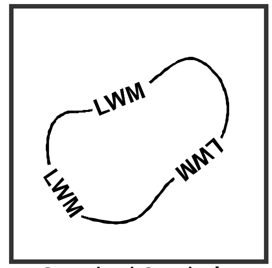
Maintenance and Inspection

- Inspect sanitary and septic waste facilities weekly, and before and after every rainfall events. During extended rainfall events, inspect sanitary and septic waste facilities at least once every 24 hours.

Liquid Waste Management

WM-10





Standard Symbol

BMP Objectives

- ○ Soil Stabilization
- ○ Sediment Control
- ○ Tracking Control
- ○ Wind Erosion Control
- ● Non-Storm Water Management
- ● Materials and Waste Management

Definition and Purpose

Procedures and practices to prevent discharge of pollutants to the ground, storm drain system or to watercourses as a result of the creation, collection, and disposal of non-hazardous liquid wastes.

Appropriate Applications

Liquid waste management is applicable to construction sites that generate any non-hazardous byproducts, residuals, or wastes not limited to the following:

- Drilling slurries and drilling fluids.
- Grease-free and oil-free wastewater and rinse water.
- Dredgings.
- Other non-storm water liquid discharges not permitted by separate permits.

Limitations

- Disposal of some liquid wastes may be subject to requirements of other permits secured by the Agency (e.g., National Pollutant Discharge Elimination System [NPDES] permits, Army Corps of Engineers permits, RWQCB Water Quality Certifications, Coastal Commission permits, etc.).
- Does not apply to groundwater dewatering operations (refer to contract Special Provisions)
- Does not apply to dewatering operations (see BMP NS-2, “Dewatering Operations”), solid waste management (see BMP WM-5, “Solid Waste Management”), hazardous wastes (see BMP WM-6, “Hazardous Waste Management”), or concrete slurry residue (see BMP WM-8, “Concrete Waste Management”).
- Does not apply to approved non-storm water discharges permitted by any NPDES permit secured by the Agency. Typical permitted non-storm water discharges can include: fire hydrant flushing, irrigation of vegetative erosion control measures, pipe flushing and testing, water to control dust,

uncontaminated ground water from dewatering fire hydrant flushing, irrigation of vegetative erosion control measures, pipe flushing and testing, or water to control dust.

Standards and Specifications

General Practices

- Instruct employees and subcontractors how to safely differentiate between non-hazardous liquid waste and potential or known hazardous liquid waste. Educate employees and subcontractors on liquid waste generating activities, and liquid waste storage and disposal procedures. Hold regular meetings to discuss and reinforce disposal procedures (incorporate into regular safety meetings).

- Instruct employees, subcontractors, and suppliers that it is unacceptable for any liquid waste to discharge to the ground, or enter any storm drainage structure, waterway, or receiving water.

- Verify with the Engineer which non-storm water discharges are permitted. Some listed discharges may be prohibited if the Agency determines the discharge to be a source of pollutants.

- Apply the NS-8, "Vehicle and Equipment Cleaning" BMP for managing wash water and rinse water from vehicle and equipment cleaning operations.

Containment of Liquid Wastes

- Drilling residue and drilling fluids shall not be allowed to discharge to the ground, or enter storm drains and watercourses and shall be disposed of in conformance with all applicable laws and regulations.

- Liquid wastes generated as part of an operational procedure, such as water-laden dredged material and drilling mud, shall be contained and not allowed to discharge to the ground or to flow into drainage channels or receiving waters prior to treatment and meeting water quality requirements.

- Contain liquid wastes in a controlled area, such as a sediment basin, watertight roll-off bin, or portable tank.

- Containment devices must be structurally sound and leak free.

- Containment devices must be of sufficient quantity or volume to completely contain the liquid wastes generated.

- Take precautions to avoid spills or accidental releases of contained liquid wastes. Apply the education measures and spill response procedures outlined in BMP WM-4, "Spill Prevention and Control."

- Do not locate containment areas or devices where accidental release of the contained liquid can threaten health or safety, or discharge to water bodies, channels, or storm drains.

- Contain and properly dispose off-site all liquid wastes running off a surface such as wash water and rinse water from cleaning walls or pavement.

- Do not allow liquid wastes to flow or discharge uncontrolled to the ground, storm drain system or watercourse. Use temporary dikes or berms to intercept flows and direct them to a containment area.

- Use a sediment trap (see BMP SC-3, "Sediment Trap") for capturing and treating the liquid waste stream, or capture in a containment device and allow sediment to settle.

Disposal of Liquid Wastes

- All liquid waste must be disposed of offsite. If liquid waste is allowed to be discharged to the storm drain system in accordance with permits, laws and regulations, the discharge shall be approved by the Engineer,

- Dispose of liquid wastes as required in the contract Special Provisions or per the Water Quality Reports, NPDES permits, Environmental Impact Reports, 401 Water Quality Certifications or 404 permits, local agency discharge permits, etc., or as specified in the contract Special Provisions.

- Liquid wastes, such as from dredged material, may require testing and certification whether it is hazardous or not before a disposal method can be determined. Sampling is the responsibility of the Contractor unless specified in the contract Special Provisions.

- For disposal of hazardous waste, see BMP WM-6, "Hazardous Waste Management."

- If necessary, further treat liquid wastes prior to disposal. Treatment may include, though is not limited to, sedimentation, filtration, and chemical neutralization.

Maintenance and Inspection

- Inspect all liquid waste management facilities weekly, and before and after every rainfall events. During extended rainfall events, inspect liquid waste management facilities at least once every 24 hours.

- Inspect containment areas and capturing devices frequently for damage, and repair as needed. Remove deposited solids in containment areas and capturing devices as needed, and at the completion of the task. Dispose of any solids as described in BMP WM-5, "Solid Waste Management."

Definition of Terms

Active Areas of Construction: All areas subject to land surface disturbance activities related to the project including, but not limited to, the project site, project staging areas, immediate access areas and storage areas. All previously active areas are still considered active areas until final stabilization is complete. [The construction activity Phases are the Preliminary Phase, Grading and Land Development Phase, Streets and Utilities Phase, and the Vertical Construction Phase.]

Antecedent Moisture: Amount of moisture present in soil prior to the application of a soil stabilization product.

Best Management Practice (BMP): BMPs are scheduling of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the discharge of pollutants. BMPs also include treatment requirements, operating procedures, and practices to control site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage. Any program, technology, process, siting criteria, operating method, measure, or device that controls, prevents, removes, or reduces pollution.

Construction Activity: Includes clearing, grading, or excavation and contractor activities that result in soil disturbance.

Construction Site: The area involved in a construction project as a whole including but not limited to the project site, storage areas, access roads, staging areas, drainage areas.

Contamination: An impairment of the quality of the waters of the state by waste to a degree that creates a hazard to the public health through poisoning or through the spread of disease including any equivalent effect resulting from the disposal of waste, whether or not waters of the state are affected.

Contractor: Party responsible for carrying out the contract per plans and specifications. The contract Special Provisions contain storm water protection requirements the contractor must address.

Degradability: Method by which the chemical components of a soil stabilization product are degraded over time.

Discharge: Any release, spill, leak, pump, flow, escape, dumping, or disposal of any liquid, semi-solid or solid substance.

Disturbed Areas: Areas that have been purposefully cleared, grubbed, excavated, or graded by the contractor; ground surface that has been disrupted by construction activities, including construction access/roads, producing significant areas of exposed soil and soil piles. Staging and storage sites are considered as part of the total disturbed land area, whether located on or off the project site.

Drying Time: Time it takes for a soil stabilization product to dry or cure for it to become erosion control effective.

Engineer: Agency representative on a construction project. The Engineer may be the inspector or engineer representing the Agency on site.

Environmental Protection Agency (EPA): Federal Agency that issues the regulations to control pollutants in storm water runoff discharges (The Clean Water Act and NPDES permit requirements).

Erosion: The process, by which soil particles are detached and transported by the actions of wind, water, or gravity.

Erosion Control Effectiveness: The ability of a particular product to reduce soil erosion relative to the amount of erosion measured for bare soil. Percentage of erosion that would be reduced as compared to an untreated or control condition.

Exempt Construction Activities: Activities exempt from the Construction General Permit, including routine maintenance to maintain original line and grade, hydraulic capacity, or original purpose of the facility; and emergency construction activities required to protect public health and safety. Local permits may not exempt these activities.

Existing vegetation: Any vegetated area that has not already been cleared and grubbed.

Fair Weather Prediction: When there is no precipitation in the forecast between the current calendar day and the next working day. The National Weather Service NOAA Weather Radio forecast shall be used. The contractor may propose an alternative forecast for use if approved by the Resident Engineer.

Feasible: Economically achievable or cost-effective measures which reflect a reasonable degree of pollutant reduction achievable through the application of available nonpoint pollution control practices, technologies, processes, site criteria, operating methods, or other alternatives.

General Permit: The General Permit for Storm Water Discharges Associated with Construction Activity (Order No. 99-08-DWQ, NPDES Permit CAS000002) issued by the State Water Resources Control Board.

Good Housekeeping: A common practice related to the storage, use, or cleanup of materials, performed in a manner that minimizes the discharge of pollutants.

Local permit: See MS4 Permit.

Longevity: The time the soil erosion product maintains its erosion control effectiveness.

Mode of Application: Type of labor or equipment that is required to install the product or technique.

MS4 Permit: Regional Water Quality Control Board (RWQCB) – Los Angeles Region, adopted Order No. 01-182, NPDES Permit No. CAS004001, Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharge within the County of Los Angeles, and Incorporated Cities Therein. This is commonly referred to as MS4 permit or local NPDES permit.

National Pollutant Discharge Elimination System (NPDES) Permit: A permit issued pursuant to the Clean Water Act that requires the discharge of pollutants to waters of the United States from storm water be controlled.

Native: Living or growing naturally in a particular region. Compatibility and competitiveness of selected plant materials with the environment.

Non-active Construction Area: Any area not considered to be an active construction area. Active construction areas become non-active construction areas whenever construction activities are expected to be discontinued for a period of 14 days or longer.

Non-Storm Water Discharges: Discharges that do not originate from precipitation events. They can include, but are not limited to, discharges of process water, air conditioner

condensate, non-contact cooling water, vehicle wash water, water truck water, sanitary wastes, concrete washout water, paint wash water, irrigation water, or pipe testing water.

Permit: The Construction General Permit or local MS4 NPDES permit, whichever or both are applicable to the construction project.

Pollution: The man-made or man-induced alteration of the chemical, physical, biological, and radiological integrity of water. An alteration of the quality of the water of the state by waste to a degree, which unreasonably affects either the waters for beneficial uses or facilities that serve these beneficial uses.

Qualified SWPPP Practitioner (QSP): Individual assigned responsibility for non-storm water and storm water visual observations, sampling and analysis, and responsibility to ensure full compliance with the contract Special Provisions and implementation of all elements of the SWPPP.

Receiving Waters: All surface water bodies within the County of Los Angeles.

Regional Water Quality Control Board (RWQCB): California agencies that implement and enforce Clean Water Act Section 402(p) NPDES permit requirements, and are issuers and administrators of these permits as delegated by EPA. There are nine regional boards working with the State Water Resources Control Board.

Residual Impact: The impact that a particular practice might have on construction activities once they are resumed on the area that was temporarily stabilized.

Runoff Control BMPs:
Measures used to slow and convey concentrated flow, dissipate velocity to prevent or minimize erosion and sediment discharges.

Runoff Effect: The effect that a particular soil stabilization product has on the production of storm water runoff. Runoff from an area protected by a particular product may be compared to the amount of runoff measured for bare soil.

Run-on: Discharges that originate offsite and flow onto the property of a separate project site.

Run-on Control BMPs - Measures used to divert run-on from offsite and runoff within the project site.

Sediment: Solid particulate matter, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface either above or below sea level.

Sediment Control BMPs: Practices that trap soil particles after they have been eroded by rain, flowing water, or wind. They include those practices that intercept and slow or detain the flow of storm water to allow sediment to settle and be trapped (e.g., silt fence, sediment basin, fiber rolls, etc.).

Statewide Permit: The National Pollutant Discharge Elimination System (NPDES) Permit, Statewide Storm Water Permit and Waster Discharge Requirements (WDRs) for the State of California Department of Transportation (Caltrans). Order No. 99-06-DWQ, NPDES No. CAS000003.

State Water Resources Control Board (SWRCB): California agency that implements and enforces Clean Water Act Section 402(p) NPDES permit requirements, is issuer and administrator of these permits as delegated by EPA. Works with the nine Regional Water Quality Control Boards.

Storm Drain System: Streets, gutters, inlets, conduits, natural or artificial drains, channels and watercourses, or other facilities that are owned, operated, maintained and used for the purpose of collecting, storing, transporting, or disposing of storm water.

Storm Water: Rainfall runoff, snow melt runoff, and surface runoff and drainage. It excludes infiltration and runoff from agricultural land.

Storm Water Pollution Prevention Plan (SWPPP): A plan required by the Permit that includes site map(s), an identification of construction/contractor activities that could cause pollutants in the storm water, and a description of measures or practices to control these pollutants. It must be prepared and approved in accordance with the contract special provisions and the LACDPW SWPPP Preparation Manual before construction begins.

Temporary Construction Site BMPs: Construction Site BMPs that are required only temporarily to address a short-term storm water contamination threat. For example, silt fences are located near the base of newly graded slopes that have a substantial area of exposed soil. Then, during rainfall, the silt fences filter and collect sediment from runoff flowing off the slope.

Waste Discharge Identification Number (WDID): The unique project number issued by the SWRCB upon receipt of the notice of intent (NOI).

Appendix B
Best Management Practices (BMP) Checklist

General

- The BMP Checklist is available as a separate Excel file.
- Use this BMP Checklist for documenting all inspections. This BMP Checklist meets the Construction General Permit requirements for BMP inspections, storm event inspections, and non-storm water inspections (quarterly inspections).
- In order to properly fill out the BMP Checklist, these instructions must be followed. The BMP Checklist does not provide instruction on how to conduct the inspection and fill out the BMP Checklist. BMP design, implementation, and maintenance for the BMPs numbered and named on the BMP Checklist are detailed in the BMP Fact Sheets attached to Sections 3 through 8 of this BMP Manual.
- For SWPPP projects, the BMP Checklist shall be completed and signed by the Contractor's Qualified SWPPP Practitioner (QSP).
- Evaluate BMPs for adequacy and proper maintenance and whether additional BMPs are required in accordance with the contract Special Provisions and the Construction General Permit (Order No. 2009-0009-DWQ).
- All paved areas that provide access to the project site shall be inspected daily. The question, "Are all paved roads that provide access to the project inspected daily for tracking of sediment and other debris?" shall be answered.
- If the answer is "no" to any of the questions listed in Columns B, C, or D of the BMP Checklist, describe the corrective action(s) to be taken and implementation dates of when corrective actions are completed. Should more space be needed to describe corrective actions, identify the corrective action numerically and use additional sheets as necessary.
- The inspection type is documented to ensure and document that inspections are conducted with the required frequency. Check either "Weekly," "Pre-storm," "Post-storm," "During" or "Other." If "other" is checked, describe what type of inspection in the space provided. For example, if an inspection is conducted more frequently that once per week, the "Other" box should be checked and the inspector shall fill in "additional weekly" for the inspection type. Another example would be a consultant or oversight inspection or audit.

Project Information

- The Project Name and Project ID Number shall be obtained from the front cover of the contract Special Provisions.
- The PCA number is an internal LACDPW billing number not necessary for the Contractor to fill in. The Office Engineer and Area Supervisor and signature are not necessary for the Contractor to fill in.
- If the BMP Checklist is used for a catch basin cleanout contract, referred to specific BMPs that may apply: SS-1, SS-7, SS-10, NS-6, WM-2, WM-4, WM-5, WM-6.

Inspector's name, title, and signature

- For SWPPP projects, the inspector shall be Contractor's Qualified SWPPP Practitioner (QSP). The QSP name, title and signature are required. For projects that do not require a SWPPP, the inspector is the Contractor staff responsible for the BMPs.

SWPPP Projects

- Whether the project requires a SWPPP is determined by Section 7-8.6 of the Contract Special Provisions. SWPPP projects are required to answer the question in Column "A" whether each BMP is included in the SWPPP. Projects that do not require a SWPPP are not required to answer the question in Column "A."
- Whether SWPPP revisions are necessary shall be based on the entire inspection and review of the SWPPP.
- The inspector shall review the SWPPP prior to an inspection in order to determine whether a SWPPP amendment is necessary.
- If the SWPPP adequately addresses installed BMPs and BMPs required for the project, and if the SWPPP matches the site, answer "no" to indicate that amendments to the SWPPP are NOT necessary.
- If the SWPPP does not match the actual construction site conditions or if corrective actions need to be made on the site that do not match the current SWPPP, answer "yes" to indicate that SWPPP amendments are necessary. If "yes" is checked, include SWPPP amendments as part of the corrective actions for the associated BMPs in the BMP Checklist Section 1 thru 6.
  - For example, if during an inspection a drain inlet is identified that was not shown on the project SWPPP, the question regarding whether the SWPPP revisions are necessary should be answered "yes." Then, under Section 2, SC-10 Storm Drain Inlet Protection, not only should any deficiencies, corrective actions and implementation dates for the BMP inspected be noted, but an additional deficiency, corrective action, and implementation date should be noted to amend the SWPPP to include the additional drain inlet location.
  - For another example, if the Contractor implements an additional BMP, approved by the Engineer, such as a fiber roll to break up slope lengths, and fiber rolls were not previously selected, included and described in the SWPPP, the corrective actions under SC-5 Fiber Rolls shall include a revision to the SWPPP to add fiber rolls.

Inspection date, time, and date the inspection report was written

- The inspection report shall be completed the same day that the inspection was conducted. In order to document that the inspection was completed the same day, both the inspection date and report date are required.
- The report number is a consecutive number from the first inspection conducted on the project.

Stage of construction, activities completed, and approximate area of the site exposed. (SWPPP Projects Only)

- The area of construction exposed shall be approximated in acres. Exposed areas include but are not limited to:

  Clearing of the land both for access (i.e. access roads) as well as preparing the site for construction,
  Construction of access roads and existing unpaved roads,
  excavation and grading of the site,
  equipment staging, maintenance, and construction easement areas if they occur on top of a soil surface,
  material and/or soil staging or stockpiles if atop a soil surface (not if atop an impervious surface such as concrete or asphalt),
  area of asphalt or concrete pavement removal if it is removed entirely to the soil surface,
  area related to demolition and removal of existing structures if the work is to the soil surface,
  concrete truck clean-out or other construction activity areas if on top of a soil surface

- The stage of construction shall be documented by checking one or more of the boxes on the BMP Checklist for utilities, grading/excavating/drilling, paving/general construction, vertical, or final landscaping/stabilization.

- The activities completed shall be filled in. This information is project-specific and shall be updated for each inspection as construction progresses. For example, if sawcutting operations were completed and the project was working on utilities, write "sawcutting" as a completed activity. If paving operations were completed and the project was in landscaping, write "paving" as a completed activity. If the project had completed a portion of paving but was still conducting paving, write a percentage of paving as a completed activity (e.g., "40% paving"). There may be more than one activity completed. For example, if the excavation, backfill, and utility work were completed and the project was being paved, write "excavation, backfill and utility work" as completed activities.

Weather Information (SWPPP Projects Only)

- If it is raining or drizzling during the inspection answer "yes" to was precipitation present during inspection. Otherwise, answer "no."

- The beginning time of the storm event shall be documented when the rain event starts during working hours. If the rain event begins outside work hours, include an estimate of the start time. For example, if it started raining after leaving the site at 3:00 p.m. and before arriving at 7:00 a.m., the beginning must be estimated.

- The elapsed time since the last rain event shall be obtained by reviewing the previous rain event BMP Checklists and counting the days in between events.

- Rainfall/Rain gauge information shall be monitored daily during a rain event. The inches of rain that has fallen shall be obtained from the Los Angeles County Department of Public Works, Water Resources Division, Hydrology Precipitation Map. The rain gauge for the past 24 hours shall be obtained from the website. Select the closest rain gauge station to the project site location at http://ladpw.org/wrd/precip/alert_rain/ and click on the 24-hour tab at the top of the page. Record the rain in inches and the name of the selected rain gauge station on the BMP Checklist. The rain gauge shall be monitored at the same time each day.

- Estimate the time of the duration of the rain event for the day the inspection was conducted.

Odors, sheens, turbidity, floating or suspended material or discoloration

- Inspect water discharges for any odors, sheens, turbidity, floating or suspended material or discoloration on the surface. Answer "yes" or "no" to whether there are any odors, sheens, turbidity, floating or suspended materials or discoloration noticed during the inspection. If there is no water discharge noticed, answer not applicable "N/A." If "yes" is the answer identify the source and describe in the space provided.
  - For example, if a sheen is noticed on the surface of the discharge, look upgradient to find and identify the location of the oil/grease/fuel that may have been the source of the sheen and document the findings. The source may have been a leaking vehicle or equipment. The corrective action shall be documented under the BMP Checklist section that addresses vehicles and equipment (See Section 5, NS-8, NS-9, and NS-10)

Description of any BMPs evaluated and any deficiencies noted as well as locations.

- Answer whether each BMP is deployed on site, whether the BMPs are adequately designed and implemented, and whether the BMPs are maintained and effective.
- Locations, deficiencies, corrective actions and implementation dates shall be noted in the space allotted or additional sheets shall be attached. The locations may be referenced to the SWPPP water pollution control drawings (WPCDs) or called out specifically.
  - For example, if the Storm Drain Inlet Protection BMPs are implemented on all drain inlets as shown on the WPCDs, reference to the WPCDs would be adequate.
- If BMPs need maintenance, the locations of each BMP deficiency (e.g., BMP that requires maintenance) shall be identified.
  - For example, "the gravel bag barrier along South St. between Broad Ave. and Park Ave. has broken bags that require replacement."

Corrective actions required and the associated implementation dates.

- The corrective actions may include implementation of BMPs, maintenance, repair or replacement.
  - For example, the stockpile BMPs under WM-3 may have plastic covers on stockpiles that are no actively being used that have been displaced and need to be replaced. The corrective action shall require a cover and berm for

stockpiles not actively being used. In addition, once the corrective actions have been implemented, the implementation date shall be entered.

- Corrective actions identified on the BMP Checklist shall be implemented by the end of the day of the inspection. If the corrective actions are not completed the same day, enforcement action will be taken. If 2 days can be allowed to complete a corrective action, a Notice of BMP Noncompliance form shall be completed and issued to the Contractor. If 2 days cannot be allowed, the Engineer may implement other enforcement actions or begin monetary penalties immediately.
- The corrective action for SWPPP amendment may require more time than "by the end of day." In case a corrective action requires more time than the end of the day, the inspector must track the implementation and document that the SWPPP was amended to complete the BMP Checklist. SWPPP amendments must be completed in accordance with the contract Special Provisions Section 7-8.6.3.7.
- The BMP Checklist must indicate implementation dates of when corrective actions are completed.

Photographs taken during the inspection, if any.

- Photographs if taken during the inspection shall be documented at the end of the inspection form and attached. If more space is needed, attach additional sheets.

LOS ANGELES COUNTY DEPARTMENT OF PUBLIC WORKS
CONSTRUCTION DIVISION

BEST MANAGEMENT PRACTICES (BMP) CHECKLIST INSTRUCTIONS

PURPOSE: To verify the Contractor's effective implementation and maintenance of Best Management Practices (BMPs), and compliance with the project's Storm Water Pollution Prevention Plan (SWPPP).

PROCEDURE: The LACDPW Staff shall thoroughly evaluate each project site and complete all sections of the form. The detailed instructions for filling out the BMP Checklist included in the BMP Manual and Staff Guide must be followed. The BMP Checklist must be signed by the LACDPW Staff inspector and the Area Supervisor.

The LACDPW Staff shall indicate on the checklist, which BMPs are identified in the Contractor's County certified SWPPP with the actual BMPs being deployed on the project. The LACDPW Staff shall indicate whether the BMPs are adequately designed and implemented, maintained and effective. The location, deficiency, corrective action and implementation date must be provided under the comments for any BMP not adequately designed, implemented or maintained and effective.

When one or more of the BMPs have not been effectively designed, implemented or maintained, the LACDPW Staff shall:

1. Verbally discuss the problem with the Contractor's Qualified SWPPP Practitioner (QSP).
2. If the problem is not resolved by the end of the same working day, the LACDPW Staff shall complete a Notice of BMP Noncompliance form which directs the Contractor to take immediate action to implement or maintain the BMP on the project and/or to make appropriate amendments to the project SWPPP. See Notice of BMP Noncompliance form for further instructions if not corrected by end of day.

FREQUENCY: Weekly and before, during and after each storm.

DISTRIBUTION: Original report shall be forwarded to the Office Engineer with each week's project records. A copy shall be retained in the field project files and a copy shall be given to the Contractor.

Notice of BMP Noncompliance Form

(Blank Page)

LOS ANGELES COUNTY DEPARTMENT OF PUBLIC WORKS

NOTICE OF BMP NONCOMPLIANCE FORM
INSTRUCTIONS

PURPOSE: To document and monitor a Contractor's noncompliance with the proper implementation, effectiveness and maintenance of Best Management Practices (BMPs) on all construction projects.

PROCEDURE: When the Contractor has failed to comply with contract Special Provisions or has failed to complete the recommended corrective action(s) identified on the Best Management Practices (BMP) Checklist, the LACDPW Staff shall complete Part 1 of the form.

PART 1

1.) Complete and sign Part 1:
(A) BMP Description,
(B) Location
(C) Recommended corrective action(s), and
(D) Date Corrective Action to be Completed (specify 2 working days or less).

2.) The form shall be signed by the Area Supervisor or the Environmental Compliance Unit (ECU) and then a copy shall be given to the Contractor. Request Contractor signature and make a copy after Contractor signs as recipient.

3.) When the corrective action is completed by the Contractor, write in the date in Column (E) "Date Corrective Action Completed."

4.) If the corrective action is completed by the specified date, check "Yes" in Column (F) Corrective action completed by time/date required (Column D).

5.) If the corrective action is not complete by the required time/date (Column D), the LACDPW Staff shall check "No" in Column (F) indicating the corrective action was not completed, and immediately notify the ECU.

PART 2

6.) Complete and sign Part 2 of the form if a corrective action was not completed by required time/date. Contractual Sanctions shall be implemented on a daily basis until the recommended corrective action is completed to the satisfaction of the LACDPW Staff and the ECU. Write the date once the corrective action is completed in Column (E).

7.) All completed forms shall be reviewed and signed by the Area Supervisor or ECU prior to forwarding them to the Contractor and the main office.

FREQUENCY: When the Contractor is not in compliance with contract Special Provisions or fails to complete recommended corrective actions on the BMP Checklist.

DISTRIBUTION:
1.) Copy to be given to Contractor.
2.) Original form shall be forwarded to the Office Engineer with each week's project records.
3.) The office Engineer shall forward a copy to the ECU.
4.) Copy to be retained in the field project files.

Potential BMP Noncompliance Sanctions

You are advised that failure to comply with or late response to fully implement any of the above required corrective actions for BMP Noncompliance will result in ASSESSIING $1,000.00 per day for each noncompliance described above pursuant to Section 7-8.6 of the contract specifications. Such noncompliance may also be subject to Los Angeles County Code - Section 12.80.630 punishable by a fine of not more than $1,000 or by imprisonment in the county jail for a period of not to exceed six months, or by both such fine and imprisonment. In addition, any noncompliance may also be subject to the Regional Water Quality Control Board assessment of fines up to $10,000 per day for each noncompliance and $10 per gallon of water discharged pursuant to Section 13385 and 13387 of the Porter-Cologne Act.

Introduction

1.1 PURPOSE AND SCOPE

This manual establishes the Los Angeles County Department of Public Works' hydrologic design procedures and serves as a reference and training guide. This manual contains charts, graphs, and tables necessary to conduct a hydrologic study within the County of Los Angeles. Examples provide guidance on using the hydrologic methods.

The primary purpose of this manual is to explain the steps involved in converting rainfall to runoff flow rates and volumes using Public Works' standards. This manual contains procedures and standards developed and revised by the Water Resources Division based on historic rainfall and runoff data collected within the county. The hydrologic techniques in this manual apply to the design of local storm drains, retention and detention basins, pump stations, and major channel projects. The techniques also apply to storm drain deficiency and flood hazard evaluations. Low flow hydrology methods related to water quality standards are also discussed.

This manual compiles information from previous editions of the County of Los Angeles Hydrology Manual, the 2002 Hydrology Manual Addendum, and other reference materials. The standards set forth in this manual govern all hydrology calculations done under Public Works' jurisdiction. Hydrologic procedures in manuals prepared for use by other Divisions within Public Works must be compatible with this manual.

1.2 OVERVIEW OF HYDROLOGIC METHOD

The Los Angeles County Flood Control District initiated its Comprehensive Plan in 1931. Engineers determined that the runoff data within the District was insufficient to create empirical runoff calculations due to limited stream flow data. Lack of stream flow data made it difficult to establish standards

RB-AR33530

and a hydrologic method based on runoff observations. Therefore, the engineers decided that computing design flows based on rainfall was necessary. A rainfall based hydrologic method was deemed more acceptable due to the availability of rainfall data. Figure 1.2.1 shows a rain gage used to collect rainfall data for hydrologic analysis.

Figure 1.2.1
Rain Gage #47D Located at Clear Creek School

Using rainfall-runoff relationships, methods are developed to compute flow rates and define hydrographs based on a design storm event. The two rainfall-runoff methods that apply to hydrology studies within the County of Los Angeles are the Rational and Modified Rational Methods. The use of these rainfall-runoff methods depends on the study requirements.

The Rational Method, Q = CIA, is used for simple hydrology studies within the County of Los Angeles. This method produces a peak flow rate and is only applicable to small areas. The Rational Method applies to development of small areas when no storage volume information is required and overland flow is the primary collection method.

The primary method, in use since the 1930's, is the Modified Rational Method (MODRAT). MODRAT is based on the Rational Method, but uses a time of concentration and a design storm to determine intensities throughout the storm period. The intensities are used to determine the soil runoff coefficient. The rational formula then provides a flow rate for a specific time. Plotting the time specific flow rate provides a hydrograph and an associated flow volume. MODRAT is the standard method for hydrologic studies within the county. Computer programs implement MODRAT to compute runoff data from input parameters.

MODRAT relies on a design storm defined by a time-intensity relationship and a spatial precipitation pattern. The temporal and spatial distributions of rainfall used with MODRAT have changed over the years based on analysis of historic rainfall records. A dimensionless design storm represents rainfall events commonly observed during major extratropical storms in the Los Angeles area. The storm duration is four days. The maximum rainfall quantity occurs on the fourth day.

Rainfall isohyets show the spatial distribution of rainfall over the county. The isohyets represent the depth of rainfall for a standard design frequency over a specified period of time. Multiplying the unit hyetograph by the rainfall isohyetal depth produces the design storm for a specific area. Figure 1.2.2 shows rainfall isohyets in the County of Los Angeles. This area-specific design storm and an area-specific time of concentration define the time-intensity relationship for a particular subarea. Each subarea requires an area specific time of concentration and design storm.

RB-AR33532

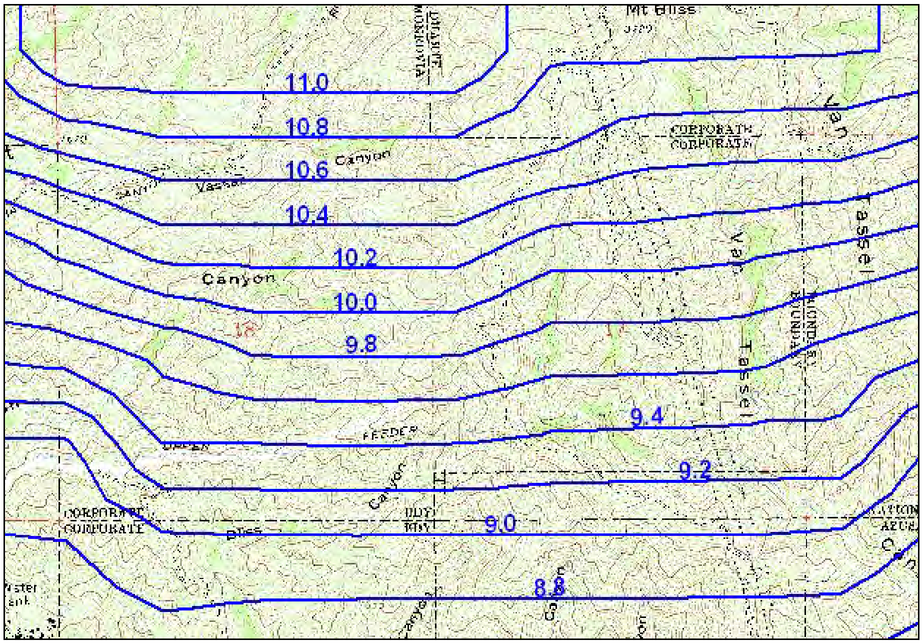

Figure 1.2.2
50-year, 24-hour Rainfall Isohyets in the County of Los Angeles

Calculation of the time of concentration has evolved over time. Currently, time of concentration calculations rely on a regression equation based on the kinematic wave theory.

Reservoir routing of hydrographs for storage uses the Modified Puls method. This method is based on a finite difference approximation of the continuity equation coupled with an empirical representation of the momentum equation.[1] This method is widely used for reservoir routing in hydrologic studies and is the approved method for use within the County of Los Angeles.

RB-AR33533

CHAPTER

2

Physical Factors Affecting Hydrology

2.1 TOPOGRAPHY

The County of Los Angeles covers 4,083 square miles and measures approximately 66 miles from east to west and 73 miles from north to south. The topography within the county is 25 percent mountains, 10 percent coastal plain, and 65 percent foothills, valley, or desert. Elevations range from sea level to a maximum of 10,064 feet at the summit of Mount San Antonio. The county is divided into five principal drainage systems: Los Angeles River Basin, San Gabriel River Basin, Santa Clara River Basin, Coastal Basin, and Antelope Valley.

The coastal plain slopes mildly and contains relatively few depressions or natural ponding areas. The slopes of the main river systems crossing the coastal plain, such as San Gabriel River, Los Angeles River, and Ballona Creek, range from 4 to 14 feet per mile.

The mountain ranges within the County of Los Angeles are generally aligned in an east-west direction and are part of the Transverse Ranges. The major range in the county is the San Gabriel Mountains. Most of the mountainous areas lie below 5,000 feet with only 210 square miles above this elevation. The mountainous area is rugged. The deep "V"-shaped canyons with steep walls are separated by sharp dividing ridges. The average slope of the canyon floors ranges from 150 to 850 feet/mile in the San Gabriel Mountains.

2.2 GEOLOGY AND SOILS

The geologic setting of the County of Los Angeles is largely the result of the tectonic plate boundary between the North American and Pacific plates that runs along the northern edge of the county. The San Andreas Fault forms the boundary between these plates and bisects the state in a northwest to southeast direction. In the Los Angeles area, the fault bends to an east-west

RB-AR33535

orientation before returning to its former course. Crustal forces resulting from this change in geometry are uplifting the San Gabriel Mountains. The San Gabriel Mountains experience a high rate of uplift that is being counteracted by high erosion rates. As a result, the county's valleys contain deep deposits of alluvial sediments.[1]

Igneous, sedimentary, and metamorphic rock groups are present within the county. The San Gabriel Mountains and Verdugo Hills are composed primarily of highly fractured igneous rock, with large formations of granitic rock exposed above coarse and porous alluvial soils. Faulting and deep weathering have produced pervious zones in the rock formations. These rock masses have a comparatively shallow soil mantle caused by accelerated erosion on the steep slopes. Figure 2.2.1 illustrates a weathered igneous rock outcrop along Highway 39 in San Gabriel Canyon.

Figure 2.2.1
Weathered Igneous Rock Outcrop Along Highway 39 in San Gabriel Canyon

Other mountainous and hilly areas within the county are composed primarily of folded and faulted sedimentary rocks, including shale, sandstone, and

RB-AR33536

conglomerate. Residual soils in these areas are shallow and are generally less pervious than those of the San Gabriel Mountains.

Valley and desert surface soils are alluvial and grade from coarse sand and gravel near canyon mouths to silty clay and clay in the lower valleys and coastal plain. The alluvium builds up through repeated deposition of debris and reaches depths as great as 2,000 feet. Where there is little clay, this material is quite porous. Impervious lenses and irregularities divide the alluvium into several distinct groundwater basins. Valley soils are generally well drained with relatively few perched water or artesian areas.

2.3 VEGETATIVE COVER AND LAND USE

The principal vegetative cover of upper mountain areas consists of various species of brush and shrubs known as chaparral. Most trees found on mountain slopes are oak. Figure 2.3.1 shows oak trees along a stream in the San Gabriel Mountains. Pine, cedar, and juniper are found in ravines at higher elevations and along high mountain summits. Alder, willow, and sycamore are found along streambeds at lower elevations.

Figure 2.3.1
Oaks Trees Along a Stream in the San Gabriel Mountains

RB-AR33537

The chaparral is extremely flammable, and extensive burning of the mountain vegetation frequently occurs during dry, windy weather. Chaparral depends on fire to germinate and has the ability to sprout quickly after fire, reestablishing the watershed cover within a period of five to ten years. Figure 2.3.2 shows the revegetation of chaparral after a fire.

Figure 2.3.2
Revegetation of Chaparral After Fire

Grasses are the principal vegetation on the low elevation hills. Most of the hills and valleys have been converted to urban and suburban use in the portion of the county south of the San Gabriel Mountains. Development of the desert areas north of the San Gabriel Mountains and in the Santa Clarita Valley has increased in recent years and is proceeding at an accelerated rate.

2.4 CLIMATE

The climate within the county varies greatly. The windward side of the San Gabriel Mountain range is subtropical while the leeward side in the Mojave Desert is arid. Seasonal, normal precipitation totals for representative areas are shown in Table 2.4.1.

RB-AR33538

Location	Average Annual Precipitation (in)
Coastal Plain	15.5
San Gabriel Mountains	32.9
Desert – Antelope Valley	7.8

Table 2.4.1
Seasonal Normal Precipitation for Various Climate Zones

Most precipitation occurs between December and March. Precipitation during summer months is infrequent, and rainless periods of several months are common.

Snow rarely falls on the coastal plain. Snowfall at elevations above 5,000 feet frequently occurs during winter storms. This snow melts rapidly except on the higher peaks and north facing slopes.

January and July are the coldest and warmest months of the year, respectively. Table 2.4.2 illustrates the seasonal variation of temperature in the mountain and coastal plain areas.

	Los Angeles (Coastal Plain)	Mt Wilson (San Gabriel Mts)
Average January Minimum Temperature	48°	35°
Average July Maximum Temperature	84°	80°
Record High	112°	99°
Record Low	28°	9°

Table 2.4.2
Characteristic Temperatures of the Mountain and Coastal Plain Areas

RB-AR33539

2.5 HYDROMETEOROLOGIC CHARACTERISTICS

Hydrometeorological characteristics are greatly influenced by the mountains within the county. Winter storms affect the coastal areas while convective storms affect the desert areas.

Coastal and Mountain Areas

Most precipitation in the Los Angeles area occurs in the winter due to extratropical cyclones from the North Pacific. Major storms consist of one or more frontal systems, extending 500 to 1,000 miles in length. The frontal systems produce rainfall simultaneously throughout the county, occasionally lasting four days or longer.

These storms approach Southern California from the west or southwest with southerly winds that continue until the front passes. The mountain ranges lie directly across the path of the inflowing warm, moist air. The coastal and inland ranges cause the warm air to rise. As it rises, precipitation forms and falls. This orographic effect intensifies rainfall along the mountains and coastal areas. As a result, rainfall intensities and totals in these areas increase. The effect of snow melt on flood runoff is significant only in the few cases where warm spring rains from southerly storms fall on a snow pack. Temperatures throughout the county usually remain above freezing during major storms. Figure 2.5.1 is a view of the coastal area within the County of Los Angeles.

Figure 2.5.1
Coastal Area

RB-AR33540

Desert Areas

Orographic precipitation over the mountains produces a rain shadow on the leeward side of the mountains. As a result, the northern San Gabriel Mountains and the Mojave Desert regions experience primarily summer convective rainfall. The most serious floods in many desert areas may result from convective summer storms. Figure 2.5.2 shows a view of the desert area within the County of Los Angeles.

Figure 2.5.2
Desert Area Near Lancaster

2.6 RUNOFF CHARACTERISTICS

Runoff characteristics are influenced by soil type, slope, vegetation, and many other conditions. General regions behave differently based on these factors and runoff varies greatly between mountain and valley areas.

Mountain Areas

Steep canyon walls and channel slopes rapidly concentrate storm runoff in mountainous areas. Depression and detention storage effects are minor in this rugged terrain.

RB-AR33541

The moisture content of mountain soils has a pronounced effect on runoff during a storm. Precipitation during periods of low soil moisture is almost entirely absorbed by the porous soils. Soil moisture is lowest at the beginning of the rainy season due to evapotranspiration during the preceding summer months. Significant surface runoff does not occur until soil moisture is near field capacity, except during extremely intense rainfall. Consequently, in certain areas, significant runoff occurs as subsurface flow, or interflow, rather than direct runoff. Most streams in the county are intermittent. Natural year-round perennial discharge is mostly limited to springs in portions of the San Gabriel Mountains.

Hill and Valley Areas

Runoff concentrates rapidly below the generally steep slopes in hilly areas. Runoff rates from undeveloped hilly areas are normally smaller than those from mountain areas of the same size. Development in hilly areas decreases runoff concentration times considerably due to increased channelization. Runoff volumes and rates increase due to increased imperviousness.

Debris production from undeveloped hilly areas is normally less than debris production from mountainous areas of the same size. Increased development reduces erosion and limits debris in storm flow.

Figure 2.6.1 shows a hilly area located in the Santa Clara River Watershed.

Figure 2.6.1
Hills in Santa Clara River Watershed

RB-AR33542

Runoff in the valleys and coastal plain is affected by ponding and spreading of flows. Valley areas are affected by development. In highly developed valley areas, local runoff volumes increase as impervious materials replace the soil. Peak runoff rates for valley areas increase due to the elimination of natural ponding areas and improved hydraulic efficiency. Conveyances, such as streets and storm drain systems carry the water to the ocean more rapidly and do not allow infiltration. Figure 2.6.2 shows a view of the Los Angeles basin from the San Gabriel Mountains.

CHAPTER

3

Major Watersheds and Tributaries

There are five major watersheds within the County of Los Angeles. Four of these drain to the ocean and the fifth enters dry lakes in the desert. The watersheds are unique and are developed to different extents. Watershed descriptions and a location map shown in Figure 3.1 are provided to help understand the hydrologic conditions within each watershed.

Figure 3.1
Major Watersheds in the County of Los Angeles

RB-AR33544

3.1 LOS ANGELES RIVER[1]

The Los Angeles River Watershed covers over 830 square miles. The watershed includes the western portion of the San Gabriel Mountains, the Santa Susana Mountains, the Verdugo Hills, and the northern slope of the Santa Monica Mountains. The river flows from the headwaters in the western San Fernando Valley and outlets in San Pedro Bay near Long Beach. The river crosses the San Fernando Valley and the central portion of the Los Angeles Basin. The watershed terrain consists of mountains, foothills, valleys, and the coastal plain.

The Los Angeles River and many of its tributaries have been the subject of extensive engineering work to reduce the impacts of flood events. Prior to development, the Los Angeles River system was typical of other streams in the southwest. The river's channel was broad and often shifted location within the flood plain due to the high sediment loads. The stream location within the coastal plain has varied greatly over the years. Between 1815 and 1825, the river changed course completely. Breaking its banks in what is now Downtown Los Angeles, the river followed the course of Ballona Creek, reaching the ocean at a location 20 miles from its current outlet.

Numerous flood control facilities were constructed in the early 20th century, as development began to take place on this wide flood plain. The concrete sections of the Los Angeles River were constructed between the late 1930's and the 1950's. Channel improvements and extensive watershed development decrease times of concentration and increase runoff flow rates and volumes. The Los Angeles County Flood Control district constructed three major dams during this period: Pacoima, Big Tujunga and Devil's Gate. The dams were built to reduce downstream flow rates and conserve water for ground water recharge purposes. In the Rio Hondo drainage area, several dams were constructed including Eaton Wash, Sierra Madre, Santa Anita and Sawpit. Additionally, the U.S. Army Corps of Engineers operates four major dams in the watershed to assist in flood control. The four dams are Hansen, Lopez, Sepulveda and Whittier Narrows. Figure 3.1.1 is a view of Big Tujunga Dam after the January 2005 storms.

RB-AR33545

Figure 3.1.1
Big Tujunga Dam
January 11, 2005

The parts of the San Gabriel Mountains tributary to the Los Angeles River contain some of the most prolific sediment producing streams in the world. Intense rainfall, coupled with highly erodible sediment, produces damaging debris discharges. Numerous debris basins have been constructed along the foothills of the San Gabriel Mountains to remove sediment from the flow.

The Los Angeles River Watershed has a diverse land use pattern. The upper portions of the watershed are covered by Angeles National Forest and other rural areas. The remainder of the watershed is highly developed. The watershed has large areas of commercial, residential, and industrial development. Few parks or natural areas exist in the lower watershed.

The major tributaries of the Los Angeles River include Burbank Western Channel, Pacoima Wash, Tujunga Wash, and Verdugo Wash in the San Fernando Valley; and the Arroyo Seco, Compton Creek, and Rio Hondo in the Los Angeles Basin. Much of this tributary network has also been lined with concrete to meet flood control needs. Figure 3.1.2 shows a view of the Los Angeles River at Willow Street.

RB-AR33546

Figure 3.1.2
Los Angeles River
At Willow Street

3.2 SAN GABRIEL RIVER

The San Gabriel River Watershed is located in the eastern portion of the county. The river drains the San Gabriel Mountains to the north and is bounded by the Los Angeles River Watershed and Santa Ana River Watersheds. The watershed drains 640 square miles. The watershed outlets into the Pacific Ocean between Long Beach and Seal Beach after passing through the Alamitos Bay estuary. Tributaries to the San Gabriel River include: Walnut Creek, San Jose Creek, and Coyote Creek.

The upper portions of the watershed are contained almost entirely within the Angeles National Forest and are nearly untouched by development. The mountains in this area are extremely rugged with steep V-shaped canyons. The vegetation is dominated by chaparral and coastal sage scrub with patches of oak woodlands. Conifers are dominant at higher elevations. The streambeds in the area contain sycamore and alder woodlands.[2]

RB-AR33547

In contrast, the lower part of the watershed is mostly developed below the mouth of the San Gabriel Canyon. The developments include commercial, residential, and industrial use. The developed area in the San Gabriel Valley and Los Angeles Basin comprises 26% of the total watershed area. Figure 3.2.1 shows the upper natural portion of the San Gabriel River.

Figure 3.2.1
Upper Portion of the San Gabriel River

Similar to the Los Angeles River, the San Gabriel River once occupied a wide floodplain and shifted course to accommodate large flows and sediment loads. Development of the floodplain required changing the character of the river dramatically since periodic inundation of the floodplain was not compatible with the new land uses.

Several major dams and debris basins impound floodwaters and prevent debris flows originating in the San Gabriel Mountains. These include Cogswell Dam, San Gabriel Dam, Morris Dam, Big Dalton Dam, San Dimas Dam, Live Oak Dam, and Thompson Creek Dam. Many of these facilities were constructed in the 1930's and have proven their worth by preventing significant damage from large flood events. Major flood events occurred in 1938, 1969, 1978, 1983, 1998, and 2005. Additionally, the U.S. Army Corps of Engineers operates the Santa Fe Dam and Whittier Narrows Dam in the watershed to assist in flood control. Figure 3.2.2 shows the San Gabriel Dam at full capacity.

RB-AR33548

Figure 3.2.2
San Gabriel Dam at Full Capacity

The San Gabriel River has been channelized below Santa Fe Dam to aid in flood prevention. However, the channel invert was left unlined for much of its length between Santa Fe Dam and Florence Avenue in Downey. The unlined bottom promotes infiltration of flood waters released from upstream dams. Public Works installed rubber dams to further utilize the river bottom for ground water recharge. Figure 3.2.3 is a rubber dam located in the lower portion of the river.

Figure 3.2.3
Rubber Dam Located in the Lower Portion of the San Gabriel River

RB-AR33549

The most significant spreading ground facilities in the county are located in the San Gabriel River watershed. Runoff resulting from storm events is diverted into the spreading facilities and allowed to recharge groundwater. Major spreading grounds are located at the mouth of San Gabriel Canyon and in the Montebello area downstream of the Whittier Narrows Dam.

3.3 SANTA CLARA RIVER

The Santa Clara River originates in the northern slopes of the San Gabriel Mountains at Pacifico Mountain and travels west into Ventura County, discharging into the Pacific Ocean near the City of Ventura. The river runs approximately 100 miles from the headwaters near Acton, California, to the ocean. The river drains an area of approximately 1,600 square miles.

The upper portion of the river, within the County of Los Angeles, has a watershed area of approximately 644 square miles. Ninety percent of this area is mountainous with steep canyons; while the remaining ten percent is alluvial valleys.[3] The area is mostly undeveloped with a large portion in the Angeles National Forest. There are some mixed-use developed areas concentrated in or near the City of Santa Clarita. The watershed is currently experiencing an accelerated rate of development in areas adjacent to the river. Figure 3.3.1 shows the Santa Clara River after the 1978 storms.

Figure 3.3.1
Santa Clara River Downstream of Magic Mountain Parkway
March 4, 1978

RB-AR33550

The Santa Clara River and its tributaries are ephemeral streams characterized by alluvial soils. Discharge occurs quickly during rainfall events and diminishes quickly after rainfall has ceased. As in other county watersheds, the mountain and foothill areas are susceptible to debris-laden flows during intense rainfall, especially when a watershed is recovering from fire.[4]

The river remains in a generally natural state with some modifications related to the development of the floodplain. The expected population increase will continue to produce floodplain encroachment, requiring additional bank protection, channelization, and channel crossings. The expected population increase, as well as increased imperviousness, will impact the hydrologic characteristics of the river and the sediment balance.

Some of the major tributaries in the county's portion of the Santa Clara River watershed include: Castaic Creek, San Francisquito Canyon, Bouquet Canyon, Sand Canyon, Mint Canyon, and the South Fork of the Santa Clara River.

3.4 COASTAL[5]

The Coastal watershed is comprised of a number of individual watersheds that outlet into Santa Monica and San Pedro Bays. These include the major watersheds of Malibu Creek, Topanga Creek, Ballona Creek, and the Dominguez Channel. These watersheds have unique topographic and hydrologic characteristics ranging from undeveloped to highly urbanized. For simplicity, these coastal watersheds are grouped together due to their relatively small sizes.

The Malibu Creek Watershed is comprised of 109 square miles at the western end of the County of Los Angeles and extends into Ventura County. Most of the watershed is undeveloped public land. There is sporadic but increasing development throughout the area. The most extensive development is centered along US Highway 101. The northern portion is hilly while the southern portion, near the ocean, is rugged mountain terrain. Malibu Creek drains into the Pacific Ocean near the Malibu Civic Center. A portion of Malibu Creek is shown in Figure 3.4.1.

RB-AR33551

Figure 3.4.1
Malibu Creek

Topanga Creek drains 18 square miles in the central Santa Monica Mountains. The watershed is primarily rural with widely scattered residential and commercial development. The creek flows unobstructed along its course and empties into the Santa Monica Bay in an unincorporated portion of the county east of Malibu.

Ballona Creek is a flood control channel that drains the western Los Angeles basin. The watershed area is bounded by the Santa Monica Mountains on the north and the Baldwin Hills on the south. It extends east nearly to downtown Los Angeles. The total watershed area is roughly 130 square miles. The area is primarily developed but includes undeveloped areas on the south slope of the Santa Monica Mountains. The land use is 64%

RB-AR33552

residential, 8% commercial, 4% industrial, and 17% open space. The major tributaries to Ballona Creek include: Centinela Creek, Sepulveda Canyon Channel, Benedict Canyon Channel, and numerous storm drains. The watershed drains into Santa Monica Bay at Marina del Rey.

Figure 3.4.2 is a view of the concrete lined portion of Ballona Creek.

Figure 3.4.2
Ballona Creek

The Dominguez Watershed is comprised of approximately 133 square miles in the southern portion of the county. The watershed extends from near the Los Angeles International Airport to the Los Angeles Harbor. The area is almost completely developed with regions of residential, commercial, and industrial land use. The storm drains and flood control channel network, as opposed to natural drainage features, define the watershed.

There are many other smaller watersheds in the Coastal drainage area that drain developed and undeveloped areas directly to the Pacific Ocean.

RB-AR33553

3.5 ANTELOPE VALLEY

The Antelope Valley encompasses approximately 1,200 square miles in the northern portion of the County of Los Angeles. The valley is bounded on the north by the Tehachapi Mountains and on the south by the Sierra Pelona and the San Gabriel Mountains. Numerous streams from the mountains and foothills flow across the valley floor. The valley lacks defined drainage channels outside of the foothills and is subject to unpredictable drainage patterns.

Nearly all the surface water runoff from the Los Angeles portion of the Antelope Valley accumulates on Rosamond Dry Lake near the Kern County Line. A small portion is tributary to other dry lakes in the area. This 20 square mile playa is dry during most of the year, but is likely to be flooded during prolonged periods of winter precipitation. Surface runoff, as well as discharges from groundwater, remain on the dry lake until removed by infiltration and evaporation. Anecdotal evidence indicates that at times the playa may be underwater for up to five months at a time, as occurred during the winter of 1965-66.

The valley contains the developed areas of Lancaster and Palmdale. The remainder of the valley is sparsely developed. However, the valley is one of the most rapidly developing areas in the county. Rapid development is likely to continue for some time. This development will significantly alter the hydrologic characteristics of the basin.

A view of Antelope Valley is shown in Figure 3.5.1.

CHAPTER

4

Policy on Levels of Protection

4.1 DEPARTMENT POLICY MEMORANDUM

A Department of Public Works memorandum dated March 31, 1986, General Files No. 2-15.321, established the policy on levels of flood protection. This policy describes degrees of flooding and which design storms should be used for certain conditions and structures. Chapter 5 defines the design storms for use in the County of Los Angeles.

4.2 CAPITAL FLOOD PROTECTION

The Capital Flood is the runoff produced by a 50-year frequency design storm falling on a saturated watershed (soil moisture at field capacity). A 50-year frequency design storm has a probability of 1/50 of being equaled or exceeded in any year. Capital Flood protection also requires adding the effects of fires and erosion under certain conditions. This section describes specific criteria for applying the burning and bulking requirements for Capital Flood protection.

The following sections describe facilities and structures required to meet the Capital Flood level of protection.

Natural Watercourses

The Capital Flood level of protection applies to all facilities, including open channels, closed conduits, bridges, dams, and debris basins not under State of California jurisdiction. These facilities must also be constructed in or intercept flood waters from natural watercourses. Facilities under the State of California jurisdiction must also meet the state's criteria, which may include the Probable Maximum Flood criteria described in Section 4.4.

RB-AR33556

A natural watercourse is a path along which water flows due to natural topographic features. For definition purposes, a natural watercourse drains a watershed greater than 100 acres. Natural watercourses have not been subject to major engineering works such as channel realignment or bank protection. The watercourse must also meet one or more of the following conditions during a Capital Flood:

1. Flow velocities greater than 5 ft/sec.

2. Flow depths greater than 1.5 feet.

Replacement of the natural watercourse with flood control facilities that do not provide the Capital Flood level of protection requires water surface elevation analysis. The water surface elevation must be at least one foot below the base of existing dwellings adjacent to the channel. The construction must also meet the requirement of the National Flood Insurance Program described in Section 4.6. An example of a natural watercourse in Bouquet Canyon is shown in Figure 4.2.1.

Figure 4.2.1
Bouquet Canyon
Natural Watercourse
in June 2005

RB-AR33557

Floodways

The Capital Flood applies to all areas mapped as floodways. See Section 4.6 for more information on floodways.

Natural Depressions or Sumps

The Capital Flood level of protection applies to all facilities constructed to drain natural depressions or sumps. These facilities include channels, closed conduits, retention basins, detention basins, pump stations, and highway underpasses. A depression or sump is an area from which there is no surface flow outlet and must meet one or more of the following conditions during a Capital Flood:

1. Ponded depth of 3 feet or greater.

2. Ponded water surface elevations within one foot below the base of adjacent dwellings resulting from construction of facilities with less than the Capital Flood capacity. This condition does not apply if ponded water can escape as surface flow before reaching the base of adjacent dwellings during the Capital Flood.

Figure 4.2.2 shows an example of a flooded sump at the intersection of San Fernando Road and Tuxford Street in Sun Valley.

Figure 4.2.2
Flooded Sump at Intersection of San Fernando Road and Tuxford Street
January 9, 2005

RB-AR33558

Sumps with drainage from roadways require special care. If flows reach the sump by following the roadway from upstream, use the Capital Flood on all areas upstream of the sump that drain to the roadway. The roadway must carry the Capital Flood capacity with a water surface elevation below the private property line. Otherwise, drainage facilities must be added beneath the roadway. See the Los Angeles County Highway Design Manual[1], and Chapter 44 of the Land Development Division Guidelines.

Culverts

The Capital Flood level of protection applies to all culverts under major and secondary highways.

Tributary Areas Subject to Burning

Canyons and mountainous areas within the County of Los Angeles are subject to burning. The Capital Flood applies to all areas likely to remain in a natural state, regardless of size. Burned canyons and mountainous areas also add debris to the runoff. Therefore, flow from "burned" areas must be "bulked." Bulking reflects increases in runoff volumes and peak flows related to inclusion and transport of sediment and debris.

Section 6.3 discusses the development of burned watershed hydrology. Section 3.3 of the Public Works' Sedimentation Manual contains information on bulking flows.

4.3 URBAN FLOOD PROTECTION

All drainage facilities in developed areas not covered under the Capital Flood protection conditions must meet the Urban Flood level of protection. The Urban Flood is runoff from a 25-year frequency design storm falling on a saturated watershed. A 25-year frequency design storm has a probability of 1/25 of being equaled or exceeded in any year.

Street flow due to the urban flood may not exceed the private property line elevation. However, runoff can be conveyed in drains under the street and on the street surface. Urban Flood runoff is allowed to flow in the street to the point where the flow reaches the street capacity at the property line. Depth analysis is to be started at the upstream end of the watershed. The flow should be split to allow conveyance in the street and in a drain below the street when flows exceed street capacity. Drains must at least carry flow

RB-AR33559

from the 10-year frequency design storm. See the Los Angeles County Highway Design Manual[1] and Chapter 44 of the Land Development Division Guidelines for road design requirements.

The street or highway must carry the balance of the 25-year frequency design storm below the property line. The drain may carry more flow to lower the water surface on the street to below the private property line or meet other requirements for vehicular or pedestrian traffic. See the Los Angeles County Highway Design Manual for the traffic requirements[1]. The maximum allowable pipe diameter for hydrology studies is 96 inches. Beyond this size, choose a rectangular channel conveyance. Figure 4.3.1 provides an example of street flow.

Figure 4.3.1
Street Flow After 1938 Storm

4.4 PROBABLE MAXIMUM FLOOD PROTECTION

The Probable Maximum Flood (PMF) results from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in the region[2]. The Probable Maximum Precipitation[3] (PMP) represents the greatest depth of rainfall theoretically possible for a

RB-AR33560

given duration over a given drainage basin. The PMF occurs when the PMP falls over watersheds that have reached field capacity (saturated) conditions.

California's Division of Safety of Dams (DSOD) requires a PMF analysis for dams and debris basins that hold at least 1,000 acre-feet, are 50 feet or higher, would require at least 1,000 people to be evacuated, and have a damage potential of $25,000,000 or more. Most dams and debris basins (earth embankment, concrete, or other materials) in the County of Los Angeles must safely pass the PMF[4]. Figure 4.4.1 shows a chart of the State's height and storage parameters that define dam jurisdiction[5]:

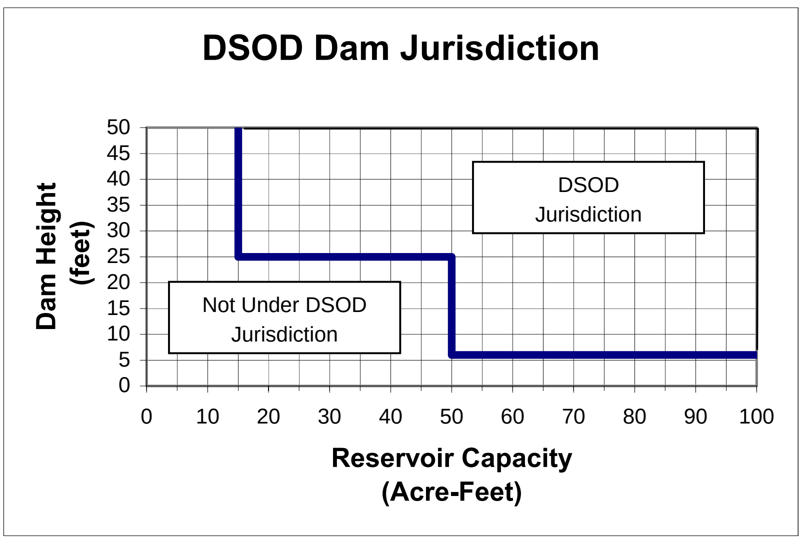

Figure 4.4.1
Dam Jurisdiction Chart

Spillway sizing requirements for dams and debris basins is available through the California Department of Water Resources, Division of Safety of Dams[4]. Figure 4.4.2 is a picture of Morris Dam, constructed in 1932, which falls under DSOD jurisdiction.

RB-AR33561

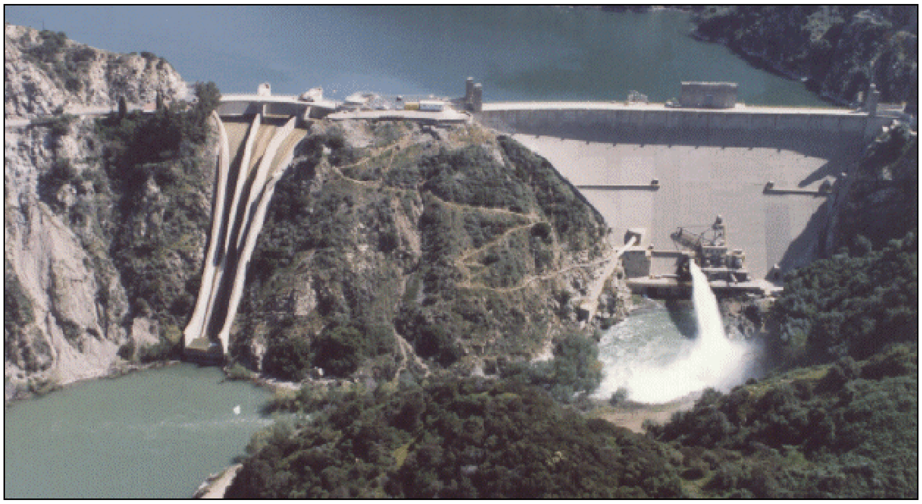

Figure 4.4.2
Morris Dam
1993

4.5 NATIONAL FLOOD INSURANCE PROGRAM

The National Flood Insurance Program (NFIP) set the 100-year flood as the standard for flood insurance protection. The 100-year flood relies on historic runoff records for definition. The standard makes no allowance for future urbanization or the possible inclusion of debris in the flow. In flood hazard areas, the federal standard requires the finished floor elevation of proposed dwellings to be at least 1 foot above the water surface elevation of the 100-year flood[5]. The Base Flood Elevation (BFE) refers to the water surface elevation of the 100-year flood on the pre-developed condition.

Public Works uses the Capital Flood peak flow rate for Los Angeles County floodway mapping standards. FEMA Flood Insurance Rate Maps (FIRM Maps) are available at: http://www.ladpw.org/apps/wmd/floodzone. More information about the NFIP level of protection requirements are available at the www.fema.gov/nfip/ website.

The floodway is determined using the 1-foot rise criterion. Some misinterpret this to mean that development in a floodway is permitted if it does not raise the BFE more than one foot. Floodplain management regulations dictate that any rise in the BFE, as a result of a floodway encroachment, is unacceptable without a Conditional Letter of Map Revision[6]. FEMA provides guidelines and standards for flood hazard mapping and requirements to meet the NFIP level of protection. More information on the FEMA requirements is found at http://www.fema.com/fhm/gs_main.shtm.

RB-AR33562

4.6 COMPATIBILITY WITH EXISTING SYSTEMS

The level of protection standards may require modification if the receiving system has limited capacity at the proposed drain's outlet. If the receiving drain will be replaced or relieved in the future, size the proposed drain for the appropriate level of protection. The proposed drain capacity is restricted to match the capacity available in the downstream drain when no future relief is planned.

Solutions to the situations with restricted capacities require project specific decisions. The Design Division of Public Works should review the proposed drainage system and the outlet conditions to determine the compatible level of protection.

4.7 EXISTING LEVEL OF FLOOD PROTECTION

Sub-surface drainage often replaces surface drainage when land is developed. Replacing or modifying surface drainage systems requires maintaining or increasing the original level of flood protection. The total capacity, sub-surface and surface, must equal or exceed the original surface capacity. Adequate surface drainage capacity must be retained if the proposed sub-surface drain provides a lower level of protection than the original surface drainage system.

4.8 MULTIPLE LEVELS OF FLOOD PROTECTION

There are numerous instances where a drainage system must provide more than a single level of flood protection. Drainage systems must meet the criteria described in this chapter of the Hydrology Manual.

For example, there may be a natural canyon area tributary to a proposed drainage system that drains an urban area containing a sump. The proposed drainage system must convey the burned and bulked Capital Flood flow from the canyon area, protect the sump from a Capital Flood, and protect the developed area from the Urban Flood. Refer to Table 4.1.1 of the Sedimentation Manual to determine if a structure, such as a debris basin, is needed for the natural canyon. If a structure is needed, then only the burned flow is carried through the drainage system.

RB-AR33563

CHAPTER

5

Rainfall and Design Storm Characteristics

The Department of Public Works' hydrologic method uses a design storm derived from historic rainfall data. Observed major extratropical storms in the Los Angeles region provided a pattern for the design storm. The storm does not represent an actual event but is an idealized series of precipitation data that fits a specific design objective. The design storm is a composite determined by analysis of regional rainfall patterns. Three components define the design storm: an Intensity-Duration-Frequency (IDF) equation, a temporal distribution, and a spatial rainfall distribution.

Public Works developed the rainfall distribution and design storms in 2002. A network of approximately 250 rain gages allowed an accurate definition of the spatial and temporal variability of rainfall over the county. The average historic record length for these gages is 75 years.

Data analysis provided the three components needed for the design storm. Analysis of rainfall data within the county provided the IDF equation, which is a relationship between rainfall intensity, duration, and frequency. Then a 24-hour temporal distribution was established using the IDF relationship. The 24-hour temporal distribution is represented by the unit hyetograph, which plots rainfall intensity versus time. Finally, a set of isohyets was established for the county. The isohyets represent rainfall depths for a specific duration and frequency and are applied to the unit hyetograph. The result is a hyetograph for a given location and recurrence interval, which is the design storm for a specific subarea.

RB-AR33565

5.1 RAINFALL INTENSITY-DURATION-FREQUENCY

The fundamental unit of rainfall is depth. Rain gages directly measure depth. Measuring depth and time provides intensity. Intensity is the amount of rain that has fallen per unit of time. The average intensity is calculated by dividing a rainfall depth by the duration, the time over which the rainfall accumulated. The average intensity is:

Equation 5.1.1

$$\text{Intensity} = \frac{\text{Rain Depth}}{\text{Duration}}$$

The peak intensity produces the largest runoff rate. If rainfall were constant throughout a storm, any duration less than the storm duration would produce the same intensity. However, rainfall is rarely constant for the storm duration and intensity varies.

Table 5.1.1 shows the calculated intensity for various durations. Intensities are calculated using the rainfall depth and storm times in the first two rows. Each of the duration rows show intensities calculated based on different durations. For example, I_5 is the intensity calculated over a period of 5 minutes starting at t = 0 and ending at t = 5 minutes, or starting at t = 5 and ending at t = 10 minutes, etc. Bold text denotes the maximum intensity for each intensity duration. The table shows a decrease of maximum intensity as duration increases for a storm with non-uniform precipitation.

Table 5.1.1
Rainfall Intensity Calculations for Various Durations

	Storm Time (minutes)	0	5	10	15	20	25	30	35	40	45	50	55	60
	Cumulative Precipitation (in)	0	0.5	1.5	2.0	2.25	2.5	2.5	2.5	2.5	2.5	2.5	2.5	2.5
Durations	I_5 (in/hr)	-	6.0	12.0	6.0	3.0	3.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
	I_{10} (in/hr)	-	-	9.0	9.0	4.5	3.0	1.5	0.0	0.0	0.0	0.0	0.0	0.0
	I_{30} (in/hr)	-	-	-	-	-	-	5.0	4.0	2.0	1.0	0.5	0.0	0.0
	I_{60} (in/hr)	-	-	-	-	-	-	-	-	-	-	-	-	2.5

Design decisions often require assigning a probability of occurrence to the rainfall event. Statistical analysis of rainfall intensity data yields a probability that such a rainfall will occur in a given year. The reciprocal of this probability is the frequency. The frequency represents the time between two occurrences of a specific rainfall event. The rainfall frequency is inversely proportional to the size of the event. Large rainfall events are much less common than small rainfall events.[1]

A study of rain gage data provided relationships between intensity, duration, and frequency within the County of Los Angeles. The study analyzed historic records for 107 rain gages and determined the maximum intensities for rainfall durations of 5, 10, 15, 30, 60, 120, 180, 240, 300, 720, and 1440 minutes. The analysis looked at the frequencies associated with the various intensities. Each intensity was assigned frequencies of 2-, 5-, 10-, 25-, 50-, 100-, and 500-years based on the Gumbel extreme value distribution of each gage.

The 1440 minute, or 24-hour duration, was a primary focus of this analysis. Sets of factors were developed to relate the rainfall depths of various frequencies to the 50-year rainfall frequency. Section 5.3 details the development of these factors.

The normalized intensity equation relates the intensity, duration, and frequency (IDF). The Hydrologic Method authorization memorandum outlines development of the equation.[2] Equation 5.1.2 provides the normalized IDF relationship:

$$\frac{I_t}{I_{1440}} = \left(\frac{1440}{t}\right)^{0.47}$$ **Equation 5.1.2**

Where: t = Duration in minutes

I_t = Rainfall intensity for the duration in in/hr

I_{1440} = 24-hour rainfall intensity in in/hr

$\frac{I_t}{I_{1440}}$ = Peak normalized intensity, dimensionless

RB-AR33567

Equation 5.1.2 allows calculation of the peak-normalized intensity for durations from 5 to 1440 minutes. For durations less than 5 minutes, I_t / I_{1440} = 14.32. Figure 5.1.1 graphically presents the peak-normalized intensity for durations of 5 minutes to 30 minutes.

In addition to its role in defining the design storm, Equation 5.1.2 is used to calculate the peak intensity for time of concentration calculations described in Section 7.3. The equation calculates the intensity for any duration when the 24-hour rainfall intensity is known. Section 5.4 contains an example that illustrates the use of Equation 5.1.2 and Table 5.1.1 to determine the 25-year, 10-minute intensity from the 50-year, 24-hour rainfall isohyetal data.

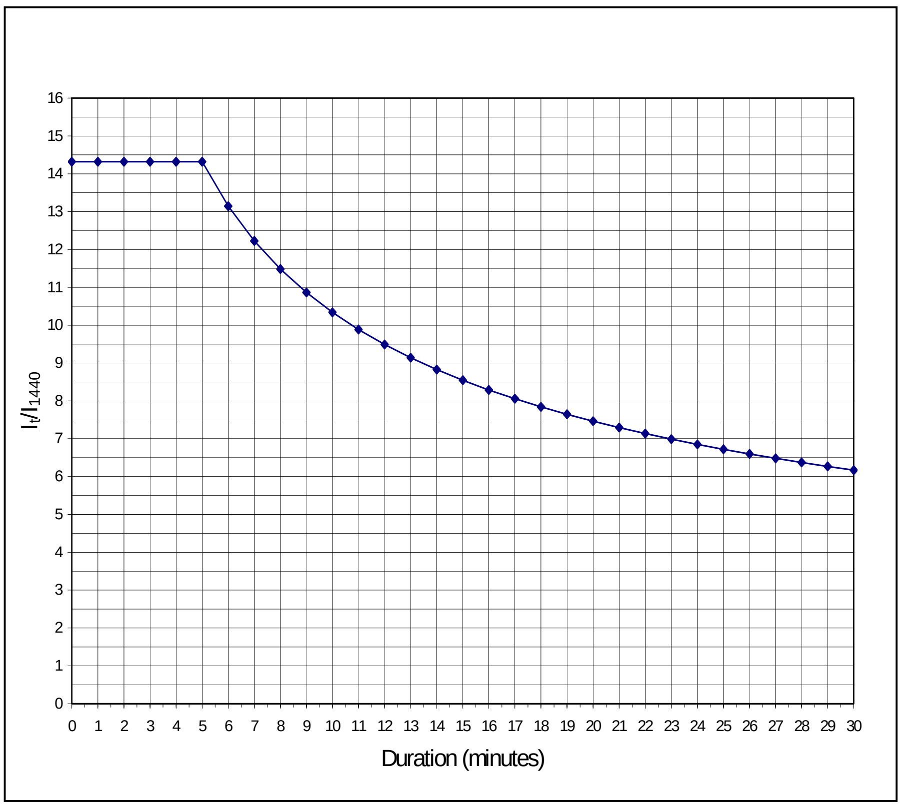

Figure 5.1.1
Normalized Intensity Curve

RB-AR33568

5.2 UNIT HYETOGRAPH

The definition of a design storm requires a description of how rainfall occurs over time. Public Works' design storm uses a 24-hour cumulative unit hyetograph to describe the temporal distribution of precipitation. The unit hyetograph provides the temporal distribution of one inch of rainfall occurring over a 24-hour period. Figure 5.2.1 shows an example of a cumulative hyetograph and its accompanying incremental hyetograph.

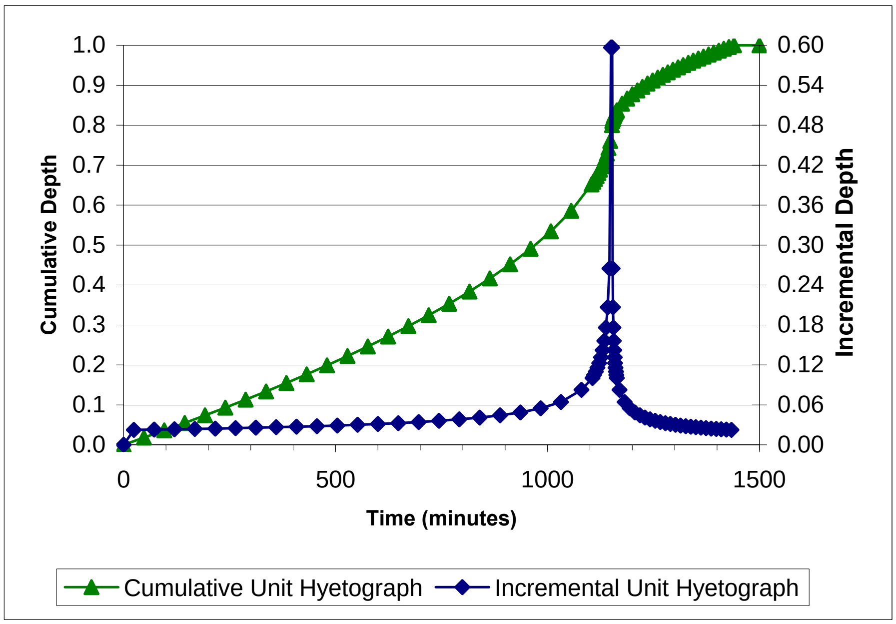

Figure 5.2.1
Relationship Between Cumulative and Incremental Unit Hyetographs

The unit hyetograph is scaled to match design rainfall depths. Design storm rainfall depths are determined from isohyets based on hydrologic design standards. Construction of the hyetograph used the normalized intensity equation solutions with an assumption about where the inflection point of the cumulative hyetograph occurs.

Development of the rainfall hyetograph used a modified alternating block method. See *Applied Hydrology* for a description and example of the alternating block method.[3] Modifications resulted from the use of the normalized intensity curve, instead of a traditional IDF curve, and the regionally specific location of the inflection point. This process produces an

RB-AR33569

incremental unit rainfall distribution for a 24-hour period. The cumulative distribution is developed by summing the incremental distribution at each time step.

Developing the unit hyetograph using the IDF equation required an assumption about the timing of the most intense rainfall. The inflection point of the cumulative unit hyetograph represents the highest intensity. An analysis of the hourly distribution of large historical 24-hour events showed rainfall intensities increasing during the first 70 to 90 percent of the period and decreasing for the remaining time. Approximately 80 percent of the total 24-hour rainfall occurs within the same 70 to 90 percent of the period.

The unit hyetograph assumes the rainfall inflection point occurs when 80 percent of the 24-hour rainfall total has fallen and 80 percent of the 24-hour period has elapsed. Ratios of the depth at a given time relative to the total 24-hour depth were derived from the intensity equation. These ratios were then used to define the unit hyetograph curve. The depth ratios shown in Figure 5.2.1 were calculated at 5-minute time steps from 5 to 60 minutes and 60-minute time steps between 60 and 1440 minutes.

The rainfall depth ratios for each intensity were placed on either side of the inflection point. The alternating blocks were placed around the inflection point. However, instead of alternating the blocks on either side with decreasing intensity, the depth ratios for each time step were split with 20 percent of depth for each time step after the inflection point and 80 percent before the inflection point. The distribution of the time steps was similarly divided using 80 percent before the time of inflection and 20 percent after. Table 5.2.1 illustrates the first few intervals in this process:

Table 5.2.1
Rainfall Distribution Around Hyetograph Inflection Point

t	(D_t/D_{1440})	t*20%	$0.8+(D_t/D_{1440})*20\%$	t*80%	$0.8-(D_t/D_{1440})*80\%$
5	0.0497	1	0.8099	4	0.7602
10	0.0717	2	0.8143	8	0.7425
15	0.0890	3	0.8178	12	0.7287

With the inflection point at 80 percent of the time (1152 minutes) and 80 percent of the rainfall depth (0.8), the t = 5 time step contributes a point above the inflection point at 1153 minutes, 0.8099 and below the inflection

RB-AR33570

point at 1148 minutes, 0.7602. Continuing this process provides the points that define the entire design unit hyetograph.

As described in Section 2.5.1, most major precipitation events in the county are the result of extratropical winter storms. Significant runoff tends to occur when these storms last several days and are comprised of several individual bands of intense precipitation. In the case of a multiple day storm, the most intense rainfall tends to occur on the last day. These observations form the basis for Public Works' 4-day design storm.

The unit hyetograph is multiplied by the 24-hour rainfall depth to produce a rainfall hyetograph for the fourth day. The first through third days have respectively 10, 40, and 35 percent of the fourth day's rainfall. Appendix A contains the unit hyetograph in tabular form. Multiplying the unit hyetograph by the depth for each day results in the daily hyetograph.

5.3 RAINFALL ISOHYETS

Historical data indicates that spatial distribution of precipitation across the county is not uniform during storm events. To account for this spatial variability of rainfall, Public Works developed rainfall isohyetal maps for the County of Los Angeles.

Isohyetal maps show the 24-hour rainfall depths expected for the 50-year storm frequency. The rainfall pattern depicted on these maps shows the influence of topography on rainfall.

The isohyetal maps incorporate information from Public Works' rain gages and the National Oceanic and Atmospheric Administration's (NOAA) gridded rainfall maps of the area. The process used NOAA's *Atlas 2,* 2-year, 24-hour isohyetal data to provide the spatial rainfall pattern. NOAA is a widely accepted source for meteorological data, and NOAA *Atlas 2* is a recognized standard for spatial rainfall distribution data.

Detailed rain gage analysis was performed to determine the various rainfall depth and frequency relationships. Table 5.3.1 summarizes the relationship between various frequencies as factors of the 50-year frequency depths. The factors are normalized to the 50-year event because this event is used for Capital Flood Hydrology.

RB-AR33571

Frequency	Multiplication Factor
2-yr	0.387
5-yr	0.584
10-yr	0.714
25-yr	0.878
50-yr	1.000
100-yr	1.122
500-yr	1.402

Table 5.3.1
Rainfall Frequency Multiplication Factors

Appendix B contains isohyetal maps for the 50-year, 24-hour rainfall depth. The isohyetal contour lines are spaced at intervals of two-tenths of an inch. The spatial rainfall distributions for the county design storms were converted to grid data for use with Geographic Information System (GIS) compatible hydrologic models.

5.4 DESIGN STORM

The three components of the design storm include the IDF equation, the unit hyetograph curve, and the isohyets. These components are used to define the design storm for a particular location and frequency. As an example, consider the 25-year design storm for the Palmer Canyon watershed in Figure 5.4.1. Subarea 1A of this watershed, shown in Figure 5.4.2, will be used for the sample calculations.

1. Compute the area between successive isohyetal lines and multiply by the average of the isohyet values. Table 5.4.1 shows the areas between isohyets for Subarea 1A.

2. The sum of these precipitation-area values divided by the total subarea area provides the area weighted average rainfall depth. The average rainfall should be calculated to the nearest two-tenths of an inch. Table 5.4.1 contains the calculations for the isohyetal values in this subarea.

It may be noted that for small subareas, the isohyet nearest the centroid of the subarea usually equals the design depth. Selecting the isohyets nearest the subarea centroid is an acceptable method for determining the design rainfall for subareas of approximately 40 acres.

RB-AR33572

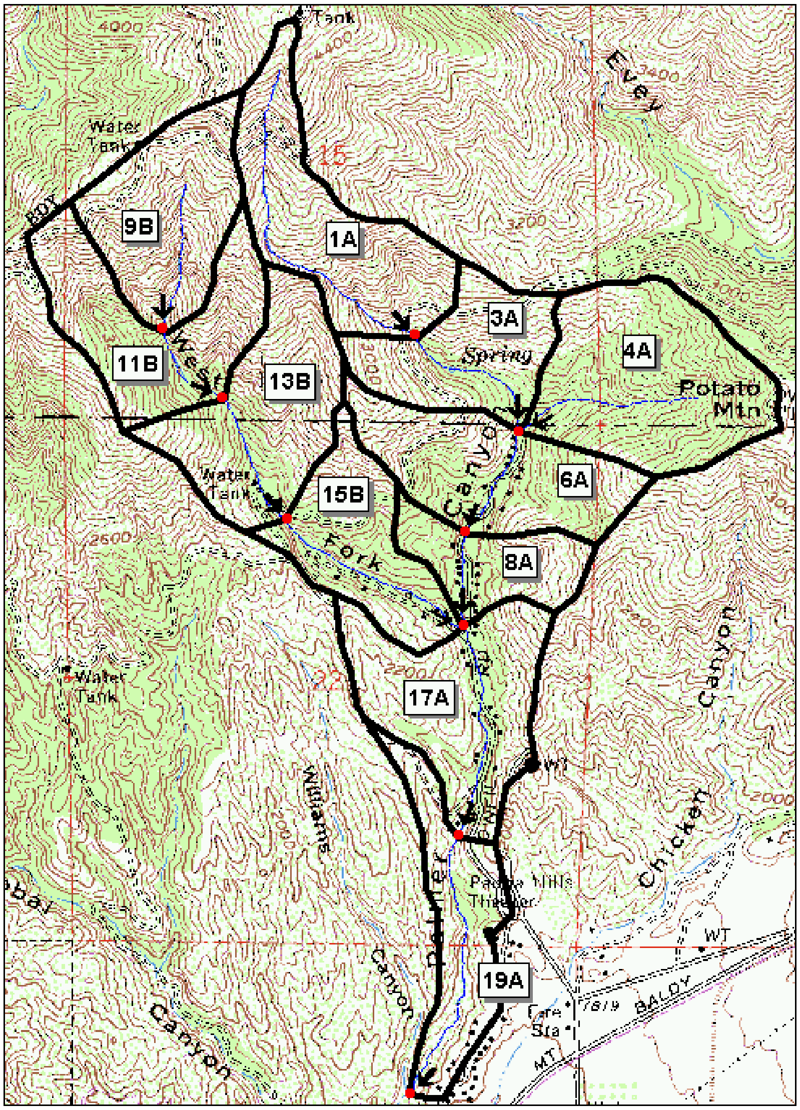

Figure 5.4.1
Palmer Canyon Watershed

RB-AR33573

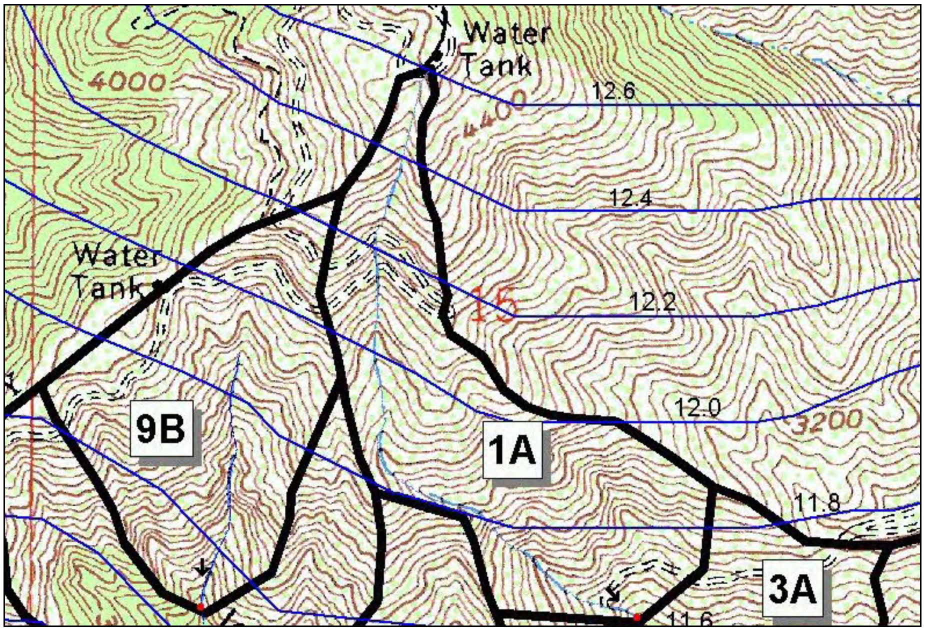

Figure 5.4.2
Subarea 1A with 50-Year, 24-Hour Rainfall Isohyets

Subarea 1A	Isohyet (in)	Area between Isohyets (acres)	Average Depth (in)	Precipitation * Area (in-acres)
	12.6			
	→	2.6 *	12.5 =	32.5
	12.4			
		6.9	12.3	84.9
	12.2			
		13.4	12.1	162.1
	12.0			
		29.7	11.9	353.4

		15.1	11.7	176.7
	11.6			
Total		67.7		809.6
809.6 in-acre / 67.7 acre = 11.96 in → 12.00 in				

Table 5.4.1
Subarea 1A Average Rainfall Depth Calculation

RB-AR33574

Table 5.4.2 shows average rainfall values calculated for the other subareas using the method from steps 1 and 2.

Table 5.4.2
Subarea Average Rainfall Depths

Subarea	Isohyetal Depth (in)
3A	11.4
4A	11.2
6A	11.0
8A	10.8
9B	11.4
11B	11.2
13B	11.0
15B	10.8
17A	10.2
19A	9.4

3. Using the rainfall frequency factor, the 50-year, 24-hour depths are scaled to match the required 25-year, 24-hour depths. The 25-year, 24-hour factor from Table 5.3.1 is 0.878.

Table 5.4.3
Scaling Rainfall Depths

Subarea	50-year depth (in)	50-year to 25-year factor	25-year depth (in)
1A	12.0	* 0.878 =	10.5
3A	11.4	* 0.878 =	10.0
4A	11.2	* 0.878 =	9.8
6A	11.0	* 0.878 =	9.7
8A	10.8	* 0.878 =	9.5
9B	11.4	* 0.878 =	10.0
11B	11.2	* 0.878 =	9.8
13B	11.0	* 0.878 =	9.7
15B	10.8	* 0.878 =	9.5
17A	10.2	* 0.878 =	9.0

4. Next, apply this 25-year, 24-hour depth to the unit hyetograph to produce the design storm hyetograph for the subarea. Multiply each depth on the

unit hyetograph by the 25-year, 24-hour rainfall depth. This produces a cumulative hyetograph for the fourth day. Calculate hyetographs for the first three days by multiplying the unit hyetograph by 10, 40, and 35 percent of the fourth day's rainfall depth. Figure 5.4.3 shows Subarea 1A's temporal rainfall distribution for each day of the design storm.

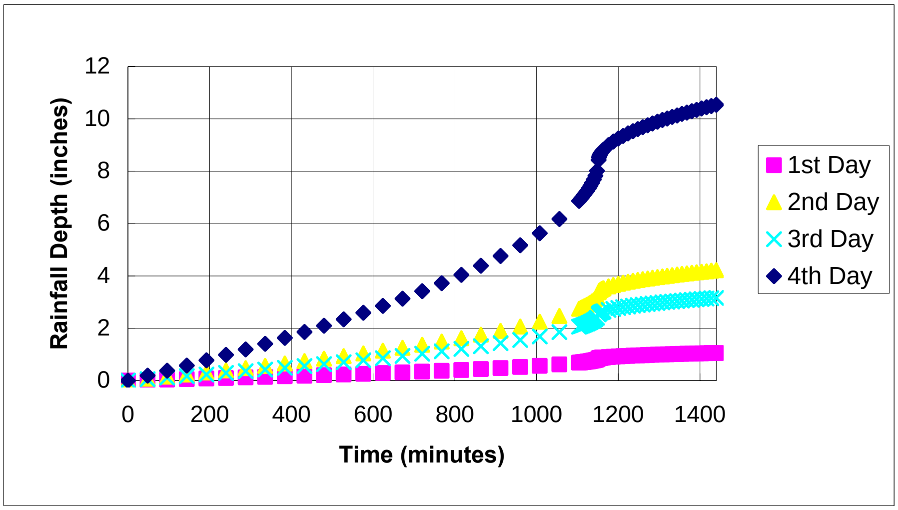

Figure 5.4.3
Hyetographs for Each Storm Day – Subarea 1A

Equation 5.1.2 determines the maximum intensity for the design storm assuming the time of concentration for Subarea 1A is 8 minutes.

$$\frac{I_t}{I_{1440}} = \left(\frac{1440}{t}\right)^{0.47}$$

(Equation 5.1.2)

Where:
- I_t = Rainfall intensity for the duration given in in/hr
- t = 8 minutes
- I_{1440} = 10.5 in / 24 hrs = 0.4375 in/hr

$$I_8 = \left(\frac{1440}{8\,\text{min}}\right)^{0.47} \times 0.4375 = 5.02 \ \text{in}/\text{hr}$$

The peak 8-minute intensity for the 25-year storm is 5.02 in/hr. If the time of concentration is 8 minutes, the peak flow will be Q = CIA, where I = 5.02 in/hr.

RB-AR33576

5.5 PROBABLE MAXIMUM PRECIPITATION (PMP)

As noted in Section 4.5, many dam spillways that fall under the State of California jurisdiction must safely pass runoff from the Probable Maximum Precipitation (PMP). The National Weather Service developed PMP design storms for use in the United States.

There are two types of PMP storms: the 3-day general-storm and the 6-hour local-storm. Facilities requiring protection from the Probable Maximum Flood must follow the PMP procedures to develop design storms. The National Weather Service's Hydrometeorological Reports No. 58 and 59 detail procedures for developing the design storm.[4,5] These reports are available at http://www.nws.noaa.gov/oh/hdsc/On-line_reports

CHAPTER

6

Rainfall-Runoff Relationships

Only a portion of the rain that falls on a watershed appears as surface runoff in a stream. This section of the manual describes two methods for estimating the portion of rainfall that becomes runoff. This portion is called the rainfall excess or effective rainfall.

6.1 RAINFALL LOSSES AND RUNOFF PRODUCTION

Rainfall becomes runoff when all loss processes are satisfied. Runoff results from rainfall not lost to infiltration, interception, depression storage, and evaporation.

"Infiltration is the process of water penetrating the ground surface into the soil."[1] Interception loss occurs when water is retained on vegetation and other surfaces. Intercepted water may evaporate or infiltrate. Loss due to depression storage occurs when water accumulates in depressions of all sizes that are not connected to a flow path. Evapotranspiration, a dominant force in the hydrologic cycle, proceeds slowly during a storm.

Different methods have been developed to model rainfall losses. These include runoff coefficients, constant loss parameters, the Horton method, exponential loss calculations, and Green-Ampt losses. The Modified Rational Method uses runoff coefficients. The following sections discuss infiltration and loss methods used within the County of Los Angeles.

6.2 INFILTRATION

Infiltration losses have the greatest effect on surface runoff. The rate of infiltration is a function of the state of the soil and is highly heterogeneous over space and time. Hydraulic conductivity is a measure of the ease with which water can travel through the soil and is a measure of the infiltration

RB-AR33578

rate when the soil is saturated. Similar soils generally have similar hydraulic conductivities. However, the infiltration rate is also affected by the degree of soil saturation. Dry soil allows more infiltration than wet soil. Factors such as ground cover or recent fires within the watershed affect the soil surface and infiltration rates.

Public Works' hydrologic standards assume that watersheds subject to design rainfall are at a field capacity soil moisture condition. This condition is also referred to as a saturated condition. At field capacity, the forces due to gravity and the surface tension on a drop of water in the soil column are in balance. At this point, no water is draining from the soil. Adding water to the soil forces downward movement and allows infiltration to begin.

6.3 MODIFIED RATIONAL LOSS CALCULATIONS

The modified rational method (MODRAT) uses a runoff coefficient that is a function of the rainfall intensity. The runoff coefficient reflects the fraction of rainfall that does not infiltrate and is based on the rainfall intensity for a given time period.

The Modified Rational Method uses the following equation at each time step:

$$Q = C*I*A$$ **Equation 6.3.1**

Where: Q = Volumetric flow rate in cfs
C = Runoff coefficient, dimensionless
I = Rainfall intensity at a given point in time in in/hr
A = Watershed area in acres

The following sections describe development of the unburned soil runoff coefficient, C_u, the developed soil runoff coefficient, C_D, and the burned soil runoff coefficient, C_{ba}. The appropriate coefficient represents runoff for different watershed conditions.

Undeveloped Runoff Coefficient (C_u)

MODRAT uses runoff coefficient curves to model the runoff response of the soil to changing intensity. The 179 undeveloped runoff coefficient curves, plotted in Appendix C, correspond to different soil types within the County of Los Angeles. Figure 6.3.1 shows the shape of a typical runoff coefficient curve.

RB-AR33579

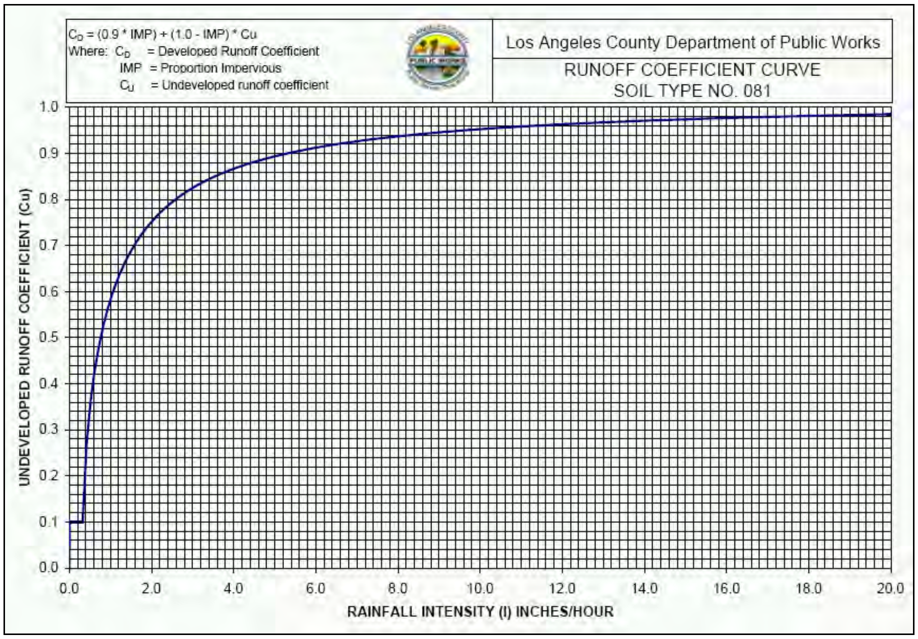

Figure 6.3.1
Runoff Coefficient Curve for Soil 081

Double ring infiltrometer tests provided data for the runoff coefficient curves. The infiltrometer tests used a department-designed, sprinkling–type infiltrometer. Before performing infiltrometer testing, the county was divided into regions of likely hydrologic homogeneity. Areas of homogenous runoff characteristics in the valley and desert areas were based on soil classifications published by the United States Department of Agriculture, Natural Resources Conservation Service. Criteria for homogeneity included topography, rock type, soil type, vegetative cover, and litter. Results from the infiltrometer tests within the homogenous areas determined the infiltration rate.

A series of runoff coefficient-intensity pairs compose each runoff coefficient curve. Each of the curves has a minimum coefficient (C_u) of 0.1 indicating that there is some runoff even at the smallest rainfall intensities. Appendix C contains the runoff coefficient curves for all the soils within the County of Los Angeles.

MODRAT requires assigning a single soil type for each subarea modeled. If a subarea contains more than one soil type, the predominant soil type in the subarea is used.

Developed Soil Runoff Coefficient Curves (C_D)

Each undeveloped runoff coefficient curve represents natural soil conditions. When precipitation occurs over a developed watershed, the rain falls on directly connected impervious areas and pervious areas. Runoff from pervious areas only occurs during heavy rainfall. Directly connected impervious area always produces direct runoff. As impervious area increases, the amount of direct runoff increases. The runoff coefficient curve must be modified to match the developed condition. Equation 6.3.2 accounts for the effects of development based on the undeveloped runoff coefficient and the amount of impervious area.

$$C_d = (0.9 * IMP) + (1 - IMP) * C_u$$

Equation 6.3.2

Where: C_d = Developed area runoff coefficient
IMP = Percent impervious
C_u = Undeveloped area runoff coefficient

The 0.9 in the equation represents the general assumption that no development is completely impervious. This assumption also accounts for initial abstraction losses in developed areas.

Imperviousness is assigned based on the land use types present in a subarea. Land use information requires existing and/or planned development patterns. If more than one type of development is present within a subarea, a composite impervious value must be determined using an area-weighted average. For example, consider a subarea with the characteristics in Table 6.3.1.

Table 6.3.1
Composite Impervious Values

	Percent Impervious	Area (acres)	Impervious*Area
	91%	20	1820
	42%	5	210
	21%	10	210
	1%	5	5
Total	-	40	2245

To determine the composite impervious value for this subarea, calculate the area weighted average of imperviousness. First, multiply each impervious

RB-AR33581

value by the area it represents. Then sum these products and divide by the total area. The composite area weighted imperviousness for the example subarea is:

$$\text{Composite imperviousness} = {}^{2245}\!/_{40} = 56\%$$

The Southern California Association of Governments (SCAG) land use studies establish the land use patterns within the county. SCAG creates land use maps based on development type. Public Works assigns imperviousness values to each development type and then verifies these values using previous studies and aerial photos. The current land use map is based on SCAG data from 2000.

Representative proportion impervious values have been developed by measuring sample areas for each land use type. Appendix D has a table of these values. For undeveloped rural areas, 1% of the area is assumed impervious. Table 6.3.2 shows the standard range of percent impervious values for different development types.

Table 6.3.2
Standard Range of Percent Impervious

Type of Development	Percent Impervious
Single-Family	21% to 45%
Multi-Family	40% to 80%
Commercial	48% to 92%
Industrial	60% to 92%
Institutional	70% to 90%

Burned Soil Runoff Coefficient Curves (C_{ba})

Wildfires frequently burn undeveloped watersheds within the County of Los Angeles. Infiltrometer tests conducted in burned chaparral-covered mountain watersheds indicate that these watersheds suffer from a decreased infiltration rate after a fire. The decrease results from calcification caused by intense heat, plugging of the soil pores by ash or other fines, and other chemical reactions that produce a hydrophobic condition. A lack of surface cover also promotes the formation of a crust of fine soil due to the impact of raindrops. This crust further impedes infiltration.[2]

RB-AR33582

Collection of field infiltrometer data in recently burned areas quantified the infiltration rate decrease for all soil types. Tests were done in burned and unburned portions of an area with previously homogenous infiltration.

Figure 6.3.2 is a picture of the 2002 Williams Fire in the San Gabriel Mountains viewed from Santa Fe Dam.

Figure 6.3.2
Williams Fire in the San Gabriel Mountains Viewed From Santa Fe Dam 2002

Burned area runoff calculations use a runoff coefficient curve adjusted for the burned watershed condition. For burned watersheds, the rational equation becomes $Q_{ba} = C_{ba}IA$, in which Q_{ba} and C_{ba} are respectively the peak runoff from a burned area and the statistically adjusted burned soil runoff coefficient. The burned runoff coefficient is adjusted using a fire factor. The fire factor is an index between the natural and completely burned watershed conditions, which ranges from 0 to 1 respectively. An analysis of historic fires in the major watersheds within the County of Los Angeles provided design fire factors for undeveloped watersheds.[3,4] Table 6.3.3 contains the design fire factors.

RB-AR33583

Table 6.3.3
Design Fire Factors for Use with Burned Watershed Hydrology

Watershed	Fire Factor
Santa Clara River Watershed & Antelope Valley	0.34
Los Angeles River Watershed	0.71
San Gabriel River Watershed	0.71
Coastal Watershed	0.83

Only undeveloped subareas with 15% or less imperviousness require burn calculations. Equation 6.3.3 calculates the burned runoff coefficient.

$$C_{ba} = FF \times [(1 - K) \times (1 - C_u)] + C_u$$

Equation 6.3.3

Where:
- C_{ba} = Adjusted burned soil runoff coefficient, dimensionless
- FF = Fire Factor, the effectively burned percentage of watershed area, dimensionless
- K = Ratio of burned to unburned infiltration rates for I, $0.677 \times I^{-0.102}$, dimensionless
- I = Rainfall intensity in in/hr
- C_u = Undeveloped runoff coefficient, dimensionless

The K factor represents the ratio of burned to unburned infiltration rates. The ratio varies with the rainfall intensity. Equation 6.3.4 is useful for determining the burned peak flow when an unburned flow and intensity are known.

$$Q_{ba} = FF \times [(0.677 \times I^{-0.102} - 1) \times (Q_u - A \times I)] + Q_u$$

Equation 6.3.4

Where:
- Q_{ba} = Peak runoff from a burned area in cfs
- FF = Fire Factor, the effectively burned percentage of watershed area
- I = Rainfall intensity in in/hr
- A = Watershed area in acres
- Q_u = Peak runoff from an unburned area in cfs

Fires increase runoff and debris production. Higher runoff rates entrain more debris and burned watersheds have more debris available for entrainment. Debris production yields as much as 120,000 cubic yards/square mile of watershed for major storms. Boulders up to eight feet in diameter have been deposited in valley areas at considerable distances from their source. Debris quantities equal in volume to the storm runoff (100 percent bulking) have been recorded in major storms. The Flood Control District and the

RB-AR33584

Department of Public Works have built many debris control and storage structures in the foothills to minimize the chance of channels clogging with debris.

Peak flows from burned watersheds are “bulked” to account for volume changes caused by debris entrainment. Debris basins remove the sediment so that downstream flows are equal to flows from burned watershed. For more information on debris production, bulking flows, sediment transport, and design of debris retaining structures and basins, see the Department of Public Works Sedimentation Manual.

6.4 CONSTANT LOSS METHOD

The constant loss method is a frequently used and generally accepted rainfall loss method for flood hydrology. The constant loss method models infiltration by allowing all rainfall to infiltrate when the rainfall intensity is below a certain rate. All rainfall exceeding this infiltration rate will run off. Table 6.4.1 contains example calculations of direct runoff using the constant loss method. A constant loss rate of 0.1 in/hr is applied to an incremental rainfall series. Rainfall exceeding the loss rate becomes runoff.

Table 6.4.1
Application of Constant Loss Method

Time (hours)	Incremental Rainfall (in)	Loss (CL=0.10 in/hr)	Runoff (in)
1	0.00	0.00	0.00
2	0.05	0.05	0.00
3	0.08	0.08	0.00
4	0.10	0.10	0.00
5	0.20	0.10	0.10
6	0.12	0.10	0.02
7	0.05	0.05	0.00

Figure 6.4.1 illustrates the relationship between the constant loss rate and the total rainfall. In this example, a total of 0.60 inches of rain fell in 7 hours. Of this rain, a total of 0.48 inches was lost to infiltration while 0.12 inches became runoff. The runoff coefficient for this entire period is 0.2, representing that 20 percent of rainfall becomes runoff.

RB-AR33585

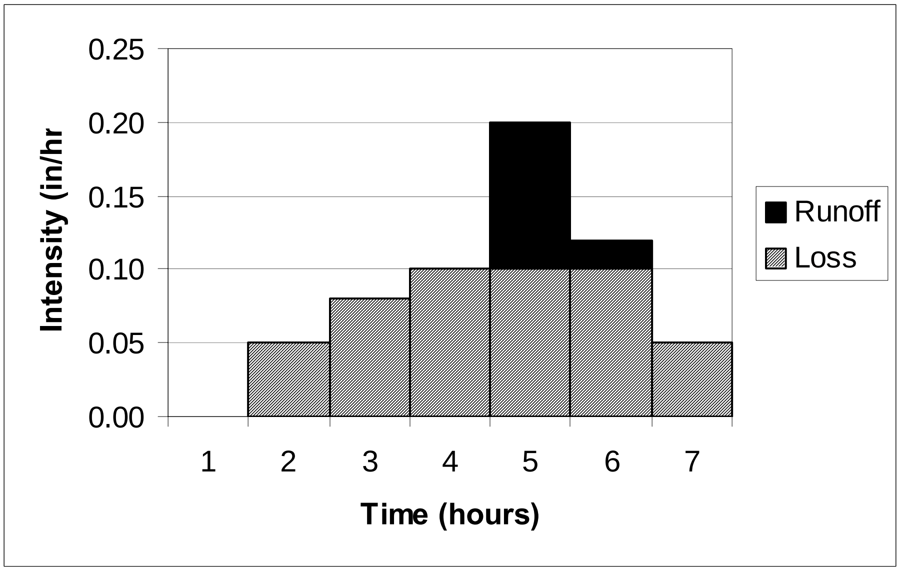

Figure 6.4.1
Rainfall Hyetograph and resulting Constant Loss Runoff

In general, application of a constant loss rate requires model calibration to estimate the loss rate parameters. Constant loss rates are highly variable and depend on the degree of saturation, soil type, storm duration, and rainfall intensity.

CHAPTER

7

Runoff Calculation Methods

The design of drainage systems for stormwater conveyance within the County of Los Angeles requires converting rainfall into runoff volumes and flow rates. There are many methods available for converting the rainfall to runoff.

The Department of Public Works uses two basic methods for converting rainfall to runoff, depending on the conditions. The methods are facilitated by software for use on a personal computer. The sections in this chapter explain how to select the proper method for hydrologic studies and the theory and application of the two methods.

7.1 SELECTING THE PROPER METHOD

Table 7.1.1 provides a brief description of the uses and limitations of each method.

Table 7.1.1
County of Los Angeles Hydrologic Methods

Method	Use / Limitations	
Rational Method	Use:	For drainage areas 40 acres or less; finds the peak flow rate for any frequency design storm
	Limitations:	Does not create hydrographs or determine runoff volumes. Area limited to approximately 40 acres.
Modified Rational (MODRAT)	Use:	For any size watershed; for any combination of laterals; for any combination of developed and undeveloped drainage areas; to create hydrographs and runoff volumes at specified locations; to find peak subarea and mainline flow rates; recommended method for systems incorporating pumping or water impoundment.
	Limitations:	Underestimates volumes in rural areas when interflow and baseflow add to the runoff volume.

RB-AR33587

7.2 RATIONAL METHOD

Mulvaney first outlined the rational method[1], which assumes that a steady, uniform rainfall rate will produce maximum runoff when all parts of the watershed are contributing to outflow[2]. This occurs when the storm event lasts longer than the time of concentration. The time of concentration is the time it takes for rain in the most hydrologically remote part of the watershed to reach the outlet. The method assumes that the runoff coefficient remains constant during a storm. The rational method formula is Q = CIA, previously mentioned in Chapter 6 as Equation 6.3.1. The direct runoff volume is calculated using the following equation:

$$V = C * \left(\frac{P}{12}\right) * A$$ **Equation 7.2.1**

Where: V = Volume in ac-ft
C = Runoff coefficient, proportion of rainfall that runs off the surface
P = Rainfall depth in inches
A = Drainage area in acres

Use of the rational method for drainage system design in small urban areas is appropriate. Use within the County of Los Angeles requires subarea division when[3]:

- Subareas are larger than approximately 40 acres
- There is more than one drainage channel
- Hydrologic properties are different within the area
- The time of concentration is greater than 30 minutes

The following are disadvantages of the classic rational method:

- Does not produce a hydrograph
- Runoff coefficient, C, is usually the same regardless of rainfall intensity
- Results are unreliable for areas greater than 200 acres[8]

The rational method applies to small watersheds where storage routing is not necessary. The method is useful for determining peak flows from small subdivisions and development projects or to determine flows to catch basins.

RB-AR33588

Section 7.5 describes catch basin hydrology in detail. Section 12.2 contains an example using the rational method to compute runoff.

7.3 MODIFIED RATIONAL METHOD

The modified rational method (MODRAT) uses a design storm and a time of concentration to calculate runoff at different times throughout the storm. Section 5.2 describes the temporal distribution of the design storm. Section 5.3 describes the spatial distribution of design storm rainfall within the County of Los Angeles.

Calculating flows based on the rainfall distribution results in a runoff hydrograph. The volume of runoff equals the area under the hydrograph curve. MODRAT allows users to route hydrographs generated in each subarea through conveyances and combine hydrographs based on time. MODRAT produces peak flows equal to or lower than flows calculated using the rational method. The reduction in peak results from attenuation, channel storage, and combining flows that peak at different times. Figure 7.3.1 shows an example of channel flow and storage.

Figure 7.3.1
Water storage occurring in Bradbury Channel May 28, 1981

RB-AR33589

Time of Concentration

The time of concentration (T_C) is the time it takes for rain in the most hydrologically remote part of the watershed to reach the outlet. Using a rainfall duration equal to the T_C ensures that the runoff from the entire subarea is contributing flow at the outlet. MODRAT requires a time of concentration in order to calculate intensities for use with the rational equation.

There are several methods for calculating the T_C. Simple relationships use the length of flow multiplied by an assumed flow velocity based on the type of conveyance (overland flow, sheet flow, pipe flow, etc.) Other methods include empirical equations derived through research and the use of the kinematic wave theory. The T_C calculation method for hydrology studies within the County of Los Angeles relies on a regression equation derived from hundreds of studies using the kinematic wave theory.

Time of Concentration - Kinematic Wave Theory[4]

The kinematic wave theory is a method accepted by Public Works, to calculate the time of concentration, T_C. Use of the kinematic wave theory to calculate the T_C requires separating the longest flow path into two parts: overland flow and conveyance flow. Equation 7.3.1 demonstrates this:

$$T_C = t_o + t_c$$

Equation 7.3.1

Where:
- T_C = Time of concentration in minutes
- t_o = Overland flow travel time in minutes
- t_c = Sum of all conveyance travel times in minutes

RB-AR33590

Conservation of mass and the momentum equation are used to determine the time associated with overland flow. Equations 7.3.2 and 7.3.3 are used to calculate overland flow time, t_o:

$$t_o = \frac{0.94 * L_o^{0.6} * n_o^{0.6}}{I_x^{0.4} * S_o^{0.3}}$$

Equation 7.3.2

$$I_x = C * I$$

Equation 7.3.3

Where:
- t_o = Overland flow travel time in minutes
- L_o = Overland flow length in feet
- n_o = Roughness for overland flow surface, dimensionless
- I_x = Rainfall excess in in/hr
- S_o = Slope of overland flow in ft/ft
- C = Runoff coefficient, ratio of runoff rate to rainfall intensity in in/in
- I = Rainfall intensity in in/hr

Values for the roughness coefficient of overland flow surfaces are found in Table 7.3.1.

Table 7.3.1
Roughness Coefficients for Overland Flow Computation

Surface Cover[5]	n_o
Smooth Asphalt	0.012
Concrete Paving	0.014
Packed Clay	0.030
Light Turf	0.250
Dense Turf	0.350
Industrial/Commercial	0.014
Residential	0.040
Rural	0.060

Table 7.3.2 shows standard values for different types of lots. The kinematic wave method requires evaluation of each subarea to determine the overland flow length and slope.

Table 7.3.2
Standard Values for Overland Flow Computation

Surface Cover[6]	Lot Length (ft)	Range of Lot Slope
Industrial/Commercial	200	0.005 - 0.020
Residential	100	0.010 - 0.050
Rural	200	0.050 - 1.000

Figure 7.3.2 illustrates the different types of lots where overland flow occurs.

INDUSTRIAL/ COMMERCIAL | **RESIDENTIAL** | **RURAL**

Figure 7.3.2
Different Types of Lots Where Overland Flow Occurs

The kinematic wave approach is applicable to channel flow as well as overland flow. The Manning equation is a form of kinematic wave theory for channels. The Manning equation is used to determine the average velocity in the channel. This velocity is used to determine travel times as shown in equation 7.3.4:

$$t_c = \left(\frac{1}{60}\right)\left(\frac{L_c}{V_{ave}}\right)$$

Equation 7.3.4

Where: t_c = Conveyance flow travel time in minutes
L_c = Conveyance flow length in feet
V_{ave} = Average conveyance velocity based on Manning equation in ft/sec

Comparison of results from Equation 7.3.1 with Izzard's overland flow experimental results and the results of Yu and McNown showed good correlation[6].

Use of the equations in this section requires an iterative approach since the rainfall excess and T_C are related to each other. An example problem illustrates application of the kinematic wave method for calculating T_C. Figure 7.3.3 shows the subarea that will be analyzed to determine the T_C using the kinematic wave method.

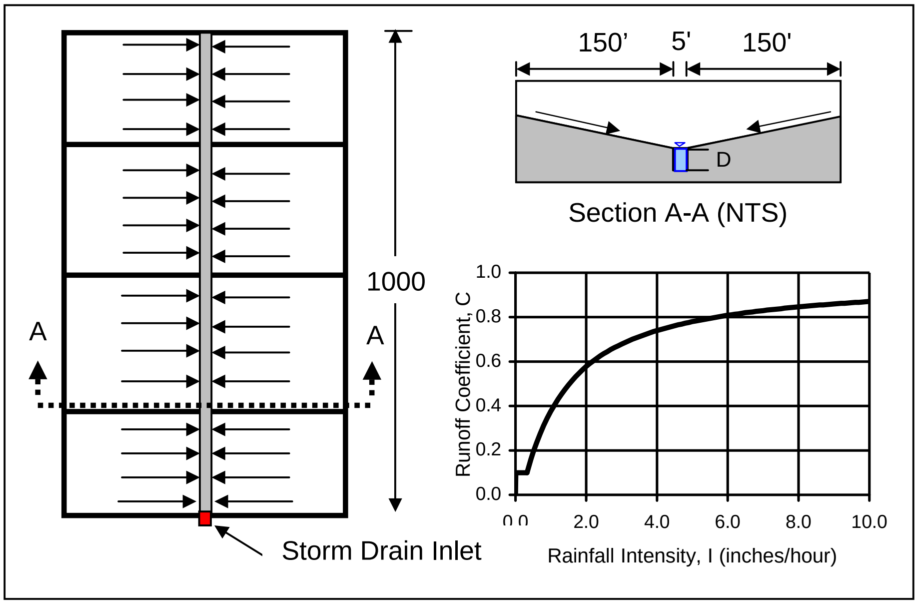

Figure 7.3.3
Example Subarea Demonstrating Kinematic Wave Method

This example shows eight residential lots that drain to a small grassy channel that eventually flows into a storm drain. Table 7.3.3 provides the lot and channel characteristics. The 50-year 24-hour rainfall for this area is 5 inches.

Table 7.3.3
Kinematic Wave Conveyance Data

Flow Path	Length (ft)	Slope (ft/ft)	Manning n	Width (ft)	Max. Depth (ft)
Overland Flow - Lot	150	0.020	0.040	-	-
Concrete Channel	1000	0.005	0.013	5	1

The steps involved in calculating a time of concentration using the kinematic wave method and example calculations are provided:

1. Assume an initial time of concentration

Assume a T_C of 12 minutes for the subarea in Figure 7.3.3

2. Calculate the intensity using Equation 5.1.2 and runoff coefficient using Equation 6.3.2 for overland flow using the time of concentration as the duration

$$I_t = I_{1440} * \left(\frac{1440}{t}\right)^{0.47} \Rightarrow I_{12} = \frac{5\text{ in}}{24\text{ hr}} * \left(\frac{1440}{12\text{ min}}\right)^{0.47} = 1.98 \text{ in/hr}$$

With the 2.0 in/hr intensity, the runoff coefficient is determined from the runoff coefficient curve in Figure 7.3.3. The undeveloped runoff coefficient is 0.58. Assuming a percent impervious of 0.42 for residential land use, the developed runoff coefficient is:

$$\begin{aligned} C_d &= (0.9 * IMP) + (1.0 - IMP) * C_u \\ &= (0.9 * 0.42) + (1.0 - 0.42) * 0.58 = 0.71 \end{aligned}$$

3. Calculate the time required for overland flow to reach the channel using Equation 7.3.2

$$t_o = \frac{0.94 * L_o^{0.6} n_o^{0.6}}{i_x^{0.4} S_o^{0.3}} = \frac{0.94 * (150)^{0.6} (0.040)^{0.6}}{(1.98 * 0.71)^{0.4} (0.020)^{0.3}} = 7.78 \text{ minutes}$$

RB-AR33594

4. Calculate the average flow in the channel using the rational method

$$\frac{Q}{2} = \frac{C * I * A}{2} = \frac{0.71}{2} * 1.98\,\frac{in}{hr} * \left(\frac{1000\text{ ft} * 305\text{ ft}}{43560\text{ ft}^2/\text{ac}}\right) = 4.92\text{ cfs}$$

5. Determine the velocity for the average channel flow

Solving Manning's Equation for V = 3.39 ft/s

6. Calculate the conveyance flow travel time using Equation 7.3.4

$$t_c = \left(\frac{1}{60}\right)\left(\frac{L_c}{V_{ave}}\right) = \left(\frac{1}{60}\right)\left(\frac{1000}{3.39}\right) = 4.92\text{ minutes}$$

7. Add the overland flow time and the conveyance flow time to determine the time of concentration using Equation 7.3.1

$$T_C = t_o + t_c = 7.78 + 4.92 = 12.7\text{ minutes}$$

8. If the value is within 0.5 minutes of the original estimate, use the estimate. If the value is not within 0.5 minutes, round the value from step 7 to the nearest minute and use the value as the new estimate to start the calculations again.

Round the value to 13 minutes and start at step 2. The second iteration provided the values used to find the final T_C:

I = 1.90 in/hr
t_o = 7.94 minutes
Q_{ave} = 4.66 cfs
V_{ave} = 3.33 ft/s
t_c = 5.00 minutes
T_C = 7.94 + 5.00 = 12.94 minutes

Public Works developed a computer program to calculate T_C for hydrologic study subareas. Public Works used the computer program from 1986 until 2001.

RB-AR33595

Time of Concentration - Regression Equation[7]

Determining the overland flow length and roughness was time consuming and determining the T_C for the conveyance often required solving the Manning equation many times. A 1999 study resulted in the creation of a regression equation for T_C calculations. The regression equation relied on T_C computations from a large number of subareas. The subareas were taken from diverse hydrology studies that used the kinematic wave theory equations to calculate T_C. This representative sample of subarea T_C's came from hydrologic studies performed between 1986 and 1999.

Equation 7.3.5 correlates the T_C to independent hydrologic parameters: flow path length and slope, land use, rainfall intensity, and the soil runoff coefficient. Equation 5.1.2 from Chapter 5 provides the relationship between the 24-hour intensity and the intensity related to the T_C. Equation 6.3.2 from Chapter 6 provides a relationship between the developed and undeveloped soil runoff coefficients.

$$T_C = \frac{0.31 * L^{0.483}}{(C_d * I_t)^{0.519} * S^{0.135}}$$

Equation 7.3.5

$$I_t = I_{1440} * \left(\frac{1440}{t}\right)^{0.47}$$

(Equation 5.1.2)

$$C_d = (0.9 * IMP) + (1.0 - IMP) * C_u$$

(Equation 6.3.2)

Where:

	T_C	= Time of concentration in minutes
	L	= Longest flow path length from watershed boundary to outlet in feet
	C_d	= Developed runoff coefficient, ratio of runoff rate to rainfall intensity in in/in
	I_t	= Intensity at time t in in/hr
	S	= Slope of longest flow path in ft/ft
	IMP	= Percent Impervious, percent expressed as 0.0 to 1.0
	C_u	= Undeveloped runoff coefficient, ratio of runoff rate to rainfall intensity in in/in

RB-AR33596

The regression method still uses an iterative process to calculate the time of concentration. See Section 11.1 for sample time of concentration calculations using the regression equation.

Reviewing the example in Section 11.1 shows that the regression equation calculation is approximately one minute longer than the kinematic wave method calculation for the same example. This difference is explained by the fact that many studies and calculations were used to create the regression equation. The regression equation provides the best fit for all of the studies, but may not match kinematic wave calculations exactly.

Chapter 10 describes the data necessary for watershed modeling and calculation of the time of concentration. Spreadsheet applications and computer programs listed in Chapter 11 automate the iterative process.

Hydrograph Generation

MODRAT relies on the dimensionless temporal rainfall distribution, an isohyetal depth, and the T_C to generate hydrographs. The steps for calculating the runoff are:

1. Determine the rainfall intensity for a time period equal to the T_C
2. Determine the undeveloped soil runoff coefficient for the time period using the intensity
3. Adjust the soil runoff coefficient using Equation 6.3.2 or 6.3.3 to determine C_d or C_{ba}, depending on the subarea conditions
4. Use the rational equation, Equation 7.2.1, to determine the runoff for the time period
5. Repeat steps 1 through 4 for each time period

Figures 7.3.4, 7.3.5, and Table 7.3.4 illustrate how to determine three flow rates based on the design storm for a specific subarea. The following subarea information is needed:

Area:	40 acres
T_C:	30 minutes
Soil:	068
IMP:	20%
Rain:	10 inches

Figure 7.3.4 shows the steepest portion of the rainfall mass curve related to the 50-year 24-hour rainfall depth of 10 inches. The three time segments

RB-AR33597

represent the intensity at the end of each time period. Figure 7.3.5 shows the soil runoff coefficients for soil 068. Table 7.3.4 shows the intensity, undeveloped runoff coefficient, developed runoff coefficient, the area, and the runoff for each time period. Three time periods are shown to demonstrate the changes in intensity that occur around the inflection point on the mass curve.

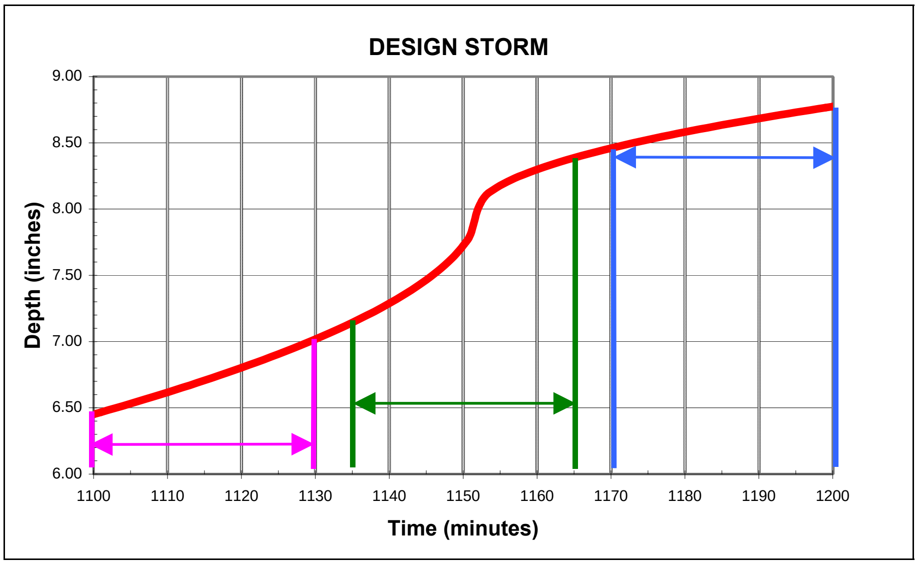

Figure 7.3.4
Three Time Steps for Modified Rational Runoff Calculations

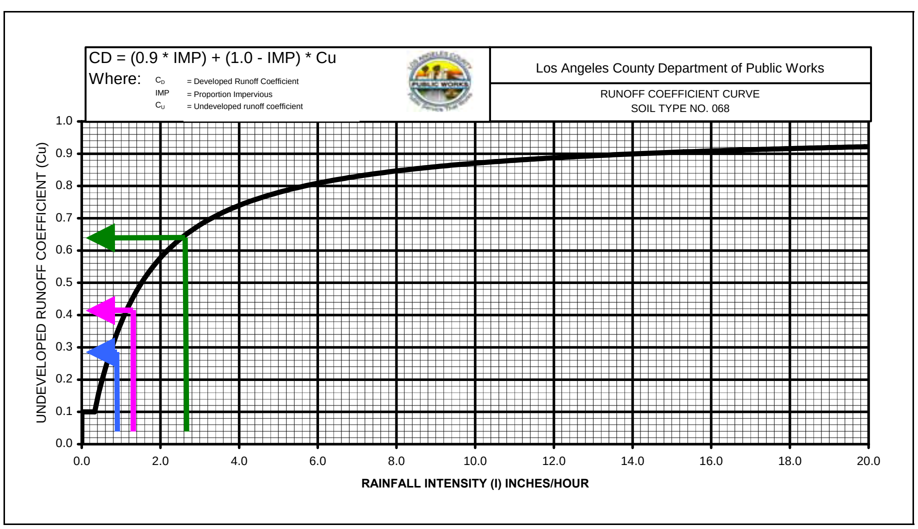

Figure 7.3.5
Undeveloped Runoff Coefficients for 3 Time Steps

RB-AR33598

Using Figures 7.3.4, 7.3.5 and Equation 6.3.2, Table 7.3.4 shows the runoff calculations for three time steps.

Time (minutes) To	Time (minutes) From	Rainfall (in)	Intensity, I (in/hr)	Undeveloped Runoff Coefficient, C_u Fig. 7.3.3	Developed Runoff Coefficient, C_d Eq. 6.3.2	Area (acres)	Q = C_d*I*A (cfs)
1100	1130	0.567	1.134	0.39	0.492	40	22.3
1135	1165	1.243	2.487	0.62	0.676	40	69.6
1170	1200	0.314	0.627	0.26	0.388	40	9.7

Table 7.3.4
Table of Runoff Calculations

Using the rainfall mass curve, the rainfall depth, and the time of concentration, the runoff value can be calculated for each one-minute increment. This is done by moving the time window forward one step and completing the process shown above. Computer programs or spreadsheets automate this time consuming process. Calculating the runoff at different time increments allows the user to create a hydrograph. Figure 7.3.6 shows the hydrograph for the three points calculated in Table 7.3.4. The figure assumes that at t = 0 and t = 1440 minutes, the flow rate is zero.

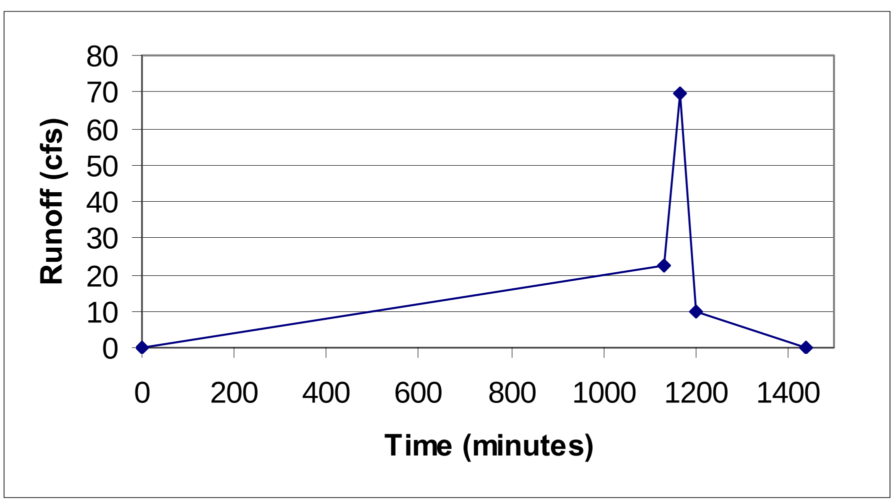

Figure 7.3.6
Hydrograph Generate Using MODRAT Method

RB-AR33599

The volume of runoff is calculated by summing up the area under the curve. For example, the volume for the first 1130 minutes is equal to the area under the curve. Finding the area of this triangle:

$$\text{Vol} = \frac{1}{2} * b * h = \frac{1}{2} * 1130\,\text{minutes} * 22.3\frac{\text{ft}^3}{\text{sec}} * 60\frac{\text{sec}}{\text{min}} = 755{,}970\,\text{ft}^3 = 17.35\,\text{ac - ft}$$

Defining the hydrograph with smaller time steps increases the accuracy of the flow rate and volume calculations. Hydrograph routing shows the affects of attenuation and allows superposition of hydrographs. This provides a more realistic evaluation of runoff than adding the peak flow rates calculated using the rational equation.

Channel Routing of Flows

Two types of channel routing exist: hydrologic and hydraulic. Hydrology studies within the County of Los Angeles use hydrologic routing to approximate unsteady flow through channels. Hydrologic routing balances inflow, outflow, and storage volume using the continuity equation. Routing the hydrographs results in outflow hydrographs that are smaller due to peak attenuation and occur later than the inflow due to flood wave translation.

Peak flow attenuation occurs when flows are stored in a channel reach. Figure 7.3.7 shows a graphical representation of peak attenuation. The volume of water stored increases as water fills the channel. Storage continues until the channel depth reaches the maximum water surface elevation. Storage then decreases as the peak flow passes and the water stored in the channel drains.

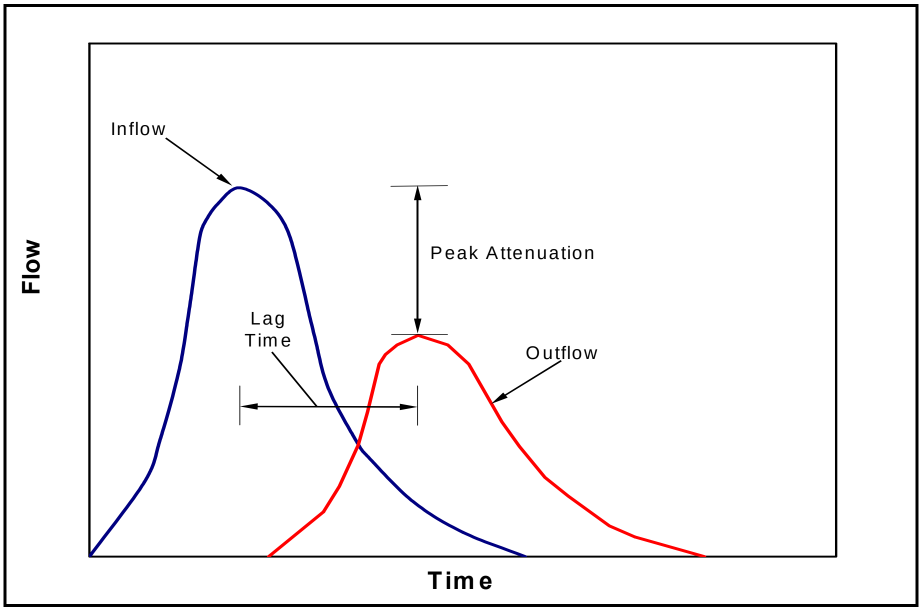

Figure 7.3.7
Peak Attenuation Related to Channel Storage

The water entering the channel must also travel from the upstream end of the section to the downstream end. Hydrologic routing considers this process by shifting the hydrograph in time. The shifting is related to the wave velocity for the specific channel.

There are many methods available for hydrologic routing[8]. The MODRAT method uses the Modified Puls, or level pool, routing method to determine channel storage effects. The method relies on a finite difference approximation of the continuity equation and an empirical representation of the momentum equation. Equation 7.3.8 is the basic equation for the Modified Puls method. The equation allows calculation of the outflow for each time step except the first. Chapter 8 shows another way to write the equation for the Modified Puls method that removes the need to calculate the storage for each time step.

$$\frac{1}{2}\left(I_i + I_{i-1}\right) - \frac{\left(S_i - S_{i-1}\right)}{t_i - t_{i-1}} = \frac{1}{2}\left(O_{i-1} + O_i\right)$$

Equation 7.3.8

Where:

Where:	I_{i-1}	= Inflow at t_{i-1}
	I_i	= Inflow at t_i
	t_i	= Time at step i
	t_{i-1}	= Time at step i-1
	S_{i-1}	= Storage at t_{i-1}
	S_i	= Storage at t_i
	O_{i-1}	= Outflow at t_{i-1}
	O_i	= Outflow at t_i

The method ignores wedge storage within the channel reach and assumes that lateral inflow effects are insignificant. A storage-discharge relationship is also required between the inflow rate and storage in the system[9]. The method requires a defined channel storage versus inflow relationship. The relationship is established using the Manning equation to determine depth of flow. Multiplying channel length, water depth, and cross sectional area provides the channel storage for a specific flow value. Using different flow values produces a storage curve. Figure 7.3.8 presents the channel storage relationship for a triangular channel with the following characteristics: slope = 0.001 ft/ft, length = 1000 ft, Manning n = 0.03, side slope = 1:1 ft:ft, and max depth = 6.8 ft.

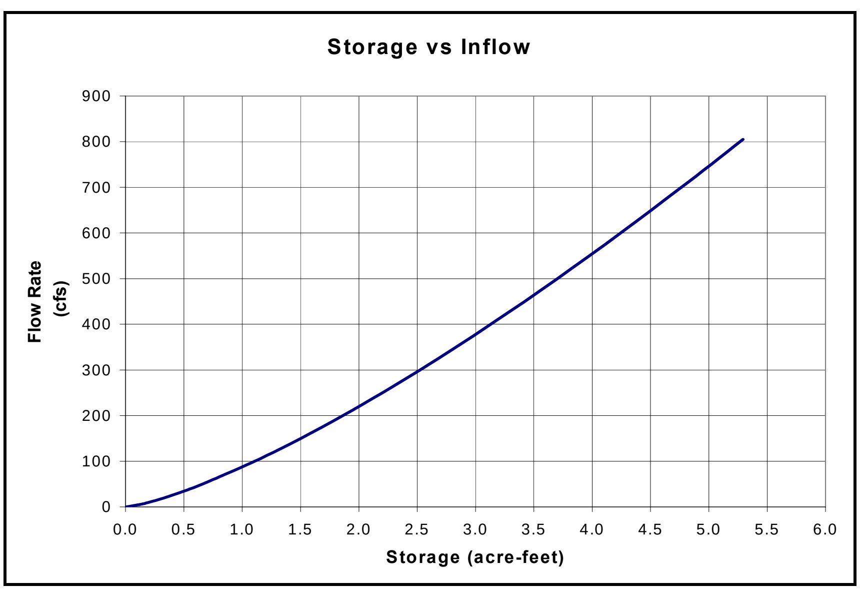

Figure 7.3.8
Storage-Inflow Relationship for a Triangular Channel

RB-AR33602

Calculation of translation time, the time it takes for the flood wave to travel from one end of the reach to another, requires using wave velocities. Table 7.3.5, Figure 7.3.9, and Figure 7.3.10 located at the end of the section provide more detail on velocity equations used for translation. Table 7.3.5 contains the equations used for translation time calculations. Figure 7.3.9 shows a typical street cross section. Figure 7.3.10 contains information for determining effective slopes of mountain and valley channels. The figure relates map slopes to slopes that match measured flow rates more accurately. The end of the section also contains a list of variables for the equations.

Correct hydrologic routing allows superposition of hydrographs at different locations within the study area. MODRAT starts at the upstream end of the watershed and calculates a runoff hydrograph. The hydrograph is then translated through the downstream channel. The Modified Puls routing then occurs to determine the effects of channel storage and the modified outflow hydrograph is computed. This hydrograph is then combined with the hydrographs from other subareas or is routed through another channel reach.

Computer programs implement this approach to reduce the amount of work required to define these relationships and route flows through the channels. Chapter 8 contains a detailed example of the Modified Puls routing method.

Table 7.3.5
Hydrograph Translation Equations

$T = \frac{L}{60 * V_W}$	Travel Time (minutes)
$V = \frac{Q}{A}$	Average Channel Velocity (ft/s)
$V = 5.6 * Q^{0.333} S_{eff}^{0.500}$	Velocity for Natural Mountain Channels (ft/s)
$V = (7.0 + 8.0 * Q^{0.352}) S_{eff}^{0.500}$	Velocity for Natural Valley Channels (ft/s)
$V_W = 1.5 * V$	Wave Velocity for Natural Mountain and Valley Channels (ft/s)
$D = \frac{B}{2 * \left(\left(Z^2 + 1 \right)^{0.500} - Z \right)}$	Most Efficient Rectangular or Trapezoidal Open Channel Section
$V = \frac{1.486}{n} * R^{0.667} S^{0.500}$	Pipe, Streets, Rectangular, or Trapezoidal Channels (ft/s)
$V_W = V * \left[\frac{\theta * (3 - 5\cos\theta) + \sin\theta}{3 * \theta(1 - \cos\theta)} \right]$	Wave Velocity for Partially Full Pipes (ft/s)
$V_W = V * \left[\frac{5}{3} - \frac{4 * (B + ZD)}{3 * (2 + B) * (B + 2ZD)} \right]$	Wave Velocity for Rectangular and Trapezoidal Channels (ft/s)
$\theta = 4 * \sin^{-1} \left(\frac{D}{d} \right)^{0.500}$	Angle Measurement to Determine Flow Depths in Pipes
$R = \frac{A}{P}$	Hydraulic Radius (ft)
$n = \frac{n_1 B + 2 * n_2 L_w}{B + 2 * L_w}$	Composite Manning's n for Trapezoidal Channels

Variables:

Variables:	A	= Cross Sectional Area in ft^2
	B	= Channel Bottom Width in feet
	C	= Curb Height in feet
	D	= Flow Depth in feet
	d	= Pipe Diameter in feet
	L	= Length of Channel Reach in feet
	L_w	= Length of Wetted Channel Wall in feet
	n	= Channel Roughness Coefficient
	n_1	= Length of Wetted Channel Wall in feet
	n_2	= Length of Wetted Channel Wall in feet
	P	= Wetted Perimeter in feet
	Q	= Flow Rate in cfs
	R	= Hydraulic Radius in feet
	S	= Slope of channel reach (ft/ft)
	S_{eff}	= Effective channel slope, natural valley and mountain conveyances

Effective Slope to Map Slope Relationship

7.4 CATCH BASIN FLOW CALCULATIONS

Flows that drain to catch basins usually come from areas smaller than the 40-acre subareas recommended in the hydrology manual. Determining flow to the catch basins is done by apportioning flow rates from the subarea based on the area draining to individual catch basins. Figure 7.4.1 shows a residential subarea of 35.5 acres that contains nine catch basins.

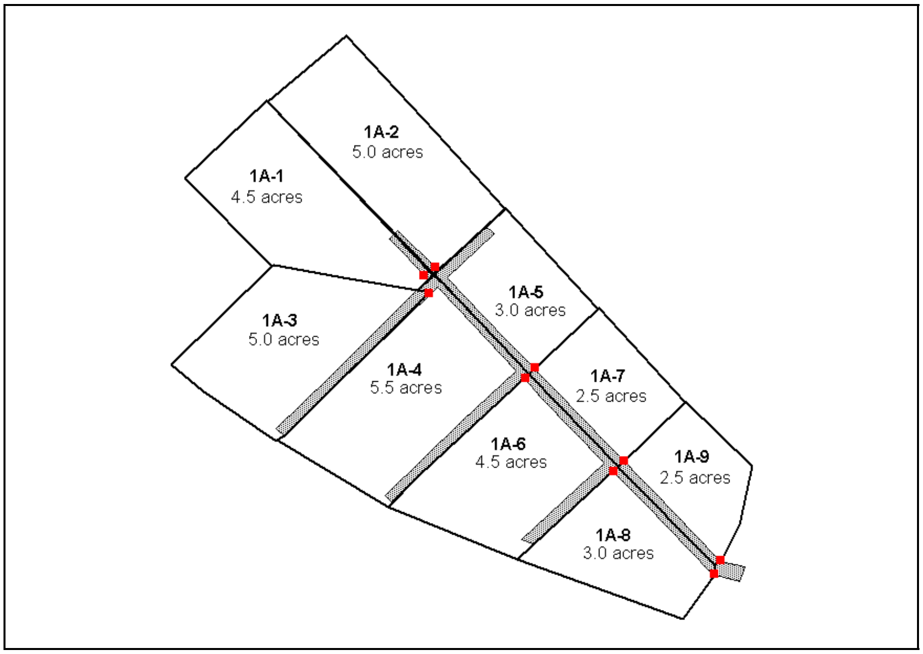

Figure 7.4.1
Catch Basin Flow Allotment

Catch basin allotment relates the peak subarea flow calculated using the MODRAT method to the subareas contributing flow. The steps for determining catch basin flow rates are:

1. Determine the area contributing flow to each proposed catch basin
2. Sum up the subarea areas to determine the total area
3. Divide each catch basin drainage area by the total area to get a weighting factor
4. Multiply the weighting factor by the MODRAT subarea watershed peak flow to get the catch basin peak flow rate for each basin

Table 7.4.1 contains the peak flow calculation for each catch basin in Figure 7.4.1. The total area for the MODRAT subarea 1A is 35.5 acres with a peak flow of 100 cfs.

RB-AR33607

Catch Basin Drainage Name	Area (A_i) (acres)	Weighting Factor (A_i/A_T)	Subarea Peak Flow (cfs)	Catch Basin Flows (cfs)
1A-1	4.5	0.13	100	13
1A-2	5.0	0.14	100	14
1A-3	5.0	0.14	100	14

1A-9	2.5	0.07	100	7
Total Area (A_T)	35.5			

Table 7.4.1
Peak Flow Allotment for Catch Basins within Subarea 1A

7.5 REPORTING RUNOFF VALUES

Reporting official peak flow rates on maps and data sheets requires a standard method. This section describes two methods for flow reporting. The first method is used when reporting flow rates from each subarea and is consistent with the United States Geologic Survey (USGS) flow reporting procedures. The second method is for reporting burned and bulked flow rates using the reach grouping method.

Peak Flow Reporting - USGS Method

The USGS is recognized for expertise in flow measurement and reporting. Flow rates reported for subareas and reaches within The County of Los Angeles must use the USGS rounding rules. Table 7.5.1 shows the rules for reporting flow rates using the USGS standard.

Flow Rate (cfs)	Round Flow To Nearest
$0 \leq Q < 1$	0.01 cfs
$1 \leq Q < 10$	0.1 cfs
$10 \leq Q < 100$	1 cfs
$100 \leq Q < 10,000$	10 cfs
$10,000 \leq Q < 100,000$	100 cfs
$Q \geq 100,000$	1,000 cfs

Table 7.5.1
USGS Flow Reporting Rounding Rules

Peak Flow Reporting - Reach Grouping

Reporting flow rates for burned and bulked runoff requires grouping flow rates by reach. A reach is a segment of a watercourse between specified collection points. A grouped reach is a collection of reaches grouped together based on rounding rules listed below. Reach grouping reduces the number of calculations required when bulking flow rates.

Reach grouping involves dividing a watercourse into grouped reaches and then bulking each grouped reach individually. This eliminates the need to bulk flow rates at every collection point along a watercourse. Reach grouping must be used to report burned and bulked flow rates for debris-producing watersheds. The following is the procedure for determining grouped reaches used for bulking.

1. List the burned flow rates (Q_{burn}) for all collection points along the desired watercourse
2. Round the burned flow rates according to the rules in Table 7.5.2
3. Group reaches based on rounded burned flow rates of the same value
4. Determine the Debris Production Area (DPA) zone breakup using the most downstream collection point of the grouped reach to account for all DPA zone areas
5. Bulk the largest non-rounded burned flow rate value from the grouped reach
6. When reporting clear flow rates for the grouped reach, use the largest rounded clear flow rate value from the reaches within the grouped reach

When reporting final grouped reach flow rates, if the flow rate decreases downstream along a watercourse, use the flow rate from the immediate upstream grouped reach.

Table 7.5.2
Rounding Rules for Reach Grouping

Flow Rate (cfs)	Round Flow To Nearest
$0 \leq Q_{burn} < 20$	0.1 cfs
$20 \leq Q_{burn} < 100$	5 cfs
$100 \leq Q_{burn} < 1{,}000$	10 cfs
$1{,}000 \leq Q_{burn} < 100{,}000$	100 cfs
$Q_{burn} \geq 100{,}000$	1,000 cfs

EXAMPLE – Reach Grouping for Reporting Bulked Flow Rates

Figure 7.5.1 shows a portion of a watercourse that contains three reaches. Table 7.5.3 shows the burned flow rates for these reaches. Each of the burned flow rates is rounded using the rules in Table 7.5.2. Following the reach grouping steps, the burned flow rates for each collection point are listed and rounded. The flow rate at 6A is the largest unrounded burned flow rate and is used in the bulk flow calculations. The DPA zones are calculated from collection point 8A upstream to include the area tributary to the entire grouped reach and the bulked flow is calculated. The burned and bulked flow is then rounded for reporting based on Table 7.5.2. Chapter 3 of the Sedimentation Manual contains more information on bulking flows.

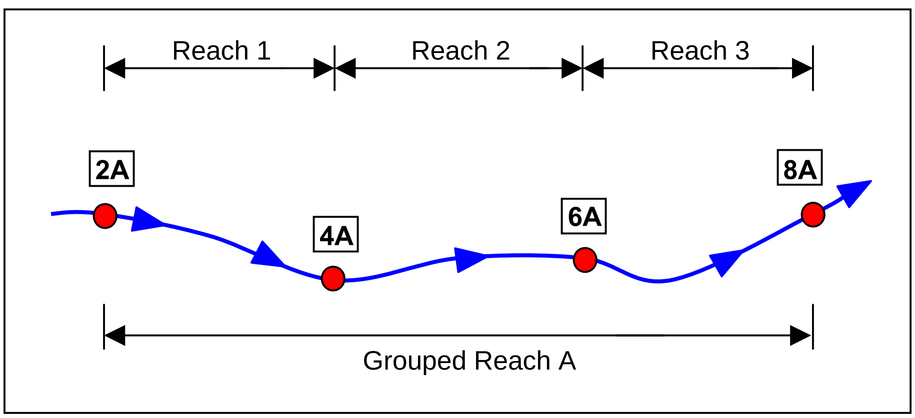

Figure 7.5.1
Grouped Channel Reach Based on Reach Flows

Table 7.5.3
Grouped Reach Flow Rates

Reach	Grouped Reach	Collection Point	50-Year Q_{burn} (cfs)	50-Year Q_{burn} *Rounded* (cfs)	50-Year $Q_{burn\ \&\ bulk}$ (cfs)	50-Year $Q_{burn\ \&\ bulk}$ *Rounded* (cfs)
1	A	4A	6,714.7	6,700	8,939.4	8,900
2		6A	6,724.6	6,700		
3		8A	6,667.8	6,700

CHAPTER

8

Reservoir and Basin Routing

Reservoirs and detention ponds are an important aspect of water resources management. Reservoirs and detention ponds change runoff timing and peak runoff rates while storing flows. Hydrologic studies must consider these effects when evaluating existing conditions or planning for future changes within the watershed. Figure 8.1 shows the San Gabriel Reservoir on April 28, 1975.

Figure 8.1
San Gabriel Reservoir
April 28, 1975

Reservoir routing for hydrologic studies within the County of Los Angeles uses the Modified Puls or Level Pool routing method. The method is similar to the method for channel routing, except that no translation is considered. Section 7.3, Channel Routing of Flows discusses the concepts of the

Modified Puls method in more detail. Equation 8.1 is the finite difference form of the continuity equation used for reservoir routing[1]. Equation 8.2 provides a relationship that is used to calculate outflow without actually calculating storage for a given time step. The example problem illustrates use of the equations.

$$(I_n + I_{n+1}) + \left(\frac{2S_n}{\Delta t} - O_n\right) = \left(\frac{2S_{n+1}}{\Delta t} + O_{n+1}\right)$$

Equation 8.1
Form of the Continuity Equation Used for Reservoir Routing

$$\left(\frac{2S_n}{\Delta t} - O_n\right) = \left(\frac{2S_n}{\Delta t} + O_n\right) - 2O_n$$

Equation 8.2
Relationship Used to Calculate Outflow Without Calculating Storage

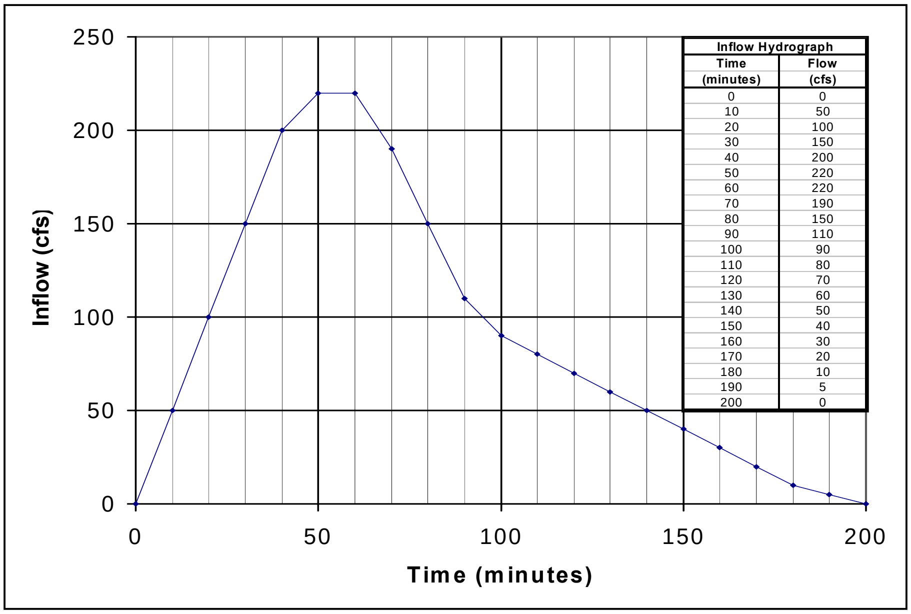
Where:
- I_n = Inflow at $time_n$
- I_{n+1} = Inflow at $time_{n+1}$
- Δt = Difference in time, $time_{n+1}$ - $time_n$
- S_n = Storage at $time_n$
- S_{n+1} = Storage at $time_{n+1}$
- O_n = Outflow at $time_n$
- O_{n+1} = Outflow at $time_{n+1}$

Reservoir routing using the Modified Puls method requires a storage-elevation relationship, an outflow-elevation relationship, and an inflow hydrograph. The relationships, the inflow hydrograph, and a known initial storage condition provide the information necessary to calculate outflow. The following example illustrates the use of the Modified Puls reservoir routing method.

EXAMPLE – Modified Puls Routing Through a Reservoir

This example routes an inflow hydrograph through a simple detention basin. Figure 8.2 defines the inflow hydrograph to be routed through the detention basin in this example.

The detention basin has the storage capacity shown in Table 8.1. Outflow from the basin occurs through an 24-inch drain when the water surface elevation is below 6 feet. When the water surface elevation is above 6 feet, outflow occurs through the drainpipe and over a weir. The weir is 20 feet long and has a weir coefficient of 3.5. Equations 8.3 and 8.4 provide the outflow relationships for the weir and drainpipe based on elevation as shown in Table 8.1.



Inflow Hydrograph

Figure 8.2
Inflow Hydrograph

Table 8.1 contains the storage-elevation and outflow-elevation relationships for this example. When outflow is based only on storage and no inflow is entering the reservoir, these relationships provide enough information to calculate outflow for a specified water surface. If there is inflow occurring at the same time as outflow, the Modified Puls method can be used to calculate outflow. The method requires building a storage indication curve using a specific time interval. The time interval must equal the time interval for the inflow hydrograph. This example uses a 10-minute time interval.

8.0	340,000	46.4	198.0	244.3	1377.7	889.0

Figure 8.3 plots the storage indication curves for this detention pond using the 10-minute time increment. The storage indication curve relates storage to outflow and provides a graphical method for calculating outflow based on the Modified Puls Method. Without the graph, solving for outflow requires interpolation of Table 8.1.

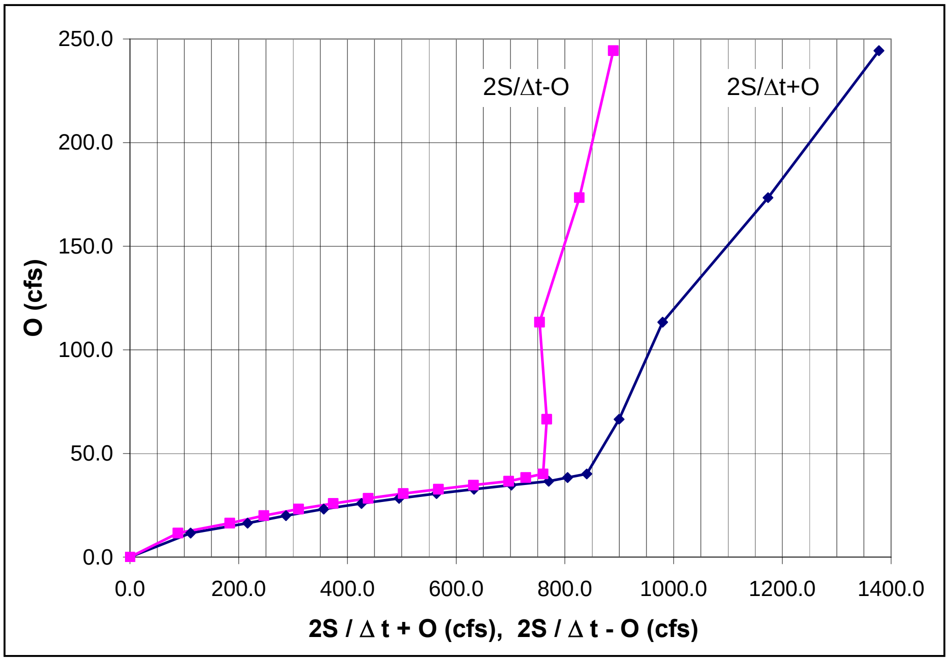

Figure 8.3
Storage-Indication Curve Based on 10-minute Time Interval

The storage-indication curve relates outflow to storage. Routing the flow through a reservoir requires solving graphically, or setting up a spreadsheet or computer program to perform the following steps:

1. Determine the initial storage, inflow, and outflow conditions and the inflow at the first time step (S_n, I_n, O_n, and I_{n+1}). The inflow cannot be greater than the outflow for the first time step.

2. Use the storage-indication curve to determine the storage and outflow for the second time step (S_{n+1} and O_{n+1}).

3. Repeat the steps 1 and 2 until the outflow hydrograph is completed.

The initial values for this example are:

S_1 = 0 ft^3
I_1 = 0 cfs
O_1 = 0 cfs
I_2 = 50 cfs
Δt = (10 minutes)*(60 sec/minute) = 600 sec

RB-AR33616

The initial values provide a solution to determine the first value on the storage indication curve. This value is calculated as follows:

$$(I_1 + I_2) + \left(\frac{2S_1}{\Delta t} - O_1\right) = \left(\frac{2S_2}{\Delta t} + O_2\right) \Rightarrow$$
$$(0 + 50) + (0) = \left(\frac{2S_2}{\Delta t} + O_2\right) = 50$$

The outflow value for the second time step is found by reading the storage indication curve for 50 cfs along the X-axis and finding the Y-axis value, or by interpolating between the values shown in the last two columns of Table 8.1.

O_2 = 5.2 cfs (from storage indication curve)

The outflow at 10 minutes is 5.2 cfs. This value then provides the information for the next time step.

Equation 8.2 provides the values for $2S_n/\Delta t\text{-}O_n$ at time steps after the initial time step:

$$\left(\frac{2S_2}{\Delta t} - O_2\right) = \left(\frac{2S_2}{\Delta t} + O_2\right) - 2O_2$$

The calculation for the second time step value of $2S_n/\Delta t\text{-}O_n$ is:

$$\left(\frac{2S_2}{\Delta t} - O_2\right) = (50) - 2(5.2) = 39.6 \text{ cfs}$$

The values for the second iteration are:

I_2 = 50 cfs
O_2 = 5.2 cfs
I_3 = 100 cfs
Δt = (10 minutes)*(60 sec/minute) = 600 sec

$$(I_2 + I_3) + \left(\frac{2S_2}{\Delta t} - O_2\right) = \left(\frac{2S_3}{\Delta t} + O_3\right) \Rightarrow$$
$$(50 + 100) + (39.6) = \left(\frac{2S_3}{\Delta t} + O_3\right) \Rightarrow 189.6$$

O_3 = 15.2 cfs (from storage indication curve)

Spreadsheets facilitate the Modified Puls calculations for reservoir routing. Table 8.2 provides the rest of the calculations for the detention basin routing problem. Many computer programs use this method to calculate outflow from reservoirs and detention basins.

CHAPTER

9

Water Quality Hydrology

Water quality has been an important aspect of water resources planning and use for many years in Southern California[1]. Regulations protect water quality and seek to limit pollution in part by requiring that new developments meet certain criteria for pollution prevention. Other regulations sometimes result in the retrofitting of existing storm water conveyances to reduce pollution of impaired receiving water bodies. Since problems with the quality of runoff can be associated with common rainfall events, smaller, more frequent storms must be addressed. This section discusses several of the issues that relate hydrology to water quality issues.

9.1 STANDARD URBAN STORMWATER MITIGATION PLANS (SUSMP)[2]

The Standard Urban Stormwater Mitigation Plan (SUSMP) is part of the Development Planning Program of the National Pollution Discharge Elimination System, Phase I, Stormwater Permit for the County of Los Angeles. SUSMP applies to development and redevelopment projects within the County that fall within specific categories. The County of Los Angeles has developed a SUSMP manual that includes the permitting and inspection process for projects required to meet SUSMP regulations. Table 9.1.1 provides a summary of the types of development and activities that fall under SUSMP regulation. The SUSMP manual provides more specific information.

RB-AR33619

Table 9.1.1
Development or Redevelopment Activities Regulated by SUSMP

Development Type and Activities
• Single-family hillside homes
• Residential development of ten or more units
• Industrial/commercial developments with 1 acre or more of impervious surface area
• Automotive service facilities
• Retail gasoline outlets
• Restaurants
• Parking lots 5,000 ft^2 or more of surface area or with 25 or more parking spaces
• Redevelopment projects in these categories that meet redevelopment thresholds
• Locations within or directly adjacent to or discharging directly to an environmentally sensitive area
• Fueling Areas
• Equipment maintenance, washing and repair areas
• Commercial/Industrial waste handling or storage
• Outdoor hazardous material handling or storage
• Outdoor manufacturing areas
• Outdoor food handling or processing
• Outdoor animal care, confinement, or slaughter
• Outdoor horticultural activities

The objective of SUSMP is to effectively prohibit non-storm water discharges and reduce the discharge of pollutants from storm water conveyance systems to the Maximum Extent Practicable (MEP) statutory standard. SUSMP defines hydrology standards for designing volumetric and flow rate based Best Management Practices (BMPs).

Design of BMPs to meet hydrologic standards for SUSMP must follow the methods outlined in the SUSMP manual. The design must mitigate flows or volumes using one of the required runoff calculations.

RB-AR33620

SUSMP regulations allow four methods of runoff volume calculation for BMPs that treat stormwater on a volumetric basis. The four methods allowed to calculate flow volume are:

1. The 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ ASCE Manual of Practice No. 87, (1998).

2. The volume of annual runoff based on unit basin storage water quality volume, to achieve 80 percent or more volume treatment by the method recommended in California Stormwater Best Management Practices Handbook – Industrial/Commercial, (1993).

3. The volume of runoff produced from a 0.75-inch storm event, prior to its discharge to a storm water conveyance system.

4. The volume of runoff produced from a historical-record based reference 24-hour rainfall criterion for “treatment” (0.75 inch average for the county area) that achieves approximately the same reduction in pollutant loads as the 85th percentile 24-hour runoff event.

SUSMP regulations also allow three methods to calculate flow rates for BMPs that treat stormwater on a flow through basis. The three methods allowed to calculate flow rates are:

1. The flow of runoff produced from a rain event equal to at least 0.2 in/hr intensity.

2. The flow of runoff produced from a rain event equal to at least two times the 85th percentile hourly rainfall intensity for the County of Los Angeles.

3. The flow of runoff produced from a rain event that will result in treatment of the same portion of runoff as treated using volumetric standards above.

SUSMP also requires controlling peak flow discharges to provide stream channel and overbank flood protection. This requirement relies on hydrology based on flow design criteria selected by the local regulatory agency. Chapter 4 specifies the peak flow discharge criteria.

RB-AR33621

www.mcstoppp.org/acrobat/StartattheSourceManual.pdf

9.2 TOTAL MAXIMUM DAILY LOADS (TMDL)

Total Maximum Daily Loads fall under Section 303 of the Federal Clean Water Act, which is a different section than the NPDES permit section. Impaired water bodies require reducing the pollutant discharge to a level that the water body can assimilate. The reduction could decrease the pollutant discharges to levels lower than required by an NPDES permit in order to meet the TMDL. TMDLs apply to both wastewater and stormwater discharges. Control of stormwater pollutant concentrations and loads requires implementing Best Management Practices (BMPs). TMDL requirements can relate to storms greater than storms required by SUSMP[3].

Understanding and implementing the TMDL program mandated by the Clean Water Act (Section 303(d)) presents significant challenges for the responsible State Environmental Agencies. States develop TMDLs to determine how to reduce pollution from point sources and non-point sources so that the pollutant loads stay below the maximum specified in the TMDL. Point sources include industrial and municipal facilities that discharge to water bodies. Non-point sources of pollution include urban runoff, agriculture, forestry, septic systems, and air deposition[4].

RB-AR33622

States are required to prioritize waters/watersheds for TMDL development. States compile this information in a list and submit the list to the United States Environmental Protection Agency for review and approval. The list is known as the 303(d) list of impaired waters. TMDLs are documents that describe a specific water quality attainment strategy for a water body and the related impairment identified on the 303(d) list. TMDLs may include more than one water body and more than one pollutant.

The TMDL defines specific measurable features that describe attainment of the relevant water quality standards. TMDLs include a description of the total allowable level of the pollutant(s) in question and allocation of allowable loads to individual sources or groups of sources of the pollutant(s) of concern[5].

Each TMDL is for a specific water body and runoff mitigation can be represented by various hydrologic methods. For example, current trash TMDL regulations require that no man-made trash enter the water body at any time. However, hydrology studies for the trash TMDL use the 1-year, 1-hour storm to determine the flow rate that certain treatment systems must accommodate. The Santa Monica Bay Bacteria TMDL does not specify a design storm, but requires that bacteria levels remain below a certain concentration within the wave-wash of the bay. Figure 9.2.1 shows an example of low flow in a channel.

Figure 9.2.1
San Gabriel River
Low Flow Channel

Establishing TMDL hydrology requires data for rainfall, runoff, and water quality. Several agencies recognize the need to collect more water quality data, standardize collection methods, and create reporting methods that make this data more available[6,7]. Defining hydrology methods used to design systems to meet TMDL standards requires understanding of the TMDL and water quality issues. As more data is collected and more TMDLs are established, standard TMDL hydrology procedures must be established.

9.3 BEST MANAGEMENT PRACTICES (BMPS)

Best Management Practices (BMPs) are actions and devices that improve or prevent the pollution of urban runoff and stormwater. The 2001 Los Angeles Municipal Stormwater Permit defines BMPs as "…methods, or practices, designed and selected to reduce or eliminate the discharge of pollutants to surface waters from point and non-point source discharges including storm water. BMPs include, but are not limited to, structural and nonstructural controls, and operation and maintenance procedures. BMPs can be applied before, during, and after pollution-producing activities."

BMPs can be proprietary or nonproprietary. Proprietary BMPs include patented and/or manufactured devices. Nonproprietary BMP designs are public domain and include detention basins, grassy drainage swales, catch basin stenciling, and public education.

Under the stormwater requirements of the federal Clean Water Act, stormwater quality must be improved to the "Maximum Extent Practical." The installation of BMPs is considered to meet that requirement.

In Phase II of the Federal Stormwater Permit process, the EPA breaks BMPs into six categories that deal with prevention and treatment of stormwater. The list is:

1. Public education and outreach on stormwater impacts
2. Public involvement/participation
3. Illicit discharge detection and elimination
4. Construction site stormwater runoff control
5. Post-construction stormwater management in new development and redevelopment
6. Pollution prevention/good housekeeping for municipal operations

Each of the six categories contains specific BMPs targeted to improve water quality. More information on the categories and BMPs is available through the EPA[8]. Figure 9.3.1 shows an example of a coastal wetland.

CHAPTER

10

Hydrologic Data Requirements and Sources

Hydrologic studies require the use of mathematical models. A model is a representation of physical systems using equations. The parameters in these equations change to represent different hydrologic conditions. Hydrologic models have many forms and attempt to represent many different physical processes. The models used by the County of Los Angeles are lumped parameter models. This means that they consider the spatial variation of parameters only down to a certain level. Below this level, parameters are aggregated using an average.

Whether using hand or computer automated calculations, an important task of model preparation is gathering the input data. Section 10 provides information on obtaining various types of data required for hydrologic modeling.

10.1 REQUIRED DATA

Creating watershed models commonly requires the data types shown in Table 10.1.1. The following sections and chapters present the procedures for obtaining and using data for hydrologic modeling.

Table 10.1.1
Required Watershed Data

Required data	**Description**
Subarea Size	The surface area inside the subarea boundaries
Flow Path Length	Length of the conveyance between subarea collection points
Flow Path Slope	Slope of the flow path used for calculating the T_C
Conveyance Data	A description of the flow conveyance between subarea collection points (length, slope, width, roughness, etc.)
Soil Types	A soil classification identifying the hydrologic characteristics of the area's surface soils
Land Use / Imperviousness	A classification of impervious surface area based on development types within the subarea
Design Storm Definition	Each subarea has a unique design storm based on the location and the rainfall recurrence interval being modeled
Time of Concentration	The time required for runoff from the most hydrologically remote point in a subarea to reach the subarea collection point

10.2 DATA SOURCES

The Hydrology Manual is the official reference for developing design hydrology. There are several other resources available to provide data for hydrologic studies within the County of Los Angeles.

Hydrology Manual Appendices

The Hydrology Manual and Appendices contain the maps and charts necessary to create the hydrologic models.

Appendix A includes a chart and a table representing the unit hyetograph used to develop design storms for the County of Los Angeles. Section 5.2 discusses the development and application of this temporal rainfall distribution.

Appendix B contains USGS Quadrangle maps overlaid with spatial data for the entire county. These include overlays of the 50-year, 24-hour rainfall isohyets, soil type, and debris production area (DPA) zones. Soil type boundaries assist in determining the predominate soil type within a subarea and the appropriate runoff coefficient curve. DPA zones are provided for use in the bulking process and to determine sediment production rates (see the Sedimentation Manual).

Appendix C contains soil names and characteristic information for the 179 soils defined for use with the Modified Rational Method. A soil identification table relates the soil numbers used by Public Works to the Natural Resources Conservation Service (NRCS) or Public Works assigned soil names. Graphs of the soil runoff coefficient curves represent the relationship between undeveloped runoff coefficients and rainfall intensity.

Appendix D contains a table of proportion impervious values for each of the SCAG land use types. While not shown in Appendix B, the land use patterns for the entire county are available as Geographic Information System (GIS) shapefiles.

Geographic Information System (GIS) and Electronic Data

Geographic Information Systems have an important role in current Public Works hydrologic studies. Most watershed characteristics vary by location. These spatial distributions lend themselves to GIS uses. The use of GIS allows the modeler to collect data quickly and accurately. Some computer programs integrate GIS and hydrologic modeling. These programs import and extract GIS data and provide this data to the hydrologic model for use in calculations.

Table 10.2.1 contains information on the principle GIS data available for hydrologic studies within the County of Los Angeles.

Georeferenced USGS Quadrangle map images are used as topographic maps for developing county design hydrology. These images can be opened in the GIS. These maps serve as the basis for delineation of watershed subareas and flow paths. These maps also serve as the basis for delineating the location of hydrologically important structures. Since the image is georeferenced, the resulting lines and subarea polygons have an associated length and area.

Aerial photographs can serve a similar function to map images. Photographs are useful because they can be used to identify various features such as roads, structures, land use, vegetative cover, and bodies of water. Aerial photos are also georeferenced images.

RB-AR33629

Digital Elevation Models (DEMs) and Triangular Irregular Networks (TINs) are used to find slopes for each subarea. Some programs automatically delineate watershed boundaries and stream channels using these data sources. DEMs are grids with an elevation assigned to each grid block. USGS DEMs are available in 10 meter and 30 meter resolutions for most of the county. The resolution refers to the size of each block in the grid. TINs replicate the ground surface using triangles formed by irregularly spaced points with known X, Y, and Z coordinates. DEMs and TINs are created from topographic survey data.

Table 10.2.1
GIS Data Types

GIS Data Types	**File Type**
USGS Topographic "Quad" Maps	Image, typically "quad name".tif
Aerial Photographs	Image, typically *.jpg, *.tif
Digital Elevation Models (DEMs)	*.asc,
Triangulated Irregular Networks (TINs)	*.tin
LA County soil shapefile	soils_2004.shp
LA County land use shapefile	ladpw_landuse_2005.shp
LA County rainfall grid	lac50year24hr.asc, for the 50-year frequency

The soil type is another attribute represented spatially as GIS data. A soil shapefile indicates the areas covered by each soil type. GIS models then assist in determining which soil type is predominate in a given subarea.

Land use data is available only as a GIS file. Each of the land use polygons represent a different development type and have an imperviousness value assigned. GIS based models can calculate and assign an area weighted composite imperviousness value to each subarea based on the land use data in the GIS files.

10.3 FIELD RECONNAISSANCE

A field investigation is necessary for all design hydrology projects. The purpose is to gather information that might not be apparent from the data sources discussed in Section 10.2, and to confirm that the data gathered is

RB-AR33630

correct. The field investigation is also an opportunity to resolve any discrepancies present in other data collected. Assumptions such as land use and roughness of conveyances should also be verified.

In urban areas, a field investigation is required. Watershed boundaries in these areas are influenced greatly by man-made drainage features. Many of these features are not significant enough to be represented in elevation data or topographic maps and are not visible on aerial photos. The only way to determine the flow pattern in these cases is by field investigation.

While no standard procedure suits all projects, listed below are some basic field check guidelines as a starting point for urban studies.

1. Take a base map overlaid with the existing and proposed flow paths and conveyances identified in the initial research. Take an enlarged street map to use as your field check map.

2. Start your field check at the outlet of the drainage area. Crisscross the watershed heading upstream while preparing the map.

3. Note the following on the field check map:

   - Surface flow directions at every street intersection for both sides of the street; note the flow direction with an arrow pointing downhill. Show gutters, cross gutters, catch basins, burpers, sumps and grade breaks. Also, note any streets without curbs. Use the field check symbols in Figure 10.3.1.

RB-AR33631

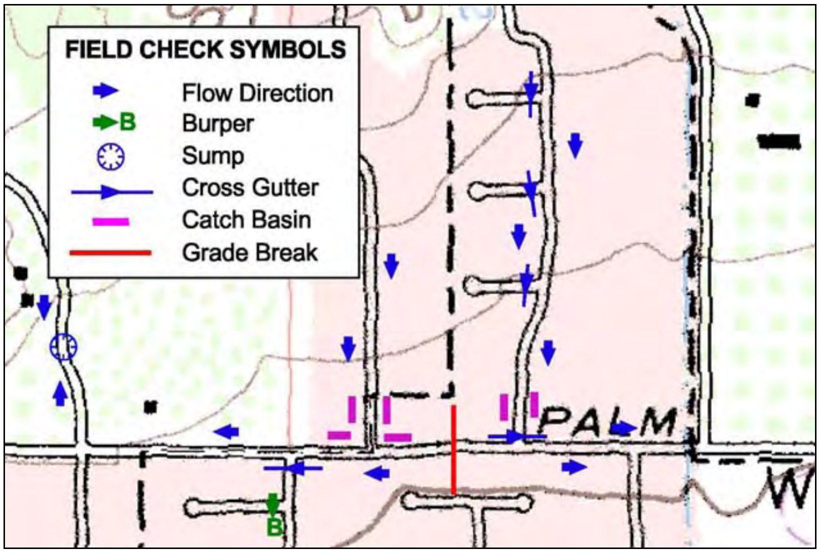

Figure 10.3.1
Field Check Symbols Map

- Check the types of development, such as single family or industrial, in order to verify the percent impervious.

- Check surface flow directions off property so that "frontage" along streets can be accounted for.

4. Get out of the car to investigate when there is uncertainty about flow directions.

5. Take a carpenter's level and place it in the gutter to determine the direction of flow on streets that are flat. Slopes are sometimes deceiving; use the level when in doubt.

6. Before leaving the area, check the map and note any flow contradictions. Now is the time to go back and resolve them. After the field check, research any new issues that may have come up such as unexpected drain locations or flow patterns.

10.4 WATERSHED DELINEATION

A watershed is an area of land that drains to a given location. The process of delineating the watershed for a given point is an important part of creating a hydrologic model.

RB-AR33632

Watershed delineation requires a source of elevation data such as a topographic map. For the purposes of delineation, there are several important things to remember about topographic maps.

The contour lines are of equal elevation.

Water will follow a path perpendicular to the contour lines. All streams are perpendicular to the contour lines. Contour lines will generally form a "V" or an arrow pointing upstream where they cross streams.

Ridgelines are lines of high ground separating one watershed from another. Ridges may also appear as "V"s or arrows pointing down hill. A watershed boundary follows ridgelines. A drainage boundary will not intersect a stream or flow path except at the drainage area outlet.

See Figure 10.4.1 for examples of typical topographic forms.

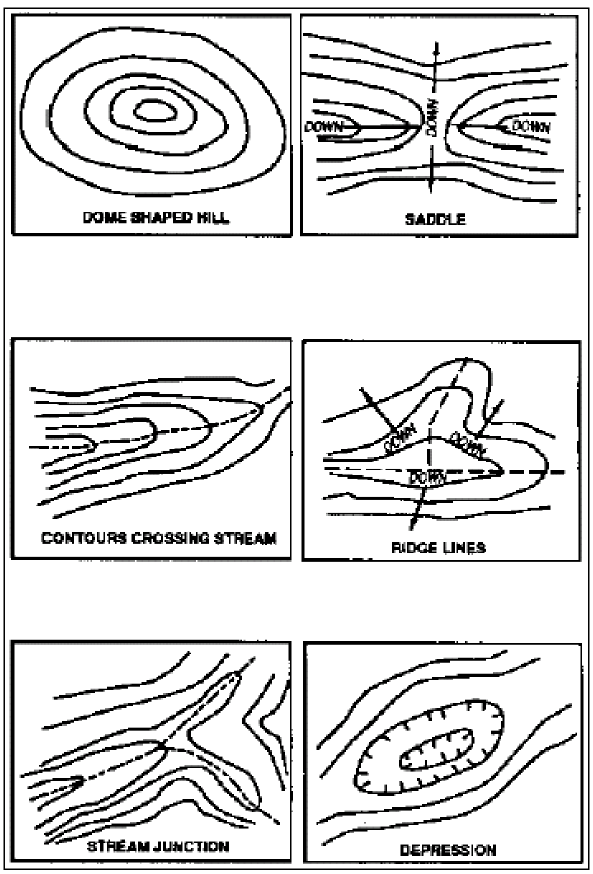

Figure 10.4.1
Typical Topographic Forms
Courtesy of Army Corps[1]

RB-AR33633

As an example, consider the watershed delineation of Webber Canyon. Figure 10.4.2 shows the topographic map in the area surrounding Webber Canyon.

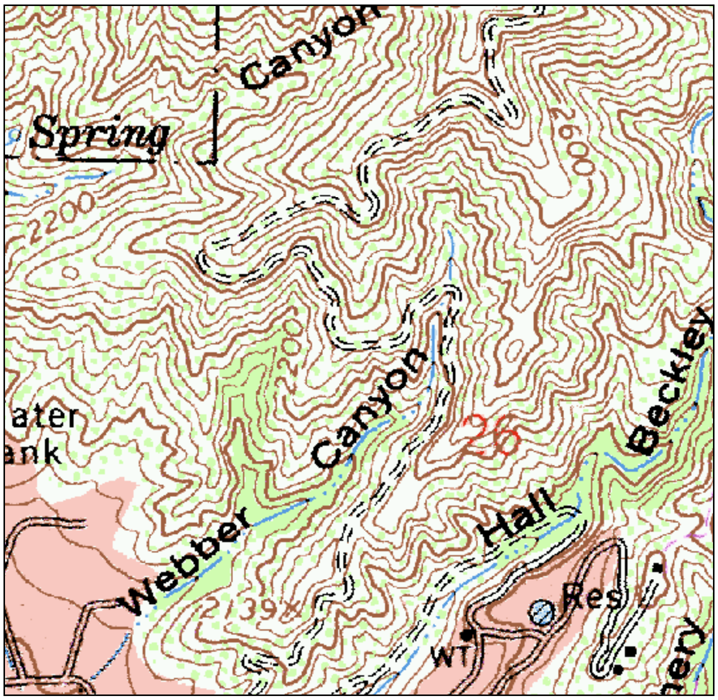

Figure 10.4.2
Topographic Map of Webber Canyon

Consider a point at the mouth of Webber Canyon, just below the "W" in the word "Webber". Webber Canyon and its tributaries upstream of this point comprise the watershed for the hydrology study.

Start by determining the outlet location where a flow rate value is needed, which for this example is location 1 in Figure 10.4.3. From this location, draw a line separating areas that contribute water to this location from areas that do not. Draw a line from the outlet point to the point on the adjacent contour. The line must be perpendicular to the contour line at the point where it crosses location 2.

Continue following and crossing the contours lines. Note that where the watershed boundary coincides with a sharp ridge, the line will be following the "V"s. Where ridgelines meet, it is important to make sure that the areas enclosed within the boundary are part of the same stream network.

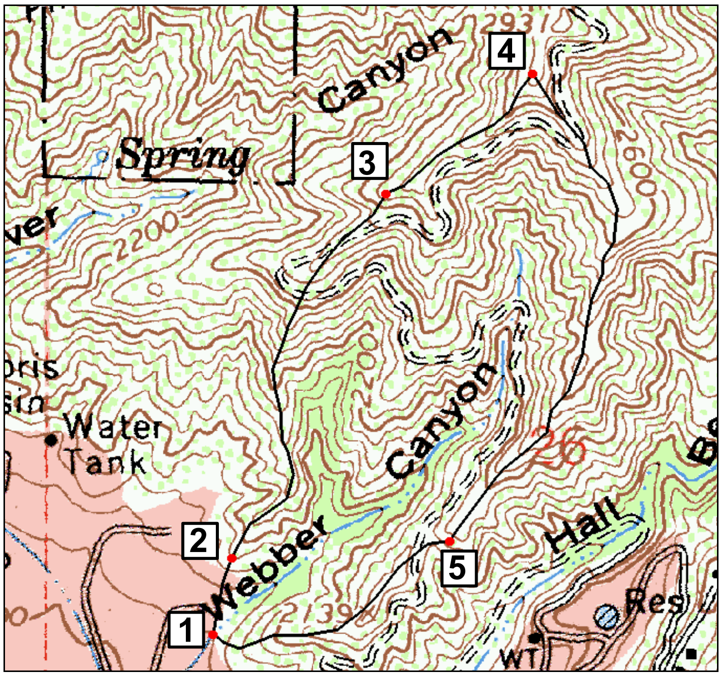

Figure 10.4.3
Webber Canyon Watershed Delineation

At location 3, continue connecting "V"s past the intersection of ridgelines because the intersecting ridge separates Webber Canyon from a tributary. However, location 4 shows the ridgeline intersection that separates Webber Canyon from other watersheds. Stop at a point on the nose of the ridge and then continue back downhill following the intersecting ridge along the arc between locations 4 and 5. Continue down this ridge until you reach the watershed outlet once again at location 1. The area inside the boundary you have drawn is the watershed tributary to the chosen outlet point.

For modeling purposes, it is sometimes necessary to break a watershed up into smaller pieces called subareas. This is done by adding additional outlets upstream of the final outlet and following the same procedure. Outlets should be added at break points on the flow path. These points might include changes in slope, changes in conveyance, entry of laterals or external flows, or points where catch basins are needed. Subarea definition often depends on the purpose of the hydrologic study.

This simple example shows watershed delineation using only a topographic map. As discussed in Section 10.2, topographic maps are insufficient to define the drainage pattern in flat areas and urban areas where man-made drainage features must be considered. In these cases, watershed delineation must account for the actual drainage patterns and collection systems.

Determine the drainage area boundaries for the entire project watershed first. Then draw in the flow paths. The flow paths should include existing and proposed drains. Divide the drainage area into subareas by locating significant collection points in the watershed and delineating the subareas. Subarea delineation follows the same steps as watershed delineation.

10.5 COLLECTING SUBAREA DATA

A primary task in any hydrology study is gathering site specific data that will dictate the way runoff is produced. After delineating the watershed and subareas as described in Section 10.4, it is now possible to collect subarea data. Studies commonly require the lengths and slopes of flow paths and time of concentration paths, characteristic soil types, and percent imperviousness. Data collection is described in the following list.

1. Determine the subarea size using a planimeter or GIS.

2. Determine the length and average slope of conveyances. Draw a path that follows the main watercourse between the outlet of the upstream subarea and the next downstream subarea outlet. Measure the conveyance length using a scale or GIS. Determine the top and bottom elevation and calculate the slope of each conveyance length.

3. Determine the length and average slope of time of concentration paths. The procedure for T_C paths is the same as for conveyances. However, T_C paths are drawn from the furthest or most hydrologically remote point in a watershed subarea to the outlet. This is not necessarily the longest path distance but the one that would take the longest time for water to travel to the outlet.

4. Locate the soil type boundaries on the maps in Appendix B or using GIS, and determine the predominate soil type in the subarea. For the Modified Rational Method, the selected soil's runoff coefficient curve will be used to carry out all the necessary runoff calculations in the subarea.

5. Determine the type and extent of development in each subarea. Land use helps determine the amount of directly connected impervious area and hence the amount of rain that will runoff directly. The land use types have been assigned a percent imperviousness as shown in Appendix D. Each subarea requires an area-weighted average of percent imperviousness.

10.6 COLLECTING RAINFALL DATA

For simulation of a single event, rather than using the rainfall data from a real storm, a design storm is used. The design storm is described in Chapter 5. In order to account for the spatial variability of rainfall, the design storm assumes different magnitudes based on its location. Each subarea has a distinct, 50-year, 24-hour rainfall depth based on its position within the rainfall grid. The procedure for determining the average design rainfall is called the Isohyetal Method.

1. Locate the isohyetal lines on the quad maps from Appendix B and use the methods from Section 5.4 to assign each subarea an isohyetal depth for the 50-year, 24-hour event.

2. If the modeled event will be other than the 50-year, use the Rainfall Frequency Factors in Table 5.3.1 to convert this isohyetal depth for the desired frequency.

3. Produce the design hyetograph by multiplying each point on the unit hyetograph by the isohyetal depth.

For some dams it is necessary to evaluate runoff from standard design storms and the Probable Maximum Flood (PMF). Development of the design storm for the PMF must follow the procedures of Hydrometerological Report (HMR) No. 59. In this case, other specific data about the watershed may need to be collected.

Chapter 5 describes the derivation of the design storm and the isohyetal maps from rain gage data collected in the county. Public Works' operates and maintains over 250 rain gages. These rain gages record rainfall amounts for durations from 5 minutes to 24 hours. Many of these rain gages have records that are greater than 50 years in length. Daily and annual rainfall amounts are available in the annual Public Works' Hydrologic Report

RB-AR33637

and at http://www.ladpw.org/wrd/report/. Intensities for other durations are available by contacting the Hydrologic Records Section.

Public Works collects rainfall data using non-recording and automatic recording rain gages. Non-recording gages collect rain and hold it in a container until it can be measured using a dipstick or graduated marking on the side of the collector. Volunteer observers typically read these gages daily at a specified time.

The automatic recording gages record the rainfall amounts for shorter time intervals. All of the Public Works' recording gages use tipping buckets to measure rainfall. The gages have a set of buckets that are alternately filled. When one of the buckets fills to a predefined amount, it tips. The other bucket then moves into the filling position. The frequency of the tipping allows the corresponding rainfall intensity to be calculated. This type of recording gage allows for very precise definition of a hyetograph. Most of the recording rain gages are connected to a central computer system using radio and satellite links so that rainfall amounts can be monitored in real-time. These gages are part of the Automatic Local Evaluation in Real-Time (ALERT) network. This network provides information for decision making during storm events.

10.7 CONVEYANCES

Conveyances are the links within a hydrologic model that simulate the flow of water through channel reaches. A hydrograph is specified at the top of a reach and a resulting outflow hydrograph is calculated at the bottom. Conveyance modeling is necessary due to the reduction of peak flow rates by attenuation and travel time. These processes affect the hydrograph at the downstream end of the conveyances.

The Modified Rational method uses six conveyance types: mountain, valley, street, circular pipe, rectangular channel, and trapezoidal channel. The types of conveyances between subarea collection points must be determined. The type of conveyance is important because water will flow much faster in a pipe than through a valley. Select the type that best characterizes the existing or planned conveyance. Several of the types require additional information about the dimensions and characteristics of the conveyance. The various conveyance types are described in detail in Section 7.3.

RB-AR33638

The length and slope of the conveyance between collection points are also important in determining the effects of hydrologic routing. The conveyance lengths are determined by measuring the flow path length using a scale or GIS. This length information is combined with the elevation data from a DEM or topographic map to determine the slope. For natural mountain and valley conveyances, the slope must be corrected using the slope correction curve, Figure 7.3.10.

Figure 10.7.1 shows water being conveyed on the streets of Lakewood after the 1950 storm season.

CHAPTER

11

Time of Concentration Calculation

The time of concentration is the time required for runoff from the most hydrologically remote point in the subarea to reach the subarea outlet. The Modified Rational Method requires a time of concentration calculation for each subarea.

In the past, Public Works used kinematic wave theory to calculate the time of concentration (Section 7.3). To simplify these calculations, Public Works developed a regression equation based on hundreds of studies using kinematic wave theory. The regression equation replaces the original kinematic wave calculations.

Time of concentration calculations can either be done by hand (Section 11.1) or using the T_C calculator program (Section 11.2). Watershed Modeling System (WMS) and XP-SWMM software also incorporate these calculations.

11.1 TIME OF CONCENTRATION – HAND CALCULATIONS

The following provides a step-by-step approach for using the regression equation to calculate the time of concentration. The steps show the calculations for the example in Chapter 7 shown in Figure 7.3.3.

1. **Determine subarea boundaries and then calculate flow path length and flow path slope**

   L = 1,150 feet
   S = (150*0.02+1,000*0.005) / 1,150 = 0.007 ft/ft

2. **Assume an initial value for T_C**

   Assume T_C = 12 minutes

RB-AR33640

3. Use Equation 5.1.2 to calculate intensity at time t, I_t

$$I_t = I_{1440} * \left(\frac{1440}{t}\right)^{0.47} \Rightarrow I_{12} = \frac{5\,\text{in}}{24\,\text{hr}} * \left(\frac{1440}{12}\right)^{0.47}$$
$$= 1.98 \text{ in/hr}$$

4. Determine the developed soil runoff coefficient using the soil curve data and Equation 6.3.2.

$$C_d = (0.9 * IMP) + (1.0 - IMP) * C_u$$
$$= (0.9 * 0.42) + (1.0 - 0.42) * 0.58 = 0.71$$

5. Use Equation 7.3.5 to determine a new T_C value

$$T_C = \frac{0.31 * L^{0.483}}{(C_d * I_t)^{0.519} * S^{0.135}}$$

$$= \frac{0.31 * 1150^{0.483}}{(0.71 * 1.98)^{0.519} * 0.007^{0.135}} = 15.27 \text{ minutes}$$

6. Compare initial assumption with new T_C value

15.27 minutes > 12.0 minutes

7. If the value is not within 0.5 minutes of the assumed, use the new T_C value and begin at Step 3 to complete another iteration

Use T_C = 15 minutes for the next assumption

8. Iterate until initial and final T_C values are with 0.5 minutes

The new values using T_C = 15 minutes are:

I_t = 1.78 in/hr
C_u = 0.54
C_d = 0.69
T_C = 16.37 minutes

RB-AR33641

The difference between 15 and 16.37 is greater than 0.5 minutes
Use T_C = 17 minutes and recalculate

I_t = 1.68 in/hr
C_u = 0.53
C_d = 0.69
T_C = 16.87 minutes

The difference between 17 and 16.87 is less than 0.5 minutes, use T_C = 17 minutes for subarea.

The acceptable T_C range is from 5 to 30 minutes. If a T_C of less than 5 minutes is calculated, use 5 minutes. If a T_C greater than 30 minutes is calculated for the 50-year 24-hour design storm, the subarea must be divided into two subareas.

11.2 TIME OF CONCENTRATION - T_C CALCULATOR

Public Works developed a time of concentration calculator to automate time of concentration calculations. In addition to carrying out the T_C calculation process, the T_C Calculator completes the full modified rational runoff calculation process yielding peak runoff rates and volumes. Routing is not a feature in the calculator.

The T_C Calculator spreadsheet, “TC_calc_vol.xls”, has been included on the CD with the Hydrology Manual.

1. The inputs to the calculator are the same as for the hand calculation method and are summarized in Table 11.2.1:

Table 11.2.1
T_C Calculator Inputs

Subarea size	7 acres
Soil type	068
Land use	42% impervious
Flow path length	1150 feet
Flow path slope	0.007
Rainfall depth	5 inches

RB-AR33642

2. If burned flow rates are desired, the appropriate fire factor should be determined from Table 6.3.3. In this case, no burned flow rate was necessary. A fire factor of 0 was used.

3. Figure 11.2.1 shows the interface for the T_C calculator with the data for Subarea 1A entered. For calculating the runoff from a single subarea, fill out the boxes in the upper left hand corner of the calculator under "Subarea Parameters Manual Input." Depressing the "Calculate T_C" button in the lower right will display the results shown in the figure.

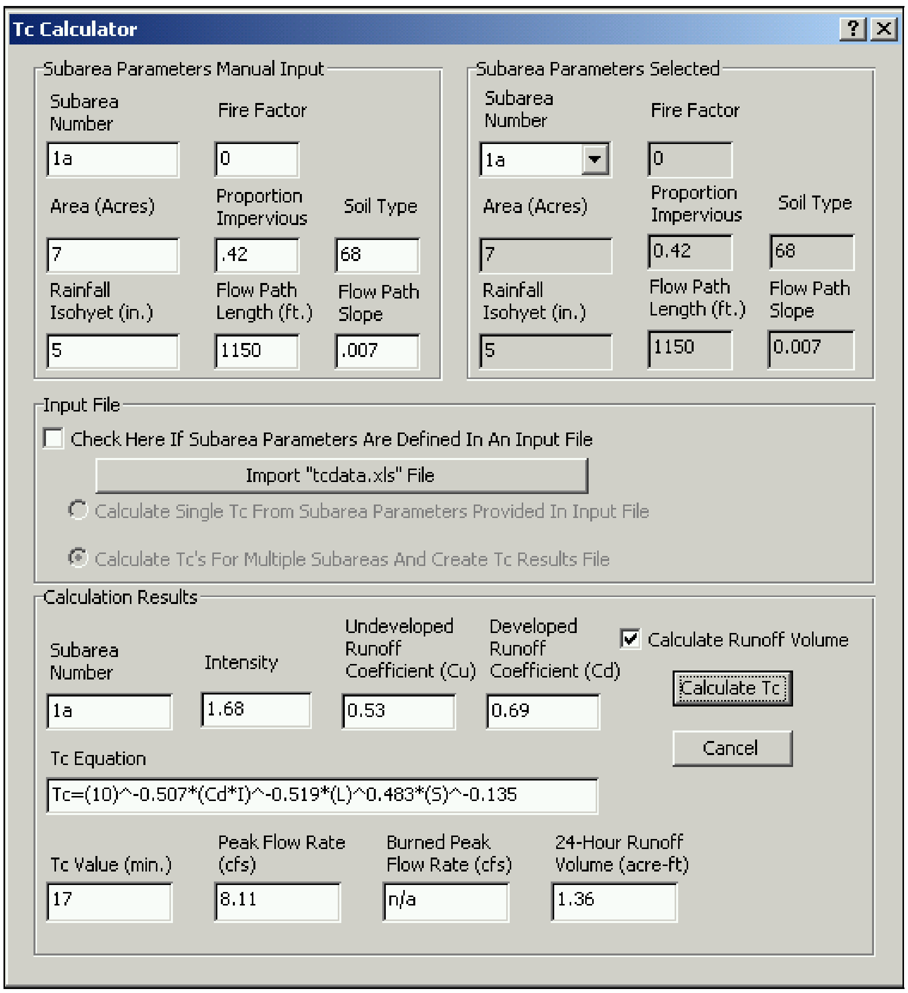

Figure 11.2.1
T_C Calculator Interface with Subarea 1A Results

RB-AR33643

The calculated T_C value, intensity, runoff coefficients, and peak flow rate are all the same as the values reached by hand calculation. Round off error and the uncertainties of reading table values cause the minor differences. The 24-hour runoff volume is also calculated if the "Calculate Runoff Volume" box is checked. By checking this box, the number of calculations increases and may take more time to display the results.

4. To calculate multiple subareas simultaneously, the T_C calculator can also accept Excel spreadsheets as input files containing a number of subareas. This file must be in the format specified in the “datasamp” sheet of the T_C calculator and in Figure 11.2.2

	A	B	C	D	E	F	G	H	I	J
1	Project	Subarea	Area	%imp	Frequency	Soil Type	Length	Slope	Isohyet	Fire Factor
2	Example	1a	7	0.42	standard	68	1150	0.007	5	0
3	Herondo Drainage	32j	30	0.92	standard	10	2525	0.008	4.52	0
4	Herondo Drainage	24g	19	0.92	standard	10	1950	0.006	4.38	0
5	Herondo Drainage	6a	11	0.92	standard	10	1600	0.017	4.24	0
6	Herondo Drainage	32j	30	0.92	standard	10	2525	0.008	4.1	0
7	Herondo Drainage	24g	19	0.92	standard	10	1950	0.006	3.96	0

Figure 11.2.2

T_C Calculator Input File Format

Name the Excel spreadsheet “tcdata.xls”. To use an input file with the program, first check the box on the input dialog that says, “Check Here If Subarea Parameters Are Defined In An Input File”. Then select the button labeled, “Calculate T_C’s for Multiple Subareas and Create a T_C Results File.”

Import the data by clicking “Import ‘tcdata.xls’ File” button. Once the data is imported, the box in the upper right corner of the calculator window displays data for individual subareas. You can select a subarea of interest by scrolling through the pull down box called “Subarea Number” at the right.

5. After pressing the “Calculate Tc” button, you will be prompted to name the results file. The results can then be viewed using Excel or individually using the pull down box. The results file shown in Figure 11.2.3 contains all the input and output information.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N
1	Project	Subarea	Area (acres)	%imp	Frequency	Soil Type	Length (ft)	Slope (ft/ft)	Isohyet (in.)	Tc-calculated (min.)	Intensity (in./hr)	Cu	Cd	Flow rate (cfs)
2	Example	1a	7	0.42	standard	68	1150	0.007	5	17	1.68	0.53	0.69	8.11
3	Herondo Drainage	32j	30	0.92	standard	10	2525	0.008	4.52	25	1.27	0.23	0.85	32.39
4	Herondo Drainage	24g	19	0.92	standard	10	1950	0.006	4.38	23	1.28	0.23	0.85	20.67
5	Herondo Drainage	6a	11	0.92	standard	10	1600	0.017	4.24	17	1.42	0.27	0.85	13.28
6	Herondo Drainage	32j	30	0.92	standard	10	2525	0.008	4.1	27	1.11	0.18	0.84	27.97
7	Herondo Drainage	24g	19	0.92	standard	10	1950	0.006	3.96	25	1.11	0.18	0.84	17.72

Figure 11.2.3
T_C Calculator Results File for Multiple Subareas

Peak Flow Rate and Volume Calculations

Runoff volumes are calculated by calculating runoff rates for multiple time steps. Section 7.3.2 explains the calculations needed to define a hydrograph. The volume of flow equals the total area under the hydrograph.

Calculating flow volume by hand is impractical for all but the simplest cases. The T_C Calculator program has an option that allows the user to calculate the total runoff volume. After indicating this intention by checking the box marked "Calculate Runoff Volume," the user can produce the 4th day runoff volume by pressing the "Calculate Tc" button and naming the output file as before.

Substituting the rainfall depths for the first through third days into the calculator produces daily runoff volumes for the other days of the design storm. Rainfall depths for these days are a specified percentage of the fourth day as Table 11.2.2 indicates.

Day of Storm	Percentage
1st day	10%
2nd day	40%
3rd day	35%

Table 11.2.2
Percentage of Fourth Day Depth

The T_C calculator also produces a hydrograph plot when calculating runoff volumes. The hydrographs are accessed by pressing cancel in the calculator. This takes you to the workbook that contains the sheets that store the data behind the calculator interface. One of these sheets is labeled "hydrograph chart". The hydrograph shown is from the last subarea selected for analysis. Figure 11.2.4 shows the runoff hydrograph for the previous example.

RB-AR33645

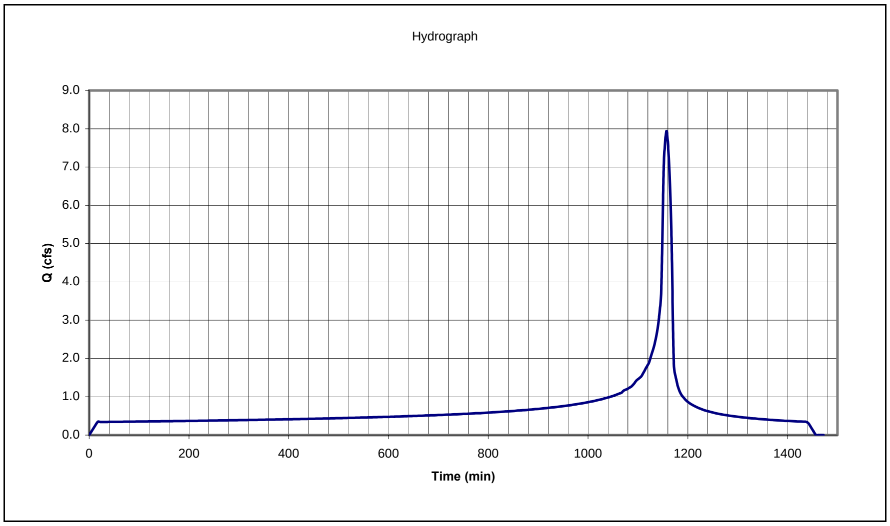

Figure 11.2.4
Runoff Hydrograph From the T_C Calculator

Storage Volume Requirements

Regional Basins

Regional Basins must be able to handle the 4-day design storm runoff volume. This may be accomplished by passing the first 3 days of storm flow through the basin, if the flow rate increase does not exceed pre-development flow rate levels. The regional basins must be able to store the post-development 4-day runoff volume, excluding the outflow during the storm. The basins must also meet other requirements determined by Land Development Division and Building and Safety Division.

ΔQ Basins – Antelope Valley

ΔQ Basins must store the change between pre- and post-development flow volumes, from all 4 days, for a 25-year event for percolation.

CHAPTER

12

Rational & Modified Rational Modeling

12.1 WATERSHED MODEL CREATION

The County of Los Angeles uses two related methods, the Rational and Modified Rational Method to calculate runoff rates. This section describes the necessary steps for creating a watershed model using both methods.

The first step in creating a model is to delineate the watershed using the methods described in Section 10.2. For countywide uniformity, subarea sizes should be approximately 40 acres. Smaller subarea sizes are acceptable.

Once the watershed and subareas are delineated, subareas and outlets must be numbered. The County of Los Angeles uses a subarea numbering system for hydrologic modeling that indicates the spatial relationships without the need for a diagram. A number and letter are assigned to each subarea and collection point.

Figure 12.1.1 shows an example of watershed numbering. Subarea IDs are indicated with a box and outlets are indicated with a leader. Numbers are assigned starting along the “mainline”. This is typically the longest stream channel in a watershed.

The upper most subarea on the mainline is assigned the label 1A. The watershed outlet of Subarea 1A is labeled 2A. The next watershed downstream from 1A is labeled 3A. In the example, Subarea 3A shares its outlet with another subarea, so instead of assigning the ID 4A to this outlet, 4A is assigned to the connecting subarea. The outlet downstream of 3A and 4A is labeled 5A. The numbering continues sequentially downstream.

When a confluence point with another stream or tributary is reached, numbering continues at the upstream end of the second stream or tributary. In the example, the A-line subarea upstream of the confluence is numbered

RB-AR33647

8A. The most upstream subarea in the confluencing stream is numbered 9B. The B-line is numbered the same way as the A-line. When the B-line reaches the confluence with the A-line, the confluence ID requires two suffix letters. One represents the mainline and the other represents the lateral. In this case, the confluence is labeled 16AB. This ends the B-line numbering. Continue the numbering in sequence using the suffix A. This numbering system can be extended to accommodate any number of confluencing laterals.

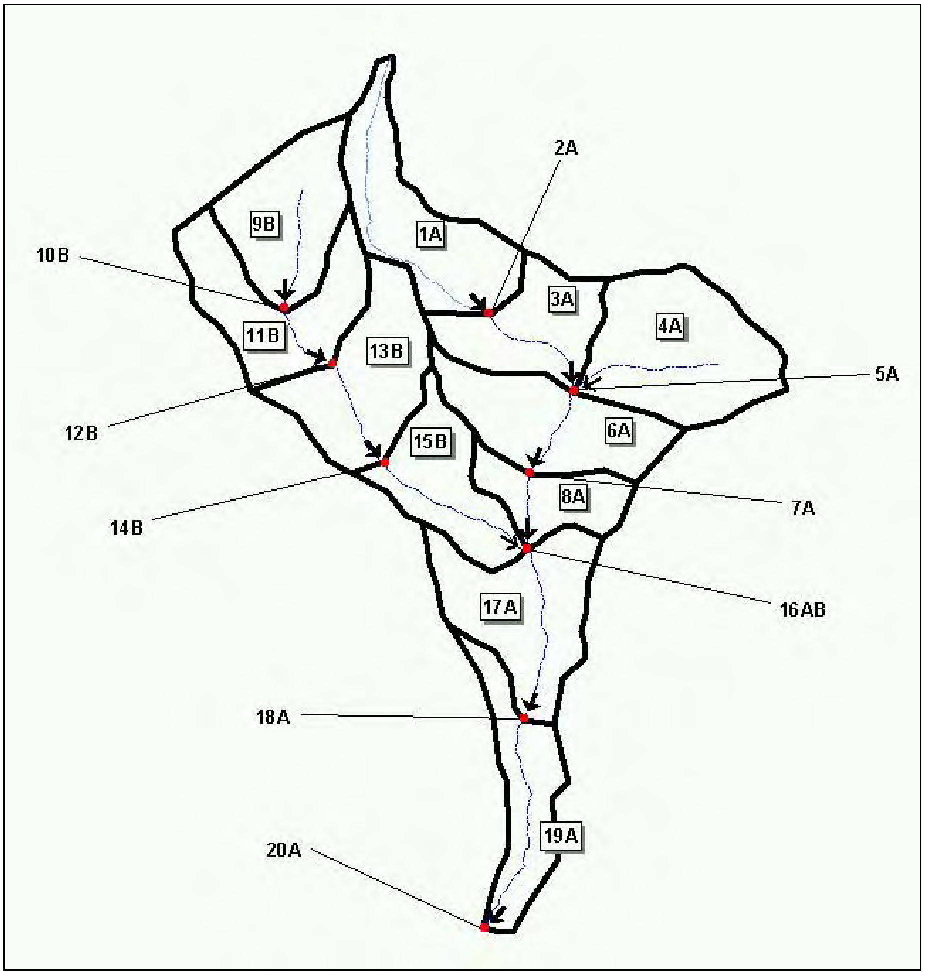

Figure 12.1.1
Watershed Numbering Example

RB-AR33648

Diversions are numbered as reverse confluences and begin at a collection point numbered with two suffix letters. The first letter represents the line where the diversion occurs. The second represents the letter for the diversion line. The diversion can be collected further downstream at a confluence or be allowed to divert water out of the watershed being studied. Figure 12.1.2 shows the same example of watershed numbering except with a diversion just upstream of the watershed outlet.

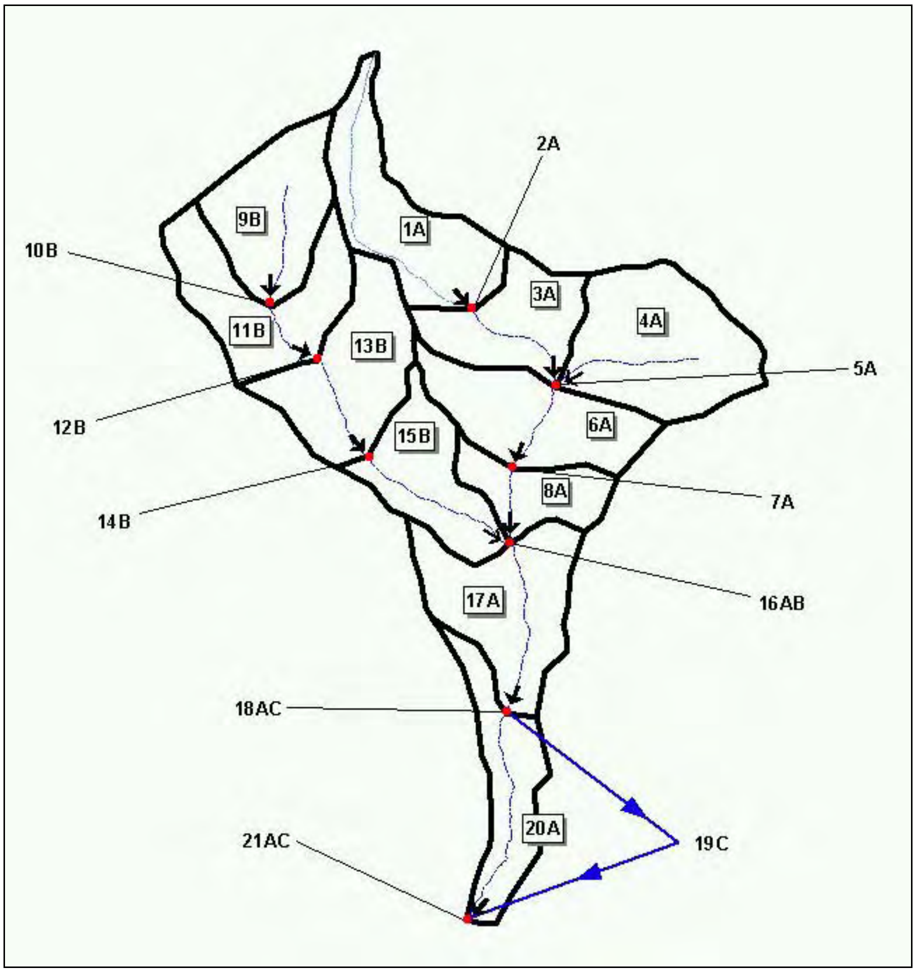

Figure 12.1.2
Watershed Numbering Example With a Diversion

RB-AR33649

After labeling the subareas and collection points, subarea characteristics must be determined. Table 12.1.1 contains a description of each of these characteristics and the procedure for calculating them. These steps are illustrated in examples in the following two sections. Also, see Section 10.5.

Table 12.1.1
Required Parameters for Rational and Modified Rational Modeling

Parameter	Units	Symbol	Procedure	Related Section
Basin Area	Acres	A	Measure the drainage area from a scaled topographic map.	-
Conveyance Length	Feet	L	Measure the length of the conveyances between subarea collection points.	-
Conveyance Slope	Feet/Feet	S	Slope is the change in elevation between collection points divided by the conveyance length. If mountain or valley slopes exceed 0.1 see Figure 7.3.8.	-
Soil Type	-	-	Use the maps in Appendix B or the GIS shapefile to determine the predominate soil type.	Section 6.3
Percent Impervious	%	IMP	Assign each subarea a percent impervious based on land use. When more than one land use exists, assign an area-weighted imperviousness average.	Section 6.3
Rainfall Depth	Inches	-	Use the isohyetal method to determine the average rainfall depth for a subarea.	Section 5.4
Time of Concentration	Minutes	T_C	Use Regression Method Equation.	Sections 7.3, 11.1, 11.2

12.2 RATIONAL METHOD

The Los Angeles County Hydrology Method allows use of the rational method for runoff calculation in small watersheds. The Rational Method is the basis of the Modified Rational Method and allows calculation of the peak runoff rate for a single subarea.

Since the rational method generates only peak flow rates and not hydrographs, the only way to combine the flows from two subareas is to add the peak flow rates together. This method of combination neglects the effects of channel routing, peak flow attenuation, and variable times of concentration. These factors reduce the peak flow rate in larger watersheds.

RB-AR33650

The peak-to-peak method is overly conservative in watersheds larger than a few subareas.

Subarea 1A, a typical rural watershed from the example in Section 5.4, will be used to illustrate the rational method. Figure 12.1.1 shows the entire watershed. Figure 12.2.1 shows an enlarged view of Subarea 1A.

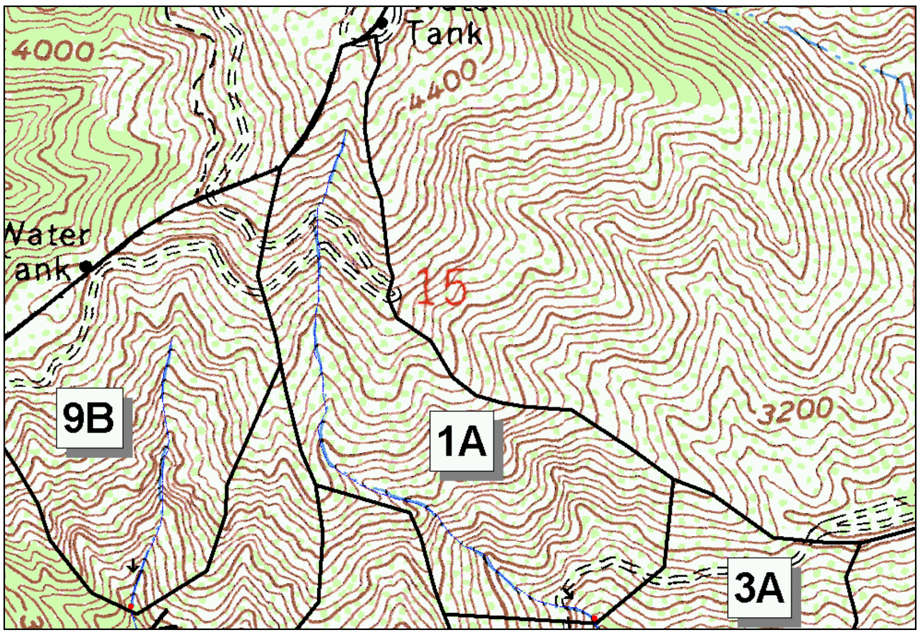

Figure 12.2.1
Subarea 1A

1. Section 5.4 contains the following data for Subarea 1A.

   Subarea size: 67.7 acres
   Rainfall Depth (50-year, 24-hour): 12.0 inches

2. Appendix B contains maps with hydrologic data. Figure 12.2.2 shows the Mount Baldy Quad, 1-H1-31, with soil types delineated. Subarea 1A contains soil types 081 and 088. However, the majority of the area is soil type 081. The characteristics of soil type 081 are used in the runoff calculation.

RB-AR33651

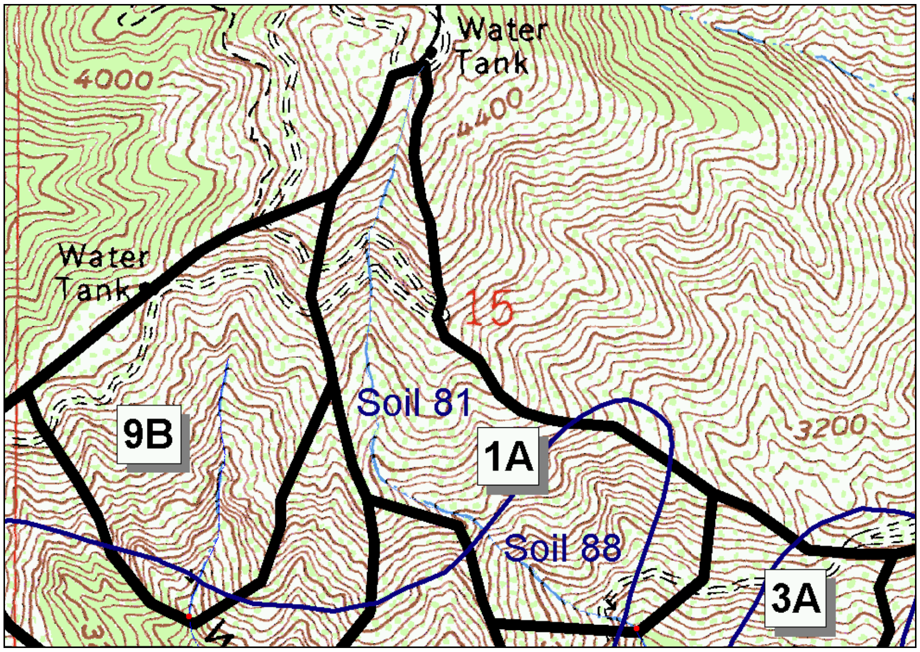

Figure 12.2.2

Appendix B Hydrologic Data Map – Mt. Baldy Quad with Subarea 1A and Soil Types Delineated

3. Appendix D contains information on imperviousness values based on land use. Subarea 1A is mountainous and undeveloped. Undeveloped rural areas are given an imperviousness of 1% in the Los Angeles County Method. For developed areas, the area-weighted imperviousness value is needed for each subarea. Section 6.3 illustrates area-weighted imperviousness calculations.

4. A time of concentration flow path is drawn from the most hydraulically remote location to the subarea outlet. The length and slope of this path needs to be determined. For Subarea 1A, the upper end of the T_C path is at an elevation of 4,612 feet and the collection point elevation is 2,739 feet. The flow path length measured using a planimeter is 4,109 feet.

   The slope is:

$$\text{Slope} = (4{,}612 \text{ ft} - 2{,}739 \text{ ft}) / 4{,}109 \text{ ft} = 0.456$$

5. Find the time of concentration by iteration:

- Convert the 24-hour rainfall depth into intensity, I_{1440}.

  I_{1440} = 12.0 in / 24 hrs = 0.5 in/hr

- Assume an initial T_C value of 12 minutes.

- Use the rainfall intensity-duration-frequency relationship, Equation 5.1.2, to determine the ratio of the 12-minute intensity to the 24-hour intensity.

$$\left(\frac{I_{12}}{I_{1440}}\right) = \left(\frac{1440}{12}\right)^{0.47} = 9.49$$

- Calculate the 12-minute intensity in in/hr;

$$I_{12\ min} = I_{1440} * \left(\frac{I_{12}}{I_{1440}}\right)$$

$$I_{12\,min} = 0.5 * 9.49 = 4.75 \text{ in/hr}$$

- Figure 12.2.3 is the soil runoff coefficient curve for soil type 081 from Appendix C. Using the intensity, I_{12min}, determine the undeveloped runoff coefficient: $C_u = 0.89$.

RB-AR33653

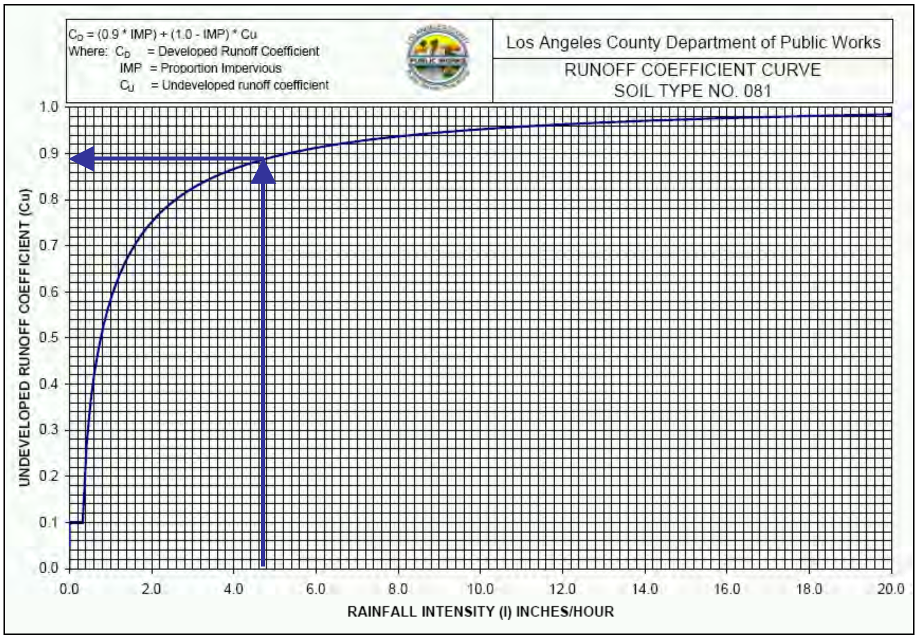

Figure 12.2.3
Soil Type No. 081, Runoff Coefficient Curve from Appendix C

- Calculate the developed runoff coefficient using Equation 6.3.2;

$$C_d = (0.9 * IMP) + (1.0 - IMP) * C_u$$

$$C_d = (0.9 * 0.01) + (1.0 - 0.01) * 0.89 = 0.89$$

- Calculate the value for rainfall excess;

$$\text{Excess rainfall} = C_d * I_{12min}$$
$$= 0.89 * 4.75 = 4.23 \text{ in/hr}$$

- Calculate the time of concentration using Equation 7.3.5;

$$T_C = \frac{0.31 * L^{0.483}}{(C_d * I_t)^{0.519} * S^{0.135}}$$
$$= 0.31 * 4.23^{-0.519} * 4{,}109^{0.483} * 0.456^{-0.135} = 9.1 \text{ minutes}$$

- Since the resulting T_C, 9.1 minutes, is not within half a minute of the assumed T_C, 12.0 minutes, assume another T_C and repeat the calculations. Use the calculated T_C as the guess for the next iteration.

RB-AR33654

- Table 12.2.1 contains data for each iteration of the T_C calculations

Table 12.2.1
Iterative T_C Calculations for Subarea 1A

Iteration Number	I_{1440} (in/hr)	Initial T_C (min)	I_t/I1440	I_t (in/hr)	C_u	C_d	C_d*I (in/hr)	Calculated T_C (min)	Difference (min)
1	0.5	12.00	9.49	4.75	0.89	0.89	4.23	9.1	2.9
2	0.5	9.1	10.8	5.4	0.90	0.90	4.86	8.4	.7
3	0.5	8.4	11.2	5.6	0.90	0.90	5.0	8.3	.1
Final	0.5	8.0	11.5	5.75	0.90	0.90	5.18		

- When the T_C is within half a minute of the assumed T_C, round to the nearest minute to get the final T_C and calculate the I_t, C_u and C_d.

- The subarea peak flow rate in cfs is calculated using the rational method. Multiply the rainfall excess (in/hr) by the area of the catchment (acres) to get peak flow.

$$Q_{peak} = (C_d * I_t) * Area$$
$$= (0.90 * 5.75 \text{ in/hr}) * (67.7 \text{ ac}) = 350.3 \text{ cfs}$$

Using the rational method for multiple subareas requires adding peak flow rates. For example, Subarea 3A has a peak flow rate of 146.9 cfs. The total flow rate at outlet 4A is 497.2 cfs using the rational method.

12.3 MODIFIED RATIONAL METHOD

The Modified Rational Method is an extension of the rational method used to create runoff hydrographs from a watershed of any size over a specific time period. The Rational method is limited to considering storms with a duration equal to the time of concentration and provides only a peak flow. The Modified Rational Method can consider single event storms with changing intensities and longer durations. The Modified Rational Method was developed as a means to produce hydrographs for storage design based on the rational method.

In the Modified Rational Method, the rational method is applied to each subarea's hyetograph to produce a hydrograph for each subarea in the watershed. The hydrograph for Subarea 1A of the Palmer Canyon watershed will be generated to show how calculations are performed. Computational implementations of the modified rational method use 1-minute timesteps to define the hyetograph. For illustration, only a few timesteps around the peak runoff at 1152 minutes will be used to define the hydrograph. The following information is needed:

Area:	67.7 acres
T_C:	8 minutes
Soil type:	088
Percent Impervious:	1%
4th day rainfall:	12.0 inches

The steps for hydrograph generation from Section 7.3 are as follows:

1. Determine the rainfall intensity for a time period equal to the T_C.
2. Determine the undeveloped soil runoff coefficient for the time period using the intensity.
3. Adjust the soil runoff coefficient using Equation 6.3.2 to determine C_d.
4. Use the rational equation, Equation 7.2.1, to determine the runoff for the time period.
5. Repeat steps 1 through 4 for each time period.

Illustration of hydrograph calculations will use time steps ending at 1128, 1153, and 1178 minutes. Figure 12.3.1 shows the three time periods used from the portion of the hyetograph near the peak rainfall intensity. Start with the time step ending at 1128. The 8 minute T_C calculated in Table 12.2.1 is used to define the time increment.

The first time interval of interest becomes minutes 1120 to 1128. The slope of the subarea hyetograph in Figure 12.3.1 changes during this period. The average intensity is used for the calculation. To calculate the average intensity, determine the total rainfall during this time and divide by the T_C in hours. The total rainfall from 1120 to 1128 is 0.203 inches in 8 minutes. This is equivalent to an intensity of 1.52 in/hr.

RB-AR33656

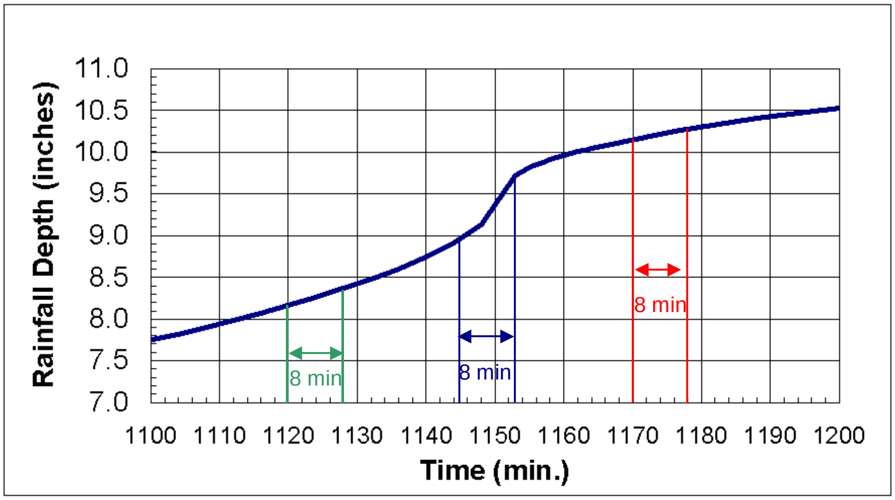

Figure 12.3.1
Subarea 1A Hyetograph With Calculation Points and T_C's Indicated

Figure 12.3.2 provides the C_u values for the three time steps of interest. From Figure 12.3.2, the undeveloped runoff coefficient for this intensity is 0.69.

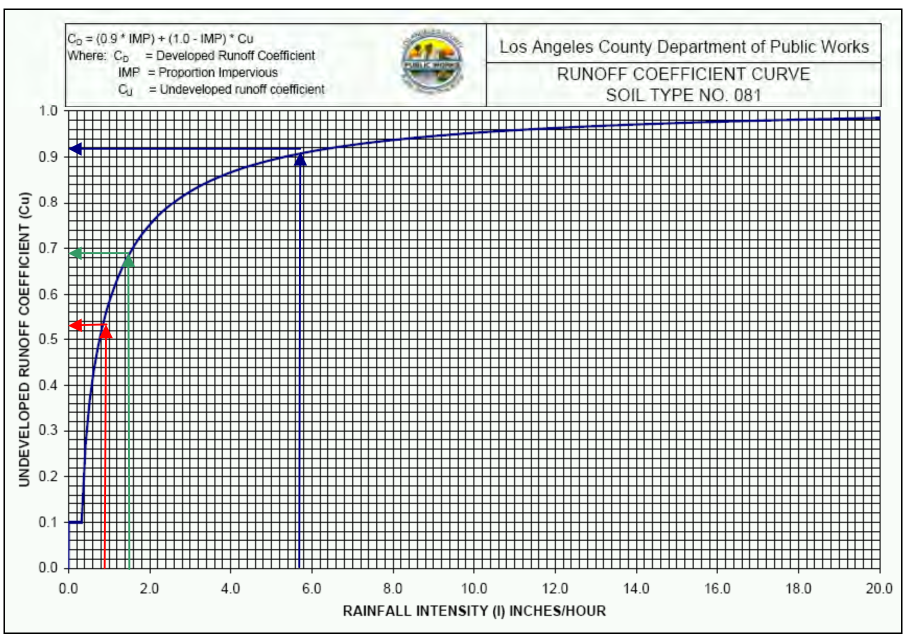

Figure 12.3.2
Soil Type 081 with Runoff Coefficients for 3 Time Steps Indicated.

Since this area has an imperviousness of 1%, the developed runoff coefficient as calculated using Equation 6.3.2 is also 0.69. The runoff for this time step is:

$$Q = C_d*I_t*A$$
$$= 0.69*1.52*67.7 = 71.0 \text{ cfs}$$

Table 12.3.1 shows the values used for the calculations at the end of each of the three time periods.

Table 12.3.1
Table of Runoff Calculations

Time (minutes) From	Time (minutes) To	Rainfall (in)	Intensity, I (in/hr)	Undeveloped Runoff Coefficient, C_u Fig. 7.3.3	Developed Runoff Coefficient, C_d Eq. 6.3.2	Area (acres)	Q = C_d *I*A (cfs)
1120	1128	0.20	1.52	0.69	0.69	67.7	71.0
1145	1153	0.76	5.71	0.90	0.90	67.7	348.0
1170	1178	0.12	0.89	0.53	0.53	67.7	23.52

Figure 12.3.3 shows the hydrograph made by connecting these points and assuming no flow at the start or end of the day. The shape would be further defined by calculating runoff at additional time increments.

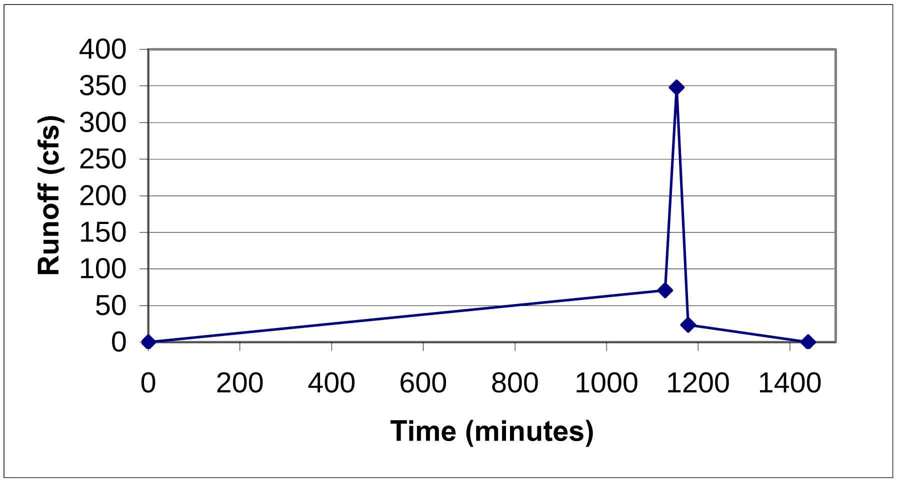

Figure 12.3.3
Hand Calculations Hydrograph for Subarea 1A

RB-AR33658

Figure 12.3.4 shows the hydrograph defined using 1-minute time shifts throughout the 24-hour time period.

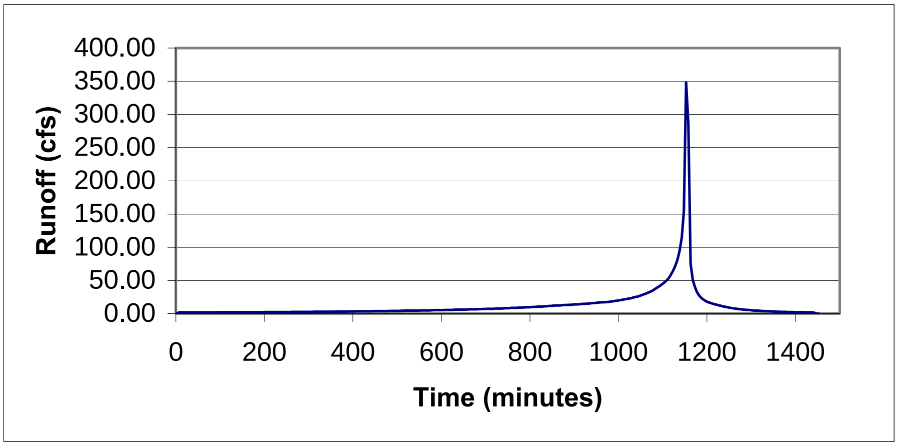

Figure 12.3.4
Subarea 1A Hydrograph, Using 1-minute Time Shifts

The hydrographs produced from successive subareas or laterals are routed and combined to produce hydrographs for successively larger watersheds. Section 7.3 describes the hydrologic routing process. The hydrographs are subjected to routing time lags and attenuation. The flow values for each time increment from all the hydrographs are added together. This hydrograph superposition allows large watersheds to be modeled using the modified rational method.

Table 12.3.2 compares the peak outflow from the Palmer Canyon watershed created by combining hydrographs peak-to-peak and hydrograph superpositioning for each time period. As shown, combining peak-to-peak always results in higher peak flow rates than hydrograph superposition after routing and channel storage.

RB-AR33659

Table 12.3.2
Comparison of Peak Watershed Outflow using Peak-to-Peak Combination and Hydrograph Superposition

Method		Rational	Modified Rational
Flow Combination		Peak-to-Peak	Hydrograph Superposition
Subarea Id	Area (acres)	Total Q (cfs)	Total Q (cfs)
1A	67.7	350.3	350.3
3A	47.7	497.2	475.0
4A	82.9	821.6	799.4
6A	62.5	1,060.8	1,004.5
8A	31.5	1,177.7	1,092.3
9B	57.7	264.5	264.5

15B	48.9	924.0	836.6
16AB	233.0	2,101.7	1,928.4
17A	69.3	2,311.5	2,088.2
19A	46.0	2,448.4	2,173.2
Total	640.6	2,448.4	2,173.2

Figure 12.3.5 is the modified rational method hydrograph for the entire Palmer Canyon watershed.

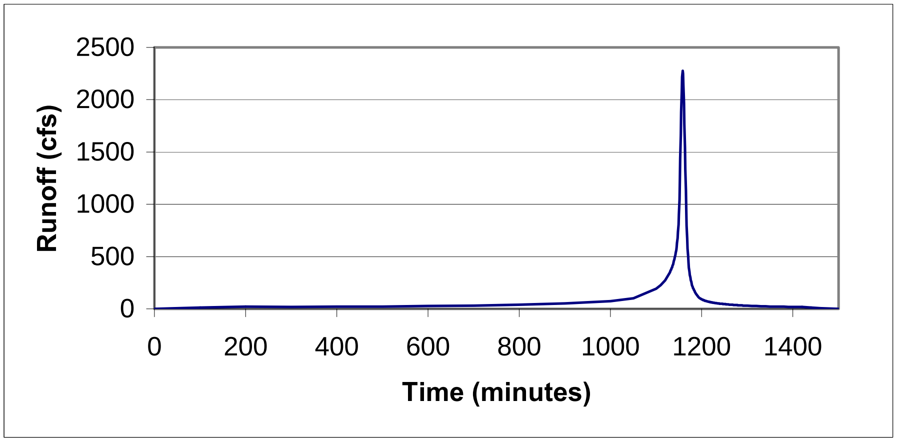

Figure 12.3.5
Modified Rational Method Hydrograph at Outlet of Palmer Canyon Watershed

RB-AR33660

Hand calculations for hydrographs, hydrograph routing, and superposition require a lot of time and careful organization. The calculations are ideally suited for computer programming and have been included in several software packages. Use of this software is encouraged to reduce the time required to reach a solution. Chapter 15 contains a list of software for Modified Rational Hydrology Studies within the County of Los Angeles.

Figure 12.3.6 is a view of the Palmer Canyon watershed used in the previous example.

CHAPTER

13

Classification of Hydrologic Models

13.1 EVENT VERSUS CONTINUOUS MODELS

Hydrologic models are divided into two categories: event or continuous models. Models that calculate runoff from a single storm lasting up to several days are called event models. The Los Angeles County Modified Rational Method model is an *event* model. Models that account for changes in the watershed over a long period of time and through several storm events are called *continuous* models. The Stanford Model and its descendant Hydrologic Simulation Program – Fortran (HSPF) are examples of continuous models. It is important to understand the differences between these types of models.

Hydrologists and engineers typically use event models to calculate runoff from a design storm event. This event may last from several hours to several days with nearly continuous rain. Event models lack mechanisms to account for changes over time in watershed conditions such as soil moisture. Event models must therefore use assumed watershed conditions. These assumptions work well for specific design criteria, but do not provide adequate results for longer periods. Watershed conditions may change between storms and through dry periods due to infiltration, evaporation, and transpiration. Watersheds also change over longer periods due to fire, construction, and changes in land uses. Event models have the advantage of being relatively simple to create and run.

Continuous models attempt to represent the effect of soil moisture and processes such as evaporation, transpiration, and flow through the subsurface on the runoff process. Continuous models account for changes in watershed characteristics at each time period and are suited to modeling runoff over long periods. Continuous model inputs require several months or years of historic data that contain most expected watershed conditions. The increased data requirements over event based models make the continuous models more complex to develop and calibrate. The spatial and temporal

RB-AR33662

variation of parameter values for soil infiltration rates, soil moisture capacity, evaporation rates, and rainfall are required. Table 13.1.1 contains examples of event and continuous models. The table also lists some of the parameters required by the models.

Table 13.1.1
Comparison of Event and Continuous Models

Model Type	Rainfall Input	Data Requirements	Examples
Event	Design Storm	Soil runoff characteristics, land use data, relevant rainfall duration.	HEC-HMS, SWMM, Modified Rational
Continuous	Historic Data or Design Storms	Land use, detailed soil and vegetation information, seasonal data, time series data including rainfall, runoff, evaporation, temperature, etc..	Stanford Model, HSPF, SWMM

13.2 LUMPED AND DISTRIBUTED PARAMETER MODELS

The Los Angeles County Modified Rational Method is classified as a lumped parameter model because parameters influencing runoff are lumped together and assumed uniform for each subarea. The model uses a combination of physical and analytical relationships to model runoff response to a rainfall design storm. Subareas are defined with reference to the drainage pattern of the watershed. Properties of a subarea such as rainfall, imperviousness, and soil properties are lumped for the entire subarea. Lumped parameter models usually require less data that is easier to obtain or estimate.

The alternative to a lumped parameter model is a distributed model. Instead of breaking up the watershed using drainage boundaries, a distributed model represents the properties of a watershed using small grid cells. These regularly spaced cells are assigned unique properties, reducing the simplification that occurs when parameters are lumped at the subarea level. Distributed modeling is compatible with watershed data inputs such as radar rainfall and soil moisture accounting. Distributed models generally require more data that may not be readily available.

CHAPTER 14

Divisions With Hydrologic and Hydraulic Responsibilities

In addition to the Water Resources Division, several divisions within the Los Angeles County Department of Public Works have responsibilities associated with hydrology and hydraulics. The divisions that provide these services are listed below along with key responsibilities that relate to hydrology and hydraulics.

14.1 BUILDING AND SAFETY DIVISION

The primary function of Building & Safety is the enforcement of Los Angeles County Building, Plumbing, Mechanical, and Electrical Codes, as well as other local and State requirements relevant to the construction and occupancy of public and private structures. The Division provides this enforcement through plan checking and inspection of new commercial and residential construction. The County's unincorporated area and 21 contracted cities are served by 25 branch or city inspection offices and a central administrative office. The Drainage and Grading Section provides the following services related to hydrology and hydraulics:

Hydrology Review Includes:

- Reviewing hydrologic studies for single lot residential and commercial projects based on Public Works' standards. The review identifies flood hazards due to inundation, overflow, or debris, and verifies that the appropriate levels of protection exist against these hazards.

RB-AR33664

- Verifying single lot residential and commercial project compliance with the Department's National Pollution Discharge Elimination System (NPDES) permit, including the enforcement of Standard Urban Stormwater Mitigation Plan (SUSMP) compliance.

- Verifying that post-development flow rates in watercourses adjacent to the development are no greater than pre-development flow rates.

Hydraulics Review Includes:

- Reviewing proposed drainage facilities and storm drains for capacity, appropriate levels of protection, and negative impacts on existing drainage systems.

- Checking pre- and post-development flows, velocities, and flow areas at the upstream and downstream of proposed single lot residential and commercial projects to verify that no negative impacts, including diversions, are created.

- Enforcing compliance with the National Flood Insurance Program (NFIP), including FEMA and County floodplain and floodway regulations.

- Reviewing hydraulic models of floodway and flood plain encroachments to determine development requirements and effects to upstream and downstream properties.

Grading Review Includes:

- Verifying that grading plans for single lot residential and commercial projects do not affect off-site areas negatively in terms of hydrology or debris production.

- Verifying compliance with the Department's NPDES permit by reviewing grading plans and inspecting the installation of required BMP's.

RB-AR33665

14.2 CONSTRUCTION DIVISION

The Construction Division is responsible for the administration and inspection of Public Works construction contracts; inspection of subdivision improvements; issuance and inspection of permits for road, drainage, and sewer projects; and utility coordination. In addition, the division awards and administers contracts to clean approximately 70,000 catch basins during the late summer months prior to each rainy season. Cleaning the basins improves storm water quality by minimizing the amount of debris that would otherwise flow through the storm drains and into the ocean. Construction Division's Permits and Subdivisions Section hydrology related responsibilities include:

- Confirming hydrology of tributary area and check the drainage area map of a proposed site with the existing sub-area map.

- Checking hydrology calculations using Public Works' standards. Check Design Hydrology peak flow rate and T_C calculations using the Public Works' T_C calculator.

- Submitting requests to Water Resources Division to perform hydrologic studies for the areas of interest, when no hydrologic study is available.

- Verifying that the allowable discharge flow rate, $Q_{Allowable}$ (cfs/acre), for the existing subarea has been obtained from Design Division.

- Comparing design hydrology with the system design hydraulics and requiring that any connections are designed based on the smaller value.

- Reviewing permit applications and construction projects for impacts of water releases into flood control facilities and coordinating with Water Resources Division on operational activities of Public Works' facilities.

14.3 DESIGN DIVISION

Design Division is responsible for preparing contract drawings, cost estimates, and specifications for Public Works' new construction, repair, retrofit, and rehabilitation projects. Projects include streets and highways, bridges, storm drains, water and sewer lines, debris control facilities, pumping plants, and facilities appurtenant to dams. The division also lends technical design support to other agencies and the public, and it publishes its *Standard Plan Manual* and *Standard Specifications Book* for construction contractors. The Design Division's Hydraulic Analysis Unit has the following duties:

- Providing the allowable discharge flow rate, $Q_{Allowable}$ (cfs/acre), which is the maximum discharge allowed for new connections to a drainage facility. The $Q_{Allowable}$ is based on the design hydrology study and any hydraulic capacity limitations of the subject drain or the downstream connecting system(s).

- Providing hydrologic data/information from facility design hydrologic studies including: the design storm frequency, scale-down factors, sub-area acreage, peak flow rates (including specific catch basin design subarea acreage and flow rates), and design reach peak flow rates throughout the system.

- Providing hydrology maps that graphically outline the limits of all subareas within the facility drainage area. Each subarea is individually identified with a corresponding number from the design hydrology study, as well as the acreage and peak flow rate.

- Providing hydraulic analysis calculations for drainage facilities. These include the hydraulic calculation sheets or Water Surface Pressure Gradient (WSPG) output data with the design flow rate, velocity, and hydraulic grade line (H.G.L.) or water surface elevation (W.S.E.) at various locations throughout the system. A WSPG hydraulic calculation for a proposed connection to a drainage facility must be based on the facility design H.G.L. or W.S. E. at the point of connection.

- Providing conceptual review on the preliminary hydraulic design of projects involving connections to, or modifications/realignment of, a drainage facility. The conceptual review determines the hydraulic,

RB-AR33667

hydrologic, and/or structural feasibility of the proposal prior to proceeding with the design.

14.4 ENVIRONMENTAL PROGRAMS DIVISION

The Environmental Programs Division is responsible for five major environmental programs within the County: Hazardous Material Underground Storage Tank (UST) Regulation; Solid and Hazardous Waste Management Planning and Implementation; Stormwater Discharge/Water Quality Monitoring and Control; Industrial Waste Control; and administration of the County's Garbage Disposal Districts. In addition, Environmental Programs provides technical support and advice for County recycling, composting, and hazardous waste programs, reviews road and utilities improvement plans relative to sanitary sewers, reviews building construction plans for the Methane Gas Intrusion Protection System, and provides waste management advice and coordination. Environmental Program's specific hydrologic duties include:

- Reviewing SUSMP plans for non-residential projects within the Industrial Waste Unit's areas of jurisdiction. After the commercial or industrial developer receives approval of the peak mitigated flow, "Q_{pm}", from the County Building and Safety, Land Development, or the local City Building & Safety office, the developer submits the approved "Q_{pm}" report and the required sets of plans to the Industrial Waste Unit. A permit application and fees for plan checking and permit processing are required. See the website http://www.ladpw.org/epd/industrial_waste/index.cfm for more information.

- Checking the storm water treatment devices and post-BMPs for suitability to the "Q_{pm}" and the site's storm water constituents. The approved storm water treatment devices are placed under a SUSMP permit.

- Inspecting storm water treatment devices to ensure that the devices are properly maintained.

14.5 LAND DEVELOPMENT DIVISION

Land Development Division is responsible for plan reviews and approval of all types of Public Works' infrastructure and final maps as part of the land development subdivision process. These subdivisions range in size from two lot parcel maps to 12,000-acre master plan communities including residential, commercial, and industrial development. In addition, this Division reviews and approves proposals to comply with storm water quality requirements of the Regional Water Quality Control Board. Land Development Division's responsibilities regarding hydrology are:

Hydrology Review Includes:

- Reviewing development plans to determine if on-site hydrology meets Public Works' standards.
- Checking SUSMP compliance and requiring use of BMPs during and after construction.
- Checking for required debris control structures for areas upstream of tracts and on-site locations.
- Checking post-development flow rates in adjacent watercourses to ensure that they do not exceed pre-development flow rates.

Hydraulics Review Includes:

- Reviewing proposed on-site drains for capacity, maintenance issues, and adequate downstream capacity. Ensuring that appropriate levels of protection exist.
- Checking pre- and post-development flows, velocities, and flow areas at the upstream and downstream tract boundaries to prevent negative off-site impacts.
- Enforcing floodplain and floodway regulations.
- Reviewing HEC-RAS models of floodway encroachments for compliance with regulations to prevent negative effects to the upstream and downstream areas.

RB-AR33669

Grading Review Includes:

- Reviewing grading plans to ensure that topographic changes do not affect off-site areas negatively in terms of hydrology or debris production.

14.6 WATERSHED MANAGEMENT DIVISION

Watershed Management Division is responsible for planning and implementing watershed management projects that protect the County's residents from flooding while integrating the elements of natural resources, groundwater, and stormwater conservation, improved stormwater runoff quality, and socio-economic, environmental, and recreational features. Watershed Management's hydrologic responsibilities include:

- Providing Flood Zone determinations for the public and lending institutions.

- Interpreting Flood Insurance Rate Maps (FIRMs) and identifying flood zone designations for properties and construction projects.

- Processing Letters of Map Revision (LOMR) and Conditional Letters of Map Revision (CLOMR).

RB-AR33670

CHAPTER

15

Computer Programs for Use in Los Angeles County Hydrologic Studies

Computer programs are powerful tools that simplify hydrologic computations. Several hydrologic software packages include the Los Angeles County Modified Rational Method. The software packages listed in Table 15.1 have been reviewed for use in hydrologic studies within the County of Los Angeles. The table provides contact information for purchasing the software and provides a brief description of approved uses for the software.

RB-AR33671

Approved Computer Programs

Name	Version	Description	Publisher
Watershed Modeling System (WMS)	7.1 and later	Implements the Modified Rational Method with reservoir routing and optional GIS capability	Environmental Modeling Systems www.ems-i.com 1-801-302-1400
XP-SWMM	9.0 and later	Implements the Modified Rational Method with some enhancements and the ability to model hydraulics and water quality	XP Software www.xpsoftware.com 1-888-554-5022
HEC-HMS	2.2.2 and later	Physically based, single event model can be used for reservoir routing.	Corps of Engineers Hydrologic Engineering Center www.hec.usace.army.mil
LAR04		Implements the Modified Rational Method	Civildesign Corp www.civildesign.com 1-909-885-3806
RETARD		Performs reservoir routing using the Modified Puls method.	Civildesign Corp www.civildesign.com 1-909-885-3806
TC_calc_vol.xls TC_calc_depth.xls		Implements the Modified Rational Method into calculations for single subareas and small watersheds.	LA County Dept. of Public Works www.ladpw.org

15.1 WATERSHED MODELING SYSTEM (WMS)

Watershed Modeling System (WMS) is a hydrologic modeling software that incorporates many standard hydrologic models. A key capability of WMS is the extraction of model input parameters from GIS data such as DEMs, TINs, and shapefiles. The program also allows use of georeferenced images for

RB-AR33672

backgrounds. WMS is modular and pricing is based on the number of modules purchased.

The Los Angeles County Modified Rational Method has been fully implemented in WMS. This implementation maintains the functionality of the prior F0601 code with several useful additions. WMS includes a graphical user interface to the model which facilitates data input and model creation. Reservoir routing, automatic T_C calculation, and automatic burned watershed simulations are recently added features.

15.2 XP-SWMM

The Storm Water Management Model (SWMM) is widely used to model storm drain systems. The United States Environmental Protection Agency (EPA) maintains this model. XP-SWMM is a Windows based interface for the SWMM model developed by XP Software.

XP-SWMM version 9.0 allows for the simulation of runoff, water quality, and hydraulic routing using the Los Angeles County Modified Rational Method. The XP-SWMM software has a graphical interface with the Modified Rational Method. Reservoir routing, automatic T_C calculation, and automatic burned watershed simulations are included features. A scenario manager also allows simultaneous simulation of multiple design storms. Future upgrades of XP-SWMM plan to include GIS capabilities.

15.3 HEC-HMS

HEC-HMS was developed by Hydrologic Engineering Center (HEC), Corps of Engineers. HEC-HMS does not support the Modified Rational Method. However, HEC-HMS was adopted as a replacement for the Mountain Hydrology Method (Q-S Method)[1]. Currently, Public Works uses HEC-HMS to model debris basins and dams.

15.4 LAR04/RETARD

The LAR04 program is a modified version of Public Works' F0601 program. The modifications include changing the program to a Windows console program, adoption of the latest soil and rainfall data files distributed by Public

RB-AR33673

Works, and user options to select output data for design storms ranging from 2-year to 500-year events. There is also the option to output data in metric units, include volume calculations with hydrographs and, an input option for areas as small as 0.1 acres.

LAR04 is a text-based implementation of the Modified Rational Method similar to F0601. This program uses the Los Angeles County Flood Control District program source code for the F0601 series programs. It also includes an independent program module, which assists the user in preparing an input data file for use by the F0601 program.

The RETARD program reads F0601 hydrographs, up to a 4-day storm series, and performs detention basin calculations using the Modified Puls, or storage indication method. The resulting outflow hydrograph may be inputted into the LAR04/F0601 program.

15.5 T_C CALCULATOR

The T_C Calculator may be used to calculate runoff and runoff volumes for small subareas and for small watersheds. Since it has no routing capabilities, use for watersheds larger than 100 acres is discouraged because routing alters peak flows and changes timing. These changes normally reduce flow rates in a storm drain system.

Best Management Practices (BMPs) Attachment

The Los Angeles County Department of Public Works (LACDPW) requires Permittees and their contractors to implement a program to effectively control water pollution during all Permit construction projects. This project shall conform with the requirements of the following County Code and Permits:

- Los Angeles, California County Code Chapter 12.80 Stormwater and Runoff Pollution Control
- Waste Discharge Requirements for Municipal Storm Water and Urban Runoff Discharges within the County of Los Angeles, and the Incorporated Cities Therein, Except the City of Long Beach (Order No. 01-182, National Pollutant Discharge Elimination System [NPDES] No. CAS004001),
- NPDES General Permit No. CAS000002, Order No. 99-08-DWQ, Waste Discharge Requirements for Discharges of Storm Water Runoff Associated with Construction Activities.

The Permittee or Authorized Representative and their contractors shall know and fully comply with the applicable provisions of these permits and Federal, State and local regulations that govern the Permittee or Authorized Representative's operations and the storm water discharges from the project site.

In order to ensure a minimum level of water quality control, the Permittee or Authorized Representative and their contractors shall effectively implement and maintain appropriate Best Management Practices (BMPs) shown in Table 1. In addition, the Permittee or Authorized Representative and their contractors shall comply with the following requirements:

- Sediments shall not be discharged to the storm drain system or receiving waters. Sediments generated on the construction site shall be retained.
- No construction-related materials: waste, spills, or residue shall be discharged from the project site to streets, drainage facilities, receiving waters, or adjacent property by wind or runoff.
- Non-storm water runoff from equipment, vehicle washing, or any other activity shall be contained within the project site using appropriate BMPs.
- Erosion from slopes and channels shall be prevented.
- Minimize grading during the wet season (October 15 through April 15). All erosion susceptible slopes shall be covered, planted, or protected in any way that prevents sediment discharge from the project site.

BMPs shall conform to the requirements in the LACDPW Construction Division's "Construction Site Best Management Practices (BMPs) Manual," and addenda thereto issued up to and including, the date of issuance of the Permit for the project. Copies of the Manual are available for purchase from:

Los Angeles County Department of Public Works

Alhambra, CA 91803
Telephone (626) 458-6959

Year-Round Implementation Requirements

The Permittee or Authorized Representative and their contractors shall have an effective program for implementing, inspecting, and maintaining water pollution control practices for wind erosion control, tracking control, non-storm water control, and waste management and materials pollution control.

Soil stabilization and sediment control practices shall be provided throughout the rainy season, defined as between October 15 and April 15, and whenever the National Weather Service predicts rain within 24 hours. The National Weather Service weather forecast shall be monitored and used by the Permittee on a daily basis.

The non-rainy season shall be defined as all days outside the defined rainy season. Disturbed soil areas within the project shall be protected in conformance with the requirements in the Construction Site BMP Manual with sediment controls implemented prior to a predicted rain event.

Maintenance and Inspection

The Permittee or Authorized Representative and their contractors shall be responsible throughout the duration of the project for installing, constructing, inspecting, maintaining, removing and disposing of the BMPs. Unless otherwise directed by LACDPW, the Permittee or Authorized Representative and their contractors are responsible for BMP implementation and maintenance throughout any temporary suspension of work. The Permittee or Authorized Representative shall reimburse LACDPW for the full costs of cleaning or repairing of storm drain, water course, or channel which may be necessary due to ineffective implementation of BMPs.

The project site shall be inspected by the Permittee or Authorized Representative or their contractors a minimum of once every week or at least once for projects that last only one week or less.

Report of Non-Permitted Discharge and Enforcement

If the Permittee or Authorized Representative or their contractors identify any non-permitted discharge into the storm drain system or receiving waters in a manner causing, or potentially causing, a condition of pollution, or if the project receives a written notice or order from any regulatory agency, the Permittee or Authorized Representative or their contractors shall immediately inform LACDPW Construction Division Permits Section by calling the assigned Field Office. The Permittee or Authorized Representative or their contractors shall submit a written report (see attached Notice of Non-Permitted Discharge) to the LACDPW within 5 days of the discharge event, notice or order.

The Permittee or Authorized Representative and their contractors are subject to enforcement action by Chapter 12.80 of the Los Angeles County Code that states, "*Any person, firm, corporation, municipality or district or any officer or agent of any firm, corporation, municipality or district violating any provision of this chapter shall be guilty of a misdemeanor. Such violation shall be punishable by a fine of not more than $1,000 or by imprisonment in the county jail for a period not to exceed six months, or by both fine and imprisonment. Each day during any portion of which such violation is committed, continued or permitted shall constitute a separate offense and shall be punishable as such (Ord. 98-0021§1(part), 1998).*"

In addition, the Permittee or Authorized Representative and their contractors are subject to enforcement action by the State Water Resources Control Board (SWRCB), Environmental Protection Agency, private citizens and citizen groups. The Permittee or Authorized Representative and their contractors shall be responsible for the costs and for liabilities imposed by law as a result of the Permittee or Authorized Representative or their contractor's failure to comply. Costs and liabilities include, but are not limited to, fines, penalties and damages whether assessed against LACDPW or the Permittee or Authorized Representative or their contractors, including those levied under the Federal Clean Water Act and the State Porter Cologne Water Quality Act.

CLARIFICATION TO PART 4.D. DEVELOPMENT PLANNING PROGRAM, THE LOS ANGELES COUNTY MUNICIPAL STORM WATER PERMIT, ORDER No. 01-182, NPDES PERMIT No. CAS004001

Dear Mr. Pestrella and Municipal Directors:

Thank you for requesting clarification on the Development Planning requirements of the Los Angeles County Municipal Storm Water Permit (L.A. County MS4 Permit).

This letter restates the compliance expectation of the California Regional Water Quality Control Board, Los Angeles Region (L.A. Water Board), when it adopted the requirements in ‘Part 4 §D, Development Planning’ of the L.A. County MS4 Permit. Part 4.D contains specific provisions that are fully enforceable, and which were also contained in the Development Planning Model Program submitted by the L.A. County Permitees, and which was approved in 2000.

Our evaluation of the implementation of the Development Planning and Standard Urban Stormwater Mitigation Plan (SUSMP) requirements on land development projects in Los Angeles County has revealed that many Permittees’ planning and public works departments and their associated staff, including architects, planners and engineers have failed to integrate SUSMP implementation adequately with other storm water quality management strategies required in the L.A. County MS4 permit. The L.A. Water Board has identified several instances of inadequate or uncoordinated implementation by Permitttes for ‘Part 4.D Development Planning’.

U.S. EPA Guidance

In areas undergoing new development or redevelopment, the most effective method of controlling impacts from storm water discharges is to limit the amount of rainfall that is converted to runoff. By utilizing design techniques that incorporate on-site storage and infiltration, and minimizing the amount of directly connected impervious surfaces, the amount of runoff generated from the site can be significantly reduced (***Preliminary Data Summary of Urban Storm Water Best Management Practices***, EPA 821-R-99-012, August 1999).

The three provisions in Part 4.D are consistent with guidance in Chapter 5 of ***Preliminary Data Summary of Urban Storm Water Best Management Practices***. The U.S. EPA guidance states that in order to meet the goals of post-development peak discharge rate, volume and pollutant loading to receiving waters being the same as pre-development values, BMPs should be implemented to achieve three main objectives: flow control, pollutant removal and pollutant source reduction.

California BMP Manual

Similarly, Section 2.4 of the California Stormwater Quality Association (CASQA) BMP Handbook for Development and Redevelopment (2003), in its discussion on planning and design principles, reiterates the provisions in Part 4.D. These principles promote three basic strategies in the following order of preference based on effectiveness and costs: (1) reduce or eliminate post-project runoff; (2) control sources of pollutants; and (3) treat contaminated storm water runoff before discharging it to natural water bodies.

Groundwater Quality Protection Concern

Some Permittees have expressed a concern that infiltration of storm water may present risks to groundwater aquifers. Generally, the common pollutants in storm water are filtered or adsorbed by soil, and unlike hydrophobic solvents and salts, do not cause groundwater contamination. In any case, infiltration of 1-2 inches of rainfall in semi-arid areas like Southern California where there is a high rate of evapo-transpiration, presents minimal risks.

The Water Augmentation Study conducted by the Los Angeles and San Gabriel Rivers Watershed Council, in partnership with several agencies including water districts, municipalities, and the U.S. Bureau of Reclamation, indicates that the infiltration of storm water, with appropriate pretreatment, does not adversely impact groundwater quality (***Los Angeles Basin Water Augmentation Study, August 2005***). You may view the study at www.lasgrwc.org/WAS.htm

Infiltration of storm water discharges from heavy industrial areas is seldom appropriate. Where there is a real concern on the risk of groundwater contamination from preexisting soil contamination or heavy vehicular traffic when installing infiltration systems such as extended detention basins, the L.A. Water Board and the California Department of Transportation (Caltrans) developed guidance to ensure an adequate analysis for proper siting. See, ***Infiltration Basin -Site Selection Study, Volumes I, II, and III*** June 2003, CTSW-RT-03-025**,** http://www.dot.ca.gov/hq/env/stormwater/special/newsetup/index.htm

Caltrans research indicates that infiltration basins and biofiltration BMPs are technically feasible if site site-specific considerations are taken into account (Caltrans CTSW-RT-01-050, ***BMP Retrofit Pilot Program, January 2004***).

Background of MS4 Development Planning Requirements

Standard Urban Storm Water Mitigation Plan

On March 8, 2000, the L.A. Water Board adopted the SUSMP, and required that municipalities incorporate into the planning and design phases post-construction storm water mitigation controls for specified development and redevelopment projects. Although the SUSMP action was petitioned by some municipalities to the State Water Resources Control Board (State Water Board), the State Water Board directed in Water Quality Order 2000-11 that, ***"the Permittees shall amend codes, if necessary, not later than January 15, 2001, to give legal effect to the SUSMP requirements. The SUSMP requirements shall take effect not later than February 15, 2001."***

On November 7, 2003, the L.A. Water Board transmitted the Development Planning Program Review Report after auditing four Permittee Programs (the Planning Review Report). The Planning Review Report presented and described discernible permit violations, deficiencies, and notable elements observed during the audit. Notably, the MS4 Development Planning program contained in Board Order No. 01-182 is built upon programs already established in previous Board Orders (90-079 and 96-054), after undergoing a very long process of public hearings and meetings before permit adoption.

Nearly six years later after the SUSMP was adopted, most Permittees' implementation of SUSMPs is deficient, because Permittees have not focused nor emphasized water quality pollution mitigation to protect the beneficial uses of receiving waters.

Consequently, the L.A. Water Board provides the following clarification consistent with the L.A. Water Board's mission of protecting water quality and preserving water resources:

A. Essential Post Construction Control Requirements

1. The three provisions in Part 4.D are the essential requirements for compliance with the Development Planning requirements of the L.A. County MS4 Permit. The three provisions are to: (1) maximize the percentage of pervious surfaces to allow percolation of storm water into the ground; (2) minimize the quantity of storm water directed to impervious surfaces and the MS4; and (3) minimize pollution emanating from parking lots through the use of appropriate treatment control BMPs and good housekeeping practices.

The basic site design planning considerations for post-construction storm water BMP implementation are to:

a. Preserve the natural drainage system, protect slopes and provide controls for stream protection. These controls are achieved through the basic control measures that include infiltration, retention/detention, bioretention and biofilters;

b. Integrate fully the opportunities to maximize the percentage of pervious surfaces and minimize the volume of storm water runoff;

c. Utilize a BMP treatment-train that (i) captures and infiltrates using infiltration basins, infiltration trenches, retention and/or detention BMPs; and/or (ii) provide flow through treatment in the order of preference for the prescribed storm water quality runoff volume **(Q_{wv})** based on the numerical mitigation criteria in Part 4.D;

d. Identify the combination of BMP treatment trains that are to be sized, designed and constructed based on **Q_{wv}** required for water quality. Using **Q_P** from 10, 20, or 50-year return-period for flood management is inappropriate for water quality purposes and not cost effective. Capturing and treating a larger percentage of the annual storm water runoff volume greater than **Q_{wv}** provides only a small increase in additional removal of pollutants and considerably increases the sizing and cost of the structural and treatment storm water controls; and

e. Establish in addition, for downstream channel protection, instead of **Q_P** a flow control criteria (Q_{HMC}) which takes into consideration flow volume, duration, and frequency to maintain the predevelopment distribution of in-stream flows above the critical flow for streambed erosion, thus preserving the pre-development capacity to transport sediment, while not accelerating down stream erosion. An appropriate hydromodification flow duration control criteria might be to set the Q_{HMC} such that the post-construction discharge rates and duration match the ranges from 10 percent of the pre-development 2-year 24 hour peak flow up to the pre-development 10 year 24 hour peak flow, unless an alternative criterion can be demonstrated as equally protective using hydrodynamic modeling.

2. <u>Measures and Approaches for Minimizing Impervious Surface Area</u>

a. Permittees must minimize the percentage of impervious surfaces to support the percolation and infiltration of storm water into the ground and/or minimize pollutants emanating from impervious surfaces by reducing the percentage of effective impervious area to a generally accepted standard of 5 percent or less of total project area.

The U.S. EPA storm water technology fact sheet for bioretention recommends that sizing criterion should be 5 to 7 percent of the drainage area multiplied by the rational method runoff coefficient "C" determined for the site (***Storm Water Technology Fact Sheet, Bioretention***, U.S. EPA Document No. EPA 832-F-99-012, September 1999). However, a lower sizing criterion may be more appropriate for

Southern California. A recent study determined that physical degradation of stream channels in semi-arid climates such as in Southern California may be detectable with watershed impervious cover between 3 and 5 percent (***Effects of Increases in Peak Flows and Imperviousness on the Morphology of Southern California Stream,*** SCCWRP, April 2005).

b. Permittees must also control pollution emanating from impervious surfaces such as roof-tops, parking lots, and roadways through the use of appropriate source controls such as the use of low impact development (LID) and integrated water resources management strategies that:

1. Emphasize conservation and the use of on-site natural features;
2. Integrate engineered small-scale hydrologic controls to more closely reflect pre-development hydrologic functions. Small-scale hydrologic controls are BMPs that create green infrastructure and spaces such as park-like open space, rainwater collection barrels, planter boxes, and garden-like areas that promote community awareness and improve storm water quality; and
3. Implement primarily a source control and minimize the need for large sub-regional and regional treatment control BMPs.

B. <u>Plan Preparation/ Review Procedures and Guidelines</u>

1. Permittees must possess clear and adequate legal authority in municipal storm water ordinances to address post-construction requirements in the L.A. County MS4 Permit. The legal authority must direct land developers to review and mitigate the adverse storm water quality impacts in the Environmental Impact Report (EIR), and to ensure that adequate post-construction control measures are incorporated during the development project's site planning and design phases. In addition, clear instructions should be provided on how to illustrate on plans the BMPs selected, adequate sizing, and BMP siting;

2. The selection of the treatment train of BMPs must be conducted through a methodical selection process that matches the type of BMP with the type and nature of pollutants that are expected to be generated from the site. For example, vortex separation devices installed in high commerce areas for removing trash and gross solids are not suitable for removing pollutants in dissolved state or smaller size/lighter weight fractions from vehicular traffic areas;

3. Permittees should also prescribe guidelines for the submittal of standard final SUSMP plans so that relevant storm water BMP locations and specifications in design sheets are clearly identified. Separate SUSMP detail plan sheets will facilitate technical review.

   Delineation of drainage area and/or sub-areas, natural drainage systems, storm drains, and other relevant parameters at pre-development and post-development water flow paths, outfall (drainage) locations, BMP detail plans, and other relevant information should be presented. Simply inserting post-development plans within the grading plans, storm drain plans, or civil plans with unrelated detail drawings, numbers, and

RB-AR33691

construction notes makes it difficult to review and evaluate. Small-scale controls may be combined with the landscaping plans;

4. Plan view and sectional plans for small-scale hydrologic controls for a lot size and sub-drainage area of the sites should be prescribed; and

5. BMP design specifications must be incorporated in the SUSMP report together with hydrologic calculations for sizing BMPs. This report should support and show how criteria were adequately utilized in sizing BMPs (e.g., infiltration, retention/detention BMPs, bioretention facilities, etc.);

If you have any questions, please call Dr. Xavier Swamikannu at (213) 620-2094 or Carlos D. Santos at (213) 620-2093.

Sincerely,

Executive Summary

Southern California is facing increased demands from urbanization, which can create adverse impacts to water quality and quantity. Urban areas can discharge polluted runoff and degrade alluvial channels. Two-thirds of urban streams have excessive nutrient pollution, and fecal coliform bacteria in these streams commonly exceed standards for water recreation (USGS, 2008). Water pollution not only impacts the beneficial uses of our receiving waters (e.g. aquatic life, recreation), but also represents a significant cost to cities as they strive to comply with increasingly stringent state and federal water quality regulations. The Southern California region, under the jurisdiction of three California Regional Water Quality Control Boards (RWQCBs), is faced with rapid population growth and continuous budget constraints. The region will meet the challenge of improving receiving water quality by incorporating low impact development (LID) stormwater techniques.

Stormwater is increasingly being managed through the strategies and principles of Low Impact Development, which is defined as an ecosystem-based approach to designing a built environment that remains a functioning part of an ecosystem rather than existing apart from it. It is an innovative approach to urban stormwater management that does not rely solely on conventional end-of-pipe structural methods; rather, it strategically integrates stormwater controls into the urban landscape. Targeted watershed goals and objectives can be addressed through the use of structural and non-structural LID techniques in order to reduce the discharge of pollutants and the effects of changes to runoff patterns caused by land use modifications (hydromodification).

Land developments in Southern California that drain to the Pacific coast and to inland waters and reservoirs have generated significant increases in stormwater runoff volume, which in turn has contributed to the discharge of pollutants into receiving waters, degraded aquatic habitat, impacted recreational use of these waters, and interfered with their use as water supply (California Department of Water Resources, 2009). LID for new development may only reduce the rate of increase of water quality degradation. Incorporating LID in redevelopment, where feasible, can replicate and enhance a site's hydrologic function, though it should be noted that creating a built environment that is a functioning part of an ecosystem in developed areas where water quality is already degraded may take extensive redevelopment and long periods of time, perhaps 50 to 100 years, before any benefits to water quality may be observed.

The purpose of this LID Manual is to serve as a resource that can be used to guide communities in the development of design, construction, and maintenance standards and specifications, as well as codes and ordinances, which can support their water quality management and regulatory compliance programs. It is intended to complement evolving local stormwater management requirements driven by the adoption of new municipal separate storm sewer system (MS4) permits under the Clean Water Act. New MS4 permits are increasingly requiring the adoption of LID techniques to minimize increases in runoff volume and peak discharge rates resulting from land development. Local permits are discussed in Appendix B.

Hydromodification has been identified as a leading source of water quality impairment in the United States (EPA, 2004). Hydrologic modifications change a site's runoff and transport characteristics, diminishing infiltration, interception, and evapotranspiration, thereby altering the distribution and flow of water across a site. LID is a design strategy that utilizes decentralized, small-scale source control structural and/or non-structural stormwater practices to meet certain technical requirements of federal, state, and local government stormwater management regulations, as well as natural resource protection and restoration goals. This approach can be used as an alternative or enhancement for conventional end-of-pipe stormwater pond technology. This alternative tool is important because it has the potential to lessen the energy impacts of large concentrated volumes of runoff from conventional end-of-pipe approaches on receiving waters and to reduce the development footprint and long-term maintenance considerations for end-of-pipe facilities. LID has also been used to meet targeted regulatory and resource protection objectives. LID addresses hydromodification through the use of "customized" small-scale source controls that allow the designer to select BMPs that best meet the watershed goals and objectives. This approach also allows for the creation of treatment trains, which use a system of different techniques to provide multiple opportunities to reduce pollutant loads.

How to Use This Manual

This manual provides site planning and design guidance, but given the varying site conditions and regulations throughout the region it is not practical to provide suggestions and guidance for every possible situation. The recommendations in this manual are not intended to supersede any local regulations. The manual consists of concepts and techniques presented in a format that will facilitate dialogue between developers, engineers, and local governments to encourage adaptation and integration of these strategies and techniques into local regulatory and watershed protection programs.

In summary, this is a manual of practice for LID that provides:

- Details on how to use LID Principles and LID Best Management Practices (BMPs) to reduce the impacts of land development or re-development on water resources at the project level.
- Guidance for municipalities, land use planners, land developers, consultants, design professionals who prepare stormwater engineering plans and specifications, and others in private industry and public service.
- A site planning and design reference that will facilitate the implementation of LID for projects in Southern California. It is designed to complement the Stormwater BMP Manual(s) that have been developed and are maintained by the California Stormwater Quality Association (CASQA).
- A tool that can be applied at the site level for the development of integrated water and stormwater management regulatory compliance and resource protection programs.

The Manual is structured as follows:

Executive Summary
Provides an overview of the Manual's structure and objectives.

Section 1: The Impacts of Development and How LID Can Help
Describes how LID can be used to address major water quality and regional environmental challenges.

Section 2: The LID Site Design Process

- **Step 1: Assess Site**
  Outlines the data to be collected prior to site design and directs the user to data resources.
- **Step 2: Define Goals**
  Describes how LID fits into the regulatory environment and how it can be used in green building.
- **Step 3: Implement LID Principles**
  Presents site planning strategies to minimize the generation of stormwater runoff.
- **Step 4: Use LID BMPs to Mitigate Impacts**
  Discusses the selection and application of LID BMPs mitigate unavoidable stormwater runoff.
- **Step 5: Evaluate Design**
  Identifies methods for assessing the successful application of LID to a given site. Discusses the use of a number of modeling methods to evaluate LID designs.

Section 3: Case Studies
Presents case studies showing how LID is applied in various contexts.

Appendix A: Lists of Plants Suitable for LID in Southern California
Provides lists of plants suitable for general landscaping, bioretention, and green roofs in Southern California.

Appendix B: California Planning and Regulatory Framework for LID
Discusses how LID fits into California's regulatory environment.

Appendix C: LID, LEED, and the Sustainable Sites Initiative
Details how LID can be used to achieve LEED or Sustainable Sites Initiative Certification.

Section 1: The Impacts of Development and How LID Can Help

There are many potential benefits associated with the use of Low Impact Development (LID) practices. In addition to stormwater management, LID implementation can result in environmental, economic, and community benefits.

Potential Environmental Benefits
- Improved water quality
- Maintenance of predevelopment runoff volume
- Maintenance of predevelopment runoff discharge rate
- Groundwater recharge
- Terrestrial and aquatic habitat preservation
- Reduced potable water and energy demand
- Improved air quality
- Carbon sequestration
- Recycling and beneficial reuse
- Reduction in urban heat island effect

Potential Economic Benefits
- Reduced construction and maintenance costs (see SPU Cost-Benefit Analysis in *References and Resources* below)
- Improved marketability
- Energy cost reduction and water conservation

Potential Community Benefits
- Improved aesthetic value
- Provides “green job” opportunities
- Educational opportunities
- Health benefits

The primary factor to be considered when evaluating how to reduce and mitigate the impacts of stormwater is the pattern of rainfall in the watershed. The Southern California region experiences strong seasonal rainfall variation, with the wet season typically extending from October through April and virtually no rain from May through October. The region’s diverse topography results in a high degree of regional variation in total rainfall and storm size and annual rainfall totals can vary greatly from year to year. These variations will affect the feasibility, effectiveness and as a result the selection of various LID practices.

In addition to evaluating local climatic conditions in LID selection and sizing for stormwater benefits, it is necessary to understand the local hydrologic cycle in order to maintain or mimic the natural hydrologic function of a site.

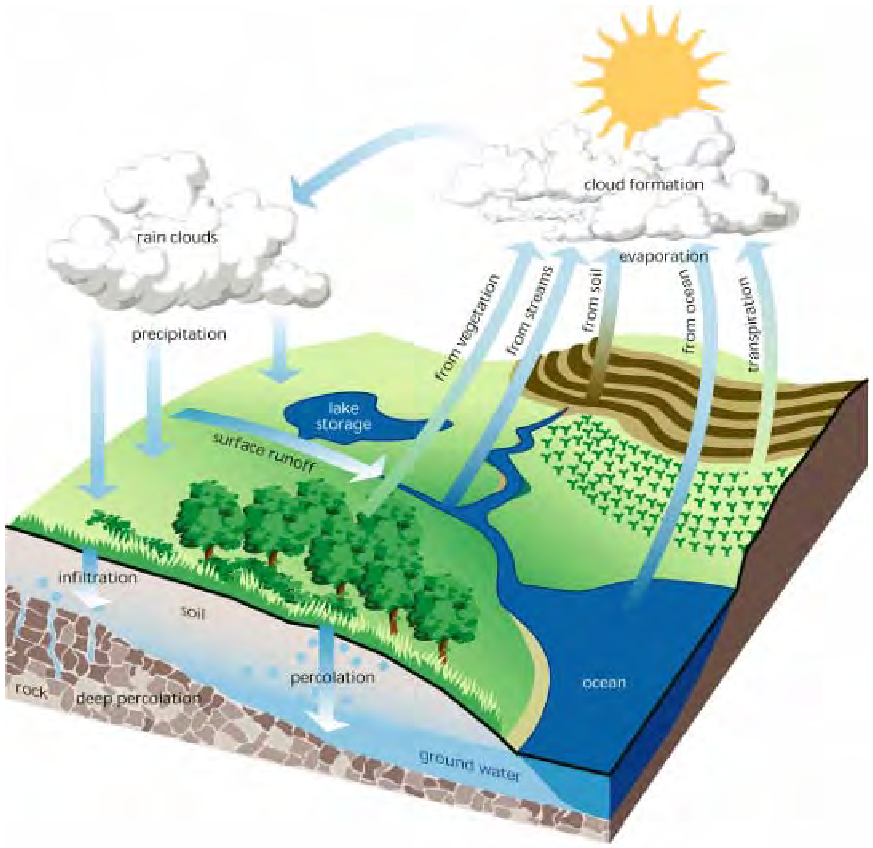

Figure 1. The Hydrologic Cycle.
Source: FISRG, 1998

Water cycles in the various regions of Southern California behave differently based on the amount of precipitation received. For example, in the northern part of Southern California, Pasadena receives 20 inches per year, while San Diego in the southwest receives just 10 inches. Los Angeles falls in the middle, averaging 15 inches per year. The low rainfall and high population of Southern California have lead to increasing concern over water importation. This, in turn, has led to efforts to manage groundwater resources and promote groundwater recharge (EMWD, 2005; OCWD, 2004).

Land development adds impervious surfaces such as rooftops, roads, and parking lots to the natural environment. As a result, the quantity and velocity of runoff increases, the amount of water that infiltrates to groundwater decreases, and pollutants deposited on the impervious surfaces are washed into stormwater conveyance systems and water bodies.

Typical alterations due to development may include:

- Increased imperviousness
- Increased runoff volume
- Reduced infiltration/groundwater recharge
- Introduction of new pollutants into watershed
- Increased pollutant concentrations
- Modifications to streams and channel banks

As a result of expansive development, the current hydrologic cycle in Southern California bears little resemblance to the natural system of a century ago. For example, in the 1920's approximately 95 percent of rainfall in Los Angeles was either infiltrated or evaporated, but that has dropped to approximately 50 percent as result of urban development (Green, 2007).

The primary goal of Low Impact Development is to preserve a site's predevelopment hydrology. The effects of changes to runoff patterns caused by land use modifications, or hydromodification, can be reduced by addressing targeted watershed goals and objectives through the use of structural and non-structural techniques that store, infiltrate, evaporate, and detain runoff. Achieving site design goals often requires consideration of the larger, less-frequent storm events that play a significant role in hydromodification, in addition to the small, frequent storms that are largely responsible for deteriorating water quality. Land use modifications may impact every aspect of site development and affect the hydrologic response of the site.

Figure 2 illustrates effects of development on the natural hydrologic cycle. The hydrologic response of a site is affected by every aspect of site development. Connected impervious areas and soil compaction characteristic of developed sites can cause runoff to be generated from even small amounts of rainfall. This results in an increase in volume and velocity of runoff, thereby increasing generation of sediment and suspended solids resulting from bank erosion.

Both LID and conventional stormwater management techniques attempt to control rates of runoff using accepted methods of hydrologic and hydraulic analysis, but conventional approaches typically include only the hydrologic components of precipitation, runoff conveyance and storage capacity. LID site design recognizes the significance of other components of the hydrologic cycle as well. How these other hydrologic components are taken into account will depend on the data available and purpose of the design. One LID design objective, for example, may be to preserve sediment load for a given site. There are many site design techniques that allow the site planner/engineer to create stormwater control mechanisms that function in a manner similar to that of natural control mechanisms. If LID techniques can be used for a particular site, the net result will be to more closely mimic the watershed's natural hydrologic functions or the water balance between runoff, infiltration, storage, groundwater recharge, and evapotranspiration. With the LID approach, receiving waters may experience fewer negative impacts in the volume, frequency, and quality of runoff, so as to maintain base flows and more closely approximate predevelopment runoff conditions.

Section 2: The LID Site Design Process

This manual establishes a framework for the LID site design process that informs all stages of planning and design. LID is not intended to be implemented as an afterthought, with a few BMPs placed on an otherwise conventionally designed site; proper implementation of LID techniques involves specialized site planning methods which are intended to be integrated into the overall site design. On a Low Impact Development project, consideration of natural resources such as soils, vegetation, and flow paths will influence the placement of buildings and paved surfaces, and as such LID needs to be considered at the earliest planning stages of a project.

A common misstep of developers and engineers is to wait until the final stages of development planning and design to attempt to incorporate LID, which often ends up requiring the loss of planned building space - or a costly re-design of the site. When LID is considered from the beginning, many designs can adequately meet the requirements for a project without significant loss of building space.

The process of planning a Low Impact Development project begins with a comprehensive understanding of the unique features of the site to be developed, which will guide the development of goals for minimizing the impact of the project. Next, a set of LID principles are included in the site planning process, to guide the creation of a site plan that works with the site's natural features and minimizes the generation of runoff. Once a sound site plan has been created, selected LID BMPs are included to capture and treat runoff where they are needed. The site plan is then evaluated to ensure that the stated goals have been met.

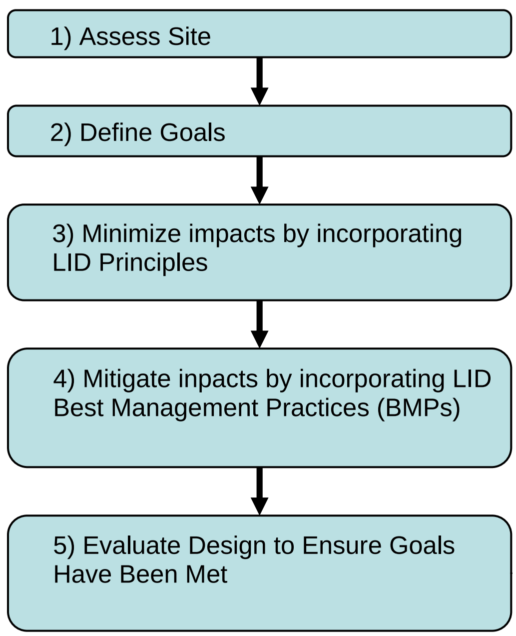

Figure 3. The LID Site Design Process.
Source: The Low Impact Development Center, Inc.

It is important to note that while the LID Site Design Process is presented in a linear fashion, in practice, steps three through five are an iterative process, where structural and non-structural design elements are added and adjusted in response to the modeling results until the project goals are met.

This design process is intended to be adaptable to a wide range of sites, economic constraints, and regulatory requirements, including those associated with new development, redevelopment, and retrofits, which may be subject to a variety of water quality, water quantity, and other requirements. These factors drive the site design, and guide the selection of the most appropriate practices and BMPs for the site.

The LID Site Design Process can be expected to require the balancing and rebalancing of a myriad of requirements placed on today's development projects in addition to those for water quality and water quantity, from the Americans with Disabilities Act requirements to xeriscaping requirements. Through the LID Site Design Process, the project professional must search for a balance that meets all requirements within the project budget.

The economics of LID are influenced by many factors, and the costs to implement LID will likely be a key factor in the level of LID implementation. New development projects are expected to provide the most economical opportunities for LID implementation. In new development, LID can be integrated into a project from its initiation when there are usually fewer project constraints and where LID features may be used in lieu of conventional, non LID features, potentially at savings to the project. Redevelopment and retrofit projects are expected to present more constraints to LID implementation, and these constraints are expected to make LID implementation on these types of projects more costly than in new development.

The economics of LID implementation warrants evaluation on both a capital and lifecycle basis. The capital cost analysis should include not only the cost to implement LID features, but also the potential savings in other features resulting from LID implementation. For example, a pervious paver parking lot may cost more to implement than a conventional asphalt concrete parking lot, but these costs may be offset by a reduction in storm drain costs or treatment control BMP costs made possible by the runoff reduction provided by the LID BMP. The lifecycle cost analysis should include not only the operation and maintenance costs, but also the potential savings in energy use and replacement costs. In the previous example, a pervious paver parking lot may have a life two the three times the life of an asphalt concrete parking lot, resulting in replacement savings. Perhaps the most complicated economic factor associated with LID is appropriately valuing the potential increase in marketability and desirability of LID projects.

Figure 4. Use of the LID Site Design Process to Maintain or Restore Hydrologic Function.
Source: The Low Impact Development Center, Inc.

Integration with MS4 Permit Requirements
LID principles have been incorporated into local MS4 permits. The exact structure of these requirements varies by municipality, therefore, an effort has been made to present a design method that is sufficiently general to conform to a variety of local requirements. Discussion of specific local permitting issues is included in Appendix B.

Step 1: Conduct Site Assessment

A comprehensive site assessment is a fundamental starting point in the development of an LID site design. The site assessment will be a compilation of data from a variety of sources. These sources range from on-site visual inspection to professional surveys and geotechnical reports. The most important component of the site assessment process is the evaluation of the existing soils and drainage on-site and how they relate to the selection of specific LID practices.

The United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) Web Soil Survey (WSS) is a common starting reference for the preliminary investigation of site suitability for LID. Soil Surveys include a plethora of planning level information for a site, from soil types to hydrologic soils groups. This resource can be used to develop a preliminary understanding of how LID would be best applied to the site. After the preliminary assessment of site soils has suggested the general site layout, then a site-specific geotechnical evaluation of soils is warranted. By conducting a geotechnical evaluation of site soils early in the LID Design Process, decisions regarding specific LID measures can be made with a higher degree of certainty, potentially reducing the number of iterations required to integrate LID into the site design.

The objective of the site assessment is a detailed site map, showing all of the data collected. This map will guide the selection and placement of site development (roads, parking lots and structures), structural, and non-structural BMPs.

The following list represents the foundation data for a comprehensive site assessment:

- Hydrology
- Topography
- Soils
- Geology
- Vegetation
- Eco-region
- Sensitive and Restricted Areas
- Existing Development
- Contamination
- Geological Considerations

Table 1 outlines each of the site assessment elements, what specific data should be collected and sources for the data of interest. Additional detail can be found in the sub-sections that follow.

Depending on the complexity of the site, a team of specialists may be required in order to conduct a thorough site assessment. These professionals may include: geotechnical engineers, surveyors, soil scientists, and restoration ecologists.

Table 1. Necessary Data Collection for Site Assessment.

Factor	Data of Interest	Data Sources	Development Stage
Hydrology	• Streams and receiving waters • Floodplains • Flow paths • Upslope drainage • Connection to existing drainage	• GIS maps • Professional property survey • National Atlas • FEMA Map Service Center	• Hydrology Study (usually prior to CEQA)
Topography	• 1' contours • Elevations of existing curbs and gutters	• Professional property survey • GIS maps • As-built drawings	• Phase One site assessment (usually part of due diligence)
Soils & Geological Considerations	• Hydrologic Soils Group • Soil texture • Impermeable or restrictive layers • Depth to bedrock • Depth to groundwater • Infiltration rate • Landslide potential	• NRCS soil maps • Professional soil testing • Assessment by geotechnical engineer	• Phase One site assessment • Geotechnical Report (usually prior to CEQA and included in CEQA document; often part of WQMP but best done earlier)
Vegetation	• Existing cover • Existing plant communities • Well-established trees	• GIS maps • Professional site survey	• Biological report (almost always done before CEQA and included in the circulated CEQA document)
Ecoregion	• Ecoregion	• USDA Forest Service • US EPA	• Biological reports
Sensitive and Restricted Areas	• Wetlands • Streamside Management Areas • Watercourse and Lake Protection Zones • Floodplains • Established trees • Intact forest • Habitat for threatened or endangered species • Easements • Underground storage tanks • Underground utilities	• Local County/City • California EPA • Deed search • Site survey	• Biological report • Jurisdictional delineation (almost always done before CEQA document prepared) • Special surveys (vireo, fairy shrimp, etc.) almost always done before CEQA document is prepared • Phase One
Existing Development	• Buildings • Paved areas • Landscaped areas • Utilities	• As-built site plans • Site Survey	• Many venues for gathering this information
Contamination	• Brownfield designation • Abandoned landfills • Groundwater contamination	• Local County/City • US EPA • California EPA • California Department of Toxic Substances Control	• Phase One

Source: The Low Impact Development Center, Inc.

LID Site Assessment – *Existing Hydrology*

One of the key pieces of the site assessment will be to map the site's existing hydrology. The map should include:

- Onsite streams and other water bodies
- Existing flow paths
- Floodplains
- Depth to groundwater
- Connections to and routing of existing storm drain systems
- Receiving waters
- Upslope drainage

Much of this information may be available from city and county municipal agencies. Where such data is not available, the site will need to be mapped by a qualified professional.

Existing flow paths and upslope drainage concerns can be assessed by examining topographic maps of the site.

Information on depth to groundwater can be found in the Natural Resources Conservation Service (NRCS) Web Soil Survey.

One of the best ways to get a sense of how water moves on the site is to visit during a heavy rain, taking note of where the water flows.

Additionally, the site should be placed in the context of the larger watershed. Identify any special concerns in the watershed. Find out whether the receiving waters are listed as impaired under section 303(d) of the Clean Water Act. The list is maintained by the State Water Resources Control Board (http://www.waterboards.ca.gov/water_issues/programs/tmdl/docs/303dlists2006/epa/state_usepa_combined.pdf). If the receiving water is listed, the development may be subject to additional regulatory requirements.

LID Site Assessment – *Topography*

The topography of the site defines both the location and capacity requirements for potential LID implementations. The topography of upstream and downstream sites should also be considered with respect to any potential contribution to the total runoff generated during a storm event.

To design effective LID into new or existing sites requires a careful analysis of the topography and how and where stormwater runoff will concentrate and flow. Visiting the site during a storm event can provide an enormous amount of information regarding areas of concentration and flow. In the event preliminary data cannot be found, a topographic survey should be ordered prior to proceeding with the design phase of the project.

To be able to perform a detailed topographic site analysis, the following information must be acquired and evaluated:

- A detailed site topographic map showing the smallest contour interval possible; a contour map showing the contours at a 1-foot interval is preferred. For initial planning and scoping purposes, additional intervals can be interpolated from maps with larger intervals if necessary. If possible, try to obtain as-built drawings that may exist from previous construction.
- The location and elevation of existing drainage or stormwater structures, including the elevation of the rim of the structure where stormwater enters and the inverts of drainage pipes entering or exiting the structure.
- Elevation of all curbs and gutters on the site. The drawing should show top of curb and bottom of curb elevations. High and low points of walkways, driveways, and parking areas should also be noted.
- Location of drainage swales on the site. Indicate the flow direction in the channel for reference.

Check with the property owner for as-built drawings that might be available.

The local county GIS office may have a topography layer available that could provide working information, but keep in mind this data is typically not survey-quality data and should only be used for preliminary evaluation of the contributing watershed for your site LID BMPs.

USGS 1:24,000 Quad maps can be used to calculate the contributing watershed on larger sites.

LID Site Assessment – *Soils and Geology*

As many LID BMPs are designed to infiltrate runoff, understanding the site's soil type, characteristics, and profile will help focus efforts on measures that are most appropriate for managing stormwater on the site. This section describes considerations for assessing the site's soils that will help inform the placement of buildings and paved areas, and suggest the most suitable BMPs and where they would be best placed.

Failure to understand the characteristics and capabilities of the specific site soils results in poorly functioning LID designs. Proper understanding of the analysis and application of soil type and its capacity to infiltrate stormwater and mitigate non-point pollutants is imperative to the success of any LID implementation.

The following is a summary of soil considerations that should be assessed for the site. Additional information on each of these is provided below:

- Initial Soils Assessment
    - Hydrologic Soils Group

- On-Site Soils Assessment
    - Measured infiltration rates
    - Trench / Boring Logs
    - Depth to or presence of limiting soil types, i.e. expansive soils, caliche, fragipan, corrosive soils
- Geologic Assessment
    - Depth to bedrock
    - Depth to water table
    - Susceptibility to landslides

Initial Soils Assessment

Information regarding a site's hydrologic soils group can generally be gathered from available regional soils studies and may **only** be used as a preliminary source for soil characterization and early planning. When this information is used to estimate infiltration rates or BMP sizes, a safety factor of 10 is appropriately applied – and can usually be reduced once in situ testing has been completed. Site specific soil testing, by a qualified civil or geotechnical engineer, is essential before preliminary and final design and implementation of LID projects in order to confirm soil properties including infiltration capacity and should be done as early in the design process as possible.

The Natural Resources Conservation Service (NRCS) has compiled soils data on the U.S. Department of Agriculture (USDA) website. The online soil survey is called the Web Soil Survey (WSS) and can be viewed at the following URL: http://websoilsurvey.nrcs.usda.gov/app/HomePage.htm.

In the event the WSS is unable to provide a soil map for the site of interest, which is often the case in areas of urban development, soil maps may be available from state or municipal government agencies. The local NRCS office may have access to published printed soil survey data which has not yet been posted online.

Soil series are assigned a Hydrologic Soil Group (HSG) rating, A through D, which describes the physical drainage and textural properties of each soil type and is useful for stormwater, wastewater, and other applications. This HSG rating is usually based on a range of permeability, as well as certain physical constraints such as soil texture, depth to bedrock, and seasonal high water table (SHWT). Soil types assigned an HSG Group A classification are very well drained and highly permeable (sand, loamy sand, sandy loam); Group D soils (clay loam, silty clay loam, sandy clay, silty clay, clay) are poorly drained and often situated in a valley bottom or floodplain. HSG-rated B and C soils offer good (B; silt loam, loam) to fair (C; sandy clay loam) drainage characteristics (USDA-SCS, 1986). The heavier D soils have little if any infiltration potential during rainfall events and produce much greater surface runoff in response to rainfall. Many soils in Southern California are classified with a HSG rating of C or D, which are usually not especially conducive to and will limit applicability of infiltration practices. In fact, data for the six counties covered by Regional Boards 4, 8, and 9 indicates that 3 percent of the soils are classified as A, 17 percent of soils are classified as B, 30 percent as C, 33 percent as D, and 16 percent as Urban Soils. It should be noted that the permeability ranges listed for the HSG ratings are based on the minimum rate of infiltration obtained for bare soil after prolonged wetting (USDA-SCS, 1986). A vegetative cover can increase these rates 3 to 7 times (Lindsey et. al., 1992).

These NRCS soil maps can be used to identify areas with potentially high infiltration rates (HSG Group A and B), which are potential areas for locating infiltration-based BMPs. Where possible, buildings and paved surfaces should be sited on less permeable soils.

Although initial soils information may be estimated using regional soils studies (typically using web-based or GIS data), in most cases this will not be an adequate replacement for on-site analysis. Additionally, it is important to adequately understand and characterize the infiltration capacity of the entire soil profile, as deeper soils may be more limiting to infiltration than surface soils.

On-Site Soils Assessment

Infiltration Testing

Infiltration tests should be performed in areas where infiltration-based BMPs are proposed and typically a minimum infiltration rate of 0.5 inch per hour is required. A variety of field testing techniques can be used to determine infiltration rate, including basin flooding, sprinkler infiltrometers, cylinder or double-ring infiltrometers, and lysimeters. Appropriate techniques should be selected based on the method of stormwater application being considered and may be subject to local guidance. Basin flooding and cylinder infiltrometer tests are preferred for the design of stormwater retention facilities (US EPA, 1998). The standard US Public Health Service percolation test used to design septic drain fields is not recommended.

Trench / Boring Logs
Once potential building and BMP locations have been identified, a qualified soil scientist or geotechnical engineer should dig test pits to gather more detailed information on the soils present at these locations. Test pits are required to confirm the types of soils present onsite, and will uncover the presence of soil layers that may impede infiltration, such as caliche or fragipan. Test pits will also determine the depth to bedrock and will help to establish the high groundwater elevation.

In developed sites being evaluated for redevelopment or retrofits, soil bulk density should be measured in a number of areas to determine the level of soil compaction, which can dramatically impede the movement of water into the soil.

Other Limiting Factors
Many of the soils in Southern California contain fairly shallow, moderately cemented restrictive layers of lithic or paralithic bedrock. These restrictive layers will limit the applicability of infiltration designs. Another likely challenge to infiltration is a type of soil known as caliche, which is found in many areas of the region. Caliche is a layer of soil in which the soil particles have been cemented together by lime (calcium carbonate, $CaCO_3$). It is usually found as a light-colored layer in the soil or as white or cream-colored concretions (lumps) mixed with the soil. Layers will vary in thickness from a few inches to several feet, and there may be more than one caliche layer in the soil.

Caliche is also problematic for vegetation in at least three ways. First, the caliche layer can be so tight that roots cannot penetrate through it. The result is that plants have only the soil above the caliche to use as a source of nutrients and water and normal root development is restricted. Second, the same conditions that restrict root penetration also reduce water movement. Water applied to the soil cannot easily move through the profile if a restrictive caliche layer is present. The restricted water penetration can contribute to problems arising from inadequate root aeration and can lead to accumulations of salt in the soil surface. Both problems, lack of aeration and salt accumulation, reduce the vigor of growing plants. Third, the pH and free calcium carbonate in a caliche soil are often high enough to cause iron to become unavailable for plants. The symptoms of iron deficiency are a yellowing of the youngest plant leaves while the veins in the leaves remain green. Iron deficiencies are further aggravated by the water saturation of the soil.

In some cases, near-surface caliche layers can be broken apart through mechanical means during site grading. This is typically accomplished by deep ripping, a process that involves using a bulldozer to drag a long tine through the soil on a checkerboard pattern. This process may remove the water penetration restriction, but may not mitigate the other challenges associated with caliche soils.

Many areas in Southern California have soils that are corrosive to metals and concrete. These soils are characterized by: high moisture content, high dissolved salts, and high acidity. Caltrans has established the following criteria for corrosive soils (Caltrans, 2003):

- Chloride concentration ≥ 500 ppm,
- Sulfate concentration ≥ 2,000 ppm, or
- pH ≤ 5.5

If one or more of these conditions is met, the site may require corrosion mitigation prior to the installation of any underground BMPs.

Pollutant Removal

Unpaved surfaces provide both infiltration and pollutant removal functions. Soils have a high capacity to remove soluble and insoluble pollutants from stormwater. Many factors influence a soil's pollutant removal capacity. Fully understanding soil pollutant removal involves a detailed understanding of hydrology, soils physics and chemistry, aquatic chemistry, biology, and botany. Factors that influence pollutant removal include the quality of the infiltrating water, and soil characteristics such as age, pH, mineral content, organic matter content, oxidation-reduction potential (redox), as well as the soil flora and fauna at the surface and in the subsurface.

Soil provides the medium for decomposition of organic material that is deposited on the land surface. Soil is the habitat for a vast spectrum of micro- and macro-organisms that form a natural recycling system. The rhizosphere (the rooting zone) includes roots, viruses, bacteria, fungi, algae, protozoa, mites, nematodes, worms, ants, maggots, other insects and insect larvae (grubs), earthworms and rodents. Processed nutrients in the rhizosphere are in turn used by the vegetative systems that develop on the soil mantle. When precipitation is infiltrated, pollutants from surface activities move into this soil treatment system, which effectively and efficiently breaks down most non-point source pollutants (biologically), removes them from the stormwater by cation exchange (chemically), and/or physically filters them through soil particles.

One important measure of chemical pollutant removal potential is cation exchange capacity (CEC), which describes the soil's ability to adsorb positively charged ions. A soil's CEC is a function of its clay and organic contents. Soils with a CEC of at least 10 milliequivalents per 100 grams are very efficient as a treatment medium, and offer the best opportunity to reduce or completely remove most common stormwater pollutants, such as phosphorus, metals and hydrocarbons. Non-point source pollutants that are solutes, such as nitrate, are the exception. Nitrates typically move with the infiltrating rainfall and do not undergo significant reduction or transformation, unless an anaerobic environment with the right class of microorganisms is encountered.

Phosphorus is a key pollutant of concern in many watersheds. Soils can act as either a source or a sink for certain forms of phosphorus, depending on their innate phosphorus content, measured by the P-index (Hunt et al, 2006). This can be of particular concern when soil is used as a pollutant filter, such as in bioretention. Use of high P-index soils in bioretention can lead to the bioretention cell exporting rather than removing certain forms of phosphorus. Table 2 summarizes the ideal soil properties for infiltration and pollutant removal. It is important to note that LID principles can be adapted to any site soil conditions. This table is intended only to facilitate the identification of areas where infiltration BMPs would be best suited, and to flag any special soil conditions that may need to be considered.

Table 2. Ideal Soil Properties for Infiltration and Pollutant Removal.

Property	Ideal range for infiltration/ pollutant removal
USDA textural classification	Sand, loamy sand, sandy loam, or loam
HSG	A or B
Infiltration rate	0.5 in/hr
CEC	> 10 milli-equivalents/100 grams
Organic Content	1.5 – 10%
P-index	< 25
pH	5.5-7.5
Depth to impermeable layers	> 5 feet
Depth to groundwater	> 10 feet

Source: The Low Impact Development Center, Inc.

Geologic Assessment

The primary geologic factors that influence selection and placement of LID BMPs are the depth to bedrock and the water table, and susceptibility to landslides. The depths to bedrock and the water table can be easily obtained as part of the site soils assessment described above.

Landslides

Southern California's physiography makes certain areas prone to landslides. Landsliding is a form of mass wasting, or gravity-caused erosion, and is a natural process which occurs readily in certain earth materials. The action of landsliding is heavily influenced by the saturation of soil and rock masses and is, to the dismay of thousands of its residents, a natural process on California's hill slopes.

LID design in areas prone to landslides, especially those that utilize infiltration, should be given careful consideration and should be subject to review by a licensed civil or geotechnical engineer. Since soil saturation is a primary cause of landslides, infiltration should be limited in areas of high landslide risk. Local construction best practices should also be considered when implementing LID in an area that is subject to landslides.

LID Site Assessment – *Vegetation*

Knowledge of the plant communities occurring onsite is a factor in developing a site design that is well-integrated into the natural environment. Although development pressures have removed or strongly modified much of the natural vegetation in the area, ongoing development, redevelopment, and restoration efforts may present opportunities to protect and/or recapture some of the region's native plant communities.

When a site is disturbed by either natural events or human intervention, invasive species have the opportunity to gain a toe hold and dominate indigenous plant communities. Invasive species are plants that have been recently introduced and have the ability to thrive beyond their range of natural dispersal. Typically invasive species are characterized as adaptable, aggressive and have a high reproductive capability. These characteristics allow them to monopolize the limited resources available after a site disturbance has occurred and to outcompete native plant species. It is critical to identify these invaders during site assessment and, as part of the plant community restoration plan, to minimize the introduction and establishment of invasive plants into the landscape. Where a site is completely dominated by invasives, it may be possible to restore native vegetation into the planned landscaping. A qualified restoration ecologist should be consulted to create an appropriate restoration plan.

Southern California's natural vegetation reflects the region's climate and diverse topography and soils. The structure and function of the area's natural plant communities are strongly influenced by drought, seasonal flooding, elevation, slope and aspect, geological variation, fire history, and unique occurrence of the Santa Ana winds. The vegetation exhibits high levels of species diversity and endemism, and provides habitat for a great range of animals.

A site assessment should include a survey of existing vegetation onsite, identifying:

- Existing or historical plant communities
- Existing invasive species
- The presence/location(s) of dense/native plant cover
- The presence/location(s) of well-established trees

The following points briefly summarize important characteristics of several major plant communities in Southern California to help in identifying native plant cover versus invasive species. (Bornstein et al, 2005; Lenz and Dourley, 1981; Las Pilitas Nursery):

- Coastal Scrub:
    - primarily small to medium shrubs, subshrubs, or succulents
    - some species produce large green leaves with winter rains and small grayish leaves in summer; other species are drought-deciduous
    - annual precipitation is generally 10-20 inches
    - relatively narrow temperature range
    - plants can be somewhat sparsely distributed in the landscape
    - tend to be found in flat to moderately-sloped areas; slopes may be rocky
    - shallow to moderate soil depth

Figure 5. Coastal Scrub.
Source: © Marc Hoshovsky, California Department of Fish and Game

- Chaparral:
  - most extensive type of vegetation in California
  - primarily medium to large shrubs with thick, small, evergreen leaves; also contains fire-adapted annuals
  - can form dense thickets
  - many types of chaparral are recognized, depending on dominant species and combinations of species; this variation reflects different elevations, moisture levels, and soil types
  - annual precipitation is generally 12-35 inches, occurring in infrequent, heavy events
  - found on hills and lower mountain slopes in areas with generally mild winters; often on steep slopes that are very hot in summer
  - fairly drought-tolerant and adapted to fire; many shrub species can sprout from stumps following fire
  - shallow, usually well-drained, rocky soils

Figure 6. Chaparral.
Source: California Chaparral Institute

- Grassland:
    - comprises bunchgrasses, sedges, and annual and perennial wildflowers
    - merges with chaparral or oak woodland at higher elevations
    - annual precipitation is generally 6-20 inches
    - soils range from: deep alluvial fan and floodplain, to moderately deep upland with high organic matter, to low terrace land soils having moderately dense subsoils, to poorly drained valley basin soils
    - no longer abundant (largely replaced by agricultural land uses)
    - invasive exotic grasses and other herbs have impaired some remaining California grassland

Figure 7. Grassland.
Source: I. Anderson Center for Biological Diversity

- Coastal Oak Woodland:
    - discontinuous overstory of Coast Live Oak, other oak trees, or California Walnut
    - canopy coverage can vary, with a mix of shrubs and grasses occurring in the understory
    - annual precipitation is generally 15-25 inches with substantial runoff
    - soils are generally deep terrace land or upland soils

Figure 8. Oak Woodland.
Source: Daniel Griffin, University of Arkansas Tree-Ring Laboratory

- Riparian Woodland:
    - species composition varies with elevation
    - soils vary, depending on composition of materials deposited along waterways
    - plants generally require year-round presence of nearby surface water

Figure 9. Riparian Woodland.
Source: V.L. Holland, Ph.D.; Biological Sciences Department, California Polytechnic State University

- Pinyon-Juniper Woodland:
    - consists of juniper on shallower slopes and pinyon pine on higher and steeper slopes in mountain regions
    - plant community may have a variety of other trees, shrubs, and succulents
    - annual precipitation is generally 10-30 inches

Figure 10. Pinyon-Juniper Woodland.
Source: Joel Michaelsen; Department of Geology, UC Santa Barbara

- Pine Forest:
  - lower montane coniferous forest, with a great number of potential species (canopy and understory)
  - elevation generally ranges from 5,000 to 8,000 feet
  - annual precipitation is generally 25-80 inches (much of it falls as snow)
  - deep upland soils with moderate to high acidity

Figure 11. Pine Forest.
Source: Joel Michaelsen; Department of Geology, UC Santa Barbara

- Creosote Bush Scrub:
  - open, sparse desert community dominated by Creosote bush and prickly pear cactus
  - elevation generally less than 3,500 feet
  - annual precipitation is generally 5-10 inches
  - alkaline soils

Figure 12. Creosote Bush Scrub.
Source: Carrie Tai

- Joshua Tree Woodland:
  - desert community dominated by Joshua trees, shrubs and wildflowers
  - elevation generally ranges from 2,500 to 5,000 feet
  - annual precipitation is generally 5-10 inches
  - neutral soils

LID Site Assessment – *Ecoregion*

Ecoregions and Native Plant Communities

Landscaping within a Low Impact Development project can be modeled on native plant communities found within an area's ecoregion. According to the World Wildlife Fund, an ecoregion is a "large area of land or water that contains a geographically distinct assemblage of natural communities that:

- share a large majority of their species and ecological dynamics;
- share similar environmental conditions, and;
- interact ecologically in ways that are critical for their long-term persistence."

Ecoregions can be described at a variety of spatial scales and further delineated into different subregions, such as provinces and sections. Two ecological subregions occur within the jurisdictions of Regional Water Quality Control Boards 4, 8 and 9, and have direct significance to this manual (USDA-FS, 1997):

1. Southern California Coast
2. Southern California Mountains and Valleys

In addition to the above subregions, large portions of Los Angeles, San Bernardino, Riverside, and San Diego Counties fall within three other ecoregions to the east:

1. Mohave Desert
2. Sonoran Desert
3. Colorado Desert

The ecoregions for the three RWQCB Regions in the project area are very broadly outlined; they can be further subdivided into sections and subsections within the hierarchical framework of ecoregions. Individual subsections have characteristic topography, soils, climate, and associated vegetation types. These features are summarized in Table 3 and Table 4 for the subsections that occur in the project area. Understanding the unique elements in a specific ecoregion the BMP is located in will inform the choices of plant materials incorporated into the BMP. This consideration will enhance the survival and sustainability of the selected plant material as well as provide habitat and cover for native wildlife.

Table 3. Climate and Vegetation of the Southern California Coast Ecoregion.

Subsection	Mean Annual Temp. & Precip.	Surface Water	Predominant Vegetation	Less Common Vegetation
Santa Ynez – Sulphur Mountains	45° - 60° F 18-30 in	Rapid runoff; all but larger streams dry in summer; no natural lakes	Coastal Oak Woodland; Montane Hardwood Forest; Chamise Chaparral; Mixed Chaparral	Coastal Scrub; Duneland; Grassland
Oxnard Plain – Santa Paula Valley	56° - 60° F 12-18 in with summer fog	Santa Clara River is perennial, Calleguas Creek is year-round; no natural lakes	Coastal Scrub	Saline Emergent Wetland; Grassland; Coastal Oak Woodland; Valley Foothill Riparian Woodland
Simi Valley – Santa Susana Mountains	52° - 62° F 16-20 in	Rapid runoff; streams dry in summer; no natural lakes	Coastal Scrub; Chamise Chaparral; Coast Oak Woodland	Valley Oak Woodland; Montane Hardwood Forest; Grassland; Valley Foothill Riparian Woodland; Montane Riparian Forest
Santa Monica Mountains	54° - 62° F 15-25 in	Rapid runoff; streams dry in summer; no natural lakes	Coastal Scrub; Chamise Chaparral; Mixed Chaparral	Coast Oak Woodland; Grassland; Valley Foothill Riparian Woodland; Montane Riparian Forest; Valley Oak Woodland
Los Angeles Plain	58° - 64° F 12-20 in with summer fog	Most streams dry in summer; no natural lakes	Coastal Scrub	Coast Oak Woodland; Chamise Chaparral; Mixed Chaparral; Valley Foothill Riparian Woodland; Saline Emergent Wetland; Duneland; Grassland
Coastal Hills	56° - 62° F 12-16 in with summer fog	Rapid runoff; mix of perennial and summer-dry streams; no natural lakes; some reservoirs	Coastal Scrub; Coast Oak Woodland	Chamise Chaparral; Mixed Chaparral; Valley Foothill Riparian Woodland; Grassland
Coastal Terrace	58° - 62° F 10-12 in with summer fog	Rapid runoff except for terraces with vernal pools; mix of perennial and summer-dry streams; no natural lakes	Coastal Scrub; Chamise Chaparral	Coast Oak Woodland; Saline Emergent Wetland; Torrey Pine Stands; Vernal Pools; Duneland; Grassland; Mixed Chaparral; Valley Foothill Riparian Woodland

Table 4. Climate and Vegetation of the Southern CA Mountains and Valleys Ecoregion.

Subsection	Mean Annual Temp. & Precip.	Surface Water	Predominant Vegetation	Less Common Vegetation
San Raphael – Topatopa Mountains	45° - 60° F 18-30 in	Rapid runoff; rain except at higher elevations; all but larger & high-elevation streams dry in summer; no natural lakes	Chamise Chaparral; Mixed Chaparral	Coastal Oak Woodland; Coastal Scrub; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Jeffrey Pine Forest; White Fir Forest; Grassland; Wet Meadow
Northern Transverse Ranges	40° - 54° F 12-30 in	Rapid runoff; rain except at higher elevations; all but larger & high-elevation streams dry in summer; no natural lakes	Juniper Woodland; Jeffrey Pine Forest; Montane Hardwood Conifer Forest; Chamise Chaparral; Mixed Chaparral;	Coastal Scrub; Montane Hardwood Forest; Pinyon-Juniper Woodland; Montane Chaparral; Subalpine Conifer Forest; White Fir Forest; Grassland; Wet Meadow
Sierra Pelona – Mint Canyon	45° - 60° F 12-20 in	Rapid runoff; rain except at higher elevations; all but larger streams dry in summer; sag ponds along San Andreas Fault	Chamise Chaparral; Mixed Chaparral; Coastal Oak Woodland	Coastal Scrub; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Jeffrey Pine Forest; Juniper Woodland; Montane Chaparral; Grassland; Wet Meadow;
San Gabriel Mountains	45° - 60° F 20-30 in	Rapid runoff; rain except at higher elevations; all but larger streams dry in summer; sag ponds along San Andreas Fault	Chamise Chaparral; Mixed Chaparral	Jeffrey Pine Forest; Juniper Woodland; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Grassland; Montane Chaparral; Coastal Oak Woodland; Pinyon-Juniper Woodland; Wet Meadow
Upper San Gabriel Mountains	40° - 50° F 30-40 in	Rapid runoff; rain except at higher elevations; all but larger streams dry in summer; no natural lakes	Jeffrey Pine Forest	Lodgepole Pine Forest; Subalpine Conifer Forest; Montane Chaparral; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Coastal Oak Woodland; Juniper Woodland; Wet Meadow
Santa Ana Mountains	45° - 62° F 15-25 in	Rapid runoff; rain except at higher elevations; all but larger streams dry in summer; no natural lakes (but some drainage to Lake Elsinore)	Coastal Oak Woodland; Chamise Chaparral; Mixed Chaparral	Montane Hardwood Conifer Forest; Montane Hardwood Forest; Coastal Scrub; Jeffrey Pine Forest; Montane Chaparral; Grassland; Vernal Pools

Table 4 (cont.): Climate and Vegetation of the Southern CA Mountains and Valleys Ecoregion.

Subsection	Mean Annual Temp. & Precip.	Surface Water	Predominant Vegetation	Less Common Vegetation
San Gorgonio Mountains	45° - 60° F 20-30 in	Rapid runoff; rain except at higher elevations; all but larger streams dry in summer; no natural lakes	Chamise Chaparral; Mixed Chaparral; Jeffrey Pine Forest	Subalpine Conifer Forest; Montane Chaparral; Juniper Woodland; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Coastal Oak Woodland; Pinyon-Juniper Woodland; Coastal Scrub; Grassland
Upper San Gorgonio Mountains	40° - 50° F 30-40 in	Rapid runoff; much precipitation is snow; all but larger streams dry in summer; previously natural lakes replaced by reservoirs	Jeffrey Pine Forest	Mixed Chaparral; Subalpine Conifer Forest; Lodgepole Pine Forest; Juniper Woodland; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Montane Chaparral; White Fir Forest; Pinyon-Juniper Woodland; Wet Meadow; Alpine Meadow
Fontana – Calimesa Terraces	62° - 64° F 20-20 in	Rapid runoff (even from alluvial fans); all but larger streams dry in summer; Santa Ana River flows year-round; no natural lakes	Coastal Scrub; Grassland	Mixed Chaparral; Juniper Woodland; Valley Foothill Riparian Woodland
Perris Valley and Hills	58° - 64° F 10-16 in	Rapid runoff (except from floodplains and lake basins); all but larger streams dry in summer; sag ponds along Elsinore Fault Zone; reservoirs	Coastal Scrub; Grassland	Coastal Oak Woodland; Chamise Chaparral; Mixed Chaparral; Juniper Woodland; Vernal Pools
San Jacinto Foothills – Cahuilla Mountains	50° - 60° F 10-20 in	Rapid runoff (except from alluvial plains); all but larger streams dry in summer; no natural lakes	Coastal Oak Woodland; Coastal Scrub	Chamise Chaparral; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Mixed Chaparral; Montane Chaparral; Juniper Woodland; Jeffrey Pine Forest; Pinyon-Juniper Woodland; Grassland
San Jacinto Mountains	40° - 58° F 16-30 in	Rapid runoff (except from alluvial plains); rain except at higher elevations; all but larger streams dry in summer; no natural lakes	Jeffrey Pine Forest; Lodgepole Pine Forest; Mixed Chaparral	Coastal Oak Woodland; Juniper Woodland; Pinyon-Juniper Woodland; Montane Hardwood Conifer Forest; Montane Hardwood Forest; Montane Chaparral; Chamise Chaparral; Subalpine Conifer Forest; White Fir Forest; Wet Meadow; Grassland

LID Site Assessment – *Sensitive and Restricted Areas*

Mapping of all sensitive and restricted areas on the site is required as part of the site planning and layout. Conservation easements that have been dedicated on the site will require special attention since these areas may fall under the control of regulatory agencies, such as the United States Army Corps of Engineers (USACE) or the State Department of Fish and Game (DFG).

Work that would affect the natural function of areas of environmental interest is often regulated by Federal or State agencies and must be identified and delineated. Additionally, several jurisdictions in Southern California have completed Multiple Species Habitat Conservation Plans, which identify key species and their associated habitats and may set requirements for conservation or mitigation.

Other types of easements and rights of way should also be identified prior to the selection of LID practices. Access easements can be established for sub-grade, on-grade and aerial utilities, and will dictate specific limitations to potential locations of LID BMPs.

Required Information

The following sensitive and restricted areas should be identified and delineated on the project site plan:

- Wetlands
  - http://www.ceres.ca.gov/wetlands/
- Streamside Management Areas / Watercourse and Lake Protection Zones
  - http://www.swrcb.ca.gov/water_issues/programs/nps/encyclopedia/2b_sma.shtml
- Floodplains
  - http://www.fema.gov/plan/prevent/fhm/dfm_dfhm.shtm
  - http://www.water.ca.gov/floodmgmt/lrafmo/fmb/fes/
  - Contact appropriate local agency for additional flood hazard areas
- Habitat for threatened or endangered species
  - Local MSHCP
  - http://www.dfg.ca.gov/habcon/
- Environmental easements on the property such as woodland, wetland, farmland, scenic areas, historic areas, wild and scenic rivers and other undisturbed natural areas that have been recorded as perpetual conservation easements in the property deed
- Location of buried storage tanks and utilities
  - As-built plans
  - Utility companies
